Wave growth formulas and nomographs are expressed in terms of wind stress factor (USACE, SPM Vol. I, 1984). After all the appropriate wind speed adjustments and conversion are made, the wind speed may be converted to a wind stress factor by the following equation:

$$U_A = 0.589U^{1.23} \qquad \textit{[Equation 4, SPM Vol. I, 1984]}$$

Where:

U_A = wind stress factor (mph)
U = wind speed (mph)

2.4.2 Wind Setup

The DCM-2 identifies for different equations to consider when estimating wind setup: the Zeider Zee Equation, the Sibul Equation, the Bretschneider Equation, and an average of the Zeider Zee and Sibul Equations. However, the DCM-2 guidelines indicate that for impoundments greater than 16 feet in depth, the Zeider Zee is recommended.

The Zeider Zee equation is expressed as:

$$S = \frac{U^2 F}{1400 d} \qquad \textit{[Equation 5, DCM-2, 2006]}$$

Where:

S = wind setup (feet) above the stillwater level
U = wind speed (mph)
F = fetch length (miles)
d = average depth of water (to include surcharge depth) taken generally along fetch line (ft)

2.4.3 Wave Height

The determination of wave height involves an assessment of wave properties to determine the wave classification and the conditions that control wave height. The assessment involves determining the deep water wave properties, wave classification, calculation of shallow water wave properties (if necessary), the assessment of controlling significant wave height based upon the depth limited wave breaking height and finally the computation of an equivalent deep water wave height.

As previously mentioned, wave height calculations are the same for all design cases required by the DCM-2.

2.4.3.1 Deep Water Wave Calculations

The determination of the deep water wave properties within the impoundment is the first step in the determination of wave height. The deep water wave equations are:

$H_{mo} = 0.000282 U_A F^{1/2}$ *[Eqn. 3-33c, SPM Vol. I]*
$T_o = 0.02825 (U_A F)^{1/3}$ *[Eqn. 3-34c, SPM Vol. I]*
$L_o = 5.12 T_o^2$ *[Eqn. 2-8b, SPM Vol. I]*

Where:

H_{mo} = deep water significant wave height (feet)
T_o = deep water wave period (seconds)
L_o = deep water wave length (feet)
U_A = wind stress factor (mph)
F = fetch length (in feet)

2.4.3.2 Effective Depth

For purposes of this project, the effective depth is defined as the normal full storage level (NFSL) depth plus the surcharge depth resulting from the routing of a design storm event through the reservoir. Section 2.5.3 discusses in more detail the determination of effective depth as part of this project.

2.4.3.3 Wave Classification

Waves are classified by the water depth at which they travel. Wave classification is based upon the ratio of the effective depth to the deep water wave length (d/L_o). If $d/L_o > 0.5$, the waves are classified as deep water. If $d/L_o \leq 0.5$, the waves are classified as shallow water or transitional and shallow wave properties need to be computed.

For the C-43 West Storage Reservoir, waves are considered shallow water/transitional.

2.4.3.4 Shallow Water Wave Calculations

The shallow water equation for wave period is:

$$T = 7.54 \tanh\left(0.833\left(\frac{gd}{U_A^{\,2}}\right)^{\frac{3}{8}}\right) \tanh\left(\frac{0.0379\left(\frac{gF}{U_A^{\,2}}\right)^{\frac{1}{3}}}{\tanh\left(0.833\left(\frac{gd}{U_A^{\,2}}\right)^{\frac{3}{8}}\right)}\right) \frac{U_A}{g}$$

Where:

T = shallow water wave period (seconds)
g = 32.2 ft/s^2
d = effective depth (feet)
U_A = wind stress factor (ft/s)
F = fetch length (feet)

[Eqn. 3-40, SPM Vol. I]

The shallow water equation for significant wave height is:

$$H = 0.283 \tanh\left(0530\left(\frac{gd}{U_A^{\,2}}\right)^{\frac{3}{4}}\right) \tanh\left(\frac{0.00565\left(\frac{gF}{U_A^{\,2}}\right)^{\frac{1}{2}}}{\tanh\left(0.530\left(\frac{gd}{U_A^{\,2}}\right)^{\frac{3}{4}}\right)}\right) \frac{U_A^{\,2}}{g}$$

Where:

H = shallow water significant wave height (feet)
g = 32.2 ft/s^2
d = effective depth (feet)
U_A = wind stress factor (ft/s)
F = fetch length (feet)

[Eqn. 3-39, SPM Vol. I]

2.4.3.5 Significant Wave Height

The value of the significant wave height depends upon the wave classification. Since the C-43 West Storage Reservoir waves are classified as shallow water/transitional waves, the significant wave height is equivalent to the calculated shallow water wave height.

2.4.3.6 Zero Overwash Wave Height

The DCM-2 establishes the freeboard height that results in zero overwash as the design criteria for high and significant hazard dams. However, for purposes of preliminary case analyses of alternative embankment designs, the "zero overwash wave height" is assumed to be comparable to a wave height with a 2% frequency of occurrence. The computation of this preliminary "zero overwash wave height" is given by the following equations:

$$\overline{H} = H_{rms}\left(-Ln\left(\frac{n}{N}\right)\right)^{\frac{1}{2}} \qquad \textit{[Eqn. 3-7, SPM Vol. I]}$$

Where:

$\overline{H}$ = zero overwash wave height (feet)

n/N = 0.02, the probability of being overtopped

$H_{rms} = \frac{H_s}{\sqrt{2}}$ = the root mean square wave height *[Eqn. 3-10, SPM Vol. I]*

H_s = significant wave height (feet)

For final design, an "overtopping rate" will be estimated using STWAVE/ACES. Geotechnical documentation assuring embankment integrity and agency approval will also be provided for any overtopping rate exceeding zero.

2.4.3.7 Wave Breaking Height

Theoretically, the maximum wave height cannot exceed 0.78 D, where D is the depth of water without wave action (EM-1110-2-1420, 1997). At this height, the wave breaks and then reforms at a lower height within a few wave lengths. The calculated zero overwash wave height is compared to the calculated wave breaking height to confirm it does not exceed the theoretical maximum sustainable wave height.

For the C-43 West Storage Reservoir, the calculated zero overwash wave height for both cells is less than the wave breaking height in all cases. Therefore, the maximum wave height is not limited by wave breaking and the calculated zero overwash wave height is used for wave runup analyses.

