On September 29, 2005, Service staff participated in two interagency teleconferences, one to discuss the overall project status and needs and the second to discuss the hydrologic model and 2050 conditions. A decision needs to be made on whether or not to use all projected 2050 demands on the Caloosahatchee River or only the Savings Clause demands when selecting alternatives. The Service recommended that the Corps use all projected 2050 demands to develop alternatives as this will more accurately reflect the conditions under which the reservoir will operate. Using only the Savings Clause demands is unrealistic because upstream water use cannot be controlled or limited to the Savings Clause levels without legislation. The Service believes that this conservative approach is necessary to provide water to the estuary to protect fish and wildlife resources for the life of the project.

On October 11, 2005, Service staff participated in an interagency teleconference to discuss the C-43 hydrologic model and 2050 conditions. A decision needs to be made on whether or not to use all projected 2050 demands on the Caloosahatchee River or only the Savings Clause demands when selecting alternatives. The agencies have not come to a consensus and will most likely elevate the issue to the Quarterly Review Board (QRB).

On October 12, 2005, the Service reviewed and provided comments on the Water Quality Monitoring Plan for the C-43 Test Cell Project.

On October 13, 2005, Service staff attended the C-43 stakeholders meeting.

On November 3, 2005, Service staff participated in an interagency teleconference to discuss project status and needs. A decision still needs to be made on whether or not to use all projected 2050 demands on the Caloosahatchee River or only the Savings Clause demands when selecting alternatives.

On November 9, 2005, Service staff attended an interagency meeting to discuss preliminary designs to incorporate littoral zones for fish and wildlife habitat adjacent to the seepage canal bordering the C-43 West Reservoir. Designs will be further developed by SEA and distributed to the group for review. The extent of wetland acreage is much smaller than originally discussed (*i.e.*, total is less than 30 acres) and will be spaced every 500 feet between areas reserved for potential ASR wells.

On November 10 and 17, 2005, Service staff participated in the weekly interagency teleconferences to discuss project status and needs. The revised project schedule and milestones

were discussed. The AFB was pushed back to May 11, 2005, and the AFB package submittal to headquarters was planned for April 11, 2005.

Service staff attended the November 14, 2005, scoping meeting for the Corps' upcoming Supplemental EIS on the Lake Okeechobee Regulation Schedule held in Fort Myers.

Service staff attended the November 18, 2005, Southwest Florida Water Resources Conference on Water Quality in the Caloosahatchee Basin.

On November 30, 2005, the Service completed formal and informal consultation on the Test Cell project via a letter and accompanying Biological Opinion addressing project effects on the Florida panther.

Service staff participated in a three day interagency meeting held December 6 through 8, 2005, in Fort Lauderdale to review the formulas and results generated by the Habitat Suitability Index (HSI) models that will be used to evaluate the ecological performance of the proposed project alternatives. Recommendations included changes in the spatial extent of model boundaries for oysters, sea grasses, and *Vallisneria;* and changes in model computations when variables have zero values.

On December 21, 2005, Service staff reviewed responses to our comments on the water quality monitoring plan for C-43 test cells. The District has satisfactorily addressed or incorporated the Service's concerns and recommendations.

On January 3, 2006, the Service email to Corps and District regarding follow up on the Test Cell project 404 permit and threatened and endangered educational materials; caracara and indigo snake surveys for the full reservoir footprint; and the design, location, and acres of littoral zones and other fish and wildlife features.

Service staff participated in the January 6, 2006, conference call on the C-43 Reservoir project status.

Service staff participated in the February 2, 2006, conference call on outstanding project issues. Discussions focused upon: 1) Use of a regression model or the recently available hydrodynamic model to model salinity conditions in the estuary. The regression model still needs refinement, does not incorporate tidal fluctuations, and the Interagency Modeling Center review resulted in 69 comments that need to be addressed. 2) If the proposed monthly output of the HSI models is appropriate or sensitive enough for the species being modeled. For example, juvenile oysters cannot tolerate salinities below 5 parts per thousand for more than 14 days and the monthly out put would not detect this occurrence.

The Service met with the District and the Corps on the February 6, 2006, to review the March 28, 2005, draft Fish and Wildlife Recommendations for Comprehensive Everglades Restoration Plan (CERP) Stormwater Treatment Area and Reservoir Operation and Design developed by the Service and the FWC and discussed incorporating those recommendations in

the design of the C-43 West Reservoir. The District will not incorporate any of the recommendations in the reservoir design that might encourage birds to nest in the vicinity. Additionally, the interior slopes of the reservoir levees will be lined with a concrete soil mixture to prevent erosion, reduce seepage, and increase levee stability. The current reservoir design does include construction of 9 to 28 acres of shallow wetland habitat adjacent to the seepage canal that will be constructed 80 to 100 feet from the outside perimeter of the reservoir. Any existing canals and new borrow pits or canals dredged during levee construction will not be filled to provide deep water habitat for fish during periods of drought or when the reservoir is drawn down.

Service staff participated in the February 7, 2006, interagency review of the HSI models for spotted seatrout, blue crabs, and oysters.

Service staff participated in a February 15, 2006, field investigation of seagrass conditions in San Carlos Bay and Pine Island Sound. Density and biomass observations suggest that seagrass health declines as distance from the mouth of the Caloosahatchee River decreases.

Service staff participated in a February 21, 2006, teleconference regarding the current project status and projected timeline for completion of the Interim PIR.

On February 22, 2006, the Service received a Freedom of Information Act request from People United to Restore Our Rivers and Estuaries (PURRE). PURRE's request includes all documents related to water management of Lake Okeechobee and discharges from the lake into the Caloosahatchee estuary and related to federally listed species in the Caloosahatchee estuary.

The Service received an informal summary of the first caracara surveys conducted by SEA in compliance with our survey protocol on March 6, 2006, via email and a formal Memorandum summarizing that first survey on March 22, 2006.

The Service received a formal Memorandum summarizing the second caracara surveys conducted by SEA in compliance with our survey protocol via email on March 24, 2006.

On March 30, 2006, Service staff participated in the third caracara surveys conducted by SEA and received a Memorandum summarizing those surveys via email on April 10, 2006.

The Service received the March 31, 2006, Work Plan for Additional soil Investigations to delineate chlordane contamination on the Bryan Paul Citrus Grove. The Service concurred with the work plan via an April 4, 2006, email.

By letter dated April 18, 2006, the Service provided comments on the October 13, 2003, Ecological Risk Assessment for the Berry Labelle-Congen Grove. In that letter, the Service recommended remediation of areas known to be contaminated with copper and that additional soil sampling for copper be conducted.

On April 24 and 25, 2006, the Service attended the C-43 West Reservoir Critical Criteria Meeting in Labelle, Florida. On April 25, 2006, a breakout session was held to review information needs for upcoming permit applications, including information on federally-listed species. Reservoir fill rates protective of indigo snakes recommended for other CERP projects (*i.e.*, C-44) were discussed. The District indicated that those rates were acceptable and that they probably couldn't fill the reservoir faster anyway.

On April 26, 2006, and May 15, 2005, the Service provided information to the Corps and District via email, on the need for and appropriate methodology to conduct panther prey surveys to adequately address project impacts and associated habitat loss to the Florida panther.

The Service held an internal meeting on May 24, 2006, in Vero Beach, Florida, on Eastern Indigo Snake section 7 consultation issues.

On June 19, 2006, Service staff participated in the review of the output from the HSI models for the benefits analysis and comparison of the preliminary project alternatives. Once the benefits analysis is complete, the Tentatively Selected Plan will be determined.

Service staff attended a briefing on July 21, 2006 on the Acceler8 preliminary design for the C-43 West Reservoir Design. Service staff provided comments and recommendations including: development of 3 sets of operating criteria for the reservoir based on current conditions and predicted long-term climatological conditions such as drought, normal, and above average rainfall years; ensure manatee protection measures will be incorporated in design of all water control structures where necessary; ensure inclusion of Indigo snake protection measures in construction contracts; potential decreased surface water elevations in wetlands southwest of the project area in primary panther habitat indicated by preliminary model results need to be evaluated in more detail; and to ensure that current proposed recreation plans for the project area do not conflict with project goals. Storage in the reservoir is not sufficient to meet the restoration target of 450 cfs flows at the S-79 structure for all years modeled nor the state-mandated Minimum Flow and Level of 300 cfs at S-79.

The Service reviewed the July 21, 2006, Additional Soil Assessment Report for the Bryan Paul Citrus Grove. Chlordane contamination was identified to be within a 20-acre area. The Service concurred with the 18micrograms per kilogram (ug/kg) target clean-up level for chlordane in our August 9, 2006, letter.

The Service provided comments on the Additional Soil Investigations, Berry Labelle-Congen Groves report submitted to the District by URS Corporation by letter dated July 26, 2006. In that letter, the Service recommended that further sampling be conducted to accurately delineate the spatial extent of copper contamination and that soil remediation be considered for grids 56 and 145.

The Service attended a tour of the test cell project on July 28, 2006. Construction of the C-43 test cells was completed in June and monitoring of seepage and water quality has been initiated.

On June 30, 2006, the Service received a Freedom of Information Act request on the C-43 BSR project and provided the records requested on August 14, 2006, and September 18, 2006.

On July 13, 2006, the C-43 BSR Project Implementation Report team has identified the Tentatively Selected Plan (TSP) which mirrors the Acceler8 project design. However, the TSP includes greater pumping capacity (*i.e.,* 1500 cfs versus 3800 cfs) and improved operations that more closely achieve the hydrologic target of flow distribution at S-79 (*i.e.,* the EST05 flow distribution). The Corps has recently determined that the Townsend canal and the State Road 80 bridge that crosses the canal can only handle a maximum flow of 2500 cfs. Structural changes to the canal and bridge to accommodate 3800 cfs flows will be needed to implement the TSP and will increase project costs.

The Service provided comments on the 30 percent design review of the Acceler8 design on July 18, 2006.

The Service biologist attended the August 10, 2006 public meeting on the C-43 West Reservoir preliminary design.

On August 14, 2006, Service staff participated in an interagency (Corps, District, Service, and EPA) helicopter survey of the Caloosahatchee River basin and estuary to assess basin-wide project benefits for the Corps' mitigation ledger.

Service staff participated in a September 6, 2006, interagency conference call regarding the Environmental Assessment for the C-43 land swap.

The Service provided comments on the July 20, 2006, document titled "Additional U.S. Fish and Wildlife Service Soil Investigations, Berry Labelle-Congen Groves" in a September 14, 2006, letter. In that letter, the Service concurred that copper contamination was adequately delineated and that grids 56, 58, 124, 125, 134, 135, and 143 require remediation.

The Service attended the October 5, 2006, team meeting to discuss current project status. Issues discussed include: 1) optimizing reservoir operations to bring the TSP and the Acceler8 design closer together; 2) additional project costs include modifications to the Townsend canal to accommodate greater flows associated with the greater pumping capacity, removal of the weir at the river, and reinforcement of the highway 80 bridge; 3) The Corps and District make project decisions based on the long-term benefits and cost analyses with CERP in place. However, this does not reflect the need for and importance of the estuarine benefits from the reservoir that are provided before the rest of CERP is in place. It is this interim period from 2010 to 2025 when Lake Okeechobee releases will be highest that the greater pumping capacity will be needed and the project benefits would be greatest. Using 2050 conditions with CERP to calculate benefits and justify project costs masks the "real" benefits to the estuary during the short-term when the need is most critical. Larger pumps are needed to make a difference during the damaging high flows; 4) The project team was instructed to abide by the new GMs 3 and 4 which require an Interim Operation Run for the year the project will be operational. This will take additional time and money not originally in the schedule; 5) The Corps' schedule has changed due to the

additional modeling; 6) Phase II of the project has been funded for Fiscal Year (FY) 07. Phase II will focus on water quality and water supply needs, as well as additional storage needs, and will be built in the eastern Caloosahatchee Basin (*i.e.,* between S-77 and S-78). The project team has already identified potential locations and gone through the screening process for those sites.

Service staff participated in an October 11, 2006, interagency meeting to recalculate project benefits based on the new optimized model runs and to select a new, "optimized" TSP.

On October 30, 2006, the Service responded to the Response to Corps' October 27, 2006, email regarding section 7 consultation process and keeping the Corps' C-43 West Reservoir Project Implementation Report and the District's Acceler8 C-43 West Storage Reservoir project on the same timeline with one consultation. The Service reiterated that formal consultation would be needed for three species, the caracara, indigo snake, and panther, and requested advanced review of the Biological Assessment before the Corps requested formal consultation.

Service biologist participated in the Corps' CERP vertical team AFB on November 3, 2006.

The Service reviewed and provided comments to the Corps on the Draft Biological Assessment for the C-43 West Storage Reservoir Project, Hendry County, Florida on November 9, 2006.

The Service received combined Department of Army and state of Florida Environmental Resource Permit Application for C-43 project on November 20, 2006.

The Service received a letter and a Biological Assessment (BA) from the Corps on January 12, 2007, requesting initiation of formal consultation on the C-43 West Reservoir Project. Service staff reviewed the information provided and requested additional information pertaining to consultation for wood storks and snail kites.

Two project status teleconferences were held January 23, and January 30, 2007, to discuss changes in the project schedule to accommodate modeling needs. The proposed alternatives will be evaluated with the updated MIKE SHE model by March 19, 2007. The Benefits Analysis will be completed by May 7, and the Tentatively Selected Plan will be identified by May 21. The Draft FWCA Report will be due May 19, and the Draft PIR will be completed by June 28.

Service staff participated in the February 1, 2007, interagency meeting to develop and review the Monitoring and Assessment Plan for the C-43 project; and in the February 2, 2007, Natural Systems Group meeting.

Service staff participated in two interagency project status teleconferences held February 6, 2007, and February 13, 2007. The project schedule has now been revised again to have a Final PIR by July 2007. A spreadsheet model will be used instead of MIKE SHE for Assurances and Savings Clause Analyses and to develop the Operation Manual. Results from the spreadsheet model will be available by March 1. Existing data used for the AFB will be used for plan formulation and comparison. The preliminary Draft FWCA Report and the Draft PIR will be completed by March 23 and Final drafts printed in the Federal Register by April 13, 2007. The

Final PIR and FWCA Report are due June 29 and will be published in the Federal register by July 27, 2007.

The Service met with the Corps and District on February 7, 2007, to discuss outstanding threatened and endangered species issues for consultation. Additional information is needed for consultation on wood storks, snail kites, and caracara.

Service staff participated in the February 7, 2007, interagency teleconference regarding modeling needs for Assurances and Savings Clause Analyses.

Service staff conducted two site visits, February 7 and 8, 2007, to determine if the caracara territory and nest site off State Road 80 is active this year. A pair of caracara were observed perched near the nest tree which had been used last year. Although the territory is occupied, no nesting activity was observed. Follow-up surveys will be conducted through the end of April to determine if a nest is initiated this year.

Service staff participated in two project status teleconferences held February 20, 2007, and February 27, 2007. The project team is working on the draft PIR and Service staff is working on the draft FWCA Report.

The Service attended the February 21, 2007, interagency site visit to evaluate wetlands and potential wood stork foraging habitat within the C-43 West Reservoir footprint.

The Service submitted the Draft Fish and Wildlife Coordination Act Report to the Corps via letter dated March 19, 2007.

On April 10 and 17, 2007, Service staff participated in the weekly C-43 interagency conference calls to review project status. The project team is in the process of reviewing the Draft PIR and making changes as appropriate due to comments received to date. The Final FWCA Report will be completed by July 12, 2007, and the Final PIR by July 20, 2007.

The Service participated in a May 15, 2007, interagency meeting to review the water quality modeling section of the Draft PIR and the Draft Project Operating Manual and Monitoring Plan. The major outstanding water quality issue is if operation of the reservoir will meet the State's requirement for the project to "not cause or contribute" to existing water quality problems in the Caloosahatchee River and Estuary. Specifically, the annual nitrogen load will not change as a result of the project but a seasonal shift in the loads will occur with a significant increase of nitrogen loading during the dry season (*i.e.,* November through May).

The Service met with the Corps and District on May 15, 2007, to discuss outstanding threatened and endangered species issues in order to complete informal and formal consultation on the effects of the C-43 project. Outstanding issues included incorporation of CERP Thermal Guidelines in Manatee-Accessible Waters in the project monitoring plan, compensation for impacts to wood stork foraging habitat, and compensation for impacts to crested caracara habitat.

On May 17, 2007, the Service attended the Corps and District public workshop on the Draft PIR in LaBelle. No new issues significant to the design and operation of the reservoir were raised by the public.

On May 22, 2007, the Service met with the Superintendent of Duda and their consultant to confirm the location of the caracara nest on Duda property southeast of the reservoir.

The Service held a conference call with the Corps and District on June 5, 2007, to discuss the outstanding issue regarding incorporation of CERP Thermal Guidelines in Manatee-Accessible Waters in the project design and monitoring plan. Both operational and structural modifications to the reservoir project were discussed.

The Service received the Intermediate Design Report (*i.e*, 60 percent design) via overnight mail on June 7, 2007, and the associated design plans on June 8, 2007.

On June 7, 2007, an interagency conference call was held to discus the thermal guidelines for manatees. The District obtained temperature data for the Townsend Canal and the Caloosahatcee River in the vicinity of the Townsend Canal from the Florida Department of Environmental Protection (DEP) and provided that data as well as temperature data from the Test Cell project to the participants on the conference call.

On June 7, 2007, the Service and FWC further developed monitoring protocol to define what constitutes a shift in manatee distribution as a result of warm-water discharges into the Townsend Canal.

The Corps, EPA and the Service participated in a teleconference on June 12, 2007, to finalize the UMAM Scores for the Caloosahatchee River and Estuary and the tapegrass beds in the upper Caloosahatchee Estuary that will be used for mitigation for on-site wetland impacts and compensation for the loss of on-site wood stork foraging habitat.

On June 20, 2007, the Service, Corps and District held a conference call to discuss a timeline for resolving the outstanding manatee issues. The Corps and District are researching appropriate weirs or gates that would serve as a barrier to prevent manatee access to the Townsend Canal while still achieving desired flow rates through the canal. The Corps requested more time to research barriers and develop cost estimates for construction and operation and maintenance of a structure. They requested we reach a resolution by August 1, 2007.

III. AREA SETTING

A. Project Location

The project study area encompasses the Caloosahatchee River Basin (*i.e.*, C-43 Basin) located in southwest Florida and downstream estuarine habitats including the Caloosahatchee Estuary, San Carlos Bay, Matlacha Pass, and Pine Island Sound (Figure 1). The Caloosahatchee River serves as a major outlet from Lake Okeechobee to the Gulf of Mexico, extending about 70 miles

from Lake Okeechobee to San Carlos Bay. The river drains an area of about 1,327 square-miles in Glades, Hendry, Charlotte, and Lee Counties, and is the major source of surface water supply for the Lower West Coast region. The river basin constitutes the northern portion of the District's Lower West Coast Water Supply planning area.

The Caloosahatchee River and Estuary is at the head of a vast estuarine and marine ecosystem that includes aquatic preserves managed by the State of Florida [*e.g.*, Matlacha Pass Aquatic Preserve (AP), Estero Bay AP, Pine Island Sound AP], and the federally designated Charlotte Harbor National Estuary (CHNE); the J. N. "Ding" Darling National Wildlife Refuge (NWR) Complex which includes the Caloosahatchee, Matlacha Pass, Pine Island, and Island Bay NWRs; along with numerous other state and local parks and recreation areas. Restoration of a healthy, productive aquatic ecosystem in the Caloosahatchee River is essential to maintaining the ecological integrity and associated economic activity in these publicly owned and managed areas.

The Caloosahatchee Estuary, which is generally considered to be that portion of the Caloosahatchee River west of the W. P. Franklin Lock and Dam, including the Matlacha Pass, San Carlos Bay, and Pine Island Sound at the mouth of the Caloosahatchee River, encompasses approximately 80 square miles of estuarine habitat on Florida's southwest coast in the vicinity of Fort Myers, Florida. The Fort Myers area, including Cape Coral, Fort Myers Beach, Sanibel and Captiva Islands, Bonita Springs and unincorporated areas is one of the fastest growing areas in the southeastern United States (2000 population was approximately 440,000 according to U.S. Census figures) and is an extremely popular tourist destination.

The proposed reservoir footprint is located in Hendry County west of LaBelle, Florida. The site is approximately 10,492 acres located a few miles south of State Road 80 and approximately two miles west of State Road 29 (Figure 2).

B. Description of Study Area

1. Hydrological Description

The Caloosahatchee River was originally a shallow, meandering river with headwaters in the proximity of Lake Flirt (Kimes and Crocker 1998). The Caloosahatchee River historically bisected its basin and probably only rarely received water from outside its watershed or from Lake Okeechobee except during extreme regional flooding events that sent water to the marshlands at the headwater of the river. The Caloosahatchee was connected to Lake Okeechobee in 1881 as an attempt to lower the Lake's water table. The river now functions as a primary canal (*i.e.,* Canal-43 or C-43) ranging from about 50 to 130 meters (164 to 426.5 feet [ft]) in width and 6 to 9 meters (19.7 to 29.5 ft) deep that conveys both basin runoff and regulatory releases from the lake. Wet season runoff that was historically retained within the undeveloped Caloosahatchee Basin now reaches the river in greater volume and less time through an intricate canal system (Corps 1957) and is often compounded by lake releases.

The river has undergone a number of alterations to facilitate navigation, flood control, and regulatory releases, including channelization, bank and levee stabilization, and the addition of three locks and dams. The locks and dams were constructed to control flow and stage height in the lake and river. The Moore Haven Lock (S-77), located on the southwest shore of Lake Okeechobee, regulates Lake Okeechobee waters. The Ortona Lock (S-78) aids in control of water levels on adjacent lands upstream and separates the Caloosahatchee watershed into eastern and western basins. Water levels upstream of S-78 are maintained at approximately 11 ft National Geodetic Vertical Datum (NGVD), and 3 ft NGVD downstream. The W.P. Franklin Lock and Dam (S-79) is the most downstream structure and marks the beginning of the Caloosahatchee Estuary. The S-79 structure regulates freshwater discharge into the estuary and maintains an upstream level of approximately 3 ft NGVD and a downstream level near 1 ft NGVD. S-79 also acts as barrier to saltwater intrusion and tidal action which historically extended far upstream. Thus, S-79 truncates the estuary and now spatially limits the dry season oligohaline (*i.e.,* freshwater and low salinity brackish water) zone of the estuary, as well as the free passage of organisms seeking refuge, nursery, and breeding areas characteristic of this zone (Chamberlain and Doering 1998a; 1998b, Doering et al. 2002; District 2002). The operation schedule for these structures is dependent on rainfall conditions, agricultural practices, the need for regulatory releases from Lake Okeechobee, and the need to provide water quality control for the Public Water Supply facilities. Detailed operation information for structures S-77, S-78 and S-79 can be obtained from the Water Control Plan for Lake Okeechobee and the Everglades Agricultural Area (EAA), Jacksonville District, USACE, July 2000.

The Caloosahatchee Estuary now extends approximately 42 kilometers (26 miles) from S-79 to Shell Point. The estuary width between S-79 and Shell Point is irregular, ranging from 160 meters (524.9 ft) in the channelized upper portion of the estuary to 2,500 meters (8,202.1 ft) downstream (Scarlatos 1988). The narrow portion extends about 12 kilometers (7.6 miles) downstream from S-79 to Beautiful Island and has an average depth of about 6 meters (19.7 ft), while the overall mean depth of the estuary in the section downstream of Beautiful Island is 1.5 meters (4.9 ft; Scarlatos 1988). Water leaving the Caloosahatchee Estuary passes Shell Point and enters lower Charlotte Harbor through San Carlos Bay, which is at the confluence of Pine Island Sound to the west, Matlacha Pass to the north, and the Gulf of Mexico to the south (Figure 1). Most of the fresh water that enters southern Charlotte Harbor comes into San Carlos Bay from the Caloosahatchee Estuary and normally leaves the system by moving south under the Sanibel Causeway to the Gulf of Mexico (Goodwin 1996). However, when freshwater inflows are high, some of this fresh water is pushed by Gulf of Mexico tides up into Pine Island Sound and Matlacha Pass.

a. Primary Drainage Basins

The Caloosahatchee River Basin can be divided into three primary basins (Figure 3) based on their hydrologic characteristics, hydrologic control features, and topography as defined in the District's Caloosahatchee Water Management Plan (CWMP), April 2000 Planning Document. The freshwater portion of the Caloosahatchee River extends approximately 68 kilometers (42 miles) from Lake Okeechobee to S-79 and can be divided into two primary basins. The East Caloosahatchee basin includes 285,502.5 acres of land that drains into the river between Lake

Okeechobee and S-78. The West Caloosahatchee basin includes 324,979.3 acres (includes S-4) of land that drains into the river between S-78 and S-79. The predominant land use in both of these basins is agriculture. While all of the East Caloosahatchee basin is upstream of the proposed reservoir, approximately 70 percent of the West Caloosahatchee basin is upstream of the planned reservoir.

The Caloosahatchee Estuary basin is downstream of S-79 and contains three watershed planning units: Telegraph Swamp, Orange River, and Caloosahatchee Estuary. Within these three planning units, land use patterns transition from agricultural and natural areas in the east to residential in the west. The Caloosahatchee Estuary basin includes 289,982.4 acres of land that drains to the Caloosahatchee Estuary downstream of S-79. Two major tributaries in this basin are the Orange River and Telegraph Swamp, which drain into the river west of S-79. However, the Orange River planning unit contributes a small amount of the total fresh water entering the estuarine system (Scarlatos 1988; Bierman 1993).

The S-4 and S-236 Basins can drain into, or use irrigation from, the Caloosahatchee River Basin depending on hydrologic conditions. Antecedent water levels, runoff volume, and location of man-made structures determine the direction of storm water drainage. Drainage water from the C-21 is released into the Caloosahatchee River through S-235 when the lake stage is greater than 15.5 ft or the stage exceeds the Lake Regulation Schedule. Stormwater runoff from this basin may be discharged into C-43 through a private drainage pump or discharged into Lake Hicpochee through private drainage pumps.

Each of these primary basins contains several tributaries such as native streams, sloughs, and canals and many small tributaries that drain small areas adjacent to the Caloosahatchee River (Figure 3). There are also several small tributaries that drain directly to the estuary.

b. Surface and Ground Water

Water for urban and agricultural uses in the C-43 basin is supplied from both groundwater and surface water systems. Surface water is used primarily for agricultural irrigation, with groundwater being used in areas that do not have access to the river. In addition, the Caloosahatchee River is a source for potable water supply in Lee County. Groundwater and surface water are dependent upon rainfall for recharge.

The C-43 Canal receives water from Lake Okeechobee, runoff from the basin, and base flow from the Surficial Aquifer System (SAS). The river in turn supplies water for public supply, agriculture, and the environment. This source can be unreliable during the dry season or periods of inadequate rainfall, when releases are required from Lake Okeechobee to meet demand. The Corps manages the C-43 Canal via a regulation schedule, which presently accommodates navigational, flood protection, water supply, and environmental needs.

The Lake Okeechobee Demand Service Area is defined as the area that is or could be supplied by surface water from the Caloosahatchee River and is the primary source for agricultural

irrigation and potable surface supply water in the Caloosahatchee Basin. This area extends from the S-79 eastward to the S-77 and includes land in Lee, Glades, and Hendry Counties.

Other surface water bodies in the Caloosahatchee Basin area include lakes, rivers, and canals. These areas provide storage and allow conveyance of surface water. Lake Hicpochee is the largest lake in the area and is bisected by the C-43 just west of Lake Okeechobee. Numerous canals and tributaries in the basin area drain into the Caloosahatchee River. The majority of the canals in the basin were constructed as surface water drainage systems rather than for water supply purposes.

Surface water flows are derived from rainfall within the basin and discharge from Lake Okeechobee. Runoff from the West Caloosahatchee Basin is slightly higher than runoff from the East Caloosahatchee Basin indicating greater flow attenuation in the eastern basin due to the flatness and thick, sandy soils (Fan and Burgess 1983). Inflow from Lake Okeechobee is the primary flow in the river during the dry season. Water is released from the lake to meet the supplemental agricultural water demand as well as supplying water for municipal consumptive use. Water is also released to reduce lake stage before the hurricane season that may result in high flows to the estuary. There is little water storage in the basin. The intensive drainage on the south side of the river provides little storage. The north side of the river is largely undeveloped west of Lake Hicpochee and while there is considerable wetland water storage it is not managed water storage.

Ground water is an important component of the agricultural water supply in the freshwater portion of the Caloosahatchee Basin. The ground water resources in the area include the SAS, the Intermediate Aquifer System (IAS), and the Floridan Aquifer System (FAS). The yield and storage of the groundwater is highly variable throughout the basin, and surface water has been used for irrigation where possible. The SAS is used for some irrigation in eastern Hendry and Glades Counties.

The IAS is used primarily for irrigation in the western portion of Hendry County. There is local recharge to both the SAS and the IAS. The FAS is used in northern Glades County for irrigation and in the northwest corner of the basin and mixed with surface water for irrigation. The water from the FAS is too mineralized elsewhere in the basin. This deep aquifer is recharged from outside the area.

2. Geology and Soils

The major physiographic provinces of the Caloosahatchee River Basin are the Caloosahatchee Valley, Gulf Coast Lowlands, DeSoto Plain and the Immokalee Rise. Within the study area, the Immokalee Rise includes most of Hendry County and eastern Lee County. The average elevation is about 8 meters (25 ft) but can peak at 11 to 13 meters (36 to 43 ft) in some areas. All soils are deep, nearly level, and poorly drained, with a water table less than 25 centimeters (10 inches) from the surface during at least part of the year.

The soils of the Caloosahatchee River Basin are predominately Spodosols with some Entisols, Histols south of the river, and miscellaneous types in coastal areas. Spodosols are dominated by somewhat poorly to poorly drained sandy soils with dark sandy subsoil layers. They have a subsurface zone where there has been an accumulation of iron, aluminum, and organic matter that has cemented into a layer that may inhibit water flow. Entisols are new or recent soils of limestone origin, underlain by marl and limestone and they are dominated by very poorly drained, coarse and thin, sandy soils. Histols are organic soils such as muck and peat and they are very poorly drained soils underlain by marl and limestone. Coastal sediments mostly consist of Entisols and Histols.

A geotechnical engineering evaluation was performed for at the project site. The subsurface conditions encountered at the site consist of a surficial layer of sands with isolated zones of silty sand material. This sandy deposit varies in thickness from 1 to 15 ft. Below this sandy deposit, a layer of interbedded zones of silty sand, clayey sand, sandy clay, and sandy silt materials was encountered. This layer varies in thickness from 1 to about 20 ft. Below this sand, silt, clay mix deposit, limestone material was generally encountered with a thickness ranging from 2 to 12 ft, with isolated areas where the limestone deposit was thicker than 30 ft. Some of the borings performed did not encounter the limestone material. Below the limestone material and until boring termination depths, clayey deposits were encountered. These clayey deposits mainly consist of sandy silt, sandy clay, and clayey sand materials.

3. Land Use

Land use in the eastern Caloosahatchee River Basin is primarily agriculture (*i.e.,* improved and unimproved pasture, citrus, and sugarcane), interspersed with higher-quality natural areas (*i.e.,* pine flatwoods, hardwood forests, freshwater marshes, and cypress). Sugarcane production in the Caloosahatchee Basin occurs in close vicinity to Lake Okeechobee in Hendry and Glades Counties, where transportation costs to the mills can be minimized. Seasonal crops (*i.e.*, row and field crops such as tomatoes or wheat) are minimally present. Land use in the western portion of the basin is primarily urban and residential, and the spatial extent of natural areas is reduced.

4. Water Quality

Water quality data are collected by numerous agencies and volunteer organizations in the project impact area including the U.S. Geological Service (USGS), Charlotte Harbor Estuaries Volunteer Water Quality Monitoring Network, DEP, FWC, Fish and Wildlife Research Institute (FWRI), District, Lee County, Lee County Hyacinth Control District, Cities of Cape Coral and Sanibel, and the Charlotte Harbor National Estuary Program (CHNEP). All of these entities have water quality monitoring programs that sample at varying frequencies for various core parameters and the results are normally placed into a central database that is maintained by the State of Florida. The database STOrage and RETrieval (STORET) is a structure used nation-wide for water quality analysis.

The DEP is responsible for identification of impaired waters pursuant to the Impaired Waters Rule (IWR) adopted in 2001 as Chapter 62-303, Florida Administrative Code. The IWR

establishes a methodology to identify surface waters of the state that will be included on the state's planning list. It also establishes a scientific methodology for analyzing environmental data to determine if a waterbody is impaired or healthy. DEP must list waters that do not meet applicable quality standards and establish Total Maximum Daily Loads (TMDLs) for those waters on a prioritized schedule. TMDLs establish the maximum amount of pollutants a water body can assimilate without exceeding water quality standards.

The construction of canals, levees, and roads within the Caloosahatchee Basin have resulted in changes to the timing, quantity, and quality of surface waters within and around the project area. Groundwater flow and quality throughout the project area may also be influenced by these anthropogenic features. Additional impacts include nutrient loads from agricultural activities, anthropogenic organic compounds, trace elements, as well as overall urban growth and development within the basin. San Carlos Bay and Pine Island Sound are Class 2 waters which are designated for shellfishing. The Caloosahatchee Basin and Estuary are Class 3 waters which are designated for swimming and fishing. The DEP's IWR Assessment determined the following conditions at locations within and adjacent to the project area (Figure 4):

- Six water bodies in the East Caloosahatchee basin are impaired for lead, coliforms, iron, dissolved oxygen, copper, and nutrients.
- Three water bodies in the West Caloosahatchee basin are impaired for iron, copper, lead, and nutrients.
- There are no impaired waters in Telegraph Swamp planning unit.
- The Caloosahatchee estuary has 13 impaired water bodies. All thirteen listed water body segments are impaired for coliforms (either total or fecal), seven are impaired for nutrients, six are impaired for dissolved oxygen, three are impaired for heavy metals (copper, lead), and one is impaired for specific conductivity.

The DEP Caloosahatchee Basin Status Report (DEP 2002) states that the observed water quality violations are probably linked to urban land uses within the Caloosahatchee Estuary planning unit, poorly flushed residential tributary streams, and the effect of heavy pollutant loads discharged from upstream sub-basins. Water quality pollutant loading upstream of the S-79 structure is composed of loading from runoff generated within the basin and Lake Okeechobee releases. Excluding the load from Lake Okeechobee releases, approximately 50 percent of the total nitrogen load resulting from runoff in the Caloosahatchee Basin comes from basin lands upstream of S-79. Similarly, excluding the phosphorus load from Lake Okeechobee releases, approximately 65 percent of the total phosphorus load resulting from runoff in the Caloosahatchee Basin comes from basin lands upstream of the S-79. When Lake Okeechobee flows and loads are included, more than 75 percent of total nitrogen and total phosphorus loads to the Caloosahatchee Estuary are a result of discharges at S-79 (ERD 2002).

The Caloosahatchee pollutant loading report (ERD 2002) includes pollutant-loading estimates for the four largest sewage treatment plants in the Caloosahatchee Estuary as well as for eight tributaries downstream of the S-79 structure. This report includes loading estimates for the following pollutants: ammonia, nitrate, nitrite, total kjeldahl nitrogen, total nitrogen, orthophosphorus, and total phosphorus, and total suspended solids. With the exception of

ammonia, 10 percent or less of the wet or dry season load of each of these pollutants to the Caloosahatchee Estuary comes from the portion of the watershed downstream of the S-79 structure. During the dry season, approximately 5 percent of the total ammonia load in the estuary comes from the portion of the watershed downstream of the S-79 structure; however, during the wet season, approximately 40 percent of the ammonia load to the estuary comes from downstream of the S-79 structure. A relatively large amount of the ammonia loading from downstream of the S-79 structure comes from the four large sewage treatment plants. The Caloosahatchee Estuary non-point sources of total nitrogen and phosphorus contribute around 20 percent of the total loads delivered to the estuary.

5. Ecological Description

a. Upland and Freshwater Habitats

Upland plant communities serve as recharge areas, absorbing rainfall into soils where it is distributed into plant systems or stored underground within the aquifer. Ground water storage in upland areas reduces runoff during extreme rainfall events, while plant cover reduces erosion and absorbs nutrients and other pollutants that might be generated during a storm event. With few exceptions the functions and values attributed to wetlands also apply to upland systems. Upland and wetland systems are ecological continuums, existing and adapting to geomorphic variation. The classification of natural systems is artificial and tends to convey a message that they survive independently of each other. In reality, wetland and upland systems are interdependent. To preserve the structure and functions of wetlands, the linkage between uplands and wetlands must be maintained (Mazzotti et al. 1992). Existing upland and wetland habitats in the Caloosahatchee Basin are shown in the 2000 land cover and land use map (Figure 5).

Based on the 2000 land use and land cover data and maps, wetlands comprise approximately 135,277 acres (15.9 percent) of the land cover within the C-43 Basin. The wetland cover classes occurring in the C-43 Basin include freshwater marsh and wet prairie, slough waters, wetland hardwood forest, wetland coniferous forest (cypress swamp and cypress, pine, cabbage palm) wetland mixed forest, mangrove swamp, and salt marsh. Other aquatic habitats in the C-43 Basin include streams and waterways, lakes, and reservoirs. Those habitats comprise approximately 21,682 acres (2.5 percent) of the land cover within the C-43 Basin.
Pine flatwoods continue to dominate the landscape of the study area even though their pre-development aerial extent has been reduced by agricultural and urban development. Large areas of flatwoods are found throughout Hendry and Lee Counties, as well as portions of Charlotte and Glades Counties. They are interspersed with tropical hardwood hammocks, Florida scrub, dry or wet prairies, freshwater marshes, and freshwater forested wetlands.

Pine Flatwoods
Pine flatwood occur in areas of level topography and poorly drained sands. They range from open forests of scattered pines with little understory to dense stands with a dense undergrowth of grasses (paticularly wire grass, *Aristida stricta*), saw palmettos (*Serenoa repens*), and other low shrubs (Abrahamson and Hartnett 1990). The majority of the pine flatwoods that occur within the C-43 Basin are hydric pine flatwoods.

Hydric pine flatwoods occur in seasonally inundated flatlands with sandy soils and have canopies of slash pine (*Pinus elliottii* var. *densa*), pond pine (*P. serotina*), and cabbage palm. They have an understory of mixed hydrophytic shrubs such as wax myrtle (Myrica cerifera), gallberry (*Ilex glabra*), grasses, and forbs that varies with fire frequency. Mesic flatwoods occur on sandy, seldom inundated soils and have canopies of slash pine (*P. elliottii* var. *elliottii* and var. *densa*) and longleaf pine (*P. palustris*) with a dense understory of saw palmetto. Gallberry, *Lyonia* spp., wax myrtle, and wiregrass are also abundant.

The hydric pine flatwoods of south Florida are of critical, regional importance as: (1) one of the principal dominant forest covers of south Florida that provides essential forested habitat for wildlife including wide-ranging species such as the Florida panther, the Florida black bear, mid-sized carnivores, fox squirrels, and deer; (2) the major tree canopy for canopy-dependent species including neotropical migrants, tree-cavity dependent species, and tree-nesting species; (3) a habitat that seasonally functions as both a wetland and an upland. The relatively predictable nature of this hydrologic transformation allows for an abundant diversity of plant life, including both wetland and upland annuals, and supports a diverse invertebrate fauna and, as a result, a diverse vertebrate fauna. The hydric pine flatwoods of south Florida provide essential habitat to the breeding life cycle of aquatic and wetland-dependent animals, and a major forest cover for cover-dependent species. Hydric pine flatwoods provide both aquatic habitat for young and adult amphibians and adult tree frog climbing areas. Hydric flatwoods serve as wading bird foraging areas, black bear foraging, denning, and travelways, and essential red-cockaded woodpecker foraging and nesting habitat. Hydric pine flatwoods are an important habitat for a number of common pine flatwoods vertebrate species, including the pine woods tree frog (*Hyla femoralis),* oak toad (*Bufo quercicus),* box turtle (*Terrapene carolina),* eastern diamondback rattlesnake (*Crotalus adamanteus),* black racer (*Coluber constrictor),* brown-headed nuthatch (*Sitta pusilla),* Bachmans sparrow (*Aimophila aestivalis*), pine warbler (*Dendroica pinus),* great horned owl (*Bubo virginianus),* least shrew (*Cryptotis parva),* cotton mouse (*Peromyscus gossypinus)*, cotton rat (*Sigmodon hispidus),* and gray fox (*Urocyon cinereoargenteus)* (Layne 1974; Layne et al. 1977).

Tropical hardwood hammocks

Tropical hammocks are found nearly throughout the southern half of south Florida, with large concentrations in Miami-Dade County on the Miami Rock Ridge, in Miami-Dade and Monroe Counties in the Florida Keys and along the northern shores of Florida Bay, and in the Pinecrest region of the Big Cypress Swamp. Analogous communities are also found in the Bahamas and the Greater Antilles (Robertson 1955). Most maritime hammocks on barrier islands in south Florida are similar to this community. Large areas of tropical hardwood hammocks are still found in Everglades and Biscayne National Parks in Miami-Dade County, throughout the Florida Keys in Monroe County, and in Big Cypress National Preserve in Collier County. Tropical hardwood hammocks also persist in small preserves along the Atlantic coastal strip from Miami-Dade County north to Martin County.

Tropical hardwood hammocks are rare in the basin. This diverse woody upland plant community occurs on elevated areas, often in Indian shell mounds along the coast, or on marl or

limestone outcroppings inland. As a result of urban development, tropical hammocks are among the most endangered ecological communities in south Florida.

Tropical hardwood hammock is a closed canopy forest, dominated by a diverse assemblage of evergreen and semi-deciduous tree and shrub species, mostly of West Indian origin. It is also important habitat for ferns and orchids of West Indian origin. Tropical hardwood hammock is not a fire maintained community, although fire may burn into tropical hardwood hammocks under certain conditions. Soils in tropical hardwood hammocks are primarily composed of organic material which has accumulated directly on top of mineral substrate, and are moist, but rarely inundated.

Except for some birds and bats, most vertebrate animal species found in tropical hardwood hammocks are temperate in origin (Snyder et al. 1990). While plant species can be transported by birds, waves, or wind from the Caribbean, most animal species have to travel to south Florida by land, and a land bridge has never connected south Florida with the Caribbean. Tropical hardwood hammocks provide food, cover, roosting, and nesting sites to a wide variety of wildlife species.

Florida Scrub

Interior Florida scrub occurs sporadically on well-drained sandy ridges on the Georgia Fall Line and within the Florida peninsula from Kingsley Lake, Clay County south to Immokalee, Collier County (Myers 1990; Wharton 1978). Most interior Florida scrubs are associated with north-south tending ridges that were formed by wind and wave action during periods of higher sea level. The expansive stands of sand pine in the Ocala National Forest in Lake and Marion Counties are forests, not scrub, and occupy a landscape with yellow sand that may have supported high pine savanna during the earlier Holocene. Within the South Florida Ecosystem, interior Florida scrub occurs on the Lake Wales, Winter Haven, Lake Henry, Lakeland, and Bombing Range ridges (White 1970) in Polk, Osceola, and Highlands Counties; on lesser ridges within the Osceola Plain and Eastern Valley in Osceola, Okeechobee, Indian River, St. Lucie, and Martin Counties; and scattered on small rises in Hardee, DeSoto, Glades, Hendry, and Collier Counties.

Florida scrub soils are well-drained, nutrient-poor, and sandy. Depending on elevation, scrub has a fire return frequency of 10 to 80 years. "Florida scrub can be identified by the dominance of several species of woody shrubs, especially myrtle oak or scrub oak (*Quercus myrtifolia* or *Q. inopina*), sand live oak (*Q. geminata*), Chapman's oak (*Q. chapmanii*), crookedwood (*Lyonia ferruginea*), saw palmetto (*Serenoa repens*) and Florida rosemary (*Ceratiola ericoides*); the absence of a tree canopy; the absence of a continuous vegetative ground cover; and the absence of longleaf pine (*Pinus palustris*), wiregrass (*Aristida beyrichiana*), and turkey oak (*Q. laevis*). When sand pines (*Pinus clausa*) are present in scrub, they do not form a continuous canopy, but occur as scattered individuals or clumps of individuals. Most scrubs occur on white sand and patches of bare sand with or without scattered clumps of ground lichens" (Service 1999).

Scrubby flatwoods is an intermediate between mesic pine flatwoods and scrub, and sometimes occurs as an ecotone between them (Abrahamson and Hartnett 1990). "Scrubby flatwoods is

more hydric than scrub, has a higher water table, denser vegetation, and almost never has standing water" (Abrahamson et al. 1984). It also "differs from scrub by the presence of scattered wiregrass and a preponderance of flatwoods species such as fetterbush (*Lyonia lucida*), wax myrtle, and gallberry. Shrubby oaks, including sand live oak, Chapman's oak, and myrtle oak or scrub oak, are often dominant and slash pine, sand pine, or longleaf pine may be present. Plant species typical of scrubby flatwoods that may be considered indicators of the community include tarflower (*Befaria racemosa*), scrub St. John's wort (*Hypericum reductum*), and pennyroyal (*Piloblephis rigida*)" (Service 1999).

Scrub habitats in south Florida are important for a number of xeric-adapted species including: Florida gopher frog (*Rana capito*), Florida mouse (*Podomys floridana*), short-tailed snake (*Stilosoma extenuatum*), scrub lizard (*Sceloporus woodi*), rufous-sided towhee (*Pipilo erythrophthalmus*), gopher tortoise (*Gopherus polyphemus*), Florida worm lizard (*Rhineura floridana*), other subspecies of mole skink (*Eumeces egregius sspp.),* and the crowned snakes (*Tantilla spp.).* Federally listed scrub inhabitants include the Florida panther, Florida scrub-jay (*Aphelocoma coerulescens*), eastern indigo snake, blue-tailed mole skink (*Eumeces egregius lividus*), and sand skink (*Neoseps reynoldsi*; Service 1999).

Wet Prairies and Freshwater Marshes

Wet prairies and freshwater marshes are interspersed throughout the study area. The differences between the two are based on hydroperiod. Wet prairies are flooded less than 6 months per year (short hydroperiod). Freshwater marshes can be flooded 6 to 9 months per year (intermediate hydroperiod) or more than 9 months per year (long hydroperiod). As a result, wet prairies are more susceptible to fire, and burn more frequently than marshes. These differences in hydroperiod and fire regime are reflected in the vegetative communities. The common plants of wet prairies are sawgrass (*Cladium jamaicense*), muhly grass (*Muhlenbergia capillaris*), beakrush (*Rhynchospora* spp.), black sedge (*Schoenus nigricans*), wiregrass (*Aristida* spp.), and dwarf cypress (*Taxodium* spp.; Service 1999).

Freshwater marshes are frequently categorized based on their dominant vegetation [*e.g.,* sawgrass marsh; cattail marsh; flag marsh (*Pontederia lanceolata* and one or more *Sagittaria* spp.); mixed emergent grass and sedge marsh; maidencane (*Panicum hemitomon*) marsh; beakrush and spike rush (Eleocharis spp.) marsh; or floating vegetation marsh (the water lilies *Nymphaea odorata* and *Nuphar luteum*, and floating hearts, *Nymphoides aquatica*)]. The majority of freshwater marshes in the study area are beakrush, maidencane, and pickerelweed flag marsh (Kushlan 1990). Marshes can also be categorized based on physiognomy. Flatwoods marshes, also called depressional marshes, are small, elliptical wetlands that occupy the low areas within pine flatwoods. They have moderate to long hydroperiods with depths less than a meter, and are generally disconnected (Kushlan 1990). Conversely, sloughs are larger, linear, connected marshes with deeper water and long hydroperiods (Service 1999). Good examples of flatwoods marshes and sloughs can be found in the study area at the Allapattah Ranch and Cane Slough in Martin County.

Regardless of their category, marshes and wet prairies are another "vital component for the biodiversity of south Florida" (Service 1999). Federally listed birds such as snail kite (*Rostrhamus sociabilis plumbeus*), wood stork (*Mycteria americana*), whooping crane (*Grus americana*), and Audubon's crested caracara [*Polyborus* (= *Caracara*) *plancus audubonii*], and state listed birds such as Florida sandhill crane (*Grus canadensis pratensis*), roseate spoonbill (*Ajaia ajaja*), little blue heron (*Egretta caerulea*), reddish egret (*Egretta rufescens*), snowy egret (*Egretta thula*), tricolored heron (*Egretta tricolor*), and white ibis (*Eudocimus albus*) all use these habitats for nesting and foraging. The growth, maintenance, and reproduction of many other species of birds, amphibians, reptiles, fish, invertebrates, and mammals are directly linked to the quality and quantity of these wetland habitats.

Dry Prairie

Florida dry prairie is a natural landscape that is endemic (Fitzgerald and Tanner 1992, Bridges 1997) to the state, with no similar communities found in adjacent states. It is geographically restricted to the interior of central, south-central and west-central peninsular Florida. Dry prairie is often (but not exclusively) found on the same soil series, topographic positions, and moisture regimes as mesic flatwoods, with dry prairie being the essentially treeless endpoint of a continuum of variation in canopy cover across pine flatwoods landscapes in central Florida.

Dry prairie is an essentially treeless (Harshberger 1914), pyrogenic community with a ground cover diverse in regionally endemic plant taxa. It is most commonly dominated by wiregrass, sparse, scattered, low stunted saw palmetto, and low-growing runner oak (Bridges 1997). Quantitative sampling of vegetation across hydrologic gradients within dry prairie at Avon Park AFR (Polk and Highlands Counties), Kissimmee Prairie State Preserve (Okeechobee County), Ordway-Whittell Kissimmee Prairie Sanctuary (Okeechobee County) and Three Lakes WMA (Osceola County) in 1995 and 1997 confirm that these three species share dominance in most frequently burned dry prairies (Bridges and Reese 1998). Other common shrubs of dry prairie include *Lyonia fruticosa*, *Lyonia lucida*, *Ilex glabra*, and *Vaccinium myrsinites* (Bridges 1997; Huffman and Judd 1998). Infrequently burned sites, shrub cover is reduced, resulting in a diverse herbaceous ground cover (Bridges 1997; Cole et al. 1994a). Other characteristic grasses of dry prairie include *Andropogon ternarius* var. *cabanisii*, *Andropogon virginicus* var.*decipiens*, *Schizachyrium stoloniferum*, and *Sorghastrum secundum*. Typical dry prairie has a mixture of wetland and upland plants, the most characteristic of these mixtures being the co-occurrence of *Quercus minima* and *Xyris elliottii* (Bridges 1997). As wetter areas are reached, there tends to be an increase in wet-mesic species such as *Ctenium aromaticum* and *Xyris ambigua* (Bridges 1997).

There are many common faunal components of dry prairies. Both breeding and seasonal migrants utilize dry prairies extensively. Breeding birds of the dry prairies include the Florida mottled duck (*Anas fulvigula*), common nighthawk (*Chordeiles minor*), red-winged blackbird (*Agelaius phoeniceus*), common yellowthroat (*Geothlypis trichas*), eastern towhee (*Pipilo erythrophthalmus*) and eastern meadowlark (*Sturnella magna*) (T. Dean, Department of Forestry and Wildlife, University of Massachusetts, personal communication 1998). Seasonal use by northern avian species during the winter season substantially increases the avifauna diversity of dry prairie (T. Dean, Department of Forestry and Wildlife, University of

Massachusetts, personal communication 1998). Species that migrate into the central Florida area and overwinter within dry prairie include the savannah sparrow *(Passerculus sandwichensis)*, swamp sparrow *(Melospiza georgiana)*, Henslow's sparrow *(Ammodramus henslowii)*, as well as the northeastern race of grasshopper sparrow *(Ammodramus savannarum pratensis)* (T. Dean, Department of Forestry and Wildlife, University of Massachusetts, personal communication 1998). Other wintering species include yellow rail *(Coturnicops noveboracensis noveboracensis)*, palm warbler *(Dendroics palmarum)*, and a variety of other songbirds. In addition, a variety of avian predators, including northern harrier *(Circus cyaneus)*, American kestrel *(Falco sparverius)*, and *Accipiter* spp. (hawks) migrate into central Florida (T. Dean, Department of Forestry and Wildlife, University of Massachusetts, personal communication 1998). The effect of this influx on the resident avifauna is uncertain, and the importance of Florida dry prairie as wintering grounds for the seasonal residents is poorly known (T. Dean, Department of Forestry and Wildlife, University of Massachusetts, personal communication 1998). Herpetofauna of the dry prairies include common species such as Florida boxturtle *(Terrapene carolina bauri)*, glass lizards *(Ophisaurus* spp.), ground skink *(Scincella lateralis)*, Florida ribbon snake *(Thamnophis sauritus sackenii)*, Florida banded water snake *(Nerodia fasciata)*, black racer (*Coluber constrictor priapus)*, and rough green snake *(Opheodrys aestivus)* (T. Dean, Department of Forestry and Wildlife, University of Massachusetts, personal communication 1998). Amphibians including oak toad *(Bufo quercicus)*, southern cricket frog *(Acris gryllus gryllus)*, and pine woods tree frog *(Hyla femoralis)* are also abundant in dry prairies (T. Dean, Department of Forestry and Wildlife, University of Massachusetts, personal communication 1998). Common mammals include eastern cottontail *(Sylvilagus floridanus)*, hispid cotton rat *(Sigmodon hispidus)*, oldfield mouse *(Peromyscus polionotus)*, spotted skunk *(Spilogale putorius)*, and bobcat *(Lynx rufus floridanus)* (T. Dean, Department of Forestry and Wildlife, University of Massachusetts, personal communication 1998).

Freshwater Forested Wetlands

Freshwater forested wetlands are present in the study area both in the form of flowing water swamps and the more stagnant seepage swamps. The flowing water swamps can be classified further as floodplain wetlands - those along clearly defined river channels; and strand swamps - those of shallower and more diffuse flow-ways. The vegetative community of flowing water swamps is frequently dominated by bald cypress (*Taxodium distichum*). Pop ash (*Fraxinus caroliniana*) and pond apple (*Annona glabra*) may also be present. "Other typical plant species include, red maple (*Acer rubrum*), cabbage palm (*Sabal palmetto*), strangler fig (*Ficus aurea*), swamp bay (*Persea palustris*), sweetbay (*Magnolia virginiana*), royal palm (*Roystonea regia*), coastal plain willow (*Salix caroliniana*), wax myrtle, myrsine (*Rapanea* spp.), poison ivy (*Toxicodendron usneoides*), swamp lily (*Crinum* spp.), leather fern (*Acrostichum* spp.), and royal fern (*Osmunda regalis*). The canopy plants are mainly temperate, while the understory and epiphytic plants are generally tropical" (Service 1999).

"Seepage swamps are forested wetlands characterized by saturated soils rather than periodic inundation. They include baygalls at the base of seepage slopes, bayheads in peat-filled depressions or at the downstream ends of Everglades teardrop islands, and hydric hammocks on low sand or limestone rises within periodically inundated wetland systems. Baygalls and bayheads are dense evergreen forests or shrub thickets with a spongy understory of sphagnum

moss and ferns. The canopy is composed of tall, densely packed, generally straight-boled evergreen hardwoods dominated by sweetbay (*Magnolia virginiana*), swamp bay (*Persea palustris*), red bay (*Persea borbonia*), dahoon holly (*Ilex cassine*), and loblolly bay (*Gordonia lasianthus*). There is typically a more or less open understory of shrubs and ferns and a ground surface of sphagnum mats interlaced with convoluted tree roots. Hydric hammocks are open forests dominated by cabbage palms and laurel oaks (*Quercus laurifolia*) mixed with other hardwoods. They often have minimal understory and a floor carpeted by fallen palm fronds" (Service 1999).

Many animal species utilize these forested wetlands in south Florida including the following federally listed species: Florida panther, bald eagle (*Haliaeetus leucocephalus*), wood stork, and eastern indigo snake (*Drymarchon corais couperi*) (Service 1999).

b. Coastal and Estuarine Habitats

The Caloosahatchee Estuary, San Carlos Bay, Matlacha Pass, and Pine Island Sound include important mangrove and marsh habitats, a rich diversity of native wildlife, and habitat for several notable threatened and endangered species. The estuarine system consists of innumerable small islands, tidal bars, and channels, which provide the following habitat types:

Submerged Aquatic Vegetation (SAV)
Both fresh- and salt-water SAV beds are some of the most productive and valuable habitats in the Caloosahatchee Estuary and San Carlos Bay. They convert sunlight into food for fish, sea turtles, manatees, invertebrates, and other species; they provide habitat for many aquatic organisms; they provide oxygen; and they reduce turbidity by stabilizing sediments and removing nutrients from the water column that might otherwise cause harmful algal blooms. Many commercial and recreational fisheries (*e.g.*, clams, shrimp, lobster, and fish) are dependent upon healthy seagrass beds (Service 1999). Each species of SAV has a specific temperature and salinity tolerance range and their tolerance towards variations in salinity is similar to their tolerances for variations in temperature. Furthermore, estuarine biota is well adapted to and depends upon natural seasonal changes in salinity. When salinity falls outside of these normal and seasonal ranges, it may result in a reduction in densities and shifts in distribution of both SAV species and organisms dependant upon them (Chamberlain and Doering 1998b). Currently, the cover, density and geographic extent of existing SAV in the estuary have been reduced, eliminated, or shifts in their community composition have occurred due to extreme salinity fluctuations, increased turbidity, sedimentation, nutrient enrichment, and algal blooms which can all influence light penetration (Corbett 2006; Greenawalt-Boswell et al. 2006).

Tape Grass
Tape grass (*Vallisneria americana)* is the dominant SAV in the upper Caloosahatchee Estuary and occurs in well-defined beds in shallow water (Figure 6). Tape grass is an important habitat for a variety of freshwater and estuarine invertebrate and vertebrate species, including some commercially and recreationally important fishes (Bortone and Turpin 1999). During times of extended low inflow conditions, when salinity is too high, tape grass becomes very sparse and can disappear completely (Chamberlain et al. 1995; Doering et al. 2002; District 2000).

Vallisneria beds occur within the 40-acre Caloosahatchee NWR, a satellite refuge located the upper estuary administered under the J.N "Ding" Darling NWR Complex.

Seagrasses

McNulty et al. (1972) and Harris et al. (1983) mapped SAV in the lower estuary upstream of Shell Point, as well as throughout the outer embayments. Shoal grass (*Halodule wrightii*) is the only seagrass species consistently located upstream of Shell Point (Figure 6) until it mixes downstream with turtle grass (*Thalassia testudinum*) in San Carlos Bay. Shoal grass has a wide salinity tolerance (McMahan 1968); it does not survive below 3.5 parts per thousand (ppt) and prefers salinity as high as 44 ppt (Zieman and Zieman 1989). This wide tolerance is probably why it is the only true seagrass species encountered upstream of Shell Point. District monitoring results (Chamberlain et al 1995, Chamberlain and Doering 1998b, Doering et al. 2002) indicate that shoal grass biomass is lowest upstream where salinity is lowest and most variable. The greatest biomass occurs where salinity is consistently above 20 ppt. Literature summarized by Zieman and Zieman (1989) indicates that the optimum salinity range for turtle grass is 24 to 35 ppt. The maximum photosynthetic activity of turtle grass occurs in full strength seawater and decreases proportionately with decreasing salinity. Turtle grass does not grow in areas with salinity below 17 ppt and will suffer significant leaf loss when exposed to lower salinity. Turtle grass does not exist upstream of Shell Point where salinity during the District study was more variable.

Oyster Reefs and Bars

The American or eastern oyster (*Crassostrea virginica*) is an important recreational and commercial species that occupies sediment-free, firm bottom substrates in brackish and saltwater. Adults can survive salinities of 5 to 40 ppt, but the optimal range is 10 to 20 ppt. Oysters spawn at water temperatures over 20°C (68°F), with mass spawning occurring in the Gulf during spring and fall. Larval development normally requires two weeks, and can occur at salinities of 7.5 to 35 ppt, although growth is slower between 7.5 and 10 ppt. Following larval development, attachment (or settling) occurs and requires a salinity range of 5 to 35 ppt, with an optimal range of 10 to 30 ppt. The ideal substrate is shell or a firm mud-sand-shell mix. Soft muds or shifting sands are unsuitable. In addition to substrate type, the local distribution of oysters can be controlled by tidal currents. Water currents import food and remove waste. If the currents are too slow, growth is reduced. If the currents are too fast, erosion of substrate or reduction of settling can occur. Excessive turbidity and large volumes of stormwater runoff can also adversely affect oyster growth or reproduction. Predators to oysters, besides humans, include American osytercatcher (*Haematopus palliatus*), stone crab (*Menippe mercenaria*), blue crab (*Callinectes sapidus*), oyster drills (*Thais haemastoma*), sheepshead (*Archosargus probatocephalus*), black drum (*Pogonias cromis*) and other fish and crustaceans.

Oyster reefs and bars are other valuable, aquatic, benthic habitats needed for healthy, diverse, and productive estuarine ecosystems. They provide food for fish and crustaceans, provide solid structure within the water column for sessile organism attachment (*e.g.*, barnacles and sea anemones), provide habitat as nursery areas and for organisms seeking refuge from predation (*e.g.*, polychaete worms and soft-shell blue crabs), provide spawning substrate for fish (*e.g.*, gobies and blennies), stabilize bottom sediments for other benthic organisms (*e.g.*, hard

clams) and aquatic plants, and concentrate prey for larger predator fishes (*e.g.*, red drum and striped bass (Maryland Sea Grant 2000)). Another important function of oysters, relative to the restoration of the Caloosahatchee Estuary, results from their mode of feeding. Like all bivalves, oysters are filter feeders and they can remove suspended algae and particulates from the water and greatly increase water transparency. This, in turn, can allow seagrasses to grow better and at greater depths within the estuary and lagoon.

The general distinction between an oyster reef and a bar is that a reef occupies that area between the high and low tide lines, and bars (or beds) are submerged (Bahr 1981). Intertidal populations are different in structure and ecology from their subtidal counterparts. Reefs are generally less diverse. Bahr (1981) estimated that 50 macrofaunal species occupy oyster reefs in Georgia. Wells (1961) listed 303 species associated with both oyster reefs and bars. The wide distribution of oysters (along the Atlantic and Gulf coasts from Canada to Mexico) is based, in part, on their tolerance of a wide range of salinity, temperature, turbidity, and dissolved oxygen. However, even with this tolerance, populations have decreased dramatically throughout their range due to over harvesting, habitat destruction, disease, sediment deposition, and pollution. Historic oyster bars upstream of Shell Point have been mined and removed to be used for road construction.

Salt Marsh

Saltwater marsh habitat is found landward or is interspersed on the upland side of mangrove fringing forest where it is periodically inundated at high spring tides and during storm surge. Salt marshes vary in structure and are commonly described as needle rush marshes dominated by *Juncus roemerianus*; salt flats or salterns dominated by saltgrass (*Distichlis spicata*), seashore dropseed (*Sporobolus virginicus*), sea purslane (*Sesuvium* spp.), glassworts (*Salicornia* spp.) sea lavender (*Limonium carolinianu*), sea blite (*Suaeda* spp.); and cordgrass marshes dominated by *Spartina patens* or *S. bakeri*. The borders or high areas in these saltmarshes often include groundsel tree or false-willow (*Baccharis augustifolia*), wax myrtle, marsh elders (*Iva* spp.), and Christmas berry (*Lycium carolinianum*).

Mangrove Forest

Mangroves are another highly productive and vital ecosystem of estuarine systems. They contribute significantly to the economy of the coastal communities of Lee and Charlotte Counties and southwest Florida. By occupying the lower wave energy shorelines, they provide a wide variety of benefits to both aquatic and terrestrial ecosystems. Their roots provide habitat for many plants and animals, including commercially and recreationally important fish, crustaceans, and shellfish; their canopies provide habitat for birds, and some mammals and reptiles. Mangrove shorelines act as storm buffers, and wind and wave breaks. They reduce turbidity by stabilizing sediments and recycling nutrients. Mangrove forests occur in the intertidal zone of estuaries. Three species of mangrove are the major components of the mangrove forest: the red mangrove (*Rhizophora mangle*); the black mangrove (*Avicennia germinans*); and the white mangrove (*Laguncularia racemosa*). Another species, the buttonwood (*Conocarpus erectus*), is classified as a "mangrove associate" and forms an important upland fringe in Florida's mangrove ecosystems (Tomlinson 1980, 1986). Red mangroves comprise the dominant vegetation on most of the islands, particularly on the fringe along the bays and tidal creeks. Black and white mangroves comprise mixed forests on island

interiors and in the tidally flushed basins located more landward. Buttonwood is common on beach strands of outer islands and on natural and man-made levee ridges near mainland margins. Mangrove understory in some areas contains saltmarsh species, such as glasswort, saltwort (*Batis maritima*), sea purslane (*Sesuvium portulacastrum*), and sea ox-eye (*Borrichia frutescens*); as well as leather fern (*Acrostichum* spp.); spider lily (*Hymenocallis latifolia*); sea blite; marsh elder (*Iva frutescens*); and lianas, such as *Ipomoea tuba* and *Hippocratea volubilis*.

Coastal Strand
Coastal strand vegetation dominates high-energy coastal barrier islands that are exposed to moderate and high-energy wave action and sediment transport via littoral currents. Vegetation includes sea oats (*Uniola paniculata*), beach carpet (*Philoxerus vermicularis*), sea blite, and railroad vine.

Coastal Hammock
This habitat occurs within the scattered shell mounds of mangrove forest and marsh habitats. This assemblage is dominated by stoppers (*Eugenia axillaries*), gumbo-limbo, live oak, red bay (*Persea borbonia*), cabbage palm, nicker bean (*Caesalpinia crista*), and sea grape (*Cocoloba uvifera*).

6. Fish and Wildlife Resources

a. Federally Listed and Candidate Species

Seventeen federally listed threatened or endangered animal species, two listed plant species, and one endangered fish species are present or potentially present in the study area or proposed project footprint, and may be impacted by the construction and operations of the project. Many of these species have been previously impacted by adverse effects on habitat due to wetland drainage, alteration of hydroperiod, wildfire, and water quality degradation. Those species not directly affected by the project include species that are rare in the project area or utilize estuarine habitat that is only indirectly affected by the restoration project.

Although some of these species may be impacted by the loss of habitat within the project footprint, when implemented, the project has the potential to significantly contribute towards environmental restoration beyond the project footprint. For additional information on these species please refer to the District's Final BA for the C-43 West Storage Reservoir Project, Hendry County, Florida in the Environmental Annex A of the Draft PIR/EIS. The site information included in this report is based on surveys referenced in the BA. Table 1 lists the threatened and endangered species within the C-43 Basin Storage Reservoir Project study area.

Everglade Snail Kite
The snail kite (*Rostrhamus sociabilis plumbeus*) inhabits the watersheds of the Everglades, lakes Okeechobee and Kissimmee, the upper St. Johns River, and the Caloosahatchee basin. Critical habitat for the snail kite is present immediately adjacent to the Caloosahatchee basin inside of the Herbert Hoover Dike in Lake Okeechobee. The snail kite can also be found foraging in a number of native wetlands and in canals and ditches adjacent to the project area. This medium-

sized rapter has a highly specific diet composed almost entirely of Florida apple snails (*Pomacea paludosa*), which are found in palustrine emergent, long hydroperiod wetlands. As a result, the snail kite's survival is directly dependent on the hydrology and water quality of its habitat (Service 1999).

One snail kite was observed perched on a wire and eating a snail along SR 80 during a February 2006 survey. This location was approximately 0.75 miles west of the project footprint. In addition, during several field visits between 2004 and 2006, of two species of apple snails, the Florida apple snail (*Pomacea paludosa*) and the exotic ramshorn apple snail (*Marisa cornuarietis*), were observed in large ditches of the project site. The network of large agricultural ditches provides suitable foraging opportunities but evidence of foraging and feeding (shell discards) was not observed.

Table 1. Federally Listed Threatened (T) and Endangered (E) Species known or expected to occur within C-43 Basin Storage Reservoir Study Project Area

Common Name	Scientific Name	Status
REPTILES		
American crocodile	*Crocodylus acutus*	E
Eastern indigo snake	*Drymarchon corais couperi*	T
Atlantic green sea turtle	*Chelonia mydas mydas*	E
Hawksbill sea turtle	*Eretmochelys imbricata*	E
Kemp's ridley sea turtle	*Lepidochelys kempi*	E
Loggerhead sea turtle	*Caretta caretta*	T
Leatherback sea turtle	*Dermochelys coriacea*	E
BIRDS		
Audubon's crested caracara	*Polyborus plancus audobonii*	T
Everglade Snail kite	*Rostrhamus sociabilis plumbeus*	E
Florida grasshopper sparrow	*Ammodramus savannarum floridanus*	E
Florida scrub jay	*Aphelocoma coerulescens*	T
Piping plovers	*Charadrius melodus*	T
Red-cockaded woodpecker	*Picoides borealis*	E
Southern bald eagle	*Haliaeetus leucocephalus*	T
Wood stork	*Mycteria americana*	E
MAMMALS		
Florida panther	*Puma concolor coryi*	E
West Indian manatee	*Trichechus manatus*	E
PLANTS		
Beautiful pawpaw	*Deeringothamnus pulchellus*	E
Okeechobee gourd	*Cucurbita okeechobeensis*	E

FISH*

Smalltooth Sawfish	*Pristis pectinata*	E

* Federally listed fish species are regulated by the National Oceanic and Atmospheric Administration- National Marine Fisheries Service (NOAA Fisheries Service).

Wood Stork

The wood stork (*Myctria Americana*) is primarily associated with freshwater and estuarine habitats for nesting, roosting, and foraging. They have nested, at one time or another, in every county in south Florida. Typical foraging sites include freshwater marshes and stock ponds, shallow, seasonally flooded roadside or agricultural ditches, narrow tidal creeks or shallow tidal pools, managed impoundments, and depressions in cypress heads and swamp sloughs. Wood storks use a specialized feeding behavior called tactolocation, or grope feeding. A foraging wood stork wades through the water with its beak immersed and partially open (7 to 8 cm) (2.7 to 3.9 inches). When it touches a prey item, a wood stork snaps its mandibles shut, raises its head, and swallows what it has caught (Kahl 1964). This unique feeding method of the wood stork gives it specialized habitat requirements; the habitats on which wood storks depend have been disrupted by changes in the distribution, timing, and quantity of water flows in south Florida. The loss or degradation of wetlands in central and south Florida is one of the principal threats to the wood stork.

The reservoir footprint overlaps the 18.6-mile core foraging areas (CFA) of three wood stork colonies. Individuals have been observed foraging and loafing onsite, although not frequently.

West Indian Manatee

The West Indian manatee (*Trichechus manatus*) is recognized as an endangered species by both the Service and FWC. Manatees are also protected under the provisions of the Marine Mammal Protection Act of 1972, as well as Florida law. The manatee, or sea cow, is a large, plant-eating aquatic mammal that can be found in the shallow coastal water, rivers, and springs of Florida. Florida is essentially the northern extent of the West Indian manatee's range, though some manatees occasionally are reported from as far north as Virginia and the Carolinas (FP&L 1989). The endangered West Indian manatee is regularly found in the Caloosahatchee River and the Charlotte Harbor estuary. This large, aquatic mammal migrates along the Florida coast through fresh, brackish, and marine waters, with a seasonal distribution based on water temperatures. Water depths of at least 3 to 7 ft are preferred. Water colder than 20 degrees Celsius (68 degrees Fahrenheit) increase the manatee's susceptibility to cold-stress and cold-induced mortality. Distribution is also controlled by aquatic vegetation availability, proximity to channels of at least 2 meters (6.6 ft) in depth, and location of fresh water sources (Service 1999). During the summer months manatees range throughout water bodies of south Florida, usually in small groups. In the winter months they tend to congregate in warm water areas such as springs and electric generation facilities (FP&L 1989).

Designated critical habitat for the manatee is located in the Caloosahatchee River Basin. Critical habitat extends downstream from the State Highway 31 Bridge and includes all U.S. territorial waters adjoining the coast and islands of Lee County.

Primary threats to manatees today are collisions with watercraft, degradation of seagrasses and accidents occurring at water control structures. Navigational locks along the Caloosahatchee River have a history of causing manatee mortality. Sixteen navigational locks and water control structure-caused manatee deaths have been recorded near Ortona Lock (S-78) between 1980 and 2001. Throughout those same years, six were discovered near S-77 at Moore Haven, and just one in 1999 at the Franklin Lock (S-79). Existing operational protocols for the structures and locks (unaffected by project planning for the C-43 reservoirs) are important considerations in reducing these deaths.

Manatees have been known to utilize the Townsend Canal, which lies immediately adjacent and to the west of the project footprint. During times of inflow from the Caloosahatchee River, manatees are capable of passing over the weir and traveling southward into the Townsend Canal. Individuals have been observed at the outfall area immediately west of the project boundary as well as at the mouth of the canal in the Caloosahatchee River. However, manatees cannot access the main distribution canal (*i.e.*, Header Canal) for the grove property due to differences in elevation.

Bald Eagle

The bald eagle (*Haliaeetus leucocephalus*) is currently listed as a threatened species by both the Service and FWC. However, the Service has recently determined that the bald eagle has recovered and published the Final Rule to delist the bald eagle in the Federal Register on July 9, 2007. Removal of the bald eagle from the list of endangered and threatened wildlife will be effective August 8, 2007. Accordingly, the bald eagle is considered common in Florida and known to breed throughout the state. Nest sites are usually located near large rivers, lakes, or estuaries where they feed primarily on fish and water-dependent birds. Their distribution is influenced by the availability of suitable nest and perch sites near large, open waterbodies, typically with high amounts of water-to-land edge (Service 1999). The bald eagle is the only eagle unique to North America. It ranges over most of the continent, from the northern reaches of Alaska and Canada down to northern Mexico. Current threats to the bald eagle include habitat loss and fragmentation, collisions with cars and powerlines, and shooting (Service 1998).

Data obtained from the FWC 2004 Eagle Nest Database indicate that the closest documented bald eagle nest, HE002, is located 3.4 miles east of the project, eastward of SR 29. This nest is documented to be last active as of the 2003 nesting season (was not active in the 2004 nesting season). No other nests were observed in the project vicinity during summer 2004 or spring 2006 field efforts.

Eastern Indigo Snake

The threatened eastern indigo snake (*Drymarchon corais couperi*) is present throughout the state, but its abundance is reduced to a point where it is uncommon. Habitat includes pine flatwoods, scrubby flatwoods, high pine, dry prairie, tropical hardwood hammocks, edges of freshwater marshes, agricultural fields, coastal dunes, and human altered habitats. This species was listed as a result of dramatic population declines caused by over-collecting for the domestic and international pet trade as well as mortalities caused by rattlesnake collectors who gassed gopher tortoise burrows to collect snakes. Since its listing, habitat loss and fragmentation by residential

and commercial expansion have become much more significant threats to this species (Service 1999).

The project study area contains suitable habitat for the eastern indigo snake. Although the eastern indigo snake was not observed during field visits, habitat exists on the project site; therefore, it could potentially occur. The species is known to utilize a variety of habitat types including citrus grove (Service 2006).

Florida Scrubjay
The Florida scrubjay (*Aphelocoma coerulescens*), a threatened species, is present in limited areas of scrub habitat in the study area. It is a relict species of fire-dominated oak scrub habitat that occurs on well-drained sand soils in peninsular Florida. Scrub-jays are extremely habitat-specific, sedentary, and territorial. Florida scrub-jays form family groupings; fledglings remain with their parents in their natal territory as helpers. The Florida scrub-jay is listed as a threatened species because of loss, fragmentation, and degradation of scrub habitats throughout Florida, due primarily to urbanization, agriculture, and fire suppression. During the last 10 to 23 years, the population has declined by an estimated 25 to 50 percent, and they have been extirpated from seven counties statewide.

No individuals, nests, or appropriate habitat were detected in the project footprint during site visits. The nearest documented Florida scrub jay habitat and population occurs 1.1 miles west of the project area. This colony is beyond the foraging distance for the species to access the project area.

Red-cockaded Woodpecker
The red-cockaded woodpecker (*Picoides borealis*) was listed as threatened in 1970. The red-cockaded woodpecker is one of 22 species of woodpeckers native to North America. Its historic range encompasses the southeastern U.S. from eastern Texas to Oklahoma to New Jersey, and it was characterized as "abundant" in the 19th century literature. Throughout the 20th century, however, the species' distribution within its historic range has become fragmented, and its total population numbers have decreased dramatically due to the destruction of its habitat. The primary threat to the species continues to be the destruction or degradation of its habitat as a result of timbering and other land-clearing activities. Although south Florida is not a designated recovery population for the red-cockaded woodpecker, the area contains support populations for recovery of the species in the southeast. Additional population surveys and research on habitat requirements within the hydric pine flatwoods of south Florida are needed to assess the current status of the birds and to adapt conservation measures used elsewhere to the distinct conditions in this area. The nearest documented red-cockaded woodpecker population occurs approximately 14 miles northwest of the project area (FWC data).

Florida Panther
The Florida panther (*Puma concolor coryi*), a subspecies of mountain lion, is one of the most endangered large mammals in the world. The most recent population estimate for the Florida panther is a total of 87 individuals, not including denning kittens (McBride 2003). This small population in south Florida represents the only known remaining wild population of an animal

that once ranged throughout most of the southeastern United States from Arkansas and Louisiana eastward across Mississippi, Alabama, Georgia, Florida, and parts of South Carolina and Tennessee. The panther presently occupies one of the developed areas in the eastern United States; a contiguous system of large private ranches and public conservation lands in Broward, Collier, Glades, Hendry, Lee, Miami-Dade, Monroe, and Palm Beach Counties totaling more than 809,400 hectares (2,000,070.9 acres). Panthers have a strong affinity for hardwood forests and mixed swamps but also use freshwater marshes, prairie and shrub and scrub habitats, agricultural lands (*i.e.,* wooded pasture, rangeland, citrus groves, row crops, etc.), and even urban areas. Geographic isolation, habitat loss, population decline, and associated inbreeding have resulted in a significant loss of genetic variability and overall health of the Florida panther population. Natural gene exchange ceased when the panther became geographically isolated from other subspecies of *Puma concolor*. Population viability projects have concluded that, under current demographic and genetic conditions, and without implementation of recovery actions, the panther would probably become extinct within two to four decades.

The Caloosahatchee basin plays an important role in the recovery of the Florida panther. The Service has organized a multi-agency subgroup of the Multi-species and Ecosystem Recovery Implementation Team (MERIT) to produce a Florida panther landscape conservation strategy. That strategy included the identification and prioritization of habitat zones (Dispersal, Primary, and Secondary Zones) that are essential for effective Florida panther conservation (Kautz et al. 2006). In addition to protection of habitat for adult home ranges, the strategy includes corridors for dispersal of juveniles between larger areas of contiguous habitat. Dispersal across the Caloosahatchee River, between existing primary habitat south of the river and habitat that is presently only occasionally used by panthers north of the river, is considered essential for recovery of the species.

A large portion of the proposed project is located outside the panther focus area (PFA), while the remainder of the project area is located in an agricultural area that provides some functional value for panthers. This portion of the proposed project would impact areas within the panther primary, secondary, and "other" zones, as identified by the Florida panther subteam of the MERIT and Service's PFA updates. The most recent available FWC telemetry data of radio collared Florida panthers, current through January 2004, depicts three (3) Florida panthers and one (1) Texas cougar (*Felis concolor*) within a five-mile radius of the project area. The status and activities of uncollared Florida panthers within the project area are unknown. The Service believes the project site may occasionally be used by foraging and dispersing panthers because it contains habitat types used by panthers and their prey and the project vicinity has been used historically by panthers as indicated by telemetry locations over a 10-year period. A more landscape level inspection (25-mile radius) identifies habitat utilization by several additional panthers, particularly within Okaloacoochee Slough and other conservation lands.

Audubon's Crested Caracara

Audubon's crested caracara (*Polyborus plancus audobonii*) is another federally listed species present in the Caloosahatchee basin. It is a large, boldly patterned raptor, with a crest and unusually long legs. It is a resident, diurnal, and non-migratory species that occurs in Florida as well as the southeastern United States and Central America. In Florida, this species is found in

the prairie area of the south-central region of the state. Historically, this species was a common resident in Florida from northern Brevard County, south to Ft. Pierce, Lake Okeechobee, and Hendry County. Today, the region of greatest abundance for this large raptor is a five-county area north and west of Lake Okeechobee. The preferred native habitat is dry or wet prairie with scattered cabbage palms (Service 1999). Improved and unimproved pastures are also highly utilized. Effect determinations for caracara are based mostly on potential impacts within the primary nest zone (*i.e.*, within a radius of 985 ft from a nest tree) or the secondary zone (a radius of 6,600 ft). Additionally, potential effects within juvenile congregation areas are also considered.

The project falls within the Service's caracara Consultation Area. One caracara nest site was confirmed to the north of the project during spring 2006 surveys. This nest is located along the southern edge of the SR 80 right-of-way (ROW) and approximately 4,750 ft north of the project boundary. While individuals were not observed foraging in the project footprint, a portion of the project falls within 2000 meters (secondary zone) of this nest, as defined in the Standard Local Operating Procedures for Endangered Species (SLOPES). Another caracara nest was confirmed approximately 1,065 ft southeast of the project boundary, within a pasture of the A. Duda & Sons, Inc. property. Individuals were observed flying into and out of the C-43 reservoir site by staff of Scheda Ecological Associates, Inc. during the 2006 surveys. While the C-43 project area provides only sub-optimal foraging habitat for the species, and individuals were only observed utilizing the project area in the southeast portion of the footprint, it does fall within the home range of both the confirmed and possible nests.

Florida Grasshopper Sparrow

The Florida grasshopper sparrow (*Ammodramus savannarum floridanus*) is a subspecies of grasshopper sparrow that is endemic to the dry prairie of central and southern Florida. This subspecies is extremely habitat specific and relies on fire every two to three years to maintain its habitat. It is now known to occur only from Highlands, Okeechobee, Osceola, and Polk Counties, but other populations may occur in Glades County, which may bring it into the study area considered here. The species is not known to occur in Hendry County but populations may occur in nearby Glades County as documented in our April 11, 2002 Planning Aid Letter. The nearest Florida grasshopper sparrow record in the 1999 FNAI database is a 1984 observation located 17.3 miles north of the project. Mapping of potential Florida grasshopper sparrow habitat (Shriver and Vickery 1999) shows marginal habitat zones to the northeast and southeast of the project, and the project area falls within the Service's Florida grasshopper sparrow CA. However, the nearest marginal habitat zone is located approximately 2.5 miles to the southeast of the project footprint. No grasshopper sparrows were observed during field surveys and no suitable habitat exists in the project area.

Piping Plovers

A wintering population of piping plovers (*Charadrius melodus*) uses the tidal area of the Caloosahatchee River. The piping plover was listed as threatened along the Atlantic coast in 1985. It is a small, migratory shorebird that breeds only in three geographic locations of North America: on sandy beaches along the Atlantic Ocean, on sand shorelines throughout the Great Lakes, and on riverine systems and prairie wetlands of the Northern Great Plains. This species

does not breed in Florida, but all three breeding populations winter here. Bunche Beach, at the mouth of the Caloosahatchee, has a population of wintering piping plovers and is also designated critical habitat for this species. The Service established critical habitat areas for the species, which include several locations on barrier islands west of the Caloosahatchee Estuary. The nearest piping plover critical habitat zone to the project area includes Punta Rassa, a mainland location at the southwestern edge of the Caloosahatchee Estuary, and Bunch Beach.

Okeechobee Gourd

The Okeechobee gourd (*Cucurbita okeechobeensis*) is a vine that was locally common in the extensive pond apple forest that once grew south of Lake Okeechobee (Small 1922). It is a vine that is now restricted in the wild to two small distinct populations; one along the St. Johns River which separates Volusia, Seminole, and Lake Counties in north Florida, and a second around the shoreline of Lake Okeechobee in south Florida. Although the gourd occurs within the Caloosahatchee Basin, no individuals occur in the project area or would be impacted by reservoir releases.

American Crocodile

The Service and the FWC list the American Crocodile (*Crocodylus acutus*) as endangered. This species occurs in extreme south Florida primarily in Biscayne and Florida Bays. Crocodiles have been observed as far north as the coasts of Lee and Collier Counties, but these counties are not thought to support a significant resident population of crocodiles. The American crocodile has not been documented in Hendry County. The nearest documented individual occurrence to the project is on Sanibel Island in Lee County. The American crocodile is known to inhabit mangrove and seagrass habitats in coastal areas of south Florida.

Sea Turtles

Sea turtles including the Atlantic loggerhead turtle (*Caretta caretta*), Atlantic green turtle (*Chelonia mydas*), leatherback turtle (*Dermochelys coriacea*), Kemp's ridley turtle (*Lepidochelys kempii*), and hawksbill turtle (*Eretmochelys imbricata*) are listed as endangered by the Service and the FWC with the exception of the loggerhead turtle, which is listed as threatened. These are marine species with a presence in south Florida waters and are known to utilize bays and estuarine habitats, such as the Caloosahatchee estuary, for feeding and resting. Sea turtles forage in the near shore waters, bays and sounds of Florida and come ashore at night to nest on the beaches above the high tide line. Alterations in the timing and quantity of freshwater flowing through the estuary has an impact on natural biodiversity by affecting food availability, predation pressure, reproductive success, and most likely has caused chronic and acute stress to these species.

Estuarine Fishes

One endangered fish, the smalltooth sawfish *(Pristis pectinata)*, occurs or may occur in estuaries downstream of the project area. Federally listed fish species are regulated by the NOAA Fisheries Service.

b. State-listed Species

The following fish and wildlife species (Table 2) are State-listed as threatened (T), endangered (E), or species of special concern (SSC), and may occur or are known to occur in the study area.

Table 2. Species listed by the Florida Fish and Wildlife Conservation Commission as threatened (T), endangered (E), or of special concern (SSC) that potentially occur within the Caloosahatchee River Basin (Charlotte, Lee, Collier, Hendry, and Glades Counties) or the Proposed C-43 West Reservoir footprint excluding federally listed species (Florida Natural Areas Inventory 2001).

c. Other Fish and Wildlife Resources

In 1994, the FWC (Cox et al. 1994) assessed Florida's wildlife habitat conservation system in order to provide recommendations to meet minimum conservation goals for declining wildlife species and rare plant and animal communities. The report (termed the GAPS report) described habitat areas in Florida that should be conserved if key components of the state's biological diversity were to be maintained. A GIS was used to assess land use, geographic data sets of fish and wildlife species, rare plants, and habitats to recommend lands (Strategic Habitat Conservation Areas [SHCA]) for additional protection. The SHCAs are lands needed to meet minimum conservation goals for 30 species of wildlife inadequately protected by conservation lands, rare habitats, bat maternity caves and winter roost caves, wetlands important to the breeding success of eight species of wading birds, and lands important to the long-term survival of 105 globally rare plant species. The project also identified Regional Biodiversity Hot Spots (RBHS) where large numbers of 52 selected species co-occur with areas that support rare plant and wildlife communities and coastal areas that support key components of biological diversity. The SHCAs encompass 4.82 million acres or approximately 13 percent of the land area in Florida.

The Southwest Florida Region was identified in the GAPS report as the most important region in Florida in terms of maintaining several wide-ranging species. The C-43 West Storage Reservoir project is included in Area 1 of the region which contains SHCAs for the Florida panther, Florida black bear, wood stork, American swallow-tailed kite, Florida sandhill crane, Everglade snail kite, Audubon's crested caracara, Florida scrub jay, snowy egret, little blue heron, glossy ibis, great egret, mottled duck, eastern indigo snake, and large flowered flax.

In 1999, the Service finalized the South Florida Multi-Species Recovery Plan. This plan is an ecosystem-based recovery plan to restore and maintain the biodiversity of native plants and animals, as well as the threatened and endangered species of south Florida. The plan identifies several ecological communities that are found in the C-43 West Storage Reservoir project area, including mesic temperate hammock, tropical hardwood hammock, forested wetlands (cypress forest), mesic and hydric flatwoods, and freshwater marshes and wet prairies.

Migratory Birds

Migratory birds are protected under the Migratory Bird Treaty Act (16 U.S.C. 703-712). The South Florida ecosystem is located along one of the primary migratory routes for bird species that breed in temperate North American and winter in the tropics of the Caribbean and South America. Many species of neotropical migrants have been recorded in the South Florida Ecosystem. In 1995, the Service prepared a list of migratory nongame birds of management concern in the U.S. to stimulate a coordinated effort by Federal, State, and private agencies to develop and implement comprehensive and integrated approaches for management of these

selected species (Service 1995). Forty-three of these species are found in the south Florida Ecosystem. Other migratory species like the tanagers (*Pirange* spp.), chimney swifts (*Chaeturaa pelagica*), tree swallows (*Iridoprocne bicolor*), nighthawks (*Chordeiles minor*), royal terns (*Sterna maxima*), and blue-winged teal (*Anas discors*) also have major migratory pathways through and to (as winter residents) south Florida. More than 129 bird species migrate to the South Florida Ecosystem to overwinter. Another 132 bird species breed in south Florida. Because the South Florida Ecosystem is located near Cuba and the West Indies, it draws tropical species that rarely appear elsewhere in North America. Examples include the smooth-billed ani (*Crotophaga ani*), mangrove cuckoo (*Coccyzus minor*), Antillean nighthawk (*Chordeiles gundlachii*), white-crowned pigeon (*Columba leucocphala*), gray kingbird (*Tyrannus dominicensis*), short-tailed hawk (*Buteo brachyurus*), Everglade snail kite, and black-whiskered vireo (*Vireo altiloquus*). The South Florida Ecosystem has an endemic race of the yellow warbler (*Dendroica petechia*) and contains the majority of the nesting locations for the reddish egret (*Egretta rufescens*), roseate spoonbill (*Ajaia ajaja*), swallow-tailed kite, and short-tailed hawk in the United States.

Southwest Florida has been identified as a core conservation area for the swallow-tailed kite (Meyer 1996). The swallow-tailed kite requires tall, accessible trees for nesting with open areas that provide sufficient small, easily subdued prey. Suitable habitat may be small stands or tree islands in prairie-like settings, low-density forests of uneven structure interrupted by open areas of shrub, swamp, or marsh vegetation, or denser forest, frequently interspersed with various sorts of openings (Meyer 1995). A large, pre-migratory roost (280 birds in 1988) of swallow-tailed kites has been documented 27 km (16.8 miles) away in Corkscrew, Collier County (Meyer and Collopy 1990).

Fifteen species of herons, storks, and ibises nest in south Florida and are considered ecological indicators because of their wide foraging ranges, relatively narrow food requirements, and relatively specific habitat requirements. Their breeding success reflects the health of the wetland and coastal habitats of south Florida. Migratory songbirds, raptors, and wading birds utilize a variety of habitats within the C-43 West Storage Reservoir project area and represent an important trust resource for the C-43 West Storage Reservoir project area. The Audubon WatchList for the State of Florida (Muehter 1998) also includes several avian species known to inhabit the C-43 West Storage Reservoir project area (*i.e.*, American swallow-tailed kite, and loggerhead shrike [*Lanius ludovicianus*]). State WatchLists promote the conservation of local bird populations and serve as an early warning system that focuses attention on at-risk bird species before they become endangered.

Essential Fish Habitat

Aquatic habitats within the Caloosahatchee Basin have been altered through the channelization of the river. Nevertheless, the basin continues to support fishery resources of some recreational or commercial importance. At least 70 percent of Florida's recreationally or commercially sought fishes depend on estuaries for at least part of their life histories (Harris et al. 1983; Estevez 1998; Lindall 1973). Seagrass communities within the Caloosahatchee estuary provide critical refugia for juvenile fish such as redfish, grouper, snook, and spotted seatrout. The decline in juvenile abundance and distribution of these and other species, along with an overall

decrease in species richness may be related to the loss of seagrass habitat and a result of alterations in the salinity regime and the timing of the freshwater discharges from the S-79 structure. The "without project" condition would impact essential fish habitat by projected further disruptions in the distribution, timing and quantity of water flows into the Caloosahatchee estuary.

C. Description of Proposed C-43 West Storage Reservoir Site

The proposed C-43 West Basin Reservoir footprint is located in Hendry County west of LaBelle, Florida. The site is located on approximately 10,492 acres south of State Road 80 and approximately two miles west of State Road 29 (Figure 2). The majority of the property is owned by the District and is under a lease agreement with Jack M. Berry, Inc. for continued citrus grove operations.

At the landscape level, the C-43 project is surrounded by a matrix of agricultural, forested, and wetland land covers with pockets of urban land use. Citrus groves, row crops and improved pasture with scattered cypress and mixed wetland hardwoods surround the project to the north, east, and south. The area to the north also contains some low-density residential areas. Forested uplands, parceled into low-density residential lots in various stages of development, comprised of pine flatwoods, longleaf pine-xeric oak, sand pine, and xeric oak are adjacent to the west of the project. Urban areas are present to the southwest and northeast of the project area with small parcels along the Caloosahatchee River. Regions to the northwest and southeast of the project area are generally undeveloped.

Natural and biological features and land use within the reservoir footprint were initially reviewed using the 2000 Florida Land Use, Cover and Forms Classification System (FLUCCS) Geographic Information System (GIS) data (District 2000). Citrus grove covers approximately 90 percent of the study site, more than any other land cover type. The citrus grove land use classification includes acreage covered by citrus trees, grove maintenance roads, and small berms, brush piles, and other small features related to citrus grove operations. Water comprises 8.9 percent of the site and includes extensive agricultural canals and ditches, classified as streams and waterways, and excavated ponds, classified as reservoirs less than 10 acres in size. Wetland comprises 1.1 percent of the site and includes mixed wetland hardwoods, willow and elderberry, exotic wetland hardwoods, cypress, wetland shrub, and freshwater marsh.

The project site has numerous agricultural canals and ditches for irrigation and drainage. The site contains three major arterial canals that transport water for the purpose of irrigation and attenuation of Caloosahatchee Basin runoff waters. Two of the primary canals, Roberts and Townsend, lie along the eastern and western perimeters of the footprint, respectively. The Header Canal, also called the LPDD Canal, bisects the entire reservoir area and is used primarily to cross-feed water between the Roberts and Townsend Canals.

Most of the reservoir footprint contains north and south oriented tertiary canals spaced every tenth row of trees (*i.e.,* approximately every 250 ft) to irrigate the citrus beds. The tertiary canals drain into a network of larger secondary canals, both of which are considered jurisdictional

waters of the United States by the Corps. The secondary canals drain into the Header Canal. Water eventually flows the Header Canal to the Caloosahatchee River through the Townsend or Banana Branch and Roberts canals or through Fort Simmons Branch (Figures 13). The planned reservoir intake is located on the Townsend Canal immediately downstream from the segment identified by DEP as impaired for copper and lead.

Intensive agriculture in the study area occurs mainly as citrus, with some row crops, sod farms, plant nurseries, and sugar cane. These disturbed areas are generally less desirable habitats for fish and wildlife. They exhibit habitat uniformity and are subject to disturbance from humans, machinery, and pesticide usage. Still, some wildlife is usually present in these areas as either residents or transients from native habitats. Mazzotti et al. (1992) reported on wildlife usage in citrus groves southwest of Lake Okeechobee. They found 203 vertebrate species out of a possible total of 380 that were regionally present, however, 78 percent of those were observed not in the production areas, but in associated agricultural reservoirs or wet detention areas.

IV. FISH AND WILDLIFE RESOURCE CONCERNS

A. Introduction

The Service recognizes the importance of this project as an initial step to improve the timing and quantity of freshwater flows to the Caloosahatchee estuary and adjacent waters and to enhance or conserve aquatic and estuarine habitats. The principal focus of this report is the protection, conservation, and enhancement of fish and wildlife resources in the region, consistent with the project purposes of promoting an ecologically viable salinity regime in the Caloosahatchee estuarine system.

As mentioned previously, the Caloosahatchee River and Estuary is at the head of a vast estuarine and marine ecosystem that includes aquatic preserves managed by the State of Florida (*e.g.*, Matlacha Pass AP, Estero Bay AP, Pine Island Sound AP), and Federal entities (*i.e.*, the CHNE Program, and the J.N. "Ding" Darling NWR Complex) along with numerous other State and local parks and recreation areas. Restoration of healthy, productive aquatic ecosystems in the Caloosahatchee River and estuary is essential to maintaining the ecological integrity and associated economic activity in these publicly owned and managed areas. The intent of this section is to define fish and wildlife resource values in terms of the issues and areas of concern generated by the proposed project.

B. Resource Concerns

1. Protection of Estuarine and Marine Resources

The Caloosahatchee estuary extends from S-79 about 40 km downstream to Shell Point where it empties into San Carlos Bay and adjacent waters (Figure 7). Major environmental concerns for the Caloosahatchee estuary and adjacent waters are altered freshwater inflows and extreme variation in salinity levels, eutrophication, and habitat loss. Altered salinity in the estuary has resulted from hydrological modifications that have dramatically changed the natural quantity,

quality, timing, and distribution of freshwater flows to the estuary (Haunert et al. 2000). Salinity is a major ecological variable that controls important aspects of the estuarine community structure and food web (Myers and Ewel 1990). Flow alterations impact the natural biodiversity of the estuary by affecting food availability, predation pressure, and reproductive success, as well as directly causing chronic and acute stress on biota. Altered freshwater inflow can also influence primary productivity, zooplankton biomass, and nekton abundance by influencing nutrient concentrations and light attenuation.

a. Management of freshwater flows and salinity conditions

The excessive variation in discharge and salinity in the Caloosahatchee Estuary (Figure 8) maintains estuarine biota in a constant flux between those favoring higher salinity and those favoring lower salinity (Chamberlain and Doering 1998a; Bulger et al. 1990). Optimal salinity conditions may not last long enough for organisms to complete their life cycle and the estuary can become devoid of some populations, even keystone species that support major ecosystem components along the estuary's salinity gradient such as oysters or submerged aquatic vegetation.

Depending on day of the year, the long-term mean daily discharge at S-79 ranges between 300 and 3,000 cfs. However, daily and monthly inflows often exceed this long-term average particularly in the wet season, with prolonged inflows commonly exceeding 4,500 cfs, which adversely affects the San Carlos Bay area and the Caloosahatchee and Matlacha Pass NWRs. Flows reaching above the 4,500 cfs threshold and those occasionally exceeding 10,000 cfs can push freshwater into Pine Island Sound and the Gulf of Mexico, thus impacting ecologically and commercially important high-salinity marine resources that historically were not directly affected by Caloosahatchee River discharges. During the dry season, the combination of limited rainfall, lack of water storage in the basin and withdrawals to meet human demands for irrigation and potable water often results in periods of no freshwater discharge to the estuary. Saltwater can intrude all the way upstream to S-79, threatening species that require low salinity to complete their life cycle (Chamberlain and Doering 1998a; 1998b, Doering et al. 2002; District 2002).

Environmental research by the District began in the Caloosahatchee Estuary during the mid-1980s and focused on the impacts associated with the extreme variability in freshwater inflow from S-79 (Chamberlain and Doering 1998a). The purpose of the research was to determine the proper timing and volume of water quantity required to support valued ecosystem components (VECs), such as oysters and SAV, as well as the impacts of flows on general biotic indicators, such as plankton and benthic invertebrates (District 1998). This research has resulted in the development of optimum S-79 flow ranges and delivery patterns for the estuary (Chamberlain and Doering 1998b; Doering et al. 2002; Volety et al. 2003). This information has formed the basis for development of hydrologic performance measures for CERP, Southwest Florida Feasibility Study (SWFFS), and the Lake Okeechobee Regulation Schedule, as well as meeting legislative mandates for the establishment of the Caloosahatchee River and Estuary Minimum Flow and Level (MFL) (District 2000, 2003).

The MFL was based on a flow-salinity relationship that was based on flows at S-79 and downstream salinity levels. The MFL salinity criteria were initially designed to protect tape grass upstream of Ft. Myers but those criteria are also beneficial for other organisms that utilize this low salinity region of the estuary (Chamberlain and Doering 1998b; Doering et al 2002). Additionally, the MFL study determined that the proposed criteria for the Caloosahatchee River and Estuary will be exceeded on a regular and continuing basis until additional storage is provided in the basin to supply the additional water needed.

The optimum distribution of flows at S-79 and salinity criteria (*i.e.*, hydrologic performance measures) were derived from relationships between the distribution, abundance, growth, and survival of estuarine organisms or VECs and the changes in salinity or freshwater discharge to the estuary. Initially, the salinity tolerances of submerged grasses were used to identify minimum and maximum inflows at S-79. A distribution of monthly average inflows with the greatest frequency range from 300 to 1,500 cfs and a peak between 300 and 800 cfs was originally identified as the most beneficial for the species evaluated. Mean monthly flows less than 300 cfs were thought to allow salinity in the upper estuary to exceed the tolerance of tape grass and cause mortality. Flows greater than 2,800 cfs reduce salinity in the lower estuary and threaten the marine shoal grass typical of this region (Chamberlain and Doering 1998b; Doering et al. 2002). Research has shown that the flows from 300 to 1,500 cfs with a peak between 300 and 800 cfs, can benefit other organisms as well (*e.g.*, oysters, plankton, blue crab, and redfish) (Chamberlain and Doering 1998b; Volety et al. 2003).

As more information about the salinity requirements of key biota became available, the original frequency distribution would be updated (Chamberlain and Doering 1995, 1998a, and 1998b). The MFL identified 300 cfs as the minimum average monthly inflow at S-79 needed to prevent significant harm to the oligohaline zone of the estuary and tape grass. However, salinity in the estuary is influenced by additional inflows from creeks and groundwater downstream of S-79. When flow at S-79 is 300 cfs, an additional 150 to 200 cfs comes from sources downstream of S-79 for a total inflow of approximately 450 cfs. During low flow conditions, the entire system is drier than normal and the downstream contribution is much lower than 150 to 200 cfs. Thus, a minimum flow of 300 cfs at S-79 is insufficient to achieve the MFL salinity criteria. The original basin flow optimization model used historic S-79 flow data from 1965 to 1990 to recommend a time series of basin flows (Labadie 1995; Otero et al 1995). More recent modeling efforts for the CERP, the CWMP, and the proposed C-43 West Storage Reservoir project use a 2000 Base and have resulted in reconsideration of the original time series of flows to the estuary. The EST05 time series (*i.e.,* an average monthly flow distribution between 450 and 2,800 cfs at S-79) provides a higher level of protection in the upper estuary than the previous time series by establishing a low flow limit of 450 cfs at S-79. Likewise, the EST05 distribution is consistent with the total flow requirements associated with the MFL and its salinity criteria for protecting tape grass.

In an ordinary year, flows less than 450 cfs at S-79 occur approximately 4.2 months per year and flows greater than 2,800 cfs at S-79 occur approximately 2.6 months per year. Thus, flows are less than or greater than the target range about seven months per year, reinforcing the need for the additional basin storage identified by the CERP, CWMP, and the MFL, and reaffirmed by the

proposed C-43 West Storage Reservoir project. High water levels in Lake Okeechobee from the 2005 hurricane season and heavy basin rains resulted in a single day's discharge of 21,000 cfs and extremely high mean monthly flows at S-79 during the wet season of Water Year (WY) 2006 which extended from May 2005 to April 2006 (Figure 9). The mean monthly flows were above the upper limit of the EST05 flow range during the first eight months (*i.e.*, May through December 2005). Flows exceeded 4,500 cfs during six of those eight months and decreased salinities as far as San Carlos Bay which can adversely impact seagrasses in that area significantly. Half (four) of those exceedances were average monthly flows greater than 8,000 cfs, which can decrease salinities well into lower Pine Island Sound and impact estuarine resources in the J.N. "Ding" Darling NWR, and Sanibel, Pine, and possibly Captiva Islands. However, the current dry season extending into 2007 has been extremely dry. Thus, the resultant salinity levels have exceeded the monthly criteria in the upper estuary (*i.e.*, the Fort Myers salinity sensor), and the tape grass beds have almost disappeared.

Effects on Tape Grass

Tape grass beds had essentially vanished from the upper estuary as a result of extremely high salinity levels during the 2001 drought. Tape grass density remained low and started a slight increasing trend during the growing season of 2003. The beds began to recover while salinity conditions were favorable during the spring and summer growing seasons of WY2004 and WY2006.

Before the 2001 drought, plant density was significantly greater at Station 2. WY2006 was the first time since the drought that this pattern was evident. During the high freshwater inflows in June, plant density decreased upstream at Station 1, possibly due to the associated drop in water clarity, while more plants persisted at Station 2 during November 2005 through March 2006 than in previous years since 2001. However, due to the unusually high salinity associated with the 2007 dry season the plants have again almost disappeared.

Effects on Oysters

Salinity is also important in determining the distribution of coastal and estuarine bivalves, such as oysters. Short pulses of freshwater inflow can greatly benefit oyster populations by killing predators, while excessive freshwater inflows may kill entire populations of oysters (Gunter 1953; Schlesselman 1955; MacKenzie 1977). Although an oyster population still exists within the lower Caloosahatchee Estuary, historical accounts of the river indicate that oysters were once a more prominent feature in the area upstream (Sackett 1888). Oysters are more than an important recreational and commercial fisheries resource; their reefs serve as essential fish habitat. Oyster reefs provide a complex, three-dimensional, reef structure used as nesting habitat and refugia by numerous species of invertebrates and fishes (*e.g.*, blue crab, stone crabs, mud crabs, grass shrimps, blennies, gobies, killifishes). Furthermore, many of those organisms serve as forage for other important fisheries (*e.g.*, snook, sheepshead, grouper, redfish, spotted sea trout, black drum), birds (*e.g.*, American oystercatchers, pelicans, osprey), and mammals (*e.g.*, raccoons). They also promote the growth of sea grasses by improving water clarity. Individual oysters can filter 4 to 34 liters (1 to 9 gallons) of water per hour, removing phytoplankton, sediments, pollutants, and microorganisms from the water column (Volety 2003).

Aerial surveys for oysters conducted during WY2004 found only 3.02 acres of oysters in the lower Caloosahatchee Estuary near Shell Point and only 15.04 acres in lower Charlotte Harbor. This low number of oysters, especially near Shell Point, is most likely a result of a combination of: (1) high freshwater inflows into the estuary from the C-43 basin and Lake Okeechobee; (2) the lack of suitable shell or a firm mud-sand-shell mix substrate; and (3) shell mining in the 20th century for construction material that decimated the live oyster population and destroyed the existing reefs.

Monitoring of the health and recruitment of oysters in San Carlos Bay and lower Charlotte Harbor began in 2000 (Corps and District 2007). Results indicate that oysters in the Caloosahatchee Estuary spawn continuously from April through October, a period that coincides with freshwater releases into the estuary. High freshwater flows flush out oyster larvae and spat from upstream areas with suitable for cultch settlement and reduce salinities to levels that reduce larval growth rates and survival (Dekshenieks et al. 2000). The high flows from Lake Okeechobee and basin runoff following Hurricanes Katrina, Rita, and Wilma during WY2005 reduced salinities (Figure 8) in the estuary and flushed out spat, resulting in one of the lowest years of oyster recruitment observed (Corps and District 2007). Drastically high flows during June 2006 resulted in another poor year for oyster survival and recruitment, particularly upstream of Shell Point.

A preliminary target for the aerial extent of oyster reefs in the lower Caloosahatchee Estuary and lower Charlotte Harbor is 40 and 60 acres respectively, during the next 10 to 15 years. With the addition of hard substrate, this target can be increased to 200 to 300 acres upstream of Shell Point and 150 to 200 acres downstream from Shell Point. Eighty-seven volunteers from Florida Gulf Coast University, concerned citizens, District, and other state, federal, and local agencies placed 200 shell-bags at two locations upstream of Shell Point (*i.e.,* Iona Cove and Piney Point) during October and November 2005 to provide substrate for oyster recruitment and reef development.

Effects on Seagrasses

Aerial surveys of seagrass cover throughout the Lower Charlotte Harbor region (*i.e.*, the lower Caloosahatchee estuary, Matlacha Pass, San Carlos Bay, and Pine Island Sound) were conducted in 1999, 2002/2003, and 2004. No aerial surveys were conducted during 2005 or 2006. The aerial extent of seagrasses increased dramatically from approximately 38,197 acres during WY1999 to 43,591 acres during 2002 and 2003. That increase may be due to improved photography, different methodologies, or other differences between surveys rather than a real change (Corbett et al. 2006). However, that increase followed the 2000 and 2001 drought when flows from S-79 were low and salinity in the Lower Charlotte Harbor region was consistently within the optimal ranges of seagrasses. Results of the 2004 survey indicate that there are approximately 38,494 acres in the lower Caloosahatchee estuary, Matlacha Pass, San Carlos Bay, and Pine Island Sound combined, with coverage in each of those areas area of 62 acres, 7,168, 3,905, and 27,359 acres, respectively.

b. Water Quality Improvement

The American Rivers organization listed the Caloosahatchee River as one of the top ten endangered rivers in the United States (American Rivers 2006). The need for water quality improvements in the Caloosahatchee Estuary has been well documented. During the 1980s, the Florida Department of Environmental Regulation conducted waste load allocation studies and, based on elevated chlorophyll *a* levels and low dissolved oxygen (DO) concentrations, concluded that the Caloosahatchee had reached its nutrient loading limits (Doering and Chamberlain 2004). Subsequent water quality studies have found that nitrogen is the most likely limiting nutrient for primary production in the Caloosahatchee estuary and total nitrogen concentrations exceeded the state median (McPherson and Miller 1990; Doering and Chamberlain 1998, 1999, 2004). These studies also found that the highest concentrations of Chlorophyll *a*, total nitrogen, total phosphorus, and color tended to occur most frequently in the upper estuary, most likely as a function of discharges at S-79. Similarly, the occurrences of low DO levels (*i.e.*, less than 2 milligrams/liter) were also observed at the head of the Caloosahatchee estuary. The discharge of water at S-79 is also a major determinant of macro-nutrient concentrations and other aspects of water quality in the Caloosahatchee Estuary. Influence of this discharge can be detected nearly 60 kilometers (37.2 miles) downstream in Pine Island Sound (Doering and Chamberlain 1999). This control of water quality stems from the overwhelming dominance of Caloosahatchee River flows at S-79 over local runoff, as a source of nutrients and other materials to the downstream estuary.

As mentioned previously, the DEP has recently identified impaired water bodies in the Caloosahatchee Basin as part of their TMDL Program (DEP 2004). DEP lists the tidally influenced Caloosahatchee River and Estuary as impaired due to high levels of nutrients (*i.e.*, Chlorophyll *a*), metals (*e.g.*,copper), and fecal coliform, and due to low levels of DO (Figure 4). Under DEP's IWR, estuarine segments are considered impaired if the average annual chlorophyll *a* concentration is greater than 11 mg/l. Chlorophyll *a* concentrations reported for three estuarine water bodies in the Revised Draft Verified List of Impaired Waters for the Caloosahatchee River Basin ranged from 17.21 to 24.77 mg/l during 2000 (DEP 2004). Additionally, high nutrients were identified as the causative pollutant for DO impairment.

High nutrient loads may adversely impact the natural resources within the Caloosahatchee River estuarine system, including the state-managed aquatic preserves, the CHNEP, and the J.N. "Ding" Darling NWR Complex, and the fish and wildlife populations that depend on those resources during various stages of their life cycles. Estuarine habitats provide suitable escape, feeding, breeding and spawning, brood rearing and nursery, and wintering sites for a wide variety of aquatic, estuarine, and wetland-dependent organisms for which the Service has Federal-trust conservation responsibilities (*e.g.*, migratory waterfowl, wading birds, shorebirds, seabirds, other water birds, neotropical migratory songbirds, threatened and endangered species, and interjurisdictional fisheries).

Increased nutrient levels such as nitrogen and phosphorus stimulate phytoplankton and algal blooms and thus, reduce light penetration which can lead to reduced SAV abundance in fresh and marine habitats. The loss of feeding and nursery habitat can lead to population declines in

commercial and sport fishes (*i.e.*, anchovy, redfish, black drum, and spotted seatrout) and shellfishes (*i.e.*, oysters, pink shrimp, and blue crab), and shifts in species composition.

Additionally, changes in abundance and distribution of SAV in the estuary may also impact manatees by increasing travel distance between warm water refugia and suitable food sources. A change in manatee use of the estuary during periods of cold stress could also change exposure to boat traffic.

Likewise, siltation is known to have deleterious effects on epiphytic organisms that are found on mangrove prop roots. High turbidity levels affect fish feeding and growth because the ability of fish to find and capture food is impaired at higher turbidity levels. In addition, gill function in some fish may be impaired after prolonged exposure to high turbidity levels. Sediments can also be contaminated with potentially toxic concentrations of metals, herbicides, and pesticides. Unnatural sediment deposition can limit the quality of the benthic communities (*e.g.*, seagrasses and oyster bars) by abrasion, habitat loss, and reduction of dissolved oxygen concentrations. These limitations, in combination with "freshwater shock," negatively affect the overall ecological health of the estuary.

Sediment loads can also increase oxygen demand. When turbidity is largely due to organic material, dissolved oxygen depletion may occur. Organics contain excess nutrients that encourage microbial breakdown, a process that requires valuable dissolved oxygen. The concentration of dissolved oxygen in the estuary is crucial to fish production, and fish kills often result from extensive or extended oxygen depletion.

c. Preservation of Habitat Quality

Loss of habitat has also been of concern. Hardening of the shoreline, increased freshwater discharge, and oyster mining are thought to have singly or in combination, reduced mangrove, seagrass and oyster bar habitats (Harris et al 1983). Riverine mangrove wetlands occur in floodplains near the mouth of freshwater systems and may be composed of all mangrove species. These wetlands receive nutrients from freshwater flow and are most sensitive to variations in this flow, as well as variations in water quality. Decreasing riverine runoff through channelization of adjacent drainages reduces inputs of nutrients and sediments to these forests and reduces water ventilation of mangrove roots (Lugo 1976).

2. Hydrologic Modeling Issues

a. Errors in MIKE SHE Irrigation Module

Plan formulation and selection of the recommend plan for the C-43 project was based on output produced by the MIKE SHE hydrologic model containing a significant error in the water budget. The Corps identified a water budget discrepancy during review of the model results for the suite of alternatives. The source of this water budget error was within the MIKE SHE irrigation routines and was caused by the irrigation module pulling water from an external source treated as an infinite source of water when irrigation demands were not met by surface and groundwater

systems. The quantity of water coming from external sources also varied significantly among the various model runs. The average-annual volume of water coming from external sources ranged from 125,100 ac-ft for the 2000 without-project run to 260,500 ac-ft for one of the with-project runs. For certain model runs this discrepancy equates to greater than half of the total irrigation volume coming from an artificial external source of water. The precise impacts of these discrepancies on the hydrologic performance of, and habitat benefit calculations for, the alternatives are not clear.

b. Modeling Uncertainty

Different models were used for plan formulation, alternative selection, and assurance analyses adding complexity and uncertainty to alternative comparisons. Ground and surface water hydrology and hydraulics of the Freshwater Caloosahatchee River Basin (FCRB) watershed from S-77 to S-79 were simulated using the MIKE SHE model. Output from the regional South Florida Water Management Model (SFWMM), which simulates the hydrology and water management of Lake Okeechobee and south Florida, was used as input for boundary conditions to the FCRB. Output from the FCRB model was then used in a salinity regression model to simulate the salinity in the tidally influenced Caloosahatchee Estuary. Output from both the FCRB and salinity regression models were used to evaluate system-wide effects of the proposed alternatives and to select the recommended plan based on comparisons of hydrologic performance measures and calculation of estuarine habitat benefits from these models despite the issues previously outlined. The next added increment (NAI) analysis of alternative 3B was performed to ensure compliance with savings and takings clause requirements using a spreadsheet analysis based on output from the regional SFWMM and a localized reservoir MIKE SHE model application for project level impacts. The NAI saving clause compliance spreadsheet model was based primarily on achieving the EST05 flow targets for S-79 using output from the SFWMM hydrologic simulation model and fill and release rates from the reservoir.

Differing model capabilities and assumptions, boundary conditions, spatial and temporal resolutions, discretization and input of model parameters, and the source code error in the FCRB model, all contribute to risk and uncertainty associated with model results, adding complexity to alternative comparisons. Design of project features, (*i.e.*, levees, canals and structures) account for this uncertainty by applying the factor of safety principle. However, the operational flexibility allowed through soundly engineered features combined with ecologic and hydrologic monitoring and an adaptive management program ensure that projected environmental benefits predicted are actually achieved upon implementation.

c. Analyses Required by WRDA 2000

The post-project MIKE SHE model is complex. It includes a 10,500 acre reservoir (16.4 mi2) with proposed operational water depths greater than 10 feet; conceptualization of the reservoir construction technologies; and complex operational rules for existing and proposed water control structures. Annex C of the PIR describes the Savings Clause and Takings analyses required by WRDA 2000. The "no adverse effects within the local watershed" MIKE SHE output presented

in Annex C required a blend of applying sound engineering practices coupled with best professional judgment during an iterative process requiring multiple simulations to achieve the outcome. The model uncertainty briefly discussed above only tangentially addresses the issue and its significance with respect to the design of water management structures and their associated operational criteria. Applying these models and achieving desired results is often a trial and error proposition that results from ill-formed input assumptions. For example, discretization and input of model parameters (*i.e.,* hydraulic conductivity, Manning's *n* and evapotranspiration) often require a merging of values available through the literature with those developed through local evaluations and other correlations all the while applying best professional judgment. As such, these parameters are frequently changed to achieve a best fit match to the observed historical hydrologic data during the calibration and verification process.

To achieve the "no adverse effects within the local watershed" more than 20 simulation runs were required to fine tune the operational criteria. Models were used to predict project induced changes in depth to groundwater and overland flow in the project vicinity. However, historical hydrologic data for the watershed immediately adjacent to the reservoir (*i.e.,* water levels in adjacent wetlands southeast of the reservoir) or further upstream of the project area (*i.e.*, SOW and the OSSF WMA) is limited or not available. The Roberts Canal extends from the C-43 West Reservoir project area approximately 10 to 12 miles southeast and terminates in SOW WMA which is adjacent to and hydrologically connected to the OSSF WMA, particularly during wet periods. Water levels in Roberts Canal upstream of the proposed C43-S15 structure were not available for the calibration and verification. As such, the model could easily be predicting surface water depths with an error of plus or minus 1.0 ft from existing conditions in the adjacent natural areas and the SOW WMA. Additionally, the duration of time water depths are above the ground surface may not be accurately represented, (*i.e.,* hydroperiods 30 to 60 days shorter or longer than existing, or both).

The timing, depth, and duration of flooding are extremely important in maintaining wetland function and community structure and associated fish and wildlife populations (Mitsch and Gosselink 1993). Altering wetland depth by inches or the timing and duration of flooding by days can result in significant changes in wetland function and vegetation community composition and structure. Likewise, such changes can significantly affect the distribution and productivity of fish and wildlife populations using those wetlands. Studies have shown that canal systems can impact adjacent wetland hydrology as far as a mile from the wetland and canal interface (Duever 2006). Thus, the Service is concerned that operation of the C43-S15 structure on the Roberts Canal could impact nearby wetlands southeast of the reservoir and those as far as the SOW and OSSF WMAs. Those areas support state- and federally-listed species species such as the Florida panther, Florida black bear, Audubon's crested caracara, and wood stork. Those areas are also included in the primary panther habitat zones as designated by Kautz et al. 2006.

Low confidence in the calibration and verification is not limited to water level data. Simulated MIKE SHE flows could easily be an order of magnitude from those that currently observed. These factors preclude acceptance of the key assumption "that with the exception of changing flows to the estuary downstream of S-79, there will be no impact on the West Caloosahatchee Basin" made in Annex C of the DPIR. To summarily dismiss the hypothesis that water levels in

the project watershed will not change as a result of the project is not logical because many of the simulations showed that water levels would increase in adjacent areas as a result of the project (*e.g.,* location 10 in the simulated groundwater levels). Only through changing the operational criteria at the C43-S15 structure could the effects to adjacent and upstream wetlands be minimized. This highlights the models sensitivity to the operational criteria yet operational criteria are not clearly articulated in the Draft Project Operational Manual (DPOM), Annex D of the DPIR. No sensitivity analysis was performed to determine which one of 20 or more simulations gave the most accurate predictions. Therefore, the Service recommends that the hydrologic monitoring plan in Section D.2 of Annex D in the PIR be expanded beyond the immediate footprint of the reservoir to include both existing canals and adjacent and upstream wetlands to ensure operation of the reservoir will not result in adverse impacts to the SOW and OSSF WMAs, and that the Corps formulate and incorporate related ecological hypotheses to be tested in the adaptive management protocol in Section D.4 of Annex D in the PIR.

3. Adverse Effects of Reservoir Construction

a. C-43 Basin Storage Reservoir and the STAR Recommendations

The primary goal of the C-43 reservoir is to increase water storage in the C-43 Basin to provide environmental water supply deliveries to the Caloosahatchee Estuary. The C-43 reservoir is likely to exhibit widely fluctuating water levels ranging from dry to 15 to 25 ft deep that are incompatible with the establishment of high-quality, native, fish and wildlife habitat.

As per the Restudy, one of the goals and objectives of CERP projects is to enhance Everglades ecosystem ecological values by: (1) increasing the spatial extent of natural areas; (2) improving habitat and functional quality; and (3) improving native plant and animal species abundance and diversity (Corps and District 1999). CERP will create more than 118,000 acres of reservoirs and 36,000 acres of Stormwater Treatment Areas (STAs) in south Florida, including the C-43 West Reservoir, to replace lost natural water storage, improve water quality, and provide other ecological benefits. Thus, the Service developed *Fish and Wildlife Recommendations for Comprehensive Everglades Restoration Plan: Stormwater Treatment Area and Reservoir Operation and Design* (STAR recommendations) to provide guidance for the incorporation of fish and wildlife features into the construction and operation of reservoirs and STAs and reservoirs (*i.e.*, facilities) (Appendix B; Service 2005). The STAR recommendations are provided in Appendix A of this report.

CERP presents an opportunity to provide extensive wildlife habitat compatible with the primary function and expected environmental benefits of these facilities. The primary functions of STAs and reservoirs are improvement of water quality by reduction of nutrients and pollutants released downstream and water storage during peak periods of stormwater discharge into estuaries and marine environments. Existing facilities prove that wildlife usage is compatible with their primary functions. Those in current operation provide valuable insight into design features that attract wildlife, and methods to minimize contamination issues that pose risk to wildlife during construction and operation.

Location and Design of Facilities

The Service was an active participant in the C-43 BSR planning process and supports the approach used to select the reservoir location. Site selection for the C-43 reservoir footprint was based primarily on the potential for a site to meet the project objectives and secondarily on the suitability of a land parcel for the project (Corps 2005). Suitability was based on the parcels location in the C-43 Basin and its potential storage capacity. Additionally, parcels located in natural upland and wetland habitats, significant threatened and endangered species resources, known superfund sites, and known cultural resources were less suitable. The site screening process is described in more detail in the Corps' Formulation Scoping Meeting Report for the C-43 West Storage Reservoir project. Thus, the site selection process was consistent with the STAR recommendations, and the reservoir was preferentially located in an area of active citrus operations. Although citrus groves do provide habitat for many species (Mazzotti et al. 1992), groves are generally considered less valuable than other more natural habitats.

The Service met with the District and Corps on February 11, 2005, to review the STAR recommendations and to determine which features would be compatible with the C-43 BSR Reservoir objectives, design, and operations. The following fish and wildlife features have been incorporated in the planning and design of the reservoir:

- Phase I and II Environmental Site Assessments (ESA) were performed to identify and characterize any contaminated areas within each of the five parcels acquired for the C-43 reservoir project and Environmental Risk Assessments (ERA) where necessary. Results of those assessments are summarized in the next section;

- Existing canals, depressional wetlands, and agricultural reservoirs will be maintained within the reservoir footprint to provide deep-water refugia for fisheries and other aquatic resources during periods of low water or dry conditions. The only areas that will be graded during site preparation are those in close proximity to the dams to maintain their integrity;

- Existing cypress wetlands will not be cleared from the interior of the reservoir during site preparation to provide underwater structure for fisheries and aquatic invertebrates, and perching and roosting habitat for birds;

- Less than 40 acres of shallowly-sloped littoral habitats will be created along the perimeter seepage canal of the reservoir. That acreage is low compared to the size of the reservoir; however, rights-of-way must be maintained for adjacent landowner access, and for proposed ASRs to be constructed along the perimeter if they are deemed feasible. The interior walls of the reservoir will be lined with a soil and bentonite mixture to prevent erosion; thus, no emergent wetland vegetation is expected to establish on the interior dams.

b. Reservoir Water Quality

The need for water quality improvements in the Caloosahatchee River and Estuary was described above. Reservoirs and natural storage areas have proven to be successful at removing nutrients and total suspended solids and their efficiency can be evaluated based on hydrologic retention time and measured using hydrologic models. In our March 29, 2005, Planning Aid Letter, we recommended that the Corps and the District design the C-43 West Reservoir to provide water quality benefits by reducing nutrient loads to the river and estuary in accordance with CERP Guidance Memorandum Number-Revision 023.01 (GM 023.01). The C-43 Project is described in the Restudy as a Category B project. Category B projects are not required to include specific water quality improvement features, but are to be designed to achieve water quality improvement. Evaluation criteria must be developed ". . . for alternative plan evaluation, comparison, and selection purposes, as well as for maximizing the water quality improvement efficiency during design of the selected plan" (District and Corps 2004). The intent of GM 023.01 was to maximize nutrient and total suspended solid reductions of proposed alternatives without significant loss of water storage potential or the addition of water quality improvement features.

Additionally, the State of Florida's environmental resource permit (ERP) program regulates virtually all alterations to the landscape, including all tidal and freshwater wetlands and other surface waters (including isolated wetlands), and uplands. Impacts to water quality and quantity are also regulated under that program, and issuance of the ERP also constitutes a water quality certification under section 401 of the Clean Water Act, 33 U.S.C. 1341. At a minimum, the reservoir project must not adversely affect the quality of receiving waters such that state water quality standards would be violated, nor cause adverse secondary impacts to water resources. To meet state water quality standards, the proposed project may not increase average annual chlorophyll *a* concentration in the Caloosahatchee Estuary above 11 mg/l. Janicki Environmental (2003) identified a critical annual load threshold of 3,000 tons per year for Total Nitrogen (TN) at S-79 to meet state standards. Monthly critical load thresholds for TN were also identified by season. The critical load threshold for the dry season is 190 tons of TN and 350 tons of TN in the wet season. Thus, water quality analyses were conducted for plan formulation to determine if the selected plan meets the following criteria (PIR Appendix C):

1. The quality of the water discharged from the reservoir should be no worse than the quality of the water pumped into the reservoir, measured in terms of projected flow-weighted nutrient concentrations at the reservoir;

2. Operation of the reservoir should not result in an increase in the frequency of wet or dry season high nutrient loading periods, measured as the number of times monthly TN loads exceed the critical load thresholds developed for the DEP by Janicki Environmental (2003).

3. Operation of the reservoir should not result in an increase in the frequency in which annual nutrient loads exceed a previously defined threshold quantity.

4. Operation of the reservoir should not result in an increase in the total nutrient load discharged into the estuary at the S-79 structure.

5. The operation of the reservoir should not result in a substantial shift of nutrient loading from the wet season to the dry season.

The analyses presented in the Appendix C of the PIR indicate that the reservoir is unlikely to cause or contribute to water quality degradation downstream of the reservoir discharge point. Although the proposed project is not likely to increase the average annual critical load threshold of 3,000 tons of TN per year at S-79, a shift in nutrient (TN) loads from the wet season to the dry season will most likely occur. Results indicate, however, that the frequency of exceeding the seasonal critical load threshold of 190 tons of TN per month is unlikely to increase as a result of the project, and that the frequency of exceeding the wet season critical load threshold of 350 tons of TN per month will be reduced by approximately 25 percent. Likewise, the proposed project will not increase average annual chlorophyll *a* concentration in the Caloosahatchee Estuary above the 11 *mg*/l state standard.

As mentioned previously, the Service recommended in our March 29, 2005, PAL, that the Corps and the District design the C-43 West Reservoir to provide water quality benefits by reducing nutrient loads. However, the proposed design and operation of the C-43 West Reservoir project primarily focuses on salinity control by improving the timing and volume of freshwater delivery to the estuary and does not address other water quality needs within the river basin and estuary. Reservoirs and natural storage areas have proven to be successful at removing nutrients and total suspended solids and their efficiency can be evaluated based on hydrologic retention time and measured using hydrologic models. The Service notes that by not including design features to provide water quality benefits and adopting state water quality standards as a minimum "target", the C-43 West Reservoir project does little to reduce nutrient loading at S-79 to restore water quality in the estuary.

In 2006, the District constructed two test cells within the footprint of the reservoir (*i.e.*, the C-43 West Reservoir Test Cell Project) primarily to evaluate on-site seepage and seepage control methods and the suitability of on-site materials for project construction. However, the District implemented a C-43 Storage Reservoir Test Cell Water Quality Monitoring Plan (WQ Plan; WSI 2005) to evaluate potential water quality impacts resulting from initial flooding of on-site soils, steady-state water quality conditions, and the effects of water residence time, drawdowns, and seepage on water quality. The WQ Plan focuses on nutrients (nitrogen and phosphorus), but includes other chemical, physical, and biological parameters. Monitoring began in June 2006 and will continue for 12 months. The Service recommends that the Corps evaluate results of the Test Cell Water Quality Monitoring Plan and incorporate that information in the reservoir design and water management operation and maintenance plan to maximize the reduction of nutrient loads from C-43 West Reservoir outflows.

c. Loss of On-site Wetland Habitats

The project site is an active citrus grove. Upland habitats associated with the grove include citrus trees, grove maintenance roads, small berms, brush piles, and other features related to citrus grove operations. There are no natural upland areas within the project site. The project site includes approximately 1,061.3 acres of jurisdictional Waters of the United States, including 934.6 acres of man-made ditches and canals which serve as irrigation and drainage conveyances for the citrus operation and 126.7 acres of wetlands (Figure 10). On-site freshwater wetlands are primarily impacted wetlands functioning as agricultural retention and detention areas. Existing wetland communities include mixed wetland hardwoods, exotic wetland hardwoods, cypress swamp, wetland shrub, and freshwater marsh. Although the hydrology of agricultural canals and ditches is dependent on rainfall and irrigation, they may provide suitable habitat for wetland-dependent or aquatic species. As a result of the recommended plan, the project area will be converted primarily to an open-water, aboveground reservoir including associated structures and a seepage canal.

The Corps, District, and Service, used the WRAP and the UMAM (Chapter 62-345, F.A.C. [effective date 02-04-2004]) to evaluate the current condition (*i.e.*, wetland value) of the existing wetlands (126.7 acres) and drainage canals and ditches (934.6 acres) within the project area and the proposed compensation for that wetland loss. Aerial surveys were conducted during on June 14 and 15, 2004 to classify wetlands based on the percentage of woody, herbaceous, native, and exotic/nuisance vegetation present (Table 5). WRAP and UMAM assessments of randomly selected representative wetlands and agricultural ditches and canals were conducted on the ground on June 8, 9, and 10, 2004; and July 13, 14, and 15, 2004. Data sheets are provided in Appendix B of this report. Functional scores for the existing conditions were averaged by wetland type, then the functional scores for the future with project condition were subtracted and then the difference was multiplied by the total acreage of that wetland type. A total of 141.39 functional wetland units will be lost as a result of the C-43 West Storage Reservoir project (Table 5).

The Service understands that the Corps will account for the unavoidable adverse impacts to wetlands and other aquatic resources resulting from both he C-43 West Storage Reservoir project in an Acceler8 system-wide mitigation ledger which includes the C-43 West Storage Reservoir project. As described in the Corps' April 30, 2007, Public Notice (PN), that ledger includes accounting for system-wide interdependencies and watershed benefits of the District's Acceler8 projects (*i.e.*, Band 1 projects) in satisfying the regulatory mitigation requirements for wetland and other aquatic resource impacts resulting from construction of individual Acceler8 projects. The Corps is using the UMAM to assess the function and value of aquatic resources adversely impacted by construction of the C-43 West Storage Reservoir project and to assess the anticipated environmental lift to the Caloosahatchee Estuary (Appendix B) as a result of implementation of Alternative 3B and the remaining Acceler8 projects (*i.e.*, Band 1 projects) (Table 5). Through implementation of CERP (and Acceler8), the quality, quantity, timing, and delivery of water to the south Florida ecosystem will be improved.

Although not considered as compensatory mitigation, the proposed C-43 West Storage Reservoir project incorporates features that will enhance fish and wildlife habitat. The existing agricultural canals and interior borrow areas excavated for fill material will provide deep-water refugia for fish and other aquatic organisms within the reservoir during drawdown conditions. The exterior face of the external embankments will be planted and maintained as grass. However, the interior face of the external embankments will be covered in concrete to reduce erosion potential and will not possess a vegetated littoral area. The perimeter canal will include approximately 109 acres of littoral zones to provide foraging and nursery habitat for aquatic fauna (*e.g.*, wading birds, fish, herpetofauna, etc.). Also, portions of the test cell embankments will be left in places to provide roosting habitat for birds, turtles, and other fauna when the reservoir is full.

Accordingly, the restoration and enhancement of approximately 16,300 acres in the upper (*i.e.*, 4,130 acres) and middle and lower (*i.e.*, 12,170 acres) Caloosahatchee Estuary will provide approximately 1,139 wetland mitigation credits (Table 5) and will compensate for the loss of approximately 141.4 functional wetland units over 1,061.3 acres of impacted wetlands and agricultural canals and ditches on-site.

4. Contaminants

As noted above, the Service is concerned about the disposal or use of potentially contaminated soils during construction of the reservoir. Agricultural areas are frequently contaminated with metals, pesticides, and petroleum products. In high enough concentrations, these pollutants indicate a degraded habitat condition and a potential threat to plant and animal species. All five of the land parcels (*i.e.*, Berry Groves-LaBelle Congen, Bryan Paul Citrus Groves, Bob Paul Citrus Groves, Winthrop Citrus, and Griffin Brothers) acquired for this reservoir project, were active citrus groves (Figure 11). According to District and Service guidelines (*e.g.*, District Guidance in the Design of a Project-level Monitoring and Assessment Plan for Mercury, Pesticides, and Other Toxicants; and our Ecological Risk Assessment Guidance for Wetland Restoration on Agricultural Lands in South Florida *in* the STAR recommendations; Appendix A), Phase I and II ESAs were performed to identify and characterize any contaminated areas within each of the five parcels acquired for the C-43 reservoir project, and ERAs were performed where necessary. In addition to identifying human health impacts, the site assessments also investigated the presence of widespread residual soil contamination in the cultivated areas to determine if the level of contamination might pose a threat to fish and wildlife during long-term facility operation and maintenance. A primary concern is the common application of fungicides containing copper in citrus groves and its potential to bio-accumulate in the food chain.

The Service believes that the Corps and District are adequately assessing the potential ecological risks on the five parcels. The Phase I and II ESAs were coordinated early and throughout the plan development process with the Service, and were well-designed, comprehensive in scope, and represent the state-of-the art in ecological risk assessment. The environmental assessments for each parcel are summarized below.

Berry Labelle–Congen Groves
Phase I/II Environmental Site Assessment Soil sampling has identified seven grids (*i.e.*, grids 56, 58, 124, 125, 134, 135, and 143) that will require remediation due to copper impacts (Figure 11). The Service recommended remediation for the entirety of Grids 124, 125, 134, 135, and 143 (*i.e.*, 250 acres) and for the portions of Grids 56 and 58 that will be within the footprint of the proposed reservoir. The Service concurred that removing contamination from the seven grids would remove the risk of direct impacts to Service trust resources; however, it was noted that the remaining copper concentration in some areas of the property may be high enough to adversely impact benthic organisms. No further copper application was recommended for Grids 38, 39, and 145, since copper concentrations in those grids were close to the interim screening level.

Bryan Paul Citrus Grove
The 2004 Phase I/II Environmental Site Assessment on this 600-acre property identified seven point source areas that were recommended by the contractor, and agreed to by the Service, for remediation. These areas included pump stations, a nursery barn, a mix station, an auxiliary tank area, a graded area, burn areas, and irrigation canals. This assessment also identified two 50-acre grids with chlordane concentrations (100 µg/kg and 22.5µg/kg) above the DEP Sediment Quality Assessment Guideline (SQAG) probable effects concentration (18 µg/kg). The 2006 Additional Soil Assessment for the property delineated the chlordane contamination to be within a 20-acre area (Figure 11). The proposed remedial action included removing the top two ft of soil in the contaminated area and relocating it in dams constructed for the creation of the C-43 water retention reservoir. The Service agreed to an 18 µg/kg cleanup target level for chlordane.

Bob Paul Citrus
The 2005 Phase I/II Environmental Site Assessment for this 2,025-acre property identified eight point source areas that required remediation. The recommend corrective action for the majority of these point sources included on-site burial of contaminated soils. Since this might present a risk to groundwater, the Service suggested consulting with the DEP regarding this method of corrective action. Within the cultivated area, two 50-acre grids were identified as having minor organichlorine pesticide contamination. To delineate this contamination, individual discrete samples were analyzed. The organochlorine pesticides 4,4′-DDE and chlordane were detected at concentrations exceeding their respective SQAG threshold effect concentrations (3.2 µg/kg). A screening level ecological risk assessment identified no risk to avian species that feed across the site; however, there was the possibility of risk from 4,4′-DDE exposure for species with small home ranges, such as the clapper rail. The contractor recommended further sampling to delineate contamination.

Winthrop Citrus
Phase II soil sampling in the cultivated areas identified the pesticides aldicarb, aldrin, and paraquat as contaminants of concern. The contractor recommended no further application of aldicarb at least 12 months prior to project implementation and immediate cessation of paraquat. After review of the fugacity-based food chain model done by the contractor, the Service agreed that the single 50-acre grid where aldrin was detected was not likely to present a significant ecological risk. Metals, petroleum hydrocarbons, and pesticides were detected in soils around the maintenance areas. In order to remove the potential ecological risk from these point sources, soil removal was recommended and is included in the remediation plan for the proposed project.

Griffin Brothers
The Phase I/II ESA for this 954-acre property detected concentrations of the pesticide aldicarb in the cultivated area that exceeded its site-specific SQAG (1.75 µg/kg). The Service concurred that aldicarb degrades quickly and would present little to no risk to ecological resources, provided that its application is discontinued at least six months before inundation. Contamination of metals and polycyclic aromatic hydrocarbons was detected in the burn area, chemical barn, and fertilizer mix and load area. The Service concurred that removing the top 12-inches of soil from these point sources would adequately remediate contamination. A sediment sample from a canal detected pentachlorophenol (an organochlorine pesticide) at a concentration (32 µg/kg) exceeding the Florida Administrative Code Soil Cleanup Target Levels based on groundwater criteria (30 µg/kg). Since this pesticide is often associated with highly toxic dioxin compounds, the Service recommended further delineation within the canals. After review of Service comments and recommendations, the contractor calculated a site-specific SQAG for pentachlorophenol (617 µg/kg) to determine if further delineation was necessary. Since the detected value of pentachlorophenol was much less than the calculated site-specific SQAG, the Service agreed that no further delineation was necessary.

5. Recreational Opportunities

The Service recommends that compatible public recreational opportunities, which do not conflict with the primary function of the reservoir, be provided. Proposed recreational opportunities include a 12-mile multi-purpose trail loop atop the levee for nature study, hiking, and horseback riding, as well as boat and bank fishing, canoeing or kayaking, boating and hunting. Reservoir operations will be monitored for 1 to 2 years to determine safe boating access per reservoir water regulation schedules. Boat access will be regulated by type (*e.g.*, non-motor or motor) and operation or through closures to prevent conflict with project purposes in accordance with State Rule 40E-7, Special Provisions for Impoundment Areas of the District Open to the Public. For example, the type and extent of boat access will be tied to the reservoir operations schedule and therefore, recreational boating may only be allowed during the wet season when there is ample water in the reservoir.

Rule 40E-7.5384, permits boats in impoundments managed by the District under the following limitations:

- Vessel and vessel operation limitations shall be posted by sign;
- Vessel and vessel operation limitations shall be made specific to each Impoundment Area for: resource protection; protection of District structures, equipment, and levees; and operation and maintenance of the Impoundment Area;
- Vessels shall be limited as motorized or non-motorized, and by engine horsepower, engine type, and vessel type;
- Airboat operation shall be limited to designated areas; and
- Vessel operation shall be limited by area, water depth, by distance from District structures, equipment, or levees, and by speed.

That rule also prohibits the following from occurring in District-managed impoundments:

- Personal watercraft;
- Vessel operation greater than Idle Speed within 300 feet of any District, structure or equipment;
- Vessel operation which causes damage to plants, injures animals or fish, or other environmental resources;
- Vessel operation within an area delineated by vessel barriers; and
- Anchoring or tying a vessel or watercraft to a road, levee, maintenance berm, structure, fence, tree, post, sign, gauge, data recorder, weed barrier or vessel barrier.

6. Integrating the Project with Comprehensive Restoration Efforts

The effects of Lake Okeechobee discharges to the Caloosahatchee River and Estuary need to be evaluated for specific impacts to seagrasses and biological resources as part of the Lake Okeechobee Regulation Schedule Study. Recently, due in part to the active 2004 hurricane season, the current management scheme (Water Supply and Environment) has been undergoing evaluation by the District and Corps of Engineers to determine whether alternate levels of water in the Lake may be appropriate. Additionally, the Lake Okeechobee Estuary Restoration program has identified that outfall structures from the lake will be changed in order to reduce the sediment load going to the Caloosahatchee River.

V. EVALUATION METHODOLOGY

A. Evaluation of Estuarine Habitat Benefits for System Formulation

The primary functions of the reservoir are two-fold: to capture excess basin runoff and discharges from Lake Okeechobee during wet periods, and to provide an additional source of water to maintain desirable salinity in the Caloosahatchee Estuary during dry periods. Due to the complex nature of this ecosystem, there is no single resource which tells the full story. Thus, the study team based the environmental evaluations on five attributes:

- Average Habitat Suitability Index (HSI) for eastern oyster *(Crassostrea virginica)* - based on all seasons of dry years and all seasons of wet years.
- Average HSI for *Vallisneria* - based on dry seasons of dry years.
- Average HSI for seagrass - based on wet seasons of wet years.
- Extreme Events - Average HSI of oyster, *Vallisneria*, and seagrass during the three driest months and three wettest months in the period of record.
- EST05 Index - This attribute reflects the percentage of weeks each alternative matches our target flow (EST05). EST05 is a time series of flow developed to maximize beneficial conditions for a suite of organisms in the C-43 estuary. EST05 was adopted as the system-wide performance measure for the Caloosahatchee estuary (NE-03) by the Restoration Coordination and Verification (RECOVER) team.

After a quality index was determined for each benefit attribute, these were combined to calculate a total project habitat unit score for each alternative (Tables 3 and 4).

Habitat Suitability Indices
The forecasting model used to evaluate alternatives for the C-43 West Reservoir project consisted of a set of stressor-response (habitat suitability) models for individual species. These HSI models were developed from scientific literature, expert knowledge, and available field data. The HSIs portray each stressor variable spatially and temporally across the study area at a scale appropriate to the organism or community being portrayed. HSI models were incorporated into a Geographic Information System (GIS) to describe responses spatially and temporally for the selection of restoration alternatives for each project.

Models were created for species of ecological, recreational, or economic importance, and that have a well established linkage to stressors of management interest. The models include the eastern oyster, blue crab (*Callinectes sapidus*), spotted seatrout (*Cynoscion nebulosus*), tape grass, turtle grass, shoal grass, and selected species of zooplankton. Habitat suitability for each species was determined using specific life stages of the organism with the most limited, restricted, or tightest range of suitable conditions. By doing this, the highest sensitivities of the organisms to environmental changes associated with the planned restoration activities are captured. For the eastern oyster, habitat suitability is modeled for both adult and larvae life stages because of the tighter range of suitable conditions necessary for larval success. The adult blue crab tolerates a very wide range of salinity conditions, so the limiting conditions for successful blue crab habitat are the more restricted conditions necessary for blue crab recruitment. As a result, the blue crab habitat suitability indices are focused on the megalopae larvae and spawning female life stages. Spotted seatrout require specific conditions for forage and spawning, including suitable habitat and the proximity of that habitat to deeper refugia. Flow is important, as large inputs of freshwater can cause spotted seatrout eggs to sink, reducing survival of the larvae. Therefore, the spotted seatrout model will include forage and spawn components.

Each HSI model describes a response surface of habitat suitability values between 0 (unsuitable) and 1 (most suitable) that varies spatially according to stressor levels throughout the estuary and temporally according to temporal patterns in stressor variables. Much of the temporal variation is a result of temporal cycling of important stressor inputs, such as salinity. The models calculate habitat suitability monthly as the weighted geometric mean of the environmental variables identified as important for each model. The geometric mean is derived from the product of the variables rather than the sum (as in the arithmetic mean), and has the appropriate property that if any of the individual variables are unsuitable for species success (*i.e.*, the value of the variable is zero) then the entire index goes to zero. This HSI value was then multiplied by the area within each grid cell and the grid cell values added to calculate Habitat Units for each species. Figure 12 represents how the various HSIs were combined to generate habitat unit scores and support the cost effectiveness and incremental cost analysis (CE and ICA) effort.

After results of initial models runs were reviewed, the study team decided to narrow the full analysis to three species - oysters, *Vallisneria* and seagrasses. It was useful to run all of the

species models, as they affirmed that all species showed an improvement over base conditions. However, it was determined that some species would be dropped for purposes of quantification for the final analysis because:

- They were mobile species that can move to areas of more favorable conditions so they were less sensitive to changes between alternatives;
- They were redundant and added little additional value; and
- The team decided to focus on habitats rather than individual species.

The final group of species included in the benefits analyses covers a full range of both temporal and spatial attributes. Oysters are found in the 5,829 acres of the middle estuary (Figure 12a) and are impacted by both extreme flows during the wet and dry season. Seagrasses are found in the lower estuary or San Carlos Bay area (12,547 acres) (Figure 12b) and are most impacted by the extreme wet season. *Vallisneria* is limited to the 4,129 acres in the upper or fresher portions of the estuary (Figure 12c) and is most impacted by the dry season. Thus, benefits were calculated using the appropriate period of record to reflect flows and salinity conditions when species are most affected. Wet years analyzed include 1979, 1982, and 1983. Dry years include 1980, 1981, and 1985. The wet season was defined as July through November. The dry season was defined as December through May. June was not included, because for some years June is dry and for some years it is wet, therefore it causes inconsistency in the benefits calculations. However, in practice benefits will be realized in June based on the current recommended operations.

The HSI formulas for each species are as follows:

Eastern Oyster HSI$_{\text{May-November}}$ = MIN (LarvaeComponentIndex, AdultComponentIndex)
Eastern Oyster HSI$_{\text{December-April}}$ = (AdultComponentIndex)
LarvalComponentIndex = (Salinity^{w} * Temperature^{w} * Flow^{w})
AdultComponentIndex = (Salinity^{w} * Temperature^{w})
Seagrass HSI = (Previous^{w} * Salinity^{w} * Temperature^{w} * LightAvailability^{w})

***Vallisneria* HSI** = (Previous^{w} * Salinity^{w} * Light Availability * Temperature^{w})

Where *w* is a weight between 0 and 1 assigned to each variable and where "previous" means that the current month's suitability also depends on the how well the grass was doing last month (previous score) (*e.g.*, Previous = previous_month_HSI + 0.05 (not to exceed 1.0) - This allows for growth from month to month if other conditions are suitable).

Extreme event
The extreme event attribute is perhaps the best indicator of how the reservoir alternatives will perform during high and low flow events. This calculation indicates the gain in benefits for eastern oyster (wet and dry months), *Vallisneria* (dry months), and seagrass (wet months) during the three most extreme (wettest and driest) events for the nine-year period of record analyzed. This benefit is calculated by averaging the HSI for the most stressful months (based on highest

and lowest average monthly flows during model runs for 2050 without project conditions) in the period of record for each of the three species. The months and years used were as follows:

- Wet - Oct 82, March 83, April 83
- Dry - March 81, April 81, May 81

After a score is calculated for each species during the extreme events, the HSI of the three species is averaged for one extreme event HSI score for each alternative.

EST05 Index
As described above in Section IV.B.1.a, the EST05 flow distribution is a hydrologic target for a suite of estuarine organisms. Because it represents a time series and flow range necessary for an ecological balance within the estuary, it may not reflect the optimal hydrology for any one species. Because all of the species indicators are also somewhat dampened by the effect of averaging over months, seasons, spatially, etc... the team thought it would be beneficial to have at least one benefit attribute which evaluates how well each alternative is matching the EST05 target flow. This is why a benefit stream has been derived by the percentage of fit to EST05. This time series of flows was initially created to benefit the ecology of the estuary and as a result, an alternative that can most closely mimic this time series would be most beneficial to the estuary as a whole.

A method for evaluating flows associated with the C-43 West Reservoir project was developed to easily compare potential project flows (cfs) with the percent distribution of the target flows from S-79 for any time period (one year or longer). The resulting index scale (0 to 1) reflects the relative amount that the project related flows move toward the target flows (score of 1) from the base condition (score of 0) for the period being evaluated. For application purposes, the C-43 West Storage Reservoir project used the year 1982 as the base condition to calculate the Target Flow Index Base Condition for the representative years 1978 to 1986 that were evaluated by the project. This year represents the worst single year regarding flows that exceed EST05 on both the dry and wet extremes. This score can then be expressed as the percent toward achieving the target flows (percent of target achieved: PTA).

Habitat Unit Combination Methodology (HUCM)
In order to use the Habitat Units for the project in further comparisons (*i.e.*, CE and ICA), it is useful to produce one single HU number for the project. Therefore a HUCM was created. The basis of the HUCM is that the total quality index values in any one area are summed and then divided by the total number of quality index scores for that area to find an average quality score for the area. Then that score is multiplied by the number of acres for that area. Two of the attributes cover the entire area of benefit (*i.e.*, extreme event and EST05). Therefore, all areas have at least those two scores in addition to any species specific HSI values. For example, the only species specific HSI calculated for the area in red in Figure 13 was for oysters. To calculate the HUCM, the oyster score would be added to the extreme event score and the EST05 score, and the total would be divided by 3. That value would then be multiplied by the number of acres in red. The habitat units calculated for each area are then added together to quantify the total

HUs for the project. By using this method, there is no "double counting" of benefits, even where scores have been calculated for overlapping attributes.

The equation used to calculate the total HUs for the C-43 project using the HUCM is as follows:

Total Project Habitat Units =
((Vallisneria score + Extreme Event score + EST05 score)/3) x 4130) +
((Oyster score + Extreme Event score + EST05 score)/3 x 2392) +
((Seagrass score + Extreme Event score + EST05 score)/3 x 9041) +
((Seagrass score+ Oyster score+ Extreme Event score+ EST05 score)/4 x 3506) +
((Extreme Event score + EST05 score)/2 x 51910)

Hydrologic Modeling
For plan formulation, MIKESHE hydrologic model output was used to calculate all five of the environmental attributes and estuarine habitat units (*i.e.*, HUCM) to evaluate system-wide effects of the proposed alternatives and selecting the recommended plan.

B. Evaluation of Hydrologic Performance

As discussed in Section IV.B.1.a of this report, the optimum distribution of flows (*i.e.,* EST05) at S-79 (Table 6) and salinity criteria (*i.e.,* hydrologic performance measures) were derived from relationships between the distribution, abundance, growth, and survival of estuarine organisms or VECs and the changes in salinity or freshwater discharge to the estuary (Chamberlain and Doering 1998b; Doering et al. 2002; Volety et al. 2003). The EST05 frequency distribution targets mean monthly inflow between 450 and 2,800 cfs during all months. Low flows events occur when the mean monthly inflow at S-79 falls below a flow limit of 450 cfs. High flows greater than 2,800 cfs typically occur as a result of Lake Okeechobee regulatory releases in combination with flows from the C-43 Basin. The hydrologic performance or flow frequency distribution, of each of the alternatives will be compared to the targeted EST05 frequency distribution of freshwater inflows through S-79 from the watershed and Lake Okeechobee for the nine year period of record (nine years out of 36 year period of record containing three wet, three dry and three normal years on record). The alternative with the flow frequency distribution that best emulates the EST05 distribution will be considered better for protecting estuarine resources, while further promoting biotic diversity. Hydrologic performance comparisons were also based on the MIKE SHE hydrologic model output used to evaluate system-wide effects of the proposed alternatives and select the recommended plan or SAP.

C. Next-added Increment Analysis

Hydrologic performance comparisons were also based on the MIKE SHE hydrologic model output used to evaluate system-wide effects of the proposed alternatives and select the recommended plan or SAP. The CERP Programmatic Regulations require evaluation of the tentatively selected plan as the "next-added increment." The next-added increment (NAI) analysis evaluates the effects, or outputs, of the tentatively selected plan as the next project to be added to the group of already approved CERP projects to evaluate the amount of benefits the

selected alternative plan contributes without regard to future CERP projects. Only the SAP was evaluated for the NAI analysis. A separate spreadsheet analysis utilizing modeling output from the SFWMM regional hydrologic simulation model was used in the next added increment analysis but only for the SAP. The spreadsheet model output was then used to calculate all five of the environmental attributes and estuarine habitat units (*i.e.*, HUCM) to justify and describe the benefits of the C-43 Basin Storage Reservoir as a stand-alone project without the system wide benefits attributed to other CERP projects.

VI. FISH AND WILDLIFE RESOURCES WITHOUT THE PROJECT

The study area is experiencing extremely rapid population growth. Most of Hendry and Glades Counties are presently in agricultural use and the western portion of Lee County is largely urban and residential. Even with county growth restrictions, the population of the coastal areas is and will continue to gradually spread eastward. In doing so, agricultural areas along State Road 80 are likely to become more residential, including the reservoir footprint, and the magnitude of short-term, high-volume runoff will increase. Proposals for larger residential and commercial enterprises are in the planning stages for Hendry and Glades Counties to expand their tax base. As more residential areas are built to the east, agricultural areas will be reduced. Land use projections for 2050 predict that the acreage of natural habitats (*e.g.*, upland forests) and low intensity agricultural lands (*e.g.*, unimproved and woodland pastures) in the area will decline. The extent of natural areas, such as scrub, pine flatwoods, and cypress will likely decline to make room for more citrus, row crops, sod farms, rangeland, and residential developments. The number and sizes of ditches and canals will likely increase causing additional losses in wetland habitat and associated species.

The Service does not fully accept the modeling assumptions used in the PIR for the projection of 2050 land use for the C-43 West Storage Reservoir project. Specifically, the modeling assumed only a slight change in the total area of irrigated agriculture (primarily citrus groves). This assumption is dependent on urban development pressure and on long-range market trends for the citrus industry in Florida, which in turn are dependent on international competition with foreign citrus growers. The model also assumed that the total area of wetlands would remain unchanged by 2050. This analysis is not supported by the current Corps and District regulatory process, which has consistently allowed impacts to large areas of wetlands in favor of off-site mitigation strategies and at ratios that do not replace the geographic extent, type, or watershed functions of many wetlands. The Service believes that continued loss of wetlands will be unavoidable under the current regulatory process.

Because the area of irrigated agriculture is assumed to increase by 2050, and substantial areas of active or recently abandoned citrus will be converted to urban development, the model predicts total acreage of improved and unimproved pasture and rangeland will decrease from 201,420 acres in 2000 to 103,437 acres by 2025 and remain the same through 2050, resulting in a reduction in pasture and rangeland of approximately 51 percent within the study area. The District assumed that the citrus production predicted to be removed by urban development would all be compensated by conversion of pasture and rangeland to citrus. Displaced citrus production will most likely be developed in rangeland; however, the Service believes that some wetland

habitats will also be converted to agricultural and urban developments. The extent of forested uplands, primarily pine flatwoods and some hardwood hammocks, is expected to decline by almost 25 percent by 2025 through conversion to urban development.

As natural areas are developed or converted to more intensive uses, fish and wildlife habitat quantity and quality will likely decrease and become more fragmented. Habitat losses without the project might be even greater than predicted as continued degradation of habitat conditions due to fire suppression in some habitats, unnatural timing of fire in others, additional draining and/or filling of wetlands, and uncontrolled expansion of exotic vegetation. As a result, fish and wildlife populations dependent on upland forests, pastures, and wetlands may decrease, including threatened and endangered species such as the RCW, Audubon's crested caracara, Everglade snail kite, Florida panther, and wood stork.

The future without project condition would exacerbate the altered timing, distribution, quality, and quantity of freshwater flows to the Caloosahatchee Estuary. Urban development and expansion at the expense of undeveloped land and low intensity agricultural land is expected to increase runoff to local drainage systems and the C-43 canal during the wet season, thereby increasing flow rates and contributing to poor water quality. The same increase in urban land area and impervious surfaces is expected to further decrease low flows during the dry season, as less water is conducted to groundwater systems, water tables decline, and base flows to surface canals and rivers decrease. Increased water supply and flood control demands will further decrease available water for the environment. Thus, annual variability in flow and salinity will remain high and established MFLs for the Caloosahatchee River at S-79 will not be met. Such conditions will likelyresult in salinity extremes outside of the tolerance ranges of many estuarine organisms, and will, therefore, result in decreased species diversity.

Declines in estuarine habitats such as seagrasses and oysters and the species that utilize these habitats are expected. Without the reduction of extreme flow and high salinity events, oyster reefs will eventually loose a large percent of the adult population and the ability to produce enough spat to reestablish previously stressed reefs. Without continued settlement, reefs (*i.e.*, hard substrate) will eventually break down and become buried in the soft organic sediments. SAV populations (*i.e.*, turtle grass and shoal grass) will continue to follow current trends of spatial reduction. There will be substantial losses of *Vallisneria* and its seed bank, possibly to the point of no recovery in the low salinity areas, as it tends to be more fragile than the higher salinity species.

In addition, water clarity is expected to decrease resulting in additional stress on the SAV. The deterioration of SAV and marsh habitats may temporarily benefit some estuarine-dependant fisheries, but an eventual decline in productivity will result as detrital input and SAV are significantly reduced due to extreme variations in salinity levels. The long-term loss of nursery habitat will result in population declines for many species of estuarine and marine fishes and macroinvertebrates, including those whose young of the year use fresher (less saline) habitats. At least 70 percent of Florida's recreationally or commercially sought fishes depend on estuaries for at least part of their life histories (Harris et al. 1983, Estevez 1998, Lindall 1973). Seagrass communities within the Caloosahatchee Estuary provide critical refugia for juvenile fish such as

redfish, grouper, snook, and spotted seatrout. The decline in juvenile abundance and distribution of these and other species, along with an overall decrease in species richness may be related to the loss of seagrass habitat and a result of alterations in the salinity regime and the timing of the freshwater discharges from the S-79 structure. As freshwater, estuarine, and associated marine ecosystems would further deteriorate, the economic income from eco-tourism, commercial and recreational fishing, and real estate would be greatly reduced.

VII. DESCRIPTION OF SELECTED PLAN AND OTHER ALTERNATIVES

A. Background

The formulation completed and described in the Restudy served as the foundation for the formulation of alternatives for the PIR. The alternative described in the Restudy used the Everglades Screening Model to identify approximately 160,000 acre-feet of storage volume as the targeted amount of storage necessary to capture wet season flows and to meet dry season minimum flows in order to provide desired salinity levels in the Caloosahatchee estuary. The project team used the Restudy alternative (construction of above ground storage reservoirs totaling approximately 160,000 ac-ft) as a starting point for the basis of developing of alternatives. At a minimum, the alternatives considered encompassed the following range of scales and features:

- No Action – same as future without condition
- Alternative(s) with smaller storage volumes than the Restudy
- Alternative(s) with storage volumes similar to the Restudy
- Alternative(s) with larger storage volumes than the Restudy

The screening and evaluation of plan components proposed in the Restudy determined that above ground water storage provided the most cost effective means for freshwater attenuation. Reservoirs were the major management measure suggested for this project along with associated canal improvements to move water to and from the reservoirs. Improvements in the timing, distribution, and magnitude of water deliveries to the estuary should result from improvements in the distribution of surface storage. Additional in-basin storage can potentially supplement other water uses in the study area.

Originally, an in-depth site analysis was performed for both the upper and lower (east and west) Caloosahatchee basins to identify potential reservoir sites prior to the splitting of the project into two phases. For the West Caloosahatchee Basin, in addition to the Berry Groves site, six additional sites were investigated as possible locations for placement of storage reservoirs. As a result of the in-depth screening analysis, all six sites were eliminated either due to impacts to threatened or endangered species or due to geotechnical concerns with seepage rates of the soils on site. Based on this analysis the Berry Groves site was selected (Figure 2) since it represented the most promising site given the location, land use, geology, soils, and cost. Once the potential site location for locating components was determined, the next step was to develop preliminary designs of reservoirs that would utilize the site to its fullest potential. The design of the reservoirs took into consideration the amount of useable land, proximity to major and minor

canals, water table conditions, topography, land uses and required minimum and maximum levee heights.

Since the time of the Restudy, additional information has been developed (improved modeling, improved analysis of local hydrology and water budgets, and new estimates of land use and water demands) that has increased the amount of storage necessary to meet the needs of the Caloosahatchee estuary and basin.

In 1998, the District undertook a water supply planning initiative to ensure prudent management of south Florida's water resources in the Caloosahatchee River Basin (District 2000). The resultant CWMP analysis determined that the projected surface water needs of the Caloosahatchee River and Estuary could be met during a 1-in-10 drought condition with the development of water management and storage infrastructure that effectively captures and stores surface water flows in the basin. The CWMP determined that improved management for surface water through storage could increase freshwater availability in the region and reduce potential impacts resulting from water use. The CWMP determined that a storage reservoir with a capacity of 220,000 acre-feet located in the lower Western C-43 Basin at Berry Groves would provide for environmental restoration of the Caloosahatchee Estuary. Thus, both the Restudy and the CWMP determined that above ground water storage areas were the most cost effective and appropriate means for attenuation of freshwater runoff and capture of Lake Okeechobee inflows in the C-43 Basin Project area.

Additional information has been developed out of the District's Acceler8 planning process that recommends a 170,000 acre-foot reservoir. As part of the Acceler8 and C-43 PIR planning process various site configurations were evaluated. Some of the features screened from consideration through these processes were multiple pump stations and larger footprint and multiple cell configurations of the 170,000 acre-foot option. Preliminary analyses determined that a single pump station in the northwest corner of the site was the most cost effective configuration, saving approximately $13 million over a two pump station option with the same pumping capacity. In terms of reservoir layout configurations, a two cell 9,530 acre reservoir alternative was found to be more cost effective in providing a given storage volume than a three cell option utilizing approximately 2,100 additional acres. The larger footprint with a three cell option, while having a somewhat lower dam embankment height, was estimated to increase cost by 14 to 15 percent while maintaining the same storage volume.

B. Alternatives Considered

The final array of alternatives consists of seven alternative plans, including the no action alternative and variations on three reservoir capacities of 100,000, 170,000 and 220,000 acre-feet. Option 4b, would require the purchase of approximately 5,610 additional acres to support an expanded footprint and lower dam heights. This array of alternatives would serve the needs of the C-43 Basin through the creation of a single reservoir in a location that would capture water from Lake Okeechobee and basin runoff from a majority of the C-43 Basin. The Berry Groves location also provides for efficient and flexible management of the stored water.

The reservoir options were designed based on the latest design guidelines and standards at the time of this report. The conceptual designs have been developed to withstand hurricane force winds of over 150 mph as well as combinations of both severe wind and rain conditions. The alternatives under consideration were developed as a result of the analysis of numerous reservoir sizes and cell configurations and represent cost effective options. The design of the reservoirs took into consideration the amount of useable land, proximity to major and minor canals, water table conditions, topography, land uses and required minimum and maximum levee heights.

Alternative 1 - No Action Plan

Alternative 1 is the No Action Plan, which is also the Future Without Project Condition. This alternative was developed from the existing hydrology with modifications for anticipated changes in the watershed due to land use changes, water supply changes, water quality changes, and changes caused by other water resource projects in the watershed.

The following assumptions were made to predict Future Without Project Condition in the C-43 Basin:

1. Non-CERP projects as described below are successfully implemented by 2050 (including the implementation of best management practices).

2. Lake Okeechobee Releases will continue following the current WSE schedule.

3. No CERP projects would be implemented. Despite some minor improvements in flow conditions, it is anticipated that the principal problems associated with harmful flows to the estuary will remain unaddressed.

Future land use, the operation schedule of Lake Okeechobee, and the implementation of Best Management Practices (BMPs) to control nutrient discharges will strongly influence future water quality conditions in the basin. It is assumed that the State of Florida will still be compelled by the TMDL regulations to achieve reductions in nutrient loads in order to meet requirements of the Federal Clean Water Act. This alternative also assumes that local government stormwater retrofits will be constructed in urban areas, and that State, District, and County Surface Water Improvement projects (*e.g.,* District Lake Okeechobee Protection Plan; DEP Lake Okeechobee TMDL; District Caloosahatchee MFL; District Caloosahatchee River Water Management Plan; DEP Caloosahatchee Basin TMDL; FDACS/DEP Agricultural BMP Program for the Caloosahatchee Basin; District Urban Irrigation and Landscape BMP Implementation Projects; District Stormwater Management Regulations; and Lee and Hendry Counties Stormwater Management Projects) will all be in place. When implemented, these programs should result in a reduction of nutrients contained in Lake Okeechobee discharges which in turn will reduce nutrient loading to the Caloosahatchee Estuary. However, even with the noted programs and features in place, degradation of the Caloosahatchee estuary will continue to occur in the future without project condition.

Alternative 2 - 100,000 acre-foot Reservoir with 1,500 cfs Pumping Capacity

Alternative 2 was developed as a smaller restoration alternative for the Lower Caloosahatchee Basin. This alternative is consistent with the CERP recommendation for a reservoir in this area, but it should be noted that this alternative's total storage volume of 100,000 acre-feet is significantly reduced from the 160,000 acre-feet of storage CERP estimated would be needed in this sub-region.

Alternative 2 is a two-cell reservoir with a "normal pool" storage capacity of 100,000 acre-feet. See Figure 14 and Table 7 configuration and design details. The two-cell design was selected based on the fact that an internal embankment reduces wind set-up and wave-run up helping to reduce the embankment size and cost and it also allows for independent dewatering for unscheduled maintenance if necessary. The reservoir design includes a pump station (1,500 cfs capacity) to pump water from the C-43 Canal through the Townsend Canal to fill the Reservoir. While a two pump station design was considered, the single pump station option was found to be most cost effective. Locating the pump station in the northwest corner minimizes improvements necessary for the Townsend Canal.

The water surface elevation of 35 ft NAVD88 at "normal pool" is constant within the cells, with the depths ranging from 10 to 15 ft based on the elevation of the existing land surface. Dam heights for Alternative 2 will range from 27 to 32 ft. The maximum water depths and dam heights will occur in Cell 1, due to lower land surface elevations. The exterior and interior dams are to have a top width of 15 ft. The side slopes are 3 Horizontal: 1 Vertical (3H:1V). The exterior dams are to be constructed from existing on-site material and have a low permeability core. A graded filter is to be provided on the exterior side of the dam to direct seepage. Soil cement protection would be included on the interior side of all reservoir slope faces. A freeboard of 17 ft was used based on detailed analysis of wind and wave height run-up.

A Perimeter Canal (seepage canal) is provided on the south, east, and north sides of the reservoir. The existing Townsend Canal will act as a seepage canal on the west side of the reservoir. In addition to seepage collection, the Perimeter Canal will also convey discharges from the Reservoir; convey surface runoff from the south and east of the Reservoir including improved drainage for S.R. 29; provide flows to the Crawford Canal, Banana Branch and Fort Simmons Branch; and maintain the surface water elevation in the expanded NE Rim Ditch that provides irrigation for the A. Duda and Sons (Duda) citrus operations, located to the south of the reservoir. A 17-foot cutoff wall along the perimeter of the dam embankment has also been included.

Improvements to the Townsend Canal are based on the necessary capacity to meet maximum pumping requirements to fill the Reservoir. Pre-storm and post-storm event flows have been simulated to evaluate flows in the Townsend Canal and other local canals and tributaries. Storm event flows in the Townsend Canal will be decreased over existing conditions with the construction and operation of the Reservoir.

Each cell in the alternative is designed to discharge independently through separate discharge structures (Figure 14). Cell 1 discharges via S-1 into the Townsend Canal. Cell 2 discharges via S-8 into the Perimeter Canal. These structures will be designed for incremental operation allowing required flows to be released to the C-43 Canal during periods of low flow. These structures could also serve as design storm control structures for releases prior to and during a storm event. The storm releases must be balanced with the targeted maximum flow allowed over S-79, which is 4,500 cfs. An emergency spillway with a crest elevation based on retaining the 25-year, 72-hour storm event is to be provided within each cell's discharge structure. The 25-year, 72-hour storm captured in the reservoir would be a "control release" after the storm event in order to restore the water surface to the normal pool elevation while not exceeding the maximum flow of 4,500 cfs at S-79. The final design of the emergency spillway(s) will be in accordance with the requirements of Design Criteria Memorandum 3 (DCM-3).

Within the reservoir, structure S-12 hydraulically connects the reservoir cells and is designed to be gated so that either cell can be "isolated" for operational or maintenance purposes. A number of other culverts, weirs, and spillways are included to operate the reservoir and maintain appropriate water levels in existing canals and the perimeter canals.

Alternative 3A and B – 170,000 acre-foot Reservoir with 1,500 cfs Pumping Capacity

This alternative comes closest to approximating the Restudy C-43 recommended volume of an approximately 160,000 acre-foot storage reservoir and is the size evaluated and recommended in the Acceler8 planning process. Alternative 3 is a two-cell reservoir with a "normal pool" storage capacity of 170,000 acre-feet. The reservoir design includes a pump station with 1,500 cfs capacity to pump water from the Townsend Canal to fill the Reservoir. The site layout would remain unchanged. Table 7 provides design details. The key distinction between alternatives 3A and 3B is the operational methodology related to filling and draining the reservoir, rather than any structural differences. In general, Alt 3A attempts to maintain very specific flow rates at S-79 at all times while Alt3B attempts to meet the dynamic flow targets supplied by the ecological sub team (EST05).

For alternative 3 the water surface elevation would be 42 ft at "normal pool" (NAVD88), with the average depth ranging from 17 to 22 ft. Dam heights for alternatives 3A and 3B range from 34 to 39 ft. The maximum water depths and dam heights will occur in Cell 1 due to lower land surface elevations in that cell. The exterior and interior dams are to have a top width of 15 ft. The side slopes are 3 Horizontal to 1 Vertical (3H:1V). The exterior dams are to be constructed from existing on-site material and have a low permeability core. A graded filter is to be provided on the exterior side of the dam to direct seepage. Soil cement protection would be included on the interior side of all reservoir slope faces. A freeboard of 17 ft was used based on detailed analysis of wind and wave height run-up.

The perimeter canal, improvements to the Townsend Canal, and construction of culverts, weirs, and spillways is essentially unchanged from Alternative 2. Because this alternative has a larger storage volume yet maintains the same pumping capacity, the amount of time required to fill the reservoir is approximately 24 days longer.

Alternative 3C - 170,000 acre-foot Reservoir with 3,800 cfs Pumping Capacity

Alternative 3C is very similar to alternatives 3A and 3B, the only differences being a larger pumping capacity and the associated modified reservoir operations to optimize storage performance with greater pumping flexibility (Table 7). Alternative 3C is a two-cell reservoir with a "normal pool" storage capacity of 170,000 acre-feet. The reservoir design includes a pump station (3,800 cfs pumping capacity) to pump water from the Townsend Canal to fill the Reservoir. The water surface elevation of 42 ft (NAVD88) at "normal pool" is the same for both cells, with depths ranging from 17 to 22 ft. Other structural elements would be the same as described in the previous Alternative 3B.

The inclusion of the larger pump allows for greater operational flexibility. In particular, the reservoir can be filled approximately 34 days faster than under Alternatives 3A and 3B and 10 days faster than Alternative 2. This allows the reservoir to capture more water during the relatively short duration high flow events. See Figure 14 for additional design details.

Alternative 4A - 220,000 acre-foot Reservoir with 3,800 cfs Pumping Capacity

Alternative 4A is a two-cell Reservoir with a "normal pool" storage capacity of 220,000 acre-feet with dam heights of 39 to 44 ft and water depths of 22 to 27 ft at "normal pool." The pump station capacity is 3,800 cfs. The reservoir location and other associated features are the same as Alternative 3C.

The major difference is that by increasing the storage capacity and maintaining the same foot print normal pool elevations and levee elevations would be approximately five ft higher. In addition, by maintaining the same pump capacity as Alternative 3C approximately six additional days would be required to fill the reservoir. See Figure 14 for additional design details.

Alternative 4B - 220,000 acre-foot Reservoir on Expanded Footprint with 3,800 cfs Pumping Capacity

Alternative 4B maintains the same storage volume as Alternative 4A; however, an approximately 5,610-acre larger footprint would be utilized allowing for an approximately 8 foot lower dam height and pool elevation. Alternative 4B would also be a two-cell reservoir with 220,000 acre-feet of storage. Dam heights would range from 31 to 36 ft and water depths from 14 to 19 ft at "normal pool." The pump station location and capacity is the same as Alternative 3C and 4A. The exact locations of other culverts, weirs, and spillways would be similar to Alternative 4A. See Table 7 for design details.

Although Alternative 4B was carried into the final array of alternatives, it was screened from further consideration at this point. Alternative 4B provides the same level of ecosystem output as Alternative 4A, however, the cost estimates indicated that while construction costs would be lower, total land costs would increase by approximately $150 million resulting in a roughly $80 million higher cost. The real estate costs for the additional land area associated with

Alternative 4B were estimated to be considerably higher than previous purchases based on increasing development pressures in the area. In addition, the larger surface area of this alternative would result in greater evapotranspiration of water. Based on these findings, Alternative 4B was removed from further consideration.

C. Selected Plan: Alternative 3B

The selected plan (Figure 14) consists of two cells totaling approximately 9,220 acres providing a normal maximum storage capacity of approximately 170,000 acre-feet surrounded by a perimeter embankment and canals. Major features of the selected plan include:

- External dam embankments varying in height between 30 and 33 ft. above existing grade;
- Soil-Bentonite walls beneath the external embankments;
- An internal dam embankment separating the two cells with an approximate height of 29 ft. above existing grade;
- An inflow pump station consisting of diesel-powered pumps with a total pumping capacity of 1,500 cfs;
- A perimeter canal;
- A water supply pump station consisting of electric-powered pumps with a total pumping capacity of 150 cfs; and
- Numerous spillways, culverts, perimeter canal structures, an internal cell balancing structure, and outlet structures.

The external embankments include drainage features, and the crest width and the upper portion of the outward side will be covered with soil-cement. The internal embankment does not include drainage structures, but will be covered on both sides with soil-cement. The reservoir is designed to withstand hurricane force winds of over 160 mph, as well as a combination of hurricane force winds with a rainfall event of over 54 inches in a 72-hour period.

Operation of the selected plan is tied to conditions at S-79 approximately ten miles down-river or west of the project site. The project will be operated to improve environmental conditions in the Caloosahatchee Estuary by reducing flows over S-79 during wet periods, and helping to maintain a minimum flow of 450 cfs at S-79 during dry periods.

Project operations involve pumping inflows from the Caloosahatchee River via the existing Townsend Canal into Cell 1. An internal cell balancing structure in the internal embankment will allow water in Cell 1 to enter Cell 2. Water may be released from both cells by outlet structures into the perimeter canal for delivery back to the river via the Townsend Canal and two other direct connections, the Fort Simmons Branch and Banana Branch Canal. Other project structures help to maintain water levels in the perimeter canal and Townsend Canal, and provide water supply deliveries to adjacent lands affected by construction and operation of the reservoir.

VIII. POTENTIAL ADVERSE AND BENEFICIAL EFFECTS OF THE PROJECT

A. Construction-Related Effects

1. Existing Vegetation/Habitat

Removal or destruction of high quality native habitats was minimized through placement of the reservoir within citrus groves. Most existing plant cover within the project footprint would be removed. The project site includes approximately 1,061.3 acres of jurisdictional Waters of the United States, including 934.6 acres of man-made ditches and canals which serve as irrigation and drainage conveyances for the citrus operation and 126.7 acres of wetlands (Figure 10) as described above. In general, construction will largely replace existing vegetation communities with aquatic habitat (open-water reservoir areas) or maintained uplands (embankments, roads, berms). Water depths in the reservoir will fluctuate over time between completely dry down to depths of 15 to 25 ft, potentially impacting the survival of rooted wetland vegetation. The reservoir will lack much of a highly productive littoral zone because of the necessity to construct relatively steep sides lined with a bentonite-soil mixture to maximize water storage capacity while minimizing erosion. Floating-leaved and submergent aquatic plants will become established if conditions are suitable. Although an additional 109 acres of littoral habitat may be constructed as part of the seepage canal may, a total of 141.39 functional wetland units will be lost as a result of the C-43 West Storage Reservoir project (Table 5) consisting primarily of impacted wetlands and agricultural canals and ditches on-site. The restoration and enhancement of approximately 16,300 acres in the upper (*i.e.*, 4,130 acres) and middle and lower (*i.e.*, 12,170 acres) Caloosahatchee Estuary will provide approximately 1,139 wetland mitigation credits (Table 5) and will compensate for the loss of those functional wetland units on site.

2. Fish and Wildlife Disturbance

Construction activities will cause permanent displacement of some fish and wildlife species and could also be a temporary disturbance to wider ranging animals such as wading birds, raptors, turkey, and larger mammals. Noise, fumes, light and human presence associated with mobilization of equipment and construction activities may disturb roosting or foraging wading and waterbirds as well as breeding birds. Phasing will confine construction activities and access routes, and staging areas will likely be designated. Amphibians and reptiles may experience temporary increases in mortality associated with construction access on roadways during the wet season or the onset of dredge and fill activities after the wet season.

3. Fish and Wildlife Benefits

Wading birds will forage in standing water during and immediately after construction. Wading bird, particularly long-legged waders such as great blue herons and great egrets; wood stork; raptors; and small alligators may forage on insects, fish, amphibians, and reptiles that are trapped in depressions and canal remnants. Similar conditions would occur throughout the project site during draw-down events. The reservoir will likely be inhabited by fish and aquatic organisms that are able to enter the reservoir through the water control structures and may include:

largemouth bass, black crappie, red ear sunfish, bluegill, and mosquitofish, among others. Amphibians and aquatic retiles including frogs, turtles, snakes, and alligators will likely inhabit the deepwater reservoir. The reservoir will likely create limited foraging habitat for osprey, bald eagle, terns, cormorant, and other aquatic birds that feed on fish. Ducks may also use the reservoir, but low cover of submerged and emergent vegetation may limit the habitat value. Mammals in the reservoir will likely be limited to river otter.

4. Contaminants and Disposal/Use of Soils

Agricultural areas are typically contaminated with metals (particularly copper, arsenic, and lead), pesticides, and petroleum products. It is anticipated that all contaminated areas identified on the site will be remediated consistent with coordination with the District.

5. Exotic Vegetation

The construction of reservoir may creates the potential for the establishment of exotic and nuisance plant species in disturbed areas, along newly created dikes/levees, and within the reservoir itself. Further propagation of these species may result in a disruption of native plant communities and thus a loss of native fish and wildlife habitat.

B. Operational Effects

The C-43 West Storage Reservoir project will provide most of the storage needs for the basin, and improve estuarine health by reducing the number of damaging high and low flow events at S-79. We anticipate that the hydrologic improvements would result in significant increases in the cover and density of *Vallisneria* beds in the upper estuary by maintaining tolerable salinity levels. We expect to some increases in seagrasses but not as *Vallisneria.* Based on the model results, the proposed design and operation of the C-43 West Reservoir are more effective at augmenting flows below 450 cfs at S-79 to meet MFL criteria than at reducing extreme high flows. Daily flows frequently exceeded 3,000 cfs and in some cases exceed 10,000 cfs during extreme high flow events for all alternatives compared. When flows are that high, the ability to capture enough water to see a difference in the estuary is limited, especially with a 1,500 cfs maximum pumping capacity.

C. Oyster Reef Restoration

The Service notes that the oyster reef restoration plan included in the Draft PIR and EIS was removed from the selected plan. That plan included use of recycled and fossil oyster shell and stabilizing mesh where needed to establish 2 acres per year of suitable hard substrate for oyster recruitment over a 10-year period in the Caloosahatchee Estuary. Removal of this component reduces the likelihood of oyster expansion to 30 acres over a 10- to 15-year period and 100 acres over the project life as a direct result of the proposed project. Although the proposed project will improve salinity conditions for oysters and associated flora and fauna in the middle estuary, oyster expansion is directly tied to the availability of hard substrate for colonization. The

Service recommends that the Corps or District pursuit funding for this component under other programs.

D. Summary of Consultation under the Endangered Species Act

The Service has been an active member of the project team for the C-43 West Storage Reservoir project and has provided guidance through informal consultation during plan formulation and evaluation. The Corps Regulatory Division's January 10, 2007, and March 22, 2007, letters to the Service and the December 2006 Biological Assessment provided by the District describe the potential effects of the proposed C-43 West Storage Reservoir project on federally listed threatened and endangered species The Corps determined that the reservoir project will not affect the bald eagle, Florida scrub jay, Florida grasshopper sparrow, red cockaded woodpecker, Okeechobee gourd, or the beautiful pawpaw because they do not occur within or adjacent to reservoir footprint, nor would there be direct or indirect impacts to those species. The Corps has also determined that the proposed project may affect, but is not likely to adversely affect the wood stork, West Indian manatee, Everglade snail kite, American crocodile, piping plover, or the green, leatherback, Kemp's ridley or loggerhead sea turtles; and may adversely affect the eastern indigo snake, Audubon's crested caracara, and the Florida panther. The American crocodile, piping plover, or the green, leatherback, Kemp's ridley and loggerhead sea turtles do not occur within or adjacent to the reservoir footprint and indirect effects resulting from operation of the reservoir are expected to be negligible, discountable or beneficial to those species. Additionally, wintering piping plover critical habitat will not be adversely modified by the proposed project. Following is a summary of the effects on the remaining federally-listed species:

Wood Stork
The C-43 project area is within the CFA of three wood stork rookeries previously mentioned in the existing conditions section of the PIR. Construction of the reservoir will result in the loss of approximately 731.4 acres of potential wood stork foraging habitat within the reservoir footprint, including wetlands and secondary and tertiary drainage canals. However, the proposed project would improve salinity conditions during the dry season for 4,130 acres of *Vallisneria* beds in the upper Caloosahatchee estuary. Two of the wood stork rookeries are located on mangrove islands within the upper estuary and would directly benefit from the proposed project. Additionally, the proposed project is not expected to alter the hydroperiod of freshwater wetlands outside of the project footprint but within the wood stork CFAs as recommended in the Service' *Habitat Management Guidelines for the Wood Stork in the Southeast Region* (Service 1990). The reservoir may intermittently provide foraging habitat for wood storks during the dry season if/when water releases for the estuary are great enough to create optimal shallow-water foraging areas with concentrated prey in the reservoir. Thus, the Corps has made the determination that implementation of Alternatives 3b may affect, but is not likely to adversely affect the wood stork.

Everglade Snail Kite
No known snail kite nesting locations are documented within or adjacent to the reservoir site, and no designated critical habitat occurs within or adjacent to the project area. Construction and flooding of the proposed reservoir and seepage canals may infrequently provide wetland habitats

utilized by the snail kite on more than 10,000 acres currently under citrus production. Potential foraging habitat would be available intermittently as reservoir water levels would experience wide-ranging depth and duration fluctuations from complete dry down to 17 to 19 ft above soil surface. Citrus operations in the project area and elsewhere have routinely applied heavy copper treatments as a fungicide for many years, resulting in extensive copper contamination in the soil. Potential copper risk to the endangered snail kite may occur due to copper accumulation in the kite's primary food item, the apple snail (URS 2003). Snail kites have a specific diet comprised almost entirely of apple snails. Apple snails have been found in the larger agricultural canals adjacent to the Test Cell Project area. However, the perimeter canal may provide wetland vegetation for survival of apple snails in littoral areas created from uneven edges. The perimeter canal could potentially could attract or increase usage of snail kites, providing foraging habitat but this use would be dependent on the presence of apple snails and appropriate perching sites Thus, wetlands created as a result of the project may attract foraging snail kites.

Copper concentrations in the soils within the project area range from 13.1 to 169.0 mg/kg (URS Corporation 2003). Approximately 9 percent of the sample concentrations within the project area exceed the interim effects level of 85 mg/kg agreed upon by the Service and District until a study to evaluate that value for the snail kite is completed. Those areas will be remediated before project construction. The Corps has therefore determined the project may affect, but is not likely to adversely effect the Everglade snail kite and its critical habitat.

West Indian Manatee

Manatees are known to use major inland freshwater waterways and canals, including the Caloosahatchee River from Lake Okeechobee to the Gulf of Mexico (*i.e.,* Glades, Hendry, and Lee Counties). Additionally, there is a significant warmwater refugia for manatees located at the Florida Power and Light power generating facility on the Caloosahatchee and Orange Rivers downstream of the site. This site may support up to 600 manatees during periods of extreme cold weather. Movements of manatees to and from this facility are related to access to fresh water for drinking, the water temperatures in the Caloosahatchee and Orange Rivers and the Caloosahatchee tributaries and estuaries; and the proximity of forage resources, including *Vallisneria* in the upper estuaries and turtle and shoal grass in the middle to lower estuaries.

The manatee is known to utilize the Caloosahatchee River and the Townsend Canal on the western side of the project footprint. When water levels are high in the Caloosahatchee River, manatees are capable of passing over the existing weir or through a flap gate into the Townsend Canal and have been observed at the Berry Groves main pump station. The Townsend Canal will serve as the intake canal for the reservoir. The weir will be replaced, portions of the canal will be widened and armored, and two new pump stations will be constructed. The Service's manatee requirements for culverts *Guidelines for Culverts Located in Manatee-Accessible CERP Projects* (Service 2006), the *Standard Manatee Conditions for In-Water Work* (Florida Fish and Wildlife Conservation Commission [FWC] 2005), and *Guidelines for Manatee Conservation During Comprehensive Everglades Restoration Plan Implementation* (CERP Interagency Manatee Task Force 2006) will be followed. Therefore, the Corps has determined that the project "may affect but is not likely to adversely affect" the manatee.

Florida Panther
The proposed reservoir is within the current range of the Florida panther and will result in the conversion of approximately 10,361 acres (project footprint) of habitat suitable for use by the panther for foraging and dispersal, including wetlands and uplands, to open water habitat. The project site is adjacent to the Florida Panther Focus Area (Service 2007) and is designated as "other" lands that provide value for panthers and require consultation. In addition, the site is in the CERP Landscape Level Project Planning and Siting Map for Panther Conservation (Service and FWC 2004: Figure 15). The Corps determined that the C-43 Project "may affect" the Florida panther and requested initiation of formal consultation. The habitat loss and other project effects will be addressed during formal consultation with the Service.

Eastern Indigo Snake
Specific information on the status of this species within the project area is not available. However, indigo snakes are known to occur in the Caloosahatchee River basin in low densities and are known to occur along roads and the banks of larger ditches and canals in citrus groves, particularly if burrows (*e.g.*, tortoise, armadillo, small mammal, and land crab), debris piles, or other shelter are in close proximity. The network of ditches and canals also provide prey items. Project-related construction activities may destroy shelter and refugia sites and may cause individuals to leave the area, abandon den sites, and miss foraging and mating opportunities. The Corps assumes that eastern indigo snakes occupy the site, and are more prevalent where habitat and prey items are more plentiful.

The Service's Standard Indigo Snake Protection Conditions will be implemented during construction to minimize potential adverse effects to indigo snakes (Service 2002). Those measures include: 1) providing indigo snake educational materials to construction employees prior to project initiation; 2) if a live indigo snake is found, construction activities will cease until the snake has left the project area on its' own accord and the location of sightings will be reported to the Service; and, 3) if a dead indigo snake is found, the snake will be frozen as soon as possible and the Service will be contacted immediately for further instructions. The Corps has determined that the proposed reservoir project "may adversely affect" the eastern indigo snake. The habitat loss and other project effects will be addressed during formal consultation with the Service.

Audubon's crested caracara
The reservoir footprint occurs with the secondary (6,600-foot radius from the nest tree) protection zones of two known caracara nest sites. Caracaras were observed foraging in the southeast portion of the project footprint that overlaps with the secondary zone of one nest. However, no construction activities or habitat loss would occur within the primary (985-foot radius from the nest tree) of either nest. The Corps has determined that the proposed project "may adversely affect" the crested caracara. The habitat loss and other project effects will be addressed during formal consultation with the Service.

IX. EVALUATION OF THE PROJECT

Each alternative was evaluated against the others, and against the No Action alternative in order to identify which ones best approached the multiple goals of the project. Although Alternatives 3A and 4B were carried into the final array of alternatives, they were screened from further consideration. Operations modeled for Alternative 3A were not based on meeting the dynamic flow targets supplied by the ecological sub team (EST05) and was removed from consideration. Alternative 4B provides the same level of ecosystem output as Alternative 4A, but the additional land costs were estimated at roughly $80 million higher cost, making the project cost prohibitive.

A. Evaluation of Estuarine Habitat Benefits

The estuarine habitat benefits for each alternative were calculated using the HUCM. All the alternatives showed a net benefit to the estuary. However, Alternative 3C has the highest number of habitat units, and therefore, shows the most improvement to the estuary (Table 4).

B. Evaluation of Hydrologic Performance

The resulting flow frequency distributions from the analyses of alternatives were compared against the EST05 target distribution to determine the top performing plan. Based on the modeling results, all of the alternatives showed an increase in the number of months where flows were within the desired envelope and a decrease in the number of months flows were outside the desired flow envelope. Of the alternatives analyzed, Alternatives 3C and 4A came closest to matching the EST05 flow frequency distribution at S-79 (Table 8). When compared to the future without project condition, Alternatives 3C and 4 provide the most benefits to the estuary over the by:

- Reducing the frequency and duration of damaging high and low flows on a monthly scale.
- Increasing the frequency of times when flows to the estuary are within the desirable flow ranges.
- Achieving more of a balance in salinity patterns within the estuary.

Flows less than 450 cfs at S-79
Comparisons of alternatives using the monthly distribution of events where the flow drops below 450 cfs (especially in the middle of the dry season, between March and June) show that Alternatives 3C and 4 provide the largest decreases in damaging low-flow events during this time period when compared to the future without project condition (Figure 15).

Flows between 450 cfs and 2,800 cfs at S-79
Comparisons of alternatives based on maximizing the number of months flows from S-79 in the 450 to 800 cfs range (up to 75%) and almost all the remaining flows in the 800 to 2,800 cfs range (up to 25 percent). Alternatives 3C and 4A provided the greatest percentage of time within the desired flow envelope at 82.4% of the period of record (Table 8).

Flows Greater than 2,800 cfs at S-79
All alternatives substantially reduced the number of months and number of consecutive months with flows greater than 2,800 cfs and completely eliminated flows greater than 4,500 cfs (Table 8). Alternatives were also compared using weekly averages because short duration high flow events were dampened using monthly averages. All alternatives, even those with the additional pumping and reservoir capacity, had daily flows frequently exceeding 3,000 cfs and in some cases exceeding 10,000 cfs for these extreme events. When comparing the alternatives to the 2050 FWO condition on a weekly basis in reducing these extreme flow events, Alt 3C and Alt 4A provided decreases in the number of flow events between 2,800 cfs and 4,500 cfs and the largest decrease in the number of weeks with flows greater than 4,500 cfs.

