| <p>1. The test results shown on the enclosed General Test Report (SAD Form 158), are for those samples from the various holes where tests were requested for moisture content only. All other test results on samples that were tested for sieve analysis, Atterberg Limits, specific gravity, and visual classification are reported on ENG Form 2087 (gradation curves).</p> <p>2. This completes all testing requested on Requisition No. SAS-EN-GS-87-23, which we are closing out. If you have questions, please contact Elton Shinn at 404/421-5299.</p> <p>Encls</p> |  |                                                                                                                                              |

**Note<sup>1</sup>:** Readings are reported as the highest value in mRem/hour from a Bicon Geiger Mueller gauge Model Surveyor 50, S/N B912V, Calibrated on 13 May 2002 using a pancake probe S/N B855S.

# **Savannah Harbor Expansion Project**

Evaluation of Chloride Impacts with  
Proposed Mitigation Plan

*December 2007*

## Introduction

This report summarizes the results of chloride impacts on Abercorn Creek at the City of Savannah's water intake pipe with implementation of the proposed mitigation plan to alter flows in the estuary at each alternative navigation channel depth (44 ft, 45 ft, 46 ft, and 48 ft). The two proposed plans are: Plan 6b for the 44 ft depth, and Plan 6a for the 45 ft, 46 ft, and 48 ft depths. Details of each of the mitigation plans are shown in Figures 1 and 2. For details on how these plans were developed and selected, please see the main report document for this project.

**Figure 1:** Plan 6a (proposed mitigation for 45 ft, 46 ft and 48 ft channel depths)

Figure 2: Plan 6b (proposed mitigation for 44 ft channel depth)

## Hydrodynamic Model Input

The plans were evaluated using the 3D hydrodynamic model EFDC, which predicts salinity values. The salinity values are then converted to chlorides. The calculations for linking salinity values and chloride values are described in *Savannah Harbor Expansion Project- Chloride Data Analysis and Model Development* report dated November 15, 2006 prepared by Tetra Tech.

The run period and flow parameters are shown below and were specified by the Savannah Harbor Expansion Water Quality Technical Evaluation Group and have been consistent throughout the study process. The group developed two model input scenarios for evaluation (See Table 1).

Table 1: Model Input Conditions

| <i>Run Scenario</i>      | <i>River Flow</i>               | <i>Evaluation Period</i>        |
|--------------------------|---------------------------------|---------------------------------|
| Basic Evaluation         | <i>Critical Flow Conditions</i> | <i>1-May to 1-November 1999</i> |
| Sensitivity Analysis #1  | <i>Average Flow Conditions</i>  | <i>1-May to 1-November 1997</i> |
| *Sensitivity Analysis #2 | <i>Low Flow Conditions</i>      | <i>1-May to 1-November 2001</i> |

*\*Sensitivity Analysis #2 was evaluated in addition to the two scenarios proposed by the technical evaluation group, because it has lower freshwater flows than that of 1999 and indicates a greater chloride impact on Abercorn Creek.*

## Output Presented

This report includes analysis of chloride values on Abercorn Creek near the City of Savannah's water intake pipe. All output was evaluated in the hydrodynamic model (EFDC) at cell 8\_130, which is representative of the water quality conditions at the City's intake pipe. The analysis includes tables showing (1) percent exceedance chloride values, (2) maximum and minimum chloride values and (3) number of days the chloride values are greater than 12 ppm. There are also three figures at the end of the report that show the percent exceedance chloride values presented in the tables in graphic form for each of the three run scenarios. All chloride values presented in the output are in units of ppm.

## Results

The results of the analysis show that there is little impact expected on chloride values near the City's intake pipe. The graphics make for a quick interpretation of the results and show the obvious slight impact to the chloride values. The largest increases in chlorides were found during the low flow period of 2001. At 1 percent exceedance the chloride value increase is less than 0.4 ppm with the 48 ft channel deepening. There are no changes in the number of days the chloride values are above 12 ppm when comparing existing conditions and proposed channel geometries. When viewing the three flow conditions, it becomes apparent that lower freshwater flow conditions contribute to higher salinity values in the harbor and thus chloride values at the City's intake increase as well. The number of days that the chloride value is above 12 ppm jumps from 95 to 180 when you compare average and drought flow conditions.

## Conclusion

In summary, Mitigation Plans 6a and 6b are the proposed flow altering mitigation plans to reduce impacts in the estuary. The model results show that chloride values do increase at the intake, despite mitigation efforts, but the increases are certainly not significant. The variability of chlorides at the City's intake is highly dependent on freshwater flow conditions, much more so than deepening the navigation channel.