2.4.3.8 Equivalent Deep Water Wave Height, H'_o

Curves used to estimate wave runup were developed in reference to deep water equivalent wave height. Since waves within the C-43 West Basin Storage Reservoir are classified as shallow water/transitional waves, to estimate wave runup, it is necessary to compute an equivalent deep water wave height (H'_o). Table C-1 of the Shore Protection Manual Volume II, provides an estimate of the ratio of shallow wave height to equivalent deep water wave height (H/H'_o) based upon the ratio of effective depth to the deep water wave length (d/L_o). The equivalent deep water wave height (H'_o)is calculated by dividing the shallow water wave height (H) by the ratio obtained from Table C-1 (H/H'_o).

2.4.4 Wave Runup

The approach for determining wave runup is the same for all design case scenarios. Wave runup varies based upon the wave height, slope and roughness of the runup surface, and the incident angle of the wind to the slope surface. The approximation of wave runup is based upon design curves of empirical data from numerous small scale laboratory tests of the runup of regular (monochromatic) waves on smooth impermeable slopes (SPM Vol. II, 1984). For practical application, the results need to be corrected for scale effects and slope surface roughness. A correction is also necessary for waves impacting the slope surface at an angle other than normal to the embankment axis.

2.4.4.1 Smooth Surface Wave Runup

Figures 7-8 to 7-12 in the *Shore Protection Manual, Vol. II*, are based upon small scale laboratory tests on runup of regular waves on smooth impermeable slopes. The figures provide an estimate for the relative runup (ratio of wave runup to equivalent deepwater wave height (R/H'_o) as a function of structure slope ($\cot\theta$) and deepwater wave steepness (H'_o/gT^2) for a specified ratio of water depth to equivalent deepwater wave height (d_s/H'_o). Multiplying the relative runup by the equivalent deep water wave height yields the smooth surface wave runup.

For the C-43 West Basin Storage Reservoir, the deepwater wave steepness (H'_o/gT^2) for various cases analyses varies from 0.014 to 0.017. These values all exceed the largest value of 0.0124 observed in all the test data. For purposes of the preliminary design calculations, it was decided to perform a regression analysis to better estimate wave runup curve ratios. Given the approximate nature of regression analyses, it was assumed that a regression analysis performed on a single H'_o/gT^2 value would provide a suitable approximation. Consequently, a single value of $H'_o/gT^2 = 0.016$ was selected and assumed to provide a reasonable for the entire range of values.

For the regression analyses, data was obtained from each figure. For each figure, the ratio of R/H'_o was estimated for every H'_o/gT^2 value given a constant value for $\cot\theta = 3$ (the typical embankment slope of 3H:1V). The R/H'_o and H'_o/gT^2 data was then plotted and regression curves fitted to the data using derived logarithmic, exponential and power equations. A curve of the average of the three regression methods was also

developed from the data. The average appeared to best fit the data and therefore was used to estimate R/H'_o values for $H'_o/gT^2 = 0.016$ for each figure. The curves for each figure are shown in Figures 5, 6 and 7. Supporting documentation, calculations and more detailed figures of the regression curves are provided in the Appendix E.

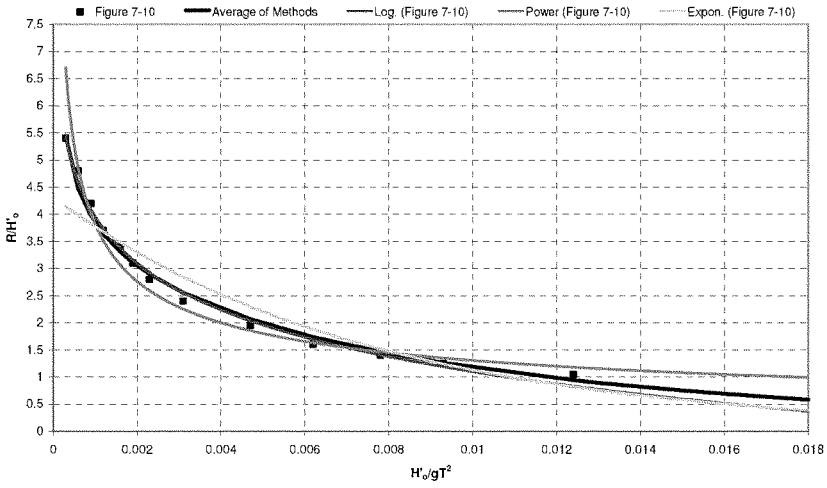

Figure 5: Regression Curves for Figure 7-10 (d_s/H'_o~0.8) [SMP Vol. II]

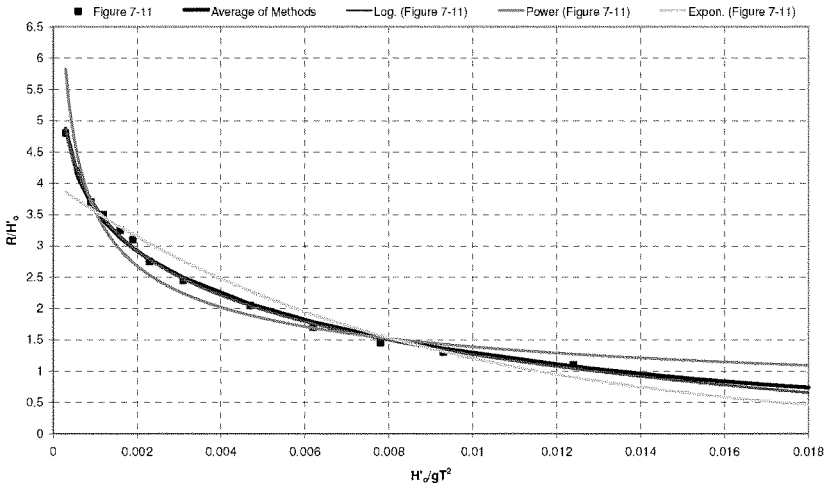

Figure 6: Regression Curves for Figure 7-11(d_s/H'_o~2.0) [SMP Vol. II]

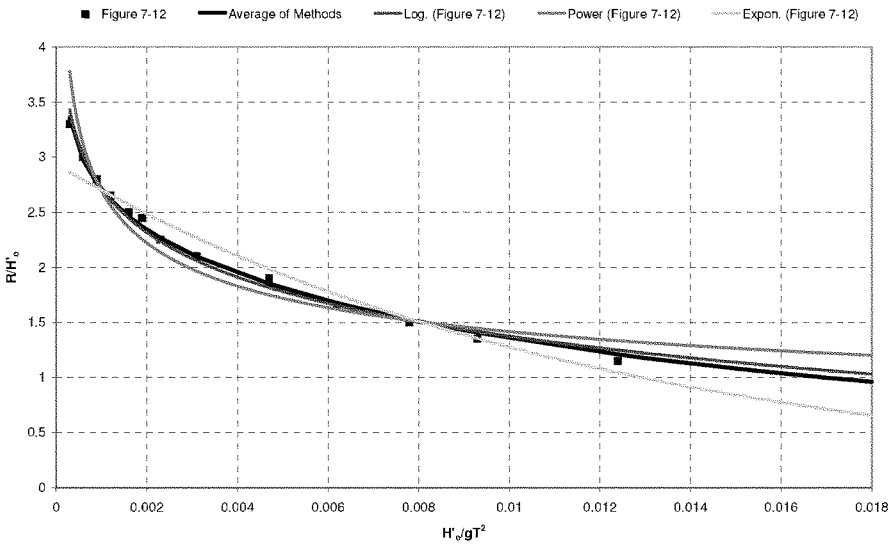

Figure 7: Regression Curves for Figure 7-12 ($d_s/H'_o \geq 3.0$) [SMP Vol. II]

In addition to the regression of curve data, the values for the ratio of d_s/H'_o for wave runup calculations generally fall between the d_s/H'_o values for which each curve was developed requiring an interpolation of results between figures in order to determine the relative runup (see detailed calculations in Appendix E).