C. Next Added Increment and Plan Selection

Originally, the Corps preferred alternative 3C (*i.e.,* 170,000 ac-ft-foot reservoir, 34 to 39 ft dam, 17 to 22 ft pool, and 3,800 cfs pumping capacity) based on an assessment of benefits (habitat units), cost effectiveness/incremental cost analysis, consideration of the four accounts, and risk and uncertainty. It provided the lowest cost per habitat unit of all the plans and provided the majority (over 97 percent) of the potential ecosystem benefits for only 90 percent of the cost compared with Alternative 4A. After a full consideration of costs and benefits, the District and Corps selected Alternative 3B. The NAI analysis and comparisons to the system formulation were made only for Alternative 3B (Table 9).

The C-43 reservoir NAI analysis demonstrates that as a stand-alone project, all of the benefits achieved in the system-wide formulation process were met or exceeded. The NAI analysis yields a greater average annual HU lift than the system-wide analysis. The reason behind the additional benefits calculated during the NAI analysis is due to different water budgets afforded to the model for both the system-wide and NAI computations, stemming from demands on Lake Okeechobee. The variables in the water budget reflect additional demands from CERP features located outside the C-43 study area. This additional water being supplied to other CERP features in the system-wide analysis leads to a lower potential benefit to the C-43 study area. This does not imply that the C-43 reservoir is operating less efficiently as part of the CERP system, but instead illustrates difficulties in comparing model results when the boundary conditions are not consistent.

Therefore, the NAI and LAI comparisons may not be valid due to different sources of data for the two analyses. The system-wide analysis utilized the MIKE-SHE model.

X. RECOMMENDATIONS/CONSERVATION MEASURES

1. The Corps and District should to consult with natural resource agencies in developing a detailed project operating manual for the reservoir to ensure restoration objectives are met. The operational plan should include the regulation schedules, operating criteria, and additional provisions as may be required to collect, analyze, and disseminate basic data. Detailed operating instructions to ensure that the project meets the restoration goals and targets should also be included in the form of a draft, interim, preliminary, and final

operational plan. The water resource allocation for the natural system as described in the PIR should be utilized and described in both documents as the project progresses. An adaptive assessment team should meet when operations begin, during interim construction operations, and after construction to review the operational plan in concert with the information obtained from the Water Quality and Ecological Monitoring Plans to assure that restoration benefits are being met and that operations are optimized for restoration (Annex D in the Draft PIR).

2. The Service recommends that the hydrologic monitoring plan in Section D.2 of Annex D in the PIR be expanded beyond the immediate footprint of the reservoir to include both existing canals and adjacent and upstream wetlands to ensure operation of the reservoir will not result in adverse impacts to the SOW and OSSF WMAs, and that the Corps formulate and incorporate related ecological hypotheses to be tested in the adaptive management protocol in Section D.4 of Annex D in the PIR. Emphasis should be placed on acquiring pre-project baseline data for existing canals (*i.e.,* Roberts Canal) that can either provide direct or indirect drainage of areas of concern such as the Spirit-of-the Wild Wildlife Management Area and the Okaloacoochee Slough State Forest and Wildlife Management Area.

3. The Corps should evaluate results of the Test Cell Water Quality Monitoring Plan and incorporate that information in the reservoir design and water management operation and maintenance plan to maximize the reduction of nutrient loads from C-43 West Reservoir outflows.

4. The Service recommends that the Corps use the results from the Test Cell Water Quality Monitoring Plan to further evaluate: the quality of water while it's retained within the reservoir; the quality of water released from the reservoir and its potential effects on water quality of flows discharged at S-79; and, the effects of the quality and volume of water released at S-79 on the estuary.

5. The Service recommends that the Corps monitor the water quality effects of the project consistent with the Water Quality portion of the Draft Project Operating Manual and Monitoring Plan (Annex D in the Draft PIR).

6. The Service recommends that the Corps monitor the surface water and groundwater effects of the project consistent with the Water Quality portion of the Draft Project Operating Manual and Monitoring Plan (Annex D in the Draft PIR) and recommendation number 2 above.

7. The Service recommends that the Corps monitor effects of the project on estuarine resources consistent with the estuarine portion of the Draft Project Operating Manual and Monitoring Plan (Annex D in the Draft PIR).

8. The Service recommends that the Corps implement the adaptive management protocols consistent with the Draft Project Operating Manual and Monitoring Plan.

9. If ASR wells are not constructed around the reservoir perimeter, the Service recommends that the Corps and the District expand the littoral zones created along the seepage canals.

10. The Service recommends that compatible public recreational opportunities which do not conflict with the primary function of the reservoir be provided in accordance with State Rule 40E-7.

11. The Service recommends that the Corps or District pursuit funding for oyster reef restoration by placement of hard substrate in the estuary through other programs to increase the likelihood of oyster reef expansion to 30 acres over a 10- to 15-year period and 100 acres over the project life. Although the proposed project will improve salinity conditions for oysters and associated flora and fauna in the middle estuary, oyster expansion is directly tied to the availability of hard substrate for colonization.

XI. SUMMARY OF POSITION

The Service recognizes the considerable effort that has gone into developing this plan and selecting an alternative. The proposed project could provide meaningful hydrologic, economic, and ecological improvements to the Caloosahatchee estuary. Maintenance of proper salinity regime and reductions in the volume and timing of damaging, releases to the estuary should promote the growth and spatial distribution of tape grass, oysters, and possibly seagrasses, and improve the overall health of the estuarine system. The C-43 West Storage Reservoir project also benefits lands of national interest, including the Charlotte Harbor National Estuary and the J.N. "Ding" Darling NWR.

The Service has participated in the development and review of alternatives for the C-43 West Storage Reservoir project since it was initiated. Throughout the evaluation process we have provided recommendations involving the location, refinement, and selection of project alternatives based on ecological considerations onsite and within the Caloosahatchee estuary. The Service believes that the SAP could provide meaningful hydrologic, economic, and ecological improvements to the Caloosahatchee estuary. Project operations will benefit the Caloosahatchee upper estuary by augmenting low flows during dry periods and reduce the number of times the estuary suffers from too high salinity. The Caloosahatchee will also receive fewer high flow events during wet season.

Executive Summary

In 1996, the Army Corps of Engineers (Corps) was directed to develop a comprehensive plan to restore, preserve and protect South Florida's natural ecosystem while providing for the water-related needs of the region, including flood control, water supply and the other objectives of the Central and Southern Florida Project. The resulting plan, authorized by Congress in 2000, is called the Comprehensive Everglades Restoration Plan (CERP), as stated in the Final Programmatic Regulations. CERP shall be implemented to ensure the protection of water quality, water supply, and environmental improvement of the South Florida ecosystem.

Because the CERP proposes the construction of more than 241 square miles of wetlands, the South Florida Federal and State fish and wildlife agencies collaborated to develop 24 recommendations consistent with Federal authorities including the Fish and Wildlife Coordination Act (FWCA), the Endangered Species Act (ESA), and the Migratory Bird Treaty Act and state authorities including the Everglades Forever Act. These recommendations are not intended to take priority over primary facility water storage and treatment functions. Many fish and wildlife recommendations compliment primary facility functions. If, however, existing contaminant levels at proposed project sites present a risk to fish and wildlife, these sites should not be considered. The South Florida Water Management District's (District) standard operation procedures (SOPs) and the U.S. Fish and Wildlife Service's (Service) protocols include environmental assessments completed during land acquisition that identify, evaluate, and recommend actions to correct existing or future contamination problems. These activities are followed by long-term monitoring to determine how facility operation and maintenance impacts fish and wildlife resources.

I. INTRODUCTION

The South Florida ecosystem is nationally and internationally unique and an important natural resource. It is also in peril, severely affected by human activities for over a hundred years. In 1948, Congress first authorized the Central and Southern Florida Project to serve the multiple objectives of flood control, prevention of salt water intrusion, water supply to Everglades National Park (ENP), preservation of fish and wildlife, recreation and navigation, and regional water supply for agriculture and urban areas. The project area extends from Orlando to the Florida Keys and is composed of a regional network of canals, levees, water storage areas and water control structures. While fulfilling these objectives, the project had unintended adverse effects on the unique natural environment that constitutes the Everglades and South Florida ecosystem.

Previous land use has severely reduced the natural water storage and cleansing capacity of South Florida wetlands through drainage, conversion, and loss of natural wetlands. Reduced natural flood storage and high nutrient levels, especially phosphorus, threaten the viability of the South Florida ecosystem. To lessen these impacts, the Central and Southern Florida Restudy (C&SF Restudy), precursor to the Central Everglades Restoration Project (CERP), incorporated stormwater treatment areas (STAs) and reservoirs to reduce pollutant levels, replace lost natural

water storage, and provide ecological benefits (Fig. 1). The large acreage involved in these constructed systems presents opportunities to include fish and wildlife features in project design, construction, operation, and maintenance after contaminant issues are addressed. The CERP includes approximately 118,000 acres of reservoirs and 36,000 acres of STAs (Table 1) for an estimated total of 154,000 acres (241 square miles, about one third the size of Lake Okeechobee). In addition, other local and system-wide non-CERP projects such as the Everglades Construction Project (58,000 acres at completion) are expected to increase the spatial extent of wetlands in South Florida.

Incorporating fish and wildlife features into CERP STAs and reservoirs is consistent with the requirements of several Federal authorities. The Fish and Wildlife Coordination Act (FWCA) establishes fish and wildlife conservation as a coequal purpose of federally-funded water resource projects such as the CERP. The Endangered Species Act (ESA) directs Federal agencies to develop proactive endangered species protection, conservation, and recovery programs. The Migratory Bird Treaty Act provides for the protection of migratory birds.

The U. S. Fish and Wildlife Service (Service) developed fish and wildlife recommendations for CERP STAs and reservoirs (Table 2) consistent with the Federal authorities cited above. Each recommendation presents expected fish and wildlife benefits and compatibility with the primary STA or reservoir functions. Due to site-specific variability and other factors, not all recommendations made in this report are practicable at all facilities. These recommendations are not constraints, but should be considered as opportunities to improve on-site fish and wildlife habitat, provided their implementation does not reduce project benefits to the South Florida ecosystem. The Service and the Florida Fish and Wildlife Conservation Commission (FWC) developed these recommendations through review of existing literature, field visits to STAs and reservoirs, as well as interviews and discussions with facility scientists, designers, and managers. An interagency meeting helped refine agency concerns and recommendations.

II. METHODS

A Service team of biologists and ecologists (STAR team) considered recommendations that support fish and wildlife resources and supports STA and reservoir functions. The FWC, U.S. Environmental Protection Agency (EPA), Arthur R. Marshall (A.R.M.) Loxahatchee National Wildlife Refuge (NWR), Dr. Robert Knight and the Department of the Interior's (DOI) consultant, Dr. Robert Kadlec, participated in STAR team deliberations. The STAR team conducted a literature search on STAs and reservoirs with emphasis on fish and wildlife features, phosphorus treatment, water quality, contaminants, design, and operation. Team members visited eight constructed wetlands in South Florida, and interviewed scientists, designers, and managers to draft a list of design and management recommendations.

The Service sent the draft recommendations to the South Florida Water Management District (District), U.S. Army Corps of Engineers (Corps), EPA, ENP, A.R.M. Loxahatchee NWR, DOI consultants, FWC, Florida Department of Environmental Protection (DEP), St. John's River Water Management District (SJRWMD), and other interested parties. In June 2004, a workshop

was conducted which included a presentation of draft recommendations to two working groups, (design and morphology, water quality and operations). Based on the input from these working groups, STA site visits, and additional interagency coordination, the Service further refined these recommendations.

III. DISCUSSION

It is essential that contaminant levels do not present a risk to fish and wildlife resources. Sites with contaminant levels that clearly present a risk in their current or future project condition are not suitable for CERP STAs and reservoirs or for incorporation of fish and wildlife features without effective remediation. If unexpected contaminant levels become a problem following project construction, the site should be remediated or abandoned.

There are a number of activities which respond to contamination issues prior to and during land acquisition, construction, and operations. For example, the District conducts pre-transactional environmental assessments as part of their routine real estate acquisition process. The Service and the District use these assessments to identify, evaluate, and correct environmental concerns or contaminant issues associated with the properties intended for STA or reservoir use. An example of the environmental assessment process was completed by the District for STA 3/4. This assessment identified concentrations of pesticides, petroleum, and metals ("compounds of concern") related to former agricultural application and operations (*e.g.*, pump stations, mix/load areas, storage facilities, and airstrips). Various contaminants were present at concentrations of potential ecological and/or human concern. Subsequently, corrective or remedial actions were taken, and additional monitoring was completed that addressed contamination conditions prior to land acquisition and construction. Environmental assessments such as these are standard operating procedures (SOPs) completed during all District land acquisitions.

After the initial environmental assessment process, the District routinely implements on-going monitoring and assessment programs to measure potential impacts from historical land use, and the effectiveness of their corrective actions. For example, after construction of STA 3/4 but prior to its operation, an intensive one-time surface water/sediment monitoring program was completed to insure the STA would not initially be a net exporter of contaminants. After STA 3/4 start-up, an additional long-term monitoring and assessment program was initiated to determine if operations cause the release of detrimental sediment compounds into the water column.

The Service and District also evaluate food chain models, bioassays, bioaccumulation studies, and soil desorption studies prior to construction to determine potential contaminant risk to fish and wildlife. At times, soil concentrations of contaminants can be orders of magnitude higher that those in the water column and can pose greater risk to fish and wildlife resources. In addition, there are concerns regarding the accumulation of contaminated sediment in any given reservoir or STA as the facility operates over time. The monitoring and assessment programs described above address these concerns. Presently, information on long-term effects is being collected (*e.g.*, the STA-3/4 monitoring program described above) that will determine if

accumulation of contaminant levels in reservoirs or STAs will pose an unacceptable risk to fish and wildlife resources. In some STAs, risk from contaminant accumulation within the entire facility is reduced by initial treatment cells designed for deposition of suspended particulate-bound contaminants; for example STA 1-East, eastern and western distribution cells. Experience obtained from the operation and monitoring of existing and future STAs will supply valuable information to address these concerns. A scientific advisory committee may be useful in providing guidance for developing research needs associated with STA and reservoir operation and maintenance.

Extensive wetland losses can degrade landscape-scale, natural systems. Such degraded systems can reflect decreases in: (1) genetically viable numbers, distribution, and reproduction of native fish and wildlife, particularly among habitat-specialist and wetland obligate or dependent species; (2) habitat diversity of native flora and fauna; and (3) the ability of species and ecosystems to recover from disturbances (Corps 1999). While STAs and reservoirs do not replace natural systems, they can be designed to supplement ecological systems and processes on local and landscape scales. Davis (*et al.* 1994) identified the loss of original wetland spatial extent, type, diversity, quality, distribution, and pattern in the south Florida ecosystem as key issues. In most cases, Project Delivery Teams discourage the location of STA and reservoir projects in natural areas. However, in some cases, the facility footprint may unavoidably fragment or otherwise impact rare or unique habitats (*e.g.*, wetlands, scrub habitats). Incidental take of federally listed species (as defined in the ESA) may occur if these species use habitats within the project footprint. In other cases, well-designed and operated facilities may provide features attractive to federally listed species, offsetting potential adverse effects. The Service continues to work with CERP partners to achieve system-wide CERP goals and to meet ESA obligations. The Service supported DOI funding to purchase lands because STAs and reservoirs will meet CERP system-wide restoration goals by benefiting downstream fish and wildlife resources and habitats.

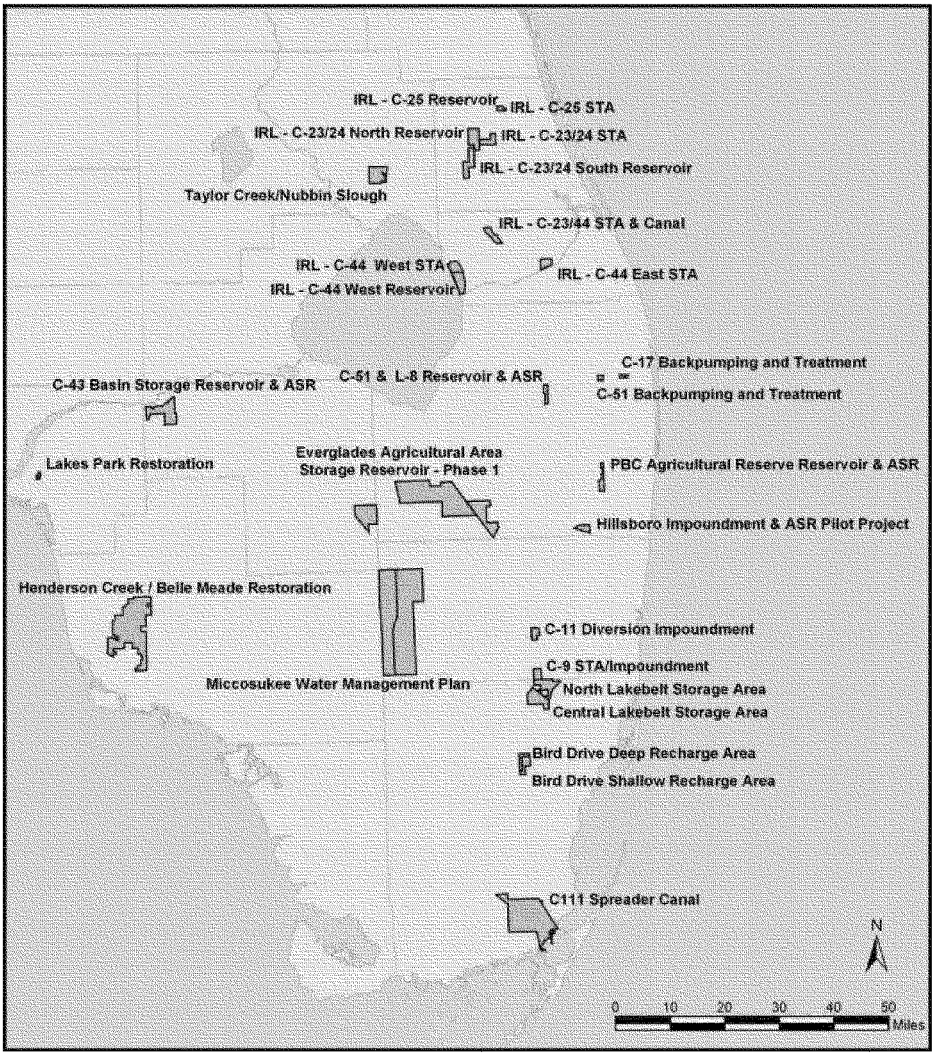

Figure 1. Location of several proposed CERP reservoirs and STAs (Corps 1999).

Table 2. Fish and wildlife recommendations for CERP stormwater treatment areas and reservoirs.

	Wildlife Recommendations	Fish And Wildlife Benefit	Compatibility/Benefit To Primary Function	Reference
	Contaminants			
1	Evaluate and Remediate Contaminants. Evaluate sites prior to acquisition in accordance with District SOPs and Service protocols (Appendices). Site remediation will occur prior to construction in areas where contaminant concentrations could compromise fish and wildlife health.	Evaluation and remediation of contaminants prior to acquisition and construction: • eliminates or reduces contaminant remobilization; • eliminates or reduces exposure risks to fish and wildlife.	Evaluating and remediating contaminants prior to acquisition and facility construction: • reduces long-term treatment and remediation cost; • optimizes STA and reservoir function by eliminating potential contaminant remobilization; • improves public health.	SJRWMD 1999. District 2005. Appendix B. Service 2001 Appendix A
2	Clean Construction Materials. Evaluate construction materials for contaminants prior to use for levees, berms, islands, etc. Do not use materials from contaminated areas.	Use of clean construction materials used for levees, berms, islands, etc.: • prevents mobilization of contaminants; • reduces exposure risk to fish and wildlife.	The District's SOP requires environmental assessment and remediation on all materials used for construction purposes.	District 2005. Appendix B
	 Evaluate and remediate contaminants.		 Clean construction materials.	

Table 2. Fish and wildlife recommendations for CERP stormwater treatment areas and reservoirs.

	Wildlife Recommendations	Fish And Wildlife Benefit	Compatibility/Benefit To Primary Function	Reference
3	Contaminant Monitoring. Implement a post-construction monitoring and contingency plan for mercury, pesticides, and other toxicants as described in the draft Contaminants of Concern CERP Guidance Memorandum (Appendix B).	Contaminant monitoring and contingency plan implementation will: • alert mangers to potential exposure risks to fish and wildlife; • prevent contaminant remobilization.	Contamination monitoring is consistent with District remediation and monitoring programs at Everglades Construction Project STAs (Appendix B, *District Guidance in the Design of a Project-level Monitoring and Assessment Plan for Mercury, Pesticides and other Toxicants, DRAFT 2005*)	SJRWMD 1999. District and Corps 2003. District 2005. Appendix B
				

Monitor contaminants.

Table 2. Fish and wildlife recommendations for CERP stormwater treatment areas and reservoirs.

	Wildlife Recommendations	Fish And Wildlife Benefit	Compatibility/Benefit To Primary Function	Reference
	Design and Location			
4	Facilities Location. Locate facilities in the watershed where water volumes will: • optimize water treatment (by placing them adjacent to reservoirs or canals) • minimize "dry-outs" (water below bed surface) • avoid ecologically sensitive area, which is a CERP goal.	Locate facilities to: • maximize water treatment and management to benefit fish and wildlife resources and habitats; • reduce direct (footprint) and indirect (*e.g.*, hydrological modifications, fragmentation) impacts to fish and wildlife resources and habitats.	When practicable, locate facilities to: • maximize water supply, treatment, and storage functions; • minimize potential remobilization of pollutants (*i.e.*, contaminants and nutrients).	Kadlec and Knight 1996.
	 G-302 delivers water to STA 1-W from the L-7 Canal.		 Proposed Indian River Lagoon-South reservoirs adjacent to canals and STAs.	

963

Table 2. Fish and wildlife recommendations for CERP stormwater treatment areas and reservoirs.

	Wildlife Recommendations	Fish And Wildlife Benefit	Compatibility/Benefit To Primary Function	Reference
	Design and Location			
5	Heterogeneous Topography. Preserve and maximize heterogeneous topography, such as berms, ditches, farms roads and emergent vegetated rows. Preserve or create features that reduce the potential for hydrologic short-circuiting.	Preserving heterogeneous topography: • supports habitat diversity; • enhances biochemical processes over a wide range of water elevations; • provides refugia for aquatic/forage species during critical periods (*e.g.*, winter or drawdown).	Heterogeneous topography has the potential to: • increase hydraulic residence time and treatment efficiency; • reduce design, construction, and maintenance costs; • reduce the potential for hydrologic short-circuiting when perpendicular to flow direction.	Mitch and Gosselink 2000.
6	Sloping Vegetated Zones. Include gradually sloping/stepped vegetated littoral zones in STAs, reservoirs, and seepage canals. Provide organic soil over hard substrates where soil is lacking, and manage for native vegetation.	• Sloping/stepped vegetated zones provide habitat for plant diversity, fish spawning, and wading bird foraging during water level manipulation. • Organic soil provides for aquatic vegetation which promotes viable aquatic ecosystems.	Sloping/stepped vegetated zones: • maintain bank stability; • resist erosion; • assist in turbidity reduction.	Honke 1993. Anderson and Brown 1991.
	Heterogeneous topography preserved in STA-5 Ditch prior to flooding  Ditch after flooding 		Sloping littoral zones included in STA 1W. 	

Table 2. Fish and wildlife recommendations for CERP stormwater treatment areas and reservoirs.

	Wildlife Recommendations	Fish And Wildlife Benefit	Compatibility/Benefit To Primary Function	Reference
	Design and Location (continued)			
7	Shallow Pools/Interior Perimeter Canal. Preserve or create shallow pools (some at least 3 feet deep), such as distribution and collection canals, and/or an interior perimeter canal. Extent (acres) should be proportional to the facility size.	Shallow pools, such as distribution and collection canals, and interior perimeter canals provide aquatic plant, and fish habitat, and refugia for other aquatic resources during critical periods (*e.g.*, low water events.	Shallow pools: • improve hydrologic mixing; • increase hydraulic residence time; • reduce resuspension of sediment-bound pollutants.	Kobza, *et al. In review.* Kadlec and Knight 1996. Walker 1987.
8	Irregular Shorelines. Preserve irregular shoreline features such as peninsulas and submerged bars.	Irregular shorelines: • provide visual cover; • increase habitat edge; • support biologically rich and diverse zones.	Irregular shorelines may provide for design and construction cost savings (example: maintenance access for existing utilities, see photo below).	Kadlec and Knight 1996. Mitch and Gosselink 2000. USEPA 2000.
	 Shallow pool created from borrow canal.		 Irregular shoreline created around existing utility pole.	

965

Table 2. Fish and wildlife recommendations for CERP stormwater treatment areas and reservoirs.

	Wildlife Recommendations	Fish And Wildlife Benefit	Compatibility/Benefit To Primary Function	Reference
	Design and Location (continued)			
9	Low-profile Vegetated Areas. Preserve low-profile vegetated areas in appropriate locations. Establish and maintain native plants.	Low-profile vegetated areas: • increase habitat diversity; • support fish and wildlife activities such as loafing, feeding, and sheltering.	Low-profile vegetated areas may: • prevent hydrologic short-circuiting; • enhance retention time; • improve hydrologic mixing.	White *et al.* 2002. Files 2003.
10	Multi-cell Flow ways. Design cell sequence to minimize wildlife use in downstream portions of polishing cells.	Multi-cell flow ways increase: • habitat diversity; • structure; • composition (*e.g.* , more edge, vertical structure).	Multi-cells: • increase operational flexibility; • increase treatment efficiency; • reduce short-circuiting.	Kadlec and Knight 1996. Swindell 2002.
		Preserve or create low profile vegetated areas.	Create multi-celled facilities. 	

Table 2. Fish and wildlife recommendations for CERP stormwater treatment areas and reservoirs.

	Wildlife Recommendations	Fish And Wildlife Benefit	Compatibility/Benefit To Primary Function	Reference
Design and Location (continued)				
11	Vegetated Buffers. Create or maintain vegetated buffers (*e.g.*, 100 to 500 meters wide) adjacent to STA and reservoir levees, and seepage collection canals. Manage buffers to control invasive exotic vegetation.	Vegetated buffers adjacent to STA/reservoir levees and seepage collection canals provide habitat for amphibians, reptiles, neotropical migrant birds, and other wildlife.	Vegetated buffers: • create natural aesthetic and safety barriers between constructed facilities and developed areas; • provide wildlife travel corridors; • reduce seepage impacts to neighboring property.	USEPA 2000. Sees 2002. Tiner 2002.

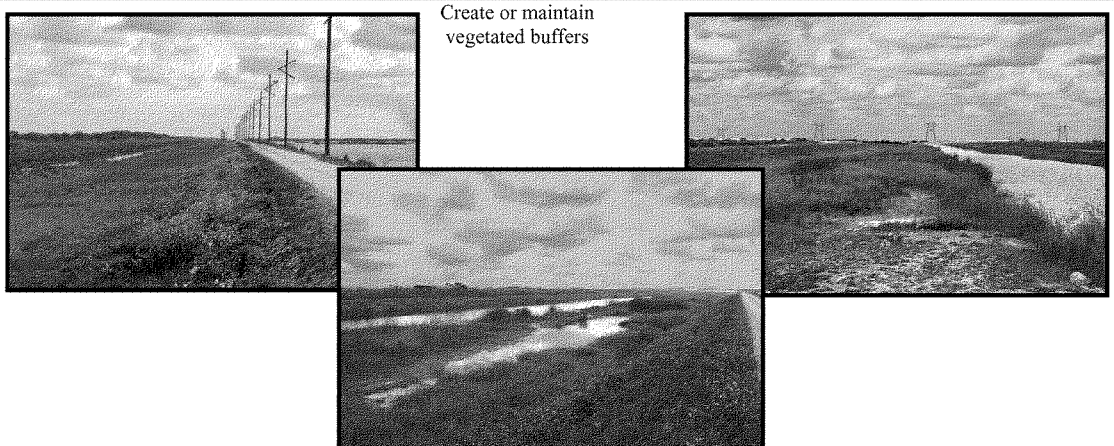

Table 2. Fish and wildlife recommendations for CERP stormwater treatment areas and reservoirs.

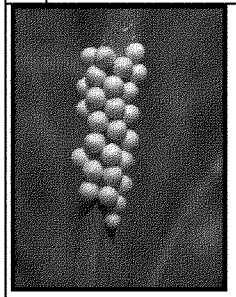
	Wildlife Recommendations	Fish And Wildlife Benefit	Compatibility/Benefit To Primary Function	Reference
	Design and Location (continued)			
12	Wading Bird Foraging Conditions. When flood control and water supply requirements are met, maintain water depths in STAs/reservoir between 6 and 14 inches (15 to 35 cm) for a minimum 90-day period from January through May. This may be achieved by heterogeneous topography and/or water management.	The maintenance of shallow water conditions would maximize wading bird foraging opportunities during the nesting season (January through May).	Maintaining wetted cells (within the constraints of weather conditions and competing water demands: • enhances phosphate removal; • reduces pollutant remobilization; • reduces mercury methylation.	Service 1999. ATLSS 2003.
	Biological Diversity			
13	Long-hydroperiod Marsh. When water supply needs are met, maintain long-hydroperiod marsh cells that are inundated 3- 5 years between dry-outs, to the maximum extent practicable.	Long-hydroperiod marsh ecosystems support natural communities, resulting in a stable food web.	Long-hydroperiod marsh ecosystems: • improve water treatment; • minimize maintenance, such as rehydration. (However, this is subject to water availability and competing water demands.)	Service 1999.
		Maintain wading bird foraging conditions.	 Maintain long hydroperiod marsh cell.	

Table 2. Fish and wildlife recommendations for CERP stormwater treatment areas and reservoirs.

	Wildlife Recommendations	Fish And Wildlife Benefit	Compatibility/Benefit To Primary Function	Reference
	Biological Diversity (continued)			
14	Delayed Cell dry-outs. In reservoir-assisted STAs, delay scheduled dry-outs until after May 15, or as late as possible, by holding water in reservoirs.	Delayed dry-outs in cells containing water during late dry season (Jan thru May) increases survival of offspring (*e.g.* apple snails and other aquatic organisms) to the following wet season.	Delayed dry-outs reduce maintenance costs associated with rehydration. (However, this is subject to water availability and competing water demands.)	R. Bennetts, USGS, personal communication, July 23, 2003.
15	Recession Rates and Reversals. Manage reservoir/STA water levels to gradually recede, and minimize rapid reversals during the dry season (Oct through Apr), when possible.	Slowing recession rates and reversals will: • concentrate wading bird prey in a manner similar to natural water recessions; • protect low-lying nests from flooding.	Slowing recession rates and reversals can: • increase retention time; • increase water treatment efficiency. (However, managing recession rates is subject to weather and competing water demands.)	Lorenz *et al.* 2001. Ogden 1994. Bancroft *et al.* 1994. Bjork and Powell 1994, 1996.



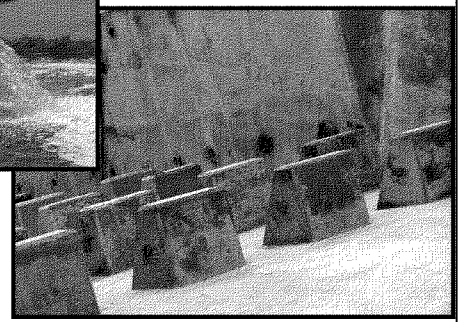


Table 2. Fish and wildlife recommendations for CERP stormwater treatment areas and reservoirs.

	Wildlife Recommendations	Fish And Wildlife Benefit	Compatibility/Benefit To Primary Function	Reference
	Water Quality			
16	Passive Flow Technology. Use best available, passive flow technology (baffles, distribution and collection canals, etc.), to evenly distribute inflows and aerate water at inflow and outflow points.	Passive flow technologies that distribute and aerate inflows/outflows can; • increase DO concentrations • reduce pockets of stagnation.	Passive flow technologies that distribute and aerate inflows/outflows increase water treatment efficacy by: • reducing short-circuiting; • distributing water evenly; • improving hydrologic mixing; • increasing DO levels.	Examples - City of Titusville, Blue Heron Wetland Treatment System, December 16, 2002. - Distribution and collection canals at ECP STAs
	  			

16

Table 2. Fish and wildlife recommendations for CERP stormwater treatment areas and reservoirs.

	Wildlife Recommendations	Fish And Wildlife Benefit	Compatibility/Benefit To Primary Function	Reference
	Water Quality (continued)			
17	Prevent Reservoir/STA Dry-outs. Maintain a 6-inch water depth to reduce mercury methylation and pollutant release.	Preventing dry-outs: • sustains aquatic communities in STAs and reservoirs; • protects aquatic resources from contaminant exposure; • protects and enhance downstream ecosystems.	Preventing dry-outs: • increases treatment efficiency; • impedes mercury methylation; • prevents release of sequestered nutrients.	Walker 1995. District 2005. Appendix B
18	Water Retention after Dry-outs. At facility start-up and after dry-outs, raise water levels in reservoir and/or STA quickly to a depth greater than 35 cm. Retain water levels until water quality is acceptable for discharge to the receiving water body pursuant to applicable federal and state regulations and legally binding documents.	Water retention after dry-outs will reduce the release of methylmercury and high nutrient pulses. Methylmercury is toxic to wildlife. High nutrient pulses can negatively impact downstream plant and animal communities.	Water retention after dry-outs improves water quality treatment efficiency.	District and Corps 2003.
	Prevent dry-outs. 			

Table 2. Fish and wildlife recommendations for CERP stormwater treatment areas and reservoirs.

	Wildlife Recommendations	Fish And Wildlife Benefit	Compatibility/Benefit To Primary Function	Reference
	Water Quality (continued)			
19	Chemical Treatment. Avoid applying chemical treatments in STAs and reservoirs to achieve phosphorus reduction targets.	Chemical treatments for pollutant reduction expose wildlife and their habitat to unknown risks.	Chemical treatments for pollutants incur continuous operation costs which are avoided with natural treatment methods.	Everglades Program Team 2001. Chimney *et al.* 2004.
	Iterative Process			
20	Hydrologic Operating Plans. Develop and implement hydrologic operating plans to maintain water levels for desired plant communities. These plans should include iterative monitoring and adaptive assessment. Coordinate STA operating issues with the District's STA Communication Team.	Hydrologic operating plans sustain vegetation for fish and wildlife survival and reproduction by planning for beneficial water management. Coordinated monitoring and communication between state/federal agencies can improve management for fish and wildlife benefits.	Hydrologic operating plans enhance; • water treatment; • storage functions. Coordinated monitoring and communication between state/federal agencies can: • improve system management; • decrease time between operational adjustments.	Miller et al. 1998. District 2005. Appendix B.
	 Avoid chemical treatment to achieve pollutant reduction targets.		 Develop and implement hydrologic operating plans.	

975

Table 2. Fish and wildlife recommendations for CERP stormwater treatment areas and reservoirs.

	Wildlife Recommendations	Fish And Wildlife Benefit	Compatibility/Benefit To Primary Function	Reference
	Iterative Process			
21	Monitoring Plan. Design and implement a monitoring plan for water and sediment quality to trigger the adaptive management process. Include standards for operation contained in the Hydrologic Operating Plan (See #20).	Monitoring provides knowledge of: • fish and wildlife habitat; • water and sediment quality; • response to STA and reservoir operations. • early detection and resolution of potential problematic wildlife issues.	Monitoring assesses water treatment and storage efficiency. (Environmental permits issued to the District include compliance criteria which necessitate routine monitoring, reporting, and adaptive management responses.)	
22	Adaptive Assessment and Management. Develop and implement a facility monitoring plan with adaptive management. Include annual evaluation of compliance with targets for adaptive assessment.	Adaptive assessment and management improves facility operations that benefit fish and wildlife.	Adaptive assessment and management improves facility operation for water treatment and storage functions. (Environmental permits issued to the District include compliance criteria which necessitate routine monitoring, reporting, and adaptive management responses.)	
	 Monitoring plans.		 Implement adaptive assessment and management.	

Table 2. Fish and wildlife recommendations for CERP stormwater treatment areas and reservoirs.

	Wildlife Recommendations	Fish And Wildlife Benefit	Compatibility/Benefit To Primary Function	Reference
	Iterative Process - continued			
23	Avian Protection Plan . Develop and implement an avian protection plan based, in part, on lessons learned from the management of existing projects.	An avian protection plan: • supports avian diversity and listed species recovery; • maintains/enhances avian populations.	An avian protection plan improves operational flexibility by defining operation and management options concerning wildlife issues.	
	Public Use			
24	Recreational Use. Provide compatible public recreational opportunities as identified in the CERP Master Recreation Plan.	Compatible recreational use: • promotes public awareness of fish and wildlife conservation; • provides multi-purpose facilities for public benefit.	Recreational uses generate public support for STA and reservoir projects. Recreational uses must be compatible and not conflict with the primary function of the STA or reservoir.	Corps *In progress.*
		Develop and implement avian protection plans.		Provide compatible recreational uses such as bird watching.

IV. CONCLUSIONS

There is an opportunity to include a number of fish and wildlife enhancement features in the design and operation of STAs and reservoirs. Features that mimic natural ecological processes, functions, and habitat diversity would promote stable wetland communities, and may be compatible with primary design functions. The Service does not suggest all recommendations presented in Table 2 are applicable or practicable for all project sites. However, these recommendations should be considered in STA and reservoir design and operation when and if they are compatible with the primary design functions of a project. It is important that all operational plans be developed with the participation and review of all appropriate state/federal agencies and disciplines, including biologists.

Ecological Risk Assessment Guidance for Wetland Restoration on Agricultural Lands in South Florida

U.S. Fish and Wildlife Service
South Florida Ecological Services Office
Vero Beach, Florida

November 2001
(Revised 8/30/04)

I. Contaminant Issues

Construction and implementation of the Comprehensive Everglades Restoration Plan (CERP) will require thousands of acres of publicly owned land (State and Federal) for the purpose of maintaining hydrologic buffer areas and the operation of regional water storage and conveyance systems. Lands determined to be feasible for incorporation into CERP projects in south Florida are limited and expensive, as increasing demands for commercial and residential development compete with the need for viable and functioning Everglades wetlands and adjacent scrub and forested uplands. A large portion of these lands are presently, or were at some time, in active agricultural production. Historical management practices, especially those associated with row crop farming, typically involved the frequent application of organochlorine (OC) pesticides for insect control. Most of these pesticides are no longer registered for use in the U.S. due to environmental concerns. However, from the 1940s to the mid 1980s, frequent applications of DDT, chlordane, toxaphene, and other OCs were common in agricultural areas of south Florida, leaving significant residual concentrations of these toxic substances and their degradation by-products bound to and sequestered in the top soil. Conversion of these soils from a dry and frequently disturbed aerobic environment to inundated (perennially or intermittent) relatively undisturbed anaerobic sediments, supporting native submergent and emergent vegetation and periphyton, will likely promote the release of these residual pesticides (along with other common contaminants such as mercury, selenium, and copper) into surface waters. More recent agricultural practices employ a different suite of pesticides, including organophosphates, carbamates, and a variety of herbicides and fungicides. Although generally not as persistent as OCs, many of these modern pesticides are highly toxic to wildlife.

Many of these lands proposed for acquisition will support functioning water reservoirs (storm water treatment areas, Aquifer Storage and Recovery detention reservoirs, and storage reservoirs) designed to impound a wide range of water capacities and depths over long periods of time. Additionally, many of these reservoirs will cover large expanses of several thousand acres, establishing local and regional aquatic ecosystems as well as providing foraging habitat for waterfowl and other aquatic wildlife. Without appropriate risk management and attention to design alternatives, the subsequent release of these pesticides and trace metals into CERP wetlands, reservoirs, and conveyances will provide exposure pathways to the regional fish and wildlife communities in south Florida.

Although the need for this guidance was prompted by the CERP land acquisition program, its use is encouraged for wetland restoration projects under other programs such as the Service's Partners for Fish and Wildlife Program, the Natural Resources Conservation Service's Wetland Reserve Program, or other water management districts in Florida.

II. Phase I Environmental Site Assessment

The Phase I Environmental Site Assessment (Phase I) is performed in accordance with the American Society of Testing and Materials (ASTM) Standard Practice E1527-00, "Standard Practice for Environmental Site Assessments: Phase I Environmental Site Assessment Process."

DRAFT

The purpose of the Phase I is to identify the presence or likely presence of any hazardous substance or petroleum product on the property. This includes conditions that indicate an existing release, a past release, or a material threat of a release of any hazardous substance or petroleum product into structures on the property or into the ground, groundwater, or surface water of the property. The Phase I should provide all available information on current and past land use, and consists of the following elements:

A. Site inspection

The site inspection usually consists of walking, driving and/or flying over the property to visually ascertain the presence of features or indicators of past land uses and possible environmental contaminants. A checklist of such indicators includes, but is not limited to, dumps, drums, construction debris, fills, unusual chemical odors, above ground and underground storage tanks, chemical storage buildings, asbestos evidence, "stressed" vegetation or bare ground, "sterile" water bodies, oiled roads, stained or discolored ground or stream banks, oil slicks, air strips, maintenance areas, pipelines, transformers or other electrical equipment, oil and gas drilling, and mining activities.

B. Historical considerations

The historical review should include interviews with owners, previous owners, and neighbors to obtain an accurate picture of past land uses, farming practices, pesticide usage, etc. Aerial photographs should be reviewed for evidence of row crops and other agricultural, commercial or industrial activities. At a minimum, the historical review should include reliable information on (1) farming practices (e.g., row crops, sugarcane, citrus, sod farm, ornamentals, grazing), (2) exact location of these practices on the property, and (3) farming chronology. For example, row cropping on a portion of the property during the period from the 1940s to the mid-1980s is strong suggestive evidence for the presence of OC pesticides at that location.

C. Review of environmental databases

An extensive review of environmental databases (Comprehensive Environmental Response, Compensation, and Liability Information System; Resource Conservation and Recovery Information System; National Priorities List; Emergency Response Notification System; state Above Ground and Underground Storage Tank records; Solid Waste Facility and Landfill Report; Florida State Hazardous Waste Site list; Facility Index System/Identification Initiative Program Summary Report; Formerly Used Defense Sites; and local mosquito control districts) should be conducted.

Information gleaned from the Phase I assessment is used to determine the necessity of a Phase II assessment.

III. Phase II Environmental Site Assessment

DRAFT

Should information gleaned from the Phase I or other credible sources (i.e., previous investigations) indicate the presence of contamination or that the potential for contamination exists, a Phase II Environmental Site Assessment (Phase II) should be initiated. Coordination between the Service and the agency performing the assessment is important starting at this point and throughout the rest of the process. Coordination will be facilitated by providing the Service with a Phase II Scope of Work (SOW) or proposal for review. The proposal should describe in detail the sampling plan (number, media, and location of samples), sample collection methods, analytical parameters, quality control/quality assurance (QA/QC) plan, standards and/or ecological screening criteria to be used for comparison, contingency for expanded sampling, and screening level risk assessment procedures, if applicable. The environmental laboratory to perform chemical analyses should be EPA certified, maintain a rigorous QA/QC program, and achieve laboratory detection limits consistent with state and federally approved ecological screening values and water/soil quality standards. More detail on sampling procedures and analytical requirements is provided in the following section. The selection of a credible laboratory is one of the highest priorities in the site assessment process.

The purpose of the Phase II is to identify sources and locations of contamination, specify contaminants of potential concern (both human health and ecological), and provide recommendations for additional sampling, testing, or risk assessment; and corresponding corrective actions. The focus of the Phase II is generally on facilities and potential point sources on the property, which includes:

1. Mixing/loading areas
2. Storage sheds
3. Vehicle turn-arounds
4. Airstrips
5. Cattle dip tanks
6. Pumping stations
7. Burn areas

In addition, limited sampling may be conducted in other areas, such as canals and agricultural fields, in order to identify contaminants that have a more widespread distribution or to establish background levels of contaminants. Media sampled may include soils, sediments, groundwater and occasionally surface water. The most commonly encountered types of contaminants at agricultural sites include pesticides, petroleum hydrocarbons, and various metals.

Chemical concentrations in the various sampled media should be compared with the appropriate ecological screening values to determine if remediation and/or additional sampling is required. Ecological screening values to be used include the following:

1. Soils and sediments: Florida Department of Environmental Protection (FDEP) Sediment Quality Assessment Guidelines (SQAGs)

2. Surface water: Florida Surface Water Quality Standards, or USEPA Ambient Water Quality Criteria for protection of aquatic life

Ecological screening values are discussed in more detail in the next section.

Generally, any point sources identified can be remediated based on the results of the Phase II, with some additional delineation work. If remediation of the point source(s) removes all ecological concerns (i.e., all contaminant concentrations are reduced below screening values), no further assessment work is required on the site. However, if the results of the Phase I and/or Phase II indicate that widespread contamination at levels of ecological concern may be present, then more extensive sampling in the agricultural fields may be required (see next section).

IV. Agricultural Field Sampling and Screening

Generally, contaminant information obtained during a standard Phase I/Phase II Environmental Site Assessment (Phase I/II) is not detailed or comprehensive enough to be suitable for use in an ecological risk assessment (ERA). The methods described in this section are designed to provide detailed information on the distribution and concentrations of contaminants of concern (COCs) identified in the Phase I/II, for use in the food chain model to predict risks to Fish and Wildlife Service trust resources. A major purpose of this section is to determine whether concentrations of contaminants in the farmed areas are uniformly distributed in the fields, or are present as "hotspots" that can be remediated. The method allows for sampling coverage of a large area while attempting to hold down analytical costs. If there is sufficient evidence to expect that pesticide contamination is likely at a site, it may be advantageous to conduct this sampling protocol concurrently with the Phase II assessment.

Sample site selection should be biased in order to maximize detection of agrochemicals in cultivated soils by sampling the entire cultivated area when possible. Random sampling on properties characterized by a mixed land use is not likely to provide the greatest degree of representation regarding contamination commonly associated with agricultural production (*i.e.*, insecticides, herbicides, fungicides, fertilizers, etc.). Prior to developing a sampling strategy, each property's land use should be reviewed in terms of spatial and temporal variables, placing the greatest sampling priority on those areas which were intensively managed for agricultural production (e.g., cultivated fields). Conversely, a lesser priority should be given to rangelands and abandoned or vacant lots which have limited or no historical agricultural land uses. Some exceptions to this rationale would include commercial and industrial land uses which are sparsely distributed within the geographic areas currently under consideration for incorporation into CERP projects. In most cases, the use of random sampling is limited to those properties demonstrating homogeneous land use across the majority of the property.

DRAFT

A. Sample collection

Soil samples will be collected using a stainless steel spoon or hand auger from 0-6 inches below land surface. This interval represents the biologically relevant depth for interaction with surface water and biological receptors. It is important that care is taken not to include sample material from more than 6 inches deep, as this may result in dilution and underestimation of contaminant concentrations. Between samples, sampling equipment should be decontaminated using standard procedures to prevent cross-contamination between samples. (Decontamination between subsamples (see below) will not be necessary because subsamples will be mixed together to form a composite.) Immediately following collection, samples should be placed on ice and submitted as soon as possible to the laboratory for analysis.

Before being placed in the sample jar, all soil samples (discreets and composites) should be thoroughly homogenized until they appear completely uniform in texture and color. Analytical laboratories should be instructed that samples received from the field should be thoroughly homogenized again in the jar before an aliquot is removed for extraction.

B. Analytical parameters

If it has been determined during the Phase I/II that a property has a history of agricultural activity prior to 1985, then each soil analysis should include, at a minimum, organochlorine pesticides (EPA Method 8081), metals (including mercury and copper), and total organic carbon (TOC). If the history of the property or more recent uses suggest that other contaminants may be present, then the list of analytes should be expanded as appropriate. The best available detection limits should be requested of the analytical laboratory, but at a minimum, detection limits (practical quantitation limits) for each chemical should be as low as the corresponding screening value (see below). As a general rule, TOC analysis should be done for all soil and sediment samples. TOC is essential for food chain modeling and interpretation of individual sample results, bioassay results, etc.

C. Discreet sampling for small properties (<500 acres)

Discreet sampling will be required for agricultural areas less than 500 acres in size. Discreet sample sites should be established at regular intervals across the property, at a density of at least one sample per 10-20 acres. The actual sampling density will depend on the size of the property, analytical cost per sample, likelihood of contamination, and other factors, and will be specified in the proposed sampling plan and agreed to by consensus between the District and the Service. A minimum of 10 samples will be necessary for most properties. Some exceptions to this minimum sample size will occur where parcels are small (<100 acres) or demonstrate a combination of land uses (i.e., residential "ranchettes", small scale livestock/garden/nursery properties, rock mining pits, etc.) where only a small percentage of the overall area was cultivated. Careful consideration should be given prior to using a sample size smaller than 10. As sample size decreases, statistical variation tends to increase, thereby increasing the size of confidence intervals used to determine the 95 percent UCL of the mean for any given analyte.

Higher UCL values may increase the probability that samples will exceed ecological screening values, thereby necessitating expanded sampling, risk assessment, and subsequent clean up. Also, higher UCL values will generate correspondingly higher Hazard Quotients (HQ) in food chain modeling exercises associated with Ecological Risk Assessments (ERA).

Within this framework, actual sample location is at the discretion of the project manager. This agricultural field sampling is in addition to, and separate from, Phase II sampling that may be focusing on facilities with a high likelihood of contamination, such as pump stations, storage sheds, mixing/loading areas, airstrips, vehicle turn-arounds, cattle dip tanks, etc. The exact location of each sample should be recorded using GPS.

D. Composite sampling for large properties (>500 acres)

The large size of some of the properties being acquired (up to 20,000 acres) makes it difficult to characterize contaminant distribution and concentrations with confidence while staying within a reasonable cost. In order to address this problem, the following sampling strategy has been developed jointly by the Service and South Florida Water Management District (District).

Using aerial photographs, a 50-acre grid pattern will be established on each property or agricultural area greater than 500 acres in size. The grids should be located and confirmed in the field using GPS. Using a random number generator, specific 50-acre grids will be selected for sampling. The number of grids selected will depend on the size of the property. Obviously, the most desirable situation would be complete coverage of all present and former agricultural areas. For example, for a 1000-acre parcel, all 20 of the 50-acre grids would be sampled. For a very large property where complete coverage is not possible due to budget constraints, a pre-arranged fraction of the 50-acre grids should be selected. For example, a 5000-acre parcel would be divided into 100, 50-acre grids. Perhaps half (50) of these grids would then be randomly selected for sampling. The number of grids to be selected will be pre-determined for each site by consensus between the District and the Service, based on site-specific factors.

Each of the 50-acre areas will be subdivided into ten 5-acre plots. One soil sample will be collected from each of the 5-acre plots in the 50-acre grid. The location of each subsample should be exactly determined using GPS. The 10 subsamples are then composited into one sample and thoroughly mixed. This composite sample, representing the entire 50-acre grid, is then submitted to the laboratory for analysis and/or testing.

E. Ecological screening values

Ecological screening values are used to identify areas that may require further attention. The Florida Department of Environmental Protection's (FDEP) Sediment Quality Assessment Guidelines (SQAGs) for Florida Inland Waters (MacDonald et al. 2003) should be used as screening values whenever possible. The SQAGs were developed for assessing sediment quality in Florida waters, based on the probability of effects on aquatic organisms. For each contaminant there are two SQAGs: Threshold Effect Concentration (TEC) and Probable Effect

Concentration (PEC). TECs were formulated to define concentrations of contaminants below which biological effects are not expected. PECs were developed to define ranges of concentrations above which biological effects are likely.

In most cases the TEC will serve as the initial screening value, especially when using the composite-random sampling design. Use of PECs as screening values may be justified under some circumstances for certain contaminants. For some contaminants, SQAGs have not yet been developed. The U.S. Environmental Protection Agency's Ecotox Thresholds (USEPA, 1996), the National Oceanic and Atmospheric Administration's ER-Ls and ER-Ms (Long and Morgan, 1990), or other ecologically-based guidelines should be used when SQAGs are not available. For some chemicals such as metals, information on natural background levels may have to be considered. Human health-based guidelines for cleanup of contaminated sites, such as FDEP's Soil Cleanup Target Levels, should not be used for this purpose.

F. Sites which exceed the PEC

Sediments with concentrations of contaminants above the PEC are considered to represent significant and immediate hazards to exposed organisms. If any of the 50-acre composite samples, described above, exceeds the PEC or other appropriate probable effect-level screening value, it will be necessary to return to that 50-acre grid and obtain individual samples from each of the ten 5-acre sub-areas, which together formed the original composite. These samples should be taken as close as possible to the original sample locations. These discreet samples should then be submitted to the laboratory for analysis. The purpose of this follow-up sampling is to determine the distribution of contaminants within the 50-acre grid; i.e, do the data indicate the presence of one or more "hotspots," or is the contaminant(s) more or less evenly distributed over the site. If only one or two of the individual (5-acre) samples are elevated, the District may choose to remediate these areas in order to reduce the contaminant levels of the 50-acre grid to below PEC. Conversely, follow-up sampling may indicate that most or all of the 50-acre grids contain elevated levels of contaminants. Remediation of widespread contamination over such a large area may not be practical. In such a case, further testing and completion of an ecological risk assessment (ERA) will be necessary in order to refine our understanding of the hazards to federal trust resources associated with contaminants on the site. These tests and assessments should include: (1) elutriate studies, (2) sediment bioassays, and (3) ERA with food chain modeling. In addition, if any of the contaminants have a tendency to accumulate in aquatic organisms or biomagnify in the food chain, such as organochlorine pesticides, PCBs, PCDDs/PCDFs, and some metals, bioaccumulation studies are recommended. Specific tests and methods to be used are discussed in the following sections.

As stated above, follow-up sampling of discreet locations within a 50-acre grid is intended to determine the distribution of contaminants within the grid, and should not constitute an attempt to confirm or refute the original composite result. If widely disparate results are obtained upon follow-up (discreet) sampling compared with the original composite, this suggests that some error has occurred in sampling, homogenization, or laboratory analysis. In these cases, the original composite result will represent the 50-acre grid in question, barring some evidence to the

contrary suggesting that the follow-up result is actually more representative of contaminant concentrations in the grid.

In order to avoid the above situation, it is strongly recommended that discreet samples collected in the field, following homogenization, be split into two jars. One sample jar will be used for producing the composite by mixing with the other samples representing a particular 50-acre grid; the other jar of each pair would be stored at 4 degrees centigrade for possible future analyses. If screening levels for any analytes of interest are exceeded in the composite sample analyses, then all 10 of the subsample aliquots used to make that sample will be reanalyzed for the observed compounds to identify more precisely the location of the observed contaminant(s). Of course, use of this methodolgy may be problematic for very large properties due to limited storage space.

G. Sites which exceed only the TEC

In general, a few scattered exceedances of a TEC by an individual contaminant at a site, when there are no PECs exceeded, is not considered to be a significant cause for concern. However, if enough samples exceed the TEC, such that the mean (estimated by the 95 percent upper confidence limit (UCL) of the mean) for the entire site (i.e., the mean of all discreet samples for a small site, or the mean of all 50-acre composites for a large site) is above the TEC, serious widespread ecological effects are possible. To evaluate this, the mean and the 95 percent UCL of the mean should be calculated for each contaminant of concern. In most cases, if the 95 percent UCL for all contaminants is below the TEC, no further action will be necessary. However, if the 95 percent UCL for any contaminant exceeds the TEC, then the additional testing and an ERA (as described above for PEC exceedances) will be necessary. These tests and assessments should include: (1) elutriate studies, (2) sediment bioassays, (3) ERA with food chain modeling, and (4) bioaccumulation studies for lipophilic contaminants. In addition, if TECs are exceeded by more than one contaminant in the same grid(s), further testing and studies will be necessary to address possible synergistic or additive effects of these co-contaminants. Bioassays will be useful in this case to identify potential toxicity from multiple contaminants that would not be predicted by using individual screening values. Specific tests and methods to be used are discussed in the following sections.

V. Desorption Studies

Contaminated soils inundated during the process of wetland restoration may release soil bound pollutants into the pore and surface waters. Soil or sediment characteristics governing pollutant desorption (e.g., total organic carbon, grain size, pH) will vary among locations. In addition, weathering or aging of some contaminants may alter their bioavailability from that predicted in the published literature. This necessitates site-specific desorption studies to accurately assess pollutant availability to aquatic organisms. Pollutant desorption is assessed on soils from the location using ASTM method E-1195-01, "Method for Determining a Sorption Constant (Koc) for an Organic Chemical in Soil and Sediments." This method simulates flooding of site soils and measures release of contaminants from the soil over time. Filtered pore water samples are

collected and analyzed for COCs after 3, 7, 14, and 21 days contact time. These results are used to determine a site-specific organic carbon partitioning coefficient (Koc), an estimate of pollutant partitioning between sediments and water. This value can be used in food chain models for predicting aquatic and terrestrial organism exposure to pollutants.

Soils used in the desorption study should represent, as near as possible, the maximum detected concentration of the contaminant on the site, in order to ensure that measurable levels of the particular COC are released into the water. Bulk soil samples collected for this purpose must be thoroughly mixed. To ensure uniform contaminant concentrations, samples should be collected and analyzed from several locations within the bulk soil sample (e.g., top, middle, and bottom of the container). In order to be useful, the water analysis results must show evidence that steady-state concentrations have been reached within the 21-day duration of the test. Contaminant concentrations in water obtained during the desorption study may be compared with Florida Surface Water Quality Standards.

VI. Sediment Toxicity Testing

Toxicity testing with representative aquatic invertebrates and vertebrates allows prediction of soil bound pollutant toxicity to aquatic organisms if the location is converted to a wetland. For properties requiring an ecological risk assessment, the following sediment toxicity tests should be conducted:

1. Amphipod (*Hyalella azteca*) 10-day sediment bioassay (flow-through)
2. Midge (*Chironomus tentans*) 10-day sediment bioassay (flow-through)
3. Fathead minnow (*Pimephales promelas*) 7-day sediment bioassay (static renewal)

"Standard Test Methods for Measuring the Toxicity of Sediment-Associated Contaminants with Freshwater Invertebrates (ASTM E-1706-95)," "Methods for Measuring the Toxicity and Bioaccumulation of Sediment-Associated Contaminants with Freshwater Invertebrates (USEPA/600-R-99/064)," and "Short-Term Methods for Estimating the Chronic Toxicity of Effluents and Receiving Waters to Freshwater Organisms (USEPA/600/4-91/002)" provide standard methods to assess soil-associated pollutant effects upon aquatic organisms.

Endpoints measured in these tests are survival and growth. Any statistically significant impacts upon these endpoints in any test are considered direct evidence of potential impairment of the prospective benthic/aquatic community in the restored wetland.

As with the other sediment studies, bulk soil samples collected for this purpose must be thoroughly mixed, and uniformity of contaminant concentrations should be confirmed by sampling from several locations within the bulk soil sample. Soils used in the sediment toxicity tests should represent, as near as possible, the maximum detected concentration of the contaminant on the site.

DRAFT

VII. Bioaccumulation Studies

Factors affecting pollutant accumulation by aquatic organisms can vary among locations. Accurate prediction of pollutant bioaccumulation at a location requires site-specific bioaccumulation studies, using species representative of those that may exist on the location once flooded. For properties requiring an ecological risk assessment, the following bioaccumulation studies should be conducted:

1. Oligochaete (*Lumbriculus variegatus*) 28-day bioaccumulation study
2. Fathead minnow (*Pimephales promelas*) 28-day bioaccumulation study

Methods described in "Great Lakes Dredged Material Testing and Evaluation Manual (USEPA and Army Corps of Engineers, 1998)" and "Standard Guide for Determination of the Bioaccumulation of Sediment-Associated Contaminants by Benthic Invertebrates (ASTM E-1688)" should be used to determine the bioaccumulation potential of soil-associated pollutants. These results are used to determine a site-specific octanol-water partitioning coefficient (Kow), an estimate of pollutant partitioning (bioconcentration) between water and the body fat of the exposed organism. This information is utilized in food chain models for estimating contaminant uptake from water and accumulation in various trophic levels.

Soils used in the bioaccumulation studies should represent, as near as possible, the maximum detected concentration of the contaminant on the site, in order to ensure that measurable levels of the particular COC are released into the water and taken up by the organisms. Bulk soil samples collected for this purpose must be thoroughly mixed. To ensure uniform contaminant concentrations, samples should be collected and analyzed from several locations within the bulk soil sample (e.g., top, middle, and bottom of the container). In order to be useful, the concentration of contaminant(s) in the test organisms must show evidence that steady-state conditions have been reached within the 28-day duration of the test.

VIII. Aquatic Food Chain Modeling

In the absence of direct measures of effects, it becomes necessary to estimate or predict potential pollutant effects upon the Service's trust resources and other organisms that may utilize the created wetland, reservoir, or STA. Testing that directly assesses soil bound pollutant toxicity to organisms, other than benthic invertebrates and fish, is relatively time consuming and costly. Food chain models allow prediction of effects on higher level organisms by combining data from the site-specific desorption and bioaccumulation studies with information on dietary composition, consumption rates, body weights, etc. and literature toxicity data.

The Service's trust resources include migratory birds and Federally listed threatened or endangered species. The bald eagle (*Haliaeetus leucocephalus*), white pelican (*Pelecanus erythrorhynchos*), snail kite (*Rostrhamus sociabilis*), osprey (*Pandion haliaetus*), clapper rail (*Rallus longirostris*), and wood stork (*Mycteria americana*) are federal trust species that should be considered as representative target organisms. Where bioaccumulating pollutants are present,

a maximally exposed piscivorous bird must always be included. Generic fish species (omnivorous and higher level predatory fish) may be used as aquatic focal species. At a minimum, the food chain model should assess risk to the following groups (trophic levels) of target organisms:

1. Benthic invertebrates (detritivores)
2. Omnivorous fish
3. 1st order carnivorous fish (trophic level 3)
4. 2nd order carnivorous fish (trophic level 4)
5. Omnivorous bird
6. 1st order carnivorous bird
7. 2nd order carnivorous bird
8. Threatened and endangered species

The following potential routes of exposure should be included in the model:

1. Direct exposure to contaminated water/sediments
2. Sediment ingestion
3. Water ingestion
4. Food ingestion

The following transfer mechanisms and processes should be included:

1. Desorption from sediment to water
2. Bioconcentration from water
3. Bioaccumulation through ingestion of contaminated prey
4. Biomagnification with increasing trophic level

Once the target species' exposure to pollutants has been modeled, the potential risk to the species needs to be assessed by comparing the modeled exposure to a toxicity reference value (TRV). Perhaps the most relevant endpoints for assessing risk are effects upon (1) survival and (2) reproduction. In the absence of toxicity tests performed with the specific target species, TRVs for the pollutant(s) of interest must be obtained from the literature. Where possible, the ideal TRV will have been generated using a similar exposure route for a taxonomically related species. Uncertainties arising from the use of TRVs based on different exposure routes or unrelated species should be discussed in the risk assessment. In general, the most sensitive TRV should be utilized to assess risk to the target species.

Risk is expressed by calculating a hazard quotient (HQ), which is simply the ratio of the modeled exposure (numerator) and TRV (denominator). HQs above one indicate a potential for adverse effects to occur in a species under a given exposure scenario. The higher the HQ above one, the greater the risk that adverse effects will occur. HQs below one generally indicate that adverse effects are unlikely. HQs that are greatly different from one provide the greatest level of

certainty in their interpretation.

IX. Final Report

Upon completion of all sampling, chemical analyses, laboratory studies, and food chain modeling, a draft Phase I/II Environmental Site Assessment and Ecological Risk Assessment report should be prepared which identifies all potential hazards to ecological receptors and provides recommendations for corrective actions and/or management of the project that will reduce the hazards to acceptable levels. The Service will review the draft report and provide concurrence or make recommendations for changes or additions. The final report will incorporate Service recommendations, providing an accurate and complete report which can be used as a planning tool to optimize wetland restoration efforts and minimize adverse affects to fish and wildlife resources.

South Florida Water Management District DRAFT, January 6, 2005

INTRODUCTION

This document is intended to guide in the design of monitoring and assessment plans for mercury (Hg), pesticides, and other toxicants for South Florida Water Management District (District or SFWMD) projects. Because Hg is a regional problem in South Florida, it should be a consideration in all plans. As discussed below, although pesticides or other toxicants are often found dispersed in various media throughout South Florida (e.g., water, sediment, biota), concentrations do not frequently exceed critical levels that are thought to result in toxicity. Therefore, risk from exposure to pesticides or other toxicants tends to be a more localized concern than for mercury. More importantly in this context, the risk from changes related to the Comprehensive Everglades Restoration Plan (CERP) increasing the likelihood that wildlife will be exposed to these constituents, to a level that is toxic, also tends to be a localized concern. Accordingly, monitoring pesticides or other toxicants should be considered on a case-by-case basis.

It is not the intent of this plan to substitute for environmental site assessments (ESA) that are conducted on acquisition tracts. The District has an excellent record in conducting ESAs, site-specific environmental risk assessments (ERA), and implementation of corrective actions, where appropriate. This guidance has been prepared in consultation with and, where possible, will be implemented in coordination with the District's program for assessing the environmental liabilities associated with land transfer. However, the potential for anomalous methylmercury (MeHg) production is not considered during the ESA and thus must be assessed separately. With regard to other toxicants, the guidance provided here should prove useful in cases where either:

- an ESA identified dispersed low-level contamination of toxicants and there is a need to reduce uncertainties, i.e., better define spatial or vertical distribution,
- where lands were purchased by other public / private entities, but may not have been subjected to the same level of ESA as current transfers,
- there has been a lengthy interval between the time of assessment and start of construction (with interim usage by a lessee), or
- where pesticides or other toxicants have previously been identified as a concern on public lands (i.e., possibly as a result of stormwater runoff).

Results from the monitoring and assessment plan, in combination with information generated during land transfers, is intended to provide state and federal regulatory and trust oversight agencies with reasonable assurance that the project will not cause or contribute to an unacceptable increase in the risk of toxic effects to aquatic or terrestrial resources. As discussed below, the current numerical water quality standard (WQS) for total mercury (THg) is not protective of human or wildlife health. Consequently, assessments will need to place greater weight on protecting designated beneficial uses, i.e., recreation, propagation, and maintenance of a healthy, well-balanced population of fish and wildlife. This will also be true for other toxicants that can be released suddenly from flooded soils and/or that have the potential to biomagnify. In addition to numerical water quality standards, assessments will need to consider Line 62 of 62-

302.530, Florida Administrative Code (F.A.C.), which states that substances in concentrations which injure, are chronically toxic to, or produce adverse physiological or behavioral response in humans, plants, or animals shall not be present. In addition to state requirements, federal legislation that may be pertinent include the Comprehensive Environmental Response, Compensation and Liability Act, the Endangered Species Act, and/or, the Migratory Bird Treaty Act.

This guidance uses a phased, multi-tiered approach that is intended to commit information gathering, assessment, and remedial resources in proportion to the likelihood of harm by following a logical and cost-effective procedure. The plan covers three phases of a project: (1) Baseline Collection and Assessment, (2) Monitoring during the Three-Year Stabilization Period, and (3) Routine Operational Monitoring (Post-Stabilization). The plan includes decision points and adaptive management recommendations if preconstruction or operational monitoring reveals conditions of immediate concern. If an identified threshold of concern (i.e., action level) is crossed, then Tier 2 expanded monitoring and risk assessment would be triggered to determine the cause and guide appropriate adaptive management decision making regarding short-term corrective actions and long-term operational optimization. The intent of this approach is to allow monitoring efforts to smoothly ramp down or up, as appropriate.

This general plan is intended to accommodate diverse projects by providing a framework that can be tailored to a project's specific design. For example, a monitoring and assessment plan for a wetland restoration project would likely differ substantially from a plan for a Stormwater Treatment Area (STA) or reservoir. While it is anticipated that this guidance will serve as a frame of reference for future permit-mandated monitoring, incorporation of all, some, or none of its elements into a permit is at the discretion of the responsible authorities.

Mercury

Although atmospheric loading is often the dominant proximate source of inorganic mercury to many water bodies, the complication lies in the relationship between influx of inorganic mercury and the amount that is methylated by sulfate-reducing bacteria (SRB) following deposition. The latter process is of fundamental concern because MeHg is the more toxic and bioaccumulative form that can build up in the food chain to levels harmful to humans and other fish-eating animals, particularly in ecosystems with complex, lengthy food chains. Accordingly, a monitoring and assessment plan must be able to detect increased amounts of MeHg in the project area or downstream waters, either through sedimentary release of THg or MeHg, or through increased net Hg methylation. Although there are some constraints in predicting outcomes, the following factors are thought to be associated with increased MeHg production, particularly when in combination with certain site conditions (i.e., sediment biogeochemistry that is, as yet, less well-defined):

- Increased proportion of source water from direct rainfall relative to surface water runoff (explanatory note: rain contains elevated levels of bioavailable inorganic Hg, particularly

during summer; whereas, surface water runoff has already lost Hg through evasion back to atmosphere, sorption and deposition, and biological uptake);

- Elevated levels of oxidized sulfur compounds (e.g., sulfate, etc.) in inflows or sediments (explanatory note: used as electron acceptor by SRBs);
- Drawdown – drying followed by rewetting (explanatory note: allows constituents in the sediments/soils to oxidize); or
- Large bioavailable carbon source (explanatory note: feeds SRBs).

The goal is to prevent these factors from combining to produce a mercury methylation hot spot both in the short term (known as the "first-flush effect") and the long term (known as the "reservoir effect"). For additional details, see evolving conceptual model presented in the Fink et al., 1999; Stober et al., 2001; Harris et al., 2003; Atkeson and Axelrad, 2004.

The Florida Department of Environmental Protection (FDEP) has recognized that the current Florida numerical water quality criterion of 12 nanograms of total mercury (THg) per liter (ng/L) in water is of limited use, because fish consumption advisories have proven necessary for waters meeting the state criterion (Atkeson and Parks, 2002). Likewise, the U.S. Environmental Protection Agency (USEPA), also recognizing the limited utility of its recommended water quality criterion for the protection of human health, recently published guidance on a new criterion expressed not as a water-column concentration of mercury, but as a concentration of mercury in fish tissue (0.3 milligrams per kilogram, or mg/kg in fish tissue; USEPA, 2001). Biomonitoring mercury provides several advantages. First, MeHg occurs at much greater concentrations in fish tissues relative to surrounding water, making chemical analysis more accurate, precise, and cost-effective. Second, organisms integrate exposure to MeHg over space and time, while corresponding water concentrations may vary by a factor of two or more over a period of hours. Finally, the tissue Hg concentration in fish is a true measure of its bioavailability and provides a much better indicator of possible exposure to fish-eating wildlife and humans than the concentration in water.

In anticipation of the state adopting a new WQS based on tissue concentration and because it is cost-effective, this generic plan has a biomonitoring program as a key component. The long-term goal is to reduce tissue Hg concentrations in predatory fish to levels that do not exceed USEPA guidance values for the protection of both human health and wildlife (for guidance values to protect wildlife, see USEPA, 1997). However, it should be recognized that the Everglades has a preexisting, widespread mercury problem (i.e., fish from most areas currently exceed one or more predatory protection criteria) and that many of the influential factors controlling MeHg production are beyond the scope of individual projects. Accordingly, use of USEPA's guidance criterion as a "risk-based" action levels is not appropriate in the short term. Instead, monitoring and assessment plans will track the status and trends of mercury bioaccumulation to ensure that it does not significantly increase over baseline levels. This monitoring and assessment plan incorporates action levels or triggers for decision points based on existing reference or baseline conditions (i.e., annual basin-wide arithmetic average or percentile concentration for all basins

pooled). For purposes of pooling related data, the basin will be operationally defined based on the physiography and land uses of the watershed, category of water body (e.g., wetland, slough, open lake, etc.), and the data set available at that time. Ideally, the data set would allow for comparisons between similar habitat or sediment types. However, near-term projects may not have this option and may need to collect reference samples (especially where data on similar sediment types are unavailable) or use surrogate data collected at Stormwater Treatment Areas or Water Conservation Areas under the Everglades Forever Act Permits for comparative purposes.

Pesticides and Other Toxicants

Potential impacts to wildlife from exposure to toxicants other than mercury (e.g., organic pesticides or trace metals) continues to be a problem. This is of particular concern in Florida because of its complex stormwater management system from both urban (e.g., lawns, golf courses, "street dust") and agriculture, high groundwater table, and significant usage of a wide variety of pesticides and fertilizers. Fertilizers (including organic and biosolids) are a concern because several studies have measured heavy metals (e.g., cadmium, lead, nickel, and copper) in mineral ores and the resulting fertilizers (USEPA, 1999). Like mercury, many other toxicants, including relic (e.g., DDT, DDE, toxaphene, etc.) and new (e.g., atrazine, alachlor) pesticides, have been found to be atmospherically deposited from both local and global sources (for details, see Eisenreich et al., 1981; Goolsby et al., 1993). Consequently, source identification can be challenging.

Owing to their absorptive capacity, soils and sediments typically act as a sink for these contaminants. As long as these soils/sediments maintain the capacity to store and thus immobilize the potential toxicant, the effects are significantly reduced. However, any alteration in the environment (e.g., flooding, anoxia and redox, microbial processes, pH changes) can suddenly reduce the sediment's storage capacity, which in turn can result in serious environmental damage (see "Chemical Time Bomb" concept in Stigliani et al., 1991).

Pesticides have been detected in sediments and surface water at District structures at various times (Miles and Pfeuffer, 1997; Pfeuffer and Matson, 2003; Pfeuffer and Rand, 2004). Likewise, pesticide residues have been found in fish and wildlife from certain locations in the central and southern Everglades (USGS National Water Quality Assessment Program at http://fl.water.usgs.gov/Abstracts/fs110_97_haag.html; Rumbold et al. 1996, Spalding et al. 1997, Rodgers 1997, Fernandez et al. 2003). Recently, a bird kill in excess of 800 birds occurred on Lake Apopka, possibly as a result of pesticide poisoning, after former farmlands were flooded (see Memorandum of Understanding between U.S. Department of Justice and St. John's River Water Management District, available at http://sjr.state.fl.us/programs/acq_restoration/s_water/lapopka/MOU.html).

The monitoring and assessment plan for other toxicants often takes advantage of the mercury monitoring program, as in many cases, additional work simply involves splitting samples.

South Florida Water Management District DRAFT, January 6, 2005
MONITORING AND ASSESSMENT FRAMEWORK

1. Phase 1 - Baseline Collection and Assessment

This section describes activities conducted during the initial stages of a project. In some cases, a Project Manager may opt to carry out these activities prior to site selection (i.e., on short-listed sites) to provide additional information to guide in the selection process. If site selection has already occurred, then a Project Manager may elect to carry out these tests to assist in selecting the final design (e.g., footprint or operational features). As previously stated, it is not the intent of this plan to substitute for ESAs that are conducted on acquisition tracts. Results of those assessments are routinely reviewed and receive necessary approvals from the FDEP and the U.S. Fish and Wildlife Service. Accordingly, where an ESA has recently been completed, baseline collection and assessment of toxicants other than Hg is not a general recommendation beyond the Phase 1 - Tier 1 task of compiling and reviewing existing data. Although these tests are a general recommendation for mercury, it should be understood that due to current limitations in predicting methylation potential, results of these tests should not be the sole factor in making site or design selection. Nonetheless, information gathered during this phase of the project will be crucial in developing the final monitoring plan and as baseline for future, post-construction cause-and-effect assessments.

1. 1 Phase 1 - Tier 1: Compilation and Review of Available Data

The first step in any project is to compile and review all available data (e.g., ESA, DBHYDRO, Battelle Monitoring Data Inventory) collected from the project footprint and surrounding area. With regard to other toxicants, data should be reviewed to answer the following questions:

- If land transfer, responsible agency and level of ESA preformed (i.e., Phase 1 or 2)?
- Did the ESA identify contaminants of concern?
- Were any corrective actions taken and was there follow-up sampling?
- Was there dispersed low-level contamination of toxicants (i.e., that did not exceed the requirements for corrective action)?
- Has there been a lengthy interval between the time of assessment and start of construction (with interim usage by a lessee) and, if so, what chemicals may have been used in the interim?
- If public lands, have toxicants been previously identified based on surface water, sediment or fish monitoring?

Answers to these questions will guide in developing an abbreviated analyte list for subsequent monitoring.

In areas that have been extensively studied, projects may have adequate baseline datasets and thus may not be required to collect any additional data before developing the Phase 2 monitoring and assessment plan. Alternatively, where datagaps exist or where the preponderance of the

baseline data demonstrate a potential problem, additional sampling (i.e., under Phase 1 - Tier 2 or Tier 3) may be necessary.

1. 2. Phase 1 - Tier 2: Field Sampling

1. 2.a Soil/Sediment

To describe conditions within each project, it is recommended that soil/sediment cores be collected from five locations within each operable unit (i.e., OU - each independently operated treatment train of an STA or reservoir) or each 1,000-acre parcel, whichever is smaller. At each location or site, three cores from the 0-to-4 cm horizon are to be collected and composited as a single soil sample. To conserve resources at large projects, sub-samples or aliquots from each of the soil samples from the five different locations can be pooled to form a single supercomposite sample for each OU or 1,000 acres. In this two-staged sampling approach, the analyses of the supercomposite representing the entire OU or 1,000 acres can be used as a screening mechanism to identify if additional, individual analysis are need to be performed (on each of the individual soil/sediment samples). Accordingly, remaining material from each soil sample will be archived separately for up to one year to allow for possible future analysis.

If the site was flooded and sediments had been saturated for some period of time (i.e., in excess of a month) with water comparable to future source water, then sediments may be immediately analyzed for THg, MeHg, moisture content, total organic carbon (TOC), total sulfur (TS), and total iron (TFe). Alternatively, if soils were collected from a dry site (i.e., orange grove, range land, etc.), then baseline concentrations will not reflect future flooded conditions (i.e., potential for MeHg production or first flush). Accordingly, soil/sediment must first be incubated with source water (i.e., surface water containing ambient concentrations of sulfate and dissolved organic carbon mixed with rainwater containing bioavailable inorganic Hg) for a period to evaluate this potential for first flush and future MeHg production. This test (i.e., beaker-scale microcosm test) will use fresh soils (i.e., the supercomposite from above) and ambient water from the anticipated inflows (i.e., appropriate mixture of surface water and rainfall, which have been subsampled for analysis for THg and MeHg), and will be run under static conditions, with frequent renewal. Upon completion of the test, sediments will be collected and analyzed for THg, MeHg, moisture content, TOC, TS, and TFe.

If deemed necessary, based on the discussion above, soil/sediment samples (wet or dry) could also be split and analyzed for toxicants of concern identified either through an ESA, available water quality (WQ) database or, if these were unavailable, previous land uses (both upstream and within the footprint). Although this course sampling would likely miss possible "hot spots" (e.g., fuel loading or pesticide mixing zones), which should have been detected during the ESA (when cores were collected from 5-acre subparcels and composited for randomly selected 50-acre parcels), this level of detail should be sufficient to characterize dispersed contaminants.

The objective of screening for toxicants is (1) to prevent direct toxicity, either acute or chronic, and (2) to prevent the biomagnification of toxicants from reaching unacceptable levels that

would pose a threat to upper trophic level wildlife. To achieve the first objective, toxicants would be evaluated against effects-based, numerical sediment quality assessment guidelines (SQAGs for sediment dwelling organisms, MacDonald Environmental Sciences Ltd.; USGS, 2003). In cases where the effects-based SQAG did not assess the potential for adverse effects on aquatic organisms due to the resuspension of sediments or partitioning of contaminants into water (i.e., using elutriates or pore water), soils may be subjected to a synthetic precipitate leaching procedure (SPLP; USEPA Method 1312, also see Brannon et al., 1994) using ambient source water to elute the column and the resulting elutriate assessed based on Chapter 62-302, F.A.C. (and other references contained in Pfeuffer and Matson, 2003); exceedances would trigger
Tier 3 assessments. To achieve the second objective, bioaccumulative toxicants would also be evaluated against established bioaccumulative-based SQAGs, if available (MacDonald Environmental Sciences Ltd.; USGS, 2003).

A project would stop and reevaluate the ESA (if completed) and/or proceed to Phase 1 - Tier 3 bioaccumulation tests and dynamic modeling if:

- concentrations in sediments exceeded the appropriate SQAG,
- concentrations in sediments exceeded a value reported in the ESA or a level that was determined to be critical in a site-specific risk assessment, or
- the concentration in the elutriate exceeded a WQS in Chapter 62-302, F.A.C.

Although bioaccumulation-based SQAGs have been developed for a limited number of toxicants, there is no chemical-specific SQAG for mercury. Consequently, there is no screening-level benchmark sediment THg or MeHg concentration that can be used to confidently predict whether a site will become a "MeHg" hotspot. However, data collected over the last nine years by various agencies working in the Everglades offer some limited capability as a reference (or baseline) to predict the potential for excessive MeHg production. Accordingly, as one of several potential tools for alternatives analysis, it is recommended that soil/sediment conditions of the site be assessed for MeHg production potential through comparisons with this reference database. If absolute concentrations of MeHg, or percent MeHg (i.e., percentage of THg that is in the MeHg form) in soils/sediment from an OU exceeds the 90% upper confidence interval for within basin sediments or, if not available, the 90^{th} percentile concentration (or %MeHg) for all basins, then the potential exists for excessive MeHg production and, accordingly, it is recommended that the project proceed to Phase 1 - Tier 3.

As previously discussed, a great deal of uncertainty remains surrounding the use of soil/sediment concentrations as a predictive tool to forecast future MeHg potential. Accordingly, as discussed in the following section, it is recommended that resident fish also be collected to assess current MeHg production and bioaccumulation.

1. 2.b Fish Tissues

At a minimum, fish samples from multiple trophic levels should be collected upstream and downstream of each project. Specifically, a sample of at least 100 mosquitofish (*Gambusia spp.*) should be collected from each location and composited into a single sample for THg analysis. Additionally, individual sunfish [sample size (n) should be greater than or equal to 5; whole-body] should be collected from each location and analyzed for THg. Where habitat will support largemouth bass (*Micropterus salmiodes*) and there is a possibility of future recreational harvesting, bass should also be collected and individually analyzed for THg (n should be greater than or equal to 5; fillets). Becasue virtually all (> 85 percent) of the mercury in fish muscle tissues is in the methylated form (Grieb et al., 1990; Bloom, 1992; SFWMD, unpublished data), the analysis of fish tissue for THg, which is a more straightforward and less-costly procedure than for MeHg, can be interpreted as being equivalent to the analysis of MeHg.

To reduce variance (i.e., due to species related differences in diet, ontological shifts in diet, exposure duration) and improve spatial and temporal comparisons of tissue levels within trophic levels, collections should target bluegill (*Lepomis macrochirus*) ranging in size from 102 to 178 mm (i.e., 4-7 inches) and largemouth bass ranging in size from 280 to 330 mm (i.e., 11 to 13 inches); however, other lepomids (first priority being given to spotted sunfish, *L. punctatus*, due to similar trophic status) or sizes are to be collected if efforts fail to locate targeted fish. If neither sunfish nor bass are present, then consideration should be given to sampling other species.

In addition, if possible (i.e., if flooded), mosquitofish should also be collected randomly from multiple locations from each OU or 1,000 acres (total should exceed 100 mosquitofish) and physically composited to form a single mosquitofish sample representative of the entire OU.

Body burdens in upstream and downstream fish do not provide predictive capabilities for alternatives analysis; however, this data set will be a crucial baseline for trend analyses following initiation of flow-through operation. Alternatively, ambient fish from the interior or footprint do provide some predictive capabilities for alternatives analysis. If these mosquitofish demonstrate excessive levels of MeHg bioaccumulation that exceed the 90% upper confidence level of the basin-wide annual average (reference basin will be defined for each specific project) or the 90th percentile concentration for the period of record for all basins, then it is recommended that the project proceed to Phase 1 - Tier 3: Bioaccumulation Tests and Dynamic Modeling.

If deemed necessary, based on the discussion above, fish samples could also be split and analyzed for bioaccumulative toxicants identified either through an ESA, available WQ database or, if these were unavailable, previous land uses (both upstream and within the footprint). Although, it is recognized that under certain circumstances a taxa other than fish may be more

appropriate biological sentinels depending on toxicant and risk assessment endpoint, this will require a thorough justification.

If levels of other toxicants in tissues exceed recognized background tissue concentrations (USGS National Water Quality Assessment Program, etc.) or benchmarks established in ecological risk assessments completed as part of the ESA, then the project would stop and reevaluate the ESA or proceed to Tier 3 Bioaccumulation Tests and Dynamic Modeling.

1. 3. Phase 1 - Tier 3: Bioaccumulation Tests and Dynamic Modeling

Tier 3 assessments during Phase 1 Baseline Collection and Assessment are triggered if one of the following action levels are exceeded:

- If absolute concentrations of MeHg, or average percent MeHg (i.e., percentage of THg that is in the MeHg form) in soils/sediments from an OU exceeds the 90% upper confidence level of within the basin average, or if not available, the 90th percentile concentration (or %MeHg) for all basins;
- If concentrations of other toxicants in soils/sediments exceeded benchmarks established in ecological risk assessments completed as part of the ESA, or exceeded an appropriate SQAG, or the concentrations in the elutriate exceeds Chapter 62-302, F.A.C.; or
- If ambient fish collected within the project boundary demonstrate excessive bioaccumulation that exceeds the critical tissue benchmark used to establish SQAGs or in site-specific risk assessments exceeds the 90% confidence level of within the basin average, or if not available, the 90th percentile concentration for all basins.

Before proceeding to full Tier 3 sampling or modeling, the following steps are recommended to better define spatial extent of problem (i.e., to focus future efforts and thus conserve resources).

Step 1. Run analytical chemistry on the five individual soil samples that comprise the supercomposite that exceeded the trigger.

Step 2. Resample mosquitofish at a finer scale (i.e., 1 sample per 200 acres) within the OU or 1,000 acres for which the Tier 1 composite sample exceeded the trigger.

1.3.a Bioaccumulation Tests

As previously discussed, uncertainties remain surrounding the use of soil/sediment concentrations as a predictive tool to forecast future MeHg potential. Depending on soil conditions (e.g., concentration of TOC, TS, or TFe) bulk concentrations could substantially overestimate the fraction of MeHg actually bioavailable to aquatic animals living on or in surficial soils and thus the short-term MeHg bioaccumulation potential.

To reduce this uncertainty, a standardized laboratory determination of MeHg bioaccumulation (ASTM 1688-00a, E1706-00e1, or equivalent; also see Ingersoll et al., 1998; Nuutinen and Kukkonen, 1998) may be carried out using soils collected from multiple locations within the footprint of the proposed component; supercomposite from above or individual composites (if area has been defined by sediment concentrations). Because most of the cost of this test is associated with the collection of soil/sediments, a Project Manager may opt to collect sufficient soil/sediments for this test during Tier 1 sampling.

The bioaccumulation test will use soils/sediments, ambient water from the anticipated inflows (i.e., appropriate mixture of surface water and rainfall, which have been subsampled for analysis for THg and MeHg) and will be run under static conditions with frequent renewal. Current standard protocols utilize infaunal invertebrates (e.g., *Lumbriculus variegatus*, a freshwater benthic worm) and are non-feeding exposures. Therefore, assessment of food chain transfers (biomagnification) require modeling (i.e., in this case to mosquitofish or sunfish) using biomagnification factors (BMFs) from the peer-reviewed literature, if basin-specific data are unavailable. A probabilistic bioenergetics-based food chain model may be used if a valid, applicable BMF cannot be obtained (e.g., Norstrom et al., 1976; Rodgers, 1994; Korhonen et al., 1995; Schultz et al., 1995).

If Tier 3 Bioaccumulation Tests and Modeling is triggered by toxicants other than Hg on a site that has recently undergone an ESA or ERA, then the Project Manager should reevaluate early model runs and rerun with additional data. Where an SQAG (either effects-based or bioaccumulation-based) has not been identified, or in cases where an exceeded SQAG is thought to be overly conservative, it is recommended that a standardized laboratory bioaccumulation test (ASTM 1688-00a, E1706-00e1, or equivalent; also see Ingersoll et al., 1998) be performed.

1.3.b Modeling

If Phase 1 - Tier 2 evaluations or Tier 3 bioaccumulation tests demonstrate the potential for excessive MeHg production and bioaccumulation over a substantial portion of the project footprint (hence, the need to define spatial extent, as discussed above), then it is recommended that the Everglades Mercury Cycling Model (E-MCM) or comparable model be used during alternatives analysis. Preferably, model output should be considered both in terms of site selection and operational design. However, due to the current limitations in the predictive strength of the E-MCM, results of the management scenarios simulated must be considered as possible, rather than probable outcomes (Harris et al., 2004), and should not be the sole factor in site selection.

Consultants under contract to the District's Land Acquisition Department have developed and routinely use several different models for evaluating biomagnification and ecological risk from exposure to other toxicants. If resulting risk estimates (either based on uptake or critical tissue concentrations) are deemed acceptable, the project would proceed and initiate Phase 2 - Tier 1 monitoring. On the other hand, if risk is deemed to be unacceptable, then the Project Manager would proceed to determine potential remedial actions/alternatives to reduce exposure and risk.

2. Phase 2 - Monitoring During Three-Year Stabilization Period

This section describes a general monitoring and assessment plan to be conducted on projects after initial flooding and through the first three years of operation.

2.1 Phase 2 - Tier 1: Routine Monitoring During Stabilization Period

2.1.a Water

At a minimum, an unfiltered surface water sample (n = 1) should be collected in accordance with Chapter 62-160, F.A.C., at the inflows and immediately upstream of the outflows of each project on a quarterly basis and analyzed for THg, MeHg, and if not included under routine WQ monitoring, sulfate. In addition, flow will be monitored at the inflow and outflow to allow for load estimation to and from the project (it should be recognized that quarterly sampling would allow for only rough estimation of loads).

This data set will provide crucial information regarding assessment measures, i.e., annual outflow loads of THg and MeHg should not be significantly greater than inflow loads, including atmospheric loading; load estimates should include confidence intervals that describe uncertainty in measures of flow and concentration (e.g., field and analytical precision) and resulting from interpolation (note: assessment protocol to be negotiated with permitting authority). Failure to satisfy this assessment measure would trigger Tier 2 Expanded Monitoring and Risk Assessment.

Until a new criterion based on tissue concentrations is promulgated, monitoring THg in surface water will likely also be necessary to demonstrate compliance with Chapter 62-302, F.A.C. (i.e., WQS of 12 ng THg/L); however, this would trigger Tier 2 Expanded Monitoring and Risk Assessment only if the loading assessment measure was also exceeded.

It is recommended that other toxicants identified during Phase 1 - Tier 1 data review (i.e., based on ESA, DBHYDRO, Battelle Monitoring Data Inventory) be included on the analyte list for quarterly water-column sampling. Because of the concern for potential acute toxicity, the initial sample collection should occur prior to flow-through operation. Subsequent sampling would occur at the same frequency as mercury monitoring and be assessed using a similar performance measure, i.e., outflow load should not be significantly > inflow load (including atmospheric load). Because of differences in the anticipated time frames under which sedimentary release are thought to occur (i.e., relative to MeHg that may have time lag associated with changes in biogeochemistry and microbial methylation driven by water quality), monitoring for other toxicants would cease after one year, if action levels are not exceeded within that time. Exceedance of WQS in Ch.62-302 would trigger Tier 2 Expanded Monitoring and Risk Assessment.

2.1.b Soil / Sediment

Soil / sediments will not be collected under Phase 2 - Tier 1 monitoring.

2.1.c Fish Tissues

At a minimum, samples of fish from multiple trophic levels should be collected from each OU and from a single downstream site for each project. Specifically, within one month following initial flooding and quarterly thereafter, mosquitofish should be collected from multiple locations within each OU (to total at least 100 fish) and physically composited into one (spatially-averaged) sample and analyzed for THg (note, a single aliquot should be analyzed per composite). Mosquitofish were selected as a primary sentinel species because of their widespread occurrence in the Everglades, ability to invade newly flooded areas, and because of their relatively small home range and short life span. Mosquitofish are known to bioaccumulate MeHg as well as, other metals, such as lead, zinc, selenium and cadmium and organochlorine pesticides including but not limited to DDT, endosulfan, and toxaphene. These characteristics make the mosquitofish an excellent indicator of short-term, localized changes in a toxicant's bioavailablity.

On an annual basis, sunfish (n should be greater than or equal to 5) should be collected and individually analyzed (whole-fish) for THg. Sunfish were selected because of their widespread occurrence (especially bluegill) and because they are a preferred prey for a number of fish-eating species. Where habitat supports largemouth bass and there is a possibility of future recreational harvesting, bass should also be collected (n should be greater than or equal to 5) and individually analyzed (fillets) for THg. Largemouth bass can be used as an indicator of potential human exposure to mercury. To reduce variance (i.e., due to species differences in diet, ontological shifts in diet, exposure duration) and improve spatial and temporal comparisons of tissue levels within trophic levels, collections should target bluegill ranging in size from 102 to 178 mm (i.e., 4 to 7 inches) and largemouth bass ranging in size from 280 to 330 mm (i.e., 11 to 13 inches); however, other lepomids (due to similar trophic status, first priority being given to spotted sunfish) or sizes are to be collected if efforts fail to locate targeted fish.

Due to their relatively longer life spans and larger home ranges, sunfish and largemouth bass integrate their exposure over a larger spatial area and longer time frame. Accordingly, caution should be exercised when assessing levels in these fish in recently flooded (or intermittingly flooded) marshes. Under those circumstances, more weight should be placed on levels in mosquitofish which, as stated previously, integrate exposure over a shorter period of time.

If after one year of monitoring, sufficient data are collected to demonstrate that conditions within the different OUs are equivalent, collection of large-bodied fish can be reduced to one OU and one downstream site. Alternatively, if OUs are shown to differ in terms of average concentration in mosquitofish, project managers may elect to sample large-bodied fish from the OU with the highest observed concentration and assess results as "worst case". However, in either case, mosquitofish collections would continue from all OUs.

This data will then be used to evaluate the following assessment measure: annual average THg levels in fishes should not increase progressively over time or become elevated to the point of

exceeding the 90% upper confidence level of the annual basin-wide average, or if basin-specific data are lacking, exceeding the 90th percentile concentration for the period of record for all basins. Exceedance of any of these action levels would trigger Phase 2 - Tier 2 Expanded Monitoring and Risk Assessment.

It is recommended that bioaccumulative toxicants identified during the Phase 1 - Tier 1 data review (i.e., based on information contained in the ESA, available WQ database, or previous land uses) be included on the analyte list for fish tissues collected during the first year of the stabilization period, if analytical procedures exist. For toxicants other than mercury, more weight may need to be placed on whole-body residues in mosquitofish and sunfish (that will include organs that may preferentially accumulate other toxicants) to assess ecological risk than levels in fillets of largemouth bass. Furthermore, it should also be recognized that under certain circumstances taxa other than fish may be more appropriate biological sentinels depending on the toxicant and the risk assessment endpoint. For example, preliminary discussions have taken place regarding the possible use of the apple snail (*Pomacea paludosa*) to biomonitor potential copper exposure to the endangered snail kite (*Rostrhamus sociabilis plumbeus*). However, a thorough justification will be required in any plan that targets species other than mosquitofish, sunfish, or bass.

Tissue levels of other toxicants should not increase significantly over time or become elevated to the point of exceeding the critical tissue benchmark used to establish SQAGs or in risk assessments, exceeding the 90% upper confidence level of the annual basin-wide average, or if not available, exceeding the 90th percentile concentration for all basins. Exceedance of these action levels would trigger Phase 2 - Tier 2 Expanded Monitoring and Risk Assessment.

2.2 Phase 2 - Tier 2: Expanded Monitoring and Risk Assessment

Phase 2 - Tier 2 is triggered if one of the following action levels is exceeded:

- If annual outflow loads of THg or MeHg are significantly greater than inflow loads (i.e., based on an uncertainty analysis of loading estimates);
- If a WQS (in Chapter 62-302, F.A.C.) for a toxicant other than mercury is exceeded;
- If annual average levels of a residue in a given fish species increases progressively over time (i.e., two or more years) ($p < 0.1$);
- If annual average Hg levels in a given fish species become elevated to the point of exceeding the 90% upper confidence level of the basin-wide average, or if basin-specific data are lacking, exceeding the 90th percentile concentration for the period of record for all basins; or
- If residue levels of other toxicants in fish become elevated to the point of exceeding the critical tissue benchmark used to establish SQAGs or developed in risk assessments.

The following steps will be taken if any action level in Phase 2 - Tier 2 is triggered:

Step 1: Resample media (e.g., water or fish) that triggered Tier 2.

If results of Step 1 (i.e., re-sampling of media that triggered Tier 2) demonstrate that the anomalous condition was an isolated event, the project will revert back and continue with Phase 2 - Tier 1 monitoring. Alternatively, if results of Step 1 reveal anomalous condition was not an isolated event, proceed to Step 2.

Step 2 involves expanding the monitoring program as follows:

- Increase frequency of mosquitofish collection from quarterly to monthly.
- If Tier 2 was triggered by excessive loading or exceedance of a WQS at common outflow, then begin sampling discharges at outflows of each OU or independent treatment train to better define spatial extent of problem. If necessary (i.e., if loading uncertainty is high), increase frequency of surface water collection to monthly (reducing temporal interpolation), or as appropriate for hydraulic retention time (HRT).
- To further define spatial extent of problem, collect multiple mosquitofish composites from within the OU or treatment train exhibiting anomalous conditions.
- If Tier 2 was triggered by tissue levels in large-bodied fish, increase sample size of large-bodied fish to n = 20, i.e., 20 each of sunfish (collect various species and sizes) and/or bass (collect various sizes and extract otolith from bass for age determination).
- To evaluate possible trends in methylation rates in sediments (i.e., to determine if problem is improving or worsening), replicate sediment cores (0-4 cm) can be collected from the suspected methylation "hot spot" and reference locations within the component (for THg, MeHg, moisture content, TOC, TS, and TFe) over a given period of time (i.e., 2 to 4 months). At these same locations and times, collect pore water samples and analyze for THg, MeHg, and sulfides, or if no acceptable pore water protocol has been developed, acid-volatile sulfide (AVS) on solids.

Projects shown to have (spatially) large or multiple MeHg "hotspots" should consider use of the E-MCM or comparable model as an assessment tool (i.e., to synthesize results of expanded monitoring).

Step 2 will also include the notification of the permitting authority that anomalous conditions are continuing. The permitting authority and the permittee may then develop an adaptive management plan using the data generated from the expanded monitoring program. This plan will evaluate the potential risks from continued operation under existing conditions (i.e., through a risk assessment for appropriate ecological receptors). If risk under existing operational conditions is deemed acceptable, then project monitoring would continue under a modified Tier 2 scheme to monitor exposure. On the other hand, if risk under existing operational conditions is deemed unacceptable, then the adaptive management plan would then proceed to determine potential remedial actions to (1) reduce exposure and risk (e.g., signage for human health concerns, reduce fish populations,

reduce forage habitat suitability); if risk of acute toxicity - immediate drawdown of OU and reevaluation of ESA [Note that assessment of potential human health impacts and corrective actions (i.e., signage) will require the involvement of the Florida Department of Health]; and (2) affect mercury biogeochemistry to reduce net methylation (e.g., modify hydroperiod or stage, water quality).

In developing this adaptive management plan, the permitting authority may conduct a publicly noticed workshop to solicit comments from the permittee, the U.S. Army Corps of Engineers, the U.S. Environmental Protection Agency, the U.S. Fish and Wildlife Service, the National Park Service, the Florida Fish and Wildlife Conservation Commission, and other interested persons.

The next step would then be to carry out such remedial or corrective action. If the remedial or corrective action is demonstrated to be successful, then the project would revert back to Phase 2 - Tier 1 monitoring. Alternatively, if monitoring data indicate that the remedial action was unsuccessful in reducing fish tissue concentrations or downstream loading, the permitting authority and the permittee would then initiate a peer-reviewed, scientific assessment of the benefits and risks of the project.

3. Phase 3 - Routine Operational Monitoring (Post-Stabilization)

This section describes assessment measures, action levels and monitoring efforts for the project following the period of stabilization, i.e., during operation in years 4 through 9. Because of differences in the anticipated time frames under which sedimentary release and bioaccumulation are thought to occur, monitoring toxicants other than mercury in water or biological tissues is not a general recommendation past the first year of stabilization.

3.1 Phase 3 - Tier 1: Routine Operational Monitoring

If after the first three years of monitoring neither downstream loading nor residue levels in fishes exceed action levels, then (1) surface water sampling would be discontinued, (2) frequency of mosquitofish collection would be reduced to semiannually, and (3) frequency of large-bodied fish collection reduced to one collection event every three years.

Phase 2 - Tier 2 Monitoring and Risk Assessment during operation is triggered if one of the following action levels is exceeded:

- If annual average THg levels in mosquitofish progressively increased over time (i.e., two or more years) or become elevated to the point of exceeding the 90% upper confidence level of the basin-wide annual average or, if basin-specific data are lacking, exceed the 90^{th} percentile concentration for the period of record for all basins; or
- If triennial monitoring of large-bodied fish (i.e., in years 6 and 9) reveals tissue Hg levels in fishes has statistically increased, progressively over time (i.e., two or more years) or has become elevated to the point of exceeding the 90% upper confidence level of the

basin-wide annual average or, if basin-specific data are lacking, exceeded the 90th percentile concentration for the period of record for all basins.

On the other hand, if fishes collected under Phase 3 Operational Monitoring have not exceeded action levels by year 9, project-specific monitoring would be discontinued; future assessments would be based on regional monitoring under RECOVER. However, Project Managers are cautioned that action levels may be revised at a future date, owing to the likelihood that a tissue-based WQS will be adopted by the state within in next 9 to 10 years.

CONTRACTOR SELECTION CRITERIA

Given the inherent difficulties of ultra-trace monitoring, it is crucial that any contractor selected to carry out field collection has demonstrated prior performance or be trained by District staff and has a stringent quality assurance/quality control (QA/QC) program in place. Likewise, the analytical lab must also demonstrate prior performance in ultra-trace analysis, have a stringent QA/QC program (including inter-laboratory comparisons) and be capable of achieving desired method detection limits.

REPORTING REQUIREMENTS

The District shall submit an annual report to the permitting authority that summarizes the most recent data and compares them with the cumulative results from previous years. This report shall also evaluate assessment performance measures (i.e., action levels) outlined above.

APPENDIX B

Wetland Classification, Wetland Rapid Assessment Procedure Data Sheets and Uniform Mitigation Assessment Method Data Sheets for the C-43 West Reservoir Project

Wetland Classification based on the percentage of woody, herbaceous, native, and exotic/nuisance vegetation within wetland.

Category	Vegetation
1	Native Herbaceous Dominated (<20% Shrub)
2	Native Mixed Herbaceous (20% to 49% Shrub)
3	Native Shrub Dominated (<20% Herbaceous or Trees)
4	Native Mixed Shrub (>50% shrub) with at least 20% Herbaceous or Trees
5	Native Tree Dominated (<20% Herbaceous or Shrubs)
6	Native Mixed Trees (>50% trees) with at least 20% Herbaceous or Shrubs
7	Exotic/Nuisance Herbaceous Dominated (<20% Shrub) Exotic/Nuisance >50 % Exotic/Nuisance present
8	Exotic/Nuisance Mixed Herbaceous (20% to 49% Shrub) >50 % Exotic/Nuisance present
9	Exotic/Nuisance Shrub Dominated (<20% Herbaceous) >50 % Exotic/Nuisance present
10	Exotic/Nuisance Mixed Shrub (20% to 49% Herbaceous) >50 % Exotic/Nuisance present
11	Exotic/Nuisance Tree Dominated (<20% Herbaceous or Shrub) >50 % Exotic/Nuisance present
12	Exotic/Nuisance Mixed Tree (20% to 49% Herbaceous or Shrub) >50 % Exotic/Nuisance present
13	Open Water

Example using Herbaceous and Shrub mixes:

0-19% Shrub = Herb Dominated
20 – 49% Shrub = Mixed Herb/Shrub Dominated
50% – 79% Shrub = Mixed Shrub/Herb Dominated
80 – 100% Shrub = Shrub Dominated

PART I – Qualitative Description
(See Section 62-345.400, F.A.C.)

Site/Project Name	Application Number	Assessment Area Name or Number
Acceler8 Projects		Caloosahatchee Estuary- Tapegrass beds

FLUCCs code	Further classification (optional)	Impact or Mitigation Site?	Assessment Area Size
645 - Submerged aquaitc vegetation		mitigation	4,130 acres

Basin/Watershed Name/Number	Affected Waterbody (Class)	Special Classification (i.e OFW, AP, other local/state/federal designation of importance)
Caloosahatchee Estuary	Class III	OFW

Geographic relationship to and hydrologic connection with wetlands, other surface water, uplands

The Caloosahatchee Estuary is hydrologically connected to upsteam wetlands by the Caloosahatchee River (C-43) then Lake Okeechobee in which flows are regulated by the S235 (Lake O), the S-78 and S-79 pumping structures along the C-43 and to downstream wetlands through flows from the river into a delta type system then flowing primarily west to San Carlos Bay, Matlacha Pass and Pine Island Sound and south along the coast to Estero Bay and the Gulf of Mexico.

Assessment area description

The Caloosahatchee Estuary is a delta type system receiving freshwater inflows from the Caloosahatchee River (C-43). Due to regulatory releases in Lake Okeechobee, the increase in freshwat water flows and the lack of MFL attainment have severly affected the overall health of the estuarine system through extreme fluctuations in salinity levels between the wet and dry seasons, and thus, the reducing the spatial extent of seagrasses (*Halodule* sp. and *Thalassia* sp.) and oysters in the middle and lower estuary and tapegrass (*Vallisneria* sp.) in the upper estuary. Extreme flows are also associated with high nutrient loading to the estuary and have contributed to poor water quality conditions in the estuary.

Significant nearby features	Uniqueness (considering the relative rarity in relation to the regional landscape.)
Urban development along the north and south borders of the estuary, increases in urban runoff flowing into the estuary due to a lack of mangrove and upland buffers.	Tapegrass is a salt tolerant, freshwater, submerged plant that has limited distribution in the upper estuary. Tapegrass beds provide food and habitat for many other species and are considered an indicator of estuarine health where they occur.

Functions	Mitigation for previous permit/other historic use
Tapegrass beds in the upper estuary provide foraging habitat for wood storks and manatees and provide feeding, breeding, and escape cover for commercial and sport fisheries and shellfish, aquatic birds, invertebrates, and other estuarine species.	None

Anticipated Wildlife Utilization Based on Literature Review (List of species that are representative of the assessment area and reasonably expected to be found)	Anticipated Utilization by Listed Species (List species, their legal classification (E, T, SSC), type of use, and intensity of use of the assessment area)
Aquatic dependant birds (native and migratory), fish, benthic macroinvertebrates, manatees, small mammals, shellfish, phytoplankton, zooplankton	Wood Stork, Bald Eagle, West Indiatn manatee, Smalltooth Sawfish

Observed Evidence of Wildlife Utilization (List species directly observed, or other signs such as tracks, droppings, casings, nests, etc.):

Fish, shellfish, Smalltooth Sawfish, Wood Storks, Bald Eagles, Manatees, birds, invertebrates

Additional relevant factors:

The estuaries overall health is considered poor due to the high volume freshwater inflow decreasing salinity levels, lack of seagrasses and quality of the water.

Accelerit Projects		Caloosahatchee Estuary-Tapegrass beds
Impact or Mitigation	Assessment conducted by:	Assessment date:
Mitigation	SFWMD, USACE, USEPA, USFWS	6/13/2007

Scoring Guidance: The scoring of each indicator is based on what would be suitable for the type of wetland or surface water assessed	Optimal (10)	Moderate(7)	Minimal (4)	Not Present (0)
	Condition is optimal and fully supports wetland/surface water functions	Condition is less than optimal, but sufficient to maintain most wetland/surface water functions	Minimal level of support of wetland/surface water functions	Condition is insufficient to provide wetland/surface water functions

500(6)(a) Location and Landscape Support

w/o proj or current: 6 | with: 6

Existing Conditions: Assessment area extends from the Franklin Lock and Dam structure (i.e., S-79) west to the Cape Coral Bridge which is the existing and predicted expansion area for tapegrass(*Vallisneria* sp.). **With Project** The C-43 West Reservoir project will construct an above-ground reservoir on an existing 10,400-acre parcel primarily consisting of citrus operations.

500(6)(b)Water Environment (n/a for uplands)

w/o proj or current: 2 | with: 6

Existing Conditions: Assessment area receives basin runoff, which is primarily agricultural in the upper basin and urban in the lower basin, as well as a damaging regulatory releases from Lake Okeechobee. This results in poor water quality and too much fresh water during the wet season and not enough water during the dry season. **With project:** Wet season basin runoff and regulatory releases from Lake Okeechobee will be captured by and stored in the C-43 Reservoir to be released during the dry season to improve salinity conditions in the upper estuary. Augmenting dry season flows will directly benefit the tapegrass beds by maintaining flows at S-79 at a minimum of 450 cfs and preventing salinity levels to increase above the tolerance tapegrass for prolonged periods. No water quality concern is associated with the reservoir

500(6)(c)Community structure

1. Vegetation and/or
2. Benthic Community

w/o proj or current: 2 | with: 6

Existing Conditions: Reduced extent or even complete loss of existing tapegrass beds due to lack of freshwater releases at S-79 during drought conditions. **With project:** Tapegrass beds are expected to recover to 2000 conditions and expand as minimum flows of 450 cfs are maintained at S-79 and salinity conditions improve. Associated invertebrate and fish communities are also expected to return.

The Caloosahatchee Estuary is hydrologically connected to upsteam wetlands by the Caloosahatchee River (C-43) then Lake Okeechobee in which flows are regulated by the S235 (Lake O), the S-78 and S-79 pumping structures along the C-43 and to downstream wetlands through flows from the river into a delta type system then flowing primary south along the coast to Caloosahatchee Estuary, San Carlos Bay, Matlache Pass,

Assessment area description

The Caloosahatchee Estuary is a delta type system receiving freshwater inflows from the Caloosahatchee River (C-43). Due to regulatory releases in Lake Okeechobee, the increase in freshwater water flows and the lack of MFL attainment have severly affected the overall health of the estuarine system through decreases in salinity levels, the spatial extent of seagrasses (Halodule and Thallassia), water quality and depressed oyster numbers.

Significant nearby features	Uniqueness (considering the relative rarity in relation to the regional landscape.)
Urban development along the north and south borders of the estuary, increases in urban runoff flowing into the estuary due to a lack of mangrove and upland buffers.	Estuarine system supporting native populations of oysters, manatees, some remaining mangrove areas

Functions	Mitigation for previous permit/other historic use
Provides habitat and foraging for aquatic dependent birds, fish assemblages, manatees, oysters. Provides breeding, feeding, escape, and cover for commercial fisheries and shellfish	None

Anticipated Wildlife Utilization Based on Literature Review (List of species that are representative of the assessment area and reasonably expected to be found)	Anticipated Utilization by Listed Species (List species, their legal classification (E, T, SSC), type of use, and intensity of use of the assessment area)
Aquatic dependant birds (native and migratory), fish, benthic macroinvertebrates, manatees, small mammals, shellfish, wood storks, phytoplankton/zooplankton	Wood Stork, Bald Eagle, Manatee, Smalltooth Sawfish

Observed Evidence of Wildlife Utilization (List species directly observed, or other signs such as tracks, droppings, casings, nests, etc.):

Fish, Smalltooth Sawfish, Wood Storks, Bald Eagles, Manatees, birds, invertebrates, shellfish

Additional relevant factors:

The estuaries overall health is considered poor due to the high volume freshwater inflow decreasing salinity levels, lack of seagrasses and quality of the water.

EAA A-1, C-43 WSR, C-44 RSTA		Middle & Lower Caloosahatchee Estuary
Impact or Mitigation	**Assessment conducted by:**	**Assessment date:**
Mitigation	USACE, SFWMD, USEPA, USFWS	6/13/2007

Scoring Guidance	Optimal (10)	Moderate(7)	Minimal (4)	Not Present (0)
The scoring of each indicator is based on what would be suitable for the type of wetland or surface water assessed	Condition is optimal and fully supports wetland/surface water functions	Condition is less than optimal, but sufficient to maintain most wetland/surface waterfunctions	Minimal level of support of wetland/surface water functions	Condition is insufficient to provide wetland/surface water functions

.500(6)(a) Location and Landscape Support	w/o pres or current: 6	with: 6	**Existing Conditions:** Assessment area extends from Lake Okeechobee to the east to the Gulf of Mexico to the west. **With Project:** Berry Groves will be replaced with above-ground reservoir rather than remaining as agriculture.
.500(6)(b)Water Environment (n/a for uplands)	w/o pres or current: 2	with: 4	**Existing Conditions: Assessment area** receives basin runoff, primarily agricultural, as well as a damaging pulse discharges from Lake Okeechobee. This results in poor water quality and too much fresh water during the wet season. **With project:** Basin runoff will be captured by C-43 Reservoir to moderate releases and return salinity levels to more natural conditions. There is no water quality component associated with the C-43 Reservoir. EAA A-1 Reservoir will storage water from Lake Okeechobee reducing damaging pulse releases. Reductions in blue green algae and improved salinity envelope.
.500(6)(c)Community structure 1. Vegetation and/or 2. Benthic Community	w/o pres or current: 2	with: 4	**Existing Conditions:** Loss of SAV and oysters due to damaging freshwater releases. **With project:** Estuarine species will return as salinity levels return to normal resulting in return of SAV and oysters.

Score = sum of above scores/30 (if uplands, divide by 20)	
current or w/o pres: 0.33	with: 0.47

If preservation as mitigation,
Preservation adjustment factor =
Adjusted mitigation delta =

For impact assessment areas
FL = delta x acres =

Delta = [with-current]
0.14

If mitigation
Time lag (t-factor) = 1.23
Risk factor = 2

For mitigation assessment areas
RFG = delta/(t-factor x risk) = 693

Re: Fish and Wildlife Coordination Act (FWCA) Report comments for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project, Draft Integrated Project Implementation Report and Environmental Impact Statement, Hendry County

Dear Ms. Mazourek:

The Division of Habitat and Species Conservation (HSC) of the Florida Fish and Wildlife Conservation Commission (FWC) has coordinated an agency review of the U.S. Fish and Wildlife Service's draft Fish and Wildlife Coordination Act (FWCA) Report for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project, Draft Integrated Project Implementation Report. The following comments and recommendations are being provided in accordance with § 662(b) of the Fish and Wildlife Coordination Act, and is not intended as a determination of consistency or inconsistency for purposes of the Coastal Zone Management Act.

The FWC concurs with the findings of the draft FWCA Report, and adds recommendations regarding the use of the facility for recreational activities that are consistent with the primary goals and intent of the project.

Project Description

The proposed project is the first of two phases of a larger project to better manage water deliveries to the Caloosahatchee River (C-43) and estuary. This phase is limited to an above-ground reservoir that would discharge to the river, and would later be supplemented by aquifer storage recovery (ASR) wells. The project is located west of Lake Okeechobee and south of the Caloosahatchee Waterway in western Hendry County near the city of LaBelle. The proposed C-43 reservoir would contain approximately 160,000 acre-feet of water storage capacity on 10,492 acres of land. The reservoir would be divided into two cells contained by an embankment ranging between 27 and 38 feet above grade. An internal embankment 31 feet high would divide the cells of the reservoir, while a perimeter canal would encompass the entire reservoir. Numerous water-control structures would be constructed in conjunction with this project. The water-control structures would include an inflow pump station, a perimeter canal pump station, and multiple spillways and culverts.

Although a boat ramp is proposed, we understand that the South Florida Water Management District plans on monitoring the performance of the reservoir for 18 months before deciding on which forms of recreation will be allowed within the reservoir.

The proposed construction of the C-43 basin storage reservoir project is to provide an overall benefit to the Caloosahatchee River by providing additional control of the timing

and quantity of water releases from watershed runoff and Lake Okeechobee water releases. The reduction of large freshwater discharges into the Caloosahatchee River, especially during the seasonal dry periods, would assist in imitating historical water flow patterns and would reduce nutrient influx and moderate salinity regimes associated with flood waters. In addition, the C-43 basin reservoir would provide the potential to reduce flooding and potentially provide water supply storage.

Potentially Affected Resources

Project Site:

The South Florida Water Management District owns the majority of the property and currently leases it for citrus farming. Of the 10,492 acres, approximately 1,024 are jurisdictional wetlands, 899.59 acres of which are canals and ditches and 125 acres are pre-existing wetlands. The uplands that would be flooded currently provide marginal wildlife habitat, while the downstream freshwater and estuarine habitats could benefit greatly from the retention of freshwater that would otherwise flow to the river and estuary, often in large pulses that are seasonally ill timed. In addition, there may be opportunities within the completed reservoir to manage for freshwater fisheries, and improving habitats for many other wildlife species including songbirds, wading birds, waterfowl, and alligators.

Caloosahatchee River and Estuary:

Major changes resulting from this project should be beneficial to most existing Florida habitats within this project's influence. The primary beneficiary will be the estuarine communities associated with the Caloosahatchee River, including submerged aquatic vegetation and oyster (*Crassostrea virginica*) populations. Improvements in water quality and more appropriate salinity regimes should provide improved conditions for associated habitats and the wildlife resources dependent upon them.

West Indian (Florida) manatee:

Improved riverine and estuarine habitats as a result of this project would benefit the endangered West Indian (Florida) manatee (*Trichechus manatus*) through increases of stable submerged aquatic vegetation. Potential adverse affects could occur to the manatee during construction and operation of numerous water-control structures associated with the proposed reservoir. Reservoir waters have the potential to retain daily solar heating due to their deep depths. Discharge of reservoir waters that are warmer than the ambient waters of the C-43 canal could create conditions similar to manatee warm-water aggregation sites; however, suitable warm-water sites require consistent flows that create refuge areas with temperatures greater than 20°C during the winter months. If the water temperatures do not remain near 20°C or are inconsistent in their availability, the site becomes an attractive nuisance that increases the risk of cold season death for manatees that locate and use them.

Concerns and Recommendations

Caloosahatchee River and Estuary:

The Caloosahatchee estuary stands to be the primary beneficiary of this project. Storing water from Lake Okeechobee and runoff from the basin's watershed for future releases that are measured and seasonally appropriate could provide a boon to estuarine habitats. Riverine and estuarine habitats in this system have long suffered due to large freshwater releases that have caused significant shifts in salinity, large influxes of nutrients and increases in turbidity (Chamberlain and Doering 1998). Habitats most likely to benefit from this project include eelgrass (*Vallisneria americana*) beds located in the upper Caloosahatchee River, shoal grass (*Halodule wrightii*), manatee grass (*Syringodium filiforme*), turtle grass (*Thalassia testudinum*) and oyster reefs all located in the estuarine waters. The increased viability of these habitats should enhance the animal communities that use them as nursery and foraging habitat. While we understand that this will remain the primary objective of this project, we add our support that measured and seasonally appropriate freshwater releases from the C-43 basin storage reservoir remain the primary goal of this project while other worthy purposes for the reservoir (flood control, agriculture, and drinking water supply) remain secondary except for emergency purposes.

West Indian (Florida) Manatee:

The numerous water-control structures associated with this project could entrap, injure, or kill manatees that may encounter them. Manatees are frequent travelers of the Caloosahatchee waterway, traversing the entire waterway through Lake Okeechobee. Water-control structures have been responsible for hundreds of manatee deaths (Fish and Wildlife Research Institute's manatee mortality database); however, with the appropriate safeguards, these structures can be rendered relatively benign. The most efficient way to achieve this goal is to prevent manatee ingress and egress to the C-43 reservoir by constructing manatee barriers at all access points to the perimeter canal and reservoir.

During the winter months manatees are dependent on warm-water refuges to survive during periods of cold air and water temperatures (O'Shea et al. 1985; Hartman 1974). Water temperatures greater than 20°C are needed for survival; however, water temperatures that inconsistently reach 20°C can create an attractive nuisance that may jeopardize the health of manatees (Worthy et al. 2000; Laist and Reynolds 2005).

Recommendations:

- Barriers should be used at all ingress structures to the perimeter canal to eliminate manatee access to the perimeter canal and reservoir.
- Standard manatee construction conditions should be used in all waters accessible by manatees during the construction of this project.
- We highly recommend using the information provided in the document entitled "Guidelines for Manatee Conservation during Comprehensive Everglades Restoration Plan Implementation."

- We recommend that manatee access to the Towsend Canal be eliminated to reduce the potential for manatees to be attracted to the warm-water discharge that may be created by water releases from the reservoir into the Towsend Canal.
- If manatee access to the Towsend Canal is not eliminated, then during the winter season (November 1 through March 31) we recommend that: 1) water releases from the C-43 reservoir be monitored hourly for temperature near the point of discharge (S-11) with data retrieved daily; 2) manatee visual surveys should be conducted daily in the Townsend canal to detect any shifts in manatee winter-use patterns and movements into the area. Observations should be conducted in four 10-minute intervals over a 2-hour period each morning; 3) during the winter season, if water released from the reservoir creates a thermal plume that is greater than 20°C, or if manatees are observed using the site of the reservoir discharge on two or more consecutive days, then we request that the FWC-Imperiled Species Management section (850-922-4330) work with the U.S. Fish and Wildlife Service, U.S. Army Corps of Engineers, and South Florida Water Management District to resolve the issue of potential adverse impacts to manatees from intermittent warm-water releases from the C-43 reservoir.

Although not part of this portion of the C-43 Basin Storage Reservoir project, aquifer storage recovery (ASR) wells are a proposed component of the overall project in a subsequent phase. We believe that the ASR component could present similar issues related to thermal effects. ASR wells at this site have a projected capacity to store an additional 220 million gallons of water. Limited information is available at this time but monitoring suggests that water from some ASR wells has been retrieved at temperatures greater than 20°C. Reservoir waters discharged at greater than ambient water temperature that are near 20°C could be attractive to manatees during the winter months. Discharge waters that are inconsistent or insufficient in temperature could result in cold stress-related manatee mortality.

Recommendation:

- FWC requests that the U.S. Army Corps of Engineers and the South Florida Water Management District keep FWC apprised of the results of ongoing ASR studies and monitoring efforts so future manatee-related issues can be identified, refined, and resolved proactively prior to the implementation of ASR technology.

Recreation:

The proposed C-43 reservoir project would create over 10,000 acres of open water with depths reaching 25 feet. Although this project's primary purpose is water storage for the benefit of the downstream estuary, some form of recreation is contemplated by the proposed project. The FWC encourages public access to areas that can allow opportunities for recreational pursuits, whenever compatible. The C-43 reservoir has the potential to be managed for public activities that include alligator and waterfowl hunting, fishing, hiking, and wildlife observation.

Specifically, we support allowing waterfowl hunting and fishing as recreational opportunities that should be allowed on the C-43 reservoir. There is a very high public

demand for waterfowl hunting and angling in the southern portion of peninsular Florida, and we believe that use of this area for these recreational purposes would meet all criteria of recreational features proposed on CERP projects:

1. Compatible with the authorized project purposes
2. Affordable within project limits
3. Easily operated and maintained

Allowing the above opportunities on the reservoir should add little to no extra cost to the project, as a boat ramp is currently a proposed Acceler8 component of the project. We recommend that the South Florida Water Management District work with our staff during the assessment period to refine what types of activities could be accommodated. We would like to operate and maintain waterfowl hunting cooperatively with the South Florida Water Management District and others, as appropriate.

Recommendations:

- The use of soil cement for construction of the reservoir embankments is not conducive to the establishment and growth of submerged aquatic vegetation, an attractant for waterfowl. We recommend the placement of a natural substrate within the interior of the reservoir to allow for vegetation growth, which will increase the wildlife habitat value and assist with improvements in water quality through the reduction of nutrients.
- We recommend planning for recreational alligator hunting on the C-43 Reservoir in the future.
- Project plans should provide roads and boat ramps allowing adequate public access.
- Portions of the reservoir footprint have been in citrus production. We recommend that these areas not be cleared prior to reservoir flooding. Citrus is fairly durable wood and should not degrade rapidly, thereby creating long-lasting fish and wildlife habitat. A similar recommendation provided a cost savings during the construction planning of the Site 1 impoundment.
- Minimizing dry outs would benefit wildlife habitat through the reduction of nutrients and re-suspension of contaminants while providing for a stable aquatic community.

Conclusion

The FWC concurs with the findings of the draft FWCA Report, and we fully support the construction and operation of the proposed reservoir for the benefit of the Caloosahatchee River and estuarine habitats. Recognizing this priority, we also recommend that completed public works projects be made available to the public for recreational opportunities that are compatible with the primary intended purposes. The C-43 reservoir project appears to offer a variety of potential recreational pursuits including waterfowl and alligator hunting, fishing, hiking and wildlife observation. The FWC is willing to assist in achieving these multiple-use goals.

If you or your staff would like to coordinate further on the recommendations contained in this report, please contact me at 850-410-5272 or email me at MaryAnn.Poole@MyFWC.com, and I will be glade to help make the necessary

arrangements. If your staff has any specific technical questions regarding our comments, please contact Ron Mezich at 850-922-4330; email ron.mezich@myfwc.com.

Sincerely,

Mary Ann Poole

B.0 NEPA INFORMATION

The National Environmental Policy Act (NEPA) of 1969, as amended, 42 U.S.C. 4321, et seq. P.L. 91-109 establishes the process requirement for this project. NEPA establishes the Federal decision making process and requires documentation of a comprehensive evaluation of all potential impacts on the human environment. The NEPA process is fully integrated with the six-step planning process in accordance with USACE planning guidelines.

In compliance with the National Environmental Policy Act (NEPA), the Caloosahatchee River (C-43) West Basin Storage Reservoir project initiated a scoping process in early 2002. An initial scoping meeting was held in February/ March of 2002, with a follow-up scoping meeting held on May 1, 2003. Following this meeting, a letter was sent to federal, state, and local stakeholders requesting their assistance in identifying the extent of significant issues to be addressed in this study. A public meeting was held on February 28, 2002 to specifically identify critical fish and wildlife habitat and any threatened or endangered species that may be within the project area or affected by the activities of the project.

Once it was determined that an Environmental Impact Statement (EIS) would be necessary for this project, a Notice of Intent (NOI) to prepare a draft Environmental Impact Statement (EIS) was published in the Federal Register in March 2003. A NEPA scoping letter was sent to federal, state, and local stakeholders, including those who had earlier expressed an interest in this project. A public meeting, identified in the scoping letter, was held on May 1, 2003 to ensure continued public involvement. This meeting was recorded and all issues identified were noted and reviewed. Comments on the scoping letter received from the federal, state, and local entities were collected and shared with the Study team. Those comments are included in this Annex.

Outreach efforts have continued throughout the project. A fact sheet was created for the project to make the information easily presentable to many members of the public. Because of the large study area, as well as the significant potential size of the project, a concerted effort was made to ensure continued public involvement throughout the planning process. The project team members held stakeholder meetings with interest groups including environmental, recreation, and agriculture. Elected officials in the project area were also given a presentation and asked to submit issues and suggestions. The issues raised in all of these meetings were recorded and considered during the planning process. Environmental justice issues were examined to ascertain that negative effects will be avoided or minimized.

B.1 INVENTORY OF PUBLIC CONCERNS FOR THE CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR

An integral component of the identification of problems and opportunities is an understanding of the public's concerns (USACE 1999). Public workshops were conducted early in the planning process for this project in order to gather public input and to document public concerns related to the problems, needs, and opportunities within the Caloosahatchee River watershed. Numerous presentations to public groups were conducted, including Lee, Collier, Hendry and Glades Counties, the Cities of LaBelle, Moore Haven, and Clewiston, local agencies, agricultural organizations, civic groups, business groups, clubs and neighborhood organizations.

In February of 2001 and 2002, representatives from the Corps and the SFWMD conducted two workshops/public meetings with various groups and individuals to provide a brief overview of the process for development of a Project Implementation Report (PIR) for the Caloosahatchee (C-43) West Basin Storage Reservoir project and to obtain an understanding of the public's concerns and issues. The public meetings were held in LaBelle, Florida at the Hendry County Extension Service Building on February 26, 2001 and at the LaBelle Civic Center on February 28, 2002. Approximately 35 people attend the meeting on the 26th of February 2001 and approximately 35 people attended the meeting on the 28th of February 2002. Information collected at these meetings was used to help inform the plan formulation process.

In addition to the earlier meetings, a NEPA scoping letter was sent out in March of 2003. A public scoping meeting was subsequently held in LaBelle on May 1, 2003. By this time the team had already completed some potential site identification and screening. The public was updated on the progress and status of the project to that point. Meetings were also held in the spring of 2003 with various stakeholders including recreational interests, agricultural interests, and local policy makers.

A NOI to prepare a draft EIS for the Caloosahatchee River (C-43) West Basin Storage Reservoir project was published in the Federal Register on March 28, 2003. A scoping letter describing the project objectives and array of alternatives was mailed on 18 March 2003, to Federal, State, and local agencies, Native American Tribes, private organizations, and other interested parties to solicit their views, comments, and information about resources, study objectives, alternatives, and important features within the study area. Comments received were reviewed and incorporated in project planning. A Notice of Availability of the draft PIR/EIS was published in the Federal Register on 27 April 2007 when this document was released for public and agency review. Comments received were addressed and are summarized along with responses in a matrix in section B.4 of this Annex.

Table B-1 outlines the public concerns that were brought to our attention through written correspondence, phone calls, and public meetings. The right hand column lists the responses to the comments.

TABLE B-1: PUBLIC COMMENTS AND HOW THEY WERE ADDRESSED

Public Comment - Issue, Problem, or Opportunity	Action taken
Health of the estuary	Main purpose/objective of study
Fish health and abundance for commercial and recreational uses	Estuarine indicators used to identify benefits and impacts of project
Water quality	Water quality analysis performed on final alternatives
Economic impacts	Socioeconomic analysis
Tourism	Healthier estuary will promote tourism
Water supply	Water reservation studies as part of project assurances analyses
Flood control	Modeling of alternatives to ensure no harm
Wildlife health and abundance	Ecological performance measures
Cost of project	Cost estimates in PIR; part of alternative screening; addressed through cost effectiveness and incremental cost analyses
Questions on ASR	Separate study – see ASR pilot project Draft PIR/EIS
Dredging of oxbows	Being accomplished by other projects
Use of water stored in reservoir	Water reservations study as part of project assurances analyses; Draft operating manual will accompany PIR
Drainage problems in basin	Not a project purpose – will recommend to SWFFS
Recreational opportunities	Recreation plan included in PIR
Loss of tax base in Hendry County	A large number of sites were considered for the study – an objective screening process was used to narrow these sites
Concern that cost will outweigh benefits	Cost effectiveness/ incremental cost analyses will be performed to justify costs
Water allocation concerns	Water reservation studies will be completed
Water level on the river	Project objective to deliver a more consistent water flow to estuary, which would result in a more consistent water level

Public Comment - Issue, Problem, or Opportunity	Action taken
Littoral zone around reservoir to promote fishing and fish habitat	There may be some secondary benefits due to littoral zone, but reservoir is not designed for littoral benefits due to extreme fluctuations in water depth
Loss of Highway 80 property for development	The reservoir was sited a significant distance from Highway 80 so that development will not be hindered.
Suggest deeper reservoir	Geotechnical studies were conducted to determine appropriate maximum depths
Visual aesthetics –high levee is not conducive to visual enjoyment	Due to the soils, aquifers, and topography, high levees were not able to be avoided
Water loss due to evaporation	ASRs are envisioned to complement the reservoir(s), and they will decrease total loss to evaporation
Lake Hicpochee for natural area restoration	Lake Hicpochee is being considered as an alternative for natural area restoration in Part II of the project which is scheduled to begin in mid-late 2007.
Hurricane evacuation route/safety issues	A meeting was held to come up with safety standards for all CERP projects
Exotic/invasive plant control	Other CERP projects are addressing this issue; proper procedures will be used to minimize this problem during construction
Active recreation opportunities (baseball fields, playgrounds, etc.)	Recreation opportunities are outlined in the Recreation Plan
"Watchable" wildlife areas	These are part of the Recreation Plan.
Recreation and restoration as opposing uses	Restoration is the main purpose of this study, so restoration will not be sacrificed for recreational opportunities. However, recreation will be considered wherever it is viable and applicable trade-offs displayed.

B.2 FISH AND WILDLIFE COORDINATION

The central objective of the Fish and Wildlife Coordination Act (FWCA) is to allow for equal consideration of wildlife resources. Transfer funds have been made available to the USFWS in order to participate in team meetings and workshops scheduled in conjunction with the Corps' planning, implementation, and evaluation process. Funding has also been provided for the USFWS to conduct surveys and investigations necessary to determine impacts of the Caloosahatchee River (C-43) West Basin Storage Reservoir project on wildlife resources and to make recommendations to the Corps on measures to prevent loss of or damage to wildlife resources. Recommendations for optimizing opportunities related to the conservation and enhancement of fish and wildlife resources have been provided through the submittal of Planning Aid Letters dated 13 August 2003 and 29 March 2005. The USFWS also identified critical fish and wildlife habitat and threatened and endangered species in a letter dated 11 April 2002, and provided scoping comments in a letter dated 10 June 2003.

There has been verbal coordination with the USFWS in 2004, 2005, and 2006. The Corps asked for formal consultation with the USFWS due to potential adverse impacts to the endangered Florida panther (*Felis concolor coryi*), threatened Audubon's crested caracara (*Polyborus plancus audubonii*), and threatened eastern indigo snake (*Drymarchon corais couperi*). This letter was sent by the Corps on January 10, 2007. The USFWS requested some additional information which was provided. .

A Final Fish and Wildlife Coordination Act Report (FCAR) report dated July 2007 has been prepared and is included in Annex A. A Biological Opinion (BO) dated July 2007 is also included in Annex A. Details of the Section 7 ESA consultation can be found in the BO.

Florida Fish and Wildlife Conservation Commission (FFWCC) has also taken part in project meetings and has been an important part of the technical sub-team process of evaluating components, determining benefits and producing performance measures for the alternatives. Additionally, FWC provided a Scoping Letter dated 10 June 2003 and comments on the dPIR dated June 8, 2007 .

B.3 OTHER AGENCY COORDINATION

The Caloosahatchee River (C-43) West Basin Storage Reservoir project team has been an interdisciplinary, multi-agency group of local, state, and Federal agency representatives (USACE, USFWS, USEPA, USGS, FFWCC, FDEP, Hendry county, and Lee county). Coordination was achieved through staff member participation on the PDT and sub-teams as necessary. The Corps, SFWMD, Natural Resource Conservation Service, U.S. Fish and Wildlife Service, Florida

Department of Environmental Protection, National Marine Fisheries Service, Florida Fish and Wildlife Conservation Commission, and Lee and Hendry counties have all been involved in the project as it has developed. The issues and concerns of these agencies and governments were continually a consideration of the project team. A compilation of all agency correspondence is included in this Annex.

Special Project/Enforcement Branch
SAJ-2005-5958(IP-TKW)

David Bernhart
Assistant Regional Administrator
Protected Resources
National Marine Fisheries Service
263 13th Avenue South
St. Petersburg, FL 33701

Dear Mr. Bernhart:

Pursuant to the Endangered Species Act (ESA), below is our determination of effects for potentially affected federally threatened and endangered species for the C-43 West Storage Reservoir Project located in Hendry County, Florida.

Scheda Ecological Associates, Inc. has prepared a Biological Assessment (BA) for the project on behalf of the South Florida Water Management District (SFWMD). The BA includes the information described in 50 CFR §402.12. This letter serves to transmit the BA and effects determination for the project. Also included with this letter is a copy of the permit application which further describes the project. The U.S. Army Corps of Engineers (Corps) has determined that the proposed project would cause the following effects on federally listed species:

No affect: The Corps has determined the proposed project will not affect threatened bald eagle (*Haliaeetus leucocephalus*), threatened Florida scrub jay (*Aphelocoma coerulescens*), endangered Florida grasshopper sparrow (*Ammodramus savannarum floridanus*), endangered red cockaded woodpecker (*Picoides borealis*), endangered Okeechobee gourd (*Cucurbita okeechobeensis*) or threatened Florida scrub-jay (*Aphelocoma coerulescens*).

May affect not likely to adversely affect: The Corps has determined the project may affect but is not likely to adversely affect the endangered smalltooth sawfish (*Pristis pectinata*), endangered American crocodile (*Crocodylus acutus*), endangered green sea turtle (*Chelonia mydas*), endangered leatherback sea turtle (*Dermochelys coriacea*), endangered Kemp's ridley sea turtle (*Lepiodchelys kempii*), endangered hawksbill turtle

-2-

(*Eretmochelys imbricata*), threatened loggerhead sea turtle (*Caretta caretta*), endangered Everglade snail kite (*Rostrhamus sociabilis*), threatened piping plover (*Charadrius melodus*), endangered wood stork (*Mycteria Americana*), and endangered West Indian manatee (*Trichechus manatus latirostris*).

May adversely affect: The Corps has determined the project may adversely affect the endangered Florida panther (*Felis concolor coryi*), threatened Audubon's crested caracara (*Polyborus plancus audubonii*), and threatened eastern indigo snake (*Drymarchon corais couperi*).

It should be noted that the SFWMD has restricted the use of copper on the site and plans to conduct all required corrective actions as recommended by the U.S. Fish and Wildlife Service prior to commencement of construction. Therefore, the Corps' determination for the snail kite in this cover letter supersedes the determination for the snail kite as specified in the BA.

The Corps has requested the U.S. Fish and Wildlife Service initiate formal consultation for the Florida panther, Audubon's crested caracara, and eastern indigo snake. Additionally, we request your written concurrence with our "may affect not likely to adversely affect" determination for those species that are within the purview of the National Marine Fisheries Service. If you need additional information or have any questions, please Tori White at the letterhead address, at 561-472-8888 or by e-mail at tori.white@saj02.usace.army.mil.

Sincerely,

for David S. Hobbie
Chief, Regulatory Division

Planning Division
Environmental Branch

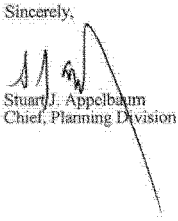
SEP 0 1 2006

Mr. Jerry Brooks
Florida Dept. of Environmental Protection
Division of Water Resource Management
Twin Towers Office Building
2600 Blair Stone Road
Tallahassee, Florida 32399-2400

Dear Mr. Brooks:

In accordance with regulations pertaining to the National Environmental Policy Act (Title 40 of the Code of Federal Regulations, part 1501.6), I am formally inviting your agency to become a cooperating agency for an Environmental Impact Statement (EIS) on the C-43 Basin Storage Reservoir project. The goal of the C-43 Basin Storage Reservoir Project is to improve the quality, quantity, timing and distribution of flows in the Caloosahatchee River and Estuary to restore ecosystem function. The plan formulation for this project focused on reaffirming that above-ground storage reservoirs in the C-43 Basin continue to meet the goals, objectives, and purposes for the project as described in the Restudy. Please see the enclosed figures of the Caloosahatchee basin as well as the proposed site of the Part I-Phase I portion of this project (C-43 West Storage Reservoir).

Please note that cooperating agency status involves actions and responsibilities beyond that normally associated with a commenting or permitting agency. We appreciate and acknowledge your participation and cooperation in the project formulation to this point, and look forward to your continued cooperation in the preparation of the Draft Project Implementation Report / Environmental Impact Statement.



The formulation of the project, alternatives, and mitigation have been in accordance with Engineer Regulation ER 1105-2-100 and have fully considered a range of environmental, economic, and social factors. As a cooperating agency, you must fully consider the views, needs, and benefits of competing interests.

No cooperating agency will have "veto" over the selection of the project plan, alternatives, or mitigation measures. Under your status as a commenting agency, you may recommend actions not ultimately adopted or implemented by the lead agency. You may also impose requirements to the extent allowed under your legal authority as a permitting agency. Conflict with the lead agency may be resolved through mediation, placing a dissenting opinion in the EIS, withdrawing your cooperating agency status, or the Lead agency pursuing an EIS without you as a cooperating agency. For additional information see the enclosed "Rights and Responsibilities of Lead and Cooperating Agencies" (Forty Most Asked Questions Concerning CEQ's National Environmental Policy Act Regulations, Council on Environmental Quality, 1981).

-2-

Please indicate whether you accept this invitation to become a cooperating agency (as described above) within 30 days of the date of this letter. If you have any questions, please contact Susan Conner at 904-232-1782.

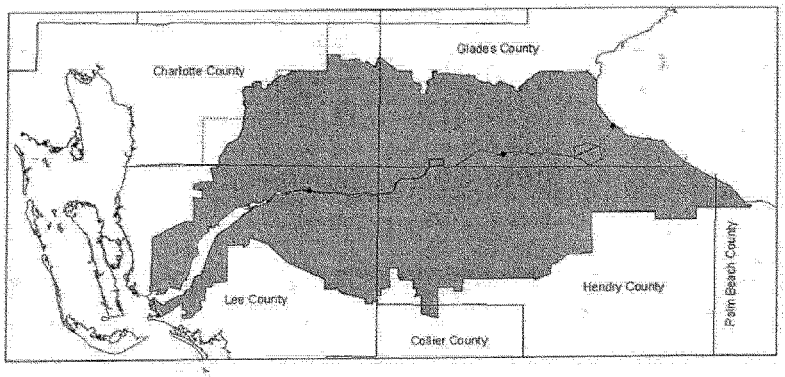
Sincerely,

Stuart J. Appelbaum
Chief, Planning Division

Enclosure

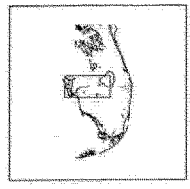
Excerpt: Forty Most Asked Questions Concerning CEQ's National Environmental Policy Act Regulations (Council on Environmental Quality, 1981)

14a. **Rights and Responsibilities of Lead and Cooperating Agencies.** What are the respective rights and responsibilities of lead and cooperating agencies? What letters and memoranda must be prepared?
A. After a lead agency has been designated (Sec. 1501.5), that agency has the responsibility to solicit cooperation from other federal agencies that have jurisdiction by law or special expertise on any environmental issue that should be addressed in the EIS being prepared. Where appropriate, the lead agency should seek the cooperation of state or local agencies of similar qualifications. When the proposal may affect an Indian reservation, the agency should consult with the Indian tribe. Section 1508.5. The request for cooperation should come at the earliest possible time in the NEPA process. After discussions with the candidate cooperating agencies, the lead agency and the cooperating agencies are to determine by letter or by memorandum which agencies will undertake cooperating responsibilities. To the extent possible at this stage, responsibilities for specific issues should be assigned. The allocation of responsibilities will be completed during scoping. Section 1501.7(a)(4).
Cooperating agencies must assume responsibility for the development of information and the preparation of environmental analyses at the request of the lead agency. Section 1501.6(b)(3). Cooperating agencies are now required by Section 1501.6 to devote staff resources that were normally primarily used to critique or comment on the Draft EIS after its preparation, much earlier in the NEPA process -- primarily at the scoping and Draft EIS preparation stages. If a cooperating agency determines that its resource limitations preclude any involvement, or the degree of involvement (amount of work) requested by the lead agency, it must so inform the lead agency in writing and submit a copy of this correspondence to the Council. Section 1501.6(c).
In other words, the potential cooperating agency must decide early if it is able to devote any of its resources to a particular proposal. For this reason the regulation states that an agency may reply to a request for cooperation that "other program commitments preclude any involvement or the degree of involvement requested in the action that is the subject of the environmental impact statement." (Emphasis added). The regulation refers to the "action," rather than to the EIS, to clarify that the agency is taking itself out of all phases of the federal action, not just draft EIS preparation. This means that the agency has determined that it cannot be involved in the later stages of EIS review and comment, as well as decisionmaking on the proposed action. For this reason, cooperating agencies with jurisdiction by law (those which have permitting or other approval authority) cannot opt out entirely of the duty to cooperate on the EIS. See also Question 15, relating specifically to the responsibility of EPA.

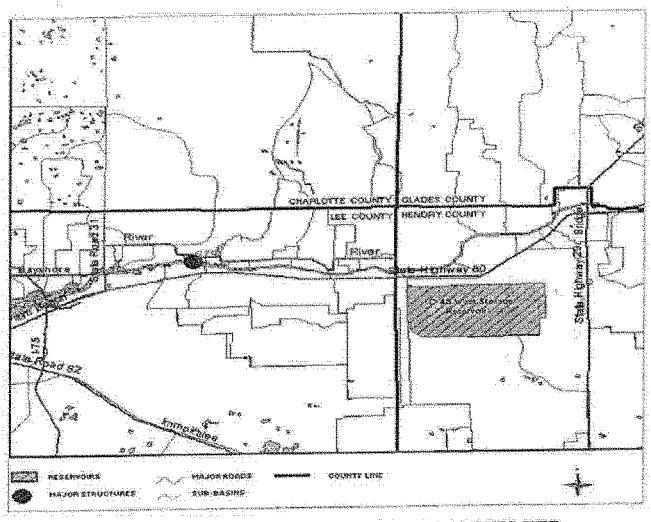


14b. How are **disputes resolved between lead and cooperating agencies** concerning the scope and level of detail of analysis and the quality of data in impact statements?
A. Such disputes are resolved by the agencies themselves. A lead agency, of course, has the ultimate responsibility for the content of an EIS. But it is supposed to use the environmental analysis and recommendations of cooperating agencies with jurisdiction by law or special expertise to the maximum extent possible, consistent with its own responsibilities as lead agency. Section 1501.6(a)(2).
If the lead agency leaves out a significant issue or ignores the advice and expertise of the cooperating agency, the EIS may be found later to be inadequate. Similarly, where cooperating agencies have their own decisions to make and they intend to adopt the environmental impact statement and base their decisions on it, one document should include all of the information necessary for the decisions by the cooperating agencies.

Otherwise they may be forced to duplicate the EIS process by issuing a new, more complete EIS or Supplemental EIS, even though the original EIS could have sufficed if it had been properly done at the outset. Thus, both lead and cooperating agencies have a stake in producing a document of good quality. Cooperating agencies also have a duty to participate fully in the scoping process to ensure that the appropriate range of issues is determined early in the EIS process.
Because the EIS is not the Record of Decision, but instead constitutes the information and analysis on which to base a decision, disagreements about conclusions to be drawn from the EIS need not inhibit agencies from issuing a joint document, or adopting another agency's EIS, if the analysis is adequate. Thus, if each agency has its own "preferred alternative," both can be identified in the EIS. Similarly, a cooperating agency with jurisdiction by law may determine in its own ROD that alternative A is the environmentally preferable action, even though the lead agency has decided in its separate ROD that Alternative B is environmentally preferable.



14c. What are the specific responsibilities of federal and state **cooperating agencies to review draft EISs**?
A. Cooperating agencies (i.e., agencies with jurisdiction by law or special expertise) and agencies that are authorized to develop or enforce environmental standards, must comment on environmental impact statements within their jurisdiction, expertise or authority. Sections 1503.2, 1508.5. If a cooperating agency is satisfied that its views are adequately reflected in the environmental impact statement, it should simply comment accordingly. Conversely, if the cooperating agency determines that a draft EIS is incomplete, inadequate or inaccurate, or it has other comments, it should promptly make such comments, conforming to the requirements of specificity in section 1503.3.



14d. How is the lead agency to treat the comments of another agency with jurisdiction by law or special expertise which has **failed or refused to cooperate or participate in scoping or EIS preparation**?
A. A lead agency has the responsibility to respond to all substantive comments raising significant issues regarding a draft EIS. Section 1503.4. However, cooperating agencies are generally under an obligation to raise issues or otherwise participate in the EIS process during scoping and EIS preparation if they reasonably can do so. In practical terms, if a cooperating agency fails to cooperate at the outset, such as during scoping, it will find that its comments at a later stage will not be as persuasive to the lead agency.

MAR 18 2003

TO WHOM IT MAY CONCERN:

The U.S. Army Corps of Engineers (Corps), Jacksonville District, is requesting your assistance in gathering information that will help define issues and concerns to be addressed in a National Environmental Policy Act (NEPA) document being prepared for the C-43 Basin Storage Reservoir adjacent to the Caloosahatchee River in Hendry, Lee, Charlotte, or Glades County. The project is part of the Comprehensive Everglades Restoration Project (CERP) authorized by the Water Resources Development Act of 2000. The Notice of Intent (NOI) to prepare an Environmental Impact Statement (EIS), which includes detailed project information, is enclosed.

This letter initiates the public scoping process under the NEPA. We welcome your views, comments, concerns and information about resources and important features within the area. An initial scoping letter was sent in February 2002, to help gather general issues related to this project. A public meeting was held following that letter. Because it is a long process, continued public participation is a normal part of the NEPA schedule. Therefore, we will be holding a public meeting to take additional questions and suggestions on significant issues and alternative plans. The meeting will be held as follows:

DATE/TIME: Thursday, May 1, 2003, 7:00 p.m.

PLACE: Dallas B. Townsend Agricultural Center
Hendry County Agriculture Extension Service
1085 Pratt Boulevard
LaBelle, Florida

If you know others who may wish to comment on this activity, please advise them of this request for public comments. Letters of comment or inquiry should be directed to the letterhead

-2-

address to the attention of Planning Division, Environmental Branch, South Florida Section, and be received by this office within 30 days of the date of this letter. If you have any questions, please contact Mrs. Susan Conner by telephone at 904-232-1782, or by electronic mail at susan.l.conner@usace.army.mil.

Sincerely,

James C. Duck
Chief, Planning Division

DEPARTMENT OF DEFENSE

Department of the Army; Corps of Engineers

Intent to Prepare a Draft Environmental Impact Statement for the C-43 Basin Storage Reservoir Project adjacent to the Caloosahatchee River, Hendry, Glades, Charlotte, or Lee County, FL

AGENCY: Department of the Army, U.S. Army Corps of Engineers, DOD.

ACTION: Notice of intent.

SUMMARY: The Jacksonville District, U.S. Army Corps of Engineers (Corps), intends to prepare an integrated Project Implementation Report and Draft Environmental Impact Statement (DEIS) for the C-43 Basin Storage Reservoir Project, Part 1. The study is a cooperative effort between the Corps and the South Florida Water Management District (SFWMD), which is also a cooperating agency for this DEIS. One of the recommendations of the final report of the Central & South Florida (C&SF) Comprehensive Review Study (Restudy) was the C-43 Basin Storage Reservoir Project. This project includes the construction of an approximately 160,000 acre-feet storage area within the Caloosahatchee Basin to capture and store stormwater runoff and water releases from Lake Okeechobee. Stored water would be used to meet the environmental demands of the Caloosahatchee River and Estuary and urban and agricultural demand as able.

1

DATES: A public meeting is scheduled for May 1, 2003, 7 p.m. in Hendry County at the Dallas B. Townsend Agricultural Center, 1085 Pratt Boulevard, LaBelle, FL.

FOR FURTHER INFORMATION CONTACT: Mrs. Susan Conner, U.S. Army Corps of Engineers, Planning Division, Environmental Branch, P.O. Box 4970, Jacksonville, FL, 32232-0019, or by telephone at 904-232-1782.

SUPPLEMENTARY INFORMATION:

a. Authorization: Section 601 of the Water Resources Development Act of 2000 authorized a framework and guide for modifications to the C&SF Project to restore the south Florida ecosystem and to provide for the other water-related needs of the region, including the C-43 Basin Storage Reservoir Project.

b. Project Scope: The purpose of this project is to capture C-43 Basin runoff and releases from Lake Okeechobee. These facilities will be designed for water supply benefits, some flood attenuation, to provide environmental water supply deliveries to the Caloosahatchee Estuary, and water quality benefits to reduce salinity and nutrient impacts of runoff to the estuary. It is assumed that, depending upon the location of the facility and pollutant loading conditions in the watershed, the facility could be designed to achieve significant water quality improvements, consistent with appropriate pollution load reduction targets. The project as proposed will include the construction of an above-ground reservoir(s) with a total capacity of approximately 160,000 acre-feet, located in the C-43 Basin in Hendry, Glades, Charlotte, or Lee Counties. Water levels could fluctuate up to 8 feet above grade.

c. Preliminary Alternatives: Formulation of alternative plans will involve the selection of the most suitable site or sites for a reservoir, depth and configurations of the

impoundment(s), investigation of intake and discharge sites, and investigation of opportunities in configuration designs to provide significant water quality improvements for the project.

The Environmental Impact Statement (EIS) evaluation of the project will include an evaluation of adverse environmental impacts, including but not limited to, water quality, socio-economic, archeological and biological. In addition to adverse impacts, the evaluation will also focus on how well the plans perform with regard to specific ecological and other performance measures.

d. Issues: The EIS will consider impacts on water quality, ecosystem habitat, threatened and endangered species, health and safety, aesthetics and recreation, fish and wildlife resources, cultural resources, water availability, flood protection, and other potential impacts identified through scoping, public involvement, and interagency coordination.

e. Scoping: Initial project scoping began in February 2002 at a public meeting in Hendry County. A scoping letter was issued in February 2002 to interested parties inviting all interested parties and government agencies to participate in the scoping process by identifying any additional concerns on issues, studies needed, alternatives, procedures, and other matters related to the scoping process. A NEPA scoping letter will be issued in March 2003, along with this notice. A public meeting is scheduled for May 1, 2003 (see DATES above).

f. Public Involvement: We invite the participation of affected Federal, state and local agencies, affected Indian tribes, and other interested private organizations and parties.

3

g. Coordination: The proposed action is being coordinated with the U.S. Fish and Wildlife Service (FWS) and the National Marine Fisheries Service under Section 7 of the Endangered Species Act, with the FWS under the Fish and Wildlife Coordination Act, and with the State Historic Preservation Officer.

h. Other Environmental Review and Consultation: The proposed action would involve evaluation for compliance with guidelines pursuant to Section 404 (b) of the Clean Water Act; application (to the State of Florida) for Water Quality Certification pursuant to Section 401 of the Clean Water Act; certification of state lands, easements and right of ways, and determination of Coastal Zone Management Act consistency.

i. Agency Role: As cooperation agency, non-Federal sponsor, and leading local expert, SFWMD will provide information and assistance on the resources to be impacted and alternatives.

j. DEIS Preparation: The integrated Project Implementation Report (PIR) including a DEIS, is currently estimated for publication in September 2004.

Re: DHR Project File No. 2006-07757 / Received by DHR: August 30, 2006
Cultural Resource Assessment Survey of the C-43 Reservoir Addition Project Area, Hendry County, Florida

Dear Chief Burns:

Our office received and reviewed the above referenced mitigation report in accordance with Section 106 of the *National Historic Preservation Act of 1966* (Public Law 89-665), as amended in 1992, and *36 C.F.R., Part 800: Protection of Historic Properties*, and Chapters 267 and 373, *Florida Statutes*, for assessment of possible adverse impact to cultural resources (any prehistoric or historic district, site, building, structure, or object) listed, or eligible for listing, in the *National Register of Historic Places (NRHP)*, or otherwise of historical, architectural or archaeological value.

In April 2006, Janus Research conducted an archaeological and historical survey of the C-43 Reservoir Project on behalf of South Florida Water Management District. Janus Research located one archaeological site (8HN129) during the course of the investigation and found the site to be potentially eligible for listing in the *NRHP*.

It is the opinion of Janus Research that since site 8HN129 is located well outside of the proposed project footprint, the activities will have no adverse effect on the potentially eligible site. Janus Research recommended no further archaeological or historical investigation of the project area.

Based on the information provided, this office concurs with these determinations and finds the submitted report complete and sufficient under 1A-46, *Florida Administrative Code*.

If you have any questions concerning our comments, please contact Scott Sorset, Historic Sites Specialist, by phone at (850) 245-6333, or by electronic mail at srsorset@dos.state.fl.us. Your continued interest in protecting Florida's historic properties is appreciated.

Sincerely,

Frederick P. Gaske, Director, and

Re: DHR Project File No. 2004-8676 (2002-1944, 2003-2300)/ Received by DHR: August 30, 2004
Cultural Resources Survey of the C-43 Berry Groves Storage Reservoir, Hendry County, Florida

Dear Mr. Duck:

Our office received and reviewed the above referenced survey report in accordance with Section 106 of the *National Historic Preservation Act of 1966* (Public Law 89-665), as amended in 1992; *36 C.F.R., Part 800: Protection of Historic Properties*; and Chapter 267, *Florida Statutes*, for assessment of possible adverse impact to historic properties listed, or eligible for listing, in the *National Register of Historic Places (NRHP)*.

In August to October 2003, New South Associates conducted an archaeological and historical survey of the C-43 Berry Groves Storage Reservoir project area in Hendry County on behalf of the U.S. Army Corps of Engineers, Jacksonville District. Four previously unrecorded historic structures were identified within the project area during the investigation.

The Ted Wells House (8HN102), a frame vernacular residence built in 1950, was identified within the project area. Due to lack of significant architectural characteristics, and a lack of historical associations, it is the opinion of New South Associates that 8HN102 does not appear eligible for listing in the *NRHP*.

The Berry Groves House (8HN103), a frame vernacular residence built in 1950, was identified within the project area. Due to lack of significant architectural characteristics, and a lack of historical associations, it is the opinion of New South Associates that 8HN103 does not appear eligible for listing in the *NRHP*.

The Berry Groves Bunkhouse (8HN104), a frame vernacular residence built in 1950, was identified within the project area. Due to lack of significant architectural characteristics, and a lack of historical associations, it is the opinion of New South Associates that 8HN104 does not appear eligible for listing in the *NRHP*.

The Jeff Jones House (8HN105), a frame vernacular residence built in 1950, was identified within the project area. Due to lack of significant architectural characteristics, and a lack of historical associations, it is the opinion of New South Associates that 8HN105 does not appear eligible for listing in the *NRHP*.

April 23, 2003

RE: DHR No. 2003-2300
Date Received by DHR: March 20, 2003
Scoping Notice – C-43 Basin Storage Reservoir
Hendry, Lee, Charlotte, or Glades Counties, Florida

Dear Mr. Duck:

Our office received and reviewed the above referenced project in accordance with Section 106 of the *National Historic Preservation Act of 1966* (Public Law 89-665), as amended in 1992, and *36 C.F.R., Part 800: Protection of Historic Properties*. The State Historic Preservation Officer is to advise and assist federal agencies when identifying cultural resources (listed or eligible for listing, in the National Register of Historic Places), assessing the project's effects, and considering alternatives to avoid or reduce the project's adverse effects.

We have reviewed the Scoping Letter for the C-43 Basin Storage Reservoir. The referenced project is part of the Comprehensive Everglades Restoration Project. We note that the Jacksonville District Army Corps of Engineers is preparing a Draft Environmental Impact Statement (DEIS). In the DEIS, environmental considerations will include effects on historic properties and archaeological sites. We look forward to receiving the DEIS, and coordinating with the Jacksonville District Army Corps of Engineers regarding cultural resources that may be impacted by this project.

If there are any questions concerning our comments, please contact Janice Maddox, Historic Sites Specialist, by electronic mail at jmaddox@mail.dos.state.fl.us, or by telephone at 850/245-6333 or 800/847-7278. Thank you for your interest in protecting Florida's cultural resources.

Sincerely,

Janet Snyder Matthews, Ph.D., Director, and
State Historic Preservation Officer

Mr. James C. Duck,
Chief, Planning Division
Department of the Army, Corps of Engineers
Environmental Branch
P.O. Box 4970
Jacksonville, Florida 32232-0019

Dear Mr. Duck:

The National Marine Fisheries Service (NOAA Fisheries) has reviewed the public scoping letter, dated March 18, 2003, requesting comments regarding the development of a Draft Environmental Impact Statement (EIS) for the feasibility phase of the C-43 Basin Storage Reservoir Project, Part 1, adjacent to the Caloosahatchee River in either Hendry, Lee, Charlotte, or Glades County, Florida. The project is part of the Comprehensive Everglades Restoration Project (CERP), and the scope of the project includes the construction of an approximately 160,000 acre-foot storage area within the Caloosahatchee Basin to capture and store stormwater runoff and water releases from Lake Okeechobee. According to the public scoping letter, anticipated benefit of the C-43 Basin Storage Reservoir Project is to capture C-43 Basin runoff and releases from Lake Okeechobee. The facilities will be designed to provide water supply benefits, some flood attenuation; environmental water supply deliveries to the Caloosahatchee Estuary; and, water quality benefits by reducing salinity and nutrient impacts of runoff on the downstream estuary.

It is our understanding that detailed information regarding the environmental and biological analyses for the C-43 Basin Storage Reservoir Project will be provided in an forthcoming EIS. Pursuant to the 1996 amendment to the Magnuson-Stevens Fishery Conservation and Management Act, it appears that an Essential Fish Habitat (EFH) Assessment should be incorporated in National Environmental Policy Act documents necessary for the project. To ensure adequate consideration of EFH and fishery resources and measures to conserve those resources, NOAA Fisheries recommends the following issues be addressed in the EIS:

1. Identify Federally managed fisheries and EFH which may be affected by project construction or operation. For example, EFH affected by the project may include submerged aquatic vegetation, estuarine emergent wetlands, mangrove wetlands, estuarine water column, oyster reefs and shell banks, and palustrine emergent and forested wetlands.

2. Include an extensive review of project impacts on EFH, including cumulative effects, an evaluation of those effects, and any proposed mitigation. Additionally, the

04/16/03 WED 16:20 FAX 727 570 5300 NMFS SERO 003

EFH Assessment should include your agency's views regarding EFH impacts.

If we can be of further assistance, please advise. Related comments, questions or correspondence should be directed to Mark Sramek in St. Petersburg, Florida, at (727) 570-5311.

Sincerely,

Rickey N. Ruebsamen

Tallahassee, Florida 32399-2100

RE: DHR No. 2002-01944 / Received by DHR: February 26, 2002
SAI #: 200202251575C
NEPA Scooping Notice for the C-43 Basin Storage Reservoir
Hendry County, Florida

Dear Mr. Murray:

Our office has received and reviewed the above referenced project in accordance with Section 106 of the *National Historic Preservation Act of 1966* (Public Law 89-665), as amended in 1992, and *36 C.F.R., Part 800: Protection of Historic Properties*, Chapters 267, *Florida Statutes*, Florida's Coastal Management Program, and implementing state regulations, for possible impact to historic properties listed, or eligible for listing, in the *National Register of Historic Places*, or otherwise of historical, architectural or archaeological value. The State Historic Preservation Officer is to advise and assist state and federal agencies when identifying historic properties, assessing effects upon them, and considering alternatives to avoid or minimize adverse effects.

Our review of the Florida Master Site File indicates that there are no archaeological or historic sites currently recorded within the project area. However, the lack of recorded historic properties is not considered significant because the area has never been subjected to a systematic, professional survey to locate such properties. Data from environmentally similar areas indicate that archaeological and historic sites, especially the former, are likely to occur in the study area. It is, therefore, the opinion of this office that there is a reasonable probability of project activities impacting historic properties potentially eligible for listing in the *National Register of Historic Places*, or otherwise of historical, architectural or archaeological value.

Since potentially significant archaeological and historic sites may be present, it is our recommendation that when the final area has been determined, it should be subjected to a systematic, professional archaeological and historical survey. The purpose of this survey will be to locate and assess the significance of historic properties present. The resultant survey report shall conform to the specifications set forth in Chapter 1A-46, *Florida Administrative Code*, and will need to be forwarded to this agency in order to complete the process of reviewing the impact of this proposed project on historic properties.

Mr. Murray
March 19, 2002
Page 2

The results of the investigations will determine if significant historic properties would be disturbed by this project. In addition, if significant remains are located, the data described in the report and the consultant's conclusions will assist this office in determining measures that must be taken to avoid, minimize, or mitigate adverse impacts to historic properties listed, or eligible for listing in the *National Register of Historic Places*, or otherwise of historical, architectural, or archaeological significance.

Based on the information provided, consistency with Section 307 of the *Coastal Zone Management Act*, Chapter 373.414 *Florida Statutes*, 16 U.S.C. Sections 1456 (c) and (d) and implementing regulations, and 15 CFR Part 930 can not be determined by this agency at this time. Under provisions of Chapter 267.061 *Florida Statutes*, it must be determined if the proposed activity will adversely affect or will enhance significant historical or archaeological resources. Meeting these consistency criteria is conditioned upon a thorough cultural resource evaluation to determine if any properties of archaeological or historical significance are present within the area of potential effect for the proposed project.

It is the opinion of this agency that until the required survey described above has been conducted, and any cultural resources identified determined to be significant or potentially significant scheduled for avoidance or mitigation, the proposed project will not be consistent with the *Coastal Zone Management Act* and implementing regulations.

Because this letter and its contents are a matter of public record, consultants who have knowledge of our recommendations may contact the project applicant. This should in no way be interpreted as an endorsement by this agency. The *Registry of Professional Archaeologists* (RPA) is the national certifying organization for archaeologists. A listing of archaeologists who are RPA members living or working in Florida can be accessed at http://dhr.dos.state.fl.us /bhp/compliance. In addition, the complete RPA Directory of Certified Professional Archaeologists is available at www.rpanet.org. Otherwise, upon request, we will forward our RPA list to the applicant.

If you have any questions concerning our comments, please contact Sarah Jalving, Historic Sites Specialist, by electronic mail at sjalving@mail.dos.state.fl.us or at 850-245-6333 or 800-847-7278. Thank you for your interest in protecting Florida's historic properties.

Sincerely,

Janet Snyder Matthews, Ph.D., Director, and

RE: Farmland Conversion Impact Rating
Form AD-1006
C-43 Basin Storage Reservoir

Dear Ms. Conner:

Enclosed is form AD 1006 with Parts II, IV, and V completed for the referenced project. The citrus groves are considered unique farmland, which is defined by the Farmland Protection Policy Act (FPPA). Completion of the project would take this farmland out of production. According to the FPPA, if the Federal Agency involved decides to fund the project, Parts VI and VII of the form should be competed and returned to this office.

If there are additional questions, please feel free to contact me at 352-338-9535.

Sincerely,

Warren Henderson

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
REGION 4
WATER MANAGEMENT DIVISION
SOUTH FLORIDA OFFICE
400 NORTH CONGRESS AVE., SUITE 120
WEST PALM BEACH, FLORIDA 33401

MAR 1 4 2005

Mr. Lawrence Skaggs
C-43 Basin Storage Reservoir Project Manager
US Army Corps of Engineers
701 San Marco Blvd.
PO Box 4970
Jacksonville, Florida 32232

SUBJECT: C-43 Basin Storage Reservoir Project

Dear Mr. Skaggs,

This letter provides comments from the U.S. Environmental Protection Agency's (EPA) on the ongoing development of the Project Implementation Report (PIR) for the C-43 (Caloosahatchee River) Basin Storage Reservoir. According to the 1999 Restudy Final Environmental Impact Statement (FEIS) and Integrated Feasibility Report, the C-43 Basin Storage Reservoir (BSR) will have water supply benefits, and provide environmental water supply deliveries to the Caloosahatchee estuary. The Project Scope is to "provide environmental, urban and agricultural water supply needs, flood attenuation and improvements to water quality and timing of releases to the Caloosahatchee Basin, River and Estuary". Specifically, "nutrient impacts of runoff into the estuary" are to be addressed by the project (C-43 Basin Draft Feasibility Scoping Meeting (FSM), page 127). The C-43 Basin Storage Reservoir Draft FSM document states that excessive nutrients, depressed levels of dissolved oxygen, and elevated coliform bacteria levels are problematic in the estuary. Reducing nutrient loads would result in substantial ecological improvement in the Caloosahatchee estuary.

Because the C-43 Basin Storage Reservoir is a "Category B" project according to CERP Guidance Memorandum number 23, it is not required that water quality improvement features be included in the project. However, Category B projects must be designed to achieve water quality (WQ) improvement during project formulation and design by:

1) Characterizing existing WQ conditions, including a baseline sampling program, if necessary;
2) Forecasting base-year WQ conditions;
3) Forecasting future without project WQ conditions;
4) Developing evaluation criteria to determine the extent of WQ improvement associated with alternative plans;
5) Identify WQ constraints;
6) Developing evaluation criteria associated with WQ constraints;

Recycled/Recyclable • Printed with Vegetable Oil Based Inks on 100% Recycled Paper (40% Postconsumer)

7) Selecting the least cost plan that meets the WQ restoration objectives; and,
8) Optimizing the design of the selected plan to maximize WQ improvement if optimization does not conflict with the purpose and objectives for the project.

We understand that the C-43 project PIR is not being formulated for water quality improvements, and that the Tentatively Selected Plan (TSP) will not make water quality worse in the basin. The CGM 23 also requires that evaluation criteria be developed for "alternative plan evaluation, comparison, and selection purposes, as well as for **maximizing the water quality improvement efficiency**" (number 4 above and CGM 23 page 11). The Water Quality Evaluation Criteria Matrix that is included in the C-43 Draft FSM report (appendix D) does address the potential for degrading water quality with the construction of the reservoir. However, the matrix does not include a method for evaluating the efficiency of project alternatives at *improving* water quality, as is required by CGM 23.

The EPA has had conversations with the U. S. Army Corps of Engineers, Jacksonville District, regarding this issue, and was informed that the Water Quality Evaluation Criteria Matrix that is included in the Draft FSM document is being revised. Evaluation Criteria that address the ability of plan alternatives to improve water quality should be added.

If you need any assistance, please feel free to contact Eric Hughes or Melanie Edwards, of my staff.

Sincerely,

Richard M. Harvey, P.E.

701 San Marco Blvd.
Jacksonville, FL 32207-8175

Dear Ms. Brooks-Hall:

During development of the conceptual plan for the Restudy, one of the main concepts of the regional storage components was to provide additional storage for water supply in the Caloosahatchee, St. Lucie and Kissimmee Basins which should ultimately reduce irrigation demands on Lake Okeechobee. Water could then be conserved in the lake and would be "...available for sustaining the health of lake and downstream natural areas ..." (Sections 6.4.2 and 6.4.1.2). The source for agricultural irrigation demands would be "switched" to the reservoirs as much as possible and be supplemented as needed by the lake. More lake water would be available for natural system needs.

Currently the C-43 BSR FSM Draft does not address this function of the C-43 BSR project. Instead, the introduction on page one of the FSM draft states: "Once the demands of the estuary are met, additional water resource benefits could be achieved by providing supplemental water resources for agriculture and urban users resulting in a reduction of demands placed on existing surface water and ground water resources such as the C-43 canal and Lake Okeechobee." Agricultural water supply from this project is treated as being supplemental, not as a "source switch" for current demands. This introductory approach is maintained throughout the C-43 BSR FSM Draft.

Our concerns are not that agricultural irrigation demands will not be addressed in the state planning and permitting processes. They are about changing the original concepts on how the CERP storage reservoirs would be operated. If the primary purpose of the C-43 reservoir is now to meet estuary demands, and not to "switch sources" for local irrigation demands, that change from the Yellowbook concept needs to be made after a public debate.

A second issue with the C-43 BSR FSM Draft is one that FDACS has previously raised at the August 24, 2004 Regional PDT meeting. The socioeconomic section contains a lot of

information on recreation and fisheries and very little on agriculture in the region. The economic impacts of removing large acreages of viable agricultural land out of production for project components needs to be better addressed in order to adequately consider the feasibility of the alternatives being considered.

If you have any questions or I can assist in any way, please feel free to call me at 561- 682-2845 or Rebecca Elliott at 561-682-6040. We would be happy to participate in any future modifications to the draft document.

Sincerely,

CHARLES H. BRONSON

Re: Department of the Army, Jacksonville District Corps of Engineers, Scoping Notice, Draft Environmental Impact Statement, C-43 Basin Storage Reservoir Project, Caloosahatchee Basin, Hendry, Glades, Charlotte, or Lee County, Florida

SAI: FL200303261382C

Dear Mr. Duck:

The Florida State Clearinghouse, pursuant to Executive Order 12372, Gubernatorial Executive Order 95-359, the Coastal Zone Management Act, 16 U.S.C. §§ 1451-1464, as amended, and the National Environmental Policy Act, 42 U.S.C. §§ 4321, 4331-4335, 4341-4347, as amended, has coordinated the review of the above-referenced Draft Environmental Impact Statement (DEIS) for the proposed project.

The Southwest Florida Regional Planning Council (SWFRPC) indicates that the project is regionally significant and consistent with its Strategic Regional Policy Plan. Please see the enclosed letter form the SWFRPC.

The Florida Department of Transportation (FDOT) indicated that it has no comments for this project; however, FDOT's initial issues and concerns, expressed in its April 5, 2002 response to the scoping notice need to be addressed. Please see FDOT comments in the enclosed Clearinghouse tracking system page.

The Department of Environmental Protection (DEP) states that additional evaluation of the properties and reservoir capacities is necessary to provide assurances that the proposed project will meet safety standards for the residential area in which it will be located. Additional properties should be considered and evaluated in the DEIS. Please see the enclosed memorandum from DEP.

Based on the information contained in the above-referenced DEIS and the comments provided by our reviewing agencies, as summarized above and enclosed, the state has determined that, at this stage, the proposed project is consistent with the Florida Coastal Management

Printed on recycled paper.

Mr. James C. Duck
May 23, 2003
Page 2

Program (FCMP). All subsequent environmental documents prepared for this project must be reviewed to determine the project's continued consistency with the FCMP. The state's consistency concurrence with the project will be based, in part, on the adequate resolution of issues identified during this and subsequent reviews. The state's final concurrence on the project's consistency with the FCMP will be determined during the environmental permitting stage.

Thank you for the opportunity to review this project. If you have any questions regarding this letter, please contact Mr. Bob Hall at 850/245-2163.

Sincerely,

Sally B. Mann, Director
Office of Intergovernmental Programs

Mr. James C. Duck,
Chief, Planning Division
Department of the Army, Corps of Engineers
Environmental Branch
P.O. Box 4970
Jacksonville, Florida 32232-0019

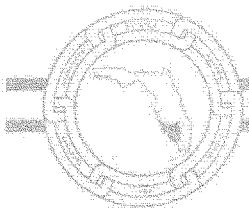
Dear Mr. Duck:

The National Marine Fisheries Service (NOAA Fisheries) has reviewed the public scoping letter, dated March 18, 2003, requesting comments regarding the development of a Draft Environmental Impact Statement (EIS) for the feasibility phase of the C-43 Basin Storage Reservoir Project, Part 1, adjacent to the Caloosahatchee River in either Hendry, Lee, Charlotte, or Glades County, Florida. The project is part of the Comprehensive Everglades Restoration Project (CERP), and the scope of the project includes the construction of an approximately 160,000 acre-foot storage area within the Caloosahatchee Basin to capture and store stormwater runoff and water releases from Lake Okeechobee. According to the public scoping letter, anticipated benefit of the C-43 Basin Storage Reservoir Project is to capture C-43 Basin runoff and releases from Lake Okeechobee. The facilities will be designed to provide water supply benefits; some flood attenuation; environmental water supply deliveries to the Caloosahatchee Estuary; and, water quality benefits by reducing salinity and nutrient impacts of runoff on the downstream estuary.

It is our understanding that detailed information regarding the environmental and biological analyses for the C-43 Basin Storage Reservoir Project will be provided in an forthcoming EIS. Pursuant to the 1996 amendment to the Magnuson-Stevens Fishery Conservation and Management Act, it appears that an Essential Fish Habitat (EFH) Assessment should be incorporated in National Environmental Policy Act documents necessary for the project. To ensure adequate consideration of EFH and fishery resources and measures to conserve those resources, NOAA Fisheries recommends the following issues be addressed in the EIS:

1. Identify Federally managed fisheries and EFH which may be affected by project construction or operation. For example, EFH affected by the project may include submerged aquatic vegetation, estuarine emergent wetlands, mangrove wetlands, estuarine water column, oyster reefs and shell banks, and palustrine emergent and forested wetlands.

2. Include an extensive review of project impacts on EFH, including cumulative effects, an evaluation of those effects, and any proposed mitigation. Additionally, the



EFH Assessment should include your agency's views regarding EFH impacts.

If we can be of further assistance, please advise. Related comments, questions or correspondence should be directed to Mark Sramek in St. Petersburg, Florida, at (727) 570-5311.

Sincerely,

Rickey N. Ruebsamen

RE: ICR Project #: 2003-068
Project Comments for Scoping Notice for Draft Programmatic EIS for C-43 Basin Storage Reservoir Project, Caloosahatchee Basin
Applicant: Department of the Army – Jacksonville District Corps of Engineers

Dear Mr. Duck:

The staff of the Southwest Florida Regional Planning Council reviews various proposals, Notifications of Intent, Preapplications, permit applications, and Environmental Impact Statements for compliance with regional goals, objectives, and policies, as determined by the Strategic Regional Policy Plan. The staff reviews such items in accordance with the Florida Intergovernmental Coordination and Review Process (Chapter 29I-5, F.A.C.), and adopted regional clearinghouse procedures.

The Southwest Florida Regional Planning Council recognizes the importance of clean, renewable water resources for the health, survival, and well being of area residents. The C-43 Basin Storage Reservoir Project is a good way to utilize stored water to help meet the regional environmental demands of the Caloosahatchee River and Estuary.

Enclosed is a copy of the Natural Resources Element Section of the Strategic Regional Policy Plan for the Southwest Florida Regional Planning Council. This section discusses the adopted goals, objectives, and actions which outline issues that need to be addressed in the draft EIS for this project.

Please contact Nichole L. Gwinnett, IC&R Coordinator, with any questions concerning staff review of this item.

Sincerely,

SOUTHWEST FLORIDA REGIONAL PLANNING COUNCIL

Marisa Erika Morr
Regional Planner

RE: Department of the Army - District Corps of Engineers - Scoping Notice - Gathering Information to Help Define Issues and Concerns to be Addressed in a National Environmental Policy Act Document Being Prepared for the C-43 Basin Storage Reservoir - Hendry, Glades or Lee Counties, Florida
SAI: FL200202251575C

Dear Mr. Duck:

The Florida State Clearinghouse, pursuant to Presidential Executive Order 12372, Gubernatorial Executive Order 95-359, the Coastal Zone Management Act, 16 U.S.C. §§ 1451-1464, as amended, and the National Environmental Policy Act, 42 U.S.C. §§ 4231, 4331-4335, 4341-4347, as amended, has coordinated a review of the above-referenced project.

The Department of Environmental Protection (DEP) notes that the project will require permits from DEP. This includes a Comprehensive Everglades Restoration Plan Regulation permit and a National Pollutant Discharge Elimination System permit. These permits will cover the construction and operation of the reservoir and discharges to surface waters. A consumptive use permit will also be required pursuant to South Florida Water Management District regulations, although this permit will probably be reviewed by DEP because the SFWMD is a co-applicant on this project. The Corps should contact these agencies regarding permitting requirements. Please refer to the enclosed DEP comments for further details.

The Florida State Historic Preservation Officer (SHPO) is concerned that project activities could disturb significant archaeological or historic sites. Therefore, the SHPO recommends that a systematic archaeological and historical survey be conducted within the project area. The Corps should contact the SHPO office early in the process for information regarding the recommended survey. Please refer to the enclosed SHPO comments for further details.

(850) 488-7956

The Florida Fish and Wildlife Conservation Commission (FWC) notes that the C-43 Basin is documented for the occurrence of many species classified by the FWC as endangered, threatened, or species of special concern. The proposed project has the potential for direct and indirect effects that could benefit or adversely impact many of these species, depending on the location, design, and operation of the proposed reservoirs. Protection and restoration of the native habitats in the region, and restoration of optimal base flows to the Caloosahatchee River and estuary can benefit general fish and wildlife resources, and assist in recovery of listed species. Please refer to the enclosed FWC comments for further details.

The Florida Department of Transportation has identified two areas of immediate concern which should be addressed as soon as possible. Currently, a section of SR 80 within the project area is being multi-laned under an expedited construction schedule. To ensure that the drainage requirements and structural integrity of this SR 80 project are maintained, the applicant must provide adequate documentation to DOT that provides assurance that the water table will not be elevated to such an extent that SR 80 roadway sub grades will be negatively impacted. Also, DOT understands that the Townsend Canal will be utilized as the main conduit for alternating hydraulic flows between the proposed reservoir and the Caloosahatchee River and will need to be widened to accommodate the extra flow. DOT has scheduled two bridge projects over the Townsend Canal which will begin this spring/summer. In order to avoid having to replace or retrofit these two soon-to-be constructed SR 80 bridges over Townsend Canal, the applicant should address this issue as soon as possible. Please refer to the enclosed DOT comments for further details.

The Southwest Florida Regional Planning Council (SWFRPC) notes that SR 80 is a critical hurricane evacuation route for Lee County. SWFRPC is concerned that an above ground reservoir along this route creates additional danger and exposure should the above ground berm fail during a hurricane event. Please refer to the enclosed SWFRPC comments for further details.

Based on the information contained in the scoping notice and the enclosed comments provided by our reviewing agencies, the state has determined that, at this stage, the above-referenced action is consistent with the Florida Coastal Management Program (FCMP). All subsequent environmental documents prepared for this project must be reviewed to determine the project's continued consistency with the FCMP. The state's continued concurrence with the project will be based, in part, on the adequate resolution of issues identified during this and subsequent reviews.

Tallahassee, Florida 32399-2100

Re: FL200202251575C, Hendry County, C-43 Basin Storage Reservoir

Dear Ms. Cranick:

The Office of Environmental Services of the Florida Fish and Wildlife Conservation Commission (FWC) has reviewed this document, and has the following comments and requests for additional information.

The C-43 Basin Storage Reservoir feature of the Comprehensive Everglades Restoration Plan (CERP) includes aboveground reservoirs, with a total storage capacity of approximately 160,000 acre-feet. The initial design assumed 20,000 reservoir acres, with water levels fluctuating up to eight feet above grade. An initial site proposed for an 8,000-acre reservoir is the Berry Groves property, located in Hendry County. The property is currently in agricultural production, with citrus as the primary crop. There are two adjacent canals that adjoin the property, the Townsend Canal to the west and the Roberts Canal to the east. The area is primarily citrus groves, with strips of shrubs along irrigation/drainage ditches in the grove. The primary vegetation in the ditches is Brazilian pepper, with some grasses and other herbaceous plants. Currently, the Berry Groves operation obtains water from the Townsend Canal through a pump, with a system of secondary ditches providing conveyance of water to, and drainage from, the citrus groves.

Other potential sites are to be identified within the C-43 Basin in Hendry, Glades, and/or Lee counties. Our understanding is that the U.S. Army Corps of Engineers (USACOE) is looking for sites throughout the Caloosahatchee Basin, and elevation contours are being used to make initial rough determinations of site suitability. The final size, depth, and configuration of these facilities will be determined through more detailed planning and design. The purpose of this project is to capture C-43 Basin runoff and releases from Lake Okeechobee. Upon implementation, the C-43 Basin Storage Reservoir project is intended to provide environmental, urban, and agricultural water supply needs, "flood attenuation," and improved timing of releases

620 South Meridian Street - Tallahassee - FL - 32399-1600
www.floridaconservation.org

to the Caloosahatchee Basin, River and Estuary. It is assumed that, depending upon the location of the facility and pollutant loading conditions in the watershed, the facility could be designed to achieve significant water quality improvements.

The C-43 Basin is documented for the occurrence of many species classified by the FWC as endangered, threatened, or species of special concern. The proposed total project has the potential for direct and indirect effects that would potentially benefit or adversely impact many of these species, depending upon the location, design, and operation of the proposed reservoirs. To date, no comprehensive surveys have been completed for fish and wildlife species within the Berry Groves property, but because of its highly altered habitat conditions, we expect that it has limited use by listed species. We assisted in coordination of the selection of the Berry Groves site with the South Florida Water Management District (SFWMD) and USACOE. In contrast, the site review of other potential sites has not been coordinated with the FWC.

We recommend that the USACOE and SFWMD consult with the FWC in the early planning stages of reservoir siting. Protection and restoration of the native habitats in the region, and restoration of optimal base flows to the Caloosahatchee River and estuary can benefit general fish and wildlife resources, and assist in recovery of listed species.

We recommend minimizing the impact of the C-43 reservoirs on native habitats. This would include native range areas that retain habitat value for species such as the Florida grasshopper sparrow, Audubon' s crested caracara, Florida sandhill crane, Florida burrowing owl, gopher tortoise, eastern indigo snake, and gopher frog. Therefore, we recommend that if siting of reservoirs allows a choice of lands with different agricultural land use histories, that areas supporting citrus and sugarcane be selected in preference to unimproved or improved pastures, and that improved pastures be selected in preference to unimproved pastures.

The Caloosahatchee Basin plays an important role in the recovery of the Florida panther. The USFWS has organized a multi-agency subgroup of the Multi-species/Ecosystem Recovery Implementation Team to produce a Florida panther landscape conservation strategy. In addition to protection of habitat for adult home ranges, the strategy includes a provision of corridors for dispersal of juveniles between larger areas of contiguous habitat. Dispersal across the Caloosahatchee River, between existing primary habitat south of the river and habitat that is used by panthers north of the river, is considered essential for recovery of the species. The dispersal habitat coincides with the proposed public land acquisition area known as the Caloosahatchee Ecoscape. Facilities proposed as part of the C-43 reservoir project should not be located in the Caloosahatchee Ecoscape.

The proposed total project is located within the feeding radius of several colonies of wood storks and other colonially nesting wading birds. The maintenance of natural hydro-periods in foraging grounds around nesting areas is vital to the recovery of these birds in south

Florida. The intended operation of the reservoirs can provide foraging opportunities, or loss of short hydroperiod shallow foraging areas. The project should address this issue and the potential for conflicts of the operation schedule with listed wading bird nesting and foraging in a wading and water bird management plan for the reservoirs. We offer our assistance in the development of such a plan. Mitigation may be needed to offset the loss of seasonal wetlands for woodstork and other listed wading bird foraging.

Since funding for this project is coming from CERP, a restoration project, the water in the reservoirs should be used to meet environmental needs before the water is allocated to urban or agricultural use. The FWC plans to participate in efforts to establish specific ecological targets for the Caloosahatchee River and the estuary, with optimal seasonal base flows and flow regimes. This will depend in part on water from the C-43 reservoirs to meet those needs. The C-43 Project Delivery Team should work closely with the Southwest Florida Feasibility Study Team to establish these goals and to ensure that the design and operation of the C-43 reservoirs are compatible with those targets.

We will continue interagency coordination on these issues. Please contact me, or Mr. Jim Beever at (941)575-5765, if you have any questions.

Sincerely,

Bradley J. Hartman, Director
Office of Environmental Services

RE: ICAR REVIEW (SAI# FL200202251575C)
USACOE C-43 BASIN STORAGE RESERVOIR (HENDRY COUNTY)

Dear Ms. Raffington:

District One, Florida Department of Transportation, has reviewed the above-referenced Intergovernmental Coordination and Review (ICAR) document, and offers the following comments:

1. The Applicant is undertaking development of a National Environmental Policy Act (NEPA) document for the proposed C-43 Basin Storage Reservoir, which is an element of the Comprehensive Everglades Restoration Project (CERP), authorized by the Federal Water Resources Development Act of 2000. The proposal calls for the construction of an above-ground reservoir with total storage capacity tentatively estimated at approximately 160,000 acre-feet; that is to say, 20,000 acres with water levels fluctuating up to eight feet above grade. Final design will be contingent, in part, upon issues and concerns raised in the NEPA document.

   Preliminary plans are to locate the proposed reservoir adjacent to State Road 80 on the south side, from Townsend Canal east for a distance of approximately seven (7) miles, in northwestern Hendry County. Half of this segment of SR 80, a Florida Intrastate Highway System (FIHS) facility, is currently being multi-laned (FM# 1941961) under an expedited construction schedule.

2. The Applicant's notification package does not provide sufficient information or engineering detail to definitively determine whether the proposed reservoir and acceptable roadway drainage mechanics for SR 80 could coexist. To ensure that the drainage requirements and structural integrity of the upcoming SR 80 multi-laning investments are maintained, the Applicant is required to provide adequate documentation to the District Drainage Engineer's Office for review and assurance that the water table will not be elevated to such extent that SR 80 roadway sub grades will be detrimentally impacted. Assurances will also be needed that tail water

District One Planning Office, Modal Development Department
District One Southwest Area Office * Post Office Box 1030 * Fort Myers, FL 33902-1030
(941) 461-4300 * (941) 338-2353 (Fax) * MS 1-98

elevations assumed for roadway drainage will not be increased as a result of the close proximity of the proposed reservoir.

The Applicant will need to contact Mr. John Previte, P.E., of the District Drainage Engineer's Office in Bartow at (863) 519-2676, in order to provide the necessary documentation, assurances and coordination, before proceeding with this project.

3. Of particular *urgent* concern to the Department is an impending design/construction conflict between a reservoir-associated flow way and two State Road 80 bridge construction projects (FM# 1941821) scheduled for letting this spring/summer. According to C-43 Basin Storage Reservoir concept plans, Townsend Canal is to be utilized as the main conduit for alternating hydraulic flows between the proposed reservoir and the Caloosahatchee River. While future capacity needs of the canal are not yet known, and thus no ultimate typical cross-section developed as yet, South Florida Water Management District hydraulic engineers have confirmed that Townsend Canal will need to be widened, and that the two SR 80 bridges soon to be constructed over the canal by the Department, will not be large enough spans to accommodate the anticipated increase in canal capacity.

   In order to avoid having to replace (or retrofit) these two soon-to-be-constructed SR 80 bridges over Townsend Canal, to the financial and operational detriment of the Department, the SR 80 projects, and motoring public, the Applicant is requested to address Department concerns with the utmost of speed, professional dialogue, and spirit of interagency cooperation. The Applicant will need to closely coordinate this critical issue with Sarah Clarke, Project Manager, of the FDOT Southwest Area Office in Fort Myers at (941) 461-4300; and Amy Shafer, SR 80 Project Manager in Bartow, at (863) 519-2276.

4. The Department finds the Applicant's project proposal to be consistent with Florida Department of Transportation policies, plans, programs, standards, rules and regulations *conditional* upon the Applicant's timely attention to, and satisfactory remediation of, Florida Department of Transportation comments No. 2 and No. 3 above, as deemed acceptable by the Department.

Thank you for allowing us the opportunity to review this document. Should you have any questions, please contact Larry Slayback, District ICAR Coordinator, at Suncom 741-4300 or (941) 461-4300.

Sincerely,

Larry G. Slayback

Re: Department of the Army, COE, Scoping Notice to Gather Information to Define Issues and Concerns to be Addressed in an Environmental Assessment for the C-43 Basin Storage Reservoir, Hendry, Glades or Lee Counties

SAI: FL 200202251575C

Dear Ms. Raffington:

We have reviewed the above-referenced Clearinghouse project and offer the following comments.

The final site location(s), project design, and other facets of the project are not yet defined, as they are continually being developed with the Project Implementation Report (PIR) phase of development just beginning. Assigned teams will evaluate designs, locations, alternatives, costs, and others factors as part of preparing the PIR, and it is our intent to ensure that the final project design will meet our rule requirements. A consistency review of the final proposal will be made prior to approval of actual construction by the Corps and the SFWMD. This review is part of the Comprehensive Everglades Restoration Plan Regulation Act (CERPRA) regulations.

The project will need permits from the Department in the form of a CERPRA permit and a National Pollutant Discharge Elimination System permit. These permits will cover the construction and operation of the reservoir and discharges to surface waters, respectively. A consumptive use permit will also be required under the SFWMD regulations. The Department will probably be reviewing this permit because the WMD is the co-applicant with the Corps. Details are still being developed.

Project managers from both the Corps and the WMD have been advised and are continually being advised of required permits as their status evolves.

If you have questions regarding this letter, or if we may be of further assistance, please give me a call at (850) 487-2231.