# Basic Evaluation

Simulation Period: May 1, 1999 to November 1, 1999

## Introduction

This report summarizes the results of fishery habitat impacts with implementation of the proposed mitigation plan to alter flows in the estuary at each alternative channel depth (44, 45, 46, 47 and 48 ft below MLLW). The two proposed plans are: Plan 6b for the 44 ft depth, and Plan 6a for the 45, 46, 47 and 48 ft depths. Details of each of the mitigation plans are shown in Figures 1 and 2. For details on how these plans were developed and selected, please see the main report document for this project.

**Figure 1:** Plan 6a (proposed mitigation for 45, 46, 47 and 48 ft channel depths)

**Figure 2:** Plan 6b (proposed mitigation for 44 ft channel depth)

In addition to the two proposed mitigation plans that alter flows in the estuary there is also a proposal to implement a Dissolved Oxygen Improvement System in the estuary that would raise DO levels during critical periods. The system would pull a sidestream of water from the river, superoxygenate the sidestream by combining the water with pure oxygen through the use of Speece Cones and then reintroduces the sidestream back into the river system where the superoxygenated water is allowed to mix with the water in the estuary system. This system allows treating the entire river for oxygen deficiencies through a small sidestream of water. For more details on the oxygen improvement system see the report titled *Design of Dissolved Oxygen Improvement Systems in Savannah Harbor* prepared by Tetra Tech and dated February 29, 2008.

## Model Input

The plans were evaluated using the 3D hydrodynamic model EFDC and water quality model WASP. The run period and flow parameters are shown below and were specified by the Savannah Harbor Expansion Fisheries Interagency Coordination Team and have been consistent throughout the study process. The group developed several model input scenarios for different species and life stages for evaluation (See Table 1).

Table 1: Model Input Conditions & Habitat Criteria

| SPECIES & LIFE STAGE          | FRESHWATER FLOW CONDITIONS | SIMULATION PERIOD | HABITAT CRITERIA                                                                                                                                                                                                          |

\*Findings from the August scenarios can be found in Design of Dissolved Oxygen Improvement Systems in Savannah Harbor prepared by Tetra Tech and dated February 29, 2008.

Long term percentile freshwater river flows needed for the simulations were determined using recorded gage data for Savannah River at Clyo, GA. The simulations run during the August time period did not use 50<sup>th</sup> percentile flows. These simulations were run by Tetra Tech and details of the findings can be found in the report titled *Design of Dissolved Oxygen Improvement Systems in Savannah Harbor* prepared by Tetra Tech and dated February 29, 2008. The DO Improvement System was designed for the critical period of August and evaluations were done for two different flow conditions: 1) 1997 representing an Average flow year and 2) 1999 representing a drought/low flow year. The long term 50<sup>th</sup> percentile freshwater flow value for August used as the upstream boundary condition in the initial habitat impact report (*Habitat Impacts of the Savannah Harbor Expansion Project* prepared by Tetra Tech and dated October 12, 2006) is 8130 cfs. The 50<sup>th</sup> percentile flow value for 1997 only is 9950 cfs and for 1999 only is 7380 cfs. The long term 50<sup>th</sup> percentile August flow value is actually between the average and drought year flows simulated in the oxygen improvement analysis and design.

## Output Presented

There are three types of output presented in this report. 1) Tables showing calculated areas of suitable habitat, 2) figures showing where these suitable habitat areas are located and how they may have changed with deepening the navigation channel and implementation of the mitigation plans, and 3) tables showing the habitat suitability for each cell, including columns for each criteria constituent. Tables and figures are compiled from runs done both by the USACE and by Tetra Tech. The evaluations performed by Tetra Tech were first presented in the Tetra Tech report titled *Design of Dissolved Oxygen Improvement Systems in Savannah Harbor* dated February 29, 2008.

## Results

Table 2 (next page) presents a summary of impacts to fisheries habitat for American Shad, Striped Bass, and Shortnose Sturgeon, and Southern Flounder. All values listed in the tables are square kilometers of the river system and are based on the criteria proposed by the Fisheries Interagency Coordination Team. The values listed for the % difference represent the percentage change between the proposed and existing project conditions. The proposed conditions in this case are with the navigation channel deepening and the mitigation plan in place. The % diff (Deepening Only) represents habitat gained or lost with deepening only and no mitigation plan in place.