2.4.4.2 Correction Factor due to Scale Effects

A correction is applied to the estimated smooth surface wave runup to account for the inability of small scale laboratory tests to model surface roughness effects. Consequently, it is expected that results based upon small scale lab tests will be smaller than prototype results or in natural conditions (SPM Vol. II). Figure 8 (Figure 7-13, SPM Vol. II, 1984) provides an estimate for the correction factor as a function of surface slope.

Given that the surface slope for the reservoir is consistently 3:1 (H:V), the wave runup scale correction factor for all C-43 West Storage Reservoir calculations is approximately 1.12.

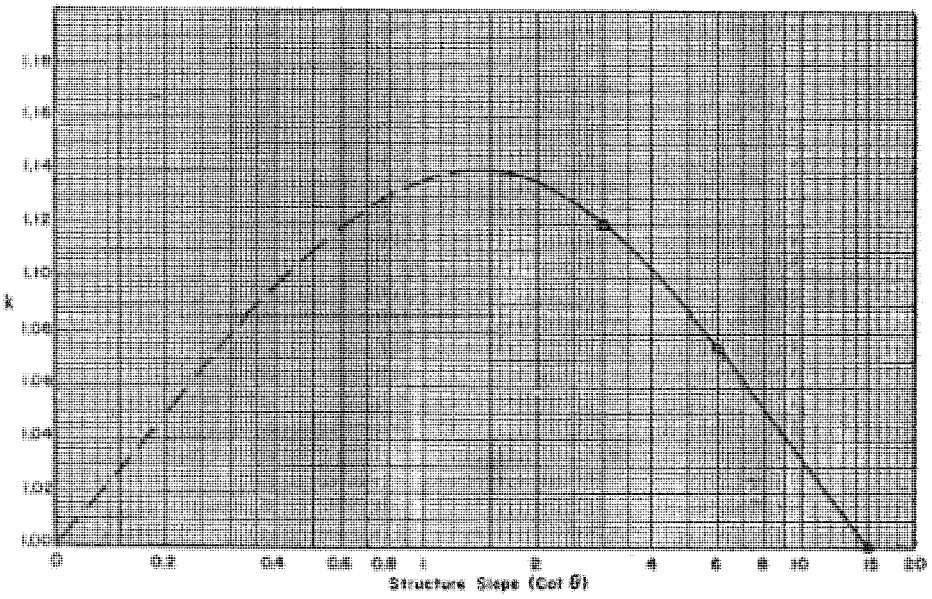

Figure 8: Correction Factor Due to Scale Effects [Figure 7-13, SPM Vol. II].

2.4.4.3 Correction Factor Due to Dam Surface Roughness

For practical application, the wave runup value derived from small scale laboratory tests on smooth surface slopes should be corrected to account for roughness of the runup surface. If there is more than one surface roughness on the slope length subjected to runup, it is recommended the surface roughness correction factor be adjusted or weighted based upon the fraction of the length of each surface roughness (subjected to runup) to the total slope length subjected to wave runup (SPM, Vol. II, 1984). The calculated smooth surface wave runup is multiplied by the adjusted surface roughness correction factor to determine an adjusted wave runup height.

The proposed dam embankments consist of 3:1 (H:V) soil cement slopes with a 3:1 stepped soil cement embankment (1' vertical steps) above the normal full storage level. For stepped embankments, a surface roughness coefficient of 0.7 is applied (Table 2-2, EM 1110-2-1614). Since the entire wave runup surface will consist of a stepped soil embankment, no subsequent weighted adjustment of the correction factor for different roughness surfaces is required.

2.4.4.4 Correction Factor due to Fetch Angle

Wave runup is most severe when a wave strikes perpendicular to the runup surface. The fetch angle is used to adjust wave height and runup for a less severe approach.

The correction factor can be estimated based upon the estimated fetch angle and from Figure 9 (Figure 8, ACER Tech Memo No. 2, USBR, 1992).

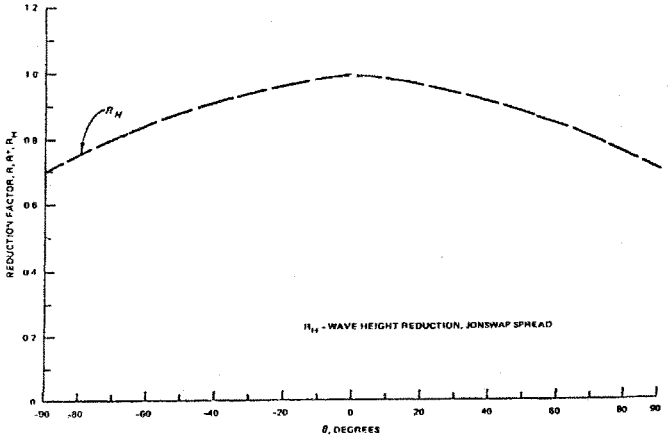

Figure 9: Correction Factor Due to Fetch Angle [Figure 8, ACER No. 2]

2.5 Freeboard Parameters

2.5.1 Normal Full Storage Level

Cell 1 and Cell 2 of the C-43 West Basin Storage Reservoir will be connected by a reinforced concrete box culvert (RCBC) through an internal embankment. The culvert will allow for the free flow of water between the two cells in order to maintain an equilibrium water surface elevation. The normal full storage level for the C-43 West Storage Reservoir is set at an elevation of 42.0 feet.

2.5.2 Fetch

The characteristics of wind-generated waves and setup are influenced by the distance that wind moves over the water surface in the "fetch" direction. Fetch is the straight line distance across a body of water subject to wind forces and is a major factor used in calculating wave heights. It is assumed that along the fetch, waves are generated by a wind having a constant wind direction and speed. Both the fetch length and the fetch angle factor into wave generation.