Sincerely,

Robert W. Hall

Mr. James C. Duck
Chief, Planning Division
Jacksonville District Corps of Engineers
Department of the Army
P.O. Box 4970
Jacksonville, FL 32232-0019

Dear Mr. Duck:

This responds to your February 15, 2002, notice received by the National Marine Fisheries Service (NMFS) Protected Resources Division (PRD) on February 21, 2002, requesting information to help define environmental issues and concerns to be addressed in a National Environmental Policy Act (NEPA) document being prepared for the C-43 Basin Storage Reservoir. The project is part of the Comprehensive Everglades Restoration Project (CERP) authorized by the Water Resources Development Act of 2000. We have assigned consultation number I/SER/2002/00107 to this action. Our comments are rendered pursuant to the section 7 requirements of the Endangered Species Act of 1973.

The project as proposed includes an above-ground reservoir(s) with a total storage capacity of approximately 160,000 acre-feet located in the C-43 Basin in Hendry, Glades, or Lee Counties. It is anticipated that the proposed reservoir would capture excess storm runoff and releases from Lake Okeechobee. The captured water could then be released into the Caloosahatchee River during times of need or drought.

Of all federally listed species under NMFS purview, NMFS considers that only the Gulf sturgeon could potentially be affected by the proposed action. The Gulf sturgeon could be present in the Caloosahatchee estuary, since it has been reported from the nearby Charlotte Harbor estuary. However, NMFS PRD believes that the release of captured stormwater runoff into the Caloosahatchee River will not adversely affect Gulf sturgeon, if present, since Gulf sturgeon spend part of their lives in freshwater and part in the marine environment and are well adapted to euryhaline conditions.

This concludes consultation responsibilities under section 7 of the ESA. Consultation should be reinitiated if there is a take, new information reveals impacts of the identified activity that may affect listed species or their critical habitat, a new species is listed, the identified activity is subsequently modified or critical habitat designted that may be affected by the identified activity. If you have any question, please call Eric Hawk, fishery biologist, of my Protected Resources staff.

Pursuant to the essential fish habitat consultation requirements of the Magnuson-Stevens Fishery Conservation and Management Act (16 U.S.C. 1855(b)(2) and 50 CFR 600.905-.930, Subpart K), the NMFS Habitat Conservation Division (HCD) is being copied with this letter. The HCD

biologist for this region is Mark Thompson. If you have any questions about consultation regarding essential fish habitat for this project, please contact Mr. Thompson at (850)234-5061.

Sincerely,

for, Joseph E. Powers, Ph.D.
Acting Regional Administrator

SUBJECT: C-43 Basin Storage Reservoir Project Description

Dear Mr. Duck:

These comments are preliminary, based solely upon the Berry Grove site, or any other site above grade along SR80. Other comments will be forthcoming.

General Comment #1: SR 80 is a critical evacuation route for Lee County in the event a hurricane evacuation is declared. Any successful evacuation depends upon all routes being open. An above ground reservoir located along this route provides additional danger and exposure should the above ground berm fail. A lake the size you have proposed will have additional forces posed by wind which will need to be modeled and brought into consideration.

General Comment #2: The Southwest Florida Feasibility Study is a component of CERP The study scope was to include an assessment of the other CERP projects, in conjunction with the detailed evaluation Southwest Florida did not get through the development of CERP. Expediting this proposal is contrary to the SWFFS, and the proposal approved by Congress. This proposal should not be expedited until the SWFFS is completed.

General Comment #3: What was the site selection and evaluation process used to designate the site in the public notice.

Comments pertinent to the Berry Grove site:

1. The original discussion included options of "above" and "below" grade. Below grade seems to have been rejected. In light of General Comment #1, why?

TO: Mr. James C. Duck
DATE: March 1, 2002
PAGE: Two
RE: C-43 Basin Storage Reservoir Project Description

2. The Berry Grove site is up to 10 feet higher in elevation than the nearby community of LaBelle. The water storage would be up to 8 feet higher than that. Has any thought been given to increasing the hazard to this community?

3. The Berry Grove site is directly adjacent to SR80, and its accompanying drainage works. Is it appropriate to locate a reservoir adjacent to a public works (SR 80) that depends upon good drainage?

4. What sort of cost evaluation has been performed to place this reservoir, above ground, at this location in comparison to any other site reviewed? What was the cost evaluation for the site being used as a below ground reservoir.

5. A workshop held on February 28th stated a different purpose for the site than that stated in the public notice. It was stated at the workshop that the site was to provide water for ASR wells. Since the ASR test well is only now being sited, and it is hoped that the test at least goes through a scientifically sound process, why is this reservoir being promoted before the test results are in, verified, and lead to this conclusion?

Additional comments will be forthcoming.

Sincerely,

SOUTHWEST FLORIDA REGIONAL PLANNING COUNCIL

Wayne E. Daltry
Executive Director

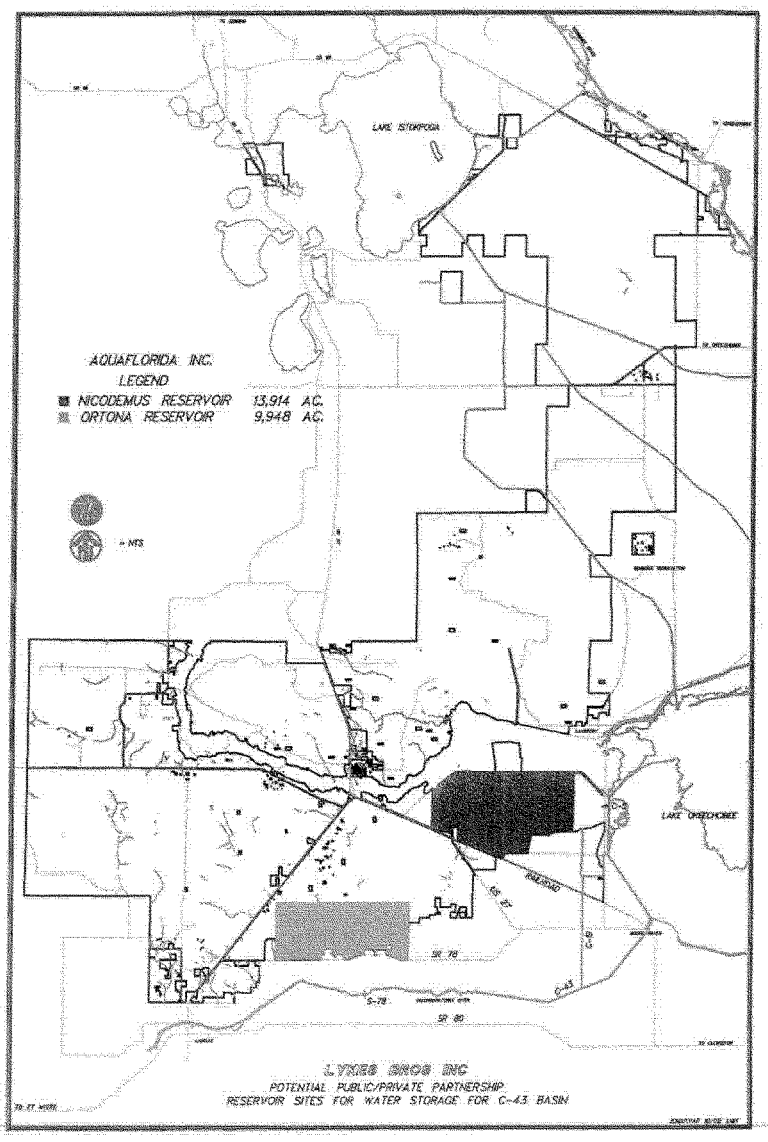
RE: C-43 Basin Water Storage Reservoirs

Dear Trent:

As we have discussed, Lykes Bros. Inc. is interested in discussing the potential for developing a public/private partnership for water storage for the C-43 Basin. I have enclosed a map showing 2 locations that we believe have a great deal of potential for such a project. I have sent this to Dave Apple with the COE and Agnes Ramsey with the SFWMD. I wanted to make sure you had a copy as well.

The Ortona site is approximately 14,000 acres with its southern boundary generally being State Road 78. This location is close to the river and could receive and discharge water either upstream or downstream (or both) of structure S-78.

The Nicodemus site is approximately 10,000 acres in size and located just west of Lake Okeechobee. This site already has a very large levee along the entire northern boundary of the site. The site also has a large canal that is connected directly to Lake Okeechobee and comes to the northeast corner of the site. The southeast corner of this site is very near C-19, which connects to C-43. It is easy to envision collecting excess water from Lake Okeechobee and storing it at this site and releasing it down C-19 to C-43 when appropriate.



If you have any questions please give me a call at 863-763-3041. I look forward to discussing this with you further.

Sincerely,

Joe Collins, PE

RESERVOIR SITES FOR WATER STORAGE FOR C-43 BASIN

B.4 DRAFT PIR COMMENT MATRIX

Name of Commenter	Comment	Response
US DOI June 11, 2007		
Letter dated June 11, 2007	1. The Department of the Interior (Department) supports the TSP for the project.	Noted.
Final FWS Coordination Act Report Recommendations July 2007	1. The Corps and District should consult with natural resource agencies in developing a detailed project operating manual for the reservoir to ensure restoration objectives are met. The operational plan should include the regulation schedules, operating criteria, and additional provisions as may be required to collect, analyze, and disseminate basic data. Detailed operating instructions to ensure that the project meets the restoration goals and targets should also be included in the form of a draft, interim, preliminary, and final operational plan. The water resource allocation for the natural system as described in the Project Implementation Report (PIR) should be utilized and described in both documents as the project progresses. An adaptive assessment team should meet when operations begin, during interim construction operations, and after construction to review the operational plan in concert with the information obtained from the Water Quality and Ecological Monitoring Plans to assure that restoration benefits are being met and that operations are optimized for restoration (Annex D in the Draft PIR).	The development of the project operating manual (POM) is an iterative process that will continue throughout the life of the project. The operational plan as presented in the draft Operating Manual is appropriate for the level of design and modeling performed for this project, as required in a PIR. The draft POM will be updated during design, construction and operational testing and monitoring phases. During these intervals of updates/refinements the Corps will be in consultation with the public, state and other federal agencies (including natural resource agencies). Though we would like to be more absolute in our operations plan, it would require a much greater effort that would still not be the final plan. It is well known and accepted by the public that initial operations after construction will be monitored and assessed comprehensively to ensure no significant impacts are caused to existing level of service flood protection, surrounding land owners, or downstream estuaries.

1148

	2. The Service recommends that the hydrologic monitoring plan in Section D.2 of Annex D in the PIR be expanded beyond the immediate footprint of the reservoir to include both existing canals and adjacent and upstream wetlands to ensure operation of the reservoir will not result in adverse impacts to the Spirit-of-the Wild (SOW) Wildlife Management Area (WMA) and the Okaloacoochee Slough State Forest (OSSF) WMA, and that the Corps formulate and incorporate related ecological hypotheses to be tested in the adaptive management protocol in Section D.4 of Annex D in the PIR. Emphasis should be placed on acquiring pre-project baseline data for existing canals (i.e., Roberts Canal) that can either provide direct or indirect drainage of areas of concern such as the SOW and the OSSF WMAs.	Groundwater and surface water modeling conducted by the SFWMD predicts that no impacts will occur to these areas. The reservoir and perimeter canal control structures will be operated to ensure that existing levels of water in the canals and upstream areas are not significantly impacted, based on project operations. No adverse impacts to the SOW, WMA and OSSF are expected.
	3. The Corps should evaluate results of the Test Cell Water Quality Monitoring Plan and incorporate that information in the reservoir design and water management operation and maintenance plan to maximize the reduction of nutrient loads from C-43 West Reservoir outflows.	The Test Cell Study Contractor is scheduled to provide the final evaluation of the test cell water quality data by the end of July. This evaluation will not be available in time for the FINAL PIR . The Corps will review the information when received and make any appropriate recommendations.
	4. The Service recommends that the Corps use the results from the Test Cell Water Quality Monitoring Plan to further evaluate: the quality of water while it is retained within the reservoir; the quality of water released from the reservoir and its potential effects on water quality of flows discharged at S-79; and, the effects of the quality and volume of water released at S-79 on the estuary.	The PIR includes a conservative assessment of water quality conditions both in the reservoir and downstream of it. The test cell contractor will provide another version of most of the requested analyses in July; however, given the relatively small size of the test cells and the short duration of the water quality study, caution should be used when interpreting the results as an indication of water quality conditions and impacts from the full size reservoir.

1149

	5. The Service recommends that the Corps monitor the water quality effects of the project consistent with the Water Quality portion of the Draft Project Operating Manual and Monitoring Plan (Annex D in the Draft PIR).	Concur
	6. The Service recommends that the Corps monitor the surface water and groundwater effects of the project consistent with the Water Quality portion of the Draft Project Operating Manual and Monitoring Plan (Annex D in the Draft PIR) and recommendation number 2 above.	Concur with the first part of the comment. See response to recommendation number 2 above.
	7. The Service recommends that the Corps monitor effects of the project on estuarine resources consistent with the estuarine portion of the Draft Project Operating Manual and Monitoring Plan (Annex D in the Draft PIR).	This type of ecological response monitoring within CERP is the responsibility of RECOVER. This project will not be able to determine what monitoring is funded for the estuarine resources.
	8. The Service recommends that the Corps implement the adaptive management protocols consistent with the Draft Project Operating Manual and Monitoring Plan.	Concur.
	9. If ASR wells are not constructed around the reservoir perimeter, the Service recommends that the Corps and the District expand the littoral zones created along the seepage canals.	This will be considered in the future when a determination is made on the feasibility of ASR wells at this site.
	10. The Service recommends that compatible public recreational opportunities which do not conflict with the primary function of the reservoir be provided in accordance with State Rule 40E-7.	The PIR includes a recreation plan which is the draft plan for implementation of recreation at the reservoir. However, after approximately a year of operations, the reservoir will be reevaluated to determine appropriate recreational activities.
	11. The Service recommends that the Corps or District pursuit funding for oyster reef restoration by placement of hard substrate in the estuary through other programs to increase the likelihood of oyster reef expansion to 30 acres over a 10- to 15-year period and 100 acres over the project life. Although the proposed project will improve salinity conditions for oysters and associated flora and fauna in the	The oyster reef restoration plan will not be a part of this project. Oyster reef restoration in the Caloosahatchee estuary has been initiated by various organizations in the past and a description of the program is included in this PIR as a recommendation

1150

	middle estuary, oyster expansion is directly tied to the availability of hard substrate for colonization.	for other organizations to pursue this restoration.
USEPA NEPA Program Office June 2007		
	1. As suggested in the DEIS, the water quality of the water released from the C-43 impoundment to the Caloosahatchee River should be no worse than the inflow water. We agree. Consistent with the purpose of the reservoir to improve estuarine health, water quality management should complement water quality management as an important project goal. As such, we recommend that the algal growth potential (AGP) of the impounded waters be assessed to minimize algal blooms and associated toxins in the water column. Intuitively, reservoir conditions are conducive for algal blooms due to the impounded water's warm temperature, high nutrient loadings and long residence time. In contrast, the potential for algal blooms could be reduced since nutrients would settle during the residence time, Lake Okeechobee water releases are expected to be less over time, and Caloosahatchee River nutrient TMDLs will be established. For the project, a 29% reduction in TP loads and a 28% reduction in TN loads at S-79, compared to the future without project condition, is predicted for preferred Alternative 3B (Table 6-3). This FEIS should further discuss nutrient water quality and the potential for algal blooms.	The FEIS will include a supplemental WQ analysis in which algal blooms will be discussed.
	2. As suggested above, nutrient levels are expected to decrease in part due to reduced discharges from Lake Okeechobee. Specifically, page 6-16 states that "…the reduction in nutrient loads at S-79 is largely the result of the reduction in discharges from Lake Okeechobee." The reasons for such "reduction in discharges" and its relationship with reduced nutrient concentrations should be further discussed in the FEIS.	Section 6.8.2 will include a sentence that states that the reduction in discharges from Lake Okeechobee is expected to be a result of the rest of CERP. (There is really no relationship between reduction in discharges and reduced nutrient concentrations so a discussion of this will not be included.)
	3. Resuspensions: Also, since nutrients and particulates are expected	The FEIS will include a supplemental WQ

1151

	to settle out in the reservoir, it becomes unclear if such precipitants would be resuspended in the water column when the reservoir is filled during the wet season. The proposed 1,500 cfs inflow pump (PS-1) could potentially also entrain sediment from the Calooshatchee River source water. Use of a larger pump (3,800 cfs) could exacerbate this water quality condition. The FEIS should discuss the potential for resuspension and sediment entrainment, as well as the overall inflow process. Reservoir operations should be designed to minimize inflow turbidity in the reservoir.	analysis in which sediment re-suspension is assessed.
	4. Site Contaminants: The residual soils of the existing orange grove proposed for the reservoir site contain pesticide and copper residues. We also understand that copper and lead were found within the Townsend Canal that would provide a conduit for reservoir inflows. As such, these contaminants can be expected to enter reservoir waters. However, we understand that introduction of these pesticides and metals in the impoundment waters are not expected to result in exceedances of State WQS. The FEIS should verify this and offer resolutions if any such contaminants are predicted to exceed WQS in the reservoir water. Beyond WQS, fish bioaccumulation may also be a concern. Regarding site contaminants, we suggest that the COE's protocol for establishing STAs on agricultural lands also be applied to the C-43 reservoir.	Presently there is no way of verifying that copper and lead concentrations in a yet to be constructed reservoir will or will not meet WQS in the future. However, it is reasonable to expect that copper concentrations in the Townsend will decrease as a result of the elimination of 10,000 acres of citrus which is the probable source of the copper. As for lead, since the "lead contaminated Townsend Canal water" will contribute only a small fraction of the total water budget to the reservoir, it is reasonable to conclude that lead concentrations in the reservoir will not exceed WQS since the Townsend water will be significantly diluted by other water that does not have excessive lead. The monitoring plan includes testing of fish for a list of contaminants that includes lead and copper. All HTRW site assessments and remediation efforts were coordinated with the FWS and reviewed by the COE.
	5. TMDLs: The FEIS should more fully discuss the ongoing TMDL	The FEIS will include more discussion of

1152

	effort in the Caloosahatchee Basin. It should also describe how the September 2007 start-up of the Caloosahatchee Watershed PIR will coordinate with the TMDL effort in setting appropriate water quality restoration targets for the Caloosahatchee Basin, particularly in the case of nitrogen loading at S-79.	the development of TMDLs.
	6. Dissolved Oxygen: Beyond nutrients and particulates, DO levels of return water could be of concern. DO levels should meet or exceed State WQS for waters returned to the Caloosahatchee River. Preferably, DO concentations should approximate or exceed ambient River levels (if greater than WQS) to prevent an in-stream oxygen sag at the discharge. Although we understand that return water can be siphoned from outlets at various reservoir depths to help increase DO levels, some DO augmentation may be needed prior to release to insure adequate levels.	The supplemental WQ analysis included in the FEIS will address the dissolved oxygen levels. The need for DO augmentation can be assessed after the reservoir is operational.
	7. Water Quality Monitoring Plan: Periodic reports from the Water Quality Monitoring Plan (WQMP) should be provided to FDEP and EPA's South Florida Office. Due to the current lack of water quality data (particularly nutrients) in peninsular Florida for above-ground pumped impoundments, reporting of water quality conditions within the C-43 Reservoir and on reservoir discharge waters is critical to future water quality modeling evaluations, project design and adaptive management for future CERP projects. EPA finds the value of the water quality data that will be provided upon operation of the C-43 Reservoir critical to the project and CERP in general.	Water quality data collected as part of this project will be stored in the SFWMD's web based DBHYDRO database as is all CERP data. The Test Cell data will be placed on DBHYDRO by Fall 2007.
	8. Reservoir Operating Manual: The Water Quality Section (D.1.6.3) in the Project Operating Manual should be expanded to more fully address possible operational actions to improve water quality conditions in discharge waters, while achieving other project objectives. The COE and SFWMD should consult with natural resource agencies (including EPA) in developing more detailed operational manuals and in implementing adaptive management activities after project start-up. EPA's South Florida Office should be	The Water Quality section of the O&M manual has been revised in the FEIS to include a discussion of how operations might be modified to improve water quality. The operating manual was and will continue to be developed with the input from the project delivery team which consists of not only SFWMD and COE members, but also

	provided copies of periodic evaluations associated with the Water Quality Monitoring Plan.	federal and state natural resource agencies.
	9. Project Sizing: As previously suggested, EPA will defer to the COE and SFWMD regarding the need for a larger inflow pump (3,800 vs 1,500 cfs) or a greater reservoir capacity (dike height or surgace area) to further minimize estuarine impacts. We note that Preferred Alternative 3B with its 1,500 cfs pump (PS-1) would require 57 days to fill the reservoir (pg.5-17), while Alternative 3C with its 3,800 cfs pump would take only 23 days (pg 5-18). In essence, how much environmental benefit will this project provide to the lower Caloosahatchee River and Estuary and is it sufficient at this time relative to the additional CERP storage capacity proposed (STAs, reservoirs, ASR wells), authorized and/or appropriated (or otherwise funded) at this time?	The project team recognizes that this project (CRWBSR) is not the full solution to the water storage issues in the Caloosahatchee Basin. That is why another project is scheduled to start the planning phase later this year. The Caloosahatchee Watershed Project will take another look at the total storage needs of the basin. However, that said, this project (CRWBSR) will provide significant and timely environmental benefit to the Caloosahatchee Estuary.
	10. Waters of the United States: We note that 125 acres of vegetated wetlands plus some 900 acres of farmland ditches would be inundated by the 10,500-acre reservoir. We understand that these waters of the United States are generally degraded due to existing orange grove farming. The FEIS should provide additional discussion on the quality and function of these areas, particularly the wetlands, from a NEPA disclosure perspective. The FEIS should also briefly discuss if the other sites considered would impact notably less or more wetlands from the selected "Berry Groves" site.	UMAM sheets depicting the function and value of the wetlands proposed for impact have been added to the FEIS. Wetland impact information for other sites considered has been added to the FEIS.
	11. Page 6-20 states that "(t)here will be mitigation for wetlands as a result of the federal project". Page xviii states that "(t)he loss of this wetland habitat will be offset by the increase in habitat function and quality in the Caloosahatchee Estuary." Specifically, the DEIS (pg xv) assumes that the project would benefit 71,000 acres in the Caloosahatchee Estuary. Compared to the No Action, it would also generate an average annual increase of approximately 13,000 habitat units within the Estuary. Since the C-43 Reservoir is a CERP project, it may also be noted that the overall CERP would restore numerous	Agreed.

1154

	acres of wetlands in the Everglades. From a cumulative impacts perspective, many more wetland acres would be restored collectively by CERP projects than would be lost.	
	12. We also note that the banks of the perimeter canal will be designed to include 109 acres of littoral zone. We concur with such design, but also assume that any existing littoral habitat will be lost along those reaches of Townsend Canal interrupted by the construction of the reservoir and perimeter canal.	Noted, however the Townsend Canal currently has limited littoral habitat due to very steep banks and overgrowth of exotic plants.
	13. Water Supply: Reference is made in the DEIS (e.g. pg 6-3) that the C-43 reservoir is not to be used for "elimination or transfer" of water supply. We assume the no "transfer: of water supply implies that new water supply will not be created by the reservoir (the FEIS should clarify). EPA believes that the C-43 impounded waters should be returned to the Caloosahatchee River during dry seasons for the benefit of natural systems as opposed to serving as source water for new urban or agricultural development. We recommend that such assurances be clarified in the FEIS	Concur.
	14. The term "water supply' is used for various purposes in the DEIS (pg 6-13). We recommend that this term be better qualified in the FEIS to indicate the intended use of the water supply (e.g. urban/potable, agricultural or natural system water supply). This would be helpful since without descriptors, we offer that the term "water supply" connotes source water for human consumption.	Concur. Will clarify water supply usage in the FEIS
	15. NEPA Process: From a NEPA disclosure, we find certain sections (e.g. Summary of Affected Resources: pg 6-7) to be well written and would likely be understandable to the layman reader. However, other analytical sections (e.g. modeling) would benefit from additional discussion in the FEIS. For example, the results from the Habitat Suitability Index modeling (Table 6-4) should be further discussed. That is, differences in suitability between Preferred Alternative 3B and the No Action (2050 FWO) are only +0.08 for oyster, +0.13 for Vallisneara, +0.05 for seagrass, and +0.13 for extreme events. It is	Table 6-4 will be removed as it is confusing in its current location. The same table can be found in section 5.3.7.4 (Table 5-12) along with an extensive explanation of our methodology as well as its limitations. Appendix C details the entire habitat unit methodology in great detail. The HSI assumptions, listed in section C.1.3.3, also speaks to the limitations of the HSI models.

1155

	unclear if these differences (or the differences for other alternatives) are significant and what the significance thresholds are for this index. The FEIS should clarify such technical sections with additional discussion for the benefit of the public.	Although we do not have a sensitivity analysis (or significance thresholds), we feel that these models are a fair comparison between alternatives and the best available science for this analysis. The models were reviewed extensively by the Interagency Modeling Center as well as peer reviewed by species experts. The team also found that the results of the models were comparable to the best professional judgement expected results of the analysis (i.e. the results made sense).
	16. System Recovery (pg ix): The DEIS states that "(w)ithout actions taken to reverse the effects of too much and too little freshwater entering the Caloosahatchee Estuary at the wrong times, the estuarine ecosystem will continue to be degraded and will likely worsen to the point that primary ecological functions such as nursery and forage habitat for aquatic plants and animals, are not recoverable." We agree that the current flow rates, volumes and timing are degrading the lower Caloosahatchee River and Estuary, and that continuance of such flows (i.e., the "without project" scenario) would extend and worsen this impact. However, most systems are recoverable once the stressors have been removed or sufficiently lessened (e.g., CERP is attempting to restore the Everglades) unless certain species become extinct in the process or hazardous materials are involved. As such, while we support the need for and implementation of the proposed reservoir project, we suggest that the "are not recoverable" portion of the above excerpt is somewhat of an over-statement.	Concur. Will change the wording in the Final PIR.
	17. Wetland Acreage (pg 6-20 vs 6-38): Regarding wetlands quantification, we note that page 6-19 suggests that the 6.39 acres of wetlands already inundated by the C-43 Test Cell Project are not included in the 125-acre total, while page 6-38 suggests the reverse.	Noted

1156

	This inconsistency should be clarified in the FEIS.	
	18. Pump Entrainment (pg6-21): The DEIS acknowledges that "(d)ue to operation of the pumps there likely will be some entrainment and impingement of fish and other aquatic organisms." Although we defer to the U.S. Fish and Wildlife Service (FWS) and their State counterparts in this regard, the FEIS should discuss how impingement of aquatic juveniles/adults and entrainment of eggs/larvae will be minimized during the 1,500 cfs pumping operations. It may be noted that are larger pump (3,800 cfs) would likely increase these impingement/entrainment impacts.	We will note that the larger pumps would likely increase the impingement/entrainment impacts. However, USFWS and FFWCC did not recommend any additional measures for minimizing impingement and entrainment.
	19. Air Quality: Although Hendry County is in attainment, emissions from the project could affect local air quality for project workers and any nearby residents. The FEIS should provide general information of the number of residences in the area that may be affected by the project. By project design, we assume populations near the proposed C-43 Reservoir are rural and scattered. The FEIS should discuss this.	The FEIS will include a few sentences regarding air emissions and potentially effected residents.
	20. As we have suggested in some of our other previous COE NEPA reviews, we recommend the use of reduced idling practices, cleaner fuels, and emission retrofits for construction equipment used by COE contractors whenever feasible to help minimize construction emissions. The COE may wish to discuss this further with EPA Region 4 (Dale Aspy at 404/562-9041). In any case, all construction equipment should be tuned to manufacturer's specifications to minimize air emissions. In addition to construction equipment, air emission from the operation of the reservoir inflow pump (PS-1) would generate emissions. For the 57 days needed to fill the reservoir for Preferred Alternative 3B using the proposed 1,500 cfs diesel pump, would the pump be operating essentially the whole time? We request that the FEIS include more information on the size of the PS-1 pump (break-horsepower, manufacturer, fuel requirements, etc) for our impact	We will ensure that this requirement is included in the contract documents. The 57 days is a general reference for the time needed to fill the reservoir if 1,500 cfs is pumping continuously. The intake pump would not run constantly in a single 57-day fill operation. Rather, the reservoir fills or releases at a given point in time based on the state of the flow in C-43 at the S-79 structure, the available capacity of the reservoir, and the season. In general, the pump would run more often in the wet season when flows occur at S-79 that would be in excess of the estuarine restoration target.

1157

	review. We also offer that use of an electric pump would eliminate such air emissions.	Horsepower information for PS-1 was provided in Section A.6.1.2.1 of the Draft PIR Engineering Appendix. Total horsepower of the proposed 4 pumps is 10,800. The pump(s) manufacturer will not be known until the bid process and the fuel requirements may vary across manufacturers.
	21. Noise: For the project PS-1 pump, we note (pg 6-5) that the pump station (housing) was offered as noise shielding. We agree that housing would provide some shielding. Source reductions with the pump itself (type, quality, etc) would also reduce noise levels. As indicated above for the air emissions, we also offer that the noise emissions would essentially be eliminated if an electric pump was used instead of the proposed diesel pump. In addition to the pump, all other construction equipment (bulldozers, etc) should be tuned to manufacturer's specifications as well as being equipped with appropriate mufflers and engine housings to minimize noise. It is clear, however, that such noise abatement is more important if residents and other sensitive receptors are located nearby and are affected by the project. In any case, however, project workers could be affected.	FP&L has indicated that their area substations do not have sufficient capacity to serve the requirements of a 1,500 cfs pump station, and therefore, a new substation would be required for a 1,500 cfs pump station with electric driven pumps. The cost benefits analysis does not support this approach.
	22. From a NEPA disclosure standpoint, the FEIS should document construction noise data available from the literature for typical construction equipment such as would be used for the reservoir project (e.g. dBA noise levels at 50 ft). Disclosure of the estimated construction time is also suggested in order to help determine the magnitude of the noise (and air) impact.	The fEIS will include the following indormation: typical construction equipment generates an average of 80-88 dBA at 50 ft. This impact should be minimal as the area within and surrounding the construction is mostly rural. The estimated timeline for construction is 38 months.

1158

	23. Environmental Justice (EJ): Page 6-43 states that "(i)n public outreach efforts to date, only one potential environmental justice issue has been identified: the loss of jobs for low income and minority workers as a result of acquiring agricultural land for the construction of the reservoir." To help offset this, we are pleased to note (pg 6-44) that "…the SFWMD is conducting training programs to allow local individuals to acquire the skills needed to construct the reservoir." We assume that the locally affected people (particularly minorities and low-income populations) will not only benefit from the training but that at least some will be candidates for actual employment. In addition to this proposed offset, we recommend that the COE also provide people affected by the project continued project updates and coordination with their community leaders.	Concur. The SFWMD will be providing regular updates at the County Commission meetings which are open to the public. They will also have public meetings with stakeholders on an as needed basis.
	24. For better NEPA documentation for EJ, the FEIS should provide U.S. Census 2000 data (e.g. one or more block groups) for the project area to specifically account for any minority concentrations ("pockets"). For perspective, this project block group data should also be compared to adjacent block groups, the project county (Hendry) and the project state (Florida) to further determine any minority concentrations near the project. Overall the number of minority and low-income residents affected by the project (through relocation or other impacts), their demographics and any potential disproportionate effects should be reasonably documented. The FEIS should address this further.	Section 2.14.1 contains a rigorous description of the demographic makeup of the study area, including census tracts. Environmental justice is described in the socio-economic appendix, and irregardless of the demographic of the study area, no adverse impacts are expected to the populations identified in the census data.
	25. EPA rates this COE DEIS as "EC-1" (i.e., we have environmental concerns and request some additional information in the FEIS).	Noted.
FDACS June 12, 2007		
	1. During development of the conceptual plan for the Restudy, one of the main concepts of the regional storage components was to provide additional storage for water supply in the Caloosahatchee, St. Lucie and Kissimmee Basins which should ultimately reduce irrigation	Per section 9.1.3.1 of the Restudy "The purpose of this feature is to capture C-43 Basin runoff and releases from Lake Okeechobee. These facilities will be

1159

	demands on Lake Okeechobee. Water could then be conserved in the lake and would be "…available for sustaining the health of lake and downstream natural areas …" (Sections 6.4.2 and 6.4.1.2). The source for agricultural irrigation demands would be "switched" to the reservoirs as much as possible and be supplemented as needed by the lake. More lake water would be available for natural system needs. Since the only purpose of the C-43 reservoir is now to meet estuary demands, and not to "switch sources" for local irrigation demands, that change from the Yellowbook concept needs to be acknowledged and the planning conditions for other projects need to be updated based on that change. At this time, urban and agricultural demands have all been removed from the alternative evaluation. How does this fit into the regional plan as developed by CERP for the capture of local basin run-off to meet existing demands in the "reservoir" basins (Caloosahatchee, St. Lucie, and EAA basins) and retaining Lake Okeechobee water for natural system needs. How will the difference in concepts be accommodated going forward?	designed for water supply benefits, some flood attenuation, and to provide environmental water supply deliveries to the Caloosahatchee Estuary and water quality benefits to reduce salinity and nutrient impacts of runoff to the estuary." The reservoir proposed in this project allows estuary demands to be supplemented by reservoir storage during the dry season, thus relieving some dry-season demands on Lake Okeechobee allowing more water within the lake to be used system wide.
FDACS June 5, 2007		
	1. Annex C4, "Analyses Required by WRDA 2000 and State Savings Clause Analyses," describes assumptions made for the current and future sources of agricultural irrigation water and concludes that the project will not affect those sources. No supporting data or analyses are provided for either the local of regional project area to support the conclusion. The Department recommends that the data and analyses used to determine that the project will not affect the quantity and quality of the existing local and regional water supply, and data used to determine the existing flood control will not be impacted, be included in Annex C. This information is necessary to provide the reasonable assurances, required by 373.1501(5)(d), Florida Statutes, that implementation of the proposed project will not diminish the	By basing the water budget analysis for the reservoir on excess flows over S-79, the spreadsheet analysis ensures that all basin uses are preserved. The uses take their input from the C-43 or connected sources upstream of S-79 and would have pulled their needed volume before flow over S-79 occurs. The decision to fill the reservoir therefore does not occur until basin needs have been met as were without the reservoir in place. While this creates a situation where available volume for restoration may

1160

	quantity of water available to existing legal users or diminish the levels of service for flood protection.	exist within the basin that is not considered for reservoir operations it ensures that the reservoir does not capture flows that could or would have been used by any existing demand. This assumption is necessary to ensure that the project located in the lower pool does not cause unintended impacts to existing users that it can not rectify. Optimization to fully utilize water within the basin will occur with subsequent projects that have the opportunity to make up flow to the entire C-43 basin (lower and upper pool).
	2. In addition, the Department is concerned regarding the absence of a plan for controlling invasive exotic plant species, and that the estimated annual and operations maintenance costs do not include costs for monitoring and controlling invasive exotic plants.	Invasive species control, both terrestrial and aquatic, are estimated in the O&M cost estimate. Standard procedures for controlling invasive exotic plant species will be implemented.
	3. The Department is also concerned about language in the report inferring that timber practices promote the decline of red-cockaded woodpecker; rather it should more specifically state that certain activities should not be conducted within red-cockaded woodpecker foraging areas designated by the U.S. Fish and Wildlife Service.	Noted. The language will be removed.
	4. A water resource concern of existing legal users in the vicinity of the C-43 Basin Storage Reservoir Phase 1 Project is the change in water quality that may occur when the groundwater source for local wells is replaced by seepage from the perimeter canal. It appears that some wells may be completely switched form a watershed seepage source to a C-43 supplied perimeter canal seepage source when the C-43 Reservoir Phase 1 becomes operational. Data should be presented that was used to determine the impacts of the perimeter canal seepage on local ground water wells, as well as any conclusions	The water levels in the various sections of the perimeter seepage canal are generally set to provide the same level of water supply and flood protection as currently exists on the site. In other words, the perimeter canal water level should largely match the existing drainage/ water supply canal levels. Given this, the project should not substantially change groundwater flow

	reached regarding the need to mitigate for deterioration in water quality. Language should also be included that reinforces the local sponsor's commitment to mitigate any future negative impacts to legal users that result from such "source switching."	patterns such that groundwater quality will be measurably altered in most cases. However, if a given groundwater well is located such that the distance to the planned perimeter canal is less than the distance the well is from an existing water body there may be measurable impact to its water quality. In any case, the project assurances requirements of CERP also protects legal users from project related water quality degradation.
	5. Water supply and flood protection in the vicinity of the reservoir might be impacted by reservoir features and operations. Reports and supporting data should be included in the report that support the local sponsor's determination that detrimental changes to water supply and flood protection in the vicinity of the reservoir are not anticipated. Language should also be included that reinforces the local sponsor's commitment to mitigate any future negative impacts to legal users resulting form the construction or operation of the reservoir.	The project team analyzed irrigation results for the entire basin from the S-77 structure to the S-79 structure and also compared irrigation results for random locations near the Caloosahatchee River. Results generated cannot be considered an exact value since the irrigation component could not be calibrated at a field scale. A summary of average irrigation applied for the selected locations for the years 1978 - 1985. Although the model results generally indicate that the amount of irrigation water applied in the "With Project" condition is very slightly less than the "Without Project" condition, this difference is attributed to uncertainty associated more with the model irrigation input parameters and scale effects than with any real irrigation impacts. The year 1981 until June 1982 was a period of drought and the predicted irrigation

1162

		results show little difference in the volume of irrigation water applied for the evaluated locations.
	6. Section 7.6.1. (pg 7-23) discusses the estimated annual operations and maintenance costs. Exotic plant monitoring and treatment costs should be factored in this section.	Invasive species control, both terrestrial and aquatic, are estimated in the O&M cost estimate.
FDEP June 11, 2007		
	1. The Department supports the project with its purpose to increase storage in the regional watershed, which will restore ecological function and productivity in the Caloosahatchee estuary.	Noted.
	2. The note under figure 2-6 says that *Vallasneria americana* is found at stations 1-3. However, there is no station 3 depicted on the figure.	Noted. We will modify the text.
	3. Page 4-30, Table 4-7: Ecological Performance Measures does not include preferred flow range (cfs) for *Vallasneria americana.* However, pages 4-25 says that flow distribution EST05 will provide mean monthly flows above 450 cfs with most flows (75 percent) in the ideal range of 450-800 cfs.	A preferred flow for Vallisneria will be added to the table.
	4. Page 5-24, Table 5-9: Target Flow Distribution for EST05 shows mean monthly flows between 450-1,500 cfs occurring 74.5 percent of the time. However, Table 4-7 shows that most flows will occur in the range of 450-800 cfs. Please explain the inconsistency.	Table 4-7 only shows preferred flow ranges for specific species. However, throughout the document there may be different flow ranges used to explain different information. Although 450-800 cfs is the optimum flow range, EST05 also allows for flows in other flow ranges such as 800-1500 cfs.
	5. The HTRW assessment and remediation plans do not indicate coordination with the Department. Please specify if HTRW coordination has occurred.	Coordination with DEP has occurred and will be noted in the FEIS.
	6. Table C-13- Typographical error in the title, "Estimates of annual TP and TP loading…"	Noted. Correction will be made.
	7. Appendix C (Section C.9.3.1.1.1 and C.9.3.1.2.1: Project vs. 2050 Future Without Project Conditions). These sections refer to TP load	Noted. Suggested changes will be made

1163

	reduction of 29%-34% and a TN load reduction of 28%-33% under the "with project" conditions, which includes the nutrient load reductions associated with flow reductions from CERP implementation. In order to avoid confusion regarding the estimated nutrient removal potential of the C-43 West Reservoir, please include language clarifying the source of the nutrient removal estimation (i.e. clarify when nutrient removal estimations include overall CERP implementation, or solely C-43 WSR). This comment also applies to Table C-13, Section C.9.5, as well as other sections referring to nutrient removal associated with the selected alternative.	
	8. Appendix C (Section C.9.3.2: Wet/Dry Season Nutrient Loading) - Suggest revising language from "targets" to either "critical loads" or "threshold loads". The term target implies a goal, however the critical loads being referred to are actually threshold loads, above which Chlorophyll a concentrations exceed water quality criteria, therefore the goal in below this threshold.	Noted. Suggested edits will be included in FEIS.
	9. "The quality of the water discharged from the reservoir should be no worse than the quality of the water pumped into the reservoir." The C-43 West Basin Reservoir is required to achieve water quality standards at the discharge point. Please clarify throughout the PIR that, in addition to outflows being equal to or of better quality than the inflows, the Reservoir will achieve state water quality standards.	The statement that water in the reservoir will meet WQS is in the document in several places. Some addition wording to the effect will be placed in the FEIS.
	10. "The operation of the reservoir should not result in a substantial shift of nutrient loading from the wet season to the dry season." The Department is of the understanding that, absent a treatment mechanism or wetland buffer design, a shift in nutrient loads from wet season to dry season is anticipated. The Department had been working concurrently with the Corps to obtain the information necessary to determine whether the shift in nutrient loads from the wet season to the dry season, consistent with the expected operations of the	The requested document will be included in the FEIS

1164

	reservoir, would be harmful to waters downstream of the S-79 structure. Upon resolution, please include *The Supplemental Analysis C-43 West Basin Reservoir Effects on Dry Season Water Quality Downstream of the S-79 Structure* in the PIR. This document should provide the Department with the reasonable assurances necessary to ensure that the C-43 West Basin reservoir will not cause or contribute to an imbalance of flora and fauna in the waters downstream of the S-79 structure.	
	11. Please note that the Programmatic Regulations (Section 385.28 (c)(xvii)) require Project Implementation Reports (PIR) to include as appropriate, information necessary for the non-Federal sponsor to address the requirements of Chapter 373 of the Florida Statutes, and other applicable planning and reporting requirements of the Florida law. In order to serve as local sponsor of the Everglades national Park Seepage Management Project, or prior to seeking an appropriation from the Save Our Everglades Trust Fund, the South Florida Water Management District (SFWMD) will be required to obtain approval from the Department under §373.026(8)(b), Florida Statutes(F.S.). Approval is based on the Department's determination that the SFWMD has provided sufficient documentation to demonstrate compliance with the criteria set forth in Section 373.1501(5) F.S. The statute requires the SFWMD to analyze and evaluate water resource issues, natural system and habitat needs, determine that project components are feasible and consistent with applicable laws and regulations, provide assurances for water supply and flood protection, and coordinate with existing utilities and infrastructure to minimize impacts. We recommend that as the federal sponsor, the U.S. Army Corps of Engineers keep these criteria in mind during PIR development, and assist the South Florida Water Management District as appropriate in providing the necessary information to comply with these and any	Agreed. The Draft State Compliance Report was informally submitted to the FDEP on May 1, 2007. The formal submittal will occur after the Civil Works Review Board. This will allow for public input and agency reviews to be reflected in the final report. The timing will allow for the FDEP approval of the State Compliance Report prior to the issuance of the Chief's Report for the FPIR/EIS. The WBS for the PIR is structured so that State requirements can be satisfied as the PIR moves through the final approval process.

	other applicable requirements. Please note that the §373.026/1501, F.S. review is separate from the State Clearinghouse review required for all federal projects under the Coastal Zone Management Act, and requires a separate formal submittal from the SFWMD to the Department.	
	12. Upon completion of detailed design, this project will require a Comprehensive Everglades Restoration Plan Regulation Act (CERPRA) permit pursuant to Chapter 373.1502, F.S. The project may require a NPDES Generic Permit for Stormwater Discharge from Large and Small Construction Activities in accordance with Rule 62-621.300(4), Florida Administrative Code (F.A.C.). Other department permits may be required during the construction phase of this project, as applicable. We recommend that the Corps and the SFWMD coordinate closely with the Department in order to facilitate permit issuance.	Concur
FFWCC June 8, 2007		
	1. The numerous water control structures associated with this project could entrap, injure or kill manatees that may encounter them. Water control structures have been responsible for hundreds of manatee deaths (Fish and Wildlife Research Institute's manatee mortality database); however, with the appropriate safeguards, these structures can be rendered relatively benign. The most efficient way to achieve this goal is to prevent manatee ingress and egress to the C-43 reservoir by constructing manatee barriers at all access points to the perimeter canal and reservoir.	The USFWS, SFWMD, and USACE are in consultation to determine appropriate measures for the manatees. We have also consulted with representatives of FFWCC on this matter. Manatees will not be allowed in the perimeter canal or reservoir.
	2. Standard manatee construction conditions should be used in all waters accessible by manatees during the construction of this project.	Concur.
	4. We highly recommend using the information provided in the document entitled "Guidelines for Manatee Conservation during Comprehensive Everglades Restoration Plan Implementation."	This document is being used as a reference as consultation occurs.

1166

	5. During the winter season (November 1 through March 31) we recommend that water releases from the C-43 reservoir be monitored hourly for temperature with data retrieved daily, near the point of discharge (S-11). Monitoring data will be used to determine if water releases from the C-43 basin have the potential to create a warm-water site that is insufficient to sustain manatees.	The USFWS, SFWMD, and USACE are in consultation to determine appropriate measures for the manatees. We have also consulted with representatives of FFWCC on this matter.
	6. During the winter season, if water released from the reservoir creates a thermal plume that is greater than 20°C, or if manatees are observed using the site of the reservoir discharge on two consecutive days, then we request that the FWC-Imperiled Species Management section (850-922-4330) and U.S. Fish and Wildlife Service be consulted to resolve the issue of impacts on manatees.	The USFWS, SFWMD, and USACE are in consultation to determine appropriate measures for the manatees. We have also consulted with representatives of FFWCC on this matter.
	7. Recommendation: FWC requests that the U.S. Army Corps of Engineers and the South Florida Water Management District keep FWC apprised of the results of ongoing ASR studies and monitoring efforts so future manatee-related issues can be identified, refined and resolved proactively prior to the implementation of ASR technology.	Concur.
	8. Specifically, we support allowing waterfowl hunting and fishing as recreational opportunities that should be allowed on the C-43 reservoir.	Agreed. Fishing will be allowed subject to satisfactory agreements with FDEP and EPA. FWC, as the SFWMD partner, would need to provide the regulatory framework, hunt administration, and law enforcement support necessary to open the reservoir for any and all hunting activities. Hunting and fishing activities would be proposed provided such hunting and fishing activity is sustainable and compatible with the resource and does not conflict with the primary project purpose. Such activities remain subject to formal SFWMD and FWC cooperative authorizations.
	9. We recommend that the South Florida Water Management District	See FFWCC #8 above.

1167

	work with our staff during the assessment period to refine what types of activities could be accommodated. We would like to operate and maintain waterfowl hunting cooperatively with the South Florida Water Management District and others, as appropriate.	
	10. Recommendation: The use of soil cement for construction of the reservoir embankments is not conducive to the establishment and growth of submerged aquatic vegetation, an attractant for waterfowl. We recommend the placement of a natural substrate within the interior of the reservoir to allow for vegetation growth, which will increase the wildlife habitat value and assist with improvements in water quality through the reduction of nutrients.	Soil cement is needed for erosion protection of an earth embankment, so it is a safety consideration.
	11. We recommend planning for recreational alligator hunting on the C-43 Reservoir in the future.	See FFWCC #8 above.
	12. Project plans should provide roads and boat ramps allowing adequate public access.	Boat ramps for maintenance purposes are being constructed in a manner that could allow public access. Public use of the ramps and reservoir will be decided upon once the reservoir has been in operation for 18 to 24 months so that reasonable use can be determined.
	13. Portions of the reservoir footprint have been in citrus production. We recommend that these areas not be cleared prior to reservoir flooding. Citrus is fairly durable wood and should not degrade rapidly, thereby creating long-lasting fish and wildlife habitat. A similar recommendation provided a cost-savings during the construction planning of the Site 1 impoundment.	The citrus trees need to be cleared, since the contractor will need to obtain material for construction of the embankment from the reservoir interior. Citrus trees left in the reservoir may also present an operational problem if any are dislodged and caught in the outlet structures.
	14. Minimizing dry outs would benefit wildlife habitat through the reduction of nutrients and re-suspension of contaminants while providing for a stable aquatic community.	The reservoir will be operated to maximize benefits to the estuary, not to maintain habitat within the reservoir.
Seminole Tribe of Florida,		

1168

Rhianna Rogers, Tribal Historic Preservation Officer June 12, 2007		
	1. How was the APE determined for ths project and what archeological criteria was used for its construction? How are the archeological sites not included in the National Register being handled? (i.e., are they being surveyed and/or excavated)? ARCGIS includes a number of sites in this area and the STOF-THPO would like to know how those are being addressed.	Initial consultation with the Florida SHPO was conducted in 2002 (DHR Project File No. 2002-1944), follow up consultation based on the EIS scoping letter occurred in 2003 (DHR Project File No. 2003-2300), based on the comments a cultural resource survey was conducted on the 12,500 acre project area that was proposed at that time. This survey was conducted under contract to the Corps by New South Associates. Out of the 12,500 project acres approximately 2000 acres in 40 areas were identified as having a moderate to high probability of containing cultural resources. These moderate to high probability areas were identified using pre-development 1940 and 1944 aerial photos. The probability areas were based on proximity to drainage systems, high ground as evidenced by vegetation, and proximity to historic travel ways (as indicated on the historic aerial photos and on historic maps). A total of 3,606 shovel tests were conducted within the moderate to high probability areas. Four historic vernacular structures dating the 1950 were identified during the survey

		(8HN102, 8HN103, 8HN104 and 8HN105) these structures were determined no eligible for listing on the National Register of Historic Places. Additionally, four archeological occurrences were also identified. These consisted of an isolated sand tempered plain sherd, an isolated chert flake, a chert shatter fragment along with a railroad spike, and 11 bone fragments recovered from three shovel test units spaced 60 and 90 meters apart. There was no evidence that the bone fragments were part of a prehistoric archeological site. A no effect determination was made and concurred with by the Florida SHPO (DHR Project File No. 2004-8676). Because the proposed project area was modified to include areas not covered by the 2004 New South survey an additional survey was conducted in 2006 by Janus Research under contract with the South Florida Water Management District. This supplemental survey covered 597 acres and resulted in the identification of the prehistoric site 8HN129. This site is located near the eastern edge of the project area. The project was designed to exclude this site from the impact area. Because the identified site is outside of the potential impact area a determination of no effect was made for the additional project area (DHR Project File No. 2006-04319 and 2006-07757).

1170

	2. Is more archeological work planned for this project area?	At this time no additional cultural resource work is planned for the project area.
	3. The report provided sparse information about the archeology conducted for this project area. STOF-THPO did notice the mention of site (8HN129) and its possible eligibility for the NRHP but we could not determine if the other sites alluded to in the project as well as sites not mentioned planning to be surveyed and/or excavated in association with this project.	If you would like copies of the survey reports I can send them to you.
Hendry County June 11, 2007		
	1. The recreation features are being planned in the C-43 West Basin Reservoir project as an incidental project benefit according to language in Appendix H, Section H.2.1. Hendry County believes the proposed recreational activities should be a permanent part of the reservoir project. The recreational activities need to be clearly defined and not subject to removal. Hendry County would like a commitment, from SFWMD, to provide equestrian trails, biking and hiking trails, fishing, hunting, nature watching, and ramps for motorized and non-motorized boating.	The current plans for public access and recreation facilities will serve a wide variety of nature based recreation. All the activities asked for are reasonably expected activities and are not eliminated by the design. The levees, external canals and littoral zone designs will accommodate public access but their designs are not specific to that purpose. Specifics on how activities will be managed have not been determined and would likely change over time based on number of users and actual affects to the project. Managing recreational activities will be needed to ensure the project's purposes are served first, user conflicts managed second. SFWMD has developed rule 40E-7 which provides the ability to regulate the public access as may be needed.

1171

	2. Hendry County believes the recreational activities should be available upon completion of the construction and opening of the reservoir.	Recreational facilities will be opened to the public after the engineers and operations and maintenance staff are confident the project is functioning properly. The initial operational period is uncertain, but thought to be one to two years.
	3. The reservoir, during low volumes, should be opened to non-motorized boating and airboats at a minimum. There needs to be agreement between SFWMD and Hendry County on set standards that define low volumes.	Boat types and operations will be determined following the initial operational phase which will last from one to two years. Boats would need to be regulated. It is expected especially so during low water conditions. SFWMD hopes to develop a recreation management partnership with Hendry County and boat regulation would be a part of that.
	4. In Appendix H, Section H.2.1, page H-3, it is stated that shade trees are proposed on the outside area of the north rim canal adjacent to parking. Hendry County would like to see additional trees and vegetations planted outside and around the reservoir to promote bird watching, aesthetics, shade areas for the public, etc. The County wants the reservoir to become an asset and not an eyesore.	To date engineers have not allowed landscaping on the levee itself as this undermines the integrity of the levee and hinders the ability to visually inspect for signs of problems. We can consider landscaping on the outside edges of the exterior canal but will need to discuss the issue with Operations and Maintenance staff to determine any possible impacts.
	5. Restroom facilities should be provided and operated by the SFWMD. Additional facilities should be added at the expense of SFWMD, as the need arises, determined by Hendry County. The recreational opportunities of the reservoir should not be limited due to the size and number of restroom facilities.	We hope to develop a recreation management partnership with Hendry County. Types, location and management of recreational facilities will be a part of that negotiation.
	6. In Appendix H, Section H.2.2, page H-4, it is stated that the SFWMD has the ability to regulate boat types and engine types.	Please see Hendry County #3 above.

1172

	Hendry County wants the reservoir to be open to motorized boats and airboats. Any limitations on boat and engine types should be proposed in agreement with Hendry County.	
	7. No mention is made of SFWMD's plan, expressed publicly, to lease to Hendry County 100 acres north of the power line adjacent to SR 80 for a park. This is a critical component to the recreational opportunities this project should provide.	SFWMD hopes to develop a recreation management partnership with Hendry County and lease of the 100 acres north of the power line adjacent to SR 80 will be a part of that discussion. Full access for the SFWMD for operations and maintenance will need to be maintained through the 100 acres.
	8. Hendry County would like to see walking and biking trails placed around the levee.	Please see Hendry #1 above
	9. Hendry County would like to see the reservoir and rim canal open to boating, fishing, and hunting.	Please see Hendry #1 above
	10. SFWMD needs to provide additional littoral areas in the rim canal and within the reservoir to provide appropriate and adequate habitat for fish.	The reservoir design calls for littoral shelves on both banks of the perimeter canal, with "expanded" areas at the corners. The reservoir itself will have soil cement on the interior sides.
	11. The reservoir should be open from dawn to dusk for recreational activities.	We envision daylight hours as well
Lee County Southwest FL Board of County Commissioners June 11, 2007		
	1. Page XII Goals and Purposes of the Project—The document discusses the need to ensure that current levels of service for water supply in the Caloosahatchee basin could still be met with implementation of the Tentatively Selected Plan. In other portions of	Ensuring that the 2000 level of service for water supply are met is a project constraint for purposes of plan formulation. Any

	the document, water supply benefits are described as "indirect." According to the C-43 Draft PIR, all water available from the CRWBSR is slated to be available only for the environment. If there is even an "indirect" potable water supply benefit, this should be quantified. The County is supportive of placing a priority on the needs of the Caloosahatchee Estuary, but the multiple purposes of the project should not be lost.	additional water supply which may be provided by the project are considered incidental benefits, as increasing water supply for agricultural and municipal use is not a goal of this project. No water supply benefits will be quantified.
	2. Page XVI Goals and Purposes of the Project—The document describes the requirements for water to be identified for the natural system and other water related needs. This analysis was based on a draft of Programmatic Guidance Memorandum 4. It is the County's understanding that the methodology to make these determinations has not be(en) finalized and that a final methodology is still forthcoming in terms of this Guidance Memorandum. Is that still the case and will this have an effect on identifying water for the natural system and other water related needs?	GM 4 does not specify a methodology for identifying water made available. The methodology for determining water made available for the natural system and other water related needs may be found on pg. C-8 of Annex C. Identification of water for the natural system is based on the concept of water needed to achieve the benefits of the project and the overarching objective of restoration, preservation and protection of the S. Florida Ecosystem.
	3. Page XVI Goals and Purposes of the Project—The document lists the primary functions of the reservoir as capturing excess runoff and discharges and providing an additional source of water to maintain desirable salinity in the Caloosahatchee Estuary during periods of low flow. All water from the CRWBSR is then identified for the natural system. First, there are several differing goal and purpose statements for the project throughout the document. The goals and purposes for the CRWBSR from the original CERP "Yellow Book" should guide the project's implementation (see page 1-9 of the C-43 Draft PIR for a portion of this statement). If those goals and purposes have changed for some reason, the document should state that and the rationale for the change. Second, as stated earlier in these comments, the multiple purposes of the project should not be lost and even "indirect" water	The purpose and objectives of this project have not changed. This PIR is an affirmation of the conceptual plan developed in the Yellow Book. Water supply for agricultural and municipal use is considered a secondary benefit and will not be quantified in this report. As discussed on pages 5-3 and 5-4 the complexity of creating a whole-basin approach within one report would require a significantly extended study period and does not provide immediate relief to the

1174

	supply benefits should be quantified. The statement on this page, "The project will not provide any additional water for water supply of other water-related needs in the Caloosahatchee River basin," contravenes these concepts. See similar discussion on pages 5-3 and 5-4.	estuary. An incremental approach to restoration through smaller focus reports allows the immediate needs to be met sooner.
	4. Page XVI Goals and Purposes of the Project—The County supports maintaining the same level of water supply deliveries to agricultural lands adjacent to the CRWBSR where water supply canals were interrupted due to the location of the project, consistent with Section 601(h) of the Water Resources Development Act of 2000.	The operational plans provide for continued water supply deliveries to the adjacent agricultural lands.
	5. Page 1-9 Goals and Purposes of the Project—Page 1-9 lists a portion of the CRWBSR restoration objective from the original CERP documents (1999) as including water supply benefits, some flood attenuation, to provide environmental water supply deliveries to the Caloosahatchee Estuary, and water quality benefits to reduce salinity and nutrient impacts of runoff to the estuary. All of these benefits should be identified, consistent with 33 C.F.R. Part 385, or the Programmatic Regulations for CERP. Additionally, this restoration objective limits nutrient impacts to "runoff to the estuary" while ignoring the effects of Lake Okeechobee discharges. Estuary benefits and water quality benefits are "primary" system benefits and flood attenuation and water supply are "secondary" system benefits. Again, the water supply benefit originally envisioned in the restoration objective should not be lost and should be identified and this "restoration objective" should be consistently listed throughout the document.	The intent of the reservoir is to capture some of the releases from Lake Okeechobee and basin runoff. The water supply benefits are referred to throughout the report and are intended to supplement deliveries to the estuary during the low periods to maintain proper salinity balance to promote habitat suitability. Table 4-4 shows the relationship of project specific objectives with the CERP goals. The draft PIR does follow the programmatic regulations for CERP which include meeting all legal requirements of WRDA 2000 including maintaining existing levels of service for water supply, water quality and flood protection.
	6. Page 1-11 Goals and Purposes of the Project—While the County is supportive of addressing water supply needs and water quality in the upper basin in the subsequent PIR, any water supply benefits achieved now by the CRWBSR, although they may be de minimis, should be identified consistent with Federal law and the Programmatic	DPIR is consistent with Federal Law and Programmatic Regualtions. Benefits due to additional water made available are considered incidental and will not be quantified in this report.

	Regulations. This comment is also relative to Section 4.1.4.1 on Water Supply and the Annex C Saving Clause Analysis. See also Section 8.5.3.1 on identification of water made available and water for other water related needs.	
	7. Page XXIV CERP Project Phasing—The document describes that a subsequent PIR will be initiated to address the remaining water resource problems in the Caloosahatchee River basin which were not fully addressed by the Tentatively Selected Plan. These remaining water resource problems include: additional pumping and storage capacity, the need for additional water storage and management features in the upper basin and improving water quality. The County has been supportive of the "Phase II" approach for the CRWBSR. The last paragraph of that section further describes the Caloosahatchee ASR features being investigated as part of a **third PIR.** While we understand the need for the two-phase approach, the County is concerned that three PIRs, phases or studies to address the Caloosahatchee basin is excessive and sets a bad precedent for the implementation of CERP projects. The County does not support a third PIR effort for this project and all outstanding issues should be resolved in the Phase 2.	The decision to separate the Caloosahatchee ASR features from the rest of the basin features was made several years ago in order to gather more technical data from pilot projects prior to development of specific alternative plans, and in order to reduce risk and uncertainty associated with the technology. Depending on the timing of pilot project results, we may consider including the ASR analysis in the second PIR.
	8. Pages XI-XII-The Tentatively Selected Plan—The document lists the array of final alternatives. Alternative 3B, 170,000 acre-foot ("ac-ft") storage reservoir with a 1,500 cubic feet per second ("cfs") pump station is the chosen alternative. The County supports these features for the Tentatively Selected Plan at this time.	Noted.
	9. Pages XII-The Tentatively Selected Plan—The document lists a minimum flow of 450 cfs at the S-79 during dry periods. In later sections of the document (pages1-16 &2-34) there is an explanation of why this target was chosen in lieu of the established minimum flow and level ("MLF") criteria of 300 cfs. The County is supportive of using this higher minimum target although it is quite possible that this 450 cfs target is also slightly lower than the true needs of the restored	Noted.

1176

	Caloosahatchee Estuary. This should form the basis for the guiding the Phase II PIR effort. This comment also relates to the discussion on page 4-10.	
	10. Page XII-The Tentatively Selected Plan—The document describes structures C-43s 16, 17, 18 and 19 as possibly being constructed in "partnerships" between the SFWMD and Hendry County as a separate project under a different program. The cost of these structures is $4.5 Million. This commitment does not appear to be strong, because the structure "may" be constructed under the partnership. The document needs to address whether or not this partnership is tentative in nature or not and if so, the structures, and their cost, needs to be added to the overall project cost for the CRWBSR.	The SFWMD is currently in negotiations with Hendry County to go forward with the design, permitting and construction of needed infrastructure to resolve the problems that S16, S17, S18, and S19 were identified to resolve.
	11. Page XIV-The Tentatively Selected Plan—The document describes the added feature for the placement of 20 acres of artificial substrate in the Caloosahatchee Estuary for oyster, plant and animal recruitment. Although the County is supportive of this project feature this 20 acres equates to reaching roughly half to a third of the 40-60 acre targets for increases in the aerial extent of oyster reefs. See also page 7-4.	Your comment is noted. However, the oyster reef restoration plan has been removed from the federal project. The PIR is still recommending this placement for the health of the estuary, but it will not be recommended for funding as part of this PIR. It was felt that this plan could be executed more effectively by other entities.
	12. Page XX-The Tentatively Selected Plan—The document lists the project cost as $446,460,000. See also page 7-15 & page 8-2. It is unclear whether or not contamination clean-up costs, or a contingency fund for them, are included in this figure. A contingency should be added for the $4.5 Million in structures listed in the comment above (C-43s, 16-19) if that partnership project is tentative in nature. On page 5-36, Total Project Investment for Alternative 3B is listed as $486,307,000. Consistent cost figures should be used throughout the document.	Costs associated with the remediation of HTRW contamination is by law not cost-shared in Federal Civil Works projects. The project cost estimate included in the PIR does not include land remediation costs. The SFWMD is responsible for coordinating and paying for all remediation. The structures are being removed from the Federal project so their costs will be removed. Concur - consistent costs will be used

1177

		throughout the FPIR.
	13. Page XX-The Tentatively Selected Plan—The document states that the SFWMD constructed a test cell project to evaluate seepage and embankment design and water quality effects of the project (see also page 2-2). A brief summary of the results of that analysis and project in this section should be included. This comment is also relative to page 4-16.	Concur. This will be provided.
	14. Page 5-6-The Tentatively Selected Plan—Table 5-1 describes the various "management measures" (both structural and non-structural) that were considered in conjunction with the CRWBSR. All management measures were then screened out leaving only the actual reservoir and operations of that reservoir to achieve the planning goals and objectives. This entire analysis seems a bit misleading because the two factors driving this analysis were likely cost and time delay. While the County is supportive of expediting the CRWBSR and we support the approach of a Phase II to more fully address basin needs, it should be clear that these management measures will again be analyzed throughout the Phase II process. While they are not being implemented in conjunction with this phase of the project, they have not been removed from the table for further consideration. This seems to be why Table 5-2 was included, but the statement in that Table that "STAs may not be needed" is alarming before that analysis has concluded.	The second PIR will focus on water supply and water quality in the Caloosahatchee watershed. Therefore, the second PIR will develop structural and non-structural measures which are appropriate for the objectives of the project. The primary focus for this PIR is to evaluate various reservoir sizes for use in storing basin run off and lake releases to supplement dry season flows while proving high-flow attenuation.
	15. Page 5-24-The Tentatively Selected Plan—The County is supportive of the rational for the Alternative 3B being chosen as the Tentatively Selected Plan. It appears to achieve comparable environmental performance while taking an incremental approach on determining the appropriate pump size. Until more water storage is provided in the overall basin, it does not seem as though a larger pump is warranted at this time (see page 5-26). Page5-34 states that most project benefits accrue in the dry season and pump size would not affect these benefits. Any operational or incidental environmental or	The environmental benefits have been measured using habitat units as described in the document. The larger pump (Alternative 3C) did show higher environmental benefit, but additional factors were also used to determine the TSP. A larger pump allows more flows to be captured during the wet season and reduces

	water supply benefit achieved by a larger pump should be clearly reflected in the C-43 Draft PIR. This comment is also relevant to discussion of page 5-42.	the time to fill the reservoir.
	16. Page 5-43-The Tentatively Selected Plan—Is there an effect on project performance if there is a reduction in the 13-foot assumption for freeboard?	Project performance is related to the reservoir's design storage volume (approx 170,000 acre-ft). The required freeboard is necessary for embankment safety and is added to the embankment height which is necessary to provide the design storage volume. Passive overflow spillways C43CS1 and C43CS2 are included to prevent overfilling of the reservoir above the design volume.
	17. Page 5-47-The Tentatively Selected Plan—When the MIKESHE water budget modeling shortfalls discussed in this section be rectified? This should be completed before the C-43 Final PIR.	The MIKESHE irrigation water budget discrepancy was corrected. The corrected model was then used in the local flood protection assurance analysis presented in the DPIR. A separate spreadsheet analysis which utilizes modeling output from the SFWMM regional hydrologic simulation model was used in the next added increment analysis of the TSP to show no impacts to water supply. Therefore, rerunning the corrected MIKESHE model for all the project alternatives in order to evaluate water-supply related performance is not necessary to move forward with the TSP in the Final PIR.
	18. Page 5-49-The Tentatively Selected Plan—What "alternative methods" were used to show the Tentatively Selected Plan is in compliance with CERP Programmatic Regulations, WRDA 2000 and Florida State Law?	A spreadsheet analysis, utilizing modeling outputs, was used in the next added increment analysis of the TSP. A revised MikeSHE/Mike11 model was used to look

1179

		at the localized areas around the reservoir to demonstrate that the project does not have an impact to flood levels on lands adjacent to the reservoir.
	19. Page 6-9-The Tentatively Selected Plan—Alternative 3B is projected to meet the desired flows for the Estuary 74.8% of the time as compared to the current 46% estimate. This appears to be significant improvement but full restoration benefits must be the guide to project success.	Noted. We are trying to achieve the greatest benefit possible in a timely manner. There is recognition that additional water storage may be needed in the basin. This is why a second PIR is planned for the near future.
	20. Page 6-10-The Tentatively Selected Plan—The structural canal changes contemplated do not appear to be significant, but coordination with affected property owners must commence to avoid any delay in project implementation. See also discussion on page 7-3.	All needed easements and rights of way have been acquired.
	21. Page 6-15-The Tentatively Selected Plan—It does not appear as though there are any significant effects on groundwater elevations except the small increase (albeit in the dry season) north of the project site. Again, this effect must be coordinated with affected property owners to avoid any delay in project implementation.	Modeling indicates localized impacts less than 0.5 foot, which will likely be imperceptible to downstream users.
	22. Page 7-16-The Tentatively Selected Plan—The benefits and potential detriments of the public-private partnership described in this section are unclear. Which project features would be constructed in this fashion and are there any formal proposals for this effort?	There is no plan to form a public-private partnership for the design or construction of the project. The report will be corrected.
	23. Page X-Related Project, Permitting and Process Issues—The document discusses how aquifer storage and recover ("ASR") project features will be evaluated and implemented separately. Will this occur in a second PIR or separate initiative? How will this project be coordinated with the ASR contingency plan?	The ASR project features are currently being evaluated under the ASR pilot project program. These pilot projects will help determine "if" and "how many" and "where" permanent ASR wells might be established. A second PIR or separate initiative (not yet determined) would then use that information to further evaluate the ASR feature for this basin. The ASR

		contingency plan would be engaged if ASR technology is found to be not feasible for parts or all of the basin. Essentially, ASR in the C-43 Basin is a separate initiative.
	24. Page X-XI-Related Project, Permitting and Process Issues—The document similarly discusses an additional project to store basin runoff for backpumping and treatment form the C-43 Canal to return to Lake Okeechobee. Will this occur in a second PIR or separate initiative?	The backpumping and treatment that is discussed is a stand alone project under CERP. It will not be included in the second PIR.
	25. Page XXI-Related Project, Permitting and Process Issues—The document lists the C-43 Draft PIR process and the Department of the Army Section 404 (Clean Water Act) permit as separate but related activities. The estimated timeframes for the issuance of the permit should be included in the document. Will this be the July 2007 date for initiation of clearing and grubbing of the site?	The Regulatory Division anticipates using the FEIS as the NEPA documentation for the 404 permit. Consistent with CEQ Regulations the Corps cannot proceed with a federal action until 30 days after NOA of a FEIS. Therefore a Section 404 permit is not anticipated until after October 7, 2007. Additionally, clearing and grubbing in uplands anticipated to commence in July 2007, does not require a Section 404 permit.
	26. Page 1-12-Related Project, Permitting and Process Issues—The document lists the ASR Pilot Project as being conducted in parallel with a regional study on ASR. The timing of this pilot project and regional study needs to be listed to determine if these features can, and should, be included in the Phase II PIR. The document also lists the Caloosahatchee Backpumping with Stormwater Treatment (20,000 ac-ft) as a project used to agument regional system water supply. The County has not been supportive of this backpumping effort until we are sure the Caloosahatchee system targets are met first, including wet season and dry season flows, but again, any indirect water supply benefits from the CRWBSR must be identified in the current C-43 Draft PIR. The land acquisition needs to f this feature are uncertain at the time and due to land value escalation, this effort should be	The ASR Pilot Project for the Caloosahatchee is currently being reviewed. One unsuccessful well was began on the Berry Groves site. Other sites are currently being considered. In addition, the regional study is currently ongoing. The Caloosahatchee Backpumping project is not currently scheduled.

1181

	expedited.	
	27. Page 1-15-Related Project, Permitting and Process Issues—This section lists the various "State Initiatives" having an impact on future water quality both upstream and downstream of S-79. Projects and programs included in this year's Northern Everglades and Estuary Protection Act should be included in this section. This information should also be added to Section 3.6 on Water Quality, page 3-7 and page 6-40	At the time that the draft report was issued the Northern Everglades and Estuary Protection Act had not be signed in to law. It will be added.
	28. Page 1-17-Related Project, Permitting and Process Issues—The Caloosahatchee Water Management Plan ("CWMP") is referenced as identifying the need for 220,000 ac-ft of storage in the lower West Caloosahatchee Basin as a target for environmental restoration of the Caloosahatchee Estuary. With the CRWBSR including 170,000 ac-ft of storage, a gap of 50,000 ac-ft storage need to be met exists based on the CWMP. The 20,000 ac-ft target in the Caloosahatchee Backpumping with Stormwater Treatment project is less than this target. This additional storage need must be identified as quickly as possible due to the aforementioned land value escalation issues. This comment is relevant to Section 5.3.4.5 on Alternative 4A.	As mentioned in previous responses, a recognition that there may be a need for additional storage in the basin is one of the reasons for the second PIR which is planned to begin later this year.
	29. Page 1-18-Related Project, Permitting and Process Issues—Will the permits referenced on this page, Section 404 Clean Water Act, be issued before construction commences in July 2007?	Clearing and grubbing in uplands with anticipated to begin in July 2007 does not require a Section 404 permit provided there is no discharge of dredge of fill material in waters of U.S. At this time the SFWMD does not anticipate any discharge associated with clearing and grubbing.
	30. Page 2-11-Related Project, Permitting and Process Issues—Water use analysis is based on the CWMP document dated April 2000. The 2005-2006 Updated to the Lower West Coast Water Supply Plan should be utilized and referenced for this analysis. This comment is also relevant to Section 3.16 on municipal and agricultural water supply.	Your comment is noted. However, due to the expedited schedule we will not have time to utilize the new data.

1182

	31. Page 3-8-Related Project, Permitting and Process Issues—The Lake Okeechobee Operating Permit ("LOOP") is currently being used and discussion are ongoing regarding changes to the LOOP relative to structures that discharge from Lake Okeechobee into the Caloosahatchee basin. This information should be incorporated into the C-43 Final PIR. It should also be added the section on "Existing Operations" on page 8-4.	Operation of Lake Okeechobee is not a part of this PIR. The proposed reservoir does not affect the operations of the lake.
	32. Page 4-18--Related Project, Permitting and Process Issues—The Water Supply discussion references the Lower West Coast Water Supply Plan Update. This Plan has already been adopted by the SFWMD and should be a basis for water supply information in this C-43 Draft PIR.	The Lower West Coast Water Supply Plan is the basis for the water supply information in the Draft PIR.
	33. Page 6-22-- Related Project, Permitting and Process Issues—Will formal consultation with the U.S. Fish and Wildlife Service be completed by the release of the C-43 Final PIR?	Yes. Formal consultation with USFWS will be complete for the Florida panther, Audubon's crested caracara, and Eastern indigo snake.
	34. Page XVII – Water Quality Benefits and Impacts—The document states that "Impoundment water quality will be further assessed as part of the permit application and review process." It is important that this analysis occur as quickly as possible so that operational adjustments can be made or additional features can be analyzed to address any problems. The timing of this water quality analysis in conjunction with "the permit application and review process" is unclear. Is that a concurrent effort?	The referenced paragraph has been removed from the final document. The FEIS includes additional water quality analysis that further demonstrates that the project will not cause or contribute to water quality degradation. This additional information will be available for the 404 permit application review as well as subsequent permit applications.
	35. Page 3-8 – Water Quality Benefits and Impacts—Reference is made to the land use specific runoff quality factors adapted from Harper 2003. These figures have been updated since that time and a more current reference may be more accurate.	Using updated runoff quality coefficients is not possible at this time. While the total nutrient load calculations would change as a result of using different land use quality runoff coefficients, it would not materially change the overall water quality analysis or the project design.

	36. Page 3-9 – Water Quality Benefits and Impacts—The document makes the statement that nutrient loads delivered through S-79 to the estuary are expected to be no more than presently delivered to the estuary. This assumption is highly speculative given historical loading from Lake Okeechobee and the changes to those loading rates based on unforeseen events such as hurricanes. The summary of that section should include a statement on these unforeseen effects.	The prediction of 2050 water quality conditions are based on 20 years of historical water quality data, 35 years of hydrologic data, projected land use, and planned future operations. The effects of one time event such as hurricanes are reflected in the predictions since the historical data include these events. As with any prediction of the future, there is a good deal of uncertainty regarding its accuracy. The write up provided in the PIR adequately reflects this uncertainty.
	37. Page 4-8 – Water Quality Benefits and Impacts—The document states, "According to CERP guidance memorandum 23.01 "Water Quality Considerations for the PIR Phase," the C-43 Basin Project falls into Category B, which means the project should be designed to achieve water quality improvements." The significance of this statement, and reason for referencing this document, are unclear.	The purpose of referencing GM 23 is to indicate that CERP guidance was followed in regards to assessing and considering the water quality aspects of the project.
	38. Page 4-16–Water Quality Benefits and Impacts—The "Nutrient Reductions Opportunities" section discusses water quality benefits from just operation of the CRWBSR, but there is no mention of the actual amount of nutrient loading that will be reduced. It is the County's understanding that some of this more detailed information is available based on the Test Cell project. This section would benefit from some specificity in terms of the actual reduction contemplated by the CRWBSR alone.	The Environmental Appendix includes the detailed water quality analysis results requested here. The final analysis and interpretation of the Test Cell data is not available at this time (June 2007).
	39. Page4-30–Water Quality Benefits and Impacts—The Section on Water Quality Evaluation Criteria lists improving water quality as a secondary goal of the project. Improving water quality is not listed as a secondary goal in the original "Yellow Book" purpose statements regarding the project. This statement should be struck from the document.	Though water quality improvement may not be specifically mentioned in the "Yellow Book" as a "secondary goal" for this project it is one of the goals of the CERP. The statement will not be struck from the FEIS.

1184

	40. Page 5-34–Water Quality Benefits and Impacts—The document states that assuming no water quality treatment in the basin, TP, and TN loads are expected to be reduced 28 to 35% at S-79. On page 6-16, this figure is listed as 28%. Please explain the methodology for the 35% figure and the methodology to calculate these figures overall should be included in document. Additionally, the short term increases contemplated in TN, yet the achievement of the average annual load reduction, are unclear.	The water quality analysis presented in Appendix C includes a complete description of the calculation methods used to estimate project related nutrient removal. The water quality analysis did include an investigation of the likely impact of short-term increases in TN concentration. These short-term increases in TN concentration are not likely to have a significant impact on the average annual TN load at S-79.
	41. Page 5-35–Water Quality Benefits and Impacts—While the County agrees there may be a benefit from mere operations of the CRWBSR without a water quality feature at this time, it may be premature to conclude that the CRWBSR will not cause or contribute to water quality degradation under future conditions. See also page 6-17. Based on additional issues associated with contamination and clean up of the land and the short term TN issues identified in the comment above, this statement cannot be substantiated at this time. This comment is also relevant to the statement made on page 8-15, "The Caloosahatchee River (C-43) West Basin Storage Reservoir project selected plan complies with water quality standards applicable to the project and adjacent waters."	The water quality analysis presented in Appendix C includes a supplemental analysis prepared in conjunction with the FDEP that concludes that the project is unlikely to cause or contribute to water quality degradation. The Corps believes that the project will comply with state and federal water quality standards.
	42. Page 1-2—Miscellaneous Comments—There is a typographical error in the last paragraph on this page. "Achieve" should be changed to "achievement".	Noted. We will fix the text.
	43. Page 2-1—Miscellaneous Comments—The land exchange between the 541.31 acres located north of the project boundary for the 600.13 acre Paul property should be clarified. The effects of this swap on adjacent property owners should be reviewed. Will this land be needed for the activities commencing in July of 2007?	The land exchange is needed for the activities commencing in July 2007. The SFWMD has been coordinating with the adjacent land owners.
	44. Page 2-37—Miscellaneous Comments—The document states that without additional basin storage planned by CERP projects, flows	To be clear, we will change this sentence to read "in an average year flows exceed the

	exceed the target about seven months per year. The "CERP projects" referenced in the sentence should be identified.	target about seven months of the year."
	45. Section 2.12—Miscellaneous Comments—This section describes Hazardous, Toxic and Radioactive Waste property issues. The costs and commitments on remediating the sites are unclear. For example, is this issue considered in the $446 Million estimated project cost or is it a future cost to be borne by the State of Florida?	Costs associated with the remediation of HTRW contamination is by law not cost-shared in Federal Civil Works projects. The project cost estimate included in the PIR does not include land remediation costs. The SFWMD is responsible for coordinating and paying for all remediation.
	46. Pages 4-18—Miscellaneous Comments—The Flood Damage Reduction section says that the project will not compromise the existing level of protection and that some incidental benefits may be achieved. These incidental benefits should be more clearly identified.	This PIR will not quantify any incidental benefits. Only environmental benefits will be quantified.
	47. Page 5-4—Miscellaneous Comments—The County is in agreement that the Caloosahatchee Estuary is in need of immediate helps and cannot wait until a holistic approach is developed to address all of the issues within the entire basin. But, there should also be specific timelines and commitments to address the remaining issues in one additional single study to be completed by a dated certain. Potentially three PIRs and "subsequent studies" will continue to piecemeal the solution, cost more and delay that holistic approach to solving the Estuary's problems.	The second PIR will address the needs and issues of the Caloosahatchee watershed and will incorporate the findings of this PIR. Dennis Duke has committed that a second PIR will be initiated in Sept. 2007 to evaluate solutions to broader Caloosahatchee Basin restoration needs. The timeline for completion of this PIR is expected to be approximately 3 years.
	48. Page 5-37—Miscellaneous Comments—The following statement in the document is confusing, "If nothing was done to improve the conditions in the estuary, the project team determined that the future without project condition would experience a gradual improvement for 15 year at which point the ecosystem would stabilize." The statement should be clarified or struck from the document because it seems to say that the CRWBSR may not even be needed because eventually the ecosystem will stabilize. For instance, how will it stabilized when data shows (such as water quality) conditions have been deteriorating?	The statement will be altered to state that "eventually the ecosystem will stabilize at a severely degraded condition". The original statement addressed the fact that an outcome of our boundary conditions for the 2050 RD was a reduction in large volume flows released to the Caloosahatchee. This is thought to be due to a larger water demand on Lake Okeechobee from the southeast region of Florida. So although the

1186

		Caloosahatchee is expected to continue to deteriorate under existing conditions, the boundary conditions on our "future without project" model run result in less excessive flows released to the river.
	49. Page6-7—Miscellaneous Comments—The document should clarify the difference between "completely resolving the problems of the Caloosahatchee Estuary and Caloosahatchee River (C-43) Basin and "the immediate needs of the estuary."	The last sentence of the paragraph will be reworded to state "However, they all help to move towards restoration of the estuary by lowering the number and severity of extreme events and they all provide a significant improvement to the health of the estuary."
	50. Page 6-31--Miscellaneous Comments—The "commitment" from the SFWND that "all of the outstanding point source remediation efforts will be completed" is unclear. Does the SFWMD have funding allocated to meet this commitment and when will it occur? Is it subject of an agreement and if so, what agreement? This section is concerning because soil contamination has also been identified in cultivated areas on the site. Remediation efforts are to place these soils into the core of the reservoir dam. While the County understands the funding constraints on the project the efficiency of using on site resources to construct the dam. The document states that there is still a risk to benthic organisms and the solution would be additional remediation efforts if needed. Costs for these efforts and more detail is necessary to assure that this issued does not cause project delay. See discussion also on pages 7-18—17-19.	The point source remediation is about 75% complete, and the remaining point sources will be remediated by November 2007. The larger area copper and chlordane contaminated soils will be incorporated into the reservoir interior embankment (covered with soil cement).
Southwest Florida Regional Planning		

1187

Council June 5, 2007		
	1. A water quality treatment component needs to be included in the design of the reservoir project. The need for a water quality treatment component was identified early in the process of alternative development review by federal, state, regional and local agency participants of the PDT in the development of the PIR. It was deferred from consideration by the SFWMD and USACOE. Apparently, this reservoir project is the only reservoir design currently under consideration for CERP funding that does not have a water quality treatment feature. Based upon materials posted on the CERP web-site, east coast reservoirs have water quality treatment features included in their design. It is important that the current project design not preclude the necessary water quality treatment features. It is important that land not be surplused from the project footprint before necessary water quality treatment features are planned and constructed. Addressing hydrology without including water quality improvement is insufficient in protecting the estuary and aquatic resources of the Caloosahatchee River and the nationally recognized Outstanding Florida Waters estuaries at its confluence. H.R. 1816, the "Restoring the Caloosahatchee River: A Legacy for Florida" Act, was introduced by Congressman Connie Mack and the State of Florida Appropriations Bill delivered to Governor Crist includes funding a water quality component for the C-43 Reservoir project. The TSP should include water quality treatment features with sufficient space for their construction.	The need for a water quality treatment facility as a part of the CRWBSR Project was never identified. The need for a water quality treatment facility is being investigated through the State of Florida's Northern Everglades Program as well as the Caloosahatchee Watershed Project Implementation Report which is scheduled to begin in September 2007. In this PIR, the broader needs of the Caloosahatchee Watershed, including the need for water quality improvements, will be addressed.
	2. The littoral areas proposed at the corners of the seepage canal as part of the project should be constructed. We concur with the Florida Fish and Wildlife Conservation Commission that these littoral areas will provide habitat benefits and potential water quality benefits.	The reservoir design calls for littoral shelves on both banks of the perimeter canal, with "expanded" areas at the corners.
	3. All shade trees proposed on the outside area of the north rim canal adjacent to parking areas should be native to the Caloosahatchee	Noted.

	basin. Past selection and planting of exotic tree species in USACOE projects has led to damage to reservoir banks and project canal banks resulting in expensive remove programs and the need to construction repairs.	
	4. The missing pages in the Final Biological Assessment concerning methodology that should be present between pages A-95 and A-96 in Annex A of the FWCA Report and Endangered Species Act Compliance should be inserted into the documentation of the PIR.	This information is available at the Jacksonville District office and can be requested at any time. It was left out of the document in order to reduce the size of the final document and save paper.
	5. The SWFRPC supports the concept and development of the C-43 reservoir project to reduce the negative hydrologic discharges to the Caloosahatchee River, restoration of base flows for the Caloosahatchee River, and improvement in water quality of the Caloosahatchee River. Our staff has participated cooperatively in the development of the PIR and EIS. We did not and do not agree; however, that water quality protections should be deferred in development of this project.	See response SFRPC #1 above.
Committee of the Islands May 10, 2007		
	1. COTI urges the Army Corps of Engineers to work with South Florida Water Management District to include a filtration marsh in plans for the proposed C-43 Reservoir.	See response SFRPC #1 above.
A. Duda & Sons, Inc June 11, 2007		
	1. Well abandonment and ASR effects on local groundwater supply.	ASR is not a part of the CRWBSR Project. All wells at the reservoir site will be abandoned as appropriate.
	2. Public recreation on the outside of the Reservoir perimeter canal. This would provide the public with direct access to our property. Real recreational activity exists inside the proposed perimeter canal.	The SFWMD hopes to develop a recreation management partnership with Hendry County. Types, location and management

1189

	Access to the outside should be restricted to provide a buffer between offsite lands and the public.	of recreational facilities will be a part of that negotiation.
	3. The Townsend Canal capacity may become a problem in terms of our irrigation withdrawal. What measures are in place to offset this potential conflict?	The Townsend Canal is being improved to assure that the required capacity for both the Duda pump station and the CRWSBR pump station is available. Detailed Townsend Canal modeling has been performed, which included A. Duda & Sons current operations. Additionally, the CRWBSR goals are to pump water in the wet season, when A. Duda & Sons will most likely be discharging, and release water in the dry season when A. Duda & Sons will be irrigating. Therefore, the Townsend Canal capacity is thought to be sufficient to not impact A. Duda & Sons current operations.
	4. Will the Reservoir become a "consumptive user" of water in dry times? Other South Florida reservoirs require a minimum water level.	No, in periods of the drought, the reservoir will be dry. Only the perimeter canal will require water, but A8 modeling has shown that it is less than what is currently supplied to the same property for irrigation.
	5. ADS has an existing easement along the east side of the Townsend to SR80. What provisions have been made for equivalent access?	ADS access along the east side of the Townsend Canal will be maintained and accessible to ADS.
	6. Piezometers are in place to monitor lateral seepage to adjacent lands.	Agree
	7. Conversion of habitat on a tract this large may displace a	The animal population will disperse in all

	significant wildlife population. What mitigation avenues are available to an adjacent landowner if their property becomes a site for a refugee population?	directions and is not expected to cause a noticeable change in animal population for any adjacent landowners, as any area of land will only support the carrying capacity for each species. Please contact the USFWS for specific programs regarding threatened and endangered species movement to new lands.
	8. Page 1-5–1.1 Report Authority—this paragraph approves the ecosystem restoration, "while providing for other water related needs of the region." This phrase indicates a corresponding action, i.e., the water supply element is authorized along side the environmental releases to the estuary.	The CRWBSR Project does not have a water supply element associated with other than for the natural system to meet environmental demands downstream. This phrase indicates the intention to balance ecosystem restoration while maintaining existing levels of service for water supply, water quality and flood protection.
	9. Page 2-53—2.15 Existing Land Use—This paragraph limits the regional water supply benefit to a secondary concern. This is inconsistent with Section 601 of WRDA (see page 49)	The CERP is a multi-purpose project. The entire CERP will address water supply but each individual PIR may not address water supply. The analysis conducted is not inconsistent with section 601 of WRDA. Please note the following language as found in the WRDA. The savings clause is addressed elsewhere in the report. Calculating water supply benefits as incidental on a specific project is not inconsistent with WRDA *" (A) IN GENERAL- Except as modified by this section, the Plan is approved as a framework for modifications and operational changes to the Central and Southern Florida Project that are needed to*

1191

		restore, preserve, and protect the South Florida ecosystem while providing for other water-related needs of the region, including water supply and flood protection." Please note the language on the savings clause for water supply protection, which this PIR does address, additionally this PIR does provide water-related needs of the region which are not used for justification but are incidental to ecosystem restoration goals. Please see the agreement and project justification sections. The agreement below depicts the logic behind Section 2.15 *(2) AGREEMENT-* *(A) IN GENERAL- In order to ensure that water generated by the Plan will be made available for the restoration of the natural system, no appropriations, except for any pilot project described in subsection (b)(2)(B), shall be made for the construction of a project contained in the Plan until the President and the Governor enter into a binding agreement under which the State shall ensure, by regulation or other appropriate means, that water made available by each project in the Plan shall not be permitted for a consumptive use or otherwise made unavailable by the State*

1192

		until such time as sufficient reservations of water for the restoration of the natural system are made under State law in accordance with the project implementation report for that project and consistent with the Plan. Please see the section on evaluation of projects for language regarding the justification of a PIR. *(f) EVALUATION OF PROJECTS-* *(1) IN GENERAL- Before implementation of a project authorized by subsection (c) or (d) or any of clauses (i) through (x) of subsection (b)(2)(C), the Secretary, in cooperation with the non-Federal sponsor, shall complete, after notice and opportunity for public comment and in accordance with subsection (h), a project implementation report for the project.* *(2) PROJECT JUSTIFICATION-* *(A) IN GENERAL- Notwithstanding section 209 of the Flood Control Act of 1970 (42 U.S.C. 1962-2) or any other provision of law, in carrying out any activity authorized under this section or any other provision of law to restore, preserve, or protect the South Florida ecosystem, the Secretary may determine that--* *(i) the activity is justified by the environmental benefits derived by the South Florida ecosystem; and*

1193

		(ii) no further economic justification for the activity is required, if the Secretary determines that the activity is cost-effective. *(B) APPLICABILITY- Subparagraph (A) shall not apply to any separable element intended to produce benefits that are predominantly unrelated to the restoration, preservation, and protection of the natural system.* *(5) SAVINGS CLAUSE-* *(A) NO ELIMINATION OR TRANSFER- Until a new source of water supply of comparable quantity and quality as that available on the date of enactment of this Act is available to replace the water to be lost as a result of implementation of the Plan, the Secretary and the non-Federal sponsor shall not eliminate or transfer existing legal sources of water, including those for--* *(i) an agricultural or urban water supply;* *(ii) allocation or entitlement to the Seminole Indian Tribe of Florida under section 7 of the Seminole Indian Land Claims Settlement Act of 1987 (25 U.S.C. 1772e);* *(iii) the Miccosukee Tribe of Indians of Florida;* *(iv) water supply for Everglades National Park; or*

1194

		(v) water supply for fish and wildlife.
	10. Page —2-44--2.12 Hazardous, Toxic and Radioactive Waste—I did not see any summary of wells to be abandoned. Significant local and regional ground water contamination could result from improper or no well abandonments. Any proposed ASR wells would be far below any local aquifers, I presume?	See response to Duda #1 above.
	11. Page 2-49—4-17-- (repeated on page 173) The dependence of these "critical industries" on water supply points to the importance of maintaining the water supply benefits while providing the environmental releases for the estuaries. Agriculture and tourism have co-existed for over 100 years. To suddenly subjugate one to the other is unwarranted.	The intention of this project is to balance the needs of the natural system while allowing tourism and agriculture, both of which have a reliance on water, to continue.
	12. Page 4-14--..This comparison of the urban areas along the estuary to areas upstream of the S-79 tells only part of the story. If an acreage or total flow comparison of the entire S-79 tributary watershed were included, the 90% to 95% conclusion would not be surprising, given that the watershed extends from the S-79 to Orlando. In other words, the urban areas along the estuary are a very small portion of the total flow and therefore a small contributor to loading. Water quality issues within the local urban watershed should not be overlooked.	Comment noted.
	13 Page 4-18-- 4.1.4.1 Water Supply---The classification of water supply as "incidental" is contrary to Section 601 of WRDA 200o.	WRDA 2000 requires that water supply for existing legal users be maintained. Any additional water supply which may be made available through this project is considered an incidental benefit and not a primary purpose of this project.
Concerned Citizen Craig Mary @ Juno.com	1. In regards to the modeling of the Townsend Canal what eng. data or hydrolic data did you use as a baseline for the modeling. The question still remains how the 1500 cfs and or any additional pumps in the future and the 195 cfs pump st. to the south will effect the ability of other users of the canal.	CRWBSR will be pumping water in the wet season and releasing water in the dry season, which is opposite the Townsend Canal's current use. Detailed Townsend Canal modeling has

1195

	Beth comments mention the possibility of additional pumps but without saying at that time Townsend Canal improvements must take place. Why such a big pump st. to the south just to maintain an elevation in the perimeter canal	been performed, which included a 1,500 cfs pump station and A. Duda & Sons 300 cfs current operations. Improvements to the Townsend Canal to ensure sufficient capacity for the C-43 project and A. Duda & Sons are based on this modeling. If additional pumps were added, analysis would be conducted to determine what (if any) modifications would be needed to the Townsend Canal. The CRWBSR project needs to continue to supply the Paul property to the east and Berry groves to the north with the 195 cfs pump station.
Private Citizens	Comment	Response
William Morscheck, private citizen	1. I am writing to insist that the storage reservoir planned along the Caloosahatchee must include a filtration marsh. I understand that the Army Corps and the South Florida Water Management District (SFWMD) is planning this "C-43" reservoir without any stormwater treatment area (STA), or filtration marsh. STAs are included with other such reservoirs to the east and south of Lake Okeechobee. Why shouldn't the Caloosahatchee's reservoir also have such a filtration marsh? As the test cells for the planned reservoir have demonstrated, the water stored there will grow algae in great quantities. When it is time to release that water into the river, it will be even more degraded than when it went into the storage	The Caloosahatchee River (C-43) West Basin Storage Reservoir Project has, from the Restudy forward, always been envisioned primarily as a water storage feature. In addition to restoring more natural flows and salinities in the Estuary, the Restudy acknowledged the West Basin Storage Reservoir could achieve some water quality improvement benefits. Analysis conducted during this study indicates the Tentatively

1196

	reservoir. Without filtration, the reservoir will be simply an algae farm, and releases will be even more damaging. Releases into the Caloosahatchee River are having a huge negative impact on the estuaries along the Gulf to the south. Everything that can be done, must be done to mitigate this impact if the releases continue.	Selected Plan will reduce the average annual load of Total Phosphorus passing S-79 by approximately 29%, compared to the predicted future without-project conditions in 2050. It will reduce the average annual load of Total Nitrogen passing S-79 by approximately 28%. Most of this positive benefit is due to a reduction in flows from Lake Okeechobee. Nutrient loads will be shifted from the wet season to the dry season, but there will be a net decrease in frequency of exceeding dry and wet season, and annual TN loading performance measures. Some small amount of nutrient removal may occur due to settling out during residence time in the reservoir. Construction and operation of the reservoir neither cause, nor contribute to, water quality degradation. Both the US Army Corps of Engineers and the South Florida Water Management District want to construct this reservoir and provide benefits to the Caloosahatchee Estuary as quickly as possible. Further analysis of water quality treatment in this Project Implementation Report would delay the construction of the reservoir and realization of positive ecosystem restoration benefits to the Estuary. Water quality improvement features cannot be adequately designed without nutrient load targets, or

1197

		Total Maximum Daily Load targets. Unfortunately, such targets have not yet been developed for the Caloosahatchee River Watershed and Estuary. We have committed to further address water quality improvement needs in a follow-on Caloosahatchee Watershed Project Implementation Report, scheduled to begin in September, 2007. In this PIR, the broader needs of the Caloosahatchee Watershed, including the need for water quality improvement, will be addressed. In addition, the SFWMD is moving forward with plans to address water quality needs in the Caloosahatchee Watershed through its Northern Everglades program.
Richard B. Hasselman, private citizen	2. Please include a water treatment plant in the design of this reservoir and its associated systems, so that all nutrients and other pollutants are removed from any and all water which flows down the Caloosahatchee River. Thousands of us residents of Southwest Florida are suffering from the red drift algae and other problems which have been created by the flow of untreated water from Central Florida, and we desperately need the Corps of Engineers to correct that quickly. May we hear from you, please?	See reply to private citizen comment #1 above.
Henry Glissman, private citizen	3. Why are you doing only half a job on thus critical project. No way to clean the water is criminal!	See reply to private citizen comment #1 above.

1198

Barbara Joy Cooley, private citizen	4. I object to the plans for the C-43 reservoir because they do not include a stormwater treatment area (STA, or filtration marsh) to treat the water before it is released into the Caloosahatchee. Without such an STA, the reservoir will be an algae farm and will actually harm the water quality in the Caloosahatchee estuary.	See reply to private citizen comment #1 above.
Hazel & Ed Schuller, private citizen	5. Please attend to our community-in-crisis and need for environmentally safe water quality. Isolated chemical elements, and/or combinations of red-tide organisms & algae-producing agents, are poisoning Florida rivers, estuaries, Gulf of Mexico and the City of Sanibel coasts and waterways. Red drift algae, especially offensive when stinking dead fish decay within an algae tidal mass, makes the beach undesirable at times for recreation and visitor uses. The City is considering approval of abusive cleaning methods that may destroy unknown minutest beach & marine life, bird habits and other conservation uses. Resorting to mechanically cleaned beaches, achieving a sterile environment such as in Naples, may soon be Sanibel Island's final "last resort" solution. Thank you.	See reply to private citizen comment #1 above.
William (Bill) Kelley, private citizen	6. It makes absolutely no sense to store polluted water in the C-43 Reservoir and release it into the Caloosahatchee river. It is absolutely necessary to provide storm water treatment such as a filtration marsh. If all other reservoirs for the project has filtration what possible reason can their be for no filtration for C-43.	See reply to private citizen comment #1 above.
Eric Orkin, private citizen	7. It has come to my attention that a "C-43" reservoir without any stormwater treatment area (STA), or filtration marsh is planned along the Caloosahatchee. This will undoubtedly lead to increased algae in	See reply to private citizen comment #1 above.

	the estuaries and coastal waters around Sanibel. I have lived here for just over three years and have already seen a remarkable degradation in the water quality, the presence of grasses, and the presence of fish. We participate in the Osprey counting and the number of offspring has dropped precipitously from over 80 last year to the mid-teens this year. Although it may not yet be proven, it is very likely due to the water quality around the island. In addition to our usual incidence of red tide, this year we have had unheard of quantities of red drift algae. This has had a serious economic impact on the island. It is my understanding that STAs are included with other reservoirs to the east and south of the lake. Why has the Caloosahatchee reservoir been singled out? Please consider the impact of the plan on this area that is so dependent on the quality of its waters for its economic health. Do not make short term decisions. Do not sacrifice one region, which is a gem within the nation and the state, for the economic gain of powerful commercial interests. Imagine that you lived in one of the towns around Pine Island Sound, that you boated with your family and fished these waters. Imagine that your family had jobs dependent on tourism. Now, make the right decision.	
Private citizen	8. The c-43 reservoir must have a STA to be effective	See reply to private citizen comment #1 above.
Allen Cater, Private citizen	9. It would be a gross waste of out taxes to build C43 without an STA!	See reply to private citizen comment #1 above.
Newton E. Cook, private citizen	10. I will be unable to attend the meeting 5/17 in LaBelle due to conflicts, including a meeting the evening before on the CERP DECOMP project. However, I want to emphasize the need to include sufficient access for public recreational use on the Reservoirs and STAs being constructed in the massive Everglades project. The Reserviors will be meccas for ducks and other waterfowl, as well as	The current plans for public access and recreation facilities will serve a wide variety of nature based recreation. All the activities asked for are reasonably expected activities and are not eliminated by the design. The levees, external canals and littoral zone

1200

	offer some fishing. The inititial construction plans for the C-43 Reservior must include a boat ramp or ramps that will be suitable for public use. We understand a test period will be required on the reservoirs before public access, but there is no reason to expect any restrictions on access and the basic construction is much less expensive if done as part of the project. We also want to insure "hunting", specifically "waterfowling", will be included in the approved recreational plan. Thank you for the opportunity to comment.	designs will accommodate public access but their designs are not specific to that purpose. Specifics on how activities will be managed have not been determined and would likely change over time based on number of users and actual affects to the project. Managing recreational activities will be needed to ensure the project's purposes are served first, user conflicts managed second. SFWMD has developed rule 40E-7 which provides the ability to regulate the public access as may be needed.
Donald L. and Meleanor L. Deming, Private citizens	11. We would like to add our voice to the insistence that the storm water treatment area proposed for C-43 must include a filtration marsh to go with the C-43 reservoir.	See reply to private citizen comment #1 above.
Curt Stendahl, Private citizen	12. Now after Hurricane Charlie the local eco system has been seriously disrupted and Sanibel Island as well as neighboring municipalities have been plagues with red drift algae accumulating on our shores. We now urge the U.S. Army Corps of Engineers to do your part in assisting our efforts to eliminate this plague from our beaches. You can help by adding a storm water treatment area (STA) to C-43 as you have done with other reservoirs you have developed in south Florida. Without these STAs I am convinced that some form of algae will form, be subsequently discharged to the Caloosahatchee River and end up on our beaches when C-43 is drained. We are only asking for fairness. If other areas are provided with STAs to provide them with quality water why not do the same for Southwest Florida?	See reply to private citizen comment #1 above.
Rhonda Roff,	How many acre-feet are capable of being stored in both cells?	The reservoir will be able to store 170,000

1201

Conservation Chair for the Hendry-Glades Audubon Society, President of the Save It Now, Glades! organization		acre-feet of water and the average depth will be seventeen to nineteen ft.
	Where would the natural salt line of the Caloosahatchee River be in the absence of the Franklin lock?	There would be no specific salt line. The salinity would vary as a function of wet season and dry season conditions. The saline water would move upriver during the dry season and then back out into the estuary in the wet season.
	And with the lock in place, is it right there at the lock all the time?	No, it depends on freshwater flows. At high flows the saltwater/freshwater interface will move out into the estuary, and at low flows it will move upstream to the lock or beyond. During the dry season, we actually release freshwater from the lake specifically to manage the salinity at the Olga Water Treatment plant located upstream of the Franklin Lock. So the saltwater/freshwater interface still fluctuates, but not like it did when it was a natural system.
	Any habitat augmentation that would be available within the project to allow for bird nesting, migration, and wildlife utilization of the reservoir would be greatly appreciated.	
	There are plans to build a coal-fired power plant in Moore Haven. Some SFWMD employees have stated that a benefit of the power plant would be its potential to withhold upstream freshwater from moving downstream and creating additional freshwater pulses. The plant, if built, will occupy 4,900 acres, some of which will be used to store recycled cooling water. Will this power plant offer substantial freshwater storage and is it needed for that capacity. Will the reservoir provide enough storage so that the power plant is not needed as a source of water storage?	The power plant would only be holding enough water to operate their cooling system, probably not anywhere near the amount the reservoir will hold. The power plant is not looking just at surface water as a water source, but also ground water. The Northern Everglades Project that the state of Florida has initiated will provide the most water storage in the region. This project will hold excess water north of Lake Okeechobee. The SFWMD has not taken an

1202

		official position on the Glades Power Plant at this time. The power plant is currently in the siting permit review phase. You can submit your questions to DEP as part of the public response process to the power plant's application for approval.
	The proposed power plant is requesting 28 million gallons of water per day. Of the average daily volume of flow in the Caloosahatchee River, what percentage does 28 million gallons constitute?	We do not have an answer for you at this time, but we will get that information to you.
Chris Shepard, Lake Okeechobee fishing guide	When the reservoir is completely filled, how many feet above sea level will the average water level be? And how high will the levees be?	The water will be at about 42ft. above sea level when the reservoir is full. The levees will be 38ft. to 48ft. above grade.
	During a major event, what percent of the volume of water moving downstream in the Caloosahatchee can be captured in the reservoir?	The pump on the reservoir can pump 1,500 cubic feet per second (cfs). What passes down the Caloosahatchee obviously varies with the amount of discharge coming out of the lake. But we've passed as much as 20,000 cfs or 25,000 cfs over the S-79 structure, but keep in mind that a lot of that's generated within the basin downstream of the proposed reservoir. So water can be pumped into the reservoir at a rate of 1,500 cfs, and we see peak flows of 20,000 cfs in the river. Fortunately, the peak flows happen rarely. We cannot give you an exact number but that gives you an idea.
	Is there going to be a hurricane preparedness/response plan in place for the reservoir?	Yes, that will be part of the operating plan for the reservoir.

1203

	If the reservoir is full and Lake Okeechobee is full and we get hit with another Wilma, who's going to be bringing the boats around to pick everybody up? The downstream flow from those two reservoir cells is going to go to Lehigh and Ft. Myers and there are a lot of homes in that area. I would rather see the $$ for C-43 go to fixing Lake Okeechobee. Do not see C-43 helping that much.	The addition of the reservoir to the Caloosahatchee system should reduce the chance of flooding to the areas downstream of the reservoir because the reservoir will provide a place for some of that flood water to be captured. We are able to release water 72 hours in advance of a storm to make room for flood waters. The reservoir levee system will be built to compliance so that the reservoir itself should not flood. Noted.
Joe Frank, Tribal Representative	1. If the aim of this project is to restore the quality and timing of flows to the natural levels, then it seems a more worthy project would be to restore the Caloosahatchee River, not build another lake. 2. It seems that this project is just being built to further the development of western Hendry county, so maybe the developers should pay for the project rather than the tax payers. 3. If the project is for Everglades restoration, the excess lake water that the reservoir is supposed to be receiving should be going south through the Everglades not west out the river. 4. You should consider building the reservoir in the likeness of and in the historic location of Lake Flirt so that the reservoir mimics a feature of the original Caloosahatchee watershed.	1 – 4. The Everglades system today is only half the size it used to be. We still have the same amount of rainfall. Because of Herbert Hoover Dike, the lake can only hold half of the water it historically could. So we've got the same amount of water but only half the area to put it. If we direct all of the water that used to go to the Everglades back into the Everglades, it would be twice as deep as it used to be. This would be extremely harmful to the health of the system. So we are trying to balance the water budget. That's part of the overall goal of CERP.

1204

	5. Will there be job training for agricultural workers displaced by this project?	5 - 6. The Water Management District, Senator Pruit, and other state representatives have been very active in developing job training programs with the local college communities; and they've been training people for that. They're structuring their contracts to provide on-site training for workers. We're projecting the loss of up to 5,000 jobs as a result of the project. However, the project itself and many of the CERP projects will offer some new opportunities for employment in the areas of construction, operations, and maintenance. The SFWMD has taken the lead on developing the job training programs. The Corps is currently looking at incorporating the job training into our contract for this project and future CERP projects.
	6. How will this project affect the tax base of Hendry county?	
	7. Will seepage problems ultimately drive up the cost of this project? The soil is pretty sandy out there. It's going to be very expensive to line 20,000 acres with barriers.	7 – 8. There were test cells constructed to determine the rate of seepage in the Berry Grove area. Cutoff walls will be constructed around the embankment to control seepage, and the canal around the
	8. Such a large body of water is going to lead to increased algal blooms in the river. It's also going to create more pestilence problems,	

1205

	more insects and such.	perimeter will collect the seepage that gets out of the reservoir. Water Resource Development Act of 2000 states that when a project is built for restoration purposes, the project cannot harm existing levels of service for flood protection or existing sources of water for water supply without a similar source being made in lieu of that. A thorough water quality monitoring plan has been recommended to track any water quality issues (such as algal blooms) in the reservoir. In addition, a second PIR for the Caloosahatchee Basin is planned which will evaluate water quality in the basin and propose potential solutions.
Margaret England, Hendry-Glades Audubon Society and Caloosahatchee River System Association River Watch representative	Will the littoral zone on the perimeter canal provide habitat, like a sloped area for wading birds and migratory birds, and if so will this habitat be seasonal or year-round? Will habitat be provided or maintained for the caracara and other birds that are currently on this site and will native vegetation be planted to encourage some of our native species including the caracara and gopher tortoise? How will water quality be monitored and when will this begin? What	The littoral zone habitat will be a year-round feature. The caracara nests are actually not on the reservoir site. There's one to the north and one to the southeast of the site. We're currently in formal consultation with the Fish and Wildlife Service on the caracara to determine what we'll do to account for those nests. The reservoir is actually part of the caracara's secondary foraging zones. There will be some kind of compensation, but it hasn't been worked out yet what that will be. In terms of permitting released discharges

1206

	pollutants will be monitored; nutrients, fertilizers, chemicals from sewage?	from the reservoir, part of the water quality certification that are we going through with the State specifies monitoring requirements that address a lot of those parameters. The State will compose a list of parameters of concern. Our water quality monitoring plan will depend on what parameters of concern; phosphorus, nitrogen, e-coli, et cetera, are indicated by the State. The Phase 2 PIR for the Caloosahatchee River basin will deal more directly with water quality issues.
John Cassani, Private Citizen	At any time after the reservoirs construction, will the stored volume of water be available to water supply users for uses such as agricultural irrigation? If so, is there any mechanism or requirement to legally reserve the water for its intended purpose?	The water is not going to be discharged directly from the reservoir to any water supply user. Now, considering that, when the water is released from the reservoir into the Caloosahatchee River, it's going to flow downstream past the Lee County water supply intake, and we can not control water uptake there.
	In the modeling for this project, under average conditions during the period of record regarding low flows, the performance of the system on average, the do nothing alternative was about 38 percent of the time that low flow exceedences would occur. With the reservoir in place and working, what would be the performance on low flows? What percentage of the time would it be out of specs operating at peak performance under average rainfall conditions?	We're within the desired flow envelope 75 percent of the period of record that we modeled. We can get you more detailed information explaining by what margin we're within that minimum flow rate. Our model was based on period of record, not average conditions.
	You shouldn't imply that the project is going to get flows in spec 75 percent of the time because they're already within specs 60 percent of the time. So you're going from about 38 or 40 percent out of specs to about 25 percent. So the difference between the two is really the performance on the project. It's not 75 percent of the time. It's kind of	We're actually comparing to the future without project condition. And as we

1207

	an important distinction.	modeled that future without project conditions, the model flows were only within the envelope about 46 percent of the time, so it's jumped from 46 percent to 75 percent.
Richard Hamann, University of Florida	Will the PIR recommend an amount of water to be reserved?	Yes, this PIR will have that in the operating plan, but that amount has not been defined yet. The way the law reads, the reservation has to be adopted into rule prior to or at the time of our signing of the Project Cooperation Agreement. And the Project Cooperation Agreement will not be signed until Congress authorizes the project because the federal government can't sign a cooperative agreement if they're not authorized to do the work. Within the Caloosahatchee Western Basin Storage Reservoir PIR there is a whole chapter on project assurances discussing what amount of water will be reserved, how we got to that amount, and how we're impacting existing legal uses. The water amount is not a simple number though.
	Does that reflect the fact that you don't quite know how to describe the reservation for the rule making yet?	No. It's actually a function of how the water is to be delivered to be of benefit to the environment. We want to not only reserve the quantity but also the timing and distribution of that water. It's a complicated process.

1208

B.4.1 Written Correspondence

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
REGION 4
ATLANTA FEDERAL CENTER

June 7, 2007

Mr. Stuart J. Appelbaum, Chief
Planning Division
U.S. Army Corps of Engineers
Jacksonville District
P.O. Box 4970
Jacksonville, FL 32232-0019

SUBJ: EPA NEPA Review of the COE "Draft Caloosahatchee River (C-43) West Basin Storage Reservoir Project" (April 2007); Hendry County; CEQ# 20070159; ERP# COE-E39068-FL

Dear Mr. Appelbaum:

In accordance with our responsibilities under Section 102(2)(C) of the National Environmental Policy Act (NEPA) and Section 309 of the Clean Air Act, the U.S. Environmental Protection Agency (EPA) has reviewed the referenced U.S. Army Corps of Engineers (COE) Draft Environmental Impact Statement (DEIS) for the proposed Caloosahatchee River (C-43 Canal) West Basin Storage Reservoir Project (C-43 Reservoir). This proposal is a major component of the Comprehensive Everglades Restoration Plan (CERP) and therefore was reviewed as a project implementing the overall goals and objectives of Everglades restoration. EPA (Water Management Division) attended the COE's project Public Hearing in LaBelle, Florida on May 17, 2007.

Current Ecological Conditions

The Caloosahatchee River and Estuary are being stressed by seasonal freshwater releases from Lake Okeechobee and historic water management/urban/agricultural development within the C-43 Basin. The downstream releases from Lake Okeechobee result in seasonal high and low flows (too much or too little freshwater), elevated nutrients, and salinity fluctuations for the fresh and brackish water ecosystems below S-79 (including riverine and estuarine fisheries, oysters and submerged aquatic vegetation (SAVs) such as *Vallisineria*). While the COE's ongoing modifications to Lake Okeechobee's water release schedule (WSE) will temper these downstream impacts, additional water storage is needed to more effectively reduce these impacts and control the volume and timing of releases to the affected lower Caloosahatchee River and Estuary. In addition to these natural system impacts from seasonal flows, the impacts of losing large volumes of freshwater to tide is another consideration. Overall, 1.7 billion gallons of water per day are lost to the Gulf of Mexico and Atlantic Ocean that once flowed through the Everglades.

Proposed C-43 Reservoir

The proposed C-43 reservoir would be an above-ground, 10,500-acre impoundment with a 34-39 ft high dike constructed on an existing 12,372-acre orange grove farmland site in Hendry County. The 15-25 ft deep reservoir would have a 170,000 ac-ft storage capacity and would be compartmentalized into two cells. Water inflows would be controlled by a 1,500 cfs pump that would process some 20% of average annual Caloosahatchee River flows (Lake Okeechobee release water and basin runoff water) by way of Townsend Canal during wet seasons, and return impounded water back to the Caloosahatchee River upstream of S-79 during dry seasons. The average hydraulic residence time (HRT) of the impounded waters would be lengthy (192 days), allowing for some settling of nutrients (TP&TN) and particulates (TSS). Such water quality benefit could be slightly counteracted by algal nitrogen fixation in the reservoir.

Resident fish and other fauna can be expected to establish within the impoundment, although the reservoir habitat will be minimal since it will have no littoral zones and will experience dry-downs. However, the impoundment's sloped bottom design could create a remaining pool in the northwest deep end (25 ft) for fish refugia. Much better habitat would exist in the perimeter canal that would surround the reservoir and include 109 acres of littoral habitat along its banks. The perimeter canal is designed for impoundment seepage control and to allow continued agricultural water supply from Townsend Canal.

In addition to flow management to moderate the impacts to the lower Caloosahatchee River and Estuary, the project is to also provide a total of 20 acres of oyster habitat (shell for spat) over a period of the first 10 years of the project. Also, although the impoundment is designed to benefit the lower Caloosahatchee systems rather than provide agricultural or urban water supply, it would nevertheless generate some water supply benefit by providing more dependable, year-round flows at S-79 where an existing urban water supply intake is located.

Alternatives

In addition to the No Action Alternative, four action alternatives were carried forward for analysis in the DEIS (Alts. 2, 3B, 3C & 4). These alternatives would have the similar designs (2 cells and a 10,500-ac footprint), differing only in capacity (100,000, 170,000 or 220,000 ac-ft volume with a 27-44 ft high dike, and an inflow pump size of 1,500 or 3,800 cfs). The COE's Tentative Selected Plan (= preferred alternative) for the C-43 reservoir is Alternative 3B, which proposes a 34-39 ft high dike and a 1,500 cfs pump (PS-1). Although a larger pump would be beneficial in minimizing pulsed high flows and providing greater flexibility (pg. 6-9), we understand that the 3,800 cfs pump would be considerably more expensive. A larger reservoir would also have similar benefits but would also have higher attendant land and other costs (e.g., a larger reservoir alternative (4B) was eliminated due to cost).

The performance of these final four action alternatives was reviewed (Table 6-2) against a "desired envelope" or flow target (EST05). Preferred Alternative 3B agreed with the desired envelope 74.8% of the time compared to only 45.5% for the No Action (= 2050 Future Without Project). As expected, project alternatives with a larger pump (Alt. 3C: 82.3%) and greater reservoir volume (Alt. 4: 83.8%) performed slightly better (since they would reduce high flows better), while those with a smaller volume and similar pump (Alt. 2: 67.9%) performed slightly less. Therefore, at its capacity level, Preferred Alternative 3B is in the middle of the ordered performance range (Alts. 2, 3B, 3C & 4). We will defer to the COE as to whether such capacity is sufficient to recover the lower Caloosahatchee River and Estuary, or if additional performance is needed through the selection of a larger design in the FEIS, or through monitoring and adaptive management of preferred 3B (if implemented), and/or through the addition of supplemental storage capacity along the Okeechobee Waterway in the near future.

Project Implementation

Above-ground, in-ground and/or underground reservoirs were planned components of the original Restudy and current CERP. However, due to federal delays in project authorization and funding, the present C-43 Reservoir project is being implemented by the State of Florida (South Florida Water Management District sponsor) for the COE through its Acceler8 Program to expedite the project. The present EIS is expected to serve as the COE's NEPA documentation for the federal project (once appropriated) and presumably also for any regulatory permitting responsibilities. EPA appreciates the State's role in this regard in order to advance the implementation of CERP components of Everglades restoration.

EPA appreciates that the Jacksonville District has committed to initiating a Calooshatchee Watershed Project Implementation Report (PIR) effort in September 2007, to further address water storage and water quality treatment needs in the Caloosahatchee basin. Under the 1999 TMDL (Total Maximum Daily Load) Consent Decree, TMDLs for nutrients, DO, fecal coliforms and metals must be proposed by the Florida Department of Environmental Protection (FDEP) and approved by EPA no later than September 30, 2010 (or proposed by EPA by that date). The recently passed State of Florida 2007 Northern Everglades legislation requires earlier action by FDEP; specifically, to "...no later than 12/31/2008, propose for final agency action, TMDLs for nutrients for the tidal portions of the Caloosahatchee river and estuary." It is therefore important that close coordination between the Caloosahatchee Watershed PIR effort and FDEP/EPA TMDL programs occurs, such that nutrient reduction target setting is consistent between these efforts. It appears likely that future proposed TMDL-related nitrogen (TN) loading requirements at S-79 will require additional water quality treatment efforts in the Basin, such as agricultural BMPs and Stormwater Treatment Areas (STAs). In addition to the PIR effort, the Project Operating Manual should be expanded to more fully address possible operational actions to improve water quality conditions in discharge waters, while still achieving other project objectives.

When completed, the proposed project will be a large reservoir. As a reservoir, it will be considered waters of the United States and waters of the State, and State Class III Water Quality Standards (WQS) will apply. EPA has water quality concerns with the reservoir given the potential for high nutrient loads into the reservoir, and the resulting potential for high nutrient concentrations, low DO, presence of nuisance aquatic plants such as blue-green algae, and pesticides within the reservoir and downstream during releases. Since there is the potential for the reservoir to have poor water quality, it is important to identify what potential operational, management or other steps will be taken to address these water quality concerns if they arise. We also note that the Section 401 water quality certification has not been issued at this time and reserve our authority to comment further at that time.

Project Impacts

EPA fully supports the concept of providing additional water storage along the Okeechobee Waterway such as the C-43 Reservoir. Therefore, our concerns with the C-43 reservoir project are not conceptual but rather focus on project improvements from an environmental perspective. Our main concern is water quality assurance for flows released from the impoundment to benefit the lower Caloosahatchee natural systems. More specifically, we are concerned about the potential for warm weather blue-green algal blooms with algal toxins in reservoir waters, as well as low levels of dissolved oxygen (DO) in the waters released from the reservoir. Reductions in the algal growth potential and augmentation of DO levels for impoundment waters may be needed to improve water quality for the proposed project. Warm weather blue-green algal monitoring (monthly) should be required in the reservoir Water Quality Monitoring Plan.

EPA DEIS Rating

EPA rates this COE DEIS as "EC-1" (i.e., we have environmental concerns and request some additional information in the FEIS). Our primary concern for this project is water quality assurance. Our water quality and other comments are further developed in the *Detailed Comments* enclosure.

Should you have questions regarding our comments, feel free to contact Chris Hoberg of my staff for NEPA-related issues (404/562-9619 or hoberg.chris@epa.gov) or Eric Hughes in our EPA Water Management Division (located in your Jacksonville District office) for technical issues (904/232-2464 or hughes.eric@epa.gov).

Sincerely,

Heinz J. Mueller, Chief
NEPA Program Office
Office of Policy and Management

DETAILED COMMENTS

We offer the following recommendations for the COE's consideration in the development of the FEIS:

Water Quality

* *Nutrients* - As suggested in the DEIS, the water quality of the water released from the C-43 impoundment to the Caloosahatchee River should be no worse than the inflow water. We agree. Consistent with the purpose of the reservoir to improve estuarine health, water quality management should complement water quantity management as an important project goal. As such, we recommend that the algal growth potential (AGP) of the impounded waters be assessed to minimize algal blooms and associated toxins in the water column. Intuitively, reservoir conditions are conducive for algal blooms due to the impounded water's warm temperature, high nutrient loadings and long residence time. In contrast, the potential for algal blooms could be reduced since nutrients would settle during the residence time, Lake Okeechobee water releases are expected to be less over time, and Caloosahatchee River nutrient TMDLs will be established. For the project, a 29% reduction in TP loads and a 28% reduction in TN loads at S-79, compared to the future without project condition, is predicted for preferred Alternative 3B (Table 6-3). The FEIS should further discuss nutrient water quality and the potential for algal blooms.

As suggested above, nutrient levels are expected to decrease in part due to reduced discharges from Lake Okeechobee. Specifically, page 6-16 states that "...the reduction in nutrient loads at S-79 is largely the result of the reduction in discharges from Lake Okeechobee." The reasons for such "reduction in discharges" and its relationship with reduced nutrient concentrations should be further discussed in the FEIS.

* *Resuspensions* – Also, since nutrients and particulates are expected to settle out in the reservoir, it becomes unclear if such precipitants would be resuspended in the water column when the reservoir is filled during the wet season. The proposed 1,500 cfs inflow pump (PS-1) could potentially also entrain sediment from the Caloosahatchee River source water. Use of a larger pump (3,800 cfs) could exacerbate this water quality condition. The FEIS should discuss the potential for resuspension and sediment entrainment, as well as the overall inflow process. Reservoir operations should be designed to minimize inflow turbidity in the reservoir.

* *Site Contaminants* – The residual soils of the existing orange grove proposed for the reservoir site contain pesticide and copper residues. We also understand that copper and lead were found within the Townsend Canal that would provide a conduit for reservoir inflows. As such, these contaminants can be expected to enter reservoir waters. However, we understand that introduction of these pesticides and metals in the impoundment waters are not expected to result in exceedances of State WQS. The FEIS should verify this and offer resolutions if any such contaminants are predicted to exceed WQS in the reservoir water. Beyond WQS, fish bioaccumlation may also be a concern.

Waters of the United States – We note that 125 acres of vegetated wetlands plus some 900 acres of farmland ditches would be inundated by the 10,500-acre reservoir. We understand that these waters of the United States are generally degraded due to existing orange grove farming. The FEIS should provide additional discussion on the quality and function of these areas, particularly the wetlands, from a NEPA disclosure perspective. The FEIS should also briefly discuss if the other sites considered would impact notably less or more wetlands than the selected "Berry Groves" site.

Page 6-20 states that "[t]here will be no mitigation for wetlands as a result of the federal project". Page xviii states that "[t]he loss of this wetland habitat will be offset by the increase in habitat function and quality in the Caloosahatchee Estuary." Specifically, the DEIS (pg. xv) assumes that the project would benefit 71,000 acres in the Caloosahatchee Estuary. Compared to the No Action, it would also generate an average annual increase of approximately 13,000 habitat units within the Estuary. Since the C-43 Reservoir is a CERP project, it may also be noted that the overall CERP would restore numerous acres of wetlands in the Everglades. From a cumulative impacts perspective, many more wetland acres would be restored collectively by CERP projects than would be lost.

We also note that the banks of the perimeter canal will be designed to include 109 acres of littoral zone. We concur with such design, but also assume that any existing littoral habitat will be lost along those reaches of Townsend Canal interrupted by the construction of the reservoir and perimeter canal.

Water Supply – Reference is made in the DEIS (e.g., pg. 6-3) that the C-43 reservoir is not to be used for "elimination or transfer" of water supply. We assume the no "transfer" of water supply implies that new water supply will not be created by the reservoir (the FEIS should clarify). EPA believes that the C-43 impounded waters should be returned to the Caloosahatchee River during dry seasons for the benefit of natural systems as opposed to serving as source water for new urban or agricultural development. We recommend that such assurances be clarified in the FEIS.

The term "water supply" is used for various purposes in the DEIS (pg. 6-13). We recommend that this term be better qualified in the FEIS to indicate the intended use of the water supply (e.g., urban/potable, agricultural or natural system water supply). This would be helpful since without descriptors, we offer that the term "water supply" connotes source water for human consumption.

NEPA Process – From a NEPA disclosure perspective, we find certain sections (e.g., *Summary of Affected Resources*: pg. 6-7) to be well written and would likely be understandable to the layman reader. However, other analytical sections (e.g., modeling) would benefit from additional discussion in the FEIS. For example, the results from the Habitat Suitability Index modeling (Table 6-4) should be further discussed. That is, differences in suitability between Preferred Alternative 3B and the No Action (2050 FWO) are only +0.08 for oyster, +0.13 for *Vallisneria*, +0.05 for seagrass, and +0.13 for extreme events. It is unclear if these differences (or the differences for other alternatives)

requirements, etc.) for our impact review. We also offer that use of an electric pump would eliminate such air emissions.

* Noise – For the project PS-1 pump, we note (pg. 6-5) that the pump station (housing) was offered as noise shielding. We agree that housing would provide some shielding. Source reductions with the pump itself (type, quality, etc.) would also reduce noise levels. As indicated above for air emissions, we also offer that noise emissions would essentially be eliminated if an electric pump was used instead of the proposed diesel pump. In addition to the pump, all other construction equipment (bulldozers, etc.) should be tuned to manufacturer's specifications as well as being equipped with appropriate mufflers and engine housings to minimize noise. It is clear, however, that such noise abatement is more important if residents and other sensitive receptors are located nearby and are affected by the project. In any case, however, project workers could be affected.

From a NEPA disclosure standpoint, the FEIS should document construction noise data available from the literature for typical construction equipment such as would be used for the reservoir project (e.g., dBA noise levels at 50 ft). Disclosure of the estimated construction time is also suggested in order to help determine the magnitude of the noise (and air) impact.

* *Environmental Justice (EJ)* – Page 6-43 states that "[i]n public outreach efforts to date, only one potential environmental justice issue has been identified: the loss of jobs for low income and minority workers as a result of acquiring agricultural land for the construction of the reservoir." To help offset this, we are pleased to note (pg. 6-44) that "...the SFWMD is conducting training programs to allow local individuals to acquire the skills needed to construct the reservoir." We assume that the locally affected people (particularly minorities and low-income populations) will not only benefit from the training but that at least some will be candidates for actual employment. In addition to this proposed offset, we recommend that the COE also provide people affected by the project continued project updates and coordination with their community leaders.

For better NEPA documentation for EJ, the FEIS should provide U.S. Census 2000 data (e.g., one or more block groups) for the project area to specifically account for any minority concentrations ("pockets"). For perspective, this project block group data should also be compared to adjacent block groups, the project county (Hendry) and the project state (Florida) to further determine any minority concentrations near the project. Overall, the number of minority and low-income residents affected by the project (through relocation or other impacts), their demographics and any potential disproportionate effects should be reasonably documented. The FEIS should address this further.

United States Department of the Interior

OFFICE OF THE SECRETARY
Washington, D.C. 20240

June 11, 2007

Colonel Paul Grosskruger
U.S. Army Corps of Engineers
701 San Marco Blvd.
Jacksonville, FL 32207

Dear Colonel Grosskruger:

Thank you for the opportunity to review and provide comments on the *Central and Southern Florida Project Comprehensive Everglades Restoration Plan Caloosahatchee River West Basin Storage Reservoir (C-43) Draft Integrated Project Implementation Report and Environmental Impact Statement* (Draft Report), dated April 2007. We appreciate the efforts of your staff in producing the Draft Report and support the Tentatively Selected Plan (TSP).

The Caloosahatchee River and Estuary is at the head of a vast estuarine and marine ecosystem that includes aquatic preserves managed by the State of Florida, the federally designated Charlotte Harbor National Estuary and the J.N. "Ding" Darling National Wildlife Refuge. Currently, there is not enough storage capacity in the regional water management system to minimize or prevent the harmful of periodic excessive discharges of freshwater to the Caloosahatchee Estuary. Conversely, during dry periods, there are many times when there is not enough freshwater available in the regional system to maintain desirable salinity levels in the estuary. The combined result of too much or too little freshwater flowing to the Caloosahatchee Estuary is a degraded estuarine ecological community. Restoration of a healthy and productive aquatic ecosystem in the Caloosahatchee River is essential to maintaining the ecological integrity in these publicly owned and managed areas.

1. The Department of the Interior (Department) supports the TSP for the project. When constructed, the plan will provide approximately 170,000 acre-feet of above-ground storage in a two-cell reservoir. The proposed reservoir would allow the capture of some excess basin runoff and discharges from Lake Okeechobee. This stored water would then provide an additional source of freshwater to maintain desirable salinity levels in the Caloosahatchee Estuary during dry periods. The project features would be constructed on approximately 10,500 acres acquired, in part, with federal funds appropriated to the Department for Everglades Watershed Restoration.

Ms. Susan L. Conner
Jacksonville District, Planning Division
U.S. Army Corps of Engineers
P. O. Box 4970
Jacksonville, FL 32232-0019

RE: Department of the Army, Jacksonville District Corps of Engineers – Draft Integrated Project Implementation Report and Environmental Impact Statement for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project – Hendry County, Florida.
SAI # FL200704263301C

Dear Ms. Conner:

The Florida State Clearinghouse, pursuant to Presidential Executive Order 12372, Gubernatorial Executive Order 95-359, the Coastal Zone Management Act, 16, U.S.C. §§ 1451-1464, as amended, and the National Environmental Policy Act, 42 U.S.C. §§ 4231, 4331-4335, 4341-4347, as amended, has coordinated a review of the Draft Integrated Project Implementation Report and Environmental Impact Statement (DPIR/EIS).

The Florida Department of Environmental Protection (DEP) supports the proposed project, which will increase storage in the regional watershed and restore ecological function and productivity in the Caloosahatchee Estuary. DEP staff has provided a number of comments requesting clarification of certain items in the DPIR/EIS and inclusion of the water quality/resource data and information necessary to address the applicable planning, permitting, and reporting requirements of Chapter 373, *Florida Statutes*. For further information, please refer to the enclosed DEP memorandum.

The Florida Department of Agriculture and Consumer Services (FDACS) appreciates the opportunity to review the DPIR/EIS and notes that Annex C.4, "Analyses Required by WRDA 2000 and State Savings Clause Analyses," describes assumptions made for the current and future sources of agricultural irrigation water and concludes that the project will not affect those sources. No supporting data or analyses are provided for either the local or regional project area to support that conclusion. The FDACS recommends that the data and analyses used to determine that the project will not affect the quantity and quality of the existing local and regional water supply, and data used to determine that existing flood control will not be impacted, be included in Annex C. This information is

Ms. Susan L. Conner
June 11, 2007
Page 2 of 3

necessary to provide the reasonable assurances, required by Section 373.1501(5)(d), *Florida Statutes*, that implementation of the proposed project will not diminish the quantity of water available to existing legal users or diminish the levels of service for flood protection.

In addition, the FDACS Division of Forestry has expressed concerns regarding the absence of a plan for controlling invasive exotic plant species, and that the estimated annual and operations maintenance costs do not include costs for monitoring and controlling invasive exotic plants. FDACS staff requests that the language in the report inferring that timber practices promote the decline of red-cockaded woodpeckers be revised to specifically state that certain activities should not be conducted within red-cockaded woodpecker foraging areas designated by the U.S. Fish and Wildlife Service. Please refer to the enclosed FDACS comments for further details and recommendations.

The Florida Fish and Wildlife Conservation Commission (FWC) fully supports the construction and operation of the proposed reservoir for the benefit of the Caloosahatchee River and estuarine habitats and recommends that the completed open waterbody also be made available and accessible to the public for compatible recreational opportunities. FWC staff has provided a number of comments and recommendations regarding operation and design of the proposed project water-control structures to prevent manatee entrapment, injuries, and mortalities and reservoir design features to enhance wildlife habitat and recreational use. Please see the enclosed FWC letter for additional details.

The Florida Department of Transportation (FDOT) has expressed concerns that the existing bridges on State Road 80 (Bridges 070066 & 070067, SR 80 over the Townsend Canal) have experienced scour below the 500-year projection as indicated in the Bridge Hydraulics Report. The primary reason for the excessive scour is likely that the drainage basin supplying runoff is approximately 38% larger than the basin identified in the Bridge Hydraulics Report prepared for the construction of the bridges. Stanley Consultants, Inc. has identified a drainage basin of 77 square miles, whereas the Bridge Hydraulics Report identified a basin of 56 square miles. Further scour could jeopardize the integrity of the structures.

FDOT personnel have met with the representatives of the SFWMD and Stanley Consulting, Inc. - engineers for the SFWMD. Stanley Consulting's contract with the SFWMD proposes to modify the Townsend Canal Channel and the cross section through the bridges. They are proposing to excavate the existing channel a depth of four feet and to line the channel beneath the structures with four-foot deep rubble rip-rap. The flows through the structure and the projected stage of the 100-year storm event are proposed to be reduced by the construction of the reservoir. The FDOT has reviewed the proposal and is in agreement with the proposed modifications to the channel beneath the structures. As construction plans for the channel modifications are prepared, FDOT District One Structures and Facilities, Structures Design and Drainage staff requests the opportunity to

Ms. Susan L. Conner
June 11, 2007
Page 3 of 3

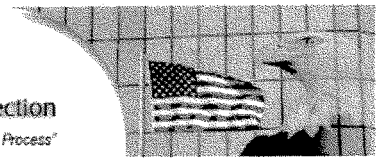
review the proposed plans to insure compliance in accordance with the agreed-upon conceptual plan presented to the FDOT.

The Southwest Florida Regional Planning Council (SWFRPC) notes the project's potential beneficial effects on Caloosahatchee River area hydrology, water quality, wetlands, and wildlife and recommends that the Tentatively Selected Plan incorporate: a water quality treatment component in the design of the reservoir project; plans for construction of littoral areas at the corners of the seepage canal; and the planting of native shade tree species where new trees are proposed. Though the SWFRPC supports the concept and implementation of the C-43 reservoir project, water quality protections should not be deferred in development of the project. Please refer to the enclosed SWFRPC letter for further comments and recommendations.

Based on the information contained in the DPIR/EIS and the enclosed state agency comments, the state has determined that, at this stage, the proposed activities are consistent with the Florida Coastal Management Program (FCMP). The concerns identified by our reviewing agencies must be addressed prior to project implementation. The state's continued concurrence with the project will be based, in part, on the adequate resolution of issues identified during this and subsequent reviews. The state's final review of the project's consistency with the FCMP will be conducted during the environmental permitting stage.

Thank you for the opportunity to review the proposed project. Should you have any questions regarding this letter, please contact Ms. Lauren P. Milligan at (850) 245-2170.

Yours sincerely,



Sally B. Mann, Director
Office of Intergovernmental Programs

Agency Comments:

AGRICULTURE - FLORIDA DEPARTMENT OF AGRICULTURE AND CONSUMER SERVICES

The FDACS appreciates the opportunity to review the proposal and notes that Annex C.4, "Analyses Required by WRDA 2000 and State Savings Clause Analyses," describes assumptions made for the current and future sources of agricultural irrigation water and concludes that the project will not affect those sources. No supporting data or analyses are provided for either the local or regional project area to support that conclusion. The FDACS recommends that the data and analyses used to determine that the project will not affect the quantity and quality of the existing local and regional water supply, and data used to determine that existing flood control will not be impacted, be included in Annex C. This information is necessary to provide the reasonable assurances, required by Section 373.1501(5)(d), Florida Statutes, that implementation of the proposed project will not diminish the quantity of water available to existing legal users or diminish the levels of service for flood protection. In addition, the FDACS Division of Forestry has expressed concerns regarding the absence of a plan for controlling invasive exotic plant species, and that the estimated annual and operations maintenance costs do not include costs for monitoring and controlling invasive exotic plants. FDACS staff requests that the language in the report inferring that timber practices promote the decline of red-cockaded woodpeckers be revised to specifically state that certain activities should not be conducted within red-cockaded woodpecker foraging areas designated by the U.S. Fish and Wildlife Service.

COMMUNITY AFFAIRS - FLORIDA DEPARTMENT OF COMMUNITY AFFAIRS

DCA has no comments.

ENVIRONMENTAL PROTECTION - FLORIDA DEPARTMENT OF ENVIRONMENTAL PROTECTION

DEP supports the proposed project, which will increase storage in the regional watershed and restore ecological function and productivity in the Caloosahatchee Estuary. DEP staff has provided a number of comments requesting clarification of certain items in the DPIR/EIS and inclusion of the water quality/resource data and information necessary to address the applicable planning, permitting, and reporting requirements of Chapter 373, Florida Statutes.

FISH and WILDLIFE COMMISSION - FLORIDA FISH AND WILDLIFE CONSERVATION COMMISSION

The FWC fully supports the construction and operation of the proposed reservoir for the benefit of the Caloosahatchee River and estuarine habitats and recommends that the completed open waterbody also be made available and accessible to the public for compatible recreational opportunities. FWC staff has provided a number of comments and recommendations regarding operation and design of the proposed project water-control structures to prevent manatee entrapment, injuries, and mortalities and reservoir design features to enhance wildlife habitat and recreational use.

STATE - FLORIDA DEPARTMENT OF STATE

No Comment/Consistent

TRANSPORTATION - FLORIDA DEPARTMENT OF TRANSPORTATION
The Florida Department of Transportation (FDOT) is concerned that the existing bridges on SR 80 (Bridges 070066 & 070067, SR 80 over the Townsend Canal) have experienced scour below the 500-year projection as indicated in the Bridge Hydraulics Report. The primary reason for the excessive scour is probably because the drainage basin supplying runoff is approximately 38% larger than the basin identified in the Bridge Hydraulics Report that was prepared for the construction of the bridges. Stanley Consultants, Inc. has identified a drainage basin of 77 square miles whereas the Bridge Hydraulics Report identified a basin of 56 square miles. Further scour could jeopardize the integrity of the structures. FDOT personnel have met with the representatives of the SFWMD and Stanley Consulting, Inc., Engineers for the SFWMD. Stanley Consulting, Inc., in their contract with the SFWMD is proposing to modify the Townsend Canal Channel and the cross section through the bridges. They are proposing to excavate the existing channel a depth of four feet and to line the channel beneath the structures with four-foot deep rubble rip-rap. The flows through the structure and the projected stage of the 100-year storm event are proposed to be reduced by the construction of the reservoir. The FDOT has reviewed the proposal and is in agreement with the proposed modifications to the channel beneath the structures. As construction plans for the channel modifications are prepared, FDOT District One Structures and Facilities, Structures Design and Drainage staff requests the opportunity to review the proposed plans to insure compliance in accordance with the agreed-upon conceptual plan presented to the FDOT.
SOUTH FLORIDA WMD - SOUTH FLORIDA WATER MANAGEMENT DISTRICT
This project will require an Environmental Resource Permit (ERP). The project design should minimize impacts to wetlands and aquatic resources via practicable design modifications and should include mitigation for any remaining unavoidable impacts. It appears that the proposed activities will occur over state-owned sovereign submerged lands. A title determination from the FDEP will be necessary. If the submerged lands are state-owned sovereign lands, the ERP application submitted to the SFWMD will need to include information for a sovereign submerged lands public easement. If any construction dewatering activities are proposed, certain activities may require a Water Use Permit. If any ground or surface water withdrawals are proposed for project landscaping, a Water Use Permit will be required. Further inquiries concerning the above should be directed to the SFWMD's permitting staff in the Ft. Myers Service Center at 1-800-248-1201.
SW FLORIDA RPC - SOUTHWEST FLORIDA REGIONAL PLANNING COUNCIL
The SWFRPC notes the project's potential environmentally beneficial effects on Caloosahatchee River area hydrology, water quality, wetlands, and wildlife and recommends that the Tentatively Selected Plan incorporate: a water quality treatment component in the design of the reservoir project; plans for construction of littoral areas at the corners of the seepage canal; and the planting of native shade tree species where new trees are proposed. Though the SWFRPC supports the concept and implementation of the C-43 reservoir project, water quality protections should not be deferred in development of the project.

SUBJECT: USACE, Jacksonville District – Draft Integrated Project Implementation Report and Environmental Impact Statement for the Caloosahatchee River West Basin Storage Reservoir Project, Hendry County, Florida

SAI#: FL37-3011C

Background:

The purpose of the Caloosahatchee River (C-43) West Basin Reservoir project is to contribute to the restoration of the Caloosahatchee Estuary as part of the Comprehensive Everglades Restoration (CERP) established by the 2000 Water Resources Development Act. The tentative selected plan, Alternative 3B, consists of a 170,000 acre-feet above-ground storage reservoir, a 1500 cfs pump station, external and internal embankments, internal control and outflow water control structures, and environmentally responsible design features to provide fish and wildlife habitat such as littoral areas in the perimeter canal and deep water refugia within the reservoir.

At the present time, there is a lack of adequate water storage capacity in the regional watershed to prevent episodic large discharges of freshwater flow below S-79 to maintain submerged aquatic vegetation and the diversity of organisms they support. The project is designed to capture and store basin runoff and excess water delivered from Lake Okeechobee and to release the stored water in a way that will mimic more natural flow regimes to the Caloosahatchee Estuary below S-79.

The Department supports the project with its purpose to increase storage in the regional watershed, which will restore ecological function and productivity in the Caloosahatchee Estuary. It is expected that the construction permit for the C-43 West Basin Reservoir will be issued for the Acceler8 project, which would not authorize operations of the project. The Department expects that a final operations plan will be developed during the construction and operational testing and monitoring, which would be necessary for the operational permit. The Department believes that this project, in its entirety, will meet Department permitting requirements. The project should result in an improvement in overall water quality conditions at S-79 as well as in the estuary.

Comments:

1. The note under Figure 2-6 says that *Vallisneria Americana* is found at stations 1-3. However, there is no station 3 depicted on the figure.

2. Page 4-30, Table 4-7: Ecological Performance Measures does not include preferred flow range (cfs) for *Vallisneria Americana*. However, page 4-25 says that flow distribution EST05 will provide mean monthly flows above 450 cfs with most flows (75 percent) in the ideal range of 450-800 cfs.

3. Page 5-24, Table 5-9: Target Flow Distribution for EST05 shows mean monthly flows between **450-1,500 cfs** occurring 74.5 percent of the time. However, Table 4-7 shows that most flows will occur in the range of **450-800 cfs**. Please explain the inconsistency.

4. The HTRW assessment and remediation plans do not indicate coordination with the Department. Please specify if HTRW coordination has occurred.

5. Table C-13 – Typographical error in the title, "Estimates of annual TP and TP loading..."

6. Appendix C (Section C.9.3 (C.9.3.1.1.1 and C.9.3.1.2.1: Project vs. 2050 Future Without Project Conditions). These sections refer to TP load reduction of 29%-34% and a TN load reduction of 28%-33% under "with project" conditions, which includes the nutrient load reductions associated with flow reductions from CERP implementation. In order to avoid confusion regarding the estimated nutrient removal potential of the C-43 West Reservoir, please include language clarifying the source of the nutrient removal estimation (i.e. clarify when nutrient removal estimations include overall CERP implementation, or solely C-43 WSR). This comment also applies to Table C-13, Section C.9.5, as well as other sections referring to nutrient removal associated with the selected alternative.

7. Appendix C (Section C.9.3.2: Wet/Dry Season Nitrogen Loading) - Suggest revising language from "targets" to either "critical loads" or "threshold loads". The term target implies a goal, however the critical loads being referred to are actually threshold loads, above which Chlorophyll a concentrations exceed water quality criteria, therefore the goal is below this threshold.

On page C-81 of the draft PIR, the Corps states that the project delivery team and FDEP have identified the following issues as components of the primary measure of acceptability of the project in terms of water quality:

8. "The quality of the water discharged from the reservoir should be no worse than the quality of the water pumped into the reservoir."

- The C-43 West Basin Reservoir is required to achieve water quality standards at the discharge point. Please clarify throughout the PIR that, in addition to outflows being

equal to or of better quality than inflows, the Reservoir will achieve state water quality standards.

9. "The operation of the reservoir should not result in a substantial shift of nutrient loading from the wet season to the dry season."

- The Department is of the understanding that, absent a treatment mechanism or wetland buffer design, a shift in nutrient loads from wet season to dry season is anticipated. The Department has been working concurrently with the Corps to obtain the information necessary to determine whether the shift in nutrient loads from the wet season to the dry season, consistent with the expected operations of the reservoir, would be harmful to waters downstream of the S-79 structure. Upon resolution, please include *The Supplemental Analysis C-43 West Basin Reservoir Effects on Dry Season Water Quality Downstream of the S-79 Structure* in the PIR. This document should provide the Department with the reasonable assurances necessary to ensure that the C-43 West Basin Reservoir will not cause or contribute to an imbalance of flora and fauna in the waters downstream of the S-79 structure.

Please note that the Programmatic Regulations (Section 385.28 (c)(xvii)) require Project Implementation Reports (PIR) to include as appropriate, information necessary for the non-Federal sponsor to address the requirements of Chapter 373 of the Florida Statutes, and other applicable planning and reporting requirements of Florida law. In order serve as local sponsor for the Everglades National Park Seepage Management Project, or prior to seeking an appropriation from the Save Our Everglades Trust Fund, the South Florida Water Management District (SFWMD) will be required to obtain approval from the Department under §373.026(8)(b), Florida Statutes (F.S.). Approval is based on the Department's determination that the SFWMD has provided sufficient documentation to demonstrate compliance with the criteria set forth in Section 373.1501(5), F.S. The statute requires the SFWMD to analyze and evaluate water resource issues, natural system and habitat needs, determine that project components are feasible and consistent with applicable laws and regulations, provide assurances for water supply and flood protection, and coordinate with existing utilities and infrastructure to minimize impacts.

We recommend that as the federal sponsor, the U.S. Army Corps of Engineers keep these criteria in mind during PIR development, and assist the South Florida Water Management District as appropriate in providing the necessary information to comply with these and any other applicable requirements. Please note that the §373.026/1501, F.S. review is separate from the State Clearinghouse review required for all federal projects under the Coastal Zone Management Act, and requires a separate formal submittal from the SFWMD to the Department.

Upon completion of detailed design, this project will require a Comprehensive Everglades Restoration Plan Regulation Act (CERPRA) permit pursuant to Chapter 373.1502, F.S. The project may require a NPDES Generic Permit for Stormwater Discharge from Large and Small Construction Activities in accordance with Rule 62-621.300(4), Florida Administrative Code (F.A.C.). Other department permits may be required during the construction phase of this

project, as applicable. We recommend that the Corps and the SFWMD coordinate closely with the Department in order to facilitate permit issuance.

If you have any questions regarding these comments, please contact LaDawna McDonald at (850) 245-7534.

SUBJECT: Clearinghouse Review of the Draft Integrated Project Implementation Report (PIR) and Environmental Impact Statement for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project

---

The Florida Department of Agriculture and Consumer Services (Department) appreciates the opportunity to comment and requests the following concerns be considered in the state clearinghouse review of the Corps' April 2007 Draft Integrated Project Implementation Report and Environmental Impact Statement for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project.

Annex C.4, "Analyses Required by WRDA 2000 and State Savings Clause Analyses", describes assumptions made for the current and future sources of agricultural irrigation water and concludes that the project will not affect those sources. No supporting data or analyses are provided for either the local or regional project area to support that conclusion. The Department recommends that the data and analyses used to determine that the project will not affect the quantity and quality of the existing local and regional water supply, and data used to determine that existing flood control will not be impacted, be included in Annex C. This information is necessary to provide the reasonable assurances, required by 373.1501(5)(d), Florida Statutes, that implementation of the proposed project will not diminish the quantity of water available to existing legal users or diminish the levels of service for flood protection.

In addition, the Department is concerned regarding the absence of a plan for controlling invasive exotic plant species, and that the estimated annual and operations maintenance costs do not include costs for monitoring and controlling invasive exotic plants. The Department is also concerned about language in the report inferring that timber practices promote the decline of red-cockaded woodpeckers; rather, it should more specifically state that certain activities should not be conducted within red-cockaded woodpecker foraging areas designated by the U.S. Fish and Wildlife Service.

An attachment, "FDACS Comments," provides additional detail regarding the issues raised above. We would appreciate your considering inclusion of our comments in the state clearinghouse review. If you have any questions or I can assist in any way, please feel free to call me at (850) 410-6714.

FDACS Comments on the Draft Integrated Project Implementation Report (PIR) and Environmental Impact Statement (EIS) for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project

Staff Comments from the Office of Agricultural Water Policy

1) Water Supply in the C-43 basin

Construction and operation of the C-43 Phase I Reservoir on the Berry Groves site will create a substantial change in the hydrodynamic interactions between groundwater, surface water, and water use in the vicinity of the reservoir that could impact water availability for existing legal users dependent upon the C-43 Canal and Lake Okeechobee for water supply.

The slurry wall will prevent seepage currently flowing north from properties south of the reservoir site from reaching the C-43 Canal along the historic path under the reservoir site. The C-43 Canal and the properties between the reservoir and the C-43 Canal will no longer be supplied by the historic groundwater seepage source. The C-43 Phase I Reservoir operating plan uses perimeter canal seepage to maintain groundwater levels and water supply to existing legal users in the vicinity of the reservoir. Water will be pumped from the C-43 Canal to maintain the perimeter canal water levels and seepage during dry conditions when the reservoir can no longer be used to supply the perimeter canal.

Supporting data and an analysis of potential impacts on existing legal users are not presented in Annex C of the Draft document. According to the RECOVER report included in the Draft C-43 Phase I Reservoir PIR, the type of data needed to determine if the Lake Okeechobee Service Area water shortage frequency of occurrence target was met was not available and the water supply evaluation was incomplete. The report should include an analysis to determine that basin-wide water use assurances have been quantified and met. Data and an evaluation tool to project the changes from pre-project to post-project conditions are not provided. An analysis is needed that compares pre-project and post-project water volumes associated with "replacing" the historic ground water seepage flows into the C-43 Canal along the length of the reservoir and maintaining surface water levels of the perimeter canal throughout the period of record. Ideally, a subregional evaluation tool would be used to compare the pre-project and post-project water budget performance over the period of record between S-77 and S-79.

2) Water Quality in Ground Water Supply Wells in the Vicinity of the Reservoir

A water resource concern of existing legal users in the vicinity of the C-43 Basin Storage Reservoir Phase I Project is the change in water quality that may occur when the groundwater source for local wells is replaced by seepage from the perimeter canal. It appears that some wells may be completely switched from a watershed seepage source to a C-43 supplied perimeter canal seepage source when the C-43 Reservoir Phase I becomes operational. Data should be presented that was used to determine the impacts of the perimeter canal seepage on local ground water wells, as well as any conclusions reached regarding the need to mitigate for deterioration in water quality. Language should also be included that reinforces the local sponsor's commitment to mitigate any future negative impacts to legal users that result from such "source switching."

3) Determination that Reservoir Operations will not Result in Negative Impacts to Agricultural Operations in the Vicinity of the Reservoir

Water supply and flood protection in the vicinity of the reservoir might be impacted by reservoir features and operations. Reports and supporting data should be included in the report that support the local sponsor's determination that detrimental changes to water supply and flood protection in the vicinity of the reservoir are not anticipated. Language should also be included that reinforces the local sponsor's commitment to mitigate any future negative impacts to legal users resulting form the construction or operation of the reservoir.

Staff Comments from the Division of Forestry

Section 2.9.6.7 (page 2-26) states that the primary threat to red-cockaded woodpeckers (RCW) continues to be the destruction or degradation of its habitat as a result of "timbering" and other land-clearing activities. The language should not infer as it does now that all timber practices promote the decline of RCW habitat. It should be specified that certain activities should not be conducted within U.S. Fish and Wildlife Service designated RCW foraging areas.

Section 6.10.2 (pages 6-18 & 19) discusses anticipated impacts to plant communities. The last paragraph states that exotic plant species are not expected to be a problem as appropriate construction and maintenance procedures would be established to deter and control exotic establishment at the project site. Exotic plants are likely to come in regardless of initial construction and maintenance procedures to deter them. A plan should be developed to address this issue before construction begins.

Section 7.6.1 (page 7-23) discusses the estimated annual operations and maintenance costs. Exotic plant monitoring and treatment costs should be factored in this section.

Re: SAI #FL200704263301C, Draft Integrated Project Implementation Report and Environmental Impact Statement for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project, Hendry County

Dear Ms. Milligan:

The Division of Habitat and Species Conservation of the Florida Fish and Wildlife Conservation Commission (FWC) has coordinated an agency review of the proposed C-43 Basin Storage Reservoir project in Hendry County. The following comments and recommendations are being provided in accordance with Chapters 370 and 372, Florida Statutes, and are intended as a determination of consistency for purposes of the Florida Coastal Management Program/Coastal Zone Management Act.

Project Description

The proposed project is the first of two phases of a larger project to better manage water deliveries to the Caloosahatchee River (C-43) and estuary. This phase is limited to an above-ground reservoir that would discharge to the river, and would later be supplemented by aquifer storage recovery (ASR) wells. The project is located west of Lake Okeechobee and south of the Caloosahatchee Waterway in western Hendry County near the city of LaBelle. The proposed C-43 reservoir would contain approximately 160,000 acre-feet of water storage capacity on 10,492 acres of land. The reservoir would be divided into two cells contained by an embankment ranging between 27 and 38 feet above grade. An internal embankment 31 feet high would divide the cells of the reservoir, while a perimeter canal would encompass the entire reservoir. Numerous water-control structures would be constructed in conjunction with this project. The water-control structures would include an inflow pump station, a perimeter canal pump station, and multiple spillways and culverts.

Although a boat ramp is proposed, we understand that the South Florida Water Management District plans on monitoring the performance of the reservoir for 18 months before deciding on which forms of recreation will be allowed within the reservoir.

The proposed construction of the C-43 basin storage reservoir project is to provide an overall benefit to the Caloosahatchee River by providing additional control of the timing and quantity of water releases from watershed runoff and Lake Okeechobee water releases. The reduction of large freshwater discharges into the Caloosahatchee River, especially during the seasonal dry periods, would assist in imitating historical water flow patterns and would reduce nutrient influx and moderate salinity regimes associated with flood waters. In addition, the C-43 basin reservoir would provide the potential to reduce flooding and potentially provide water supply storage.

Ms. Lauren Milligan
Page 2
June 8, 2007

Potentially Affected Resources

Project Site:

The South Florida Water Management District owns the majority of the property and currently leases it for citrus farming. Of the 10,492 acres, approximately 1,024 are jurisdictional wetlands, 899.59 acres of which are canals and ditches and 125 acres are pre-existing wetlands. The uplands that would be flooded currently provide marginal wildlife habitat, while the downstream freshwater and estuarine habitats could benefit greatly from the retention of freshwater that would otherwise flow to the river and estuary, often in large pulses that are seasonally ill timed. In addition, there may be opportunities within the completed reservoir to manage for freshwater fisheries, and improving habitats for many other wildlife species including songbirds, wading birds, waterfowl, and alligators.

Caloosahatchee River and Estuary:

Major changes resulting from this project should be beneficial to most existing Florida habitats within this project's influence. The primary beneficiary will be the estuarine communities associated with the Caloosahatchee River, including submerged aquatic vegetation and oyster (*Crassostrea virginica*) populations. Improvements in water quality and more appropriate salinity regimes should provide improved conditions for associated habitats and the wildlife resources dependent upon them.

West Indian (Florida) manatee:

Improved riverine and estuarine habitats as a result of this project would benefit the endangered West Indian (Florida) manatee (*Trichechus manatus*) through increases of stable submerged aquatic vegetation. Potential adverse affects could occur to the manatee during construction and operation of numerous water-control structures associated with the proposed reservoir. Reservoir waters have the potential to retain daily solar heating due to their deep depths. Discharge of reservoir waters that are warmer than the ambient waters of the C-43 canal could create conditions similar to manatee warm-water aggregation sites; however, suitable warm-water sites require consistent flows that create refuge areas with temperatures greater than 20°C during the winter months. If the water temperatures do not remain near 20°C or are inconsistent in their availability, the site becomes an attractive nuisance that increases the risk of cold season death for manatees that locate and use them.

Concerns and Recommendations

Caloosahatchee River and Estuary:

The Caloosahatchee estuary stands to be the primary beneficiary of this project. Storing water from Lake Okeechobee and runoff from the basin's watershed for future releases that are measured and seasonally appropriate could provide a boon to estuarine habitats. Riverine and estuarine habitats in this system have long suffered due to large freshwater

releases that have caused significant shifts in salinity, large influxes of nutrients and increases in turbidity (Chamberlain and Doering 1998). Habitats most likely to benefit from this project include eelgrass (*Vallisneria americana*) beds located in the upper Caloosahatchee River, shoal grass (*Halodule wrightii*), manatee grass (*Syringodium filiforme*), turtle grass (*Thalassia testudinum*) and oyster reefs all located in the estuarine waters. The increased viability of these habitats should enhance the animal communities that use them as nursery and foraging habitat. While we understand that this will remain the primary objective of this project, we add our support that measured and seasonally appropriate freshwater releases from the C-43 basin storage reservoir remain the primary goal of this project while other worthy purposes for the reservoir (flood control, agriculture, and drinking water supply) remain secondary except for emergency purposes.

West Indian (Florida) Manatee:

The numerous water-control structures associated with this project could entrap, injure, or kill manatees that may encounter them. Manatees are frequent travelers of the Caloosahatchee waterway, traversing the entire waterway through Lake Okeechobee. Water-control structures have been responsible for hundreds of manatee deaths (Fish and Wildlife Research Institute's manatee mortality database); however, with the appropriate safeguards, these structures can be rendered relatively benign. The most efficient way to achieve this goal is to prevent manatee ingress and egress to the C-43 reservoir by constructing manatee barriers at all access points to the perimeter canal and reservoir.

During the winter months manatees are dependent on warm-water refuges to survive during periods of cold air and water temperatures (O'Shea et al. 1985; Hartman 1974). Water temperatures greater than 20°C are needed for survival; however, water temperatures that inconsistently reach 20°C can create an attractive nuisance that may jeopardize the health of manatees (Worthy et al. 2000; Laist and Reynolds 2005).

Recommendations:

- Barriers should be used at all ingress structures to the perimeter canal to eliminate manatee access to the perimeter canal and reservoir.
- Standard manatee construction conditions should be used in all waters accessible by manatees during the construction of this project.
- We highly recommend using the information provided in the document entitled "Guidelines for Manatee Conservation during Comprehensive Everglades Restoration Plan Implementation."
- During the winter season (November 1 through March 31) we recommend that water releases from the C-43 reservoir be monitored hourly for temperature with data retrieved daily, near the point of discharge (S-11). Monitoring data will be used to determine if water releases from the C-43 basin have the potential to create a warm-water site that is insufficient to sustain manatees.
- During the winter season, if water released from the reservoir creates a thermal plume that is greater than 20°C, or if manatees are observed using the site of the reservoir discharge on two consecutive days, then we request that the FWC-Imperiled Species Management section (850-922-4330) and the U.S. Fish and Wildlife Service be consulted to resolve the issue of impacts on manatees.

Although not part of the proposed project, aquifer storage recovery (ASR) wells are also a proposed component of this overall project, but in a subsequent phase. We believe that the ASR component could present similar issues related to thermal effects. ASR wells at this site have a projected capacity to store an additional 220 million gallons of water. Limited information is available at this time but monitoring suggests that water from some ASR wells has been retrieved at temperatures greater than 20°C. Reservoir waters discharged at greater than ambient water temperature that are near 20°C could be attractive to manatees during the winter months. Discharge waters that are inconsistent or insufficient in temperature could result in cold stress-related manatee mortality.

Recommendation:

- FWC requests that the U.S. Army Corps of Engineers and the South Florida Water Management District keep FWC apprised of the results of ongoing ASR studies and monitoring efforts so future manatee-related issues can be identified, refined, and resolved proactively prior to the implementation of ASR technology.

Recreation:

The proposed C-43 reservoir project would create over 10,000 acres of open water with depths reaching 25 feet. Although this project's primary purpose is water storage for the benefit of the downstream estuary, some form of recreation is contemplated by the proposed project. The FWC encourages public access to areas that can allow opportunities for recreational pursuits, whenever compatible. The C-43 reservoir has the potential to be managed for public activities that include alligator and waterfowl hunting, fishing, hiking, and wildlife observation.

Specifically, we support allowing waterfowl hunting and fishing as recreational opportunities that should be allowed on the C-43 reservoir. There is a very high public demand for waterfowl hunting and angling in the southern portion of peninsular Florida, and we believe that use of this area for these recreational purposes would meet all criteria of recreational features proposed on CERP projects:

1. Compatible with the authorized project purposes
2. Affordable within project limits
3. Easily operated and maintained

Allowing the above opportunities on the reservoir should add little to no extra cost to the project, as a boat ramp is currently a proposed Acceler8 component of the project. We recommend that the South Florida Water Management District work with our staff during the assessment period to refine what types of activities could be accommodated. We would like to operate and maintain waterfowl hunting cooperatively with the South Florida Water Management District and others, as appropriate.

Recommendations:

- The use of soil cement for construction of the reservoir embankments is not conducive to the establishment and growth of submerged aquatic vegetation, an

attractant for waterfowl. We recommend the placement of a natural substrate within the interior of the reservoir to allow for vegetation growth, which will increase the wildlife habitat value and assist with improvements in water quality through the reduction of nutrients.

- We recommend planning for recreational alligator hunting on the C-43 Reservoir in the future.
- Project plans should provide roads and boat ramps allowing adequate public access.
- Portions of the reservoir footprint have been in citrus production. We recommend that these areas not be cleared prior to reservoir flooding. Citrus is fairly durable wood and should not degrade rapidly, thereby creating long-lasting fish and wildlife habitat. A similar recommendation provided a cost savings during the construction planning of the Site 1 impoundment.
- Minimizing dry outs would benefit wildlife habitat through the reduction of nutrients and re-suspension of contaminants while providing for a stable aquatic community.

Conclusion

The FWC fully supports the construction and operation of the proposed reservoir for the benefit of the Caloosahatchee River and estuarine habitats. Recognizing this priority, we also recommend that completed public works projects be made available to the public for recreational opportunities that are compatible with the primary intended purposes. The C-43 reservoir project appears to offer a variety of potential recreational pursuits including waterfowl and alligator hunting, fishing, hiking and wildlife observation. The FWC is willing to assist in achieving these multiple-use goals.

If you or your staff would like to coordinate further on the recommendations contained in this report, please contact me at 850-410-5272 or email me at MaryAnn.Poole@MyFWC.com, and I will be glade to help make the necessary arrangements. If your staff has any specific technical questions regarding our comments, please contact Ron Mezich at 850-922-4330; email ron.mezich@myfwc.com.

Sincerely,

Mary Ann Poole

Re: IC&R #s: 2007-032 & 2007-035/SAI #: FL200704263301C
Permit 3005-5958 (IP-TKW), Hendry County, Caloosahatchee River (C-43) West Basin Storage Reservoir, Draft Project Implementation Report (PIR), Environmental Impact Statement (EIS), and Tentatively Selected Plan (TSP), http://www.evergladesplan.org/pm/projects/docs_04_c43_pir.aspx

Dear Ms. Mann:

The Southwest Florida Regional Planning Council (SWFRPC) has reviewed the Proposed Permit 3005-5958 (IP-TKW) for the Caloosahatchee River (C-43) West Basin Storage Reservoir, Draft Project Implementation Report (PIR) and Environmental Impact Statement (EIS), and has the following comments.

The request dated April 30, 2007 was received for our review on May 4, 2007.

The proposed project has the potential to effect hydrology, water quality, wetlands, and wildlife within one of the largest manmade canal systems within the Southwest Florida Region.

There are several components of the Tentatively Selected Plan (TSP) that will have environmental benefits including:

- Construction of a 170,000 acre-feet reservoir with the expressed purpose of reducing the number and duration of extreme hydrologic events at S-79 locks on the Caloosahatchee River.
- Reduction in the number and duration of high flow (>4500 cfs) and low flow (<450 cfs) events in the Caloosahatchee River.
- Adopting and implementing targets of 0 flows below 450 cfs and above 4500 cfs for the Caloosahatchee River.

TO: Ms. Sally B. Mann
DATE: 6/5/2007
PAGE: 2
RE: IC&R #s: 2007-032 & 2007-035/ SAI #: FL200704263301C

- An Oyster Restoration Plan for the Tidal Caloosahatchee which anticipates an increase from 3.02 acres of oyster reef habitat in 2004 to 30 acres of oyster reef habitat within 10 to 15 years. With the ultimate addition of hard, suitable substrate the target of oyster reef habitat increases to 100 acres.
- Commitment to use the water quality prediction tools currently in development, such as reservoir and estuary water quality models, to optimize the reservoir operations with the goal of improving downstream water quality.
- Commitment to 5 years of water quality monitoring associated with design and initial operations of the reservoir

The SWFRPC strongly recommends for incorporation into the TSP of:

1) A water quality treatment component needs to be included in the design of the reservoir project. The need for a water quality treatment component was identified early in the process of alternative development review by federal, state, regional, and local agency participants of the PDT in the development of the PIR. It was deferred from consideration by the SFWMD and the USACOE. Apparently, this reservoir project is the only reservoir design currently under consideration for CERP funding that does not have a water quality treatment feature. Based upon materials posted on the CERP web-site, east coast reservoirs have water quality treatment features included in their design. It is important that the current project design not preclude the necessary water quality treatment features. It is important that land not be surplused from the project footprint before necessary water quality treatment features are planned and constructed. Addressing hydrology without including water quality improvement is insufficient in protecting the estuary and aquatic resources of the Caloosahatchee River and the nationally recognized Outstanding Florida Waters estuaries at its confluence. H.R. 1816, the "Restoring the Caloosahatchee River: A Legacy for Florida" Act, was introduced by Congressman Connie Mack and the State of Florida Appropriations Bill delivered to Governor Crist includes funding a water quality component for the C-43 Reservoir project. The TSP should include water quality treatment features with sufficient space for their construction.
2) The littoral areas proposed at the corners of the seepage canal as part of the project should be constructed. We concur with the Florida Fish & Wildlife Conservation Commission that these littoral areas will provide habitat benefits and potential water quality benefits.
3) All shade trees proposed on the outside area of the north rim canal adjacent to parking areas should be native to the Caloosahatchee basin. Past selection and planting of exotic tree species in USACOE projects has led to damage to reservoir banks and project canal banks resulting in expensive remove programs and the need to construction repairs.

PAGE: 3
RE: IC&R #s: 2007-032 & 2007-035/ SAI #: FL200704263301C

4) The missing pages in the Final Biological Assessment concerning methodology that should be present between pages A-95 and A-96 in Annex A of the FWCA Report and Endangered Species Act Compliance should be inserted into the documentation of the PIR.

The SWFRPC supports the concept and development of the C-43 reservoir project to reduce the negative hydrologic discharges to the Caloosahatchee River, restoration of base flows for the Caloosahatchee River, and improvement in water quality of the Caloosahatchee River. Our staff has participated cooperatively in the development of the PIR and EIS. We did not and do not agree; however, that water quality protections should be deferred in development of this project.

We look forward to cooperating with the applicant and other relevant agencies to resolve the issues that we have identified in this letter in order to ensure consistency with the Coastal Zone Management Act/Florida Coastal Management Program and to ensure that the TSP proceeds in a fashion that minimizes impacts to water quality, hydrology and fish and wildlife resources in the Southwest Florida Region. Staff has been in contact with Hendry County Planning and they had indicated that they will be submitting comments; but to this date they have not been completed. Please note that Hendry County's comments will be submitted under separate cover.

Please call me if you would like to coordinate further discussion of these issues; I will be glad to facilitate any such efforts. If you have specific questions about the content of this letter, please contact Mr. Jim Beever directly at (239) 338-2550 ext 224, e-mail jbeever@swfrpc.org.

Sincerely,

Draft Project Implementation Report with an integrated Environmental Impact Statement
Caloosahatchee River (C-43) West Basin Storage Reservoir Project
Hendry County

Dear Mr. Applebaum:

Our office received and reviewed the above referenced project in accordance with Section 106 of the *National Historic Preservation Act of 1966*, as amended and *36 CFR Part 800: Protection of Historic Properties* and the *National Environmental Policy Act of 1969, as amended.* The State Historic Preservation Officer is to advise Federal agencies as they identify historic properties (listed or eligible for listing, in the *National Register of Historic Place*, assess effects upon them, and consider alternatives to avoid or minimize adverse effects.

We reviewed the referenced environmental document, and concur that the recommended action will not impact culturally significant properties.

If you have any questions concerning our comments, please contact Laura Kammerer, Deputy State Historic Preservation Officer for Review and Compliance, by telephone at 850-245-6333, or by electronic mail at lkammerer at dos.state.fl.us. Thank you for your interest in protecting Florida's historic properties.

Sincerely,

Frederick P. Gaske

Re: Comments Regarding the Central and Southern Florida Project Comprehensive Everglades Restoration Plan, Caloosahatchee River (C-43) West Basin Storage Reservoir Project, Draft Integrated Project Implementation report and Environmental Impact Statement

Dear Ms. Starnes and Ms. Conner:

Please find attached to this correspondence are specific comments, submitted on behalf of Lee County ("the County"), regarding the *Caloosahatchee (C-43) West Basin Storage Reservoir ("CRWBSR") Draft Integrated Project Implementation Report and Environmental Impact Statement* ("C-43 Draft PIR"). As you are well aware, the County is supportive of the expedited implementation of the Caloosahatchee (C-43) West Basin Storage Reservoir ("CRWBSR") in order to bring immediate benefits to the Caloosahatchee River and Estuary. The County must balance multiple interests, as must the United States Army Corps of Engineers ("Corps") and the South Florida Water Management District ("SFWMD"), but our primary concern is the health of the Caloosahatchee River and Estuary. Our comments on the C-43 Draft PIR can generally be summarized as follows:

- Reconcile conflicting statements regarding the availability of water to meet municipal and agriculture needs from the CWBSR project;
- Please indicate whether or not there is a contingency fund for contamination clean-up costs for the project lands and whether or not the C-43s structures (16, 17, 18 and 19 at $4.5 million) are included in the overall cost estimates;
- The discharges from the CRWBSR under Alternative 3B are projected to meet the flow targets 74.8% of the time. Although this shows a benefit, the C-43 Draft PIR

must show that this actually results in the restoration needs of the Estuary being met based on current water budgets and consumptive use permit withdrawals;

- To accomplish expedited implementation of the CRWBSR, unnecessary procedural obstacles must be avoided, such as multiple project phasing and PIRs. More water storage options need to be included in this C-43 Draft PIR effort rather than delayed to a Phase 2 or even a Phase 3; and,

The County considers itself a partner in the Comprehensive Everglades Restoration Plan ("CERP") in addition to your respective agencies. We appreciate the opportunity to participate in the process for the implementation of the CRWBSR and look forward to timely completion of the C-43 Final PIR.

Sincerely,

DEPARTMENT OF PUBLIC WORKS
Division of Natural Resources

(Signed in his absence to avoid delay)

Roland Ottolini, P.E.
Division Director

Attachment

Detailed Comments Regarding the Caloosahatchee (C-43) West Basin Storage Reservoir Draft Integrated Project Implementation Report and Environmental Impact Statement ("C-43 Draft PIR" or "the document")

Goals and Purposes of the Project

Page XII — The document discusses the need to ensure that current levels of service for water supply in the Caloosahatchee basin could still be met with implementation of the Tentatively Selected Plan. In other portions of the document, water supply benefits are described as "indirect". According to the C-43 Draft PIR, all water available from the CRWBSR is slated to be available only for the environment. If there is even an "indirect" potable water supply benefit, this should be quantified. The County is supportive of placing a priority on the needs of the Caloosahatchee Estuary, but the multiple purposes of the project should not be lost.

Page XVI — The document describes the requirements for water to be identified for the natural system and other water related needs. This analysis was based on a draft of Programmatic Guidance Memorandum 4. It is the County's understanding that the methodology to make these determinations has not be finalized and that a final methodology is still forthcoming in terms of this Guidance Memorandum. Is that still the case and will this have an effect on identifying water for the natural system and other water related needs?

Page XVI — The document lists the primary functions of the reservoir as capturing excess runoff and discharges and providing an additional source of water to maintain desirable salinity in the Caloosahatchee Estuary during periods of low flow. All water from the CRWBSR is then identified for the natural system. First, there are several differing goal and purpose statements for the project throughout the document. The goals and purposes for the CRWBSR from the original CERP "Yellow Book" should guide the project's implementation (see page 1-9 of the C-43 Draft PIR for a portion of this statement).[1] If those goals and purposes have changed for some reason, the document should state that and the rationale for the change. Second, as stated earlier in these comments, the multiple purposes of the project should not be lost and even "indirect" water supply benefits should be quantified. The statement on this page, "The project will not provide any additional water for water supply or other water-related needs in the Caloosahatchee River basin", contravenes these concepts.[2] See similar discussion on pages 5-3 and 5-4.

[1] The C-43 Draft PIR states at page 1-11, "Draft Programmatic Regulations Guidance Memoranda #1 and #2 instruct project teams to affirm and optimize the component identified in the Restudy unless conditions or planning objectives have changed, or if the component no longer meets the purposes outlined in the Restudy, to formulate new alternatives."

[2] For comparison, see page 2-53 which states, "This reservoir is intended to reduce the fresh water pulses into Charlotte Harbor and the Caloosahatchee Estuary, and provide water storage for meeting environmental needs. Additional water, after environmental needs are met, could be used as supplemental water to help meet the needs of agriculture and urban communities in Southwest Florida." See also page 4-8, "The project was formulated to provide water supply benefits, some flood attenuation, environmental water supply deliveries to the Caloosahatchee Estuary and water quality benefits to reduce salinity and nutrient impacts of runoff to the estuary." Finally, see page 4-19 stating, "The Restudy purpose of the Caloosahatchee River (C-43) West Basin Storage Reservoir is to capture Caloosahatchee Basin runoff and releases from Lake Okeechobee as a means to meet water demands (moderate extreme damaging high and low flows) for ecosystem restoration within the Caloosahatchee Estuary, with some benefits to municipal and agricultural water supply."

Page XVI The County supports maintaining the same level of water supply deliveries to agricultural lands adjacent to the CRWBSR where water supply canals were interrupted due to the location of the project, consistent with Section 601(h) of the Water Resources Development Act of 2000.

Page 1-9 Page 1-9 lists a portion of the CRWBSR restoration objective from the original CERP documents (1999) as including water supply benefits, some flood attenuation, to provide environmental water supply deliveries to the Caloosahatchee Estuary, and water quality benefits to reduce salinity and nutrient impacts of runoff to the estuary. All of these benefits should be identified, consistent with 33 C.F.R. Part 385, or the Programmatic Regulations for CERP. Additionally, this restoration objective limits nutrient impacts to "runoff to the estuary" while ignoring the effects of Lake Okeechobee discharges. Estuary benefits and water quality benefits are "primary" system benefits and flood attenuation and water supply are "secondary" system benefits. Again, the water supply benefit originally envisioned in the restoration objective should not be lost and should be identified and this "restoration objective" should be consistently listed throughout the document.

Page 1-11 While the County is supportive of addressing water supply needs and water quality in the upper basin in a subsequent PIR, any water supply benefits achieved now by the CRWBSR, although they may be de minimis, should be identified consistent with Federal law and the Programmatic Regulations. This comment is also relative to Section 4.1.4.1. on Water Supply and the Annex C Saving Clause Analysis. See also Section 8.5.3.1 on identification of water made available and water for other water related needs.

CERP Project Phasing

Page XXIV The document describes that a subsequent PIR will be initiated to address the remaining water resource problems in the Caloosahatchee River basin which were not fully addressed by the Tentatively Selected Plan. These remaining water resource problems include: additional pumping and storage capacity, the need for additional water storage and management features in the upper basin and improving water quality. The County has been supportive of this "Phase II" approach for the CRWBSR. The last paragraph of that section further describes the Caloosahatchee ASR features being investigated as part of a **third PIR**. While we understand the need for the two-phase approach, the County is concerned that three PIRs, phases or studies to address the Caloosahatchee basin is excessive and sets a bad precedent for the implementation of CERP projects. The County does not support a third PIR effort for this project and all outstanding issues should be resolved in the Phase 2.

The Tentatively Selected Plan

Pages XI-XII The document lists the array of final alternatives. Alternative 3B, 170,000 acre-foot ("ac-ft") storage reservoir with a 1,500 cubic feet per second ("cfs") pump station is the chosen alternative. The County supports these features for the Tentatively Selected Plan at this time.

Page XII The document lists a minimum flow of 450 cfs at the S-79 during dry periods. In later sections of the document (pages 1-16 & 2-34) there is an explanation of why this target was chosen in lieu of the established minimum flow and level ("MFL") criteria of 300 cfs. The County is supportive of using this higher minimum target although it is quite

possible that this 450 cfs target is also slightly lower than the true needs of the restored Calooshatchee Estuary. This should form the basis for the guiding the Phase II PIR effort. This comment also relates to the discussion on page 4-10.

Page XIV — The document describes structures C-43s16, 17, 18 and 19 as possibly being constructed in "partnerships" between the SFWMD and Hendry County as a separate project under a different program. The cost of these structures is $4.5 Million. This commitment does not appear to be strong, because the structure "may" be constructed under the partnership. The document needs to address whether or not this partnership is tentative in nature or not and if so, the structures, and their cost, needs to be added to the overall project cost for the CRWBSR.

Page XIV — The document describes the added feature for the placement of 20 acres of artificial substrate in the Caloosahatchee Estuary for oyster, plant and animal recruitment. Although the County is supportive of this project feature this 20 acres equates to reaching roughly half to a third of the 40-60 acre targets for increases in the aerial extent of oyster reefs. See also page 7-4.

Page XX — The document lists the project cost as $446,460,000. See also page 7-15 & page 8-2. It is unclear whether or not contamination clean-up costs, or a contingency fund for them, are included in this figure. A contingency should be added for the $4.5 Million in structures listed in the comment above (C-43s, 16-19) if that partnership project is tentative in nature. On page 5-36, Total Project Investment for Alternative 3B is listed as $486,307,000. Consistent cost figures should be used throughout the document.

Page XX — The document states that the SFWMD constructed a test cell project to evaluate seepage and embankment design and water quality effects of the project (see also page 2-2). A brief summary of the results of that analysis and project in this section should be included. This comment is also relative to page 4-16.

Page 5-6 — Table 5-1 describes the various "management measures" (both structural and non-structural) that were considered in conjunction with the CRWBSR. All management measures were then screened out leaving only the actual reservoir and operations of that reservoir to achieve the planning goals and objectives. This entire analysis seems a bit misleading because the two factors driving this analysis were likely cost and time delay. While the County is supportive of expediting the CRWBSR and we support the approach of a Phase II to more fully address basin needs, it should be clear that these management measures will again be analyzed throughout the Phase II process. While they are not being implemented in conjunction with this phase of the project, they have not been removed from the table for further consideration. This seems to be why Table 5-2 was included, but the statement in that Table that "STAs may not be needed" is alarming before that analysis has concluded.

Page 5-24 — The County is supportive of the rationale for Alternative 3B being chosen as the Tentatively Selected Plan. It appears to achieve comparable environmental performance while taking an incremental approach on determining the appropriate pump size. Until more water storage is provided in the overall basin, it does not seem as though a larger pump is warranted at this time (see page 5-26). Page 5-34 states that most project benefits accrue in the dry season and pump size would not affect these benefits. Any operational or incidental environmental or water supply benefit achieved by a larger

pump should be clearly reflected in the C-43 Draft PIR. This comment is also relevant to discussion on page 5-42.

Page 5-43 Is there an effect on project performance if there is a reduction in the 13-foot assumption for freeboard?

Page 5-47 When will the MIKESHE water budget modeling shortfalls discussed in this section be rectified? This should be completed before the C-43 Final PIR.

Page 5-49 What "alternative methods" were used to show the Tentatively Selected Plan is in compliance with CERP Programmatic Regulations, WRDA 2000 and Florida State Law?

Page 6-9 Alternative 3B is projected to meet the desired flows for the Estuary 74.8% of the time as compared to the current 46.% estimate. This appears to be significant improvement but full restoration benefits must be the guide to project success.

Page 6-10 The structural canal changes contemplated do not appear to be significant, but coordination with affected property owners must commence to avoid any delay in project implementation. See also discussion on page 7-3.

Page 6-15 It does not appear as though there are any significant effects on groundwater elevations except the small increase (albeit in the dry season) north of the project site. Again, this effect must be coordinated with affected property owners to avoid any delay in project implementation.

Page 7-16 The benefits and potential detriments of the public-private partnership described in this section are unclear. Which project features would be constructed in this fashion and are there any formal proposals for this effort?

Related Project, Permitting and Process Issues

Page X The document discusses how aquifer storage and recovery ("ASR") project features will be evaluated and implemented separately. Will this occur in a second PIR or separate initiative? How will this project be coordinated with the ASR contingency plan?

Pages X-XI The document similarly discusses an additional project to store basin runoff for backpumping and treatment from the C-43 Canal to return to Lake Okeechobee. Will this occur in a second PIR or separate initiative?

Page XXI The document lists the C-43 Draft PIR process and the Department of the Army Section 404 (Clean Water Act) permit as separate but related activities. The estimated timeframes for the issuance of the permit should be included in the document. Will this be the July 2007 date for initiation of clearing and grubbing of the site?

Page 1-12 The document lists the ASR Pilot Project as being conducted in parallel with a regional study on ASR. The timing of this pilot project and regional study needs to be listed to determine if these features can, and should, be included in the Phase II PIR. The document also lists the Caloosahatchee Backpumping with Stormwater Treatment (20,000 ac-ft) as a project used to augment regional system water supply. The County has not been supportive of this backpumping effort until we are sure the Caloosahatchee system targets are met first, including wet season and dry season flows, but again, any

indirect water supply benefits from the CRWBSR must be identified in this current C-43 Draft PIR. The land acquisition needs of this feature are uncertain at this time and due to land value escalation, this effort should be expedited.

Page 1-15 This section lists the various "State Initiatives" having an impact on future water quality both upstream and downstream of S-79. Projects and programs included in this year's Northern Everglades and Estuary Protection Act should be included in this section. This information should also be added to Section 3.6 on Water Quality, page 3-7 and page 6-40.

Page 1-17 The Caloosahatchee Water Management Plan ("CWMP") is referenced as identifying the need for 220,000 ac-ft of storage in the lower West Caloosahatchee Basin as a target for environmental restoration of the Caloosahatchee Estuary. With the CRWBSR including 170,000 ac-ft of storage, a gap of 50,000 ac-ft storage need to be met exists based on the CWMP. The 20,000 ac-ft target in the Caloosahatchee Backpumping with Stormwater Treatment project is less than this target. This additional storage need must be identified as quickly as possible due to the aforementioned land value escalation issues. This comment is relevant to Section 5.3.4.5 on Alternative 4A.

Page 1-18 Will the permits referenced on this page, Section 404 Clean Water Act, be issued before construction commences in July 2007?

Page 2-11 Water use analysis is based on the CWMP document dated April 2000. The 2005-2006 Update to the Lower West Coast Water Supply Plan should be utilized and referenced for this analysis. This comment is also relevant to Section 3.16 on municipal and agricultural water supply.

Page 3-8 The Lake Okeechobee Operating Permit, ("LOOP") is currently being issued and discussion are ongoing regarding changes to the LOOP relative to structures that discharge from Lake Okeechobee into the Caloosahatchee basin. This information should be incorporated into the C-43 Final PIR. It should also be added the section on "Existing Operations" on page 8-4.

Page 4-18 The Water Supply discussion references the Lower West Coast Water Supply Plan Update. This Plan has already been adopted by SFWMD and should be a basis for water supply information in this C-43 Draft PIR.

Page 6-22 Will formal consultation with the U.S. Fish and Wildlife Service be completed by the release of the C-43 Final PIR?

Water Quality Benefits and Impacts

Page XVIII The document states that "Impoundment water quality will be further assessed as part of the permit application and review process." It is important that this analysis occur as quickly as possible so that operational adjustments can be made or additional features can be analyzed to address any problems. The timing of this water quality analysis in conjunction with "the permit application and review process" is unclear. Is that a concurrent effort?

Page 3-8 Reference is made to the land use specific runoff quality factors adapted from Harper 2003. These figures have been updated since that time and a more current reference may be more accurate.

Page 3-9 The document makes the statement that nutrient loads delivered through S-79 to the estuary are expected to be no more than presently delivered to the estuary. This assumption is highly speculative given historical loading from Lake Okeechobee and the changes to those loading rates based on unforeseen events such as hurricanes. The summary of that section should include a statement on these unforeseen effects.

Page 4-8 The document states, "According to CERP guidance memorandum 23.01 "Water Quality Considerations for the PIR Phase," the C-43 Basin Project falls into Category B, which means the project should be designed to achieve water quality improvements." The significance of this statement, and reason for referencing this document, are unclear.

Page 4-16 The "Nutrient Reduction Opportunities" section discusses water quality benefits from just operation of the CRWBSR, but there is no mention of the actual amount of nutrient loading that will be reduced. It is the County's understanding that some of this more detailed information is available based on the Test Cell project. This section would benefit from some specificity in terms of the actual reduction contemplated by the CRWBSR alone.

Page 4-30 The Section on Water Quality Evaluation Criteria lists improving water quality as a secondary goal of the project. Improving water quality is not listed as a secondary goal in the original "Yellow Book" purpose statements regarding the project. This statement should be struck from the document.

Page 5-34 The document states that assuming no water quality treatment in the basin, TP and TN loads are expected to be reduced 28 to 35% at S-79. On page 6-16, this figure is listed as 28%. Please explain the methodology for the 35% figure and the methodology to calculate these figures overall should be included in the document. Additionally, the short term increases contemplated in TN, yet the achievement of the average annual load reduction, are unclear.

Page 5-35 While the County agrees there may be a benefit from mere operations of the CRWBSR without a water quality feature at this time, it may be premature to conclude that the CRWBSR will not cause or contribute to water quality degradation under future conditions. See also page 6-17. Based on additional issues associated with contamination and clean up of the land and the short term TN issues identified in the comment above, this statement cannot be substantiated at this time. This comment is also relevant to the statement made on page 8-15, "The Caloosahatchee River (C-43) West Basin Storage Reservoir project selected plan complies with water quality standards applicable to the project and adjacent waters."

Miscellaneous Comments

Page 1-2 There is a typographical error in the last paragraph on this page. "Achieve" should be changed to "achievement".

Page 2-1 The land exchange between the 541.31 acres located north of the project boundary for the 600.13 acre Paul property should be clarified. The effects of this swap on adjacent

property owners should be reviewed. Will this land be needed for the activities commencing in July of 2007?

Page 2-37 The document states that without additional basin storage planned by CERP projects, flows exceed the target about seven months per year. The "CERP projects" referenced in the sentence should be identified.

Section 2.12 This section describes Hazardous, Toxic and Radioactive Waste property issues. The costs and commitments on remediating the sites are unclear. For instance, is this issue considered in the $446 Million estimated project cost or is it a future cost to be borne by the State of Florida?

Page 4-18 The Flood Damage Reduction section says that the project will not compromise the existing level of protection and that some incidental benefits may be achieved. These incidental benefits should be more clearly identified.

Page 5-4 The County is in agreement that the Caloosahatchee Estuary is in need of immediate helps and cannot wait until a holistic approach is developed to address all of the issues within the entire basin. But, there should also be specific timelines and commitments to address the remaining issues in one additional single study to be completed by a date certain. Potentially three PIRs and "subsequent studies" will continue to piecemeal the solution, cost more and delay that holistic approach to solving the Estuary's problems.

Page 5-37 The following statement in the document is confusing, "If nothing was done to improve the conditions in the estuary, the project team determined that the future without project condition would experience a gradual improvement for 15 year at which point the ecosystem would stabilize." The statement should be clarified or struck from the document because it seems to say that the CRWBSR may not even be needed because eventually the ecosystem will stabilize. For instance, how will it stabilize when data shows (such as water quality) conditions have been deteriorating?

Page 6-7 The document should clarify the difference between "completely resolving the problems of the Caloosahatchee Estuary and Caloosahatchee River (C-43) Basin and "the immediate needs of the estuary".

Page 6-31 The "commitment" from the SFWMD that "all of the outstanding point source remediation efforts will be completed" is unclear. Does the SFWMD have funding allocated to meet this commitment and when will it occur? Is it subject of an agreement and if so, what agreement? This section is concerning because soil contamination has also been identified in cultivated areas on the site. Remediation efforts are to place these soils into the core of the reservoir dam. While the County understands the funding constraints on the project the efficiency of using on site resources to construct the dam. The document states that there is still a risk to benthic organisms and the solution would be additional remediation efforts if needed. Costs for these efforts and more detail is necessary to assure that this issue does not cause project delay. See discussion also on pages 7-18 – 7-19.

HENDRY COUNTY PLANNING & ZONING DEPARTMENT

POST OFFICE BOX 2340 • 165 S. LEE STREET • LABELLE, FLORIDA 33975 • (863) 675-5240 • FAX: (863) 675-5317 • SUNCOM 744-4750

Jacksonville, Fl 32232-0019

RE: Comments on the Caloosahatchee (C-43) West Basin Storage Reservoir Draft Integrated Project Implementation Report and Environmental Impact Statement

Dear Mrs. Conner,

The Hendry Planning and Zoning Department is in receipt of the Draft Integrated Project Implementation Report and Environmental Impact Statement. Based upon our review of the draft package, we offer the following comments:

1. The recreation features are being planned in the C-43 West Basin Storage Reservoir project as an incidental project benefit according to language in Appendix H, Section H.2.1. Hendry County believes the proposed recreational activities should be a permanent part of the reservoir project. The recreational activities need to be clearly defined and not subject to removal. Hendry County would like a commitment, from SFWMD, to provide equestrian trails, biking and hiking trails, fishing, hunting, nature watching, and ramps for motorized and non-motorized boating.
2. Hendry County believes the recreational activities should be available upon completion of the construction and opening of the reservoir.
3. The reservoir, during low volumes, should be open to non-motorized boating and airboats at a minimum. There needs to be agreement between SFWMD and Hendry County on set standards that define low volumes.
4. In Appendix H, Section H.2.1, page H-3, it is stated that shade trees are proposed on the outside area of the north rim canal adjacent to the parking. Hendry County would like to see additional trees and vegetation planted outside and around the reservoir to promote bird watching, aesthetics, shade areas for the public, etc. The County wants the reservoir to become an asset and not an eyesore.
5. Restroom facilities should be provided and operated by the SFWMD. Additional facilities should be added at the expense of SFWMD, as the need arises,

Re: IC&R #s: 2007-032 & 2007-035/SAI #: FL200704263301C
Permit 3005-5958 (IP-TKW), Hendry County, Caloosahatchee River (C-43) West Basin Storage Reservoir, Draft Project Implementation Report (PIR), Environmental Impact Statement (EIS), and Tentatively Selected Plan (TSP), http://www.evergladesplan.org/pm/projects/docs_04_c43_pir.aspx

Dear Ms. Mann:

The Southwest Florida Regional Planning Council (SWFRPC) has reviewed the Proposed Permit 3005-5958 (IP-TKW) for the Caloosahatchee River (C-43) West Basin Storage Reservoir, Draft Project Implementation Report (PIR) and Environmental Impact Statement (EIS), and has the following comments.