The model results show that the impact to American Shad, based on the habitat suitability criteria, is very low. The majority of the small loss shown comes with the mitigation plan implemented. However, this number is a bit misleading. Modeling the mitigation features involved closing some of the grid cells to mimic placement of material for either a plug type of feature of a diversion structure. To model these features an entire cell was virtually deleted from the model grid and no DO, salinity, or velocity calculations were made for this area. Therefore the post processor considered these cells to fail the habitat criteria and were tagged as habitat lost. Although, there will likely be some habitat area lost due to construction of the mitigation features, it will likely be very small.

Striped Bass eggs, larvae and spawning do show less habitat loss with implementation of the mitigation features. The greatest gain is with the 46 ft depth, there is no net loss and the habitat gain is actually 191.4% for the 20<sup>th</sup> percentile flows. While that is a dramatic gain, it isn't typical of all the results.

Shortnose Sturgeon juveniles see reductions in impacts with implementation of the mitigation plan. However, the Shortnose Sturgeon adults see a greater impact on their habitat with implementation of the mitigation plan.

## Conclusion

In summary, Mitigation Plans 6a and 6b are the proposed flow altering components of the mitigation plans. Both of the proposed plans include operation of the DO Improvement System during critical periods (July through September). The plans do have an effect on fisheries habitat. The positive impacts occur with Striped Bass, especially larvae, Southern Flounder, and Shortnose Sturgeon juveniles. There is little to no impact shown with American Shad. Shortnose Sturgeon adults experience the greatest negative impact during the January flow period, however, the August flow period shows improvement over the deepened only condition when the DO Improvement System is activated.

Striped Bass - Eggs

50th percentile APRIL 2006

Subsidiary Hospital when

7) Molar % of permeable solute = 5 mol

(7) Mean velocity = 0.30 cm/s; and  
(8) Mean discharge is 13.3 m<sup>3</sup>/s.

[illegible]

# Striped Bass - Eggs

50th percentile AFPL Rows

Source: Natural Resources Canada  
 (1) Mean 50th percentile safety is 3.0%  
 (2) 50th percentile safety is 3.0%  
 (3) 50th percentile safety is 3.0%

Striped Bass - E

Know Your Own Mind

Qualitative feedback obtained

(1) Mean: 50th percentile salinity = 9 ppt

(2) Mean velocity  $\approx 20$  cm/s, and[illegible]

77. Mean velocity of 30 cm/s and 10% permeable D.C. = 4.9 mph

[illegible]

Striped Bass - Eggs

BRUCE TILDEY @NCSU0101

Evolutionary Psychology Review

(1) Mean 50th percentile activity = 6 kcal.

(2) Mean velocity  $\approx 30$   
(3) 1976 density  $\approx 1.5$ [illegible]

Striped Bass - Larvae  
20th percentile MAY flows

Sublethal halibut when

- (1) Mean 50m permeon salinity between 2 and 8 ppt, and
- (2) Mean 10m percentile D.O. >= 4.3 mg/l

**Striped Bass - Larvae**  
**50th percentile MAY flows**

Suitable habitat when  
 1) Mean 50th percentile density between 3 and 8 ppt, and  
 2) Mean 10th percentile D.O. >= 6.2 mg/l

**Striped Bass - Larvae**  
80th percentile MAY flows

Sulphable habitat when

1) Mean 50th percentile salinity between 3 and 9 ppt and

2) Mean 10th percentile D.O.  $\approx 4.5$  maj[illegible]

**Striped Bass - Larvae**  
80th percentile MAY flows

Suitable habitat when

(1) Mean 50th percentile salinity between 3 and 9 ppt, and

(2) Mean 10th percentile D.O. = 4.5 mg/l

[illegible]

**Striped Bass - Spawning**  
20th percentile APRIL flows

Sustainable habitat when

95th percentile safety cut point and

(2) Mean velocity  $\approx 37$  cm/s[illegible]

# Striped Bass - Spawning 20th percentile APRIL flows

Schedule: Natural flows  
(1) 50m<sup>3</sup>/sec, (2) 100m<sup>3</sup>/sec, (3) 150m<sup>3</sup>/sec  
(4) Mean velocity = 30 cm/s

Striped Bass - Spawning  
50th percentile APRIL flows

Suitable habitat when

1) 50th percentile salinity &lt; 1 ppt, and

2) Mean velocity  $v = 30 \text{ cm/s}$

[illegible]

Striped Bass - Spawning  
50th percentile APRIL flows

Sustainable Habitat when

<sup>1)</sup> 90th percentile salinity  $\leq 1$  ppt. and2) Mean velocity  $\bar{u}$  (m/s)[illegible]