For both Cell 1 and Cell 2 of the C-43 West Basin Storage Reservoir, two fetches are evaluated. Table 1 provides summary information of each cell fetch evaluated. Supporting documentation of fetch lengths, angles and average depth (a component of effective depth, see Section 2.5.3) are provided in Appendix B.

Table 1: Fetch Parameters

Cell	Fetch	Fetch Length (miles)	Fetch Angle	Average Depth[1] (ft)
Cell 1	1A	3.51	0°	20.4
	1B	3.04	7°	20.2
Cell 2	2A	3.40	42°	17.5
	2B	3.62	45°	17.1

1. Based upon an Normal Full Storage Level (NFSL) elevation of 42.0 feet.

2.5.2.1 Fetch Length

The fetch length in a confined body of water is generally the longest average linear path across the water surface from one side of an impoundment to the other. The fetch lengths for the C-43 West Basin Storage Reservoir were calculated based upon guidelines published by the U.S. Bureau of Reclamation (USBR, 1992). The recommended procedure consists of drawing a center radial from one side of the impoundment to the other then drawing four radials on each side of the center radial spaced at an interval of 3° (Figure 10). The fetch length is then estimated as the average of the nine of the radial path lengths. This process is performed several times to determine the 24° spread that results in the longest set of radials and thereby longest fetch length.

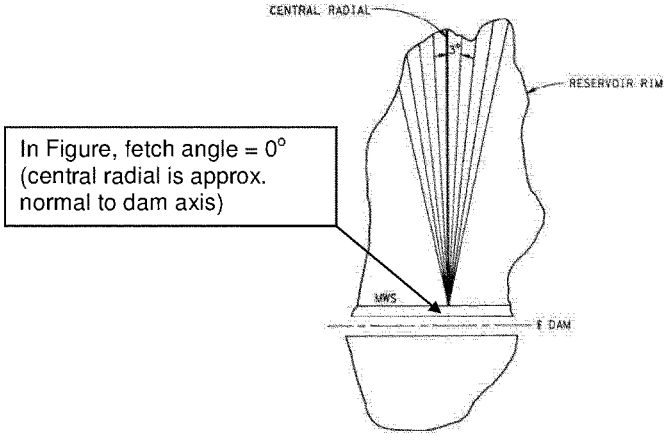

Figure 10: Calculating Fetch Length

2.5.2.2 Fetch Angle

The incident angle between the fetch (taken to be the center radial of the fetch length calculations) and a line normal to the axis of the embankment is the fetch angle. Wave runup is most severe when a wave strikes the embankment perpendicular to the

embankment. The fetch angle is used to adjust wave height and runup for a less severe approach.

2.5.3 Effective Depth

The effective depth of water along the fetch also influences the estimated wave height/wave runup. The effective depth is estimated to be the average normal full storage level (NFSL) depth along the center radial used to estimate fetch length (see Table 1), plus the surcharge depth associated with the routing of the design storm event through the reservoir. Since inflow to the reservoir is limited to forced pumping and precipitation falling directly on the reservoir itself, the maximum surcharge depth that can be realized is equal to the total depth of rainfall falling on the impoundment during the design event (it is assumed that during the threat of an extreme storm event, pumping into the basin will be ceased). However, routing the design storm event through the reservoir provides a more realistic estimate of actual surcharge depth and helps reduce required freeboard.

For Case 1 and Case 2, the hydrologic scenarios presented in the DCM-2 are routed PMP through the reservoir cells to estimate flood surcharge. Case 3 is not associated with any precipitation event and therefore no surcharge is realized. As subsequently discussed in Section 3.1.6.4., for Case 4, the maximum flood surcharge is conservatively assumed to be (at most) equal to the routing of the PMP as in Case 1. Table 2 provides the effective depths used for the wind setup and wave runup analyses for the freeboard case scenarios.

Table 2: Effective Depths for Cell Analyses

Cell - Fetch	Average NFSL Depth[1] (ft)	Surcharge Depth (ft)				Effective Depth (ft)			
		Case 1: PMP[2]	Case 2: 100-Yr[3]	Case 3: PMW[3]	Case 4: EASY[4]	Case 1: PMP	Case 2: 100-Yr	Case 3: PMW	Case 4: EASY
Cell 1 - 1A	20.36	4.13	0.77	0.0	3.77	24.49	21.13	20.36	24.13
Cell 1 - 1B	20.22	4.13	0.77	0.0	3.77	24.35	20.99	20.22	23.99
Cell 2 - 2A	17.51	4.13	0.77	0.0	3.77	21.64	18.28	17.51	21.28
Cell 2 - 2B	17.06	4.13	0.77	0.0	3.77	21.19	17.83	17.06	20.83

Note:
1. Based upon NFSL elevation = 42.0 & estimated average bottom elevation along fetch center radial (see Appendix B)
2. Based upon routing of design storm event (see calculations)
3. Based upon maximum precipitation or routing of design storm event (see calculations)
4. Based upon maximum possible surcharge for PMP (see discussion in Section 3.1.6.4)

2.5.4 Dam Embankments

The slope and roughness of the dam embankment has a significant influence on wave runup. The proposed dam embankments consist of 3:1 (H:V) soil cement slopes with a stepped soil cement embankment (1' vertical steps) above the normal full storage level.

3 PRELIMINARY DESIGN FREEBOARD ANALYSES

3.1 Determination of Design Freeboard Components and Camber

The freeboard components of surcharge depth, wind setup and wave height/wave runup all vary between different fetch and/or case analyses. Camber provided above freeboard to account for embankment settlement varies based upon the total estimated embankment height.

3.1.1 Camber and Embankment Settlement

The estimated amount of embankment settlement varies depending upon the proposed embankment location and height. A settlement analysis conducted as part of the C-43 West Storage Reservoir BODR estimates embankment settlement in various zones around the reservoir perimeter and for a range of embankment heights. Settlement zones are shown in Figure 11. To approximate embankment settlement around the perimeter of Cell 1, settlement data for Zones A, C and D are averaged. For Cell 2, settlement data for Zones A, C and E are averaged. Results from the settlement analyses are provided in Table 3.