The request dated April 30, 2007 was received for our review on May 4, 2007.

The proposed project has the potential to effect hydrology, water quality, wetlands, and wildlife within one of the largest manmade canal systems within the Southwest Florida Region.

There are several components of the Tentatively Selected Plan (TSP) that will have environmental benefits including:

- Construction of a 170,000 acre-feet reservoir with the expressed purpose of reducing the number and duration of extreme hydrologic events at S-79 locks on the Caloosahatchee River.
- Reduction in the number and duration of high flow (>4500 cfs) and low flow (<450 cfs) events in the Caloosahatchee River.
- Adopting and implementing targets of 0 flows below 450 cfs and above 4500 cfs for the Caloosahatchee River.

TO: Ms. Sally B. Mann
DATE: 6/5/2007
PAGE: 3
RE: IC&R #s: 2007-032 & 2007-035/ SAI #: FL200704263301C

4) The missing pages in the Final Biological Assessment concerning methodology that should be present between pages A-95 and A-96 in Annex A of the FWCA Report and Endangered Species Act Compliance should be inserted into the documentation of the PIR.

The SWFRPC supports the concept and development of the C-43 reservoir project to reduce the negative hydrologic discharges to the Caloosahatchee River, restoration of base flows for the Caloosahatchee River, and improvement in water quality of the Caloosahatchee River. Our staff has participated cooperatively in the development of the PIR and EIS. We did not and do not agree; however, that water quality protections should be deferred in development of this project.

We look forward to cooperating with the applicant and other relevant agencies to resolve the issues that we have identified in this letter in order to ensure consistency with the Coastal Zone Management Act/Florida Coastal Management Program and to ensure that the TSP proceeds in a fashion that minimizes impacts to water quality, hydrology and fish and wildlife resources in the Southwest Florida Region. Staff has been in contact with Hendry County Planning and they had indicated that they will be submitting comments; but to this date they have not been completed. Please note that Hendry County's comments will be submitted under separate cover.

Please call me if you would like to coordinate further discussion of these issues; I will be glad to facilitate any such efforts. If you have specific questions about the content of this letter, please contact Ms. Jim Beever directly at (239) 338-2550 ext 224, e-mail jbeever@swfrpc.org.

Sincerely,

SOUTHWEST FLORIDA REGIONAL PLANNING COUNCIL

CENTRAL AND SOUTHERN FLORIDA PROJECT
COMPREHENSIVE EVERGLADES RESTORATION PLAN

CALOOSAHATCHEE RIVER (C-43)
WEST BASIN STORAGE RESERVOIR PROJECT

DRAFT INTEGRATED
PROJECT IMPLEMENTATION REPORT
AND
ENVIRONMENTAL IMPACT STATEMENT

Comments prepared by:
Pete Coultas, P.E.
Manager of Agricultural Engineering
A.Duda & Sons, Inc.

Dated:
June 11, 2007

As a landowner adjacent to the proposed Reservoir south boundary, A.Duda & Sons (ADS) has specific concerns, some of which have been, are being, or should be addressed through direct discussions with the Reservoir Project management. Some of these specific concerns are as follows:

1) Well abandonment and ASR effects on local groundwater supply.
2) Public recreation on the outside of the Reservoir perimeter canal. This would provide the public with direct access to our property. Real recreational activity exists inside the proposed perimeter canal. Access to the outside should be restricted to provide a buffer between offsite lands and the public.
3) The Townsend Canal capacity may become a problem in terms of our irrigation withdrawal. What measures are in place to offset this potential conflict?
4) Will the Reservoir become a "consumptive user" of water in dry times? Other South Florida reservoirs require a minimum water level.
5) ADS has an existing easement along the east side of the Townsend to SR80. What provisions have been made for equivalent access?
6) Piezometers are in place to monitor lateral seepage to adjacent lands.
7) Conversion of habitat on a tract this large may displace a significant wildlife population. What mitigation avenues are available to an adjacent landowner if their property becomes a site for a refugee population?

Following a review of a large portion of the Draft Report and Statement, I am providing the following general comments. Excerpts were taken from the ACOE Draft Integrated Project Implementation Report and Environmental Impact Statement. Each is followed by the PDF file page number and my associated comments.

1.1 REPORT AUTHORITY

The CERP was approved in Section 601 of WRDA 2000, which states, in part:

> *(b) Comprehensive Everglades Restoration Plan Approval –*
> *(1) APPROVAL*
> *(A) IN GENERAL. —Except as modified by this section, the Plan is approved as a framework for modifications and operational changes to the Central and Southern Florida Project that are needed to restore, preserve, and protect the South Florida ecosystem while providing for other water-related needs of the region, including water supply and flood protection. The Plan shall be implemented to ensure the protection of water quality in, the reduction of the loss of fresh water from, and the improvement of the environment of the South Florida ecosystem and to achieve and maintain the benefits to the natural system and human environment described in the Plan, and required pursuant to this section, for as long as the project is authorized.*

Page 49
This paragraph approves the ecosystem restoration, "while providing for other water related needs of the region". This phrase indicates a corresponding action, i.e. the water supply element is authorized along side the environmental releases to the estuary.

2.15 EXISTING LAND USE

The Caloosahatchee River (C-43) West Basin Storage Reservoir is proposed for construction in north-western Hendry County. This reservoir is intended to reduce the fresh water pulses into Charlotte Harbor and the Caloosahatchee Estuary, and provide water storage for meeting environmental needs. Additional water, after environmental needs are met, could be used as supplemental water to help meet the needs of agriculture and urban communities in Southwest Florida. The study area includes Lee, Hendry, Glades and parts of Charlotte County. Collier County is located in the general vicinity of the study area. ***Figure 2-12*** depicts the 2000 land use map for the South West Florida Region. This map was generated for the South West Florida Feasibility Study and includes the Caloosahatchee River (C-43) West Basin Storage Reservoir study area.

Page 121
This paragraph limits the regional water supply benefit to a secondary concern. This is inconsistent with Section 601 of WRDA 2000 (see page 49).

2.12 HAZARDOUS, TOXIC, AND RADIOACTIVE WASTE

The five major land parcels acquired for the Caloosahatchee River (C-43) West Basin Storage Reservoir project are the Berry Groves tract, Bryan Paul Grove tract, Bob Paul Grove tract, the Winthrop property, and the Griffin property. Prior to the 1960s these lands were primarily used as unimproved pasture. For the last 30 to 40 years these five parcels have been used to cultivate citrus. Over the operating life of these groves, fertilizers, herbicides and pesticides have been applied routinely as part of normal agricultural operations. From the 1960s to 1980s, pesticide use would have included the application of persistent organic

Page 112
I did not see any summary of wells to be abandoned. Significant local and regional ground water contamination could result from improper or no well abandonments. Any proposed ASR wells would be far below any local aquifers, I presume?

The Governor's Commission for a Sustainable South Florida identified agriculture and tourism as "critical industries" for maintaining the economy in the southern part of the state. In Lee and Hendry County, agriculture is a major industry and citrus production predominates. A rapidly expanding human population demanding more developable lands and advancing agricultural development now threatens the relatively pristine natural areas. The tourism industry is also dependent upon the region's ability to sustain its economy and its quality of life through management of its resources. Agriculture and tourism depend on a system that can provide vital water supply needs and flood protection.

Page 118 (repeated on page 173)
The dependence of these "critical industries" on water supply points to the importance of maintaining the water supply benefits while providing the environmental releases for the estuaries. Agriculture and tourism have co-existed for over 100 years. To suddenly subjugate one to the other is unwarranted.

The watershed downstream of the S-79 structure that contributes directly to the Tidal Caloosahatchee River is primarily urban (Cape Coral and Fort Myers). Although some of this urban area pre-dates the 1979 state rule regarding the prevention of the pollution of state waters from stormwater runoff (62-25 Florida Administrative Code), much of it was developed after this rule went into place. Although urban areas can be significant sources of nutrients and pollutants, the impact from this urban area appears to be relatively minor compared to the proportion of nutrient loads delivered to the Caloosahatchee Estuary through S-79 inflows. A study by ERD (2003) found that, discharge from S-79 contributes from 90 percent to 95 percent of the mean annual mass of total nitrogen (TN) and total phosphorus (TP) to the Tidal Caloosahatchee River (for this report, the USACE has estimated that S-79 contributes more than 75 percent of the nutrient loads). The next largest contributor to the Tidal Caloosahatchee River was the Orange River with 1.1 percent to 3.8 percent of the annual mass of TN and TP.

Page 170
This comparison of the urban areas along the estuary to areas upstream of the S-79 tells only part of the story. If an acreage or total flow comparison of the entire S-79 tributary watershed were included, the 90% to 95% conclusion would not be surprising, given that the watershed extends from the S-79 to Orlando. In other words, the urban areas along the estuary are a very small portion of the total flow and therefore a small contributor to loading. Water quality issues within the local urban watershed should not be overlooked.

4.1.4.1 Water Supply

While providing additional water supply for urban and agricultural users represents a potential opportunity to be addressed by the Caloosahatchee River (C-43) West Basin Storage Reservoir, providing water supply to meet the environmental needs of the estuary during dry periods is one of the primary purposes of this project. Upon meeting flow targets at the S-79 structure necessary for ecosystem restoration in the Caloosahatchee Estuary, any additional water stored by the Caloosahatchee River (C-43) West Basin Storage Reservoir could be delivered to the C-43 Canal and would be available for other water related needs.

Water supply and flood control benefits of the Caloosahatchee River (C-43) West Basin Storage Reservoir implementation will be classified as incidental. Increases to flood damage reduction benefits and water supply benefits will not be further analyzed as part of this study; however, a later PIR will investigate opportunities to increase the quantity of water available for municipal, agricultural, and other environmental interests in the basin. Analysis of area water supply is being conducted by the SFWMD in a report entitled Lower West Coast Water Supply Plan Update.

Page 174
The classification of water supply as "incidental" is contrary to Section 601 of WRDA 2000.

Subject: Draft PIR and EIS on the Caloosahatchee River (C - 43) West Basin Storage Reservoir Project

Dear Ms. Conner:

Committee of the Islands (COTI) is a Florida not - for - profit corporation which has as one of its missions, preservation of the unique natural environment of Sanibel and Captiva Islands. COTI urges the Army Corps of Engineers to work with the South Florida Water Management District to include a filtration marsh in plans for the proposed C - 43 Reservoir.

The waters surrounding our islands are being degraded by excessive nutrient run off into the Caloosahatchee River. As a direct result, abnormal algae blooms threaten our wildlife, the tourism business which supports tens of thousands of workers and property values of all residents of Lee County. The proposed C - 43 Reservoir will do little to alleviate this problem unless it includes a Storm Water Treatment Area (STA) to remove excess nitrogen and phosphorous before the stored water is reintroduced into the Caloosahatchee. This will require the prompt acquisition of lands for use as a filtration marsh near the C - 43 Reservoir.

Storm Water Treatment Areas are routinely included in projects of this type throughout the state of Florida. The Calooshatchee is in dire condition. Rather than be singled out for less effective treatment than other localities, it should be treated in the same way. A STA for he C - 43 Reservoir is therefore essential.

We thank you for your consideration of these comments.

Respectfully submitted,

Lawrence M. Schopp, President

U.S. Army Corps of Engineers
701 San Marco Blvd.
Jacksonville, Fl. 32207-8175

Attention: Susan Conner

Dear Sirs,

We would like to add our voice to the insistence that the storm water treatment area proposed for C-43 must include a filtration marsh to go with the C-43 reservoir.

Sincerely,

Donald L. Deming
Melanora L. Deming

May 10, 2007

Ms. Susan Conner
U.S. Army Corps of Engineers
701 San Marco Blvd.
Jacksonville FL 32207-8175

Dear Ms Conner,

I greatly appreciate the opportunity to comment on the C-43 reservoir project. Regrettably I will not be able to attend your public meeting on May 17, but please accept this letter as a substitute for the comments I would have made had I been able to attend.

My wife and I have been residents of Sanibel for some 22 years after I retired from a position up north. We were attracted to this area because of its pristine environment and we like to think that we have contributed in some small way to keep it that way. Now after Hurricane Charlie the local eco system has been seriously disrupted and Sanibel Island as well as neighboring municipalities have been plagued by red drift algae accumulating on our shores. We now urge the U.S. Army Corps of Engineers to do your part in assisting our efforts to eliminate this plague from our beaches.

You can help by adding storm water treatment areas (STA) to C-43 as you have done with other reservoirs you have developed in south Florida. Without these STAs I am convinced that some form of algae will form, be subsequently discharged to the Caloosahatchee River and end up on our beaches when C-43 is drained. We are only asking for fairness. If other areas are provided with STAs to provide them with quality water why not do the same for Southwest Florida?

Regards,

Curt Stendahl

Attention: Susan Conner

Service Federal Activity Code: 41420-2006-0443
Date Received: September 7, 2006
Project: C-43 Basin Storage Reservoir Project, Part I-Phase I
Counties: Hendry, Glades, Charlotte, Lee

Dear Mr. Appelbaum:

Thank you for your letter dated September 1, 2006, in which you formally invited the Fish and Wildlife Service (Service) to become a cooperating agency for an Environmental Impact Statement (EIS) on the C-43 Basin Storage Reservoir Project, Part I-Phase I (C-43 Project). The C-43 Project is a component of the Comprehensive Everglades Restoration Plan, authorized under the Water Resources Development Act of 2000.

The objective of the proposed action is to improve the quality, quantity, timing and distribution of freshwater flows in the Caloosahatchee River and Estuary to restore ecosystem function. The proposed action includes construction of an above-ground storage reservoir (i.e., C-43 West Reservoir) in Hendry County, Florida, that will provide a significant portion of the overall water storage needed in the Caloosahatchee basin for estuary restoration as described in the Central and South Florida Project Comprehensive Review Study.

The Service, as part of the C-43 Project Environmental Sub-team, is actively working with project managers to develop alternative plans that provide significant ecological benefits while supporting project goals and objectives. Although we intend to continue our work on the study team, the Service declines your invitation to become a cooperating agency for the development of the EIS on this project. We will continue to take a broad system-wide perspective and a balanced approach in our evaluation of the potential effects of the proposed action on fish and wildlife resources, including threatened and endangered species, and to assist with the development of appropriate alternatives to avoid and minimize potential adverse affects of the action. The Service must balance its role as a study team member with its statutory

responsibilities to independently review this proposed action under the Fish and Wildlife Coordination Act and the Endangered Species Act.

Thank you for this opportunity to provide comments on this project. The Service appreciates your efforts in helping to protect the fish and wildlife resources of south Florida. If you have questions regarding this letter, please call Joyce Mazourek at 239-472-1100, extension 231.

Sincerely yours,

Paul Souza
Field Supervisor

GUARDIAN REPORTING, INC.
~ Proudly Serving Southwest Florida ~
(941) 575-9533 * www.guardianreporting.com * *Fax* (941) 575-8618

MR. DUKE: We're going to get started.

THE INTERPRETER: Before beginning, if there's anyone here who would prefer to hear the presentations in Spanish, there is simultaneous translation available. (Continues in Spanish).

MR. DUKE: Okay. Thanks. Okay. Thank you all for coming out tonight. We brought a little rain with us, much needed. At least it cleans the lovebugs off the windshield after a while. Tonight's meeting's about the Caloosahatchee C-43 west basin storage reservoir. This is a part of the Comprehensive Everglades Restoration Plan, the ten and a half billion dollar program that the State of Florida and the Corps of Engineers on behalf of the federal government are launched into in partnership with other state and federal agencies to restore the South Florida ecosystem which includes primarily the Florida Everglades as well as the estuaries and other areas around the entire peninsula of southern Florida. This is one of the components of the 68 total components that comprise that comprehensive plan. It is -- was approved as part of the Water Resource Development Act of 2000 by congress as a road map and overall plan for the restoration of the ecosystem.

What we're here tonight to talk about and, hopefully, this is not the bus to Abilene. This is about

the C-43 basin reservoir. We're going to go through a detailed presentation of where we are to date. The team has been working. We have what's called a project delivery team that comprises members of the Corps of Engineers, the Water Management District, US Fish & Wildlife, and other agencies that participate on this team to develop the plan that was originally identified in that -- what we call the Restudy Report that was submitted to congress that provided the basis for the authorization back in the year 2000.

We've been working on this for several years now developing and refining that plan, identifying the benefits, and so forth, and they'll walk you through the purpose, the objectives of the overall study, what they've identified as alternatives, and the results of the findings to date. We'll go through part of the plan and describe the features of the plan, the components of that, and the operations of the reservoir once it's completed, and then we'll take public comments.

Okay. We do have transcriber here who will be taking a record of the meeting. It will be recorded in that fashion. Comments will be taken. If you have long comments, I'll go through that. Just remind you, please submit them in written form. We take written comments now as a part of this overall process and include them in

our environmental document, environmental impact statement that we have for this project. Okay. That'll all become part of the official record, and I encourage you to participate and provide comments to us and feedback.

Again, this is part of the overall CERP plan. The state of Florida through the South Florida Water Management District is part of the initiative to bring restoration benefits earlier initiated back in 2004, a program they called Acceler8. It was dubbed the A8 program in which they would up front fund and initiate the design and construction of certain components of the South Florida Restoration program in advance of the Corps of Engineers receiving funding from congress.

They also have as a part of this a -- one of their A8 programs or projects is the C-43 reservoir; so they've been out there building test cells and doing their detail, design, and so forth on this project to move forward with construction. They're waiting for us to finish the PIR to identify the plan that is to be actually implemented, and that will be the project that's actually constructed by them. So in case you're wondering, we're going to answer questions about how the two fit together and how that's being funded totally by the state at this point in time and what the ultimate

benefits and purpose of this.

So if you have questions, I'd ask that you hold it to until end of the presentation. Hopefully we'll answer a lot of those as we go through this. But we'll get into the public comment period. If you have additional questions or questions at that time, please feel free to state those. If you would like to make a public comment, there was comment cards up at the table. Please fill one out for our records with your name, address, and so forth. We don't sell it to a mailing list, but we do keep it as part of our official record so we know who you are and what your comment is and have that for our transcription. Okay?

Okay. And with that, I'll introduce Janet Starnes from the South Florida Water Management District who will start this off. Thank you, Janet.

MS. STARNES: Okay. In that case, and I'll have to play with this first. The first thing I want to point out is I am Janet Starnes. I am with the South Florida Water Management District, and I am the project manager for the South Florida Water Management District. But with us here tonight are many, many staff members that have dedicated a tremendous amount of time, energy, and effort, in particular over the last five months, to getting this project to a Draft Project Implementation

Report; and they are here to assist us in answering your questions and providing you the information you need.

In particular, Beth Marlowe is here. Beth is the -- my counterpart at the Corps. She is the project manager. We also have David Apple. He is our planning technical lead. He's the one who makes sure that all the actual hard work gets done. And we also have Aaron Kelly with us, which is our engineering technical lead, and he's the one that makes sure that when we build it it'll actually stay up. And those are very important things.

That being said, the purpose of this meeting, as Dennis was pointing out, is to go over the project and kind of give you an overview of what the project is and why we are building the Caloosahatchee River West Basin Storage Reservoir Project. And I should have pointed out this sooner. We actually have changed the name of this project. Many of you may have known it as the C-43 Basin Storage Reservoir Project. It is actually officially now known as the Caloosahatchee River West Basin Storage Reservoir Project, and that's -- that is the official name. That was changed, oh, a couple weeks ago through the process of internal reviews. It was just felt that rather than referring to it as a numbered canal that due to the fact that this was an environmental restoration it was far more appropriate to refer to it as the

Caloosahatchee River, which is what we are actually attempting to restore is the Caloosahatchee River and the associated estuary of the Caloosahatchee estuary.

We are also going to go over the draft operating manual. That is required; so we will be doing that. In addition to that, as Dennis was pointing out, we will be taking questions, concerns, and issues.

That being said, the purpose of this project is to restore the quality of -- the quantity of water, the timing, the flows to the Caloosahatchee estuary. This is a basin storage reservoir project, and we have named it "basin storage" for a very specific reason. It is -- the focus, the primary focus of this project is actually on the quantity of water when it hits S-79 or the Franklin lock and dam and the impact that that fresh water has on that estuary. Fresh water, in and of itself, in high level -- high quantities affects the salinity in such a fashion that it, in and of itself, can cause a water quality problem; so we thought we need to solve that problem first, really focus on that quantity issue, and then we'll work with the quality issue as we move along.

What we will be doing is we will be grabbing the high flows in the river during wet season, and then during dry season when those high flows are no longer there and we actually have extreme dry seasons or dry

seasons beyond what would be the normal range, we will then release that water out of the reservoir so that it goes to the estuary. And the whole purpose and intent of that is actually to maintain a more natural salinity regime within the estuary. So the focus of this project is environmental restoration of the estuary. And that's a real important piece to remember as we go through this process.

Just to familiarize you all with the Caloosahatchee watershed, although I know many of you are familiar with it, and then I know there are some folks here that are less familiar, the Caloosahatchee watershed begins at Lake Okeechobee. It's at Structure 77. It travels down, it passes through another structure, which is the Structure 78. These are both lock and dams. And then at S-79 -- in this project we actually consider the Structure 79, or the Franklin lock and dam, to be the beginning of the saline or the estuarine system. So we are -- we basically are looking and we will be managing and operating based on flows at S-79, and that's fresh water flows at S-79. And we are going to manage it for quantity and for timing so that we get a flow regime that is closer to the more natural regime prior to man impacting this system.

Before the C-43 canal was put into place, the

Caloosahatchee River was actually not connected to Lake Okeechobee. It was only during very, very, very extreme events when the lake came out of its banks and flowed as sheet flow towards the west that it would end up actually coming into Lake Flirt, which is right about in here. So it was not -- the natural river was not connected to Lake Okeechobee. That is actually a function of man's actions.

The Caloosahatchee River estuary is actually going to be located here in LaBelle. It's just west of LaBelle. It is along State Road 80. It's at the Berry Grove site for those of you who are familiar with the Berry Grove citrus operation, that is actually the location of the reservoir itself.

And as Dennis pointed out, this project was authorized for planning purposes in the Water Resources Development Act of 2000; however, it will go back to congress as a Project Implementation Report for full authorization and then subsequent appropriation. It is one of the critical projects in terms of the implementation of the Comprehensive Everglades Restoration Plan; so, therefore, the State of Florida is moving forward with the construction of this project under what's known as our Acceler8 project.

And that -- The whole intent of the Acceler8 project

is to get the larger projects in the ground as quickly as possible so we can move as quickly as possible forward with implementation of CERP in order to begin to alleviate some of the impacts that the management of Lake Okeechobee has been having on the Caloosahatchee estuary as well as the St. Lucie estuary and south.

To accomplish the goal of getting the Acceler8 project -- keeping the Acceler8 project moving, and still dealing with all of the many, many concerns within the Caloosahatchee watershed, a determination was made about two years ago that rather than going forward with a single Project Implementation Report that covered both the upper basin and the lower basin and covered not only quantity problems and issues but quality problems and issues, as well, a decision was made that, again, the first and foremost issue is the quantity. We've got to solve the quantity problem first; so a decision was made to split the Project Implementation Report into two project implementation reports.

The first one, the one we're here about tonight, is the Caloosahatchee River west basin storage reservoir. It is a reaffirmation of the restudy or the Comprehensive Everglades Restoration Plan as adopted in the Water Resources Development Act of 2000. And it will provide immediate relief to the Caloosahatchee estuary by pulling

off many of those high flows that occur today because it is a man-influenced system and switching those flows out so that they actually get there during dry season when it is more appropriate for -- when we're short on water during dry season and we've got lots of extra water during wet season. We're going to be able to now grab the wet season flows and then release them during dry season when the system is desperately in need of fresh water.

We will be doing the second Project Implementation Report that will also go to congress for authorization. We're actually going to kick that off in September of this year. It will focus on the broader problems in the watershed itself. It will also deal to a much greater extent with what we call the upper watershed or those portions that are in Glades and eastern Hendry County. It is also where we will focus more on water quality features and the needs to do water quality -- I don't want to use the word "treatment." That's not a good term -- but water quality enhancements. Thank you, Aaron. That's a perfect good. And our goal is to identify where there's a problem so we can -- and do the treatment or do the -- do the restoration associated with water quality where the problem occurs, not all the way at the downstream end of this system. So that's much of

the focus in the second Project Implementation Report of the Caloosahatchee River watershed will actually be -- we will focus on watershed -- on water quality.

In addition to that, we know that this Project Implementation Report is only going to solve about 70 percent of the quantity problems. In other words, we're still going to have high flows going to the estuary in times that we don't want them. And there will still be dry season flows that are too low to maintain a healthy estuary even within what would be a average kind of regime. There will always be floods. There will always be extreme events. We aren't even attempting to do away with extreme events. The natural systems actually need it, extreme events, in order to stay healthy. But we have about 30 percent additional storage capacity that we will need to identify and then move forward with in terms of the Project Implement -- the second Project Implementation Report as well as deal with the water quality issues within the basin itself.

And at this point, I do believe I'm turning this over to Beth, and she's going to walk you through the technical aspect of the Project Implementation Report.

MS. MARLOWE: Hi, everyone. Thank you very much for joining us this evening. We really appreciate everybody's interests in this project.

When the Corps of Engineers goes through a ecosystem restoration planning study, or in this case we had the restudy or the yellow book road map as a starting point. But, still, before we can go to congress and say, you know, we'd really like the American taxpayers to invest money in this project because we think it's really important, we need to do a study so that we can be sure that we've looked at all the problems and opportunities, we've come up with some good alternative plans, and we've really picked the best one.

So one of the things that we need to do is look at the future without project condition. Well, what really is that? We look out into the future, usually about 50 years, and say what do we expect the conditions in this ecosystem that we're trying to restore to be like if we don't do anything. So that's kind of what this is -- this is looking at: What if we didn't do anything for the Caloosahatchee estuary. What would we expect to happen.

Well, we would expect the regulatory releases from Lake Okeechobee to continue with the extreme highs in the wet season and then not enough flow in the dry season. For the ecosystem of the estuary we would expect the continuing extreme changes and variability in salinity that is degrading the ecosystem there. And that would

have impacts on sea grasses, on small fish and other little invertebrates that the larger animals in the ecosystem depend on. And that eventually has an impact, too, on people and our socioeconomics. It would impact commercial and recreational fisheries as well as just boating and people liking to be out in the estuary. So that would be our future without project condition.

From there we say, okay, well, what can we and should we do based on the problems and opportunities. We work with the public to identify and start coming up with solutions to try to solve these problems. As Dennis and Janet mentioned, we have the restudy as a road map and a starting point. And if you're not familiar with that, the feature that was identified to try to help solve Caloosahatchee estuary problems in the restudy was an above-ground reservoir. At the time they were guessing around 160,000 acre-feet of storage would be needed and an approximate location and approximate size and depth. And the restudy said when we go into this Project Implementation Report phase, we'll refine that design and the actual location. And that's what we've been focusing on in this draft report. We've been optimizing the feature that was in the yellow book.

So what we did was look at some smaller reservoirs, larger reservoirs, and one kind of in the middle that was

about the same size. Also, if you're not familiar with an acre-foot of water, that's just a way of saying imagine one acre of land with water one foot deep. And we're looking at several hundred thousand acre-feet; so it's a lot of water. We developed lots of different alternatives throughout our study and eventually screened them down to these five.

The first alternative is always the no action alternative or the future without project condition, what if we didn't do anything. That's what we're going to compare all of our alternatives to. The others are the different variations on the reservoir.

If you look at the second and third columns, you see the difference in size. And it's a difference in the storage capacity, but all of these reservoirs are looking at actually the same footprint on the ground. The embankment heights would differ to hold the different amounts of water. We also have differing pump capacities. The pump is used to pull water out of the Townsend Canal, ultimately the Caloosahatchee River, into the reservoir. And the pump capacity has to do with how fast you can pull water in.

And then the other columns go into how we look at benefits and costs for these alternatives. If you have several different alternatives for something you want to

try to accomplish, it's a good idea to look at, well, what kind of benefits do I get from that and how much does it cost me. If you're looking at something that has benefits you can measure in dollars, that's pretty easy. You look at, you know, what's the dollar benefit that you get out of it versus the dollar cost that you put into it. Well, with ecosystem restoration there's no good or easy or agreed upon way to put a dollar value on a healthy Caloosahatchee estuary; so we had to come up with another method to do that.

And right now the Corps of Engineers were using something that's called a habitat unit which is a way of trying to capture a quality -- an index of the quality of your ecosystem and also the spacial extent of it. And we'll talk about that a little bit more later on. Bottom line, these numbers show how much more benefit we think the estuary is going to get compared to the future without project condition; so the higher the number the better, all other things equal.

Then we also look at the costs, and what you have here are average annual costs over the life of the project and a cost per habitat unit. The three rows in the middle are highlighted in green because they are -- have been determined to be cost-effective projects. And what does that mean? Well, that means that you can't get

more benefits for less cost -- no -- for the same cost for any one of those or you can't find another project that costs less for the same amount of benefits. I may have confused you a little bit there, but we can talk more about that after the presentation.

So how do we start talking about ecosystem benefits. Well, first we do have a hydrologic flow range that we're trying to target. We have a minimum flow level we want to try to be above and an upper flow level we want to try to stay below. And that range is about 450 to 2,800 cubic feet per second of flow over Structure 79 at the beginning of the estuary. Our analysis shows that about 75 percent of the time the alternative that we're recommending will be within that flow range. Now, as Janet mentioned, we can't solve all of the problems with excessive flow or low flows with this one reservoir, but we can get there about 75 percent of the time. So that's one way of looking at it. But that's -- that's a change in flow.

How do we relate that to positive benefits in the estuary. What our team did was take several species from the estuary that are ecologically important because they influence a lot of other species or are economically or recreationally important, and we developed some habitat suitability models for these species. And we looked at

how our flows from our alternatives would affect these species, how these species would respond in these models. And we came up with kind of a quality score. So if you combine that with our hydrologic performance, you can get sort of an overall indicator of what's the improvement in the quality of this ecosystem as a result of what I'm trying to manage in my alternatives. And we did pick these species because they all provide habitat or they're at the base of a food chain; and they also, importantly, have an established link or response to this stressor that we're trying to manage, which is flow, which impacts salinity.

So bottom line we came up with a way to try to predict the change in quality of the ecosystem as a result of our alternatives; and then we tried to apply, well, how much area would that change in quality affect. And if you look at this graphic, it shows you up here -- Sorry. Let me go back. Up here that is where Structure 79 is at the head of the estuary. And we are anticipating that this project will affect all of these areas where you see the red, and that's approximately 71,000 acres of estuary. So to get that habitat unit that you saw in the chart, you take your quality index score times your area of benefit; and you come up with that habitat unit number.

And, again, this is just a recap of the alternative that we are recommending. It's 170,000 acres of reservoir with 1,500 cfs pump. Our total initial cost is about $446 million, and we're expecting the benefit in habitat units to be about close to 13,000 a year. Now, why did we pick this alternative and not one of the others. Well, it is a cost-effective plan. We have to pick a cost-effective plan. We wouldn't be doing our duty to the American taxpayers if we didn't do that. It also fully meets our planning objectives.

Now, there is another alternative, 3C, that is identical to 3B except that it has a little bit larger pump size. That one has a little bit lower cost per habitat unit; but when we looked at that, we said, well, there are some potential risks associated with that one in terms of what we might have to do to improve the Townsend Canal to allow the amount of flow that would be coming through to use that larger pump. So since this alternative is cheaper, it meets our goals and objectives, why don't we build this one. It's acceptable to our local sponsor. If we decide at some point in the future that we do need more pump capacity, that can always be added on; and we can -- we can base that on actual operations of the reservoir as we go forward.

Okay. This graphic is virtually the same as this

display board up here. This one actually might be easier to see than this. It just gives you a little bit of an overview of the site plan. The red line in the rectangle is showing you where the top of the embankment would be. We're looking at a reservoir approximately 10,500 acres; so it is very large. We're looking at two cells. That helps us be able to manage the water better, and it also minimizes the water we lose to the atmosphere from evaporation. Up here in the northwest corner is our main pump station. That's where we would draw the water from the Caloosahatchee River, that you can see up here in this corner, through the Townsend Canal and into the reservoir. The -- Both cells have a main discharge structure up in the northwest corner. There's two.

Then, let's see, the average depth of the reservoir pools would be 17 to 19 feet. The embankments are about 35 feet above grade; so if you're trying to picture this, it's a pretty massive structure. We are designing the embankments to dam safety criteria. These are not just hills of dirt. They're very exactly engineered, and they are designed first and foremost to be safe, to be sure that no property or people are impacted. We also have in this design some armoring to help prevent erosion of the embankments as well as a cutoff wall which helps -- it's kind of a wall that's built into the embankment structure

that helps eliminate seepage water out of the reservoir. Also around the embankments the blue line that you see is the perimeter canal. That helps control seepage as well as delivering water to users around this site that got their water from I think this canal here previously. So we are maintaining the flows that those water users are entitled to. I think those are the major points on the design.

We also are including, as kind of an add-on to the project, some potential recreation features. I do need to point out that the primary purpose of this reservoir is to be operated to maintain the health of the estuary. But from the Corps of Engineers's perspective, if we can add on some recreational features to this project without compromising the purpose of it for ecosystem restoration, then, by all means, we want to try to do that. So some of the features that are anticipated are a boat ramp that would allow access to both cells, some hiking and biking along the embankment, the top of the embankment, at least part of it, maybe not all the way around, and then also an access road around the perimeter canal. We would envision fishing, bird watching, horseback riding, potentially some boating. I think we're not settled yet on exactly which types of boats we would be talking about but definitely some boating.

And this is a breakdown of the costs of the recommended plan. Again, total initial cost of $446 million, and that does include about $2 and a half million for the recreation features. So that is, in a nutshell, the Caloosahatchee River west basin storage reservoir.

If you would like to make comments, please, by all means, we would love to have your comments tonight. But I know this is a lot of information. If you're hearing some of this for the first time, it can be hard to digest. Our full report is posted on our website, evergladesplan.org. You can also ask us to send you a copy, either a paper copy or a CD. We'll be more than happy to do that. If you have comments after you do some thinking about it or after you read a little bit of the report, by all means, please send them to us. Our 45-day public comment period runs until June 11th. And what we will do then is we will have a matrix of all the comments we got and then how we respond to those comments; and that will become part of our final report and our official record. All the comments can be sent to Susan Conner. And, Susan, would you mind standing up and waving? Susan is the one who will take your comments. She's very nice. She's not scary at all. You can send her your comments. And that's her contact information

right there. Okay.

That said, I think we will move now to the draft operating manual.

MS. RAULERSON: Hi. My name is Stephanie Raulerson, and I'm a hydraulic engineer in the water management section with the Corps of Engineers. And I guess I'll say this is the no-frills portion of the presentation because I don't have any pretty pictures or anything; so hopefully I'll get this right, too.

Okay. What's the purpose of an operating manual. The purpose is to describe the day-to-day water management operations for all conditions affecting the reservoir and the project. Now, I think a better description is they used to be called the Water Control Plan. So we're actually saying how we're going to control -- the waters will be operated to control that water. And Beth had already touched on some of the features; so I won't dwell on this too long. But the main inflow pump station is Pump Station 1 over -- let me get this -- over here to this corner. And then the Culvert 12.

She had mentioned that we have two cells, and that allows us more flexibility in the operations. And we have Culvert 12 right here in the middle. If we wanted to perform maintenance in either one of these cells, we

can cut off one and operate, like -- so we could cut off cell one and operate cell two or vice versa because of the structure. The reservoir we operate to store excess basin runoff and discharges from Lake Okeechobee and deliver water to the Caloosahatchee River. And operations are based on maintaining desirable salinity levels in the Caloosahatchee estuary system. And, as said previously, as measured by the flows at S-79.

One thing is we -- the operations would be seasonal. And the bullets are all back there, too, and I won't elaborate too much, but the main gist of this without reading it to you is that early in the dry season we will partially begin releasing from the reservoir rather than just send it all out initially. And then, like I said, this is based on when -- on S-79 flows. For instance, when flow at S-79 is less than 450 cfs, we'll begin partially opening to allow releases out of the reservoir. And that's early in dry season. And when it -- the flows increases above --

MR. FRANK: You need to speak into the microphone, please.

MS. RAULERSON: I'm sorry. Maybe I need to lower it, too. I'm short. Is that better?

MR. FRANK: Yes.

MS. RAULERSON: Sorry. When the flow is greater

than 450 cfs, then we will close off the reservoir and, see, the pump station will begin bringing into the reservoir rather than releasing. Excuse me. Let me restate that. Okay. As we move along in the dry season, we'll begin releasing more when we have flows decreasing at S-79.

Okay. When we begin our early in the wet season, and, once again, we have flows at S-79 less than 450 cfs, then the Structure 1 will be opened to allow releases from the reservoir and the pump station will be off. And, once again, when S-79 has flows greater than 450 cfs, Structure 1 will be closed and the pump station will begin pumping to the reservoir. When we go into the late -- late wet season, these flows are still -- are decreasing, Structure 1 will be open to allow releases and the pump will be off. Likewise, when the flows -- when it increases, the structure will be closed and Pump Station 1 will begin to send in this water over to the reservoir.

I'm not sure about -- This is that pretty slide that someone stuck in here. Okay. Yeah. This is your artwork, isn't it, Dave? Sorry. I can't take credit for this one. It is pretty, though, isn't it? And I guess -- Whose thunder did I -- Dennis, did I steal those pretty ones from you?

MR. DUKE: Yeah.

MS. RAULERSON: Sorry about that.

MR. DUKE: What I want to point and note is that one where it showed the water running out of the reservoir, under extreme dry conditions, that could actually happen, the reservoir could go dry. Okay. There may be some holes, deep holes, to provide fish for effusion and so forth in there. But that's part of one of the challenges with the restoration program. We're rebuilding a reservoir to capture water for water storage and water supply and to attenuate floods. Understand that it may go dry; so, yeah, if your boat -- if you're trying to launch a boat, it will become difficult.

By the way, I apologize. My name is Dennis Duke. I am the chief of the Everglades division for the Army Corps of Engineers out of Jacksonville. I do this a lot; so sometimes I forget that little piece of information.

The next step for this overall program or project, to get it implemented, is basically we have the public review and comment period closes June the 11th. Okay. If we get comments after that, hm, it's kind of tough because everybody has the same time line. We go on to make some revisions, incorporate those comments, address those comments. And we do pay attention. We address -- we do look at all the comments. Yeah. We're a

government agency, so sure, you know. No. We do go through, and, yeah, yes, we'll contain the comments and responses to those comments. Like, the Lake Okeechobee regulation schedule we got 3,000 comments. We had to go through each and every one of those comments. You know, we get a lot of comments on our different stuff.

The final Project Implementation Report, PIR, and the Environmental Impact Statement, EIS, will be published in the Federal Register in the September time frame. That means that we'll have that final document out, have been reviewed, approved by our headquarters, hopefully, and for release to the public for 30-day review. And that's normally state and agency and general public review of the final document. We'll have a what we call a Chief's Report, that is a Chief of Engineers, when he signs the report and transmits it to the secretary of the Army for final processing and administration review. That should happen in the November time frame. And the record decision signed, hopefully, in January 2008.

That's after the administration, that's the Office of Management Budget, assistant secretary's office, Council on Environmental Quality, and the really top guys at Washington have reviewed it and concur on the findings and recommendations such that it will be transmitted to

congress with a recommendation for authorization, okay? And then congress will consider that authorization and take action as they deem necessary to either include it in their Water Resources Development Act or, you know, some other bill to get it authorized.

Let's see here. Okay. Well, that was good. Last slide. So at this point in the proceedings here what I'd like to do is take public comments. I have eight cards. We'll go through these. Again, if you have a lengthy statement, I would ask you to submit -- you can summarize your remarks and submit the written text for our records so we'll have an accurate transcript of those remarks. Okay. The first card I have is Kim Koleos.

MS. KOLEOS: I'm good.

MR. DUKES: You're good? Okay. Is that what your teachers say? You're from Gainesville? Well, welcome. I'm glad to have you all with us here tonight. I understand there's -- How many students are here tonight from Gainesville? And the course is about -- you're here because government action or government inaction? Sometimes those two words get thrown together too close for me. I'm sorry. What was the course?

MS. SPEAKER: Everglades ecosystem.

MR. DUKE: Everglades ecosystem. Okay. 18,000 square miles and you picked this place. Okay. It's

good. Sorry. Oh, the sheriff's coming to get me now, isn't he? I'm in trouble. No. This is a nice place. It's got a great place for pie and stuff down here. I guess you know Flora and Ella's. Okay. Enough of the local folklore. I'm sorry.

Rhonda Roff. Hi, there. Thank you. And if you would, just repeat your -- state your name and any organization affiliation that you --

MS. ROFF: Yeah. Hi. I'm Rhonda Roff. I actually have a couple of questions.

MR. DUKE: Absolutely.

MS. ROFF: How many acre-feet are capable of being stored in both cells?

MR. DUKE: I think the total is 170,000 acre-feet. That's the two cells together.

MS. ROFF: That's it? Seventeen to nineteen feet deep?

MR. DUKE: Yes, uh-huh.

MS. ROFF: Within that I would, as a conservation chair for the Hendry-Glades Audubon Society, I would like to comment that any habitat augmentation that would be available within the project to allow for -- for bird nesting, migration, for wildlife utilization of this would be greatly appreciated.

MR. DUKE: Okay.

MS. ROFF: But I wanted to also ask where the natural salt line of the Caloosahatchee would be in the absence of the Franklin lock.

MS. STARNES: It was variable. It was a function of wet season, dry season. There is no specific line. It was a function of -- Truly -- I'm sorry. It's truly a function wet season, dry season. With the structure not there, the saline water would come in during dry season. It has gone up past LaBelle well up into the river. During wet season it would have moved back out into the estuary, and it would have had that natural variability.

MS. ROFF: And with the lock in place, it's right there at the lock all the time?

MS. STARNES: No.

MS. ROFF: No. It's down --

MS. STARNES: No. Depending on the fresh water flows, the fresh water -- the salt/fresh interface will actually move out into the estuary -- well, as flows are coming down it, the high flows, it actually moves southwestish out in the estuary. And then during low flows it will move right up to the lock. And it actually does leak under the lock. Plus it's a lock and dam; so when that lock is open, if it's dry season, the salt water will actually move into the lock; and when they open it for the boat to move into the river, it will go

in with the river. The Olga water plant is actually -- which is the Lee County water supply plant which is just upstream of S-79, we actually do releases specifically to manage their saline content during dry season. So it does fluctuate but not like it did during -- when it was an all-natural system.

MS. ROFF: Another hat that I wear is the president of the Save it Now, Glades! organization. We focus on the lack of need that we perceive for a coal-fired power plant in Moore Haven. And one of the benefits that some South Florida Water Management District employees have stated is the ability to withhold upstream fresh water from moving downstream and creating additional fresh water pulses, nutrient-laden pulses, to the Caloosahatchee. What I was wondering is if anybody has an opinion, scientific opinion, engineering opinion, whether or not such upstream withholding would be just as well accomplished by this project.

MR. DUKE: You mean the holding of water by the plant, power plant?

MS. ROFF: The power plant is going to be occupied, if it's built, 4,900 acres, and some of that will be held -- recycled cooling water; so they're looking forward to that as being a potential source for withholding upstream fresh water pulses from the lake.

Will this kind of cover us on those needs even in the absence of that capacity?

MR. DUKE: Actually, the thing that helps the most is what's called the Northern Everglades Project to store -- that the State has initiated to store additional water north of the Lake Okeechobee, to help hold water out of the lake. And then as we divert water in through the system, that will be capturing more water. They will have storage on site for the -- you know, if they proceed and build the coal-fired plant. I don't think it'd be anywhere near this amount here.

MS. ROFF: That's what it seems to me, right.

MR. DUKE: Okay.

MS. ROFF: That's what I expected.

MR. DUKE: Yeah. Because generally they don't -- they have enough to operate their cooling systems. And the impact will probably be -- well, it just depends on, you know, how much they actually keep in their cooling cycling system.

MS. ROFF: And my last question is on that same vein. The proposed power plant is requesting above 28 million gallons per day of water. And how would -- how did that -- how does that number fit within -- There are a lot of minds who have spent a lot of time thinking about water supply in the Caloosahatchee watershed. What

does 28, or possibly more, million gallons a day mean to any of us here per day in Moore Haven?

MR. DUKE: What happens is that gets into the water allocation that the state does. And so, Janet, if you want to address that.

MS. STARNES: In reality, the South Florida Water Management District does not have and has not taken an official position on the Glades power park. We are in the process now. They are in -- they are in what's known as their siting permit review. That application is in house for review right now. We do not have -- I don't know what employee said what. And Agnes can probably speak to it probably better than I can, but we don't have an official position. And they're not looking just at surface water as a source, by any means, so --

MS. ROFF: No. I total -- I completely recognize that. And at this point I think the recommendation is that they're going to need to go down to the middle of Florida for their supply. But my question is 28 million gallons per day is what fraction of, say, the Caloosahatchee natural flow that we would desire to be able to send downstream?

MS. STARNES: I don't think there's anyone here that can answer that off the top of our head. And what I would suggest is because that -- that application is in

for review now that you submit that question as a part of that public review process.

MS. SPEAKER: Janet, that's not from our agency. That's the Department of Environmental Protection and the Department of Community Affairs. South Florida Water Management District is a commenting agency. South Florida Water Management District is a commenting agency on the site certification, and we're dealing with the same questions you're asking.

MS. ROFF: Yeah. I know. I didn't mean to shanghai this meeting to turn into a power plant discussion. I actually wanted to know about how that fits in terms of volumes what -- In general. Forget the power plant. Just say what does 28 million gallons a day mean in terms of the Caloosahatchee River.

MR. DUKE: Yeah. We'll get you an answer to that question, okay?

MS. ROFF: Okay. Thank you.

MR. DUKE: Sure. The engineers should be calculating that by now.

Okay. Chris Shepard.

By the way, just as -- while he's getting up here, one of the problems we face in constructing South Florida projects these days is our drain on our other construction materials, concrete and so forth. And since

she brought up the power plant, I saw on the news the other day that China is the major drain of our concrete and other building materials. They're building essentially one coal-powered plant a day. Yeah. That's what I said, Wow.

All right, Chris. How are you doing?

MR. SHEPARD: Pretty good. My name is Chris Shepard. I'm a LaBelle resident and a fishing guide Lake Okeechobee. The first question I got for you is when that C-43 is completely full, what's the average water level going to be above sea level for that containment area? Does anybody really have a ballpark?

MR. DUKE: It's going to be 40-something feet.

MS. JANET: Where's LuAnn? LuAnn's got an elevation.

MS. McVICKER: It's about elevation 42 when it's full.

MR. SHEPARD: So that's 42 foot above sea level when it's full. Okay. And the levees themselves are going to be how high --

MR. DUKE: Well, they said --

MR. SHEPARD: -- above grade? Thirty-five feet above grade?

MS. McVICKER: It's about 38 feet.

MR. SHEPARD: 38 feet?

MS. McVICKER: Thirty-eight to forty-eight feet maximum height.

MR. SHEPARD: Okay. Now, the amount of water that's going to be coming into that reservoir during a major event, what are we looking at as far as percentages for what goes down the Caloosahatchee that's actually going to actually get into those cells?

MR. DUKE: Well, as you saw on that, the pump size is 1,500 cfs is the pump. What passes down the Caloosahatchee obviously varies with the amount of discharge coming out of the lake. But we've passed as much as 20,000, 25,000, 20-, 25,000 cfs, cubic feet per second, over the S-79 structure; so you can see during -- but keep in mind that a lot of that's generated within the basin that will -- won't -- you know, won't be able to capture with this. But that gives you an idea. That's 1,500 compared to 20,000 on a peak flow. Fortunately, the peak flows happen rarely.

MR. SHEPARD: Right. Okay. Now, if we ever get the water level of Lake Okeechobee back up to where it needs to be and this reaches its capacity, okay, and then we're at, say, just an average heavy rainy season, okay, where is the water that's not going to be -- you know, where is the excess water going to end up? Is there going to be a plan -- I should rephrase it. Is there going to be a

planned stage for that reservoir for hurricane season?

MR. DUKE: Yeah. There's -- That's part of the operating plan in, you know, this case because of the size of the reservoir. You can pass -- you can release water in advance of, you know, like, 72-hour notice of water prep that we do. Unfortunately, the size of this it's kind of hard to get a lot of water out of it, but we'll do that.

But there is -- will be an operating rule for the reservoir. It won't be anything like Lake Okeechobee, you know, where we have quite an extreme fluctuation. It will operate over that way just in response to the natural rainfall. But in terms of hurricane season doing a load we've got, you know, what we're building into the levee is the levee height. And what makes it so high -- I mean, you heard the pool will be 17 to 19 feet high, and then on top of that we're having a 38-foot high levee or dam around it to actually provide for storage of that water and capture it so we don't have to get into a massive release at the same time we're doing our hurricane passing with "X" runoff, if that makes sense.

MR. SHEPARD: It sort of does, but the main thing I'm concerned with is if that's at capacity, Lake Okeechobee's at capacity, and we get hit with another Wilma, okay, who's going to be bringing the boats around

to pick everybody up because the levee at Lake Okeechobee -- fortunately, Wilma was a fast-moving storm, and during Wilma we started to incur breaches over around Pahokee. And I've been all over the levee, and I know the levee's got issues; but the levee's been a mainstay for many a year. You all did a good job of putting it together.

What I'm concerned with is because we are right here in this county, the down flow of those two cells is going to go to Lehigh and Fort Myers; and there's a lot of homes in that area, and that's my main concern.

MR. DUKES: Yeah. And basically, well, when they all get full, when everything's full, I mean, it would have been full with or without this one. The good news is with this one we have 170,000 acre-feet that we can actually hold out until the storm passes that we don't have to release during that time frame. And we can hold that out and not have to release it; so you're --

For heaven's sakes, one of the things we try and tell everybody is regardless of how big we think engineers think we can build stuff to guard against everything, Mother Nature always shows us who's the boss at the end of the day. And so you will still be subject to flooding same way you are now. It will be less than what you have now during those flood events because of

this. But when this thing gets full, Lake Okeechobee is full, and we have to release water out of Lake Okeechobee, you'll still get that. But because we're pulling water out, you know, it's going to be less than you have now.

MR. SHEPARD: Okay. One other thing I want to say to you all, you all are doing an excellent job on the Everglades. The fishery is kicking butt. It's some of the best water I've seen down there in years. All the birds seem to be really happy and kicking. The gators are really doing their thing. And all the things are really thriving really well, and I congratulate you all on that.

MR. DUKE: Well, thank you. We're just getting started. Kissimmee's a great project. But that's exactly right. And you mentioned something about the fishery habitat and that kind of thing. The perimeter canal's going to be one of the primary locations of that. Obviously, a deep reservoir, you know, when it gets up to 16 and 17 feet you lose all the vegetation that you would have. Some of our more productive areas are our stormwater treatment areas that we have around the Everglades agricultural area which provide wonderful habitat for wildlife.

Okay. Let's see. Joe Frank. Hi, Joe.

MR. FRANK: Good evening, Dennis. I'm glad to see you all made it down to Hendry County.

MR. DUKE: Hey, once in a while.

MR. FRANK: Yeah. Brought a lot of staff, too. Must have been them free cowboy hats you all were offering.

MR. DUKE: They come down here to protect me.

MR. FRANK: Just a few comments on some thoughts that went through my head as you all was doing the presentation. That's why I was asking the lady to speak into the microphone a little bit more. If the aim of this project, you know, is to restore the quality and timing of flows, you know, to the natural levels, then it seems to me that a more worthy project would be to restore the Caloosahatchee River, not build another lake. It just crossed my mind that this project is, you know, is just being built to further the development of western Hendry County and that maybe developers should pay for this project instead of the taxpayers.

If it's for Everglades restoration, the excess lake water that this is supposed to be receiving should be going south through the Everglades. If you're going to build a lake, you should consider what the water is for the watershed from where it would have been at Lake Flirt, or whatever, and build a lake to that

specification.

Secondly, if this project is implemented, it's going to result in some loss of jobs, the very people that need these agricultural jobs out there. Will there be job training programs for the displaces workers? How will it affect the tax base of Hendry County?

The seepage problems, will it ultimately drive up the cost of this half-a-billion-dollar project? Because it's pretty sandy soil out there. Probably barriers are going to be needed, and I think the plans call for some project or some test barriers now. But if you have to line 20,000 acres, that's going to be an expensive project.

And, further, with all this water here, you know, it's going to lead to more increased algae blooms for the river. It's going to create more of a pestilence problem, you know, a lot more insects year round and stuff. But, anyway, just some thoughts that crossed my mind. Thank you.

MR. DUKE: Okay. Thank you, Joe. One, on the seepage, there were some test cells that were constructed out by the Water Management District to determine the seepage that would be coming on so we could get a handle on that. They mentioned -- I think it was mentioned in the presentation about the cutoff walls that are being

put in the embankment to control seepage, the canal around the perimeter to collect the seepage that gets out of the system so -- I mean, one of the requirements of Water 2000, Water Resource Development Act of 2000, is what's called the savings clause. It means that when we build a project for restoration it cannot harm existing levels of service for flood protection or existing sources of water for water supply without a similar source being made in lieu of that.

Some of your other questions. Gee, you had a lot in that one question. Some of those were challenges for us. The Water Management District has been very active, so has Senator Pruitt and some other state representatives in developing job training programs with the local college communities; and they've been training people for that. They're structuring the contracts to provide on-site training for workers and retrain those.

This does provide some new opportunities as we build this huge reservoir there with operations and so forth the reservoir will require. So we've been taking a bigger look at that for the overall impact, not just for this reservoir but for the entire restoration program because we're, you know, projecting as many as 4- to 5,000 jobs could be lost because of impacts to agriculture by -- I mean, we're turning up -- this is,

you know, 10,000-plus acres of land. The entire CERP program has over 170,000 acres of land in surface reservoirs. But at the same time those jobs will be replaced by other jobs in the construction, operation, and maintenance industry.

And we've been working, again, like I said, primarily the lead of the Water Management District on those training programs. The Corps is actually looking now at trying to incorporate that into our contracts, as well, to train workers, provide a training program for workers, not only for these but for future projects. So it's a little bit of shift in the work force as we've seen throughout our economy, anyhow.

Okay. If you have another one, I've kind of lost it. But the water supply, again, is to capture water. I hear what you're saying about sending water south. Yes. Keep in mind, though, the Everglades -- for the restoration students here -- the Everglades is half the size it used to be. Okay. We still have the same amount of rainfall. Because of Herbert Hoover Dike, the lake can only be half the size it used to get to. So we've got the same amount of water; we've got half the area to put it. So if we put all of the water that used to go to the Everglades back into the Everglades, it will be twice as deep as it used to go. That will not be good. So,

anyhow, but it's a water budget balance that we're working through, and that's part of the overall comprehensive plan.

There's no silver bullet out there. It's a combination of all these things. Okay. And that's why there's 68 different components. Interestingly enough, there's 68 threatened and endangered species. I think we just picked one for each species to include in the plan so everybody would have one. What's the snail kite feature? What's the -- you know, those things. Okay. Sorry. Got off a little bit. See, you thought you were missing something at home. Craig Bartoshuk.

MR. BARTOSHUK: That was pretty good. I wrote my comments down.

MR. DUKE: Okay. Thank you. You can get up here. Go ahead. Margaret England. Good evening.

MS. ENGLAND: I'm Margaret England. I'm representing two organizations, Hendry-Glades Audubon and Caloosahatchee River System Association, Riverwatch. My first question is about the littoral zone on the perimeter canal. It's been mentioned several times, but will this littoral zone only be seasonal or will it be year round like a sloped area to provide habitat for wading birds and migratory birds year round, or is this seasonal?

MR. DUKES: It's a year-round feature.

MS. ENGLAND: Year round. Okay. Because in your information it said "may also include," and I didn't know if it should say "will."

MR. DUKE: Okay.

MS. ENGLAND: Also, in reading the environmental study I did notice that there were some caracara listed on the site. Is habitat going to be provided or maintained for the caracara and other birds who are currently on this site and native vegetation planted to encourage some of our native species including the caracara and gopher tortoise?

MR. DUKE: Okay. You want to --

MS. RAULERSON: We're currently --

MR. DUKE: Wait. A mic.

MS. RAULERSON: The caracara nests are actually not on the reservoir site. There's one to the north and one to the southeast. And we're currently in consultation with the Fish and Wildlife Service. We're in formal consultation on that species to determine what we'll do to account for those nests. The reservoir is actually part of their secondary foraging zones --

MS. ENGLAND: Right.

MS. RAULERSON: -- so there will be some kind of compensation for that, but it hasn't been worked out yet

what that will be.

MS. ENGLAND: Okay. Thank you. Okay. Now I'm going to put on my Riverwatch hat. I know there's been a discussion about, you know, the changes in water quality: How will the water quality be monitored, and when will this monitoring begin. And, also, I was very interested in exactly what will be monitored. Will it be nutrients, fertilizers, or chemicals from sewage, you know, or will it be a combination of all of these because I know we do have, you know, all of these components in the Caloosahatchee; and I'm very, you know, I'm very concerned about the chemicals and nutrients and fertilizers.

MR. DUKE: Yes. Basically, there is water quality monitoring that's going on now. In addition, when we put in the reservoir, part of the water quality certification that we go through with the State in terms of permitting released discharges from the reservoir has specific monitoring requirements that address a lot of the parameters. They list them as their parameters of concern. In this case, you know, phosphorus, nitrogen, e-coli, et cetera, those things, if they are designated or the State indicates they're a matter of concern, then, you know, those will be requirements of our monitoring plan. I don't believe -- we haven't applied for a permit

yet --

MS. STARNES: But it's in the Draft Monitoring Plan and in the report.

MR. DUKE: Yeah. So it is in the Draft Monitoring Plan and the report. Yeah. Okay? So thanks. By the way, right now the State of Florida, through the Water Management District, is spending over $50 million a year in monitoring, just monitoring, around the southern part of the system. So it's one thing to build these things; it's another thing to see how they operate and what impacts they do. That's a huge part of it is the water quality. That's actually what the second PIR, that overall Caloosahatchee River basin, we'll look at the water quality issues on a more holistic standpoint and determine if there is a need for a long-term fix. Okay. Thank you, ma'am.

John Cassani.

MR. CASSANI: Good evening. I live in Lee County, and I like to fish in the estuaries. There's concerns about downstream impacts. A couple quick questions. One, will the stored volume be available for water supply at any time after it's constructed? And if the answer is yes, is there a mechanism or requirement to legally reserve the water for its intended purpose?

MR. DUKE: There's two things here. One that the

stored water is to be released back into the Caloosahatchee. You saw the drive-maintained levels, desirable levels downstream. The requirement of Water 2000 is basically any water that's identified to be made available for the environment will be reserved and protected by the state. Now, considering that, to be perfectly frank, when we take the water out of the reservoir and put it back in the Caloosahatchee River, it's going to flow downstream, and here we have the Lee County water supply intake sitting downstream; so you can't separate the water.

MR. CASSANI: That's not what I meant. Yeah.

MR. DUKE: But it's not going to be discharged directly from the reservoir to any water supply user.

MR. CASSANI: So none of the volume will be available for any agricultural irrigation water supply at any time after construction?

MR. DUKE: That's correct. That's the way it's set up right now.

MR. CASSANI: That's good to know. Okay. Second quick question is the modeling that I remember in the past was that under average conditions during the period of record regarding low flows, the performance of the system on average, the do nothing alternative was about 38 percent of the time that low flow exceedences would

occur. And I'm wondering now with the reservoir in place and working, I'm not sure what year you modeled up to, but what would be the performance on low flows? What percentage of the time would it be out of specs operating at peak performance under average rainfall conditions?

MR. DUKE: Yeah. We'll have to get that information. I'm not sure -- I mean, he's looking for it now if we can answer that in a little bit.

MS. MARLOWE: We're within the flow envelope 75 percent of the period of record that we modeled. But I can't personally tell you how much we're within that bottom number. But we can get that information to you. It's just I don't have it off the top of my head.

MR. CASSANI: That's under average rainfall conditions?

MS. MARLOWE: That was over the period of record which includes --

MR. DUKE: That's actually over the period of record.

MR. CASSANI: Under average conditions. Yeah.

MS. MARLOWE: Well, but it includes all the different kind of -- It's got wet and dry and average years.

MR. CASSANI: I think it's just kind of liberal to say that the project -- or maybe you shouldn't imply that

the project is going to get low flows to 75 percent of the time because they're already within specs 60 percent of the time. So you're going from about 38 or 40 percent out of specs to about 25 percent. So the difference between the two is really the performance on the project. It's not 75 percent of the time.

MS. MARLOWE: Well, we're comparing actually -- We're actually comparing to the future without project. And as we modeled that future without project conditions, it was only within the envelope about 46 percent of the time --

MR. CASSANI: That's pretty poor, yeah.

MS. MARLOWE: -- so it's jumped from 46 to 75.

MR. CASSANI: Forty-six within or without?

MS. MARLOWE: In the future without we were only within our desired envelope 46 percent of the time. So less than half of the time were we able to stay within that desired envelope in our projected future without scenario.

MR. CASSANI: Kind of an important distinction. But it's good news about it's only for its intended purpose. Very good. Thank you.

MR. DUKE: Okay. The next speaker is John Fumero. You're good, John?

Okay. That's all of the cards I have. Are there

any other questions?

Was this helpful to the class? Okay. Yeah. You think it's all about just come up with this great idea for restoring something and you go out there and just do it. Nope, sorry. It's a long process.

Yes, sir. Please identify yourself, if you would.

MR. HEYMAN: Richard Heyman from the University of Florida.

MR. DUKE: Yes.

MR. HEYMAN: It wasn't clear to me whether there's going to be a -- whether this PIR recommends a reservation of water amount.

MR. DUKE: Every PIR has to address the water that's to be reserved through this. This PIR will have that in the operating plan about the amount of water to be reserved. I can't tell you what it is. It's in the -- it will be in the document or is in the document.

MR. HEYMAN: It will be? Okay. I though we were at the stage where that would have been developed.

MS. STARNES: It's -- the reservation actually will not be adopted and ruled -- the way the law reads the reservation has to be adopted and ruled prior to or at the time of our signing of the Project Cooperative Agreement. And the Project Cooperative Agreement will not be signed until congress authorizes the project

because the federal government can't sign a cooperative agreement if they're not authorized to do the work. So that's actually down the road.

Within this Project Implementation Report there is a whole chapter on project assurances and what water will be held back and reserved and how we got to that and how we're impacting existing legal uses. That is within the -- that is within the Project Implementation Report. I don't remember exactly what chapter it is. So that analysis has been done. It will be revisited at the time that we actually go to rule making because we, obviously, if we're going to go to rule making, want to make sure we're as close to correct as we can possibly be. So the information is in the existing report, but we will not actually go to rule making until right around the time that we're going to sign a Project Cooperative Agreement. That's true of all the Everglades restoration projects.

MR. HEYMAN: So there's a recommendation for what the reservation will encompass?

MS. STARNES: Well, it's not a simple number; so it's not a simple answer, it's not a flow of. That is -- It's far more complicated than that. But, yes, the analysis that we've done in terms of project assurances and savings clause analysis and reservations is within the report itself.

MR. HEYMAN: Is that the fact that you don't -- does that reflect the fact that you don't quite know how to describe the reservation for the rule making yet?

MR. DUKE: No. It's actually a function of how the water is to be delivered for beneficial to -- to be of benefit to the environment. I mean, even -- This is one of the hardest things for the Corps of Engineers to get its arms around because normally when we reserve water or allocate water within a reservoir, we can say it's, you know, so many thousand acre-feet, da, da, da, da within this reservoir. Here we're talking about releasing and reserving water that has a benefit over, as you saw, 71,000 acres of estuary. Okay. So what we want to do is we want to not only reserve the quantity but also the timing and distribution of that water. So that's why she meant -- It gets very complicated.

This actually, perhaps, is one of the simpler ones we have to deal with as opposed to, like, the Everglades agricultural reservoir which is going to spread its water over, you know, half a million acres and we have to reserve that, not just the quantity but the timing and distribution. Because if I get a half a million acre-feet of water all at one time, I don't want to reserve that, you know, because that'll flood everything. So it's a complicated process. It covers, basically, a

hydroperiod in the distribution of water. Okay?

MR. HEYMAN: Thanks.

MR. DUKE: And I'm sure I'll have fun trying to explain that to congress.

Any other questions? Well, thank you all for coming tonight. Be careful going home. Again, if you have any written comments, June the 11th, please get them to us by then. Good luck on your studies.

(The hearing concluded at 0:00)

STATE OF FLORIDA)

COUNTY OF CHARLOTTE)

I, DAWN M. ROUSH, Court Reporter, Notary Public in and for the State of Florida at Large, do hereby certify that a public meeting was held in the cause styled in the caption hereto, on Page 1 hereof; that I was authorized to and did attend said public meeting and report the proceedings had therein, fully and accurately, and the foregoing transcription consisting of pages numbered 01 through 66, inclusive constitute a correct transcript of my notes of the proceedings taken at said public meeting.

I FURTHER CERTIFY that I am neither an attorney nor counsel for the parties to this cause nor a relative or employee of any attorney or party connected with this cause and that I have no interest in the outcome of this action.

IN WITNESS WHEREOF, I have hereunto subscribed my name and affixed my seal this the 27th day of May, 2007.

C.0 ANALYSES REQUIRED BY WRDA AND STATE LAW SAVINGS CLAUSE ANALYSES

C.1 LEGAL BASIS - BACKGROUND

Federal law and regulation implementing the Comprehensive Everglades Restoration Plan (CERP) require Project Implementation Reports (PIRs) to address certain assurances as part of the project being recommended for approval and implementation. This section addresses provisions of Section 601(h) of the Water Resources Development Act of 2000 (WRDA 2000) and the Programmatic Regulations for the CERP (33 CFR Part 385) for Savings Clause requirements and Project-Specific Assurances.

The following sections describe the specific requirements from WRDA 2000 and the CERP Programmatic Regulations and present the methods and results of the analyses necessary to meet those requirements.

C.1.1 WATER RESOURCES DEVELOPMENT ACT (WRDA 2000)

Congress enacted the Water Resources Development Act of 2000, Section 601, Comprehensive Everglades Restoration Plan (WRDA 2000) which approved the CERP "as a framework for modifications and operational changes to the Central and Southern Florida (C&SF) Project that are needed to restore, preserve, and protect the South Florida ecosystem while providing for other water-related needs of the region, including water supply and flood protection." Section 601(h) of WRDA 2000, entitled "Assurance of Project Benefits" establishes project-specific assurances to be addressed as part of CERP implementation.

Section 601 (h) (1) of WRDA 2000 provides:

> *IN GENERAL - The overarching objective of the Plan is the restoration, preservation, and protection of the South Florida Ecosystem while providing for other water-related needs of the region, including water supply and flood protection. The Plan shall be implemented to ensure the protection of water quality in, the reduction of the loss of fresh water from, the improvement of the environment of the South Florida Ecosystem and to achieve and maintain the benefits to the natural system and human environment described in the Plan, and required pursuant to this section, for as long as the project is authorized.*

Sections C.1.1.1 and C.1.1.2 discuss the assurances required by WRDA 2000 to be addressed in each PIR. Section C.1.2 discusses the assurances provisions of the CERP programmatic regulations, which are intended to provide supplemental information for implementing the WRDA 2000.

C.1.1.1 Savings Clause Analyses

The Savings Clause analysis is listed in WRDA 2000 as a means to assure project benefits. Specifically, Section 601(h)(5) of WRDA 2000, entitled "Savings Clause", requires an analysis of each project's effects on legal sources of water that were in existence on the date of enactment of WRDA 2000 (i.e., December 2000) and effects on levels of service of flood protection in existence on the date of enactment of WRDA 2000. Section 601(h) (5) of WRDA 2000 states:

> *(A) NO ELIMINATION OR TRANSFER. – Until a new source of water supply of comparable quantity and quality as that available on the date of enactment of this Act is available to replace the water to be lost as a result of implementation of the Plan, the Secretary and the non-Federal sponsor shall not eliminate or transfer existing legal sources of water, including those for –*
>
> *(i) an agricultural or urban water supply;*
> *(ii) allocation or entitlement to the Seminole Indian Tribe of Florida under section 7 of the Seminole Indian Land Claims Settlement Act of 1987 (25 U.S.C. 1772e);*
> *(iii) the Miccosukee Tribe of Indians of Florida;*
> *(iv) water supply for Everglades National Park; or*
> *(v) water supply for fish and wildlife.*
>
> *(B) MAINTENANCE OF FLOOD PROTECTION. – Implementation of the Plan shall not reduce levels of service for flood protection that are –*
>
> *(i) in existence on the date of enactment of this Act; and*
> *(ii) in accordance with applicable law.*
>
> *(C) NO EFFECT ON TRIBAL COMPACT. – Nothing in this section amends, alters, prevents, or otherwise abrogates rights of the Seminole Indian Tribe of Florida under the compact among the Seminole Tribe of Florida, the State, and the South Florida Water Management District, defining the scope and use of water rights of the Seminole Tribe of Florida, as codified in section 7 of the Seminole Indian Land Claims Act of 1987 (25 U.S.C. 1772e).*

Section C.2.2 of this report contains a description of the assumptions, concepts and methodologies based on the procedures and guidance described in draft Programmatic Regulations Guidance Memorandum 3 (GM 3), "Savings Clause Requirements", at the time this PIR was being developed for identifying project effects on:

1. Existing legal sources of water as of the date of enactment of WRDA 2000 on the user categories listed in Section 601(h)(5)(A) of WRDA 2000.

2. Levels of service for flood protection as required by WRDA 2000.

Section C. of this report summarizes the results of these analyses.

C.1.1.2 Project-Specific Assurances

Section 601(h) (4) (A) of WRDA 2000, entitled "Project-Specific Assurances", contains the following requirements for project implementation reports:

> *(A) PROJECT IMPLEMENTATION REPORTS. –*
> *(i) IN GENERAL. – The Secretary (of the Army) and the non-Federal sponsor shall develop project implementation reports in accordance with Section 10.3.1 of the Plan.*
> *(ii) COORDINATION. – In developing a project implementation report, the Secretary and the non-Federal sponsor shall coordinate with appropriate Federal, S ate, tribal, and local governments.*
> *(iii) REQUIREMENTS. – A project implementation report shall –*
> > *(I) be consistent with the Plan and the programmatic regulations promulgated under paragraph (3);*
> > *(II) describe how each of the requirements stated in paragraph (3)(B)[sic] is satisfied*
> > *(III) comply with the National Environmental Policy Act of 1969 (42 U.S.C. 4321 et seq.);*
> > *(IV) identify the appropriate quantity, timing, and distribution of water dedicated and managed for the natural system;*
> > *(V) identify the amount of water to be reserved or allocated for the natural system necessary to implement under State law, subclauses (IV) and (VI);*
> > *(VI) comply with applicable water quality standards and applicable water quality permitting requirements under subsection (b)(2)(A)(ii);*
> > *(VII) be based on the best available science; and*
> > *(VIII) include an analysis concerning the cost-effectiveness and engineering feasibility of the project.*

Section C.2 of this report contains a description of the assumptions, concepts and methodologies for identifying water made available by the project for the natural system and for other water related needs of the region. The methodologies are based on the procedures and guidance described in draft Programmatic Regulations Guidance Memorandum 4 (GM 4), "Identifying Water Made Available for the Natural System and for Other Water Related Needs", available at the time this PIR was being developed.

Section C.3 of this report summarizes the results of these analyses, including identifying the amount of water made available by the project for the natural system to be reserved or allocated by the State of Florida and the amount of water made available for other water-related needs.

C.1.2 PROGRAMMATIC REGULATIONS (33 CFR PART 385)

The following summary of requirements of the Programmatic Regulations provides supplemental information for implementing the Savings Clause and Project Specific Assurances of WRDA 2000.

C.1.2.1 Pre-CERP Baseline

Section 385.35(a) of the Programmatic Regulations requires the development of a pre-CERP baseline to aid the Corps of Engineers and the South Florida Water Management District (SFWMD) when implementing the Savings Clause to determine if existing legal sources of water will be eliminated or transferred and to demonstrate that the levels of service of flood protection in existence on the date of enactment of WRDA 2000 and in accordance with applicable law will not be reduced by implementation of a project.

The final draft Pre-CERP Baseline document was issued by the U.S. Army Corps of Engineers and the SFWMD in April 2005. In accordance with the programmatic regulations, the final draft Pre-CERP Baseline document will be submitted to the Secretary of the Army for approval and concurrence by the Secretary of the Interior and the Governor.

C.1.2.2 Elimination or Transfer of Existing Legal Sources of Water

Section 385.36 of the Programmatic Regulations requires that project implementation reports determine if existing legal sources of water are to be eliminated or transferred as a result of project implementation. If a project is expected to result in an elimination or transfer of an existing legal source of water, the PIR shall include an implementation plan that ensures a new source of water of comparable quantity and quality is available to replace the source that is being transferred or eliminated.

C.1.2.3 Flood Protection

Section 385.37 of the Programmatic Regulations requires that PIRs include an analysis of the project's impacts on levels of service for flood protection that existed on the date of enactment of WRDA 2000, December 2000, and in accordance with applicable law. These conditions will be included in the Pre-CERP Baseline (see section C.1.2.1).

C.1.2.4 Identification of Water for the Natural System

Section 385.35(b) of the Programmatic Regulations requires that each project implementation report identify the quantity, timing, and distribution of water to be dedicated and managed for the natural system necessary to meet the restoration goals of CERP. This evaluation considers the availability of the Pre-

CERP Baseline water and previously reserved water, and whether improvements in water quality are necessary. The existing conditions model simulation for this project does not include any previously reserved water, since there have been no water reservations yet completed within the geographic boundary of the SFWMD.

C.1.2.5 Identification of Water for Other Water-Related Needs

Section 385.35(b) of the Programmatic Regulations also requires that procedures be developed for identifying water generated by CERP for use in the human environment and that the quantity, timing, and distribution of water for other water-related needs be identified in project implementation reports.

C.2 METHODS

C.2.1 Key assumptions for all project assurance analyses

C.2.1.1 Comparison of Pre-CERP Baseline, Existing Conditions Baseline and Initial Operating Regime

The analyses of the Saving Clause requirements includes considerations of three different sets of assumptions at potentially three different points in time or conditions: 1) Pre-CERP Baseline, 2) Existing Conditions, and 3) the Initial Operating Regime (IOR). The Pre-CERP Baseline is the condition existing on the date of enactment of WRDA 2000, December 2000. For this project, the Existing Conditions Baseline is the condition in 2000, and the IOR is the conditions existing in 2006. In accordance with GM #1, the 2006 conditions were used for the IOR because this is the year the Selected Alternative Plan (SAP) was identified. To perform the required project assurance analyses, land use and demand assumptions for the basins affected by the project were identified for each of these timeframes.

The Western Caloosahatchee River Basin, specifically the Caloosahatchee River and Estuary system west of the W. P. Franklin Lock and Dam (S-79 structure), is the only basin affected by the project as it is currently proposed to be constructed and operated in this PIR. Therefore, an analysis was conducted comparing changes in actual land use in 2000 to the actual land use in 2006 in the Western Caloosahatchee River Basin. The analysis showed that changes in actual land use between 2000 and 2006 were insignificant. As a result, analytical comparisons of the three conditions, 1) Pre-CERP Baseline, 2) Existing Conditions Baseline and 3) Initial Operating Regime without project, contains the same land use and demand assumptions, and are then labeled as the Existing Conditions Baseline.

C.2.1.2 Assumptions Associated with Reservoir Operations and Spreadsheet Analyses

The conceptual intent of the project is that the reservoir will be operated to supply water to the Caloosahatchee River (C-43 Canal) based on maintaining desirable salinity levels in the Caloosahatchee Estuary System as measured by flows calculated for the S-79 structure. The following are key assumptions utilized in this analysis and are consistent with this conceptual intent.

- The source of Caloosahatchee River (C-43 Canal) flow data for the spreadsheet analyses for the Existing Conditions Baseline (2000) and Future Without Project Condition (2050 with no-CERP projects in place) is derived from South Florida Water Management Model (SFWMM) version 5.4.2 base model simulation 2000RD, for the Existing Conditions Baseline and 2050RD model simulation for the 2050 with no CERP projects in place.
- The spreadsheet will take into consideration the ET losses from the reservoir. The mass balance terms for the reservoir are reservoir inflow, reservoir releases, reservoir seepage (assumed to be zero based on results of the C-43 Test Cell Pilot Project – July 2006), ET losses (based on area volume relationship), and reservoir direct precipitation.
- No agricultural or urban water supply deliveries will be supplied by the reservoir. These demands continue to be supplied from Lake Okeechobee or existing groundwater sources.
- The Eastern Caloosahatchee River Basin (east of the S-78 structure) will not be affected by the project.
- With the exception of changing flows to the Caloosahatchee Estuary downstream of S-79, there will be no impacts on the Western Caloosahatchee River Basin.

C.2.2 Savings Clause - Elimination or Transfer of Existing Legal Sources and Flood Protection

The operations of the Caloosahatchee River (C-43) West Basin Storage Reservoir as described in C.2.1.2 focus on meeting estuary hydrologic restoration targets for the Caloosahatchee Estuary. However, the analyses associated with Savings Clause occurred at both the system-wide and project levels to confirm there will be no unexpected elimination or transfer of existing legal sources of water or significant adverse affects on the level of service of flood protection as a result of the project.

C.2.2.1 Project Effects

The effect of the Caloosahatchee River (C-43) West Basin Storage Reservoir on existing legal sources and flood protection will be documented at the system-

wide and project-level scale. Both the system-wide and project-level analyses compared the following shown in Table C-1.

TABLE C-1: SUMMARY OF COMPARISONS USED FOR SAVINGS CLAUSE ANALYSIS

Analysis	*"Without Project Condition"*	*"With Project Condition"*
	Savings Clause Analyses GM #3	
1. Elimination or Transfer 2. Flood Protection [system-wide: no impact by definition, project level: confirm with Acceler8-generated analyses]	Existing Conditions Baseline [2000 Without Project]	Initial Operating Regime [Existing Conditions Baseline + SAP]

C.2.2.1.1 System-wide effects

Defined as the hydrologic effects due to the storage, management, treatment, and delivery of water via the C&SF Project occurring outside the immediate project vicinity. By reviewing all of the water basins identified in GM #3 and based upon the assumptions described in C.2.1.2, the only basin that will be affected by the project is the Caloosahatchee Estuary.

C.2.2.1.2 Project-level effects

Project-level effects are defined as the hydrologic effects occurring within the immediate project vicinity (e.g., natural areas, wetlands, salinity control) or within the features of the project components (e.g., reservoirs, storm water treatment areas, well field recharge distribution canal).

The SFWMD Acceler8 design process evaluated field conditions at the project reservoir site through geotechnical evaluations which were followed by the construction of test cells. The test cells were constructed to determine the seepage potential of the proposed reservoir and to document local project-level groundwater affects. The embankment of test cell one did not contain a cut-off slurry wall, while the embankment of test cell two did contained a cut-off slurry wall designed to contain seepage. Results of the test cells are presented in the C-43 West Storage Reservoir Test Cell Pilot Project, July 2006. In summary, the groundwater levels within the embankment and seepage rates immediately increased upon filling of test cell one, while test cell two (with a cut-off slurry wall) showed virtually no impact to groundwater levels or in the rate of seepage through the embankment.

In addition, sections 6 and 12 in the C-43 West Basin Storage Reservoir Final Basis of Design Report (SFWMD, April 2006) describe the intended purpose and proposed operations of the perimeter canal. The primary operational intent for seepage management is to maintain the water levels in the perimeter canal to preserve existing groundwater levels and to intercept seepage, if any, from the reservoir.

These project-level, site specific investigations have been used to design a project that will have no adverse affects to the localized surface and ground-water resources adjacent to the project reservoir. In addition, modeling and analysis was conducted using the local MIKESHE reservoir model to assist in the design efforts and to evaluate the effects of the reservoir construction and operation on the area adjacent to the reservoir footprint.

C.2.3 Identifying Water Made Available for the Natural System and for Other Water Related Needs by the Caloosahatchee River (C-43) West Basin Storage Reservoir

The primary functions of the reservoir are two-fold: 1) to capture excess basin runoff and discharges from Lake Okeechobee during wet periods, and 2) to provide an additional source of water to maintain desirable salinity in the Caloosahatchee Estuary during low flow periods. Since the estuarine system is not in need of additional fresh water during wet periods, the analysis of water made available focused on the additional water delivered from the reservoir to the Caloosahatchee River (C-43 Canal) and Caloosahatchee Estuary during low flow periods.

The operational assumptions of the Caloosahatchee River (C-43) West Basin Storage Reservoir as described in C.2.1.2 focus on meeting estuary hydrologic restoration targets for the Caloosahatchee Estuary. In addition, as described in C.2.2.1, the project has been designed to be operated so there will be no adverse impacts on existing legal sources of water at the project level. Therefore, the analysis associated with identifying water made available by the project will focus on the project's effects to the Caloosahatchee Estuary. Furthermore, as noted in C.2.1.2, there will be no water made available for other water related needs by the reservoir and all water made available by the project is provided to the natural system.

Identification of water for the natural system is based on the concept of water needed to achieve the benefits of the project and the overarching objective of restoration, preservation and protection of the South Florida Ecosystem. The water made available for the natural system is the water required for the protection of fish and wildlife within natural systems, including water that contributes to meeting hydrologic, water quality, and ecologic targets for restoration of natural systems. A hydrologic target for the natural system (flow

at S-79) was utilized to identify the quantity of water that is required to meet estuary restoration objectives, in contrast to water which may be harmful or otherwise not contribute to meeting the estuary restoration targets.

C.2.3.1 Inflow Basins affected by the Project

Draft Guidance Memorandum #4 (GM #4) requires the identification of the inflow basins that will be affected by a project. In the case of the Caloosahatchee River (C-43) West Basin Storage Reservoir project the only inflow basin affected by the project is the Caloosahatchee Estuary.

C.2.3.2 Summary of the Analytical Method Used to Identify Water Made Available

To identify water made available by the project, a simplified spreadsheet analysis of the Caloosahatchee River (C-43) West Basin Storage Reservoir project was produced based on the capture of excess flow over S-79, which was derived from the SFWMM simulation of the 2000 (a.k.a Initial Operating Regime) and 2050 (a.k.a Nest Added Increment) conditions. The spreadsheet analysis evaluated the 2000 and 2050 condition with and without project for the purposes of fulfilling GM #4 requirements and incorporated the operational assumptions outlined in C.2.1.2.

The spreadsheet analysis is centered on a water budget equation for the reservoir. Equations are based on conservation of mass and relates the inflows to the reservoir and the outflows from the reservoir to the change in storage in the reservoir over some fixed time scale. The spreadsheet calculated the daily change in storage and associated water surface elevation, both of which are considered in determining fill and release operation in subsequent time steps. Then the spreadsheet created an updated flow over S-79 that reflects the changes to the original flow resulting from reservoir fill or release activities.

The focus of the spreadsheet analysis is the modification or adjustments of flow over S-79 with the intent of improving the salinity distribution in the downstream estuary. The spreadsheet however, has no salinity or ecological component and relies on a hydrologic surrogate to infer improved performance. The hydrologic surrogate used is the flow over S-79 and its ability to achieve, or trend towards, an estuary flow target time series (EST05 – See appendix C) which has been demonstrated to be a restoration time series that would result in optimal habitat conditions for several indicator species in the Caloosahatchee Estuary.

In this spreadsheet analysis and to satisfy GM #4 requirements to identify the variability of water made available by the project for the natural system, inflow volume probability curves were calculated and presented as total annual

cumulative inflow into the Caloosahatchee Estuary. The data presented are the daily numbers summed to yield an annual volume.

As a means to display achieving or trending toward the EST05 flow target as a whole and quantifying other desirable matches to portions of the restoration flow series, two graphics (***Figure C-13*** and ***Figure C-14***) were generated for the period of record 1965 - 2000 from the spreadsheet calculations for both the existing "without project" or base condition and the "with project" condition.

1. **Volume probability curves** - Plot flows in acre feet over S-79 for the EST05 restoration time series and the "with" and "without" project conditions for both the IOR and Next Added Increment (NAI) condition.

2. **Difference curves** - generated showing the percentage of time that flow is less than or equal to the target restoration flow series EST05 by ranking and plotting the flow over S-79 of the "with" and "without project" for the IOR and NAI conditions.

C.2.3.2.1 Comparisons of Conditions Used in Identifying Total Water, Water Made Available for the Natural System, and Water to Be Reserved or Allocated for the Natural System

The total water and the water made available for the natural system are quantified in terms of both when the project is expected to be initially operational (IOR) and in the future (NAI). For purposes of quantifying the water to be reserved or allocated, the timeframe of when the project is expected to become initially operational (IOR) is used.

To determine the quantity of water made available for the natural system and the quantity of water to be reserved or allocated in the Caloosahatchee Estuary, the restoration target EST05 flow target (Appendix C) were used to determine the quantity of water that is needed for the protection of fish and wildlife in the estuary, versus that which may be harmful to it or otherwise not contributing to the restoration targets of the estuary.

The IOR simulation is used to quantify the water to be reserved or allocated because physical and operational constraints may exist temporarily in the system that prevent the attainment of all of the project's projected benefits immediately upon initiation of operation. Once these constraints are removed, as evaluated in the NAI simulations, the quantity of water made available is expected to change. Furthermore, project operations would be expected to change due to a variety of reasons, including adjustments to operations and the construction and operation of other CERP and non-CERP projects. As conditions change, affecting the quantity of water made available for the natural system,

the reservation or allocation of water for the natural system will be updated to reflect the changed conditions.

The comparisons to be used to identify water made available and water to be reserved or allocated are shown in ***Table C-2.***

TABLE C-2: SUMMARY OF GM #4 ANALYSIS FOR THE IDENTIFICATION OF WATER MADE AVAILABLE AND THE WATER TO BE RESERVED OR ALLOCATED

Analysis	*"Without Project Condition"*	*"With Project Condition"*
Identification of Water Made Available		
Identification of Water Made Available 1. Total Water 2. Water for the Natural System 3. Water for Other Water Related Needs (non for this project)	1. Existing Conditions Baseline (2000) 2. Next Added Increment Baseline (2050)	1. Initial Operating Regime (IOR) – (existing conditions baseline + project) 2. Next Added Increment (NAI baseline + project)
Identification of Water to be Reserved or Allocated		
Identification of Water to be Reserved or Allocated	Existing Conditions Baseline (2000)	Initial Operating Regime (IOR) – (existing conditions baseline + project)

C.2.3.2.2 Identifying Water Made Available for Other Water Related Needs

The operations for this project focus on reducing excess, harmful flows in the wet season from S-79 and provide supplemental flows during low flow periods across S-79 to the Caloosahatchee Estuary to meet restoration targets. No additional water will be made available for other water related needs by this project. Agricultural and urban water supplies will continue to be met from the same sources as they are currently. Therefore, no additional analysis was conducted.

C.2.3.2.3 Volume probability curves

For purposes of identifying the water made available by the project for the natural system, inflow volume probability curves representing total annual cumulative inflows in accordance with GM #4 were produced depicting the range of the quantities of water delivered to the Caloosahatchee Estuary through S-79 under all climatic conditions through the period of record (1978 – 1986) described in C.2.3.2. This period includes sufficient climatological variability (including natural fluctuations of water) to be representative of long term hydrologic conditions in the region.

The identification of the total water made available by the project and water made available for the natural system will be determined by comparing the inflow volume-probability curves for two separate conditions (***Table C-2***). As noted in section C.2.3.2, to determine the quantity of water for the natural system and the water to be reserved or allocated in the Caloosahatchee Estuary, the EST 05 salinity envelope will be used to determine the portion of water that is needed for the protection of fish and wildlife in the estuary, versus that which may be harmful to it or otherwise not contributing to the restoration targets of the estuary. Changes in the quantities of water made available for the protection of fish and wildlife in the estuary as a result of the project will be displayed using four volume probability curves: the Existing Condition Baseline, the IOR, the NAI Baseline and the NAI with Project Condition.

C.2.3.2.4 Difference Curves

After the quantities of water needed for the protection of fish and wildlife have been identified and displayed using volume probability curves, two difference curves will be developed. The two difference curves will be derived from comparing the annual volume of inflows in the two conditions (Existing Conditions Baseline vs. IOR and NAI Baseline vs. NAI). The results will then be sorted, ranked (from greatest to least), and plotted as difference curves. The 10%, 50% and 90% exceedance points on the difference curve will be identified for each of the three percentiles.

C.2.3.2.5 Summary Tables to Identify Total Water, Water Made Available for the Natural System, and Water to Be Reserved or Allocated for the Natural System

The year corresponding to the volume for each of the percentiles will then be identified for both conditions. These results will then be displayed in a table. The table will display the total water made available by the project (NAI and IOR), the water made available for the natural system (NAI and IOR), and the water to be reserved or allocated for the natural system (IOR).

C.3 RESULTS

C.3.1 Savings Clause - Elimination or Transfer of Existing Legal Sources and Flood Protection

C.3.1.1 System wide Elimination or Transfer

The operations for this project focus on reducing detrimental, excess flows from S-79 and providing supplemental flows across S-79 to the Caloosahatchee Estuary to achieve restoration targets. Sources of water to meet agricultural and urban demand in the Caloosahatchee River (C-43 Canal) Basin will remain the

same as before the project. Sources of water for the Seminole and Miccosukee Tribes and Everglades National Park are influenced by the regional water management system (C&SF Project, including Lake Okeechobee), and will not be affected by this project. Therefore, there will be no elimination or transfer as a result of this project on existing legal sources of supply for:

- Agricultural or urban water supply
- Allocation or entitlement to the Seminole Indian Tribe of Florida under Section 7 of the Seminole Indian Land Claims Settlement Act of 1987 (25 U.S.C. 1772e)
- The Miccosukee Tribe of Florida
- Water supply for Everglades National Park
- Water supply for fish and wildlife

C.3.1.2 System-wide Flood Protection

The operations of this project will not change the operations of the Caloosahatchee River (C-43 Canal) based on the key assumptions outlined in C.2.1.2. Therefore, there will be no system-wide effects on flood protection as a result of the project.

C.3.1.3 Project level Elimination or Transfer

The existing water levels in the area adjacent to the reservoir will be maintained through the operating levels and control structures of the seepage canals surrounding the project reservoir. Output of groundwater level simulations using the local Reservoir-level MIKESHE model were displayed for eleven locations (represents a 1500 ft grid cell) around the reservoir shown in ***Figure C-1***. For each location modeled, a groundwater stage duration comparison (***Figure C-2*** through ***Figure C-12***) shows the groundwater levels below the land surface, represented as zero on the figures, and the percentage of time those levels are maintained for the with and without project conditions. The results of this groundwater analysis show there are no adverse affects to groundwater levels as a result of the project.

With the project in place, portions of the Roberts Canal and Header canal will become part of the project footprint. To continue to provide an irrigation source to the Bob Paul property, which in existing conditions pumps irrigation water from the Header canal and the Crawford canal, pump station #3 was included in the reservoir perimeter canal to pump water to the east down the remaining Header canal assuring the same volume of water is available compared to existing condition. The Crawford Canal will still be available to the Bob Paul property and is not affected by the project.

Therefore, there will be a transfer of existing legal sources of water from the Header Canal to the Perimeter canal, although there is no elimination of existing legal sources in the vicinity of the reservoir.

C.3.1.4 Project level Flood Protection

The results from the local reservoir-level MIKESHE modeling indicate a boundary slurry wall within the embankment prevents seepage out of the reservoir and impacts to groundwater levels. In addition, optimization of the operating levels of the seepage canals and canal control structures surrounding the reservoir will maintain existing groundwater levels adjacent to the project.

Of the eleven locations (***Figure C-1***) evaluated using the MIKESHE model, the only location where simulated groundwater elevations were increased compared to the without-project conditions was north of the project. Simulated "with project" groundwater elevations increased slightly compared to the "without project" condition. The greatest difference was during the dry period (e.g., 1981) not the wet periods. This minor effect is can be addressed through further optimization of perimeter canal control structure operations for the project. The remaining ten locations (***Figure C-2*** through ***Figure C-12***) show practically no differences in groundwater elevations.

Therefore, there will be no adverse effects on existing levels of flood protection in the vicinity of the reservoir.

C.3.2 Identifying Water Made Available by the Project for the Natural System

C.3.2.1 Total Water Made Available by the Project

A graphic comparing how the project trends towards meeting the Caloosahatchee Estuary salinity restoration targets for the "with" and "without" project conditions is shown by the volume probability curves (***Figure C-13***) below. This graphic contains five volume probability curves. The period of record salinity target flows (EST 05) were plotted for comparison of both the IOR and NAI conditions to show project trends towards meeting restoration targets in both scenarios. To show the relative increase in water made available in both the IOR and NAI conditions, the baselines for each of those conditions were also plotted. It should be noted that the y-axis for this graphic indicates acre-feet per day. .

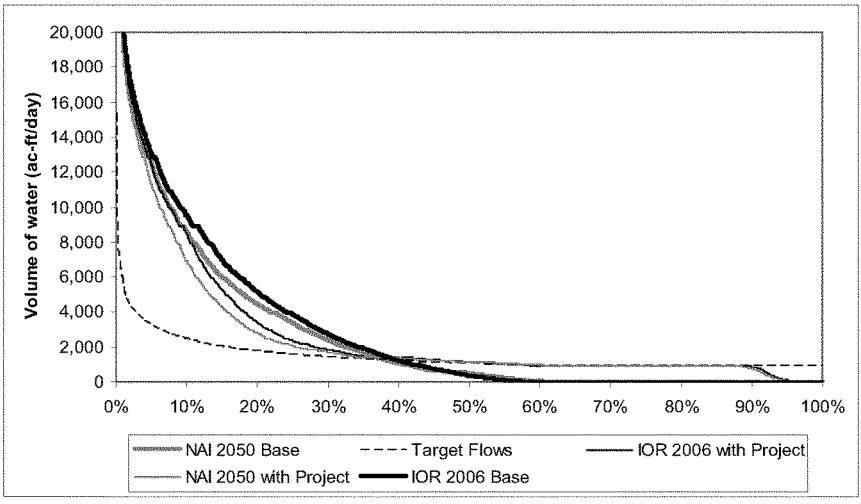

FIGURE C-13: VOLUME PROBABILITY CURVES OF TOTAL WATER MADE AVAILABLE TO ACHIEVE BENEFITS OF THE PROJECT

C.3.2.2 Water Made Available by the Project for the Natural System

Using the total water made available data two curves were plotted showing the variability of the water made available by the project for the natural system for both the IOR and NAI conditions (***Figure C-14***). These volumes were calculated by summing the difference between the two conditions and ranking the differences. A summary of the total water made available for the natural system with the project and without the project IOR and NAI conditions is provided (***Table C-3***). In addition the water made available by the project is identified for the 10th, 50th and 90th percentiles based on annual volume of water provided to the estuary.

C.3.2.3 Identifying Water to be Reserved or Allocated for the Natural System

The quantity of water to be reserved or allocated for the natural system is based upon the IOR condition. As described above, these volumes are shown in ***Figure C-14*** and ***Table C-3***. The annual volumes identified at 10th, 50th and 90th percentiles for the IOR condition are 159,485 ac-ft/year, 105,990 ac-ft/year and 27,619 ac-ft/year, respectively. This volume of water made available by the project in the IOR condition will be reserved or allocated for the natural system to achieve the benefits of the project.

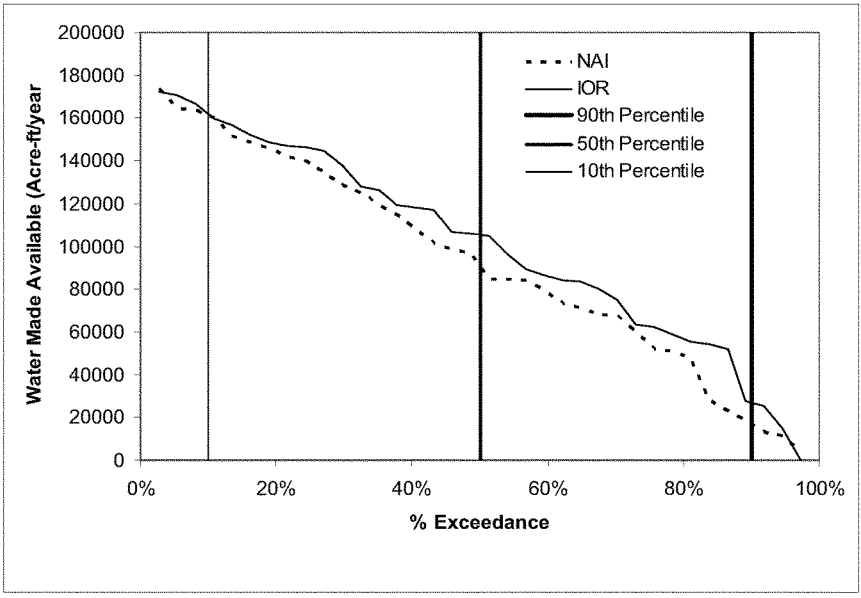

FIGURE C-14: VARIABILITY OF WATER MADE AVAILABLE BY THE PROJECT FOR THE IOR AND NAI CONDITIONS

C.3.3 Project Assurances

The overarching objective of the Comprehensive Everglades Restoration Plan ("Plan") is the restoration, preservation, and protection of the South Florida ecosystem while providing for other water-related needs of the region, including water supply and flood protection. The Federal Government and the State of Florida are committed to the protection of the appropriate quantity, quality, timing, and distribution of water to achieve and maintain the benefits to the natural system described in the Plan. As envisioned in WRDA 2000 and the Programmatic Regulations, each PIR will identify this appropriate quantity, quality, timing, and distribution of water for the natural system.

The following language sets forth these commitments:

> "The overarching objective of the Plan is the restoration, preservation, and protection of the South Florida ecosystem while providing for other water-related needs of the region, including water supply and flood protection. The Federal Government and the non-Federal sponsor are committed to the protection of the appropriate quantity, quality, timing, and distribution of water to ensure the restoration, preservation, and protection of the natural system as defined in WRDA 2000, for so long as the project remains authorized. This quantity, quality, timing, and distribution of water shall meet applicable water quality standards and be consistent with the natural system restoration goals and purposes of CERP, as the Plan is defined in the programmatic regulations. The non-Federal sponsor will protect the water for the natural system by taking the following actions to achieve the overarching natural system objectives of the Plan:
>
> 1. Ensure, through appropriate and legally enforceable means under Federal law, that the quantity, quality, timing, and distribution of existing water that the Federal Government and the non-Federal sponsor have determined in this Project Implementation Report is available to the natural system, will be available at the time the Project Cooperation Agreement for the project is executed and will remain available for so long as the Project remains authorized.
>
> 2a. Prior to the execution of the Project Cooperation Agreement, reserve or allocate for the natural system the necessary amount of water that will be made available by the project that the Federal Government and the non-Federal sponsor have determined in this Project Implementation Report.
>
> 2b. After the Project Cooperation Agreement is signed and the project becomes operational, make such revisions under Florida law to this reservation or allocation of water that the Federal Government and the non-Federal sponsor determines, as a result of changed circumstances or new information, is beneficial for the natural system.

3. For so long as the Project remains authorized, notify and consult with the Secretary of the Army should any revision in the reservation of water or other legally enforceable means of protecting water be proposed by the non-Federal sponsor, so that the Federal Government can assure itself that the changed reservation or legally enforceable means of protecting water conform with the non-Federal sponsor's commitments under paragraphs 1 and 2. Any change to a reservation or allocation of water made available by the project shall require an amendment to the Project Cooperation Agreement

AF

1.1 Introduction

The Caloosahatchee River (C-43) West Basin Storage Reservoir Project will achieve estuarine restoration benefits in the Caloosahatchee Estuary, which is integral to achieving system-wide benefits in the south Florida ecosystem. The Project will help reduce damaging wet season high flows from Lake Okeechobee as well as contributing basin runoff from the lower West Caloosahatchee River Basin by capturing and storing a portion of these flows in the reservoir. Then during the dry season when water levels are at their lowest, water will be released from the reservoir to the Caloosahatchee River (C-43 Canal) to promote a healthy salinity balance in the Caloosahatchee Estuary, thereby reducing saltwater migration into the freshwater portion of the estuary. The Caloosahatchee River (C-43) West Basin Storage Reservoir Project achieves the benefits described in the Comprehensive Everglades Restoration Plan (CERP) and is an integral part of CERP.

The Caloosahatchee River (C-43) West Basin Storage Reservoir Project is located in western Hendry County and features a reservoir with a storage capability of 170,000 acre feet, a normal pool storage depth between 17 and 22 feet with a footprint of approximately 10,480 acres. The reservoir includes an individual inflow pump station of 1,500 cfs, discharge structures, emergency overflow spillways, and seepage control canals with associated structures.

Stakeholders in the basin have expectations that the Caloosahatchee River (C-43) West Basin Storage Reservoir Project will address additional water supply demands for urban and agricultural users in the area while providing water quality improvement features. The ability of the project to address these needs is affected by at least two factors:

- Agriculture in the area depends upon surface water and groundwater for water supply to meet irrigation needs, especially in the upper basin., and
- Several public water supplies sources in the basin rely on surface water withdrawals from the Caloosahatchee River (C-43 Canal) to meet urban water demands.

In order to address changing conditions and other issues and concerns that have arisen since the development of the Comprehensive Everglades Restoration Plan, it is recommended that the Caloosahatchee River (C-43) West Basin Storage Reservoir Project use an Incremental Adaptive Restoration approach, in which the project would be divided into two phases. This first phase, the Caloosahatchee River (C-43) West Basin Storage Reservoir Project will address the most immediate needs of the estuary, while ensuring that it is fully compatible and consistent with CERP. Then the second phase under

DRAFT

Caloosahatchee River (C-43) West Basin Storage Reservoir Project will provide a complete solution to addressing the needs of the entire basin.

It is important to note that the local sponsor for the project, South Florida Water Management District (SFWMD) is exploring alternative project delivery methods to expedite implementing portions of the Caloosahatchee River (C-43) West Basin Storage Reservoir Project through the Acceler8 Program. Expedited implementation may involve the SFWMD initiating construction activities prior to executing a Project Cooperation Agreement (PCA) with the United States Army Corps of Engineers (USACE). Expedited implementation of portions of the Caloosahatchee River (C-43) West Basin Storage Reservoir Project will provide early restoration benefits, potential cost savings and reduced cash flow demands. The USACE is recommending that SFWMD be credited for expenditures for work on the Caloosahatchee River (C-43) West Basin Storage Reservoir Project completed in advance of executing a PCA and for services provided under a public-private partnership. Credit for such work will be subject to the Secretary of the Army determining that the work is integral to the authorized CERP Project and that the construction is consistent with applicable USACE construction standards.

The total estimated first cost for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project is $462,860,000 (October 2006 price level). The total first cost includes recreation features totaling $2,930,000. The estimated total annual cost of operation, maintenance, repair, rehabilitation and replacement (OMRR&R) of the ecosystem restoration elements is $3,160,000 with an estimated Federal annual cost of $1,580,000 and an estimated non-Federal cost of $1,580,000. The estimated cost for OMRR&R of the recreation elements is $25,000 which is 100% non-Federal.

This State Compliance Report is intended to address the requirements of Chapter 373, Florida Statutes (F.S.) as well as fulfill the requirements of WRDA 2000 and the Programmatic Regulations for CERP (33 CFR Part 385) which specifies requirements for the PIR. Section 373.470, F.S., requires the SFWMD, prior to executing a Project Cooperation Agreement (PCA), to complete a PIR to address the project component's economic and environmental benefits, engineering feasibility, and other factors provided in Section 373.1501 sufficient to allow the SFWMD to obtain approval under Section 373.026, F.S. In addition, Section 373.026(8), F.S., requires that prior to submitting a PIR to Congress for authorization, or receipt of an appropriation of State funds for construction of a CERP project, the Florida Department of Environmental Protection (FDEP) must first approve a PIR pursuant to Section 373.026(8), F.S. This review and approval is based on a determination that the SFWMD has complied with the requirements set forth in subparagraphs (a) through (e) of Section 373.1501(5),

F.S. and Section 373.470, F.S. This State Compliance Report addresses each of these requirements in subparagraphs (a) through (e).

This State Compliance Report seeks approval from the FDEP for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project that includes:

- a two-cell reservoir with a "normal pool" storage capacity of 170,000 acre-feet with armoring, cutoff walls, and embankments
- a project footprint of approximately 10,492 acres
- an intake pump station with 1,500 cfs capacity to pump water from the Townsend Canal to fill the reservoir
- pump stations, spillways with emergency overflow and vertical lifts, drawdown structures, culverts, canals, earthwork artificial habitat creation, and recreational features

1.2 Comprehensive Needs Analysis and Evaluation

Section 373.1501(5)(a), F.S. requires the SFWMD to "Analyze and evaluate all needs to be met in a comprehensive manner and consider all applicable water resource issues, including water supply, water quality, flood protection, threatened and endangered species, and other natural system and habitat needs." The following sections describe the procedures and methodologies used in assessing these water resources issues along with a description of how these issues have been met or resolved for this project. For detailed descriptions of these analyses the reader should refer to the Caloosahatchee River (C-43) West Basin Storage Reservoir Project Draft PIR/EIS.

1.2.1 Water Supply

Water for urban and agricultural uses in the C-43 Basin is supplied from both groundwater and surface water systems. Surface water is used primarily for agricultural irrigation, with groundwater being used in areas that do not have access to the Caloosahatchee River. In addition, the Caloosahatchee River is a potable water supply source in Lee County. Groundwater and surface water are dependent upon rainfall for recharge.

The Caloosahatchee River (C-43 Canal) receives water from Lake Okeechobee, runoff from the basin, and base flow from the Surficial Aquifer System (SAS). The river in turn supplies water for public supply, agriculture, and the environment. This source can be unreliable during the dry season or in periods of inadequate rainfall, when releases are required from Lake Okeechobee to meet demands.

DRAFT

The Caloosahatchee River Water Use Basin is within the Lake Okeechobee Service Area (LOSA) and is primary source for agricultural irrigation and surface potable water supply. This area extends from the Franklin Lock (S-79) eastward to the Moore Haven Lock (S-77) and includes land in Lee, Glades, and Hendry counties. Discharges from Lake Okeechobee provide the primary flow in the river during the dry season. Water is released from the lake to meet the supplemental agricultural water demand as well as supplying water for municipal consumptive use.

Groundwater is an important component of the agricultural water supply in the freshwater portion of the Caloosahatchee Basin. The groundwater resources in the area include the surficial aquifer, the intermediate aquifer and the Floridan aquifer system. The yield and storage of the groundwater is highly variable throughout the basin. The surficial aquifer system is used for some irrigation in eastern Hendry and Glades counties.

The intermediate aquifers are used primarily for irrigation in the western portion of Hendry County. There is local recharge to both the surficial and intermediate aquifers. The Floridan aquifer is used in northern Glades County for irrigation and in the northwest corner of the basin and mixed with surface water for irrigation. The water from the Floridan aquifer is too highly mineralized elsewhere in the basin. This deep aquifer is recharged from outside the area.

Non-environmental surface water demands within the basin are primarily agricultural with some potable water supply, commercial and industrial uses. The commercial and industrial demands vary greatly by type of business. In the project vicinity, commercial and industrial demands constitute about one percent (1%) of the overall water demand. Because the demand is relatively small and difficult to generalize, an average demand is not calculated for this use category. The emphasis is placed on estimation of agricultural and potable water uses.

A thorough investigation of water use for the Caloosahatchee River and surrounding basins was conducted by the SFWMD for the Caloosahatchee Water Management Plan (April 2000). Table 1 summarizes the water use allocation for major agricultural land use categories based on the Integrated Surface Water/Ground Water Model.

Table 2 presents the United State Geological Survey estimate of water use, excluding mining and power generation water use, for 2000 for the four county study area. Total public-supply water use for the region is estimated at 71.85 million gallons per day (mgd), and total municipal and industrial (M&I) water use is estimated at 115.17 mgd. The addition of the 680.63 mgd of agricultural water use increases total water demand for the region to 796.24 mgd.

DRAFT

Agricultural water use accounts for 85% of the total use; public-supply water use accounts for 19% and recreational self-supply accounts for about 3%.

Table 1: Summary of 1995 Water Use Demand Based on the Integrated Surface Water/Ground Water Model for Major Agricultural Land Use Categories

Crop	Water Use (1,000 acre-feet/year)
Citrus	143
Sugarcane	110
Vegetables	36
Total	290

Note: Based on 1995 land use, MIKE SHE results indicate an additional 30,000 acre-ft/year of irrigation in addition to citrus, sugarcane and vegetables.

On the county-level, the largest total water user in the study area in 2000 was Hendry County, mainly because of agricultural water use. Hendry County used a total of 512.11 mgd, or 64% of the total regional water use. Of this amount, 503.91 mgd (98%) was agricultural use and 4.72 mgd was public-supply water use. Lee County's public-supply water use was about 52 mgd. Lee County's total water use was 144.95 mgd, the third highest in the region. Lee County had the highest self-supply domestic water use in the region at 8.86 mgd. Lee County also had high recreational water use of 22.66 mgd.

Table 2: USGS Estimated Total Water Use, for Selected Counties, 2000 - Excluding Mining and Power Generation (mgd)

	Municipal and Industrial							
		Self-Supply						
County	Public Supply	Domestic	Commercial	Industrial	Recreation	Sub Total	Agriculture	Grand Total
Charlotte	14.21	3.55	0.11	0	3.48	21.35	47.19	68.54
Glades	0.55	0.61	0.04	0	0.42	1.62	69.02	70.64
Hendry	4.72	1.67	0.21	0.51	1.09	8.2	503.91	512.11
Lee	52.37	8.86	0.46	0.09	22.66	84.4	60.51	144.95
Total	71.85	14.69	0.82	0.6	27.65	115.57	680.63	796.24

Note: Recreation self-supply water use includes golf course irrigation.
Source: USGS unpublished data, 2002.

Table 3 represents the conservation-adjusted, most likely population scenario, water use forecast and the percent of total water use associated with each county or county area in the study area, for 2000, 2025, and 2050. Lee County accounted for 90.7% of all municipal and industrial water use in the study area in 2000, and will account for 90.4% of all water use by 2050. The population of

Lee County is projected to increase by 97% over the same time period. The Glades County Area generates the smallest use, at slightly more than 2% of the total regional water use over all time periods. Due to the small population in the Charlotte County portion of the study area, the water use totals for Charlotte County are incorporated into those of Glades County and therefore the USGS 2000 baseline totals do not exactly equal the IWR-MAIN 2000 totals.

Table 3: C-43 Study Area, Municipal and Industrial Conservation-Adjusted Water Use and Distribution, by County Area Most-Likely Population Scenario, 2000, 2025, and 2050

	2000		2025		2050	
Area	MGD	Percent of Total	MGD	Percent of Total	MGD	Percent of Total
Lee County	92.7	90.7 %	129.5	90.4 %	148.0	90.4 %
Glades County Area	2.4	2.4 %	4.0	2.8 %	4.5	2.8 %
Hendry County Area	7.1	6.9 %	9.7	6.8 %	11.2	6.8 %
Total	**102.2**	**100.0%**	**143.2**	**100.0%**	**163.7**	**100.0%**

The Southwest Florida Regional Planning Council has estimated that total agricultural acreage will increase between 3% and 7% between 1995 and 2020 while citrus acreage will increase between 54% and 81% and sugarcane between 62% and 190%. The increase in citrus and sugarcane acreage is due in a large part to conversion of existing irrigated acreage that is in other crop types to citrus and sugarcane.

Table 4 summarizes the simulated 2020 irrigation demand for major agricultural land use categories for the area based on the MIKE SHE model. Irrigation demands are expected to increase approximately 55% in the Caloosahatchee Basin between 1995 and 2020. No projected increases in irrigated acreages between 2020 and 2050 are expected, and there may potentially be a slight decline, therefore 2050 demands are expected to approximate 2020 demands of 450,000 acre feet annually.

Table 4: Summary of 2020 Water Use Demand Based on the MIKE SHE for Major Agricultural Land Use Categories.

Crop	Water Use (1,000 acre-feet/year)
Citrus	242
Sugarcane	181
Vegetables	27
Total	450

Providing additional water supply for urban and agricultural users represents a potential opportunity to be addressed by the Caloosahatchee River (C-43) West Basin Storage Reservoir Project. Upon meeting flow targets at the S-79 structure necessary for ecosystem restoration in the Caloosahatchee Estuary, any additional water stored by the C-43 project could be delivered to the C-43 Canal and would be available for urban and agricultural users.

It is anticipated that non-environmental water supply benefits associated with the Caloosahatchee River (C-43) West Basin Storage Reservoir Project will be incidental. Ongoing analysis and planning for water supply within the project area is being conducted by the SFWMD through updated to the Lower West Coast Water Supply Plan.

1.2.1.1 Increasing Water Supply through Storage

The main purpose of the Caloosahatchee River (C-43) West Basin Storage Reservoir Project is to provide for the retention and management of excess water within the natural system that is lost to tide (Gulf of Mexico), then release it back into the natural system when needed to help moderate extreme salinity changes in the estuary which are detrimental to estuarine communities. Captured excess water is made up of regulatory releases from Lake Okeechobee, basin runoff from storm events passing through the Caloosahatchee Basin, and irrigation runoff from agricultural fields (Figure 1).

1.2.1.2 Impoundment Seepage Management

Seepage control of embankment through-seepage and underseepage is critical to managing the water resource as well as maintaining a safe and stable reservoir. Therefore, the control of seepage is a prime consideration for the proposed impoundment. Seepage can occur directly through an embankment constructed with pervious material (through-seepage) or it can occur as underseepage that travels in one of the foundation layers beneath an embankment. Both of these seepage pathways need to be controlled and monitored. Guidelines used by the USACE are found in EM-1110-2-1901 entitled "Seepage Analysis and Control for Dams".

Currently groundwater seeps from the project site north towards the river. All of the reservoir alternatives include a slurry wall within the embankment to effectively prevent this seepage. Once constructed the perimeter canal will provide this groundwater flow to the areas north of the project. In order to minimize the disturbance to the natural groundwater flow, the perimeter canal will be kept at levels adequate to maintain existing levels of groundwater in the area.

DRAFT

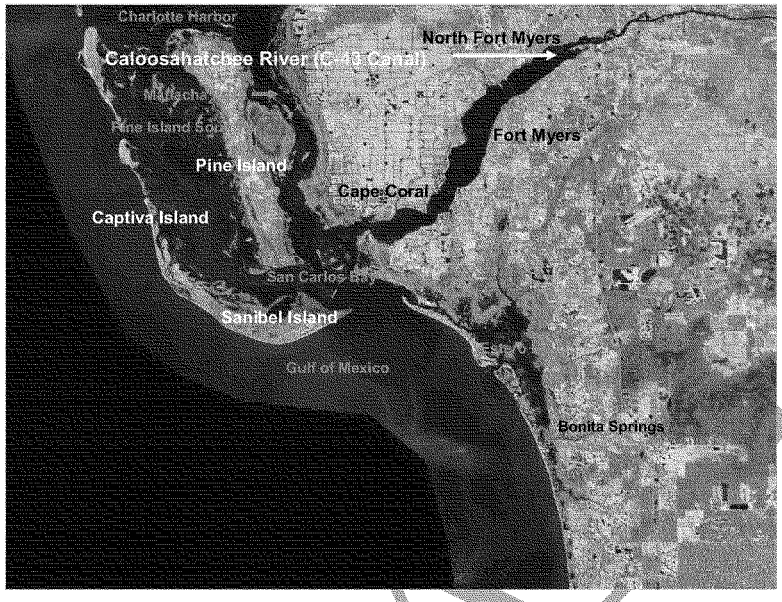

Figure 1: Caloosahatchee Estuary Area Map

1.2.2 Water Quality

The water quality conditions upstream and downstream of the S-79 structure were evaluated as part of recent Florida Department of Environmental Protection (FDEP) efforts within the C-43 basin. The FDEP Verified List for the Caloosahatchee, (FDEP June, 2005) identifies impaired waters in the C-43 sub-basin as well as the Caloosahatchee Estuary sub-basins. The report was prepared in order to meet the requirements of the Federal Clean Water Act. Under Florida's implementation of the Clean Water Act, waters listed as impaired are then subject to the development of Total Maximum Daily Loads (TMDLs) intended to limit the future discharge of the offending pollutant by point and non-point contributors. The FDEP has divided the Caloosahatchee Basin into five planning units. Two planning units, East Caloosahatchee, and West Caloosahatchee, are the two sub-basins that are upstream of the S-79 structure on the C-43 Canal. The three remaining planning units, Telegraph Swamp, Orange River, and Caloosahatchee Estuary, are downstream of the S-79 structure. In 2002, the FDEP performed a study to determine the relative loadings of total nitrogen and total phosphorus in the C-43 basin (Janicki, 2002). This report ranks the sub-basins within the C-43 basin in terms of their relative contribution of total nitrogen and total phosphorus. A third study, the Caloosahatchee Water Quality Data Collection Program" (ERD, 2002) sponsored

by the SFWMD, quantifies pollutant concentrations and loads from the various sub-basins within the C-43 basin.

Water quality within this study area has been significantly altered due to the construction of the three locks and dams, excavation of the riverbed to 25 feet, increases in both urban and agricultural land use, and by the construction of an extensive network of canals and drainage ditches to accommodate this level of development. These hydrologic alterations have resulted in discharges of unnaturally large quantities of freshwater runoff into the river and eventually into the downstream receiving estuarine systems. Extensive documented research on the tidal portion of the Caloosahatchee River has shown that salinity changes in the estuary are the result of either low to no flows or too high flows of freshwater being discharged at the S-79 structure. Together, extreme flows and changes in salinity are by far the largest problem affecting the ecologic health of the estuary.

1.2.2.1 Restoration Objective and Receiving Waters

The primary restoration objective for the C-43 Basin Storage Reservoir identified in the Restudy was:

> *"... to capture C-43 Basin runoff and releases from Lake Okeechobee. These facilities will be designed for water supply benefits, some flood attenuation, to provide environmental water supply deliveries to the Caloosahatchee Estuary, and water quality benefits to reduce salinity and nutrient impacts of runoff to the estuary..."*

Primary system benefits would include:

(1) Improvements in salinity and
(2) Improvements in water quality in the estuary.

Secondary system benefits would include:

(1) Improvements in flood attenuation within the basin; and
(2) A possible additional water supply source for agricultural and urban uses (via runoff capture and reuse methodology) once the needs of the estuary are met.

Several ecological functions of the Caloosahatchee Estuary are directly affected by water quality. The water quality problems negatively impacting ecological resources are primarily related to excessive variations in freshwater inflow and salinity as well as increased nutrient loads and color that result from excessive freshwater discharges in the wet season.

DRAFT

It has long been established that freshwater inflow dynamics and salinity are major determinants of the distribution of estuarine species and those species' life stages, especially regarding their location and association with favorable habitat for rearing, protection and settlement. Therefore, the ability of each estuary to function as a nursery differs according to its biological features, physical configuration, and inflow volume, magnitude and timing. Research by the SFWMD on the tidal Caloosahatchee began in the mid-1980s to determine the proper timing and volume of water required to support valued ecosystem components (i.e., such key estuarine species as oysters and SAV, such as *Vallisneria* spp.) and general biotic indicators (plankton and benthic invertebrates). Since the predominant source of freshwater to the Tidal Caloosahatchee (especially in the wet season) is water through the S-79 (70 percent of total flow), the research focused on issues of timing and volume of water through this structure; however, the latest models and methods do take into account the other major sources of freshwater discharged to the Tidal Caloosahatchee from the "tidal" watershed. The SFWMD has focused on development of optimum S-79 flow ranges and delivery patterns for the estuary. As part of the state-mandated minimum flows and levels (MFLs) process, the SFWMD initially determined that a minimum dry season discharge at S-79 of 300 cfs (monthly average flow) is required to provide salinity conditions capable of supporting *Vallisneria*; however, the minimum flow target has been revised upwards to 450 cfs based on more recent scientific research by SFWMD staff. *Vallisneria* in the upper estuary is still recovering from the last drought and could suffer additional harm as the MFL requirements continue to be unmet.

Also as part of this research, maximum freshwater inflow limits (set at mean monthly values of 2,800 cfs and 4,500 cfs depending on frequency) and a frequency distribution of flows have been recommended that support valued ecosystem components and promote estuarine ecological benefits. It is these recommended flows that were used initially to determine CERP storage requirements and infrastructure changes in the Caloosahatchee Basin and Lake Okeechobee during the Restudy. These minimum and maximum flow targets have also been adopted for the PIR.

Restoring the flows and achieving the hydrologic targets is an environmental priority within the Caloosahatchee River Basin. The estuary will remain at risk as long the quantity and timing of freshwater flows into the estuary remains unchanged. Large releases will continue to have far reaching salinity and water quality impacts that may even influence Florida Bay unless water management practices are changed.

The majority (75 - 90%) of the nitrogen and phosphorus load sent to the Caloosahatchee Estuary comes from sources upstream of S-79. To address questions regarding the effect of reservoirs on water quality, specifically

DRAFT

nutrients, FDEP contracted with Tetra Tech (and subcontractors Janicki Environmental and Soil and Water Engineering Technology, Inc.) to examine the potential nutrient impairment problem in the estuary. The study developed regression equations to describe two relationships: 1) between chlorophyll-a concentration and nitrogen loading and 2) between chlorophyll-a concentration and phosphorus loading. Due to the naturally occurring high levels of phosphorus in the watershed, the indication was that nitrogen was the limiting nutrient, which is consistent with the other studies identified earlier. Thus, of the two regression equations, this study determined that the nitrogen/chlorophyll-a relationship was the best means of predicting nutrient impairment (or phytoplankton algal blooms) in the estuary. The report identified three preliminary targets for total nitrogen (TN) loading to the estuary from releases at S-79 in order to achieve chlorophyll-a concentration limits of 11 micrograms per liter (ug/l):

Maximum annual load less than 3,000 tons/year, where annual load ~ (wet season monthly load x 5) + (dry season monthly load x 7)
Dry season monthly load less than 190 tons/month, and
- Wet season monthly load less than 350 tons/month.

1.2.2.2 Applicable Water Quality Standards

Water quality within the Caloosahatchee watershed is influenced by fresh water inflows from Lake Okeechobee, non-point pollution in local basin runoff, as well as point sources such as wastewater treatment plant discharges. Due to the geology of the region, there is also a direct interaction between the surface water and groundwater, which can affect the dissolved oxygen and iron concentrations in the surface water column. The upper Caloosahatchee River watershed from the Moore Haven Lock and Dam (S-77) to the Lee/Hendry county line has been classified by the State of Florida as a Class III water body in accordance with Chapter 62-302, Florida Administrative Code. The Class III designation establishes specific water quality parameter requirements that are intended to protect and sustain the natural attributes necessary for these waters to meet their intended use (recreation, propagation and maintenance of a healthy, well-balanced population of fish and wildlife). The surface water directly upstream of S-79 east to the Lee/Hendry county line is designated as a Class I water body and must meet the standards required for use as a potable water supply (see Table 5 for surface water classification status of Caloosahatchee River).

1.2.2.3 Water Quality Characterization in the Project Area

Water Quality Conditions Upstream of S-79 - The East Caloosahatchee and West Caloosahatchee planning units are the two sub-basins that lie upstream of the S-79 structure. While all of the East Caloosahatchee sub-basin is upstream

of the planned reservoir, approximately 70% of the West Caloosahatchee sub-basin is upstream of the planned reservoir. The water quality conditions in these two sub-basins will have a significant impact on the reservoir water quality. The predominant land use in both of these planning units is agriculture. Water quality impairments in this sub-basin are primarily caused by non-point sources rather than point discharges such as sewage treatment plants or other industrial activity. Within the East Caloosahatchee unit, six water body segments have been identified as impaired. The impairments are lead, coliforms, iron, dissolved oxygen, copper, and nutrients. Within the West Caloosahatchee planning unit, a total of three water body segments have been identified as impaired. One of these water bodies is impaired for iron and lead, one is impaired for nutrients, and the last one is impaired for copper and lead. Of direct interest to this project is the Townsend Canal, which is immediately upstream of the planned reservoir intake and is impaired for copper and lead.

Table 5: Surface Water Classification for Caloosahatchee River

Class I Water: Caloosahatchee River	East Lee County line to SFWMD structure S-79 (Franklin Lock & Spillway)
Class III Water: Caloosahatchee River	SFWMD structure S-77 (Moore Haven Lock & Spillway) at Lake Okeechobee to Lee/Hendry County line.

Water quality pollutant loading upstream of the S-79 structure is composed of loading from runoff generated within the basin and from loading associated with Lake Okeechobee releases. Excluding the load from Lake Okeechobee releases, approximately 50% of the total nitrogen load resulting from runoff in the Caloosahatchee Basin comes from basin lands upstream of S-79. Similarly, excluding the phosphorus load from Lake Okeechobee releases, approximately 65% of the total phosphorus load resulting from runoff in the Caloosahatchee Basin comes from basin lands upstream of the S-79. When Lake Okeechobee flows and loads are included, more than 75% of total nitrogen and total phosphorus loads to the Caloosahatchee Estuary are a result of discharges at S-79.

Water Quality Conditions Downstream of S-79 - The three watershed planning units downstream of S-79 are Telegraph Swamp, Orange River, and Caloosahatchee Estuary. Within these three planning units, land use patterns transition from agricultural/natural areas in the east to residential in the west. In the FDEP Verified List, there are no impaired waters in Telegraph Swamp planning unit.

DRAFT

As the furthest downstream planning unit, the Caloosahatchee Estuary has to contend with its own pollution plus pollutants from the four upstream planning units. According to the June 2005 (FDEP) Verified List for the Caloosahatchee, the estuary-planning unit has 13 impaired water body segments, six of which are part of the main estuary and seven are tributary streams. All thirteen listed water body segments are impaired for coliforms (either total or fecal), seven are impaired for nutrients, six are impaired for dissolved oxygen, three are impaired for heavy metals (copper, lead), and one is impaired for specific conductivity. The FDEP Basin Status Report (FDEP 2002) states that the observed water quality violations are probably linked to urban land uses within the Caloosahatchee Estuary planning unit, poorly flushed residential tributary streams, and the effect of heavy pollutant loads discharged from upstream sub-basins.

Within the Caloosahatchee Estuary planning unit there are a total of 31 permitted sewage treatment plants. The Caloosahatchee pollutant loading report (ERD 2002) includes pollutant-loading estimates for the four largest sewage treatment plants in the Caloosahatchee Estuary as well as for eight tributaries downstream of the S-79 structure. This report includes loading estimates for the following pollutants: ammonia, nitrate, nitrite, total kiejahl nitrogen, total nitrogen, orthophosphorus, and total phosphorus, and total suspended solids. With the exception of ammonia, 10% or less of the wet or dry season load of each of these pollutants to the Caloosahatchee Estuary comes from the portion of the watershed downstream of the S-79 structure. During the dry season, approximately 5% of the total ammonia load in the estuary comes from the portion of the watershed downstream of the S-79 structure; however, during the wet season, approximately 40% of the ammonia load to the estuary comes from downstream of the S-79 structure. A relatively large amount of the ammonia loading from downstream of the S-79 structure comes from the four large sewage treatment plants. The Caloosahatchee Estuary non-point sources of total nitrogen and phosphorus contribute around 20% of the total loads delivered to the estuary.

Unlike the St. Lucie Estuary, a geographically extensive muck sediment layer is not present in the Caloosahatchee Estuary. This is evidenced by the presence of both freshwater and marine submerged aquatic vegetation (SAV) that usually does not coexist in areas where muck sediments are present. Scientists from the SFWMD and U.S. Fish and Wildlife Service (USFWS) have concluded that flocculent sediments are not a significant cause of water quality problems in the main channel of the Caloosahatchee Estuary.

In 1999 the USGS collected 58 sediment samples from downstream of the S-79 structure and two sediment samples from just upstream of the structure. The five sampling locations relative to the S-79 structure were downstream at mile

3.1, 9.3, 10.5, 12.2, and 23.8. Samples were tested for physical characteristics, organic content, pesticides, and heavy metals. Heavy metal results were compared with Florida Sediment Quality Assessment Guidelines (SQAG). Samples from five sites contained heavy metals (chromium, copper, lead, mercury, and zinc) at levels that exceed the Probable Effects Level (PEL) concentration published in the Florida SQAGs. Although a limited number of samples exceeded the PEL concentrations, bioaccumulation and bioconcentration studies would have to be done to quantify the impact of these sediments on in-situ biota. At present, there is no reason to believe that sediment contamination is a significant concern within the main stem of the estuary.

1.2.2.4 Pre-land Acquisition Environmental Site Assessments

The five major land parcels acquired for the C-43 reservoir project are the Berry Groves tract, Bryan Paul tract, Bob Paul tract, the Winthrop property, and the Griffin property. Prior to the 1960s these lands were primarily used as unimproved pasture. For the last 30 to 40 years these five parcels have been used to cultivate citrus. Over the operating life of these groves, fertilizers, herbicides and pesticides have been applied routinely as part of normal agricultural operations. From the 1960s to 1980s, pesticide use would have included the application of persistent organic compounds such as DDT, chlordane, and toxaphene. Use of these and other persistent pesticides has since been severely restricted by the U.S. Environmental Protection Agency (USEPA). Normal farm operations would also typically result in point-source contamination associated with maintenance areas, pesticide mixing and loading sites, and fuel storage areas.

Over the last six years, the SFWMD has performed multiple Environmental Site Assessments (ESAs) as well as worked to remediate most of the point source contamination sites. At present, most of this land is leased to agricultural operators who continue to cultivate the thousands of acres of citrus groves located on the properties.

At this time, most if not all of these potential contamination sites have been either remediated or further investigated to characterize the sites and prepare remediation plans. The SFWMD has made a commitment to the USACE and USFWS that after it takes control of the properties from the present lessees and begins construction of the reservoir, all of the outstanding point source remediation efforts will be completed. In addition to the point source contamination sites, the SFWMD also identified distributed soil contamination in portions of the cultivated areas on all of the acquired properties. The remediation of the cultivated soil sites involves the placement of these soils into the core of the reservoir dam. This will isolate the contaminated soils from

DRAFT

benthic organisms that serve as food for higher level organisms and thus reduce the potential for bioaccumulation of contaminants by fish and wildlife.

The USFWS service has reviewed all of the SFWMD's remediation plans and indicated that they believe that the efforts will sufficiently reduce the risk of harm to fish and wildlife in those areas where the remediation will be performed. The USFWS has also stated that moderate levels of copper and other contamination of the cultivated areas are believed not to pose a direct threat to species of concern; however, they believe that an indirect effect may occur since widespread low-level soil contamination may reduce the population of benthic organisms upon which the species of concern normally feed.

Despite the diligent work performed by the SFWMD and USFWS to reduce the risk to environmental resources, it is possible that once the reservoir is built, bioaccumulation of soil contaminants does result in harm to one or more species of interest. If this does happen, additional remediation efforts, such as more extensive removal of the reservoir bottom sediments, could be done to further reduce the exposure of benthic organisms to near surface soil contamination at the end of a dry season. The cost of additional remediation, if necessary, would be the responsibility of the SFWMD. If such remediation is necessary, this remediation effort may be scheduled in one cell at a time, possibly during the late dry season, thereby keeping the reservoir somewhat operational. Short summaries of the environmental audits for each property are provided below.

Berry Groves Property - Phase I and II ESA studies as well as ERAs were performed on this parcel during the period from December 1999 through 2006. These investigations identified more than 40 potential point source contamination sites within the parcel boundaries. These point source sites typically consist of refueling sites, maintenance sheds, pesticide storage/mixing sites, and irrigation pump stations. Seventeen (17) of the 40 sites were designated as requiring no further action because further investigation determined that contamination was not present at levels requiring remedial action. Fifteen (15) of the sites were identified as presenting a contingent hazardous, toxic and radioactive waste (HTRW) risk because contamination has been identified and quantified but remediation has either not begun or been completed. An additional five sites were identified in March 2003 as requiring remediation. The 40 contaminated sites discussed above can be generally categorized as point source contamination sites in which the contamination is contained within an area of a few acres or less. Though most of these sites have been remediated as of February 2007, remediation of the remaining sites will be completed prior to transferring control of the land from the lessee to the SFWMD.

DRAFT

Of greater concern to the USACE and the USFWS is the widespread presence of elevated copper concentrations in the cultivated soils on the Berry Groves property. The presence of elevated copper in the soils is a result of the application of fungicides that have been applied to the citrus groves. To investigate the risk posed by copper, a Phase III ERA was conducted by the URS Corporation under contract with the SFWMD and in coordination with the USFWS. The purpose of the ERA was to determine the risk that elevated concentrations of copper in the soil posed to populations of invertebrates, fish, and birds (the listed snail kite, for instance) that would use the C-43 reservoir for habitat.

Winthrop Property - The Winthrop property is located south and west of the larger Berry Groves property. The Winthrop property (2,399 acres) has been used to cultivate citrus for the last 30 or more years. Like the Berry Groves property, persistent pesticides such as DDT, toxaphene, and chlordane were probably widely used until the application of such chemicals was restricted by the USEPA in the 1980s. A Phase II ESA report was prepared in March 2003 by Environmental Consulting & Technology, Inc. (ECT) on behalf of the SFWMD. This report identified five areas of potential concern including the cultivated areas, canal sediments, two maintenance areas, and an exploratory oil/gas well. Grid based testing was performed in the cultivated areas such as was done on the Berry Groves property. The results of these sediment analyses indicated the presence of aldrin and aldicarb at levels exceeding the threshold concentrations. A preliminary ERA was done using a fugacity-based food chain model to determine the risk that elevated aldrin concentrations might pose to avian species. The results of this modeling indicated that at the highest detected concentration (29 ug/kg), the calculated hazard quotient ranged from 0.01 to 0.02 for birds exposed to the contamination. Two of the remaining four suspected areas, Maintenance Area A and Maintenance Area B, require corrective action. Soils samples collected in the vicinity of Maintenance Area A had high levels of endrin, copper, and zinc. No contamination of groundwater was detected at this site. Soil samples collected in the vicinity of Maintenance Area B had high levels of anthracene, flourene, and acenaphthalene. No groundwater contamination was detected at this site.

Griffin Property - The Griffin property is located south and west of the larger Berry Groves property. The Griffin property (954 acres) has been used to cultivate citrus for the last 30 or more years. The Phase I/II report identified five areas of potential concern including the cultivated areas, canal sediments, maintenance area/chemical barn, fertilizer mix/load area, and burn area. Grid based testing in the cultivated areas was performed by dividing the property into 20 cells of 50 acres each. Discrete samples were collected from ten 5-acre sub-grids on each larger grid and composited into one sample. The results of these sediment analyses indicated evidence of low level contamination of barium,

copper, lead, mercury, zinc and paraquat. However, none of these analytes exhibited concentrations which exceeded the SQAG PEC. Aldicarb was detected in one sample grid at a concentration of 67 ug/kg which exceeds the site-specific SQAC of 1.75 uk/kg developed specifically for this site. Soils contaminated with polyaromatic hydrocarbons (PAHs) were found at the maintenance area/chemical barn. At the burn area, soils contaminated with copper were found. Seven sediment samples were collected from the drainage canal. One of these samples contained residual copper at a concentration exceeding the TEC of 32 mg/kg but not exceeding the interim screening concentration of 85 mg/kg. Another sample contained pentacholorophenol (PCP) at a concentration of 32 mg/kg which is well below the site-specific effect level of 617 ug/kg. Remediation was recommended for the maintenance area, and burn area.

Brian Paul Grove Property - The 600-acre Brian Paul Grove property is located east of the Berry Groves property. In the 1960s the property was converted from a cattle ranch to row crops such as tomatoes, watermelons, and peppers. In 1972, the property was converted to citrus groves. In 2004, the SFWMD conducted a Phase I/II Environmental Assessment as part of a due diligence investigation prior to acquiring the lands. The Phase I assessment identified the following seven sites of environmental concern: 1) pump stations, 2) former nursery barn, 3) C-1 mixing site, 4) auxiliary tank area, 5) solid waste site, 6) burn area, and 7) grove area. The results of the analysis indicated that the soil in two grids (8 and 9) had elevated chlordane levels in excess of the recommended 100 ug/kg limit. Further testing indicated that approximately 13 acres had chlordane impacted soils. At the solid waste area, soil samples were collected from below the buried waste. These samples indicated that the soils were not impacted though the presence of buried solid waste would have to be addressed. At the burn area, soil samples were collected to determine if concentrations of heavy metals exceed the standards. At the former pump stations, soil samples were collected and analyzed for petroleum and heavy metal contamination. The results indicate that the visibly contaminated soils should be removed. At the burn site, the analysis of soils indicated that the surrounding soils were not impacted. However, the removal of ash was recommended by the environmental consultant. From the drainage canal, eight soil/sediment samples were collected for analysis. The results indicated that canal sediments were not contaminated; however, some canal bank soil directly adjacent to a burn area had high levels of barium, copper, and silver. The consultant's recommendation was to remove the canal bank soil that appears to be contaminated by the adjacent burn site.

Bob Paul Grove Property - The 2,025-acre Bob Paul Grove property is located east of the Berry Groves property. Prior to 1972, the property was used as a cattle ranch. After 1972, the property was converted to citrus groves. The SFWMD performed Phase I/II ESA audits in 2004 and 2005. The Phase II audit

DRAFT

included the investigation of 12 point source sites of probable contamination previously identified in the Phase I audit and the investigation of residual soil contamination in the cultivated areas. Out of the 21 composite samples collected in the cultivated area, 15 of them had copper concentrations in excess of the TEC (32 mg/kg). Six of the discrete samples had copper concentrations in excess of 85 mg/kg which is the interim screening value; however, none of the calculated means for the grids exceeded 85 mg/kg. Concentrations of carbaryl and aldicarb were above their respective SCTLs in several of the composite samples. One composite sample contained chlordane at a concentration above its TEC of 3.2 ug/kg. Another composite sample contained 4,4' DDE at a concentration (4.3 ug/kg) above the TEC of 3.2 ug/kg. A screening level ecological risk assessment (SLERA) determined that the detected levels of aldicarb, chlordane and carbaryl do not present an unacceptable risk to any of the nine avian species of concern. This SLERA did find that the maximum concentration found in a discrete sample of 4,4' DDE did pose a risk to the nine avian species; however, the mean concentration of each grid cell was below TEC of 3.2 ug/kg so the overall risk to avian birds was considered acceptable by the USFWS.

The 12 point source areas identified for Phase II investigation included a maintenance area, chemical storage building, pole barn, shop, above ground storage tanks (ASTs), fuel dispenser island, equipment staging area, storage area, irrigation pump stations, burn areas, former airstrip, irrigation canals, and cultivated areas. Discrete soil, sediments, and groundwater samples were collected in the vicinity of the suspected point source contamination sites. Soil contaminated with multiple pesticides (chlordane, dieldrin, hepatochlor epoxide, and endrin) were detected at the chemical storage building. Chlordane and 4,4' DDE were detected above levels of concern at the pole barn/storage building, maintenance staging area, grove building, airstrip, and irrigation canals. Petroleum contamination at levels exceeding the SCTL for total recoverable petroleum hydrocarbons (TRPH) was detected at the pole barn, spray oil AST, grove building, and in the canal sediments. The remediation plan for each of these sites includes the removal of contaminated soils.

At the spray oil AST, petroleum hydrocarbon contamination was detected in the groundwater at a concentration exceeding the GCTL. The remediation plan for this site includes air sparging of the groundwater in addition to the soil removal

1.2.2.5 Water Quality Impacts Improvements Expected from Other Programs

Future water quality conditions in the basin will be strongly influenced by future land use, the operation schedule of Lake Okeechobee, and the implementation of Best Management Practices (BMPs) to control nutrient discharges. Since the 2050 population will be substantially greater than the year 2000 population, the quantity of treated wastewater effluent discharged to

the estuary will increase. However, with the expected implementation of TMDLs for the discharge of nutrients into the estuary, it is not unreasonable to expect that by 2050 most existing wastewater treatment plants and all future plants will incorporate tertiary treatment process to remove nutrients. If the TMDL program is effective, the 2050 nutrient loads from wastewater effluent will be similar to or less than the present nutrient loads.

Future water quality conditions will depend upon the overall change in nutrient loads delivered to the estuary from upstream of S-79 as well as below this structure. Nutrient loads to the estuary will likely increase by 10% or more if no BMPs or nutrient TMDLs are implemented in the Caloosahatchee basin. If the implementation of BMPs substantially reduces non-point source nutrient loads, discharges from Lake Okeechobee are significantly reduced and tertiary wastewater treatment is implemented basin wide, the 2050 Future Without nutrient loads may decrease by more than 30% as compared to the existing condition.

1.2.2.6 Water Quality Performance of Impoundment Project

Under the conservative assumption that no water quality treatment occurs in the reservoir, the project alternatives will reduce TP and TN loads at S-79 by approximately 28% to 35% in comparison to the future without the project condition. This reduction in nutrient loads at S-79 is largely the result of the reduction in discharges from Lake Okeechobee. All of the selected alternatives will cause a shift in nutrient load from the wet season to the dry season; however, all of the alternatives will decrease the frequency in which the monthly TN load exceeds the dry season, wet season, and annual targets established by DEP (dry-season 190 tons/month, wet-season 350 tons/month, annual 3,000 tons/month). While it is possible that nitrogen fixation within the reservoir will result in short-term increases in TN loading to S-79, the average annual TN load at S-79 will be reduced. Each of the alternatives results in an improvement in overall average water quality conditions at S-79 as well as downstream in the estuary. Given the uncertainty in the threshold chlorophyll-a concentration required for the restoration of the ecological function of the estuary, the degree to which the reservoir project will improve downstream water quality is unknown at this time. Based on the evidence presented here, it appears that the project will not cause or contribute to water quality degradation under future conditions.

The total load of sediments transported to the estuary from the freshwater Caloosahatchee sub-basin with the project will be reduced relative to future without conditions since some fraction of the available sediment load will be retained within the reservoir. Additionally, since construction of the reservoir will reduce the total area of farmed land by some 10,000 acres, sediment

DRAFT

transport associated with farming this acreage will also no longer be transported to the estuary. The reduction in sediment load will be on the order of 5% to 10% relative to existing without project conditions and approximately 30% relative to future without project conditions. This reduction in sediment delivered to the estuary should result in a slight improvement in sediment quality relative to without project conditions. However, since urbanization of the basin will continue over the next 50 years, non-project related anthropologic impacts will likely result in the continued degradation of estuary sediment quality over time.

1.2.2.7 Adaptive Assessment and Monitoring Program

An extensive Adaptive Assessment Program that includes a system-wide monitoring and evaluation program will be conducted to support the goals and objectives of CERP. Details of this monitoring program are included in Annex D of the PIR/EIS. As a region specific component of CERP, monitoring and assessment of the Caloosahatchee River (C-43) West Basin Storage Reservoir Project will need to be closely coordinated with the larger comprehensive monitoring program for CERP. This program will provide an opportunity to continue investigating concepts and issues relative to the overall Caloosahatchee Watershed Plan while implementation of the initial project features is underway.

A fundamental component of adaptive assessment is a monitoring program that is based on the goals and objectives of the project. The Monitoring Program will be further developed during the Planning, Engineering, and Design (PED) phase of the project. There will be project specific monitoring (including water quality) and overall CERP monitoring. The current cost estimate is based on CERP estimates, and a more detailed estimate will be developed during PED. The project specific monitoring plan discussed in this document complements the regional monitoring plans developed by Restoration, Coordination, and Verification (RECOVER) and is at a feasibility level (enough detail for costs). Early during PED, the monitoring plan will be refined and coordinated with the appropriate agencies.

1.2.3 Flood Damage Reduction

1.2.3.1 Maintenance of Existing Level of Service

The intent of the level of service analysis for flood protection, required by WRDA 2000 and the CERP Programmatic Regulations as well as Florida State law regarding the implementation of CERP, is to ensure that CERP components do not negatively impact existing levels of flood protection.

DRAFT

The operations of this project will not change the operations of the C-43 Canal based on the key assumptions outlined in the Federal Assurances and Savings Clause Analysis in the PIR/EIS. Therefore, there will be no system-wide effects on flood protection as a result of the project.

1.2.3.2 Flood Protection Performance of Impoundments and Seepage Management System

Hydrologic and hydraulic analysis was performed, using surface water and groundwater modeling, to ensure that the levels of service of flood protection will not be diminished by this project. The results of the analysis indicate that the project is not expected to result in increases in stages in canal systems adjacent to the project site.

The results from the local reservoir-level MIKESHE modeling indicate a boundary slurry wall within the embankment will prevent seepage out of the reservoir and impacts to groundwater levels. In addition, optimization of the operating levels of the seepage canals and canal structures surrounding the reservoir will maintain existing groundwater levels adjacent to the project.

Of the eleven locations evaluated using the MIKESHE model, the only location where simulated groundwater elevations increased compared to the without-project conditions was north of the project. Simulated "with project" groundwater elevations increased slightly compared to the "without project" condition. The greatest difference was during the dry period (e.g., 1981) not the wet periods. This minor effect can be addressed through further optimization of perimeter canal control structure operations for the project. The remaining ten locations show practically no differences in groundwater elevations.

Therefore, there will be no adverse affects on existing levels of service for flood protection in the vicinity of the reservoir.

1.2.4 Threatened and Endangered Species

Nineteen federally listed species may potentially occur in the proposed project footprint or may be impacted by operations of the project. Although some of these species may be impacted by the loss of habitat within the project footprint, when implemented, the project has the potential to significantly contribute towards environmental restoration beyond the project footprint. For additional information on these species please refer to the Final Biological Assessment (BA) for the C-43 West Storage Reservoir Project found in Annex A of the PIR/EIS. The site information included in this report is based on surveys referenced in the Biological Assessment. Table 6 lists the threatened and endangered species within the study area.

Snail Kite - The snail kite (Rostrhamus sociabilis plumbeus) inhabits the watersheds of the Everglades, Lake Okeechobee, Lake Kissimmee, the upper St. Johns River, and the Caloosahatchee basin. Critical habitat for the snail kite is present immediately adjacent to the Caloosahatchee basin inside of the Herbert Hoover Dike in Lake Okeechobee. The snail kite could also be found foraging in a number of native wetlands and in canals and ditches adjacent to the project area. This medium-sized raptor has a highly specific diet composed almost entirely of Florida apple snails (Pomacea paludosa), which are found in palustrine emergent, long hydroperiod wetlands. As a result, the snail kite's survival is directly dependent on the hydrology and water quality of its habitat (Service 1999).

Table 6: Federally Listed Threatened (T) and Endangered (E) Species in C-43 Basin (Caloosahatchee River) Storage 1–Phase 1 Study Area

Scientific Name	Common Name	Status
Caretta Caretta	Loggerhead sea turtle	T
Chelonia mydas	Green sea turtle	E
Crocodylus acutus	American crocodile	E
Dermochelys coriacea	Leatherback sea turtle	E
Drymarchon corais couperi	Eastern indigo snake	T
Eretmochelys imbricata	Hawksbill sea turtle	E
Lepidochelys kempii	Kemp's (=Atlantic) ridley sea turtle	E
Ammodramus savannarum floridanus	Florida grasshopper sparrow	E
Aphelocoma coerulescens	Florida scrub jay	T
Charadrius melodus	Piping plover	T
Haliaeetus leucocephalus	Bald eagle	T
Mycteria americana	Wood stork	E
Picoides borealis	Red-cockaded woodpecker	E
Polyborus plancus audubonii	Audubon's crested caracara	T
Rostrhamus sociabilis plumbeus	Everglades snail kite	E
Felis concolor coryi	Florida panther	E
Trichechus manatus latirostris	West Indian manatee	E
Cucurbita okeechobeensis	Okeechobee gourd	E
Pristia pectinata	Smalltooth sawfish	E

One snail kite was observed on a wire and eating a snail along state road (SR) 80 during a February 2006 survey. This location was approximately 0.75 miles west of the project footprint. In addition, during several field visits 2004-2006, populations of two species of apple snails, the Florida apple snail (*Pomacea paludosa*) and the exotic ramshorn apple snail (*Marisa cornuarietis*) were observed in large ditches of the project site. The network of large agricultural

ditches provides suitable foraging opportunities but evidence of foraging/feeding (shell discards) was not observed.

Wood Stork - The wood stork (*Myctria Americana*) is primarily associated with freshwater and estuarine habitats for nesting, roosting, and foraging. They have nested, at one time or another, in every county in south Florida. Typical foraging sites include freshwater marshes and stock ponds, shallow, seasonally flooded roadside or agricultural ditches, narrow tidal creeks or shallow tidal pools, managed impoundments, and depressions in cypress heads and swamp sloughs. Wood storks use a specialized feeding behavior called tactolocation, or grope feeding. A foraging wood stork wades through the water with its beak immersed and partially open (7 to 8 cm). When it touches a prey item, a wood stork snaps its mandibles shut, raises its head, and swallows what it has caught (Kahl 1964). This unique feeding method of the wood stork gives it specialized habitat requirements; the habitats on which wood storks depend have been disrupted by changes in the distribution, timing, and quantity of water flows in south Florida. The loss or degradation of wetlands in central and south Florida is one of the principal threats to the wood stork.

The majority of the lands within the project footprint fall within the 18.6-mile core foraging area (CFA) of three wood stork colonies. The Biological Assessment only identified two colonies with a CFA that overlapped the project site but since that time a new colony has been identified. Individual wood storks have been observed foraging and loafing onsite, primarily in the tertiary and secondary canals. Within the project there are limited acres of wetlands that provide suitable wood stork foraging habitat. Wood stork foraging habitat available within the project site includes 6.72 acres of wetlands and 778.34 acres of ditches/canals.

West Indian Manatee - The West Indian manatee is recognized as an endangered species by both the USFWS and Florida Fish and Wildlife Conservation Commission (FFWCC). Manatees are also protected under the provisions of the Marine Mammal Protection Act of 1972, and by Florida law. The manatee, or sea cow, is a large, plant-eating aquatic mammal that can be found in the shallow coastal water, rivers, and springs of Florida. Florida is essentially the northernmost extent of the West Indian manatee's range, though some manatees are occasionally spotted as far north as Virginia and the Carolinas (FP&L, 1989). The endangered West Indian manatee is regularly found in the Caloosahatchee River and the Charlotte Harbor estuary. This large, aquatic mammal migrates along the Florida coast through fresh, brackish, and marine waters, with a seasonal distribution based on water temperatures. Water depths of at least 3 to 7 feet are preferred. Water temperatures below 20 degrees Celsius increase the manatee's susceptibility to cold-stress and cold-induced mortality. Distribution is also controlled by the availability of aquatic

DRAFT

vegetation, proximity to channels of at least 2 meters in depth, and location of fresh water sources (Service 1999). During the summer months manatees range throughout water bodies of South Florida, usually in small groups. In the winter months they tend to congregate in warm water areas such as springs and electric generation facilities (FP&L, 1989).

Designated critical habitat for the manatee is located in the Caloosahatchee River Basin. Critical habitat extends downstream from the State Highway 31 bridge and includes all U.S. territorial waters adjoining the coast and islands of Lee County.

Primary threats to manatees today consist of collisions with watercraft, degradation of seagrasses and accidents occurring at water control structures. Navigational locks along the Caloosahatchee River have a history of causing manatee mortality. Sixteen navigational lock/water control structure-caused manatee deaths have been recorded near Ortona Lock (S-78) between 1980 and 2001. Throughout those same years, six were discovered near S-77 at Moore Haven, and just one in 1999 at the Franklin Lock (S-79). Existing operational protocols for the structures and locks (unaffected by project planning for the C-43 reservoirs) are important considerations in reducing these deaths.

Manatees have been known to utilize the Townsend Canal, which lies immediately adjacent to and west of the project footprint. During times of inflow from the Caloosahatchee River, manatees are capable of passing over the weir and traveling southward into the Townsend Canal. Individuals have been observed at the outfall area immediately west of the project boundary as well as at the mouth of the canal in the Caloosahatchee River. However, manatees cannot access the main distribution canal (i.e., Header Canal) for the grove property due to differences in elevation.

Southern Bald Eagle - The bald eagle is currently listed as a threatened species by both the USFWS and Florida Fish and Wildlife Conservation Commission (FFWCC). The southern bald eagle (*Haliaeetus leucocephalus*) is considered common and known to breed throughout the state. Nest sites are usually located near large rivers, lakes, or estuaries where they feed primarily on fish and water-dependent birds. Their distribution is influenced by the availability of suitable nest and perch sites near large, open waterbodies, typically with high amounts of water-to-land edge (Service 1999). The bald eagle is the only eagle unique to North America. It ranges over most of the continent, from the northern reaches of Alaska and Canada down to northern Mexico. Current threats to the bald eagle include habitat loss and fragmentation, collisions with cars and powerlines, and shooting (USFWS 1998).

Data obtained from the Florida Fish and Wildlife Conservation Commission (FFWCC) 2004 Eagle Nest Database indicate that the closest documented bald eagle's nest, HE002, is located 3.4 miles east of the project and east of SR 29. This nest was documented to be last active during the 2003 nesting season. No other nests were observed in the project vicinity during field efforts in the summer of 2004 or spring of 2006.

Eastern Indigo Snake - The threatened eastern indigo snake (*Drymarchon corais couperi*) is present throughout the state, but its abundance is reduced to a point where it is uncommon. Its known habitat includes pine flatwoods, scrubby flatwoods, high pine, dry prairie, tropical hardwood hammocks, edges of freshwater marshes, agricultural fields, coastal dunes, and human altered habitats. This species was listed as a result of dramatic population declines caused by over-collecting for the domestic and international pet trade as well as mortalities caused by rattlesnake collectors who gassed gopher tortoise burrows to collect snakes. Since its listing, habitat loss and fragmentation by residential and commercial expansion have become much more significant threats to this species (Service 1999).

Specific information on the status of this species within the project area is not available; however, indigo snakes are known to occur in the Caloosahatchee River basin in low densities and are known to occur along roads and the banks of larger ditches and canals in citrus groves, particularly if burrows (e.g., tortoise, armadillo, small mammal, and/or land crab), debris piles, or other shelter are in close proximity. Although the eastern indigo snake was not observed during field visits, suitable habitat exists on the project site; therefore, it could potentially occur. Additionally, the species is known to utilize a variety of habitat types including citrus groves.

Florida Scrub-Jay - The Florida scrub-jay (*Aphelocoma coerulescens*), a threatened species, is present in limited areas of scrub habitat in the study area. It is a relict species of fire-dominated oak scrub habitat that occurs on well-drained sandy soils in peninsular Florida. Scrub-jays are extremely habitat-specific, sedentary, and territorial. Florida scrub-jays form family groupings; fledglings remain with their parents in their natal territory as helpers. The Florida scrub-jay is listed as a threatened species because of loss, fragmentation, and degradation of scrub habitats throughout Florida, due primarily to urbanization, agriculture, and fire suppression. During the last 10 to 23 years, the population has declined by an estimated 25 to 50%, and they have been extirpated from seven counties statewide.

No individuals, nests or appropriate habitat were detected in the project footprint during site visits. The nearest documented Florida scrub jay habitat

DRAFT

and population occurs 1.1 miles west of the project area. This colony is beyond the foraging distance for the species to access the project area.

Red-Cockaded Woodpecker - The red-cockaded woodpecker (*Picoides borealis*) was listed as threatened in 1970. The red-cockaded woodpecker (RCW) is one of 22 species of woodpeckers native to North America. Its historic range encompasses the southeastern Unite States from eastern Texas to Oklahoma to New Jersey, and it was characterized as "abundant" in the 19th century literature. Throughout the 20th century, however, the species' distribution within its historic range has become fragmented, and its total population numbers have decreased dramatically due to the destruction of its habitat. The primary threat to the species continues to be the destruction or degradation of its habitat as a result of timbering and other land-clearing activities. Although south Florida is not a designated recovery population for the red-cockaded woodpecker, the area contains significant support populations for recovery of the species in the southeast. Additional population surveys and research on habitat requirements within the hydric pine flatwoods of south Florida are needed to assess the current status of the birds and to adapt conservation measures used elsewhere to the distinct conditions in this area. The nearest documented RCW population occurs approximately 14 miles northwest of the project area (FFWCC data).

Florida Panther - The Florida panther (*Puma concolor coryi*), a subspecies of mountain lion, is one of the most endangered large mammals in the world. The most recent population estimate for the Florida panther is a total of 87 individuals, not including denning kittens (McBride 2003). This small population in south Florida represents the only known remaining wild population of an animal that once ranged throughout most of the southeastern United States from Arkansas and Louisiana eastward across Mississippi, Alabama, Georgia, Florida, and parts of South Carolina and Tennessee. The panther presently a contiguous system of large private ranches and public conservation lands in Broward, Collier, Glades, Hendry, Lee, Miami-Dade, Monroe, and Palm Beach counties totaling more than 809,400 ha. Panthers have a strong affinity for hardwood forests and mixed swamps but also use freshwater marshes, prairie and shrub/scrub habitats, agricultural lands (i.e., wooded pasture, rangeland, citrus groves, row crops, etc.), and even urban areas. Geographic isolation, habitat loss, population decline, and associated inbreeding have resulted in a significant loss of genetic variability and overall health of the Florida panther population. Natural gene exchange ceased when the panther became geographically isolated from other subspecies of *Puma concolor*. Population viability projects have concluded that under current demographic and genetic conditions, and without implementation of recovery actions, the panther will probably become extinct within two to four decades.

DRAFT

The Caloosahatchee basin plays an important role in the recovery of the Florida panther. The Service has organized a multi-agency subgroup of the Multi-species/Ecosystem Recovery Implementation Team (MERIT) to produce a Florida panther landscape conservation strategy. That strategy included the identification and prioritization of habitat zones (Dispersal, Primary, and Secondary Zones) that are essential for effective Florida panther conservation. In addition to protection of habitat for adult home ranges, the strategy includes provision of corridors for dispersal of juveniles between larger areas of contiguous habitat. Dispersal across the Caloosahatchee River, between existing primary habitat south of the river and habitat that is presently only occasionally used by panthers north of the river, is considered essential for recovery of the species.

The proposed project is located within the USFWS Consultation Area (CA) and includes areas within the panther primary, secondary, and "other" zones, as identified by the Florida panther subteam of the MERIT and USFWS CA updates. The most recent available FFWCC telemetry data of radio collared Florida panthers, current through January 2004, depicts three (3) Florida panthers and one (1) Texas cougar (Felis concolor) within a five-mile radius of the project area. A more landscape level inspection (25-mile radius) identifies habitat utilization by several additional panthers, particularly within Okaloacoochee Slough State Forest and other conservation lands.

Audubon's Crested Caracara - Audubon's crested caracara (*Polyborus plancus audobonii*) is another federally listed species present in the Caloosahatchee basin. It is a large, boldly patterned raptor, with a crest and unusually long legs. It is a resident, diurnal, and non-migratory species that occurs in Florida as well as the southeastern United States and Central America. In Florida, this species is found in the prairie area of the south-central region of the state. Historically, this species was a common resident in Florida from northern Brevard County, south to Ft. Pierce, Lake Okeechobee, and Hendry County. Today, the region of greatest abundance for this large raptor is a five-county area north and west of Lake Okeechobee. The preferred native habitat is dry or wet prairie with scattered cabbage palms (Service 1999). Improved and unimproved pastures are also highly utilized. Effect determinations for caracara are based mostly on potential impacts within the primary nest zone (i.e., within a radius of 985 feet from a nest tree) or the secondary zone (a radius of 6,600 feet). Additionally, potential effects within juvenile congregation areas are also considered.

The project falls within the caracara USFWS Consultation Area. One caracara nest site was confirmed to the north of the project during spring 2006 surveys. This nest is located along the southern edge of the SR 80 right-of-way (ROW) and approximately 4,750 feet north of the project boundary. While individuals

were not observed foraging in the project footprint, a portion of the project falls within 2,000 meters (secondary zone) of this nest, as defined in the Standard Local Operating Procedures for Endangered Species (SLOPES). In addition, a possible nest was identified approximately 1,065 feet south of the project boundary, within a pasture of the A. Duda & Sons, Inc. property. Individuals from the possible nest site were seen flying into and out of the C-43 project site. While the C-43 project area provides only sub-optimal foraging habitat for the species, and individuals were only observed utilizing the project area in the southeast portion of the footprint, it does fall within the home range of both the confirmed and possible nests.

Florida Grasshopper Sparrow - The Florida grasshopper sparrow (*Ammodramus savannarum floridanus*) is a subspecies of grasshopper sparrow that is endemic to the dry prairie of central Florida. This subspecies is extremely habitat-specific and relies on fire every two to three years to maintain its habitat. It is now known to occur only from Highlands, Okeechobee, Osceola, and Polk counties, but other populations may occur in Glades County, which may bring it into the study area considered here. The species is not known to occur in Hendry County but populations may occur in nearby Glades County (USFWS 4-11-02 PAL). The nearest Florida grasshopper sparrow record in the 1999 FNAI database is a 1984 observation located 17.3 miles north of the project. Mapping of potential Florida grasshopper sparrow habitat (Shriver and Vickery, 1999) shows marginal habitat zones to the northeast and southeast of the project, and the project area falls within the Florida grasshopper sparrow USFWS Consultation Area. However, the nearest marginal habitat zone is located approximately 2.5 miles to the southeast of the project footprint. No grasshopper sparrows were observed during field surveys and no suitable habitat exists in the project area.

Piping Plover - A wintering population of piping plovers (*Charadrius melodus*) uses the tidal area of the Caloosahatchee River. The piping plover was listed as threatened along the Atlantic coast in 1985. It is a small, migratory shorebird that breeds only in three geographic locations of North America: sandy beaches along the Atlantic Ocean: sand shorelines throughout the Great Lakes: and on riverine systems and prairie wetlands of the Northern Great Plains. This species does not breed in Florida, but all three breeding populations winter here. Bunche Beach, at the mouth of the Caloosahatchee, has a population of wintering piping plovers and is also designated critical habitat for this species. The USFWS established critical habitat areas for the species, which include several locations on barrier islands west of the Caloosahatchee Estuary. The nearest piping plover critical habitat zone to the project area includes Punta Rassa, a mainland location at the southwestern edge of the Caloosahatchee Estuary, and Bunch Beach.

DRAFT

Okeechobee Gourd - The Okeechobee gourd (*Cucurbita okeechobeensis*) is a vine that was locally common in the extensive pond apple forest that once grew south of Lake Okeechobee (Small 1922). It is a vine that is now restricted in the wild to two small distinct populations–one along the St. Johns River which separates Volusia, Seminole, and Lake Counties in north Florida, and a second around the shoreline of Lake Okeechobee in south Florida.

American Crocodile - The USFWS and the FFWCC list the American Crocodile (*Crocodylus acutus*) as endangered. This species occurs in extreme South Florida primarily in Biscayne and Florida Bays. Crocodiles have been observed as far north as the coasts of Lee and Collier Counties, but these counties are not thought to support a significant resident population of crocodiles. The American crocodile has not been documented in Hendry County but is present in coastal counties of the Caloosahatchee River basin, namely Lee and Collier Counties. The nearest documented individual occurrence to the project is on Sanibel Island in Lee County. The American crocodile is known to inhabit mangrove and seagrass habitats in coastal areas of south Florida.

Sea Turtles - Sea turtles including the Atlantic loggerhead turtle (*Caretta caretta*), Atlantic green turtle (*Chelonia mydas*), leatherback turtle (*Dermochelys coriacea*), Kemp's ridley turtle (*Lepidochelys kempii*), and hawksbill turtle (*Eretmochelys imbricata*) are listed as endangered by the USFWS and FFWCC with the exception of the loggerhead turtle, which is listed as threatened. These are marine species with a presence in south Florida waters and are known to utilize bays and estuarine habitats, such as the Caloosahatchee estuary, for feeding and resting. Sea turtles forage in the near shore waters, bays and sounds of Florida and come ashore at night to nest on the beaches above the high tide line. Alterations in the timing and quantity of freshwater flowing through the estuary has an impact on natural biodiversity by affecting food availability, predation pressure, reproductive success, and most likely has caused chronic and acute stress to these species.

1.2.4.1 Endangered Species Act (ESA) Consultation

The USFWS has been an active member of the project team for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project and has provided guidance through informal consultation during plan formulation and evaluation. The USFWS provided a Biological Opinion on November 30, 2005, for construction of the C-43 West Storage Reservoir Test Cells, an area of approximately 267 acres. This area is not included in the ongoing Section 7 evaluation for the reservoir since consultation has been completed.

The Final Biological Assessment for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project (January 2007) describes the potential effects of the

proposed Caloosahatchee River (C-43) West Basin Storage Reservoir Project on federally listed threatened and endangered species. The USACE determined that the Caloosahatchee River (C-43) West Basin Storage Reservoir Project would not affect the bald eagle, Florida scrub jay, Florida grasshopper sparrow, red cockaded woodpecker, Okeechobee gourd, or the beautiful pawpaw because they do not occur within or adjacent to reservoir footprint, nor would there be direct or indirect impacts to those species. The USACE determined that the proposed project may affect, but is not likely to adversely affect the smalltooth sawfish, wood stork, West Indian manatee, Everglade snail kite, American crocodile, piping plover, or the green, hawksbill, leatherback, Kemp's ridley or loggerhead sea turtles. The American crocodile, piping plover, or the green, leatherback, Kemp's ridley and loggerhead sea turtles do not occur within or adjacent to the reservoir footprint and indirect effects resulting from operation of the reservoir are expected to be negligible, discountable or beneficial to those species. Additionally, wintering piping plover critical habitat will not be adversely modified by the proposed project. Additionally, the USACE determined the project may adversely affect the eastern indigo snake, Audubon's crested caracara, and the Florida panther and requested initiation of formal consultation for these species. Formal consultation with the USFWS is ongoing for these species.

1.2.4.2 Fish and Wildlife Coordination Act (FWCA)

The central objective of the Fish and Wildlife Coordination Act (FWCA) is to allow for equal consideration of wildlife resources. Transfer funds have been made available to the USFWS in order to participate in team meetings and workshops scheduled in conjunction with the USACE's planning, implementation, and evaluation process. Funding has also been provided for the USFWS to conduct surveys and investigations necessary to determine impacts of the C-43 project on wildlife resources and to make recommendations to the USACE on measures to prevent loss of or damage to wildlife resources. Recommendations for optimizing opportunities related to the conservation and enhancement of fish and wildlife resources have been provided through the submittal of Planning Aid Letters listed above. A draft CAR has been prepared and is included in Annex A of the PIR/EIS. Additionally, the Florida Fish and Wildlife Conservation Commission (FWC) has been an active participant on this project and have provided a Scoping Letter dated June 10, 2003.

This project has been coordinated with the USFWS and the Florida Fish and Wildlife Conservation Commission (FWC). The FWC has been an active participant of the project team. The FWCA report is included in the PIR/EIS for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project. This project is in full compliance with the Fish and Wildlife Coordination Act.

DRAFT

1.2.4.3 Florida State Historic Preservation Officer

The USACE has reviewed information regarding historical properties that might be affected by the C-43 project, in compliance with Section 106 of the National Historic Preservation Act of 1966 (PL89-665), as amended in 2000; its implementing regulations (36 CFR Part 800) and the Archaeological and Historic Preservation Act of 1974 (PL93-291), as amended. A Phase I survey has been completed on all sections of the C-43 West Reservoir site.

Coordination with the State Historic Preservation Office (SHPO) has occurred and the Section 106 process is complete. In consultation with the Florida State Historic Preservation Officer (Florida State Department of Historic Preservation numbers 2004-8676 and 2006-07757) a determination of no historic properties affected has been made. This project is in compliance with the National Historic Preservation Act.

1.2.5 Other Natural System and Habitat Needs

The existing condition of the Caloosahatchee River (C-43) West Basin Storage Reservoir Project area is described in detail in Section 2 of the PIR/EIS. The differing hydrologic conditions were assessed as to the effects on flora and fauna.

1.3 Determination of Project Component Feasibility [373.1501(5)(b)]

Section 373.1501(5)(b), F.S. requires the SFWMD to "Determine with reasonable certainty that all project components are feasible based upon standard engineering practices and technologies and are the most efficient and cost-effective of feasible alternatives or combination of alternatives, consistent with restudy purposes, implementation of project components, and operation of the project." The following sections form the basis for this determination.

1.3.1 Standard Engineering Practices and Technologies

1.3.1.1 Summary of Project Features

The selected plan consists of the following features: construction, operational modifications, real estate requirements, an adaptive assessment and monitoring program, and operation and maintenance details of the completed project.

The risk and uncertainty associated with the construction and operation of these features of the proposed project should be minimal. All features have been designed and constructed through established and applied technology. No experimental design was necessary for any component of the proposed impoundment. Additionally, both the U.S. Army Corps of Engineers and the

DRAFT

South Florida Water Management District have extensive and reputable credibility in the design, construction, and operation and maintenance of the proposed features from previous water resources planning efforts.

Purpose - The Caloosahatchee River (C-43) West Basin Storage Reservoir Project is planned and designed primarily to restore the ecosystem function in the Caloosahatchee Estuary by reducing the number and severity of events where harmful amounts of freshwater from basin runoff and Lake Okeechobee releases are discharged into the estuary system. The project also helps to maintain a desirable minimum flow of fresh water to the estuary during dry periods. These two primary functions help to moderate unnatural changes in salinity which is extremely detrimental to estuarine communities.

Location - The Caloosahatchee River (C-43) West Basin Storage Reservoir Project is located in western Hendry County. The site is a few miles south of State Road 80 and approximately two miles west of State Road 29.

Existing Site Development and Conditions - The project footprint covers approximately 10,492 acres located in Hendry County west of LaBelle (Figure 2). The property is predominantly owned by the South Florida Water Management District (SFWMD) and is under a leasing agreement with Jack M. Berry Inc. for agricultural land use. (Currently the SFWMD is processing an exchange of 541.31 acres located north of the project boundary for the 600.13-acre Paul Property. This was necessitated by a requirement to locate the reservoir footprint away from existing power lines to the north and a need for additional lands to the east or west in order to maintain storage). The project site is currently a producing citrus grove. The site contains three major arterial canals that transport water for the purpose of irrigation and attenuation of Caloosahatchee Basin runoff waters. Two of the three canals, Roberts and Townsend, lie along the eastern and western perimeters of the footprint, respectively, The Header Canal, also called the LPDD Canal, transects the entire reservoir area and its use is primarily to cross feed water between the Roberts and Townsend Canals.

Approximately 267 acres within the project site have been impacted through construction of the C-43 Basin Storage Reservoir Test Cells Project. The SFWMD initiated construction of the test cells in January 2006, in order to evaluate seepage and water quality effects and improve embankment design. The test cells are also shown in Figure 2.

Operation and Design - The operation of the selected plan is keyed to conditions at the W. P. Franklin Lock and Dam (structure S-79) on the Caloosahatchee River as the flows over the dam are a good indicator of the resulting health of the estuary. The project will be operated to improve

environmental conditions in the Caloosahatchee Estuary by reducing flows over S-79 during wet periods, and helping to maintain a minimum flow of 450 cfs at S-79 during dry periods. The S-79 structure is located approximately ten miles down-river (west) of the project site.

Project operations involve pumping inflows from the C-43 Canal (Caloosahatchee River) via an existing canal (Townsend Canal) into Cell 1. An internal cell balancing structure in the internal embankment will allow water in Cell 1 to enter Cell 2. Water may be released from both cells by outlet structures into the perimeter canal for delivery back to the C-43 Canal via the Townsend Canal and two other direct connections (Fort Simmons Branch and Banana Branch Canal) to the C-43 Canal. Other project structures help to maintain water levels in the perimeter canal and Townsend Canal, and provide water supply deliveries to adjacent lands affected by construction and operation of the reservoir.

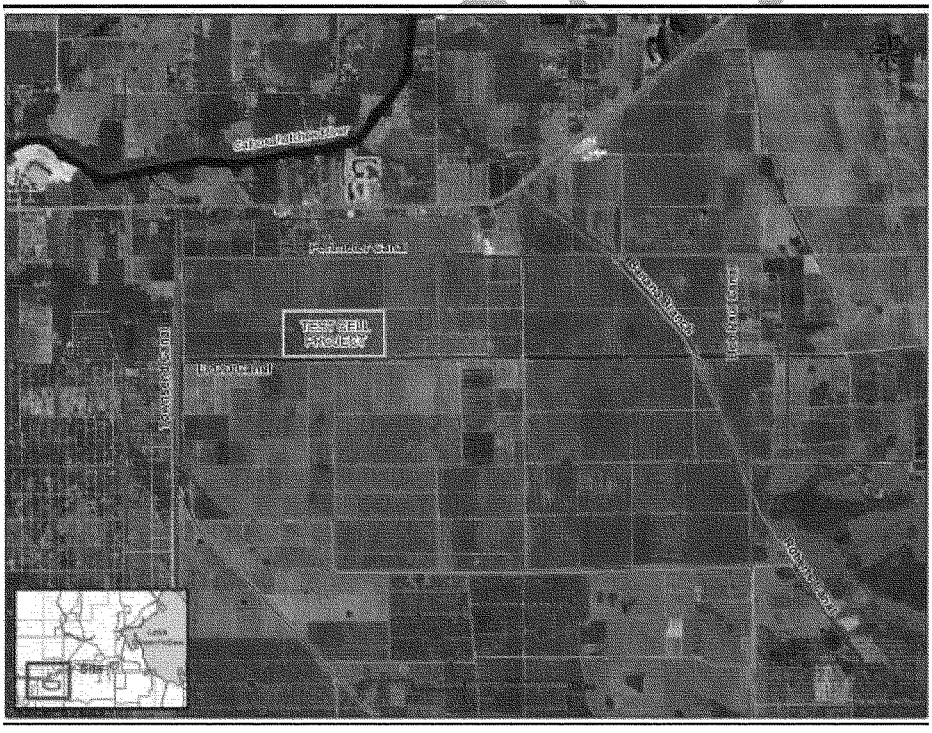

Figure 2: Caloosahatchee River (C-43) West Basin Storage Reservoir Project Site Map

Comparison to CERP Component - Programmatic Regulations for CERP require that one of the alternative plans to be evaluated is the project described in the Final Integrated Feasibility Report and Programmatic Environmental Impact Statement for the Central and Southern Florida Project Comprehensive Review Study (Restudy). The Restudy alternative description for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project cited:

"This feature includes above-ground reservoir(s) with a total storage capacity of approximately 160,000 acre-feet and aquifer storage and recovery wells with a capacity of approximately 220 million gallons per day and associated pre- and post water quality treatment located in the C-43 Basin in Henry, Glades, or Lee Counties. The initial design of the reservoir(s) assumed 20,000 acres with water levels fluctuating up to 8 feet above grade. The final size, depth and configuration of this facility will be determined through more detailed planning and design. The initial design of the wells assumed 44 wells, each with the capacity of 5 million gallons per day with chlorination for pre-treatment and aeration for post-treatment. The level and extent of treatment and number of the aquifer storage and recovery wells may be modified based on findings from a proposed aquifer storage and recovery pilot project (U.S. Environmental Protection Agency, 1999)".

The Comprehensive Review Study included two primary structural components focused on improving environmental conditions in the Caloosahatchee River and Estuary: 1) an approximately 160,000 ac-ft reservoir with associated aquifer storage and recovery (ASR) wells and 2) basin runoff backpumping and stormwater treatment facilities. Due to technical uncertainty and implementation issues, the ASR features (Part 2) originally associated with a storage reservoir in the Caloosahatchee Basin will be evaluated and implemented separately. The availability and effectiveness of storing basin runoff for backpumping to the C-43 Canal and Lake Okeechobee will also be further evaluated as part of future CERP updates.

Plan formulation in the Restudy began with a range of components that were screened during the initial phases of formulation. In the initial phase, information gained through a cost effectiveness analysis was joined with information from hydrologic modeling and information gained through previous studies to support best professional judgment in the selection of specific project components. The screening phase aimed to identify which components would be carried forward in the development of alternative comprehensive plans.

Following the initial screening, four alternatives (A-D) were carried through further formulation to arrive at the Selected Plan, also known as D-13R. The plan is composed of forty-nine operational and structural features that are also referred to as components.

For this project, plan formulation efforts initially involved reaffirming that an above-ground storage reservoir, as originally described in the Comprehensive Review Study, is a cost-effective means for achieving the purposes of the project consistent with the goals and objectives of the CERP. After reaffirming that the benefits of the project could be achieved with an above-ground reservoir, formulation efforts focused on optimizing reservoir size and features on lands already acquired for project implementation, combined with a consideration of planning and policy constraints such as the WRDA 2000 Savings Clause.

Selected Plan (Alternative 3B) - The formulation process has identified that Alternative 3C is the best buy plan and should be recommended to be implemented. The difference between Alternative 3C and Alternative 3B is the major pump stations size. Alternative 3C carries with it many uncertainties such as the potential to modify numerous structures downstream of the reservoir thus adding cost and time to the project. This cost and time will ultimately result in a loss of time for the estuary to realize benefits. While Alternative 3B is not a best buy plan it ultimately may be if Alternative 3C needs to be modified to include modifications to downstream features. Alternative 3B is cost effective and implementable while also having the highest score based on the P&G selection criteria.

The recommendation here is to selected Alternative 3B as the selected alternative plan and adaptively monitor and manage the project.

As part of the Phase 2 Project Implementation Report the Project Delivery Team will evaluate if additional pump capacity is required and the feasibility of making modifications to the 1,500 cfs pump station. The design of the Phase 1 Project allows for a future retrofit to add additional pumping capacity (1,500 cfs pump to 3,800 cfs pump) to the reservoir if it is determined necessary under the Phase 2 analysis. This would require the demolition of the old main pumping station and construction/installation of a new pumping station at substantially higher construction cost in order to improve reservoir pumping capacity. Additionally, temporary pumps may need to be installed while the new pumping station is constructed, adding additional costs. The results of the addition pumps will allow the reservoir to capture additional flows from the Caloosahatchee River and to be filled in a shorter period of time, but it would not add any additional volume for water storage.

This decision will be based on real time data collection and engineering and ecological analysis that will be evaluated while Alternative 3B is functioning and benefits are being realized in and around the estuary.

The following is a general description of the location and design of project features. For a detailed description of project features refer to Appendix A of the

DRAFT

PIR/EIS. Although shown in Appendix A, the Selected Alternative Plan does not include construction of culvert structures C43s-16, C43s-17, C43s-18, and C43s-19.

General Plan Description - The Selected Alternative Plan, as shown in Figure 3, consists of a two-cell reservoir with a "normal pool" storage capacity of 170,000 acre-feet. This Selected Alternative Plan comes closest to approximating the Restudy C-43 Reservoir recommended volume of approximately 160,000 acre-feet of storage and is the size evaluated and currently being designed by the SFWMD under their Acceler8 program. The project footprint for the Selected Alternative Plan encompasses approximately 10,492 acres and consists of major features and components to include a two-cell reservoir with armoring, cutoff walls, and embankments. Other features are pump stations, spillways with emergency overflow and vertical lifts, drawdown structures, culverts, canals, earthwork artificial habitat creation, and recreational features. The reservoir design includes a pump station with 1,500 cfs capacity to pump water from the Townsend Canal to fill the Reservoir.

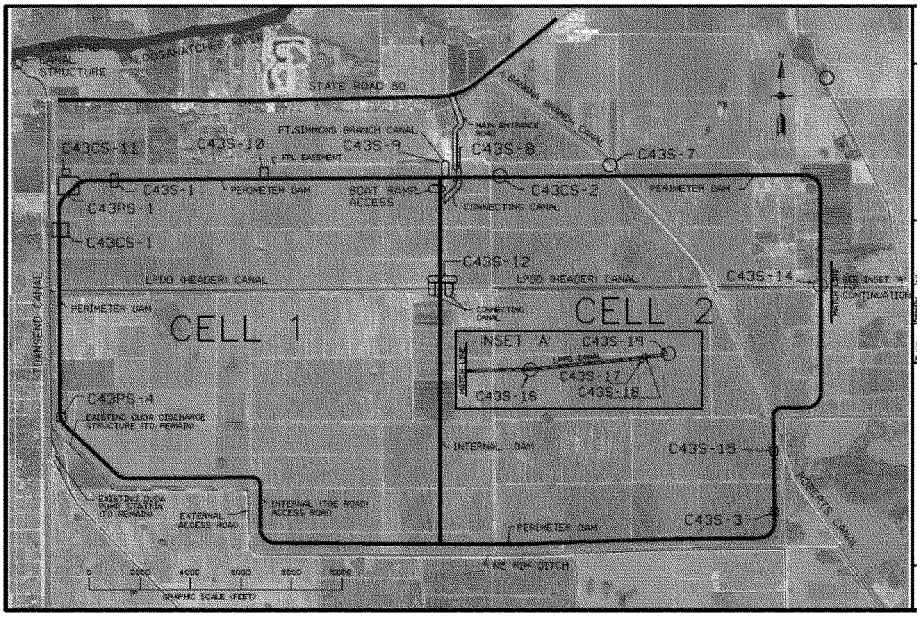

Figure 4: The Selected Alternative Plan

The existing Townsend Canal, located along the west perimeter of the reservoir will serve as the west perimeter canal. The existing disposal mounds along the east side of the Townsend Canal will be removed as part of the project. A drainage culvert will be located on the east perimeter canal connecting the LaBelle Private Drainage District (LPDD) Canal (a.k.a. the Header Canal), which will maintain historical drainage from the Paul Property east of the project. Improvements to or the relocation of the existing weir structure located at the mouth of the Townsend Canal are included. Work to that structure will be done within an existing easement.

The Selected Alternative Plan has a water surface elevation of 42 feet at "normal pool" (NAVD88), with the average depth ranging from 15 to 25 feet. Dam (embankment) heights for the Selected Alternative Plan range from 27 - 38 feet. The maximum water depths and dam heights will occur in Cell 1 due to lower land surface elevations in that cell. The exterior and interior dams are to have a crest width of 14 ft. The side slopes are 3 Horizontal to 1 Vertical (3H:1V). The exterior dams are to be constructed from existing on-site material and have a low permeability core. A graded filter is to be provided on the exterior side of the dam to direct seepage. Soil cement protection would be included on the interior side of all reservoir slope faces. A freeboard of 15 feet was used based on detailed analysis of wind and wave height run-up.

A perimeter canal (seepage canal) is provided on the south, east, and north sides of the reservoir. The existing Townsend Canal will act as a seepage canal on the west side of the reservoir. In addition to seepage collection, the perimeter canal will also convey discharges from the reservoir; convey surface runoff from the south and east of the reservoir including improved drainage for SR29; provide flows to the Crawford Canal, Banana Branch and Fort Simmons Branch; and maintain the surface water elevation in the expanded NE Rim Ditch that provides irrigation for the A. Duda and Sons (Duda) citrus operations, located to the south of the reservoir. A 17 foot cutoff wall along the perimeter of the dam embankment has also been included.

Improvements to the Townsend Canal are based on the necessary capacity to meet maximum pumping requirements to fill the reservoir. Pre-storm and post-storm event flows have been simulated to evaluate flows in the Townsend Canal and other local canals and tributaries. Storm event flows in the Townsend Canal will be decreased over existing conditions with the construction and operation of the reservoir.

Each cell is designed to discharge independently through separate discharge structures. Cell 1 will discharge via the S-1 structure into the Townsend Canal. Cell 2 will discharge via S-8 structure into the perimeter canal. These structures will be designed for incremental operation allowing required flows to

be released to the C-43 Canal during periods of low flow. These structures could also serve as design storm control structures for releases prior to and during a storm event. The storm releases must be balanced with the targeted maximum flow allowed over S-79, which is 4,500 cfs. An emergency spillway with a crest elevation based on retaining the 25 year, 72 hour storm event is to be provided within each cell's discharge structure. The 25 year, 72 hour storm captured in the reservoir would be a "control release" after the storm event in order to restore the water surface to the normal pool elevation while not exceeding the maximum flow of 4,500 cfs at S-79. The final design of the emergency spillway(s) will be in accordance with the requirements of Design Criteria Memorandum 3 (DCM-3).

Within the reservoir, structure S-12 will hydraulically connect the two reservoir cells and is designed to be gated so that either cell can be "isolated" for operational or maintenance purposes. A number of other culverts, weirs, and spillways are included to operate the reservoir and maintain appropriate water levels in existing canals and the perimeter canals.

Major Project Components

Reservoir - The Reservoir is an earthen impoundment consisting of approximately 9,400 acres of interior storage that is to be constructed above the existing ground. It will consist of an approximate 170,000 acre-feet two-cell reservoir. Water will be pumped from the C-43 Canal and into the reservoir by utilizing the existing Townsend Canal and a new pump station (C43PS-1) located in the northwest corner of the project.

Water will be discharged from the reservoir through gravity discharge structures in each cell that discharge into a perimeter canal. Both flows into and out of the reservoir will be controlled by monitoring flows at S-79.

Intake Canal - The existing Townsend Canal will serve as intake canal. The reservoir has been designed so that during storm events flows in the Townsend will not exceed the "pre-existing" condition. Therefore, there will be no negative impacts to the Townsend Canal, SR 80 Bridges, or the existing Flap Gate Weir structure. However, two additional flap gates will be installed in the Weir structure to provide capacity for pumping rates of 1,500 cfs at C43PS-1.

The perimeter canal will serve as a seepage canal and as a means of conveying both surface water runoff and off site flows entering the project. The perimeter canal design includes littoral shelves along the exterior slope that are intended to promote wetland vegetation, fisheries, and recreation activities.

DRAFT

Embankments (Dams) - The perimeter embankment will have an external geometry that includes a 14-foot wide crest and 3 horizontal to 1 vertical sideslopes. Crest elevations have been established at +56.5 feet NAVD for both Cell 1 and Cell 2. The embankment will be constructed largely of random fill, but will also include a low permeability soil-bentonite wall, an internal drain, and upstream slope protection. The soil-bentonite wall will extend from an elevation that is 5 feet above the normal pool elevation to 5 feet below the top of a clay layer which underlies the project site at depths generally in the range of 20 to 25 feet below existing surface grades. A few structures pass through the perimeter embankment. At these locations, the above ground portion of the soil-bentonite wall will be replaced with select fill. A roughly 100 foot wide bench will be raised above the existing ground surface immediately downstream of the perimeter embankment. A perimeter canal is to be located on the outside of the bench.

The separator dam between Cells 1 and 2 will be a homogenous embankment with a crest elevation of +51.4 feet NAVD. It will not include any soil-bentonite wall or internal drain. The separator dam will be covered on both sides with soil-cement. The components of the embankments are described in more detail in the following sections.

Pumping Station C43PS-1 – This pump station will consist of a steel and reinforced concrete structure that will house the main pumps and pumping motors for the project. The structure will be located adjacent to the downstream side of the dam and will have plan dimensions of approximately 200 feet (parallel with the dam) by 100 feet (measured at the intake level). It will have a base slab elevation on the intake side of the structure of -16 feet with respect to the North American Vertical Datum of 1988 (NAVD). The structure bottom will step up to elevation +10 feet NAVD for a distance of about 30 feet in the area between the intake bay and the toe of the dam. The existing surrounding grades at the site of the proposed construction are approximately +16 to +17 feet NAVD.

Pumping Station C43PS-4 – This pump station will provide water to the perimeter canal during dry periods when water cannot be released from Cell 2 of the reservoir due to low reservoir water levels. C43P-S4 will maintain the water level in the perimeter canal, provide water to the Paul Property, and supply water to the Banana Branch and Ft. Simmons Branch.

It will consist of a steel and reinforced concrete structure that will include a "can" type intake. The structure will be located adjacent to the top of bank of the Townsend Canal and will have plan dimensions of approximately 55 feet by 45 feet. It will have a separate intake bay that will have a top of slab elevation of -12 feet with respect to the NAVD. The intake pipes will consist of 3 48-inch diameter steel pipes that connect the intake bay with the vertical cans. Invert

DRAFT

elevations for these pipes will be approximately elevation -10 feet NAVD. The bottom of the can structures will be elevation -20.4 feet NAVD. Surface water levels in the Townsend Canal are expected to range between +3 and -3 feet NAVD. The pumping station floor level will be elevation +10 feet NAVD, and will step up to elevation +19 feet NAVD in the discharge bay. The existing surrounding grades at the site of the proposed construction are approximately +22 to +23 feet NAVD.

Culvert Structure C43s-7 - This culvert structure will provide a hydraulic connection between the perimeter canal and the Banana Branch Canal. It will consist of a 222 foot long double barrel concrete box culvert that rests upon a combined footing with bottom width of approximately 26 feet. The culvert will have an invert elevation of +10 feet with respect to the NAVD. The normal water level on the perimeter canal side of the structure will be +19 feet NAVD. Finished grades above the culvert are expected to be about +22 to +23 feet NAVD.

Culvert Structure C43s-9 - This culvert structure will provide a hydraulic connection between the perimeter canal and the Fort Simmons Branch. It will consist of a 102 foot long double barrel concrete box culvert that rests upon a combined footing with bottom width of approximately 26 feet. The culvert will have an invert elevation of +14 feet with respect to the NAVD. The normal water level on the perimeter canal side of the structure will be +19 feet NAVD. Finished grades above the culvert are expected to be about +21 to +22 feet NAVD.

Culvert Structure C43s-14 - This culvert structure will provide a hydraulic connection between the perimeter canal and the Header Canal. It will consist of a 97 foot long single barrel concrete box culvert that rests upon a footing with bottom width of approximately 15 feet. The culvert will have an invert elevation of +15 feet with respect to the NAVD. The normal water level on the perimeter canal side of the structure will be +19 feet NAVD. Finished grades above the culvert are expected to be about +28 to +29 feet NAVD.

Culvert Structure C43s-15 - This culvert structure will provide a hydraulic connection between the perimeter canal and the Roberts Canal. It will consist of an 86 foot long double barrel concrete box culvert that rests upon a combined footing with bottom width of approximately 26 feet. The culvert will have an invert elevation of +14 feet with respect to the NAVD. The normal water level on the perimeter canal side of the structure will be +19 feet NAVD. Finished grades above the culvert are expected to be about +26 to +27 feet NAVD.

Gated Culvert Structure C43s-3 - This structure will consist of a gated dual culvert that will be situated in the perimeter canal and will control the water

DRAFT

levels in the canal. It will have base dimensions of 65 feet (parallel with the canal) by 25 feet (across the canal). The structure will bottom new elevation +11.5 feet with respect to the NAVD. A concrete tremie seal will be placed between the structure bottom level and elevation +6.5 feet NAVD. The ground surface elevation in the project vicinity is estimated to be +26 feet NAVD. Surface water levels across the structure will be +23 and +19 feet NAVD on the upstream and downstream sides of the structure, respectively. Steel sheet piling will be used to construct wingwalls as needed. A seepage cutoff wall will be set below the upstream edge of the structure. The bottom of the cutoff wall is currently designed at elevation -1.5 feet NAVD.