Striped Bass - Spawning  
50th Percentile APRIL 10th

Suitable habitat when  
(1) 50th percentile salinity > 1 ppt. and  
(2) mean velocity >= 50 cm/s

**Striped Bass - Spawning**  
80th percentile APRIL flows

Suitable habitat when

Suitable habitat when

(1) 50th percentile salinity  $\leq 1$  ppt, and  
(2) Mean velocity  $\geq 30$  cm/s

(2) Mean velocity  $\geq 30$  cm/s[illegible]

# Striped Bass - Spawning

60M profile APRIL flows

Suitable habitat when

(1) 50th percentile salinity <= 1 ppt. and

(2) Mean velocity >= 30 cm/s

Shortnose Sturgeon - Juvenile  
50th percentile JANUARY flows

Cultivable habitat when 00

 $\mu = 3.5$  mol/l at 90% exceedance (10th 99ile). $\mu = 3.0$  at 95% (5th percentile) and $\mu = 2.0$  at 99% (1 percentile)

Suitable habitat when Max Salinity <= 4 ppt

[illegible]

**Shortnose Sturgeon - Juvenile**  
50th percentile JANUARY flows

Sustainable habitat when CO

 $\alpha = 3.5$  mol at 90% excedance (10th %ile). $\geq 3.0$  at 95% (5th percentile), and $p=2.0$  at 99% (1 percentile)Suitable habitat when Max Salinity  $\leq 4$  ppt.

# Shorthose Sturgeon - Juvenile 50th percentile JANUARY flows

Suitable habitat when DO

>= 1.5 mg/l at 90% exceedance (10th %ile).

>=3.0 at 95% (5th percentile), and

>=2.0 at 99% (1 percentile)

Suitable habitat when Max Salinity <= 4 ppt

# Shortnose Sturgeon - Adults

## August average flows

Suitable habitat when DO

>= 4.0 mg/l at 50% exceedance (10th %ile),

>= 3.0 at 95% (5th percentile), and

>= 2.0 at 99% (1 percentile)

Suitable habitat when Max Salinity <= 10 ppt

# **Savannah Harbor Expansion Project**

Evaluation of Hurricane Surge Impacts with  
Proposed Mitigation Plan

*December 2007*

## Introduction

This report summarizes the results of hurricane surge impacts with implementation of the proposed mitigation plan to alter flows in the estuary at each alternative navigation channel depth (44 ft, 45 ft, 46 ft, and 48 ft). The two proposed plans are: Plan 6b for the 44 ft depth, and Plan 6a for the 45 ft, 46 ft, and 48 ft depths. Details of each of the mitigation plans are shown in Figures 1 and 2. For details on how these plans were developed and selected, please see the main report document for this project.

The purpose of the hurricane surge modeling is to determine the impacts of deepening the navigation channel and implementation of the proposed mitigation plan and its effect on the propagation of a hurricane storm surge traveling upstream through the estuary and river system.

**Figure 1:** Plan 6a (proposed mitigation for 45 ft, 46 ft and 48 ft channel depths)

**Figure 2:** Plan 6b (proposed mitigation for 44 ft channel depth)

## Hydrodynamic Model Input

The plans were evaluated using the 3D hydrodynamic model EFDC, which predicts, among other variables, water surface elevations. For the hurricane surge analysis, the water surface elevations are compared at different points in the harbor to determine impacts.

To incorporate a hurricane storm surge in the 3D hydrodynamic model the tidal boundary was modified. The hurricane surge data set was developed by Applied Technology and Management, Inc. (ATM). The data set is based on measured water surface elevations collected at the USGS Customs House gage located in Charleston, SC during Hurricane Hugo which made landfall on September 21, 1989. ATM separated the hurricane storm surge component from the harmonic tidal component. The max increase in water surface elevation for the hurricane storm surge component collected at this gauging station is 7.69 ft. However, the storm surge as Hurricane

Hugo made landfall varied with some places receiving a near 20 ft storm surge. Due to the difficulty in directly applying the storm surge gage data in Charleston to Savannah the data set was ratioed by ATM to create three synthetic storm surges with peaks of 5 ft, 10 ft and 15 ft. For the initial impact analysis all three of the synthetic storm surges were modeled, see *Hurricane Surge Modeling* dated September 23, 2005. However, for the purposes of analyzing the impacts with the proposed mitigation plans only the 15 ft storm surge was modeled.

The modeling time period is late August 1997, which was chosen for several reasons. (1) 1997 closely represents historic average flow conditions at Clyo (the upstream flow boundary, (2) August is close to peak hurricane season when the likelihood of a large storm hitting the Savannah coastline would be more probable, and (3) spring tidal conditions occur on August 19, 1997.