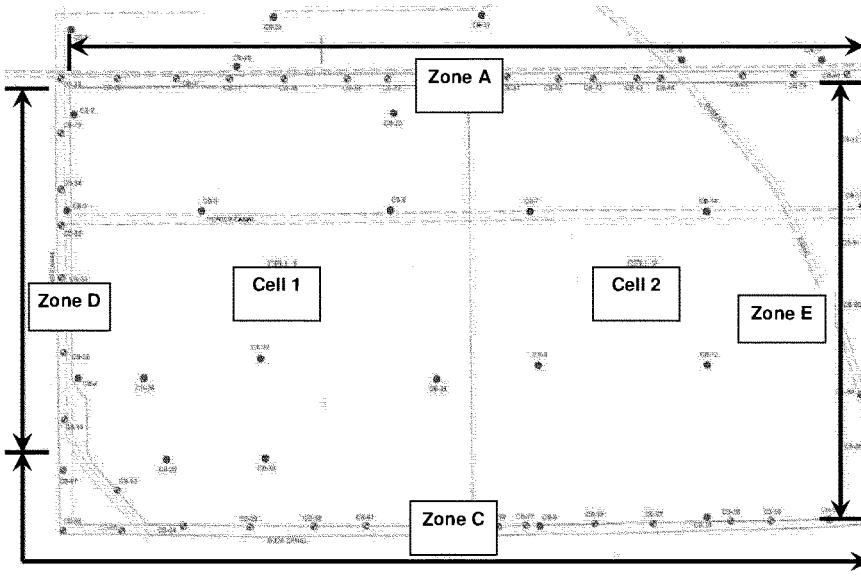

Figure 11: Settlement Zones [Figure 8A-3, C-43 BODR]

Table 3: Embankment Settlement Data

Embankment Height (ft)	Settlement (inches)					
	Section A	Section C	Section D	Section E	Average Cell 1[1]	Average Cell 2[2]
25	4.26	4.15	4.68	3.50	4.4	4.0
26	4.75	5.20	4.89	4.21	4.9	4.7

44	23.89	21.83	23.81	23.23	23.18	22.98

1. Average of Zones A, C and D
2. Average of Zones A, C and E

3.1.2 Provisions for the Malfunction of the Spillway and/or Outlet Works

No additional freeboard is directly provided for the potential malfunction of the C-43 spillway and/or outlet works. However, as previously mentioned in Section 2.2.1, this component is indirectly accounted for in the determination of the flood pool surcharge. When routing design storm events through the reservoir, it is conservatively assumed that all mechanically operated outlet structures are closed for the duration of the storm event thereby increasing the maximum estimated reservoir surcharge.

3.1.3 Landslide Induced Wave Height

It is assumed that the potential for catastrophic landslides is negligible and therefore no additional freeboard is provided for potential landslide induced wave height.

3.1.4 Wind Setup

Detailed calculations for the determination of wind setup for each fetch and case analysis are presented in the Appendix C of this memorandum.

3.1.5 Wave Height and Wave Runup

Detailed calculations for the determination of wave height and wave runup for each fetch and case analysis are presented in the Appendix C of this memorandum.

3.1.6 Surcharge Pool Depth

The routing of inflow design floods through the reservoir system based on the DCM-2 design criteria and guidelines is presented in the Appendix A.

3.1.6.1 Case 1: 100-Yr Wind + Probable Maximum Precipitation

For Case 1, the DCM-2 identifies two flood routing scenarios based upon the Probable Maximum Precipitation (PMP) that must each be assessed. Both scenarios include sequential storm events occurring over an extended period of time separated by brief dry periods. The PMP for the C-43 West Basin Storage Reservoir site is approximately 55.7 inches (Figure 11). Since the reservoir area is greater than 10 square miles, the PMP was adjusted to 54.95 inches for the 72-hr PMP for the two scenarios.

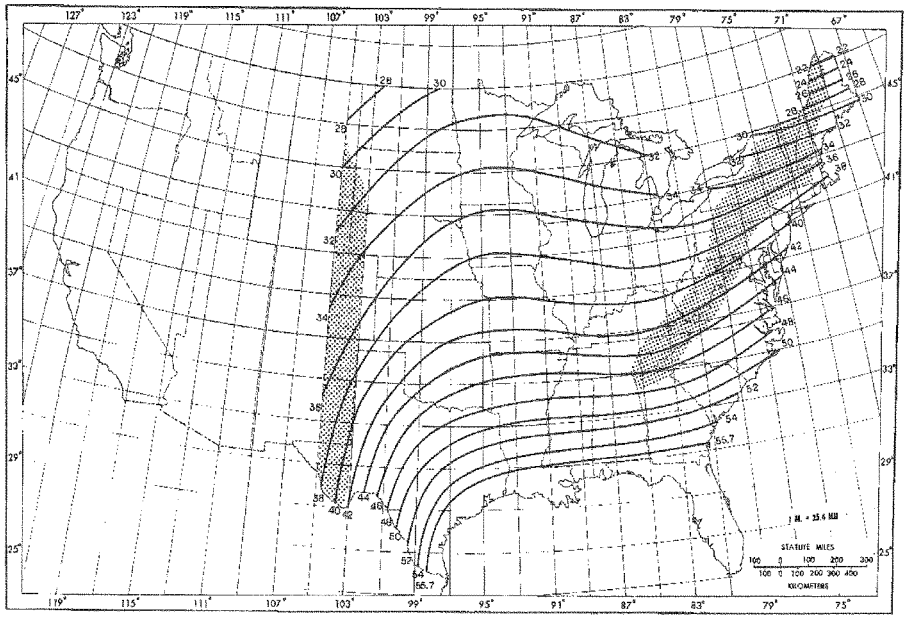

Figure 12: All Season PMP (72-hr, 10 sq. mi.) [Figure 22, HR 51, NOAA]

The preliminary hydrologic analyses to route both PMP scenarios through the reservoir are discussed in detail and documented in the Appendix A. The results of the analyses indicate that the maximum surcharge pool depth for Case 1 is approximately 4.13 for both Cell 1 and Cell 2.

3.1.6.2 Case 2: Category 5 Wind + 100-Yr Precipitation

For Case 2, the 100-year, 3-day precipitation is the design storm event (DCM-2, 2006). The 100-year, 3-day precipitation for the C-43 West Basin Storage reservoir site is approximately 13 inches (Figure 12). A preliminary hydrologic analysis routing of the 100-year event through the reservoir indicated that the maximum surcharge pool depth for Case 2 is approximately 0.77 for both Cell 1 and Cell 2.