Gated Spillway Structure C43s-10 - This structure will consist of a gated spillway that will be situated in the perimeter canal and will control the water levels in the canal. It will have a base slab that has plan dimensions of 64 feet (parallel with the canal) by 55 feet (across the canal). The structure will bottom near elevation +2 feet with respect to the NAVD. A concrete tremie seal will be placed between the structure bottom level and elevation -3 feet NAVD. The ground surface elevation in the project vicinity is estimated to be +20 feet NAVD. Surface water levels across the structure will be +19 and +15 feet NAVD on the upstream and downstream sides of the structure, respectively. Steel sheet piling will be used to construct wingwalls and seepage cutoff walls. A seepage cutoff wall will be set below the upstream edge of the structure. The bottom of the cutoff wall is designed to be approximately elevation -8 feet NAVD.

Gated Spillway Structure C43s-11 - This structure will consist of a gated spillway that will be situated in the perimeter canal and will control the water levels in the canal. It will have a base slab that has plan dimensions of 75 feet (parallel with the canal) by 62 feet (across the canal). The structure will bottom near elevation -8 feet with respect to the NAVD. A concrete tremie seal will be placed between the structure bottom level and elevation -13 feet NAVD. The ground surface elevation in the project vicinity is estimated to be +17 feet NAVD. Surface water levels across the structure will be +15 and +3 feet NAVD on the upstream and downstream sides of the structure, respectively. Steel sheet piling will be used to construct wingwalls and seepage cutoff walls. A seepage cutoff wall will be set below the upstream edge of the structure. The bottom of the cutoff wall is designed to be approximately elevation -18 feet NAVD.

Cell 1 Main Outlet Structure C43s-1 - Structure C43S-1 refers to the main operational outlet from Cell 1 to the perimeter canal. It will consist of twin concrete conduits, which will be constructed essentially at existing grade, and will be buried beneath the perimeter dam and oriented perpendicular to the dam. The conduits will each be 10 feet wide and 6 feet high. The outlet will include an intake structure located on the upstream side of the dam, consisting

DRAFT

of a concrete box supported on a reinforced concrete mat foundation. The top of the box has been established at elevation +44 feet with respect to the NAVD. The existing ground elevation in the vicinity of the intake box is estimated to be +17 feet NAVD. The crest of the dam will have an elevation of +55 feet: NAVD. Operational and emergency gates will be located within a control building near the center of the dam. The control works will also be supported on a reinforced concrete mat foundation. The outlet works will discharge to an impact stilling basin located on the downstream side of the dam. The stilling basin will be approximately 26 feet wide and have an invert elevation of +5 feet NAVD. This portion of the facility will also be supported on a reinforced concrete mat foundation. The downstream water surface elevation at this structure is designed at +15 feet NAVD.

Cell 2 Main Outlet Structure C43s-8 - Structure C43S-8 refers to the main operational outlet from Cell 2 to the perimeter canal. It will consist of twin concrete conduits, which will be constructed essentially at existing grade, and will be buried beneath the perimeter dam and oriented perpendicular to the dam. The box culverts will each be 10 feet wide and 6 feet high. The outlet will include an intake structure located on the upstream side of the dam, consisting of a concrete box supported on a reinforced concrete mat foundation. The top of the box has been established at elevation +29 feet with respect to the NAVD. The existing ground elevation in the vicinity of the intake box is estimated to be +20 feet NAVD. The crest of the dam will have an elevation of +54 feet NAVD. Operational and emergency gates will be located within a control building near the center of the dam. The control works will also be supported on a reinforced concrete mat foundation. The outlet works will discharge to an impact stilling basin located on the downstream side of the dam. The stilling basin will be approximately 26 feet wide and have an invert elevation of +9 feet NAVD. This portion of the facility will also be supported on a reinforced concrete mat foundation. The downstream water surface elevation at this structure is designed at +19 feet NAVD.

Balancing Outlet Structure C43s-12 - Structure C43S-12 refers to the operational hydraulic connection between Cells 1 and 2. It will consist of triple concrete conduits, which will be constructed essentially at existing grade, and will be buried beneath the internal dam and oriented perpendicular to the dam. The box culverts will each be 10 feet wide and 6 feet high, and will be supported on a reinforced concrete mat foundation. The existing ground elevation in the vicinity of the spillway is estimated to be +21 feet with respect to the NAVD. The top of the internal darn is expected to have a crest elevation of +50 feet NAVD.

Crest Spillway Structure C43cs-1 - Crest Spillway Structure C43CS-l refers to the service spillway from Cell 1 to the Townsend Canal. It will consist of a

DRAFT

concrete conduit, which will be constructed across the perimeter dam and oriented perpendicular to the dam. The conduit will be 12 feet wide. The invert elevation for the conduit will be set at elevation +38 feet with respect to the NAVD. A concrete weir will be set at elevation +42 feet NAVD. The existing ground elevation in the vicinity of the spillway is estimated to be +17 feet NAVD. The crest of the dam will have an elevation of +55 feet NAVD. The spillway will discharge down a concrete lined channel to a stilling basin located on the downstream side of the dam. The stilling basin will be approximately 12 feet wide and have an invert elevation of -7 feet NAVD. This portion of the facility will also be supported on a reinforced concrete mat foundation. The downstream water surface elevation at this structure is designed at +3 feet NAVD.

Crest Spillway Structure C43cs-2 - Crest Spillway Structure C43CS-2 refers to the service spillway from Cell 1 to the perimeter canal. It will consist of a concrete conduit, which will be constructed across the perimeter dam and oriented perpendicular to the dam. The conduit will be 12 feet wide. The invert elevation for the conduit will be set at elevation +38 feet with respect to the NAVD. A concrete weir will be set at elevation +42 feet NAVD. The existing ground elevation in the vicinity of the spillway is estimated to be +21 feet NAVD. The crest of the dam will have an elevation of +54 feet NAVD. The spillway will discharge down a concrete lined channel to a stilling basin located on the downstream side of the dam. The stilling basin will be approximately 12 feet wide and have an invert elevation of +7 feet NAVD. This portion of the facility will also be supported on a reinforced concrete mat foundation. The downstream water surface elevation at this structure is designed at +19 feet NAVD.

1.3.1.2 Impact of Project Discharges on Public Health, Safety, or Welfare

As described in earlier sections of this report the primary means for restoring the ecosystem involve the creation of project components to store excess runoff from the watershed and control the discharge of excess flows from Lake Okeechobee and the Caloosahatchee Watershed. This storage function is achieved through an impoundment and levee seepage management. Based upon the information provided in this report, the SFWMD has determined the project discharges will not negatively impact public health, safety, or welfare.

1.3.1.3 Availability of Engineering Drawings

Preliminary engineering drawings are available for review in Appendix A of the PIR/EIS. As the project moves through the authorization and design phases, it is anticipated that engineering drawings will be refined. Copies will be provided to the FDEP when available.

1.3.1.4 Summary of Engineering Designs and Evaluations

1.3.1.4.1 Engineering

Pre-Construction Engineering and Design activities will be in accordance with USACE and SFWMD requirements. Preliminary design activities, which include survey and geotechnical investigations as well as cultural resources compliance, commenced in early 2004. Under the State's Acceler8 program, the SFWMD prepared a Basis of Design Report (BODR) for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project (otherwise known in Acceler8 as the C-43 West Storage Reservoir). The BODR includes all engineering assumptions and conceptual designs for each of the projects features. Upon reviewing the BODR, the SFWMD will prepare initial, intermediate and final plans and specifications for construction contract award. All design work will be coordinated and reviewed with the USACE to meet USACE standards and regulations.

The project components that will require engineering design includes levees, pump stations, and water control structures such as weirs and culverts, ditches and canals. These elements can be found in standard engineering designs for surface water management systems for agricultural, commercial and residential projects and flood control projects throughout south Florida. These are also standard elements utilized in many water resource and flood control projects constructed by the USACE. Sound engineering judgment, experience gained from past projects and studies, and other published criteria were utilized in the component design.

Although detailed design work remains to be completed, at this stage it has been determined with reasonable certainty that the project components are feasible based upon standard engineering practices.

1.3.1.4.2 Evaluation Tools

System-wide and sub regional computer models were developed to address watershed hydrology, seepage management and reservoir operations for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project. The South Florida Water Management Model (SFWMM) provided the simulated levels for Lake Okeechobee. This system-wide model simulates the water resources system from Lake Okeechobee to Florida Bay. It is used to estimate the hydrologic responses to proposed structural and operational modifications to the water management system in south Florida. The specific details about the system-wide and sub regional models used as evaluation tools as well as the assumptions used and additional modeling can be found in Appendix A of the PIR/EIS.

DRAFT

In formulating and evaluating project alternatives, operational effects of proposed management measures on the existing ecosystem must be considered. To do this, computer simulation models and spreadsheets were used to evaluate the proposed operational criteria for each alternative in terms of its hydrologic influences on potentially affected natural areas.

South Florida Water Management Model (SFWMM) - The most commonly used integrated model in South Florida is the South Florida Water Management Model (SFWMM). The model simulates the hydrology and the management of the water resources system from Lake Okeechobee to Florida Bay covering an area of 7,600 square miles with a mesh of 1.61 km (2 miles) by 1.61 km (2 mile) cells. The SFWMM incorporates current or proposed water management protocols and operational rules and has the ability to simulate water management practices and policies that affect urban, agricultural, and environmental water uses in South Florida in one of its major strengths. Since the boundary of the SFWMM does not extend into the C-43 project area, the SFWMM model can only provide boundary conditions at the point where Lake Okeechobee discharges in to the C-43 Canal (S-77). Therefore, a sub-regional model was needed to simulate the hydraulics and hydrology of the project area.

MIKESHE Model - Hydrologic indicators and hydraulic models were used to evaluate potential affects that could occur in the watershed for average wet season water levels (July 1 to October 1), average dry season water levels (April 1 to May 15), and hydroperiods. The MIKESHE modeling platform was used to develop sub-regional models of the C-43 basin to simulate the hydraulics and hydrology for purposes of showing hydrographs and stage duration curves, water level fluctuations and hydroperiods for selected indicator regions within natural areas associated with each of the alternative plans. These modeling results provide a comparisons between Pre-Development, Existing (2000) conditions, 2050 Without Project conditions, and with project conditions for each of the proposed alternatives for the system wide analysis (with CERP) to identify the selected alternative plan (SAP).

Spreadsheet Analyses - As an additional verification of modeling results used in selection of the SAP, a spreadsheet analysis calculated flow data for the S-79 structure for use in a Next Added Increment (NAI) analysis of each alternative to verify environmental benefits achieved by each plan evaluated.

The source of Caloosahatchee River (C-43 Canal) flow data for the spreadsheet analyses for the Existing Conditions Baseline (2000) and Future Without Project Condition (2050 with no-CERP projects in place) is derived from South Florida Water Management Model (SFWMM) version 5.4.2 base model simulation 2000RD, for the Existing Conditions Baseline and 2050RD model simulation for

DRAFT

the 2050 with no CERP projects in place. Below are key assumptions utilized in these analyses and are consistent with this conceptual intent.

- The spreadsheet will take into consideration the ET losses from the reservoir. The mass balance terms for the reservoir are reservoir inflow, reservoir releases, reservoir seepage (assumed to be zero based on results of the C-43 Test Cell Pilot Project – July 2006), ET losses (based on area volume relationship), and reservoir direct precipitation.
- No agricultural or urban water supply deliveries will be supplied by the reservoir. These demands continue to be supplied from Lake Okeechobee or existing groundwater sources.
- The eastern Caloosahatchee Basin (east of the S-78 structure) will not be affected by the project.
- With the exception of changing flows to the Caloosahatchee Estuary downstream of S-79, there will be no impacts on the Western Caloosahatchee Basin.

Description and interpretation of all model results including a review of the reliability and accuracy of the assumptions and data used in the in the model, as well as risks and uncertainties associated with their use are described further in Appendix A of the PIR/EIS.

1.3.1.4.3 Discussion of New Technologies or Features with Higher Levels of Uncertainty

The Caloosahatchee River (C-43) West Basin Storage Reservoir Project selected plan relies on existing technologies that have proven to be effective in managing and restoring south Florida's water resources. The USACE has extensive experience and reputable credibility in the construction of the types of features recommended for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project. A summary of the project features and associated risks and uncertainties is provided in Table 7.

The risk and uncertainty associated with the construction and operation of these features of the proposed project should be minimal. All features have been designed and constructed through established and applied technology. No experimental design was necessary for any component of the proposed impoundment.

A cutoff wall along the perimeter of the dam embankment is being considered and will be further investigated as the project proceeds to design. For estimating purposes, a 17-foot cutoff wall was included. These use standard technology and should pose minimal risk.

DRAFT

Soil cement protection was included for armoring. This will be further investigated as the team proceeds with the design. Armoring generally uses standard technology and should pose minimal risk.

TABLE 7: SUMMARY OF PROJECT FEATURES AND ASSOCIATED RISK AND UNCERTAINTY

Feature	Risk	Uncertainty
Reservoirs • Armoring • Cutoff Walls • Freeboard	Minimum	Minimum- established and applied technology
Pump Stations	Minimum	Minimum- established and applied technology
Spillways • Emergency Overflow • Vertical Lifts	Minimum	Minimum- established and applied technology
Drawdown Structures	Minimum	Minimum established and applied technology
Culverts	Minimum	Minimum established and applied technology
Canals	Minimum	Minimum- established and applied technology
Earthwork • Filling canals • Plugging culverts	Minimum	Minimum-established and applied technology
Artificial Habitat Creation Oyster substrate	Minimum	Minimum- established and applied technology

A freeboard of approximately 17 feet was used in preparing the rough order of magnitude cost estimates. This value for freeboard was developed by Acceler8 and presented in their March 2006 Draft Technical Memorandum detailing their design assumptions and calculations for freeboard. Based on interagency review of the Draft Memorandum, it is expected that the final freeboard design will be somewhat less than the initial 17 foot assumption. The freeboard design will be further refined in accordance with applicable CERP Design Criteria Memoranda (DCM). These DCMs were developed to provide consistent working level guidance for impoundment design by the Acceler8 teams. The DCMs consolidate and incorporate design criteria from various agency regulations and guidelines including U.S. Army Corps of Engineers, U.S. Bureau of Reclamation, Federal Energy Regulatory Commission, Florida Building Code, and the American Society of Civil Engineers. The DCMs do not supersede Corps of Engineers' regulations. Freeboard designed in compliance with the DCMs, and thusly Corps of Engineers regulations, should result in minimal risk of embankment failure due to overtopping (refer to DCM-2 for additional detail).

Through the Caloosahatchee Watershed plan, lands necessary for the construction, operation, and maintenance of the C-43 West Reservoir have

already been acquired by the SFWMD using funds appropriated to the Department of Interior in Section 390 of the Federal Agricultural Improvement and Reform Act of 1996. As such, there is no uncertainty associated with land availability and acquisition.

1.3.2 Efficiency and Cost Effectiveness

Plan formulation and evaluation for this project focused on management measures and plans developed in prior ecosystem restoration studies (including the Comprehensive Review Study) for the Everglades. All of the prior studies with similar planning objectives (to restore fish and wildlife habitat functions in the remaining Everglades) concluded that additional storage to supplement the regional water management system was needed at the Caloosahatchee River (C-43) West Basin Storage Reservoir Project location, and aboveground impoundments with a seepage management feature were the most cost-effective management measure for creating additional storage.

Cost Effectiveness Analysis - Cost effectiveness analysis begins with a comparison of the costs and outputs of alternative plans to identify the least cost plan for every level of output considered. Alternative plans are compared to identify those that would produce greater levels of output at the same cost, or at a lesser cost, as other alternative plans. Alternative plans identified through this comparison are the cost effective alternative plans. Next, through incremental cost analysis, the cost effective alternative plans are compared to identify the most economically efficient alternative plans. Cost effective plans are compared by examining the additional (incremental) costs for the additional (incremental) amounts of output produced by successively larger cost effective plans. The plans with the lowest incremental costs per unit of output for successively larger levels of output are the "Best Buy" plans. The results of these calculations and comparisons of costs and outputs between alternative plans provide a basis for addressing whether the additional outputs are worth the costs incurred to achieve them.

The cost estimate for the alternatives includes construction, LERRDs (lands, easements, right-of-ways, relocation, and disposal), PED (pre-construction, engineering and design) costs, and construction management. Data for initial construction/implementation, land acquisition, monitoring, and periodically recurring costs for O&MRR&R (operation, maintenance, repair, replacement, and rehabilitation), have been developed through engineering design and cost estimation, and real estate appraisal efforts (See Appendix B of the PIR/EIS for details of data development for cost estimates).

National Economic Development (NED) Costs are expressed in 2007 price levels and are based on costs estimated to be incurred over a 40 year period of analysis.

Costs of a plan represent the value of goods and services required to implement and operate and maintain the selected plan. These costs are included in Table 8 and were used in the cost effectiveness analysis of the alternatives. Based on additional engineering and design that would be performed in the planning, engineering and design phase, Alternative 3C may require modifications to the Townsend Canal and a major road downstream of the impoundments. For this purposes of this planning level cost estimate these costs were not included.

Cost effectiveness and incremental cost analyses were conducted for each of the C-43 alternative plans. The analyses compared the alternative plans' average annual costs against the appropriate average annual habitat unit estimates. The average annual outputs were calculated as the difference between with-plan and without-plan conditions over the period of analysis (through year 2050). CE/ICA was performed using a combination of the following five metrics to represent various ecosystem outputs of the C-43 alternatives:

- Vallisneria
- Oyster
- Seagrass
- EST05
- Extreme Event

Table 8: Cost of Final Array of Alternatives (rounded to the nearest $10,000)

	Alternative 2	Alternative 3B	Alternative 3C	Alternative 4
Cost Component*				
Construction	$285,800,000	$316,900,000	$368,000,000	$464,300,000
S/A	$18,400,000	$20,400,000	$23,700,000	$29,800,000
PED	$23,000,000	$25,500,000	$29,600,000	$37,300,000
Lands	$80,507,000	$80,507,000	$80,507,000	$80,507,000
Initial Cost	$407,707,000	$443,307,000	$501,807,000	$611,907,000
Interest During Construction				
Construction	$26,600,000	$29,500,000	$34,000,000	$43,000,000
Lands	$13,500,000	$13,500,000	$13,000,000	$13,000,000
Total IDC	$40,100,000	$43,000,000	$47,000,000	$56,000,000
Total Project Investment	**$447,807,000**	**$486,307,000**	**$548,807,000**	**$667,907,000**
Average Annual Cost				
Interest & Amortization	**$25,700,000**	**$27,900,000**	**$31,400,000**	**$38,300,000**
Operation & Maintenance	$3,265,000	$3,358,000	$5,267,000	$5,556,000
Total Average Annual Cost	**$28,965,000**	**$31,258,000**	**$36,667,000**	**$43,856,000**

*Note – Final Costs of Selected Alternative Plan will be revised based on additional engineering and design

DRAFT

The total cost of CERP is not included in this cost effectiveness and incremental cost analyses. The cost of the balance of the CERP features, those not included in the C-43 alternatives, is the same for all the alternatives. As such, including it in this analysis does not bring any additional insight or differentiation between alternatives. For this analysis, the difference between the alternatives can be shown through a display of the outputs and costs of each alternative without the cost of the "other CERP" features.

All of the environmental outputs were calculated on an average annual basis to account for the fact that several years may be required for full attainment of the functional capacities to be realized. This was performed for the expected future with and without project habitat units, which were used to calculate the average annual benefits for each ecosystem output. A summary of the average annual lift calculations and average annual costs used in the CE/ICA analysis are provided in Table 9. Alternatives 2, 3B and 3C are all cost effective alternatives. Alternative 3C provides the greatest habitat lift of all the alternatives, and this alternative also has the lowest average cost per unit of output.

Table 9: Results of Cost Effectiveness Analysis

Alternatives	Average Annual Cost ($1,000)	Output	Average Cost Per Output	Cost Effective?
Without Plan	$0	0	N/A	
Alternative 2	$28,965	10,628	$2,725	YES
Alternative 3B	$31,258	12,809	$2,440	YES
Alternative 4A	$43,856	15,907	$2,757	NO
Alternative 3C	$36,667	16,397	$2,236	YES

Note: Freshwater Wetland Habitat Units (HU)
All plans and cost effective plan arrayed by increasing output for each output category.

Incremental Cost Analysis - The initial and final arrays of alternative plans for this project consisted of an aboveground impoundment of varying storage volumes. All other management measures were screened from further consideration as a result of prior studies. Since all of the plans in the final array of alternative plans consisted of the same cost effective management measure, an incremental cost analysis was performed to determine the incremental costs of the benefits produced by the remaining two structural plans.

Incremental cost analysis of the system-wide effects of the final array of plans was performed using IWR Plan software. This analysis was performed for both the next-added (stand-alone) incremental output and the last-added (with-rest-of-CERP) increment output. The output for this analysis was the increase in annual average volume in acre-feet of water retained in the natural system plus

the volume of water stored by the impoundments compared to the future without project condition. The water retention and water storage functions of the project are surrogate metrics for the other environmental outputs affecting the adjacent natural areas (Caloosahatchee River and Estuary).

This analysis is based on and follows guidance from the US Army Corps of Engineers Institute for Water Resources publication, Evaluation of Environmental Investment Procedures Manual, Interim: Cost Effectiveness and Incremental Analyses, May 1995, IWR Report #95-R-1. Costs are based initially on a rough order of magnitude (ROM) and include PED and construction costs, interest during construction, as well as operations and maintenance costs after construction.

Typically, cost effective plans are arrayed by increasing outputs to clearly demonstrate changes in costs (i.e., increments of cost) and in outputs (i.e., increments of output). For comparison purposes, each cost effective alternative plan is compared to the Without Plan condition to determine which of the alternative plans has the lowest incremental costs per unit of output of all plans. This plan is then considered the first Best Buy plan. After the first Best Buy plan is identified, all larger cost effective plans are compared to the first Best Buy plan in terms of increases in (increments of) cost and increases in (increments of) output. The alternative plan with the lowest incremental cost per unit of output (for all cost effective plans larger than the first Best Buy plan) is then considered the second Best Buy plan.

Table 10 present the results of the incremental cost analysis of the different alternative plans for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project (for the respective ecological zones). The results of the analysis show that there is only one best buy plan for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project. From the analysis of incremental cost for all of the alternatives, Alternative 3C provides the greatest Habitat Unit lift while having the lowest cost per unit of output and is considered the First Best Buy for the project.

Average Annual Benefits - The analysis of ecological response times for large, diverse ecosystems is extremely difficult to calculate. For example, when analyzing an estuarine system, certain attributes will have to be examined when predicting the response to changes in salinity. While some species will generally provide responses within a year of salinity change towards normal conditions, others will respond fairly quickly, but are difficult to measure due to changing conditions. To account for this, a linear approach to predict ecological response time was used and it resulted in:

- 80% of the benefits would be realized by 3 years from start of construction,

DRAFT

- 90% within five years after that,
- 100% of the lift would be realized within 10 years of construction.

If nothing was done to improve the conditions in the estuary, the project team determined that the future without condition would experience a gradual improvement for 15 years at which point the ecosystem would stabilize.

Table 10: Results of Incremental Cost Analysis – Cost Effective and Best Buy Plans Arrayed by Increasing Output

	Average Annual Cost ($1000)	Output	Average Cost Per Output ($1,000)	Incremental Average Annual Cost ($1,000)	Incremental Output	Incremental Cost Per Output	Best Buy?
Without Plan	$0	0	N/A	N/A	N/A	N/A	
Alternative 3C	$36,667	16,397	$2,236	$36,667	16,397	$2,236	Best Buy

Cost effectiveness and incremental cost analysis requires a comparison of average annual costs and average annual benefits. In an ecosystem restoration project, the analyses compare the alternative plans' average annual costs against the appropriate average annual habitat unit estimates. The average annual outputs were calculated as the difference between with-plan and without-plan conditions over the period of analysis (through year 2050). Costs used for CE/ICA and outputs used for CE/ICA are displayed in Table 11.

Table 11: Costs and Outputs Used in Cost Effectiveness and Incremental Cost Analyses

	Alternative 2	Alternative 3B	Alternative 3C	Alternative 4
Annual Cost	**$28,965,000**	**$31,258,000**	**$36,667,000**	**$43,856,000**
Average Annual Habitat Units	**10,628**	**12,809**	**16,397**	**15,907**

Note: Values assume system benefits (ecosystem outputs that would accrue to the C-43 study area if rest of CERP is constructed). Values for Alternatives are Differences Between "Without" Plan and "With" Plan (on an average annual basis)

1.4 Determination of Project Consistency with Applicable Laws and Regulations [373.1501(5)(c)]

Section 373.1501(5)(c), F.S. requires the SFWMD to "Determine with reasonable certainty that all project components are consistent with applicable laws and

DRAFT

regulations, and can be permitted and operated as proposed. For purposes of such determination:

1. The district shall convene a preapplication conference with all state and federal agencies with applicable regulatory jurisdiction;
2. State agencies with applicable regulatory jurisdiction shall participate in the preapplication conference and provide information necessary for the district's determination; and
3. The district shall request that federal agencies with applicable regulatory jurisdiction participate in the preapplication conference and provide information necessary for the district's determination."

The following sections form the basis for this determination. Copies of the letters received from agencies with jurisdiction over the various aspects of the project can be found in Annex B of the PIR/EIS.

1.4.1 Pre-application Conference

A pre-application conference was held for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project on March 6, 2007 at the City of LaBelle Civic Center in LaBelle, Florida.

1.4.1.1 Summary of Pre-application Conference

A Pre-application Conference was held on March 6, 2007. The purpose of this meeting was to update the agencies and the public on the schedule for the Project Implementation Report. Although some concern was expressed regarding additional culvert structures requested by Hendry County to assist with local drainage problems, those concerns will be addressed in future detailed design documents, review procedures, and permit processes.

Federal, state and local regulatory agencies attended. Representatives from the following agencies were present:

- U. S. Army Corps of Engineers
- Florida Department of Environmental Protection
- Florida Department of Agriculture and Consumer Services
- Florida Department of Transportation
- South Florida Water Management District

The conference was also open to public, and representatives from the following offices attend:

- Earth Works of Naples

DRAFT

- URS Corporation
- ZFI Engineering and Construction

As a follow up to the Pre-application Conference, each of the agencies was asked in a letter by the District to specify the applicable laws and regulations, and the likelihood that the project components would comply with those laws and regulations. The agencies were also asked to address the following: 1) the applicable permitting requirements administered by that agency; 2) the likelihood of obtaining those permits; 3) other laws administered by the agency which might affect the project; and 4) the likelihood that the projects would comply with those other laws.

In the request, the District acknowledged that the agency responses would be non-binding and non-final agency action, since the Comprehensive Plan components are still undergoing design and review. Nevertheless, the agency responses contribute to the District's reasonable certainty that the project components can be permitted and operated as designed, and will conform to applicable laws and regulations. The FDEP indicated that it did not anticipate any problems with the 373.1501 process, but that determination will be made once the SFWMD submits the 373.1501 State Compliance Report to the FDEP for review. Agency responses are summarized in the following subsections.

The following sections form the basis for this determination. Copies of the letters received from agencies with jurisdiction over the various aspects of the project can be found in the PIR/EIS.

1.4.2 Local Agency Information

All components of the Caloosahatchee River (C-43) West Basin Storage Reservoir Project will need to comply with the Hendry County Land Development Code and all applicable development ordinances. Review of the conceptual design for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project by Hendry County staff indicates that the project will comply, or can be designed to comply with all ordinances and codes administered by the County.

1.4.3 State Agency Information

1.4.3.1 Florida Department of Environmental Protection (DEP)

The Department of Environmental Protection (DEP) has participated actively in the planning and evaluation process directed by the SFWMD and USACE leading to the development of the Comprehensive Plan. Through that process, DEP identified potential permitting obstacles to the implementation of the Comprehensive Plan. DEP will also continue to assign agency staff to work with

DRAFT

the SFWMD and the interagency teams working on ongoing and future detailed planning efforts. Furthermore, to effectively fulfill their responsibilities under the approval process created in s. 373.026(8), F.S. and the criteria for approval listed in s. 373.1501(5), F.S., DEP is continuing to participate with SFWMD staff in the coordination of pre-application conferences and the preparation of information to be submitted to DEP for review and approval. DEP has committed to working with the SFWMD and USACE to issue these permits in a timely manner.

DEP has determined that its Water Quality Standards and Special Projects Program of the Division of Water Resource Management in Tallahassee will have primary responsibility for coordinating their planning and permitting activities associated with CERP components. This will be done in close coordination with the CERP planning and permitting staff in the District Office in Fort Myers.

DEP has reviewed the information presented at the pre-application conferences and have discussed the available information provided to date through the Project Implementation Report process. Based on that review and discussion, it is their initial opinion that with a reasonable degree of certainty, the project components, as currently understood, will be permittable, operable and will comply with relevant laws and regulations.

Achieving water quality standards will be an underlying consideration of the FDEP during the permitting of these project components. FDEP has and will continue to work with the SFWMD and USACE to ensure that surface water discharges and ground water recharge from these components will meet water quality standards and water quality objectives. This position is consistent with both the intent and language of the CERP and the Comprehensive Everglades Restoration Plan Regulation Act (CERPRA) permitting legislation (373.1502, F.S.).

1.4.3.2 Florida Fish and Wildlife Conservation Commission

The FWCC has two areas of regulatory function in the permitting process of the Comprehensive Plan. The first is when construction activities trigger regulations that the FWCC has developed and enforced under Chapter 39 of the Florida Administrative Code. These regulations protect species that the FWCC has designated as endangered, threatened, or of special concern (Chapter 39-027.002 through 39-27.005 of the Florida Administrative Code). These rules protect individuals of listed species, their active nests, their eggs, and their young. The rules do not include habitat protection. The rules would only impact the Comprehensive Plan efforts if the construction or operation activities directly

DRAFT

killed or harmed a listed animal or fish, or if the species were disturbed from their nests such that juveniles were killed.

The second area of permit involvement is an indirect role of commenting when solicited via rules of other agencies that are issuing permits or approvals for projects that have the potential to affect fish and wildlife habitat. The FWCC started this process with information in the CARs found in the Comprehensive Plan documents. SFWMD staff will continue to coordinate with the FWCC to develop satisfactory wildlife-survey methodologies to identify the extent to which listed species may be affected by the individual projects, and if necessary, propose actions to avoid "taking" an individual of a state listed species.

The FWCC has indicated that it supports the goals and concepts of the Comprehensive Plan and anticipates that Caloosahatchee River (C-43) West Basin Storage Reservoir Project is "permittable" pursuant to agency regulations. Furthermore, the FWCC has no indications that it would object to the components being approved via a Comprehensive Everglades Restoration Plan Regulation Act (CERPRA) Permit.

1.4.3.3 Florida Department of State, Division of Historic Resources

The USACE is reviewing information regarding historical properties that might be affected by the Caloosahatchee River (C-43) West Basin Storage Reservoir Project, in compliance with Section 106 of the National Preservation Act of 1966 (PL89-665), as amended in 2000; its implementing regulations (36 CFR Part 800) and the Archeological and Historical Preservation Act of 1974 (PL93-291), as amended.

There are numerous recorded historical properties within Hendry County and there is a possibility that the project may impact known and unknown sites. Investigations to evaluate the cultural resources and high probability areas, which included a literature review, site visit and cultural resource survey resulted in finding no historic or cultural resources were found. This determination was made according to the guidelines established in 36 CFR Part 800 and compliance with Section 106 of the National Historic Preservation Act.

1.4.4 Federal Agency Information

1.4.4.1 U.S. Army Corps of Engineers (USACE)

Based on the current best available information, the proposed project is an integral component of CERP and will be refined and designed, constructed, and cost-shared jointly by the SFWMD and the USACE. As such, the project components should not need federal Clean Water Act 404 permits. However,

DRAFT

should circumstances change to remove this partnership for any of the components and the SFWMD becomes the sole proponent, then 404 permits may be required.

Operation and regulation schedules are to be developed concurrently with the National Environmental Policy Act (NEPA). Each component will be reviewed to assure such compliance, with supplemental NEPA documentation prepared for each component. If the USACE determines during this review that there are no significant impacts for any of the components, the USACE has elected to prepare an Environmental Impact Statement (EIS).

To be eligible for funding, a federal project must comply with all federal laws and regulations. Present understanding is that the final projects will be in complete compliance. The USACE has indicated that based on the present understanding of these project components, the USACE believes that this project will be fully permittable and buildable.

1.4.4.2 U.S. Fish and Wildlife Service (USFWS)

In accordance with Section 7(a)(2) of the Endangered Species Act, the USACE is required to ensure that any action it takes will not jeopardize the continued existence or modify designated critical habitat of federally listed species. The USACE must first make a determination of whether the federal action is "likely to adversely affect" any listed species. If, through informal consultation with the USFWS, the USACE determines that the federal action is "not likely to adversely affect" listed species and the USFWS concurs, then informal consultation is concluded and no further action is required. If the USFWS does not concur with the USACE's determination, the USFWS will request that the USACE enter formal consultation leading to the preparation of a Biological Opinion.

If the USACE determines that the federal action is "likely to adversely affect" listed species, then the USACE will request a Biological Opinion from the USFWS. The USFWS and the USACE then enter formal consultation and the USFWS renders its Biological Opinion.

Additionally, the USACE is required to consult with the USFWS and the appropriate state fish and wildlife agency and seek their views and recommendations on measures to protect, conserve and mitigate for damages to fish and wildlife resources. At this stage of the planning process, the USFWS has provided the USACE with a Planning Aid Report for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project which provides specific recommendations to protect fish and wildlife resources in accordance with the Fish and Wildlife Coordination Act.

DRAFT

The central objective of the Fish and Wildlife Coordination Act (FWCA) is to allow for equal consideration of wildlife resources. Transfer funds have been made available to the USFWS in order to participate in team meetings and workshops scheduled in conjunction with the USACE's planning, implementation, and evaluation process. Funding has also been provided for the USFWS to conduct surveys and investigations necessary to determine impacts of the C-43 project on wildlife resources and to make recommendations to the USACE on measures to prevent loss of or damage to wildlife resources. Recommendations for optimizing opportunities related to the conservation and enhancement of fish and wildlife resources have been provided through the submittal of Planning Aid Letters listed above. A draft CAR has been prepared and is included in Annex A of the PIR/EIS. Additionally, the Florida Fish and Wildlife Conservation Commission (FWC) has been an active participant on this project and have provided a Scoping Letter dated 10 June 2003.

1.4.4.3 Reasonable Certainty that Project is Consistent with Applicable Laws and Regulations and can be Permitted and Operated as Proposed

Based upon these interagency discussions at the Federal, state and local levels, the SFWMD has determined with reasonable certainty that the Caloosahatchee River (C-43) West Basin Storage Reservoir Project is consistent with applicable law and regulations and can be permitted and operated as proposed.

1.5 Reasonable Assurances [373.1501(5)(d)]

Florida Statute s. 373.470(3)(c) states that "Prior to executing a project cooperation agreement with the Corps for the construction of a project component, the District, in cooperation with the Corps shall complete a project implementation report to address the project component's economic and environmental benefits, engineering feasibility, and other factors provided in s 373.1501 sufficient to allow the District to obtain approval under s. 373.026. Each project implementation report shall also identify the increase in water supplies resulting from the project component. The additional water supply shall be allocated or reserved by the District under chapter 373."

Florida Statute s 373.1501(5)(d) states that the SFWMD shall "Consistent with this Chapter, the purpose for the restudy in the Water Resources Development Act of 1996, and other applicable federal law, provide reasonable assurances that the quantity of water available to existing legal users shall not be diminished by implementation of project so as to adversely impact existing legal users, that existing levels of service for flood protection will not be diminished outside the geographic area of the project, and that water management practices will continue to adapt to meet the needs of the restored natural environment."

DRAFT

Key Assumptions for State Compliance Analyses Associated with Reservoir Operations and Spreadsheet Analyses - The conceptual intent of the Caloosahatchee River (C-43) West Basin Storage Reservoir Project is that the reservoir will be operated to supply water to the C-43 Canal (Caloosahatchee River) to maintain desirable salinity levels in the Caloosahatchee Estuary System as measured by flows calculated for the S-79 structure. The following are key assumptions utilized in these analyses and are consistent with this conceptual intent.

- The source of Caloosahatchee River (C-43 canal) flow data for the spreadsheet analyses for the Existing Conditions Baseline (2000) is derived from South Florida Water Management Model (SFWMM) version 5.4.2 base model simulation 2000RD.
- The spreadsheet will take into consideration the ET losses from the reservoir. The mass balance terms for the reservoir are reservoir inflow, reservoir releases, reservoir seepage (assumed to be zero based on results of the C-43 Test Cell Pilot Project – July 2006), ET losses (based on area volume relationship), and reservoir direct precipitation.
- No agricultural or urban water supply deliveries will be supplied by the reservoir. These demands continue to be supplied from Lake Okeechobee or existing groundwater sources.
- The eastern Caloosahatchee Basin (east of the S-78 structure) will not be affected by the project.
- With the exception of changing flows to the Caloosahatchee Estuary downstream of S-79, there will be no impacts on the Western Caloosahatchee Basin.

The operations of the C-43 reservoir focus on meeting estuary hydrologic restoration targets for the Caloosahatchee Estuary. However, the analyses associated with State Assurances will occur at both the system-wide and project levels to confirm there will be no unexpected impacts to existing legal users of water or significant adverse effects on the level of service for flood protection as a result of the project.

System-wide effects – Defined as the hydrologic effects due to the storage, management, treatment, and delivery of water via the C&SF Project occurring outside the immediate project vicinity. The only basin that will be affected by the project is the Caloosahatchee Estuary. Therefore, there are no System-wide effects on existing legal users or existing levels of flood protection.

Project-level effects – Defined as the hydrologic effects occurring within the immediate project vicinity (e.g., natural areas, wetlands, salinity control) or within the features of the project components (e.g., reservoirs, stormwater treatment areas, wellfield recharge distribution canal).

DRAFT

The SFWMD Acceler8 design process evaluated field conditions at the project reservoir site through geotechnical evaluations which were followed by the construction of test cells. The test cells were constructed to determine the seepage potential of the proposed reservoir and to document local project-level groundwater effects. The embankment of test cell one did not contain a cut-off slurry wall, while the embankment of test cell two did contained a cut-off slurry wall designed to contain seepage. Results of the test cells are presented in the C-43 West Storage Reservoir Test Cell Pilot Project, July 2006. In summary, the groundwater levels within the embankment and seepage rates immediately increased upon filling of test cell one, while test cell two (with a cut-off slurry wall) showed virtually no impact to groundwater levels or in the rate of seepage through the embankment.

In addition, sections 6 and 12 in the C-43 West Basin Storage Reservoir Final Basis of Design Report (SFWMD, April 2006) describe the intended purpose and proposed operations of the perimeter canal. The primary operational intent for seepage management is to maintain the water levels in the perimeter canal to preserve existing groundwater levels and to intercept seepage, if any, from the reservoir.

These project-level, site specific investigations have been used to design a project that will have no adverse effects to the localized surface and ground-water resources adjacent to the project reservoir. In addition, modeling and analyses was conducted using the local reservoir MIKESHE model to assist in the design efforts and to evaluate the affects of the reservoir construction and operations on the area adjacent to the reservoir footprint.

Analyses performed to make these determinations are based in part on simulations produced by the SFWMM for the hydrologic period of record of 1965 through 2000. Details regarding these analyses are included in Annex C of the PIR/EIS.

1.5.1 Water Supply Assurance

This section provides sufficient information "reasonable assurances that the quantity of water available to existing legal users shall not be diminished by implementation of project components so as to adversely impact existing legal users," Section 373.1501(5)(a), F.S. Pursuant to Section 373.219, F.S., existing legal users are those that have a consumptive use permit or are exempt from permitting requirements, such as domestic users.

These assurances require a quantification of the amount of water permitted to all existing legal users and used by exempt users within the Caloosahatchee River (C-43) West Basin Storage Reservoir Project area during the PIR process.

DRAFT

This quantification is determined on a system-wide basis by evaluating flows at S-79 simulated by the SFWMM model simulations of the Existing Conditions PIR Baseline (2000 land use, 2007 permitted demands) without project components to the Existing Conditions PIR Baseline with project components to examine the potential impact of the selected plan on the quantity and quality of water for the existing legal users.

The operations for this project focus on reducing detrimental, excess flows from S-79 and providing supplemental flows across S-79 to the Caloosahatchee Estuary to achieve restoration targets in the estuary. The water supply provided to permitted existing legal users, agricultural and urban demands in the Caloosahatchee Basin, will remain the same as before the project. The project will not affect the regional water management system. Therefore, there will be no system-wide impacts as a result of this project on existing legal users.

At the project level, the existing water levels in the area adjacent to the reservoir will be maintained through the operating levels and control structures of the perimeter canals surrounding the project reservoir. Output of groundwater level simulations using the local reservoir-level MIKESHE model were displayed for eleven locations (each represents a 1,500 ft grid cell) around the reservoir shown in Figure 5. For each location modeled, a groundwater stage duration comparison (see Part 1 Federal Assurances section 3, Figures 2 a-k) shows the groundwater levels at or below the land surface (represented as zero on the figures) and the duration of time for the period of record those levels are maintained for the with and without project conditions.

Location 10 (Figure 6) shows an approximate three foot reduction in groundwater elevations between the "with" and "without" project simulations. This location is adjacent to the Roberts Canal, which functions primarily for drainage, and the perimeter canal, which is held at a lower water elevation between two structures, C-43 S-10 and C-43 S-3, located in the perimeter canal. This reduction in water elevation differences across the project footprint will not affect existing legal users. The results of this groundwater analysis show there are not adverse effects to groundwater levels and, therefore existing legal users will not be affected as a result of the project.

With the project in place, portions of the Roberts Canal and Header Canal will become part of the project footprint. To continue to provide an irrigation source to the Bob Paul property, which in existing conditions pumps irrigation water from the Header Canal (via the Townsend Canal), pump station #3 was included as a project component in the reservoir perimeter canal to pump water to the east to the remaining Header Canal assuring the same volume of water is available compared to existing conditions. The Crawford Canal will still be available to the Bob Paul property for drainage and is not affected by the project.

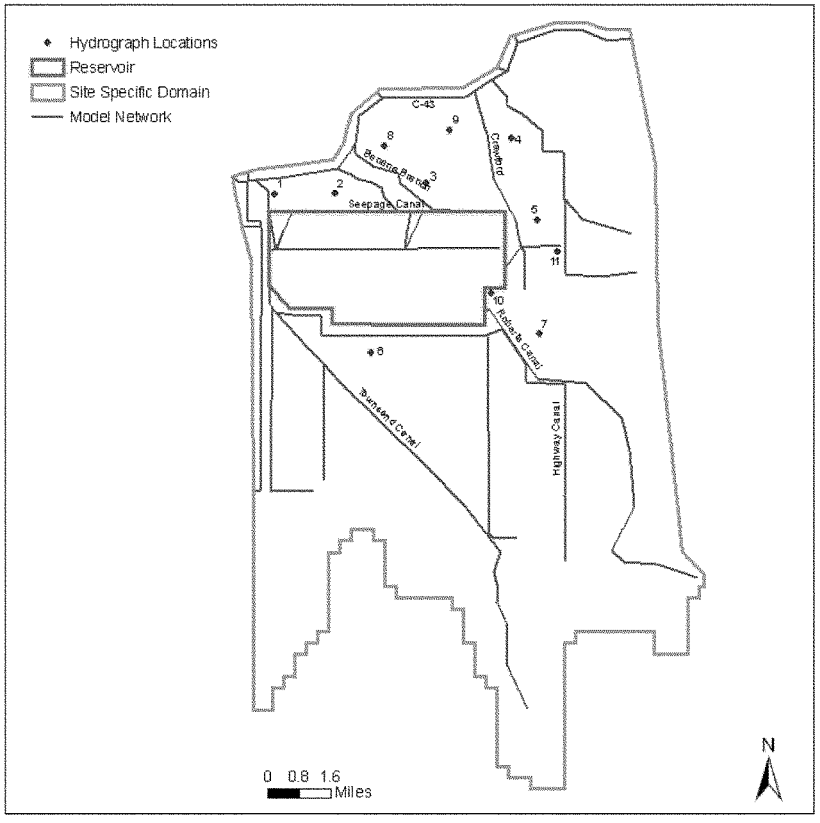

Figure 5: Local Reservoir MIKESHE model boundary outlining the project footprint, local canals and the locations of the simulated groundwater levels for the groundwater hydrographs.

Based on the information contained in this section, the SFWMD is providing reasonable assurances that water supply for existing legal users shall not be diminished through project implementation.

1.5.2 Flood Protection Assurance

An initial analysis of the project's potential impacts on flood protection in the C-43 basin was conducted by reviewing and analyzing the following information:

- Historic stage/discharge relationships;
- Existing groundwater data;
- Canal water surface profiles (with and without the project); and
- Project design and operations;

As a result of this review and analysis, initial recommendations were developed for operational and/or structural changes to the plan necessary to mitigate potential adverse impacts on flood protection associated with project implementation.

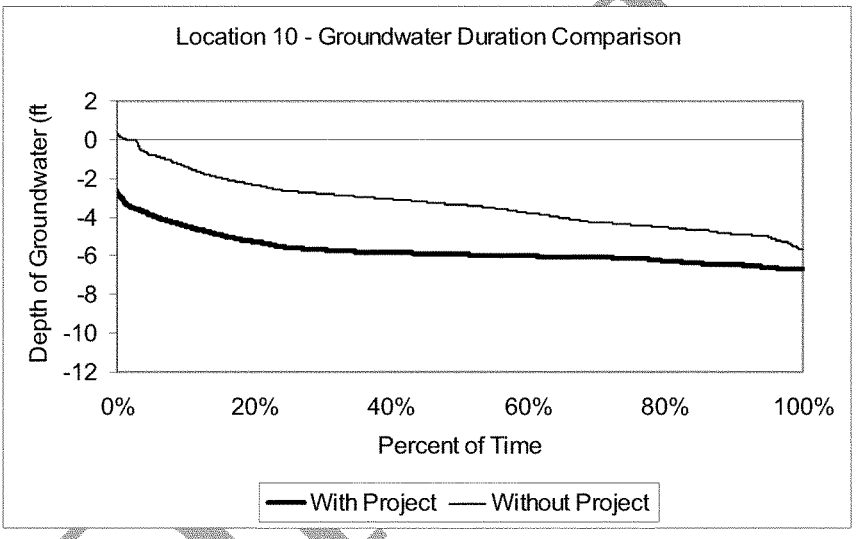

Figure 6: Depth to groundwater level for with project and without project at Location 10

The intent of the level of service analysis for flood protection, required by WRDA 2000 and the CERP Programmatic Regulations as well as Florida State law regarding the implementation of CERP, is to ensure that CERP components do not negatively impact existing levels of service for flood protection.

The operations of this project will not change the operations of the C-43 Canal based on the key assumptions outlined in the Federal Assurances and Savings Clause Analysis, Section 8.4. Therefore, there will be no system-wide effects on flood protection as a result of the project.

Operating levels of the seepage canals and canal structures surrounding the reservoir will be refined to maintain existing groundwater levels adjacent to the

project. In addition, results from the local reservoir-level MIKESHE modeling and the test cell pilot project indicate a boundary slurry wall within the embankment will prevent seepage out of the reservoir and minimize impacts to groundwater levels.

Of the eleven locations (see Figure 5) evaluated using the MIKESHE model, the only location where simulated groundwater elevations increased compared to the without-project conditions was north of the project (Figure 7). Simulated "with project" groundwater elevations increased slightly compared to the "without project" condition. The greatest difference was during the dry period (e.g., 1981) not the wet periods. This minor effect can be addressed through further refinement of perimeter canal control structure operations for the project. The remaining ten locations show no to very little differences in groundwater elevations.

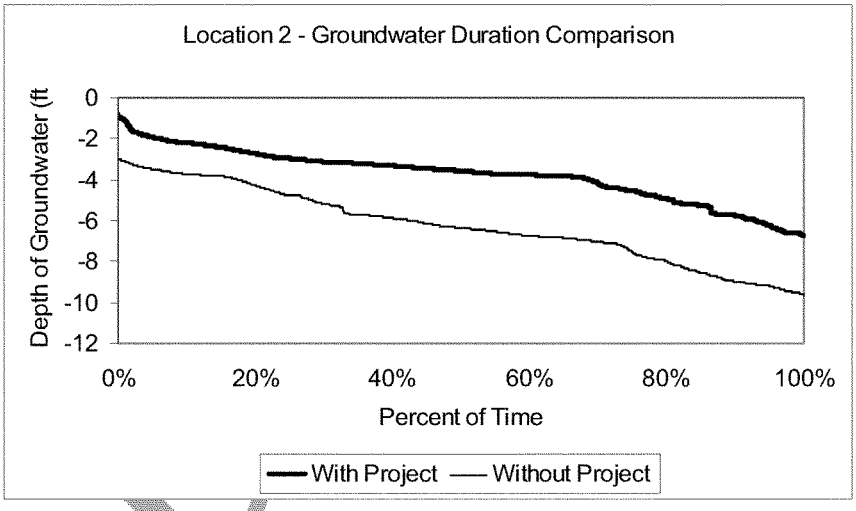

Figure 7: Depth to groundwater level for with project and without project at Location 2

Based upon this information, the SFWMD is providing reasonable assurance through structural and operational modifications that existing levels of service for flood protection will not be diminished through implementation of the Caloosahatchee River (C-43) West Basin Storage Reservoir Project.

Adaptive Management to Meet the Needs of the Restored Natural Environment

Based upon the procedures outlined for the planning process, adaptive water management practices were utilized during the modeling runs and the development of the Caloosahatchee River (C-43) West Basin Storage Reservoir Project selected plan. Along with standard engineering practices and procedures for the detailed design and the establishment of the Restoration Coordination and Verification (RECOVER) process, adaptive water management practices will continue throughout plan implementation. These practices and procedures will ensure that the Caloosahatchee River (C-43) West Basin Storage Reservoir Project will contain the most efficient and cost effective components to meet the needs of the restored natural environment and human environment. The project which is the subject of this report has been a part of past procedures and will be a part of future procedures to maintain this assurance.

Adaptive management (AM) consists of an active strategy for dealing with the considerable uncertainties that characterize management of large natural ecosystems, which are complex and difficult to predict. The overall purpose of AM is to maximize the chance of success and includes methods, such as proactive approaches to dealing with uncertainties, the use of modern ecosystem science and scientific practices, active collaboration, and the use of open, inclusive, and integrative processes.

Five key principles help implement this approach to adaptive management:

1. Anticipate future uncertainties and contingencies
2. Employ science-based approaches to build knowledge
3. Design robust projects that can be adapted to changing conditions
4. Build a shared understanding through collaboration and conflict resolution
5. Reconcile competing objectives to benefit both nature and society

The C-43 project is a component of the CERP, which consists of sixty-eight (68) major components. The uncertainty associated with a program of this magnitude was recognized during the Restudy, which led Congress to address the necessity of AM in the Water Resources Development Act of 2000.

As such, a fundamental implementation principle for CERP is to utilize adaptive assessment and management in order to continually refine and improve the performance of CERP projects so that planned benefits are attained. Incremental revisions of optimal project designs and project operations throughout the planning and implementation process will lead to improved performances. The use of the adaptive assessment policy minimizes the effects

DRAFT

of uncertainty with respect to the effects of CERP projects on the natural system and other water-related needs of the region related to the design and implementation of the CERP.
The measurement of benefits attributable to CERP projects must consider individual outputs as well as system-wide interdependencies among projects. This evaluation methodology applies to hydrologically linked projects that operate optimally in a synergistic fashion. Therefore, until other CERP projects are implemented, some benefits may not be realized. Moreover, interim and long-term impacts will be largely determined by implementation of CERP components and operational strategies. Regional evaluations will be used to improve information necessary to predict and assess shortfalls attributable to sequencing issues versus shortfalls in performance.

The project team considered the uncertainty in the estimation of habitat unit values for the various alternatives and how would ecological outputs respond over time, and how do continued high Lake Okeechobee inflows and runoff volumes affect outputs over time. Consideration of "if" and "when" other CERP components were constructed were also considered in the estimate of ecological outputs, demonstrating the sensitivity of Caloosahatchee Estuary outputs to the construction of other CERP components.

As part of the AM process, careful flow monitoring will occur to evaluate the ability of any implemented features to meet the performance measures. In addition, biological response data will be collected for use in further refining the performance measures, project operations, and system understanding. The next added increment analysis showed that essentially all of the estuary outputs would still be produced by the C-43 Basin project even if other CERP projects were never constructed. This same analysis also indicated that no other alternative performed more cost effectively than the recommended alternative (Alternative 3C) when other CERP project were not constructed. Furthermore, cost effectiveness analysis indicated that the various alternatives were sufficiently separate and distinct so that relatively large changes in either cost or output would be required before an alternative would appear to be the superior.

Coordination with Existing Utilities and Public Infrastructure [373.1501(5)(e)]

Section 373.1501(5)(e), F.S. requires the SFWMD to "Ensure that implementation of project components is coordinated with existing utilities and public infrastructure and that impacts to and relocation of existing utility and public infrastructure are minimized."

1.6.1 Summary of Utilities Within the Project Area

This project is located south of the Caloosahatchee River in a rural area developed in citrus groves east of the City of LaBelle in Hendry County. It is south of State Road 80, a major state road that is designated on the Strategic Intermodal System (SIS). This road serves as a major evacuation and commerce route in and out of Southwest Florida.

There are very few local roads within the project area. These roads will be abandoned and removed as part of the Project.

The only power lines that exist within or immediately adjacent to the Caloosahatchee River (C-43) West Basin Storage Reservoir Project area are local distribution lines that served residential and commercial land uses that have since been acquired for the projects. All the other distribution lines will either be removed or upgraded, once it has been determined which ones need to remain to provide either interim construction and/or permanent operational power for the projects' facilities.

Since telephone lines are co-located with the FPL electrical power lines, removal and relocation of telephone lines due to the construction of the Caloosahatchee River (C-43) West Basin Storage Reservoir Project is approximately the same as described above for electrical lines.

1.6.2 Summary of Coordination Efforts with Existing Utilities and Public Infrastructure

Meetings with the other utilities and local governments have been held, as needed, over the years to discuss specific project features and potential impacts on the utility or local government facilities/infrastructure. Follow up meetings will continue to provide an update on project schedules, design analysis to date, and related topics and to discuss actions needed to resolve any remaining issues.

1.7 Increased Water Supply Available from Project [373.470]

1.7.1 State Requirements

Section 373.470, F.S., requires that the PIR identify the increase in water supplies resulting from the project components and that the additional water be allocated or reserved under Chapter 373, F.S.

Identification of water for the natural system is based on the concept of water needed to achieve the benefits of the project and the overarching objective of restoration, preservation and protection of the South Florida Ecosystem. The

DRAFT

water made available for the natural system is the water made available that contributes to meeting hydrologic, water quality, and ecologic targets for restoration of natural systems. In the case of the C-43 Storage Reservoir Project the only inflow basin affected by the project is the Caloosahatchee Estuary. The primary functions of the reservoir are two-fold: 1) to capture excess basin runoff and discharges from Lake Okeechobee during periods of high flow, and 2) to provide an additional source of water to maintain desirable salinity in the Caloosahatchee Estuary during low flow periods. Therefore, the analysis associated with identifying water made available by the project will focus on the project's effects on the Caloosahatchee Estuary.

There will be no water made available for other water related needs by the reservoir and all water made available by the project is for the natural system. The operational assumptions of the C-43 reservoir focus on meeting estuary hydrologic restoration targets for the Caloosahatchee Estuary.

Since the estuarine system is not in need of additional fresh water during wet periods, the analysis of water made available for the natural system focused on the additional water delivered from the reservoir to the C-43 Canal and Caloosahatchee Estuary during low flow periods. A hydrologic target for the natural system (flow at S-79) was utilized to identify the quantity of water that is required to meet estuary restoration objectives, in contrast to water which may be harmful or otherwise not contribute to the estuary restoration targets.

Summary of the Analytical Method Used to Identify Water Made Available - To identify water made available by the project, a simplified spreadsheet analysis of the C-43 Reservoir Project was produced based on the capture of excess flow over S-79, which was derived from the SFWMM simulation of the 2000 base conditions. The spreadsheet analysis evaluated the 2000 condition with and without project and incorporated the operational assumptions.

The spreadsheet analysis is centered on a water budget equation for the reservoir. Equations are based on conservation of mass and relate the inflows to the reservoir and the outflows from the reservoir to the change in storage in the reservoir over some fixed time scale. The spreadsheet calculated the daily change in storage and associated water surface elevation, both of which are considered in determining fill and release operations in subsequent time steps. Then the spreadsheet created an updated flow over S-79 that reflects the changes to the original flow resulting from reservoir fill or release activities.

The focus of the spreadsheet analyses is the modification or adjustments of flow over S-79 with the intent of improving the salinity distribution in the downstream estuary. The spreadsheet however, has no salinity or ecological component and relies on a hydrologic surrogate to infer improved performance.

DRAFT

The hydrologic surrogate used is the flow over S-79 and its ability to achieve, or trend towards, an estuary flow target time series (EST05) which has been demonstrated to be a restoration time series that would result in optimal habitat conditions for several indicator species in the Caloosahatchee Estuary.
In this spreadsheet analyses to identify the variability of water made available by the project for the natural system, inflow volume probability curves will be calculated and presented as total annual cumulative inflow into the Caloosahatchee Estuary. The data presented are the daily numbers summed to yield an annual volume.

As a means to display achieving or trending toward the estuarine salinity targets, EST05, as a whole and quantifying other desirable matches to portions of the restoration flow series, two graphics were generated from the spreadsheet calculations for both the 2000 existing condition "without project" or base condition and the "with project" condition.

1. **Volume probability curves** - Plot of flows in acre feet over S-79 that help meet the EST05 restoration time series for the "with" and "without" project conditions

2. **Water made available by the project** – the increase in water released by the project are described as the percentage of time that flow is less than or equal to the target restoration flow series, EST05, by ranking and plotting the flow over S-79 of the "with" and "without project" conditions.

Volume probability curves - For purposes of identifying the water made available by the project for the natural system, volume probability curves representing total annual cumulative inflows were produced depicting the range of the quantities of water delivered to the Caloosahatchee Estuary through S-79 under all climatic conditions simulated by the period of record. This period includes sufficient climatological variability (including natural fluctuations of water) to be representative of long term hydrologic conditions in the region.

The identification of the water made available in the existing condition and water made available with the project will be determined by comparing the inflow volume-probability curves for the "with" and "without" project conditions. To determine the quantity of water for the natural system in the Caloosahatchee estuary, the EST05 salinity envelope was used to determine the portion of water that is needed, to meet the restoration targets of the estuary. In both the with and without project condition, the quantities of water made available for the estuary as a result of the project will be displayed using volume probability curves.

DRAFT

Water Made Available by the project - After the quantities of water needed to help meet restoration targets have been identified and displayed using volume probability curves, the increase in water made available for the project. The increase in water made available will be derived from annual difference between the 2000 "without" project" condition or the base and the 2000 "with project" condition flows to trend towards the estuarine targets. The results will then be sorted, ranked (from greatest to least), and plotted as a difference curve.

1.7.2 System-Wide Effects

The only basin that will be affected by the project is the Caloosahatchee Estuary. Therefore, there are no System-wide effects.

1.7.3 Caloosahatchee River (C-43) West Basin Storage Reservoir Project Effects

A graphical comparison of how the project trends towards meeting the Caloosahatchee Estuary salinity restoration targets for the "with" and "without" project conditions is shown by the volume probability curves (Figure 7) below. This graphic contains three volume probability curves. The period of record salinity target flows (EST 05) were plotted for comparison of both the "with" and "without" project conditions to show project trends towards meeting restoration targets. The graph displays the relative increase in water made available by the project. It should be noted that the y-axis for this graphic indicates acre-feet per day. A summary of the total water made available by the project is provided in Annex C of the PIR/EIS.

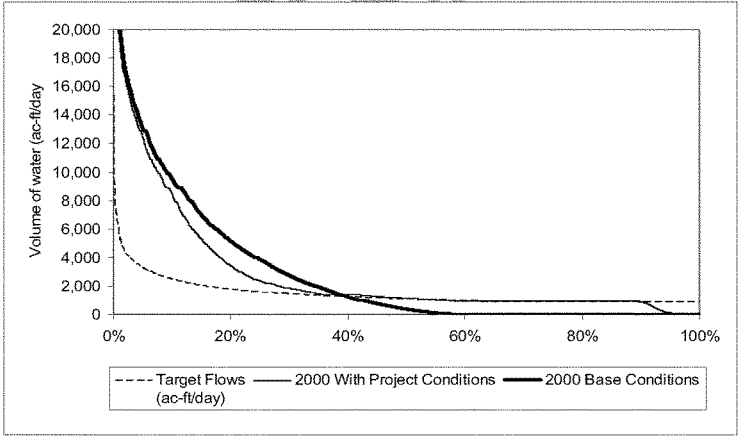

Figure 7: Volume probability curves of water made available for the 2000 Existing Conditions without and with the project

Water Made Available by the Project for the Natural System - The increase in the quantity of the water made available by the project was plotted showing the variability of the water made available for the natural system by the project (Figure 8).

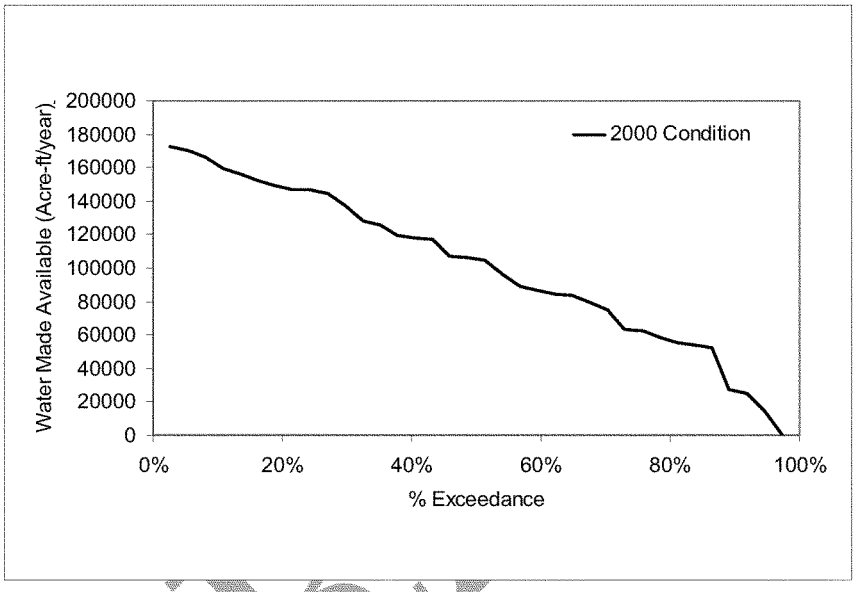

Figure 8: Water made available by the project for the natural system

1.7.4 Water for Other Water-related Needs of the Region

There will be no in water supplied by the project for agricultural and urban needs by the reservoir. All water made available by the project is for the natural system. The operational assumptions of the C-43 reservoir focus on meeting estuary hydrologic restoration targets for the Caloosahatchee Estuary.

D.0 DRAFT PROJECT OPERATING MANUAL AND MONITORING PLAN

D.1 PROJECT OPERATING MANUAL

The main purpose of a draft project operating manual is to describe day-to-day water management operations for essentially all foreseeable conditions affecting the Caloosahatchee River (C-43) West Basin Storage Reservoir project as developed for the Project Implementation Report/Environmental Impact Statement (PIR/EIS) Phase. Modifications to this project operating manual may occur during the remaining project phases (Construction, Operational Testing and Monitoring, and Long-Term Operations and Maintenance). Operating manual preparation is pursuant to Engineering Regulation 1110-2-240 and is in accordance with guidance contained in Engineering Manual 1110-2-3600, Engineering Regulation 1110-2-8156, and CERP Programmatic Guidance Memorandum #5, "Operating Manuals."

The Fill Phase for the reservoir will follow the Initial Reservoir Fill Plan, which will be developed during design and construction.

All elevations referenced in this draft POM are based on the North American Vertical Datum of 1988 (NAVD 1988) unless otherwise noted.

D.1.1 GENERAL PROJECT PURPOSES, GOALS, OBJECTIVES, AND BENEFITS

The purpose of the Caloosahatchee River (C-43) West Basin Storage Reservoir project is to address the declining health of the Caloosahatchee River and estuarine ecosystem by improving water delivery to the estuary. The project will increase the availability of water for the estuarine system during the dry season while reducing excessive high flows during the wet season. This will result in providing a downstream salinity range suitable for a healthy ecosystem that promotes estuarine habitat, increased fish and wildlife populations, and biological diversity.

D.1.2 PROJECT FEATURES

D.1.2.1 Existing Features

(See ***Figure A-1*** of the Engineering Appendix for a map of proposed project features)

1. Structure 77 (S-77). This structure is a reinforced concrete, gated spillway with discharge controlled by four cable-operated vertical lift gates. Operation of the gates is manually controlled. The structure is located on Lake Okeechobee and is the outlet to the Caloosahatchee River (C-43 Canal). The purpose of S-77 is to provide control of regulatory discharge from Lake Okeechobee to the

Caloosahatchee River. In addition, S-77 restricts discharge during floods to levels which will not cause damaging velocities downstream, and passes sufficient discharge during low-flow periods to maintain stages and to satisfy irrigation demands downstream.

Approximately 530 ft west of S-77 is the Moore Haven Lock. The lock serves to facilitate navigation. In addition, the upper gates of the lock also serve as hurricane gates; the structure is designated as Hurricane Gate No. 1 of the Lake Okeechobee levee system.

2. Structure 78 (S-78). This structure is a reinforced concrete, gated spillway with discharge controlled by two cable-operated vertical lift gates and two tainter gates. The structure is located in Glades County, near Ortona, Florida. S-78 is in the existing by-pass channel adjacent to the Ortona Lock. The Ortona Lock is also part of the Lake Okeechobee Waterway. The purpose of S-78 is to maintain optimum upstream water stages in the Caloosahatchee River (C-43 Canal). S-78 also controls discharges during 30 percent standard project flood events without exceeding desirable stages, and passes lake regulatory releases without exceeding desirable stages or velocities.

3. Structure 79 (S-79). This structure is a reinforced concrete, gated spillway with discharge controlled by eight chain-operated vertical lift gates and a reinforced concrete lock with two sets of sector gates. The lock, W.P. Franklin Lock, is located south and adjacent to S-79. The lock is also part of the Lake Okeechobee Waterway. Operation of one of the spillway gates is automatically controlled to ensure the gate is operated in accordance with operational criteria. S-79 is located on the Caloosahatchee River (C-43 Canal) about 30 miles west of S-78 and about 7 miles upstream of the Caloosahatchee Estuary. The purpose of S-79 is to maintain optimum upstream water stages between 2.8 and 3.2 National Geodetic Vertical Datum of 1929 (NGVD) in the Caloosahatchee River (C-43 Canal).

4. Townsend Canal. The canal will serve as an intake and discharge canal to the reservoir. The Townsend canal borders the western side of reservoir cell 1. Currently, the canal has a flap gate weir structure to provide flood conveyance for the citrus operations south of the reservoir. In 2003, SR 80 bridges were replaced which allowed for increased flow in the Townsend Canal. Two additional flap gates will be installed on the flap gate weir structure to provide capacity for pumping rates of 1500 cfs at C43PS-1. In addition, the canal provides irrigation water during the dry season for citrus production on the following properties: Berry Groves, Griffin, and the MG Paul & Duda Property (all in ownership of SFWMD—South Florida Water Management District). Upon completion of construction, proposed pump station, C43-4 will provide water supply to adjacent landowners.

D.1.2.2 Proposed Features

(See ***Figure A-1*** of the Engineering Appendix for a map of proposed project features)

1. Caloosahatchee River (C-43) West Basin Storage Reservoir. This will be a two-celled reservoir designed to contain approximately 170,000 acre-feet of storage. Cell 1 will be located in the western portion of the reservoir; Cell 2 is the eastern portion. The purpose of the reservoir is to improve water deliveries to the estuary, provide for dry season flow, reduce magnitude of wet season high volume flows, restore downstream salinity levels and ensure the availability of water for the natural system needs of the Caloosahatchee Estuary.

2. Pump Station 1(C43PS-1). This will be a 1500 cfs (cubic feet per second) capacity pump station that will provide inflow to Cell 1of the reservoir. C43PS-1 will consist of two 250 cfs pumps and two 500 cfs pumps. C43PS-1 will pump water from the Townsend Canal (intake canal) to the reservoir. All pumps are diesel powered. C43PS-1 will be located in the northwest corner of the reservoir.

3. Perimeter Canal. This canal is adjacent to the reservoir on the south, east, and north sides. The Townsend Canal serves as the "Perimeter Canal" on the west side. The Perimeter Canal will provide the following:
   - Route drainage around both the reservoir and the Roberts Canal
   - Provide water to the Paul property, Banana Branch, and the Fort Simmons Branch
   - Minimize water table impacts to land surrounding the reservoir
   - Collect any seepage from the reservoir

4. Pump Station 4 (C43PS-4). This will be a 195 cfs capacity pump station that will maintain the stage in the Perimeter Canal for seepage control and to maintain pre-project water supply to the neighboring landowners. The purpose of the C43S-4 is for water supply to the neighboring landowners and to maintain the stage in the Perimeter Canal for seepage control. The C43PS-4 site will be adjacent to the southwest corner of the reservoir at the southern limit of SFWMD property. The C43PS-4 discharge will be conveyed to the Perimeter Canal through a conveyance canal paralleling the toe slope of the reservoir embankment.

   The following are assumed for the design of C43PS-4:

   - Normal Dry Season Stage; 0.0 ft
   - Design Low Water Stage: -3.0 ft

- Design High Water Stage: +3.0 ft
- Design Upper Pool Stage: +23.5 ft

5. Perimeter Canal. This canal is adjacent to the reservoir on the south, east, and north sides. The Townsend Canal serves as the "Perimeter Canal" on the west side. The Perimeter Canal will provide the following:
   - Route drainage around both the reservoir and the Roberts Canal. The Roberts Canal/Banana Branch Canal traverses through the Berry Grove and discharges downstream into the Caloosahatchee River. The reservoir bisects the Roberts/Banana Branch Canal; therefore, flow from the Roberts Canal will be re-routed through the perimeter Canal and discharged to the Banana Branch Canal through C43S-7.
   - Provide water to the Bob Paul property to the east, Banana Branch, and the Fort Simmons Branch
   - Minimize water table impacts to land surrounding the reservoir
   - Collect any seepage from the reservoir

6. Discharge Structure 1 (C43S-1). This structure is the main outflow structure for Cell 1. This structure will be located in the northwest corner of the reservoir in Cell 1. C43S-1 will discharge into the northern segment of the Perimeter Canal

7. Discharge Structure 8 (C43S-8). This structure is the main outflow structure for Cell 2. This structure is located in the northwest corner of the reservoir in Cell 2. C43S-8 will discharge into the north Perimeter Canal

8. Uncontrolled Crest Spillway 1 (C43CS-1). This structure is located on the west side of Cell 1 and discharges into the Townsend Canal The purpose of C43CS-1 is to discharge Cell 1 water when Cell 1 water level exceeds 42.0 ft.

9. Uncontrolled Crest Spillway 2 (C43CS-2). This structure is located in the northwest corner of Cell 2, just east of C43S-8. Like C43CS-1, the purpose of C43CS-2 is to discharge Cell 2 water when Cell 2 water level exceeds 42.0 ft.

10. Culvert 12 (C43S-12). This structure is located in the interior berm between Cells 1 and 2 of the reservoir. C43S-12 will convey half the C43PS-1 pump capacity of 1500 cfs. C43S-12 will consist of three 6ft x 10 ft barrels. If one barrel of the structure is out of service the other barrels will convey 750 cfs between the cells .The primary function of the structure is to convey water between the cells and allow the cells to operate independently if necessary. If one of the cells needs to be dewatered for maintenance, C43S-12 may be closed to isolate the cells

11. Culvert 3 (C43S-3). This structure is located in the southeast portion of the Perimeter Canal. C43S-3 will consist of a double-barrel 10 ft x 10 ft box

culvert. One barrel will have an independent intake structure consisting of a 10 ft x 10 ft sluice gate and the other barrel will have a 10 ft x 10 ft weir gate with allowance for a 5 ft high weir opening. The purpose of the weir gate is to maintain a constant water surface elevation of 23.5 ft upstream of C43S-3 and pass the base flow of 28 cfs. The weir gate is capable of passing the peak design flow of 195 cfs which is the flow pumped via C43S-4, plus base flow (seepage) of 28 cfs should the sluice gate be removed for maintenance. This is also true should the weir gate be removed from service. Redundancy was incorporated into the C43S-3 design to allow the peak design flow to pass even if one of the gates is removed from service for maintenance.

12. Spillway 10 (C43S-10). This structure is located on the northern segment of the Perimeter Canal. C43S-10 will be a concrete spillway with one 14 ft x 10ft vertical roller gate and two 10ft x 10ft weir gates to control flow within the Perimeter Canal. Note the design flow received by the Perimeter Canal from the Roberts Canal will be conveyed and discharged into the Banana Branch Canal reaching to C43S-10.

    The Perimeter Canal between C43S-3 and C43S-10 has a varying channel bottom elevation. Tailwater elevation during normal water levels (NWL) at C43S-3 and C43S-10 is 19 ft. During HWL the tailwater at both of these structures is 15.5 ft.

    The vertical roller gate alone, or in combination with the weir gates, is capable of handling the flows required to achieve drawdown. The vertical gate can fully manage the required drawdown discharge with a gate opening of 3.1 ft during NWL conditions. In the event of high water conditions, the gate opening would be approximately 3.6 ft, since the gate is operating under submerged controlled flow conditions.

13. Spillway 11 (C43S-11). This structure is the largest of the Perimeter Canal structures. C43S-11 consists of a reinforced concrete spillway with two 14 ft W x 8 ft H vertical roller gates and two 10 ft x 8 ft weir gates to control flow through the Perimeter Canal, ultimately to the Townsend Canal. Unlike C43S-3, and C43S-10, and C43S-11, has limited redundancy. Should a vertical roller gate be removed from service, the weir gates provide a discharge capacity that is less than normal daily operations.

    The two proposed weir gates, in addition to the vertical roller gates, will be capable of discharging up to the normal daily discharge flow of 500 cfs should a vertical roller gate be removed for service. The weir gates will be set to maintain a water elevation of 15 ft upstream of C43S-11.

14. Culvert 7 (C43S-7). This structure is double barreled with a weir set for normal operations and a gate for larger releases during storm events. This culvert will be constructed to prevent flooding and to maintain historic flows in the Fort Simmons Branch Canal (located north of reservoir) that are necessary to maintain existing environmental conditions.

    C43S-7 is located at the intersection of the upstream end of Banana Branch Canal and the Perimeter Canal. It consists of a double 10 ft x 10 ft box culvert with one sluice gate and one weir gate. The headwater elevation for NWL is 19.25 ft and 20 ft for HWL. Tailwater elevation for NWL is 15.1 ft and 18.5 ft for HWL. With an invert elevation of 12 ft, the HWL conditions are contained within the box culvert height.

15. Culvert 9 (C43S-9). This structure is a double-barreled 6ft W x 6ft H box culvert that conveys flow from the Perimeter Canal to the Fort Simmons Branch Canal which discharges into the Caloosahatchee River. Inlet control used for C43S-9 is a sluice gate and a weir gate. The weir gate is used to allow base flow to pass. The sluice gate is used to pass design flows greater than the base flow. C43S-9 has no redundancy; therefore, maintenance of the sluice gate would require special consideration and must be done during low flow periods. Therefore, both gates must be operational to convey flows greater than base flow.

16. Culvert 14 (C43S-14): This structure is a 10ft W x 6ft H single barrel box culvert with a sluice gate which conveys water from the LPDD Header Canal to the Perimeter Canal to serve the Bryan Paul Property.

    The tailwater elevation for this structure is the tailwater elevation for C43S-10 which is 19 ft for NWL and 20 ft for HWL. HWL flow from the header canal will be contained within the box culvert. The flow regime for discharge from C43S-14 is between ***Submerged Controlled Flow*** and ***Free Controlled Flow*** as tailwater, which is roughly 0.5 ft above the gate sill, and has a limited effect upstream of C43S-14.

17. Culvert 15 (C43S-15): The Roberts Canal/Banana Branch Canal traverses through the Berry Grove and discharges into the Caloosahatchee River. The reservoir bisects the Roberts/Banana Branch Canal; therefore, flow from the Roberts Canal will be re-routed through the Perimeter Canal and discharged to the Banana Canal through C43S-7. The Roberts Canal discharges into the Perimeter Canal downstream of C43S-3. Flow from the Roberts Canal is conveyed through C43S-15 which consists of a double 10 ft x 8 ft box culvert with an independently operated sluice gate and weir gate.

D.1.2.3 Removed Features

There are many small structures within the reservoir footprint that will be removed or demolished. Most of these are small pump stations. Several larger pump stations along the Labelle Private Drainage District (LPDD) Header Canal will also be removed. This includes the 340 cfs Berry Groves No. 1 and No. 2 pump stations that lift water from the Townsend Canal to the Header Canal (the Header Canal bisects, from east to west, the reservoir). However, the Berry Groves No. 1 and No. 2 pump stations in the Header Canal cannot be removed until C43S-4 and the Perimeter Canal are constructed and operational. This is to ensure that a continuous supply of irrigation water can be provided to the Bob Paul Properties.

D.1.3 PROJECT RELATIONSHIPS

Project operations will be dependent upon the stage in the Caloosahatchee River upstream of S-79, Lake Okeechobee, the conditions at S-77, S-78, S-79, and the estuary. All of these locations are affected primarily by seasonal and short-term hydrologic and climatic conditions.

S-77, S-78, and S-79 are operated by the U. S. Army Corps of Engineers (USACE) based on the current Water Control Plan for Lake Okeechobee and Everglades Agricultural Area (USACE, July 2000). The water control plan contains the Lake Okeechobee regulation schedule referred to as WSE (Water Supply and Environmental), and was developed to provide increased operational flexibility, and to optimize environmental benefits with minimal or no impact to competing Lake Okeechobee uses. WSE incorporates tributary hydrologic conditions and climate forecasts into operational guidelines. The WSE regulation schedule is used in conjunction with the Operational Guidelines Decision Tree. Refer to ***Figure D-1*** and ***Figure D-2*** for details.

The WSE schedule has multiple operational Zones (A through E) which correspond to Lake Okeechobee stages throughout the calendar year. (Refer to ***Figure D-3*** for details.) The WSE schedule uses a decision tree that indicates whether or not regulatory releases are required. Discharges at higher lake stages (Zones D and above) are determined based on meteorological forecasts, the effects of climate outlooks on the ecosystems, and review of regional hydrologic conditions. Technical information is provided by an interdisciplinary group of scientists, engineers, and resource managers, while release decisions are made by USACE in accordance with WSE guidelines (USACE 1999). However, the current schedule has required the USACE to deviate on occasion from the WSE. Therefore, in an effort to improve the regulation schedule, an effort to improve the regulation schedule (the Lake Okeechobee Regulation Schedule Study (LORSS)) is currently well underway. A draft Water Control Plan and Environmental Impact Statement was released for public and agency

review in October 2006. A revised draft was released to the public and agency review in July 2007.

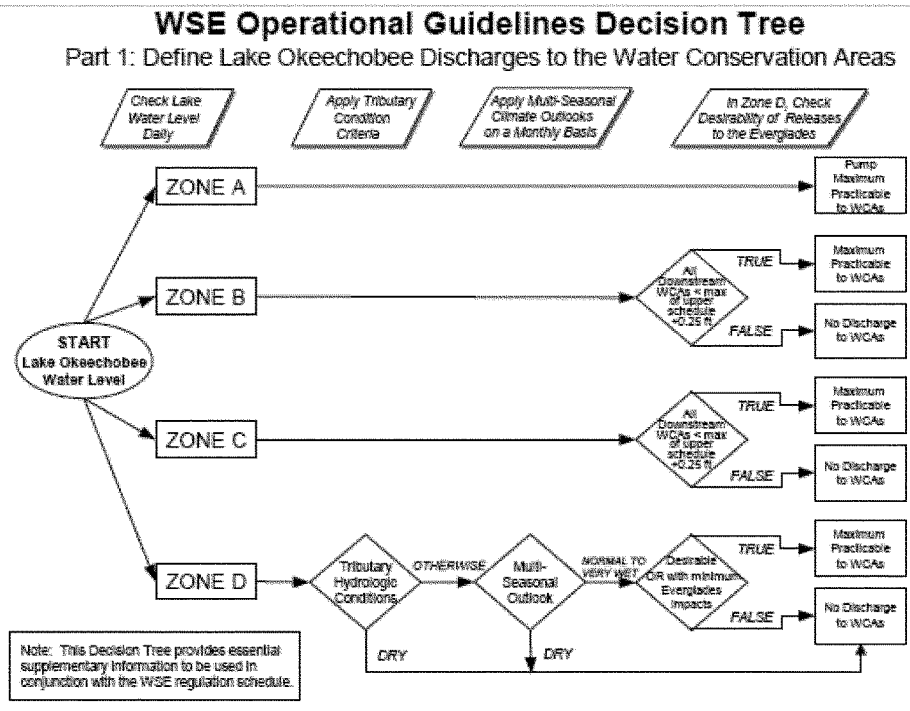

FIGURE D-1: WSE OPERATIONAL GUIDELINES

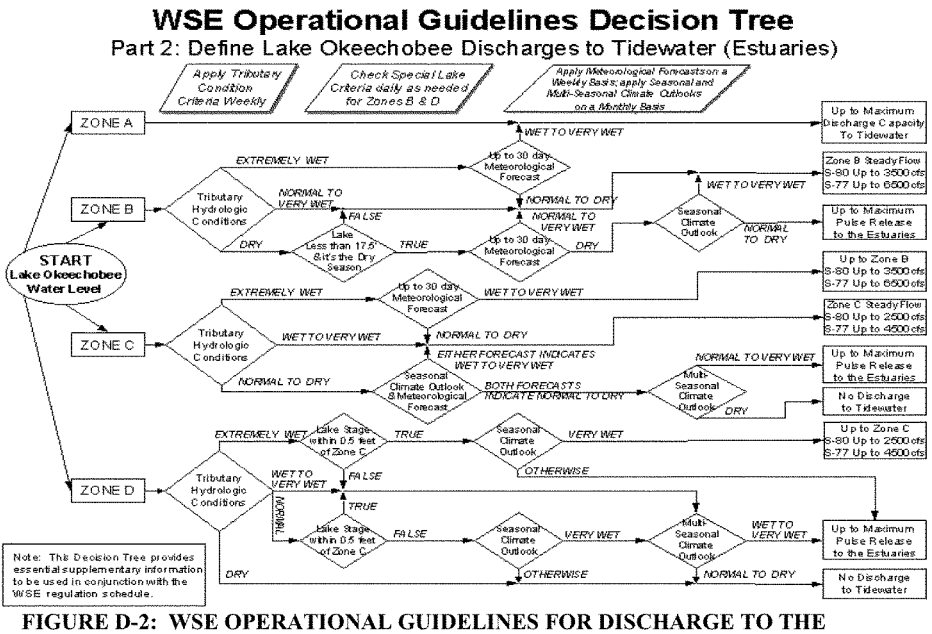

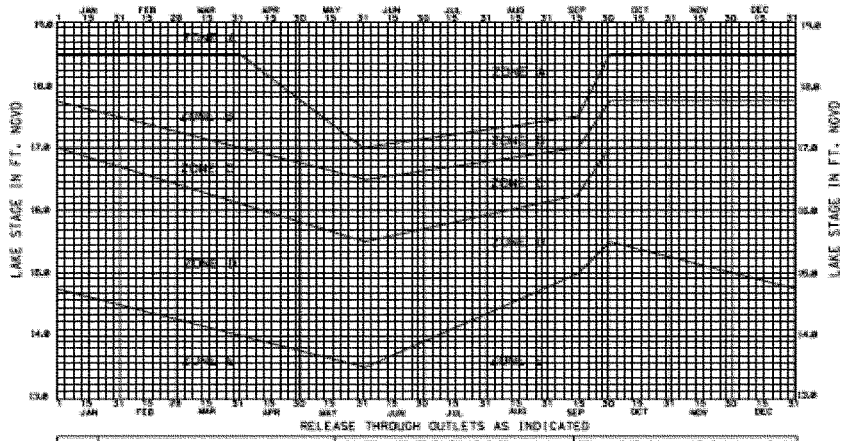

FIGURE D-2: WSE OPERATIONAL GUIDELINES FOR DISCHARGE TO THE CALOOSAHATCHEE ESTUARY

Within the WSE is an Operational Guidelines Decision Tree for discharge to the Caloosahatchee Estuary ***(Figure D-2)***. The range of water released to the Caloosahatchee estuary in the decision tree is from "up to maximum discharge" in the case where the lake is in Zone A of the regulation schedule, and "no discharge to tidewater" when the lake is in Zone D and the tributary conditions are dry. The operational flexibility of the WSE schedule allows for adjustments to be made in the timing and magnitude of Lake Okeechobee regulatory discharges based on conditions in the lake and in the tributary basins, and on extended meteorological and climate outlooks. For example, if the outlook suggests that drought conditions are likely, water might be held in the lake; if the outlook suggests higher than average rainfall, water might be released. The decision criteria in ***Figure D-1*** and ***Figure D-2*** are the starting points from which operational decisions are made. (USACE, 2000).

SFWMD has further defined a process, termed Adaptive Protocols for Lake Okeechobee Operations, for implementing opportunities for operational flexibility that exist in the WSE schedule that address non-regulatory releases of water for fish and wildlife protection and salt water management. The key feature of decisions made under the Adaptive Protocols is balancing water

supply, flood protection, and environmental protection, within the constraints of the approved WSE schedule and Water Control Plan for Lake Okeechobee. The overall purpose of the Adaptive Protocols is to provide information to system operators for greater protection of Lake Okeechobee and downstream ecosystems including the Caloosahatchee Estuary, while continuing to provide a reliable supply of water for agricultural and urban areas that depend on the lake. Adaptive Protocols are proposed to be implemented where the WSE schedule indicates that water must be released from the lake, but does not indicate the exact amount. Adaptive Protocols are also proposed when the Lake Okeechobee Water Control Plan authorizes releases of water from Lake Okeechobee for water supply, fish and wildlife protection, and salt water management (USACE, 2000).

ZONE	AGRICULTURAL CANALS TO WCAs (1,2)	CALOOSAHATCHEE RIVER AT S-77 (1,2,4)	ST. LUCIE CANAL AT S-80 (1,2,4)

NOTES: (1) SUBJECT TO FIRST REMOVAL OF RUNOFF FROM DOWNSTREAM BASINS
(2) GUIDELINES FOR WET, DRY AND NORMAL CONDITIONS ARE BASED ON 13 SELECTED CLIMATIC INDICES AND TROPICAL FORECASTS AND 23 PROJECTED INFLOW CONDITIONS. RELEASES ARE SUBJECT TO THE GUIDELINES IN THE WSE OPERATIONAL DECISION TREE, PARTS 1 AND 2.
(3) RELEASES THROUGH VARIOUS OUTLETS MAY BE MODIFIED TO MINIMIZE DAMAGES OR OBTAIN ADDITIONAL BENEFITS. CONSULTATION WITH EVERGLADES AND ESTUARINE BIOLOGISTS IS ENCOURAGED TO MINIMIZE ADVERSE EFFECTS TO DOWNSTREAM ECOSYSTEMS.
(4) PULSE RELEASES ARE MADE TO MINIMIZE ADVERSE IMPACTS TO THE ESTUARIES
(5) ONLY WHEN THE WCAs ARE BELOW THEIR RESPECTIVE SCHEDULES

CENTRAL AND SOUTHERN FLORIDA
INTERIM REGULATION SCHEDULE
LAKE OKEECHOBEE
DEPARTMENT OF THE ARMY, JACKSONVILLE DISTRICT
CORPS OF ENGINEERS, JACKSONVILLE, FLORIDA
DATED: 9 NOVEMBER 1999

WSE (WITH CLIMATE OUTLOOK)

FIGURE D-3: WSE REGULATION SCHEDULE

D.1.4 MAJOR CONSTRAINTS

1. S-77, S-78, and S-79 Operations. Releases are made in accordance with the Lake Okeechobee operation schedule. In addition, releases are made as required to maintain the optimum tailwater elevation of 11.1 ft. S-78 maintains the upstream stages in the Caloosahatchee River (C-43 Canal). The optimum stage for S-78 is between 10.6 ft and 11.5 ft. If the optimum stages at these structures are exceeded, releases from the reservoir may be reduced until stages are within the optimum range.

2. Caloosahatchee Estuary minimum flows and levels (MFL). The minimum flow is defined as the "limit at which further withdrawal would be significantly harmful to the water resources or ecology of the area. . ." MFL criteria for the Caloosahatchee River are based on maintaining freshwater base flows to the upper reaches of the Caloosahatchee Estuary. This will prevent excessive salinity levels in the estuary from causing significant harm to submerged aquatic vegetation and fish and invertebrate communities. Compliance with the MFL may limit, at times, the amount of water that can be pumped into the reservoir.

D.1.5 STANDING INSTRUCTION TO PROJECT OPERATORS

Once the operational testing and monitoring phase of the Caloosahatchee River (C-43) West Basin Storage Reservoir project is complete, SFWMD will be responsible for the day-to-day water management operations of the newly constructed project features. During normal conditions, the project structures shall be operated in accordance with the approved operating manual (draft and project). Elevations in the plan shall be followed. Deviation from the normal operations will be permitted as stated in Section D.1.12.1. More complete details will be provided in future revisions to the Draft Project Operating Manual in a separate exhibit as stated in CERP Programmatic Guidance Memorandum 5 ("Operating Manuals").

D.1.6 OPERATIONAL STRATEGY TO MEET PROJECT OBJECTIVES

D.1.6.1 Achieving Natural System Goals, Objectives, and Benefits

The Caloosahatchee River is the primary source of water to the Caloosahatchee Estuary. The conceptual intent of the project is for the reservoir to be operated to store excess runoff and discharges from Lake Okeechobee and to deliver water to the Caloosahatchee River (C-43 Canal) based on maintaining desirable salinity levels in the Caloosahatchee Estuary System as measured by flows at S-79.

Early Dry Season (November through January):

- When the flow measured at S-79 is less than 450 cfs and the reservoir water elevation is between 29.0 and 42.0, C43S-8 will be partially opened to allow releases from the reservoir. C43PS-1 will be off.
- When the flow measured at S-79 is less than 450 cfs, and the reservoir water elevation is between 19.2 and 29.0, C43S-8will be opened to allow releases. C43PS-1 will be off.
- When the flow measured at S-79 is greater than 450.0 cfs, and the reservoir water elevation is between 29.0 and 42.0, C43S-1 will be closed, C43PS-1 will begin pumping to the reservoir.

Late Dry Season (February through May):

- When the flow measured at S-79 is less than 450 cfs and the reservoir water elevation is between 29.0 and 42.0. C43S-1 will be opened to allow releases from the reservoir. C43PS-1 will be off.
- When the flow measured at S-79 is greater than 450.0 cfs, and the reservoir water elevation is between 19.2 and 29.0, C43S-1 will be closed, C43PS-1 will begin pumping to the reservoir.

Early Wet Season (June through July):

- When the flow measured at S-79 is less than 450 cfs and the reservoir water elevation is between 29.0 and 42.0, C43S-1 will be opened to allow releases from the reservoir. C43PS-1 will be off.
- When the flow measured at S-79 is greater than 450.0 cfs, and the reservoir water elevation is between 19.2 and 29.0, C43S-1 will be closed, C43PS-1 will begin pumping to the reservoir.

Late Wet Season (August through October):

- When the flow measured at S-79 is less than 450 cfs and the reservoir water elevation is between 29.0 and 42.0, C43S-1 will be opened to allow releases from the reservoir. C43PS-1 will be off.
- When the flow measured at S-79 is greater than 450.0 cfs, and the reservoir water elevation is between 19.2 and 29.0, C43S-1 will be closed, C43PS-1 will begin pumping to the reservoir.

Water management operations outlined above are associated with the traditional/normal understanding of dry and wet season patterns. However, there will be dry and wet periods outside of the traditional seasons in which the water resource will be managed as stated above.

Please note that more detailed operations will be developed for this POM upon following further analyses.

D.1.6.2 Flood Damage Reduction

D.1.6.2.1 Normal and Emergency Operations

Flow in the Perimeter Canal and releases to the Townsend Canal, Fort Simmons Canal, and the Banana Branch Canal are managed using multiple gate and weir structures. These structures are described in Section D.3.2.

The main goal of the Caloosahatchee River (C-43) West Basin Storage Reservoir project is not flood protection. As an incidental benefit, project operations may possibly include reduced flows and stages in the SR 29 Canal during large storm events.

D.1.6.2.2 Hurricane or Tropical Storm Operations

The hurricane season is from 1 June through 30 November. When there are tropical depressions, tropical storms, and/or hurricanes in the Atlantic/Caribbean Basin or Gulf Coast of Florida, the National Hurricane Center (NHC) issues tropical cyclone public advisories, forecast advisories, forecast discussions, and strike probability forecasts. Water Management operations within the Caloosahatchee River (C-43) West Basin Storage Reservoir project area for hurricanes or tropical storms should follow Water Management SFWMD Emergency Preparedness Manual – Suggested Hurricane Operating Procedures, April 2004. The USACE Jacksonville District Emergency Operations Standard Operating Procedures document (CESAJ SOP 500-1-1) should also be consulted for emergency preparedness and actions.

D.1.6.2.3 Storage Area Weir Discharge

The Perimeter Canal structures are C43S-3, C43S-10, and C43S-11. These structures are designed to pass flows along the Perimeter Canal. C43S-3 is a culvert structure and contains both a weir gate and a slide gate. C43S-10 and C43S-11 are gated spillway structures. Both structures have weir gates and roller gate(s). The weir gates for all three structures can be adjusted at each of the structures to provide proper headwater elevations in the Perimeter Canal. The weir gates can be adjusted to at least 5 ft. Although the weir elevations have been established by modeling analyses and will be set at these elevations initially, it is anticipated that adjustments will be required to meet the "field" conditions that will likely change over time, i.e., the adjacent property may be developed as opposed to farmed. For normal day-to-day operations, the weirs will remain at a constant elevation and will pass rainfall events up to the 25-year storms without opening the slide or roller gates. The slide or roller gates will be adjusted by telemetry to allow for discharges that vary based on demands at S-79 and flows during storm events.

D.1.6.2.4 Uncontrolled Discharge

Each cell of the reservoir has an ungated service spillway with a crest elevation 42 ft. C43CS1 is located on the west side of Cell 1 and discharges to the Townsend Canal. C43CS-2 is located just east of C43S-8 in the northwest corner of Cell 2 and discharges to the Perimeter Canal. Both of these spillways consist of a single 50 ft. long weir structure. Any inflows to the reservoir that raise the water level above 42 ft. will discharge from the structure without the use of outlet gates.

D.1.6.3 Water Quality

To minimize the potential for inadvertently causing a water quality problem within the reservoir or downstream, it is important that the operations plan include mechanisms to prevent or minimize potential water quality problems within the reservoir such as thermal stratification, low dissolved oxygen, and algae blooms. Fortunately, some measures to enhance water quality in the reservoir and in the discharge water can be incorporated into future operations with little cost to the project given the reservoir's design. Below is an example list of water quality problems and measures that might be considered to reduce their impact to water quality both within the reservoir and downstream.

1. Measures to Control Thermal Stratification:
   a. Periodic pulse inflows to Cell 1 to disrupt thermal setup in this cell.
   b. Periodic pulse discharges from lower discharge ports to induce mixing of upper and lower water column water. (Combine with upper discharge port discharges to meet DO standards.)
   c. Operation of Cell 1 and Cell 2 semi-independently to transfer water between cells and disrupt thermal setup.
2. Measures to Increase Dissolved Oxygen in Discharge Water:
   a. Discharge from upper port to allow greatest turbulence and re-aeration potential.
   b. Discharge from upper and lower ports to blend high DO water with low DO water.
   c. Install re-aeration mixers to increase DO in reservoir prior to discharge.
3. Measures to Reduce the Impact of Reservoir Algal Production:
   a. Induce mixing of upper photic zone water with lower water to reduce phytoplankton production.
   b. Reduce discharges when reservoir Chl-a exceeds receiving water Chl-a concentration or 11 ug/L.
   c. Installation of aeration devices to reduce algal production
   d. Careful application of algaecides.
   e. Introduction of phytophageous fish or other biological controls to limit phytoplankton.

Some of these example water quality measures may not be necessary, desirable, or perhaps effective. To assist in the development of operational water quality measures, the project includes a water quality monitoring plan for sample collection at the reservoir outfall and downstream in the estuary. Water quality data will be matched with operational information and analyzed to determine which operations schemes provide the best water quality conditions. Once sufficient water quality data is collected, these operational schemes might then be optimized using a reservoir water quality model specifically adapted to this project.

In the event that during operations, the discharge water does not meet water quality standards, the DEP will be notified and the reservoir operations will be modified in an attempt to meet standards. If the operational modifications do not eliminate the standards violation(s), discharges will cease (if this can be done with no threat to human life) and the DEP will be further consulted.

D.1.6.4 Water Supply Operations

The reservoir is within the LaBelle Private Drainage District (LPDD) service area. The LPDD has historically served both the Berry Groves property and the Bob Paul property by pumping water from the Townsend Canal to the Header Canal. Project implementation will transfer an existing legal source of water available to the Bob Paul property from the existing Header Canal to the project's Perimeter Canal. With the project in place, a portion of the Header Canal will become part of the project footprint. To continue to provide an irrigation source to the Bob Paul property, which currently pumps irrigation water from the Header canal and the Crawford canal, C43PS-4 was included in the reservoir perimeter canal to pump water from the reservoir to the east to the remaining Header canal segment, assuring that the same volume of water will still be available. The Crawford Canal will still be available to the Bob Paul property and is not affected by the project. The existing Berry Groves No. 1 and No. 2 pump stations will remain in operation until C43PS-4 and the Perimeter Canal are constructed and operational.

D.1.6.5 Recreation

There are some recreational facilities in or adjacent to the C43BSR. SFWMD intends to allow certain types of recreational use in the impoundments, these plans are currently being prepared (see Appendix H – Recreation Plan). However, there will be no specific operations to provide for recreation.

D.1.6.6 Fish and Wildlife

The reservoir does not have specific water management operations to enhance fish and wildlife resources within project features. Areas of the project that will remain hydrated, even during periods of low water, include the Perimeter Canal and existing drainage/irrigation canals that will remain intact during construction. In addition, features that will enhance fish and wildlife resources are the littoral areas that will be constructed within the Perimeter Canal. However, no special operations will be required for the hydration of these areas. Pre-project flows will be maintained for the Roberts Canal and Banana Branch Canal.

The West Indian manatee is a federally endangered species. Therefore, special considerations will be implemented during design and construction of the project. All pump stations and outfalls will be designed to prevent manatees from entering the system. Because manatees are known to inhabit the Caloosahatchee River (C-43 Canal) and Townsend Canals, special construction precautions will be used to safeguard these animals. Once construction is complete, no special operations will be necessary to protect the manatees.

Construction precautions will be implemented to protect various federally protected species such as the Florida panther, Eastern indigo snake, wood stork, and Audubon's crested caracara. Although no special operations will be necessary for any of these species, operators will be required to follow a set of operational guidelines designed to protect nesting wading birds against severe water rising or lowering which could affect the integrity of the nests.

D.1.6.7 Navigation

The Okeechobee Waterway traverses the state from the Gulf of Mexico to Lake Okeechobee via the Caloosahatchee River (C-43 Canal) and from Lake Okeechobee to the Atlantic coast via the St. Lucie (C-44) Canal. Project operations should not adversely affect maximum or minimum navigational depths in the Caloosahatchee River (C-43 Canal). C43PS-1 will not be operated to deliver water from the Caloosahatchee River (C-43 Canal) to the reservoir when the Caloosahatchee River (C-43 Canal) upstream of S-79 is below 2.8 ft. NGVD. Therefore, operation of the project will not adversely affect navigational on the Okeechobee Waterway.

D.1.7 PRE-STORM/STORM OPERATIONS

If a heavy rainfall is forecast for the Caloosahatchee River (C-43) Basin, the main pump station (C43PS-1) will be placed on standby. If a storm occurs and there is capacity in the reservoir, normal operating conditions will be in effect.

D.1.8 CONSISTENCY WITH THE IDENTIFICATION OF WATER AND RESERVATIONS OR ALLOCATIONS OF WATER FOR THE NATURAL SYSTEM

The operating criteria within this Draft POM are consistent with the operating criteria used to identify the water reservations or allocations for the natural system to be made by the State of Florida in accordance with WRDA 2000. Refer to Annex C for details regarding the assumptions utilized in the technical procedures for identifying water to be reserved or allocated by the State. The project will be operated consistent with the assumptions set forth in Section C.2.1.2 and with the identification of water as set forth in Table C-3 of Annex C.

D.1.9 CONSISTENCY WITH SAVINGS CLAUSE AND STATE ASSURANCES PROVISIONS

The project has been designed to be operated so that there will be no adverse impacts on sources of water at the project (basin) level. Project implementation will transfer an existing legal source of water available to the Bob Paul property from the existing Header Canal to the project's Perimeter Canal. With the project in place, a portion of the Header Canal will become part of the project footprint. To continue to provide an irrigation source to the Bob Paul property, which currently pumps irrigation water from the Header canal and the Crawford canal, C43PS-4 was included in the reservoir perimeter canal to pump water from the reservoir to the east to the remaining Header canal segment, assuring that the same volume of water will still be available. The Crawford Canal will still be available to the Bob Paul property and is not affected by the project. The existing Berry Groves No. 1 and No. 2 pump stations will remain in operation until C43PS-4 and the Perimeter Canal are constructed and operational. The savings clause analysis will be updated to ensure continued compliance with the Savings Clause once the project becomes operational.

D.1.10 DROUGHT CONTINGENCY PLAN (DCP)

During a drought in the Caloosahatchee River (C-43) Basin or project area, operations will be modified in accordance with SFWMD Rules, Chapter 40E-21 F.A.C., Water Shortage Plan.

D.1.11 FLOOD EMERGENCY ACTION PLAN

The Flood Emergency Action Plan will be completed for the C43BSR Project prior to construction completion. The purpose of the Flood Emergency Action Plan is to describe the procedures to be followed in the event of a reservoir failure. The Flood Emergency Action Plan to be developed should be consulted for related emergency preparation and action. Local emergency management offices will be provided copies of the Flood Emergency Action Plan as necessary.

This plan may be used to supplement Hurricane or Tropical Storm Regulations. As outlined in Engineering Regulation 1130-2-530, the Flood Emergency Action Plan shall include:

- A written Emergency Notification Procedure for serious abnormal conditions to provide for the safety of people near the storage area and trigger immediate response for remedial assistance to the levee/water control structure
- A description or list of conditions leading to emergency situations and ways of dealing with them should they occur
- Storage area dewatering procedures
- Levee/water control structure failure inundation maps
- Listing of location, types, and quantity of emergency repair materials and equipment
- Details outlining responsibilities for inspection and execution of emergency repairs
- List of contractors available within a reasonable distance of the project area

D.1.12 DEVIATION FROM NORMAL REGULATION

The USACE, Jacksonville District Engineer is occasionally requested to deviate from the normal regulation of the project. Prior approval for a deviation is to be obtained from the Jacksonville District Office (SAJ) except as noted below. In turn, SAJ will obtain the necessary approvals from the South Atlantic Division (SAD) except as noted below. Deviation requests usually fall into the following categories.

D.1.12.1 Emergencies

Some expected emergencies include drowning and other accidents, failure of project facilities, and flushing of pollutants. Antecedent conditions as well as forecasted storm events may result in SFWMD declaring an Emergency Authorization Order, which would result in an Emergency Deviation. Necessary action under emergency conditions is taken immediately unless such action would create an equal or worse condition. SAJ should be informed as soon as practicable. Written confirmation should be furnished after the incident. SAJ will report these deviations to SAD.

D.1.12.2 Unplanned Minor Deviations

There are unplanned instances where there is a temporary need for a minor deviation from normal regulation, albeit these instances are not considered emergencies. A change in releases is sometimes necessary for construction, maintenance, or inspection. These requested deviations are usually for the

duration of a few hours to a few days. Each request is analyzed on its own merit. Consideration is given to upstream watershed conditions, potential flood threat, conditions of lakes, and possible alternative measures. In the interest of maintaining good public relations the request is typically recognized, providing there are no adverse effects on the overall project regulation for authorized project purposes. Approval for minor deviations will normally be obtained from the Jacksonville District by telephone. A written confirmation will be furnished after the deviation is completed. SAJ will report these deviations to SAD.

D.1.12.3 Planned Deviations

Each circumstance should be analyzed on its own merits. Sufficient data on flood potential, lake and watershed conditions, possible alternative measures, benefits to be expected, and probable effects on other authorized and useful purposes, coupled with the USACE district recommendation, will be presented by memorandum, facsimile, or electronic mail to the USACE-SAD for review and approval. In addition, the non-Federal sponsor, the State of Florida (FDEP and SFWMD), and the Department of the Interior should be consulted as part of the process of receiving approval from SAD for the deviation.

D.1.13 RATE OF RELEASE CHANGE

Control structures should be opened and closed gradually. This technique provides an even transition to the new flow regime and minimizes hydraulic effects downstream. Special attention should be given to the maximum gate-opening curve for each structure to ensure the tailwater has a chance to build up before large-scale openings are made.

D.1.14 SEEPAGE CONTROL

The perimeter embankment is designed to include a soil-bentonite wall that is vertically tied into the clay layer that underlies the project site. An internal drain is also designed to gather seepage that passes through the soil-bentonite wall/or through the foundation soils. The internal drain has intermittent discharge pipes that drain to the Perimeter Canal.

Offsite seepage will be monitored using piezometers that are already installed around the perimeter of the reservoir footprint. Groundwater level data is being acquired on a monthly basis and used to establish baseline groundwater elevation conditions. These piezometers will be used during and following construction of, and filling of the reservoir to evaluate the impacts (if any) of the reservoir on the offsite groundwater table conditions. Should the piezometers indicate groundwater mounding occurring offsite, the surface water levels in the Perimeter Canal will be adjusted (lowered). Effects on offsite conditions due to

the lowering of the water table will be monitored and further adjustments will be made on an as-needed basis.

D.1.15 INITIAL RESERVOIR/STORAGE/TREATMENT AREA FILLING PLAN

The Initial Storage Area Filling Plan (ISAFP) is defined as the deliberate impoundment of water to meet project purposes. It is a continuing process as successively higher water levels are attained. The initial reservoir filling is the first test of containing levees and water control structures to perform the function for which they were designed. In order to monitor this performance, the rate of filling will be controlled to the extent feasible to allow as much time as needed for a predetermined monitoring program including the observation and analysis of instrumentation data. Information furnished in the ISAFP will generally be concerned with action that can be taken without a significant impact to project purposes, provided no unsafe conditions are observed. An ISAFP will be developed during design and construction. This plan will include, but is not limited to, the following:

- Preferred filling rate and the available options to control the rate of filling as well as the consequences of operation with the prime objective of controlling the rate of reservoir rise
- The most likely type of problem(s) that may develop during initial filling and the monitoring necessary to detect those problems
- A description of the proposed hydrologic data collection and transmission system and a plan for reading the instruments and evaluating the data with regard to the filling plan
- A plan for inspecting the dam and downstream areas prior to and during filling, including the relationship between frequency of inspection and rate of pool rise
- Instructions for observers on conditions that require immediate attention of personnel authorized to make emergency decisions. Clearly identify who is responsible for decisions and how they can be contacted. Alternative decision makers should be identified
- An emergency plan listing responsibilities, name and/or positions, telephone numbers, page numbers, and radio frequencies to be used
- Water quality requirements, if any, for the initial filling

D.1.16 NON-TYPICAL OPERATIONS FOR RESERVOIR/STORAGE/ TREATMENT AREA PERFORMANCE

Non-typical operations would apply during periods of extreme drought or rainfall. During drought conditions, it may be necessary to pump water more often at lower rates or to release water more slowly from the reservoir.

D.1.17 AQUIFER STORAGE AND RECOVERY SYSTEM PLAN

Not applicable.

D.1.18 WATER CONTROL DATA ACQUISITION SYSTEM PLAN (WCDASP)

The remote automation components installed at the pump station and other structures are the Remote Terminal Unit (RTU) and communication channel to SFWMD control center. Access for the RTU to the control center is via field interface units (FIU). The automation components of all pump stations and structures that will eventually be operated and maintained by SFWMD will conform to SFWMD standards. Equipment used in data acquisition essential to the water control management function will be included in the WCDASP, which will initially be developed during the project design phase. This will include all hardware and software to be used for acquisition, transmission, processing, display, and dissemination of hydrologic meteorology, water quality, and project data for the purposes of supporting the water control goal. This includes, but is not limited to, uninterruptible power supplies, field data collection platforms, and data communication devices and circuits. The WCDASP will also identify the site location of all hardware included in the plan. Hardware referencing and gage reference datum will be determined through coordination with appropriate agencies such as the U.S. Geological Survey (USGS) and SFWMD. The WCDASP will be completed during the plans and specifications phase and will be a subset of the Water Control Data System that is specific to the Caloosahatchee River (C-43) West Basin Storage Reservoir project.

D.1.19 CONSISTENCY WITH THE ADAPTIVE MANAGEMENT PROGRAM AND PERIODIC CERP UPDATES

After long-term operations and maintenance of the CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR Project has been initiated, the project operating manual may be further modified based on operating criteria approved by the USACE and SFWMD resulting from CERP updates and recommendations from the adaptive management of the CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR Project.

D.1.20 INTERIM OPERATIONS DURING CONSTRUCTION

Interim operations will be developed in conjunction with the detailed construction schedule. The interim operations will preserve existing Central and Southern Florida (C&SF) Project authorized purposes and/or achieve the Comprehensive Everglades Restoration Plan (CERP) authorized purposes as identified in the PIR. All interim operations will be conducted to meet the Assurances of Project benefits as set forth in WRDA 2000 and as discussed in the Programmatic Regulations and the Guidance Memoranda.

D.1.20.1 Preliminary Operations During Operational Testing and Monitoring Phase (OTMP)

Preliminary operations for the OTMP will be developed in conjunction with the plan for the OTMP. Operations will be conducted to meet the Assurances of Project benefits as set forth in WRDA 2000 and as discussed in the Programmatic Regulations and the Guidance Memoranda.

D.1.20.2 Conceptual Description for Transition from the Initial Operating Regime to the Next-Added Increment

Analysis of project benefits performed for plan formulation, selection, and justification indicates that there will be no significant difference between next-added incremental operations and the Initial Operating Regime. For this project, water management operations as described for the Initial Operating Regime would be expected to remain in effect if no other CERP projects affecting the regional water management system were to become operational.

D.2 HYDROLOGIC AND METEOROLOGICAL MONITORING AT THE CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR

D.2.1 Introduction

The purpose of this document is to provide a summary of the approach to be used for monitoring and control of the CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR and associated gated structures; spillways and culverts. This document will address measure points and methods, as well as telemetry to transfer measured data to pump station One (C43PS-1) and ultimately to the South Florida Water Management District (SFWMD) SCADA System at Gun Club Road.

The parameters to be monitored include the following:

- Reservoir level
- Perimeter and branch canal levels
- Water flows discharging from the reservoir cells and within the perimeter and branch canals
- Gate positioning and control
- Embankment monitoring
- Ambient conditions

Two data collection systems will be used:

- Motorola MOSCAD and MOSCAD-L RTU
- Campbell Scientific CR-1000 datalogger

Each data collection system will utilize independent radio telemetry networks. Details related to the communication type, licensed versus spread spectrum radios, are yet to be determined. All Motorola applications will be powered from a 120-volt ac power source. Campbell Scientific applications will utilize solar cells and battery power storage because of their remote locations.

All data collected will be transmitted to the C43PS-1 site microwave tower. The Motorola data will be stored on the telvent SCADA server located in the C43PS-1 control room. The Campbell Scientific data will be stored in the LoggerNet® Server in the microwave shelter. All data will be available to the C43PS-1 SCADA system and to the district SCADA system via the district microwave network.

D.2.2 Stage Monitoring

The reservoir water level will be measured using submersible pressure transducer type devices. This will allow level measurements in addition to the district's standard Balluff rod-type linear transducer. Reservoir level measurements not associated with gated structures will input into a Campbell Scientific datalogger due to standalone type of measurement. Reservoir level measurements associated with gated structures will be input into the site Motorola MOSCAD RTU with other site parameters. Upstream and downstream levels will be measured at all gated structures.

Canal water level will be measured using district standard Balluff rod-type linear transducers. The level measurements will be associated with gated structures and thus input into the site Motorola MOSCAD RTU with other site parameters. Upstream and downstream levels will be measured at all gated structures.

Stage measurements will be taken every 15 minutes by electronic equipment. For redundancy, a staff gage will be read.

D.2.3 Flow Monitoring

Water flow discharge from each of the reservoir cells will be measured independently. Flow measurement is expected to utilize level measurements within the intake structure and the gate well, and calculated based on the known fixed area of the flooded channel between to two level measurement locations. The exact method of flow measurement still needs to be determined. Flow measurement within the Perimeter Canal and branch canals will be calculated using level measurements and gate positioning.

D.2.4 Groundwater Monitoring

During the preliminary stages of exploration work (i.e. 2004), fifteen clusters of piezometers were installed along the proposed perimeter embankment alignment in order to provide information related to groundwater levels for design purposes. Each of these clusters consists of three 2-inch diameter Schedule 40 PVC well screens that are flush joint coupled to a riser pipe of similar composition. The well screens were set at depths corresponding to above, within and below the clay layer, and are designated A, B, and C, respectively. Each piezometer installation includes a sand pack surrounding the screened interval, and the borehole annulus was grout sealed above the sand pack to ground level.

In 2006, an additional 22 clusters of piezometers were installed in areas outside of the proposed reservoir footprint, adjacent to its north, south, and east sides. These piezometers were installed to enable monitoring of background groundwater levels before, during and after construction and filling of the reservoir, and to assess the hydrologic impacts of filling of the C43BSR on regional hydrogeology. Each of these additional clusters includes two piezometers similar to those described above, with one screened above the clay layer and one below it. In addition, there are two USGS piezometers, and one Lee County piezometer that are located west of the proposed reservoir footprint.

D.2.5 Weather

One or more weather stations measuring rain amount, wind speed and direction, barometric pressure, temperature and relative humidity will be placed around the reservoir area. The data will be collected using a Campbell Scientific CR-1000 data logger at each weather station location. Logged data will be transmitted as indicated above.

D.2.6 Structure Monitoring

Motorola MOSCAD RTU. Each sample at each selected gated structure will be deposited in a separate bottle. Samples will be manually collected weekly and lab tested for phosphorus content.

Gated structure roller gates, sluice gates, slide gates, and weir gates will be monitored for position using external potentiometer devices, where applicable and input into the area Motorola MOSCAD, MOSCAD-L RTUs. Fully open and fully closed gate position signals received from either the gate positioning electric actuator or gate assembly installed limit switch will also be input into RTU. Remote manual control of gate positioning will be available from the C43PS-1 and locally at the gated structure building. Gated structures with one

or two gates will implement the Motorola MOSCAD-L RTU, while gated structures with three or more gates will use the full Motorola MOSCAD RTU.

D.3 ECOLOGICAL MONITORING PLAN

The purpose of the ecological component of this monitoring plan is to make recommendations for monitoring to RECOVER and to provide enough detail of these recommendations to enable RECOVER to develop appropriate scopes of work for each component, if necessary, and to determine when adaptive management would be needed related to the project. This plan proposes the addition of 3 water quality stations, 2 salinity stations, and additional oyster sampling sites as new reefs are built, to current monitoring efforts.

The Caloosahatchee River (C-43) West Basin Storage Reservoir project is the first part of the Basin Storage Reservoir (BSR) and Aquifer Storage and Recovery (ASR) component as identified in the Restudy. It is authorized as one of the initial projects for implementation under Section 601(b) (2) (C) of the Water Resources Development Act (WRDA) 2000. The reservoir has been designed for water supply benefits, some flood attenuation, to provide environmental water supply deliveries to the Caloosahatchee Estuary, and water quality benefits to reduce salinity and nutrient impacts of runoff to the estuary.

This section represents a monitoring plan for the Caloosahatchee Estuary and is a component of a larger project level monitoring program. This program establishes the framework for measuring project level responses, determines how well the project is meeting its goals and objectives, and identifies opportunities for improving the operation of the reservoir where needed.

The monitoring program has 3 objectives:

1. Establish baseline variability for each of the performance measures prior to project implementation;
2. Determine the status of and trends in the performance measures during and following project implementation;
3. Detect responses of the ecosystem to changes resulting from the project.

This plan consists of a minimal set of estuarine performance measures necessary to determine the success of the project as identified by a team of local scientists and water resource managers. It includes the objectives of the monitoring component, monitoring measures and targets for each performance measure, and a recommended monitoring approach. Also incorporated, where enough information is known, are triggers for adaptive management.

This monitoring plan is intended to address concerns related to downstream estuary impacts and benefits related to changes in freshwater inflows, water quality, and salinity due to project implementation. It was developed for the Caloosahatchee River (C43) West Basin Storage Reservoir Project Implementation Report (PIR) document. The PIR development phase has requirements for sections detailing monitoring and adaptive assessment methods for the recommended alternative. This monitoring plan is to be implemented prior to project start up and will be adhered to for a duration of the time during operation (post construction) sufficient to determine if there has been project impacts. Changes to the plan may occur in the future, commensurate with analysis of the monitoring data to date, funding limitations, and the need for adaptive management.

Modification of this monitoring plan will be determined by the needs of the project. This plan may be changed to reflect any future design changes, permit requirements and/or may be terminated according to permit expiration dates or changes to the project objectives. The plan will be reviewed and/or modified annually or more frequent if necessary, to reflect new requirements and updates regarding the parameters sampled and the expected duration of monitoring.

It is a recommendation of the C43 West Basin Reservoir Part I Project Delivery Team that the following plan be implemented by RECOVER and incorporated into their adaptive management strategy for South Florida.

D.3.1 Salinity Monitoring Plan

This salinity monitoring plan is intended to help address concerns related to downstream estuary impacts and benefits related to changes in freshwater inflow and salinity due to project implementation.

D.3.1.1 Background

Freshwater inflow and salinity vary naturally in an estuary and exert a profound influence on the survival and distribution of estuarine organisms, especially early life history stages and sessile benthic organism. However, excessive variation in salinity can maintain estuarine biota in a constant sate of flux between those favoring high salinity and those lower salinity. Proper management of water entering the estuary via the S-79 structure (***Figure D-4***) is the predominant requirement for a healthy Caloosahatchee Estuary, because the volume of freshwater passing through S-79 from the watershed and Lake Okeechobee overwhelms any other source. Environmental research and modeling, conducted mostly since 1985, has been employed to determine the optimum range and distribution of freshwater inflow from S-79 that protect key biota. This distribution of target flows ensures a complete range of salinities from freshwater to marine conditions along the longitudinal gradient of the

estuary, providing salinities that remain stable within geographical zones of the estuary that support the organisms within these zones.

A shift from the current undesirable, often extreme flow and salinity conditions, to maintaining the target flows and related estuarine salinity gradient can not be achieved without: (1) implementing the portion of the Comprehensive Everglades Restoration Plan (CERP) that reduces Lake Okeechobee releases; and (2) the building and operation of the Caloosahatchee River (C-43) West Basin Storage Reservoir project. Therefore, as a component of the CERP effort and C-43 West Basin Storage Reservoir (BSR) Project, monitoring freshwater discharge from the Lake and S-79, as well as salinity in the estuary are necessary to determine if project flow and salinity targets are achieved; the cause for under achievement; and if adaptive management is required (e.g., changes in operations of project reservoirs). The available of inflow and location specific salinity information also is required for assessing the level of beneficial impacts of CERP and the Caloosahatchee River (C-43) West Basin Storage Reservoir project on key species and ecosystem components within their preferred range (e.g., oysters). Therefore, the guidance contained in this document will assist in maintaining consistency in sampling locations, parameter lists and frequencies as well as provide documentation of the project scope and an ongoing historical perspective.

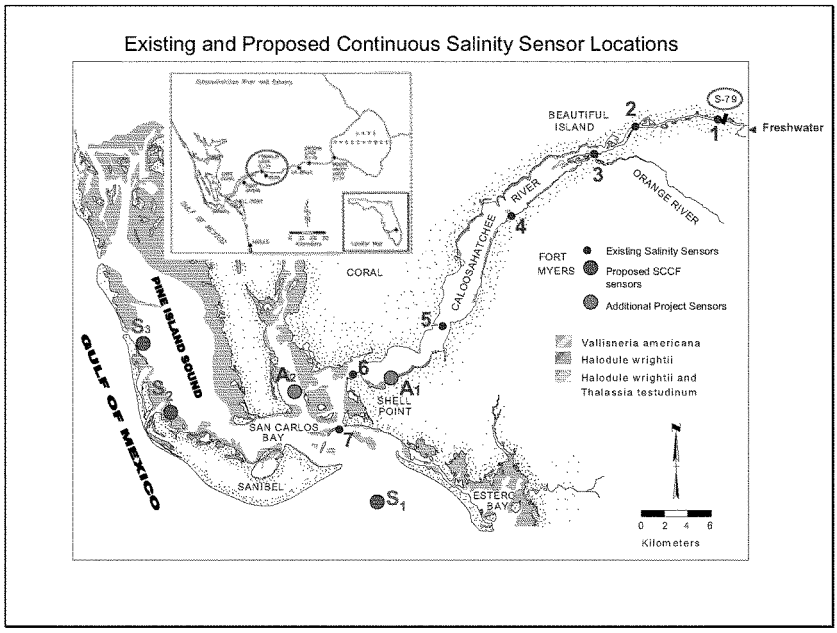

FIGURE D-4: MAP OF THE CALOOSAHATCHEE ESTUARY, THE EXISTING SALINITY SENSORS (1 – 7), SENSOR STATIONS PROPOSED BY SANIBEL-CAPTIVA CONSERVATION FOUNDATION, AND ADDITIONAL SENSORS SUPPORTED BY THE CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR PROJECT.

D.3.1.2 Monitoring Objectives

1. (a) Compare the discharge distribution from S-79 to the Caloosahatchee River (C-43) West Basin Storage Reservoir target distribution; and (b) determine if the source of the variation is due to basin rainfall runoff and Lake Okeechobee Releases, as well as the influence of Caloosahatchee River (C-43) West Basin Storage Reservoir operations.
2. Collect salinity information along the downstream gradient of the estuary with sufficient frequency to detect annual and season change for comparison to pre-project conditions.
3. Determine if the low flow target for the project is sufficient and the associated salinity criteria in the upper estuary are achieved for protection of *Vallisneria americana*. Provide short term and long term operation recommendations based on the monitoring information.
4. Provide salinity information useful for the seagrass monitoring plan to determine if the salinity target for supporting seagrass in the lower Caloosahatchee River and San Carlos Bay are being achieved. Again,

provide short term and long term operation recommendations based on the monitoring information collected in the seagrass region.

5. Provide salinity information useful for the oyster monitoring plan to determine if the salinity target for supporting oysters near Shell Point is being achieved. Provided short term and long term operation recommendations based on the monitoring information collected in the oyster region.
6. Adequately collect salinity information throughout the estuary that enables the construction of salinity and computation hydrodynamic models, which allows the: (a) estimation of daily salinity throughout the estuary for understanding impacts to key species during non-sampling days of biotic indicators; (b) the determination of internal cause of salinity variation not related to project influence or discharges from S-79 (e.g., influence of freshwater from Gator Slough on salinity in the Matlacha Pass and San Carlos Bay); and (c) salinity model comparison of pre-project spatial and temporal patterns with new model output during project operation.
7. Address the null hypothesis stated below that is intended to asses the success of the project.

D.3.1.3 Null Hypothesis

The general null hypothesis - As a result of the operation of the Caloosahatchee River (C-43) West Basin Storage Reservoir, there are no beneficial changes in freshwater inflows from S-79, nor improvement in the resulting downstream salinity, related to (a) the historic longitudinal salinity gradient and valued ecosystem habitat locations; (b) historic season salinity patterns; and (c) variation in salinity within distinct estuarine zones of the estuary.

D.3.1.4 Monitoring Measures and Targets

1. Monitoring Measure: Freshwater discharge through S-79, S-77 and from Caloosahatchee River (C-43) West Basin Storage Reservoir.

Target:

TABLE D-1: TARGET FLOW RANGE

Discharge Range (cfs) from S-79	Percent Distribution Of Flows From S-79
0 to 450	0%
450 to 500	42.8%
500 to 800	31.7%
800 to1500	19.2%
1500 to 2800	5.6%
2800 to 4500	0.7%
>4500	0%

Adaptive Management Trigger: (1) Long term - If operation of the Caloosahatchee River (C-43) West Basin Storage Reservoir does not result in a significant increase toward achieving the above flow targets, thus satisfying the null hypothesis; and (2) Short Term (real time) - When there is a significant decrease in estuarine health or threat of adverse impacts related to flow from the Caloosahatchee River (C-43) West Basin Storage Reservoir (e.g., algae blooms in the upper estuary or insufficient delivery of water to achieve the MFL).

2. Salinity along a downstream gradient of the estuary and correlated freshwater inflow.

Target: Sufficient temporal and spatial salinity information to assess positive change regarding reduction in salinity variability and achieving the salinity targets as required for submerged aquatic vegetation, oyster, and fish (as specified in their respective monitoring plans).

Adaptive Management Trigger: (1) Long term - If operation of the Caloosahatchee River (C-43) West Basin Storage Reservoir and it's related flow alterations does not result in: (a) significant decrease in salinity variability; and (b) stabilization in desirable salinity ranges along the estuary's downstream gradient and within valued ecosystem habitats, thus satisfying the null hypothesis; and (2) Short Term (real time) – (a) impending violation of the MFL rule and associated salinity criteria; and (b) adverse immediate impacts to estuarine biota as a result of the operation of the Caloosahatchee River (C-43) West Basin Storage Reservoir

D.3.1.5 Monitoring Approach

Daily freshwater discharge from S-79 and the Lake Okeechobee structure at Moore Haven are measured by the Corp of Engineers and posted electronically on COE and South Florida Water Management District (SFWMD) web sites. This information is part of normal operation and therefore no additional Caloosahatchee River (C-43) West Basin Storage Reservoir project cost is required.

A network of continuous salinity sensors is required to meet the above monitoring objectives. The data from the sensors should be collected at the frequency and location necessary to support future modeling with minimum uncertainty and provide the salinity information necessary for other species and VEC monitoring efforts. ***Table D-2*** identifies each sensor site (as indicated in ***Figure D-4***), its monitoring objective (from above 6), and the expected funding sponsor of the site.

The existing sensors (soon to be 1-7) collect salinity every 15 minutes at 20% and 80% of the water depth. These are considered permanent sensors, most of which have long term data sets beginning in 1992 (source of pre-project data). These sensors have been critical in the development of salinity models and should be maintained at their current operation capacity to provide data for future modeling efforts related to assessing project change. The information from most of these sensors are used as part of the daily operation of the Corp of Engineers and SFWMD and available to provide short term and long term project feed back. The cost to maintain these sensors should be minimal to the Caloosahatchee River (C-43) West Basin Storage Reservoir project. The locations of S-sites are also identified in ***Figure D-4***. These sensors should be similar in operation as the existing 7. The cost for supporting the S-site sensors is being considered by the Sanibel-Captiva Conservation Foundation.

TABLE D-2: MONITORING SITES, PARAMETERS SAMPLED, MONITORING OBJECTIVES (FROM MONITORING OBJECTIVES SECTION), AND THE FUNDING SOURCE SPONSORING THE SITE INSTALLATION AND MAINTENANCE. CORPS OF ENGINEERS (COE), SOUTH FLORIDA WATER MANAGEMENT DISTRICT (SFWMD), AND SANIBEL-CAPTIVA CONSERVATION FOUNDATION (SCCF)

Monitoring Site and Parameters	Objective(s) Addressed	Funding Sponsor
S-77 (Moore Haven) & S-79 (Franklin Dam)	1a -Compare flow from S-79 to project target 1b - Determine if any change in S-79 flow due to basin or lake.	COE & SFWMD
1 - Salinity, temperature & water level	Null Hypothesis -Provide/Protect oligohaline zone.	SFWMD
2 - Salinity & temperature	Null Hypothesis -Provide/Protect oligohaline zone.	SFWMD
3- Salinity & temperature	3 - Determine if low flow salinity criteria achieved to protect tape grass (monthly average <10ppt). -Support short term operation and long term adaptive management needs. 6a - Estimation of salinity during non-	SFWMD

	sampling days for key biota (VECs)	
4- Salinity & temperature	3 - Determine if low flow salinity criteria achieved to protect tape grass (monthly average <10ppt). -Critical MFL measurement station. -Support short term operation and long term adaptive management needs	SFWMD
5 - Salinity & temperature	4 -Support seagrass monitoring, and meets target salinity for area (>15 ppt)	SFWMD
6 - Salinity, temperature & water level	4 -Support seagrass monitoring, and meets target salinity for area. 5 - Support oyster monitoring, and meets target salinity for area (> 5ppt) -Support short term operation and long term adaptive management needs. 6a - Estimation of salinity during non-sampling days for key biota (VECs)	SFWMD
7 - Salinity & temperature	4 -Support seagrass monitoring, and meets target salinity for area (>25ppt). -Support short term operation and long term adaptive management needs. 6a - Estimation of salinity during non-sampling days for key biota (VECs).	SFWMD
S1- Salinity & temperature	4 - Support seagrass monitoring	SCCF
S2 - Salinity & temperature	4 - Support seagrass monitoring -Support short term operation and long term adaptive management needs.	SCCF
S3 - Salinity & temperature	4 - Support seagrass monitoring	SCCF
A1 - Salinity & temperature	4 -Support seagrass monitoring, and meets target salinity for area (>20 ppt). -Support short term operation and long term adaptive management needs. 6a - Estimation of salinity during non-sampling days for key biota (VECs)	CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR
A2 - Salinity & temperature	4 -Support seagrass monitoring 6a - Estimation of salinity during non-sampling days for key biota (VECs). 6b - Salinity variation due to non-project sources.	CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR
All Sensors	2 - Detect desired seasonal, annual, and spatial change along the downstream gradient. 6c -Salinity model to compare w/ pre-op.	

The locations of additional sites are proposed in ***Figure D-4***, along with their suggested priority ranking. These A-site sensors should be similar in operation as the existing 7. The majority of the cost for these additional sensors will probably be funded by the Caloosahatchee River (C-43) West Basin Storage Reservoir project, with possible support from other CERP sources and RECOVER.

Sensors 1 -7 provide real time data, with live access available to restricted SFWMD staff. These sites, the S-sites, and the proposed A-sites should also provide similar real time data. The information from all sites should be required to have broader access for scientist conducting research and analysis.

D.3.1.6 Data Quality

Routine samples and routine quality control samples are collected in accordance with the Florida Department of Environmental Protection (Department) Quality Assurance Rule, 62-160.200 and 62-160.320, F.A.C. and the District Field Sampling Quality Manual (FSQM). Applicable sections of the FSQM include auto-sampler collection methods; field test methods; and quality control procedures. Corrective actions for data not meeting the quality objectives may be taken as outlined in the Quality Assurance Systems Requirement (QASR).

D.3.2 Project Monitoring and Assessment Plan: Water Quality

This water quality monitoring plan is intended to help address concerns related to downstream estuary impacts and benefits related to changes in freshwater inflow and associated water quality due to project implementation.

D.3.2.1 Background

Quality of water is a major factor of influence as to the degree which an estuary may successfully sustain the diverse biological communities and habitats within its boundaries. Estuaries provide an area of dynamic chemistry where substances are naturally deposited. Freshwater, in the process of flowing from the land to the sea, transports a wide range of materials, that when coupled with internal estuarine dynamics of circulation, nutrient flux, sediment type, and resuspension, results in each estuary being unique in its appearance and ability to support biological activity and the nature of that activity. Therefore, among aquatic ecosystems, estuaries are uniquely complex systems, since they act as sinks for substances delivered in freshwater flows, possess mixing and flow patterns controlled by the ebb and flow of tide and tidal-influence, and exhibit interrelated chemistries connecting atmosphere, water and sediment. Key water quality characteristics of concern for the Caloosahatchee considered by this Monitoring Plan are nitrogen and phosphorus nutrients, algal bloom dynamics, dissolved oxygen regime, water color, suspended solids, and water clarity;

however, these characteristics are inter-related and cannot be adequately or properly evaluated except within the context of their interdependencies in delineating acceptable from unacceptable water quality conditions. This monitoring plan is accordingly constrained to consider water quality from the perspective of sustainable and desirable estuarine ecological response; that is water quality requirements of valued ecosystem components and habitats addressed in the other Caloosahatchee River (C-43) West Basin Storage Reservoir Project Monitoring Plans for submerged aquatic vegetation (SAV), fisheries, oysters, and the soft-bottom benthos. With that said, the purpose of this Monitoring Plan is to define Caloosahatchee River (C-43) West Basin Storage Reservoir project expectations regarding water quality improvements brought about by implementation of CERP and this Project, and to provide a tool with which to evaluate and assess those improvements. Other state and local efforts, e.g. the State's Total Maximum Daily Load (TMDL) program, are expected to compliment and supplement this Project and the larger CERP effort, thus affording additional improvements in water quality; however, implementation of these efforts, including effective agricultural and urban Best Management Practices (BMPs) are outside the purview of this project and CERP and are not addressed by this monitoring plan.

Extensive development of the Caloosahatchee watershed has changed the source and character of water entering the estuaries, from a historical drainage pattern dominated by wetland and forested land uses to that of urban and agricultural stormwater runoff. The modifications inherent in the original Central and Southern Florida (C&SF) Project resulted in increases in quantity and rate of water entering the estuaries. These modifications also served to extend the expanse of the estuaries' drainage basins to include Lake Okeechobee. The combined effect of changes in land use, expansions in acreage drained, and the manner in which water is delivered to the estuaries has resulted in varying degrees of degradation of water quality.

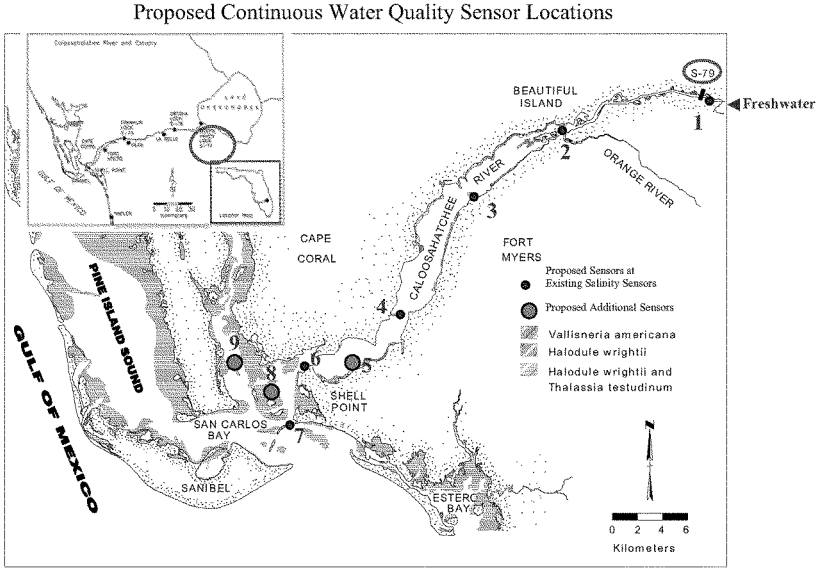

FIGURE D-5: MAP OF CALOOSAHATCHEE ESTUARY AREA AND LOCATION OF PROPOSED WATER QUALITY MONITORING SENSORS; STAGED ON EXISTING SALINITY SENSORS PLATFORMS AND AT PROPOSED NEW SITES

Efforts currently underway to retain, re-direct, treat, or otherwise better control water deliveries holds the promise of ameliorating excess nutrient loading, reducing sediment and turbidity causing conditions, improving water clarity, and decreasing intensity and frequency of algal blooms. Otherwise, judiciously managing water will result in improved estuarine water quality. For example, freshwater inflow through S-79 is directly related to the amount of total nitrogen entering the estuary (***Figure D-6***). This relation also holds for other primary constituents, including phosphorus and water color. The loading and flow together thereby effects parameter concentration in the estuary, distance downstream of influence, and the amount of change in related parameters like chlorophyll (algae), water clarity and dissolved oxygen (D.O.).

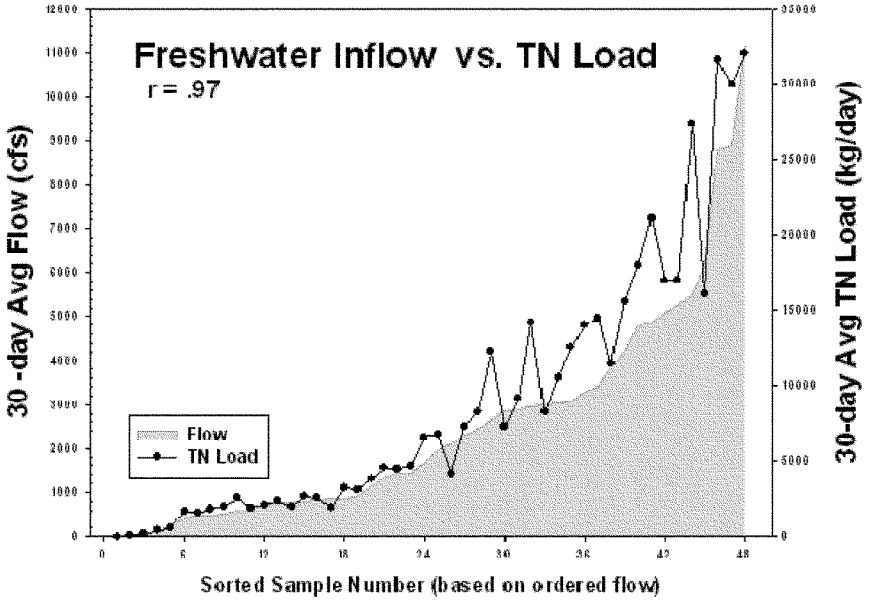

FIGURE D-6: MONTHLY LOAD OF TOTAL NITROGEN FROM S-79 COMPARED TO MONTHLY AVERAGE FLOW FROM THE STRUCTURE

Figure D-6 serves to indicate not only that parameter loading of constituents is strongly related to flow volume, but also the concentration of the constituents upstream - in the water being discharged to the estuary. However, for many constituents, loading and subsequent water quality downstream will greatly improve if the S-79 inflow targets are achieved (***Table D-3***). For example, if 75% of the flows are within the 450-800 cfs range, and almost all flows are less than 2,800 cfs, than the load to the estuary will be restricted to the very low end of ***Figure D-6***.

Provisional analysis indicates that flows in the range of 450-800 cfs per month will equate to ~ a average 2000 kg/day (2 metric tons/day = 60 metric tons month), flows of 2,800 cfs will produce an average TN load of 10,000 kg/day (10 metric tons/day, 300 mt/month), and 4,500 cfs per month correlates to about 14,000 kg/day (14 mt/day, 420 mt/30days).

TABLE D-3: TARGET FREQUENCY DISTRIBUTION OF MEAN MONTHLY FLOWS FROM S-79 (CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR - CALOOSAHATCHEE ESTUARY HYDROLOGIC EVALUATION PERFORMANCE MEASURES, 2005).

Discharge Range (cfs) From S-79	Percent Distribution Of Flows From S-79
0 to 450	0%
450 to 500	42.8%
500 to 800	31.7%
800 to1500	19.2%
1500 to 2800	5.6%
2800 to 4500	0.7%
>4500	0%

Based on ***Figure D-6***, discharges at S-79 contain 70 to 80 percent of the nutrient load delivered to the Caloosahatchee Estuary. Waste load allocation studies conducted over twenty years ago in the Caloosahatchee Estuary by the Florida Department of Environmental Regulation (DeGrove 1981) concluded that the estuary had reached its nutrient loading limit as indicated by elevated chlorophyll α and depressed dissolved oxygen levels. Janicki (2003) determined that nitrogen loads were more responsible for degraded water quality in the estuary than phosphorus, and calculated that achieving an annual average chlorophyll-a concentration of 11 ug/l would require reducing the nitrogen load at S-79 to less than 190 metric tons/month (average of 6.3 mt/day) during the dry season, 350 tons/month during the wet season (average 11.7mt/day), and an annual cumulative load less than 3000 U.S. tons per year (2721 mt/year, average 7.45 mt/day). Recent estimates of average load (Crean and Irican 2005) indicate that on average (1993-2003) 2,905 and 233 U.S. tons of total nitrogen and total phosphorus, respectively, enter the estuary annually, with nitrogen loads in excess of 3000 U.S. tons occurring 30 to 40% of the time.

The Janicki recommendation for nitrogen loading to maintain a chl-a of 11ug/l is for the entire estuary, which would serve to keep the estuary from violating the state impaired water rule (also 11 ug/l). However, the estuary chl-a concentration varies between segments of the estuary. Doering and Chamberlain (2005) found current median chl-a in 4 section of the estuary (upper, mid, lower estuary above Shell Pt, and in San Carlos Bay) were 10.7ug/l, 12.7ug/l, 5.3ug/l, and 4.2ug/l, which were usually below the goal used by Janicki. Doering and Chamberlain (2005) determined that the seagrass targets listed in the SAV Monitoring Plan were associated with chl-a concentrations of below 4.6 in the lower estuary, and 4.0 in San Carlos Bay, which also is close to the Charlotte Harbor National Estuarine Program's chl-a target to promote seagrass growth to 2 meters in San Carlos Bay. Doering and Chamberlain (2005) further correlated a nitrogen load of 186-192 mt/month (2230-2310 mt/year) at S-79 with the chl-a goals for seagrass downstream. Therefore, Janicki's estimate for the dry season

should be promoted all year. Doering and Chamberlain (2005) ended their analysis by indicating that a chlorophyll a concentration of 5 ug/l in San Carlos Bay corresponds to an Estuary-wide average of 8.3 ug/l. Given the variability, this compares well with the standards/rule based value of 11 ug/l.

The Florida Impaired Waters Rule (IWR) states that an estuary is impaired if the annual mean chlorophyll concentration is greater than 11 µg/L. Even though the current median values identified in the previous paragraph exceed 11ug/l only in the mid-estuary, the average chl-a is greater than 11ug/l throughout the upper, middle, and into the lower estuary. Therefore, maintaining current nutrient dynamics of loading, concentrations, and bloom frequency that allows monthly chl-a values to fluctuate at their current highly variable concentrations will result in the denigration of the estuary and its continued designation as an impaired water body.

Since the IWR is calculated on an annual average basis, then one approach to determine a target for allowable bloom frequencies is to ascertain the number of months that average chl-a values above 11 µg/L can occur and not cause the estuary to be designated as an impaired water body. This approach is summarized in ***Table D-4***. This premise assumes that the average chl-a value during the non-bloom months is < 8 µg/L, which is the expected median value for the area upstream of Shell Pt. when nitrogen loading is reduced to the suggested target of 190 mt/month discussed above.

TABLE D-4: SUGGESTED LIMITS FOR THE RANGE OF CHL-A CONCENTRATION VALUES IN A BLOOM, THE NUMBER OF MONTHS A SPECIFIC RANGE CAN OCCUR, AND THE CORRESPONDING ANNUAL FREQUENCY. NON-BLOOM MONTHS ARE ASSUMED TO BE < 8 µG/L.

Range of Chl-a (µg/L)	Allowable # of Months	Annual bloom frequency (Allowable Months/12)100
>50	0	0%
30-50	1	9%
23-29	2	17%
18-22	3	25%
17-18	4	33%
11-16	5	42%
< 5: Upper and Mid-Estuary	Minimum = 4 months	Minimum = 33%
< 5: Lower estuary	Minimum = 7 months	Minimum = 60%

A review of the data found that the maximum frequency of months that exceeded 20 µg/L has been about 20 percent, which is within the table values. However,

the current maximum frequency of monthly values above 11 µg/L has only been about 40 percent. Therefore, to suggest that 100% is allowable to avoid an IWR designation may actually result in a decline of water quality conditions. In this same spirit, the existing frequency of chl-a values of < 5 µg/L in the upper and middle estuary is about 35%, which should be promoted as a good chl-a target. In the lower estuary, the minimum desirable frequency of 5 µg/L jumps to 60%. Including these minimum frequency targets in ***Table D-4*** will help preserve existing condition important for seagrass.

As discussed above, keeping the upper and mid-estuary from being designated impaired water bodies will further promote chl-a values of < 5 µg/L in the seagrass areas (lower estuary and San Carlos Bay). Also as indicated above target flows between 450 and 800 cfs account for 75% of the total distribution When flows are < 800 cfs, chl-a has historically been < 5 µg/L (***Figure D-7***). Therefore, achieving the hydrologic targets should help meet the chlorophyll goals as well as the nutrient loading target. Although, it should be noted that chl-a values in San Carlos Bay that exceed 5 µg/L may be unconnected with nutrient loading or chlorophyll values upstream, in part because of the occasional impacts of "red tide" on this area. Red tide originates in Gulf waters and may move inshore when oceanographic conditions are favorable.

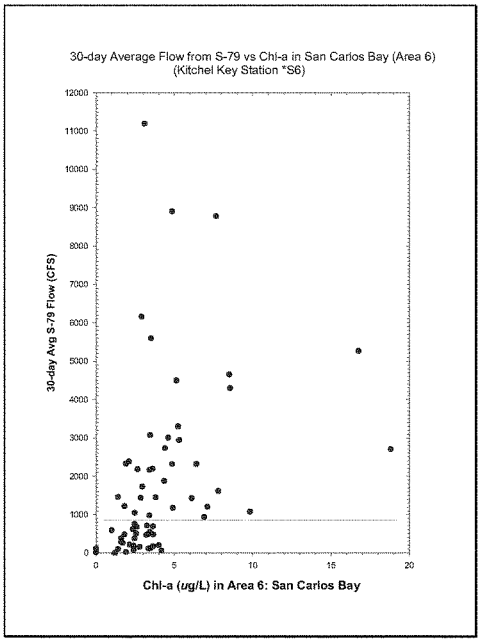

FIGURE D-7: CHL-A IN SAN CARLOS BAY COMPARED WITH 30-DAY AVERAGE FLOW FROM S-79 (FRANKLIN LOCK AND DAM)

High concentrations of chlorophyll a in surface waters can be associated with low concentrations of dissolved oxygen in bottom waters (0.5 m above bottom) in the Caloosahatchee on short time scales of weeks (Doering and Chamberlain (2005). Such an instance is depicted in ***Figure D-8***. The crash of a chlorophyll a bloom coincided with a rapid decline in oxygen in bottom waters during the month of June 2000. On longer time scales, the high concentrations of chlorophyll a may be associated with lower oxygen concentrations one or two months in the future. Establishing a maximum chl-a bloom target of 50 µg/L in the upper and middle estuary will help protect against sub standard D.O. as depicted in ***Figure D-8***.

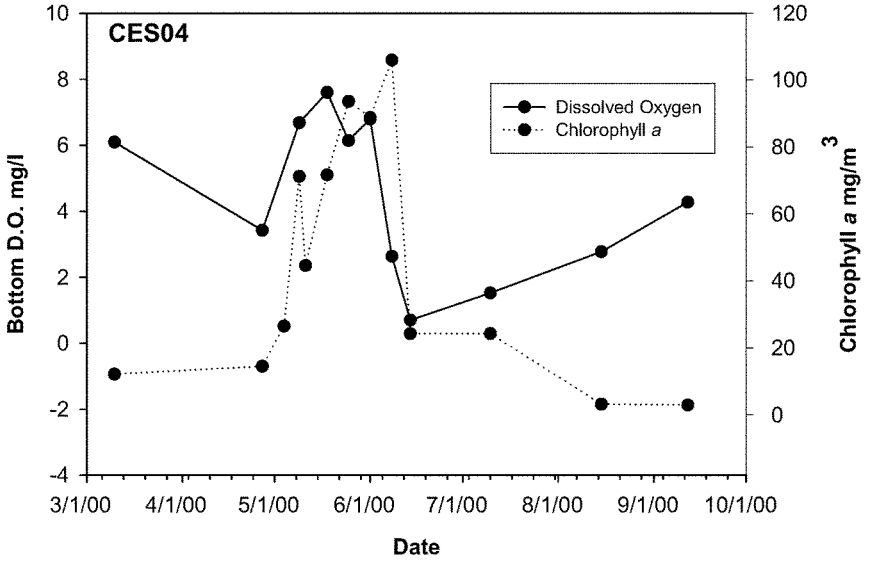

FIGURE D-8: TIME SERIES OF CHLOROPHYLL *A* AND DISSOLVED OXYGEN IN BOTTOM WATER IN THE UPPER CALOOSAHATCHEE ESTUARY NEAR BEAUTIFUL ISLAND.

In general, the D.O. goal is to improve or maintain suitable conditions for establishment and maintenance of healthy, well-balanced biological communities. Bottom dissolved oxygen regime is most meaningful as regards to biological response and success. Jordan et al. (1992) developed dissolved oxygen targets for the Chesapeake Bay for the protection of desirable species of fish, mollusks and crustaceans. These targets recommended that dissolved oxygen is greater than or equal to 1.0 mg/l at all times everywhere in the water column; dissolved oxygen never falls within 1.0-3.0 mg/l for longer than 12 hours every 48 hours; monthly mean dissolved oxygen is greater than 5.0 mg/l at all times above the pycnocline (above the wedge of saltier water that typically exists as a function of tides); and dissolved oxygen is always greater than 5.0 mg/l in spawning and nursery areas.

The targets recommended by Jordan are supported by the conclusions of other researchers that report low dissolved oxygen (DO) concentrations even in the water column can increase mortality, reduce growth rates and alter the distribution and behavior of aquatic organisms (Diaz and Rosenberg 1995, Breitburg 2002, U.S. EPA 2002, 2003). Mortality can occur rapidly from short-term exposure (less than 6 to 12 hours) to low oxygen concentrations (Breitburg 2002). Continuous exposures to even moderate reductions in DO can

substantially reduce growth rates of both fishes and invertebrates (for review see U.S. EPA 2000); best evidence of this is from aquaculture studies – for example, Davis (1990) reports that DO is the most critical aspect of water quality for red drum, *Sciaenops ocellatus*, and that growth reduction is apparent when DO levels drop below 4 mg/L. However, many species exhibit behavioral responses (e.g., blue-crab migrations, Bailey and Jones 1989, as cited by Tomasko 1997, etc.) that allows them to avoid not only lethal oxygen concentrations but also those that would require greatly increased ventilation and reduce growth. Emigration leading to reduced densities of fishes can begin at oxygen concentrations approaching 3 to 4 mg/l (Diaz and Rosenberg 1995, Breitburg 2002, U.S. EPA 2003). Consequently, habitat loss due to depressed DO can be far greater than if based on concentrations thought to be lethal. Although the breakpoint for hypoxia and community change in the benthos was considered to be 2 mg DO/l, a study by Ritter and Montagna (1999) suggest it may occur at 3 mg DO/l. Impacts from hypoxia induced community change can lead to altered sedimentary processes (e.g., bioturbation, etc.) and, as a consequence, altered geochemistry (Diaz and Rosenberg 1995). Habitat squeeze from low DO can interrupt seasonal migrations for spawning or of organisms seeking optimal temperatures. Because they are limited in their behavioral avoidance, eggs and larvae can be more vulnerable to low DO (Breitburg 2002). Moreover, in many species, eggs and larvae have higher DO requirements than adults (Breitburg 2002; for tolerances of red drum larvae, see Miller et al. 2002, for newly set (3-4 days) eastern oysters *Crassostera virginica*, see Osman and Abbe, 1994; as cited in U.S. EPA, 2000).

U.S. EPA (2003) adopted a number of dissolved oxygen criteria (for various designated uses and temporal applications) including, but not limited to, the following: 1) a criterion minimum concentration (CMC = 1-day mean concentration) of 2.3 mg/l to protect juvenile and adult survival in open-water, 2) a criterion continuous concentration (CCC = 30-day mean) of 5 mg/l to protect against adverse effects on growth of larval, juvenile and adult fish and shellfish in tidal habitats (>0.5 ppt salinity) and, 3) an instantaneous minimum concentration of 1.7 mg/l to protect the survival of eggs and larvae in deep water. The most rigorous criteria adopted was a 7-day mean concentration of 6 mg/l for the protection of survival and growth of larval and juvenile fish in tidal-freshwater habitats (< 0.5 ppt), which was based on information contained in U.S. EPA (1998).

In summary, if achieved, the current State water quality standard appears to a good general target for the Caloosahatchee, which would be protective for Class II or III marine waters. This standard includes a 24-hour average ≥ 5.0 mg/L; instantaneous minimum [as indicated by pre-dawn concentrations] ≥ 4.0 mg/l (≈ FAC 62-302.530 (31).
The need to establish suitable Chl-a targets in the estuary related to SAV is due to the impact that increased phytoplankton can have on water clarity. Other

water quality constituents also influence water clarity, including water color and total suspended solids. These parameters are either directly related to freshwater inflow (i.e., color) or indirectly (Chlorophyll and TSS). However, limiting flow to the targets in ***Table D-3*** will promote SAV as depicted in ***Figure D-10*** and in the SAV Monitoring Plan. Therefore, the establishment of additional water clarity targets will be best served by identifying the actual light requirements of SAV species and monitoring to determine if requirements are achieved. Current median values of secchi disk depth are 1.0m near *Vallisneria americana* (tape grass) beds in the upper estuary, 1.1 – 1.3m adjacent to the Halodule wrightii (shoal grass) beds in the lower estuary, and 1.4m in San Carlos Bay. Improvement in freshwater inflows should also improve these secchi measurements, such that variability in measurement decreases and the current median values trend toward the 25 percentile, instead of the median.

In addition to secchi depth measurements, direct monitoring of light using photosynthetic radiation (PAR) sensors should become standard practice. Traditionally, these this type of sensor has been used deployed through the water column during site sampling to determine light attenuation. However, researchers have estimated the amount of light required by specific SAV species to survive, including tape grass and shoal grass. The minimum average daily bottom light (ADBL) measured in the PAR spectrum of 400-700 nanometers is about 20 microEinsteins (uE = micromoles/m2/sec). ADBL is based on daily light reaching the bottom during the entire 24 hour day (not just daylight or peak light periods). During high salinity conditions (>9.5 ppt) when the plant is stressed, about 100 uE represents plant saturation. When salinity is < 9.5 ppt, 100 uE represents about 60-70% saturation, which doesn't occur until ADBL reaches about 390 uE. ADBL exists for shoal grass can also be divided into stressed environments like in Iona Cove, and more desirable areas as in San Carlos Bay. Minimum ADBL in Iona Cove area is about 50-60 uE, with 50 and 100% saturation equal to about 140 and 220-275 uE , respectively. In San Carlos Bay, the minimum, 50% and 100% levels of ADBL equates to about, 75-100uE, 150-175, and 325 uE, respectively.

D.3.2.2 Monitoring Objectives

The Caloosahatchee River (C-43) West Basin Storage Reservoir project is authorized as one of the initial projects for implementation under Section 601(b)(2)(C) of the Water Resources Development Act (WRDA) 2000. To clarify the intent of WRDA 2000, projects in the category of this Caloosahatchee River (C-43) West Basin Storage Reservoir project must not attain their primary quantity performance objectives by degrading water quality. Therefore, it is not the goal of this project to improve water quality in the estuary, but the project also can't degrade water quality. The targets discussed earlier act as benchmarks for desirable water quality trends if change is detected. As discussed earlier, improvement in water quality is expected from controlling water quantity.

Other state and local efforts, for example the State's Total Maximum Daily Load program (TMDL), are expected to compliment and supplement this Project and the larger CERP effort, thus affording additional improvements in water quality; however, implementation of these efforts, including effective agricultural and urban Best Management Practices (BMPs) are outside the purview of this Project and CERP in this region and are not addressed by this Monitoring Plan Determining if the "no degradation" of water quality requirement is achieved depends on monitoring and evaluating estuarine water quality commensurate with the project operation, with the following objectives:

1. Compare water quality during project operation with the historic data sets described by Doering and Chamberlain (2005) and new monitoring information prior to operation to determine if there is a change in nutrient loading. To assist this effort, compare project related water quality and nutrient loading with similar seasonal conditions when freshwater inflows would have been equal to non project flow.
2. Compare historic chl-a data as explained in Doering and Chamberlain (2005) with new monitoring data collected during project operation, to determine if there is a change in chl-a concentration and blooms within the same regions.
3. Compare D.O. as described above for other parameters.
4. Monitor water clarity by secchi disk reading and PAR measurements at SAV habitats. Compare variability in these parameters as discussed above for the other parameters.
5. Using the same monitoring approaches as discussed above, compare concentrations of TN, inorganic nitrogen, TP, inorganic P and color. If change is detected, determine if it is it toward decreasing concentrations.
6. Addresses the null hypothesis stated below that is intended to assess the success of the project.

D.3.2.3 Null Hypothesis

The general null hypothesis - As a result of the operation of the Caloosahatchee River (C-43) West Basin Storage Reservoir, there will be a statistically significant degradation in current water quality condition, compared to – (a) historic water quality samples along the estuary's longitudinal gradient and at valued ecosystem habitat locations; (b) historic seasonal water quality patterns; and (c) variation in water quality within distinct estuarine zones of the estuary.

D.3.2.4 Monitoring Measures and Targets

1. Monitoring Measure: Mean monthly flows from S-77, the Caloosahatchee River (C-43) West Basin Storage Reservoir, as well as flows and loading from S-79.

Target: Reduction in current mean monthly flows from S-79 toward achieving the Project target flows (***Table D-3***) should also equate to a reduction in nutrient loading. The target nutrient loading from S-79 is 190 mt/month. Review of historical data indicates that flows < 2000 cfs will achieve this loading target. Therefore, as flows trend toward that of project target, reduction in loading variability should occur, and eventually 95% of monthly loading will be < 190 mt.

Adaptive Management Trigger: Significant increase in average monthly and annual loading as a result of project operation.

2. Monitoring Measure: Phytoplankton production as estimated by chlorophyll-a.

Target: As a result of the reduction in loading and freshwater inflows, phytoplankton production will decrease as measured by chl-a concentrations and variability. Ultimately, upon Project build-out with other CERP components in place, chl-a values are expected to average below 5 ug/l in the Iona Cove area and < 4 ug/l in San Carlos Bay. The target average chl-a in the remainder of the upstream areas of the estuary is 8 ug/l. As project completion precedes, reduction in chl-a variability should occur as monthly chl-a values approach the targets. Phytoplankton bloom frequency should diminish with a target to be less than the frequencies listed in ***Table D-4***.

Adaptive Management Trigger: Increase in chl-a, especially upstream associated achieving minimum flow targets. Increase in bloom frequencies and chl-a concentrations that negative impacts the estuary's IWR standing.

3. Monitoring Measure: Dissolved Oxygen.

Target: D.O. should be the same as state standards, such that 24-hour average D.O. is ≥ 5.0 mg/L and instantaneous minimum [as indicated by pre-dawn concentrations] is ≥ 4.0 mg/l (≈ FAC 62-302.530 (31).

Adaptive Management Trigger: Increase in the violation occurrence of Florida's D.O. standards.

4. Monitoring Measure: Turbidity (Secchi).

Target: Variability in secchi readings should not decline below the current median values of 1.0 m in the tape grass area, 1.2 m in Iona Cove, and 1.4 in San Carlos Bay. It should tend toward the 25 percentile as project operation approaches the target flows. In addition, ADBL in the tape grass area should be > 20 UE and average > 100 uE at 1.0 meters (MLLW). ADBL in Iona Cove should exceed 70 uE and average 150 uE at 1.0 m. In San Carlos Bay, the

minimum ADBL should exceed 80 uE and average at least 150 uE at 1.5 m (MLLW).

Adaptive Management Target: Project operation that causes: (a) secchi measurements and variability to decline below the above stated current median values; and (b) a decline in PAR below current median values.

5. Nutrients (inorganic nitrogen, total phosphorous, inorganic phosphorous) and Color.

Target: Concentrations of TN, inorganic nitrogen, TP, inorganic P, and color should detect a decrease in concentrations compared to the data sets described and evaluated by Doering and Chamberlain (2005) and any new data collected as outlined in this monitoring plan prior to project operation.

Adaptive Management Trigger: Increase in concentrations of TN, inorganic nitrogen, TP, inorganic P, and color compared to the data sets described and evaluated by Doering and Chamberlain (2005) and any new data collected as outlined in this monitoring plan prior to project operation.

D.3.2.5 Monitoring Approach

Daily freshwater discharge from Lake Okeechobee and S-79 are measured by the Corp of Engineers and posted electronically on COE and SFWMD web sites. This information is part of normal operation and therefore no additional Caloosahatchee River (C-43) West Basin Storage Reservoir project cost is required. Salinity information will be provided by the network of continuous sensors described in the Salinity Monitoring Plan and additional information collected concurrent to SAV monitoring.

Standard method of water quality sampling (grab samples) are too expensive and have such a high variability, that the results would probably be unable to detect change until many years of sampling are completed. This type of monitoring also is inappropriate for sampling on the sub-daily basis required to address the above objectives.

Currently, RECOVER is testing in situ instruments (Microlab) capable of automatically sampling nitrogen, phosphorous, and other parameters at a pre-set frequencies. These instruments, coupled with other in-situ instruments to monitor D.O. and PAR and reflectance (measure of Chl-a) are necessary.

***Figure* D-5** identifies locations where instruments should be located. To meet Objective 1 and Target 1, a Microlab will be required to sample nitrogen at 20% and 80% of the water depth twice daily. Microlab instruments will also be

required at sites 2, 3, 4, 5, and 8 to sample nitrogen, TP, inorganic P, estimate chl-a and color (if possible) twice daily to meet Objective 2 and 5. Dissolved oxygen sensors and data logger will be required at 205 and 80% of the depth at stations 2, 3, 4, and 5, in order to electronically record D.O. at 30 minute intervals to address Objective 3 and 5. Finally, a submerged PAR sensor should be located at 1.0 m at station 2, 3, and 5, as well as at 1. 5 m at station 8 and 9; recording PAR every 30 minutes to meet Objective 4 and address Target 4. An additional instrument should be established at the Ft. Myers Service Center to record natural variation in air PAR as a reference to observed changes in the submerged sensors. In addition to the instrument measurements, a secchi disk depth measurement (Objective 4) should be taken at each station when instruments are cleaned and calibrated.

TABLE D-5: MONITORING SITES, PARAMETERS SAMPLED, MONITORING OBJECTIVES (FROM MONITORING OBJECTIVES SECTION), AND THE FUNDING SOURCE SPONSORING THE SITE INSTALLATION AND MAINTENANCE. CORPS OF ENGINEERS (COE), SOUTH FLORIDA WATER MANAGEMENT DISTRICT (SFWMD), SANIBEL-CAPTIVA CONSERVATION FOUNDATION (SCCF) AND C-43 WEST BASIN STORAGE RESERVOIR PROJECT (PROJECT)

Monitoring Site and Parameters	Objective(s) Addressed	Funding Sponsor
S-79 (Franklin Dam)	Compare flow from S-79 to project target	COE
1 – Total Nitrogen (TN upstream side of S-79)	1- Determine daily loading (TN concentration X flow)	New platform & sensors – SCCF or Project
2 – TN, inorg N, TP,inorg P, Chl-a, color, turbidity, D.O.	2 - Compare Chl-a conc., trends, and blooms freq. 3 - Compare D.O conc and diurnal fluctuation 4 - Compare PAR levels and tape grass requirements 5 - Compare N, P, color, and turbidity & trends	-Existing SFWMD Platform -Sensors: SCCF or Project
3 - TN, inorg N, TP,inorg P, Chl-a, color, turbidity, D.O., PAR	2 - Compare Chl-a conc., trends, and blooms freq. 3 - Compare D.O. conc and diurnal fluctuation 4 - Compare PAR levels and tape grass requirements 5 - Compare N, P, color, and turbidity & trends	-Existing SFWMD Platform -Sensors: SCCF or Project
4- TN, inorg N, TP,inorg P, Chl-a, color, turbidity, D.O	2 - Compare Chl-a conc., trends, and blooms freq. 3 - Compare D.O. conc and diurnal fluctuation 5 - Compare N, P, color, and turbidity & trends	-Existing SFWMD Platform -Sensors: SCCF or Project
5 - TN, inorg N, TP,inorg P, Chl-a, color, turbidity, D.O., PAR	2 - Compare Chl-a conc., trends, and blooms freq. 3 - Compare D.O. conc , diurnal fluctuation, and oyster requirement 4 - Compare PAR levels and seagrass requirements 5 - Compare N, P, color, and turbidity & trends	-Existing Platform (?Salinity M Plan) -Sensors: Project
6 – D.O.	3 - Compare D.O. conc , diurnal fluctuation, and oyster requirements	-Existing SFWMD Platform -Sensor: Project
7 - TN, inorg N, TP,inorg P, Chl-a, color, turbidity,	2 - Compare Chl-a conc., trends, and blooms freq. 5 - Compare N, P, color, and turbidity & trends	-Existing SFWMD Platform -Sensors: SCCF or Project
8 - TN, inorg N, TP,inorg P, Chl-a, color, turbidity	2 - Compare Chl-a conc., trends, and blooms freq. 5 - Compare N, P, color, and turbidity & trends	SCCF
9 - TN, inorg N, TP,inorg P,	2 - Compare Chl-a conc., trends, and blooms freq.	-Existing Platform

Chl-a, color, turbidity, D.O., PAR	3 - Compare D.O. conc and diurnal fluctuation 4 - Compare PAR levels and seagrass requirements 5 - Compare N, P, color, and turbidity & trends	(?Salinity M Plan) -Sensors: Project
10 - TN, inorg N, TP,inorg P, Chl-a, color, turbidity, D.O., PAR	2 - Compare Chl-a conc., trends, and blooms freq. 3 - Compare D.O. conc and diurnal fluctuation 4 - Compare PAR levels and seagrass requirements 5 - Compare N, P, color, and turbidity & trends	SCCF
11 - TN, inorg N, TP,inorg P, Chl-a, color, turbidity, D.O.,PAR	2 - Compare Chl-a conc., trends, and blooms freq. 3 - Compare D.O. conc and diurnal fluctuation 4 - Compare PAR levels and seagrass requirements 5 - Compare N, P, color, and turbidity & trends	SCCF

D.3.2.6 Data Quality

Routine samples and routine quality control samples are collected in accordance with the Florida Department of Environmental Protection (Department) Quality Assurance Rule, 62-160.200 and 62-160.320, F.A.C. and the District Field Sampling Quality Manual (FSQM). Applicable sections of the FSQM include auto-sampler collection methods; field test methods; and quality control procedures. Corrective actions for data not meeting the quality objectives may be taken as outlined in the Quality Assurance Systems Requirement (QASR).

D.3.3 Project Monitoring and Assessment Plan: Oysters

This oyster monitoring plan is intended to help address concerns related to downstream estuary impacts and benefits related to changes in freshwater inflow and salinity due to project implementation.

D.3.3.1 Background

The eastern oyster is a bivalve in the family Ostreidae. It is important both commercially and recreationally in fisheries along the Atlantic and Gulf of Mexico coasts of North America. It requires a proper substrate and suitable salinity conditions for existence. Due to its sedentary nature, the eastern oyster is susceptible to undesirable natural and artificial environmental changes, as well as pollution within its habitat. Environmental disruptions are responsible for reducing oyster populations and their traditional habitats (Cake 1983).

In the Caloosahatchee Estuary, oysters have been identified as a Valued Ecosystem Component (VEC). Oysters are natural components of southern estuaries and were documented to be abundant in the system. The eastern oyster is important for providing reef habitat that serves as areas of concentration (Wells 1961. Bahr and Lanier 1981) and as food for numerous estuarine species including gastropod mollusks, polychaete worms, decapod crustaceans, various boring sponges, fish, and birds, including the endangered oyster catcher. The eastern oyster is the dominant species in the oyster reef community. There may be over 40 species of macrofauna living in oyster beds with the total number of species exceeding 300 (Wells, 1961; Ingle & Smith,

1956; Woodburn, 1965; McDonald, 1982; Peters, 1981; Meyer, 1994; Tolley, 2006).

Implementation of the C43 West Basin Reservoir Project expects to restore hydrology in the Caloosahatchee Estuary by reducing the number of low and high flow water delivery events. It is anticipated that if flows are restored to more natural conditions then there should be an improvement of recruitment and survivorship of the eastern oyster (*Crassostrea virginica*).

There is an existing RECOVER monitoring program for the eastern oyster (*Crassostrea virginica*) in the Caloosahatchee Estuary. This program began collecting data in January 2004.

D.3.3.2 Monitoring Objectives

1. Continue long term monitoring of oysters (*Crassostrea virginica*) in the Caloosahatchee Estuary.
2. Determine if the restoration of beneficial patterns of freshwater inflow, salinity and water quality to the Caloosahatchee Estuary will achieve the expected distribution, community structure and viability of oysters.
3. Examine the effects of variation in salinity on oyster condition and health.
4. Identify areas suitable for the development and therefore potential restoration of oyster reefs.
5. Create additional monitoring stations at newly assembled reefs, as they are constructed, in order to track
6. Addresses the null hypothesis stated below that is intended to assess the success of the project.

D.3.3.3 Null Hypothesis

The general null hypothesis - As a result of the operation of the CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR, there are either detrimental impacts to the oyster community, or no changes in the estuarine oyster population, related to – (a) the base line conditions established from years of sampling prior to reservoir operation in a variety of habitats and salinity zones along the downstream gradient of the estuary.

Determining if the null hypothesis is true depends on monitoring oysters and at least salinity commensurate with the project operation, by:

1. Comparing populations and health with historic data sets;
2. Assessing trends in oyster populations and health during project operation to determine the direction of change

3. Comparing current project related flows and oyster populations and health with similar seasonal conditions when freshwater inflows would have been equal to non-project flow.

D.3.3.4 Monitoring Measures and Targets

1. Monitoring Measure (monthly): *Perkinsus marinus* prevalence. *Perkinsus* infection is measured on a scale of 0 to 5 with five being the highest infestation of the parasite.

Target: *Perkinsus marinus* prevalence is less than 1.

Adaptive Management Trigger: When prevalence becomes a 3 or higher, additional freshwater should be released to lower salinity in the lower estuary.

2. Monitoring Measure (monthly): Spat Recruitment (May- October).

Target: 5 spat per shell per month

Adaptive Management Trigger: When there is less than 5 spat per shell for two or more consecutive months flows should be decreased to reduce the number of larvae being flushed from the system.

3. Monitoring Measure: Density of Live Oysters.

Target: Greater than 200 living oysters per m^2 at identified sample locations.
Adaptive Management Trigger: When there are less than 100 live oysters per m^2 water flow should be adjusted to provide optimum salinities in the lower estuary.

4. Monitoring Measure: Condition Index of Oysters (CI). CI measures the general health of the oyster and generally ranges from 0 to 8 with 8 being the best.

Target: CI changes seasonally but should not be less than 2.5.
Adaptive Management Trigger: A CI less than one indicates poor oyster health usually resulting in lack of food. If the CI falls below 2 flows should be adjusted to increase primary and secondary productivity in the estuary.

D.3.3.5 Monitoring Approach

A long term oyster monitoring program based on previous studies and existing monitoring will be carried out in the Caloosahatchee Estuary. The program will utilize existing methodologies and sampling locations for consistency and will incorporate existing data as baseline for a comparison to project condition.

Continued post construction monitoring will allow tends to be identified once the project becomes functional. Additional sampling locations will be established as new reefs are constructed.

Twice a year (summer, winter) one 100 m transects (parallel to shore) will be established at seven stations (***Figure D-9***). Each transect will be subdivided into seven (7) 20 m long portions (0-20, 20-40, 40-60, 60 – 80, 80 – 100) On each sampling date, 5 – 1 m2 quadrats will be placed randomly along each transect (n=5 quadrats per transect, 1 quadrat with each 20 m portion, n = 10 quadrats per site,). For each quadrat, the following measurements will be determined.

- Percent Adults Live versus Dead: Count and record the number of live adult oysters and the number of dead adult oysters within the 1 m^2 quadrat.
- Adult sizes (Live versus Dead): Measure and record the maximum length of all adult oysters (both dead and alive) within the 1 m^2 quadrat. Be sure to distinguish between the two.
- Water Depth: Measured to the nearest centimeter at the center of each of the 1 m^2 quadrats; measured from water surface; report in meters (m).
- Spat Recruitment: Oyster spat recruitment will be conducted at each oyster monitoring station using old adult oyster shells strung together with a weighted galvanized wire. Three shell strings will be deployed at the site each month. A shell string will consist of 12 oyster shells, each 5.7-7.5 cm long with a hole drilled in the center and oriented inner surface down, when suspended off the bottom. Oyster spat settlement will be monitored monthly (March – October) by counting the number of spat settled on the underside of strung shells.
- Juvenile Oyster Growth and Survival: Four hundred hatchery raised juvenile oysters (10 mm-20 mm) will be deployed at all sampling locations in 0.5 mm wire-mesh bags. Fifty randomly selected oysters will be measured to the nearest 0.1 mm every month from each location for 24 months. Beginning year 3, 250 more juvenile oysters in wire mesh bags will be deployed at each site to examine the effects of high freshwater releases and resulting low salinities on juvenile oysters. Similar to year 1 and 2, growth of juvenile oysters will be measured monthly. The effect of predation on oyster survival will be determined by placing juvenile oysters in open vs. closed cages.
- Oyster disease prevalence and intensity: 15-20 oysters / sampling location will be monitored monthly for disease prevalence and intensity of the oyster pathogen *Perkinsus marinus*.

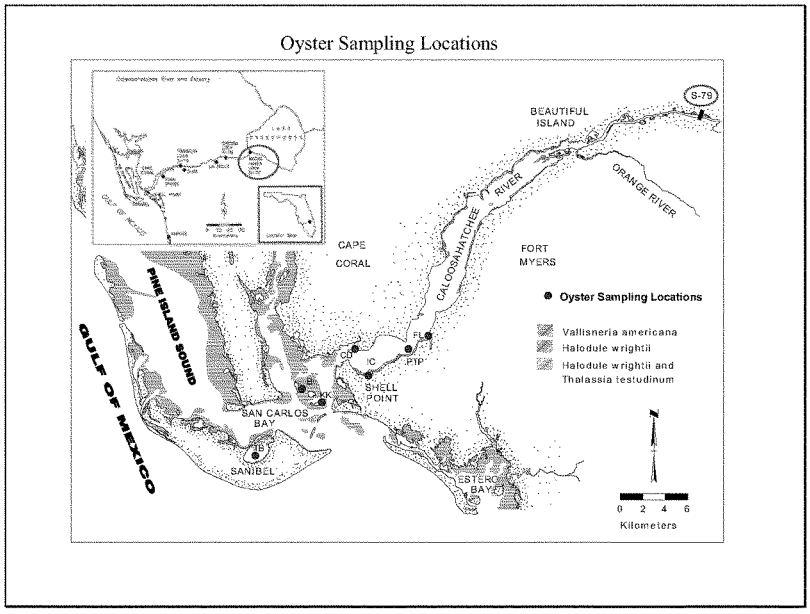

FIGURE D-9: OYSTER SAMPLE LOCATIONS (IC: IONA COVE, CD: CATTLE DOCK, BI; BIRD ISLAND, KK: KITCHEL KEY, TB: TARPON BAY, FL: FUTURE LOCATION)

Concurrent with sampling schedule, the Contractor shall obtain vertical profiles of dissolved oxygen, salinity, temperature, pH, and conductivity using standard electronic sensors calibrated to manufacturer's specifications. Contractor must meet and follow the minimum requirements in the FDEP field Sampling SOPs for field testing (FT), field documentation (FD), and field quality control (FQ). Depth intervals shall be surface and bottom if the depth is greater than 1 m. A log of pre-calibration and post-calibration checks along with records of yearly maintenance of the instruments cables and sensors should be kept. Copies of these logs must be submitted with each data submission. Water depth, weather conditions (i.e. cloudy, windy etc.), time of day and tidal stage will be recorded (low, high, ebbing, flooding).

D.3.3.6 Data Quality

Routine samples are collected in accordance with RECOVER guidelines and published standards regarding monitoring oysters.

D.3.4 Project Monitoring and Assessment Plan: Submerged Aquatic Vegetation

This submerged aquatic vegetation monitoring plan is intended to help address concerns related to downstream estuary impacts and benefits related to changes in freshwater inflow and salinity due to project implementation.

D.3.4.1 Background

Submerged aquatic vegetation (SAV) is important economically and ecologically, serving as major structural elements in estuarine and coastal waters. They provide food, habitat, and refuge to invertebrates, birds, marine turtles,

mammals, and many marine recreationally and commercially targeted fishes during some stage of their life cycle. In addition to being important constituents of coastal food webs, SAV also stabilize sediments, inhibit their re-suspension, sequester atmospheric carbon, and export carbon to other systems, improve water transparency, trap and cycle nutrients, and protect shorelines through wave energy attenuation (Duarte 2002). Because of these extensive ecosystem services, SAV ecosystems are among the most significant on the planet.

By definition, SAV includes both marine and freshwater aquatic angiosperms as well as macroalgal species. Native macroalgal species (attached and drift) are desirable constituents of estuaries, though an overabundance of these taxa may be detrimental to angiosperms (Onuf 1996).

In the Caloosahatchee estuarine system, five seagrass species are found, including the uncommon presence of *Halophila decipiens* (paddle grass) and *Halophila engelmannii* (star-grass) in San Carlos Bay area. *Halodule wrightii* (shoal grass) and *Thalassia testudinum* (turtle grass) are the dominant two species in San Carlos Bay (3), with *Syringodium filiforme* (manatee grass) also contributing to the lush beds in lower Pine Island Sound (***Figure D-10)***. Their density, coverage, and depth increases with distance from the river, while population variability decreases. Only shoal grass is found upstream of Shell Point. The dominant freshwater species of concern is *Vallisneria americana* (American wild celery - tape grass). One brackish water species *Ruppia maritima* (widgeon grass) is also found in the upper and middle section of the estuary upstream of Shell Point, but is uncommon and usually ephemeral.

Although there are species-specific variations, generally speaking SAV distributions are limited by four environmental factors: light, salinity, temperature, and nutrients (Dennison et al. 1993; Kemp et al. 2004). In the Caloosahatchee, studies have documented that SAV distribution and subsequently its functionality, is strongly related to limits on their physiological response to salinity and light. Except at the distribution margins, plant location in the estuary generally depends on salinity, while growth characteristics controlling plant height and depth strongly relates to light attenuation within salinity tolerant zones.

Submerged Aquatic Vegetation and Sampling Locations

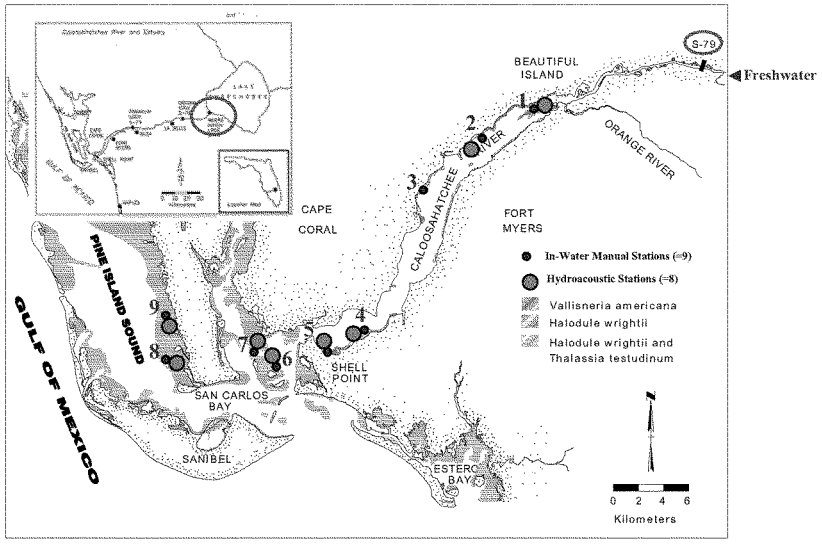

FIGURE D-10: MAP OF CALOOSAHATCHEE ESTUARY AREA AND LOCATION OF DOMINANT SAV DURING IDEAL CONDITIONS. DEPICTED ARE THE PROPOSED SAV SAMPLING SITES, USING: (1) THE TRADITIONAL MANUAL METHOD DEPLOYING DIVERS TO MEASURE PLANTS ALONG FIXED TRANSECTS; AND (2) HYDROACOUSTIC METHODOLOGY.

Superimposed upon this physiologically based template are a variety of factors, such as impacts via grazing (Lewis 1986). The relationship between SAV and herbivores is not well understood. The West Indian Manatee (*Trichechus manatus*) is among the few vertebrate grazers utilizing SAV as the main source of their diet although grass carp (*Ctenopharyngodon idella*) too have been documented as having an affect on freshwater SAV species (Hestand and Carter, 1978). Large herbivores such as manatees may graze destructively (Lefebvre et al. 2000) and thus inhibit the recovery of the SAV by disturbing their rhizospheric components when removing the photosynthetic leaves (Thayer et. al., 1984). The gaps created by grazing within the SAV habitat may alter the functionality and subsequently the value of the SAV habitat by increasing landscape heterogeneity and thus influencing both floral (may initiate succession) and faunal relationships.

Tape grass disappeared from the upper estuary sampling area following the 2000-2001 draught when salinity exceeded the plants tolerance limits. Despite

the return of the plant to the area and favorable salinity conditions, plant recovery to the pre-drought density (***Figure D-11***) and canopy height have not been sustained, possibly in part because the diminished plants have not been able to compete with the rate of grazing.

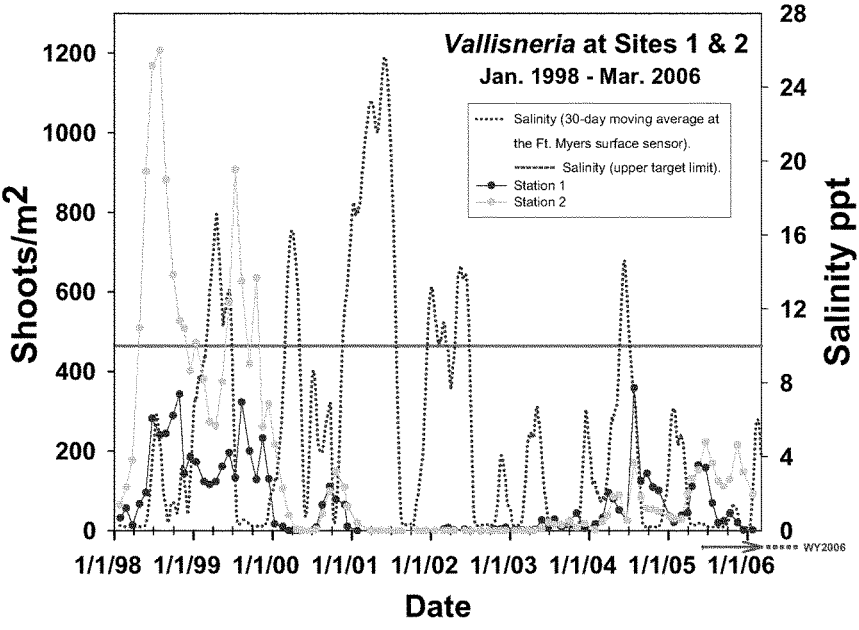

FIGURE D-11: TAPE GRASS (*VALLISNERIA AMERICANA*) SHOOT DENSITY IN THE UPPER CALOOSAHATCHEE ESTUARY. RECENT DATA ARE FROM THE STATIONS MONITORED BY THE SANIBEL-CAPTIVA CONSERVATION FOUNDATION (STATIONS 1 AND 2 IN FIGURE 7, USING MANUAL METHODS).

Pursuant to the requirements of "Florida Water Resources Act," the South Florida Water Management District established minimum flows and levels (MFLs) for freshwater inflow entering the Caloosahatchee Estuary via the Franklin Lock and Dam (structure S-79). The minimum flow is defined as" the limit at which further withdrawals would be significantly harmful to the water resources or ecology of the area" (section 373.042(1), F.S.). For purposes of establishing minimum flows, significant harm is defined as a loss of water resource functions that takes more than two years to recover. The minimum flow criterion is linked to the concept of protecting valued ecosystem components from significant harm. An MFL rule, has been established in the Caloosahatchee Estuary (SFWMD 2003 and 2005), whereby an exceedance occurs during a 365 day period, when: (a) A 30-day average salinity concentration exceeds 10 parts per thousand at the Ft. Myers salinity station

(measured at 20% of the total river depth from the water surface at a location of latitude 263907.260, longitude 815209.296; or (b) A single, daily average salinity exceeds a concentration of 20 parts per thousand at the Ft. Myers salinity station. Exceedance of either (a) or (b), for two consecutive years is a violation of the MFL. The intent of the rule is to maintain *Vallisneria* habitat that will support both estuarine and juvenile marine organisms. Currently, the Rule identifies a minimum mean monthly flow of 300 cfs is required to be delivered to the estuary between the months of November – March (dry season) in order to not reach the salinity exceedance limits. More recent modeling and field studies indicate that a flow of 450 cfs is more appropriate to avoid exceedance during periods of low rainfall and freshwater inflows. This low flow limit is reflected in the target S-79 flow distribution identified within Caloosahatchee River (C-43) West Basin Storage Reservoir - Caloosahatchee Estuary Hydrologic Evaluation Performance Measures (2005 – ***Table D-6***).

TABLE D-6: TARGET FREQUENCY DISTRIBUTION OF MEAN MONTHLY FLOWS FROM S-79 (CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR - CALOOSAHATCHEE ESTUARY HYDROLOGIC EVALUATION PERFORMANCE MEASURES, 2005).

Discharge Range (cfs) From S-79	Percent Distribution Of Flows From S-79
0 to 450	0%
450 to 500	42.8%
500 to 800	31.7%
800 to1500	19.2%
1500 to 2800	5.6%
2800 to 4500	0.7%
>4500	0%

The variability, timing, frequency, and volume of freshwater inflows effect salinity fluctuations, which in turn, can restrain SAV distribution and growth rates. For example, Montague and Ley (1993) found that SAV biomass was directly proportional to salinity, with biomass decreasing as salinity variation increased. As discussed above, in the upper estuary, naturally occurring tape grass will not survive prolonged periods of elevated salinity. The seagrass *Halodule wrightii* can persist in areas with higher variation in salinity than other seagrass, thus this species maintains a minimum presence upriver of Shell Point. *Thalassia testudinum* and *Syringodium filiforme* will not tolerate

prolonged periods of reduced salinity as a result of manipulated water release, and are located only in areas with relatively low variation in salinity. Regardless of the seagrass species, the frequent release of large volumes of freshwater from S-79 commonly results in freshening of the river to a point that downstream euryhaline SAV species are negatively impacted (***Figure D-12***). Achieving the target flow distribution (***Table D-6***) will reduce the occurrence of excessive discharges and maintain salinity variability in a range more supportive of SAV throughout the longitudinal gradient of the estuary.

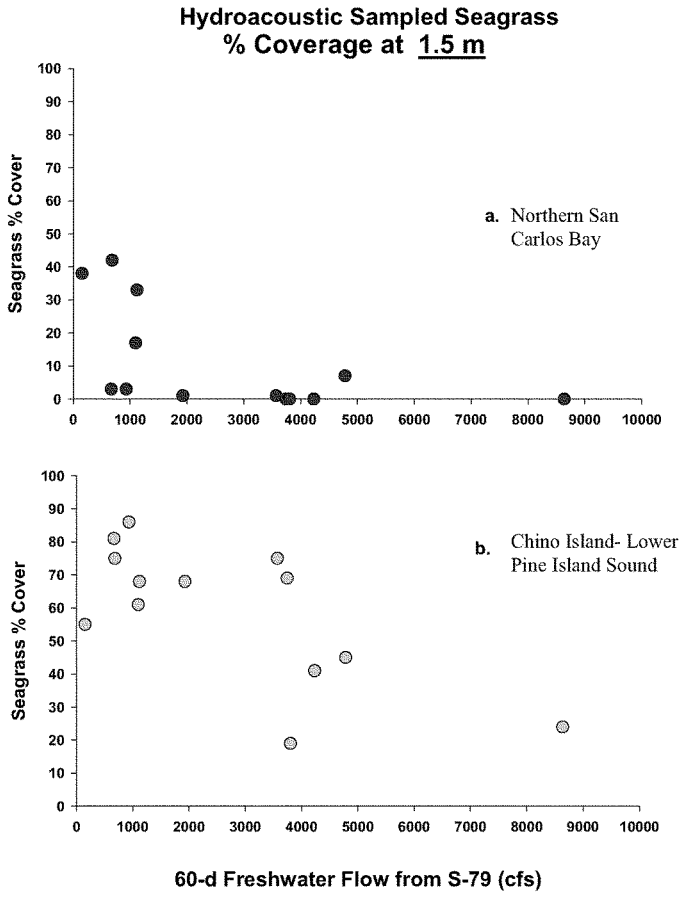

FIGURE D-12: SEAGRASS COVERAGE AT TWO LOCATIONS DOWNSTREAM OF THE CALOOSAHATCHEE RIVER (A. SITE 7; AND B. SITE 8-IN FIGURE 7) COMPARED TO 60-DAY AVERAGE FRESHWATER INFLOW FROM S-79 PRIOR TO SAMPLING.

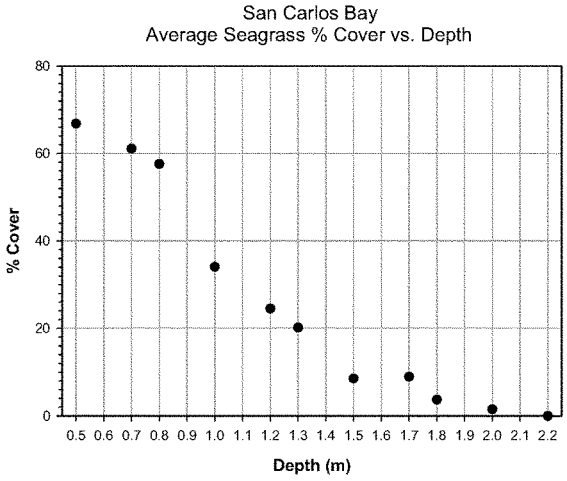

FIGURE D-13: AVERAGE SEAGRASS COVERAGE ASSOCIATED WITH DEPTH DURING A WIDE RANGE OF FRESHWATER INFLOW CONDITIONS USING HYDROACOUSTIC SAMPLING METHODOLOGY AT THE NORTHERN SAN CARLOS BAY STATION ADJACENT TO MERWIN KEY (SITE 7, FIGURE 7).