## Output Presented

Before presenting the output and discussing the results, the limitations of the EFDC hydrodynamic model grid developed for the Savannah Harbor Expansion Project. The model grid developed for the expansion study was not developed with emphasis on hurricane surge modeling. The shipping channel, Back River system and other smaller side channels are described in detail in the grid, with emphasis on salinity and dissolved oxygen levels in the estuary. The beaches and uplands are not accounted for in the model. The marshes are accounted for, but on a volumetric approach with emphasis on calibration. These areas would likely be impacted during a hurricane and would have a significant role on the propagation of a storm surge throughout the estuary. The model is useful for relative comparative purposes and NOT to describe where flooding would occur during a hurricane.

This report includes analysis of hurricane surge impacts in the estuary. All output was evaluated in the hydrodynamic model (EFDC) at two cells 14\_48, which is representative of the water quality conditions near Fort Jackson and 14\_126, which is at the I-95 bridge. The analysis includes a table showing peak surge values and two figures that show the water surface elevations over the length of the storm surge. All values presented are water surface elevations in meters-NGVD.

## Results

The results of the analysis show that there is little impact expected on hurricane surge at Fort Jackson or further upstream at the I-95 bridge. See Table 1. The figures following the report make for a quick interpretation of the results and show the obvious slight impact to the hurricane surge.

**Table 1:** Peak Surge Elevations

|                      | <b>Ft. Jackson</b> | <b>Rise in Elev.<br/>(Ft. Jackson)</b> | <b>I-95</b> | <b>Rise in Elev.<br/>(I-95)</b> |
|----------------------|--------------------|----------------------------------------|-------------|---------------------------------|
| Existing Depth       | 6.48               | -                                      | 6.66        | -                               |
| 44 ft Depth, Plan 6b | 6.54               | 0.06                                   | 6.82        | 0.16                            |
| 45 ft Depth, Plan 6a | 6.54               | 0.06                                   | 6.85        | 0.19                            |
| 46 ft Depth, Plan 6a | 6.55               | 0.07                                   | 6.87        | 0.21                            |
| 48 ft Depth, Plan 6a | 6.58               | 0.10                                   | 6.90        | 0.24                            |

*All elevations are m-NGVD. All rises in elevation are m.*

The output results in Table 1 show that the maximum increase in the water surface elevations occur for the 48 ft channel depth (deepening 6ft). At the I-95 bridge this increase is 0.24 m. While this is an increase due to deepening, it is certainly not considered significantly large as compared to the overall storm surge height of 15 ft.

The impacts analysis (*Hurricane Surge Modeling* dated September 23, 2005) showed that the 48 ft channel depth with the surge peak occurring during the spring tidal peak had the greatest impact on the surge height. All other scenarios that were modeled with varying tidal conditions during the surge peak did not have increases as great as the peak-on-peak condition that was also modeled in this analysis. Therefore, it is concluded that the 15 ft storm surge during the spring tide is the worst case and the maximum increases that are predicted are 0.24m.

## Conclusion

In summary, Mitigation Plans 6a and 6b are the proposed flow altering mitigation plans to reduce impacts in the estuary. The model results show that a hurricane surge does increase, despite mitigation efforts, but the increases are certainly not significant.

# **Savannah Harbor Expansion Project**

Evaluation of Marsh/Wetland Impacts with  
Proposed Mitigation Plan

*November 2007*

## Introduction

This report summarizes the results of marsh impacts with implementation of the proposed mitigation plan to alter flows in the estuary at each alternative channel depth (44 ft, 45 ft, 46 ft, and 48 ft). The two proposed plans are: Plan 6b for the 44 ft depth, and Plan 6a for the 45 ft, 46 ft, and 48 ft depths. Details of each of the mitigation plans are shown in Figures 1 and 2. For details on how these plans were developed and selected, please see the main report document for this project. It should be noted that these plans are not considered the Selected Mitigation Plan, but will be a component of the Selected Plan.

**Figure 1:** Plan 6a (proposed mitigation for 45 ft, 46 ft and 48 ft channel depths)

Figure 2: Plan 6b (proposed mitigation for 44 ft channel depth)

## Hydrodynamic Model Input

The plans were evaluated using the 3D hydrodynamic model EFDC. The run period and flow parameters are shown below and were specified by the Savannah Harbor Expansion Wetland Interagency Coordination Team and have been consistent throughout the study process. The group developed four model input scenarios for evaluation (See Table 1).