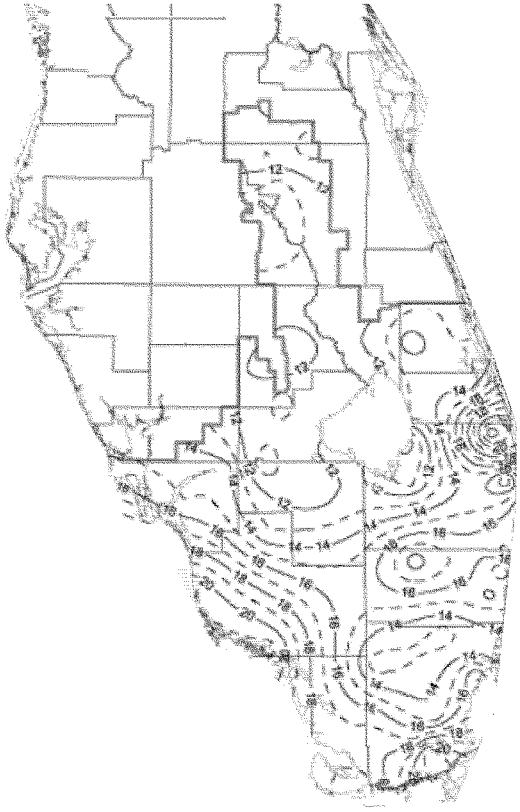

Figure 13: 100-Year, 3-Day Precipitation [Figure DCM 2-3, DCM-2]

3.1.6.3 Case 3: PMW + Normal Full Storage Level

There is no precipitation event associated with this case. Design freeboard is based solely upon the assessment of other freeboard components, therefore, there is no surcharge pool depth for Case 3 analyses.

3.1.6.4 Case 4: Hurricane Easy

For Case 4, the design storm event is based upon the recorded rainfall from Hurricane Easy in 1950. During this event, a peak 24-hr rainfall of 38.7 inches was recorded, with a 72-hr rainfall depth of 45.2 inches (3.77 ft) (DCM-2, 2006). Routing of this event was not warrant for this case. It was therefore conservatively assumed that the maximum surcharge would be equivalent to the cumulative rainfall for the 72-hr event. Therefore, a maximum surcharge depth of 45.2 inches is assumed for both cells.

3.2 Summary of Preliminary Design Freeboard with Camber Calculations

3.2.1 Cell 1

Two fetches were analyzed for Cell 1 (see Section 2.5.2). Fetch 1A represents the most severe freeboard conditions of Cell 1. Fetch 1B was considered the second most severe freeboard condition. Fetch 1B was analyzed to determine if there was a possibility to reduce embankment height (for reduced freeboard requirements) in less severe fetch conditions around the perimeter embankment of Cell 1.

3.2.1.1 Fetch 1A Analysis

The freeboard analysis for Fetch 1A results in the most conservative estimate of preliminary freeboard requirements in Cell 1.

Table 4: Cell 1 (Fetch 1A) Freeboard Analysis Summary

Freeboard Component	Case1 100-Yr Wind and PMP	Case 2 Category 5 and 100-Yr Precip.	Case 3 PMW and NFSL	Case 4 Hurricane Easy
Surcharge Depth	4.13	0.77	0.00	3.77
Wind Setup	1.03	1.86	3.21	1.03
Wave Height / Wave Runup	8.00	8.62	10.04	7.92
Landslide Induced Wave Height	0.00	0.00	0.00	0.00
Provisions for Malfunction of the Spillway and/or Outlet Works	0.00	0.00	0.00	0.00
Minimum Required Freeboard	**13.16**	**11.26**	**13.25**	**12.72**
Embankment Settlement	1.24	1.06	1.24	1.24
Minimum Required Freeboard plus Camber	**14.4**	**12.3**	**14.5**	**14.0**

3.2.1.2 Fetch 1B Analysis

Fetch 1B is a less severe condition than Fetch 1A and is used to assess the potential for reducing embankment heights around the southwest perimeter of Cell 1.

Table 5: Cell 1 (Fetch 1B) Freeboard Analysis Summary

Freeboard Component	Case1 100-Yr Wind and PMP	Case 2 Category 5 and 100-Yr Precip.	Case 3 PMW and NFSL	Case 4 Hurricane Easy
Surcharge Depth	4.13	0.77	0.00	3.77
Wind Setup	0.90	1.63	2.81	0.90
Wave Height / Wave Runup	7.15	7.61	8.91	7.07
Landslide Induced Wave Height	0.00	0.00	0.00	0.00
Provisions for Malfunction of the Spillway and/or Outlet Works	0.00	0.00	0.00	0.00
Minimum Required Freeboard	**12.18**	**10.01**	**11.72**	**11.74**
Embankment Settlement	1.15	0.96	1.06	1.15
Minimum Required Freeboard plus Camber	**13.3**	**11.0**	**12.8**	**12.9**

3.2.2 Cell 2

Two fetches were analyzed for Cell 2 of the C-43 Storage Reservoir (see Section 2.5.2).

3.2.2.1 Fetch 2A Analysis

The freeboard analysis for Fetch 2A provides a slightly lower and less conservative preliminary estimate of freeboard requirements than Fetch 2B in Cell 2.

Table 6: Cell 2 (Fetch 2A) Freeboard Analysis Summary

Freeboard Component	Case1 100-Yr Wind and PMP	Case 2 Category 5 and 100-Yr Precip.	Case 3 PMW and NFSL	Case 4 Hurricane Easy
Surcharge Depth	4.13	0.77	0.00	3.77
Wind Setup	1.12	2.09	3.61	1.13
Wave Height / Wave Runup	6.63	7.62	8.82	6.56
Landslide Induced Wave Height	0.00	0.00	0.00	0.00
Provisions for Malfunction of the Spillway and/or Outlet Works	0.00	0.00	0.00	0.00
Minimum Required Freeboard	**11.89**	**10.48**	**12.44**	**11.46**
Embankment Settlement	0.87	0.67	0.87	0.78
Minimum Required Freeboard plus Camber	**12.8**	**11.2**	**13.3**	**12.2**

3.2.2.2 Fetch 2B Analysis

The freeboard analysis for Fetch 2B provides a slightly higher and more conservative preliminary estimate of freeboard requirements than Fetch 2A in Cell 2.

Table 7: Cell 2 (Fetch 2B) Freeboard Analysis Summary

Freeboard Component	Case1 100-Yr Wind and PMP	Case 2 Category 5 and 100-Yr Precip.	Case 3 PMW and NFSL	Case 4 Hurricane Easy
Surcharge Depth	4.13	0.77	0.00	3.77
Wind Setup	1.22	2.27	3.94	1.23
Wave Height / Wave Runup	7.06	7.62	9.53	6.99
Landslide Induced Wave Height	0.00	0.00	0.00	0.00
Provisions for Malfunction of the Spillway and/or Outlet Works	0.00	0.00	0.00	0.00
Minimum Required Freeboard	**12.41**	**10.67**	**13.47**	**11.98**
Embankment Settlement	0.87	0.67	0.98	0.78
Minimum Required Freeboard plus Camber	**13.3**	**11.3**	**14.5**	**12.8**

3.2.3 Preliminary Embankment Freeboard Results and Recommendations

Per the DCM-2, Case 3 is used only for sensitivity analysis and should not be used as the design conditions (DCM-2, 2006). Excluding Case 3, Case 1 resulted in the largest preliminary estimate of freeboard requirements.