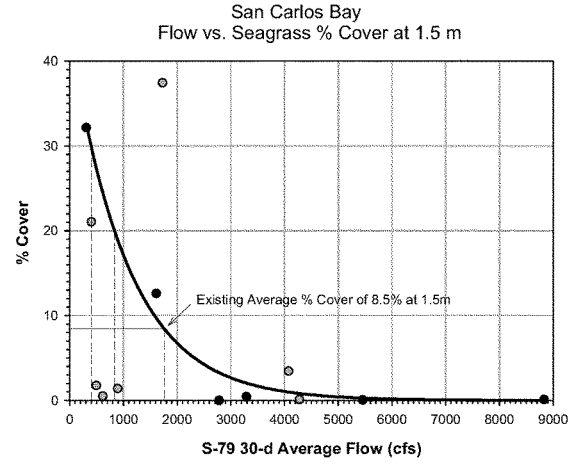

FIGURE D-14: PERCENT SEAGRASS COVERAGE AT 1.5 METER IN SAN CARLOS BAY (SITE 7. FIGURE 7) DURING A WIDE RANGE OF 30-DAY AVERAGE INFLOW CONDITIONS FROM S-79.

An exponential decay regression line is fitted to the subset of flows (bold points). Drop lines are provided from the existing 8.5% average coverage and the

expected improved coverage of 20% and 30% when flows approach the dominant target range of 450-800 cfs (***Table D-6***).

Seagrass are distributed along a depth gradient and when conditions of salinity and light are good, seagrass can extend to over 2 meters depth in San Carlos Bay (***Figure D-13***). Both salinity and light are influenced by freshwater inflow and impact the percent cover of seagrass along its depth range (***Figure D-9***). For example, when flows are within the target flow range (***Table D-6***), seagrass percent cover at 1.5 meter can be > 30% (***Figure D-14***).

D.3.4.2 Monitoring Objectives

1. Quantify SAV throughout the expected impacted area, so to: (a) Compare the discharge distribution from S-79 to the target SAV goals identified below; (b) Determine if the source of the variation is due to basin rainfall runoff or Lake Okeechobee Releases; (c) assess if SAV changes are consistent with expected values compared to salinity and water quality; and (d) where possible, relate changes in SAV to operation of project reservoir.
2. Determine tape grass coverage as it relates to (a) the 30-day moving average salinity $\leq$ 10 ppt during the dry season at the Ft. Myer's continuous salinity sensor (at 20% of water depth), such that salinity in the Beautiful Island area remains <10 ppt, in order to maintain a continuous population of tape grass in the area between the Ft. Myers U.S 41 northbound bridge and Beautiful Island (Sites 1 and 2, Figure 1), with a minimum bottom coverage of 20% to 1 meter (MLLW) and blade length $\geq$ 10 cm; and (b) take remedial action to address over grazing by herbivores that may prevent attaining this goal.
3. Determine shoal grass coverage upstream of Shell Pt. as it relates to the occurrence of average monthly salinity <15 ppt at the Cape Coral Bridge sensor. Salinity $\geq$20 ppt is promoted downstream of Peppertree Pt., in order to maintain: (a) continuous shoal grass coverage in the area immediate downstream of Peppertree Pt. (Site 4, Figure 1); and (b) continuous shoal grass coverage $\geq$ 30% in Iona Cove (Site 5) to 1 meter water depth (MLLW) with an average blade length $\geq$ 10 cm.
4. Determine changes in aerial seagrass coverage as it relates to the maintenance of average monthly salinity $\geq$ 30 ppt at the Sanibel Causeway (measured by the near surface continuous sensor), with a goal of increasing restoring seagrass coverage by 38% in the San Carlos Bay area circa Harris et al. 1983 aerial survey.
5. Determine average seagrass coverage per water depth, with a goal of maintaining a coverage of $\geq$ 30% at 1.5 m in mid-San Carlos Bay (Site 6 and 7), and $\geq$ 20% at $\geq$ 1.75 meters, with blade length $\geq$ 10 cm.
6. Determine average seagrass coverage per water depth in lower Pine Island Sound, with a goal of maintaining a coverage of $\geq$ 65% at 1.5 m.

7. Determine seagrass species composition, with a goal of maintaining annual shoal grass and turtle grass percent composition in San Carlos Bay and Pine Island Sound (Sites 6, 7, 8, and 9) at levels normally associated with S-79 monthly average flows of ≤1,000 cfs, as measured between 0.5 –1.0 meters depth.
8. Compare historical SAV coverage, density, and blade length data at all sites with similar data collected during project operation, with a goal of detecting an increase in the average amount of each of these metrics, as well as a reduction in their variability (annual, between seasons, and within seasons).
9. Addresses the null hypothesis stated below that is intended to assess the success of the project.

D.3.4.3 Null Hypothesis

The general null hypothesis - As a result of the operation of the C-43 West Basin Storage Reservoir (BSR), there will be no beneficial changes in freshwater inflows from S-79, nor improvement in estuarine SAV populations, related to – (a) recent area wide population data (positive trend of increasing area coverage); (b) historic seasonal SAV patterns; and (c) variation in SAV within distinct estuarine zones of the estuary.

Determining if the null hypothesis is true depends on monitoring SAV and related water quality commensurate with the project operation. To meet these demands the following SAV monitoring measures and targets are identified.

D.3.4.4 Monitoring Measures and Targets

1. Monitoring Measure: Average Seagrass Coverage

Targets: Maintain average seagrass coverage of > 30% at 1.5 m in mid-San Carlos Bay (Site 6 and 7), and > 20% at > 1.75 meters, with blade length > 10 cm.

Maintain average seagrass coverage of > 65% at 1.5 m in lower Pine Island Sound.

Maintain annual shoal grass and turtle grass percent composition in San Carlos Bay and Pine Island Sound (Sites 6, 7, 8, and 9) at levels normally associated with S-79 monthly average flows of <1,000 cfs, as measured between 0.5 –1.0 meters depth.

Improvement seagrass coverage, density, and blade length at all sites as indicated by an increase in the average amount of each of these metrics, as well

as a reduction in their variability (annual, between seasons, and within seasons).

Adaptive Management Trigger: (1) Long term - When there is no significant increase toward achieving the above monitoring measures within any of the geographic reference locations, thus satisfying the null hypothesis as per the condition described above; and (2) Short Term (real time) - When there is a significant decrease (or threat of adverse impacts) in the current monitoring measures as a result of project operation compared to no action (reservoir operation) or not implementing an improved operation scenario (considering other resources).

2. Monitoring Measure: SAV recovery and protection linked to meeting 30 Day Moving Average Salinity goals.

Targets: Achieve the MFL salinity criteria by augmenting freshwater releases to maintain a 30-day moving average salinity < 10 ppt during the dry season at the Ft. Myer's continuous salinity sensor (at 20% of water depth), such that salinity in the Beautiful Island area remains <10 ppt, in order to maintain a continuous population of tape grass in the area between the Ft. Myers U.S 41 northbound bridge and Beautiful Island (Sites 1 and 2, ***Figure D-15***), with a minimum bottom coverage of 20% to 1 meter (MLLW) and blade length > 10 cm. Limit the occurrence of average monthly salinity <15 ppt at the Cape Coral Bridge sensor, so salinity >20 ppt is promoted downstream of Peppertree Pt., in order to maintain: (a) continuous shoal grass coverage in the area immediate downstream of Peppertree Pt. (Site 4, ***Figure D-15***); and (b) continuous shoal grass coverage > 30% in Iona Cove (Site 5) to 1 meter water depth (MLLW) with an average blade length > 10 cm.

Maintain an average monthly salinity > 30 ppt, as measured at the Sanibel Causeway near surface continuous sensor, in order to regain historical seagrass coverage lost in the San Carlos Bay area, with a goal of increasing coverage by 38% to circa Harris et al. 1983 aerial survey.

Adaptive Management Trigger: (1) Long term - When there is no significant increase toward achieving the above recovery goals within any of the geographic reference locations, thus satisfying the null hypothesis as per the condition described above; and (2) Short Term (real time) - When there is a significant decrease, threat of adverse impacts, or loss in recovery gains for tape grass, shoal grass upstream of Shell Pt, or the area wide coverage in San Carlos Bay as a result of project operation compared to no action (reservoir operation) or not implementing an improved operation scenario (considering other resources).

D.3.4.5 Monitoring Approach

Daily freshwater discharge from Lake Okeechobee and S-79 are measured by the Corp of Engineers and posted electronically on COE and SFWMD web sites. This information is part of normal operation and therefore no additional Caloosahatchee River (C-43) West Basin Storage Reservoir project cost is required. Salinity information will be provided by the network of continuous sensors described in the Salinity Monitoring Plan and additional information collected concurrent to SAV monitoring. Water quality data also will be provided by additional sensors (see Water Quality Monitoring Plan) and concurrent measurements of important parameters.

If low tape grass coverage, density, or blade length is attributed to over grazing, then determine the species responsible and take remedial action, especially if grazing is by introduced species, like grass carp. The District is planning to investigate grazing problems and potential remedial actions, depending on the extent of the problem, the species responsible, their pervasiveness, their dependency on tape grass, and their sensitivity to water quality conditions.

Monitoring SAV to determine if the above objectives and targets are achieved requires three methodologies are employed. Each approach provides progressively more detail, but also increasingly sacrifices total area covered. Each method has inherited limitations, but when coupled together in this monitoring plan, will provided: accurate (low uncertainty) long term information for addressing the above targets and monitoring objectives; as well as provide short term feed back for changing project component operation.

Continuation of aerial photography will be required to determine if seagrass coverage is trending upward, toward achieving objective 4. Overflights are the only tested method that provides a system wide approach. A minimum of 3 flights will be required to detect a change and probably more than 5. Currently, flights are made every 2 years. Flights should be flown as late in the year (April-June) as possible to view plants within the growing season. Delays past June run the risk of missing the flight window because of wet season cloud cover and poor water clarity from runoff. Species distinction is not possible with this method, percent coverage is qualitative, and the viewing depth is limited based on water clarity. Also, very low coverage and plant density can not be detected.

Figure D-15 indicates the current location of in-water manual sampling. This is a traditional approach that requires divers to hand measure/collect plants contained in quadrants randomly placed along permanent transects. Each station consists of two 100 meter transects parallel to shore and two perpendicular transects that do not necessary reach the edge of the bed at each station. Five, 1.0 m2 quadrants, are measured per transect each month. This method provides precise quantitative estimates of species density in each

quadrant, regardless of the plant size and coverage. Sampling and information collected should at a minimum follow the guidelines being developed by RECOVER for manual SAV monitoring. Limitations to this method are sample size for the amount of staff time required (5 quads/4 transects and a sample size, n = 4 per visit monthly?). Therefore, the ability to detect change is limited by sample variability and each estimate represents only a small area. Thus patchiness (areas of increased or depressed coverage) can bias the results.

Hydroacoustic methodology has been used since 1996 (baseline) in the Caloosahatchee Estuary to detect seasonal and annual change in seagrass coverage and plant height (***Figure D-15***). This method provides an approach that fits between the total area coverage provided by remote aerial photography and the manual, site specific approach. Hydroacoustic sampling is conducted at the locations indicated in ***Figure D-15*** and is generally in close proximity to the manual method stations. Thus, water quality impacts to SAV can be considered the same for both methods. Hydroacoustic sampling design consists of 10 transects, usually hundreds of meters long, with some extending well beyond the plant depth at each station. Like the manual method, this approach is not restricted by the time of year, water and weather conditions, or number of sampling events. However, currently, sampling is conducted three times per year during the growing season between March and September. While the sample boat transverses the transect at about 2.5 knots, a digitized sample and GPS position is recorded with total plant coverage, canopy height, and bottom depth every 0.5 second, which is equivalent to every 0.5-1.0 meter. This translates to an extremely large quantitative sample size with large area coverage during a short on-site time commitment (1-2 hours). Therefore, the ability to detect change is greater then the manual method and more quantifiable than remote photography, at least for the area covered. Limitations include the inability to: distinguish species; detect plants in very low density; or when plants are shorter than 5-7 cm.

Each method is uniquely suited to address at least one objective and assist on others. ***Table D-7*** identifies each sampling method, the monitoring objective(s) of the eight identified above that the method will address, and the expected funding sponsor for each method. As indicated above, only remote aerial photography can adequately address Objective 4, and it can also contribute to confirming Objectives 3a and 8. Manual sampling is the only method able to address Objective 7, but it can contribute to objectives 2, 3, and 8. The manual method will also be critical for comparison to hydroacoustic results, especially when morphometrics decline toward the limits of hydroacoustic detection. The hydroacoustic is best suited for addressing Objectives 2, 3b, 5, 6 and also is important for evaluating Objective 8.

The results of all three SAV methods should be compared to: the salinity and water quality measured during time of collection; and the salinity and water

quality collected as specified by their respective monitoring plans. This comparison should delineate their influence on SAV related to the operation of the reservoir and help explain SAV changes if detected. If and when water quality targets discussed in the Water Quality Monitoring Plans are approached, then is there the expected positive SAV responses.

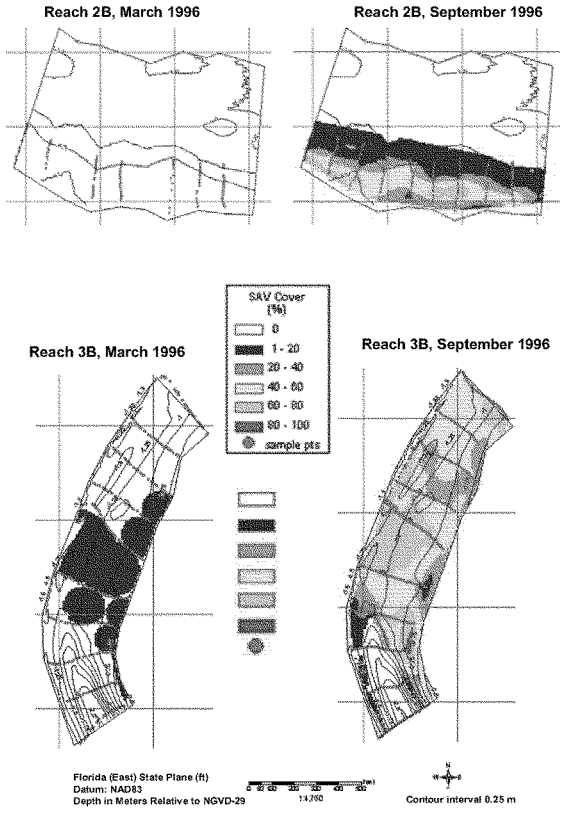

FIGURE D-15: EXAMPLE OF HYDROACOUSTIC MAPPING COVERAGE AT REACH 2B IN IONA COVE (SITE 5) AND REACH 3B IN NORTHERN SAN CARLOS BAY (SITE 7) SHOWING THE 10 TRANSECTS SAMPLED DURING MARCH AND DECEMBER 1996 AND THE RESULTING PLANT COVERAGE AND DEPTH CONTOURS.

TABLE D-7: SAV MONITORING METHODS, PARAMETERS SAMPLED, MONITORING OBJECTIVES (FROM MONITORING OBJECTIVES SECTION), AND THE FUNDING SOURCE SPONSORING THE MONITORING. CORPS OF ENGINEERS (COE), SOUTH FLORIDA WATER MANAGEMENT DISTRICT (SFWMD), SANIBEL-CAPTIVA CONSERVATION FOUNDATION (SCCF) AND CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR PROJECT (PROJECT).

Monitoring Method and Information Source	Objective(s) Addressed	Funding Sponsor
Flow from S-77 :Moore Haven & S-79: Franklin Dam	1a -Compare flow from S-79 to project target 1b - Determine if change in S-79 flow due to basin or Lake. 1c and d- Is detected changes due to altered flow from basin or Lake Okeechobee?	COE & SFWMD
Salinity and Water Quality (from respective Monitoring Plans)	1 - Influence of project on water quality and salinity and their influence on SAV. Are SAV and water condition targets valid or need to be changed?	SFWMD, SCCF and Project
1 – Aerial Photography	4 – Increase San Carlos bay Coverage and regain lost 38%.	SFWMD or Project
2 – Hydroacoustic Method (General SAV % cover, depth of occurrence, and canopy height)	1c and d- Detect SAV changes related to salinity and water quality and Project. 2 – Detect change in tape grass: meeting targets? 3 – Ground truth aerial photography and verify related trends. 4 – Detect change in Iona Cove *Halodule*: meeting targets? 5 – Detect change in San Carlos Bay SAV: targets? 8 – Improve SAV throughout estuary at historical locations and reduce variability.	SFWMD
3- In Water, manual method	1 - Ground truth/ verify Hydroacoustic sampling results & and measure plant too low in density & height trends. Use method to sample months not using Hydroacoustic method. 2 – Detect change in tape grass: meeting targets? 3 – Ground truth aerial photography and verify related trends. 4 – Detect change in Iona Cove *Halodule*: meeting targets? 7 – Maintain SAV species composition in San Carlos Bay.	SCCF, funded by SFWMD/Project

D.3.4.6 Data Quality

Routine samples are collected in accordance with RECOVER guidelines and published standards regarding monitoring SAV.

D.3.5 Project Monitoring and Assessment Plan: Fish

This fish monitoring plan is intended to help address concerns related to downstream estuary impacts and benefits related to changes in freshwater inflow and salinity due to project implementation.

D.3.5.1 Background

Estuaries are among the richest environments in the world. They provide a range of habitats for a diverse population of aquatic life; acting as a nursery for some species; and providing important physical and water quality conditions for permanent residents and temporary users, including over 75% of the commercially harvested marine fish and shellfish in Florida. An estuary is not an estuary without freshwater inflow, which provides: (1) input of nutrients and organic matter as the building block for an adequate food supply to higher trophic levels, including fish; (2) protection from predation by more mature life stages that can't tolerate lower salinity or can't find prey in naturally turbid estuarine waters; (3) a range of salinity conditions available for a variety of organisms with different requirements for growth and development; and (4) the regulation of larval transportation and retention. Within healthy estuaries are a variety of habitats, including submerged aquatic vegetation, oysters, mangroves, and a range of salinity zones that overlay these habitats which fulfill the various life stage requirements of a diverse population of fish.

Therefore, freshwater inflow and salinity in an estuary exerts a profound influence on the survival and distribution of fish, especially early life history stages. However, excessive variation in salinity can maintain estuarine biota in a constant state of flux between those favoring high salinity and those lower salinity. At the extreme, appropriate salinity conditions do not last long enough for some fish species to complete their life cycle and the estuary can become devoid of some self-sustaining populations. Therefore, changes to the salinity envelope in the Caloosahatchee will have the least detrimental effect if salinity shifts are more gradual and extreme rapid changes are avoided.

Estuarine populations of stenohaline fishes are most sensitive to atypical salinity regimes as either larvae (spotted seatrout), juveniles (tropical reef fish: yellowtail, lane and mutton snapper) or adults (spawning spotted seatrout and common snook). Therefore the timing and severity of salinity fluctuations becomes an important factor in reproduction and growth. Euryhaline fish populations that often associate with oligohaline habitats show a positive

association with increased freshwater flows relative to food availability (ex. feeding adult common snook).

Soft sediment (mud) fish communities have a positive association with healthy fine sediments, mud and their benthic animal communities as a food source (primarily gerreids, mugilids and engraulids) and habitat source (gobioid fishes). Benthic soft sediment invertebrate communities support one of the largest biomass components of indigenous Caloosahatchee fish communities. On the contrary, abiotic fine sediments ("muck") do not support this same soft sediment (mud) fish community and can create a bottom devoid of life often accompanied by anoxic conditions.

Healthy oyster bed habitat is essential for the survival of oyster dwelling fish. For example, population dynamics in *Gobiosoma bosc* (Gobiidae) is influenced by: (1) oyster reef structure; (2) live vs. dead oyster reef structure; (3) age and degradation/deterioration of oyster reef systems. *Gobiosoma bosc* plays a major trophic role in northern estuaries due to: its high production of ichthyoplankton; and its major role as an important vertebrate species directly associated with oyster reefs as critical habitat for feeding and spawning sites. *Gobiosoma bosc* is a major prey item for planktivorous fishes, chaetognaths, ctenophora, and as an adult it is prey for juvenile gray snapper *Lutjanus griseus*.

Estuarine seagrass and nearshore hard bottom dependent populations of juvenile tropical reef fish (lutjanids, serranids, scorpeanids, gobiids, blenniids and labrisomids) show a positive relationship with salinity, ex. higher densities at higher salinities. Spawning populations of seagrass and reef associated marine/mesohaline/polyhaline fish species are most affected by atypical (aseasonal) reduced salinities during their spawning period.

The Florida Fish and Wildlife Conservation Commission, Fish and Wildlife Research Institute's Fisheries-Independent Monitoring (FIM) program is a long-term program designed to monitor the relative abundance of fishery resources in Florida's major estuarine, coastal, and reef systems. The monitoring approach has been employed in the Caloosahatchee Area since 2004. FIM program was developed to: 1) address the critical need for effective assessment techniques for an array of species and sizes of fishes, turtles, and selected invertebrates; 2) provide timely information for use in management plans; and 3) monitor trends in the relative abundance of fishes and select invertebrates in a variety of estuarine and marine systems throughout Florida. In addition to the primary goals of describing long-term trends in fishery abundance and size distribution related to fishery management, FIM data have been useful for preparing species inventories for major estuaries throughout Florida, documenting habitat and dietary needs for a variety of estuarine fishes and invertebrates, displaying geographic information on fish distribution and primary nursery areas, and assessing the implications of water resource management to estuarine fish

communities. The data generated from this type of program provides resource managers with high-quality information on fish communities that may be useful when gauging the effects of natural and anthropogenic disturbances and changes in water quality and quantity (Coull 1985; Wolfe et al., 1987), related to programs like the Caloosahatchee River (C-43) West Basin Storage Reservoir.

In Fiscal year 2008, the SFWMD is planning to fund evaluation of the first 3 years of monitoring (2004-2007) to assess its ability to detect change related to freshwater inflow. Based on the evaluation, the program's sampling design may be refocused. For example, future monitoring may concentrate more effort in upstream areas and valued ecosystem habitat (such as submerged aquatic vegetation), where the greatest impacts and ability to detect change is expected. This may require the addition of fixed station for sampling vegetated and non vegetated areas, similar to efforts used by Mote Marine Laboratory (Brad Robbins, MML: 2nd contract's Final Report, expected 4th quarter 2007).

D.3.5.2 Monitoring Objectives

1. Continue long term monitoring of fish populations in the Caloosahatchee Estuary.
2. Quantify fishery in a variety of habitats and salinity zones throughout the expected impacted area of the estuary.
3. Determine changes related to the operation of the Caloosahatchee River (C-43) West Basin Storage Reservoir.
4. Provide long term and short term feed back for adaptive management and future project requirements.
5. Address the null hypothesis stated below that is intended to assess the success of the project.

D.3.5.3 Null Hypothesis

The general null hypothesis - As a result of the operation of the Caloosahatchee River (C-43) West Basin Storage Reservoir, there are either detrimental impacts to the fish community, or no changes in the estuarine fish population, related to – (a) the base line conditions established from years of sampling prior to reservoir operation in a variety of habitats and salinity zones along the downstream gradient of the estuary.

Determining if the null hypothesis is true depends on monitoring fish and at least salinity commensurate with the project operation, by:

1. Comparing populations with historic data sets;
2. Assessing trends in fish populations during project operation to determine the direction of change; and

3. Comparing current project related flows and fish populations with similar seasonal conditions when freshwater inflows would have been equal to non-project flow.

D.3.5.4 Monitoring Measures and Targets

1. Monitoring Measure: Statistical significant change (compared to preoperational data) in fish species composition, abundance per species, size of individuals, or other population morphometrics (e.g., diversity).

Target: No Change or a statistically significant increasing trend in desirable fish monitoring measures at fixed or random sampling sites along the estuary's downstream salinity gradient and at existing SAV and oyster sampling locations.

Adaptive Management Trigger: When there is an unnatural (undesirable) significant decrease in monitoring measures within any salinity zone or habitat because of project operation, thus satisfying the null hypothesis as per condition 3 described above.

D.3.5.5 Monitoring Approach

Daily freshwater discharge from S-79 and the Lake Okeechobee structure at Moore Haven are measured by the Corp of Engineers and posted electronically on COE and South Florida Water Management District (SFWMD) web sites. This information is part of normal operation and therefore no additional Caloosahatchee River (C-43) West Basin Storage Reservoir project cost is required. It will be available to compare fishery catches with daily freshwater inflow form these two structures. The information from the network of continuous salinity sensors (and water quality sensors if desired) is available (see Salinity and Water Quality Monitoring Plans) to meet the above monitoring objectives and make the required comparisons to determine the cause of any detected population changes.

The FIM program uses a stratified-random sampling design. The study area is divided into six bay zones (A-E and G) and three riverine zones (H, M, and P; ***Figure D-16***). Funding to date by RECOVER allowed the expansion of sampling into Zones E, G, and H since 2004. Zones E and G encompass the southern portion of Charlotte Harbor, including parts of Matlacha Pass, Pine Island Sound, and San Carlos Bay. Zone H extends from the mouth of the Caloosahatchee River upstream approximately 23 nm to the Franklin Lock. The zones are divided into 1-nm2 grids that are randomly selected for sampling each month. Sampling grids are stratified by habitat and depth, thereby identifying the gear types that could be used in those areas. A total of 71 samples are collected each month as part of the FIM expansion into lower Charlotte Harbor

and the Caloosahatchee Estuary (twenty-three 21.3-m Caloosahatchee River seines, seven Caloosahatchee River trawls, twenty 21.3-m bay seines, ten 183-m haul seines, and eleven bay trawls; see below for gear descriptions).

A multi-gear approach is used to collect data on fishes and select invertebrates from a wide range of habitats and life history stages. A 21.3-m center bag seine with a mesh size of 3.2 mm is used to collect young-of-the-year and juvenile fishes in shallow areas (≤1.8 m); a 6.1-m otter trawl with a 3.2 mm mesh liner is used to collect young-of-the-year, juvenile, and adult fish in deep water (1.0-7.6 m); and a 183-m haul seine with a mesh size of 38.1 mm is used to collect sub-adult and adult fish in shallow water (≤2.5 m) along shorelines.

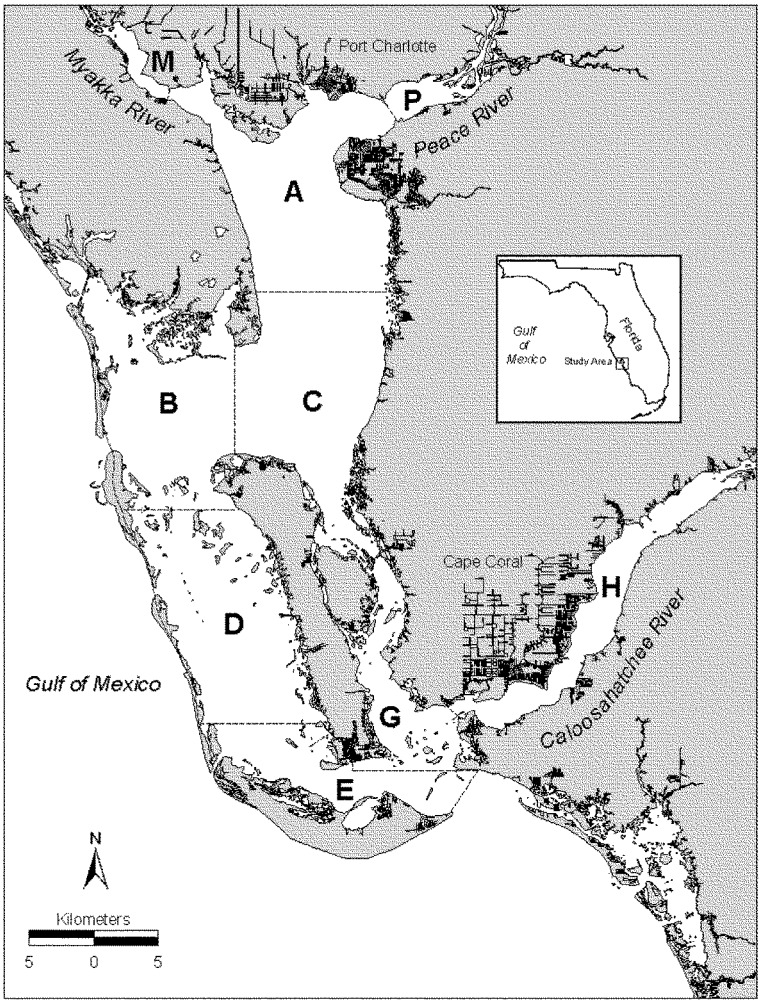

FIGURE D-16: MAP OF CHARLOTTE HARBOR SAMPLING AREA. ZONES ARE LABELED A-E, G-H, M AND P

Several different techniques are used, depending on habitat, to stratify the samples collected with the various gears. The 21.3-m center bag seine is deployed in one of two ways. The bay seine technique is used to sample shallow areas of the estuary and is pre-stratified by the presence or absence of bottom vegetation, or the presence of a shoreline. The river seine technique is used to

sample the shorelines of the rivers. Samples collected with 183-m haul seines are pre-stratified by the presence or absence of overhanging shoreline vegetation. Further sampling details are described in the FIM program's Procedure Manual.

Environmental data consisting of water chemistry, habitat characteristics, and physical parameters such as tidal conditions are recorded for each sample. The sample work-up technique was similar for all collected samples, regardless of gear type or sampling regime. All fishes and select invertebrates captured in net collections are identified to the lowest practical taxonomic level, counted, and measured (standard length for teleosts, precaudal length for sharks, disc width for rays, carapace width for crabs, and post-orbital head length for shrimp). Animals are then released except for representative samples of each taxon (for laboratory confirmation of field identifications) and samples required for specific research projects.

D.3.5.6 Data Quality

A detailed explanation of the standard sample work-up for data collection and program quality assurances are described in the FIM program's Procedure Manual. The taxonomic nomenclature in this report follows the American Fisheries Society's Common and Scientific Names of Fishes (Nelson et al., 2004).

APPENDIX

Appendix 1: Mercury and Toxics Monitoring Program for the C43 West Storage Reservoir Project 16

WATER QUALITY MONITORING PLAN

1.0 INTRODUCTION AND BACKGROUND

This document serves as a reference for monitoring of various matrices (water sediment and fish) for the C-43 West Storage Reservoir (C43) Project. The C43 includes an above ground reservoir with a total storage capacity of approximately 170,000 acre-feet located in the C-43 Basin of Hendry County.

The purpose of this feature is to capture C-43 Basin runoff and releases from Lake Okeechobee which will reduce peak flows to the Caloosahatchee Estuary, provide flood attenuation and increase regional water supply benefits.

The C-43 West Storage Reservoir is intended to improve the timing of environmental deliveries to the Caloosahatchee Estuary, including reducing the damaging flood releases from Lake Okeechobee. Though water quality improvement is not a project purpose, there is the potential for the reservoir to provide benefits from long-term nutrient removal. The long-term downstream average of various nutrients (i.e.: phosphorus and nitrogen) could be decreased as a result of the storage reservoir and other Comprehensive Everglades Resoration Program (CERP) projects affecting the basin.

The guidance contained in this document will assist in maintaining consistency in sampling locations, parameter lists and frequencies as well as provide documentation of the project scope and an ongoing historical perspective.

1.1 Active Mandates and Permits

The C-43 Project is authorized as one of the initial projects for implementation under Section 601(b) (2) (C) of the Water Resources Development Act (WRDA) 2000. This water quality monitoring plan meets the requirements outlined in the CERP Guidance Memorandum (CGM) 023.01: Water Quality Considerations for the Project Implementation Report (PIR) Phase (CGM 023, dated March 1, 2004), CGM 42.00: Toxic Substances Screening Process – Mercury and Pesticides (CGM 42.00, dated September 17, 2005) and CGM 040.00: Project Level Water Quality and Hydrometeorologic Monitoring and Assessment (CGM 040, dated May 25, 2004). These guidance memoranda address water quality considerations necessary for the formulation, evaluation, and design of project alternatives during the PIR development. This monitoring plan (Plan) will also be modified, if necessary, to be compliant with any future water quality certification conditions.

To clarify the intent of WRDA 2000 with respect to attaining Everglades water quality restoration objectives, CGM 023 establishes three categories of CERP projects (Category A, B or C). For a Category C project, design development does not include water quality improvement features or specifically reference water quality improvements as a criterion to be addressed during design. Category C

components will not have performance measures for water quality improvement and are not required to have evaluation criteria for comparing the water quality improvement of alternatives. The C-43 meets the CGM definition of a Category C project.

1.2 Project Objectives

The monitoring stations described in this document were established to satisfy requirements of the CERP PIR. This Plan will provide an outline for quantifying water quality, measure constituents of interest (i.e.: phosphorous and nitrogen) **in surface water entering and leaving the project area and measure, and evaluate pollutant sources**. As a Category C component, this project does not include water quality improvement features; however, it is anticipated the project will reduce pollutant loading into downstream receiving water bodies through the attenuation of surface flows and reduction of associated pollutant loads prior to discharge.

1.3 Duration

1.3.1 Initiation Conditions

This Plan was initiated by the Water Quality Monitoring Division and technical review provided by staff of the Environmental Resource Assessment Department of the South Florida Water Management District (SFWMD). Development of this Plan is required by the Project Management Plan (PMP) and for the development of the PIR document, due in August 2007. The PIR development phase has requirements for sections detailing the water quality monitoring and adaptive assessment methods for the recommended alternative. This Plan is to be implemented at the project start date and will be adhered to for the length of time the project is operational. Changes to the plan may occur in the future as the project nears completion as outlined in the following Section.

1.3.2 Modification or Termination Conditions

Modification of the Plan will be determined by the needs of the project as it nears the estimated completion date of 2011. This Plan may be changed to reflect any future design changes, permit requirements and/or may be terminated according to permit expiration dates or changes to the project objectives. The Plan will be reviewed and/or modified annually or more frequently if necessary, to reflect new requirements.

2.0 GEOGRAPHIC LOCATION

2.1 Regional Area

The Caloosahatchee River forms the major basin to the west of Lake Okeechobee. The Caloosahatchee River watershed includes an area of approximately 550,900 acres in parts of Lee, Glades, Charlotte and Hendry counties. Existing agriculture in the C43 Basin is dominated by citrus production with a smaller production of vegetables, rice and sod.

Physiographically, the site lies in the Sandy Flatlands region of South Florida which is characterized by surficial marine sand (consisting of predominantly unconsolidated sand and sandy marl containing abundant marine mollusks) with deposits of organic soils accumulated in fresh-water environments.

The C-43 Project is located just south of the Caloosahatchee River midway between Lake Okeechobee to the east and Fort Myers to the west. In general it will be surrounded predominately by agricultural interests, though as the value of agricultural land increases, urban development adjacent to the reservoir is likely in the future. A site map showing the site of the C-43 West Storage Reservoir Project, its setting within South Florida and the location of other CERP/ACCELER8 features in the region is shown in Figure 1.

The Townsend Canal, located west of the project outline (see Figure 2) provides an open channel connection to the Caloosahatchee River. Drainage across the property discharges to the Caloosahatchee River via Fort Simmons Branch, Bedman Flowing Creek and Roberts Canal via Banana Branch Canal.

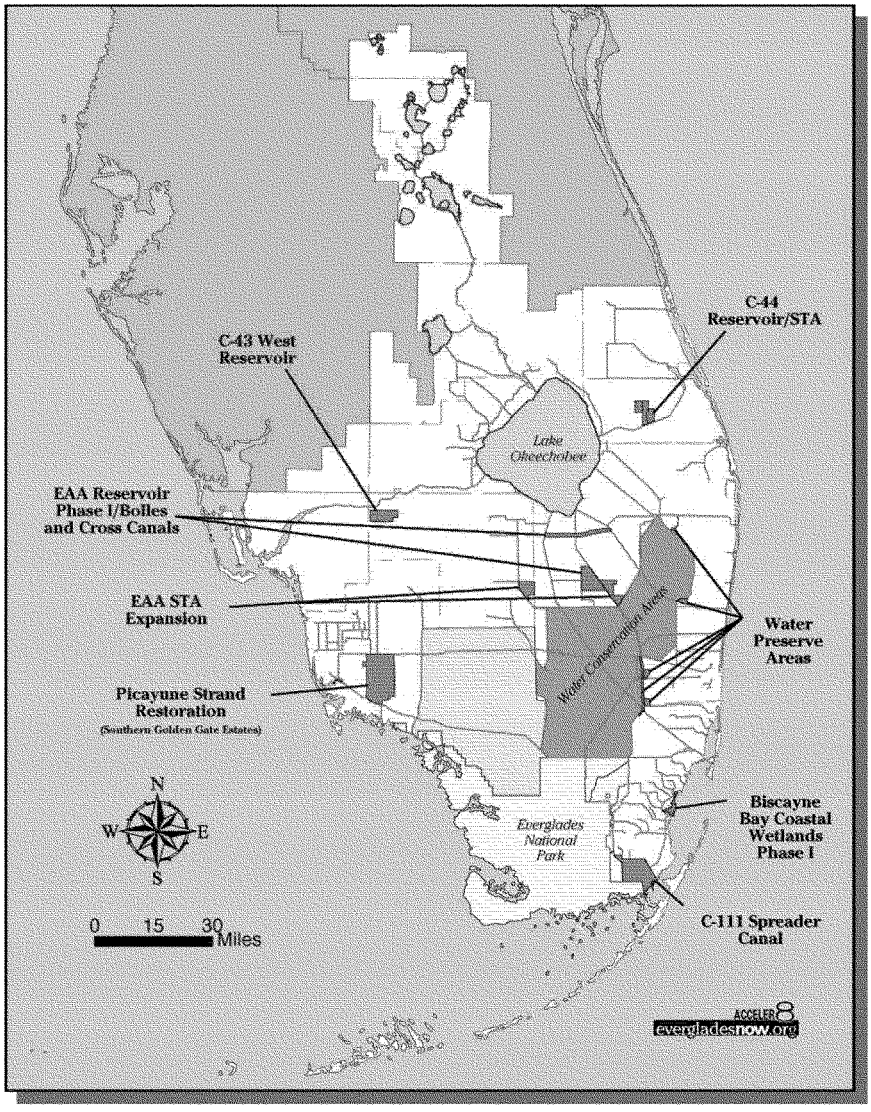

FIGURE 1: PROJECT LOCATION MAP

2.2 Sampling Locations

Monitoring will be designed to provide compliance with applicable state and federal surface water criteria. Project features are shown in Figure 2.

Sampling stations will be registered in the SFWMD Laboratory Information Management System (LIMS). Table 1 provides information on each proposed monitoring location. The locations of the monitoring stations (in addition to structures that will not be monitored for water quality) are depicted on the map in Figure 2, with the exception of interior stations. These stations (possibility of multiple interior stations within each cell-TBD) will be used for surface water monitoring.

Since the project is in the early stages of development, monitoring locations may change depending on the final construction plans and permits.

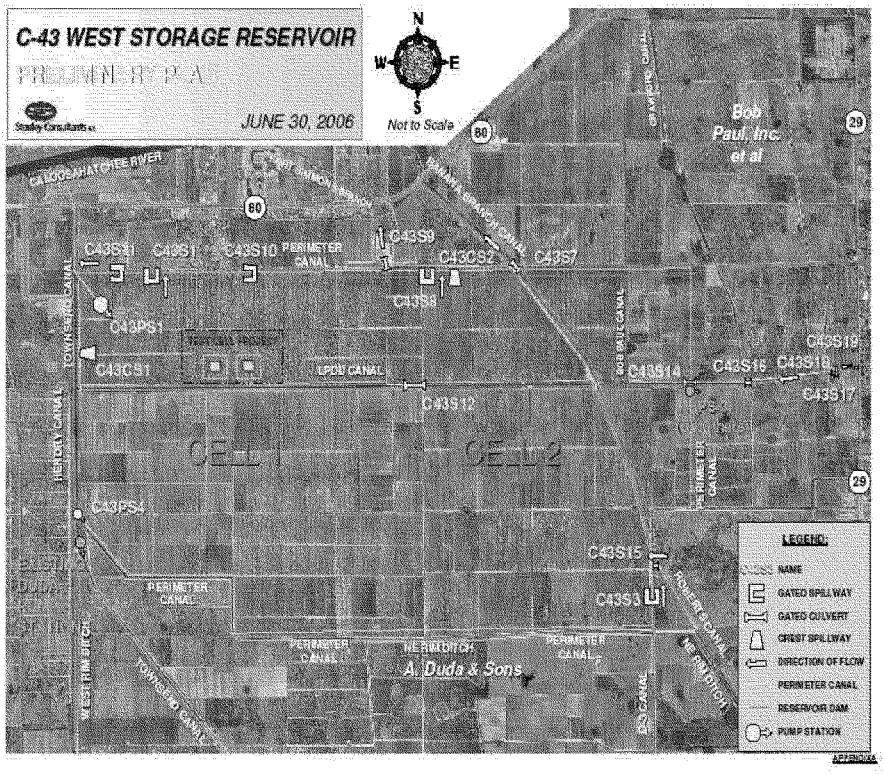

FIGURE 2: PROJECT FEATURES

TABLE 1: SURFACE WATER QUALITY MONITORING STATIONS

Site Name	Latitude	Longitude	Description
C43PS1	TBD	TBD	Cell 1 Inflow Pump Station
C43S1	TBD	TBD	Gated spillway; outflow from cell 1 to Perimeter Canal
C43S8	TBD	TBD	Gated spillway; outflow from cell 2 to Perimeter Canal

2.3 Access and Authority

The Project will be accessed from Route 80 which runs parallel along the Caloosahatchee River. Monitoring stations within the project will be accessed along the system of levees that surround the reservoir.

3.0 FIELD ACTIVITIES

3.1 Parameter and Frequency Rationale

3.1.1 Baseline Monitoring

SFWMD has been conducting water quality monitoring in the Caloosahatchee River and in the Caloosahatchee River estuary for a number of years. These surface water samples have been analyzed for multiple constituents and at various frequencies. Caloosahatchee River data are compiled in the SFWMD's DBHYDRO database under project codes X, CR and PEST. Data collected in the Caloosahatchee River estuary are compiled in the SFWMD's DBHYDRO database under project codes CESWQ. There are other agencies that also collect surface water quality data in this region (i.e. Lee County and Charlotte Harbor National Estuary Program) that may be relevant to the project as baseline data. These agencies would have to be contacted for access to their databases.

Surface water, groundwater and sediment samples also are being collected as part of the C43 Test Cell Project by Wetland Solutions, Inc. Sampling stations are located within the test cells and the Header canal that provides water to the test cells, as well as stations located in the Townsend Canal and Roberts Canal. The data collection for the C43 Test Cell Project are expected to continue until May 2007 and all data associated with this project will be accessible in the DBHYDRO database under project code C43RES. Refer to Table 2 for a complete listing of project names, stations, parameters and frequency of collection of projects that are relevant as baseline data for this project.

TABLE 2: C43 BASELINE PROJECTS IN SOUTH FLORIDA WATER MANAGEMENT DISTRICT DATABASE (DBHYDRO)

Project Name	Stations	Parameters Collected	Frequency of Collection
CR	S78, S79, CR-00.2T, CR-04.8T	ALK, MG, SIO2, CA, NA, SO4, CL, NH4, TEMP, COLOR, NO2, TKN, COND, NOX, TPO4, DO, OPO4, TSS, K, PH, TURB	Bi-monthly
X	S77	ALK, CL, NH4, TEMP, COLOR, NO2, TKN, COND, NOX, TPO4, DO, OPO4, TSS, PH MG, SIO2, CA, NA, SO4, TDS, TOTFE, K	Bi-weekly/Monthly Quarterly
CESWQ	CES02, CES03, CES04, CES05, CES06, CES07, CES08, CES09, CES10, CES11 CES01 CES01, CES03, CES04, CES06	CHLA TPO4, TN, CHLA CHLA, CHLA2, COLOR, NO2, NO3, NOX, NH4, TKN, TN, TOC, TPO4, OPO4, SILICATE, TSS, TURBIDITY	Release Release Monthly
C43RES	Surface Water - C43TC1, C43TC2, C43RC1, C43RC2 Groundwater – PZ01A, PZ13A, PZ14A, PZ15A, PZ16A, PZ17A, PZ18A, PZ19A, PZ20A, PZ21A Soil–C43TC1-Z1,C43TC1-Z2, C43TC1-Z3, C43TC2-Z1, C43TC2-Z2, C43TC2-Z3	ALKA, CHLA, CL, COLOR, NH4, NOX, OPO4, SO4, TDPO4, TKN, TOTAL, TOTAS, TOTCA, TOTCU, TOTZN, TPO4, TSS, TURB, VSS, Ametryn, Atrazine, Bromacil, Norflurazon, Simazine TDS, CA, SO4, CL, TP, TDPO4, OPO4, TKN, NH4, NOX, TOTAL, TOTAS, TOTCU, TOTFE, TOTZN BULK DENSITY, CALCIUM, TOTFE, TOTAL, TKN, TOC, TP, TS, ORGANIC P FRACTION, Ametryn, Atrazine, Bromacil, Norflurazon, Simazine	Monthly (except RC1 & RC2) 3X's during test cell operation Quarterly 2X's during test cell operation
PEST	S79, CR33.5T, S78, S235	Chlorinated acids, Organochlorine compounds, Organophoshporus and Nitrogen compounds, Urea and Other pesticides	Quarterly for Surface Water, Bi-annually for Sediment

3.1.2 Routine Operational Monitoring

Monitoring objectives and requirements for the operational phase of the C43 will depend largely on permit requirements and the final design and operational plan for the project area, and will include the following:

Flow proportional auto-samplers will be installed at one inflow and two outflow stations. Auto-samplers will be visited once per week regardless of flow in order to maintain data integrity. Grab sampling at the inflow and outflow stations of both cells will occur bi-weekly during flow events or monthly if no flow, for nutrients and other parameters listed. Autosampler and grab surface water samples will be collected as detailed in Table 3.

TABLE 3: ROUTINE OPERATIONAL MONITORING – AUTO-SAMPLER, GRAB SAMPLE AND INSITU COLLECTION

Location	Collection Method	Matrix	Frequency	Parameter
C43PS1, C43S1, C43S8	Autosampler	Water	Weekly	TPO4, TKN, NOX
C43PS1, C43S1, C43S8	Grab	Water	Biweekly if flowing or monthly	NOX, TKN, NH4, TPO4, OPO4, TURB, Sulfate, Alkalinity, Chl-a
C43PS1, C43S1, C43S8	In situ	Water	Biweekly if flowing or monthly	Temperature, PH, Conductivity, Dissolved Oxygen

3.2 Project Specific Guidelines

In general, grab samples are collected at a depth of 0.5 m in canals. When collecting a sample at a structure, samples are generally collected on the upstream side.

3.3 Sampling Procedures

Sample collection for this project shall follow the procedures and requirements found in the Field Sample Collection Procedures Section of the District's *Field Sampling Quality Manual* (FSQM).

3.4 Field Testing Procedures

Field testing procedures shall follow the procedures and requirements found in the Field Testing Section of the District's FSQM. Table 4 below describes the field parameters collected for this project. The table shows only the most commonly used parameters.

TABLE 4: FIELD ANALYTICAL PARAMETERS COLLECTION

Parameter	Resolution	Accuracy
DO	0.01 mg/L	0-20 mg/L, +/- 0.2 mg/L
Conductivity	0.001 mS/cm	+/- 0.5% of reading +0.001 mS/cm
Temp	0.01° C	+/- 0.15°C
pH	0.01 unit	+/- 0.2 unit

3.5 Field Quality Control Requirements

Field quality control requirements shall follow the procedures found in the Quality Control Section of the District's FSQM.

3.6 Autosampler Collection

TP04, TKN and NOX samples will be collected by autosamplers at the stations identified in Table 3. Flow-proportional autosamplers (ACF) will be located at all stations and are programmed to collect discrete aliquots at a frequency based on flow. That frequency is determined by a "trigger volume" established through the protocols created by Abtew and Powell (2004). The discrete bottles will be pre-acidified and composited on a weekly basis and analyzed for the above parameters. Refer to Table 5 for setup detail on the autosamplers to be installed at the inflow/outflow stations.

Due to the unique configuration of the discharge structures, C43S1 and C43S8, the autosamplers will be located in the stilling wells which operate the final gate controls for discharge from each structure. The height of the gate-wells are too great for an autosampler to lift samples, so submersible pumps will be installed in each gate-well. The submersible pumps will pump a continuous flow of water to the top of the levee where an autosampler will draw aliquots when triggered. The submersible pumps will operate only when flow is occurring within each discharge culvert.

TABLE 5: C43 WEST STORAGE RESERVOIR AUTOSAMPLER COLLECTION STATIONS

Station	Flow	Aliquot Volume (mL)*	Refrigerated Yes or No	# of Bottles	Intake Type *fixed or float*	Intake Elev *(if fixed)*
C43PS1	Yes	TBD	No	TBD	Fixed	TBD
C43S1	Yes	TBD	No	TBD	Fixed	N/A
C43S8	Yes	TBD	No	TBD	Fixed	N/A

**aliquot volume may be increased for seasonal sampling to ensure adequate volume for sample analysis.*

3.7 Sample Submission

Following completion of sample collection for each sampling trip, the samples are transported in coolers with wet ice at 4° Celsius to the laboratory for analysis. Samples are submitted to the laboratory on the same day as collection or via courier for delivery the following day. Samples are submitted according to the requirements outlined in the District's FSQM. If samples are submitted to other than the District's in house laboratory, the laboratory must be currently under contract with the District. If services can not be provided by a contract laboratory, an alternate laboratory can be used but the alternate laboratory must receive written approval from ERA's Quality Assurance Administrator prior to sample submittal.

4.0 DATA QUALITY OBJECTIVES

4.1 Data Uses

The data will be used to fulfill project purposes and to comply with monitoring requirements of an operational permit.

4.2 Data Quality

Surface water samples, including in-situ testing and field quality control samples are collected in accordance with the Florida Department of Environmental Protection (FDEP) Quality Assurance Rule, 62-160.200 & 62-160.320, Florida Administrative Code (F.A.C.) and the District FSQM. Applicable sections of the FSQM include, but are not limited to field sample collection procedures, decontamination procedures, field testing and quality control requirements. Data are qualified in accordance with the *District Chemistry Laboratory Quality Manual.* Data not meeting the quality objectives are qualified using standard FDEP qualifier codes (F.A.C. 62-160), in accordance with the FSQM data validation and reporting section.

4.3 Analytical Parameters

Tables 3 in Section 3.1.2 and Tables 2 and 3 in Appendix 1, identify all parameters in the project. All analytical work is to be conducted by a NELAC-certified laboratory following NELAC and EPA Standard Methods for which the laboratory is approved. For field analytical methods (pH, specific conductance, temperature and dissolved oxygen) refer to Section 6 of the District's FSQM.

.

4.4 Completeness Targets

For each project, monitoring parameters and frequencies will be registered in LIMS and DBHYDRO. This process aids in the creation of header sheet templates, quality assurance and determining completeness. Completeness targets, meaning the number of samples successfully collected and analyzed, are set at 95% annually for this project.

5.0 DATA AND RECORDS MANAGEMENT

After the data validation process, all data are maintained so that end users can retrieve and review all information relative to a sampling event. Field notes are maintained on an internal server either by scanning actual field note pages or by uploading narratives from field computers path to server. All analytical data and field conditions are sent to a database (DBHYDRO) for long-term storage and retrieval.

The collecting agency shall maintain records of field notes and copies of all records relative to the chain of custody and analytical data. It is the responsibility of the collection agency to maintain both current and historical method and operating procedures so that at any given time the conditions that were applied to a sampling event can be evaluated. Upon completion of the project, the collecting agency shall provide all original field notes to the District's Water Quality Management District (WQMD) for permanent archival.

Records shall be maintained for the life of the project and five years thereafter, in a manner that will protect the physical condition and integrity of the records. Storage shall follow the District's records storage procedure. Access to archived methods shall be through designated records custodian. Corrections of data or records shall follow the District SOP's.

5.1 Data Deliverables

The laboratory data shall be submitted to the District in a DBHYDRO compatible format. The laboratory shall evaluate the data in accordance with the data quality objectives stated in the FSQM. All data submittals shall conform to existing District guidelines or other format as requested by the District.

5.2 Data Storage

After the data validation process, all data are maintained so that end users can retrieve and review all information relative to a sampling event. Field notes are maintained on an internal server either by scanning actual field note pages or by uploading narratives from field computers \\ha2-fs1\kb_wqm\fieldnotes\. All analytical data and metadata are sent to a database (DBHYDRO) for long-term storage and retrieval.

6.0 REVISIONS AND MODIFICATIONS

[This section is left for future changes as they are made and should be referenced throughout the document as revisions occur. Sections should be added chronologically. As revisions are made a note should be made in the corresponding section of the plan.]

Date	Section	Page Number(s)	Change From	Change To	Reason

7.0 MONITORING COSTS

The monitoring costs (including analytical and data management) associated with this Monitoring Plan have been estimated at costs of $610,952 for the initial year and $603,198 for each subsequent operational year. These costs are based upon Fiscal Year 2007 estimates with a 3% annual inflation factor applied.

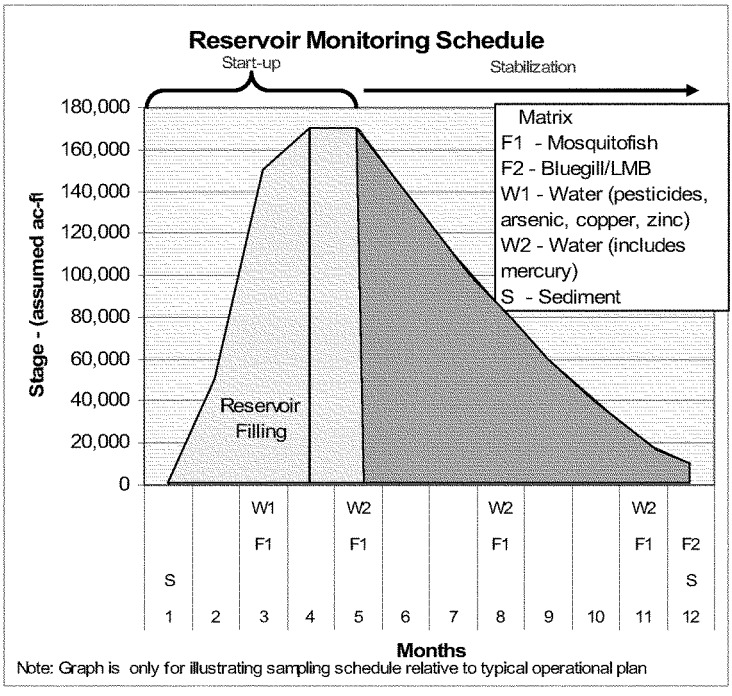
APPENDIX 1

Mercury /Toxics Monitoring Program for the C43 West Storage Reservoir Project

Introduction:

Appendix 1 follows the guidelines of CGM-42, which includes the flexibility to adapt the guidelines to a reservoir (vs. an STA). However, the language in CGM-42 is specific to the phases of startup and operation of an STA. The C43 Reservoir differs from an STA in that there is no flow-through type of operation. The Reservoir will be filled during the wet season when there is an excess of water in the Caloosahatchee basin and emptied when there is less than 450 cfs discharge at S79. Water depths in the Reservoir when full will average about 20 ft with a maximum depth of 25 ft.



Part of the monitoring regime includes sediment sampling, which at full depths is not reasonable or productive. Therefore, sediment sampling will be conducted prior to filling the reservoir and again following seasonal discharge assuming that pool levels are low enough to collect sediment cores.

Sediment sampling will also take into account the variability in site conditions which will be experienced following construction. The removal of surface soils during construction of the reservoir will be necessary in some areas to use as borrow material to construct the levee surrounding the reservoir. Exposed parent soils will be left after removal of the borrow material. Organic soils may be stockpiled or spread. In addition, the former land-use of the site was primarily citrus, therefore tree removal operations may leave disturbed soil profiles across much of the storage area, but volunteer growth of grasses and brush may fill in during the construction period. It is necessary that sediment sampling locations characterize the sampling site conditions for accurate data interpretation.

Regarding the pesticide parameters required for analysis in fish, sediment and water as outlined in this monitoring plan, the list was reduced from what is historically analyzed in those matrices (usually all of the compounds in an analytical group - i.e. chlorinated (phenoxy acid) herbicides (3 parameters), urea herbicides and imidacloprid (3 parameters), ogranophosphorus and nitrogen pesticides (32 parameters) and organochlorine pesticides (40 parameters)). The Florida Department of Environmental Protection is now able to analyze distinct analytes within an analytical group which assists in reducing the data management aspect of monitoring.

The current recommended pesticide analytical list (chlordane – gamma, chlordane – alpha, endrin and ethion – as well as arenic, copper and zinc) is based on historical data as well as the site assessment performed for this location.

Sampling of the soil, fish, and water matrices follow a schedule that is attuned to the reservoir operations. The following diagram illustrates the intent of the planned schedule.

A1. Initial Start-up Monitoring Prior to Discharge

The District shall initiate start-up monitoring prior to discharge as follows:

A1.1 Mosquitofish

i) When construction of the reservoir is complete, the District shall notify the Department and, within one month of the initial filling of reservoir, collect mosquitofish from four locations within each cell of the reservoir to total at least 100 fish per cell. Physically composite them into one (spatially-averaged) sample per cell of the reservoir for THg analysis (note, a single aliquot should be analyzed per composite). Additionally, mosquitofish (to total at least 100 fish) will be collected from a single site located in the receiving water downstream from the project and analyzed for THg (site to be located in Townsend Canal between C43PS1 and the Caloosahatchee River. Refer to Figure 2 for site location). This downstream site is located in a canal with flow velocities that will allow for a resident population. The data for the downstream site will serve as a baseline for any future evaluations of potential impacts to the receiving waters. Sampling described

above will continue quarterly after the initial collection during the period water is being pumped into the reservoir (usually during the wet season from July to November).

ii) The District shall provide the Department with the results of the first collection of mosquitofish as well as the appropriate action levels for comparison (90% upper confidence level of the basin-wide average or the 75th percentile concentration for the period of record for all basins). If tissue-concentrations from each cell of the reservoir are below the 90% upper confidence level of the basin-wide average or below the 75th percentile concentration for the period of record for all basins (if basin-specific data are lacking); after concurrence from the Department, the District may initiate discharge from the reservoir and routine monitoring for that cell of the reservoir (for details on routine monitoring, see below).

However, if Hg concentration in any of the mosquitofish composites from within the reservoir exceed one of the above referenced action levels, the District shall immediately (within 14 days of receiving quality assured data from the laboratory) collect a sample(s) to confirm the exceedance(s). In addition, the District shall consult with the Department to determine the most appropriate course of action and obtain authorization to initiate discharge from the reservoir. At a minimum, the course of action will include implementation of Tier 2 Expanded Monitoring and Risk Assessment by the District during initial reservoir discharge (e.g. collection of monthly mosquitofish within each cell of the reservoir and at the downstream location at a minimum). Additional details on expanded monitoring are provided below and in "A Protocol for Monitoring Mercury and Other Toxicants" dated January, 2006 and subsequent revisions (hereafter referred to in this document as the "Protocol"). The recommended course of action may also include additional measures as determined to be appropriate. When results of expanded monitoring demonstrate concentrations in each cell of the reservoir has decreased to acceptable levels (below action levels referenced above) and the concentrations at the downstream site are not significantly elevated above baseline levels, the District shall notify the Department and request that the monitoring revert back to Tier 1 routine monitoring.

Additionally, these tissue samples will be analyzed and assessed for bio-accumulative toxicants other than mercury identified in Table 1.

A1.2 Sediment

To expand on baseline data detailed in Section 3.1.1, monitoring of sediment within the reservoir prior to flooding will be conducted. Each cell will be divided into four quadrants, and a sediment sample will be collected in the centroid of each quadrant and one sample collected in the middle of the cell (5 samples collected per cell). In addition, sediment cores will be collected at one downstream site in the receiving water (site to be located in Townsend Canal between C43PS1 and the Caloosahatchee River). Sediment samples will be analyzed for THg, MeHg, moisture content, total organic carbon (TOC), total sulfur (TS), total iron (TFe), chlordane-alpha, chlordane-gamma, endrin, ethion, arsenic, copper and zinc (parameters of concern as outlined in the environmental site assessments). The results from this sampling will provide a baseline for future data collection to be compared against.

Upon the initial discharge from reservoir at lowest stage (after the initial filling), sediment cores will be collected from five representative locations within each cell of the reservoir (providing water levels are low enough to allow normal sediment core collection without use of specialized equipment). Each cell will be divided into four quadrants, and a sample will be collected in the middle of each quadrant and one sample collected in the middle of the cell. In addition, sediment cores will be collected at one downstream site in the receiving water (site to be located in Townsend Canal between C43PS1 and the Caloosahatchee River).

At each location or site, a minimum of three cores (number of cores in excess of three will be determined by amount of sediment required for analysis) from the 0-to-4 cm horizon are to be collected and composited as a single sediment sample.

To serve as baseline for future comparison, if future conditions warrant follow-up sampling of sediments (i.e., if Tier 2 were triggered), sediment samples will be analyzed for THg, MeHg, moisture content, total organic carbon (TOC), total sulfur (TS), and total iron (TFe). To allow for possible future analysis, remaining material from each sediment sample will be archived separately for the maximum hold time allowable for the specified parameter list.

Additionally, these sediment samples will be analyzed and assessed for the following toxicants other than mercury identified in Table 1.

A1.3 Water

Although bio-accumulative toxicants, in particular mercury, will be monitored and assessed prior to discharge based on tissue concentrations, because of the concern for potential acute toxicity, water will be collected from immediately upstream of inflows (station **C43PS1**) and outflows (stations **C43S1, C43S8**) of the project and analyzed for toxicants other than mercury as discussed below.

Selection of Toxicants Other Than Mercury

The following information sources have been reviewed for data regarding this project: Environmental Site Assessment Phase I or II or III for various properties located in the project area. Based on this review, the parameters identified in Table 1 will be analyzed in each of the specified matrices.

Table A1. Parameter list of toxicants other than mercury that will be analyzed in specified matrix.

Analyte	Surface Water	Sediment	Fish tissues
Chlordane - alpha	✓	✓	✓
Chlordane - gamma	✓	✓	✓
Endrin	✓	✓	✓
Ethion	✓	✓	✓
Arsenic	✓	✓	✓
Copper	✓	✓	✓
Zinc	✓	✓	✓

The District shall provide the Department with the results of these analyses as well as the appropriate action levels for comparison. If the following criteria are met for a given flow way or cell, the District may initiate reservoir discharge and routine monitoring for that flow way or cell (for details on routine monitoring, see below).

- If ambient mosquitofish do not demonstrate excessive bioaccumulation that exceeds a critical tissue benchmark used to establish SQAGs or in site-specific risk assessments;
- If concentrations in sediments do not exceed an effects-based, numerical sediment quality assessment guideline (SQAGs for sediment dwelling organisms, MacDonald Environmental Sciences Ltd.and USGS, 2003);
- If concentrations in sediments do not exceed an established bio-accumulative based SQAG, if available (MacDonald Environmental Sciences Ltd. and USGS, 2003), a action level reported in the ESA or a level that was determined to be critical in a site-specific risk assessment;
- If water-column concentrations do not exceeded a WQS in Chapter 62-302, F.A.C.

However, if one of the above referenced action levels are exceeded, the District shall immediately (within 14 days of receiving quality assured data from the laboratory) collect a sample(s) to confirm the exceedance(s). In addition, the District shall consult with the Department to determine the most appropriate course of action and obtain authorization to initiate reservoir discharge from that cell or flow way. At a minimum, the course of action will include implementation of Tier 2 Expanded Monitoring and Risk Assessment by the District during initial flow-through operations. The recommended course of action may also

include additional measures as determined to be appropriate. When results of expanded monitoring demonstrate concentrations in each flow way has decreased to acceptable levels (below action levels referenced above), and the concentrations at the downstream site are not significantly elevated above baseline levels, the District shall notify the Department and request that the monitoring revert back to Tier 1 routine monitoring.

Refer to Table A2 for a summary of initial start up monitoring described above.

Table A2. Summary of Initial Start Up Monitoring Prior to Discharge

Matrice	Frequency	Location	Parameters
Mosquitofish	Initial filling of reservoir than quarterly (when water is pumped into reservoir during wet season: July to November). The same sampling regime will be followed when discharge occurs from reservoir (usually during dry season: January to May).	4 locations (along perimeter of levee) within each cell and one downstream location	THg, chlordane-alpha, chlordane-gamma, endrin, ethion, arsenic, copper, zinc
Sediment	Post construction, prior to filling	5 locations within each cell of the reservoir and one downstream location	THg, MeHg, moisture content, total organic carbon (TOC), total sulfur (TS), and total iron (TFe), chlordane-alpha, chlordane-gamma, endrin, ethion, arsenic, copper, zinc
Sediment	After initial discharge at lowest stage	5 locations within each cell of the reservoir and one downstream location	Same as above
Water	Initial filling of reservoir than quarterly (when water is pumped into reservoir during wet season: July to November). The same sampling regime will be followed when discharge occurs from reservoir (usually during dry season: January to May).	C43PS1, C43S1, C43S8	Chlordane – alpha, chlordane – gamma, endrin, ethion, arsenic, copper, zinc

A2. Monitoring During Stabilization Period

The District shall initiate monitoring after initial discharge and during the stabilization period as follows:

A2.1 Tier 1: Routine Monitoring During Stabilization Period

A2.1.1. Water

On a quarterly basis, an unfiltered surface water sample (n = 1) shall be collected in accordance with Chapter 62-160, F.A.C., at the inflow (station C43PS1) and immediately upstream of the outflows (stations C43S1, C43S8) from the project (see map of project shown in Figure 2). These samples will be analyzed for THg, MeHg, and sulfate (the latter not to be duplicative if listed as a parameter under routine monitoring described elsewhere in the general monitoring plan).

Based on the discussion above regarding toxicants other than mercury, a surface water sample will be collected quarterly at the inflow (station C43PS1) and immediately upstream of the outflows (stations C43S1, C43S8) and analyzed for the parameters listed in Table 1 under surface water.

In addition, flow will be monitored at the inflow and outflow to allow for load estimation to and from the project (it should be recognized that quarterly sampling would allow for only rough estimation of loads).

This data set will be assessed to determine if outflow concentrations exceed WQS, and whether annual outflow loads of analytes are significantly greater than inflow loads, including atmospheric loading; load estimates will include confidence intervals that describe uncertainty in measures of flow and concentration (e.g., field and analytical precision) and resulting from interpolation (note: assessment protocol to be negotiated with permitting authority). Failure to satisfy these assessment measures would trigger Tier 2 Expanded Monitoring and Risk Assessment (see below).

Because of differences in the anticipated time frames under which sedimentary release are thought to occur (i.e., relative to MeHg that may have time lag associated with changes in biogeochemistry and microbial methylation driven by water quality, especially in sandy soils), monitoring for other toxicants would cease after one year if action levels are not exceeded within that time.

A2.1.2. Fish Tissues

Samples of fish from multiple trophic levels will be collected from cell of the reservoir and from a single downstream site in the receiving water of the project (Figure 2). Specifically, mosquitofish collections will be made in a similar fashion and continue on a quarterly basis from all sites that were sampled prior to discharge (see above; for rationale for the selection of this and other species listed below, see the Protocol). On an annual basis, bluegill (n should be greater than or equal to 5) should be collected and individually analyzed as whole-

fish. Because this site contains habitat that is expected to support largemouth bass and because recreational harvesting is likely in the future, bass will also be collected (n should be greater than or equal to 5) and a fillet from each individual analyzed. For the reasons discussed in the Protocol, collections should target bluegill ranging in size from 102 to 178 mm (i.e., 4 to 7 inches) and largemouth bass ranging in size from 280 to 330 mm (i.e., 11 to 13 inches); however, other lepomids (first priority being given to spotted sunfish) or sizes are to be collected if efforts fail to locate targeted fish. These samples will be analyzed for THg and other toxicants listed in Table 1 under tissues.

Assessment

To detect and minimize any adverse effects as early as possible (and to provide a basis for identifying adaptive management options, if deemed necessary), the results of this monitoring will be assessed based on the criteria and time table described under Phase 2-Tier 1 in the Protocol (specifically, A Protocol for Monitoring Mercury and Other Toxicants and appendices, as approved at the time of the assessment). Monitoring results will be provided to the Department in accordance with the reporting requirements identified in Section 4.

Refer to Table A3 for a summary of routine monitoring during stabilization described above.

Table A3. Summary of Routine Monitoring During Stabilization

Matrice	Frequency	Location	Parameters
Water	Quarterly	C43PS1, C43S1, C43S8	THg, MeHg, sulfate, Chlordane – alpha, chlordane – gamma, endrin, ethion, arsenic, copper, zinc
Mosquitofish	Quarterly	4 locations (along perimeter of levee) within each cell and one downstream location	THg, chlordane-alpha, chlordane-gamma, endrin, ethion, arsenic, copper, zinc
Bluegill, largemouth bass (n=5)	Annually	4 locations (along perimeter of levee) within each cell and one downstream location	THg, organochlorine chlordane-alpha, chlordane-gamma, endrin, ethion, arsenic, copper, zinc

A2.2 Tier 2: Expanded Monitoring and Risk Assessment During Stabilization Period

In accordance with the Protocol, if Tier 1 data exceed the action levels identified under Phase 2 – Tier 2 Expanded Monitoring and Risk Assessment, the District shall notify the Department and after obtaining the Department's concurrence, shall expand monitoring and undertake all necessary steps consistent with the Protocol.

A3. Operational Monitoring Following the Stabilization Period

The monitoring plan and associated data will be re-evaluated on a regular basis beginning after year-1 for other toxicants and after year-3 for mercury species to determine if criteria specified in the Protocol are being satisfied. Based on that assessment, and with the concurrency of the Department, monitoring and assessment efforts may be reduced (as identified in Phase 3-Tier 1 Operational monitoring of the Protocol) or eliminated all together at the project level to be subsumed by regional monitoring (as identified in Phase 3-Tier 3 Operational monitoring). However, if monitoring reveals anomalous conditions as described under Phase 3-Tier 2, the District shall expand monitoring and undertake all necessary steps under Phase 3 – Tier 2 Expanded Monitoring and Risk Assessment.

A4. Reporting Requirements

The permittee shall notify the Department immediately if monitoring data indicate that any of the action levels are exceeded. In addition, the permittee shall submit to the Department, as part of the annual South Florida Environmental Report, the results of the monitoring as defined above, including the following:

i. Comparison of inflow and discharge concentrations with state water quality criteria;
ii. Comparison of inflow and outflow loads and concentrations for total mercury, methylmercury, and other toxicants; and
iii. Comparison of data with appropriate action levels.

E.0 REPORTS PROVIDED BY RECOVER TO SUPPORT THE PLAN

E.1 INTRODUCTION AND PURPOSE OF THE EVALUATION

The Caloosahatchee River (C-43) West Basin Storage Reservoir Project Team has identified their final array of alternative plans and requested that Restoration Coordination and Verification (RECOVER) conduct a system-wide evaluation of the alternative plans being considered. The role of RECOVER is to organize and apply scientific and technical information in ways that are most effective in supporting the objectives of the Comprehensive Everglades Restoration Plan (CERP or Comprehensive Plan). One of the primary missions of RECOVER is to work with the project team to evaluate and maximize the contribution made by each project to the system-wide performance of the CERP. The RECOVER Evaluation Team (ET) is charged with the responsibility of conducting system-wide evaluations.

The ET is an interagency and interdisciplinary scientific and technical team charged with developing and using performance measures for evaluating alternative plans developed for project implementation reports (PIRs). The purposes of system-wide evaluations are to (1) inform the project team of the compatibility of proposed project alternative plans with regional CERP restoration goals and performance expectations; (2) determine the performance of each alternative plan toward meeting system-wide goals and objectives through the use of system-wide performance measures, project performance measures, and best professional judgment; (3) identify improvements for project performance that would improve its system-wide performance, and (4) provide decision-makers required information regarding system-wide performance expectations of specific projects.

The type of RECOVER evaluations may vary depending on the applied tools, new information that may have become available, the project's relationship to the Central and Southern Florida (C&SF) Project, or the project implementation schedule. In the case of hydrologically isolated projects, RECOVER may not be able to rely on regional modeling results for their evaluations. For these projects, the scope of RECOVER's evaluations may be limited to reviewing project-level model results and applying best professional judgment.

E.2 PROJECT BACKGROUND AND GENERAL DESCRIPTION OF ALTERNATIVE PLANS

E.2.1 Project Goals and Objectives

The Caloosahatchee River (C-43) West Basin Storage Reservoir Project is part of the CERP as authorized by the Water Resources Development Act (WRDA) 2000 (U.S. Congress 2000). The goal of the Caloosahatchee River (C-43) West Basin

Storage Reservoir Project is to capture Caloosahatchee River (C-43) Basin runoff and releases from Lake Okeechobee. The project's primary purpose will be to provide environmental water supply deliveries to the Caloosahatchee Estuary and water quality benefits to reduce salinity and nutrient impacts of runoff to the estuary. The objectives of this project, as identified in the Caloosahatchee River (C-43) West Basin Storage Reservoir Project Feasibility Scoping Meeting Documentation (USACE and SFWMD 2005) are as follows:

- Improve the quantity, timing, and distribution of freshwater flows to the Caloosahatchee Estuary by capturing runoff from the Caloosahatchee Basin and Lake Okeechobee releases.
- Improve water quality in the Caloosahatchee Estuary by reducing nutrient inflows from the Caloosahatchee Basin.
- Improve salinity balance in the Caloosahatchee Estuary for estuarine organisms. Reduce the spatial extent and duration of occurrences of extreme low and high salinities.
- Improve the spatial extent and functional quality of habitat for estuarine biota.
- Increase plant and animal diversity and abundance, particularly increasing the spatial extent of SAV.
- Conserve and protect water resources to ensure sustainability of economic and natural resources.
- Ensure availability of ground and surface water supplies for environmental resources while protecting existing legal sources of water for agricultural and urban uses.
- Maintain existing level of service for flood protection in the project area.
- Provide recreational, tourism, and environmental education opportunities.

E.2.2 Project Background

The overall purpose of the Caloosahatchee River (C-43) West Basin Storage Reservoir Project can best be understood in terms of its contribution and relationship to the overarching purpose of restoring the South Florida ecosystem. The Caloosahatchee River (C-43) West Basin Storage Reservoir Project will contribute to South Florida ecosystem restoration through features to increase the availability of water for the natural environment (i.e., the Caloosahatchee Estuary) to enable a more natural salinity regime for the estuary. By mitigating low flows to the estuary during the dry season (November-May) and extreme high flows during the wet season (June-October), natural salinity ranges suitable to improve habitat suitability and increase biological diversity will be established. Additional water made available by the project could supply urban and agricultural users.

The Caloosahatchee River (C-43) West Basin Storage Reservoir is intended to capture local basin runoff and Lake Okeechobee (LO) regulatory releases. The reservoirs will be used to attenuate flood conditions in the local basin, provide estuarine water deliveries, and potentially reduce nutrient impacts of runoff to the estuaries (USACE and SFWMD 1999). Through additional information development performed for the Initial CERP Update (ICU), it was determined that land-use and runoff calculations performed for the Caloosahatchee River (C-43) basin during the Restudy grossly overestimated the amount of runoff available in the local basin, while underestimating the urban and agricultural water demands. In addition to these updates, the low flow target to maintain acceptable salinities in the Caloosahatchee Estuary were updated from 300 cfs to 450 cfs, and deliveries from Lake Okeechobee were capped at Restudy-like levels. The combination of all these changes had the unintended consequence of requiring more environmental water deliveries from a system now producing less local runoff and shouldering increased agricultural and urban demand, while being unable to increase the amount of water supplied by Lake Okeechobee. Cost estimates for potential solutions to the above-listed problems were estimated to exceed the cost containment cap for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project. Consequently, the C-43 BSR Project was split into two separate PIRs. The first PIR, termed Caloosahatchee River (C-43) West Basin Storage Reservoir Project, consists of a separable western storage reservoir at the Berry Groves site to address the needs of the lower Caloosahatchee River (C-43) basin and the Caloosahatchee Estuary. This PIR will primarily address estuarine freshwater flows and will only incidentally address water quality effects regarding sedimentation during reservoir retention. A subsequent PIR, consists of the remaining reservoirs identified in the original project, primarily addressing the needs of the upper Caloosahatchee River (C-43) basin, including water quality issues within the basin. The Caloosahatchee River (C-43) West Basin Storage Reservoir project is on a compressed timescale to coordinate with SFWMD Accelerate Program activities prior to the projected beginning of construction in June 2007. It will include formulation, evaluation, and justification of the separable western storage reservoir while acknowledging that the project is a part of a more comprehensive plan for the Caloosahatchee River (C-43) Basin.

E.2.3 General Description of Alternative Plans

The Caloosahatchee River (C-43) West Basin Storage Reservoir Project identified their final array of project alternative plans. Each alternative plan that is being considered includes a reservoir to store and release water to the estuary. The configurations and operational plans that make up the final suite of alternative plans are detailed in ***Table E-1***.

TABLE E-1: SUMMARY OF CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR PROJECT ALTERNATIVE PLANS

Alternative Name	Reservoir			Pump Size (cfs)	Operating Scheme
	Size (acres)	Depth (ft)	Storage Capacity (ac-ft)		
Alt2	10,000	10	100,000	1500	PIR
Alt3a	10,000	17	170,000	1500	A8
Alt 3b	10,000	17	170,000	1500	PIR
Alt 3c	10,000	17	170,000	3800	PIR
Alt 4	10,000	22	220,000	3800	PIR

E.3 EVALUATION METHODOLOGY AND INFORMATION CONSIDERED

This section outlines the methodology used by RECOVER to conduct its system-wide evaluation of alternative plans. It also describes the modeling and technical information considered by RECOVER to evaluate the potential system-wide effects of the project. RECOVER's analyses of the information presented and implications to the system are presented in later sections of this report.

Because the Caloosahatchee River (C-43) West Basin Storage Reservoir Project is essentially outside the spatial resolution and domain of the South Florida Water Management Model (SFWMM), the MIKESHE model was developed and used to dynamically simulate the entire land phase of the hydrologic cycle within the Caloosahatchee River (C-43) basin. Because the MIKESHE model and the SFWMM are not dynamically linked, the two models operate separately. Essentially, the Caloosahatchee River (C-43) West Basin Storage Reservoir Project receives a set volume of water from the SFWMM boundary based on the planning assumptions modeled in the 2050RD condition. The MIKESHE model then uses these boundary conditions and models the individual alternative plans for the western reservoir. The MIKESHE daily output for the S-79 structure was used to evaluate the project's performance using the CERP system-wide performance measure NE-3: Caloosahatchee salinity envelope (http://www.evergladesplan.org/pm/recover/recover_docs/et/ne-03.pdf).

Because the SFWMM essentially provides a pass-off volume of water to the MIKESHE model to manage within the local basin, conditions within the rest of the system remained unchanged based on changes in alternative plans. For this reason, RECOVER focused its evaluation on the project's performance within the Caloosahatchee Estuary, and worked in conjunction with the project's environmental sub-team to apply the hydrologic performance measure and interpret habitat suitability indices (HSI) output developed by the project team. RECOVER conducted its evaluation based on the following SFWMM and MIKESHE scenarios:

- 2000 Existing Condition using revised deliveries to the Caloosahatchee basin (2000RD)
- 2050 Future without CERP Condition using revised deliveries to the Caloosahatchee basin (2050RD)
- 2050 Future without Project (FWO) Condition using the MIKESHE model (2050FWO)
- 2050 Future Condition with each alternative in place with the rest of CERP using the MIKESHE model (Alt2, Alt3a, Alt3b, Alt3c, and Alt 4)

RECOVER recognizes that the West Basin Storage Reservoir Project Team will likely perform additional model runs during refinement of their alternatives leading up to their alternative formulation briefing. When available, RECOVER will review these additional model results and provide modified and/or additional comments to the Project Team on alternative plan performance where appropriate.

E.4 CONSISTENCY WITH THE COMPREHENSIVE PLAN

The planning objectives developed for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project are generally consistent with the objectives of the Comprehensive Plan (USACE and SFWMD 1999). The planning goal of this project is to address the declining health of Caloosahatchee River and Estuary ecosystems by improving water deliveries to the estuary to reduce excessive high flows during wet season and increase the availability of water for the estuarine system during the dry season to provide a salinity range that is suitable for a healthy ecosystem that promotes estuarine habitat, increased fish and wildlife, and biological diversity. After estuarine system needs are met, any additional water could supply urban and agricultural needs. The twelve objectives developed for the Project presented in ***Table E-2*** directly correspond to specific CERP goal(s) contained in the Central and Southern Florida Project Comprehensive Review Study Final Integrated Feasibility Report and Programmatic Environmental Impact Statement (USACE and SFWMD 1999).

TABLE E-2: SUMMARY OF CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR PROJECT OBJECTIVES AND CORRESPONDING CERP OBJECTIVES

CERP Goal: Restore ecologic values by increasing habitat and functional quality and improving native plant and animal species abundance and diversity
West Basin Storage Reservoir Project Objectives:
▪ Improve the quantity, timing, and distribution of freshwater flows to the Caloosahatchee Estuary by capturing runoff from the Caloosahatchee Basin and Lake Okeechobee releases.
▪ Improve water quality in the Caloosahatchee Estuary by reducing nutrient inflows from the Caloosahatchee Basin.
▪ Improve salinity balance in the Caloosahatchee Estuary for estuarine organisms. Reduce the spatial extent and duration of occurrences of extreme low and high salinities.
▪ Improve the spatial extent and functional quality of habitat for estuarine biota.
CERP Goal: Enhance economic values and social well being
West Basin Storage Reservoir Project Objectives:
▪ Conserve and protect water resources to ensure sustainability of economic and natural resources.
▪ Ensure availability of ground and surface water supplies for environmental resources while protecting existing legal sources of water for agricultural and urban uses.
▪ Maintain existing level of service for flood protection in the project area.
▪ Provide recreational, tourism, and environmental education opportunities

E.5 SYSTEM-WIDE PERFORMANCE OF ALTERNATIVE PLANS

The following sections summarize performance of the project alternatives using the methodology described in Section E.3 of this report.

E.5.1 Caloosahatchee Estuary

RECOVER's review of alternative plans focused on freshwater discharges from the Caloosahatchee River (C-43 canal) at the S-79 structure. Based on these analyses, the project will provide substantial benefits to the area.

The CERP system-wide Caloosahatchee Estuary salinity envelope performance measure, NE-3, targets a mean monthly inflow between 450 and 2800 cfs during all months, with a low flow target of no months during October to July when the mean monthly inflow from the Caloosahatchee watershed, as measured at S-79, falls below a low flow limit of 450 cfs and the high flow target is no months with mean monthly flow greater than 2800 cfs, as measured at the S-79, from Lake Okeechobee regulatory releases in combination with flows from the Caloosahatchee River (C-43) basin. These predictive performance targets are summarized in ***Table E-3***. A reduction in the number of low flow and high flow events and a reduction in the frequency and duration of high and low flow events is required to show improvement over the base conditions.

TABLE E-3: SUMMARY OF CERP SYSTEM-WIDE PERFORMANCE MEASURE NE-3 PREDICTIVE TARGETS

Performance Metric	Target
Low Flow Events	
Mean monthly flow at S-79 <450 cfs (July-October)	0
Number of consecutive months mean monthly flow at S-79 < 450cfs	Alternative with fewest consecutive months is best
Number of consecutive years with mean monthly flows at S-79 < 450 cfs	Alternative with fewest consecutive years is best
S-79 Flow Distribution	
Percent of mean monthly flows at S-79 450-800 cfs	75%
Percent of mean monthly flows at S-79 800-2800 cfs	25%
Moderate and Extreme High Flow Events	
Mean monthly flows at S-79 > 2800 cfs	0 (especially March-October)
Mean monthly flows at S-79 > 4500 cfs	0 (especially March-October)
Lake Okeechobee Regulatory Releases (measured at S-77RG)	
Number of days with LO regulatory releases	0
Daily volume of LO regulatory releases	0
Total volume of LO regulatory releases	0

E.5.1.1 Low Flow Events (<450 cfs)

The target of no flows less than 450 cfs especially between October and July has been found to be ecologically significant to valued ecosystem components (VECs) within the estuary, primarily for submerged aquatic vegetation (SAV) and the American oyster. The health of these VECs is crucial to maintaining the ecological structure and function of the estuary by providing food, living space, and foraging sites for other naturally occurring estuarine species (RECOVER 2006). Performance between October and July, corresponding to the dry season, is especially important to the health and stability of SAV communities within the estuary. An important upper estuarine feature is the freshwater-brackish submerged grass, *Vallisneria americana* (tape grass), which when present is located near the shoreline in the upper estuary to a depth of about 1.0 m (Hoffacker et al. 1994; Chamberlain and Doering 1998). *Vallisneria americana* is the dominant type of SAV in the upper Caloosahatchee Estuary and occurs in well-defined beds in shallow water. *Vallisneria americana* is thought to be an important habitat for a variety of freshwater and estuarine invertebrate and vertebrate species, including some commercially and recreationally important fishes (Bortone and Turpin 1999). Additionally, it can serve as a food source for the Florida manatee. *Vallisneria americana* is more sensitive to low freshwater flows and high salinities than the most common higher salinity grasses in the Caloosahatchee Estuary such as shoal grass (*Halodule wrightii*), turtle grass (*Thalassia testudinum*) and manatee grass (*Syringodium filiforme*). During times of extended low flow conditions, when salinity is too high, *Vallisneria*

americana becomes very sparse and can disappear completely (Chamberlain et al. 1995; Doering et al. 2002; SFWMD 2000). By reducing or eliminating low flow events, high salinities are reduced supporting greater *Vallisneria americana* beds and their associated ecological function.

Volety et al. (2003) has demonstrated the importance of the American oyster (*Crassostrea virginica)* as a VEC in the Caloosahatchee Estuary. A greater abundance of decapods and fishes are associated with clusters of live oyster compared to dead-articulated clusters, while the structure provided by both living and dead oyster shells supports a greater abundance than no shells. Species richness and dominance are higher for samples with oyster clusters (dead or live) compared to controls with no oyster shell. While high flow events (i.e., low salinities) are more detrimental to oysters than low flow events (i.e., high salinities), extended low flows can negatively impact oysters by making them prone to disease and predation. Low flow events will increase salinities in areas normally associated with lower salinity, and result in the migration of marine predators and pests. Oyster spat that recruit to downstream areas will also be exposed to higher salinity and heavy predation pressure resulting in very little survival (Volety et al. 2003). Infection by the oyster pathogen, *Perkinsus marinus*, increases during higher salinity and temperature conditions. Field studies by Volety et al. (2003) determined that the prevalence of infection is high when salinities are high due to low flow. Reducing or eliminating low flow events with short pulses of freshwater inflow can greatly benefit oyster populations by killing predators, such as the southern oyster drill and the whelk and reducing *Perkinsus marinus* infection.

Each of the alternatives evaluated demonstrates a decrease in the number of months when flows through the S-79 structure are less than 450 cfs between October and July (***Figure E-1***). These decreases range from 8% of the period of record (POR) for Alt2 to 21% of the POR for Alt3c and Alt4 (***Table E-4***). With regard to the target for this metric, 0% of the POR, alternatives Alt3c and Alt4 perform best. When the monthly distribution of these events is evaluated, differences among the alternatives' performance is more easily observed. By focusing on the heart of the dry season, between March and June, the differences among alternatives becomes apparent. While the largest decreases in damaging low flow events during this time period occur under alternatives Alt3c and Alt4, alternatives Alt2 and Alt3a do not show substantial decreases over the FWO condition (***Figure E-2***).

TABLE E-4: MEAN MONTHLY FLOW EVENTS <450 CFS AT THE S-79 STRUCTURE OCTOBER TO JULY

	Number of Events	Percent POR
Target	0	0%
2050FWO	42	39%
Alt2	33	31%
Alt3a	32	30%
Alt3b	30	28%
Alt3c	19	18%
Alt4	19	18%

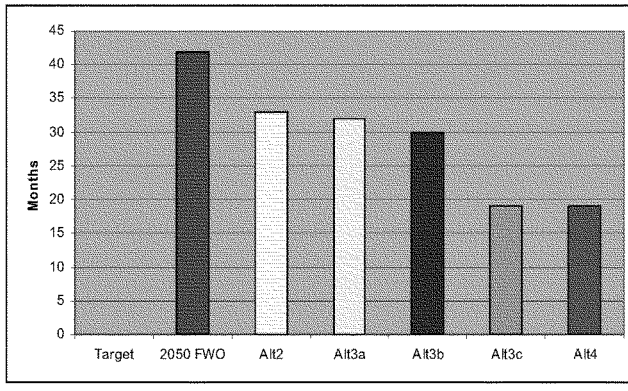

FIGURE E-1: NUMBER OF MEAN MONTHLY FLOW EVENTS LESS THAN 450 CFS OCTOBER TO JULY

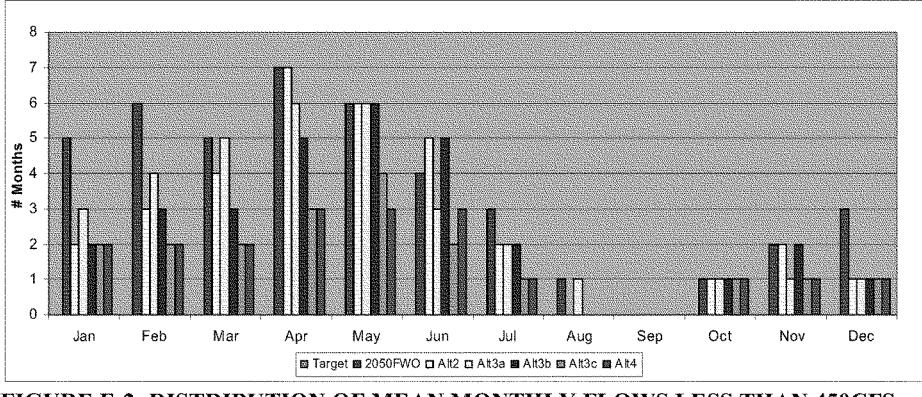

FIGURE E-2: DISTRIBUTION OF MEAN MONTHLY FLOWS LESS THAN 450CFS

E.5.1.2 Flow Distribution at S-79

The target of 75% of S-79 flows between 450-800 cfs and most of the remaining inflow between 800-2800 cfs is important for protecting and restoring estuarine resources while promoting species abundance and diversity (RECOVER 2006). Each of the alternatives increases the number of months where flow is within the desired envelope (***Table E-5*** and ***Figure E-3***). Alternatives Alt3c and Alt4 provide the greatest percentage of time within the desired flow envelope at 82% of the POR. RECOVER also evaluated the alternatives' performance based on mean weekly flows through the S-79 structure. Using this method, the ranking of alternative performance remained unchanged with alternatives. Alt3c and Alt4 again provide the best performance at 82% and 84% of the POR respectively ***Table E-6*** and ***Figure E-4.***

TABLE E-5: MEAN MONTHLY DISTRIBUTION OF FLOWS FROM S-79

	450-800 cfs	800-2800 cfs	%POR in Desired Envelope
Target	75.0%	25.0%	100.0%
2050FWO	25.0%	25.9%	50.9%
Alt2	42.6%	25.0%	67.6%
Alt3a	51.9%	15.7%	67.6%
Alt3b	45.4%	24.1%	69.4%
Alt3c	55.6%	26.9%	82.4%
Alt4	55.6%	26.9%	82.4%

TABLE E-6: MEAN WEEKLY DISTRIBUTION OF FLOWS FROM S-79

	450-800 cfs	800-2800 cfs	%POR in Desired Envelope
Target	75.0%	24.6%	99.6%
2050FWO	23.7%	21.8%	45.5%
Alt2	44.9%	23.1%	67.9%
Alt3a	47.9%	16.2%	64.1%
Alt3b	50.4%	24.4%	74.8%
Alt3c	59.4%	22.9%	82.3%
Alt4	60.7%	23.1%	83.8%

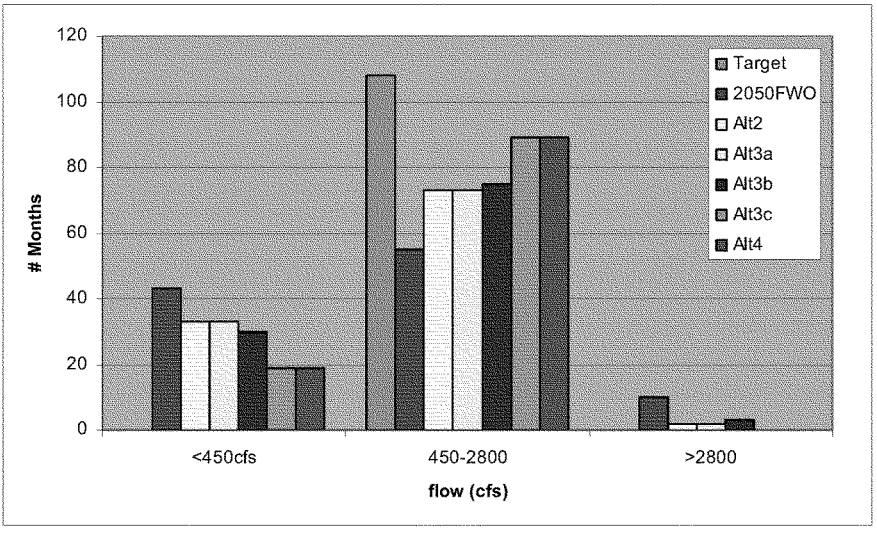

FIGURE E-3: MEAN MONTHLY FLOWS AT S-79 WITHIN THE DESIRABLE 450-2800 CFS FLOW RANGE

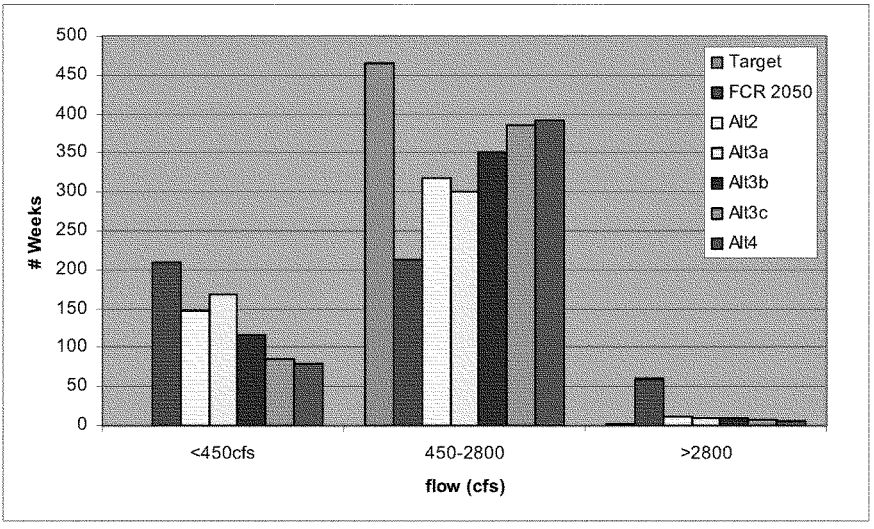

FIGURE E-4: MEAN WEEKLY FLOWS AT S-79 WITHIN THE DESIRABLE 450-2800 CFS FLOW RANGE

To understand any additional improvements in flow distributions, RECOVER evaluated the changes in seasonal flow distributions for mean monthly flows. The increases in the number of desirable flows that occur during the March-October period have been identified as most beneficial to indicator species communities in the Caloosahatchee Estuary with regard to SAV and juvenile oyster recruitment and survival. As with the previous analyses, Alt3c and Alt4 provide the largest increase in the number of months with flows within the desired envelope (***Figure E-5***).

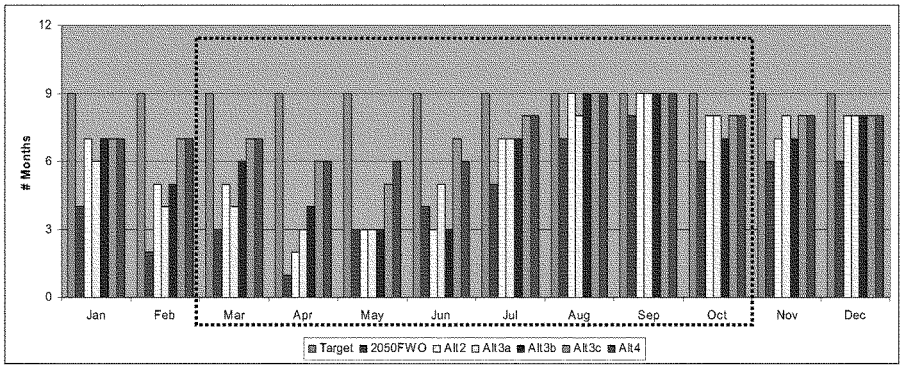

FIGURE E-5: SEASONAL MEAN MONTHLY FLOWS WITHIN THE DESIRABLE 450-2800 CFS FLOW RANGE

E.5.1.3 Moderate and Extreme High Flow Events

Moderate and extreme high flow events in the Caloosahatchee Estuary (>2800 cfs and >4500 cfs, respectively) directly impact estuarine salinities and ecosystem indicators such as the American oyster and SAV. Reduction in these high volume releases, especially during the period from March to October, may lead to decreases in mass mortality (salinity < 3 ppt) as well as poor spat production and excessive valve closure (salinity < 14ppt) in the oyster population (RECOVER 2006). Oysters are particularly susceptible to high flows that drastically lower salinity levels during the spawning season. One key component of spawning success is the requirement of salinities of approximately 7.5 ppt or greater (Sellers and Stanley 1984, Volety et al 2003). High flow events (flows > 2800 cfs, i.e., lower salinities) have a much greater impact on oysters than low flow events (i.e., higher salinities) as these inhibit reproduction and recruitment. This is exacerbated as oyster life spans are short and the effects of missed spawning opportunities prevent restoration of healthy populations. Optimum oyster ranges for physiological purposes, food abundance, and stenohaline predator avoidance is 10 to 20 ppt (Mazzoti et al. 2005). These salinities and flows have been corroborated by monitoring at S-79 structure where monthly flow volumes of 87.2 to 196 thousand ac-ft create salinities of less than 7.5 ppt. These flow volumes equate to mean monthly flows of 2800 cfs.

All alternatives measurably reduce the number of months and number of consecutive months where high flow events occurred. All alternatives substantially reduced the number of months with flows greater than 2800 cfs and completely eliminated flows greater than 4500 cfs, creating favorable conditions for the American oyster. Alternatives Alt3c and Alt4 provided the best performance and eliminated all flows greater than 2800 cfs (***Table E-7***).

TABLE E-7: SUMMARY OF MODERATE AND EXTREME HIGH MEAN MONTHLY FLOWS

Alternative	Months 2800-4500 cfs	Percent Change	Months >4500 cfs	Percent Change
Target	0		0	
2050FWO	7		3	
Alt2	2	-71%	0	-100%
Alt3A	2	-71%	0	-100%
Alt3B	3	-57%	0	-100%
Alt3C	0	-100%	0	-100%
Alt4	0	-100%	0	-100%

Note: Percent change indicates difference between the modeled alternative and the 2050 FWO condition.

To demonstrate the additional differences among alternative plans in preventing moderate high flow events (2800 cfs – 4500 cfs) a 30-day moving average of S-79

structure flows was evaluated. In most cases there is little difference between alternatives, however if attention is directed at the June 1982 to March 1983 time frame, differences among the alternative plans are apparent. To provide more resolution, ***Figure E-6*** depicts these 30-day moving averages during this critical period. For those alternatives without additional pumping and reservoir capacity (i.e. alternatives Alt2 and Alt3B), daily flows frequently exceeded 3000 cfs and in some cases exceed 10,000 cfs. When these high daily flows are converted to 30-day moving average flows, differences among the alternative plans can be discerned. Note that the 30-day moving average for flows through the S-79 structure exceed 3000 cfs for alternatives Alt2 and Alt3B during June of 1982, October of 1983, and March of 1983. Flows that exceed the moderate high flow criteria do not occur for alternatives Alt3C and Alt4. The larger pumping capacity and increased reservoir depth for these alternatives effectively prevent high flows to the estuary from the S-79 structure. From an ecological perspective, these high flows occur during oyster spawning windows. This protracted period of low salinity would have interrupted the oyster spawning cycle, potentially killing adult oysters, as well as spat that had set earlier in the season. As daily flows exceed 8,000 cfs mortality to reefs of adult oysters would also be expected to occur. These high flows also occur during the growing season for the SAV *Halodule wrightii*, which would inhibit growth.

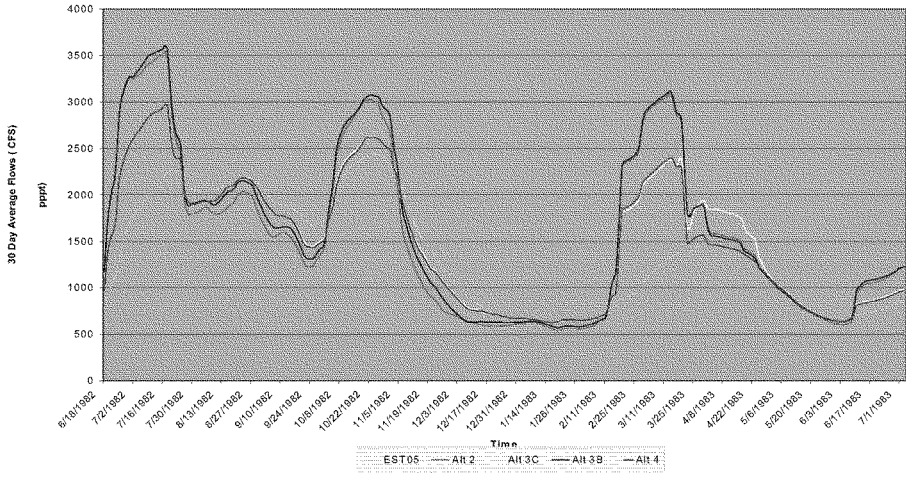

FIGURE E-6: 30-DAY MOVING AVERAGE S-79 FLOWS JUNE 1982 TO JUNE 1983

Periods of low salinity shorter than 30-days also impact oyster and *Halodule wrightii* health, therefore an analysis was conducted on a shorter time scale to

determine if more low salinity episodes were prevented through implementation of the alternative plans. For this analysis a two-week moving average was employed over the POR. Four events were identified when salinities were expected to drop below 3ppt based on flows greater than 2800 cfs: October 1979, July 1982, October 1982, and March 1983. These four episodes of low salinity did not occur for alternatives Alt3C and Alt4, but did occur for alternatives Alt2 and Alt3B. Impacts to estuarine oyster communities would have occurred in late 1979 thereby affecting the 1980 spawning season. After less than two years of recovery, three more episodes would occur in 1982 and early 1983. This would have compromised recovery of oysters in the Caloosahatchee Estuary system. If the MIKESHE period of record is representative of a longer time scale, then these episodic low salinity events could provide chronic and cyclic destruction of the oyster and *Halodule wrightii* communities. The additional pumping capacity and storage provided by alternatives Alt3C and Alt4 clearly improve ecological conditions within the estuary.

E.5.1.4 LO Regulatory Releases

Because the volumes of water provided by SFWMM boundary conditions into the MIKE-SHE model were fixed and did not vary based on the alternative plans, there was no change in the number or frequency of LO regulatory releases to the Caloosahatchee Estuary. The ability of the alternative plans to mitigate the LO regulatory releases that did occur is demonstrated through the substantial reduction or moderate high flow events (2800-4500 cfs) and the complete elimination of extreme high flow events (>4500 cfs).

E.5.1.5 Ecological Impact for the Caloosahatchee Estuary

The alternatives show a measurable reduction in low flow events due to the project and will provide significant benefit to the VECs tape grass (*Vallisneria americana)* and American oyster (*Crassostrea virginica).* A reduction in the low flow events eliminates high salinities, which has greatly reduced *Vallisneria americana* beds in the Caloosahatchee Estuary in the past (Chamberlain et al. 1995; Doering et al. 2002; SFWMD 2000). This reduction of high salinity conditions will lead to more extensive *Vallisneria americana* beds and greater ecological function in the Caloosahatchee Estuary. A reduction in low flow events eliminates high salinities that will benefit oyster populations by killing predators, such as the southern oyster drill and the whelk and reducing *Perkinsus marinus* infection (Volety et al. 2003). This reduction in high salinities not only decreases predation and disease, it also diminishes predation pressure on oyster spat, allowing greater recruitment.

In addition to the reduction in low flow events, the reduction of high flow events and the reduction in the duration of the high flow events due to the project will provide significant benefits to the area. When S-79 discharges exceed 4000 cfs,

salinities drop below 3 ppt upstream of Shell Point which can limit population survival and abundance of oysters in this region (Volety et al. 2003). A greater abundance of decapods and fishes are associated with clusters of live oyster compared to dead oyster clusters, while the structure provided by both living and dead oyster shells support a greater abundance than no shells (Volety et al. 2003). Therefore, the reduction of high flow events, which reduces low salinity events affecting oysters, will lead to increased diversity and abundance of estuarine fauna, one of CERP's primary goals.

E.5.2 Water Supply, Flood Damage Reduction, and Saltwater Intrusion

The severity and duration of water restrictions when drought levels exceed a 1-in-10 condition need to be reviewed to determine the full extent of predicted water supply impacts in the Caloosahatchee River (C-43) basin. To perform a review based on Supply-Side Management (SSM), raw or post-processed data that will allow the determination of monthly demand volume, number of days per month with cutbacks (demands not met), and volume of cutbacks (demand not met) per each month is required. Since this data is not readily available from MIKESHE output, annual average volumes (AAV) were evaluated. It is important to note that the average annual number will not allow for a determination of differences in alternative performance regarding water supply deliveries.

The results for agricultural and urban domestic self-supply in the Caloosahatchee River (C-43) basin indicate that "demands not met" dominate the model results and urban domestic self-supply for groundwater predicts over 90% of demand is not met. At this time, it is not possible for RECOVER to determine whether disparities between AAV demand and supply are a result of model assumptions/operations or accurately reflect the demands of urbanization within the basin. The following RECOVER evaluation presents performance based on the available model outputs and suggests additional areas of investigation for water supply analysis.

E.5.2.1 Caloosahatchee East Basin

A significant difference does not occur between the 2050FWO and the environmental target (EST05) for agricultural surface water and groundwater AAV demands (***Table E-8***). Only alternative Alt3a exhibits better performance for surface water AAV deliveries to agricultural users than the other alternatives and Alt3A matches the volume of surface water delivered in the 2000 base condition. All alternatives appear to slightly increase groundwater AAV agricultural demand over the 2050FWO without significant differences in performance. The agricultural groundwater AAV demand for all alternatives exceeds the AAV demands in the 2000 base condition.

All future planning conditions and alternatives are almost identical regarding surface water and groundwater AAV for urban self-supply (i.e., local irrigation-type wells). It appears the model presumes surface water will not be used for domestic supply in the future. The 2000 base condition does show a surface water demand of 800 ac-ft/year and a groundwater demand of 19,000 ac-ft/year for urban self-supply in the Caloosahatchee east basin.

TABLE E-8: EAST CALOOSAHATCHEE (S-78 BASIN) SUMMARY (1000 AC-FT)

	Irrigation and Domestic Self-supply AAV DEMAND				Irrigation AAV SUPPLY				AAV DEMAND NOT MET			
	Agriculture		Urban		Agriculture		Urban		Agriculture		Urban	
	SW	GW	SW	GW	SW	GW	SW	GW	SW	GW	SW	GW
2000Base	142.4	1.7	0.8	18.6	130.7	1.0	0.8	0.6	11.7	0.7	0.0	18.0
2050FWO	146.7	17.9	0.0	51.9	134.8	8.8	0.0	1.8	12.0	9.1	0.0	50.1
EST05	146.8	18.0	0.0	52.0	133.4	8.9	0.0	1.8	13.4	9.0	0.0	50.1
Alt2	147.4	20.2	0.0	52.2	126.8	10.7	0.0	1.9	20.6	9.5	0.0	50.3
Alt3A	148.3	20.1	0.0	52.7	130.2	10.6	0.0	1.9	18.0	9.5	0.0	50.9
Alt3B	147.4	20.3	0.0	52.2	126.8	10.7	0.0	1.9	20.6	9.5	0.0	50.3
Alt3C	147.3	20.3	0.0	52.2	126.8	10.8	0.0	1.9	20.4	9.5	0.0	50.3
Alt 4	147.3	20.3	0.0	52.2	127.3	10.7	0.0	1.9	20.0	9.5	0.0	50.3

E.5.2.2 Caloosahatchee West Basin

Agricultural AAV provided via surface water is significantly different for 2050FWO and EST05, but groundwater is only slightly different (***Table E-9***). The target deliveries to the estuary appear to reduce the surface water available for agricultural supply in the western basin. Alternative Alt3A exhibits substantially better agricultural AAV deliveries and is the only alternative providing as much AAV delivered to agriculture as the 2050FWO. Alternatives Alt3C and Alt4 provide the next highest volume of agricultural AAV and Alt2 and Alt3B are both similar in AAV to EST05 and provide the lowest AAV deliveries to agricultural users. The alternatives do not differ significantly for groundwater AAV regarding demands not met for agricultural users. Alternative Alt3A has a slightly lower volume of groundwater AAV deliveries that is offset by higher surface water AAV deliveries in the basin. Alternative Alt3A resembles the 2050FWO and the other alternatives resemble the EST05.

Surface water and groundwater AAV demands for domestic self-supply do not differ significantly between 2050FWO and EST05. All of the alternatives show increased surface water AAV demand over the 2000 base condition and the 2050FWO. Alternative Alt3A has a slightly lower surface water AAV demand. All alternatives are practically identical regarding groundwater AAV demand for urban users. Adjusting for the predicted demands not met, the alternatives

provide approximately 10% more AAV than the 2050FWO and approximately 20% less AAV than the 2000 base condition.

TABLE E-9: WEST CALOOSAHATCHEE (S-79 BASIN) SUMMARY (1000 AC-FT)

	Irrigation and Domestic Self-supply AAV DEMAND				Irrigation AAV SUPPLY				AAV DEMAND NOT MET			
	Agriculture		Urban		Agriculture		Urban		Agriculture		Urban	
	SW	GW	SW	GW	SW	GW	SW	GW	SW	GW	SW	GW
2000Base	87.7	61.2	1.1	42.4	65.7	17.9	0.8	13.4	22.0	43.3	0.3	29.0
2050FWO	61.3	54.0	6.2	118.3	52.5	18.9	2.9	9.8	8.8	35.2	3.3	108.6
EST05	56.5	58.9	6.2	118.5	34.8	20.0	2.9	9.8	21.6	38.9	3.3	108.7
Alt2	55.3	59.4	8.6	125.3	33.7	20.1	4.1	10.6	21.6	39.3	4.5	114.7
Alt3A	61.1	53.5	8.4	124.5	53.7	18.7	4.1	10.5	7.4	34.8	4.3	114.0

Alt 4	57.9	56.7	8.5	125.0	42.5	19.6	4.1	10.6	15.5	37.2	4.3	114.4

E.5.2.3 Suggestions for further investigation

The following section presents some insight and questions that might be considered during further investigation of water supply metrics within the Caloosahatchee River (C-43) basin:

- The data requested for a SSM-type water supply review might help determine discrepancies not apparent in AAV data.
- The 2050FWO, EST05, and alternative plans all exhibit increased groundwater demands over the 2000 base condition for urban users and appear to be the governing factor in increased demand not met.
- Why does the East Caloosahatchee 2000 base agricultural AAV provided seem to match the current understanding of the basin, while the West Caloosahatchee 2000 base AAV provided seems decreased from on the ground observations? What are the differences in how the two sub-basins are modeled?
- If the model results are predicting correctly, could the environmental deliveries require so much from the system that less water is available for consumptive use? The inconsistencies between the modeled 2000 base and on the ground conditions indicate issues with modeling assumptions/operations for groundwater in the basin.
- Why do the alternatives add 12,000 ac-ft/year to consumptive use demands above the amount predicted in the 2050 Bases? Most of this is added in the West Caloosahatchee Urban demands – but there are indications of smaller additions throughout.

E.5.3 Interaction with Other Projects

While each CERP project is considered as a stand-alone component, it is important to remember that the interactions among projects will ultimately determine CERP's restoration success for the South Florida ecosystem. With this in mind, RECOVER sought to understand how surrounding projects might interact with the Caloosahatchee River (C-43) West Basin Storage Reservoir project to maximize system benefits. The primary projects identified include Aquifer Storage and Recovery (ASR), Lake Okeechobee Watershed (LOW) Project, and the Lake Okeechobee Regulation Schedule (LORS). While the West Basin Storage Reservoir Project is able to capture and re-release many of the high flow events that result during the wet season in order to better mimic the natural salinity patterns of the estuary, the LOW Project and LORS will clearly impact the amount of water that travels to the estuary in the wet season. Coordination of these projects will be necessary to alleviate high lake stages to maintain littoral zone health while maximizing utilization of the reservoirs in the LOW Project and the Caloosahatchee River (C-43) West Basin Storage Reservoir project to mitigate high flows in the wet season and supplement low flows during the dry season. Additionally, the advent of ASR, or similar storage option, will help to store additional water to ensure that local water supply needs are met. The combined effect of these projects, LOW and LORS reducing the number of moderate and extreme high low events and the Caloosahatchee River (C-43) West Basin Storage Reservoir project providing water to the estuary during the dry season, are expected to meet estuary restoration goals.

E.5.4 Ability of Project Alternatives to Address Planning and Scientific Uncertainties (CERP Adaptive Management)

As with other ecosystem restoration projects throughout the nation, every potential restoration action carries with it an amount of uncertainty and risk. In the case of the Caloosahatchee River (C-43) West Basin Storage Reservoir project, this uncertainty has been identified and project alternatives have been formulated to address and alleviate those uncertainties. In general, uncertainties related to large-scale restoration can be categorized as scientific uncertainties and planning uncertainties.

E.5.4.1 Scientific Uncertainty

The environmental response corresponding to a specific action is uncertain; this is scientific uncertainty. With regard to the Caloosahatchee (C-43) West Basin Storage Reservoir project, there is little uncertainty that more natural salinity patterns in the estuary will improve habitat for desirable indicator species (SAV, oysters, and estuarine fishes) if the timing and distribution of flows meets seasonal targets. It is expected that obtaining more natural flow regimes will benefit target species populations directly by decreasing extreme salinity fluxes.

There is, however, uncertainty regarding the exact water quality benefits provided by the proposed project and the extent of secondary benefits to the broader estuarine community. The HSIs developed by the project team demonstrate the benefits to given species within the estuary over the FWO condition; however they do not demonstrate large differences among the alternative plans. The inability to reveal these differences may be an artifact of model sensitivity, or may indicate that the estuary ecology is benefited over the range of alternative plans evaluated. At this time, the scientific evidence is not available to support one of these theories over the other. Given the scientific uncertainties mentioned, it will be necessary for future scientific findings regarding the resiliency of species indicators and effects on total estuarine health to be incorporated in project operations. Additionally, in order for the project to quantify the total benefits resulting in the estuary post-implementation, activities will need to include associated monitoring and assessment activities at appropriate spatial and temporal scales to provide feedback to the predictive tools (i.e., HSIs) developed during the planning of this project.

E.5.4.2 Planning Uncertainties

The largest planning uncertainty facing the Caloosahatchee River (C-43) West Basin Storage Reservoir team is the project's affect on agricultural and urban water supply in the western Caloosahatchee River (C-43) basin. Initial modeling results indicate that additional investigation is warranted to determine the exact impacts to water supply in this region. A related issue is the cap on water deliveries from LO to the Caloosahatchee River (C-43) basin to Restudy-like levels. The CERP A Refinement currently being conducted by the System Planning and Operations Team (SPOT) is investigating the effects to LO if water deliveries are raised to 2000 levels. The results of this investigation will be presented to CERP decision-makers to determine whether revisions to the stated policy are warranted, and are outside the scope of the project team's planning effort.

E.6 OPPORTUNITIES FOR ALTERNATIVE PLAN IMPROVEMENTS AND OTHER CONSIDERATIONS

As part of the responsibilities given to RECOVER, this section presents suggested improvements to the alternative plans, which, where possible, are intended to improve the project's performance or enhance benefits to the natural system. These suggested improvements to the alternative plans should be considered by the project during the design of the final plan or reevaluation of alternative plans when appropriate.

Two primary opportunities to improve project performance have been identified. First, the project team should strive to optimize operations to coordinate with

other storage features such as ASR, the LOW Project, and the LORS in order to increase benefits to LO (i.e., fewer deviations from the LO stage envelope) and the Caloosahatchee Estuary (i.e., fewer regulatory releases, especially during sensitive periods for key indicator species). Second, the project team should further investigate water supply issues within the Caloosahatchee basin, with specific emphasis on urban groundwater demands within the western basin. RECOVER will remain available to participate in these investigations.

E.7 CONCLUSIONS

RECOVER's system-wide evaluation indicates that all of the project alternative plans improve estuary health over the FWO Project Condition by altering hydrology to achieve a more natural salinity pattern within the estuary. Alternative plans Alt3C and Alt4 provide the most benefits to the estuary by reducing the number of damaging high and low flows to the greatest extent at both the monthly and weekly scale. The project alternative plans are likely to have the following effects compared to the future without project condition:

- Increasing the period of time during which flows from the S-79 structure fall within the desirable flow envelope for the Caloosahatchee Estuary
- Decreasing the frequency and duration of low flows to the Caloosahatchee Estuary via S-79
- Decreasing the frequency and duration of moderate and extreme high flows to the Caloosahatchee Estuary via S-79
- Decreasing level of service for water supply in the LOSA and LECSA for frequency, duration, and severity of cutbacks

In conjunction with other CERP and non-CERP projects within neighboring basins, the Caloosahatchee River (C-43) West Basin Storage Reservoir project is expected to reach CERP system-wide restoration goals for the frequency and duration of moderate and extreme high flow events, and to meet CERP restoration targets for flow distributions to the estuary up to 84% of the time. Given the cumulative effects of project benefits, the coordination of the Caloosahatchee River (C-43) West Basin Storage Reservoir project with other CERP project is even expected to provide additional benefits than those that are currently able to be documented using available ecologic and hydrologic models.

F.0 COASTAL ZONE CONSISTENCY AND SECTION 404(B)(1) EVALUATIONS

F.1 FLORIDA COASTAL ZONE MANAGEMENT PROGRAM FEDERAL CONSISTENCY EVALUATION PROCEDURES

F.1.1 Chapter 161, Beach and Shore Preservation

The intent of the coastal construction permit program established by this chapter is to regulate construction projects located seaward of the line of mean high water and which might have an effect on natural shoreline processes.

Response: The proposed plans and information will be submitted to the state in compliance with this chapter. No work is proposed seaward of the mean high water line in beach areas.

F.1.2 Chapters 186 and 187, State and Regional Planning

These chapters establish the State Comprehensive Plan that sets goals that articulate a strategic vision of the State's future. Its purpose is to define in a broad sense, goals and policies that provide decision-makers directions for the future and provide long-range guidance for an orderly social, economic and physical growth.

Response: The proposed project has been coordinated with various Federal, State and local agencies during the planning process. The proposed project would achieve the goals of this chapter by contributing to a long-range master plan for south Florida's water resources, which would support the continued orderly social, economic and physical growth of the region.

F.1.3 Chapter 252, Disaster Preparation, Response and Mitigation

This chapter creates a state emergency management agency, with the authority to provide for the common defense; to protect the public peace, health and safety; and to preserve the lives and property of the people of Florida.

Response: This statute is not applicable to this project.

F.1.4 Chapter 253, State Lands

This chapter governs the management of submerged state lands and resources within state lands. This includes archeological and historical resources; water resources; fish and wildlife resources; near shore reefs; beaches and dunes; submerged grass beds and other benthic communities; swamps, marshes and other wetlands; mineral resources; unique natural features; submerged lands; spoil islands; and artificial reefs.

Response: The proposed project would make a positive contribution to preserving cultural, water, fish and wildlife, wetland and estuarine resources. The proposed project would comply with the intent of this chapter.

F.1.5 Chapters 253, 259, 260, and 375, Land Acquisition

This chapter authorizes the state to acquire land to protect environmentally sensitive areas.

Response: The property proposed for this project is already in public ownership. The proposed project would comply with the intent of this chapter.

F.1.6 Chapter 258, State Parks and Aquatic Preserves

This chapter authorizes the state to manage state parks and preserves. Consistency with this statute would include consideration of projects that would directly or indirectly adversely impact park property, natural resources, park programs, management or operations.

Response: The Caloosahatchee River and Estuary are at the head of a vast estuarine and marine ecosystem that includes aquatic preserves managed by the State of Florida (e.g., Matlacha Pass, Estero Bay, and Pine Island Sound Aquatic Preserves), the Charlotte Harbor National Estuary Program, and the J. N. Ding Darling National Wildlife Refuge (NWR) Complex which includes the Caloosahatchee, Matlacha Pass, Pine Island, and Island Bay NWRs; along with numerous other state and local parks and recreation areas. The aquatic preserves are also outstanding Florida water bodies. The proposed project would improve the timing and delivery of water to the Caloosahatchee River which will have a positive effect on these areas. The proposed project would comply with the intent of this chapter.

F.1.7 Chapter 267, Historic Preservation

This chapter establishes the procedures for implementing the Florida Historic Resources Act responsibilities and for implementing the Section 106 of the National Historic Preservation Act of 1966, as amended; and the National Environmental Policy Act of 1969, as amended.

Response: Cultural resource surveys have been completed for the Caloosahatchee River (C-43) West Basin Storage Reservoir. Three isolated prehistoric artifacts, one isolated historic artifact, one prehistoric archeological site (8HN129), and four modified historic buildings were identified. All except the prehistoric archeological site were determined to lack integrity and determined not eligible for listing on the National Register of Historic Places, the prehistoric archeological site (8HB129) is located near the edge of the

proposed project and will be avoided by project design. The USACE has determined that the project will not affect historic properties eligible for listing on the National Register of Historic Places. The Florida State Historic Preservation Officer concurred with this determination (Florida State Department of Historic Preservation numbers 2004-8676 and 2006-07757). The project will be consistent with the goals of this chapter.

F.1.8 Chapter 288, Economic Development and Tourism

This chapter directs the state to provide guidance and promotion of beneficial development through encouraging economic diversification and promoting tourism.

Response: The proposed project would achieve the goals of this chapter by contributing to a long-range master plan for South Florida's water resources, which would support economic diversification and tourism.

F.1.9 Chapters 334 (Transportation Administration), 335 (State Highway System), 338 (Intrastate Highway System and Toll Facilities) and 339 (Public Transportation)

These chapters authorize the planning and development of a safe, balanced and efficient transportation system.

Response: No public transportation systems would be impacted by this project.

F.1.10 Chapter 370, Saltwater Living Resources

This chapter directs the state to preserve, manage and protect the marine, crustacean, shell and anadromous fishery resources in state waters; to protect and enhance the marine and estuarine environment; to regulate fishermen and vessels of the state engaged in the taking of such resources within or without state waters; to issue licenses for the taking and processing products of fisheries; to secure and maintain statistical records of the catch of each such species; and to conduct scientific, economic, and other studies and research.

Response: The proposed project is consistent with the goals of this chapter. Implementation of the project will provide direct positive impacts on saltwater resources within the Caloosahatchee Estuary by attenuation of freshwater flows during the wet season, provision of freshwater flows during the dry season, and improvement of the salinity balance. This will benefit seagrass, oysters, fisheries, and wildlife.

F.1.11 Chapter 372, Living Land and Freshwater Resources

This chapter establishes the Game and Freshwater Fish Commission (now called the Florida Fish and Wildlife Conservation Commission) and directs it to manage freshwater aquatic life and wild animal life and their habitat to perpetuate a diversity of species with densities and distributions that provide sustained ecological, recreational, scientific, educational, aesthetic, and economic benefits.

Response: The project will have a long-term beneficial effect on freshwater aquatic life and wild animal life within the Caloosahatchee River through attenuation of high flows during the wet season and provision of flows during the dry season. The proposed project is consistent with the intent of this chapter.

F.1.12 Chapter 373, Water Resources

This chapter provides the authority to regulate the withdrawal, diversion, storage, and consumption of water.

Response: The non-federal sponsor for this project is the South Florida Water Management District, which is the state agency responsible for implementing this statute. Coordinated planning has been done with this agency to ensure compatibility with established policies. The project is consistent with the goals of this chapter.

F.1.13 Chapter 376, Pollutant Spill Prevention and Control

This chapter regulates the transfer, storage, and transportation of pollutants and the cleanup of pollutant discharges.

Response: The contract specifications will prohibit the contractor from dumping oil, fuel, or hazardous wastes in the work area and will require that the contractor adopt safe and sanitary measures for the disposal of solid wastes. A spill prevention plan will be required.

F.1.14 Chapter 377, Oil and Gas Exploration and Production

This chapter authorizes the regulation of all phases of exploration, drilling, and production of oil, gas, and other petroleum products.

Response: This project does not involve the exploration, drilling, or production of gas, oil or petroleum product and therefore, this chapter does not apply.

F.1.15 Chapter 380, Environmental Land and Water Management

This chapter establishes criteria and procedures to assure that local land development decisions consider the regional impact of proposed large-scale development on natural systems.

Response: The proposed project includes development of the site for an above-ground reservoir with pump stations and other related features. Operation of the reservoir would benefit and the Caloosahatchee River Region by reducing the number and severity of events where harmful amounts of freshwater from basin runoff and Lake Okeechobee releases are discharged into the estuary system. The project also helps to maintain a desirable minimum flow of fresh water to the estuary during dry periods. These two primary functions help to moderate unnatural changes in salinity which is extremely detrimental to estuarine communities. The project is consistent with the intent of this chapter.

F.1.16 Chapter 388, Arthropod Control

This chapter provides for a comprehensive approach for abatement or suppression of mosquitoes and other pest arthropods within the state.

Response: The project would not further the propagation of mosquitoes or other pest arthropods.

F.1.17 Chapter 403, Environmental Control

This chapter authorizes the regulation of pollution of the air and waters of the state by the Florida Department of Environmental Regulation (now a part of the Florida Department of Environmental Protection).

Response: An Environmental Impact Statement addressing project impacts has been prepared and will be reviewed by the appropriate resource agencies including the Florida Department of Environmental Protection. Environmental protection measures will be implemented to ensure that no lasting adverse effects on water quality, air quality, or other environmental resources will occur. Water Quality Certification will be sought from the State prior to construction. The project complies with the intent of this chapter.

F.1.18 Chapter 582, Soil and Water Conservation

This chapter establishes policy for the conservation of state soil and water through the Department of Agriculture. Land use policies will be evaluated in terms of their tendency to cause or contribute to soil erosion or to conserve, develop, and utilize soil and water resources both onsite or in adjoining

properties affected by the project. Particular attention will be given to projects on or near agricultural lands.

Response: Project construction and implementation will include appropriate erosion control plans and measures to ensure compliance with the intent of the chapter.

F.2 CLEAN WATER ACT SECTION 404(B)(1) EVALUATION

1. Project Description

a. Location.

The study area consists of the proposed project site, the Caloosahatchee River (C-43 Canal), Caloosahatchee Estuary, and the affected drainage basins. The study area extends approximately 70 miles from Lake Okeechobee to the lower Charlotte Harbor Basin at San Carlos Bay. The Caloosahatchee River watershed constitutes the northern portion of the SFWMD Lower West Coast planning area. The Caloosahatchee River watershed covers an area of 1,125,000 acres in parts of Lee, Glades, Charlotte, and Hendry Counties. The watershed can be further subdivided into seven drainage basins based on their hydrologic characteristics, hydrologic control features, and topography. Moving from east to west these basins are the C-21, East Caloosahatchee, West Caloosahatchee, Orange River, S-236, Telegraph Swamp, and the Tidal Caloosahatchee Basin.

The Caloosahatchee River watershed (or C-43 Basin) drains an area of about 1,758 square miles and was originally a shallow meandering river. Prior to human disturbance, water moved slowly from the uplands and wetlands to the river and then downstream to the estuary. The population of the four counties that make up the Caloosahatchee River Basin was 630,000 in 2000 and is expected to nearly double to 1,220,000 by 2050. Major land uses in the area include agriculture (dominated by citrus, sugar cane, vegetables, sod, and cattle production), urban and municipal development, and natural areas.

b. Alternatives Considered and Rejected

Both structural and non-structural management measures were developed to ensure the achievement of an overall CERP goal that the proposed project would provide environmental restoration benefits as outlined in the Restudy. In order to develop and select a plan that will reasonably maximize ecosystem restoration benefits while addressing the water supply issues and opportunities in the basin, restoration of estuarine and riverine health were sought by improving hydrologic conditions. This could be done by evaluating two objectives: providing additional water to augment low or no flows over S-79 during the dry season/dry periods and reducing damaging peak flows by providing adequate storage during

high flow conditions. The following measures were identified and subsequently screened for the reasons identified in parenthesis:

- Restoration of natural areas (few locations able to provide significant natural storage)
- Stormwater treatment areas (does not help meet the goals and objectives of the project)
- Backpumping with stormwater treatment (potentially insufficient water supply; does not meet the goals and objectives of the project)
- Aquifer storage and recovery (lack of information on this technology; pilot projects currently researching this possibility)

The above analysis of management measures reaffirmed that above ground reservoir storage areas along with operations of the reservoir(s) met the goals and objectives as outlined in the Restudy. The final array of alternatives for this project were then developed using the Restudy alternative as a starting point. The final array of alternatives included:

- Alternative 1 – no action
- Alternative 2 – 100,000 ac-ft reservoir with 1500 cfs pumping capacity
- Alternative 3B – 170,000 ac-ft reservoir with 1500 cfs pumping capacity
- Alternative 3C – 170,000 ac-ft reservoir with 3800 cfs pumping capacity
- Alternative 4A – 220,000 ac-ft reservoir with 3800 cfs pumping capacity

A benefits analysis and CE/ICA were performed, as well as other factors considered as discussed in Section 5 of the attached PIR/EIS, which resulted in Alternative 3B as the preferred alternative.

c. General Description.

The recommended plan for the C-43 West Storage Reservoir would consist of approximately 10,700 acres (approximately 10,480 acres of fee and 20 acres of perpetual channel easement. Approximately 200 additional acres will be required on a temporary basis during project construction for staging areas). This includes an above-ground reservoir with two cells totaling approximately 9,400 acres providing a normal maximum storage capacity of approximately 170,000 acre-feet surrounded by an embankment and perimeter canals. Major features of the recommended plan include the following:

- External (dam) embankments varying in height between 32 and 37 ft. above existing grade;
- Soil-Bentonite slurry walls within and beneath the external embankments;

- An internal (dam) embankment separating the two cells with an approximate height of 31 ft. above existing grade ;
- An inflow pump station consisting of diesel-powered pumps with a total pumping capacity of 1,500 cfs;
- A perimeter canal;
- A perimeter canal pump station consisting of electric-powered pumps with a total pumping capacity of 195 cfs;
- Numerous spillways, culverts, perimeter canal structures, an internal cell balancing structure, and outlet structures;

d. Authority and Purpose.

The Caloosahatchee River (C-43) West Basin Storage Reservoir Project was authorized by Section 601 the Water Resources Development Act (WRDA) of 2000, Public Law 106-541. The purpose of the project is to capture and store excess regulatory releases from Lake Okeechobee; capture and store excess Caloosahatchee River (C-43) basin storm-water run-off; provide environmental benefits for a better salinity balance in the downstream Caloosahatchee Estuary by attenuating high flows in the wet season and releasing essential flows during the dry season; provide groundwater recharge; provide some water supply for irrigation needs, and environmental and urban demands and prevention of saltwater intrusion.

e. General Description of Dredged or Fill Material.

(1) General Characteristics of Material: Fill material for the embankments will be dredged and excavated material that will be removed within the immediate project area. The material will consist primarily of poorly-graded sand and clayey sand above the limestone rock layer.

(2) Quantity of Material: Approximately 4,500,000 cubic yards of material would be excavated to construct the perimeter canal and suitable excavated material will be used to construct the embankments.

(3) Source of Material: The fill material will be material removed *in situ* during excavation of the perimeter canal, but mainly from excavating the upper few feet of material over several hundred feet from within the reservoir interior.

f. Description of the Proposed Discharge Site.

(1) Location: The fill material will be used to construct the perimeter embankments and internal levee between Cell 1 and Cell 2. Any excess material excavated or dredged or material that is unsuitable for levee construction will be spread throughout the interior reservoir.

(2) Size: The project area is approximately 10,700 acres in size (approximately 10,480 acres of fee and 20 acres of perpetual channel easement. Approximately 200 additional acres will be required on a temporary basis during project construction for staging areas). The project would consist of 16.3 miles of perimeter embankment with an adjacent 14.7 miles of perimeter canal and an interior embankment to divide the reservoir into two cells. The perimeter canal would have a top width of approximately 110 feet, bottom width of 10 feet, and the side slopes would be 1 Vertical on 2.5 Horizontal (1V:2.5H). Dam height of the perimeter embankment would vary from 32 feet to 37 feet with a crest width of 14 feet. The reservoir would be approximately 9,400 acres in size with a storage capacity of 170,000 acre feet and average water depth ranging from 17 feet to 19 feet.

(3) Type of Site: The disposal site is developed as a citrus grove and includes a dense network of irrigation and drainage ditches and canals that serve the groves. Additionally there are wetlands scattered throughout the grove.

(4) Type of Habitat: Citrus groves, row crops and improved pasture with scattered cypress and mixed wetland hardwoods flank the project area to the north, east, and south. The area to the north of the project site also contains some low-density residential areas. Forested uplands (parceled into low-density residential lots, various stages of development) such as pine flatwoods, longleaf pine-xeric oak, sand pine, and xeric oak are adjacent to the west of the project. At a landscape level, the C-43 West Storage Reservoir Project is surrounded by a matrix of agricultural, forested, and wetland land covers with pockets of urban land use. Urban areas are present to the southwest and northeast of the project area with small parcels along the Caloosahatchee River. Regions to the northwest and southeast of the project area are generally undeveloped.

The project site is an active citrus grove. Upland habitats associated with the grove include citrus trees, grove maintenance roads, small berms, brush piles, and other features related to citrus grove operations. There are no natural upland areas within the project site. The project site includes approximately 994.53 acres of jurisdictional Waters of the United States in the form of canals/ditches and/or wetlands. As a result of the recommended plan, most of the site would be converted to an above-ground reservoir with attendant features and would primarily consist of open water habitat after construction. Jurisdictional areas impacted as a result of the project include 899.59 acres of man-made ditches and canals which serve as irrigation and drainage conveyances for the citrus operation and 125 acres of wetlands.

(5) Timing and Duration of Discharge: Project construction is scheduled to begin in 2008 under the SFWMD Acceler8 program (pending receipt of all required permits and authorizations) and take approximately 3 years to complete.

g. Description of Disposal Method. Conventional earth moving equipment would be used during construction to excavate the perimeter canal including Townsend Canal improvements. Excavated material will be placed adjacent to the perimeter canal to construct the embankment, using only suitable excavated material.

2. Factual Determinations

a. Physical Substrate Determinations.

(1) Substrate Elevation and Slope: The perimeter embankment includes a 14-foot wide crest, with the soil cement protection, and 3 horizontal to 1 vertical side slopes. Crest elevations have been established at +57 NAVD88 for both Cell 1 and Cell 2, respectively. The embankment would be constructed largely of random fill, but would also include a low permeability soil-bentonite (SB) slurry wall, an internal drain, and upstream soil cement slope protection. The SB slurry wall would extend from an elevation 5 feet above the normal pool elevation to 5 feet below the top of a clay layer which underlies the project site at depths generally in the range of 20 to 25 feet below existing surface grades. The interior dam between Cells 1 and 2 would be a homogenous embankment with a crest elevation of +50 NAVD88. It would not include any SB wall or internal drain. The side slopes of the separator dam would be covered on both sides with soil-cement.

(2) Sediment Type: The material to be excavated and used as fill includes a combination of sand, clayey sand, silty sand, and some fine sediments.

(3) Dredge/Fill Material Movement: Suitable material excavated from the perimeter canal will be used to construct the earthen embankment. Any excess material or material not suitable for levee construction would be spread throughout the interior of the reservoir. There will be no deposition of material in unconfined waters where it would be subject to movement.

(4) Physical Effects on Benthos: Existing benthic organisms within the footprint of the levees would be covered by fill material.

b. Water Circulation, Fluctuation and Salinity Determination.

(1) Water Column Effects: During dredging operations to widen the existing Townsend Canal the water column would become temporarily more turbid. The

use of turbidity curtains may be required to confine the turbidity to the immediate vicinity of dredging.

(2) Current Patterns and Circulation: Dredging would not affect current patterns or circulation. Construction of the embankments would not affect current patterns or circulation.

(3) Normal Water Level Fluctuations and Salinity Gradients: Construction activities would not affect normal water level fluctuations and salinity gradients. Implementation of the project would reduce the number and severity of events where harmful amounts of freshwater from basin runoff and Lake Okeechobee releases are discharged into the estuary system. The project also helps to maintain a desirable minimum flow of fresh water to the estuary during dry periods. These two primary functions help to moderate unnatural changes in salinity which is extremely detrimental to estuarine communities.

c. Suspended Particulate/Turbidity Determinations.

(1) Expected Changes in Suspended Particulates and Turbidity Levels in the Vicinity of the Disposal Site: Construction of the embankment would require deposition of fill over wetlands permanently converting these areas to upland sites. Temporary increases in suspended particulates can be expected during construction at the embankment fill sites as well as the dredging location in the Townsend canal. All appropriate measures to reduce and contain turbidity will be employed so state Water Quality Standards would not be violated.

(2) Effects on Chemical and Physical Properties of the Water Column: In general, any short-term impacts to water quality associated with construction of the project will be ameliorated by construction sequencing, best management practices for erosion and sedimentation control and monitoring during construction. Longer-term impacts to water quality associated with the operation of project features will be addressed through operational monitoring and adaptive management actions, if potentially adverse affects are observed or predicted.

(a) Light penetration: During dredging operations there would be a temporary reduction in light penetration in the immediate vicinity of dredging. Once construction is completed, light penetration is expected to return to pre-construction levels.

(b) Dissolved Oxygen: During dredging operations there could be a temporary reduction in the dissolved oxygen content in the water column in the immediate vicinity of dredging. Once construction is completed, dissolved oxygen is expected to return to pre-construction levels.

(c) Toxic Metals, Organics and Pathogens: No toxic metals, organics, or pathogens would be released by project construction. Reservoir operations will also incidentally improve water quality in the Caloosahatchee Estuary, since some of the nutrient-laden runoff and lake water will be stored in the reservoir, allowing for the settling of nutrients and other pollutants within the reservoir cells prior to delivery to the estuary.

(d) Aesthetics: During construction, visual aesthetics would be negatively impacted. After completion, aesthetics would improve once new vegetation becomes established.

(3) Effects on Biota:

(a) Primary Productivity and Photosynthesis: Disposal of excavated materials would adversely affect wetlands within the project footprint destroying vegetation and smothering biota. The perimeter canals are being designed to include littoral shelves within the corners and along some of the canal banks. These shelves will be colonized by wetland, emergent plant species. The reservoir footprint will likely be too deep to support any wetland vegetation except during drawdowns, but floating vegetation may colonize the reservoir.

(b) Suspension/Filter Feeders: During dredging operations there would be a temporary increase in turbidity and possibly a decrease in suspension/filter feeders due to construction activities. This temporary increase in turbidity will be short-term and should not have any long-term negative impact on these highly fecund organisms. These organisms would return to current levels after construction is completed.

(c) Sight Feeders: During dredging operations there would be a temporary increase in turbidity and possibly a decrease in sight feeders due to construction activities. No significant impacts on these organisms are expected as the majority of sight feeders are highly mobile and can move outside the affected area. These organisms would return to current levels after construction is completed.

d. Contaminant Determinations.

Currently the SFWMD has restricted the use of copper on the site and plans to conduct all required corrective actions as recommended by the U.S. Fish and Wildlife Service (USFWS) prior to initiating any construction. Deposited fill material would not introduce, relocate, or increase contaminants. Dredging of the Townsend Canal is limited to side slopes for widening; therefore, material on the bottom of the canal which may contain toxic materials would not be dredged.

e. Aquatic Ecosystem and Organism Determinations.

(1) Effects on Plankton: No adverse affects on plankton are expected. Long-term effects on plankton should be beneficial with an improvement of salinity balance in the Caloosahatchee Estuary.

(2) Effects on Benthos: A temporary decrease in benthos in the project area may occur during widening of the Townsend Canal. It is expected that the benthos would return to current levels after construction is completed. Effects to benthos outside the project area are not anticipated.

(3) Effects on Nekton: Small forage fish may be displayed during construction; however, these effects are short-term. The project provides deepwater habitat within the reservoir, including refugia (created by embankment excavation and from existing agricultural ditches) for fish and other aquatic animals during extremely dry periods. Long-term effects to fish in the Caloosahatchee Estuary should be beneficial as a result of the project operation and subsequent improvement in salinity balance, attenuation of peak flows, and provision of flows during the dry season.

(4) Effects on the Aquatic Food Web: No adverse impacts on aquatic organisms are anticipated. A relatively minor temporary effect on the aquatic food web due to construction activities is anticipated; however, this effect is short-term. Long-term effects to aquatic food web as a result of operation should be beneficial through improving the salinity balance in the downstream Caloosahatchee Estuary for oysters, seagrasses, and wildlife.

(5) Effects on Special Aquatic Sites:

(a) Hardground and Coral Reef Communities. There are no hardground or coral reef communities within the project footprint. Oysters once flourished within the Caloosahatchee Estuary but with damaging pulse freshwater flows and lack of suitable substrate populations have declined. With the addition of hard substrate attenuation of high flows, oyster reef/recruitment would occur as a result of project implementation.

(b) Sanctuaries and Refuges. The Caloosahatchee River and Estuary are at the head of a vast estuarine and marine ecosystem that includes aquatic preserves managed by the State of Florida (e.g., Matlacha Pass, Estero Bay, and Pine Island Sound Aquatic Preserves), the Charlotte Harbor National Estuary Program, and the J. N. Ding Darling National Wildlife Refuge (NWR) Complex which includes the Caloosahatchee, Matlacha Pass, Pine Island, and Island Bay NWRs; along with numerous other state and local parks and recreation areas. The aquatic preserves are also outstanding

Florida water bodies. Improvement of the timing and delivery of water to the Caloosahatchee River will have a positive effect on these areas.

(c) Wetlands. The project site includes 125 acres of jurisdictional wetlands. The wetland communities include mixed wetland hardwoods, willow and elderberry, exotic wetland hardwoods, cypress, wetland shrub, and freshwater marsh. As a result of the project, all onsite wetlands would be eliminated. Adverse impacts include destruction of wetland habitat and adverse affects to the biological productivity of wetlands ecosystems by smothering, by dewatering, by permanently flooding, or by altering substrate elevation or periodicity of water movement. Through implementation of CERP, the quality, quantity, timing, and delivery of water to the south Florida ecosystem will be improved. This coupled with the increase in spatial extent of protected wetland acreage in the region will offset adverse impacts to wetlands associated with project implementation. The current design of the reservoir perimeter canal includes approximately 109 acres of wetland i.e., littoral habitat within the corners and along some of the canal banks.

(d) Mud Flats. Mud flats are present within the Caloosahatchee Estuary but none would be adversely impacted by the project. Regulation of the timing of water delivered to the estuary may benefit mud flats by returning inundation patterns toward natural system targets and ameliorating rates of erosion and accretion.

(e) Vegetated Shallows. Vegetated shallows are present in the Caloosahatchee River and Estuary but none would be adversely impacted as a result of the project. Excessive variation in discharges and salinity to the Caloosahatchee River and Estuary result in a flux of biota from those favoring higher salinities to those favoring lower salinities. As a result of project implementation, the timing and delivery of water to the Caloosahatchee River and salinity balance would be improved. This would sustain a variety of species of freshwater, estuarine, and marine submerged aquatic beds that once flourished historically.

(f) Riffle and Pool Complexes. There are no riffle and pool complexes within the study area.

(6) Threatened and Endangered Species: Formal consultation with the USFWS for the Florida panther, Audubon's crested caracara, and eastern indigo snake is ongoing and a Biological Opinion that the project will not jeopardize the existence of these species is anticipated. The CERP Band 1/Acceler8 projects will collectively provide for the preservation and restoration of approximately 100,492 acres in the panther core area, including 59,294 acres in the Primary Zone and 41,198 acres in the Other Zone. These "core area" lands include the majority of home ranges of the current population of the Florida panther. This

includes over 548,000 panther habitat units (PHUs) that can be used to offset the loss of panther habitat anticipated as a result of conversion of the citrus grove lands within the project footprint to open water. Additionally, the USACE has determined that the implementation of this project will either benefit, or not adversely affect, a number of other endangered and/or threatened species in the project area or areas affected by the project. Informal consultation remains open with the USFWS and the National Marine Fisheries Service. Special protection measures will be implemented during construction to minimize impacts to any listed species present.

f. Proposed Disposal Site Determinations.

(1) Mixing Zone Determination: The dredged material will not cause unacceptable changes in the mixing zone water quality requirements as specified by the State of Florida's Water Quality Certification permit procedures. No adverse impacts related to depth, current velocity, direction and variability, degree of turbulence, stratification, or ambient concentrations of constituents are expected from implementation of the project.

(2) Determination of Compliance with Applicable Water Quality Standards: The project would comply with Federal and State water quality standards.

(3) Potential Effects on Human Use Characteristics:

(a) Municipal and Private Water Supply: No municipal or private water supplies would be adversely impacted by the implementation of the project. The reservoir may provide a source for water supply during the dry season once environmental deliveries have been made.

(b) Recreational and Commercial Fisheries: Construction activities would not significantly affect recreational or commercial fisheries.

(c) Water Related Recreation: No recreation resources would be adversely affected by the project.

(d) Aesthetics: During construction, the visual appearance of the new impoundment and levees may be somewhat unattractive. The levees would be grassed to prevent erosion and help blend them into the landscape background as unobtrusively as possible. The existing landscape characteristics would be replaced with views of levees and open water within the impoundment areas.

(e) Parks, National and Historical Monuments, National Seashores, Wilderness Areas, Research Sites, and Similar Preserves: There are no such

designated areas present within the area proposed for construction of project features. Aquatic preserves and NWRs comprise the downstream area that will be positively affected by project implementation.

g. Determination of Cumulative Effects on the Aquatic Ecosystem

The implementation of CERP is anticipated to convert large areas within the Caloosahatchee River basin, the Everglades Agricultural Area, and around Lake Okeechobee to reservoirs for increasing water storage for the overall gain and long-term benefit of the regional system. This will cause some adverse consequences to agricultural land uses - permanently removing tens of thousands of acres from agricultural production. These impacts may be felt locally and/or regionally as the economic base derived from agriculture is incrementally reduced relative to other sectors of the economy. As these features occur disparately across the landscape within different hydrologic basins, and as distinct units rather than multiple features within a single watershed, they will not likely result in a significantly detrimental cumulative effect.

The overall benefit to the regional system is expected to be far greater than the localized adverse effects. The restoration of hydrology of the greater Everglades ecosystem and the increase in spatial extent of protected wetland acreage in the region will produce extensive cumulative beneficial effects. These beneficial effects are expected to substantially outweigh the cumulative adverse effects produced by the aquatic ecosystem alterations that may be necessary to construct some of the project components.

h. Determination of Secondary Effects on the Aquatic Ecosystem

There will be no adverse secondary impacts on the aquatic ecosystem as a result of the construction. During construction the site will be contained enclosing the construction areas with sedimentation barriers. Erosion will be controlled by compaction of soils, construction of ditches, and embankments, maintenance of relatively flat grades, and other appropriate erosion control techniques. Sedimentation will be controlled during construction by use of sediment controls basins and traps, filter berms, straw bales, etc. Although construction will likely include several mobilizations associated with the perimeter canal and embankment, impacts will localized and wildlife will able to utilize undisturbed portions of the site, particularly the interior. An ecological and water quality monitoring plan would be implemented during and after construction and specific environmental commitments, engineering and design commitments, and operational commitments will be incorporated to avoid, minimize, and/or mitigate for adverse effects.

Implementation of this project would beneficially affect the aquatic ecosystem in the Caloosahatchee Estuary by regulating the timing and delivery of water. Through attenuation of peak flows during the wet season, providing essential flows during the dry season, and improving the salinity balance, oyster, seagrass, and wildlife will benefit.

3. Findings of Compliance or Non-Compliance with the Restrictions on Discharge

a. No significant adaptations of the guidelines were made relative to this evaluation.

b. No practicable alternative exists which meets the study objectives that does not involve discharge of fill into waters of the United States.

c. No practicable alternative exists which would have less adverse impact on the aquatic ecosystem which does not also have other significant adverse environmental consequences

d. The discharge of fill materials will not cause or contribute to violations of any applicable State water quality standards for Class III waters. The discharge operation would not violate the Toxic Effluent Standards of Section 307 of the Clean Water Act.

e. The placement of fill materials in the project area will not jeopardize the continued existence of any species listed as threatened or endangered or result in the likelihood of destruction or adverse modification of any critical habitat as specified by the Endangered Species Act of 1973, as amended.

f. The placement of fill materials will not result in significant adverse effects on human health and welfare, including municipal and private water supplies, recreational and commercial fishing, plankton, fish, shellfish, wildlife, and special aquatic sites. The life stages of aquatic species and other wildlife will not be adversely affected. Significant adverse effects on aquatic ecosystem diversity, productivity and stability, and recreational, aesthetic, and economic values will not occur.

g. On the basis of the guidelines, the proposed disposal site for the discharge of fill and/or dredged material is specified as complying with the requirements of these guidelines.

ENGINEERING – APPENDIX A

November 2010

This Report Contains [5] Volumes

You Are Here

Volume 1 – Main Report – November 2010
- Addendum A
- Addendum B
- Executive Summary
- Section 1 – Introduction
- Section 2 – Existing Conditions/Affected Environment
- Section 3 – Future "Without Project" Condition
- Section 4 – Identification of Problems and Opportunities
- Section 5 – Formulation of Alternative Plans
- Section 6 – Environmental Effects of the Selected Alternative Plan
- Section 7 – The Selected Alternative Plan
- Section 8 – Plan Implementation
- Section 9 – Summary of Coordination, Public Views, and Comments
- Section 10 – Recommendations
- List of Report Preparers
- Index
- Glossary of Terms
- Acronyms
- References

Volume 2- Annex – September 2007
- Annex A – FWCA and Endangered Species Act Compliance

Volume 3 – Annexes – September 2007
- Annex B – NEPA Information
- Annex C – Analyses Required by WRDA 2000 and State Law
- Annex D – Draft Project Operating Manual and Monitoring Plan
- Annex E – Reports Provided by RECOVER to Support the PIR
- Annex F – CZM Consistency and 404(b)(1) Evaluations

Volume 4 – Appendices – November 2010
- Appendix A – Engineering

Volume 5 – Appendices – November 2010
- Appendix B – Cost Estimates
- Appendix C – Environmental Information
- Appendix D – Real Estate
- Appendix E – Agency / Public Coordination
- Appendix F – Plan Formulation
- Appendix G – Economic and Social Considerations
- Appendix H – Recreation

A.0 ENGINEERING

A.1 GEOTECNHICAL STUDIES

A.1.1 General

A.1.1.1 Background

The C-43 West Storage Reservoir Area, Berry Grove Site, is located near the town of Labelle in northwestern Hendry County, Florida. The Reservoir is just a couple of miles South of State Road 80 and approximately two miles west of State Road 29. The property is owned by the South Florida Water Management District under a leasing agreement with Jack M. Berry, Inc. for agricultural farm land use.

A.1.1.1.1 Purpose

The purpose of the geotechnical exploration was to develop subsurface information concerning the site from data associated with core borings and test cell construction. This information will be used to evaluate the suitability of the subsurface soils and rock in order to support a water storage reservoir. The reservoir is expected to provide 170,000 acre-feet of water with approximate normal pool depth approaching 17 feet. The reservoir is also expected to cover approximately 11,000 acres of land use. The topography of the area is variable with respect to land surface however, overall the relief is generally considered flat. The topography also contains three major arterial canals that transport water for the purpose of irrigation and attenuation of Caloosahatchee Basin runoff waters. Two of the three canals, Roberts and Townsend lie along the eastern and western perimeters of the study area, respectively. The Header Canal also called the LPDD Canal, transects the entire reservoir area and its use is primarily to cross-feed water between the Roberts and/or Townsend Canals. The potential reservoir will contain several gates and pump stations to improve water deliveries throughout the Basin. ***Figure A-1***, shows a site location map, and the proposed reservoir limits.

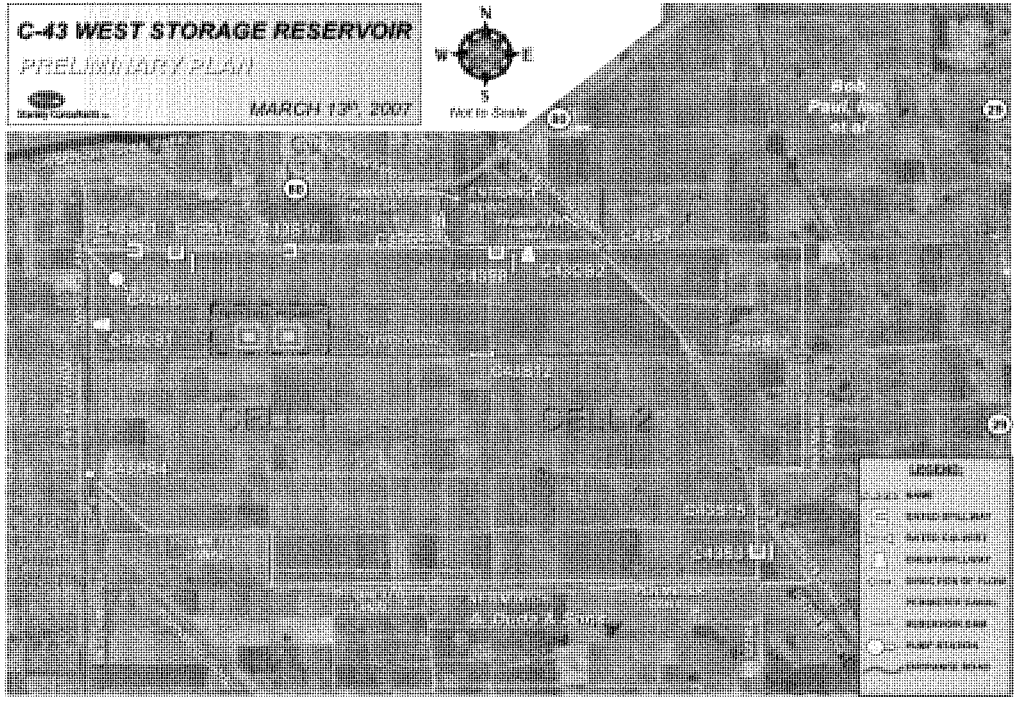

FIGURE A-1: BOUNDARY OF SITE

A.2 GEOLOGY

A.2.1 Regional Geology

The Caloosahatchee River Drainage Basin of both Collier and Hendry Counties, which lies within the physiographic region denoted as the Sandy Flatlands or Gulf Coastal Lowlands, is characterized by terraced plains. These terraced plains largely control the topography of the area that extends northward into Glades and Charlotte Counties, westward to the Gulf of Mexico, and southward into Monroe County. The sands were deposited as three marine terraces: Talbot, Pamlico, and Silver Bluff, all of which were produced during the Pleistocene Epoch. The Talbot terrace ranges from 25 to 42 feet above sea level and is considered the highest in elevation within the subject area. The Pamlico terrace ranges between eight to 25 feet above sea level, and the Silver Bluff terrace, the lowest in elevation; is less than 10 feet above sea level and gradates toward the western seaboard. The deposits were formed during the Pleistocene Era when sea level rose and fell in response to the advance and retreat of the continental ice sheets. When sea level is relatively stationary for long periods, shoreline features develop. In southwest Florida the Pleistocene deposits are represented by the Anastasia Formation (a coquinoid limestone, sand and clay), alternating marine and freshwater limestone consisting of mollusks, interbedded clays, and sands of the Ft. Thompson Formation, Caloosahatchee Formation (shell hash limestone and clay), and the Hawthorn Group sediments.

Rock units range in age within the Caloosahatchee River Basin study area from Recent to Miocene to Oligocene. Formations and groups discussed in this report include (from land surface) the Ft. Thompson Formation, Tamiami Formation (which includes the Bonita Springs Marl and Pine Crest Sand members), the Hawthorn Group (which consists of the Peace River Formation within the upper unit and Arcadia Formation belonging to the lower Hawthorn Group sediments), and, to a lesser extent, the early Oligocene Series of the Suwannee Limestone.

Since its inception in 1907, the Florida Geological Survey (FGS) has gathered data on Florida karst (sinkholes, caves, springs, etc.). FGS published Special Publication 29, entitled, "Karst in Florida" and included a Map Series 110, which explain sinkhole types, their distribution, and development. Sinkholes form in karst terrain principally from the collapse of surface sediments into underground cavities in the limestone bedrock. Slightly acidic ground water slowly dissolves cavities and caves in the limestone over a period of many years. (source: http://www.dep.state.fl.us/geology/geologictopics/sinkhole.htm)

The C-43 project area is not prone to sinkhole activities. Regionally the area is classified by the USGS as Area II where sinkholes are few and typically formed of shallow and small diameter. Locally and as a site specific, the overburden over the limestone consists of plastic clay with low permeability. This clay

impedes downward movement of groundwater and hence retards the development of solution cavities in underlying limestone. Areas underlain by relatively impervious clays are generally not affected by sinkholes. Therefore, it is expected that there is a low risk of sinkhole development at the C-43 project.

A.2.1.1 Pleistocene-Holocene Series

In the western part of the Caloosahatchee River Basin study area lies a thin veneer of undifferentiated Holocene/Pleistocene-age sediment that extends from land surface to approximately 10-feet below land surface. The Pamlico sands/Ft. Thompson Formation also occur at land surface in specific areas and is breached by either the Pliocene-age green dolosilts of the Bonita Springs Marl Member or the middle to late Pliocene-age beds of the Pinecrest Sand Member, consisting of mixed shell assemblage, both of which belong to the Tamiami Formation.

A.2.1.2 Pliocene Series

The rocks above the Tamiami Formation vary throughout the planning area, but within the Tamiami Formation two locally identifiable members are of particular interest. The Bonita Springs Marl identified by Missimer (1984) within the locale of the Bonita Springs area is the lowermost member of the Tamiami Formation. The Marl is a discontinuous deposit of unconsolidated sand, green dolosilts, and lime mud matrix. The member is considered a confining unit to the Holocene–Pliocene sediments and the water table aquifer. The Ochopee Limestone (Hunter (1968), is described as a light gray calcarenite with white fossiliferous limestone within the type section of the study area.

In overview, the Tamiami Formation within the Caloosahatchee River Basin is characterized by a fossiliferous sandy limestone. In northern Hendry and southern Glades counties the formation is thin and difficult to distinguish from the younger biogenic limestone of the Ft. Thompson Limestone and Caloosahatchee Marl. The Tamiami Formation is thickest in southern Hendry County. It thins to the north and west, pinching out in Glades County.

A.2.1.3 Miocene Series

Rocks of Miocene age in the planning area belong to the Hawthorn Group. The Hawthorn Group is divided into an upper clastic sequence and a lower carbonate sequence. The Peace River Formation is a siliclastic stratum, composed primarily of greenish-gray phosphatic silts interbedded with coarse sand and sandstones. The formation also consists of interbedded quartz sand, clays, and minor carbonates. The siliclastics comprise more than two-thirds of the formation. The lower carbonate sequence is the Arcadia Formation and is described as phosphatic dolomite, composed of poorly to moderately indurated phosphatic micrites, very pale orange, poorly sorted, fossiliferous, clayey, and

sandy. The base of the Hawthorn Group occurs at the contact between the Suwannee Limestone of the Oligocene Series and the Lower Hawthorn/Tampa Limestone. The top of the Hawthorn Group is identified by the first occurrence of a continuous greenish-gray dolosilts. In Hendry County the top of the Hawthorn Group occurs at a poorly consolidated sand or sandy silt beneath a biogenic limestone of the Tamiami Formation.

A.2.1.4 Oligocene Series

Rocks of Oligocene age in the planning area belong to the Suwannee Limestone. The Suwannee Limestone is generally fossiliferous, yellow to pale orange, moderately indurated, very porous calcerenite interbedded with sandy phosphatic limestones and dolomites. The formation varies in thickness from 50 feet to more than 150 feet. It lies within the Floridan Aquifer System and is considered the main source of irrigation within the Glades County area.

A.2.1.5 Soils

The soils of the Caloosahatchee River Basin are dominated by somewhat poorly drained sandy soils. These soils are considered recent deposits of limestone origin, underlain by marl and or limestones. South of the river and in the coastal area the soil consists of poorly drained sands and organic muck and peat. They are very poorly drained soils underlain by marl and limestone.

A.2.1.6 Aquifers

Three major aquifers or producing zones and three confining beds have been identified within this sequence of rocks for the study area. The upper surficial aquifer consists of sands, shells, and limestones, within the sediments of the Ft. Thompson and Tamiami Formations that are Holocene- Pliocene age, respectively. This aquifer and the lower Tamiami/Ochopee Aquifer are separated by the Bonita Springs Marl confining unit. Below the lower Tamiami aquifer lies another confining unit of the Miocene age sediments, Upper Peace River confinement. The Sandstone aquifer is sandwiched between the Upper Peace River and Basal Peace River confining unit.

The lower Hawthorn/Tampa producing zone (which includes the basal part of the lower Hawthorn aquifer of Sproul et al., 1972) and the Suwannee aquifer are considered parts of the Floridan Aquifer System. At this time, these aquifers are not considered for this portion of the study.

A.2.2 Local Geology

The local geology within the Caloosahatchee River (C-43) West Basin Storage Reservoir site is described based on the compilation and analysis of 92 core

borings. The borings ranged in depth from 15 feet to 150 feet below the existing ground surface. ***Figure A-2*** is a point-coverage map that shows the location of core borings within the West Storage Reservoir Area (Berry Grove Site). In addition, ***Figure A-2*** shows two transect lines (cross-sections) that strike in the East and West direction for both the northern and southern extent of the study area. These transects were used to develop general geologic cross sections within the Caloosahatchee (C-43) West Basin Storage Reservoir Area. ***Figure A-3*** shows a generalized geologic cross section that strikes East and West direction within the northernmost perimeter of the reservoir. Whereas, ***Figure A-4*** shows a generalized geologic profile that also strikes East and West but for the southern perimeter of the reservoir.

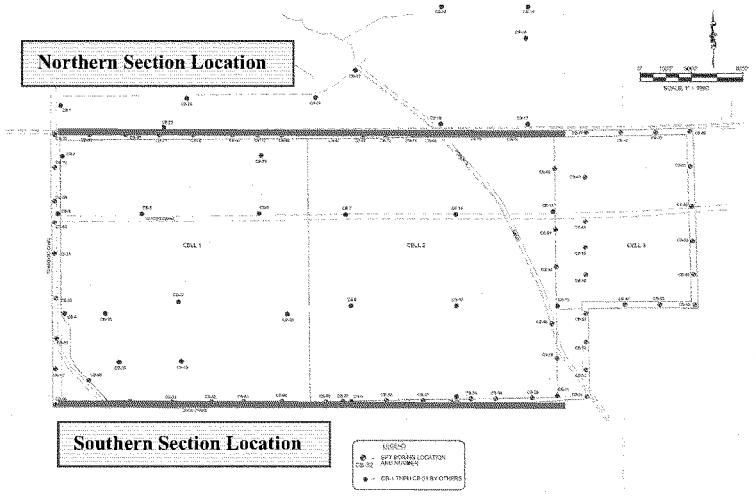

FIGURE A-2: BORINGS AND CROSS-SECTIONS LOCATIONS

This data combined with data obtained from the excavation of two test cells within the West Storage Reservoir site indicate that in general the subsurface conditions are suitable for the proposed project. The spacing of the borings ranged between 4,000 to 6,000 feet. The subsurface materials found within the borings generally consisted of relatively clean sands, clayey sands, and sandy clays. A layer of relatively clean sands, undifferentiated sediments, was found at the ground surface and extended to depths of 4 to 10 feet. In a few borings, some surficial clean sands extended to 20-feet below land surface. A minor sequence of limestone deposit (Ochopee Limestone) which thickens toward the eastern portion of the study area as shown in ***Figure A-3***, lie just beneath the clean sands to depths of approximately 20 to 25 feet. However where the limestone is absent, most of the borings indicate clayey sands exist beneath the

surficial clean sands to depths as far down as 40 feet or more. The subsurface zones beneath these layers generally are comprised of siliclastic sands and sandstones that make up the Peace River Formation to depths of approximately 100 feet below grade. The basal phosphatic clays are referred to as the Hawthorn Group sediments and no other core borings penetrated beyond these depths.

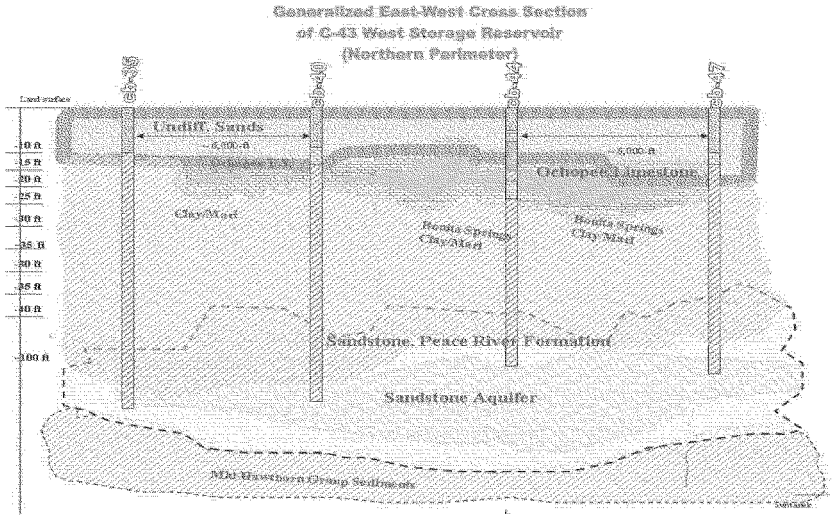

FIGURE A-3: NORTHERN GEOLOGIC CROSS SECTION, EAST – WEST

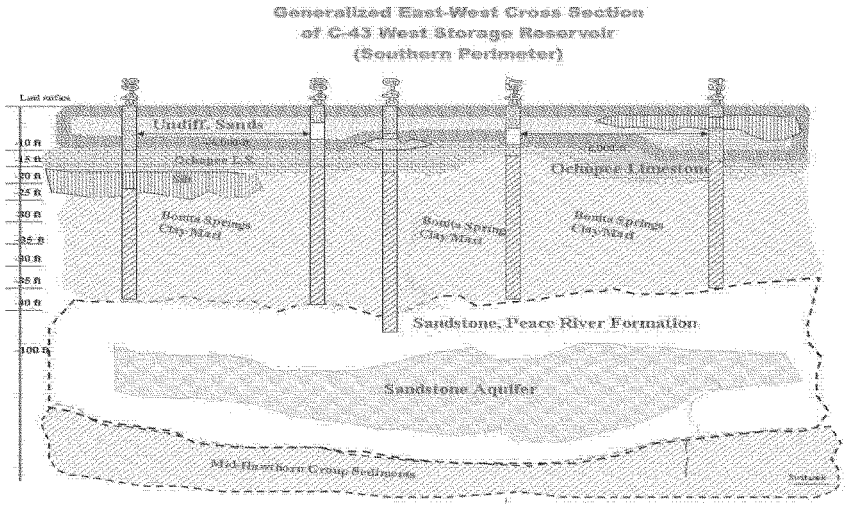

FIGURE A-4: SOUTHERN GEOLOGIC CROSS SECTION, EAST – WEST

A.3 PRELIMINARY GEOTECHNICAL ENGINEERING EVALUATION

Preliminary geotechnical engineering evaluation was performed for the planned reservoir project at the Berry Grove site. The geotechnical engineering evaluation performed was based on the geotechnical data available from the project site. The geotechnical engineering evaluation performed included evaluation of the subsurface conditions, seepage analyses, and slope stability analyses. Details of the geotechnical evaluation performed are presented below.

A.3.1 Evaluation of Subsurface Soil and Rock Conditions

Based on the available geotechnical data at the Berry Grove site, the area generally appears to be suitable for the construction of the new reservoir. This is primarily due to the presence of relatively shallow silty and clayey deposits within the site that will behave as seepage barrier or retardant and will assist in containing the reservoir stored water.

As mentioned earlier, the subsurface conditions encountered at the Berry Grove site consist of a surficial layer of sands with isolated zones of silty sand material. This sandy deposit varies in thickness from 1 to 15 feet. Below this sandy deposit, a layer of interbedded zones of silty sand, clayey sand, sandy clay, and sandy silt materials was encountered. This layer varies in thickness from 1 to about 20 feet. Below this sand/silt/clay mix deposit, limestone material was generally encountered with a thickness ranging from 2 to 12 feet, with isolated areas where the limestone deposit was thicker than 30 feet: boring CB-51 near Roberts Canal along the southern half of the eastern boundary. Some of the borings performed did not encounter the limestone material indicating the absence of limestone at these locations. Below the limestone material and until boring termination depths, clayey deposits were encountered. These clayey deposits mainly consist of sandy silt, sandy clay, and clayey sand materials.

The surficial sandy deposit is suitable for use in embankment construction. However, due to presence of shallow groundwater at the site, it is anticipated that the majority of the suitable fill material will be saturated. Therefore, during design and construction, dewatering of proposed borrow areas will be required and the material excavated may require reworking to make it suitable for compaction.

In addition based on the preliminary subsurface investigations, the limestone material encountered at the site appears to be relatively soft and may be excavated by conventional equipment such as backhoes. Blasting of the limestone may not be necessary based on the limited data available and field observations during test cells construction activities.

The underlying clays are not suitable for use in embankment construction. However, the clayey material could be used for the soil bentonite cut-off wall construction. These clayey/silty materials will be saturated and will require significant drying and reworking if used in construction. As mentioned earlier, the underlying silty/clayey zone will assist in retarding the under seepage flow and is a good geologic sequence to cut-off (minimize) outwards seepage.

A.3.2 Seepage Evaluation

A.3.2.1 General Description and Background

The SEEP/W computer program was used to perform the seepage analyses. The SEEP/W is a two-dimensional finite element computer program. The SEEP/W program was developed by Geo-Slope International Ltd.

A simplified 2-dimensional subsurface profile was developed for the Berry Grove site that utilized available core boring data obtained from the site. Hydraulic conductivity values used in the seepage model were obtained from available published data, pump test analyses, and other available laboratory test data. Due to the variability of the hydraulic conductivity data available, the hydraulic conductivity values used in the analyses were generally based on average values, engineering evaluation and correlations, and best professional judgment. The simplified subsurface profile including the hydraulic conductivity values used in the seepage analyses are presented in ***Table A-1*** below.

TABLE A-1: GENERALIZEDEMBANKMENT AND SUBSURFACE PROFILE AND ESTIMATED HYDRAULIC CONDUCTIVITY VALUES

Layer No.	Material Type	Average Estimated Depth (ft)	K (ft/day)
1	Upper Sand	0 - 7	20
2	Upper Sand/Silt/Clay Deposit	7 - 11	15
3	Limestone	11 - 15	25
4	Lower Sand/Silt/Clay Deposit	15 - 21	1.0
5	Sandy Clay/ Fat Clay	> 21	0.05
6	Embankment Fill	----	20
7	Core Zone	----	0.1

A.3.2.2 Cases Analyzed

For the final PIR, the cross-section analyzed utilized an embankment cross-section that is similar to the Acceler8 design. Acceler8 is a cooperative parallel design effort between SFWMD and USACE, whereby the SFWMD produces plans and specs in parallel with the USACE PIR planning process. The cross-section analyzed utilized a 12-foot wide crest and 3:1 (H:V) side slopes. The normal pool elevation was assumed to be at elevation 42 feet corresponding to 170,000 acre-feet storage volume. Outside the exterior embankment, the water

level within the adjacent canal was assumed to match the existing ground water level.

A cut-off wall was also modeled in the seepage analysis extended about 5 feet into the lower clay/silt deposit zone, with approximate depth of 20 feet below the existing ground surface. The top of the cut off wall was assumed to be at elevation of 47 feet, similar to the A8 design. The thickness of the cut-off wall was assumed to be 3 feet. A chimney drain and a blanket drain were also included in the analysis. The chimney drain was located about 40 feet from the cut-off wall, downstream side, and was extended to elevation 43 feet.

A.3.2.3 Seepage Analysis Results

Results of the seepage analyses performed are summarized in ***Table A-2*** below.

TABLE A-2: SUMMARY OF SEEPAGE ANALYSIS RESULTS

Case	Estimated Total Seepage ($ft^3/d/ft$)	Estimated Seepage Into Canal* ($ft^3/d/ft$)	Estimated Seepage Collected by the Blanket ($ft^3/d/ft$)
Pool Level @ Elev. 42' with a cut-off wall	16	16	15

Note: * Total seepage collected by the canal does not include the additional flows from re-routing of existing canals. Total seepage collect by the canal includes seepage from both sides of the canal.

Total seepage listed in the above table refers to total through and under seepage. Seepage into canal refers to the total of seepage from the reservoir side plus seepage from the adjacent lands to the seepage canal. Seepage collected by the blanket refers to seepage that is collected by the drainage blanket within the dam section. All quantities are in cubic feet per day per foot of dam.

With a typical critical gradient for the embankment material and the foundation soils being around 1.0, the minimum allowable safety factor against piping recommended ranges from 3 to 5. The estimated exit gradient ranged from about 0.05 to 0.1 which indicates that the development of soil piping is not anticipated. The output file from SEEP/W is shown on ***Figure A-5*** below.

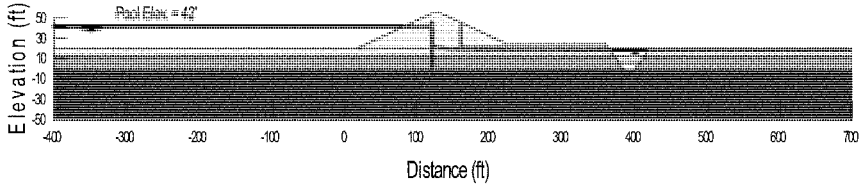

FIGURE A-5: SEEPAGE ANALYSIS OUTPUT

A.3.3 Slope Stability Analyses

A.3.3.1 General Description and Background

The embankment slopes were analyzed using Spencer's method of slices and the circular search routine of the SLOPE/W computer program. The SLOPE/W program was also developed by Geo-Slope International Ltd. All cases were analyzed using the consolidated-drained (S) shear strengths. This was done because of the predominance of granular materials that will be used for embankment construction.

A.3.3.2 Case Analyzed

The case described under the seepage analysis was also analyzed for slope stability, similar to the A8 design. The subsurface conditions used in the stability analyses were the same as those used for the seepage analysis discussed above. The phreatic surface estimated from the seepage analysis was used in the stability analyses. The shear strengths parameters used in the analysis are summarized below in ***Table A-3.***

TABLE A-3: SHEAR STRENGTH PARAMETERS

Material	Saturated Unit Weight (pcf)	Cohesion (psf)	Friction Angle (deg.)
Upper Sand	120	0	32
Upper Sand/Silt/Clay Deposit	125	800*	0
Limestone	140	2000*	45
Lower Sand/Silt/Clay Deposit	125	800*	0

Sandy Clay/Clay	125	1000*	0
Embankment Fill	120	0	32
Core Zone	125	800*	28*

Note: * Values were assumed based on typical values of the materials encountered. Data will be re-evaluated during the design phase of the project.

The cases considered for slope stability analysis were the upstream and downstream stability of the embankment using the Full-Pool condition and the side slopes stability of the seepage collection canal. The phreatic surface obtained from the full pool steady state seepage conditions was used in the analysis.

A.3.3.3 Design Requirements

The required factor of safety for the different design conditions described above are given in EM 1110-2-1902, "Engineering and Design Stability of Earth and Rock-Fill Dams", 1 April 1970, Table I, "Minimum Factors of Safety" and are shown in the table below:

Case	Shear Strength	Required Factor of Safety
Long Term with Full Pool	S	1.5
Long Term with No Pool	S	1.5
Steady State Seepage from Full Pool	S	1.5

A.3.3.4 Slope Stability Analysis Results

The Spencer's method of slices and the circular search routine was used in the analysis. Results of the slope stability analyses are presented below.

Case	Factor of Safety
Embankment, Full Pool, Upstream	2.3
Embankment, Full Pool, Downstream	2.0
Embankment, No Pool, Upstream	2.2
Canal's Side Slopes	1.7
Rapid Drawdown	1.6

All of these factors are above the minimum required factor of safety of 1.5 discussed above. Results of the stability analysis using the full pool downstream case is shown below in ***Figure A-6***.

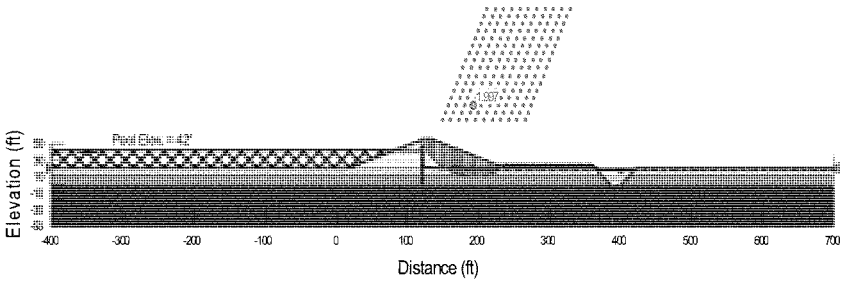

FIGURE A-6: SLOPE STABILITY OUTPUT

For the rapid drawdown analysis, it was determined that the embankment fill material (consisting mostly of fine sand materials) would have the ability to drain as quickly as the pool water level being drawn down. For that reason the RDD case was determined to be not critical with a safety factor of 1.6.

A.3.4 Settlement Analyses

Settlement analyses were performed for the reservoir dam using available consolidation data collected. Initial and consolidation settlements were evaluated at different locations of the reservoir embankment. Due to the variability in soil conditions, the total settlement estimated for the embankment ranges from about 6 to 38 inches. It is noted that most of the settlement ranges from 8 to 20 inches with isolated areas with settlements approaching 33 to 38 inches. It is that the majority of the settlement of the clayey soils beneath the embankment will take a period ranging from 1 to 3 years after construction.

A.3.5 Dewatering for Structures

It is anticipated that dewatering for structure excavations will be needed. For shallow foundations, dewatering could be potentially done by a well point system and/or perimeter ditches and sumps with dewatering pumps. However for deep foundations, it is anticipated that sheet pile cofferdams will be used with concrete tremie seal. These cofferdams then will be dewatered for structure construction. The cofferdams will be designed, by others, during the design phase of the project.

A.3.6 Other Foundation and General Construction Considerations for Structures

Though site-specific core borings will need to be drilled for each structure, it is anticipated that it will be possible to found the structures in this project on either shallow or deep foundations. During the design phase of the project, the foundations of the proposed structures will be evaluated in details to include type, bearing depth, settlement, bearing capacity determination, and construction procedures.

A.4 HYDROLOGIC MODELING

The model set used in the Caloosahatchee River (C-43) West Basin Storage Reservoir PIR is made up of three major components; 1) The South Florida Water Management Model (SFWMM), simulating the hydrology of the C&SF flood control project and the CERP, 2) The Freshwater Caloosahatchee River Basin model (FCRB), simulating the hydrology and hydraulics of the Caloosahatchee Basin from S-77 to S-79, and 3) CH3D, simulating salinity in the tidally influenced Caloosahatchee Estuary. See ***Figure A-7***.

The FCRB is the heart of the model set. Boundary conditions from the appropriate SFWMM simulation are provided to the FCRB, which simulates basin hydrology/hydraulics for the various planning conditions and alternatives. The resulting flow at S-79 provides the prime freshwater inflow boundary to CH3D. The CH3D simulates the salinity response by outputting spatially explicit time-varying salinity grids. For the alternatives evaluation modeling, a faster-running regression model was used as a surrogate for CH3D to produce the needed salinity grids. These salinity grids provide the major input to the Habitat Suitability Indicator models.

Each of these models is briefly discussed below.

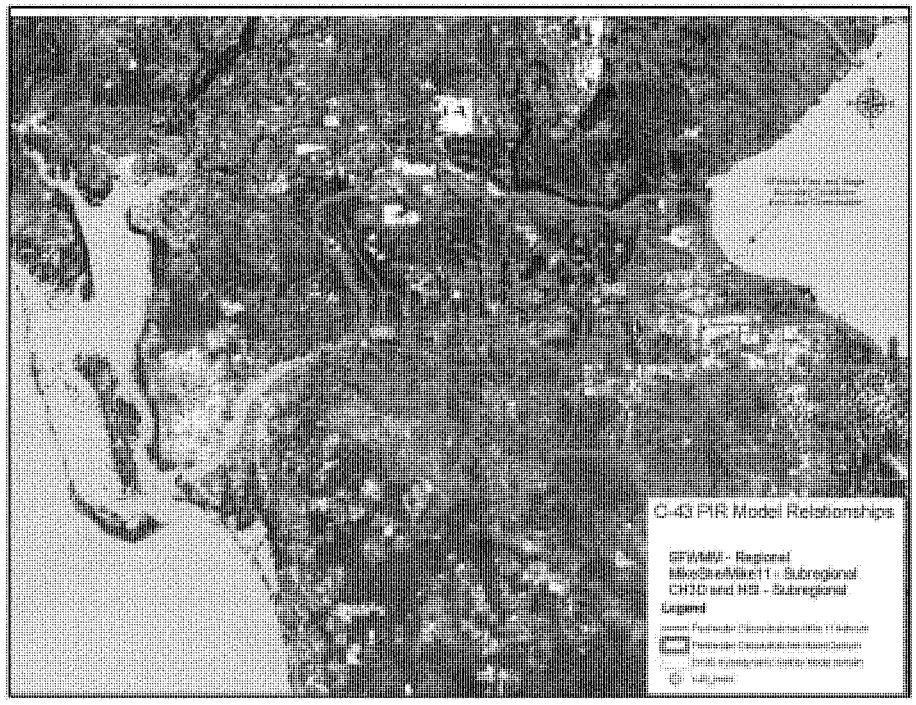

FIGURE A-7: CALOOSAHATCHEE (C-43) WEST BASIN STORAGE RESERVOIR PIR MODEL RELATIONSHIPS

1616

A.4.1 Regional Modeling

The SFWMM is a regional-scale computer model that simulates the hydrology and the management of the water resources system from Lake Okeechobee to Florida Bay. It covers an area of 7,600 square miles using a mesh of 2 mile x 2 mile cells (2x2). In addition, the model includes inflows from Kissimmee River, and runoff and demands in the Caloosahatchee River and St. Lucie canal basins. The model simulates the major components of the hydrologic cycle in south Florida including rainfall, evapotranspiration, infiltration, overland and groundwater flow, canal flow, canal-groundwater seepage, levee seepage and groundwater pumping. It incorporates current or proposed water management control structures and current or proposed operational rules. The ability to simulate water shortage policies affecting urban, agricultural, and environmental water uses in south Florida is a major strength of this model. The SFWMM simulates hydrology on a daily basis using climatic data for the 1965-2000 period which includes many droughts and wet periods. The model has been calibrated and verified using water level and discharge measurements at hundreds of locations distributed throughout the region within the model boundaries. Technical staffs of many federal, state, and local agencies, as well as public and private interest groups have accepted the SFWMM as the best available tool for analyzing regional-scale structural and/or operational changes to the complex water management system in south Florida. Detailed SFWMM documentation is available at:
http://www.sfwmd.gov/org/pld/hsm/models/sfwmm/index.html.

A.4.1.1 SFWMM Boundary Condition Simulations

Utilization of the most currently accepted Lake Okeechobee base flow data to the Caloosahatchee Basin is critical to ensure consistency between the PIR and Acceler8 modeling. The 95BSR and D13R modeling runs for the Restudy were the previous basis for regional simulation with SFWMM of the "current" and "future with project" conditions, respectively. However, with the development of the 2000B2 and CERP0/1 runs as part of the Initial CERP Update (ICU), the basis for Lake Okeechobee discharges has been revised. In addition, 2000 and 2050 demand estimates (provided by Timothy Liebermann SFWMD on 11/19/04) and other information that is improved from those in 2000B2, 2050B2 and CERP1 are now available. New runs called 2000RD, 2050RD and CERP1RD , have been prepared for the PIR and Acceler8 efforts. These new runs incorporate the latest information, including the latest 2000 and 2050 demands.

The 2000RD run is derived from the 2000B2 simulation for ICU as documented at http://modeling.cerpzone.org/pmviewer/ModelRunInfo.do?modelrunID=52. Specific differences between the run assumptions are shown in the table below.

TABLE A-4: DIFFERENCES BETWEEN THE 2000B2 AND 2000RD MODEL RUNS

	2000B2 (for ICU)	2000RD (for C43 PIR and Acceler8)
SFWMM Version	V5.4	V5.4.2
Caloosahatchee Acreage	582,839 acres	578,013 acres
Caloosahatchee Irrigated Acreage	172,189 acres	172,337 acres
S4 Acreage	50,270 acres	42,581 acres
S4 Irrigated Acreage	39,861 acres	33,178 acres
Caloosahatchee Demand (Average Annual)	118 kac-ft	121 kac-ft
Caloosahatchee Runoff (Average Annual)	652 kac-ft	641 kac-ft
S4 Demand (Average Annual)	45 kac-ft	38 kac-ft
S4 Runoff (Average Annual)	52 kac-ft	42 kac-ft
Other Differences	Everglades Construction Project as of 3/31/04	Everglades Construction Project as of 11/16/04

The 2050RD run is derived from the 2050B2 simulation for ICU as documented at http://modeling.cerpzone.org/pmviewer/ModelRunInfo.do?modelrunID=53. Specific differences between the run assumptions are shown in the table below.

TABLE A-5: DIFFERENCES BETWEEN THE 2050B2 AND 2050RD MODEL RUNS

	2050B2 (for ICU)	2050RD (for C43 PIR and Acceler8)
SFWMM Version	V5.4	V5.4.2
Caloosahatchee Acreage	588,360 acres	578,013 acres
Caloosahatchee Irrigated Acreage	230,242 acres	205,556 acres
S4 Acreage	50,270 acres	42,581 acres
S4 Irrigated Acreage	40,626 acres	30,237 acres
Caloosahatchee Demand (Average Annual)	173 kac-ft	144 kac-ft
Caloosahatchee Runoff (Average Annual)	622 kac-ft	607 kac-ft
S4 Demand (Average Annual)	46 kac-ft	34 kac-ft
S4 Runoff (Average Annual)	51 kac-ft	43 kac-ft
Other Differences	Everglades Construction Project as of 3/31/04	Everglades Construction Project as of 11/16/04

The CERP1RD run is derived from the CERP1 simulation for ICU as documented at http://modeling.cerpzone.org/pmviewer/ModelRunInfo.do?modelrunID=56. Specific differences between the run assumptions are shown in the table below.

TABLE A-6: DIFFERENCES BETWEEN THE CERP1 AND CERP1RD MODEL RUNS

	CERP1 (for ICU)	CERP1RD (for C43 PIR and Acceler8)
SFWMM Version	V5.4	V5.4.2
Caloosahatchee Acreage	588,360 acres	578,013 acres
Caloosahatchee Irrigated Acreage	230,242 acres	205,556 acres
S4 Acreage	50,270 acres	42,581 acres
S4 Irrigated Acreage	40,626 acres	30,237 acres

Indian River Lagoon (IRL) Assumptions	RESTUDY	IRL South Authorized
Other Differences	Everglades Construction Project as of 3/31/04	Everglades Construction Project as of 11/16/04

A.4.2 Sub-Regional Modeling–MIKESHE

MIKESHE, a water resources modeling system, developed by DHI Water and Environment, Inc, was selected for sub-regional modeling of the Freshwater Caloosahatchee River Basin (FCRB). Close interaction between groundwater and surface water within the study area necessitates the use of a model which can concurrently simulate groundwater and surface water within the same model run. MIKESHE is an integrated groundwater and surface water modeling package, capable of simulating all major processes in the land phase of the hydrologic cycle such as rainfall, evapotranspiration, overland flow, unsaturated zone flow with multiple soil layers and types (one-dimensional finite difference), saturated zone flow with multiple geological layers (three-

dimensional finite difference flow), irrigation, drainage, pumping wells, and can support various types of land use and vegetation.

The surface water river/canal network is simulated within MIKESHE using the MIKE11 Hydrodynamic module. This module simulates the river hydraulics through the fully dynamic solution of the complete nonlinear St. Venant equations for open-channel flow. The application of the MIKE11 module is also ideal for this study due to the large number of complex hydraulic control structures within the basin. MIKE11 is capable of simulating many types of structures including weirs, pumps, overflow and underflow gates, culverts, and bridges. MIKE11 structures can contain extremely complex and nested logical operating schemes based upon a wide array of variables within the model. The FCRB model contains 129 water control structures and 515 miles of rivers and canals within the surface water network.

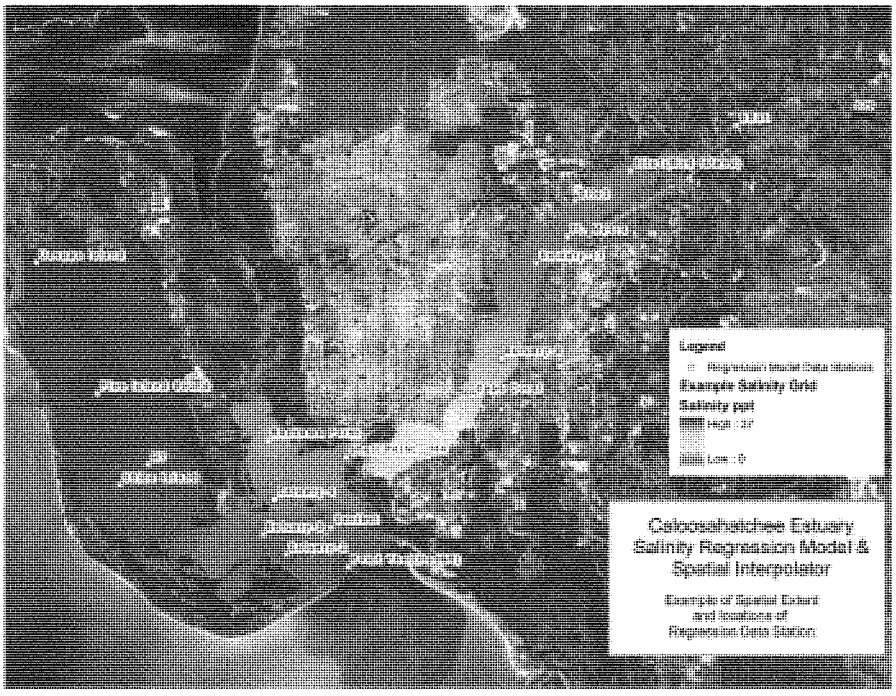
The model simulates irrigation within the basin through the use of conceptual "irrigation command areas". An irrigation command area spatially represents an irrigated area (farm, group of farms, or urban area) and describes the sources of irrigation water, including location of source, withdrawal rates, and cutoff thresholds. Each irrigation command area may have multiple sources including surface water (MIKE11 river branch), single wells, distributed shallow wells, or external sources which supply water from outside the model domain. The FCRB model contains 151 distinct irrigation command areas.