**Table 1:** Model Input Conditions

| <i>Run Scenario</i>      | <i>River Flow</i>      | <i>Sea Level Rise*</i>      | <i>Evaluation Period</i>     |
|--------------------------|------------------------|-----------------------------|------------------------------|
| Basic Evaluation         | <i>Average/Typical</i> | <i>Existing Sea Level</i>   | <i>1-March to 1-November</i> |
| Sensitivity Analysis #1  | <i>Low Flow/Dry</i>    | <i>Existing Sea Level</i>   | <i>1-March to 1-November</i> |
| Sensitivity Analysis #2A | <i>Average/Typical</i> | <i>25 cm Sea Level Rise</i> | <i>1-March to 1-November</i> |
| Sensitivity Analysis #2B | <i>Average/Typical</i> | <i>50 cm Sea Level Rise</i> | <i>1-March to 1-November</i> |

*\*25 and 50 cm sea level rise conditions were specified by the Interagency Coordination Team and are based on EPA and NOAA projections.*

Average/typical river flows needed for the Basic Evaluation and Sensitivity Analysis #2A and B were determined using recorded gage data for Savannah River at Clyo, GA. The EFDC model has continuous input boundary conditions for a 7 year period (1997 – 2003) available for simulation. 1997 was found to have flow conditions representative of the long term average flows. The flow boundary conditions for Sensitivity Analysis #1 are low flow or dry year conditions. Using the recorded gage data at Clyo, GA, 2001 (March through October) was considered to be a low flow/dry period.

The two sea level rise conditions used in Sensitivity Analysis #2A and B were modeled by adding an additional 25 or 50 cm, depending on the run scenario, to the water surface elevations on the open ocean boundary cells. The sea level rise sensitivity analyses are based only on a change in the ocean boundary water surface elevation. There was no consideration of any potential change in the ocean boundary salinity density in this modeling effort.

All other model boundary inputs remain unaltered and correspond to the run time of 1 March to 1 November for 1997 or 2001, depending on the run scenario being modeled.

## Output Presented

There are three types of maps presented in this report:

- 1- *Surface Salinity Difference Maps*- Maps show the change in riverine salinity at each EFDC grid cell between the existing condition and each mitigation plan. Salinity values are predicted using the hydrodynamic model (EFDC) and were computed for the 10% and 50% exceedance values. The grid cells are color coded to show the salinity differences. The grey shading is used to show cells that have lower salinity values than the existing condition (i.e.

deepening impacts have been reduced to 0, and, in fact, show improvement over the existing condition).

- 2- *Bottom Salinity Difference Maps*- Maps show the change in riverine salinity at each EFDC grid cell between the existing condition and each mitigation plan. Salinity values are predicted using the hydrodynamic model (EFDC) and were computed for the 10% and 50% exceedance values. The grid cells are color coded to show the salinity differences. The grey shading is used to show cells that have lower salinity values than the existing condition (i.e. deepening impacts have been reduced to 0, and, in fact, show improvement over the existing condition).
- 3- *Freshwater Threshold Maps*- Maps show the change in the freshwater threshold in the river. The threshold is based on the EFDC modeling 50% exceedance, surface salinity value. The threshold marks the line where salinity values change from below 0.5ppt to above 0.5ppt and vice versa.
- 4- *Predicted River Salinity from the Hydrodynamic Model (EFDC)*- The EFDC model grid is shown with 50% exceedance surface salinities broken into 5 categories: 0-0.5 ppt, 0.6-1.0 ppt, 1.1-2.0 ppt, 2.1-4.0 ppt, 4.0-32.5 ppt.
- 5- *Estimated Marsh Salinity Contour Lines*- Marsh salinity contour lines are shown that break the marsh into 5 categories: 0-0.5 ppt, 0.6-1.0 ppt, 1.1-2.0 ppt, 2.1-4.0 ppt, > 4.0 ppt. The first category 0-0.5 ppt represents freshwater marsh. The contour lines were extrapolated into the marsh from the riverine hydrodynamic model results shown in the maps described above 4- *Predicted River Salinity from the Hydrodynamic Model*.

Because of the subjectivity of developing the contour lines for this set of maps, two measures were taken to ensure the results are valid. First, all of the maps were developed by the same person to eliminate bias due to the possibility of different perspectives. Second, verification was done to determine a level of confidence in comparing the results. The verification was done by testing the repeatability of drawing the contour line for the freshwater zone (0-0.5 ppt) for three randomly selected maps. For the repeatability test, first the same person redrew the freshwater zone. Second a different person redrew the freshwater zone. Both of these tests produced acreages with less than a 2% difference from the original acreages. From this test, the results are considered valid within +/- 50 acres.