For Cell 1, the freeboard analysis for Fetch 1A is the most conservative estimate of freeboard requirements. The results of the Fetch 1B analysis indicated that the difference in freeboard requirements was not sufficient to merit a significant reduction in embankment heights (due to decreased freeboard requirements) in less severe fetch condition around the perimeter of Cell 1. Based upon the Cell 1 freeboard analysis for Case 1, the preliminary minimum required freeboard for Cell 1 external perimeter dam embankments is approximately 14.4 feet.

For Cell 2, Fetch 2B provides a slightly higher freeboard requirement (than Fetch 2A) and serves as the basis for preliminary freeboard requirements for Cell 2. Based upon the Cell 2 freeboard analysis, the preliminary minimum required freeboard for Cell 2 perimeter dam embankments is approximately set at 13.3 feet.

As previously noted, the preliminary calculations presented in this section and Section 2 were used during the preliminary design to estimate freeboard requirements. These manual calculations were updated during subsequent design phases as necessary to provide a check to the results of less transparent computer analyses required for final design. Final design analyses are discussed and presented in Section 4.

3.2.2.2 Fetch 2B Analysis

The freeboard analysis for Fetch 2B provides a slightly higher and more conservative preliminary estimate of freeboard requirements than Fetch 2A in Cell 2.

Table 7: Cell 2 (Fetch 2B) Freeboard Analysis Summary

Freeboard Component	Case1 100-Yr Wind and PMP	Case 2 Category 5 and 100-Yr Precip.	Case 3 PMW and NFSL	Case 4 Hurricane Easy
Surcharge Depth	4.13	0.77	0.00	3.77
Wind Setup	1.22	2.27	3.94	1.23
Wave Height / Wave Runup	7.06	7.62	9.53	6.99
Landslide Induced Wave Height	0.00	0.00	0.00	0.00
Provisions for Malfunction of the Spillway and/or Outlet Works	0.00	0.00	0.00	0.00
Minimum Required Freeboard	**12.41**	**10.67**	**13.47**	**11.98**
Embankment Settlement	0.87	0.67	0.98	0.78
Minimum Required Freeboard plus Camber	**13.3**	**11.3**	**14.5**	**12.8**

3.2.3 Preliminary Embankment Freeboard Results and Recommendations

Per the DCM-2, Case 3 is used only for sensitivity analysis and should not be used as the design conditions (DCM-2, 2006). Excluding Case 3, Case 1 resulted in the largest preliminary estimate of freeboard requirements.

For Cell 1, the freeboard analysis for Fetch 1A is the most conservative estimate of freeboard requirements. The results of the Fetch 1B analysis indicated that the difference in freeboard requirements was not sufficient to merit a significant reduction in embankment heights (due to decreased freeboard requirements) in less severe fetch condition around the perimeter of Cell 1. Based upon the Cell 1 freeboard analysis for Case 1, the preliminary minimum required freeboard for Cell 1 external perimeter dam embankments is approximately 14.4 feet.

For Cell 2, Fetch 2B provides a slightly higher freeboard requirement (than Fetch 2A) and serves as the basis for preliminary freeboard requirements for Cell 2. Based upon the Cell 2 freeboard analysis, the preliminary minimum required freeboard for Cell 2 perimeter dam embankments is approximately set at 13.3 feet.

As previously noted, the preliminary calculations presented in this section and Section 2 were used during the preliminary design to estimate freeboard requirements. These manual calculations were updated during subsequent design phases as necessary to provide a check to the results of less transparent computer analyses required for final design. Final design analyses are discussed and presented in Section 4.

4 FINAL DESIGN STWAVE/ACES FREEBOARD ANALYSES

4.1 Introduction

For final design, the DCM-2 and the U.S. Army Corp of Engineers (USACE) require that a final assessment of wave runup component of the freeboard requirements be based upon USACE Steady-State Spectral Wave Model (STWAVE) and the Automated Coastal Engineering System (ACES) computer model analyses. This section discusses the computer analyses and presents the analyses results and final design recommendations for required freeboard and reservoir embankment heights.

4.2 Design Freeboard and Overtopping Rate Criteria

Based upon the preliminary design and alternative evaluation, the Case 1: 100-year Wind combined with the Probably Maximum Precipitation freeboard criteria was shown to result in the most conservative freeboard requirements be the limiting case scenario (Case 3 is excluded and used only for sensitivity analyses per DCM-2) . For final design, the reservoir storage cells will be analyzed using only the Case 1 scenarios.

The final design criteria also has an additional embankment overtopping rate restriction which may dictate a higher embankment heights than necessary to simply meet the freeboard requirements as determined based on the previously discussed components of freeboard (wind setup, wave runup, flood surcharge, etc...). While embankment overtopping is an important consideration in determining the embankment height, the DCM-2 does not provide specific design criteria or guidelines for establishing the maximum allowable overtopping rate for reservoir embankments. This is possibly due to the fact that allowable overtopping rates can vary significantly based upon embankment design, embankment material and the possible presence of erosion resistant vegetative cover. It would seem that the most appropriate means of establishing an allowable embankment overtopping rate criteria would be based upon a geotechnical assessment of the embankment material and design and/or field testing.

4.2.1 Overtopping Rate Field Tests

To assist in establishing an allowable embankment overtopping rate necessary to determine minimum freeboard and embankment heights, field tests were conducted in the C-43 test cell site to evaluate the integrity of the proposed C-43 embankment designs under various overtopping conditions. The testing consisted of discharging water at a range of rates (0.01, 0.005 and 0.001 cfs/ft) down a vegetated and non-vegetated embankment slopes for a period of 8 hours. The vegetated condition consisted of a "natural" grass cover which was considered comparable to the vegetated condition around the Lake Okeechobee dam (see Figure 14) and would likely resemble the vegetated slopes of the C-43 embankments after 5-10 years of maintenance.

Figure 14: Grass Cover on Sections of Hoover Dike (Lake Okeechobee).

The test results revealed several findings (see Figure 15). At a rate of 0.01 cfs/ft, even a vegetated slope would experience sufficient erosion to compromise the integrity of the embankment (see Figure 16). However, at overtopping rates of 0.005 cfs/ft and 0.001 cfs/ft, the vegetated slope did not appear to experience any significant erosion that might threaten the integrity of the embankment. A bare, non-vegetated slope was tested at a rate of 0.005 cfs/ft and resulted in significant erosion and loss of embankment integrity.