The FCRB receives boundary conditions from the SFWMM (2x2) along the Lake Okeechobee boundary (MIKESHE) as well as at several structures in the surface water network (MIKE11). The rainfall and evapotranspiration inputs are the same 2-mile x 2-mile gridded time series used in the SFWMM.

Topography was developed by the SFWMD and was imported into the model through the use of GIS. The FCRB model contains 13,608 grid cells, with 1,500 feet by 1,500 feet grid cell size. Of these 13,608 cells, there are 611 boundary cells and 12,997 internal cells. This gives a total model domain of 702,900 acres or 1,098 square miles. The model simulates three distinct, spatially-explicit groundwater units—the Holocene-Pliocene, the Lower Tamiami, and the Sandstone aquifers, separated by the Bonita Springs Marl and Upper Peace River Confining units. The model also contains the Berry Farm Clay layer which rests underneath the Berry Reservoir site. The model simulates 21 different land use types and six different soil types.

The FCRB model was calibrated for the time period September 1990 through September 1999 using actual meteorological data, stream flows and stages, and groundwater monitoring wells.

A.4.3 Estuary Salinity Modeling



A.4.3.1 CH3D

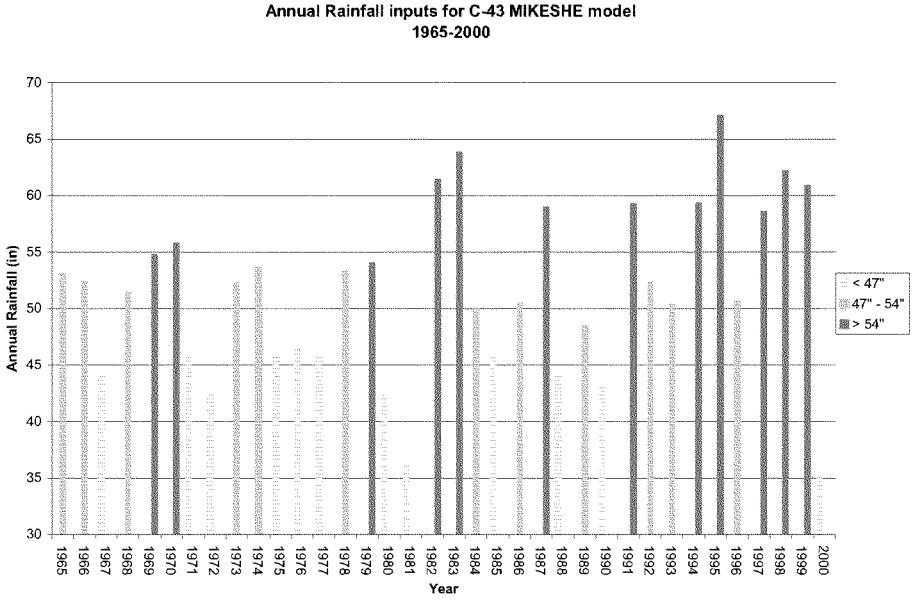
The CH3D model is three-dimensional and employs curvilinear grids. The model simulates time-dependent circulation in estuaries, lakes, and coastal waters. It solves the three-dimensional equations of motion in a non-orthogonal boundary-fitted coordinate system with given computational domain, initial conditions, and boundary conditions. For the present application to the Caloosahatchee estuarine system, the model solves the conservation equations for the following hydrodynamic variables: surface elevation, 3-D velocities, salinity, and density. Multi-year simulation of salinity in the estuary is needed to evaluate alternatives. While the CH3D model could be used for these simulations, project deadlines preclude this option. Based on the CH3D hydrodynamic model results and observed data, a salinity regression model was developed to meet the requirement for multi-year analysis.

A.4.3.2 Salinity Regression Model and Spatial Interpolator

The salinity regression model was designed to use the freshwater discharges at S-79 to estimate the salinity values at 20 downstream stations. It was constructed in two phases: (1) finding the relationships between the constant discharges at S-79 and their corresponding equilibrium salinities at the 20 downstream stations (Q~S curves); (2) using a FORTRAN program and certain coefficients to adjust the salinity variation curves to match the monitoring salinity data and salinity data for specific stations taken from the calibrated CH3D salinity model. Since the FORTRAN code runs in seconds, the processing of the S-79 flow results from the MIKESHE alternative simulations is quite manageable. In order to produce the HSI model input, the next step is to produce spatially explicit salinity data (grids) from the daily salinity time-series at each of the 20 regression points. A set of Arc Info scripts was developed to automate an interpolation process to produce ASCII grid data representing average monthly salinity values. Interpolation schemes were tested and the results coordinated with the Ecological Subteam. The Inverse Distance Weighting scheme, with barriers to represent the landforms, was chosen. The spatial extent of the interpolator and the location of the Regression model data stations are shown in ***Figure A-8***.

FIGURE A-8: CALOOSAHATCHEE ESTUARY SALINITY REGRESSION MODEL AND SPATIAL INTERPOLATOR

A.4.3.3 Simulation Period



CERP General Guidance Memorandum # 1 provides guidance regarding modeling simulation periods as follows:

> *The time series of data (beginning with the date of the first data point through the date of the last data point) that comprises the full range of known conditions constitutes the period-of-record for undertaking this analysis. If a shorter period is used, the full range of hydrologic conditions must be represented including inter- and intra- annual variations due to droughts, periods of high and low water levels and natural fluctuations. An appropriate period-of-record will include natural fluctuations in rainfall and water levels, including droughts and periods of high water levels. Uncertainty about the adequacy of the data for compiling an appropriate period-of-record should be reflected in project documents. All simulations considered should use the same period of climatic record.*

The SFWMM Period of Record (POR) is 36 years from 1/1/1965 through 12/31/2000. This long POR simulation is possible due to the relatively low computational requirements of the SFWMM. The Subregional MIKESHE/MIKE11 computational requirements are significantly greater. One year of MIKESHE simulation on a 3.0 gigahertz CPU requires about 3.5 hours of computational time, thus a 36-year POR run would take approximately 126 hours (about a week). While a 36-year MIKESHE run has been tested, the modeling turnaround is not manageable given current resources and schedule. Furthermore, the CH3D model requires even greater computation resources. Accordingly, a POR shorter than 36 years is necessary to evaluate alternatives.

Figure A-9 shows the simulated annual rainfall depths over the entire FCRB model domain for the 36-year POR. The three categories; Dry <47", 47"<Average<54", and Wet>57" were established by ranking the 36 years from the least, 35" in 2000, to the greatest, 67" in 1995. The 36 ordered rainfall years were then divided into thirds (12 years each), and each year was assigned the relative designation of Dry (1st third), Average (2nd third), Wet (last third). The selected alternatives evaluation period is January 1, 1978 through December 31, 1986. This 9-year period contains three Dry, three Average, and three Wet years each, as well as the second-most wet and dry years observed. Also note the back to back dry years in 1980 and 1981 and the following wet years in 1982 and 1983. Therefore, the selection of this POR is in compliance with the intent of CERP Guidance Memoranda # 1.

FIGURE A-9: ANNUAL RAINFALL INPUTS FOR C-43 MIKESHE MODEL

A.4.4 Model Certification, Description of Models, and Modeling Assumptions

A.4.4.1 Model Certification Process

Efforts to develop the Caloosahatchee River (C-43) West Basin Storage Reservoir Project Implementation Report have relied heavily on numerous planning and engineering models. The models are necessary for estimation of benefits, costs, operational requirements, and/or ecological outputs. These estimates are essential to determine the best alternative. Because of the importance of these models, it is necessary to evaluate their acceptability. In an effort to determine the acceptability of planning models, the U.S. Army Corps of Engineers published Engineer Circular No. 1105-2-407. This circular was published 31 May 2005 and establishes the process and requirements for certification of planning models.

Planning models, as defined by the circular, are:

> "...any models and analytical tools that planners use to define water resources management problems and opportunities, to formulate potential alternatives to address the problems and take advantage of the opportunities, to evaluate potential effects of alternatives and to support decision making. It includes all models used for planning, regardless of their scope or source..."

The circular, however, does not cover engineering models. Engineering models will undergo a certification process that will be defined by the Science & Engineering Technology Initiative.

The criteria for planning model certification are defined in Section 7 of the circular. Models are certified on the basis of technical soundness. Technical soundness is the ability of the model to represent or simulate the processes and/or functions it is intended to represent. In addition, a certified model should utilize accepted theory, integrate Corps policies and requirements, properly incorporate the theory into the software code of the model, clearly define the assumptions of the model, employ proper functions and mathematics, and estimate/forecast the actual parameters it is intended to simulate. Lastly, the models should be efficient, effective, usable, and capable of presenting results clearly.

The process for certification of existing planning models, as outlined in Section 8 of the circular, starts with a proponent identifying the model to be used. The proponent is responsible for submitting the model and documentation to the appropriate Planning Center of Expertise (PCX). The PCX then determines the appropriate level of review and establishes a review team. The team provides comments and recommendations to the PCX..The PCX can conclude with a certification of the model.

The Jacksonville District Corps of Engineers has submitted (acted as the proponent) to the appropriate entity the models listed below (planning models were submitted to the appropriate PCX). The Jacksonville District also corresponded with Headquarters to determine the acceptability of engineering models:

PLANNING MODELS	ENGINEERING MODELS
HSI	Freshwater Caloosahatchee River Basin Model
IWR-PLAN	MIKE11
	MIKESHE
	SEEP/W
	SFWMM
	SLOPE/W
	Watershed Assessment Model

In addition to the models listed above, additional models may be used in the future to determine some of the outputs of the project. There may be a need to use BATHTUB (a reservoir water quality model), CH3D (a hydrodynamic, salinity, and temperature model), DMSTA (Dynamic Model for Stormwater Treatment Areas), and PROMETHEE (Preference Ranking Organization Method for Enrichment Evaluation.) If, in the future, these models are used for

this project, they will be put through the appropriate certification process required at that time.

A.4.4.2 Models Used, Model Criteria, Status of Certification

The model certification process outlined in Engineering Circular 1105-2-407 and the SET Initiative's process to certify engineering models are currently undergoing refinement and the PCXs and Headquarters are not yet certifying models. However, the PCXs are operating under guidance from IWR that allows them to approve models for use. Headquarters has provided the SFWMD with guidance that suggests the use of "due diligence" when evaluating engineering models until the certification process is finalized.

A.4.4.2.1 Model Name: HSI (Habitat Suitability Index)

Model Description and Use: HSI was developed by the U.S. Fish and Wildlife Service (USFWS). HIS models are used to determine the impact each alternative will have on the project area.. HSI methods were used for quantifying habitat value for oysters, *Vallisneria*, and seagrasses.

HSI methods are used to evaluate attributes that represent independent aspects of the ecosystem and provide a complete picture of the performance of different alternatives. Evaluation criteria are developed and weighted for each attribute. Hydrologic and hydraulic data are applied to the evaluation criteria and attributes to predict the ecological changes likely to occur under the with and without project conditions.

Peer Review: HSI methods and models are used throughout the environmental community. The HSI concept was developed by the USFWS in the early 1980's and is still used today. The HSI process is typically conducted by a team of environmental professionals.

Documentation/Support: HSI documentation can be found in USFWS habitat evaluation procedures, Fish and Wildlife Service Manual, 870 FW 1, http://www.fws.gov/policy/870fw1.html.

HSI models can be developed using spreadsheets or through the use of software provided by the Department of the Interior, http://www.fort.usgs.gov/products/software/hsin/hsin.asp.

Point of Contact(s): United States Fish & Wildlife Service, Division of Habitat and Resource Conservation (habitat@fws.gov)

Certification Status: The United States Army Corps of Engineers Planning Center of Expertise for Ecosystem Restoration has approved HSI modeling.

A.4.4.2.2 Model Name: IWR-Plan

Model Description and Use: IWR-PLAN was developed by the Institute for Water Resources. IWR-Plan Decision Support Software is designed to assist with formulation and comparison of alternative plans. IWR-PLAN can assist with plan formulation by combining solutions to planning problems and calculating the additive effects of each combination, or "plan." IWR-PLAN can assist with plan comparison by conducting cost effectiveness and incremental cost analyses, identifying the plans which are the best financial investments and displaying the effects of each on a range of decision variables.

IWR-PLAN takes user-defined solutions to planning problems and externally-generated estimates of each solution's effects and can formulate all possible combinations of those solutions, considering user-defined relationships between solutions. IWR-PLAN will then identify which combinations are the best financial investments through cost effectiveness and incremental cost analyses. Each combination of solutions is an alternative plan. If alternative plans have already been formulated outside IWR-PLAN, the user can bypass the routine for building combinations and still use IWR-PLAN to assist in identifying which plans are the best investments.

Peer Review: IWR-Plan has a team of analysts dedicated to testing and review. The model has been in use by Corps and non-Corps parties for many years. The model was developed in accordance with procedures authored by Corps HQ.

Documentation/Support: IWR-Plan was developed in accordance with the procedures manual Cost Effectiveness and Incremental Cost Analyses published by IWR in 1995 (IWR Report 95-R-1),
http://www.water-resources.us/inside/products/pub/iwrreports/95r01.pdf

IWR-Plan is supported by the Institute for Water Resources through Planning & Management Consultants, Ltd., http://www.pmcl.com/iwrplan/

Point of Contact(s): Leigh Skaggs, IWR,
lawrence.l.skaggs@iwr01.usace.army.mil

Certification Status: This model was sent to the PCX for certification; however, the PCX determined that IWR-Plan is not an ecosystem restoration model and therefore could not approve the model. The PCX transferred the model to Headquarters for approval. Approval from Headquarters is pending.

A.4.4.2.3 Model Name: Freshwater Caloosahatchee River Basin Model

Model Description and Use: The Freshwater Caloosahatchee River Basin Model was developed using MIKE11 and MIKESHE to simulate hydrologic conditions in the lower West Caloosahatchee basin and in turn to evaluate the different alternatives and their effects on the flows to the estuary. This model is based off of MIKE11 and MIKESHE.

Model Name: MIKE11

Model Description and Use: MIKE11 is the product of the Danish Hydraulic Institute. The model is an industry standard for simulating flow and water level, water quality and sediment transport in rivers, irrigation canals, reservoirs and other inland water bodies. It is a comprehensive engineering tool with a wealth of capabilities provided in a modular framework.

MIKE11 can be used for flood risk analysis and alleviation design, real-time flood forecasting, dam break analysis, optimization of reservoir and canal gate/structure operations, ecological and water quality assessments in rivers, reservoirs and wetlands, real-time water quality forecasting and pollutant tracking, sediment transport and river morphology, salinity intrusion in rivers and estuaries, integrated surface water, and groundwater and water analysis.

Peer Review: The Interagency Modeling Center reviewed the application of the model. US Federal Emergency Management Agency (FEMA) has approved MIKE11 and has added it to its exclusive list of hydraulic simulation tools accepted for use in the National Flood Insurance Program (NFIP).

Documentation/Support: MIKE11 is supported by the Danish Hydraulic Institute, VKI-Institute for the Water Environment and Danish Toxicology Centre http://www.dhigroup.com/. Numerous professional papers can be obtained from the DHI Library, http://www.dhigroup.com/Software/WaterResources/MIKE11/References/Papers.aspx.

Point of Contact(s): DHI North American Offices, http://www.dhigroup.com/Contact/DHIOffices/USA.aspx.

Certification Status: Headquarters (HQ) has advised the SFWMD to use "due diligence," thorough review, and documentation when using engineering models in Corps studies. The above information provides detailed information about the model and the SFWMD believes it satisfies HQ's current requirements.

A.4.4.2.4 Model Name: MIKESHE

Model Description and Use: MIKESHE was developed by the Danish Hydraulic Institute. It is a modeling tool that can simulate the entire land phase of the hydrologic cycle. It is an integrated modeling environment that allows components to be used independently and customized to local needs.

MIKESHE can be used for the analysis, planning and management of a wide range of water resources and environmental problems related to surface water and groundwater, such as; surface water impact from groundwater withdrawal, conjunctive use of groundwater and surface water, wetland management and restoration, river basin management, planning environmental impact assessments, aquifer vulnerability mapping with dynamic recharge and surface water boundaries, groundwater management, floodplain studies, impact studies for changes in land use and climate, impact studies of agricultural practices including irrigation, drainage, and nutrient and pesticide management.

Peer Review: IMC has reviewed the application of the model. DHI maintains support services for MIKESHE to allow professional users to provide feedback about the software. MIKESHE has also been the subject of many external reviews,
http://www.dhigroup.com/Software/WaterResources/MIKESHE/References/References.aspx

Documentation/Support: MIKESHE is supported by the Danish Hydraulic Institute, VKI-Institute for the Water Environment and Danish Toxicology Centre. Documentation is available at their website
http://www.dhigroup.com/.

Point of Contact(s): DHI North American Offices,
http://www.dhigroup.com/Contact/DHIOffices/USA.aspx.

Certification Status: HQ has advised the SFWMD to use "due diligence," thorough review, and documentation when using engineering models in Corps studies. The above information provides detailed information about the model and the SFWMD believes it satisfies HQ's current requirements.

A.4.4.2.5 Model Name: SEEP/W

Model Description and Use: SEEP/W is a product of Geo-Slope International. It's a finite element software product for analyzing groundwater seepage and excess pore-water pressure dissipation problems within porous materials such as soil and rock.

SEEP/W is used to model both saturated and unsaturated flow. The saturated/unsaturated formulation of SEEP/W makes it possible to analyze seepage as a function of time and to consider such processes as the infiltration of precipitation. The transient feature allows you to analyze such problems as the migration of a wetting front and the dissipation of excess pore-water pressure.

Peer Review: SEEP/W is offered through a private company, Geo-Slope International. Through their website, http://www.geo-slope.com/support/kb/advsearch.aspx, they offer users the ability to provide feedback. The software appears to be used in both the professional and academic community.

Documentation/Support: Limited documentation about SEEP/W is available without purchase of the software, http://www.geo-slope.com/products/seepw2004.aspx. Geo-Slope International provides online support.

Point of Contact(s): General inquires: info@geo-slope.com
Technical support: support@geo-slope.com

Certification Status: HQ has advised the SFWMD to use "due diligence," thorough review, and documentation when using engineering models in Corps studies. The above information provides detailed information about the model and the SFWMD believes it satisfies HQ's current requirements.

A.4.4.2.6 Model Name: SFWMM, (South Florida Water Management Model [2x2]))

Model Description and Use: SFWMM is a regional-scale computer model that simulates the hydrology and the management of the water resources system from Lake Okeechobee to Florida Bay. The model domain covers an area of 7,600 square miles using a mesh of 2 mile x 2 mile cells.

The model simulates the major components of the hydrologic cycle in south Florida including rainfall, evapotranspiration, infiltration, overland and groundwater flow, canal flow, canal-groundwater seepage, levee seepage and groundwater pumping. It incorporates current or proposed water management control structures and current or proposed operational rules.

Peer Review: This model was peer reviewed in 1989 and 2005. Both peer reviews were conducted in similar manners. The most recent peer review consisted of a panel of four engineering professors and one contractor with experience in model development. The reviewers were: Rafael L. Bras, Chair (Professor of Engineering, MIT), Anthony Donigian (President, Aqua Terra Consultants), Wendy Graham (Professor of Engineering, University of Florida), Vijay Singh (Professor of Engineering, Louisiana State University), and Jery

Stedinger (Professor of Engineering, Cornell University). The panel reviewed the adequacy of the methodology. Overall, they found the model to be appropriate; they cited areas of the model that excelled as well as areas that could use improvement. The results of their review are documented in *The South Florida Water Management Model, Version 5.5: Review of the SFWMM Adequacy as a Tool for Addressing Water Resources Issues*, http://webboard.sfwmd.gov:8080/~sfwmm/guests.

Documentation/Support: SFWMM is supported by SFWMD, http://www.sfwmd.gov/org/pld/hsm/models/sfwmm/index.html, and documentation of the model can be found at http://www.sfwmd.gov/org/pld/sfwmm_doc/menu.htm.

Point of Contact(s): Jayantha Obeysekera, Ph.D., P.E., Director. jobey@sfwmd.gov
Ken Tarboton, Ph.D., P.E., Sr. Supervising Engineer.

Certification Status: HQ has advised the SFWMD to use "due diligence," thorough review, and documentation when using engineering models in Corps studies. The above information provides detailed information about the model and the SFWMD believes it satisfies HQ's current requirements.

A.4.4.2.7 Model Name: SLOPE/W

Model Description and Use: SLOPE/W is a product of Geo-Slope International. SLOPE/W is the leading slope stability software product for computing the factor of safety of earth and rock slopes.

Using limit equilibrium, SLOPE/W can model heterogeneous soil types, complex stratigraphic and slip surface geometry, and variable pore-water pressure conditions using a large selection of soil models. Slope stability analyses can be performed using deterministic or probabilistic input parameters. Stresses computed by a finite element stress analysis may be used in addition to the limit equilibrium computations, for the most complete slope stability analysis available.

Peer Review: SLOPE/W is offered through a private company, Geo-Slope International. Through their website, http://www.geo-slope.com/support/kb/advsearch.aspx, they offer users the ability to provide feedback. The software appears to be used in both the professional and academic community.

Documentation/Support: Limited documentation about SLOPE/W is available without purchase of the software, http://www.geo-

slope.com/products/slopew2004.aspx. Geo-Slope International provides online support.

Point of Contact(s): General inquires: info@geo-slope.com

Certification Status: HQ has advised the SFWMD to use "due diligence," thorough review, and documentation when using engineering models in Corps studies. The above information provides detailed information about the model and the SFWMD believes it satisfies HQ's current requirements.

A.4.4.2.8 Model Name: WAM, a.k.a. WAMView (Watershed Assessment Model)

Model Description and Use: WAM was developed and is supported by the Ecosystems Research Division of the United States Environmental Protection Agency (USEPA). It was developed to allow engineers and planners to assess the water quality of both surface water and groundwater based on land use, soils, climate, and other factors. The model simulates the primary physical processes important for watershed hydrologic and pollutant transport. The WAM GIS-based coverages including: land use, soils, topography, hydrography, basin and sub-basin boundaries, point sources and service area coverages, climate data, and land use and soils description files.

The model can be used to assess P load strategies including the use of stormwater treatment areas (STAs) and reservoir-assisted stormwater treatment areas (RASTAs). WAM also has the ability to aid in the assessment of the impact of growth changes in the watershed.

Peer Review: IMC has reviewed this model for the Lake Okeechobee Projects. In addition, USEPA is committed to maintaining an open dialogue with users of the software. They accept feedback from users and most likely incorporate that feedback into future versions of its model.

Documentation/Support: WAMView is supported by the Ecosystems Research Division of the USEPA. Fact Sheets, user documentation, and links to technical support can be found at, http://www.epa.gov/ATHENS/wwqtsc/html/wamview.html.

Point of Contact(s): Tim Wool, EPA, wool.tim@epa.gov

A.4.4.3 Hydrologic Modeling Application for Modeling of Alternatives

Daily outputs of flow for the S-79 structure were used to evaluate the project's final array of alternative plans by comparing the hydrologic performance of each alternative to the CERP system-wide performance measure "NE-3" (Caloosahatchee salinity envelope [EST05]). Performance measure NE-3 quantifies the amount of time that the flows coming through S-79 are within the range to maintain the desirable salinity envelope. The EST05 time series represents the best-case ecological scenario under the same climatological record to determine which alternative came closest to achieving the hydrologic performance targets set for the project. Because of the integral connection between groundwater and surface water in the Caloosahatchee River Basin, the MIKESHE model was used to simulate the surface and ground water hydrologic cycle. The MIKESHE modeling platform was developed as a subregional model to simulate the hydraulics and hydrology of the Caloosahatchee River Basin since the project is located outside the spatial resolution and domain of the SFWMM. Because the MIKESHE model and the SFWMM are two different modeling platforms, they operate separately. This separation requires the MIKESHE model to use boundary conditions obtained from SFWMM model to simulate Lake Okeechobee release to the Caloosahatchee River Basin. The MIKESHE model then receives a set time series of water volumes from the SFWMM boundary condition based on the planning assumptions applied in the 2050RD condition. The model runs described below are needed to identify the recommended plan (also see ***Table A-7***).

Pre Selected Alternative Plan (SAP) Model Runs:

- Pre-CERP baseline (2000 Base Conditions).

- Existing Conditions (EC): This model run includes existing land use and operations as of the initiation of the PIR. It is typically used as part of the NEPA analysis and also for state assurances related to flood protection. (It is assumed that the 2000 base run and the existing conditions are the same since it is assumed that there have been no major changes in the basin).

- 2050 Future Without Project (FWO): No project features in place (CERP). Typically the Corps uses a 50-year planning horizon so the model should be parameterized with appropriate land use, water demands, structure operations, etc. For CERP projects, the current guidance is to use 2050 as the future year.

- Alternatives Run: Run alternatives using the CERPRD boundary conditions with each alternative. Three alternative plans with different configurations will be run under this condition.

TABLE A-7: MODEL RUNS FOR USE IN SAP SELECTION

Description	Land Use	Water Del.	Boundary Conditions/ Flows	Sea Level Rise
Pre-CERP Baseline	2000	2000	2000RD (2x2)	N
Alt 1: Future Without Condition.	2050	2050	2050RD (2x2)	Y
Alt. 2 100000 ac-ft rev.	2050	2050	CERP1RD (2x2)	Y
Alt. 3A,B,C- 170000 ac-ft rev	2050	2050	CERP1RD (2x2)	Y
Alt. 4A,B- 220000 ac-ft rev	2050	2050	CERP1RD (2x2)	Y

In order to ensure consistency between the PIR and Acceler8 modeling, it is critical that the most currently accepted Lake Okeechobee base flow data to the Caloosahatchee River Basin be used in the analysis of the project. The 95BSR and D13R modeling runs for the Restudy were the previous basis for regional simulation with SFWMM of the "current" and "future with project" conditions, respectively. However, with the development of the 2000B2 and CERP0/1 runs as part of the Initial CERP Update (ICU), the basis for Lake Okeechobee discharges has been revised. Additionally, 2000 and 2050 demand estimates have been improved upon those used in 2000B2, 2050B2 and CERP1 conditions and are now available. The new runs which use the updated conditions are called 2000RD, 2050RD and CERP1RD. These conditions incorporate the latest information, including the latest 2000 and 2050 demands, and have been prepared for the PIR and Acceler8 efforts.

The 2000RD run is derived from the 2000B2 simulation for the ICU. Specific differences between the run assumptions are shown in ***Table A-8***.

TABLE A-8: DIFFERENCES BETWEEN EXISTING CONDITION RUNS (2000B2 SIMULATION AND 2000RD SIMULATION)

	2000B2 (for ICU)	2000RD (for C43 PIR and Acceler8)
SFWMM Version	V5.4	V5.4.2

In addition, the hydrologic output of each alternative will also be used as output variables to develop and conduct the cost effectiveness and incremental cost analyses (CE/ICA) procedures which are instrumental in the selection of the National Ecosystem Restoration (NER) plan. The final alternatives will also be evaluated using ecological evaluation criteria developed for the project. The SAP will be based on the performance of one of these final alternatives in terms of attaining hydrological and ecological targets. These will be expressed in habitat units for various estuarine species (also explained in the section on Habitat Units) to help demonstrate which plan provides the greatest system-wide benefits to support project justification.

A.4.5 Hydrology and Hydraulics (H&H) Considerations for Embankments and Canals

A.4.5.1 General

The Caloosahatchee River (C-43) West Basin Storage Reservoir project area would consist of approximately 10,700 acres, of which approximately 10,480

acres are required in fee, approximately 20 acres in perpetual easements and approximately 200 acres in temporary easements for staging areas.. The area would incorporate a perimeter embankment with an adjacent perimeter canal and an interior embankment to divide the area into two cells (see plan view on Plate 1).

A.4.5.2 Embankment

The embankment would be designed and constructed to satisfy the hydraulic requirements of the impoundment pool with regard to pool elevation and anticipated wave run-up and the geotechnical requirements with regard to slope stability and seepage through the embankment.

Freeboard for the perimeter and internal dams measured above the normal full storage level (Elevation of 42 feet) as follows (***Table A-11***):

TABLE A-11: REQUIRED FREEBOARD HEIGHTS

Feature	Total Required Freeboard (ft)	Top of Dam Elevation (ft)
Cell 1	15	57
Cell 2	15	57
Internal Dam	9.4	51.4

The freeboard (wind setup plus wave run up) was calculated based on the Design Criteria Memorandum (DCM)-2 design criteria using the Shore Protection Manual, Volumes I and II, published by the Waterways Experiment Station of the USACE and STWAVE/ACES. The results of these analyses were presented in the Final Technical Memorandum–C-43 West Storage Reservoir Freeboard Analysis and Recommendation (included in this appendix). This technical memorandum represents the latest refinements incorporated into the Acceler8 60% Design. Changes to input parameters in the PMP event and wind/wave modeling have resulted in an average increase in embankment height of approximately 2.5 feet between the Draft PIR and this Final PIR. Further refinements are ongoing and will be incorporated into the design as they become available.

The 2-cell Reservoir was developed in the MIKESHE/MIKE11 model through the use of multiple input files. In the MIKE11 River Network model, the primary input files include the "network" file (*.nwk11) and the "cross-section" file (*.xns11).

The network file defines the linear path of each river or branch in the model. To add the Reservoir into the model, branches were defined to represent the Perimeter (Seepage) Canal and Cells 1 and 2 of the reservoir. Dummy branches were also defined at the location of various inflow and outflow structures.

Dummy branches were defined for the inflow pump, the outflow gates, and the service spillways.

The branches defined as Cell 1 and Cell 2 maintained the same position in space as the LPDD Header canals that currently exist at the project site. Proposed cross-sections were defined for each of the cells and the Perimeter (seepage) Canal.

The cross-section assumes a 3:1 side slope and bottom gradients generally conform to the existing topography of the site. A "slot" exists in each cross section at the approximate location of the former LPDD Header canal. This slot was included in the model to increase numerical stability during those periods of time when the Reservoir is dry.

It should also be noted that the total area of the slot is less than 10 square feet. The volume of water held in the slot is insignificant relative to the total volume of the Reservoir and reflects water that would be trapped in the micro-topography of the project site.

A.4.5.3 Slope Protection

It is anticipated that a stair step style soil cement design would be constructed pool side from the top of the embankment to the normal pool elevation. Each step would be 12 inches deep by 3 feet wide. A 16-inch flat plate style soil cement design would be constructed from the normal pool elevation to the toe of the embankment. The 16-inch flat plate design would also be constructed over the entire surface of the interior embankment. Grassing would be provided over the exterior portion of the perimeter embankment including a portion of the perimeter canal bank.

A.4.5.4 Perimeter Canal

A perimeter canal would be constructed adjacent to the outside slope of the perimeter embankment. The bottom width would be 10 feet at elevation 0.0 feet and the side slopes would be 1 Vertical on 2 Horizontal (1V:2.5H).

A.4.5.5 Construction Materials

Sufficient quantities of suitable construction material for the embankments and the impervious core within the embankments should be available from within the impoundment area. See Geotechnical analysis of in-situ materials.

A.4.5.6 Construction Access

Access to the site would be from SR 80 along the existing access road to the Berry Groves Field Office. Other access roads would be added as required for both construction and operation and maintenance activities.

A.4.5.7 Perimeter Road and Ramps

A perimeter road would be constructed around the impoundment area and ramps to the top of the embankment would be provided at reasonable intervals.

A.4.5.8 Pump Station C43-PS-1

A.4.5.8.1 General Description (See Mechanical Section for detailed discussion)

Pump Station C43PS-1 will consist of a 1,500 cfs pump station 252 feet long by 84 feet wide with intake located on the Townsend Canal and an over-the embankment arrangement for discharge to the Reservoir. The facility will house four main pumps. Two pumps will be 500 cfs capacity each, and two will be 250 cfs capacity each. The pump station building will consist of an operating floor at elevation 25.0 feet NAVD for the placement of most pump station machinery and a two-story steel structure above elevation 25.0 feet NAVD housing the control room, break room and workshop. A 60-ton overhead bridge crane with a hook height approximately 25 feet above the operating floor will be provided to facilitate the maintenance of pump station equipment. The selection of a 60-ton capacity crane is based on the anticipated weight of one 500 cfs pump.

A.4.5.9 Pump Station C43PS-4

A.4.5.9.1 General Description (See Mechanical Section for detailed discussion)

The pump station shall be designed to pump water from the Townsend Canal into the Perimeter Canal at a maximum 195 cfs rated capacity. The purpose of the station is for water supply to the neighboring landowners and maintenance of stage in the Perimeter Canal for seepage control. The station site would be at the southwest corner of the Reservoir at the southern limit of the SFWMD's property. The station discharge would be conveyed a distance of 1,500 feet to 2,000 feet to the Perimeter Canal via a conveyance canal paralleling the toe of slope of the Reservoir embankment.

The Townsend Canal provides flood conveyance for the citrus operations south of the Reservoir and irrigation water during the dry season. The normal canal stage upstream of the existing pump station is maintained for the farm operations at 23.5 feet NAVD. The Townsend Canal stage varies with the Caloosahatchee River.

A.4.5.9.2 Design Stages

The following stages shall be assumed for the design of the C43PS-4 Pump Station:

- Normal Dry Season Stage: 0.0 feet NAVD
- Design Low Water Stage: -3.0 feet NAVD
- Design High Water Stage:+3.3 feet NAVD
- Design Upper Pool Stage: +23.5 feet NAVD

A.4.5.9.3 Discharge Head

The use of a weir in lieu of flap gates to prevent backflow establishes the pool to pool static head for the pumping system. The weir crest was set at 26.0 feet NAVD with a 1.38 feet calculated head over the 10 feet wide broad crested weir at the rated flow condition of 50 cfs. The current Reservoir concept design is for the toe of the Reservoir's embankment to be near the SFWMD's southwest property line requiring the station's discharge canal to parallel this proposed earthwork to the east. The head established at the discharge weir would provide more than adequate gradient for the gravity flow through this reach of canal to its discharge point.

A.4.5.10 Water Control Structures

A.4.5.10.1 Culverts

A.4.5.10.1.1 Introduction

Several canals within the proximity of the Reservoir are tributary to the Perimeter Canal or flow is diverted from the Perimeter Canal into one of these adjacent canals. These canals include the Roberts Canal, LPDD Header Canal, Banana Branch Canal and the Fort Simmons Branch Canal. Box culverts were evaluated and utilized to convey flow into and out of the Perimeter Canal from the tributary canals.

A.4.5.10.1.2 Design Criteria and Standards

Contributing canal structures were sized such that future flows for the Townsend Canal, Ft. Simmons Branch, Banana Branch, and the LPDD Header Canal do not exceed existing condition flows for the 25-year and 100-year storm events. The 25-year and 100-year storm events were applied to the calibrated Freshwater Caloosahatchee River ("without project") MIKESHE Model and flow data was extracted from the model results for each canal of interest.

Subsequent model runs were completed for the "with project" condition. Results of these simulations were compared to the "without project" flows in each canal

of interest and used to size structures and to determine the initial operational procedures for each structure.

All elevations referenced are based on the NAVD1988.

A.4.5.10.1.2.1 C43S-7

Structure C43S-7 is located at the intersection of the upstream end of the Banana Branch Canal and the Perimeter Canal. It consists of a double 10 foot wide (W) x 10 foot tall (H) box culvert with one (1) sluice gate and one (1) weir gate. Headwater elevation for Normal Water Level (NWL) is 19.50 feet and 20.5 feet for High Water Level (HWL). Tail water elevation for NWL is 15.1 feet and 18.5 feet for HWL. With an invert elevation of 10 feet, the HWL conditions are contained within the box culvert height. Flow parameters examined are as follows: base flow of 15 cfs, Q_{25} of 374 cfs and Q_{100} of 492 cfs.

The above operational criteria resulted in a variation of Froude numbers ranging from 2.3 to 4 resulting in a transition flow stage since a true hydraulic jump does not fully develop. Based on the above Froude numbers a Type IV stilling basin with baffle blocks and an end sill is proposed to help assist with energy dissipation. Rip-rap is proposed at the downstream end of the stilling basin along the channel bottom and side slopes as some of the wave action from the transition flow stage will not be fully controlled by the proposed stilling basin. Stilling basin exit velocities for the peak event are roughly 7.0 ft/s reducing to approximately 0.5ft/s 60 feet downstream.

A.4.5.10.1.2.2 C43S-9

Structure C43S-9 is a double 6 foot W x 6 foot H box culvert that conveys flow from the Perimeter Canal through to the Fort Simmons Branch Canal which discharges into the Caloosahatchee River. The operational intent of the S-9 structure is to mimic, as closely as possible, the natural flows of the Fort Simmons Branch under existing conditions. Inlet control used for the Fort Simmons Culvert is a 6 foot x 6 foot sluice gate and a 6 foot x 6 foot weir gate. Discharges examined were 1 cfs for base flow, 66 cfs for 25 year event and 68 cfs for 100 year event as obtained from the latest MIKESHE model runs provided by DHI. The weir gate has the ability to address all flows examined. The sluice gate is anticipated to pass larger design flows that are greater than the base flow. Analysis of C43S-9 resulted in a Froude number of 6.01. This indicates that a true hydraulic jump will occur resulting in a Type III stilling basin. A stilling basin with baffle blocks and end sill have been designed to assist in dissipating energy on the downstream end of C43S-9. Structure C43S-9 has the ability to convey the Q100 event either via the sluice gate or weir gate. This provides a built-in redundancy should one gate be removed from service.

Structure C43S-9 does have the ability to convey additional flow should that be decided in the future.

A.4.5.10.1.2.3 C43S-14

Structure C43S-14 is a 10 foot W x 6 foot H box culvert that connects the Header Canal to the Perimeter Canal. This structure will convey water from the Perimeter Canal, into the Header Canal up to 153 cfs. A remotely actuated sluice gate is utilized at this location to convey flood flow into the Perimeter Canal. Structure S-14 will not be used as a means for daily flow control either to or from the Perimeter Canal. If the Perimeter Canal is at capacity, no additional flow will be introduced into the Perimeter Canal from the LPDD Header Canal.

A head water surface elevation of 23 feet was used for operations to match existing conditions. The tail water elevation, for structure C43S-14, is the water surface elevation in the Perimeter Canal which is 19.5 feet for NWL and 20.5 feet for HWL. The design flows utilized for S-14 were 143 cfs for Q25 and 153 cfs for Q100. HWL flows from the Header Canal will be contained within the box culvert. The flow regime for discharge from C43S-14 is Submerged Controlled Flow as the tail water ranges from 2.5 to 3.5 feet above the gate sill which affects the upper pool by the submergence of the tail-water and the gate opening.

A.4.5.10.2 Perimeter Canal Structures

A.4.5.10.2.1 Introduction

The Perimeter Canal is a man-made canal that collects seepage from Cells 1 and 2 of the C-43 WBSR, re-routes and conveys flow from the Roberts Canal to the Banana Branch Canal, and conveys irrigation flows, cell discharge flows, and flood flows. The Perimeter Canal is vital in assisting with the regulation and stabilization of stormwater runoff, regulatory releases from Lake Okeechobee and improving the salinity balance for the Caloosahatchee estuary. The Perimeter Canal also provides flow releases to the downstream portions of the Roberts Canal (Banana Branch), Fort Simmons Branch and the Townsend Canal. The Perimeter Canal has three discharge structures that help facilitate with the flow control measures described above identified as C43S-3, C43S-10, and C43S-11.

Perimeter Canal structures were sized such that future flows for the Townsend Canal, Ft. Simmons Branch, and Banana Branch do not exceed existing condition flows for the 25-year and 100-year storm events. The 25-year and 100-year storm events were re-evaluated during the 60% design phase by DHI and similarly were applied to the calibrated Freshwater Caloosahatchee River ("without project") MIKESHE Model and flow data was extracted from the model results for each canal of interest. Subsequent model runs were completed for the *"with project"* condition. Results of these simulations were compared to the

"without project" flows in each canal of interest and used to size structures and to determine the initial operational procedures for each structure.
Development of the C-43 WBSR Perimeter Canal design consisted of creating a hydraulic model utilizing HEC-RAS River Analysis System modeling software. The Perimeter Canal model analyzed various steady state model runs that originate at Pump Station 4 (C43PS-4) and continue around the perimeter of the Reservoir to a future point of convergence with the Townsend Canal for a total distance of approximately 78,500 feet (14.8 miles). Flows were conveyed through the Perimeter Canal through the following three (3) Perimeter Canal structures: C43S-3, C43S-10 and C43S-11 with contributing flows from the Roberts Canal, via structure C43S-15 and with discharges from C43S-14. Diverging flows evaluated for the Perimeter Canal included those for the Banana Branch Canal and the Fort Simmons Canal. Model runs, for specific event scenarios described below, were conducted after numerous cross-sections were created detailing canal configuration, channel elevation and losses. Model runs evaluated various conveyances through the Perimeter Canal while maintaining flow within channel banks and ideally one (1) or more feet of freeboard. Evaluation of the aforementioned scenarios provided a foundation for structure analysis associated with the Perimeter Canal. HEC-RAS modeling results for the Perimeter Canal can be found in the *Hydrology and Hydraulics Data and Calculations* in the IDR Volume II.

Various operation scenarios, specific to each structure, were evaluated for sizing of the structures. This includes the following: 100-year return storm event, C43PS-4 pumping with base flow, C43PS-4 pumping with 25 year return storm event, drawdown with 25-year return storm event, and *PEAK* operations with 100-year return storm event.

Design Criteria Memorandum DCM-3 states that drawdown for the discharge facilities should be capable of reducing the normal pool level to 10 percent of the *Normal Full Storage (elevation) Level* (NFSL) within a given period of 4 months. An average discharge of 500 cfs, per cell, would be required to meet the Reservoir drawdown criteria.

Schematics for the Perimeter Canal are provided in ***Figure A-1.***

All elevations referenced are based on the NAVD 1988.

A.4.5.10.2.2 Design Criteria and Standards

Initial design considerations for the Perimeter Canal Structures consisted of utilizing large main sluice gates in conjunction with stop log bays. The main gates were evaluated for passing flow events greater than Q_{25} while the stop log bays addressed flow events less than Q_{25}. The intent of the stop log bay was to passively maintain a constant water surface elevation with minimal manpower.

This design was modified as a result of the Critical Criteria Meeting held in April 2006. The SFWMD indicated that they wanted to refrain from the use of stop log bays. Their experience with stop log bays has proven that they require continual oversight requiring manpower to place and remove stop logs. In an effort to limit the need for manpower and improve operation of the canal system, double leaf gates and weir gates were evaluated.

Double Leaf Gates were evaluated as an option for flow control however concerns regarding continual maintenance to remove trash and debris that collects on the riser stem discouraged their use. Devices preventing trash from becoming entangled around the riser stem could be designed and fabricated but there is a concern with reliability to withstand severe weather conditions. Therefore, the double leaf gates were not recommended for design.

Weir gates function similar to that of a stop log bay, yet provide the owner/operator the flexibility of adjusting crest elevation should discharge parameters change in the future. Weir gates have the ability to be both manually operated and remote controlled. Upon evaluation it was determined that weir gates would be an effective method of controlling flow similar to that of a stop log bay with less manpower. All weir gates will have a concrete sill that will be formed behind the lower gate opening with a gasketed seal to prevent any underflow/leakage. Only the weir portion will be used to control discharge. With automation the weir provides flexibility unlike the stop log bays.

Unlike the double leaf gate, the upper portion of the weir gate can be fabricated such that the riser stem is above the design water surface elevation. This design consideration eliminates the concern of trash becoming entangled on the riser stem and the need for an independent device to divert debris. If desired these gates are capable of controlling the discharge flows for events less than Q_{25} for all three structures. They can be used in combination with the main gates for events greater than Q_{25} and they may be a form of redundancy should a main gate(s) be removed from service.

A.4.5.10.2.2.1 C43S-3

Pump Station 4 (C43PS-4) can be found at the furthest upstream portion of the Perimeter Canal. Should there be a demand for irrigation by the Paul Grove, C43PS-4 will pump 195 cfs into the Perimeter Canal. This flow will ultimately be conveyed through the Perimeter Canal to C43S-3 at which time it will be released into the LPDD Canal and used for irrigation for the Paul Grove. Other than seepage and irrigation demand by the Paul Grove, no additional flow will be introduced into the Perimeter Canal upstream of C43PS-4 under design conditions.

The Perimeter Canal bottom elevation, upstream of C43S-3 is proposed at elevation five feet with 1V:2H side slopes. The design normal water elevation is 23.5 feet with a high water elevation at 25 feet. Normal water levels desired upstream and downstream of C43S-3 within the canal are 23 feet and 19 feet respectively, and were used in the various operating scenarios evaluated.

C43S-3 consists of a Single Barrel 10 foot x 10 foot Box Culvert. The barrel will have a 10 foot x 10 foot weir gate with allowance for a five foot high weir opening.

Events evaluated and included in the Operation Summaries include the following flows: base flow (seepage) of 10 cfs, Q25 of 28 cfs, Q100 of 44 cfs, QPumping of 195 cfs which includes the operation of C43PS-4.

The intention of the weir gate is to passively maintain a constant water surface elevation upstream of C43S-3. The weir gate is capable of passing the peak design flow of 233 cfs, which consists of flow pumped via C43PS-4 of 195 cfs and the 25-year storm event. This is also true should the weir gate be removed from service. Maintenance of the gate would require special consideration and must be performed during flow periods below or equal to the base flow conditions.

Given the design criteria above, structure C43S-3 has a well defined hydraulic jump. The installation of baffle blocks allow for the stilling basin length to be reduced. With the need to possibly dewater the structure for maintenance, it is recommended that additional clearance be provided downstream to allow for equipment and room to perform maintenance. Thus, an additional 10 foot length from the downstream invert of the double barrel box culvert would be provided prior to placing the baffle blocks. A second row of baffles is not required for maintaining the jump within the stilling basin, but is recommended to reduce the assault on downstream channel protection. The distance from the gate and the upstream face of the baffle blocks is fixed at 30 feet. The stilling basin from the upstream face of the first row of baffle blocks to the downstream face of the end sill is lengthened in an effort to force a jump in this location. An end sill was incorporated into the design to elevate the high velocity flow from the channel floor. This end sill, with the aid of the tail-water, helps stabilize the jump and prevent channel erosion downstream.

A.4.5.10.2.2.2 C43S-10

Structure C43S-10 consists of a reinforced concrete spillway with one (1) 14 foot W x 8 foot H vertical roller gate and two (2) 10 foot W x 8 foot H weir gates to control flow through the Perimeter Canal. Design flow received by the Perimeter Canal from the Roberts Canal would be conveyed and discharged into the Banana Branch Canal prior to C43S-10.

The Perimeter Canal, between C43S-3 and C43S-10 has a channel bottom elevation zero feet and a NWL of 19 feet and a HWL of 20 feet. Tail-water elevations during normal and high water conditions are 15 and 16.5 feet respectively. The bank elevation between these two structures decreases from 26 feet, just downstream of C43S-3, to approximately 21 feet just upstream of structure C43S-10. Fill will be placed as necessary so that during high water conditions, two (2) feet of freeboard will be maintained.

Structure C43S-10 consists of one 14 foot x 8 foot Vertical Roller Gate and two (2) 10 foot x 8 foot weir gates. Flows analyzed for the operation of C43S-10 consisted of the following event scenarios: 100-year event, PS-4 Pumping with Base Flow, PS-4 Pumping with 25-year event, Drawdown with 25-year event and a PEAK event combined with a 100-year event. Drawdown Operations consist of a discharge of 500 cfs from both C43S-8 and C43S-1 as required to meet drawdown criteria provided in DCM-3

The vertical roller gate alone, or in combination with the weir gates, is capable of handling the flows required to achieve drawdown, as required by DCM-3. The vertical roller gate alone can fully manage the required drawdown discharge with a gate opening of 2.6 feet during NWL conditions. In the event of high water conditions the gate opening would be approximately 3.6 feet since the gate is operating under *Submerged Controlled Flow* conditions. This type of flow regime is controlled by both the submergence effect of the tail water and the gate opening. An operational summary for C43S-10 has been provided summarizing these scenarios.

A conservative approach was utilized for C43S-10 in analyzing the computation results. The resulting Froude number for C43S-10 was 4.0 which is borderline for the use of baffle blocks. A double row of baffle blocks and an end sill were employed to help ensure the occurrence of a hydraulic jump within the stilling basin. These methods assist in the dissipation of energy and the potential for channel erosion downstream of the basin.

With a future need to dewater the structure for maintenance it is necessary to maintain additional clearance downstream to allow for equipment to conduct maintenance. A 22 foot, 1.25 inch distance was provided prior to placing the baffle blocks. A second row of baffles was provided to assist in reducing the assault on downstream channel protection. The stilling basin from the upstream face of the first row of baffle blocks to the downstream face of the end sill is lengthened in an effort to contain a jump in this location. The tail-water would also assist with energy dissipation by drowning-out the effects of the hydraulic jump. Baffle placement will be examined further in the 60 percent design phase.

Examination of channel velocities upstream of C43S-10 for NWL and HWL, were computed utilizing *'FlowMaster'* hydraulic computer program. NWL and HWL Velocities are 0.68 and 0.66 ft/s respectively. Channel velocities are much less than the *Suggested Maximum Permissible Mean Channel Velocities* of 2.0 ft/s for fine sand as recommended in EM 1110-2-1601. Velocities immediately at the downstream side of the C43S-10 structure are designed to be dissipated via baffle blocks and end sill.

A.4.5.10.2.2.3 C43S-11

C43S-11 is the largest of the Perimeter Canal structures which consists of a reinforced concrete spillway with two (2) 14 foot W x 8 foot H Vertical Roller Gates and two (2) 10 foot W x 8 foot H weir gates to control and convey flow through the Perimeter Canal. Should a vertical roller gate be removed from service, the weir gates can provide limited discharge capacity, thus maintenance of a gate would require special consideration and be performed preferably during flow periods below or equal to the base flow conditions.

Flow criteria utilized for design and analysis of C43S-11 consisted of five (5) separate scenarios as described above for C43S-10. Associated flows are as follows: 100-year event 478 cfs, C43PS-4 pumping with base flow 91 cfs, C43PS-4 pumping with 25-year event 142 cfs, drawdown with 25-year event 1213 cfs and PEAK event with 100-year scenario 1783 cfs. Drawdown requires a discharge of 500 cfs from C43S-8 and C43S-1 which is necessary to achieve reduction of the storage in the Reservoir to 10 percent of the NFSL within a period of 4 months. The PEAK event scenario has the greatest discharge capacity required for C43S-11 as it includes a operational discharge of 720 cfs and 780 cfs for C43S-8 and C43S-1. The flow control combinations can be modified or varied to accommodate changing conditions or operational parameters.

The two weir gates proposed, in addition to the vertical roller gates, are capable of discharging up to the PEAK event discharge flow of 1,783 cfs. Should a vertical roller gate be removed from service the weir gates with the remaining vertical roller gate can accommodate flows up to and including the Q_{100} event. Economically, the benefit of additional weir gates necessary to replace the vertical roller gates during drawdown discharge events may not justify the additional cost. The frequency of the drawdown events may be such that the additional weir gates are not used for several years and may fall into disrepair because of environmental factors. These additional gates may become a maintenance issue as it will be necessary to inspect and exercise them periodically. Additional gates, as a form of redundancy for drawdown discharge flows, are not recommended.

The weir gates are intended to be a passive control to maintain a water surface elevation of 15 feet upstream of C43S-11. Of course, this will vary depending on

current water elevations and necessary discharge requirements. C43S-11 is a *Free Controlled Flow regime* with a vertical gate ogee sill elevation of 8.3 feet and tail-water elevation of 4.5 feet. Therefore, the discharge is not affected by the tail-water but is based only on the gate opening.

Structure operational criteria evaluated resulted in a Froude number indicative of a transitional flow stage where a true hydraulic jump does not fully develop. The potential for wave propagation has been evaluated and a 48 foot stilling basin is proposed to help dissipate energy associated with the transitional flow stage. Baffle blocks have not been included as they will provide little assistance for suppressing wave action. Widening the downstream basin and providing a large end sill will dampen the oscillating flow. Computations provided result in a 3.0 foot end sill. It was necessary to verify that a secondary jump was not being created by the addition of the end sill. A secondary jump did not result.

Channel protection will be provided downstream of the end sill to help assist in reducing channel erosion from the hydraulic jump associated with discharges through C43S-11.

A.4.5.10.3 Main Outlet Structures

A.4.5.10.3.1 Introduction

Each cell of the Reservoir has a gated outlet structure to provide operational flows to meet the needs of the project at S-79 in the Caloosahatchee River (up to 500 cfs). The outlets also manage the Reservoir level as necessary. These outlets are located in the northwest corner of each cell and discharge to the Perimeter Canal.

A.4.5.10.3.2 Hydraulic Design Criteria

A.4.5.10.3.2.1 General

- Use Corps of Engineers Engineering Manuals as appropriate;
- Provide Reservoir draw down capability within 120 days (USACE ER1110-2-50);
- Maintain water quality (release water at selected levels within Reservoir, use Cell 2 whenever possible);
- Size gates to enable each cell to provide necessary downstream flows;

- Use identical gates and similar structural design for each cell to provide design, construction, and maintenance advantages; and
- Provide redundant gates in each cell (maintain normal operation even with one gate not functioning).

A.4.5.10.3.2.2 Inlet Structure

- Provide capability of drawing water from various levels within the Reservoir to maintain water quality;
- Minimize head losses;
- Minimize possibility of vortex formation; and
- Provide trash rakes.

A.4.5.10.3.2.3 Gates

- Designate one service gate for normal operation;
- Second gate for dewatering needs and firm capacity; and
- Provide emergency gate to allow maintenance of service gates.

A.4.5.10.3.2.4 Conduits

- Design for uniform flow– separate conduits for each gate; and
- Design to convey high velocity flow through the dam without hydraulic jump–channel sloped to maintain unpressurized (open-channel) flow.

A.4.5.10.3.2.5 Energy Dissipation

- Use hydraulic jump stilling basin (EM 1110-2-1603, Plate 7-11 or USBR standard).
- Provide transition channel with erosion protection to Perimeter Canal (5 fps > velocity > 1 fps).
- Discharge to Perimeter Canal with velocity <1 fps during 100-year event.

A.4.5.10.3.3 Description

Each outlet consists of an intake structure, gated conduits through the dam section, and stilling basins and channel leading to the perimeter canal. The design of each outlet is essentially identical with the exception of a 3-foot difference in the invert elevation. C43S-1 is set at 18 and C43S-8 is set at 21 NAVD88, approximately 1-foot above existing grades at each location.

The sizing of the main outlets considers both providing project flows to S-79 of up to 500 cfs, the flows required to manage Reservoir levels, and the flows required to draw the Reservoir down to minimum levels within 120 days (USACE ER1110-2-50). The Reservoir meets the requirements of USACE ER1110-2-50. The maximum outflow per cell is 500 cfs.

The intake structure is designed to provide the capability of drawing water from various levels within the Reservoir to maintain water quality. Elevation views show how water may be drawn from three levels within the Reservoir, the lower (for emptying the cell), the middle, and upper thirds. The design assumes that the gates at either the upper or middle levels will provide 500 cfs with flow velocities of 4 fps at the openings. The gates are to be fully opened or fully closed. Trash struts are provided at the entrances to the intake structure. The intake structure is sized and configured with converging walls toward conduits to minimize the possibility of vortices.

The intake structure discharges to two gated-conduits through the dam, one for normal operation (operational conduit) and the other for standby (secondary conduit). Flow exits the intake structure into an approximately 60-foot long, 10-foot wide by 6-foot high, conduit leading to a gatewell. The intake structure can be dewatered to allow for inspection of the structure and downstream conduit.

Each gatewell has two gates, one service gate for normal operation and one gate for emergency and maintenance purposes. The emergency gate will operate either fully closed or fully opened. The service gate can be set at various openings. A gate size of 5 feet W x 6 feet H allows for operation at typical release flows (up to 500 cfs) and conveys the necessary flows to manage the Reservoir level.

The service gate is a sluice gate with downstream seals. The emergency gate will have seals on the upstream side. Both gates will be operated by a screw hoist.

An air vent is located downstream of each gatewell to meet the air demand of the flowing water. The conduit downstream of the gatewell expands to 10 feet W x 7 feet H. The conduit width has been increased in order to reduce the stilling basin depth by decreasing the flow per unit width. A bottom slope of two percent is provided to maintain supercritical flow.

The flow exits from the conduit into an open channel chute leading to a stilling basin. The stilling basin is sized based on standard requirements. The maximum flow velocity exiting the stilling basin is about 5 fps at a discharge of 500 cfs at the normal Reservoir level. For maximum flow rates under the Reservoir levels of 42 and 46 NAVD88, the exit velocity is about 7 fps.

The transition channel between the stilling basin and the Perimeter Canal is sized to reduce flow velocities to less than 1 fps. The transition channel and a portion of the Perimeter Canal are lined to prevent erosion as the flow slows down and waves are reduced.

A.4.5.10.4 Cell Balancing Structure

A.4.5.10.4.1 Introduction

The Cell Balancing Structure, C43S-12, is located between Cells 1 and 2 of the Reservoir. The primary function of the structure is to convey water between the cells and allow the cells to operate independently if needed. If one of the cells needs to be dewatered for maintenance, C43S-12 may be closed to isolate the cells.

A.4.5.10.4.2 Hydraulic Design Criteria

- Provide multi-barreled conduit for redundancy;
- Size the conduit to convey half of the C43PS-1 pump capacity of 1500 cfs with approximately 1-foot of head across the center dam. This criterion was chosen so that the cells would operate at nearly the same level with the conduit open.
- Design conduit to operate in either direction;
- Gates will normally be fully opened or closed; and
- Use gate and conduit sizes similar to other project structures if possible to provide design, construction, and maintenance advantages.

A.4.5.10.4.3 Description

Three 6 foot x 10 foot barrels were selected for the design. The three-barreled conduit conveys 750 cfs between Cells 1 and 2 with approximate 1-foot of elevation difference (0.8 feet depending on the head loss coefficients selected). If one barrel of the structure is out of service the other two barrels will convey 750 cfs between the cells with approximately 1.8 feet of elevation difference.

The gate and conduit dimensions are the same as those designed for the main outlets (C43S-1 and C43S-8). The gates are 5-foot W x 6-foot H. Each barrel will have two gates to allow operation in either direction and provide redundancy.

Bell-mouth inlets to each barrel are designed to minimize intake losses. Trash rakes are provided to prevent large debris from entering the conduits.

Stilling basins are also provided at both ends of the barrels to dissipate energy. Each basin will be surrounded by riprap or revetment to prevent erosion. The critical period during the filling process is when one cell is empty, the other full, and energy to be dissipated is at its maximum. The most cost effective way to provide energy dissipation is to open the gates slowly until a nominal level is achieved in the cell (approximately 3-foot depth). At this level flow velocities at the sill of the stilling basin will be reduced to non-erosive rates.

The ends of the structure match the existing ground elevations in Cells 1 and 2, 21 and 22 NAVD 88, respectively. The resulting slight slope across the structure does not have a significant effect on the hydraulics. Predicted settlement of the dam does not significantly affect the hydraulics.

A.4.5.10.5 Crest Spillway Structures

A.4.5.10.5.1 Introduction

Each cell of the Reservoir has an uncontrolled crest spillway structure to manage flood flows. C43CS-1 is located on the west side of Cell 1 and discharges to the Townsend Canal. C43CS-2 is located just east of S-8 in the northwest corner of Cell 2 and discharges to the Perimeter Canal. The design objective of the crest spillway structures is to minimize the surcharge storage of the Reservoir without exceeding the Allowable Discharge in the receiving channel.

A.4.5.10.5.2 Hydraulic Design Criteria

- Use Corps of Engineer Engineering Manuals as appropriate;
- Design Criteria Memorandum (DCM) 2 and 3;
- Size spillways to convey Allowable Discharge (100-year, 72-hour storm and Inflow Design Flood [IDF] storm events) without exceeding pre-project flow downstream (DCM-2, DCM-3 and Federal Emergency Management Agency (FEMA) floodplain management requirements);
- Set crest elevation at normal Reservoir level (El. 42.0 feet);
- Allow for wind setup and wave run-up;
- Use hydraulic jump stilling basin, transition to Perimeter Canal similar to main outlets; and
- Use identical configuration for each cell to provide design, construction, and maintenance advantages.

A.4.5.10.5.3 Description

The spillway consists of a weir structure discharging to a conduit through the dam. Once through the dam the flow is conveyed to a stilling basin in an open channel chute, and then on to a transition channel to the Perimeter Canal. The crest portions of the spillways are identical. The downstream ends differ due to elevations of the receiving channels. C43CS-1 discharges to the Townsend Canal with a normal water elevation of 21 feet. C43CS-2 discharges to the north Perimeter Canal with a normal water elevation of 19 feet. For additional analysis please reference the technical memo titled "Technical Memorandum for Spillway Design."

A.4.5.10.5.4 Alternative Spillway Designs

Several configurations of spillways were investigated before the above design was selected. Three specific cases were prepared and modeled in detail as defined below (***Table A-12***). The service spillway is considered the spillway to pass flood events up to the 100-year event (Allowable Discharge). The auxiliary spillway passes floods in excess of the 100-year.

TABLE A-12: SPILLWAY INFORMATION

Case	Service Spillway	Auxiliary Spillway
I	Sized to pass 100-year	Large to pass IDF
II	Sized to pass antecedent PMP storm	Smaller than Case I
II	Minimized	Gated structure at sill 30 NAVD 88 (assuming backup power on site)

A.4.5.10.5.5 Summary of Findings

The findings of the modeling results of the above spillway configurations may be summarized as follows:

- The low-flow design of the spillways is controlled by the Allowable Discharge. The Allowable Discharge from the Reservoir for the 100-year, 72-hour storm is estimated to be 400 cfs (Cells 1 and 2 combined) based on the hydrologic modeling completed for the project;
- The critical storm for high flow spillway design is the 30 percent Probable Maximum Precipitation (PMP) event. The PMP storm events for the project include three, 3-day rainfalls events separated by several days with no rainfall (DCM-2, guidelines and criteria). The difference between the 30 percent PMP storm and the 40 percent PMP storm is the overall volume (~88 inches and ~99 inches) and the separation between the first two rains (3 days for the 30 percent and 5 days for the 40 percent). There is less time to draw down the Reservoir after the first rainfall during the 30 percent PMP, making it the critical design storm for high flows. The maximum discharge from the project for either PMP event is estimated to be 2600 cfs (Cells 1 and 2 combined) based on the hydrologic modeling completed for the project;
- Due to the large inflow from high intensity rainfall, it is not cost effective to use a large auxiliary spillway. The service and auxiliary spillways should be combined;
- Use small crest length. Large crest length does not cost effectively reduce surcharge storage or freeboard due to large inflow (high intensity rainfall); and

- Computations show that the Reservoir surcharge storage between 42 and 46 NAVD 88 is adequate for design.

Additional configurations using one spillway (combined service and auxiliary) were investigated to achieve the design objective. The simplest configuration being a number of conduits set at the normal pool level of 42 NAVD 88. It was found that ten 10 foot W x 4 foot H culverts would be needed to keep the maximum Cell 1 level at 46 without discharge from the main gated outlet of the cell. The peak discharge of approximately 3,500 cfs, however, exceeds the allowable of 2,000 cfs (one cell). Culverts and weirs were not found to be effective in minimizing surcharge storage due to the limited head range and allowable discharge. Weirs can pass significant flows at low heads, but exceed the Allowable Discharge.

Operation of gates during non-rain periods of the 30 percent PMP is more effective in minimizing the surcharge storage. C43S-1 and C43S-8 each have two gates. Each gate has a discharge capacity in excess of 600 cfs for reservoir levels above 42 feet NAVD (total capacity in excess of 2400 cfs). Opening these gates to discharge 2,000 cfs during the non-rain 3-day period after the first rainfall of the 30 percent PMP draws the Reservoir down to 42 before the main rainfall begins without considering spillway flow. Gate operation alone, however, cannot be relied on during extreme events.

C43CS-1 and C43CS-2 are designed to convey the Allowable Discharge as defined above. It is proposed that the main outlet gates (C43S-1 and C43S-8) be used to minimize surcharge storage. A gate operation policy is needed to manage overall project discharges and in order to keep releases less than pre-project levels. The documentation of pre-project discharges from the site for the 100-year and PMP events is important.

A.4.5.10.5.5.1 Options for a Combined Spillway

Two options for a combined spillway were investigated in further detail, the weir and conduit option and the multi-barrel conduit option.

A.4.5.10.5.5.2 Recommended Option

The recommended combined spillway option for C43CS-1 and C43CS-2 is the weir and conduit option. It is approximately half the cost of the multi-barrel conduit option and more efficiently conveys water through the dam and on to the Perimeter Canal. The weir controls flows up to the 100-year event and the conduit controls higher flows when the weir drowns out. The weir is effective in passing the maximum allowable flow during the 100-year event with limited fluctuation of the Reservoir level. The conduit works well in limiting high flows during the PMP storm event, keeping the flow less than pre-project conditions.

When used in conjunction with C43S-1 and C43S-8 (open during non-rain periods) the Reservoir surcharge storage is minimized.

The design of the downstream portion of the spillway as the flow exits from the conduit through the dam is very similar to the main outlet. An open channel chute leads to a stilling basin and transition channel then on to the Perimeter Canal. The stilling basins for C43CS-1 and C43CS-2 are sized differently due to the different tail-water levels in their respective locations.

A.5 EMBANKMENTS AND CANALS

A.5.1 General

This appendix presents a discussion of preliminary project design considerations and construction methods utilized to address the overall project requirements and to support development of the project cost estimate. Much of this discussion refers to the 30 percent project design prepared by Stanley Consultants, inc. for the SFWMD under the ACCELER8 Program.

A.5.2 Proposed Plan

The SAP (Alternative 3B) would require the construction of a two-cell 170,000 acre-foot above ground storage reservoir, a 1,500 cfs pumping station, and a selection of water control structures. The reservoir project site would consist of approximately 10,500 acres, not including lands required for temporary staging areas. See Plate A-1.

The project is bounded by property lines along the east, south and west sides and by the Southern Florida Power easement line along the north side. The existing Townsend Canal, located along the west perimeter of the Reservoir, would serve as the west Perimeter Canal. The existing spoil piles along the east side of the Townsend Canal would be removed as part of the project. Drainage improvements are proposed outside of the project boundary and would include new or replacement culverts in the header canal east of the project. Improvements to or the relocation of the existing weir structure located at the mouth of the Townsend canal are included. Work to that structure would be done within an existing drainage easement.

The Perimeter Canal would serve as a seepage canal and as a means of conveying both surface storm water runoff and off site flows entering the project. The Perimeter Canal design includes littoral shelves along the exterior slope that are intended to promote wetland vegetation, fisheries and recreation activities.

Refer to the Hydrology and Hydraulics Appendix of this report for a detailed discussion of the projects features and related hydraulic requirements.

A.5.3 Civil Site Work

A.5.3.1 Site Preparation

The entire reservoir project site including the proposed embankment alignments and/or canal excavations would be cleared and grubbed to a depth of approximately 8 inches or to a depth sufficient to remove roots and other organic material.

A.5.3.2 Site Access/Entrance Road

Access to the project area would be provided by the existing paved entrance road from SR 80. This access road would be maintained during construction but a new entrance road would be constructed after completion of the project to provide permanent access to the project area. Plan and profile drawings of the proposed alignment are shown on Plates A-5 through A-7. A typical section of the entrance road is provided on Plate A-8.

A.5.3.3 Townsend Canal Channel Improvements

The hydraulic design of the West Basin Storage Reservoir project has shown that for the maximum pumping and discharge flows the channel at the SR 80 Bridges will need to be improved. Plate A-9 shows the proposed channel improvements. These include widening the channel bottom elevation, as well as the addition of scour protection across the entire channel width to prevent scour that would be caused by the high frequency of these flows.

PILE BENT ANALYSIS

The bridge pile bents were analyzed to determine if they have sufficient capacity and stability with the lower channel bottom elevation. The piles were analyzed for lateral loadings at both Strength and Service limit states to determine their performance.

The analysis shows that lateral deflection at the Service limit state will control. The actual loads in the piles at Strength limit state are low, and are not close to the pile capacities.

The allowable lateral deflection was taken to be 1.5 inches from AASHTO Standard Specifications for Highway Bridges, 17th addition, Section 4.5.12. The computed lateral deflections are as follows:

- As-Designed Case, assuming 100-Year Scour-Lateral Deflection=0.55 inches.
- Proposed Case – Lateral Deflection = 1.32 inches.

CONCLUSIONS

The following are the conclusions that we draw from the design and analysis performed thus far for the Caloosahatchee River (C-43) West Basin Storage Reservoir project:

- The bridges carrying SR 80 over Townsend Canal do not have sufficient hydraulic capacity for the existing condition flows in the canal. The canal will need to be widened if the normal criteria are to be met.
- Proposed pumping requirements of the Caloosahatchee River (C-43) West Basin Storage Reservoir project would require minor improvements to the existing Townsend Canal channel.
- The impacts to the existing bridges of the proposed channel improvements are within acceptable limits.
- All canal improvements can be accommodated within existing right-of-way.

A.5.3.4 Disposal/Borrow

Disposal and material stockpile areas would be located within the project area.

A.5.4 Embankments

As generally reported in the C-43 WSR Preliminary Design Report, the perimeter embankment would have an external geometry that includes a 12-foot wide crest (14 foot Crest Width including the soil cement protection) and 3H:1V side slopes. Crest elevations have been established at +57 feet NAVD for Cell 1 and Cell 2, respectively. The embankment would be constructed largely of random fill, but would also include a low permeability soil-bentonite (SB) wall, an internal drain, and upstream slope protection. The SB wall would extend from an elevation 5 feet above the normal pool elevation to 5 feet below the top of a clay layer which underlies the project site at depths generally in the range of 10 feet to 25 feet below existing surface grades.

A few structures pass through the perimeter embankment. At these locations, the above ground portion of the SB wall would be replaced with select fill. In addition, a roughly 100-foot wide bench with a 24-foot access road would be constructed above the existing ground surface immediately downstream of the perimeter embankment. A Perimeter Canal would be located on the outside of the bench.

The Interior Dam between Cells 1 and 2 would be a homogenous embankment with a crest elevation of +51.4 feet NAVD. It would not include any SB wall or internal drain. The side slopes of the separator dam would be covered on both

sides with soil-cement. Typical Sections of the proposed embankments are provided on Plates C-2 through C-4.

The components of the embankments are described in more detail in the following paragraphs as they were presented in the "C-43 WBSR Preliminary Design Report" prepared by Stanley Consultants.

A.5.4.1 Random Fill

Random fill is to consist of reasonably well graded sands (ASTM D 2487) having a maximum size of 4 inches, placed in 12 inch thick (loose measure) horizontal lifts. Each lift is to be compacted to not less than 95 percent of the maximum dry density determined in accordance with Standard Proctor (ASTM D 698). The random fill materials are to be obtained from relatively shallow excavations on the interior side of the Reservoir. No borrow features are to be made within 200 feet of the upstream toe of the perimeter embankment. In areas where no structures exist, the perimeter embankment is to be filled to elevation +47 feet NAVD, at which time the SB wall will be constructed. Following the soil-bentonite (SB) wall construction, the remaining portions of the random fill will be placed and compacted.

A.5.4.2 Select Fill

Select fill is to be placed around structures that pass through the perimeter embankment. It is to consist of a sand-clay mixture with a maximum size of 2 inches and not less than 25 percent passing the US Standard No. 200 Sieve. Select fill shall have a Liquid Limit not less than 25, a Plasticity Index not less than 10, and a placement moisture content that is within 3 percent of the optimum moisture content for compaction. Select fill will likely be obtained by excavation from borrow areas and/or from the required seepage collection canal excavation. The excavated materials are to be mixed until the select fill material achieves a reasonably uniform moisture content and gradation. It is to be placed in 8 inch thick horizontal lifts and each lift is to be compacted to at least 95 percent of the maximum dry density determined in accordance with ASTM D 698.

Special care is required to assure that the select fill placed adjacent to the structures is compacted to high density. The select fill is to be placed within a horizontal distance of 100 feet on both sides of the structure walls. The above-ground portion of the SB wall will overlap at least 50 feet into the previously placed select fill materials.

A.5.4.3 Soil–Bentonite Wall

A soil-bentonite (SB) wall is to be constructed in order to provide a seepage barrier through the perimeter embankment. The bottom of the SB wall should extend to a depth that is at least 5 feet into the underlying clay layer. The SB wall is to be located approximately 10 feet upstream of the centerline of the perimeter embankment, and is to be 3 feet wide. Excavations for the soil-bentonite wall should be stabilized using bentonite slurry having a minimum density of 64 pounds per cubic foot.

Backfill for the slurry filled trench should consist of a mixture of bentonite slurry, soil and dry bentonite. The backfill should be thoroughly mixed into a homogeneous mass prior to placement. The backfill should meet the following criteria:

- Slump ranging from 4 to 6 inches
- Amount passing the U.S. Standard No. 200 Sieve ranging from 30 to 40 percent
- Density ranging from 85 to 110 pcf
- Permeability of not more than 1 x 10-7 cm/sec when measured in laboratory tests

The subsurface profiles indicate the presence of moderately well cemented limestone within the vertical interval of the SB wall. Equipment selected for excavation of the bentonite wall must be capable of excavation of such materials from an elevation that is 25 to 30 feet above the existing ground surface. A heavy hydraulic backhoe having a minimum breakout force of 44,000 pounds will be capable of excavating the rock formation. Blasting will not be permitted.

A.5.4.4 Drainage Blanket

The drainage blanket should consist of filter sand meeting the physical requirements of C-33 Concrete Sand. It is to be placed on the prepared foundation surface in the approximate downstream one-third of the perimeter embankment footprint. The perimeter embankment design includes a chimney drain that is composed of on-site clean sand and which is connected to the drainage blanket. Such on-site sands can be obtained from shallow excavations provided the materials contain not more than 3 percent passing the US Standard No. 200 Sieve. The C-33 Sand will need to be imported from an offsite source. The drainage blanket should also include a continuous perforated pipe (toe drain) located near the downstream toe of the embankment. The seepage flows to the toe drain will be routed to manholes with eventual outfall to the Perimeter Canal.

A.5.4.5 Soil Cement

The crest width and upstream portion of the perimeter embankment is to be covered with soil cement. This will consist of both flat plate (below the normal pool elevation) and stair-step (above the normal pool). Flat plate portions of the soil cement are to be 16 inches thick. The stair-steps will be 12 inches high and have a 3-foot wide tread. The design cement content is 11 percent by weight and the required minimum density of the soil cement mixture is 95 percent of the maximum density determined in accordance with ASTM D 558. The soil cement is to have a minimum unconfined compressive strength of 700 psi at 7 days.

Flat plate soil cement will cover the crest and slopes of the interior dam between Cells 1 and 2.

A.5.4.6 Bench

Filling of the bench area should consist of random fill placement, similar to that described earlier in this section, but may include materials up to a maximum size of 12 inches. Lift thickness for the bench material placement should be not more than 2 feet. The bench fill should be compacted to at least 90 percent of maximum density (ASTM D 698).

A.5.4.7 Seeding and Sodding

Seeding and sodding would be provided throughout the project area as required to adequately protect side slopes and other unstabilized areas from erosion. Other bank protection methods are currently being evaluated as a more economical alternative to sodding.

A.5.5 Relocations

The project sponsor would be required to assume the costs for all relocations and alterations. The alternative plan presented in this report would require relocation of utilities to provide electrical and water service to the proposed pump stations. The estimated costs for this relocation are included in the project cost estimate. Refer to the Electrical Section of this appendix for individual site requirements.

A.5.6 Operations and Maintenance

A.5.6.1 General

The project sponsor would be responsible for operation and maintenance of the improvements and features proposed in this report upon completion of the construction project. The Contractor would be responsible for all maintenance during the construction contract.

A.5.6.2 Inspection

Joint field inspections with personnel from the U.S. Army Corps of Engineers and the local sponsor would be conducted on a regular basis to evaluate the performance and condition of the various project features. Additional field inspections would be conducted following a significant storm event.

A.5.6.3 Estimated Annual Costs

The estimated annual operation and maintenance cost for the project would be approximately $3,100,000. This is based on projected estimate of costs for operation and general maintenance of the pump stations including periodic replacement of operating equipment. This cost also includes maintenance of the embankments, entrance road, perimeter ditches and other project features.

A.5.6.4 O&M Manual

Operation and maintenance of the project facilities would be performed in accordance with instructions prepared and incorporated in the "Operation and Maintenance Manual" which would be furnished to the project sponsor. The O&M Manual would be prepared in accordance with ER 1110-2-401.

A.5.7 Quantities and Cost Estimates

A 30 percent Preliminary Design Level Cost Estimate was developed for the project by Stanley Consultants for the South Florida Water Management District's Acceler8 program. This cost estimate was reviewed by Jacksonville District and used as the basis for the direct costs in the preparation of the plan formulation cost estimates and of the MCACES cost estimate used in the Draft PIR. For this reason the MCACES cost estimate for the Draft PIR show User Created Cost items in lieu of the traditional Labor, Materials and Equipment breakdown. The Labor, Materials and Equipment breakdown is found in Stanley Consultants cost estimate. The 30 percent cost estimate was prepared by Stanley Consultants using MCACES Gold 5.31 software. It is dated 31 May 2006. R.S. Means' 2006 database adjusted by the Engineering News Record index was used as the basis for Stanley Consultants' crew based estimate. Vendors and equipment manufacturers were contacted by Stanley Consultants to confirm costs for specific items. Certain mechanical equipment was estimated using the Richardson (2004) guides as the database. Labor rates used in the 30 percent design cost estimate are the Davis Bacon Union Shop Labor Rates for Fort Myers, Florida

First, the cost estimates in the Draft PIR were prepared by transcribing the direct costs from the Acceler8 contractor's estimate to the MII software. Markups and contractor/subcontractor structure consistent with Jacksonville

District practices/conventions/history were added. A printout was made of the total project costs including unit pricing. Then, the unit pricing was used to prepare the plan formulation cost estimates. Finally, the Total Project Cost Summary for the selected plan in the Final PIR was prepared using the estimate from the Draft PIR as its basis. See Appendix B for presentation of project costs.

A.6 MECHANICAL AND ELECTRICAL DESIGN

A.6.1 Mechanical Design

A.6.1.1 Pump Station General Information and Size Criteria

The two pump stations for the Caloosahatchee River (C-43) West Basin Storage Reservoir project are significantly different in size and complexity. For the purposes of this report, the stations shall be differentiated as small-sized and large-sized. The small-sized pump station (PS-4) has a total pumping capacity of less than 250 cfs and includes no pumps that have a capacity of more than 75 cfs each. The large-sized pump station (PS-1) is defined as having at least one pump with a capacity greater than 450 cfs. The large horsepower requirements for the engines also indicate that this is a large pump station. The two pump stations shall be designed in accordance with Hydraulic Institute Standards, EM 1110-2-3102 (General Principles of Pumping Station Design and Layout), and EM 1110-2-3105 (Mechanical and Electrical Design of Pumping Stations). The small pump station will also follow the guidance of ETL 1110-2-313 (Hydraulic Design Guidance for Rectangular Sumps of Small Pumping Stations with Vertical Pumps and Ponded Approaches). The use of formed suction intakes and siphon discharges for the pumps at PS-1 shall be evaluated during preparation of the plans and specifications for the pumping station, and shall be based upon the channel intake design, the required pumping heads, and life cycle cost analysis.

Vertical, mixed flow pumps will be used for PS-1. Either vertical, mixed flow pumps in separate rectangular pump bays or can (also known as barrel) pumps with the vertical pumps mounted in an enclosed container will be used for PS-4. All of the pumps for both stations will be water-lubricated. The smaller pump station will be designed with conventional-discharge pumps. The larger pump station will be designed with the pumps configured with a siphon-type discharge. Pump station information is located on ***Table A-13,*** C-43 Pump Station Information. Plates M-1 and M-2 show plan and section views of a typical large-sized pump station that includes an FSI and a siphon discharge. (Note: In accordance with Florida Statute 119.07(6)(ee), only limited [conceptual drawings have been provided for this report. See Section A. 7 *Caloosahatchee River (C-43) West Basin Storage Reservoir Structures* below for more information.

TABLE A-13: CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR PUMP STATION INFORMATION

Pump Station	Total Flow Capacity (Cfs)	No. Of Pumps	Type Of Pumps	Flow Rate (Cfs)	Intake, Ngvd Min. Drawdown Pumping Level	Discharge, Ngvd Max. Discharge Pumping Level	Total Head	Pump Selection (In.)	Min. Efficiency %	Drive H.P.	Discharge Type	Station Size
PS-1	1500	2	Diesel	500	-3.0	42.0	48.1	84	80	3600	Siphon	Large
		2	Diesel	250	-3.0	42.0	47.7	60	80	1800		
PS-4	195	3	Electric	65	-3.0	27.4	36.9	36	80	375	Conventional	Small

A.6.1.2 Pump Station PS-1

The PS-1 pump station will be configured similar to that shown on Plates M-1 and M-2. This large-sized pump station will have the following features:

A.6.1.2.1 Pumps: Pumping Capacity, Pump Sizes, and General Information

The large-sized pumping station will have four pumping systems. The pumps in each of the stations will be mixed-flow-type vertical-shaft pumps. Power to the pumps will be provided by diesel engines through right angle reduction gear drives. ***Table A-13*** lists the number of pumps, the capacities of the pumps, the drives, etc., for this (and the smaller) pump station.

Plates M-1 and M-2 represent a four-bay pumping station, similar to the four-bay PS-1. The pumps at this pump station are expected to run at less than 400 rpm with a minimum efficiency of 80%. Because of the large pumping heads, the diesel engine pump drives will be very large. The diesel engine pump drives for the 500-cfs pumps should be about 3600 horsepower each, while the engines for the 250-cfs pumps should be about 1800 horsepower each.

The large-sized pumping station will include various support items including the following:

1. Diesel fuel system, including vaulted double-wall aboveground fuel storage tanks ASTs capable of holding enough fuel to operate all of the engine driven pumps and the emergency generator continuously for 7 days. About 95,000 gallons of storage capacity will need to be available at the site. This will comprise between five and eight ASTs, depending on the type of tank that is specified. Day tanks shall be provided and sized to supply adequately the diesel engine pump drives and generator within the limitations of NFPA 37. The Florida Administrative Code (FAC) shall be followed in designing the fuel system for the pumping station.

2. An overhead bridge- type electric crane/hoist will be used. The crane/hoist shall be capable of lifting and moving loads up to the heaviest loads in the pumping station. The crane/hoist will handle pumping station equipment such as the diesel engine pump drives, reduction gears, and the pumps during initial installation as well as for general service thereafter.

3. Toilet facility with a water closet, lavatory, and a shower. An electric-powered domestic water heater will also be provided. All plumbing systems will be designed in accordance with the International Plumbing Code.

4. Kitchen-type sink.

5. Potable water system and a septic system for the plumbing fixtures. The water source will likely be an on-site well. The system will consist of a well pump, water softener, reverse osmosis treatment system, storage tank, distribution pump, pressure tank, and ultraviolet disinfection system. The water well will be designed in accordance with EPA 570/9-75/001, the Manual of Water Well Construction Practices, and the septic system shall be in accordance with Florida Department of Health (FDOH) FAC Chapter 64E-6 (2006) Standards of Onsite Sewage Treatment and Disposal Systems.

6. Ventilation system to provide fresh air in the pump bays, generator area, and toilet room. The ventilation systems will achieve an operating floor design temperature inside the station of 100°F based upon an outdoor temperature of 93°F dry bulb (1% for Ft. Myers). The ventilation air will need to dissipate the heat from the pumping equipment, lights, generator, etc. located in the pump station, along with providing air for combustion for the diesel engines and generator.

7. Air-conditioning system for the office. The office will be mechanically cooled to a design temperature of 75 degrees F. The room will be served by a dedicated, DX split system. ASHRAE Guide and Data Books will be used in the design of the office air-conditioning system

8. Stilling wells containing float switches to be used for pump operations and water level monitoring.

9. Controls systems for the engine/motor pump drives. These systems shall be as described in the Electrical Design section.

10. During the detailed design, the designer shall coordinate with local and State authorities to ensure that the various permits (air, fuel, etc.) are all adequately addressed.

The pumps for this pump station may be designed with Formed Suction Intakes (FSI) and may include siphon discharges. A representative section of a pump station with an FSI and a siphon discharge is shown on Plate M-2. FSIs have been shown to be more efficient than typical suction bell intakes, but the design decision on whether to use them will be based on comparing increased construction costs with potential efficiency savings over the life of the project.

In order to reduce the engine size, horsepower, and fuel required to overcome the head on the pumps, siphoning discharge systems may be used. If a siphon discharge system is used, priming would be accomplished by means of a station vacuum system. The vacuum system provides vacuum to prime the siphon in the discharge pipes. Four vacuum pumps are provided: two duty, and two standby. Under normal operation, two vacuum pumps are required to establish the siphon for one discharge pipe. The siphons must be established one at a time. The system includes vacuum pumps, a barometric separator, valves, and piping. Again, the design decision on whether to use siphon discharges for the pumps in the pumping stations will be based on comparing potential savings on the cost of the diesel engine pump drives and the lower fuel requirements with the increased construction costs over the life-cycle of the pumping station. Note that if the siphon discharge is used, each pump discharge tube will be provided with twin vertical-lift type backflow gates, as shown on Plate M-2, with relief flaps located at the siphon terminus. The gates are needed to prevent the possibility of reverse siphoning and backflow due to incomplete breaking of the prime during pump shut down. Each gate will be raised and lowered by a single screw stem with a Limitorque type electric motor operator controlled from within the station.

For discharge pipes that will be below high water levels, a second means of preventing backflow will also be incorporated. The discharge pipes will have their upper invert elevation (summit) above the high water level on the discharge side. The siphon would then self-break. During design development the discharge arrangement will be selected based on a life cycle cost analysis of the operational and construction costs.

A custom engineered trash rake will be provided for the removal of trash accumulated on the trash rack and its conveyance to a disposal area. There are a wide variety of systems available, unique in their design and operation. For this size facility, either a front cleaning scraper bar type trash rake will be used, or a monorail traveling gripper rake will be used. The rakes will collect and remove coarse solids from the trash rack. The rake shall be a single piece of

equipment capable of automatic or manual raking of each bar screen and transporting debris to a designated dump site. The equipment may be supplied independently or in combination with the rack. The unit shall be capable of operating effectively in high wind. The rake equipment shall be designed to withstand sustained wind speeds up to 155 mph without structural damage.

A.6.1.3 Pump Station PS-4

Pump Station PS-4 will have three pumping systems. The pumps will be mixed-flow-type vertical-shaft pumps that will be located in separate rectangular pump bays or can (also known as barrel) pumps with the vertical pumps mounted in an enclosed container. Power to the pumps will be provided by direct-drive electric motors. ***Table A-13*** lists the number of pumps, the capacities of the pumps, the drives, etc., for PS-4.

This small-sized pump station will include pumps that are expected to run at no less than 600 rpm with an efficiency of about 80%. The pump drives should be about 375 horsepower each.

This small-sized pump station will include various support items including the following:

1. Hoisting system for maintenance or repair of the pumping equipment. At a minimum, the hoisting system will be designed to lift the heaviest piece of equipment in the pump station.

2. Ventilation system to provide fresh air in the pump bays and generator area. The ventilation systems will achieve an operating floor design temperature inside the station of 100°F based upon an outdoor temperature of 93°F dry bulb (1% for Ft. Myers). The ventilation air will need to dissipate the heat from the pumping equipment, lights, generator, etc. located in the pump station, along with providing air for combustion for the generator.

3. Stilling wells containing float switches to be used for pump operations and water level monitoring.

4. Trash rake/rack system will be an automatic, continuously rolling, flex rake and trash rack system such as that manufactured by Duperon.

5. An LP-gas emergency generator to supply power for backup emergency power for the general building service only during commercial power outages. This will include providing power for the lights and ventilation fans. Since the pumps in PS-4 are for water supply, the reliability requirements for flood control pump stations do not apply. Therefore, the

pumps will not need to be operated when commercial power is unavailable.

6. The LP-gas shall be stored in an underground storage tank 20 feet from the exterior wall of the building.

7. Controls systems for the motor pump drives. These systems shall be as described in the Electrical Design section.

8. During the detailed design, the designer shall coordinate with local and state authorities to ensure that the various permits (air, fuel, etc.) are all adequately addressed.

A.6.1.4 Gates

A.6.1.4.1 Sluice Gates

Sluice gates are cast iron gates, used in critical locations at structures S-1, S-8, and S-12. The gates are operated by a rising stem with electric motor actuators. The thrust required to open and close the gates are borne by the actuator and operating deck. The gate stems are laterally supported by guides along the length of the stem. The gates are flange mounted to the concrete structures.

A.6.1.4.2 Roller Gates

Roller gates are fabricated stainless steel gates located at structures S-10 and S-11. The gates are bottom opening and typical of the kind in use at many SFWMD gate structures. Rollers (wheels) are used to reduce the thrust required to open the gates. The rollers are run along a rail recessed in the concrete walls of the structure. The gates are raised and lowered with a cable and hoist system. Plate M-3 shows a representative spillway vertical lift gate arrangement.

A.6.1.4.3 Slide Gates

Slide gates are fabricated stainless steel gates located at structures S-1, S-3, S-7, S-8, S-9, S-14, and S-15. The gates are bottom opening with a rising stem and are operated with electric motor actuators. The thrust required to open and close the gates are borne by the actuator and operating deck. Long stems are laterally supported by guides attached to the concrete wall along the length of the stem. The gates are flange mounted to the concrete structures.

A.6.1.4.4 Weir Gates

Weir gates are fabricated stainless steel gates located at structures S-3, S-7, S-9, S-10, S-11, and S-15. The gates are downward opening and are operated by a rising stem with electric motor actuators. The thrust required to open and close the gates are borne by the actuator and operating deck. The gates are flange mounted to the concrete structures. Water flows over the top of the gate through an open panel. The open panel provides open flow area without placing the stem in the stream of water.

A.6.2 Electrical Design

A.6.2.1 Pumping Stations

A.6.2.1.1 General

A.6.2.1.1.1 Design Standards

Pump Stations and other structures shall be in accordance with NEC, NFPA, IESNA, TIA/IEA, IEEE, SFWMD standards, and recommended practice.

A.6.2.1.1.2 Power Service

A 480 Volt, three phase, electrical service shall be provided by the local utility company. 480 Volt, three phase engine-generator units shall be provided to supply necessary electrical power for pumping station operations. Transient Voltage Surge Suppression (TVSS) shall be provided at the service entrance.

A.6.2.1.1.3 Grounding

Pump station main grounding will include a grounding grid consisting of ground rods and #4/0 ground wire which will be bonded to the embedded metallic masses, sheet pile, and structural steel. Frames or enclosures of electrical equipment will be bonded to the grounding system. Ground conductor will be bare, soft annealed copper cables and ground rods would be of copper clad type, 3/4 inch in diameter by 8 feet long.

A.6.2.1.1.4 Lighting

High intensity discharge, industrial high bay luminaries will be used for the main pump station area with industrial fluorescent fixtures with electronic ballasts for office and general type areas. Exterior lighting for security purposes would be automatically controlled by photo-electric cells and contactors.

A.6.2.1.1.5 Wiring

Insulated copper conductors will generally be installed in either PVC coated rigid galvanized steel conduit or schedule 40 rigid plastic conduit. Conductors will be rated for 600 volt insulated types RHW, THW, THWN, or XHHW. All wiring will conform to UFGS Guide Specifications. Conductors will all be copper. Aluminum conductors will not be used.

A.6.2.1.1.6 Lightning Protection

A roof mounted lightning protection system shall be installed. The system shall consist of interconnected air terminals with ground conductors to connect to the station grounding grid. Conductors shall be stranded.

A.6.2.1.1.7 Backup Generators and Automatic Transfer Switches

Backup generators and automatic transfer switches shall be sized sufficiently to power diesel engine auxiliaries, trash rakes, exhaust fans, lights and SCADA equipment.

A.6.2.1.1.8 Stilling Wells and Water Level Sensors

The latest SFWMD standards for stilling wells and water level sensors shall be used. The water level sensors are sole source items.

A.6.2.1.2 Large Pump Station C43PS-1

A.6.2.1.2.1 Service

A single line diagram is shown on Plate E-01. A Station Motor Control Center single line diagram is shown on Plate E-02. The Engine Control Center Single Line Diagram is shown on Plate E-03. The Engine Control Center and Schedule are shown on Plate E-04. The Engine Pump Control Diagram is shown on Plate E-05. The SCADA System Diagram is shown on Plate E-06.

A.6.2.1.2.2 Equipment

Switchgear rated for 480 volt, three phase with a main breaker will be connected to the incoming service and would feed engine control centers and station equipment. Each engine control center will house starters and controls for auxiliary equipment for respective engine unit. Main switchboard would also feed a small transformer to supply 120/208 volts for small loads.

A.6.2.1.2.3 Controls

Each large pumping station shall have a centralized monitoring and control room. Each diesel engine for pumps will have a separate motor control center to supply power and house controls for engine auxiliaries, such as jacket water pump, engine lube pump, fuel filter pump, etc. as shown on Plate E-09. Diesel engines will also be equipped with a separate instrument panel and will house engine start/stop controls, pressure and temperature indicators to indicate engine performance. The diesel engine manufacturer will be required to submit a one-line diagram and control schematics for engines driving the pumps.

A.6.2.1.3 Small Pumping Station C43PS-4

A.6.2.1.3.1 Service

A single line diagram is shown on Plate E-07. The electric motor controls are shown on Plate E-08. The SCADA System Diagram is shown on Plate E-09.

A.6.2.1.3.2 Equipment

A motor control center (MCC) rated for 480 volt, three phase with a main breaker would be connected to the incoming service and would feed electric motors and station equipment. The MCC would also feed a small transformer to supply 120/208 volts for small loads. An ATS would provide backup power for the station.

A.6.2.1.3.3 Controls

Electric motor driven pumps shall be controlled from the MCC. Diesel engines will be equipped with a separate instrument panel, which will house engine start/stop controls, and pressure and temperature indicators to indicate engine performance. The diesel engine manufacturer will be required to submit a one-line diagram and control schematics for engines driving the pumps.

A.6.2.2 Other Structures

A.6.2.2.1 Spillways and Gated Culvert

A.6.2.2.1.1 General

A single line diagram is shown on Plate E-10.

A.6.2.2.1.2 Power Service

A 120/240 volt single phase or 208Y/120 volt, three phase, electrical service shall be provided by the local utility company. A 120/240 volt single phase or

208Y/120 volt, three phase engine-generator unit shall be provided to supply necessary electrical power for gate operations. Transient Voltage Surge Suppression (TVSS) shall be provided at the service entrance.

A.6.2.2.1.3 Grounding

Structure main grounding will include a grounding loop consisting of ground rods and #4/0 ground wire which will be bonded to the embedded metallic masses, sheet pile, and structural steel. Frames or enclosures of electrical equipment will be bonded to the grounding system. Ground conductor will be bare, soft annealed copper cables and ground rods would be of copper clad type, 3/4 inch in diameter by 8 feet long.

A.6.2.2.1.4 Lighting

Industrial fluorescent fixtures with electronic ballasts will provide interior lighting. Exterior lighting for security purposes would be automatically controlled by photo-electric cells and contactors.

A.6.2.2.1.5 Wiring

Insulated copper conductors will generally be installed in either PVC coated rigid galvanized steel conduit or schedule 40 rigid plastic conduit. Conductors will be rated for 600 volt insulated types RHW, THW, THWN, or XHHW. All wiring will conform to UFGS Guide Specifications. Conductors will all be copper. Aluminum conductors will not be used.

A.6.2.2.1.6 Backup Generators and Automatic Transfer Switches

Backup generators and automatic transfer switches shall be sized sufficiently to carry the load required.

A.6.2.2.1.7 Stilling Wells and Water Level Sensors

The latest SFWMD standards for stilling wells and water level sensors shall be used. The water level sensors are sole source items.

A.6.2.2.1.8 Power Distribution

A control center will be connected to the load side of the automatic transfer switch and will house a main breaker, combination starter for the gate motor, lighting panel, relay compartment, and a circuit for exterior lighting.

A.6.2.2.1.9 Gate and Motor Controls

Duplicate open-close push button stations in the control house and at the spillway structure would be provided for manual gate control. Necessary open, close, automatic control relays, and limit switches would be incorporated in the gate control circuit. A time delay relay will provide a 5-second energization delay to a dumping solenoid valve to permit unloaded start of the hydraulic power unit motor. Power and control circuits for water level recorders and gate position recorders will be provided.

A.6.2.3 Instrumentation Design

A.6.2.3.1 General

The remote automation components installed at the pump station and other structures are the remote terminal unit (RTU) and communication channel to the SFWMD control center. The automation components of all pump stations and structures that will eventually be operated and maintained by SFWMD must conform to SFWMD standards in order to (1) achieve cost efficiency in design, construction, operation and maintenance (2) meet safety, reliability, and performance requirements during routine and emergency operations. The automation components are broadly defined to include hardware, software, communications and user interface elements.

A.6.2.3.2 Reservoir Levels

Water levels in the reservoir cells will be monitored. Solar panels with battery powered storage capabilities will be used in locations that are not near a structure.

A.6.2.3.3 Large Pump Stations

Programmable logic controllers (PLCs) will be used to monitor and control the engines and station auxiliaries. An Ethernet network will connect the PLCs and station computer. Ethernet based IP cameras will also connect to the Ethernet network. The station computer will allow for operation of the station via Telvent HMI SCADA software. The station could also be remotely operated from a central command and control center using the Telvent software.

A.6.2.3.4 Small Pump Stations

A Motorola ACE3600 RTU will provide SCADA capabilities by allowing the station to be remotely operated. Local operation will be accomplished via a Graphical User Interface and local controls.

A.6.2.3.5 Water Control Structures

The RTU at each site requiring remote automation shall be the SFWMD standard Motorola ACE3600 system. RTU software shall be in accordance with the SFWMD standard load set.

A.6.2.3.6 Network Requirements

There are several possible options for network communications: VHF, UHF, or spread spectrum. It may also be desirable to provide a high bandwidth redundant microwave Ethernet bridge to connect the SFWMD backbone to the C43PS-1 station. Decisions about final network configuration and interface with the existing SFWMD control system will be made in conjunction with SFWMD at a later stage in the project.

A.6.2.3.7 Implementation and Construction

The construction plans will contain plans for the hardware components of the telemetry system. SFWMD has a basic interface program that will be loaded as the structures are completed. The contractor would then edit the basic program for the specific structure.

A.6.2.3.8 Operation and Maintenance

SFWMD will operate and maintain the telemetry network.

A.7 CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR STRUCTURES

A.7.1 C43PS-1 - 1500 cfs Pump Station

A.7.1.1 General Description

Florida Statute 119.07(6)(ee) states "Building Plans, blueprints, schematic drawings, and diagrams, including draft, preliminary and final formats, which depict the internal layout and structural elements of a building, ...or structure owned or operated by an agency are exempt from public record". Because this Final PIR report will be distributed for public record, limited (conceptual) structural drawings for only the large pump station and embankments are provided in this report. Any agency or reviewing authority, as permitted under the FL Statute, can request additional structural details as necessary to perform their respective review requirements. All structures proposed for this project are described in written detail as follows.

Pump Station C43PS-1 will consist of a 1,500 cfs pump station 252 feet long and 84 feet wide with intake located on the Townsend Canal and an over-the

embankment arrangement for discharge to the Reservoir. The facility will house four main pumps. Two pumps will be 500 cfs capacity each, and two will be 250 cfs capacity each. The pump station building will consist of an operating floor at elevation 25.0 feet NAVD for the placement of most pump station machinery and a two-story steel structure above elevation 25.0 feet NAVD housing the control room, break room and workshop. A 60-ton overhead bridge crane with a hook height approximately 25 feet above the operating floor will be provided to facilitate the maintenance of pump station equipment. The selection of a 60-ton capacity crane is based on the anticipated weight of one 500 cfs pump.

A 3 foot thick pipe gallery floor at elevation 10.0 feet NAVD will be provided below the operating floor and will be used to route piping and conduits across the pump station. This level will also be used to house the auxiliary pump systems, water treatment systems and collection tanks for waste fuel and waste oil. Access for the installation and removal of equipment at the pipe gallery level will be provided by means of a 10 foot x 10 foot opening through the operating floor. Personnel access to the pipe gallery level from the operating floor will be provided by means of stairs located adjacent to the opening to the pipe gallery. Ladders, stairs and access ways on the operating floor will be provided at other locations across the station.

A.7.1.2 Substructure

The in-situ soils in the area of the pump station consist mainly of clean sands, clayey sands and/or silty sands over approximately 20 feet of clay on top of clayey sands.

The substructure of the pump station will consist of cast-in-place reinforced concrete walls supported on mat foundations. The substructure will be constructed with a formed suction intake (FSI) for each main pump bay. The main pumps will be supported on the pipe gallery floor on supports to be provided per pump manufacturer's recommendations.

A.7.1.3 Superstructure

The superstructure consists of a steel frame building with wide flange steel columns and steel roof trusses supported on the operating floor of the pumping station. The roof will be made up of cast-in-place concrete slab on metal deck supported by steel roof purlins. Purlins will be supported on 82 foot span, 7 foot deep steel trusses on 18 foot spacing. Trusses are supported on wide flange steel columns spaced at 18 foot centers. The roofing system will consist of fully-adhered EPDM roofing applied to the concrete roof deck. Eight inch thick precast concrete wall panels form the exterior wall cladding system. Steel girts spanning horizontally between the steel columns provide the support for the wall panels. The bridge crane runways will be supported on steel haunches welded to

the flange of steel columns. The 25 foot hook height will be adequate to operate the crane hook for lifting, lowering or moving the machinery.

A.7.1.4 Siphon Break and Saxophone Discharge Structures

To facilitate the over-the-embankment arrangement, four siphon break structures and four saxophone discharge structures will be constructed. One set of structures will be constructed for each discharge pipe. Each cast-in-place concrete siphon break structure measuring 18 feet x 96 feet will be provided where the discharge pipes cross the top of the dam embankment, and will be designed per AASHTO and FDOT Standards to permit the passage of vehicular traffic over the discharge pipes. The structures will consist of base slabs, wing walls and vaults with access manholes. The structures will be designed to be water tight.

The saxophone discharge structures, each 28 feet x 76 feet, will consist of sheet pile cofferdams with tremie concrete seals to allow for dewatering the excavations required for the installation of the steel saxophone discharge pipes. Concrete thrust blocks will be poured around each discharge pipe prior to backfilling the remaining excavation. A cast-in-place concrete cap will be constructed on top of the sheet pile on three sides to create a sharp crested weir. The fourth side will be enclosed by the dam embankment. The purpose of the sharp crested weir structure is to ensure that the discharge pipes are submerged to the minimum elevation required by the hydraulic design of the pump station.

A.7.1.5 Service Bridge

An 18.0 foot wide cast-in-place concrete Service Bridge will be provided at the suction basin of the pump station on the north side. The bridge will be used to provide vehicular access from one side of the pump station to the other, and for positioning truck cranes during the installation and removal of stop logs. The bridge will be designed as a one-lane multiple span deck, supported on suction basin walls. The deck will be fixed at an interior wall, and will be free to expand at other walls.

A.7.1.6 Trash Screen Bridge

Trash screens and rakes for the pump station will be located on a pile-supported bridge structure located on the north side of the pump station.

A.7.1.7 Fuel Oil Containment

Fuel oil supply and waste fuel and oil storage tanks will be located within a cast-in-place concrete containment structure at one end of the pump station. The

containment will be designed to accommodate the volume of the largest fuel storage tank.

A.7.1.8 Stoplogs

One set of stoplogs will be stored at the station to allow for dewatering one bay of the pump station for maintenance. The stoplogs will be designed as steel panels extending vertically from the bottom of the suction bay to the top of the suction bay walls. The stoplogs will slide down recesses cast into the suction basin walls and training piers. The panels will consist of steel plate with channel stiffeners, lifting eyes and a perimeter neoprene gasket. All steel panels will be hot-dipped galvanized.

A.7.1.9 Design Load Criteria

A.7.1.9.1 Live Loads

The following live loads will be the basis for design (***Table A-14***):

TABLE A-14: ALLOWABLE LIVE LOADS

Occupancy or Use	Live Load
Roof	50 psf
Floors	250 psf
Operating Floor (non equipment areas)	250 psf*
Operating Floor (equipment placement areas)	100
Control Room	100
Restrooms	100
Equipment Storage Rooms	200
Maintenance Work Area	300
Stairways	100
Elevator Lift	200
Deck Grating	250
Service Bridge	HS-20**
Guardrails	50 lb/ft and 220 lb concentrated load

* Equipment placement areas will be designed to support the weight of the heaviest piece of machinery anticipated.
** Service bridge design will also consider current SFWMD truck crane equipment loadings.

A.7.1.9.2 Wind Loads

The design wind loading for the structure will be in accordance with the Florida Building Code, and ASCE 7:

Wind Speed: 120 mph (3 second gust)
Exposure C
Iw = 1.3

A mean recurrence interval (MRI) of 200 years will be used in place of the standard 50 year MRI. A factor of 1.14 will be applied to the code wind pressure values to upgrade to the 200 year MRI values.

A.7.1.9.3 Crane Loads

Bridge crane wheel loading will be treated as live load for the crane runway design. The design of the runway will consider impact loads equal to 18% of the crane load, longitudinal loads equal to 10% of the crane load, and lateral loads equal to 20% of the sum of the rated capacity of the crane and the weight of the hoist and trolley.

A.7.1.9.4 Hydrostatic Uplift Loads

Hydrostatic uplift forces will be determined in accordance with procedures described in U.S. Army Corps of Engineers, Engineering Manual (EM) 1110-2-3104, "Structural and Architectural Design of Pumping Stations." Hydrostatic uplift forces will be considered when evaluating the stability of the structure from overturning, sliding, uplift and foundation bearing. The following recommendations were given for preliminary design (all elevations refer to NAVD 88) (***Table A-15***):

Reservoir Level–Elevation 42.0 feet
Toe of Dam–Elevation 20.0 feet (bench at dam toe was modeled, with a transition to Elevation 16.0 feet away from toe)

TABLE A-15: RECOMMENDED HYDRAULIC GRADE LINE

Lagoon Level – EL 0.0	
Location	Hydraulic Grade Line Elevation
Dam Side of PS-1	+8.3
Lagoon Side of PS-1	+8.0
Lagoon Level – EL 8.0	
Location	Hydraulic Grade Line Elevation
Dam Side of PS-1	+13.9
Lagoon Side of PS-1	+13.7

Groundwater levels near PS-1:
Groundwater Level @ Toe of Dam–Elevation 12.9 feet
Groundwater Level @ Intake–Elevation 12.6 feet
Groundwater Level of 13.0 was assumed for preliminary design purposes.

A.7.1.9.5 Soil Lateral Loading Criteria

All substructures and retaining walls will be designed to resist lateral soil loadings. ***Table A-16*** summarizes the design criteria presented in the Preliminary Geotechnical Memo for the design of sheet pile retaining walls at this pump station.

TABLE A-16: SOIL LATERAL LOADING CRITERIA

Depth (feet)	Unit Weight (pcf)		ϕ Degrees	δ Degrees	C (psf)	Coefficient of Lateral Earth Pressure			k (pci)
	Moist	Buoyant				Ka	Ko	Kp	
0-20	110	60	30	18	0	0.33	0.50	3.00	25
20-40	100	43	0	0	1000	1.00	1.00	1.00	500
40-100	120	65	34	20	0	0.28	0.44	3.54	125

Notes: ϕ - angle of internal friction (degrees)
δ - angle of wall friction (degrees)
C - cohesion
Ka - coefficient of active lateral earth pressure
Ko - coefficient of at-rest lateral earth pressure
Kp - coefficient of passive lateral earth pressure
k - modulus of horizontal subgrade reaction
Depth refers to existing land surface grade

A.7.1.10 Materials

Structural Steel:
W shapes: ASTM A992/A992M, Grade 50.
C, MC and S shapes: ASTM A36/A36M.
L shapes: ASTM A36/A36M.
Plates: ASTM A36/A36M.
Structural square and rectangular tubing: ASTM A500, Grade B.
Structural pipes: ASTM A53/A53M, Grade B.
Round HSS: ASTM A500, Grade B.
High-strength bolts: ASTM A325/A325M, Types 1 or 3.
Standard bolts: ASTM A307.
Anchor bolts: ASTM F1554, Grade 36.
Sheet Pile: ASTM A572, Grade 50.
Fill Concrete: f'c = 2,500 psi at 28 days. (Tremie Concrete)
Structural Concrete: f'c = 4,000 psi at 28 days.
Precast Concrete: f'c = 5,000 psi, minimum at 28 days.
Reinforcing Steel: ASTM A615/A615M, Grade 60.

A.7.1.11 Design Standards

Concrete:
ACI 318: Building Code Requirements for Reinforced Concrete, by the American Concrete Institute.
EM 1110-2-2104: Strength Design for Reinforced Concrete Hydraulic Structures.

Hydraulic factors will be applied to the overall load factor equations for structures or portions thereof that are classified as hydraulic in accordance with EM 1110-2-2104.

Structural Steel:
Manual of Steel Construction (Ninth Edition) by the American Institute of Steel Construction Inc,

Masonry:
Building Code Requirements for Masonry Structures, ACI 530.

Sheet Pile Retaining Walls:
EM 1110-2-2504, Design of Sheet Pile Walls

A.7.2 C43PS-4 - 195 cfs Pump Station

A.7.2.1 General Description

C43PS-4 will consist of a 195 cfs Pump Station 46 feet wide and 58 feet long with three pumps of 65 cfs capacity each. The main building will be supported on concrete footing. The pumps will be located at elevation 19.0 feet on a 3 feet thick floor slab. The wall units will be of fully grouted concrete masonry units (CMU). The roof framing will consist of cast-in-place concrete beams with precast concrete hollow core roof slabs. Three aluminum hatches provided along the center line of pumps will facilitate pump removal and replacement. The pump station will be un-manned and will be operated remotely or automatically operated.

A.7.2.2 Codes and Standards

The following design codes, requirements, and standards shall apply:

- SFWMD Guidelines Type 2 Water Supply Pump Station
- Florida Building Code;
- ACI 318-05 - Building Code Requirements for Reinforced Concrete ;
- ACI 350R - Concrete for Environmental Structures;
- ANSI/ASCE 7-02 Standard - Minimum Design Loads for Buildings and Other Structures;
- National Fire Protection Association - NFPA 101 - Life Safety Code;
- PCI MNL-120 - Design Handbook;
- Steel Construction Manual - AISC, Ninth Edition;
- Structural Welding Code – AWS D1.1;
- National Concrete Masonry Association Design Tables;
- Standard Specifications for Highway Bridges, American Association of State Highway Officials; and

- FDOT Standard Specifications for Road and Bridge Construction, 2000.

A.7.2.3 Loads and Design Criteria

The following loads and design assumptions shall be used in the structural analysis and calculations:

- Roof L.L. = 50 psf
- Floor L.L. = 250 psf
- Reinforced concrete unit weight = 150 pcf;
- 10 inches thick hollow core slab unit weight = 86 psf; and
- Roof covering with insulation unit weight = 9 psf

Wind loads shall be determined in accordance with the Florida Building Code and FWMD guidelines for a Type 2, water supply station and shall utilize the following criteria:

- Wind Velocity: ~120 mph per wind map FBC;
- 200 yr mean recurrence interval;
- 50 yr from 200 yr recurrence adjustment factor = 1.14;
- Roof: 0 degrees;
- Mean Roof Height: 24 feet ;
- Importance Factor = 1.15, for water supply pump station;
- Exposure category C, adjustment factor ~ 1.35; and
- Building Dimensions: 46 feet x 58 feet ~ rectangular enclosed building, no windows, low rise building.

The following load factors were utilized by Stanley Consultants in accordance with ASCE-07 Standard "Minimum Design Loads for Buildings and Other Structures and ACI-318:

U = 1.4(D + F)
U = 1.2(D + F + T) + 1.6(L + H) + 0.5(Lr or S or R)
U = 1.2D + 1.6(Lr or S or R) + (1.0L or 0.8W)
U = 1.2D + 1.6W + 1.0L + 0.5(Lr or S or R)
U = 1.2D + 1.0E + 1.0L + 1.6S
U = 0.9D + 1.6W + 1.6H
U = 0.9D + 1.0E + 1.6H

Hydraulic structures are required by SFWMD to satisfy both strength and serviceability requirements. ACI-350R requires an additional load factor of 1.3 be applied to the results of the above listed load equations. In addition, the factor for soil lateral loads is required to be increased to 1.7 as per ACI-350R.

As per SFWMD guidelines for Type 2 pump stations, the C43PS-4 substructure shall be designed to resist the saturated soil pressure to grade with an added 500 psf for traffic surcharge. Service bridges and operating floors shall be designed to support AASHTO HS25 loading.

A.7.2.4 Stability

A stability analysis shall be made of the station's retaining walls and intake structure. Unfactored loads shall be used in the stability analysis as indicated in EM 1110-2-2104. The walls shall be analyzed for failure due to sliding, rotation about the toe, and by failure of the foundation material. In accordance with EM1110-2-6058, a minimum safety factor of 2.0 and 1.5 shall be provided for overturning and sliding respectively.

A.7.2.5 Reinforced Concrete Design

The 28 day compressive strength for cast-in-place concrete elements shall be specified as 4000 psi. For precast elements, the strength shall be specified as 5000 psi. The minimum concrete cover shall be not less than 1.5 x the maximum aggregate size or 2.5 x the bar diameter. The following concrete cover shall be assumed in the analysis:

- Cast against earth: 4 inches
- Elements with surfaces exposed to abrasion, channel side faces: 3 inches
- Slabs, walls, and beams typical: 1.5 inches

The reinforcement tensile strength shall be taken as 60 ksi. The minimum temperature steel for the abutments, piers, and walls shall be specified as #5 bars at 12 inches on centers. The wall thicknesses shall be sufficient to allow the proper placement and consolidation of concrete and shall be designed in multiples of 2 inches to simplify formwork. For typical design and detailing of the reinforcement, multiples of 6 inches shall be used in the spacing of the primary and secondary steel. Bar spacing shall be taken as 1.5 x bar diameter or 1.5 x the maximum aggregate size. The minimum spacing between layers shall be 6 inches.

Construction joints shall be located to facilitate construction, limit the horizontal depth of the placement and shall not impair the strength and water tightness of the structure. Horizontal joints shall be located at the base of walls and typically at the maximum spacing of 10.0 feet.

Reinforcement shall be continuous through construction joints. Waterstops shall be used in construction joints where there is a head differential and the possibility of water flow through the joints.

A.7.3 Water Control Structures

A.7.3.1 Culverts

Cast-in-place concrete box culverts C43S-7 and C43S-9 are located north of the storage reservoir. Culverts C43S-14 and C43S-15 are located in the Header Canal east of Cell 2 of the Reservoir. All culverts have dewatering features.

Calculations for the structures include structural stability checks for flotation and preliminary design for a typical culvert section. The box culvert design program LRFD Box Culvert V2.21 as published by the Florida Department of Transportation will be used for the design. This program analyzes cast-in-place concrete box culverts for conformance to AASHTO LRFD bridge design specifications.

Anticipated settlement of the culvert structures will be minimal. Underseepage will be controlled by installing a 5 foot concrete cutoff wall.

A.7.3.1.1 Design references

- EM 1110-2-2902 Conduits, Culverts and Pipes, USACE 31 October, 1997
- ETL 11102-307 Engineering and Design Flotation Stability Criteria for Concrete Hydraulic Structures, USACE 20 August 1987;

- Geotechnical Report by DE&T, dated 01/06/06.
- ACI 318-05 – Building Code Requirements for Reinforced Concrete

A.7.3.2 C43S-7- Gated Double Barrel Box Culvert

Structure C43S-7 is a double barrel 10 foot W x 10 foot H box culvert with one sluice gate and one weir gate located at the intersection of Banana Branch Canal and Perimeter Canal. Flow parameters examined are as follows: Base flow of 80 cfs, Q25 of 816 cfs and Q100 of 840 cfs. Weir gate will be operational for base flows and when this flow is exceeded, sluice gate will be used to handle the excess flow. Energy dissipation and erosion control measures will need to be examined.

A.7.3.3 C43S-9 - Gated Double Barrel Box Culvert

Structure C43S-9 is a double barrel 6 foot W x 6 foot H box culvert with a 6 foot x 6 foot sluice gate and a 6 foot x 6 foot weir gate. It is intended to convey flow from Perimeter Canal to the Fort Simmons Canal. The weir gate will be used to allow base flow to pass. For flows greater than the base flow, the sluice gate will be used. Maintenance of the sluice gate will require special consideration and

must be done during low flow periods. Therefore, both gates must be operational to convey flows greater than the base flow.

A.7.3.4 C43S-14 - Gated Single Barrel Box Culvert

Structure C43S-14 connects the Header Canal to the Perimeter Canal. The structure is a single barrel 10 foot W x 6 foot H box culvert with a sluice gate to convey flood flow into the Perimeter Canal. The main purpose of this structure is to relieve flooding from SR 29 via the Header Canal and will not be used as a means for daily flow control either to or from Perimeter Canal. No additional flow will be introduced into the Perimeter Canal should the Perimeter Canal or the Townsend Canal reach full capacity.

A.7.3.5 C43S-15- Gated Double Barrel Box Culvert

Structure C43S-15 conveys flow from Roberts Canal to the Perimeter Canal. The structure is a double barrel 10 foot W x 8 foot H box culvert with an independently operated sluice gate and weir gate. The culvert is designed for flow parameters of 80 cfs of base flow, Q25 of 598 cfs and Q100 of 691 cfs. The 10 foot W x 8 foot H weir gate is intended to pass only the base flow. Flows above the base flow will be controlled by the sluice gate. Both gates should be operational to convey flows greater than the base flow. Maintenance of a gate should only be performed when the flows are at or below the base flow conditions.

A.7.4 Perimeter Canal Structures

A.7.4.1 C43S-3- Double Barrel Gated Culvert

C43S-3 is a double barrel reinforced concrete box culvert 10 foot W x 10 foot H which will be used to regulate water flow around the Perimeter Canal. Each barrel will have its own intake structure consisting of an upward opening stainless steel slide gate and a downward opening stainless steel weir gate. Calculations for this structure are based on structural stability check against flotation (uplift); hydraulic design data based upon the 100-year flood event and Allowable Stability Factors recommended by the USACE. Also, per geotechnical recommendations, a five foot tremie seal within a sheetpile cofferdam is assumed for construction and sheetpile cutoff walls embedded five feet into the clay layer are assumed at the upstream and downstream ends of the structure to reduce seepage flow underneath the structure. No longitudinal sheetpile cutoff wall is used since the perimeter dam includes a full depth soil-bentonite cutoff wall.

A.7.4.1.1 Design References

- EC 1110-2-6058 Stability Requirements, USACE 30 November, 2003;

- Design of Small Dams, published by United State Department of Interior, Bureau of Reclamation, A Water Resources Technical Publication; and
- Geotechnical Report by DE&T, dated 01/06/06.

A.7.4.2 C43S-10 - Three Bay Reinforced Concrete Spillway

C43S-10 is a three (3) bay concrete spillway which will be used to regulate water flow around the Perimeter Canal. The structure has one bay 14 foot x 10 foot with a roller gate on an ogee weir and two bays of 10 foot x 10 foot with downward opening weir gates. Calculations for this structure are based on structural stability checks including sliding, flotation (uplift) and bearing. Hydraulic design data based upon the 100-year flood event and Allowable Stability Factors recommended by the USACE are used for the stability checks. Also, per geotechnical recommendations, a five foot tremie seal within a sheetpile cofferdam is assumed for construction and a sheetpile cutoff wall embedded five feet into the clay layer is assumed at the upstream end of the structure to reduce seepage flow underneath the structure. No longitudinal sheetpile cutoff wall is used since the perimeter dam includes a full depth soil-bentonite cutoff wall.

A.7.4.2.1 Design References

- EC 1110-2-6058 Stability Requirements, USACE 30 November, 2003;

- Design of Small Dams, published by United State Department of Interior, Bureau of Reclamation, A Water Resources Technical Publication; and
- Geotechnical Report by DE&T, dated 01/06/06.

A.7.4.3 C43S-11 - Four Bay Reinforced Concrete Spillway

C43S-11 is the largest of the Perimeter Canal structures and is a four (4) bay reinforced concrete spillway which will be used to regulate water flow around the Perimeter Canal. The structure consists of two (2) 14 foot x 8 foot roller gate bays with vertical opening roller gates on ogee weirs and two (2) 10 foot x 8 foot weir gate bays with downward opening weir gates on fixed weirs. The two weir gates in addition to the vertical roller gates, are capable of discharging a normal discharge flow of 500 cfs should one of the roller gates be removed from service.

Calculations for this structure include structural stability checks which include sliding, flotation (uplift) and bearing. Hydraulic design data based upon the 100-year flood event and Allowable Stability Factors recommended by USACE are also used in the stability checks. Also, per geotechnical recommendations, a five foot tremie seal within a sheetpile cofferdam is assumed for construction and a sheetpile cutoff wall embedded five feet into the clay layer is assumed at the upstream end of the structure to reduce seepage flow underneath the structure. No longitudinal sheetpile cutoff wall is used since the perimeter dam includes a full depth soil-bentonite cutoff wall.

Manatee Structure

A pile founded concrete manatee structure/barrier will be installed at the mouth of the Townsend Canal to prevent manatee access to the Townsend Canal. The USFWS has determined that if manatees were allowed in the Townsend Canal, a potential threat exists by intermittingly altering the temperatures through discharges from the reservoir. This could provide an intermittent and potentially harmful warm water refugia.

A.7.5 Main Outlet Structure

A.7.5.1 General

Each cell of the Reservoir has a gated outlet structure to provide operational flows to meet the needs of the project at S-79 in the Caloosahatchee River. The outlets also maintain necessary Reservoir levels. These outlet structures are located in the northwest corner of each cell and discharge to the Perimeter Canal.

A.7.5.2 C43S-1 and C43S-8 - Gated Outlet Structures

C43S-1 and C43S-8 are the main outlets for Cell 1 and Cell 2 respectively. The designs are very similar with the major difference being that C43S-8 has a two foot higher sill elevation and 1-foot shorter dam crest. Both outlets discharge into the north Perimeter Canal with C43S-1 discharging four feet lower than

C43S-8. Each outlet consists of the following outlet components, listed from upstream to downstream:

1. Gated intake structure that allows inflows at upper or mid-level Reservoir depths for control of water quality and water temperature, the gates can be remotely or manually operated
2. Double barrel cast-in-place conduit though the base of the dam;
3. Double gatewell to house service and emergency gates;
4. Double-bay stilling basin for energy dissipation; and
5. Transition channel to Perimeter Canal

A.7.5.2.1 Structural Design Criteria

Corps of Engineers Engineering Manuals referenced:

- EC 1110-2-6058 Stability Analysis of Concrete Structures
- ETL 1110-2-307 Flotation Stability Criteria for Concrete Hydraulic Structures
- EM1110-2-2400 Structural Design & Evaluation of Outlet Works
- EM1110-2-2104 Strength Design for Reinforced Concrete Hydraulic Structures
- EM1110-2-2902 Conduits Culverts and Pipe
- EM1110-2-2502 Retaining & Flood Walls

A.7.5.2.2 General Criteria

a) Use identical gates and similar structural layout and design for each cell to provide design, construction, and maintenance advantages
b) Provide redundant gates in each outlet to allow normal operation with one gate out of service or to allow reservoir drawdown within 120 days;
c) Provide expansion and construction joints that accommodate the expected differential settlement (12 to 16 inches at the centerline of the dam);
d) Provide sufficient concrete cover over reinforcement in areas of major hydraulic activity;
e) Provide proper access for maintenance, operation, and monitoring of components;
f) Provide water tight connections at intersections with the dam's seepage controlling features;
g) Provide means for capturing and handling large debris before it enters conduits; and
h) Provide means for dewatering structural components for inspection and maintenance.

A.7.5.2.3 Stability Criteria

Each outlet component and element was evaluated by Stanley Consultants and sized to provide a suitable margin of safety between the overall forces and combinations of loads that can cause unsatisfactory resistance to flotation, sliding or bearing failure. The required factors of safety for stability were designated for "critical" structures that are new and thus well defined in EC 1110-2-6058. A flotation safety factor of 1.30 was used for scheduled maintenance of all outlet components.

A.7.5.2.4 Strength Criteria

Preliminary structural analysis, design and detailing were performed by Stanley Consultants for multiple structural elements for a typical outlet location. C43S-1 being a taller structure typically controlled the design requirements. Sections were analyzed for both shear and flexural strength based on Load Factor Design. The compressive strength of concrete was taken as 3,500 psi due to the lower stresses typical of hydraulic structures, and the steel reinforcement yield stress was chosen as 60,000 psi. This preliminary analysis only considered the load combination(s) that were regarded as critical to select the preliminary thickness and reinforcement for each element. Load combinations included self weight, dry and saturated soil weight, internal and external water pressures, uplift, and construction vehicle loading. Structural analysis was done using Staad.Pro (a finite element structural analysis software package) to determine factored moments and shears required in the design and sizing of members.

A.7.5.2.5 Serviceability Criteria

All of the outlet components were considered Hydraulic Structures and as such, factored loads were multiplied by an additional hydraulic factor (Hf) of 1.30 in lieu of performing additional serviceability analyses. Shrinkage and temperature reinforcement is taken as 0.2% of the gross section of the element. With regard to concrete cover protection over the steel reinforcement, hydraulic structures are required to have the following protection:

a) Unformed surfaces in contact with foundation - 4 inches
b) Formed surfaces subject to abrasion - stilling basin slabs and baffles - 6 inches;
c) Formed surfaces stilling basin walls, conduit slabs/walls 24 inches or >, - 4 inches;
d) Surfaces stilling basin walls, conduit slabs/walls 12 inches to 23 inches, - Formed 3 inches; and
e) Elements 12 inches or less in accordance with ACI code.

A.7.5.2.6 Intake Structure

The cast-in-place intake structure 47 feet x 39.25 feet is box shaped with an open top. Perimeter walls are two feet in thickness. A 3 foot thick base slab support the box structure. A center training wall is included to guide the water into double barrel box shape conduit which exits opposite to the headwall.

Access to the top of the intake structure can be accomplished from the crest of the dam. The top of the intake consists of heavy duty steel grating supported by eighteen concrete beams and two girders. The grating panels at the gates are removable so that gates can be accessed, raised and serviced on site or removed off site. Ladder rungs are provided for access to the interior of the intake. An outside ladder is also provided for access from a boat or barge when the reservoir is partially filled. An access road provides vehicular access to the bottom of the intake when the cell is empty.

Intake gates control the quality of the water being released through the outlet. Four upper slide gates are located on the side walls and four mid-level slide gates are located on the side wall and headwall. These gates can be remotely or manually operated to control water quality and temperature. Two lower-level slide gates are located in the headwall at the intake sill. These gates are manually operated during the rare event of a full reservoir drawdown. All the slide gates are located on the inside of the walls and operate either in the fully open or fully closed position and are subject to unseated head conditions. On the exterior face of the wall opening, trash rakes are provided at two feet on centers in both directions to prevent large debris from entering the intake. A rounded entrance at each opening minimizes turbulence.

Sluice gates located at the entrance to the conduits allow for dewatering of the conduits upstream of the gatewell without having to drawdown the entire reservoir. The sluice gates are manually operated, and also provide a second level of emergency protection for the gatewells. Sluice gates provide a better seal to minimize leakage. The gates work in either fully open or fully closed position and are subject to seated head conditions. The concrete surfaces at the entrances are bell-mouth shaped to minimize intake head losses. The gates are 8' wide to allow for a wider middle wall section to house the gate side frames.

Flotation stability was found to preclude the ability to dewater the large and relatively light intake structure with a full reservoir pool. In order to safely dewater the intake structure, the surrounding reservoir will have to be lowered to elevation 24.0 feet or lower. It is anticipated that the reservoir cells may be completely dry every 5 to 10 years at which time an intake inspection should be scheduled. The gates can all be removed from the top. The walls of the intake were designed as cantilevers to resist a nominal exterior (or interior) water load of 12 feet.

Overturning and sliding stability involves the calculation of dynamic load action due to reservoir waves during a hurricane event.

A.7.5.2.7 Double Barrel Conduit

The cast-in-place double-barrel conduit is rectangular in shape with each barrel 10 feet W x 6 feet H. The conduit is designed to resist hydrostatic loads due to a full pool during a dewatered condition. The conduits are also designed for a fully pressurized condition with moist soil conditions near the gatewell for a condition where the embankment upstream slope is faced with a fairly impervious layer.

Expansion joints are provided at the intersections of major elements in the outlet. Additional expansion joints have been introduced along the conduits to allow the structure to settle with the embankment. Camber is provided at the gatewell such that the conduits will have a final positive downward slope ranging from 2% to 3% after settlement has taken place.

Flotation stability was computed by Stanley Consultants for the upstream section of the conduits. The conduits need to be overlaid by at least one foot of soil in order to be safely dewatered. The access ramp to the intake provides more than adequate soil support.

A.7.5.2.8 Gatewell Structure

The gatewell structure is a cast-in-place double-bay rectangular chamber that provides access to the service and emergency gates. The exterior walls were designed to resist surrounding water pressures from a full pool reservoir condition while dewatered inside.

The conduits are narrowed at the gatewell to allow for smaller gates to be used. Cast iron gates are proposed for the service and emergency gates due to the high head and requirement for full operating range (as opposed to fully open or closed). The service gates are operated remotely while the emergency gates are operated manually. The service gates operate under a seated head condition while the emergency gates operate under an unseated head condition.

The massive gatewells are not subject to major overturning or flotation instabilities. Bearing pressures were computed at the base of the gatewell for the critical condition when the concrete work is complete but the structure has not yet been backfilled. The allowable bearing pressure of 4,000 psf is well above the actual pressures exerted at the base.

Each bay of the gatewell has a ladder fitted with a safety cage and a retractable safety post at the top. The grating panels at the top are removable so that gates can be accessed, raised and serviced on site or removed off site.

A.7.5.2.9 Stilling Basin

The stilling basin is a cast-in-place double-bay rectangular conveyance channel that dissipates most of the discharged water's energy before it reaches the receiving channel, the Perimeter Canal. The U-shaped channel walls were designed to resist at-rest lateral saturated soil loads and uplift pressures when dewatered.

At the downstream side, a slab connects the top of the walls to bridge over the structure and allow not only through traffic but also a location from which to install dewatering needles. A sheet pile cut-off wall is provided to prevent scouring beneath the slab in the event of failure of the riprap system.

Flotation stability of the stilling basin was computed by Stanley Consultants and found to require the Perimeter Canal water surface be set no higher than the normal water level (NWL) in order to safely dewater the stilling basin. The dewatered basin can be accessed from the gatewell and a dewatered conduit. A portable ladder can be lowered into the basin slab if there is a need to access the inside. Each conduit is independent from the other. Therefore inspection of a full conduit train is possible while the adjacent train is in operation.

Sliding stability of the basin was checked for water loading on the baffle blocks. A hydrostatic lateral pressure corresponding to the fluid energy grade line was used to compute the driving lateral force in lieu of a more detailed method of analysis. The basin was found to be safe against sliding instabilities.

A.7.5.3 C43S-12 Triple Conduit Cell Balancing Structure

A.7.5.3.1 General

Preliminary structural analysis, design and detailing were performed by Stanley Consultants. The Cell Balancing Structure, C43S-12, is located on the interior dam between Cells 1 and 2 of the reservoir. The primary function of the structure is to convey water between the cells and allow the cells to operate independently if needed. If one of the cells needs to be dewatered for maintenance C43S-12 may be closed to isolate the cells.

The general configuration of this structure is similar to the design of the main outlets C43S-1 and C43S-8 with the following major differences: C43S-12 is a triple conduit structure and water flows in the conduits in both directions depending on which cell is empty or filled. The dam crest elevation of the

interior dam at the balancing structure matches that of Cell 1. The east and west stilling basins are identical in configuration except that the east basin is set one foot higher in grade to allow water to drain by gravity from Cell 2 to Cell 1 during a drawdown event. The top of the conduits at the ends are shaped upward to minimize head losses when water flows in the opposite direction. The balancing structure consists of the following components listed from west to east:

1. Triple bay uncontrolled inlet/stilling basin structure
2. Triple barrel cast-in-place conduit along the base of the dam;
3. Triple gatewell to house service and emergency gates; and
4. Triple bay uncontrolled and un-gated inlet/stilling basin structure.

A.7.5.3.2 Structural Design Criteria

Corps of Engineer Engineering Manuals referenced:

- EC 1110-2-6058 Stability Analysis of Concrete Structures
- ETL 1110-2-307 Flotation Stability Criteria for Concrete Hydraulic Structures
- EM1110-2-2400 Structural Design & Evaluation of Outlet Works
- EM1110-2-2104 Strength Design for Reinforced Concrete Hydraulic Structures
- EM1110-2-2902 Conduits Culverts and Pipes
- EM1110-2-2502 Retaining & Floodwall

A.7.5.3.3 General Criteria

a) Use identical gates and similar structural layout and design for each conduit to provide design, construction, and maintenance advantages;
b) Provide one redundant conduit train to allow normal operation with one conduit out of service;
c) Provide expansion and construction joints that accommodate the expected differential settlement (12 to 16 inches at the centerline of the dam);
d) Provide sufficient concrete cover over reinforcement in areas of major hydraulic activity;
e) Provide proper access for maintenance, operation, and monitoring of components; and
f) Provide means for capturing and handling large debris before it enters the conduit.

A.7.5.3.4 Stability Criteria

Each outlet component and element was evaluated and sized to provide a suitable margin of safety between the overall forces and combinations of loads that can cause unsatisfactory resistance to flotation, sliding or bearing failure. The required factors of safety for stability were designated for "critical"

structures that are new and thus well defined (EC 1110-2-6058). A flotation safety factor of 1.30 was used for scheduled maintenance of all structure components.

A.7.5.3.5 Strength Criteria

Refer to Main Outlet Structures C43S-1 and C43S-8.

A.7.5.3.6 Serviceability Criteria

Refer to Main Outlet Structures C43S-1 and C43S-8.

A.7.5.3.7 Inlet/Stilling Basin Structure

The cast-in-place inlet/stilling basin structure is formed by an excavated plunge pool that dissipates the energy from water releases at the start of filling a reservoir cell. The top of the inlet wall of the east basin is set 1.0 foot higher than the surrounding grade to minimize sediment loads from entering Cell 1.

The structure is un-gated and uncontrolled, however trash rakes are provided at the entrances to prevent large debris from entering the conduit. A rounded entrance at each opening minimizes turbulence.

Flotation stability of the basin was found to preclude the ability to dewater the structure with a groundwater level to the top of the basin (same as the existing grade). Weep holes and a drain system will be designed to allow basin dewatering. The basin walls were designed for a nominal exterior water load of 10' resisted as a cantilever wall. Sliding was not considered because the excavated basin has adequate passive soil resistance behind the back wall. An access road provides vehicular access to the bottom of the intake when the particular Reservoir cell is empty.

A.7.5.3.8 Triple Barrel Conduit

Refer to Main Outlet Structures C43S-1 and C43S-8. Flotation stability was not computed for the conduits because they can not be dewatered under a full pool reservoir condition.

A.7.5.3.9 Gatewell Structure

The gatewell structure is a cast-in-place triple-bay rectangular chamber that provides access to the service and emergency gates. The exterior walls were designed to resist surrounding water pressures from a full pool reservoir condition while dewatered inside.

Normal operation of the structure is to balance the water levels at the two cells with all the gates fully open at all times. When one cell is to be dewatered, the gatewell gates operate in the same fashion as the service gates of the main outlets C43S-1 and C43S-8.

Both service and emergency gates have a dual and opposite role for reversed reservoir operation. All 6 gates are thus furnished with controls to be operated remotely. The service gates operate under a seated head condition while the emergency gates operate under an unseated head condition. Cast iron gates are proposed for the service and emergency gates due to the high head and requirement for full operating range (as opposed to fully open or closed).

The massive gatewells are not subject to major overturning or flotation instabilities. Bearing pressures were computed at the base of the gatewell for the critical condition when the concrete work is complete but the structure has not yet been backfilled. The allowable bearing pressure of 4,000 psf is well above the actual pressures exerted at the base.

Each bay of the gatewell has a ladder fitted with a safety cage and a retractable safety post at the top. The grating panels at the top are removable so that gates can be accessed, raised and serviced on site or removed off site.

A.7.5.4 C43CS-1 and C43CS-2 Crest Spillway Structures

A.7.5.4.1 General

Each cell of the reservoir has an uncontrolled crest spillway structure to manage flood flows. C43CS-1 is located on the west side of Cell 1 and discharges to the Townsend Canal. C43CS-2 is located just east of C43S-8 in the northwest corner of Cell 2 and discharges to the Perimeter Canal. The design objective of the crest spillway structures is to minimize the surcharge storage of the reservoir without exceeding the allowable discharge.

The design of the two crest spillways is very similar with the major difference being that C43CS-1 uses a deeper and different type of stilling basin design. The overflow weir and conduit for both spillways are set at the same elevation however the crest of the dam is set one foot higher at C43CS-1. Each spillway consists of the following components, listed from upstream to downstream:

- Uncontrolled/un-gated inlet weir allows overflows higher than the NFSL of 42.0
- Single barrel cast-in-place conduit through the dam at invert elevation 38.0 feet
- U-shaped spillway chute
- Single-bay stilling basin for energy dissipation
- Transition channel to Perimeter Canal

A.7.5.4.2 Structural Design Criteria

Corps of Engineer Engineering Manuals referenced:

- EC 1110-2-6058 Stability Analysis of Concrete Structures
- ETL 1110-2-307 Flotation Stability Criteria for Concrete Hydraulic Structures
- EM1110-2-2400 Structural Design & Evaluation of Outlet Works
- EM1110-2-2104 Strength Design for Reinforced Concrete Hydraulic Structures
- EM1110-2-2902 Conduits Culverts and Pipes
- EM1110-2-2502 Retaining & Flood Walls

A.7.5.4.3 General Criteria

a) Use similar structural layout and design for each spillway to provide design, construction, and maintenance advantages
b) Provide expansion and construction joints that accommodate the expected differential settlement;
c) Provide sufficient concrete cover over reinforcement in areas of major hydraulic activity;
d) Provide proper access for maintenance, operation, and monitoring of components;
e) Provide water tight connections at intersections with the dam's seepage controlling features; and
f) Provide means for dewatering structural components for inspection and maintenance.

A.7.5.4.4 Stability Criteria

Each spillway component and element was evaluated by Stanley Consultants and sized to provide a suitable margin of safety between the overall forces and combinations of loads that can cause unsatisfactory resistance to flotation, sliding or bearing failure. The required factors of safety for stability were designated for "critical" structures that are new and thus well defined (EC 1110-2-6058). A flotation safety factor of 1.30 was used for scheduled maintenance of all spillway components.

A.7.5.4.5 Strength Criteria

Preliminary structural analysis, design and detailing were performed for multiple structural elements for a typical spillway location. C43CS-1 being a taller stilling basin structure typically controlled the design requirements. Sections were analyzed for both shear and flexural strength based on Load

Factor Design. The compressive strength of concrete was taken as 3,500 psi due to the lower stresses typical of hydraulic structures, and the steel reinforcement yield stress was chosen as 60,000 psi. This preliminary analysis only considered the load combination(s) that were regarded as critical to select the preliminary thickness and reinforcement for each element.

Load combinations included self weight, dry and saturated soil, internal and external water pressures, uplift, and construction vehicle loading. Structural frame analysis was done using Staad.Pro (a finite element structural analysis software package) to determine factored moments and shears required to deign and size members of the structure.

A.7.5.4.6 Serviceability Criteria

All of the spillway components were considered Hydraulic Structures and as such, factored loads were multiplied by an additional hydraulic factor (Hf) of 1.30 in lieu of performing additional serviceability analyses. Shrinkage and temperature reinforcement is taken as 0.2% of the gross section of the element. With regard to concrete cover protection over the steel reinforcement, hydraulic structures are required to have the following protection:

a) Unformed surfaces in contact with foundation - 4 inches
b) Formed surfaces subject to abrasion, stilling basin slabs and baffles-6 inches;
c) Formed surfaces, stilling basin walls, conduit slabs/walls 24 inches-4 inches;
d) Formed surfaces stilling basin walls, conduit slabs/walls 12 inches to 23 inches-3 inches; and elements 12 inches or less in accordance with ACI code.
e) The Geotechnical Report provided in the Civil section details the soil column information under each of the structures and makes recommendations with regard to soil parameters, suitable foundation materials, dewatering methods, and estimates of expected settlement.

A.7.5.4.7 Inlet Weir Structure

The cast-in-place inlet structure is basically a flat slab on grade supporting a concrete weir. The downstream end is joined by a vertical training wall to convey properly flows into the single conduit. The radius of the weir was selected based on USACE guidelines. At the entrance to the conduit a small breast wall is provided to limit allowable discharges and to help deflect potential wave run up action.

Flotation stability criteria for hydraulic structures according to ETL 1110-2-307 (1987) report is a factor of safety of 1.50 for normal operation, which is the case

for this weir structure. However, flotation stability criteria according to the 2003 EC 1110-2-6058 (Stability Analysis of Concrete Structures), recommends a factor of safety of 1.3 for usual load conditions. The computed factor of safety is 1.40 for the proposed geometry. This is considered adequate given the massive weir shape.

Overturning and sliding stability were not of significant relevant to this structure.

Access to the inlet weir structure can be accomplished from the crest of the dam. A perimeter concrete pad is provided to allow maintenance vehicles to approach the area. The reservoir can be lowered four feet temporarily to access this site.

A.7.5.4.8 Single Barrel Conduit

The cast-in-place single-barrel conduit is rectangular in shape and designed to resist soil loads to the crest of the dam. Construction vehicle loads were also analyzed.

Expansion joints are provided at the intersections of major elements in the spillway. After pre-loading, settlement will be very small and therefore the conduits can be constructed to a final positive downward slope of 2%. A small camber and an expansion joint in the center will be provided.

A.7.5.4.9 Spillway Chute

The spillway chute structure is a cast-in-place U-shaped single-bay rectangular chute that delivers flows to the stilling basin. The walls are outside the dam prism and avoid the need for fall protection.

The spillway chute is not subject to major overturning or flotation instabilities. However, sliding stability is of concern because of the relatively steep angle of the 3:1 slope. The calculated factor of safety is about 1.2 for sliding on random fill. The required factor of safety is 1.70. The downstream stilling basin, however is embedded deep and has ample capacity to resist and carry additional sliding forces from the chute.

A.7.5.4.10 Stilling Basin

The stilling basin is a cast-in-place single-bay rectangular conveyance channel that dissipates most of the discharged water's energy before it reaches the receiving channel. The U-shaped channel walls were designed to resist at-rest lateral saturated soil loads and uplift pressures when dewatered.

At the downstream side, a slab connects the top of the walls to bridge over the structure and allow not only through traffic but also a location from which to install dewatering needles. C43CS-1 is fairly deep and thus a similar slab was continued for a portion of the basin to reduce the moment and shear requirements at the base of the walls.

C43CS-2 is provided with a sheet pile cut-off wall to prevent scouring beneath the slab in the event of failure of the sloping riprap system. C43CS-1 is not provided with sheet pile protection because the downstream channel is flat. A concrete shear key is sufficient.

Flotation stability of the stilling basins was computed and found to require the receiving canal water surface be set no higher than the NWL in order to safely dewater the stilling basin. C43CS-1 is deeper and therefore has an increased ability to resist flotation with higher canal levels in the Townsend. The dewatered basins can be accessed from the perimeter toe road. A portable ladder can be lowered into the basin slab if there is a need to access the inside.

Sliding stability of the basin was checked for water loading on the baffle blocks in the case of C43CS-2. A hydrostatic lateral pressure corresponding to the fluid energy grade line was used to compute the driving lateral force in lieu of a more detailed method of analysis. The basin was found to have ample resistance against sliding instabilities. C43CS-1 does not have baffle blocks.

A manatee structure, S-484, will be installed near the mouth of the Townsend Canal to prevent manatee access to C-43PS-1. The concrete structure consists of a pile foundation with trash rake and screens of sufficient coverage to not allow harm to manatees.

A.7.5.4.11 Structure Nomenclature

The structures numbers as described in this PIR document will be revised to reflect standard CERP naming conventions. All future documents going forward will reference the new names/numbers shown in ***Table A-17***.

TABLE A-17: STRUCTURE NOMENCLATURE

and

TECHNICAL MEMORANDUM FOR THE CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR APPLICATION OF SPREADSHEET TO EVALUATION OF C-43 STORAGE RESERVOIR PROJECT ALTERNATIVES FOR C-43 PROJECT DELIVERY TEAM MARCH 23, 2007 MSR 264

The following Technical Memorandums were provided by the SFWMD and were prepared by the Interagency Modeling Center (IMC). The memos describe the methodology used to create and utilize a spreadsheet analysis to simulate the 2000 and 2050 condition with and without project for the purposes of fulfilling requirements under GM 2,4 and 5 and describes the results and conclusions from the spreadsheet analysis.

Section 1 – Introduction

1.1 Project Background

The C-43 Basin Storage Reservoir Phase I Project comprises the C-43 West Storage Reservoir (Figure 1) located on the Berry Grove property in the western portion of the Caloosahatchee Watershed in Hendry County, Florida.

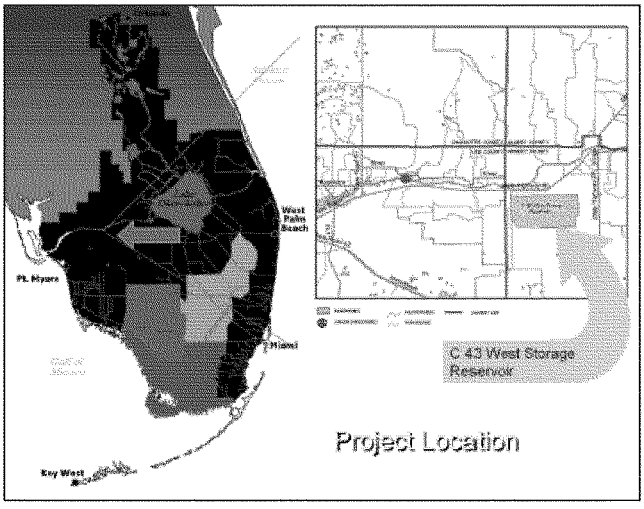

Figure 1. Location of the Proposed Site for the C-43 West Storage Reservoir.

The purpose of the C-43 Basin Storage Reservoir Phase I Project is to improve water deliveries to the estuary, provide for dry season flows, reduce magnitude of wet season high flows, restore downstream salinity levels and ensure the availability of water for the natural system needs of the Caloosahatchee Estuarine System. Subsequent phases of the C-43 Storage Reservoir Project will address these same issues in addition to providing additional water resource benefits through provision of supplemental water resources for agriculture and urban users thereby benefiting the regional system by reducing the dependence on Lake Okeechobee.

FINAL Page 4 of 58

The selected plan for Phase I of the Project is a two cell reservoir with storage capacity approximately 170,000 acre-feet, inflow pump capacity of 1500 cubic feet per second (cfs) and design outflow capacity ranging from 1,000 cfs to 1,500 cfs. The reservoir is an above ground reservoir with earthen dam and an embedded slurry wall extended to intercept a clay layer underlying the reservoir site. A seepage collection system consisting of a seepage canal and structures is included in the project to capture seepage from the reservoir. The reservoir sits on a project site of approximately 11,000 acres with the actual two cell reservoir footprint estimated at between 9,000 and 10,500 acres. The reservoir intake is on the Townsend Canal which is directly connected to the C-43 Canal (Caloosahatchee River) downstream of S-78 (Ortona Lock and Dams) but upstream of S-79 (W. P Franklin Lock and Dam) both gated structures for managing water level within the reach of the C-43 Canal.

The identified project strategy involves attenuation of high flows at S-79 (a shaving of the peaks during high flows) into storage and subsequent release from reservoir storage of the available volumes to meet dry season low flow requirements at S-79 with the intent of improving the salinity balance in the downstream estuary.

The Interagency Modeling Center (IMC) has been tasked through MSR 262 to develop a spreadsheet model of the C-43 Basin Storage Reservoir, Phase I selected project for subsequent analyses for meeting CERP planning requirements including assurances, quantification of water made available for restoration and so on as described in the scope. This report documents the objectives, scope of work approach, describes the modeling tool developed and the simulations conducted on behalf of the C-43 Project Delivery Team (PDT) per MSR 262.

1.2 Objectives and Scope of Work

The objectives of the study conducted by the IMC are as follows.

1) Develop a spreadsheet tool suitable for meeting the requirements identified in the customer requirements section (Section 1.3) and submitted as attachment to MSR 262 by the C-43 PDT.
2) Utilize the spreadsheet to simulate the 2000 and 2050 condition with and without project for the purposes of fulfilling
   a. GM #2-Next Added Increment Analysis requirement
   b. GM #4 requirements for Identifying Water Made Available by the Project-volumetric analysis from spreadsheet output, and
   c. GM #5-Serves at the basis for Draft Project Operating Manual-Spreadsheet operations of Existing Conditions with Project (same as Initial Operating Regime).
3) Deliver the spreadsheet with a user guide and model results the PDT for subsequent analyses.
4) Deliver the model results to assurances team for subsequent analyses and write-up
5) Document the spreadsheet and provide a project report describing the analyses, the key assumptions, limitations and application to the PDT.

1.3 Customer Requirements

The IMC was tasked by the PDT through MSR 262 to develop a simplified spreadsheet model of the C-43 West Reservoir based on capture of excess flow over S-79 as derived from SFWMM simulation of the base conditions. The detailed scope and customer requirements are as follows:

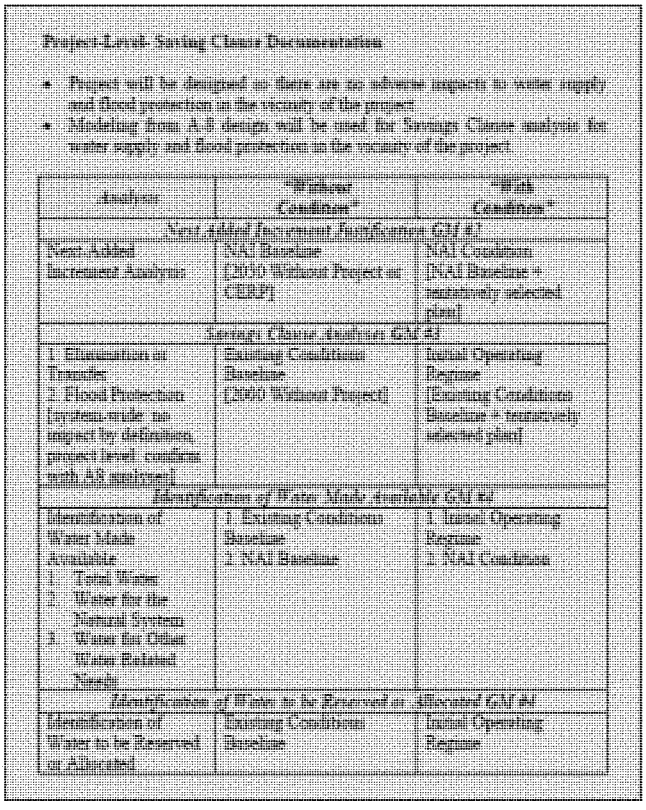
C-43 Basin Storage Reservoir - Part 1
Purpose and Key Assumptions for Spreadsheet Analysis
February 7, 2007

Purpose of Spreadsheet Analysis

- Fulfill GM #2 Next Added Increment Analysis requirement. This analysis will include an ecological assessment using the existing interface with industry grid for RSM analysis.
- Fulfill GM #4 requirements for Identifying Water Made Available by the Project: volumetric analysis from spreadsheet output.
- Fulfill GM #1-Serves as the basis for Draft Project Operating Manual. Spreadsheet operation of Existing Conditions with Project(same as Initial Operating Regime) will be used as the basis for draft operating manual.
- NOTE: The spreadsheet will not be used to fulfill of GM #3 requirements for Storage Change analysis or Elimination or Transfer of Existing Legal Sources and Flood Protection. To fulfill this requirement a combination of assumption documentation and information from AS design modeling will be used.

FINAL Page 6 of 58

System-wide



Base Spreadsheet Assumptions:

- Flow data for Existing Conditions Baseline (2000) and Future Without Project Condition (2050 with no CERP projects in place) is derived from South Florida Water Management Model runs 3000FD and 3050RD.
- Existing Conditions Baseline, Pre-CERP Baseline, and Initial Operating Regime without project are essentially all the same conditions related to demands and CERP Project operations affecting this project, therefore, the 2000 Existing Conditions Baseline will be used for analyses requiring these different conditions.
- ET from reservoir will be included. The mass balance terms for the reservoir are reservoir inflow, reservoir release, reservoir seepage will be assumed to be zero. ET losses (based on area volume relationship), and perhaps reservoir direct precipitation.
- System losses from the river to groundwater from the point of release of the reservoir to S-79 will be factored into the spreadsheet analysis.
- No agricultural or urban water supply deliveries are supplied by the reservoir these demands continue to be supplied from Lake Okeechobee or current groundwater sources.
- Eastern Caloosahatchee Basin (east of S-79) is not affected by the project.
- With the exception of changing flows to the Caloosahatchee Estuary west of S-79, there will be no impacts on the Western Caloosahatchee Basin.

Reservoir Operation Assumptions:

- Water will be pumped into the reservoir only when there are excess flows over S-79. Excess will be treated initially as high flows over some threshold that will be refined through iterations of the spreadsheet to obtain the best performance in meeting estuary targets (EST 03).
- Releases from the reservoir are made when flows over S-79 are below desirable levels (450 cfs). Releases will be refined through iterations of the spreadsheet to obtain the best performance in meeting estuary targets (EST 03).
- Including basic seasonal operational variability in the spreadsheet for filling and draining the reservoir is preferable.

FINAL Page 7 of 58

Project-Level Saving Clause Documentation

- Project will be designed so there are no adverse impacts to water supply and flood protection in the vicinity of the project.
- Modeling from A-3 design will be used for Savings Clause analysis for water supply and flood protection in the vicinity of the project.

Analysis	"Without Condition"	"With Condition"
Next Added Increment Justification (Q1 #1)		
Next Added Increment Analysis	NAI Baseline [2060 Without Project or CERP]	NAI Condition [NAI Baseline + tentatively selected plan]
Savings Clause Analysis (Q1 #2)		
1. Elimination or Transfer 2. Flood Protection [project-under no impact by definition, project level conform with AS analyses]	Existing Conditions Baseline [2060 Without Project]	Initial Operating Regime [Existing Conditions Baseline + tentatively selected plan]
Identification of Water Made Available (Q1 #3)		
Identification of Water Made Available 1. Total Water 2. Water for the Natural System 3. Water for Other Water Related Needs	1. Existing Conditions Baseline 2. NAI Baseline	1. Initial Operating Regime 2. NAI Condition
Identification of Water to be Reserved or Allocated (Q1 #4)		
Identification of Water to be Reserved or Allocated	Existing Conditions Baseline	Initial Operating Regime

FINAL Page 8 of 52

Section 2 – Approach

The approach and assumptions used by the IMC team for developing the C-43 West Reservoir spreadsheet model is discussed in the following section.

2.1 Assumptions and Considerations for the Analyses

2.1.1 Project Assumptions Provided by PDT

The following are project assumptions provided by the customer as requirements. These assumptions were implemented in the spreadsheet model except where additional information renders them inappropriate or unnecessary.

- Flow data at S-79 for the Existing Conditions Baseline (2000) and "Future Without" Project Condition (2050 with no-CERP projects in place) is derived from South Florida Water Management Model runs 2000RD and 2050RD.
- Existing Conditions Baseline, Pre-CERP Baseline, and Initial Operating Regime without project are essentially all the same conditions related to demands and C&SF Project operations affecting this project, therefore, the 2000 Existing Conditions Baseline will be used for analyses requiring these different conditions.
- ET from reservoir will be included. The mass balance terms for the reservoir are reservoir inflow, reservoir releases, ET losses, and reservoir direct precipitation. Reservoir seepage will be assumed to be zero.
- System losses from the river to groundwater from the point of release of the reservoir to S-79 will be factored into the spreadsheet analysis.
- No agricultural or urban water supply deliveries are supplied by the reservoir. These demands continue to be supplied from Lake Okeechobee or current groundwater sources.
- Eastern Caloosahatchee Basin (east of S-78) is not affected by the project.
- With the exception of changing flows to the Caloosahatchee Estuary west of S-79, there will be no impacts on the Western Caloosahatchee Basin and no effort to depict these will be included in the spreadsheet.
- Water will be pumped into the reservoir only when there are excess flows over S-79. Excess will be treated initially as high flows over some threshold that will be refined through iterations of the spreadsheet to obtain the best performance in meeting estuary targets (EST 05).
- Releases from the reservoir are made when flows over S-79 are below desirable levels (450 cfs). Releases will be refined through iterations of the spreadsheet to obtain the best performance in meeting estuary targets (EST 05).
- Basic seasonal operational variability for filling and draining the reservoir is included in the spreadsheet model.

2.1.2 Additional Assumptions

In addition to the assumption provided by the PDT, the IMC has implemented the following additional assumptions for the reasons provided.

1) Minimal natural losses to reservoir releases between the project and S-79 can be expected. An efficiency of delivery factor of 1 or 100% is used in the spreadsheet to ensure that all releases from the reservoir arrive at S-79. This assumption is based on analyses of more rigorous hydrologic modeling that was conducted using the MIKESHE model that show that within the reach of the Townsend Canal and the portion of C-43 from the Townsend Canal – C-43 Canal intersection, the canal are gaining and have water level that is consistently lower than groundwater elevation. This assumption was further verified with topographic data completed as part of the data preparation for the Southwest Florida Feasibility Study which show that the C-43 and Townsend canals in this region are at notable lower elevation than the adjacent land (Figure 2).

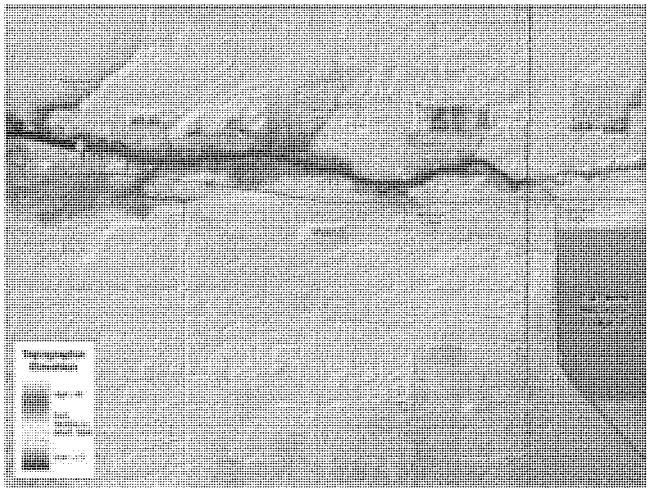


Figure 2. Topographic map of the C-43 and environ downstream of the Townsend Canal confluence.

2) Reservoir size of approximately 170,000 acre feet and pump station total capacity of 1500 cfs will be used in the spreadsheet analyses. Actual size for reservoir will be determined based on storage – depth – surface area relationship provided by the C-43 West Reservoir Acceler8 Team. This assumption was deemed appropriate in that it utilizes the most current available information on possible reservoir geometry consistent with the project site.
3) In basin flow routing and other internal details such as flow between multiple cells or multiple releases will not be included in the spreadsheet analysis as such detail are at

a more refined scale that the analysis. IMC considers this assumption appropriate since the focus of the spreadsheet analysis is the redistribution of excess flow over S-79 through use of the reservoir to improve timing and quantity of flow over S-79. The localized operations can be represented by simple reservoir filling or release operation within the spreadsheet analyses.

4) Progressively more complex operations that meet the customer requirement will be implemented, starting from simple breakpoint based flow decision to perfect knowledge (operation based on the identified estuary target EST05) to bound the solution. This assumption ensures successive suitable operations that provide increasing information on model and expected reservoir performance as the complexity increases to the recommended operations. The tool shall retain the flexibility to implement the simplified operations.
5) A preferred operation that represent best results (but not optimal) will be delivered and processed for subsequent analyses. IMC proposes this assumption or approach to ensure that a simple yet realistic set of operations that are intuitive and provide superior performance are generated and recommended to the PDT.
6) IMC will implement seasonality in reservoir operations to recognize that wet and dry season operations would differ, and same season operation would also differ based on the state (full or empty) of the reservoir. The generalized logic of the operation is provided below (Figure 3).

Fill	WET SEASON	DRY SEASON	
Early in Season	Fill slowly to retain capacity for later in the season	Fill aggressively in preparation for rest of dry season	Pump capacity (and channel capacity) are limiting. Intake threshold and volume may vary but based on a consistent logic. The Threshold will be determined by iteration.
Late in Season	Fill reservoir faster to get full by end of year (use available capacity as a factor)	Fill slowly to retain capacity for wet season	

Empty	WET SEASON	DRY SEASON	
Early in Season	Release aggressively to create capacity for filling reservoir later in the season	Release less aggressively to extend ability to release longer into the dry season	The constraint to the release strategy listed to the side are reservoir release capacity and the requirement that wet season flows should not greatly fall below EST05 and Dry season flow over S-79 should not greatly exceed EST05
Late in Season	Release more carefully to keep reservoir full going into the dry season	Release more aggressively to empty reservoir in preparation for the wet season	

Figure 3. Generalized operational logic to implement seasonality.

7) Reservoir filling and release actions will not occur on the same day.
8) Based on comment from technical review team, IMC will implement adjustment for runoff from the reservoir site using the initially specified ratio of land area of reservoir to land area of basin as well as one or more alternative approaches that consider precipitation to runoff relationship in watershed. These alternative approaches will allow simple or more complex representation of this adjustment to meet the user need. The precipitation based approach allows representation of the

delay between rainfall and runoff and was considered a desirable recommendation of the technical review team.

9) IMC will implement an operational feature that reduces fill action when the reservoir is full or close to full. The intent is to minimize the possibility of oscillations in reservoir operation and stage that could result from very sensitive pump criteria that pump every day to replenish daily losses to evapotranspiration. The justification of this assumption is the need to more closely match a realistic operation. The feature implemented can be disabled by the user at run time.
10) Reservoir base ranges from 18 feet NAVD to 20 feet NAVD with an average at 19.24 feet. This assumption is based on the most current design information available from the Acceler8 project documentation.
11) Reservoir elevation at full pool is 42 feet NAVD with a corresponding storage of 178,602 acre-foot. This assumption is based on the most current design information available from the Acceler8 project documentation plus data provided by Acceler8 project team.
12) Daily potential evapotranspiration data for the analyses will be extracted from the SFWMM modeling dataset for consistency. IMC believes that this represents the most reliable data for the purpose of the modeling exercise and that data is available for the period of record, 1965 to 2000.
13) Daily rainfall data will be extracted from the SFWMM modeling dataset for consistency. IMC believes that this represents the most reliable data for the purpose of the modeling exercise and that data is available for the period of record, 1965 to 2000.
14) Statistics and performance graphics will be generated based on a period of record simulation of 36 years, January 1965 to December 2000.

2.2 Spreadsheet Development

IMC implemented a phased dual channel approach that involved the development and initial refinement of two independent proof-of-concept spreadsheets. Each was initiated independent of the other but based on the same requirements from the PDT. Due to the aggressive schedule of the project, a simultaneous technical review was initiated to lag the development. Taking input from the review team, IMC combined the desirable features of the two approaches into a single spreadsheet model for final refinement and application.

The spreadsheet model is centered on a water budget equation for the reservoir. The equation is based on conservation of mass and relates the inflows to the reservoir, outflows from the reservoir to the change in storage in the reservoir over some fixed time scale. The equation is represented below in lay terms states that inflows to the reservoir minus outflows from the reservoir is equal to the change in storage in the reservoir.

$$\frac{dS}{dt} = Q_{in} - Q_{out}$$

Where $\frac{dS}{dt}$ is the rate of change in storage,

Q_{in} represents the rate of inflow to the reservoir, in this case direct precipitation on reservoir plus the pumped volumes.

Q_{out} represents the rate of outflow from the reservoir. It combines in this case, releases from the reservoir, spillway releases, and losses to evapotranspiration, (seepage set at zero by assumption).

The spreadsheet model implements the following actions.

Based on flows over S-79 on a daily basis

1) The spreadsheet determines if there is adequate flow to capture for storage in the reservoir. The threshold for capture depending on the operation scheme implemented could range from
   a. Checking if the flow exceeds a specified peak flow at which storage is initiated,
   b. Comparing the daily flow to daily target flows and capturing the excess subject to reservoir capacity and pump capacity, or
   c. Determined based on a specified operation strategy the seasonal threshold and volume to store subject to pump and reservoir storage capacity.
2) The spreadsheet determines what proportion of the available flow can be captured subject to the criteria below depending on the operation scheme implemented.
   a. The pump capacity (1500 cfs)
   b. The difference between total flow over S-79 and the target flow, subject to reservoir capacity and pump capacity, and
   c. Based on a specified seasonal release strategy or decision table specified by the user within the spreadsheet.

These inflows along with direct precipitation onto the reservoir represent total inflows into the reservoir used in the mass balance.

Based on flows over S-79 and available capacity in the reservoir, the spreadsheet does the following actions.

1) Determines evaporation losses by taking the product of the potential evapotranspiration rate and the surface area of the reservoir (which is varied depending on storage within the reservoir)
2) Determines if rainfall or other activity has resulted in reservoir stage in excess of the spillway elevation and releases subject to limit of the spillway (the final model has operational features that preclude or limits the likelihood of this occurrence).
3) Determines release from the reservoir for environmental purposes to augment S-79 flows depending on the operational scheme implemented. The release decision and volume of release could be
   a. Based on a fixed release to bring S-79 flows to a minimum specified threshold subject to reservoir release structure capacity,

FINAL Page 13 of 58

b. Based on meeting the deficit between S-79 flows and the target series, EST05, or
c. Based on a specified seasonal release strategy or decision specified by the user in the spreadsheet.

These outflows are accumulated to represent total outflows from the reservoir used in the mass balance equation for each daily time step.

The spreadsheet computed the daily change in storage and associated water surface elevation both of which are considered in determining fill and release operation in subsequent time steps. The model creates an updated flow over S-79 that reflects the changes to the original flow resulting from reservoir fill or release activities.

A more detailed description of the sequence of computation with a sample cycle through one time step is presented in the User Manual attached as Appendix I to this report.

Section 3 – Model Application: Simulations of 2000 and 2050

The focus of the spreadsheet model is the modification or adjustments of flow over S-79 with the intent of improving the salinity distribution in the downstream estuary. The model has no salinity or ecological component and relies on hydrologic surrogate to infer improved performance. The hydrologic surrogate used is the flow over S-79 and its closeness to a flow target time series EST05 which has been demonstrated by others to be a restoration series that would result in optimal habitat conditions for several indicator species in the estuary. The May, 2003 report titled "Existing Legal Sources for Caloosahatchee Estuary at the Franklin Lock and Dam (S-79) by the Coastal Ecosystem Division of the South Florida Water Management District describes the basis for EST05.

As a means to showing closeness to EST05 as a whole and quantifying other desirable matches to portions of the restoration flow series, a number of performance measure graphics were built in to the spreadsheet, five in total. Also, in order to confirm reasonable behavior of model features and results, several graphics and charts of these features were incorporated and used during model application to determine changes in operation necessary to yield superior performance.

3.1 Performance Measures

The performance measures are nested in the "PMs" Worksheet of the spreadsheet and include the following charts.

3.1.1 Distribution of Monthly Flows.

The first performance measure is a histogram of the distribution of monthly flows over S-79 for the target restoration flow series EST05, the existing "without project" or base condition, and the "with project" condition depicting percentage of time each flow

range occurs in the period of record simulation. A sample of the graphics is shown in below (Figure 4).

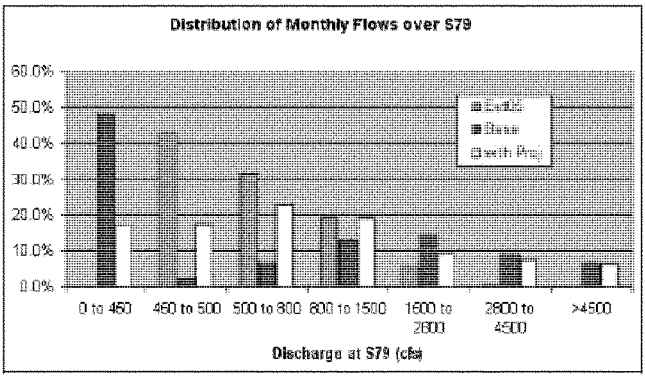

Figure 4. Histogram of monthly flows over S-79 in cfs.

An alternative that shows a closer match between the "with project" condition and the EST05 series is considered a better alternative when this measure is considered. The selection of the preferred operation is based on this and other measure evaluated in combination.

3.1.2 Caloosahatchee Estuary Salinity Envelope Criteria.

The second performance measure is the estuary salinity envelope criteria developed and used by CERP for the Caloosahatchee Estuary by the SFWMM model. This performance graphic has been duplicated in the spreadsheet and depicts the count of number of months with a low flow criteria (less than 450 cfs) not met in the "without project" (base condition) and the "with project" condition during the dry season. The measure also shows the count of exceedance of a high flow threshold (2800 cfs) with and without project. A sample graphic is shown below (Figure 5). In interpreting this measure, a series of operations that reduces the number of low flow occurrence and reduces the number of high flow exceedance represents a better set of operations. Note that EST05 has no occurrences of flows below 450 cfs and establishes a target count of zero for the low flow portion of this measure.

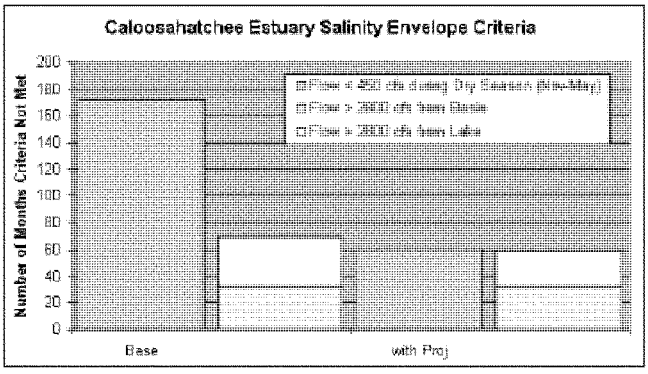

Figure 5. Caloosahatchee Estuary salinity envelope criteria.

3.1.3 Flow Duration Curve.

A flow duration curve generated by ranking and plotting the flow over S-79 and the percentage of time that the flow is equaled or exceeded is used as one of the measures. This plot is generated for the target restoration flow series EST05 as well as the "with project" and "without project" conditions. The "with project" condition that more closely matches EST05 represents the better performance. Below (Figure 5) is a sample plot extracted from the spreadsheet simulation. While it is desirable to consider the area under the curve as new water made available by the project, this does not represent the water made available as described in the guidance memoranda for assurances. Separate analyses for assurances will be delivered separately as part of this project. The curve does show the ability of the "with project" condition to extend availability of low flows from the "without project" condition towards the EST05 conditions with no occurrences of flows less than 450 cfs.

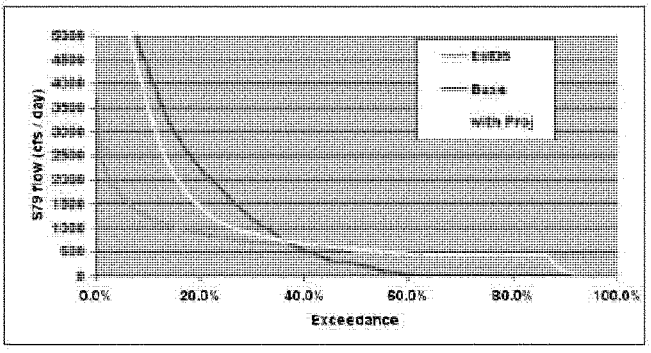

Figure 6. Flow Duration Curve.

3.1.4 Consecutive Days with No Flows to Estuary.

Based on technical input from coastal ecologists, an additional measure depicting the consecutive number of times in the simulation period of record that 10 or more days of no flows to the estuary occurred was developed. This measure counts a 30 day no flow event as one occurrence. A 30 day event with flows to the estuary introduced on the 15th day alone will result in a count of two occurrences. The measure also presents the maximum number of consecutive days with no flow under the "with project" and "without project" conditions. This measure using both parts of the chart show the frequency and extent of no flow (defined within the spreadsheet as the 5 cfs base flow rate) conditions observed in flows over S-79 over the 36 year period of record. An operational scheme that results in lower count of number of consecutive days of no flows and reduces the extent of the maximum number of consecutive no flow days represents a more desirable operational regime. A key caution in interpreting this graphic is that a small flow much less than the desirable 450 cfs will break the count of consecutive days so that releases from the reservoir of rainfall induced volumes that result in small flows in the order of tens of cfs count as breaks to the consecutive dry days count.

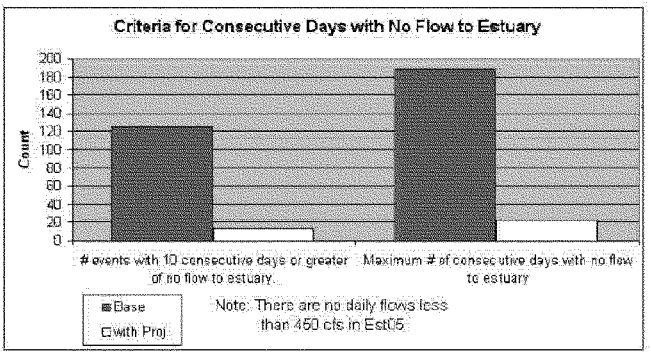

Figure 7. Criteria for consecutive days with no flow to estuary.

3.1.5 Hydrograph of flow over S-79.

The final performance measure used is a plot of flows in cfs over S-79 for the EST05 series, the "with project" and "without project" conditions. In addition, superimposed on the plot is the pump filling and reservoir release operations. This graphic allows actual comparison of improvements to S-79 discharges and closeness of those improvements to the EST05 restoration series.

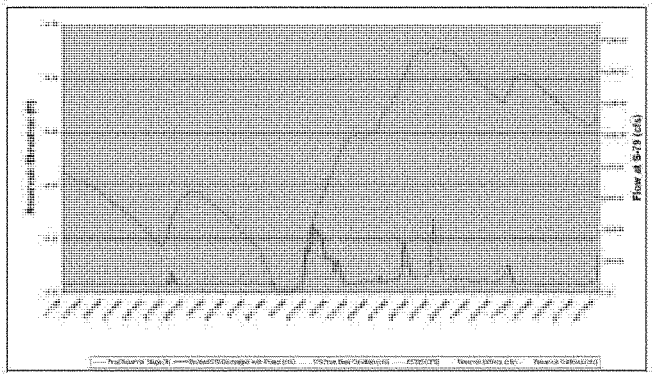

Figure 8. Flow over S-79 and reservoir stage showing reservoir fill and release actions and resulting modification to pre-project S-79 flows.

3.2. Spreadsheet Performance Checks

Six charts were used to perform checks on different aspects of the spreadsheet to ensure that assumptions were not violated and that the features in the spreadsheet were functioning as intended. The six charts are shown below (Figure 9) and include:

1) A plot of reservoir surface elevation: This chart shows the rate of use of the reservoir, how often it is full or empty.
2) A reservoir stage exceedance curve that shows what percentage of the time the reservoir surface elevation equals or exceeds a particular stage value.
3) An x-y plot of the adjustments to S-79 flows to accommodate the reduction in runoff resulting from converting the project from an agricultural land use to a reservoir. This plot shows minimal impact from the adjustment.
4) A scatter plot of inflows with reservoir stage to depict what operations are occurring as the reservoir fills.
5) A scatter plot of outflows with reservoir stage to show what release operations are occurring at different reservoir stage values, and
6) A scatter plot of inflows versus outflow to demonstrate that inflows and outflows are not occurring simultaneously.

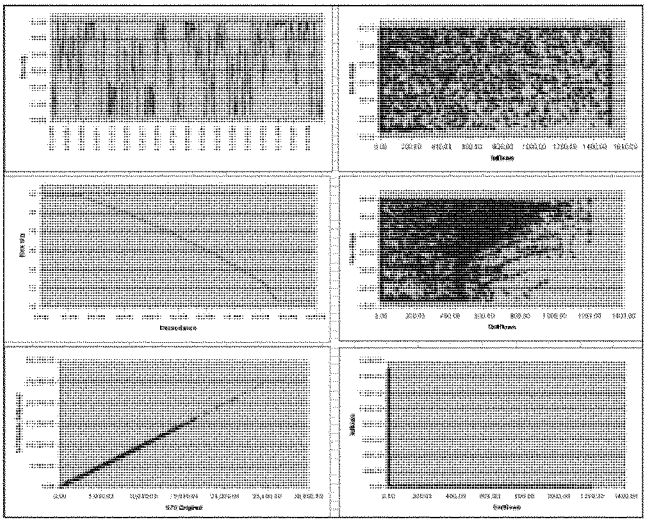

Figure 9. Plots used to check and confirm that spreadsheet model is performing as intended.

3.3. Simulation of 2000 Conditions

The spreadsheet was used to simulate the 2000 conditions.

3.3.1 Simplified Operation with Minimum and Maximum S-79 Threshold

Initial analyses used the simplified operations with a defined low flow threshold and defined high flow threshold. The high flow threshold was varied randomly between 2500 cfs and 4200 cfs and the low flow threshold was set at 450 cfs. Examination of the performance under this operational regime shows improvement over the "without project" condition but also resulted in a somewhat unnatural response with extended periods of fixed flow at 450 cfs in the low flow range. The performance measures for a high flow threshold of 2800 cfs and a low flow threshold of 450 cfs are presented below (Figure 10).

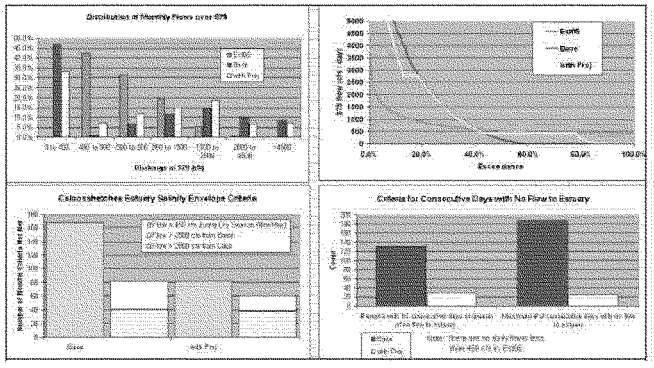

Figure 10. Performance measures for reservoir operations based on high flow (2800 cfs) and low flow (450 cfs) thresholds under year 2000 conditions.

- The histogram showed some improvement in the low flow range over the "without project" condition but flows lower than 450 cfs still occurred more than 30% of the time.
- Considering dry season flows, the number of occurrences of less than 450 cfs was reduced from 167 to 82 from the without project to the "with project" condition.
- The flow duration curve for the "with project" conditions shows two steps corresponding to the selected high flow and low flow threshold, 2800 and 450 cfs respectively. The period of time when flows over S-79 equaled or exceeded 450 cfs was extended from about 45 % of the time under the "without project" condition to greater than 70% of the time under the "with project" conditions.

- There was a marked reduction in the count of number of events with 10 consecutive days or greater of no flows to the estuary from 131 under the "without project" condition to 29 under the "with project" condition. Similarly the number of consecutive days with no flows to the estuary reduced sharply. From 188 days to 25 days with the reservoir in place.

3.3.2 Bounding Operation with Operations Tied to EST05

An operational scenario that ties fill and release decisions to S-79 flows in excess of, or in deficit of the EST05 flow series was then implemented. This operational strategy assumes perfect knowledge and under ideal condition will deliver the EST05 or restoration flows to the Estuary. This operation is similar to operation implemented in other previous analysis by the PIR team. Under the "perfect knowledge" scenario, reservoir fill decisions and reservoir empty decisions are forced to reproduce EST05 like flows at S-79 subject to availability of water within the reservoir and pump and release structure capacities. The performance measures observed under this scenario are presented below (Figure 11).

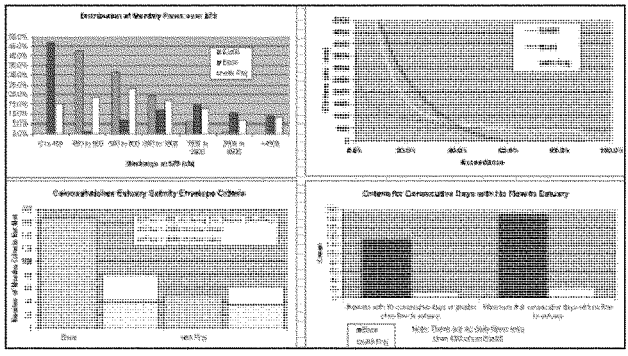

Figure 11. Performance measures for reservoir operations based on matching estuary target flow series EST05 under year 2000 conditions.

- The histogram showed some greater improvement in the low and mid flow range over both the simplified operations and the "without project" condition. There are still occurrences of flows lower than 450 cfs but this was reduced to approximately 15% of the time. This suggest that even under this operational scenario, reservoir operations to prevent occurrences of flows below 450 cfs is not possible with the current reservoir specifications (size intake and outflow features).

- Considering dry season flows, the number of occurrences of less than 450 cfs was reduced from 167 to 52 from the without project to the "with project" condition. An improvement of 30 occurrences over the simple operations.
- The flow duration curve for the "with project" conditions shows no steps but a gradual merge of the plot under the "with project" conditions to the EST05 plot until the reservoir becomes incapable of delivering 450 cfs. The reservoir is capable of delivering 450 cfs or greater 87% of the time over the 36 year simulation period, a significant improvement over the "without project" condition and a sizeable improvement over simplified operations.
- There was a marked reduction in the count of number of events with 10 consecutive days or greater of no flows to the estuary from 131 under the "without project" condition to 14 under the "with project" condition. Similarly the number of consecutive days with no flows to the estuary reduced sharply. From 188 days to 23 days with the reservoir in place.

Below (Figure 12) shows a plot of flows over S-79 for a portion of the simulation and illustrates the operations under this release strategy. While reservoir is full and excess flows over S-79 do not exceed pump capacity, the plot of modified time series of flows over S-79 is co-incident with the EST05 time series. This is the case even when there are no S-79 flows under the "without project" conditions. However, when S-79 excess flows determined from the difference between the "without project" flows and the EST05 time series exceed 1500 cfs (pump capacity), the excess is allowed to flow over S-79 under the "with project" condition.

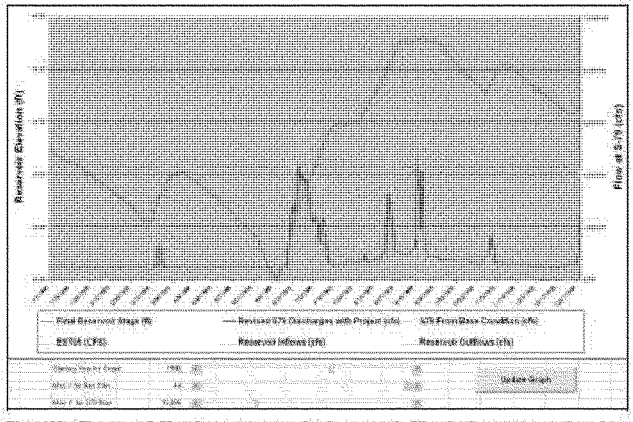

Figure 13. Flow over S-79 and reservoir stage showing reservoir fill and release actions and resulting modifications to pre-project S-79 flows under EST05 driven operations.

5.3.3 Preferred Operation – Based on Seasonality and Reservoir State.

The general logic presented in section 2.1.1 was implemented by providing a series of flow rates based on flows over S-79 that would be used for filling or releasing stored water from the reservoir considering the season of the year and the storage currently within the reservoir. The initial number specified were modified in an iterative procedure until a series of operations that performed better than the "perfect knowledge" operations were identified and a pre-specified timeline for operational improvements were reached. The result though while not necessarily optimal indicates that with operations tuning possible after the project is designed and built, the operation of the reservoir using a logical sequence of rules or a decision table can approach or exceed those forced to mimic EST05. The resulting operations are shown in the appendix to this report.

5.3.3.1 Iterative Procedure.

An initial array of operations corresponding to reservoir stage was developed by examining and analyzing flow data over S-79 derived from SFWMM simulations, actual data, and EST05 flow series. By examining plots of histograms of these flows, and volumes of water necessary to create shifts in the distribution for key years, a pattern was identified. Using best professional judgment, the identified patterns and information contained in previous more rigorous hydrologic modeling conducted for the C-43 project recommended flow and release volumes corresponding to flow over S-79 was developed. These volumes were adjusted to account for state of the reservoir. The reservoir states decided upon was empty reservoir initially defined as the bottom five feet of storage, full reservoir which corresponded to the top 9 feet of storage and medium reservoir which was the condition in between.

The initially specified operations was modified to generate more conservative or less conservative release strategies in order to determine the sensitivity of the model to selected initial operating conditions. The exercise demonstrated that more stringent release rules resulted extended the ability of the reservoir to meet low flows for a longer period but reduced the improvement during high flows. The opposite was the observation for more liberal release policies. Figure 13 shows the high range and low range of several operation iterations. As can be observed from the plot, operations that reduce the high flow occurrences (move the curve towards the lower percentage exceedance) improve towards EST05 (a portion of which is visible at the lower left corner of the upper plot), result in earlier divergence from EST05 in the lower plot. Those operations which provided low flows for the longest period show less of an improvement to high flows (were more to the right on the high flow plot).

The final selected operation (depicted as the heavy line in Figure 13) performed reasonably well, equaling or marginally surpassing the "perfect knowledge" performance on the high side and performing significantly better on the low flows.

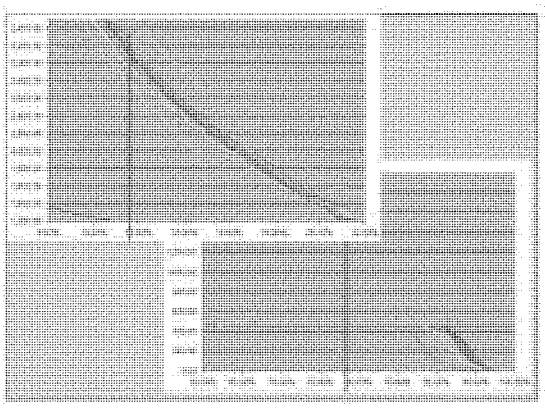

Figure 13. Extremes of the exceedance curves for several model iterations using perturbed operations for the purpose of selecting the preferred operation.

3.3.3.2 Performance Measures for the Preferred Operations

The performance measures observed under this scenario are presented below (Figure 14).

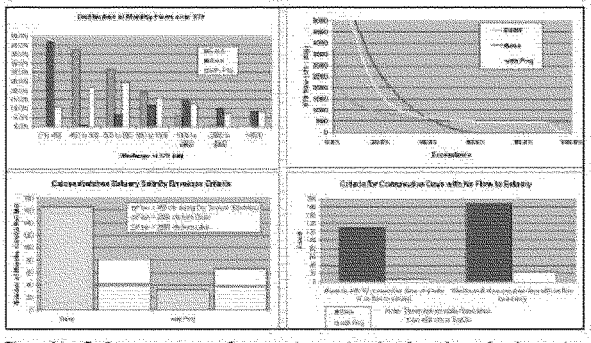

Figure 14. Performance measures for reservoir operations based on the preferred operation (considering seasonality and reservoir state) under year 2000 conditions.

- The histogram showed some greater improvement in the low and mid flow range over both the simplified operations and the "without project" condition and is similar but slightly better than the results under "perfect knowledge" operations. There are still occurrences of flows lower than 450 cfs but this was reduced to approximately 10% of the time. This suggest that even under this operational scenario, reservoir operations to prevent occurrences of flows below 450 cfs is not possible with the current reservoir specifications (size intake and outflow features).
- Considering dry season flows, the number of occurrences of less than 450 cfs was reduced from 167 to 32 from the without project to the "with project" condition. An improvement of 50 occurrences over the simple operations, and 20 over the "perfect knowledge" operations.
- The flow duration curve for the "with project" conditions shows some raggedness corresponding to several small steps at specified operation breakpoints. It is an improvement over the simple operations in appearance and over other operational regimes explored in performance. The reservoir is capable of delivering 450 cfs or greater about 90% of the time over the 36 year simulation period, a significant improvement over the "without project" condition and a sizeable improvement over simplified operations.
- There was a marked reduction in the count of number of events with 10 consecutive days or greater of no flows to the estuary from 131 under the "without project" condition to 5 under the "with project" condition. Similarly the number of consecutive days with no flows to the estuary reduced sharply. From 188 days to 23 days with the reservoir in place.

This operation strategy provided the best performance observed during the modeling exercise. While it is not the optimal solution, it is considered sufficiently close and adequate for planning level analyses. A more rigorous analysis can be conducted when the project enters the design phase.

3.4. Simulation of 2050 Conditions

The spreadsheet was used to simulate the 2050 conditions.

3.4.1 Simplified Operation with Minimum and Maximum S-79 Threshold

Initial analyses used the simplified operations previously described in section 3.3.1 was conducted using 2050 flows at S-79 derived from the SFWMM model. This future condition run does not assume other CERP components in place. The high flow threshold was varied randomly between 2500 cfs and 4200 cfs and the low flow threshold was set at 450 cfs. Examination of the performance under this operational regime shows improvement over the "without project" condition but as with the 2000 scenarios resulted in a somewhat unnatural response with extended periods of fixed flow at 450 cfs in the low flow range. The performance measures for a high flow threshold of 2800 cfs and a low flow threshold of 450 cfs are presented below (Figure 15) and are very similar to the performance observed for the 2000 scenario.

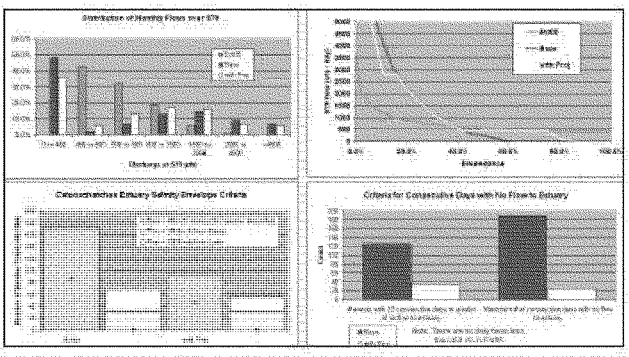

Figure 15. Performance measures for reservoir operations based on high flow (2800 cfs) and low flow (450 cfs) thresholds under year 2050 conditions.

- The histogram showed some improvement in the low flow range over the "without project" condition but flows lower than 450 cfs still occurred more than 35% of the time.
- Considering dry season flows, the number of occurrences of less than 450 cfs was reduced from 172 to 94 from the without project to the "with project" condition. The reduction in the high flow criteria, flows greater than 2800 cfs, was modest.
- The flow duration curve for the "with project" conditions as with the 2000 condition run shows two steps corresponding to the selected high flow and low flow threshold, 2800 and 450 cfs respectively. The period of time when flows over S-79 equaled or exceeded 450 cfs was extended from about 42 % of the time under the "without project" condition to greater than 75% of the time under the "with project" conditions.
- There was a marked reduction in the count of number of events with 10 consecutive days or greater of no flows to the estuary from 125 under the "without project" condition to 35 under the "with project" condition. Similarly the number of consecutive days with no flows to the estuary reduced sharply. From 189 days to 25 days with the reservoir in place.