## Results

In viewing and discussing the results of the mitigation plans it is important to remember the following:

- 1- The marsh impacts are evaluated by looking at the *net* acreage. This is especially important when discussing the impacts to freshwater marshes. The net acreage value is based on the conditions of the marsh after the project is in place. It does not take into consideration what the marsh salinity is under current conditions. For example, a mitigation plan may gain freshwater marsh on Back River and lose freshwater marsh on Front River. The net acreage

may meet the impact criteria, but in reality, it may take some time for a marsh to convert from a brackish marsh to a freshwater marsh.

- 2- The model has a limited ability to evaluate specific design parameters of a true diversion structure. The diversion structure described in each of the plans was modeled by altering the Front River width just downstream of McCoys Cut. By narrowing the passage on Front River the water surface elevation at the mouth of McCoys Cut was increased. The rise in elevation encourages more water to go down McCoys Cut. EFDC does not have options for inserting a defined diversion structure but narrowing the River channel in this area is essentially what a diversion structure will do.

Several different "sizes" of diversion structures were evaluated during the development of the mitigation plans by varying the widths of the narrow passage on Front River. This allowed us to vary the amount of flow diverted down McCoys Cut. The structure modeled in Mitigation Plan 3, and each of the additional plans in this report, was found to be the most effective at diverting freshwater flows through McCoys Cut of the several different "sizes" evaluated. A future design task will be required to develop specifications for a diversion structure that performs as in the model simulation.

The evaluation of each of the mitigation plans included review of the effects the plan has on the tide range and velocities. It was concluded that both of the selected plans do not reduce the tide range significantly in Back River, Little Back River, or Middle River. Velocities for all the additional plans are close to existing conditions. However, as expected, removing the abutments and piers in the two plans do increase velocities in Back River and Little Back River slightly above the existing condition.

Results from the modeling are presented in the following tables. Table 2 shows estimated marsh salinity impacts based on the mapping described in *5-Estimated Marsh Salinity Contour Lines* above. The contour line verification described in the previous section suggests the acreages are valid within +/- 50 acres. Table 3 shows the predicted salinities (on Little Back River at the entrance of Lucknow Canal).

**Table 2:** Estimated Marsh Salinity Acreage Impacts

*All values listed are in acres and are based on the Salinity Contour Maps derived from EFDC output.*

## Conclusion

In summary, Mitigation Plans 6a and 6b are the proposed flow altering mitigation plans to reduce salinity impacts in the harbor. The model results show that the mitigation plans do reduce the salinity impacts due to deepening the navigation channel, and in some areas the plans provide suitable conditions for freshwater marsh where it currently does not exist.

It is interesting to note, that depending on which flow condition is focused on, the impacts are variable. The three Sensitivity Analysis show that Plans 6a and 6b reduce the net freshwater marsh loss to zero under the four depth scenarios when compared to the existing conditions. The Basic Evaluation output shows some of the depths continue to have impacts on freshwater marsh and will require other measures, outside of what is presented here, to fully mitigate for the loss of freshwater wetlands. The range of flow conditions modeled, provides a broad overview of the current harbor conditions and how they will be changed with the deepening project.

# **Savannah Harbor Expansion Project**

Evaluation of Water Quality Impacts with Proposed Mitigation Plan

*September 2009*

## Introduction

As part of the Savannah Harbor Expansion Project, impacts to water quality in the Savannah River estuary were evaluated for each project alternative channel depth (44 ft, 45 ft, 46 ft, 47 ft, and 48 ft). This report summarizes the water quality impacts, in tabular format, as a result of deepening the navigation channel along with implementation of the proposed mitigation plan. The proposed mitigation plan for each alternative project depth incorporates both modifications to the flow regime in the estuary and an alternative source of dissolved oxygen. The two proposed flow altering plans are: Plan 6b for the 44 ft channel depth and Plan 6a for the 45 ft, 46 ft, 47 ft, and 48 ft channel depth. Details of the flow altering mitigation plans are shown in Figures 1 and 2.

**Figure 1:** Plan 6a (proposed mitigation for 45 ft, 46 ft, 47 ft and 48 ft channel depths)

Figure 2: Plan 6b (proposed mitigation for 44 ft channel depth)

The mitigation component of the project to offset impacts to dissolved oxygen (D. O.) concentrations in the river consists of injecting superoxygenated water into the river via Speece Cones. Speece Cones were developed by Dr. Richard Speece and are manufactured by Eco-Oxygen Technologies, LLC. See Figure 3 for a photo of Speece Cones used during a D.O. demonstration project in 2007. These Speece Cones differ from the project proposal in that they were barge-mounted rather than land-based.

The D.O. mitigation plan using Speece Cone technology was developed by Tetra Tech and details of the plan are documented in the report titled *Design of Dissolved Oxygen Improvement Systems in Savannah Harbor* dated February 29, 2008. The D.O. loading required to mitigate for channel depth increases as a result of this study is summarized in Table 1. Locations around the estuary recommended for D.O. injection points are shown in Figure 4.

Figure 3: Savannah Harbor Speece Cone Demonstration Project

Photo from the Georgia Ports Authority demonstration project managed by MACTEC in the summer of 2007. Results of the study are documented in the 2008 MACTEC report titled *Savannah Harbor Reoxygenation Demonstration Project, Savannah, Georgia* which was prepared for the GPA.

Table 1: Summary of Dissolved Oxygen Loading for SHEP Mitigation

| Alternative Channel Depth | Flow Altering Mitigation Plan | Speece Cone Location | D.O. Loading Required for Mitigation (kg/day) | D.O. Loading Required for Mitigation (lbs/day) | No. of Speece Cones Required |
|---------------------------|-------------------------------|----------------------|-----------------------------------------------|------------------------------------------------|------------------------------|
| 48 ft                     | 6A                            | Tide Gate            | 2,000                                         | 4,400                                          | 1                            |

**Figure 4: D.O. Injection Locations**

## Output Presented

Output presented in this report is supplemental to the output presented in the report titled *Design of Dissolved Oxygen Improvement Systems in Savannah Harbor* prepared by Tetra Tech and dated February 29, 2008. At the request of members of the Water Quality Interagency Coordination Team the output has been expanded to show details on model predicted changes in D.O. for four scenarios.

- Existing conditions, no deepening and no mitigation
- Navigation channel deepening only (44 ft to 48 ft)
- Deepening with flow altering mitigation plan (6a or 6b)
- Deepening with flow altering mitigation plan and the D.O. injection system

The output presented includes various tables showing D.O. concentrations and changes in concentrations for the evaluation period of August 1997 (average freshwater flow year). Since the water quality model grid is refined with a high level of detail it can be difficult to evaluate output datasets. To simplify the evaluation process the estuary has been divided into 27 spatial zones, which are areas where several model grid cells are evaluated as a group. See Figure 5.

Figure 5: Spatial Zones for Water Quality Impact Evaluation

## Results

The tables shown in the pages following the Conclusion are divided into sections for each navigation channel depth alternative, with 4 tables associated with each depth alternative and mitigation scenario. The tables present the D.O. percentile distribution in critical cells and zones. Critical cells are defined as the cell within each zone that has the lowest predicted D.O. concentration during the simulation period. In addition to the two tables showing predicted D.O. values for various percentiles for critical cells and zones there are two tables showing the change in D.O. from existing conditions for critical cells and zones.

The maximum D.O. impact to a critical cell (50<sup>th</sup> percentile value) with a 48 ft deepened channel is 0.56 mg/L and occurs in Zone FR7. With the flow altering mitigation (Plan 6a), this impact is reduced to 0.54 mg/L, which although a reduction, is not enough to fully mitigate for the impact. Once the D.O. mitigation is in place the D.O. impact to the critical cell in this zone falls to 0.01 mg/L, which is essentially a zero impact.

The maximum D.O. concentration impact within the entire zone (50<sup>th</sup> percentile value) with a 48 ft deepened channel is 0.68 mg/L and occurs in Zone FR7. With the flow altering mitigation (Plan 6a) this impact is not reduced and actually increases to 0.75 mg/L. However, with D.O. mitigation this impact is fully mitigated for and improves the D.O. concentration by 0.05 mg/L over the existing conditions.

## **Conclusion**

The results of this analysis conclude the following:

- 1) That there is an impact to water quality, specifically D.O., within the estuary due to deepening the navigation channel.
- 2) That flow altering mitigation plans, while beneficial for freshwater marshes/wetlands, do not have wide ranging benefits for impacts to D.O.
- 3) That D.O. injection, via Speece Cone technology, is a viable option for mitigating for impacts due to deepening the navigation channel.

# Difference of D.O. %-tiles for zones of Savannah Estuary

Simulation Period: Year 1997 AUGUST 1 -AUGUST 31

Baseline snario: WASP1997Existing

Project arrio: 6A6ft-withDOmitigation