3.4.2 Bounding Operation with Operations Tied to EST05

Simulating the 2050 conditions using the "perfect knowledge" operations previously described in section 3.3.2 yielded the performance depicted below (Figure 16).

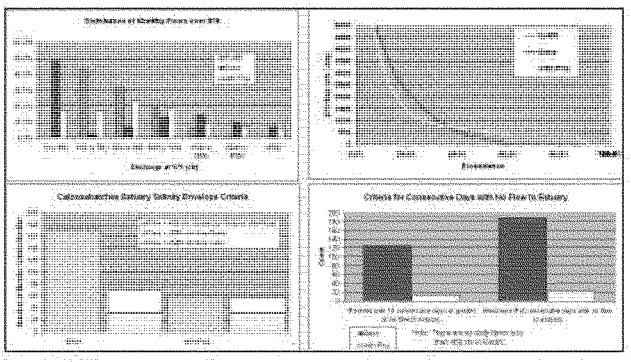

Figure 16. Performance measures for reservoir operations based on matching estuary target flow series EST05 under year 2050 conditions.

- The histogram again showed some improvement in the low and mid flow range over both the simplified operations and the "without project" condition. The occurrences of flows lower than 450 cfs were limited to approximately 17% of the time. This suggest that even under this operational scenario, reservoir operations to prevent occurrences of flows below 450 cfs is not possible with the current reservoir specifications (size intake and outflow features) under projected 2050 conditions.
- Considering dry season flows, the number of occurrences of less than 450 cfs was reduced from 172 to 60 from the without project to the "with project" condition. An improvement of 34 occurrences over the simple operations. The reduction in the high flows even with perfect knowledge was a modest 12 occurrences, reducing from 69 under the "without project" condition to 57 under the "with project" condition.
- The flow duration curve for the "with project" conditions again show a gradual merge of the plot under the "with project" conditions to the EST05 plot until the reservoir becomes incapable of delivering 450 cfs. The reservoir is capable of delivering 450 cfs or greater about 87% of the time over the 36 year simulation period, a significant improvement over the "without project" condition and some improvement over simplified operations.
- There was a marked reduction in the count of number of events with 10 consecutive days or greater of no flows to the estuary from 125 under the "without project" condition to 14 under the "with project" condition. Similarly the number of consecutive days with no flows to the estuary reduced sharply. From 189 days to 23 days with the reservoir in place.

Below (Figure 17) shows a plot of flows over S-79 for a portion of the simulation and illustrates the operations under this release strategy. The selected period is a dry period when the reservoir volume ranges from empty to the just barely over half full for the

entire year. This plot explains the details of this operation scheme. Moving from left to right on the plot, when the flow over S-79 exceed EST05, the pump kick on and pumps at a rate equal to the difference between S-79 flows under the "without project" conditions and the target defined by EST05. When the pump capacity is reached, the pumping rate is capped and the excess continues to flow over S-79 resulting in flows greater than EST05. When flows under "without project" conditions drop such that they are greater than EST05 but less than pump capacity, the pumping rate reduces until the pump shuts off when the flows from both series become equal. When the flows under the "without project" conditions fall below EST05, reservoir releases commence at a rate adequate to bring the flow rates up to EST05. This persists until the reservoir volumes are inadequate to sustain such flows and the rate drops, limited by reservoir volume until there are no flows from the reservoir. As flows become available again for capture, the reservoir fills but at a rate limited to the excess over EST05 flows and limited by pump capacity. Releases commence, even with an almost empty reservoir once flows dip below EST05 flow rates.

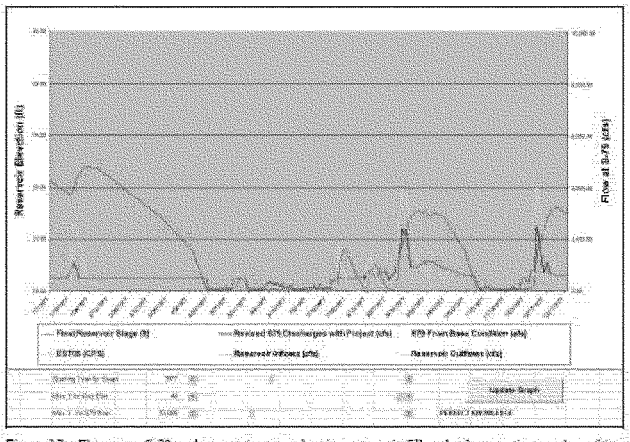

Figure 17. Flow over S-79 and reservoir stage showing reservoir fill and release actions and resulting modifications to pre-project S-79 flows under EST05 driven operations. Note extended periods of low to empty reservoir and periods of no flows over S-79 to estuary

3.4.3 Preferred Operation – Based on Seasonality and Reservoir State.

The final selected operations derived as described under 3.3.3 were implemented without change for the 2050 conditions. The iterative procedure was not duplicated. The resulting performance measures observed under this scenario are presented below (Figure 18).

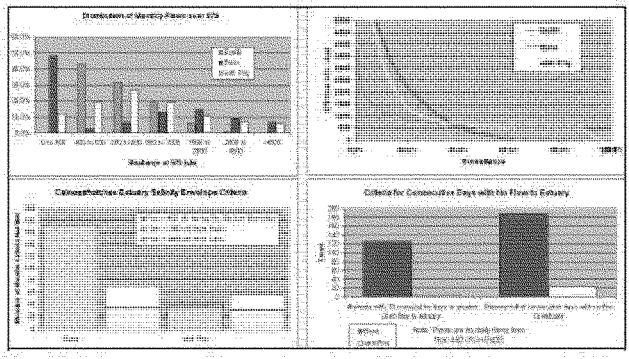

Figure 18. Performance measures for reservoir operations based on the preferred operation (considering seasonality and reservoir state) under year 2050 conditions.

- The histogram showed significantly greater improvement in the low and mid flow range over both the simplified operations and the "without project" condition and is better than the results under "perfect knowledge" operations. There are still occurrences of flows lower than 450 cfs but this was reduced to approximately 11% of the time. This suggest that even under this operational scenario, reservoir operations to prevent occurrences of flows below 450 cfs is not possible with the current reservoir specifications (size intake and outflow features) under 2050 projected conditions.
- Considering dry season flows, the number of occurrences of less than 450 cfs was reduced from 172 to 36 from the without project to the "with project" condition. An improvement of 58 occurrences over the simple operations, and 24 over the "perfect knowledge" operations.
- The flow duration curve for the "with project" conditions shows some raggedness corresponding to several small steps at specified operation breakpoints. It is an improvement over the simple operations in appearance and over other operational regimes explored in performance. The reservoir is capable of delivering 450 cfs or greater about 88% of the time over the 36 year simulation period, a significant improvement over the "without project" condition and a sizeable improvement over simplified operations.
- There was a marked reduction in the count of number of events with 10 consecutive days or greater of no flows to the estuary from 125 under the "without project" condition to 5 under the "with project" condition. Similarly the number of consecutive days with no flows to the estuary reduced sharply. From 189 days to 23 days with the reservoir in place.

The operation strategy unrefined or optimized for 2050 flow conditions provided superior performance to the EST05 driven operation. As noted previously, while this operation strategy may not be the optimal operation strategy, it is considered sufficient for planning level analyses. A more rigorous analysis can and should be conducted when the project enters the design phase.

Below (Figure 19) shows a plot of flows over S-79 for the same portion of the simulation depicted in Figure 17. Figure 19 represents the results obtained from using the preferred operations and is compared with the results of the "perfect knowledge" operation to explain why the preferred operation yields better performance.

The selected period is a dry period when the reservoir volume ranges from empty to just barely over half full for the entire year. This plot explains the details of this preferred operation strategy and shows how it is able to meet the low flow criteria for longer period by releasing less than EST05 during a very dry event. Again, moving from left to right on the plot, when the flow over S-79 some threshold defined by the operation rules and depending on the season (January and February corresponding to the last month of early dry and the first month of late dry in this case), the pump kick on and pumps at a rate specified in the rules. When the pump capacity is reached, the pumping rate is capped and the excess continues to flow over S-79. When flows under "without project" conditions drop such that it crosses a decision threshold, the pumping rate reduces until the pump shuts at the specified S-79 flows for the current season at which the reservoir makes no releases. When the flows under the "without project" conditions fall below a release threshold, reservoir releases commence at a specified rate according to the operational rules. Releases persist until modified by either, flow thresholds, reservoir state, release capacity or reservoir volumes. When reservoir volumes become inadequate to meet the specified releases, the rate drops, limited by reservoir volume until there are no flows from the reservoir. As flows become available again for capture, the reservoir fills but at the specified rate limited only by pump capacity. If the reservoir is low and is within the state defined as empty, a stingy release strategy is applied and captured flow is dolled out at a low rate specified in the release rules corresponding to the reservoir state and season. Observe that this operation results in the availability of flows throughout the early dry season (right hand side of the plot) in the period depicted while the reservoir ran dry for the EST05 driven operations.

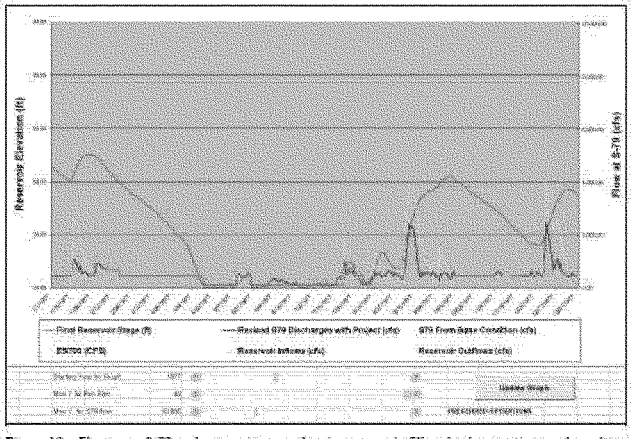

Figure 19. Flow over S-79 and reservoir stage showing reservoir fill and release actions and resulting modifications to pre-project S-79 flows under preferred operations. Note extended periods of low to empty reservoir but reduced periods of no flows over S-79 to estuary compared to Figure 17.

Section 4 - Discussion of Results

As stated in the introduction to this report, *"the purpose of the C- 43 Storage Reservoir Phase I Project is to improve water deliveries to the estuary, provide for dry season flows, reduce magnitude of wet season high flows, restore downstream salinity levels and ensure the availability of water for the natural system needs of the Caloosahatchee Estuarine System."*

The results of simulation using the spreadsheet model of both 2000 and 2050 conditions with project and comparison of those scenarios to the "without project" conditions suggest the following.

4.1 Water Deliveries to the Estuary

The "with project" runs using the preferred operations significantly extend the period of deliveries to the estuary over the "without project" conditions. The flow duration curves for both 2000 and 2050 scenarios show a shift in the percent of time flow to the estuary exceeds 450 cfs in the order of 45 percent with a slightly smaller shift for period of no flow to the estuary. If the simulated reduction is coupled with the realization that in

real life operations, actions that are different from the rule may be implemented to extend the available storage in the end of the very dry period, perhaps by implementing pulse releases, there is a possibility that zero flow to the estuary conditions may be further limited. The improvement in deliveries to the estuary is significant and should be reflected in the ecological modeling effort to establish habitat units. The current results still show period of no flow over S-79, this will have to be addressed in Phase II of this PIR.

4.2 Magnitude of West Season Flows

The results suggest more modest improvement in the area of high flows to the estuary, a reduction in percent exceedance in the order of 4 to 5 percent at 2800 cfs. The 12 to 14 point reduction in all flows over 2800 cfs, a 20 % improvement, leaves almost 50 occurrences more than the target, of flows greater than 2800 in the 36-year period of simulation. The pump capacity and reservoir volume are limiting in this respect. Without off line, long term storage (such as is projected to be capable through aquifer storage and recovery,) the reservoir fills quickly and high flow events pass by unhindered. To significantly affect the high flow conditions, other efforts such as CERP project components that result in a reduction in releases to the watershed from the regional system, along with the planned second phase of the C-43 Reservoir project will need to be implemented.

4.3 Retention of Water for Natural System

The results as described in section 4.1 show that the "with project" conditions meet the objective of storing water for the natural system. The quantification of the volume of water made available will be presented in a separate report.

Section 5 - Conclusions and Recommendations

The IMC has developed and implemented a spreadsheet model of the C-43 Basin Storage Reservoir, Phase I project. The spreadsheet model based on a water budget of the reservoir and flows over S-79 stores excess flow during high flow events for release during low flow event with the objective of achieving to the extent possible restoration flows to the Caloosahatchee Estuary.

The following are conclusions that can be reached from the results of the analyses completed using the model:

1) A reservoir project with the specifications provided by the C-43 PDT (170,000 acre ft storage, 1500 cfs inflow pump capacity, 1,200 to 1,500 outflow capacity) will provide significant benefit during low flow conditions by augmenting flows to the estuary.

2) The reservoir will significantly minimize zero flow conditions to the estuary and will reduce the frequency of occurrence of less that 450 cfs, minimum restoration flows, over the existing conditions and future condition without the project.
3) The reservoir will have modest improvement in reduction of high flow.
4) While less than the "without project" condition, without additional efforts beyond the C-43 West Phase I reservoir project, high flow event will still significantly exceed the target frequency.
5) The project stored and makes water available to the natural system when needed by the estuary

APPENDIX I

SPREADSHEET MODEL USER DOCUMENTATION

FINAL Page 35 of 58

An Overview and User Manual for the Spreadsheet Model "C43_PIR-model_Final.xls"

Walter Wilcox & Akintunde Owosina

Introduction

The proposed C43 basin reservoir is expected to provide additional storage which will allow for increased operational flexibility in controlling discharges to the downstream Caloosahatchee Estuary. In order to illustrate the potential performance associated with this project, the spreadsheet model "C43_PIR-model_Final.xls" has been developed. The spreadsheet's primarily goal is to compare the with-project discharge over S79 (the downstream point at which the basin discharges into the estuary) to both the pre-project discharge over S79 and to the EST05 time series representing restoration target flows over S79 for a 36 year, daily period of simulation. In addition, the spreadsheet also shows a water budget for the reservoir and tracks reservoir inflows, releases and storage. The factors influencing the scope of the spreadsheet development and analysis are encompassed in other project documents and therefore, the primary purpose of this document is to catalog the means and methods by which the spreadsheet functions.

Methodology

The spreadsheet is predicated on a mass balance approach assuming that flows observed in a base condition at S79 can be captured, stored offline in a defined reservoir control volume and then later released to discharge at S79 during a more desirable period. As such, the primary equations utilized in the spreadsheet involve the mechanism by which S79 flows are diverted and the criteria for such diversions (including operational intent and conveyance limitations). Climate conditions affecting the reservoir control volume are also considered. The governing equation for mass balance on the reservoir is:

$$Res_Sto_f = Res_Sto_i + Res_Inflows + Rainfall - Evaporation - Res_Releases - Seepage \quad \text{(Equation 1)}$$

where Res_Sto_f is the storage in the reservoir at the end of the time step, Res_Sto_i is the storage in the reservoir at the beginning of the time step, Res_Inflows is the inflow to the reservoir control volume during the time step and Res_Releases is the outflow from the reservoir control volume during the time step. The governing equation for modification to S79 flows as a result of reservoir operations is:

$$S79_{wproj} = S79_{pre\text{-}proj} - Runoff_Adjust - Res_Inflows + Res_Releases * Efficiency \quad \text{(Equation 2)}$$

where Runoff_Adjust accounts for a water budget correction involving the potential effect of the reservoir footprint on basin runoff and Efficiency accounts for potential losses between the reservoir discharge point and the estuary. S79 flow and other data for Existing Conditions Baseline (2000) and Future without Project Condition (2050 with no-

FINAL Page 36 of 58

CERP projects in place) are derived from South Florida Water Management Model (SFWMM) runs 2000RD and 2050RD. The following assumptions related to regional influences (excluding S79) are made in conducting the spreadsheet analysis:

- No agricultural or urban water supply deliveries are supplied by the reservoir; these demands continue to be supplied from Lake Okeechobee or current groundwater sources
- Eastern Caloosahatchee Basin (east of S-78) is not affected by the project.
- With the exception of changing flows to the Caloosahatchee Estuary west of S79, there will be no impacts on the Western Caloosahatchee Basin.
- The regional system, including Lake Okeechobee and non-C43 downstream basins will not be impacted by the project.

Example Daily Time Step

The following outlines how the model calculates an end of day reservoir storage and S79 flow value from the initial S79 flow term for a given day. Italics refer to worksheets in the "C43_PIR-model_Final.xls" workbook.

- In *Reservoir_Model*, S79 flow from the base condition (cfs) is taken from *Input TS* (originally derived from SFWMM simulations).
- S79 flow contributed by basin runoff is modified to account for the existence of the reservoir footprint. This helps to ensure that the analysis does not affect the basin water budget and artificially "generate" water from rainfall on the reservoir. The means by which runoff is adjusted is determined by which option is used to adjust runoff to S79 (described in more detail under the "User Options" section).
- Reservoir inflows are calculated based on a combination of factors including desired operational intent, inflow pump capacity and available volume in reservoir.
- Rainfall (if any) occurs on the entire reservoir footprint.
- An intermediate storage volume is calculated as the previous end-of-day storage plus inflows and rainfall. This volume (and associated stage/area) will be referenced in remaining decisions within the time step.
- Reservoir outflows are calculated based on a combination of factors including desired operational intent, outflow spillway capacity, overflow spillway capacity, expected efficiency in delivery from reservoir to S79 (assumed to be 100% for analysis, but can be user specified) and available volume in reservoir.
- Evaporation on the water surface area within the reservoir (after outflows) occurs. Total evaporation is limited to the available volume in the reservoir.
- Reservoir seepage losses occur (assumed to be zero for analysis, but can be user specified).
- End-of-day reservoir storage and associated stage is calculated using the governing mass balance in Equation 1.
- Revised, with-project S79 flows are calculated by subtracting reservoir inflows and adding reservoir outflows (including efficiency term) to the adjusted S79 flows calculated in Step 2 (application of Equation 2).

FINAL Page 37 of 58

Spreadsheet Structure

While the model produces 36 years of daily output, only the first several rows of data in each calculation column retain the equations required to perform a simulation. This is done in order to save on memory and disk storage requirements. The rows that retain active formulas are typically highlighted through use of red and/or blue text. Spreadsheet simulations are controlled by a high level macro that is accessed by clicking on the "Run Simulation" button in the *Reservoir_Model* worksheet (Figure 1). This macro propagates required equations throughout the workbook and updates all dependent series including pivot tables and sorted data prior to saving the majority of data as values. A related macro, accessed by clicking on the "Condense Spreadsheet and Save" button in the *Reservoir_Model* worksheet, deletes many data arrays in an effort to condense file size for quicker transfer through ftp, e-mail, etc.

Worksheet Descriptions

- *Reservoir_Model* – This worksheet is the primary simulation engine for the analysis. Rows 1-9 contain many of the user input options and columns E-S perform the daily simulation of the reservoir and accompanying changes to S79 flows. Data to the right of Column Z is associated with post-processing results to be displayed on subsequent worksheets.
- *PMs* – Graphs of various evaluation criteria (performance measures) associated with S79 discharges and reservoir operation. Included are the following: 1) S79 discharge histogram; 2) Caloosahatchee Estuary salinity envelope criteria (per RECOVER); 3) Daily S79 flow duration curve; 4) Criteria for consecutive days with no flow to the estuary at S79; and 5) Interactive graph showing detailed reservoir performance for a specified year.
- *Checks* – Graphs of various metrics associated with reservoir and basin performance are displayed in this worksheet. Included are the following: 1) Reservoir stage hydrograph; 2) Reservoir stage duration curve; 3) Scatter plot of original vs adjusted S79 flows for the base condition; 4) Reservoir stage vs inflows; 5) Reservoir stage vs outflows; 6) Reservoir inflows vs outflows
- *Pivot* – Houses pivot tables of monthly average S79 flow for the pre- and with-project conditions. This sheet is automatically updated when the "Run Simulation" macro is invoked.
- *Input TS* – Contains time-series data imported from the SFWMM including S79 flows, basin runoff, rainfall and potential evapotranspiration (PET).
- *Ops* – This worksheet is only utilized if option #2 (Seasonal/Res stage criteria) is used in the operational criteria drop box on the *Reservoir_Model* worksheet. The operations defined in this sheet will select a desired inflow / release volume to be used in the simulation of the reservoir operations. The decision is predicated on the definition of three terms – 1) base condition adjusted flow at S79; 2) current season (early dry, late dry, early wet or late wet); and 3) current reservoir state (empty, medium or full).
- *Res* – This sheet contains information provided by Stanley Consultants on the proposed reservoir storage to area to stage relationship. Although information is provided for individual cells (numbers 1 and 2), only the total, aggregated values are used by the workbook. This worksheet contains six defined arrays

(areasta, areasto, staarea, stasto, stoarea and stosta) which are used in the various lookup tables in other worksheets. Modifications to the proposed footprint / bathymetry of a reservoir alternative can be accommodated by changing the definition of these arrays.

- *Est05* – Contains the time-series and sorted daily restoration target flows desired over S79.

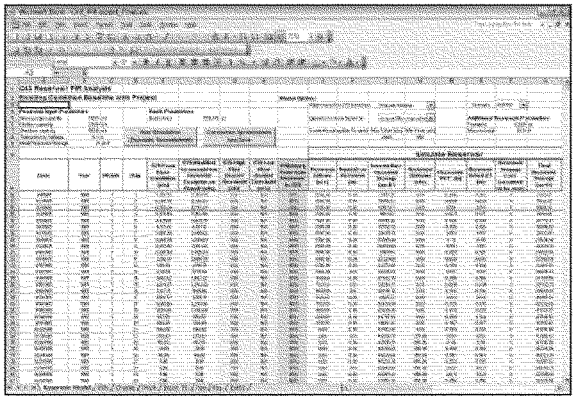

Figure 1. Screen Capture of "C43_PIR-model_Final.xls"

User Options

- Reservoir Input Parameters – In cells B-5 to B-9 of the *Reservoir_Model* worksheet, users can specify values for the following terms: 1) Reservoir inflow pump capacity; 2) Reservoir outflow capacity; 3) Reservoir overflow capacity; 4) Tolerance for Spillage; and 5) Initial Reservoir Storage. The additional parameters of reservoir footprint and maximum reservoir height are specified in cells P7 and P8. These values are referenced back the volume-stage-area relationship provided in the *Res* worksheet. Option # 4 (Tolerance for Spillage) is used in operating the reservoir to avoid overtopping. Inflows to the reservoir are stopped at the maximum reservoir height – tolerance and outflows are begun at the maximum reservoir height – tolerance + 0.1 ft.
- Adjust runoff to S79 drop box – This option has little effect on the overall analysis, but various methodologies were proposed by the technical team and incorporated into the model. The following options may be selected:
  - Landarea Ratio – S79 flow will be adjusted using the equation:
    $S79_{adj} = S79_{base} - Runoff_{Basin} * ResFootprint / Basin\ Area$
  - Daily RF/RO Ratio – S79 flow will be adjusted using the equation:

$S79_{adj} = S79_{base} - Runoff_{Basin} * Rainfall_{Res} / Rainfall_{Basin} * ResFootprint / Basin Area$

- Accumulated RF/RO Ratio – S79 flow will be adjusted using the equation:

$S79_{adj} = S79_{base} - Runoff_{Basin} * AccRF_{Res} / AccRF_{Basin} * ResFootprint / Basin Area$

where AccRF represents the 10-day moving accumulation of previous rainfall. It is recommended that Option 3 (accumulated RF/RO ratio) be selected for analysis.

- Operational criteria drop box – The following options may be selected:
  - Max/Min S79 thresholds – Reservoir operations will attempt to keep daily S79 flow between the thresholds specified in cells L8 and M8 (these can be modified by the user).
  - Seasonal/Res stage criteria – Operations will be dictated by the prescribed lookups found in the *Ops* worksheet as described above. The user can control the parameters of the lookup by modifying several fields in the *Ops* sheet including:
    - S79 flow categories in B8 to C16
    - Reservoir stage breakpoints for defining empty / medium / full in cells B20 and B21.
    - The season (early dry, late dry, early wet or late wet) associated with each calendar month in cells G8 to G19
    - The fill and release volumes by modifying the factors in columns U-X.
  - Use of EST05 – Reservoir operations will attempt to match daily flow as closely as possible to the EST05 daily value as taken from the *Est05* worksheet.
- Scenario drop box – Used to select which SFWMM run to reference for the Base Condition. The available options are the 2000RD (for existing condition) and 2050RD (for future condition) scenarios.
- Detailed reservoir performance graphic – In the *PMs* worksheet, there is an interactive graph illustrating reservoir stage as well as various simulated flows associated with the reservoir and S79. To control this graphics, the user may use the pull bars to specify the desired year (x-axis) and maximum y-axis scaling values for reservoir elevation and flows. Once appropriate values have been selected, the "Update Graph" button should be clicked to implement changes.
- Consecutive days of no-flow to S79 option - In the *PMs* worksheet, the number of consecutive days required to increment a count in the fourth graphic can be modified by updating cell AZ4 in the *Reservoir_Model* worksheet.
- Reservoir seepage loss – If desired, an equation for calculating reservoir seepage loss can be added to cells P12-P14 in the *Reservoir_Model* worksheet. As long as the equation occupies all three cells, it will be propagated during analysis.
- Efficiency term from reservoir to S79 - If desired, an equation or value for calculating efficiency in deliveries from the reservoir to S79 can be added to

cells I12-I14 in the *Reservoir_Model* worksheet. As long as the equation occupies all three cells, it will be propagated during analysis.

APPENDIX II

SENSITIVITY ANALYSIS

A sensitivity analyses of key model parameters is recommended but was not completed in a detailed manner under the current scope. An informal, ad-hoc sensitivity analyses was performed for the selection of the preferred operation scheme which showed that the model was sensitive to the operations parameters specified. These include the breakpoints depths for defining an empty, medium or full reservoir, the breakpoints for flow over S-79 at which different release of fill rates are implemented (especially at the 2000 cfs point.) The performance of the model is also sensitive to the definition of the seasons; however the sensitivity diminishes as the operations across seasons become more similar.

The IMC recommends a more robust sensitivity analyses if this tool is to used as part of future work on the C-43 phase II project.

APPENDIX III

RESERVOIR PREFERRED OPERATION RULES

The seasonal operation implemented in the spreadsheet is based loosely on the logic contained below (Figure III-1).

Fill	WET SEASON	DRY SEASON
Early in Season	Fill slowly to retain capacity for later in the season	Fill aggressively in preparation for rest of dry season
Late in Season	Fill reservoir faster to get full by end of year (use available capacity as a factor)	Fill slowly to retain capacity for wet season

Pump capacity (and channel capacity) are limiting. Intake threshold and volume may vary but based on a consistent logic. The Threshold will be determined by iteration.

Empty	WET SEASON	DRY SEASON
Early in Season	Release aggressively to create capacity for filling reservoir later in the season	Release less aggressively to extend ability to release longer into the dry season
Late in Season	Release more carefully to keep reservoir full going into the dry season	Release more aggressively to empty reservoir in preparation for the wet season

The constraint to the release strategy listed to the side are reservoir release capacity and the requirement that wet season flows should not greatly fall below EST05 and Dry season flow over S-79 should not greatly exceed EST05

Figure III-1. Generalized operational logic to implement seasonality.

In determining and assigning numerical values to the general logic above, the following definitions were adopted.

Seasons

Early wet season was defined as June to July
Late Wet season was defined as August to October
Early Dry season was defined as November to January
Late Dry season was defined as February to May
The definitions of these seasons are in the operations "Ops Worksheet" in the spreadsheet and can be changed within the spreadsheet. See below (Figure III-2).

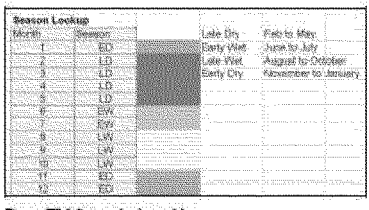

Figure III-2 Season lookup table

Reservoir State

The state of the reservoir, empty, medium or full is defined in the "Ops Worksheet" and can be changed within the spreadsheet. The initial definition is as shown below:

Empty reservoir:	Elevation 19 to 25 NAVD
Medium full reservoir:	Elevation 25 to 33 NAVD
Full reservoir:	Elevation 33 to 42 NAVD

Following changes made to this parameter to determine preferred operations, the reservoir state definition was simplified to use just two zones shown below (Figure III-3).

Reservoir Breakpoints

Stage	Storage
29	57534
42	178602

19.2	to	29.0	Empty
29.0	to	42.0	Mid
42.0	to	42.0	Full

Figure III-3. Reservoir break points for defining reservoir state.

Flow Decision Breakpoints

A series of ranges of flow were established at which fill decision or release decisions will be made. These ranges differ for fill or release but were limited to 9 categories in each case. Below (Figure III-4) shows the flow at which operational decision changes occurred within the mode.

Operations Parameters

S79 flow

Fill	Drain	Category
520.01	250.01	1
650.01	350.01	2
850.01	450.01	3
1000.01	550.01	4
1200.01	800.01	5
1500.01	1000.01	6
2000.01	1500.01	7
2800.01	2800.01	8
99999	99999	9

Figure III-4. Flow decision breakpoints

The Initial operation rules specified based on examination and analyses of available data is shown below (Table III-1 and Table III-2).

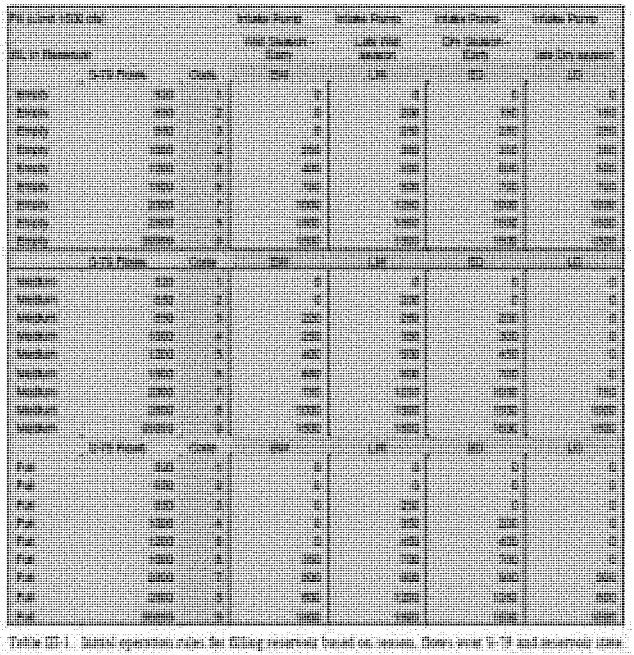

Table III-1 Initial operation rules for filling reservoir based on season, flows near S-79 and reservoir stage

As can be observed from the data contained in Table III-1 and Table III-2, the pumping and release rates (in cfs) meet the intent of the logic described in Figure III-1. These initial values were subject to small variations for the purpose of developing successively improved performance. The final set of operations described in this appendix and shown in Table III-3 and Table III-4 were the result of the iterative process and were used as the preferred operations for both the 2000 and 2050 scenarios.

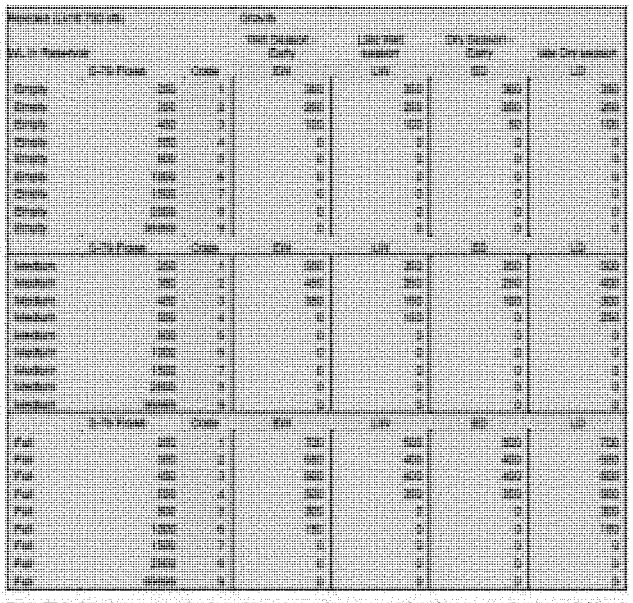

Table III-2. Initial operation rules for making releases from reservoir based on season, flows over S-79 and reservoir state.

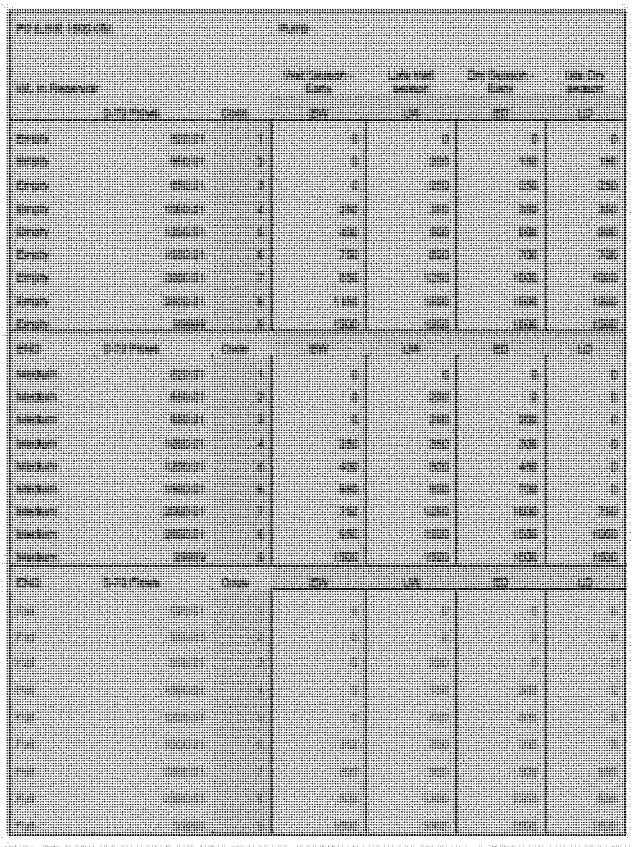

Table III-3 Initial operation rules for filling reservoir based on season, flows over S-79 and reservoir state (Note values in red while defined were not used due to reservoir state condition)

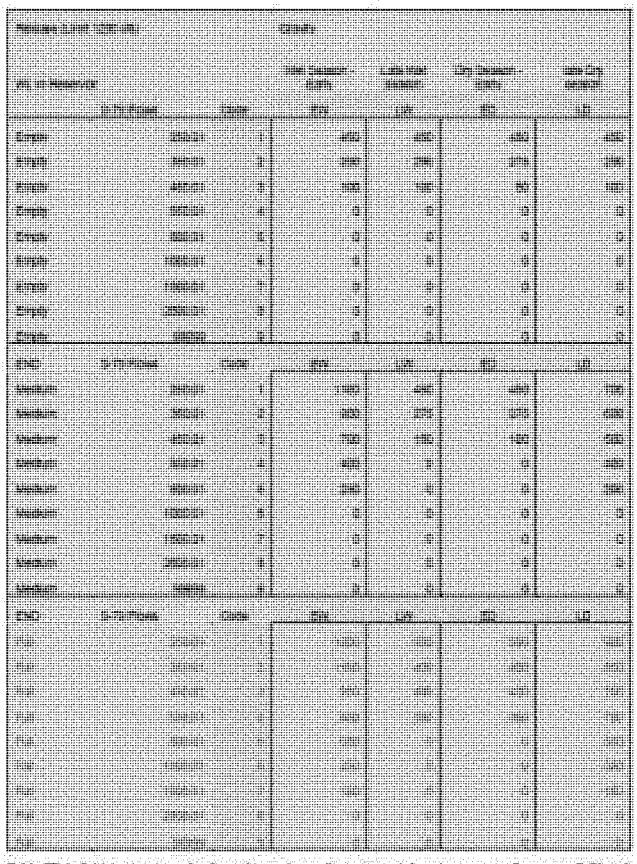

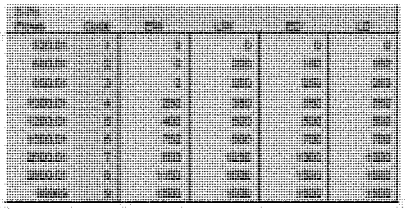

Table III-4. Initial operation rules for making releases from reservoir based on season, flows over S-79 and reservoir state (Note values in red while defined were not used due to reservoir state condition)

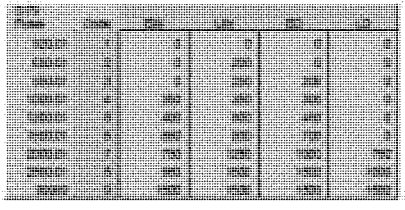
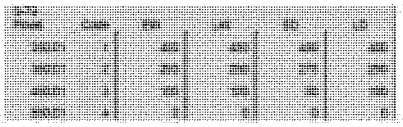


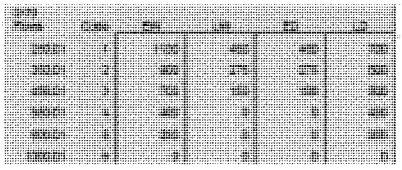
Preferred Operations

Reservoir Fill Decision

1) If the reservoir is empty, a state defines as having 10 feet or less of water or a water surface of elevation 29 feet or less, implement the following operations depending on the season (Early Wet – EW, Late Wet – LW, Early Dry – ED, Late Dry – LD) and flows over S-79 less than the value shown to the left of the table.



2) If the reservoir is medium or full, a state defines as having more than 10 feet of water, or a water surface of elevation of more than 29 feet NAVD, implement the following operations depending on the season (Early Wet – EW, Late Wet – LW, Early Dry – ED, Late Dry – LD) and flows over S-79 less than the value shown to the left of the table.



Reservoir Environmental Release Decision

1) If the reservoir is empty, a state defines as having 10 feet or less of water or a water surface of elevation 29 feet or less, implement the following operations depending on the season (Early Wet – EW, Late Wet – LW, Early Dry – ED, Late Dry – LD) and flows over S-79 less than the value shown to the left of the table.

2) If the reservoir is medium or full, a state defines as having more than 10 feet of water, or a water surface of elevation of more than 29 feet NAVD, implement the following operations depending on the season (Early Wet – EW, Late Wet – LW, Early Dry – ED, Late Dry – LD) and flows over S-79 less than the value shown to the left of the table.

Operation Exceptions

The following conditions void the rule based operation

1) Ignore reservoir filling rule if reservoir full to within a specified value of spillway (5000 acre feet used in spreadsheet) or within specified height in feet (specified within the model as tolerance for spillage = 0.3 feet used in spreadsheet) of spillway elevation.
2) Release at maximum rate (specified as 1200 cfs) despite release rule if reservoir full to within 0.2 feet of spillway elevation. (specified within the model as tolerance for spillage – 0.1)
3) Suspend release rule if reservoir is empty.

Operation pattern resulting from the rules and exceptions above are graphically depicted in the check plots shown below.

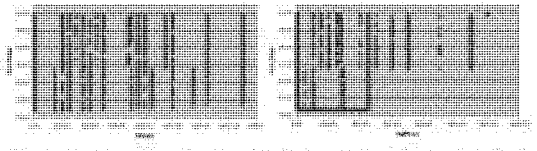


Figure III-5. Inflow and outflow operations plotted against reservoir stage for preferred operations.

Customer Requirements

The IMC has fulfilled the objectives of this project and has met the customer requirements.

The objectives of the study conducted by the IMC are as follows.

1) Develop a spreadsheet tool suitable for meeting the requirements identified in the customer requirements section (1.3) of this report and submitted as attachment to MSR 262 by the C-43 PDT.

The IMC has developed a spreadsheet suitable for meeting the requirements identified in the customer requirements section of this report. The IMC has demonstrated the application of the spreadsheet tool using the C-43 Basin Storage Reservoir, Phase 1 Project.

2) Utilize the spreadsheet to simulate the 2000 and 2050 condition with and without project for the purposes of fulfilling

a. GM #2-Next Added Increment Analysis requirement

b. GM #4 requirements for Identifying Water Made Available by the Project-volumetric analysis from spreadsheet output, and

c. GM #5-Serves at the basis for Draft Project Operating Manual-Spreadsheet operations of Existing Conditions with Project (same as Initial Operating Regime).

The IMC has used the spreadsheet model to simulate 2000 and 2050 conditions and has produced model results with and without project for subsequent analyses by others. In addition the IMC has implemented the methodology for satisfying GM # 2, GM #4 and GM #5.

3) Deliver the spreadsheet with a user guide and model results to PDT team for subsequent analyses.

The IMC has delivered the spreadsheet to the PDT and the results of the spreadsheet for subsequent analyses.

4) Deliver the model results to assurances team for subsequent analyses and write-up.

The IMC has delivered the model results to the assurances team for subsequent analyses.

5) Document the spreadsheet and provide a project report describing the analyses, the key assumptions, limitations and application to the PDT.

The IMC has documented the spreadsheet by preparing and delivering a user documentation report. The IMC has further documented it effort by developing and delivering a technical memo detailing the work completed under MSR 262.

Features Checklist

- Flow data for Existing Conditions Baseline (2000) and Future "without project" condition (2050 with no-CERP projects in place) is derived from South Florida Water Management Model runs 2000RD and 2050RD.
- ET from reservoir will be included. The mass balance terms for the reservoir are reservoir inflow, reservoir releases, reservoir seepage will be assumed to be zero, ET losses (based on area volume relationship), and perhaps reservoir direct precipitation (not yet confirmed).
- System losses from the river to groundwater from the point of release of the reservoir to S-79 will be factored into the spreadsheet analysis. (Evaluation of relevant available data indicates that use of 100% efficiency is reasonable for this project)
- No agricultural or urban water supply deliveries are supplied by the reservoir these demands continue to be supplied from Lake Okeechobee or current groundwater sources
- Water will be pumped into the reservoir only when there are excess flows over S-79. Excess will be treated initially as high flows over some threshold that will be refined through iterations of the spreadsheet to obtain the best performance in meeting estuary targets (EST 05).
- Releases from the reservoir are made when flows over S-79 are below desirable levels (450 cfs). Releases will be refined through iterations of the spreadsheet to obtain the best performance in meeting estuary targets (EST 05).
- Including basic seasonal operational variability in the spreadsheet for filling and draining the reservoir is preferable.

Section 1 – Introduction

1.1 Project Background

The C-43 Basin Storage Reservoir Phase I Project comprises the C-43 West Storage Reservoir (Figure 1) located on the Berry Grove property in the western portion of the Caloosahatchee Watershed in Hendry County, Florida.

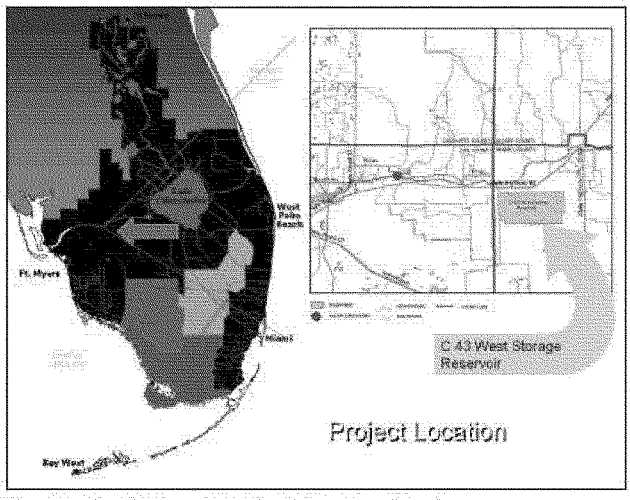

Figure 1. Location of the Proposed Site for the C-43 West Storage Reservoir.

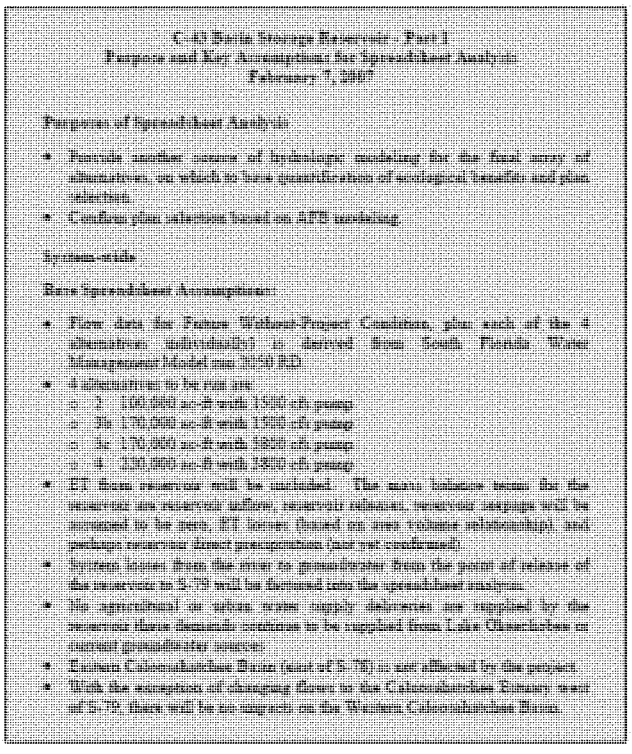
The purpose of the C-43 Basin Storage Reservoir Phase I Project is to improve water deliveries to the estuary, provide for dry season flows, reduce magnitude of wet season high flows, restore downstream salinity levels and ensure the availability of water for the natural system needs of the Caloosahatchee Estuarine System. Subsequent phases of the C-43 Storage Reservoir Project will address these same issues in addition to providing additional water resource benefits through provision of supplemental water resources for agriculture and urban users thereby benefiting the regional system by reducing the dependence on Lake Okeechobee.

In selecting the components of the Phase I project, the Project Delivery Team (PDT) used a formal plan formulation process described in Section 5 of the Draft PIR report and considering the objectives and opportunities of the project as well as documented project siting criteria. The criteria included such factors as land use and land cover, proximity to primary canal, site elevation, potential restoration value, location within the watershed (proximity to the Estuary), soil suitability for the project and so on. The screened list of potential sites was further reduced by considering threatened and endangered species and geotechnical screening concerns. One site, the Berry Groves property in the Western Caloosahatchee Basin and several in the Easter Caloosahatchee Basin were developed as a final list of potential sites. Considering the focus of the first phase of the project, improving the flows to the estuary, the project location in the Western Caloosahatchee Basin was selected for development of alternatives.

The Interagency Modeling Center (IMC) has been tasked through MSR 264 to modify a spreadsheet model of the C-43 Basin Storage Reservoir previously developed for conducting Next Added Increment (NAI) and project assurances analyses and apply the spreadsheet to the evaluation of the alternatives for the basis of selecting a recommended plan. This report documents the objectives, scope of work approach, and describes the modeling tool modification and simulations conducted on behalf of the C-43 PDT per MSR 264.

1.2 Objectives and Scope of Work



The objectives of the study conducted by the IMC are as follows.

1) Develop a spreadsheet tool suitable for meeting the requirements identified in the customer requirements section (Section 1.3) and submitted as attachment to MSR 264 by the C-43 PDT.
2) Utilize the spreadsheet to evaluate the project alternative scenario using the 2050 (NAI) condition for the purposes of plan selection.
3) Deliver the spreadsheet results to the PDT for further analyses and computation of habitat units.
4) Document the spreadsheet and provide a project report describing the analyses, the key assumptions, limitations and application to the PDT.

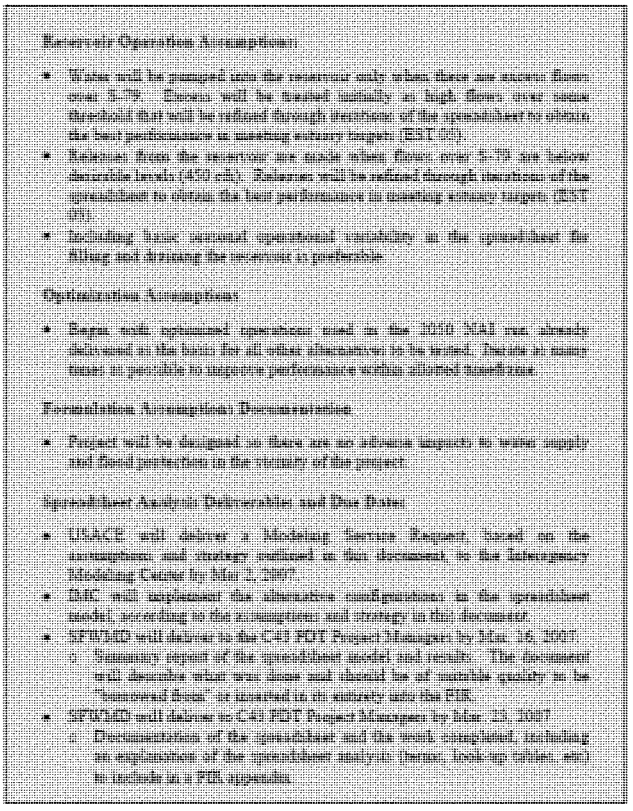
1.3 Customer Requirements

The IMC was tasked by the PDT through MSR 264 to modify and apply a simplified spreadsheet model of the C-43 West Reservoir based on capture of excess flow over S-79 as derived from SFWMM simulation of the 2050 future base conditions. The detailed scope and customer requirements are as follows:

FINAL Page 5 of 77

C-43 Basin Storage Reservoir - Part 1
Purpose and Key Assumptions for Spreadsheet Analysis
February 7, 2007

Purposes of Spreadsheet Analysis:



- Provide another source of hydrologic modeling for the final array of alternatives, on which to base quantification of ecological benefits and plan selection.
- Confirm plan selection based on ATM modeling.

System-wide

Base Spreadsheet Assumptions:

- Flow data for Future Without-Project Condition, plus each of the 4 alternatives, individually, is derived from South Florida Water Management Model run 3A09.RD
- 4 alternatives to be run are:
  - 1: 100,000 ac-ft with 1500 cfs pump
  - 2a: 170,000 ac-ft with 1500 cfs pump
  - 3a: 170,000 ac-ft with 1850 cfs pump
  - 4: 220,000 ac-ft with 1850 cfs pump
- ET from reservoir will be included. The mass balance terms for the reservoir are reservoir inflow, reservoir release, reservoir seepage will be assumed to be zero, ET (based on pan evaporation), and perhaps reservoir direct precipitation (but not confirmed)
- Seepage losses from the river to groundwater from the point of release of the reservoirs to S-79 will be factored into the spreadsheet analysis.
- No agricultural or urban water supply deliveries are supplied by the reservoir these demands continue to be supplied from Lake Okeechobee or current groundwater sources.
- Eastern Caloosahatchee Basin (east of S-79) is not affected by the project.
- With the exception of changing flows to the Caloosahatchee Estuary west of S-79, there will be no impacts on the Western Caloosahatchee Basin.

FINAL Page 6 of 17

Reservoir Operation Assumptions:

- Water will be pumped into the reservoir only when there are excess flows over S-79. Excess will be treated initially as high flows over some threshold that will be refined through iterations of the spreadsheet to obtain the best performance in meeting estuary targets (EST 05).
- Releases from the reservoir are made when flows over S-79 are below desirable levels (450 cfs). Releases will be refined through iterations of the spreadsheet to obtain the best performance in meeting estuary targets (EST 05).
- Including basic seasonal operational variability in the spreadsheet for filling and draining the reservoir is preferable.

Optimization Assumptions:

- Bages with optimized operations used in the 2010 NAI run already delivered as the basis for all other alternatives to be tested. Iterate as many times as possible to improve performance within allotted timeframe.

Formulation Assumptions Documentation:

- Project will be designed as there are no adverse impacts to water supply and flood protection in the vicinity of the project.

Spreadsheet Analysis Deliverables and Due Dates:

- USACE will deliver a Modeling Service Request based on the assumptions and strategy outlined in this document to the Interagency Modeling Center by May 2, 2007.
- IMC will implement the alternative configurations in the spreadsheet model, according to the assumptions and strategy in this document.
- SFWMD will deliver to the C-43 PDT Project Manager by May 16, 2007:
  - Summary report of the spreadsheet model and results. The document will describe what was done and should be of suitable quality to be "borrowed from" or inserted in its entirety into the PIR.
- SFWMD will deliver to C-43 PDT Project Manager by May 23, 2007:
  - Documentation of the spreadsheet and the work completed, including an explanation of the spreadsheet analysis (terms, look-up tables, etc) to include in a PIR appendix.

FINAL Page 7 of 77

Section 2 – Approach

The approach and assumptions used by the IMC team for modifying and applying the C-43 West Reservoir spreadsheet model is discussed in the following section.

2.1 Assumptions and Considerations for the Analyses

2.1.1 Project Assumptions Provided by PDT

The following are project assumptions provided by the customer as requirements. These assumptions were considered and implemented in the spreadsheet model for the evaluation of project alternatives.

- Flow data at S-79 for the "Future Without" Project Condition (plus each of the 4 alternatives individually) is derived from South Florida Water Management Model run 2050RD.
- 4 alternatives to be run are:
  - 2 100,000 ac-ft with 1500 cfs pump
  - 3b 170,000 ac-ft with 1500 cfs pump
  - 3c 170,000 ac-ft with 3800 cfs pump
  - 4 220,000 ac-ft with 3800 cfs pump
- ET from reservoir will be included. The mass balance terms for the reservoir are reservoir inflow, reservoir releases, ET losses, and reservoir direct precipitation. Reservoir seepage will be assumed to be zero.
- System losses from the river to groundwater from the point of release of the reservoir to S-79 will be factored into the spreadsheet analysis.
- No agricultural or urban water supply deliveries are supplied by the reservoir. These demands continue to be supplied from Lake Okeechobee or current groundwater sources.
- Eastern Caloosahatchee Basin (east of S-78) is not affected by the project.
- With the exception of changing flows to the Caloosahatchee Estuary west of S-79, there will be no impacts on the Western Caloosahatchee Basin.
- Water will be pumped into the reservoir only when there are excess flows over S-79. Excess will be treated initially as high flows over some threshold that will be refined through iterations of the spreadsheet to obtain the best performance in meeting estuary targets (EST 05).
- Releases from the reservoir are made when flows over S-79 are below desirable levels (450 cfs). Releases will be refined through iterations of the spreadsheet to obtain the best performance in meeting estuary targets (EST 05).
- Basic seasonal operational variability for filling and draining the reservoir is included in the spreadsheet model.

2.1.2 Additional Assumptions

In addition to the assumption provided by the PDT, the IMC has implemented the following additional assumptions for the reasons provided.

1) Minimal natural losses to reservoir releases between the project and S-79 can be expected. An efficiency of delivery factor of 1 or 100% is used in the spreadsheet to ensure that all releases from the reservoir arrive at S-79. This assumption is based on analyses of more rigorous hydrologic modeling that was conducted using the MIKESHE model that show that within the reach of the Townsend Canal and the portion of C-43 from the Townsend Canal – C-43 Canal intersection, the canal are gaining and have water level that is consistently lower than groundwater elevation. This assumption was further verified with topographic data completed as part of the data preparation for the Southwest Florida Feasibility Study which show that the C-43 and Townsend canals in this region are at notable lower elevation than the adjacent land (Figure 2).

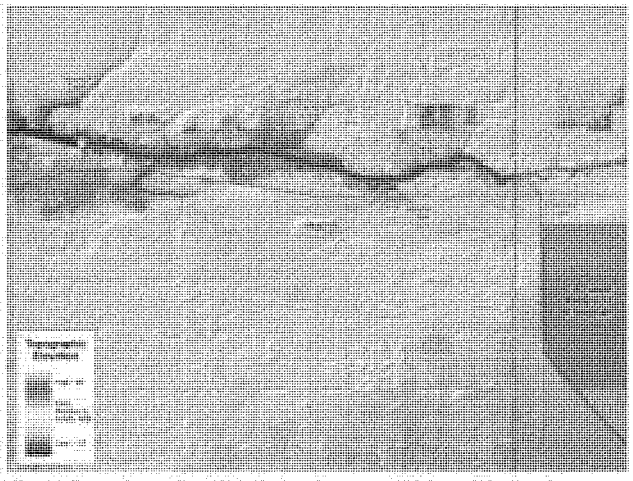


Figure 2. Topographic map of the C-43 and environ downstream of the Townsend Canal confluence.

2) Exact reservoir storage volume of 100,000, 170,000 and 220,000 acre feet and pump station total capacity of 1,500 and 3,800 cfs will be used in the spreadsheet analyses.
3) In basin flow routing and other internal details such as flow between multiple cells or multiple releases will not be included in the spreadsheet analysis as such

detail are at a more refined scale than the analysis. IMC considers this assumption appropriate since the focus of the spreadsheet analysis is the redistribution of excess flow over S-79 through use of the reservoir to improve timing and quantity of flow over S-79. The localized operations can be represented by simple reservoir filling or release operation within the spreadsheet analyses.

4) Progressively more complex operations that meet the customer requirement will be implemented; starting from simple operations based on a low and a high flow threshold to perfect knowledge (operation based on the identified estuary target EST05) to bound the solution. This assumption ensures successive suitable operations that provide increasing information on model and expected reservoir performance as the complexity increases to the recommended operations. The tool as modified retains the flexibility to implement the simplified operations.
5) A preferred operation that represent best results (but not optimal) will be delivered and processed for subsequent analyses. IMC proposes this assumption or approach to ensure that a simple yet realistic set of operations that are intuitive and provide superior performance are generated and recommended to the PDT.
6) IMC will implement seasonality in reservoir operations to recognize that wet and dry season operations would differ, and same season operation would also differ based on the state (full or empty) of the reservoir. The generalized logic of the operation is provided below (Figure 3).

Fill	WET SEASON	DRY SEASON	
Early in Season	Fill slowly to retain capacity for later in the season	Fill aggressively in preparation for rest of dry season	Pump capacity (and channel capacity) are limiting. Intake threshold and volume may vary but based on a consistent logic. The Threshold will be determined by iteration.
Late in Season	Fill reservoir faster to get full by end of year (use available capacity as a factor)	Fill slowly to retain capacity for wet season	

Empty	WET SEASON	DRY SEASON	
Early in Season	Release aggressively to create capacity for filling reservoir later in the season	Release less aggressively to extend ability to release longer into the dry season	The constraint to the release strategy listed to the side are reservoir release capacity and the requirement that wet season flows should not greatly fall below EST05 and Dry season flow over S-79 should not greatly exceed EST05
Late in Season	Release more carefully to keep reservoir full going into the dry season	Release more aggressively to empty reservoir in preparation for the wet season	

Figure 3. Generalized operational logic to implement seasonality.

7) Reservoir filling and release actions will not occur on the same day.
8) Adjustment for runoff from the reservoir site using a simple methodology based on a specified ratio of land area of reservoir to land area of basin will be implemented. A more rigorous approach that considers precipitation to runoff relationship in the watershed will also be implemented and is provided as option in the spreadsheet. These alternative approaches will allow simple or more complex representation of this adjustment to meet the user need.

9) IMC will implement an operational feature that reduces fill action when the reservoir is full or close to full. The intent is to minimize the possibility of oscillations in reservoir operation and stage that could result from very sensitive pump criteria that pump every day to replenish daily losses to evapotranspiration. The justification of this assumption is the need to more closely match a realistic operation. The feature implemented can be disabled by the user at run time.
10) Reservoir base ranges from 18 feet NAVD to 20 feet NAVD with an average at 19.24 feet. This assumption is based on the most current site information available from the Acceler8 project documentation. This reservoir base will be used for each reservoir size.
11) Reservoir elevation at full pool will be determined based on elevation necessary to result in storage capacity of 100,000, 170,000 and 220,000 acre feet. The profile will be from the current design information provided by the Acceler8 project team during the NAI and assurances analyses.
12) Daily potential evapotranspiration data for the analyses will be extracted from the SFWMM modeling dataset for consistency. IMC believes that this represents the most reliable data for the purpose of the modeling exercise and that data is available for the period of record, 1965 to 2000.
13) Daily rainfall data will be extracted from the SFWMM modeling dataset for consistency. IMC believes that this represents the most reliable data for the purpose of the modeling exercise and that data is available for the period of record, 1965 to 2000.
14) Statistics and performance graphics will be generated based on a period of record simulation of 36 years, January 1965 to December 2000.

2.2 Spreadsheet Modification

IMC made minor modifications to the previously developed spreadsheet model of the C-43 reservoir. The modifications included:

- Reviewing and modifying any spreadsheet equation hardwired to the pump and reservoir size to utilize a referenced cell that is assigned based on the alternative being simulated.
- Incorporate a drop down list of alternatives.
- Incorporate look-up and interpolation capability for computing pool elevation corresponding to reservoir capacity.
- Incorporate option for user specified reservoir storage.
- Implement operations features for alternate pump sizes.

The spreadsheet model is centered on a water budget equation for the reservoir. The equation is based on conservation of mass and relates the inflows to the reservoir, outflows from the reservoir to the change in storage in the reservoir over some fixed time scale. The equation is represented below in lay terms states that inflows to the reservoir minus outflows from the reservoir is equal to the change in storage in the reservoir.

$$\frac{dS}{dt} = Q_{in} - Q_{Out}$$

Where $\frac{dS}{dt}$ is the rate of change in storage,

Q_{in} represents the rate of inflow to the reservoir, in this case direct precipitation on reservoir plus the pumped volumes.

Q_{Out} represents the rate of outflow from the reservoir. It combines in this case, releases from the reservoir, spillway releases, and losses to evapotranspiration, (seepage set at zero by assumption).

The spreadsheet model implements the following actions.

Based on flows over S-79 on a daily basis

1) The spreadsheet determines if there is adequate flow to capture for storage in the reservoir. The threshold for capture depending on the operation scheme implemented could range from
   a. Checking if the flow exceeds a specified peak flow at which storage is initiated,
   b. Comparing the daily flow to daily target flows and capturing the excess subject to reservoir capacity and pump capacity, or
   c. Determined based on a specified operation strategy the seasonal threshold and volume to store subject to pump and reservoir storage capacity.
2) The spreadsheet determines what proportion of the available flow can be captured subject to the criteria below depending on the operation scheme implemented.
   a. The pump capacity (1500 or 3800 cfs)
   b. The difference between total flow over S-79 and the target flow, subject to reservoir capacity and pump capacity, and
   c. Based on a specified seasonal release strategy or decision table specified by the user within the spreadsheet.

These inflows along with direct precipitation onto the reservoir represent total inflows into the reservoir used in the mass balance.

Based on flows over S-79 and available capacity in the reservoir, the spreadsheet does the following actions.

1) Determines evaporation losses by taking the product of the potential evapotranspiration rate and the surface area of the reservoir (which is varied depending on storage within the reservoir)
2) Determines if rainfall or other activity has resulted in reservoir stage in excess of the spillway elevation and releases subject to limit of the spillway (the final model has operational features that preclude or limits the likelihood of this occurrence).
3) Determines release from the reservoir for environmental purposes to augment S-79 flows depending on the operational scheme implemented. The release decision and volume of release could be

a. Based on a fixed release to bring S-79 flows to a minimum specified threshold subject to reservoir release structure capacity,
b. Based on meeting the deficit between S-79 flows and the target series, EST05, or
c. Based on a specified seasonal release strategy or decision specified by the user in the spreadsheet.

These outflows are accumulated to represent total outflows from the reservoir used in the mass balance equation for each daily time step.

The spreadsheet computed the daily change in storage and associated water surface elevation both of which are considered in determining fill and release operation in subsequent time steps. The model creates an updated flow over S-79 that reflects the changes to the original flow resulting from reservoir fill or release activities.

A more detailed description of the sequence of computation with a sample cycle through one time step is presented in the User Manual attached as Appendix I to this report.

Section 3 – Initial Array of Alternatives/Options

The plan formulation and evaluation process involves identifying, organizing, and combining management measures to create the different alternative plans for the project. The alternatives proposed generally fall within the following broad definition:

- No Action – same as future without condition
- Alternative(s) with smaller storage volumes than the Restudy
- Alternative(s) with storage volumes similar to the Restudy
- Alternative(s) with larger storage volumes than the Restudy

Three alternative reservoir sizes that satisfy the general definition were identified and provided to the IMC for further analyses using the spreadsheet tool. For the middle reservoir size that was similar to the Restudy storage, two alternatives were selected for consideration based on the additional criteria of the inflow pump capacity for filling the reservoir. The resulting four alternatives were the same alternatives that were previously analyzed by the PDT using a more rigorous hydrologic model of the watershed. A detailed description of the alternatives as well as the basis for their selection can be found in the draft PIR report for the Part I-Phase I PIR. The alternatives identified by the PDT for further analyses were:

- 100,000 acre-feet storage with 1500 cfs pump – smaller storage volumes than the Restudy
- 170,000 acre-feet storage with 1500 cfs pump – storage volumes similar to the Restudy and storage and pump capacity consistent with Acceler8 design for the C-43 reservoir

FINAL Page 13 of 77

- 170,000 acre-feet storage with 3800 cfs pump – storage volumes similar to the Restudy and storage but not pump capacity consistent with Acceler8 design for the C-43 reservoir
- 220,000 acre-feet storage with 3800 cfs pump – larger storage volumes than the Restudy

These alternatives represent Alternative 2, Alternative 3b, Alternative 3c and Alternative 4 of the final array presented in Section 5.4 of the PIR. The features of each alternative are summarized and are described in more detail below (Table 1).

Feature	Alt 2	Alt 3B	Alt 3C	Alt 4
Storage Reservoir				
100,000 ac-ft Reservoir	☑			
170,000 ac-ft Reservoir		☑	☑	
220,000 ac-ft Reservoir				☑
Pump Capacity				
1500 cfs Capacity	☑	☑		
3800 cfs Capacity			☑	☑
Canals & Seepage				
Townsend Canal Imp	☑	☑	☑	☑
Seepage Management	☑	☑	☑	☑

Table 1. Features of the Four project Alternatives for Evaluation.

Alternative 2 – 100,000 ac-ft Reservoir with 1,500 cfs Pumping Capacity

Alternative 2 was developed as a smaller restoration alternative for the Lower Caloosahatchee Basin. This alternative is consistent with the CERP recommendation for a reservoir in this area, but it should be noted that this alternative's total storage volume of 100,000 acre-feet is significantly reduced from the 160,000 acre-feet of storage CERP estimated would be needed in this sub-region. Alternative 2 design summary is presented below (Table 2).

Design Parameters	Parameter Values
Storage Volume (acre-feet)	100,000
Storage Area / Reservoir Footprint (acres)	9,530 / 11,000
Project Footprint – Staging, O&M, etc. (acres)	13,300
Normal Pool Elevation / Pool Depth	35 ft NAVD88 / 10-15 ft
Dam Elevation / Dam Height	52 ft NAVD88 / 27-32 ft
Total Fill Rate – Pump Capacity (cfs)	1,500
Seepage management	Perimeter canal, 17 ft cutoff wall

Table 2. Alternative 2 Design Summary.

Alternative 3 B – 170,000 ac-ft Reservoir with 1,500 cfs Pumping Capacity

This alternative comes closest to approximating the Restudy C-43 recommended volume of approximately 160,000 ac-ft storage reservoir and is the size evaluated and recommended in the Acceler8 planning process. Alternative 3 is a two-cell reservoir with

a "normal pool" storage capacity of 170,000 acre-feet. The reservoir design includes a pump station with 1,500 cfs capacity to pump water from the Townsend Canal to fill the Reservoir. Alternative 3b design summary is presented below (Table 3).

Design Parameters	Parameter Values
Storage Volume (acre-feet)	170,000
Storage Area / Reservoir Footprint (acres)	9,530 / 11,000
Project Footprint – Staging, O&M, etc. (acres)	13,300
Normal Pool Elevation / Pool Depth	42 ft NAVD88 / 17-22 ft
Dam Elevation / Dam Height	59 ft (NAVD88) / 34-39 ft
Total Fill Rate – Pump Capacity (cfs)	1,500
Seepage management	Perimeter canal, 17 ft cutoff wall

Table 3. Alternative 3b Design Summary

Alternative 3C – 170,000 ac-ft Reservoir with 3,800 cfs Pumping Capacity

Alternative 3C is very similar to alternative 3B. The only difference is a larger pumping capacity and the associated modified reservoir operations to optimize storage performance with greater pumping flexibility. The reservoir design includes a pump station (3,800 cfs pumping capacity) to pump water from the Townsend Canal to fill the Reservoir. The water surface elevation is approximately 42 ft (NAVD88) at "normal pool". Other structural elements would be the same as described in the previous Alternative 3B. The expectation is that inclusion of the larger pump allows for greater operational flexibility. In particular, the reservoir can be filled much faster than under Alternatives 3B allowing the reservoir to capture more water during short duration high flow events. Alternative 3c design summary is presented below (Table 4).

Design Parameters	Parameter Values
Storage Volume (acre-feet)	170,000
Storage Area / Reservoir Footprint (acres)	9,530 / 11,000
Project Footprint – Staging, O&M, etc. (acres)	13,300
Normal Pool Elevation / Pool Depth	42 ft NAVD88 / 17-22 ft
Dam Elevation / Dam Height	59 ft (NAVD88) / 34-39 ft
Total Fill Rate – Pump Capacity (cfs)	3,800
Seepage management	Perimeter canal, 17 ft cutoff wall

Table 4. Alternative 3c Design Summary

Alternative 4 – 220,000 ac-ft Reservoir with 3,800 cfs Pump

Alternative 4 has the largest capacity of the reservoir sizes in the proposed alternatives with a storage capacity of 220,000 ac-ft. The inflow pump capacity is 3,800 cfs. The reservoir location and other associated features are the similar to Alternative 3C. The water surface elevation is approximately 47 ft (NAVD88) at "normal pool". Alternative 4 design summary is presented below (Table 5).

Design Parameters	Parameter Values
Storage Volume (acre-feet)	220,000
Storage Area / Reservoir Footprint (acres)	9,530 / 11,000
Project Footprint – Staging, O&M, etc. (acres)	13,300
Normal Pool Elevation / Pool Depth	47 ft NAVD88 / 22-27 ft
Dam Elevation / Dam Height	64 ft (NAVD88) / 39-44 ft
Total Fill Rate – Pump Capacity (cfs)	3,800
Seepage management	Perimeter canal, 17 ft cutoff wall

Table 5. Alternative 3c Design Summary.

Section 4 – Model Application

The focus of the spreadsheet model is the modification or adjustments of flow over S-79 with the intent of improving the salinity distribution in the downstream estuary. The model has no salinity or ecological component and relies on hydrologic surrogate to infer improved performance. The hydrologic surrogate used is the flow over S-79 and its closeness to a flow target time series EST05 which has been demonstrated by others to be a restoration series that would result in optimal habitat conditions for several indicator species in the estuary. The May, 2003 report titled "Existing Legal Sources for Caloosahatchee Estuary at the Franklin Lock and Dam (S-79) by the Coastal Ecosystem Division of the South Florida Water Management District describes the basis for EST05.

As a means to showing closeness to EST05 as a whole and quantifying other desirable matches to portions of the restoration flow series, a number of performance measure graphics were built in to the spreadsheet, five in total. Also, in order to confirm reasonable behavior of model features and results, several graphics and charts of these features were incorporated and used during model application to determine changes in operation necessary to yield superior performance. These performance measures will be used to rank the alternatives. It is expected that habitat unit created by each alternative will be developed from the spreadsheet model results will be used to rank the alternatives as well.

4.1 Performance Measures

The performance measures are nested in the "PMs" Worksheet of the spreadsheet and include the following charts.

4.1.1 Distribution of Monthly Flows

The first performance measure is a histogram of the distribution of monthly flows over S-79 for the target restoration flow series EST05, the existing "without project" or base condition, and the "with project" condition depicting percentage of time each flow

range occurs in the period of record simulation. A sample of the graphics is shown in below (Figure 4).

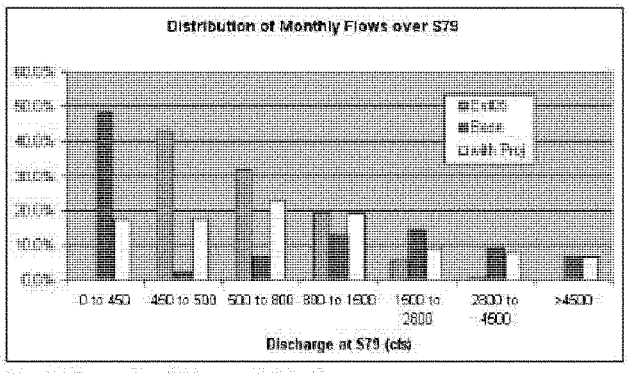

Figure 4. Histogram of monthly flows over S-79 in cfs.

An alternative that shows a closer match between the "with project" condition and the EST05 series is considered a better alternative when this measure is considered. The selection of the preferred operation for each alternative is based on this and other measure evaluated in combination.

4.1.2 Caloosahatchee Estuary Salinity Envelope Criteria

The second performance measure is the estuary salinity envelope criteria developed and used by CERP for the Caloosahatchee Estuary by the SFWMM model. This performance graphic has been duplicated in the spreadsheet and depicts the count of number of months with a low flow criteria (less than 450 cfs) not met in the "without project" (base condition) and the "with project" condition during the dry season. The measure also shows the count of exceedance of a high flow threshold (2800 cfs) with and without project. A sample graphic is shown below (Figure 5). In interpreting this measure, a series of operations that reduces the number of low flow occurrence and reduces the number of high flow exceedance represents a better set of operations. Accordingly, a project alternative that results in the lower count of low flow events and high flow events represent a better alternative based on this criterion. Note that EST05 has no occurrences of flows below 450 cfs and establishes a target count of zero for the low flow portion of this measure.

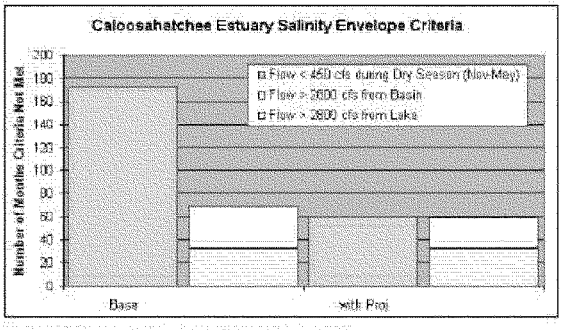

Figure 5. Caloosahatchee Estuary salinity envelope criteria

4.1.5 Flow Duration Curve

A flow duration curve generated by ranking and plotting the flow over S-79 and the percentage of time that the flow is equaled or exceeded is used as one of the measures. This plot is generated for the target restoration flow series EST05 as well as the "with project" and "without project" conditions. The project alternative that more closely matches EST05 represents the better performance. Below (Figure 5) is a sample plot extracted from the spreadsheet simulation. The plot shows, for each alternative, the ability of the "with project" condition to extend availability of low flows towards the EST05 conditions (with no occurrences of flows less than 450 cfs.)

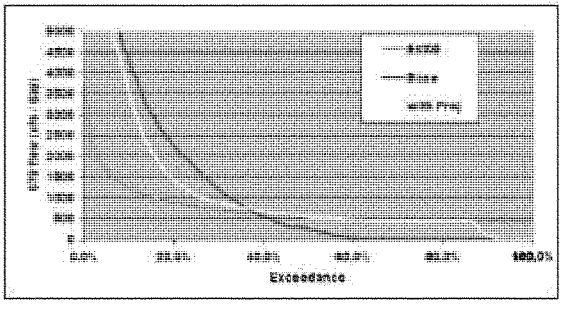

Figure 6. Flow Duration Curve

4.1.4 Consecutive Days with No Flows to Estuary

Based on technical input from coastal ecologists, an additional measure depicting the consecutive number of times in the simulation period of record that 10 or more days of no flows to the estuary occurred was developed. This measure counts a 30 day no flow event as one occurrence. A 30 day event with flows to the estuary introduced on the 15th day alone will result in a count of two occurrences. The measure also presents the maximum number of consecutive days with no flow under the "with project" and "without project" conditions. This measure using both parts of the chart show the frequency and extent of no flow (defined within the spreadsheet as the 5 cfs base flow rate) conditions observed in flows over S-79 over the 36 year period of record. A project alternative that results in lower count of number of consecutive days of no flows and reduces the extent of the maximum number of consecutive no flow days represents a more desirable alternative. A key caution in interpreting this graphic is that a small flow much less than the desirable 450 cfs will break the count of consecutive days so that releases from the reservoir of rainfall induced volumes that result in small flows in the order of tens of cfs count as breaks to the consecutive dry days count.

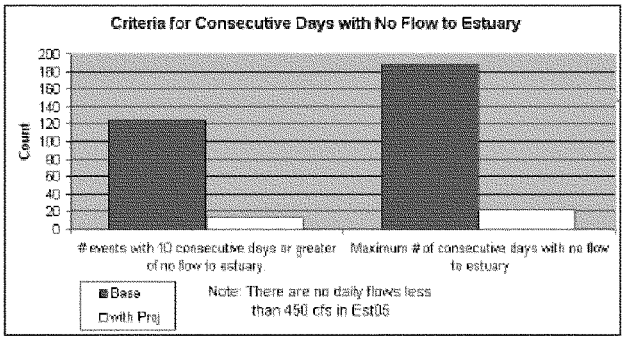

Figure 7. Criteria for consecutive days with no flow to estuary

4.1.5 Hydrograph of Flow over S-79

The final performance measure used is a plot of flows in cfs over S-79 for the EST05 series, the "with project" and "without project" conditions. In addition, superimposed on the plot is the pump filling and reservoir release operations. This graphic allows actual comparison of improvements to S-79 discharges and closeness of those improvements to the EST05 restoration series over a variable one year window for each alternative. This final measure is not quantitative but provides a qualitative assessment of the performance of each alternative. It is used significantly during simulation but has less utility for

comparing across alternatives. It can and is used to emphasize subtle performance differences that may not be apparent from the quantitative measures described above.

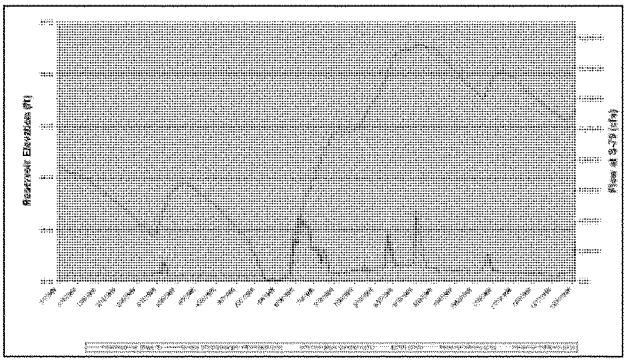

Figure 8. Flow over S-79 and reservoir stage showing reservoir fill and release actions and resulting modification to pre-project S-79 flows.

4.2 Spreadsheet Performance Checks

Six charts were used to perform checks on different aspects of the spreadsheet to ensure that assumptions were not violated and that the features in the spreadsheet were functioning as intended. The six charts are shown below (Figure 9) and include:

1) A plot of reservoir surface elevation: This chart shows the rate of use of the reservoir, how often it is full or empty. It also depicts reservoir fill elevations that correspond to the pool elevation for each alternative simulated.
2) A reservoir stage exceedance curve that shows what percentage of the time the reservoir surface elevation equals or exceeds a particular stage value.
3) An x-y plot of the adjustments to S-79 flows to accommodate the reduction in runoff resulting from converting the project from an agricultural land use to a reservoir. This plot shows minimal impact from the adjustment.
4) A scatter plot of inflows with reservoir stage to depict what operations are occurring as the reservoir fills.
5) A scatter plot of outflows with reservoir stage to show what release operations are occurring at different reservoir stage values, and
6) A scatter plot of inflows versus outflow to demonstrate that inflows and outflows are not occurring simultaneously.

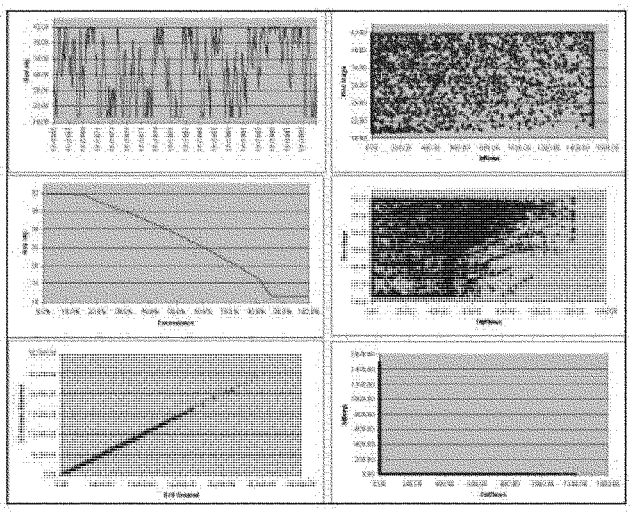

Figure 9. Plots used to check and confirm that spreadsheet model is performing as intended.

4.3 Simulation of Alternative 2

The spreadsheet was used to simulate the reservoir performance for Alternative 2. The model input parameters related to reservoir size and pump size were set at 100,000 acre-foot and 1,500 cfs respectively. The computational adjustments for maximum pool elevation were checked prior to simulations of operations. The approach used was to perform two sets of bounding simulations, the first based on a simplified operation where reservoir filling and release decisions are based on a specified flow threshold (at S-79) and the second based on the target flow distribution (also at S-79) as defined by the EST05 series. These bounding runs are then followed by several iterations of an operation scheme that is based on the general operation strategy presented in section 2.1.2. The iterative process is terminated when the resulting flow series based on the seasonal operations show performance improvements over the EST05 based simulation.

4.3.1 Simplified Operation with Minimum and Maximum S-79 Threshold

Initial analyses used the simplified operations with a defined low flow threshold and defined high flow threshold. The high flow threshold was set at 2800 cfs and the low flow threshold was set at 450 cfs. Examination of the performance under this operational

regime shows improvement over the "without project" condition. This performance represents the lower bound on performance expected from Alternative 2. The performance measures for a high flow threshold of 2800 cfs and a low flow threshold of 450 cfs are presented below (Figure 10).

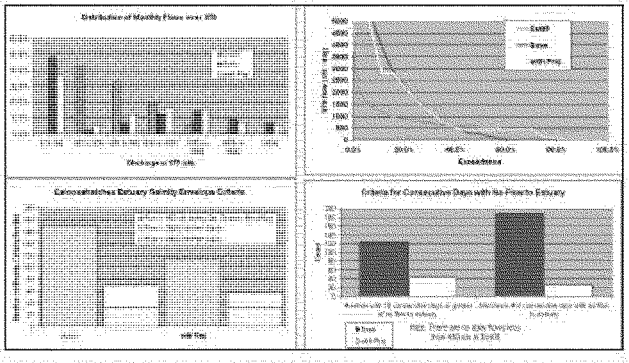

Figure 10. Alternative 2 performance measures for reservoir operations based on high flow (2800 cfs) and low flow (450 cfs) thresholds.

- The histogram showed some improvement in the low flow range over the "without project" condition but flows lower than 450 cfs still occurred more than 35% of the time.
- Considering dry season flows, the number of occurrences of less than 450 cfs was reduced from 172 to 113 from the without project to the "with project" condition.
- The flow duration curve for the "with project" conditions shows two steps corresponding to the selected high flow and low flow threshold, 2800 and 450 cfs respectively. The period of time when flows over S-79 equaled or exceeded 450 cfs was extended from below 45 % of the time under the "without project" condition to greater than 70% of the time under the "with project" conditions.
- There was a marked reduction in the count of number of events with 10 consecutive days or greater of no flows to the estuary from 125 under the "without project" condition to 42 under the "with project" condition. Similarly the number of consecutive days with no flows to the estuary reduced sharply. From 189 days to 25 days with the reservoir in place.

4.3.2 Operations Based on EST05

An operational scenario that ties fill and release decisions to S-79 flows in excess of, or in deficit of the EST05 flow series was then implemented to develop the theoretical upper bound. This operational strategy assumes perfect knowledge and under ideal

condition with adequate storage and pump capacity will deliver the EST05 flows or restoration flows to the Estuary. This operation is similar to operation implemented in other previous analysis by the PIR team. Under the "perfect knowledge" scenario, reservoir fill decisions and reservoir empty decisions are forced to reproduce EST05 like flows at S-79 subject to availability of water within the reservoir and pump and release structure capacities. The performance measures observed under this scenario are presented below (Figure 11).

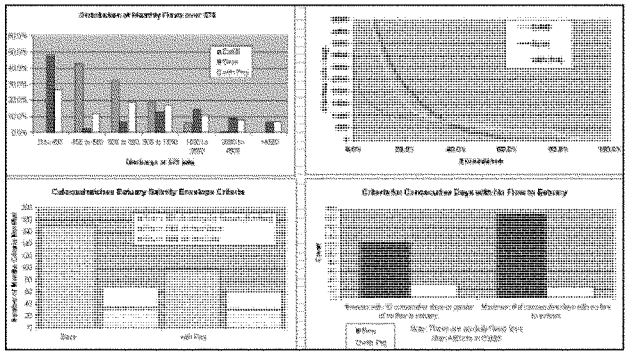

Figure 11. Alternative 2 performance measures for reservoir operations based on matching estuary target flow series EST05.

- The histogram showed some improvement in the low and mid flow range over both the simplified operations and the "without project" condition. There are still occurrences of flows lower than 450 cfs but this was reduced to approximately 25% of the time. This suggests that even under this operational scenario, reservoir operations to prevent occurrences of flows below 450 cfs are not possible with the 100,000 acre foot reservoir and a 1500 cfs pump specified in Alternative 2.
- Considering dry season flows, the number of occurrences of less than 450 cfs was reduced from 172 to 97 from the without project to the "with project" condition. A slight improvement over the results for simplified operations.
- The flow duration curve for the "with project" conditions shows no steps but a gradual merge of the plot under the "with project" conditions to the EST05 plot until the reservoir becomes incapable of delivering 450 cfs. The occurrences of flows of less than 450 cfs to the estuary reduces to 22% of the time over the 36 year simulation period for Alternative 2 with this operation scheme, a significant improvement over the "without project" condition and a slight improvement over simplified operations.

- There was a marked reduction in the count of number of events with 10 consecutive days or greater of no flows to the estuary from 125 under the "without project" condition to 32 under the "with project" condition. Similarly the number of consecutive days with no flows to the estuary reduced sharply. From 189 days to 24 days with the reservoir in place.

Below (Figure 12) shows a plot of flows over S-79 for a portion of the simulation and illustrates the operations under this release strategy. While reservoir is full and excess flows over S-79 do not exceed pump capacity, the plot of modified time series of flows over S-79 is co-incident with the EST05 time series. This is the case even when there are no S-79 flows under the "without project" conditions. However, when S-79 excess flows determined from the difference between the "without project" flows and the EST05 time series exceed 1500 cfs (pump capacity), the excess is allowed to flow over S-79 under the "with project" condition.

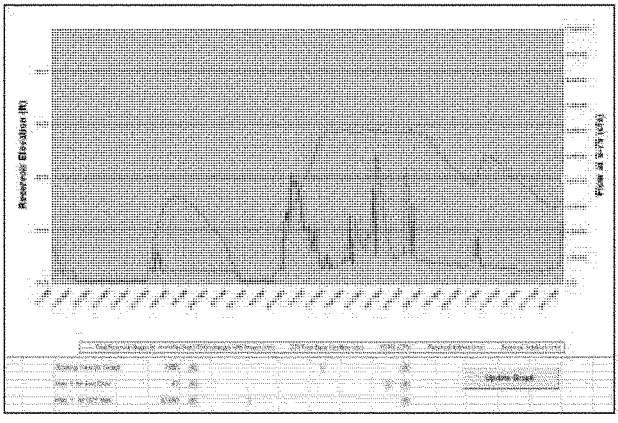

Figure 12. Flow over S-79 and reservoir stage showing reservoir fill and release actions and resulting modifications to pre-project S-79 flows under EST05 driven operations for Alternative 2.

4.3.3 Preferred Operation – Based on Seasonality and Reservoir State

The general logic presented in section 2.1.2 was implemented by providing a series of flow rates based on flows over S-79 that would be used for filling or releasing stored water from the reservoir considering the season of the year and the storage currently within the reservoir. An iterative procedure was used to generate operation ranges and magnitudes that resulted in reservoir performance that exceeded the performance from the "perfect knowledge" operations. The resulting operations while not necessarily

optimal, show that with operations tuning possible after the project is designed and built, the operation of the reservoir using a logical sequence of rules or a decision table can approach or exceed those forced to mimic EST05. The resulting preferred operations for Alternative 2 are shown in the appendix to this report.

4.3.3.1 Iterative Procedure

An initial array of operations corresponding to reservoir stage was developed by examining and analyzing flow data over S-79 derived from SFWMM simulations, actual data, and EST05 flow series. By examining plots of histograms of these flows, and volumes of water necessary to create shifts in the distribution for key years, a pattern was identified. Using best professional judgment, the identified patterns and information contained in previous more rigorous hydrologic modeling conducted for the C-43 project recommended flow and release volumes corresponding to flow over S-79 was developed. These volumes were adjusted to account for state of the reservoir. The reservoir states decided upon was empty reservoir initially defined as the bottom five feet of storage, full reservoir which corresponded to the top 9 feet of storage and medium reservoir which was the condition in between.

The initially specified operations was modified to generate more conservative or less conservative release strategies in order to determine the sensitivity of the model to selected initial operating conditions. The exercise demonstrated that more stringent release rules extended the ability of the reservoir to meet low flows for a longer period but reduced the improvement during high flows. The opposite was the observation for more liberal release policies. Figure 13 shows the high range and low range of several operation iterations. As can be observed from the plot, operations that reduce the high flow occurrences (move the curve towards the lower percentage exceedance) improve towards EST05 (a portion of which is visible at the lower left corner of the upper plot), result in earlier divergence from EST05 in the lower plot. Those operations which provided low flows for the longest period show less of an improvement to high flows (were more to the right on the high flow plot).

The final selected operation (depicted as the heavy line in Figure 13) performed reasonably well, equaling or marginally surpassing the "perfect knowledge" performance on the high side and performing significantly better on the low flows.

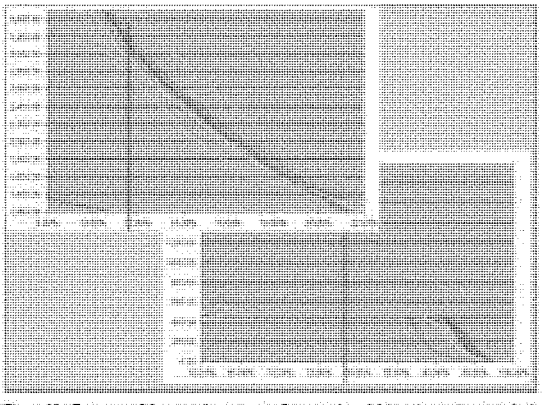

Figure 13. Extremes of the exceedance curves for several model iterations using perturbed operations for the purpose of selecting the preferred operation.

4.3.3.2 Performance Measures for the Preferred Operations

The performance measures observed using the preferred operations for Alternative 2 are presented below (Figure 14).

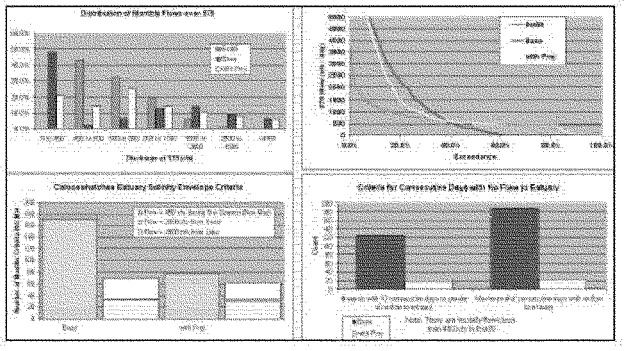

Figure 14. Alternative 2 performance measures for reservoir operations based on the preferred operation (considering seasonality and reservoir state).

- The histogram showed greater improvement in the low and mid flow range over both the simplified operations and the "without project" condition and is slightly better than the results under "perfect knowledge" operations. There are still occurrences of flows lower than 450 cfs but this was reduced to approximately 21% of the time. This suggests that even under this operational scenario, reservoir operations to prevent occurrences of flows below 450 cfs are not possible with Alternative 2 reservoir specifications (100,000 acre-foot reservoir and 1500 cfs pump).
- Considering dry season flows, the number of occurrences of less than 450 cfs was reduced from 172 to 76 from the without project to the "with project" condition. An improvement of 37 occurrences over the simple operations, and 19 over the "perfect knowledge" operations.
- The flow duration curve for the "with project" conditions shows some raggedness corresponding to several small steps at specified operation breakpoints. It is an improvement over the simple operations in appearance and over other operational regimes explored in performance. The occurrences of flows of less than 450 cfs to the estuary reduces to approximately 18% of the time over the 36 year simulation period for Alternative 2 with the preferred operations, a significant improvement over the "without project" condition and an improvement over both bounding operation schemes.
- There was a marked reduction in the count of number of events with 10 consecutive days or greater of no flows to the estuary from 125 under the "without project" condition to 20 under the "with project" condition. Similarly the number of consecutive days with no flows to the estuary reduced sharply, from 189 days to 23 days with the reservoir in place.

This operation strategy provided the best performance observed during the modeling exercise for Alternative 2 and the results will be used in the comparison of Alternative 2 to the other project alternatives. While it is not the optimal solution, it is considered sufficiently close and adequate for planning level analyses. A more rigorous analysis can be conducted if this alternative is selected as the preferred alternative for the project and when the project enters the design phase.

4.4 Simulation of Alternative 3b

The spreadsheet was used to simulate the reservoir performance for Alternative 3b. The model input parameters related to reservoir size and pump size were set at 170,000 acre-foot and 1,500 cfs respectively. The computational adjustments for maximum pool elevation were checked prior to simulations of operations. The approach previously described in Section 4.3 was applied to Alternative 3b.

4.4.1 Simplified Operation with Minimum and Maximum S-79 Threshold

Initial analyses used the simplified operations with a defined low flow threshold and defined high flow threshold. The high flow threshold was set at 2800 cfs and the low flow threshold was set at 450 cfs. Examination of the performance under this operational regime shows improvement over the "without project" condition. This performance represents the lower bound on performance expected from Alternative 3b. The performance measures for a high flow threshold of 2800 cfs and a low flow threshold of 450 cfs are presented below (Figure 15).

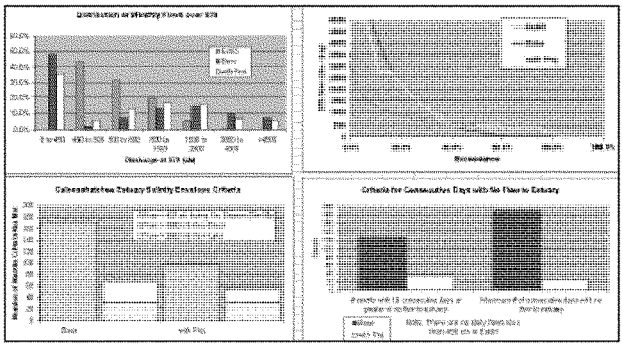

Figure 15. Alternative 3b performance measures for reservoir operations based on high flow (2800 cfs) and low flow (450 cfs) thresholds.

- The histogram showed some improvement in the low flow range over the "without project" condition but flows lower than 450 cfs still occurred more than 35% of the time.
- Considering dry season flows, the number of occurrences of less than 450 cfs was reduced from 172 to 96 from the without project to the "with project" condition.
- The flow duration curve for the "with project" conditions shows two steps corresponding to the selected high flow and low flow threshold, 2800 and 450 cfs respectively. The period of time when flows over S-79 equaled or exceeded 450 cfs was extended from below 45 % of the time under the "without project" condition to approximately 75% of the time under the "with project" conditions.
- There was a marked reduction in the count of number of events with 10 consecutive days or greater of no flows to the estuary from 125 under the "without project" condition to 36 under the "with project" condition. Similarly the number of consecutive days with no flows to the estuary reduced sharply, from 189 days to 25 days with the reservoir in place.

4.4.2 Operations Based on EST05

An operational scenario that ties fill and release decisions to S-79 flows in excess of, or in deficit of the EST05 flow series was then implemented to develop the theoretical upper bound. This operational strategy assumes perfect knowledge and under ideal condition with adequate storage and pump capacity will deliver the EST05 flows or restoration flows to the Estuary. This operation is similar to operation implemented in other previous analysis by the PIR team. Under the "perfect knowledge" scenario, reservoir fill decisions and reservoir empty decisions are forced to reproduce EST05 like flows at S-79 subject to availability of water within the reservoir and pump and release structure capacities. The performance measures observed under this scenario are presented below (Figure 16).

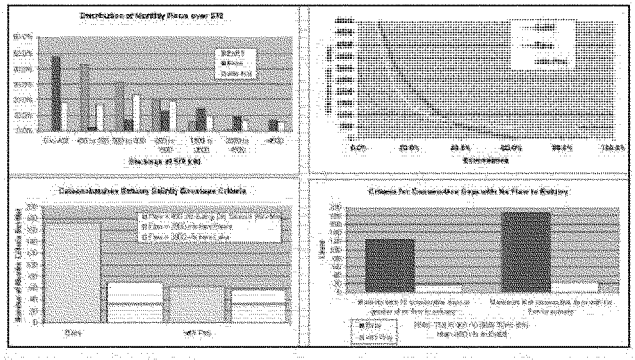

Figure 16. Alternative 3b performance measures for reservoir operations based on matching estuary target flow series EST05.

- The histogram showed some improvement in the low and mid flow range over both the simplified operations and the "without project" condition. There are still occurrences of flows lower than 450 cfs but this was reduced to approximately 18% of the time. This suggests that even under this operational scenario, reservoir operations to prevent occurrences of flows below 450 cfs are not possible with the 170,000 acre foot reservoir and a 1500 cfs pump specified in Alternative 3b.
- Considering dry season flows, the number of occurrences of less than 450 cfs was reduced from 172 to 63 from the without project to the "with project" condition. A significant improvement over the results for simplified operations.
- The flow duration curve for the "with project" conditions shows no steps but a gradual merge of the plot under the "with project" conditions to the EST05 plot until the reservoir becomes incapable of delivering 450 cfs. The occurrences of flows of less than 450 cfs to the estuary reduces to approximately 14% of the time over the 36 year simulation period for Alternative 3b with EST05 based

operations, a significant improvement over the "without project" condition and a slight improvement over simplified operations.

- There was a marked reduction in the count of number of events with 10 consecutive days or greater of no flows to the estuary from 125 under the "without project" condition to 16 under the "with project" condition. Similarly the number of consecutive days with no flows to the estuary reduced sharply. From 189 days to 23 days with the reservoir in place.

Below (Figure 17) shows a plot of flows over S-79 for a portion of the simulation and illustrates the operations under this release strategy. This figure represents the same one year period depicted in Figure 12. A comparison of Figures 12 and 17 shows a reduction in the period of time with flows less than 450 cfs with a larger reservoir. This is expected since once filled, the larger reservoir has 70,000 acre foot more of storage to use towards meeting estuary target flows.

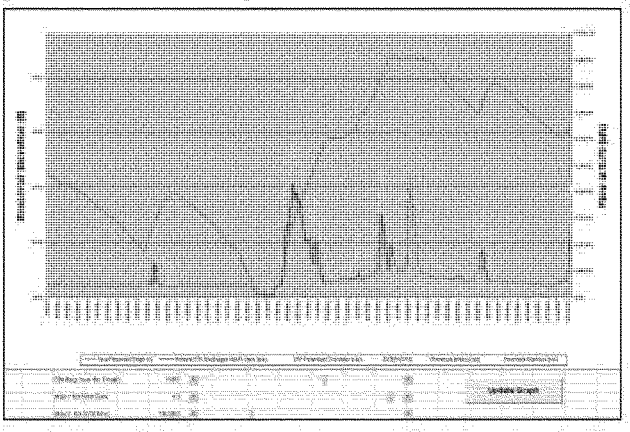

Figure 17. Flow over S-79 and reservoir stage showing reservoir fill and release actions and resulting modifications to pre-project S-79 flows under EST05 driven operations for Alternative 3b.

4.4.3 Preferred Operation – Based on Seasonality and Reservoir State

The procedure for implementing seasonal operations described in Section 4.3.3 was implemented for Alternative 3b. The iterative procedure involved specification and perturbation of fill and release operations as well as state parameters that describe the state (full, medium or empty) of the reservoir. For each of the iterations, the resulting flow series over S-79 was compared to previous iterations and results from EST05 driven operations. The parameters resulting in the better performance was recorded and further

perturbed until performance from the seasonal operations surpassed the "perfect knowledge" EST05 based operations. The best performing set of operations and parameters is the preferred operations. The initial set of operations for this alternative was the best performing set from the NAI modeling exercise.

The performance measures observed using the preferred operations for Alternative 3b are presented below (Figure 18).

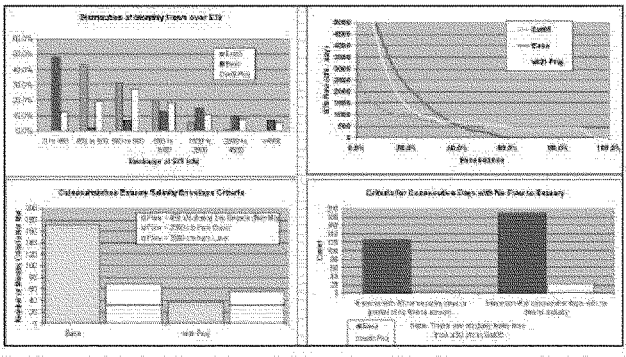

Figure 18. Alternative 3b performance measures for reservoir operations based on the preferred operation (considering seasonality and reservoir state).

- The histogram showed greater improvement in the low and mid flow range over both the simplified operations and the "without project" condition and is slightly better than the results under "perfect knowledge" operations. There are still occurrences of flows lower than 450 cfs but this was reduced to approximately 12% of the time. This suggests that even under this operational scenario, reservoir operations to prevent occurrences of flows below 450 cfs are not possible with Alternative 3b reservoir specifications (170,000 acre-foot reservoir and 1500 cfs pump).
- Considering dry season flows, the number of occurrences of less than 450 cfs was reduced from 172 to 37 from the without project to the "with project" condition. An improvement of 59 occurrences over the simple operations, and 26 over the "perfect knowledge" operations.
- The flow duration curve for the "with project" conditions shows some raggedness corresponding to several small steps at specified operation breakpoints. It is an improvement over the simple operations in appearance and over other operation schemes explored in performance. The occurrences of flows of less than 450 cfs to the estuary reduces to approximately 12% of the time over the 36 year simulation period for Alternative 3b with the preferred operations, a significant

improvement over the "without project" condition and an improvement over both bounding operation schemes.

- There was a marked reduction in the count of number of events with 10 consecutive days or greater of no flows to the estuary from 125 under the "without project" condition to 5 under the "with project" condition. Similarly the number of consecutive days with no flows to the estuary reduced sharply, from 189 days to 23 days with the reservoir in place.

This operation strategy provided the best performance observed during the modeling exercise for Alternative 3b and the results will be used in the comparison of Alternative 3b to the other project alternatives. While it is not the optimal solution, it is considered sufficiently close and adequate for planning level analyses. A more rigorous analysis can be conducted if this alternative is selected as the preferred alternative for the project and when the project enters the design phase.

4.5 Simulation of Alternative 3c

The spreadsheet was used to simulate the reservoir performance for Alternative 3c. Alternative 3c is identical to 3b with the exception of the inflow pump capacity. The model input parameters related to reservoir size and pump size for Alternative 3c were set at 170,000 acre-foot and 3,800 cfs respectively. The computational adjustments for maximum pool elevation were checked prior to simulations of operations. The approach previously described in Section 4.4 was applied to Alternative 3c.

4.5.1 Simplified Operation with Minimum and Maximum S-79 Threshold

Initial analyses used the simplified operations with a defined low flow threshold and defined high flow threshold. The high flow threshold was set at 2800 cfs and the low flow threshold was set at 450 cfs. Examination of the performance under this operational regime shows improvement over the "without project" condition. This performance represents the lower bound on performance expected from Alternative 3c. The performance measures for a high flow threshold of 2800 cfs and a low flow threshold of 450 cfs are presented below (Figure 19).

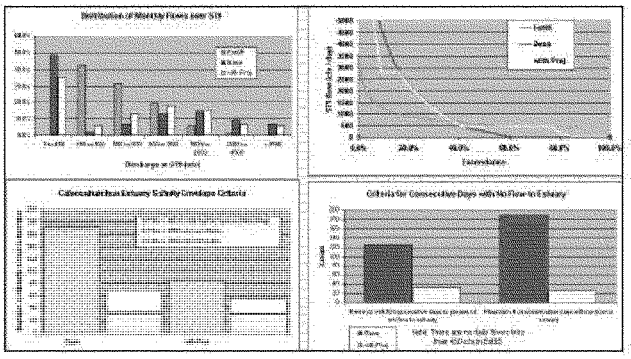

Figure 19. Alternative 3c performance measures for reservoir operations based on high flow (2800 cfs) and low flow (450 cfs) thresholds.

- The histogram showed some improvement in the low flow range over the "without project" condition but flows lower than 450 cfs still occurred more than 35% of the time.
- Considering dry season flows, the number of occurrences of less than 450 cfs was reduced from 172 to 86 from the without project to the "with project" condition.
- The flow duration curve for the "with project" conditions shows two steps corresponding to the selected high flow and low flow threshold, 2800 and 450 cfs respectively. The period of time when flows over S-79 equaled or exceeded 450 cfs was extended from below 45 % of the time under the "without project" condition to approximately 77% of the time under the "with project" conditions.
- There was a marked reduction in the count of number of events with 10 consecutive days or greater of no flows to the estuary from 125 under the "without project" condition to 31 under the "with project" condition. Similarly the number of consecutive days with no flows to the estuary reduced sharply, from 189 days to 25 days with the reservoir in place.

4.5.2 Operations Based on EST05

The performance measures for Alternative 3c using the EST05 based "perfect knowledge" operations are shown below (Figure 20). As described previously (Section 4.3.2) this operational strategy assumes perfect knowledge and delivers the restoration target flows to the Estuary subject to availability of water within the reservoir and pump and release structure capacities. As the reservoir size and pump capacity increases, this operation scheme approaches delivery of EST05 flows over S-79.

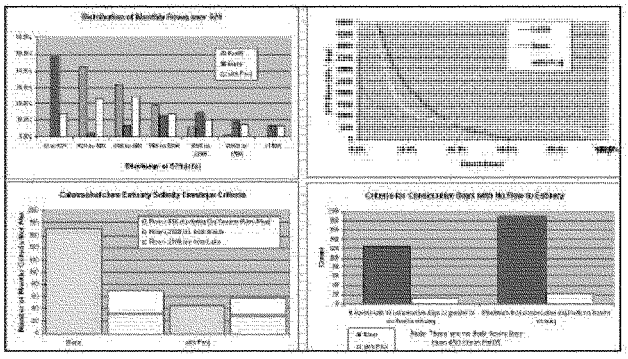

Figure 20. Alternative 3c performance measures for reservoir operations based on matching estuary target flow series EST05.

- The histogram showed some improvement in the low and mid flow range over both the simplified operations and the "without project" condition. There are still occurrences of flows lower than 450 cfs but this was reduced to approximately 14% of the time. This suggests that even under this operational scenario, reservoir operations to prevent occurrences of flows below 450 cfs are not possible with the 170,000 acre foot reservoir and a 3800 cfs pump specified in Alternative 3c.
- Considering dry season flows, the number of occurrences of less than 450 cfs was reduced from 172 to 45 from the without project to the "with project" condition. A significant improvement (41 less occurrences) over the results for simplified operations.
- The flow duration curve for the "with project" conditions shows no steps but a gradual merge of the plot under the "with project" conditions to the EST05 plot until the reservoir becomes incapable of delivering 450 cfs. The occurrences of flows of less than 450 cfs to the estuary reduces to approximately 11% of the time over the 36 year simulation period for Alternative 3c with EST05 based operations, a significant improvement over the "without project" condition and a slight improvement over simplified operations.
- There was a marked reduction in the count of number of events with 10 consecutive days or greater of no flows to the estuary from 125 under the "without project" condition to 12 under the "with project" condition. Similarly the number of consecutive days with no flows to the estuary reduced sharply, from 189 days to 23 days with the reservoir in place.

FINAL Page 34 of 77

Below (Figure 21) shows a plot of flows over S-79 for a portion of the simulation and illustrates the operations under this release strategy. This figure represents the same period depicted in Figures 12 and 17. A comparison of Figures 17 and 21 show a reduction in the period of time with flows over S-79 less than 450 cfs with the same reservoir capacity. The larger inflow pump specified for Alternative 3c allows a more aggressive capture of flow during a dry season event (left portion of the plot) sufficient to allow releases through the dry season. While flows still fell below 450 cfs in the period shown, there was no period of no-flow to the estuary with this alternative under 1986 like conditions.

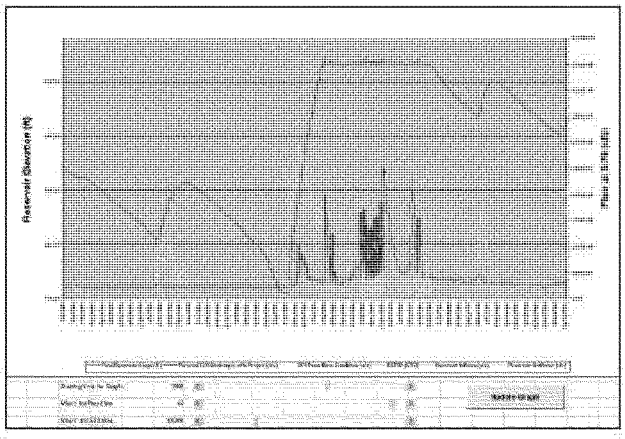

Figure 21. Flow over S-79 and reservoir stage showing reservoir fill and release actions and resulting modifications to pre-project S-79 flows under EST05 driven operations for Alternative 3c.

4.5.3 Preferred Operation – Based on Seasonality and Reservoir State.

The procedure for implementing seasonal operations described in Section 4.3.3 was implemented for Alternative 3c. The iterative procedure involved specification and perturbation of the seasonal fill and release operations as well as state parameters that describe the state (full, medium or empty) of the reservoir. For each of the iterations, the resulting flow series over S-79 was compared to previous iterations and results form EST05 driven operations. The parameters resulting in the better performance was recorded and further perturbed until performance from the seasonal operations surpassed the "perfect knowledge" EST05 based operations. The best performing set of operations and parameters is the preferred operations.

The performance measures observed using the preferred operations for Alternative 3c are presented below (Figure 22).

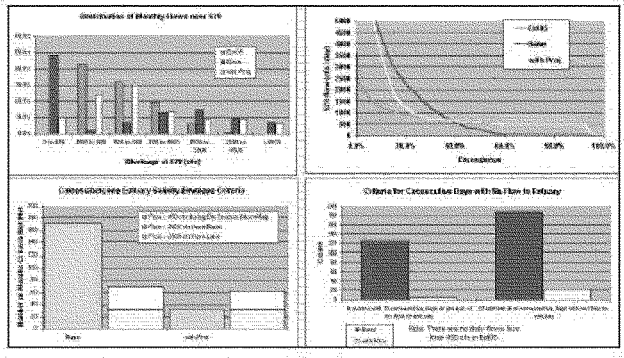

Figure 22. Alternative 3c performance measures for reservoir operations based on the preferred operation (considering seasonality and reservoir state).

- The histogram showed greater improvement in the low and mid flow range over both the simplified operations and the "without project" condition and is slightly better than the results under "perfect knowledge" operations. There are still occurrences of flows lower than 450 cfs but this was reduced to approximately 10% of the time. This suggests that even under this operational scenario, reservoir operations to prevent occurrences of flows below 450 cfs are not possible with Alternative 3c reservoir specifications (170,000 acre-foot reservoir and 3800 cfs pump).
- Considering dry season flows, the number of occurrences of less than 450 cfs was reduced from 172 to 32 from the without project to the "with project" condition. An improvement of 54 occurrences over the simple operations, and 13 over the "perfect knowledge" operations.
- The flow duration curve for the "with project" conditions shows some raggedness corresponding to several small steps at specified operation breakpoints. It is an improvement over the simple operations in appearance and over other operation schemes explored in performance. The occurrences of flows of less than 450 cfs to the estuary reduces to approximately 8% of the time over the 36 year simulation period for Alternative 3c with the preferred operations, a significant improvement over the "without project" condition and an improvement over both bounding operation schemes.
- There was a marked reduction in the count of number of events with 10 consecutive days or greater of no flows to the estuary from 125 under the "without project" condition to 5 under the "with project" condition. Similarly the

number of consecutive days with no flows to the estuary reduced sharply. From 189 days to 23 days with the reservoir in place.

For this alternative, it was possible to set a seasonal operation that provided better performance (based on the performance measures described) than the bounding operation schemes. The results obtained from these preferred operations will be used for comparing Alternative 3c to the other project alternatives. As previously noted, while it is not the optimal solution, it is considered sufficiently close and adequate for planning level analyses. A more rigorous analysis can be conducted if this alternative is selected as the preferred alternative for the project and when the project enters the design phase.

4.6 Simulation of Alternative 4

The spreadsheet was used to simulate the reservoir performance for Alternative 4. Alternative 4 represent a larger reservoir size than was identified in the Restudy. It utilizes the same pump size as Alternative 3c. The model input parameters related to reservoir size and pump size for Alternative 4were set at 220,000 acre-foot and 3,800 cfs respectively. The computational adjustments for maximum pool elevation were checked prior to simulations of operations. The approach previously described in Section 4.4 was applied to Alternative 4.

4.6.1 Simplified Operation with Minimum and Maximum S-79 Threshold

Initial analyses used the simplified operations with a defined low flow threshold and defined high flow threshold. The high flow threshold was set at 2800 cfs and the low flow threshold was set at 450 cfs. Examination of the performance under this operational regime shows improvement over the "without project" condition. This performance represents the lower bound on performance expected from Alternative 4. The performance measures for a high flow threshold of 2800 cfs and a low flow threshold of 450 cfs are presented below (Figure 23).

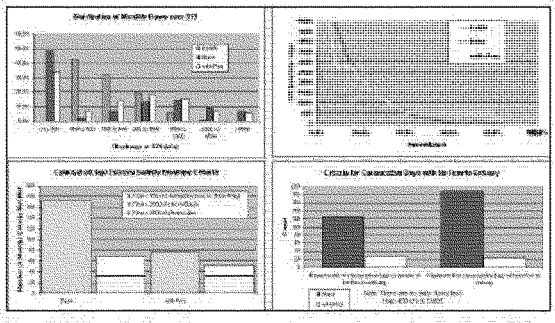

Figure 23. Alternative 4 performance measures for reservoir operations based on high flow (2800 cfs) and low flow (450 cfs) thresholds.

- The histogram showed some improvement in the low flow range over the "without project" condition but flows lower than 450 cfs still occurred about 34% of the time.
- Considering dry season flows, the number of occurrences of less than 450 cfs was reduced from 172 to 76 from the without project to the "with project" condition.
- The flow duration curve for the "with project" conditions shows two steps corresponding to the selected high flow and low flow threshold, 2800 and 450 cfs respectively. The period of time when flows over S-79 equaled or exceeded 450 cfs was extended from below 45 % of the time under the "without project" condition to approximately 80% of the time under the "with project" conditions.
- There was a marked reduction in the count of number of events with 10 consecutive days or greater of no flows to the estuary from 125 under the "without project" condition to 28 under the "with project" condition. Similarly the number of consecutive days with no flows to the estuary reduced sharply, from 189 days to 25 days with the reservoir in place.

4.6.3 Operations Based on EST05

The performance measures for Alternative 4 using the EST05 based "perfect knowledge" operations are shown below (Figure 24). As described previously (Section 4.3.2) this operational strategy assumes perfect knowledge and delivers the restoration target flows to the Estuary subject to availability of water within the reservoir and pump and release structure capacities. As the reservoir size and pump capacity increases, this operation scheme approaches delivery of EST05 flows over S-79. EST05 operations for Alternative 4 should yield superior performance that should be difficult to surpass with other operation schemes.

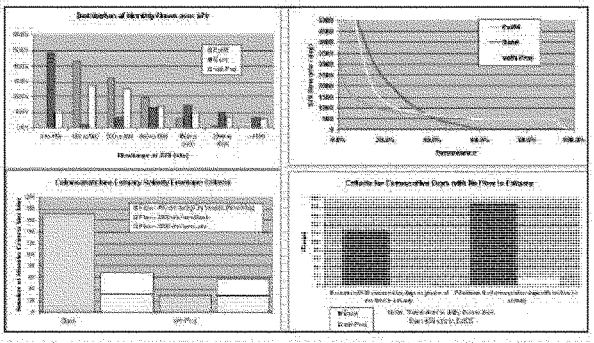

Figure 24. Alternative 4 performance measures for reservoir operations based on matching estuary target flow series EST05.

- The histogram showed some improvement in the low and mid flow range over both the simplified operations and the "without project" condition. There are occurrences of flows lower than 450 cfs but these were reduced to approximately 10% of the time. A 220,000 acre foot reservoir with a 3800 cfs inflow pump is still insufficient to prevent the estuary from having low flows event with average monthly flows of less than 450 cfs over the 36 year simulation period.
- Considering dry season flows, the number of occurrences of less than 450 cfs was reduced from 172 to 29 from the without project to the "with project" condition. A significant improvement (47 less occurrences) over the results for simplified operations.
- The flow duration curve for the "with project" conditions shows no steps but a gradual merge of the plot under the "with project" conditions to the EST05 plot until the reservoir becomes incapable of delivering 450 cfs. The occurrences of flows of less than 450 cfs to the estuary reduces to below 8% of the time over the 36 year simulation period for Alternative 4 with EST05 based operations. cfs or greater approximately 92.6% of the time over the 36 year simulation period, a significant improvement over the "without project" condition and a clear improvement over simplified operations.
- There was a marked reduction in the count of number of events with 10 consecutive days or greater of no flows to the estuary from 125 under the "without project" condition to 7 under the "with project" condition. Similarly the number of consecutive days with no flows to the estuary reduced sharply, from 189 days to 21 days with the reservoir in place.

Below (Figure 25) shows a plot of flows over S-79 for a portion of the simulation and illustrates the operations under this release strategy. This figure represents the same

period depicted in Figures 12, 17 and 21. Note that while each of the previous plots show the reservoir dry at the end of the dry season, Figure 25 shows that with a 220,000 acre foot reservoir, there is adequate storage to prevent a reservoir dry out during the period depicted. For a period with 1986 like conditions, the larger reservoir and pump specified in Alternative 4 was sufficient to meet and exceed the 450 cfs minimum to the estuary. Please note that the reservoir experienced dry-out periods when extended dry conditions as were observed in 1977 or 1981/1982 were simulated.

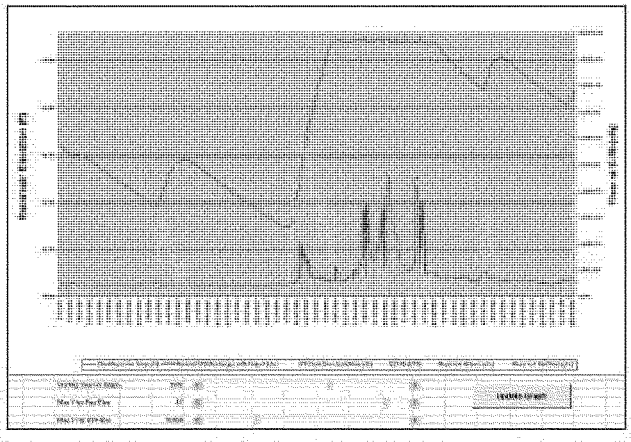

Figure 25. Flow over S-79 and reservoir stage showing reservoir fill and release actions and resulting modifications to pre-project S-79 flows under EST05 driven operations for Alternative 4.

4.6.3 Preferred Operation – Based on Seasonality and Reservoir State

The procedure for implementing seasonal operations described in Section 4.3.3 was implemented for Alternative 4. The iterative procedure involved specification and perturbation of the seasonal fill and release operations as well as state parameters that describe the state (full, medium or empty) of the reservoir. For each of the iterations, the resulting flow series over S-79 was compared to previous iterations and results form EST05 driven operations. The parameters resulting in the better performance was recorded and further perturbed until performance from the seasonal operations surpassed the "perfect knowledge" EST05 based operations. The best performing set of operations and parameters is the preferred operations.

The performance measures observed using the preferred operations for Alternative 4 are presented below (Figure 26).

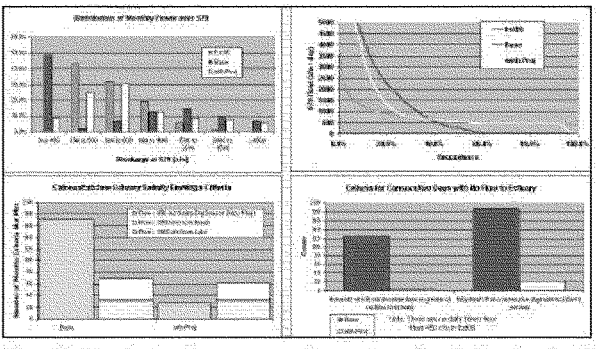

Figure 26. Alternative 4 performance measures for reservoir operations based on the preferred operation (considering seasonality and reservoir state).

- The histogram showed greater improvement in the low and mid flow range over both the simplified operations and the "without project" condition and is slightly better than the results under "perfect knowledge" operations. There are still occurrences of flows lower than 450 cfs but this was reduced to approximately 8.6% of the time. This suggests that even under this operational scenario, reservoir operations to prevent occurrences of flows below 450 cfs are not possible with Alternative 4 reservoir specifications (220,000 acre-foot reservoir and 3800 cfs pump).
- Considering dry season flows, the number of occurrences of less than 450 cfs was reduced from 172 to 27 from the without project to the "with project" condition. An improvement of 49 occurrences over the simple operations, and 2 over the "perfect knowledge" operations.
- The flow duration curve for the "with project" conditions show occurrences of flows of less than 450 cfs to the estuary reduces to less than 7% of the time over the 36 year simulation period for Alternative 4 with the preferred operations, a significant improvement over the "without project" condition and an improvement over both bounding operation schemes.
- There was a marked reduction in the count of number of events with 10 consecutive days or greater of no flows to the estuary from 125 under the "without project" condition to 5 under the "with project" condition. Similarly the number of consecutive days with no flows to the estuary reduced sharply, from 189 days to 23 days with the reservoir in place.

For this alternative, while difficult, it was possible to set a seasonal operation that provided marginally better performance (based on the performance measures described) than the EST05 based operation scheme. The results obtained from the preferred

operations will be used for comparing Alternative 4 to the other project alternatives. As previously noted, while it is not the optimal solution, it is considered sufficiently close and adequate for planning level analyses. A more rigorous analysis can be conducted if this alternative is selected as the preferred alternative for the project and when the project enters the design phase.

Section 5 – Discussion of Results

The four alternatives, Alternative 2, Alternative 3b, Alternative 3c and Alternative 4 are compared using the four quantitative performance measures previously described. The no-action or future without CERP condition is presented along with the target restoration flow series (EST05) where appropriate. Section 5 shows the results of the comparison.

5.1 Average Monthly Flows to Estuary

The first performance measure is the histogram of the distribution of average monthly flows (over S-79) to the estuary for the purpose of ensuring suitable salinity distribution for flora and fauna in the estuary. The daily distribution generated by the spreadsheet for each alternative is used to generate the corresponding average monthly flows over S-79 for each project alternative. The resulting distribution is plotted, along with the no-action alternative and the target distribution. This performance measure is first described in Section 4.1.1.

The alternatives are contrasted and the alternative that shows the closest match to the target distribution (EST05) across the entire flow range is considered a better alternative based on this performance measure. A visual comparison is made and emphasis is placed first on the ability of the alternative scenario to match the low tail of the distribution (low flows) then on the ability to match the preferred flow range and finally the ability to match the high tail (high flows) of the distribution. At each tail, the desired shift is a reduction in frequency of extreme flows.

Below (Figure 27) shows the average monthly flows over S-79 resulting from the 4 simulated alternative project configurations.

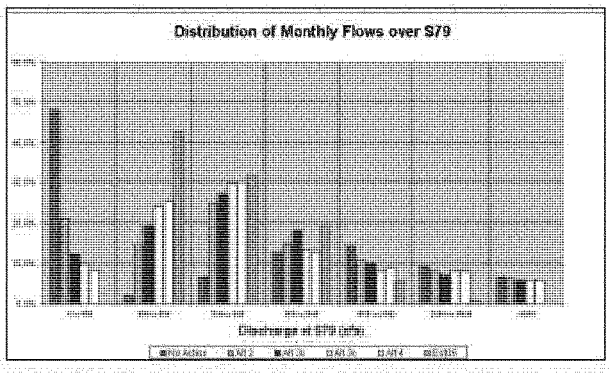

Figure 27. Distribution of average monthly flows over S-79 for the No Action alternative, Alternative 2, Alternative 3b, Alternative 3c, Alternative 4 and the EST05 target flow series.

An examination of the results show that none of the alternatives match EST05 for zero occurrences in the 0 – 450 cfs average monthly flow range. Similarly, all alternative were marginal in reduction of occurrence of high flows; monthly average greater than 2800 cfs. Over the entire range of flows, the results were consistently worse for Alternative 2 and mixed for Alternatives 3b, 3c and 4.

5.1.1 Alternative 2

The monthly average flows resulting from Alternative 2 were consistently farthest from the target distribution for all ranges with the exception of the 800 cfs to 1500 cfs range where it outperformed Alternatives 3c and 4. While Alternative 2 was an improvement over the no-action alternative, it clearly underperformed Alternatives 3b, 3c and 4 on this measure.

5.1.2 Alternative 3b

The monthly average flows resulting from Alternative 3b were consistently closer to the target flows than both the no-action and Alternative 2 results. Alternative 3b came closest to matching the target in the 800 cfs to 1500 cfs flow windows as well as for flows greater than 2800 cfs from the target distribution for all ranges with the exception of the 800 cfs to 1500 cfs range where it outperformed Alternatives 3c and 4.

5.1.3 Alternative 3c

The monthly average flows resulting from Alternative 3c were consistently closer to the target flows than the no-action alternative and Alternative 2 and 3b. Alternative 3c

underperformed Alternative 3b for the 800 – 1500 cfs range as well as for flows over 2800 cfs. Alternative 3c came closest to matching EST05 in the 1500 to 2800 cfs range.

5.1.4 Alternative 4

Based on the visual examination of the results, Alternative 4 appears to perform best overall and was marginally better than Alternative 3c in every flow range with the exception of the 800 to 1500 cfs and the 1500 to 2800 cfs ranges. This alternative resulted in the minimum number of flows in the 0 – 450 cfs range. The performance of Alternatives 3c and 4 is very similar overall.

5.1.5 Quantitative Measure of Match to EST05

To augment the qualitative visual assessment of the alternatives presented above, a quantitative measure of fit was developed. A dimensionless index of fit that scales between one for the flows resulting from the no-action alternative to zero for flows that match the EST05 time series perfectly was established. An index score closer to one is poorer and approaches the no-action alternative and a score closer to zero is better and approaches the target restoration flow series as specified by EST05. The index was created by taking the absolute value of the difference between the frequency of flow for each range from the alternative and the target series, and scaling that difference by the absolute value of the difference between the no-action alternative and the target series for the corresponding flow range. The resulting value was then averaged for the 7 flow ranges shown. The resulting index is shown in below (Table 6). As previously noted, an index score that approaches zero minimizes the difference in distribution of flows over S-79 between the project alternative receiving that score and the EST05 flow series. The comparison shown below (Table 6) assigns equal importance to every range in the distribution by assigning an equal weight to each.

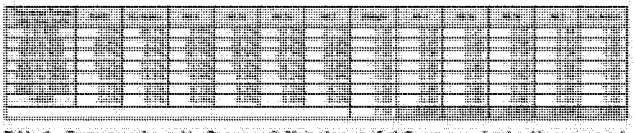

Table 6. Frequency of monthly flow over S-79 in the specified flow ranges for the Alternatives and quantitative comparison of match between each alternative and EST05 target series.

A second scoring was developed that emphasizes the tails and more specifically, the 0 to 500 cfs flow range and the range above 2800 cfs by assigning larger weights to these flow ranges. The intent was to incorporate information previously provided by users of the modeling results that suggests that meeting the critical low flows were very important to achieving desirable salinity distribution in the Caloosahatchee Estuary. Similarly larger weights were assigned to reduction in the damaging high flows based on concerns raised by ecologists. Below (Table 7) shows the index scores for each alternative based on a weighted average as well as the weights assigned to each flow range.

Discharge Range (cfs) Over S-79	Weight	Alt 4	Alt 3c	Alt 3b	Alt 2	No Action
0 to 450	5.00	0.89	1.03	1.27	2.19	5.00
450 to 500	4.00	1.70	1.84	2.32	2.79	4.00
500 to 800	1.50	0.10	0.11	0.26	0.42	1.50
800 to 1500	1.00	0.96	0.89	0.18	0.68	1.00
1500 to 2800	1.00	0.37	0.31	0.52	0.68	1.00
2800 to 4500	3.00	2.59	2.68	2.27	2.59	3.00
>4500	3.00	2.69	2.69	2.59	2.79	3.00
Weight / Index	18.50	0.503	0.516	0.509	0.651	1.000

Table 7. Quantitative comparison of match between project alternatives and target flow series using weighted average for each flow range.

The quantitative assessment confirms the findings from the visual examination of Figure 27. Table 6 shows that Alternatives 3c and 4 have lower index scores for the majority of the flow ranges, Alternative 3b however was better in the 800 to 1500 cfs flow range. With the equal weights or assumption of equal importance for each of the reported ranges, the lowest summary index was observed with Alternative 3b. This result is mostly due to the quality of its match of EST05 in the 800 to 1500 cfs flow range. Using weights that emphasize the tails, Alternative 4 provided the lowest summary index (0.503), closely followed by Alternative 3b (0.509) and Alternative 3c (0.516). The lowest index for a project alternative was Alternative 2 with an index score of 0.651.

Considering the quantitative measure presented above (Tables 6 and 7), Alternative 3b represent the best combined performance. Alternative 3b significantly outperforms both Alternative 3c and Alternative 4 using the un-weighted index and only marginally underperforms Alternative 4 but still outperforms Alternative 3c with weighted index. Combining this quantitative assessment with the qualitative assessment presented in Sections 5.1.1 to 5.1.4, Alternative 4 appears to be the best performing alternative overall but only marginally outperforms Alternative 3b and 3c.

5.2 Caloosahatchee Estuary Salinity Envelope

The second performance measure is the estuary salinity envelope criteria previously described in Section 4.1.2. This performance measure is a reproduction of a measure used with the regional simulation model for quantifying regional impact to the estuary from the CERP projects. The measure shows the count of exceedance of a low flow (lower than 450 cfs) during dry season months (November through May) as well as a count of exceedance of a high flow threshold (2800 cfs) for each of the project alternatives as well as the no-action alternative. A project alternative that minimizes either or both counts is a better performing alternative. A project alternative that results in the lower count of low flow events and high flow events represent a better alternative based on this criterion. Note that EST05 has no occurrences of flows below 450 cfs and establishes a target count of zero for the low flow portion of this measure. The results for the salinity envelope criteria are presented below (Figure 28).

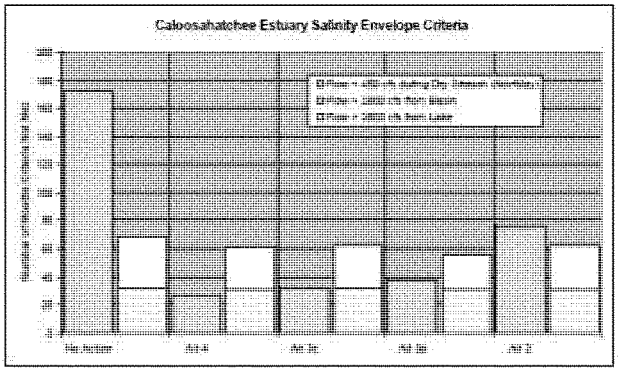

Figure 28. Salinity envelope criteria for project alternative 2, 3b, 3c and 4 and the no-action alternative (Future without project).

Considering the low flow criterion, Alternative 4 minimizes the number of events less than 450 cfs during the dry season. Alternative 3c provides the next best results followed by Alternative 3b. Alternative 2 had the poorest performance but is a significant improvement over the future without project or no-action alternative. Considering the high flow criteria, Alternative 3b resulted in the greatest reduction in flows over 2800 cfs, closely followed by Alternatives 4, 3c and 2 in that order. There wasn't much of a difference in this criterion across the projects alternatives as none significantly reduces the occurrence of high flows from the future without project conditions. This result was not expected, since Alternative 3b has a smaller inflow pump than both Alternative 3c and 4 which intuitively based on the larger pumps should have impacted the higher flows more. Examination of the model output in detail shows that the result can be explained. Below (Figure 29) shows hydrographs of flow over S-79 for Alternative 3b and Alternative 3c. As can be noted in the figure, Alternative 3b was able to prevent occurrence of any flow event over 2800 cfs in the year shown while Alternative 3c had flows in excess of 2800 cfs a few times. A closer examination of the results show the reason, under Alternative 3c with the larger pumps, the reservoir was filled faster. Once full and during wet events, the project could not reduce flows to the estuary since there was no capacity to store the flows in and occasionally, the project contributed flow to S-79 in excess of the base when runoff resulting from rainfall on the full reservoir is discharged. This illustration explains the superior performance of Alternative 3b with the smaller pump in reduction of high flow count. It is important to note that the ability to fill the reservoir early and capture more water during a high flow event (due to the larger pump) is also responsible for better performance of the alternatives with the larger pumps on the low flow criteria. Below (Figure 29) shows the reservoir in Alternative 3c did not run dry during the period depicted while the same sized reservoir went dry twice and was

unable to supply the 450 cfs to the estuary on each of those two occasions because the smaller pump was unable to maximize capture of dry season high flows.

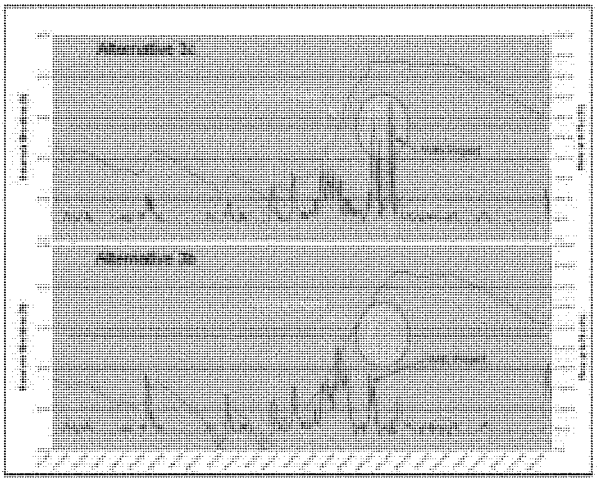

Figure 29. Flow over S-79 and reservoir stage for Alternatives 3b and 3c showing effects of larger pumps on the Estuary Salinity Envelope criteria under 1978 like conditions.

5.3 Caloosahatchee Estuary Salinity Envelope

The third performance measure are the flow duration curves derived by sorting and plotting the daily flow over rate at S-79 for each project alternative against the percentage of time that the flow is equaled or exceeded and comparing the resulting curve to the flow duration curve for the no action alternative and the target flow series (EST05). This performance measure was first described in Section 4.1.3. The project alternative that more closely matches EST05 represents the better performing alternative. Note that for this measure, the seasonality of the flow is lost and a 450 cfs occurrence in the wet season is not distinguished from a 450 cfs occurrence in the dry season. Below (Figure 30) is the flow duration curve for the four project alternatives, the no action alternative and the target flow series. The plot shows, for each alternative, the ability of the "with project" condition to extend availability of low flows towards the EST05 conditions (with no occurrences of flows less than 450 cfs.)

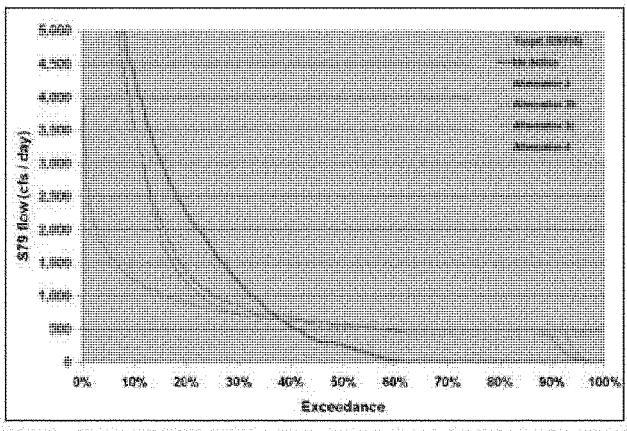

Figure 30. Flow over S-79 and reservoir stage for Alternatives 3b and 3c showing effects of larger pumps on the Estuary Salinity Envelope criteria under 1978 like conditions.

The results show that Alternative 4 performs best on the low flow end by extending the percentage of time when daily flow rates of 450 cfs or more can be delivered to the estuary. This is expected and is consistent with the expected performance of a bigger reservoir with larger storage capacity. Close in performance to Alternative 4 was Alternative 3c, middle sized reservoir with a larger pump, which was just short of Alternative 4 in ability to deliver daily flows of 450 cfs or more to the estuary. Alternative 3b lagged Alternative 3c in performance and Alternative 2, while much superior to the no action alternative was the poorest performing of the project alternatives evaluated.

The performance on the high flows was much closer for the four alternatives. All four showed improvement over the no action alternative, but none came close to matching EST05, especially for flows over 2000 cfs. Alternative 3c is the closest in the 800 to 2000 cfs range. All the project alternatives were essentially identical in performance for daily flows above 4000 cfs.

5.4 Consecutive Days with No Flows to Estuary

The fourth performance measure is the count of consecutive days with no flows to the estuary. This measure was previously described in Section 4.1.4. As noted in Section 4.1.4, this measure counts a 30 day no flow event as one occurrence and a 30 day dry event with some flows to the estuary introduced on the 15th day alone as two occurrences.

The measure also presents the maximum number of consecutive days with no flow under the "with project" and "without project" conditions. The project alternative that results in lower count of number of consecutive days of no flows and reduces the extent of the maximum number of consecutive no-flow days represents a more desirable alternative. Below (Figure 31) shows both criteria for the no action alternative as well as four project alternatives.

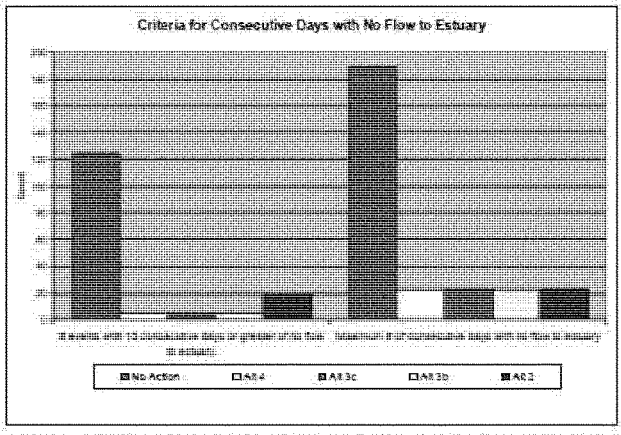

Figure 31. Flow over S-79 and reservoir stage for Alternatives 3b and 3c showing effects of larger pumps on the Estuary Salinity Envelope criteria under 1978 like conditions.

With the exception of Alternative 2, each of the project alternatives performed essentially identically on this measure. All show marked improvement over the no action alternative and were able to reduce the occurrence of 10 or more consecutive days with no flows to the estuary as well as the maximum number of consecutive days with no flows to the estuary. This measure should be interpreted with caution, since as previously stated in Section 4.1.4, release from the reservoir equal to the volume of rainfall in a day on the reservoir will count as flow to the estuary though it might be significantly less than the 450 cfs target restoration minimum flow. Also as computed by this measure, a release of 30 cfs from one project alternative counts a break in no-flow events as a release of 450 cfs from another alternative. The measure is still useful in showing that with the project alternatives, some flows, no mater how low, are sent to the estuary every 20 or so days over the 36 year simulation while the future without project condition has at least one occurrence of more than 180 days with nothing but the base flow to the estuary.

Section 6 – Discussion of Results

The four alternatives, Alternative 2, Alternative 3b, Alternative 3c and Alternative 4 were compared using performance measures as described in Section 5. The do-nothing or future without CERP condition was presented along with the target restoration flow series (EST05) where appropriate. This section discusses the results of the comparison with reference to the stated purpose of the project and the specified objective of the effort provided to IMC by the PDT.

The purpose of the C- 43 Storage Reservoir Phase I Project is to improve water deliveries to the estuary, provide for dry season flows, reduce magnitude of wet season high flows, restore downstream salinity levels and ensure the availability of water for the natural system needs of the Caloosahatchee Estuarine System.

The objective of this analyses presented in this report is to utilize the simplified spreadsheet model to evaluate the final array of alternatives using the 2050 (NAI) conditions for the purpose of confirming earlier plan selection exercise presented to the AFB. The result of the spreadsheet modeling will be used as input for the ecological analyses for plan selection.

6.1 Water Deliveries to the Estuary

The "with project" alternatives all significantly extend the period of deliveries of daily flows equal to or in excess of 450 cfs to the estuary over the no action alternative. The flow duration curves for 2050 scenarios show a shift in the percent of time flow to the estuary exceeds 450 cfs in the order of 42 to 52 percent depending on the project alternative. In order of performance, Alternatives 4 (best performance), 3c and 3b had superior performance and the improvement in deliveries to the estuary should be reflected in the ecological modeling effort to establish habitat units. The best buy project for meeting this project objective will be determined using the habitat units and project costs as determined by the PDT. None of the alternatives were able to prevent period of no flow over S-79; it is expected that additional improvements will have to be addressed in Phase II of the PIR.

6.2 Magnitude of Wet Season Flows

The results suggest more modest improvement in the area of high flows to the estuary across all the alternatives, a reduction in percent exceedance in the order of 4 to 5 percent at daily flow of 2800 cfs. Using the daily flows and the exceedance curves, Alternative 3c had the best hydrologic performance on high flows. Based on the monthly average flows, Alternative 3b had superior hydrologic performance of the four alternatives. The habitat units computed for comparison of the alternatives will incorporate effects of high flows and coupled with cost will be the basis for selecting the best alternative. The pump capacity and reservoir volume were determined to be limiting factors in the reduction of high flows. Without off line, long term storage (such as is projected to be capable

through aquifer storage and recovery,) or significantly larger storage and pumps, the reservoir fills quickly and high flow events pass by unhindered. To significantly affect the high flow conditions, other efforts such as CERP project components that result in a reduction in releases to the watershed from the regional system, along with the planned second phase of the C-43 Reservoir project will need to be implemented.

6.3 Retention of Water for Natural System

The results as presented in Section 4 and 5 show that the final array of alternatives all meet the objective of storing water for the natural system.

Section 7 – Conclusions and Recommendations

The IMC has developed and implemented a spreadsheet model of the C-43 Basin Storage Reservoir, Phase I project. The spreadsheet model based on a water budget of the reservoir and flows over S-79 stores excess flow during high flow events for release during low flow event with the objective of achieving to the extent possible restoration flows to the Caloosahatchee Estuary. IMC used the spreadsheet model for evaluation of the final array of alternatives provided by the C-43 PDT.

The following are conclusions that can be derived from the results of the analyses completed using the model:

1) The project specifications for Alternative 2, 3b, 3c and 4, provided by the C-43 PDT will provide significant benefit during low flow conditions by augmenting flows to the estuary. Alternative 4 based on hydrologic measures alone provided the most benefit.
2) The project specifications for Alternative 2, 3b, 3c and 4, will significantly minimize zero flow conditions to the estuary and will reduce the frequency of occurrence of less that 450 cfs, minimum restoration flows, over the no action or future without project conditions. Alternative 4 based on hydrologic measures alone resulted in the best performance.
3) The project specifications for Alternative 2, 3b, 3c and 4, will have modest improvement in reduction of high flow. Alternative 3c and Alternative 3b had better performance depending on consideration of daily flows or monthly averaged flows.
4) While the frequency of high flow events were less than what occurs under the no action or future without project condition, the frequency of high flow events will still significantly exceed the target frequency unless additional efforts beyond the alternatives presented as the final array of alternatives for the C-43 West Phase I reservoir project are implemented.
5) Ranked based on hydrologic measures, Alternative 4 was the best performing alternative followed by Alternative 3c and 3b which were close and may switch

based on the measure considered. Alternative 2 underperformed the other alternatives based on the analyses.

APPENDIX I

RESERVOIR PREFERRED OPERATIONS USED IN THE SPREADSHEET ANALYSES

The seasonal operations implemented in the spreadsheet for each of the alternatives that make up the final array of alternatives are presented in this section.

Alternative 2

Seasons

Early wet season was defined as June to July
Late Wet season was defined as August to October
Early Dry season was defined as November to January
Late Dry season was defined as February to May

The definitions of these seasons are in the operations "Ops Worksheet" in the spreadsheet. See below (Figure I-1).

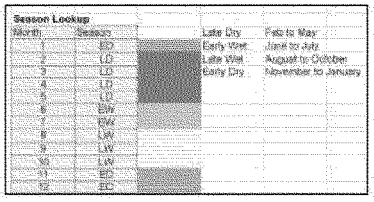

Figure I-1. Season lookup table for Alternative 2

Reservoir State

The state of the reservoir, empty, medium or full is defined in the "Ops Worksheet" and can be changed within the spreadsheet. The reservoir state definitions applied to Alternative 2 are shown in below (Figure I-2). Of the possible three states, two were used. Reservoir stages between 19.2 and 29 feet NAVD (corresponding to the bottom 10 feet of the reservoir) were considered in the empty state and reservoir operations defined for empty reservoir is applied in the analyses. Reservoir stage above 29 feet NAVD feet was considered middle to full and was operated based on operations specified for the middle state.

19.2	to	29.0	Empty
29.0	to	33.6	Mid
33.6	to	NA	Full

Figure I-2. Reservoir break points and corresponding storage for defining reservoir state, Alternative 2.

Flow Decision Breakpoints

A series of ranges of flow were established at which fill decision or release decisions will be made. These ranges differ for fill or release but were limited to 11 categories for the fill decision (to accommodate larger pumps) and 9 categories for the release decisions. Below (Figure I-3) shows the flow at which operational decision changes occurred within the model.

Operations Parameters			
	S79 flow		
	Fill	Drain	Category
	520.01	250.01	1
	850.01	350.01	2
	950.01	450.01	3
	1000.01	550.01	4
	1200.01	800.01	5
	1500.01	1000.01	6
	2000.01	1500.01	7

	3800.01	99999	9
	5000.01		10
	99999		11

Figure I-3. Flow decision breakpoints

The preferred operation rules for Alternative 2 following iterations to achieve better performance than the EST05 based operations and best possible performance within the time frame of the project for filling and releasing from the reservoir are presented below. (Table I-1 and Table I-2). Note that due to specified reservoir breakpoints, only operations specified for the two lower zones are used.

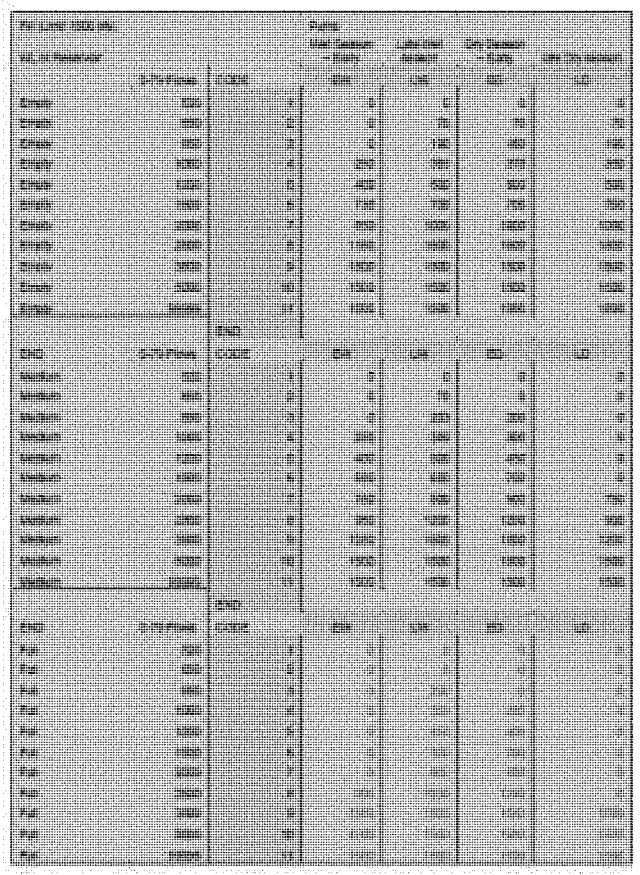

Table 6-1. Alternative 3 preferred operation rules for filling reservoir based on season, flows over S-79 and recovery zone (flow values in red = this defined zone not used due to recovery zone condition).

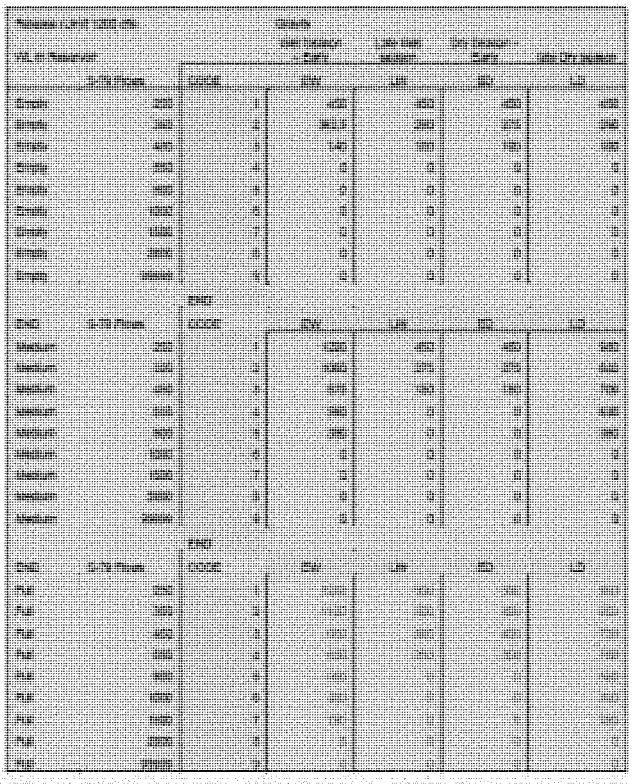

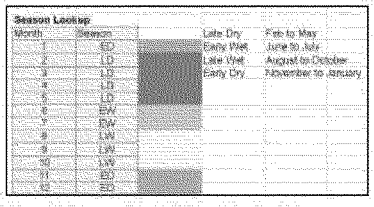

Table I-2. Alternative 2 preferred operation rules for making releases from reservoir based on season, flows over S-79 and reservoir state (Note values in red while defined were not used due to reservoir state condition).

Alternative 3b

Seasons

Early wet season was defined as June to July
Late Wet season was defined as August to October
Early Dry season was defined as November to January
Late Dry season was defined as February to May
The definitions of these seasons are in the operations "Ops Worksheet" in the spreadsheet. See below (Figure I-4).

Season Lookup

APPENDIX II

SATISFACTION OF CUSTOMER REQUIREMENTS TOOL FEATURE CHECKLIST

FINAL Page 72 of 77

Customer Requirements

The IMC has fulfilled the objectives of this project and has met the customer requirements.

The objectives of the study conducted by the IMC are as follows.

1) Develop a spreadsheet tool suitable for meeting the requirements identified in the customer requirements section (1.3) of this report and submitted as attachment to MSR 264 by the C-43 PDT.

The IMC has developed a spreadsheet suitable for meeting the requirements identified in the customer requirements section of this report. The IMC has demonstrated the application of the spreadsheet tool using the C-43 Basin Storage Reservoir, Phase 1 Project.

2) Utilize the spreadsheet to evaluate the project alternative scenario using the 2050 (NAI) condition for the purposes of plan selection

The IMC has used the spreadsheet model to evaluate the final array of alternatives, Alternative 2, Alternative 3b, Alternative 3c and Alternative 4, using 2050 (NAI) conditions for the purpose of supporting plan selection, specifically confirmation of analyses previously developed by the PDT and presented at the projects' Alternative Formulation Briefing (AFB).

3) Deliver the spreadsheet with a user guide and model results to PDT team for subsequent analyses.

The IMC has delivered the spreadsheet to the PDT and the results of the spreadsheet for subsequent analyses.

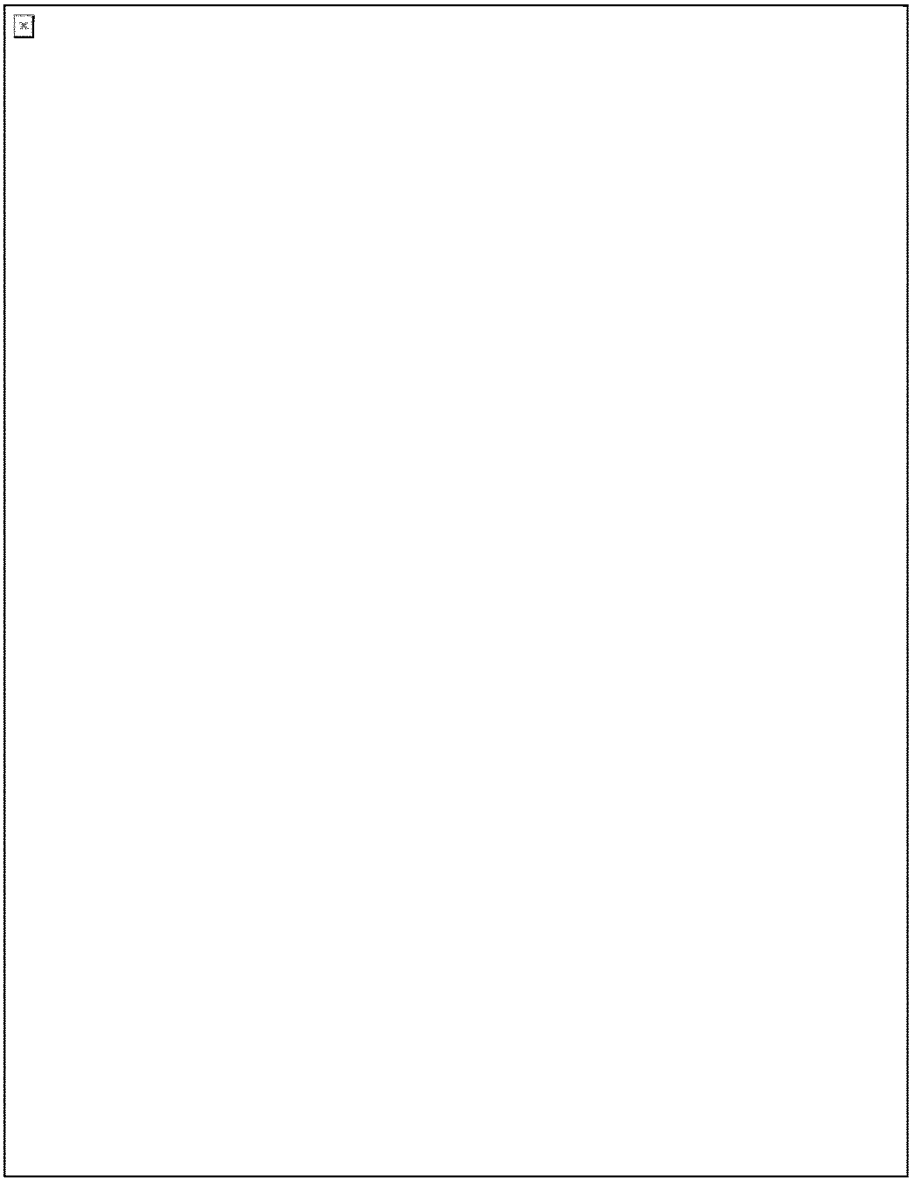
4) Deliver the spreadsheet results to the PDT for further analyses and computation of habitat units.

The IMC has delivered the model results to the PDT for subsequent analyses.

5) Document the spreadsheet and provide a project report describing the analyses, the key assumptions, limitations and application to the PDT.

The IMC has documented the work effort by developing and delivering a technical memo detailing the work completed under MSR 264.

FINAL Page 74 of 77



Features Checklist

- Flow data for Future Without-Project Condition, (plus each of the 4 alternatives individually) is derived from South Florida Water Management Model run 2050 RD.
- 4 alternatives were analyzed:
  - Alternative 2 100,000 ac-ft with 1500 cfs pump
  - Alternative 3b 170,000 ac-ft with 1500 cfs pump
  - Alternative 3c 170,000 ac-ft with 3800 cfs pump
  - Alternative 4 220,000 ac-ft with 3800 cfs pump
- ET from reservoir will be included. The mass balance terms for the reservoir are reservoir inflow, reservoir releases, reservoir seepage will be assumed to be zero, ET losses, and perhaps reservoir direct precipitation.
- System losses from the river to groundwater from the point of release of the reservoir to S-79 will be factored into the spreadsheet analysis. (Evaluation of relevant available data indicates that use of 100% efficiency is reasonable for this project).
- No agricultural or urban water supply deliveries are supplied by the reservoir these demands continue to be supplied from Lake Okeechobee or current groundwater sources.
- Water will be pumped into the reservoir only when there are excess flows over S-79. Excess will be treated initially as high flows over some threshold that will be refined through iterations of the spreadsheet to obtain the best performance in meeting estuary targets (EST 05).
- Releases from the reservoir are made when flows over S-79 are below desirable levels (450 cfs). Releases will be refined through iterations of the spreadsheet to obtain the best performance in meeting estuary targets (EST 05).
- Including basic seasonal operational variability in the spreadsheet for filling and draining the reservoir is preferable.
- Capacity to simulate varying pump and reservoir sizes implemented in spreadsheet.
- Hydrologic performance graphics for comparing alternatives built into spreadsheet.

FINAL Page 76 of 77

TECHNICAL MEMORANDUM FOR SPILLWAY DESIGN

The following Technical Memorandum documents the analysis used to determine the spillway width for the Caloosahatchee River (C-43) West Basin Storage Reservoir. This memorandum was prepared by Stanley Consultants for SFWMD and was provided to CESAJ for inclusion in the Final PIR. Hydrologic modeling was used to determine the peak reservoir levels with various spillway widths for the critical Inflow Design Flood (IDF). Larger spillways reduce the peak reservoir levels and required dam height. The added cost of the larger spillway is somewhat offset by reduced dam construction costs. The hydrologic modeling results were used in a cost analysis to determine the optimum spillway width. A description of the hydrologic modeling and input used to populate these tables are provided in a different technical memo, titled "Final Technical Memorandum on Freeboard Analysis.

Spillway Width Analysis Modeling Results		
Spillway Width (ft)	Dam Height Reduction (ft) (Preliminary Results)	Dam Height Reduction (ft) MIKE SHE Results[4]
10	0	0
20	0.09	-
30	0.17	-
40	0.23	-
50	0.29	0.33
100	0.49	-
200	0.75	0.79

[4] The average peak elevations for Cells 1 and 2 were used.

The modeled dam height reductions were used in a cost analysis to determine the overall project costs for each scenario. The results presented below show increasing the spillway width above the 10-foot width significantly increases the project cost and is not recommended. Consideration of a narrower width is not recommended due to potential clogging concerns. The final recommendation is to use a spillway width of 10 feet for both C43CS-1 and C43CS-2.

SUMMARY OF FINDINGS RELATED TO ALTERNATIVE SPILLWAY ANALYSIS IN RESPONSE TO DRCHECKS COMMENT NO. 18279

Spillway Width (ft)	Increased Flows Over C43CS-1 and C43CS2 Combined (cfs)	Dam Height Reduction[1] (ft)	SAVINGS $$			ADDITIONAL COSTS $$[2]			Project Savings
			Embankment	Soil Cement	Total	Spillway C43CS-1	Spillway C43CS-2	Total	
10	0	0.00	*As presented in the PDR - 30% Design*						
20	394	0.09	$171,368	$180,000	$351,368	$288,000	$203,000	$491,000	-$139,632
30	774	0.17	$323,695	$340,000	$663,695	$576,000	$406,000	$982,000	-$318,305
40	1,144	0.23	$437,940	$460,000	$897,940	$864,000	$609,000	$1,473,000	-$575,060
50	1,534	0.29	$552,185	$580,000	$1,132,185	$1,152,000	$812,000	$1,964,000	-$831,815

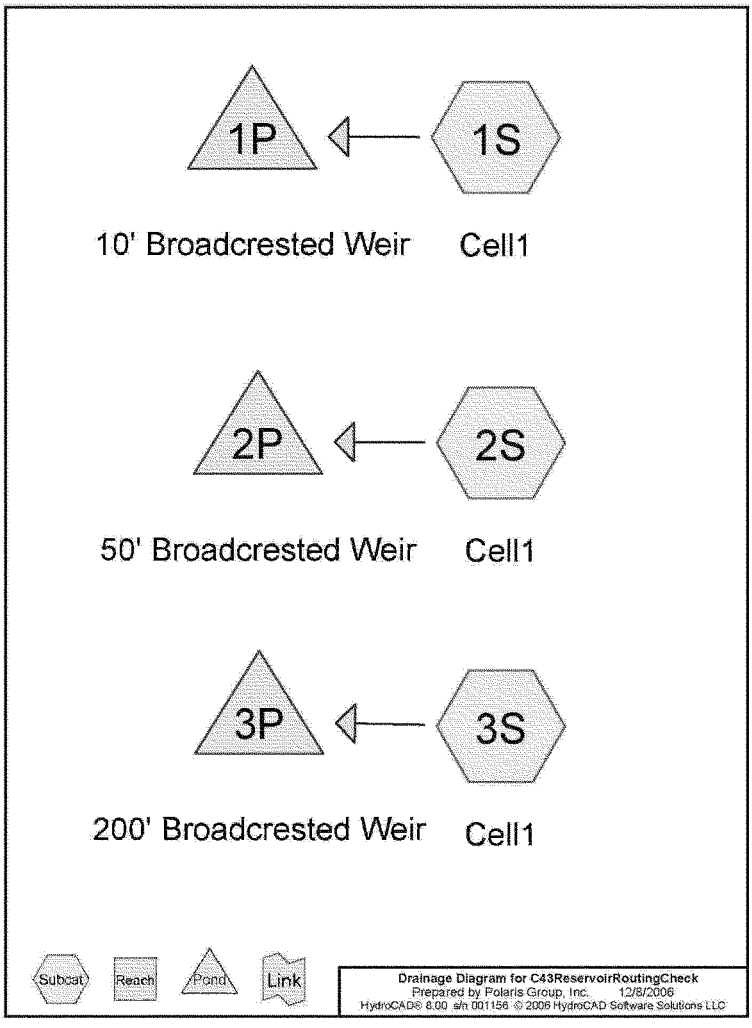
200	5,792	0.75	$1,428,065	$1,500,000	$2,928,065	$5,472,000	$3,857,000	$9,329,000	-$6,400,935

Notes: 1. Based on reducing dam height from the 90% design dam elevation.
2. Based on upgrades beyond the 30% Design.
3. Additional costs for enlarging downstream structures C43S-10, C43S-11, the Perimeter Canal, the Townsend Canal or improvements to the SR-80 bridge have not been included.



It should be made clear that the "spillway width" listed in the table above is a broad-crested weir that represents the width of the spillway structure through the dam. It is not the "weir length" of the u-shaped weir used in the

SC5022

30% design. The 30% design recognized, as indicated in the table above, that there is no cost savings advantage in increasing the spillway structure width through the dam. Therefore, the 30% design and future design submittals, will recommend a minimum practical width (10 feet) for the spillway structure.

This design, with a spillway width of 10 feet, takes advantage of a u-shaped weir at the inlet of the structure to maximize flows through the structure. The spillway structure has been designed to meet the 100-year allowable discharge. The combination of the u-shaped weir length (approximately 50 feet) and the width of the spillway structure (10 feet) have been designed to ensure that the "post" project flows never exceed the "pre" project flows in storm events. This is to protect the integrity of the SR-80 Bridge and to prevent flooding along the Townsend Canal.

A.11 FINAL TECHNICAL MEMORANDUM–C-43 WEST STORAGE RESERVOIR FREEBOARD ANALYSIS AND RECOMMENDATIONS

The following Technical Memorandum was prepared by Stanley Consultants for the SFWMD and was provided to CESAJ for inclusion in the PIR. The memorandum documents the analyses necessary to provide an estimate of the required freeboard for the 60% design of the C-43 West Storage Reservoir located in northwest Hendry County, Florida in accordance with the SFWMD Design Criteria Memorandum: DCM-2, Wind and Precipitation Design Criteria for Freeboard (SFWMD, 2006).

Freeboard is additional embankment height that is provided above a water surface level to assure that failure of the dam will not result from overtopping due to factors that may permanently or temporarily increase the water surface elevation in the reservoir. Freeboard also provides a safety factor to account for uncertainties in analytical procedures and the function of the facility in critical situations.

Spillway Width Analysis Modeling Results		
Spillway Width (ft)	Dam Height Reduction (ft) (Preliminary Results)	Dam Height Reduction (ft) MIKE SHE Results[1]
10	0	0
20	0.09	-
30	0.17	-
40	0.23	-
50	0.29	0.33
100	0.49	-
200	0.75	0.79

[1] The average peak elevations for Cells 1 and 2 were used.

The modeled dam height reductions were used in a cost analysis to determine the overall project costs for each scenario. The results presented below show increasing the spillway width above the 10-foot width significantly increases the project cost and is not recommended. Consideration of a narrower width is not recommended due to potential clogging concerns. The final recommendation is to use a spillway width of 10 feet for both C43CS-1 and C43CS-2.

SUMMARY OF FINDINGS RELATED TO ALTERNATIVE SPILLWAY ANALYSIS IN RESPONSE TO DRCHECKS COMMENT NO. 18279

Spillway Width (ft)	Increased Flows Over C43CS-1 and C43CS2 Combined (cfs)	Dam Height Reduction[1] (ft)	SAVINGS $$			ADDITIONAL COSTS $$[2]			Project Savings
			Embankment	Soil Cement	Total	Spillway C43CS-1	Spillway C43CS-2	Total	
10	0	0.00	As presented in the PDR - 30% Design

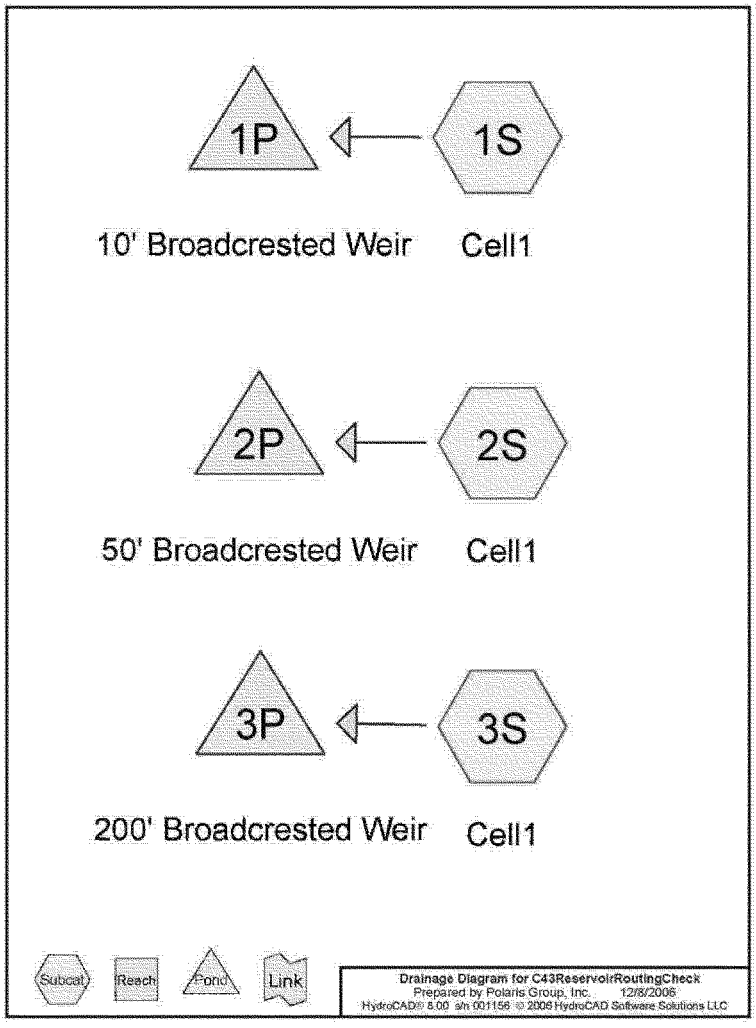
Notes: 1. Based on reducing dam height from the 30% design dam elevation.
2. Based on upgrades beyond the 30% Design.
3. Additional costs for enlarging downstream structures C43S-10, C43S-11, the Perimeter Canal, the Townsend Canal or improvements to the SR-80 bridge have not been included.



It should be made clear that the "spillway width" listed in the table above is a broad-crested weir that represents the width of the spillway structure through the dam. It is not the "weir length" of the u-shaped weir used in the

SD5022

30% design. The 30% design recognized, as indicated in the table above, that there is no cost savings advantage in increasing the spillway structure width through the dam. Therefore, the 30% design and future design submittals, will recommend a minimum practical width (10 feet) for the spillway structure.

This design, with a spillway width of 10 feet, takes advantage of a u-shaped weir at the inlet of the structure to maximize flows through the structure. The spillway structure has been designed to meet the 100-year allowable discharge. The combination of the u-shaped weir length (approximately 50 feet) and the width of the spillway structure (10 feet) have been designed to ensure that the "post" project flows never exceed the "pre" project flows in storm events. This is to protect the integrity of the SR-80 Bridge and to prevent flooding along the Townsend Canal.

1 INTRODUCTION

1.1 Purpose of Memorandum

The purpose of this technical memorandum is to document the analyses necessary to provide an estimate of the required freeboard for the 60% design of the C-43 West Basin Storage Reservoir located in northwest Hendry County, Florida in accordance with the South Florida Water Management District (SFWMD) *Design Criteria Memorandum: DCM-2, Wind and Precipitation Design Criteria for Freeboard* (SFWMD, 2006).

1.2 Project Area and Location

The C-43 West Basin Storage Reservoir is located in northwest Hendry County, south of the Caloosahatchee River, approximately 3 miles west of Labelle, Florida, and southwest of the intersection of SR80 and SR29 (Figures 1 and 2). The existing site and surrounding area is sparsely populated and primarily developed as citrus groves or similarly used for agriculture. The site is relatively flat and laced with irrigation ditches and canals. It is anticipated that the area surrounding the project site will be commercially and/or residentially developed in the future.

1.3 Project Description

According to the Central and Southern Florida Project Comprehensive Everglades Restoration Plan (CERP), the purpose of the C-43 West Basin Storage Reservoir Project is to improve water deliveries to the estuary for dry season flow, restore downstream salinity levels and ensure the availability of water for the natural system needs of the Caloosahatchee Estuarine System. The proposed facility is approximately 12,000 acres in size and will primarily consist of a two-cell reservoir with a combined minimum storage capacity of 170,000 acre-ft, a perimeter channel, reservoir spillways, and two pumping stations. Other appurtenances, support facilities, and channel improvements necessary for the operation of the facility will also be provided.

1.4 Reservoir Hazard Potential Classification

The hazard potential for a dam is defined by the possible consequences that may result from the release of stored water due to dam failure or mis-operation of the dam or appurtenances during both normal and flood flow conditions. According to the SFWMD Design Criteria Manual: DCM-1, there are three classification levels of the hazard potential for a dam: Low Hazard Potential, Significant Hazard Potential and High Hazard Potential (SFWMD, 2005).

Low Hazard Potential dams are generally defined as dams where failure or mis-operation results in low economic and/or environmental losses, no disruption of essential services and no probable loss of human life.

Significant Hazard Potential dams are generally defined as dams where failure or mis-operation can cause high economic loss, loss of valued environmental ecosystems, disruption of essential services or access, or can impact other valued concerns but results in no probable loss of life.

High Hazard Potential dams are defined as dams where failure or mis-operation will probably cause loss of human life, disruption of critical facilities and access, and major economic and environmental losses.

Based upon this classification system, the proposed C-43 West Basin Storage Reservoir has been classified as a high hazard potential impoundment. As part of the C-43 West Storage Reservoir Basis of Design Report (BODR), a dam break analysis indicated that a dam failure would compromise the safety of existing residents living near the proposed reservoir possibly resulting in the loss of life. In addition, the proximity of a major highway (SR80), the anticipated future development of areas near the facility, along with the size of the facility and volume of impounded water would all likely increase the potential for loss of life and high economic and infrastructure losses.

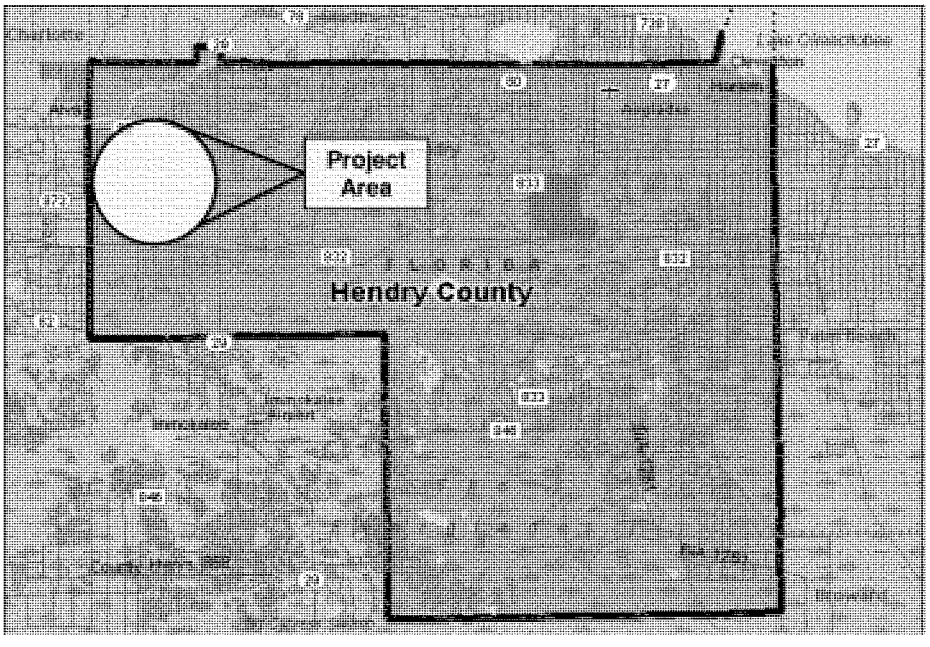

Figure 1: Location Map

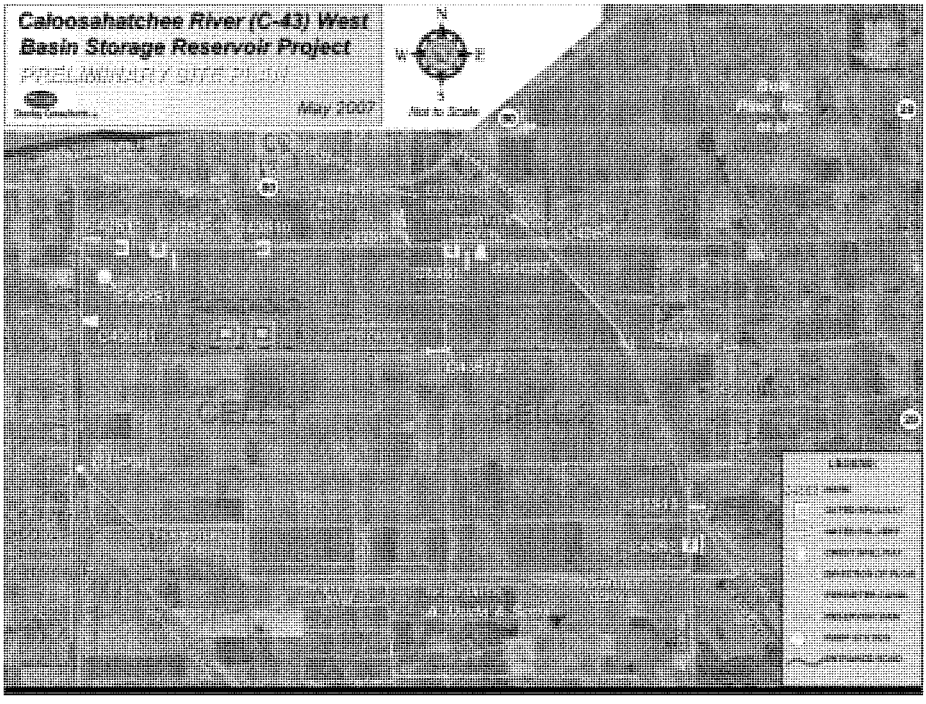

Figure 2: Site Map

2 FREEBOARD DESIGN

2.1 Introduction

The High Hazard Potential classification of the C-43 West Basin Storage Reservoir requires specific freeboard design criteria be applied to ensure the integrity and safety of the impoundment. This criteria is detailed in the South Florida Water Management District Design Criteria Memorandum 2 (DCM-2). This section presents the criteria and analyses used for the determination of design freeboard for the C-43 Reservoir.

The preliminary design of freeboard requirements and the evaluation of design alternatives were performed using manual calculations in accordance with guidelines provided in the DCM-2. For final design, the DCM-2 and the U.S. Army Corp of Engineers (USACE) require that a final assessment of freeboard requirements be based upon USACE Steady-State Spectral Wave Model (STWAVE) and the Automated Coastal Engineering System (ACES) computer model analyses.

While the computer analyses for final design require comparable input data and utilize similar methodologies, the models do not have the same computational transparency as do the manual calculations. Consequently, the detailed methodologies and approaches presented in this report in Sections 2 and 3 are primarily a discussion of the manual calculations and the preliminary design analysis. While this information is relevant to the computer analyses, actual final design analyses are presented and discussed separately in Section 4.

2.2 Freeboard Components and Camber

Freeboard is additional embankment height that is provided above a water surface level to assure that failure of the dam will not result from overtopping due to factors that may permanently or temporarily increase the water surface elevation in the reservoir. Freeboard also provides a safety factor to account for uncertainties in analytical procedures and the function of the facility in critical situations.

The DCM-2 presents conflicting information on what comprises freeboard mainly with regard to the issue of settlement and camber. However, the Bureau of Reclamation defines *freeboard* and *camber* as they relate to dams, levees and/or embankments as:

> ***Freeboard.*** *The difference in elevation between the maximum water surface in the reservoir and the dam crest. The vertical distance between a stated water level and the top of a dam, without camber. Thus "net freeboard," "dry freeboard," or "flood freeboard" is the vertical distance between the maximum water surface and the top of the dam. "Gross freeboard" or "total freeboard" is the vertical distance between the normal water surface and the top of the dam. That part of the "gross freeboard"*

attributable to the depth of flood surcharge is sometimes referred to as the "wet freeboard," but this term is not recommended as it is preferable that freeboard be stated with reference to the top of dam.

Camber. *The extra height added to the crest of embankment dams to ensure that the freeboard will not be diminished by foundation settlement or embankment consolidation. The amount of camber is different for each dam and is dependent on the amount of foundation settlement and embankment expected to occur.*

[U.S.B.R., http://www.usbr.gov/library/glossary]

Figure 3 (Figure DCM 2-1, DCM-2) is consistent with the above definition of camber and identifies the camber provided for settlement as component of embankment height separate from freeboard. Contrary to Figure 3, however, the DCM-2 example calculations and text include settlement as a component of freeboard.

For clarity and for purposes of this project, the definition and components that comprise freeboard will be consistent with the USBR definition. Design freeboard will be defined as the vertical distance between the normal full storage level (NFSL) and the top of the dam (excluding camber). Required freeboard will be comprised of the surcharge pool depth (resulting from the routing of the inflow design flood, IDF), wind setup, wave height/wave runup, wave height induced by potential landslides, and provisions for the malfunction of spillway and/or outlet works. Camber provided above freeboard to account for settlement will be considered separate from freeboard but will be included in the determination of the internal and external reservoir embankment heights.

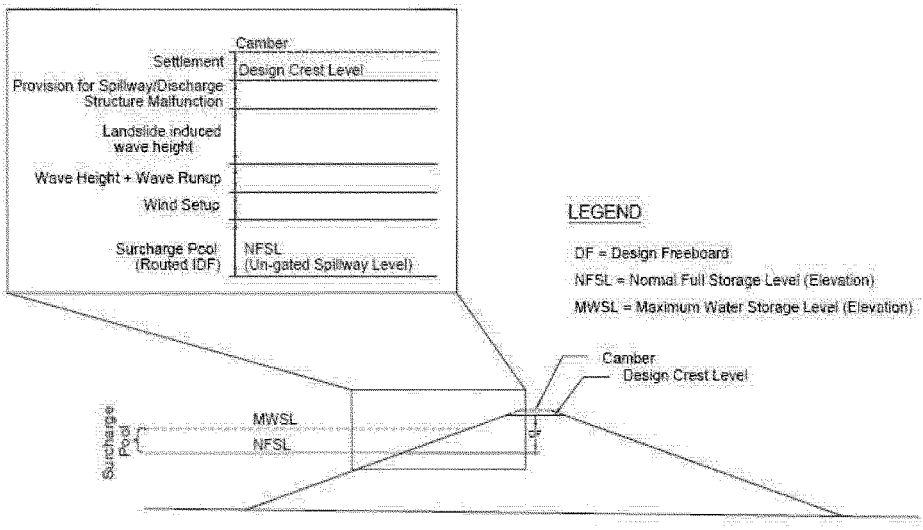

Figure 3: Design Freeboard Components [Figure DCM 2-1, DCM-2]

2.2.1 Provisions for the Malfunction of the Spillway and/or Outlet Works

Additional freeboard may be required based upon the potential for malfunctioning of the reservoir outlet facilities. While no provision for additional freeboard is directly made for this component, it is indirectly provided in the determination of the flood pool surcharge. When routing storm events through the reservoir, it is conservatively assumed that all mechanically operated outlet structures are closed for the duration of the storm event thereby increasing the maximum estimated reservoir surcharge.

2.2.2 Landslide Induced Wave Height

Landslide induced wave height arises from a sudden mass displacement of water resulting from a landslide. The C-43 reservoir is an above ground impoundment. Any significant landslide could only result from a catastrophic failure of the dam embankment which would result in the release of water from the reservoir. Consequently, it is assumed that there is no potential for landslides and no provision for additional freeboard is made for this component.

2.2.3 Wind Setup

Wind setup is the vertical distance above a stillwater level (normal full storage level) that is the result of the horizontal stress exerted by wind blowing over a water surface. In a confined body of water, the effect results in an increase in the water level at the leeward end and a lowering of the water level at the windward end. The effect of wind setup is included in the C-43 design freeboard. The design criteria and guidelines for the determination of wind setup are presented in the DCM-2. Calculations consistent with the DCM-2 design criteria and guidelines for wind setup are presented in this report.

2.2.4 Wave Height and Wave Runup

Wave run-up is the maximum vertical extent of wave up-rush on a beach or structure above the stillwater level (normal full storage level). Wave runup is a primarily a function of wave height, wave period, wave length, embankment slope and embankment surface roughness. The effect of both wave height and wave runup is included in the C-43 design freeboard. The design criteria and guidelines for the determination of wave height and wave runup are outlined in DCM-2. Calculations consistent with the DCM-2 for wave height and wave run up are presented in this report.

2.2.5 Surcharge Pool Depth

The surcharge pool depth results from the routing of an inflow design flood (IDF) hydrograph through the reservoir. Surcharge is an increase in water surface elevation above the normal full storage level resulting from the volume of inflow exceeding the volume of outflow from the reservoir. This increase in depth is included as a component of the C-43 design freeboard and depends upon the routed IDF. DCM-2 identifies several different IDFs that must be considered in conjunction with the analysis for wind

setup and wave height/wave runup. The analyses to route IDFs through the flood pool for the determination of surcharge pool depth are presented in the Appendix A.

2.2.6 Camber and Embankment Settlement

The potential for short and/or long term settlement of the dam is addressed for by providing camber or additional embankment height to account for settlement of the external and internal embankments. A settlement analysis for the reservoir site was conducted separate from this report as part of the C-43 West Storage Reservoir Basis of Design Report (BODR). A table of estimated settlement for the reservoir embankments from the BODR analyses is provided in Section 3.1.1.

2.3 Design Freeboard Criteria

Design freeboard requirements for wind setup, wave height/runup and flood surcharge are calculated based upon guidelines and criteria presented in the DCM-2. The manual requires that freeboard be assessed under the following four wind speed and inflow design flood/precipitation/reservoir level cases:

Case 1: 100-Yr wind combined with the Probable Maximum Precipitation

Case 2: Category 5 winds combined with the 100-Yr Precipitation

Case 3: Probable Maximum Wind (PMW) combined with the Normal Full Storage Level

Case 4: A storm specific wind and precipitation (Hurricane Easy in 1950)

2.4 Preliminary Design Freeboard Approach and Methodology

The general design methodologies in this section are summarized from the DCM-2 and are the basis of preliminary design freeboard calculations and alternative assessment analyses. Freeboard analyses provided in the Appendices B, C and D provide detailed step-by-step manual calculations, additional background information and references.

With the exception of the calculation of design wind speed, freeboard calculations for all four design cases follow the same methodology and approach. For the design wind speed calculations, the approach differs only slightly in the first few calculations due to the nature of initial wind speed data. Differences in recurrence interval, wind duration, and whether data is provided over water or over land determine whether certain adjustment factors are required to determine the design wind speed.

2.4.1 Design Wind Speed

The over water wind speed influences the calculation of both wind setup and wave properties. The design wind speed calculations and adjustments will vary slightly depending upon each case scenario but generally the purpose is to determine the maximum over water wind speed for the design recurrence interval and compute the wind stress factor.

2.4.1.1 Design Wind Speed Data Conversion

For Case 1, the 100-year wind speed data is derived from 50-year to 100-year, 3-second gust wind speeds (Figure 4). Data from this figure is conservatively assumed to be the 50-year gust wind speed and therefore must be converted to a 100-year wind by multiplying the 50-year wind by a factor of 1.07 (Table DCM 2-2, DCM-2).

For Case 4, the Hurricane Easy 125 mph wind speed was recorded as a maximum 3-second gust wind and is a storm specific case. Therefore, the conversion factor adjusted by return period is not relevant for this case.

For Cases 2-3, the available wind speed data is the design wind speed data and requires no data conversion.

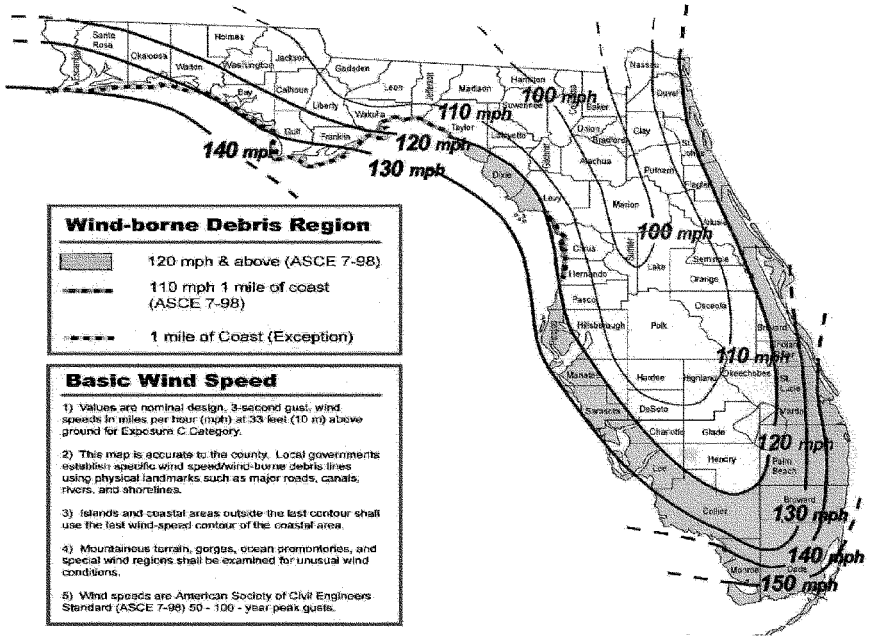

Figure 4: 50-Yr to 100-Yr, 3-Second Gust Wind Speed [Figure DCM 2-2, DCM-2]

2.4.1.2 Wind Speed Duration Adjustments

For design calculations, it is necessary to adjust and relate wind speeds to a standard average wind speed of one-hour in duration. The ratio of wind speeds of various durations to the one-hour average wind speed is approximated using the following equations:

$$For\ t \le 3{,}600: \qquad U_t / U_{3600} = 1.277 + 0.296 \tanh\left(0.9 \log_{10}\left(\frac{45}{t}\right)\right)$$

$$For\ 3{,}600 \le t \le 36{,}000: \quad U_t / U_{3600} = -0.15 \log_{10}(t) + 1.5334$$

Where:

t = duration time (seconds)
U_t = wind speed (mph) at time t (seconds)
U_{3600} = 1-hour average wind speed (mph)

[Equations 1 & 2, DCM-2, 2006]

With the exception of Case 2, all initial wind speed data for the design cases are converted to one-hour wind speed durations using the above equations. For Case 2, the Category 5, one-hour adjusted wind speed of 125 mph is provided by Table DCM 2-3 making an adjustment calculation unnecessary (Category 5 reference wind speed is 156 mph for a duration of 60 seconds).

The above equations are also used to adjust one hour wind speeds to wind speeds for a fetch limited duration time (Section 2.4.1.5).

2.4.1.3 Over Water Wind Speed Adjustment

When wind data is obtained overland, it is necessary to adjust the data to an over water wind speed. For fetch lengths less than 10 miles, the ratio of over water wind speed to overland wind speed is 1.2 (Figure II-2-20, CEM, 2003). When wind data is obtained over water, no adjustment is required.

For Cases 1 and 4, the initial wind speed data is for over land and an over water wind speed adjustment of 1.2 is required.

For Cases 2 and 3, the initial wind speed data is for over water and no adjustment is required (a factor of 1.0 is used) (DCM-2, 2006).

2.4.1.4 Fetch Limited Duration

For a given wind speed and fetch length, there is an associated wind duration that, if exceeded, will not increase the wave size because of the limiting effect of the fetch and

depth (DCM-2, 2006). This "fetch limited" duration is the duration required to develop the full wave height and can be estimated by the following equation:

$$t_{x,u} = 112\frac{X^{0.67}}{u^{0.34}} \qquad \textit{[Equation 4, DCM-2, 2006]}$$

Where:

t = wind duration time (minutes)
X = fetch length (miles)
u = wind velocity (mph)

2.4.1.5 Wind Speed Fetch Limited Duration Adjustment

As just previously mentioned, development of the full wave height for a given wind speed and fetch length is achieved at the fetch limited duration time (Section 2.4.1.4). Design wind speeds are therefore adjusted from a one-hour duration to an equivalent wind speed of fetch limited duration using the equations in Section 2.4.1.2.

2.4.1.6 Wind Speed Stability Correction

Under some conditions, it is necessary to adjust wind speed for stability of the boundary layer (between water and air) due to air-water temperature differences. This correction, however, is not necessary if the fetch is less than 10 miles in length. Estimated fetch length for both cells of the C-43 reservoir are less than 10 miles subsequently a stability factor of 1.0 (no correction) is applied (CEM, 2003).

2.4.1.7 Wind Stress Factor