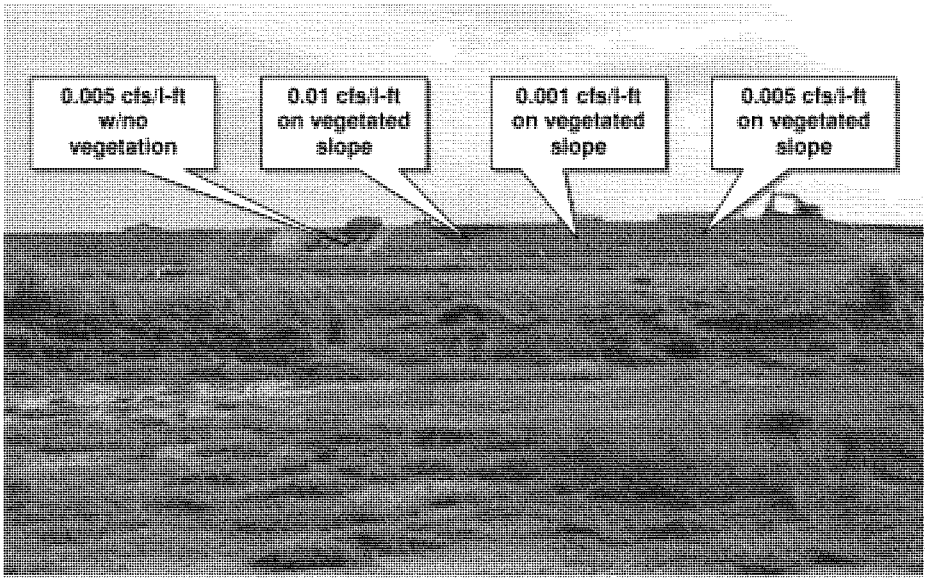

Figure 15: Overtopping Rate Field Tests.

Figure 16: Washout with Outwash Rate of 0.01 cfs/ft.

4.2.2 External Embankment Overtopping Rate Criterion

Based upon the results of the field tests, it was concluded that the embankment slopes necessarily needed to be vegetated and that after 5-10 years of continued maintenance, the C-43 embankment vegetation would be sufficiently established to provide long term erosion protection with minimal maintenance. With little difference between an overtopping rate of 0.001 cfs/ft and 0.005 cfs/ft under the vegetated conditions, it was concluded that a maximum overtopping rate of 0.005 cfs/ft would be acceptable provided that the embankment slope would be continuously maintained for several years or until the establishment of viable long-term embankment vegetation. While 0.005 cfs/ft is being considered as the embankment overtopping design criteria (see C-43 WSR Overwash Rate Memo, Appendix G), overtopping rates of 0.1, 0.01, and 0.001 cfs/ft were still assessed and the results presented in this report.

4.2.3 Internal Embankment Overtopping Rate Criterion

Unlike the external embankment, failure of the internal embankment between the two cells of the C-43 reservoir does not pose a direct threat to human life, critical facilities or economic or environmental concerns. In addition, the design of the internal embankment will include a hardened, erosion resistant soil cement layer to resist continual exposure to waves during periods of normal reservoir operation.

Tests on a soil cement embankment were not performed nor were they considered necessary. Soil cement is a durable material that is readily used for high channel velocity conditions (as much as 15 ft/s). Consequently, the internal embankment is expected to be able to withstand much higher overtopping rates (relative to external embankments) for an extended period of time with essentially no adverse effects.

Consideration of the allowable overtopping rate of the internal embankment was therefore based upon possible concerns by the SFWMD that excessive overtopping of the internal embankment, from one cell into the other, may result in additional excessive surcharge in one cell thereby possibly compromising the integrity of the external embankments.

Under that assumption, the impact of an overtopping rate of 1.0 cfs/ft was evaluated. It was estimated that if flow were to leave one cell for the other at a rate of 1.0 cfs/ft for a duration of 1 hour, and no flow left the cells by any other means, Cell 1 would either increase by 0.29 feet or Cell 2 could increase by 0.27 feet. Given the conservative approach taken in all aspects of the reservoir design including the coincidence of extreme weather and operational conditions and the amount of freeboard provided along the external embankments (~14 ft), it is not anticipated that such an increase in either cell would have any significant adverse impact that might compromise the integrity of the external embankments. Consequently, an overtopping rate of 1.0 cfs/ft was considered acceptable for the internal embankment.

4.3 Design Freeboard Approach and Methodology

Determination of the final design freeboard requirements differs from the preliminary design only in that computer models are used to determine the wave runup component of freeboard. Other freeboard components discussed previously in Section 2.2 are still applicable and use the same approaches and methodologies.

4.3.1 Computer Models

CEDAS Version 4.03 was used for the final design analyses. STWAVE and ACES have been integrated into a design and analysis system called the Coastal Engineering Design and Analysis System (CEDAS) developed by Veri-Tech. CEDAS is comprised of a comprehensive collection of coastal engineering and design software developed by and/or for the USACE and organized as modules into a single interactive Windows-based software system.

4.3.2 Steady State Spectral Wave (STWAVE) Model

STWAVE is a two dimensional finite-difference wave transformation computer model that quantifies the change in wave parameters such as height, period, direction and spectral shape, between offshore/deep water and nearshore/shallow water. For this project, STWAVE is used to determine significant wave heights and wave periods. This data is subsequently used to estimate wave runup and overtopping rates using ACES.

4.3.3 Automated Costal Engineering System (ACES) Model

ACES is an integrated collection coastal engineering design and analysis applications. Included in ACES is an application for the determination of Wave Runup and Overtopping on Impermeable Structures. This application estimates wave runup and overtopping rates on rough and smooth slope surfaces that are assumed to be impermeable.

To estimate the minimum freeboard requirements as presented in Sections 2 and 3, the ACES derived estimate of wave runup is included along with other freeboard components to establish minimum freeboard requirements.

To investigate embankment heights for a range of overtopping rates, significant wave heights and wave periods determined using STWAVE were used as input along with other physical embankment and reservoir data. Overtopping analyses based on the results of manual calculations were not performed during the preliminary design, however, ACES was used to estimate embankment heights for various overtopping rates based on the calculated significant wave heights and wave periods in this report.

4.4 STWAVE Analyses

STWAVE requires bathymetric, wind, and wave data in order to model wave characteristics. The required input and assumptions for the STWAVE analyses are briefly discussed below.

4.4.1 Bathymetry

4.4.1.1 Bathymetric Data

Bathymetric data was developed using point data site surveys and a digital terrain model (DTM) of the proposed grading of the C-43 West Basin Storage Reservoir. This point data was triangulated and converted into square grids composed of 10' x 10' elements.

4.4.1.2 Grid Orientation

During preliminary analyses using STWAVE, it was found that the grid orientation (direction of x-axis of bathymetry) in relation to the wind direction had an impact on the calculated results. Discussions with VeriTech indicated that even though wind direction for a specific grid orientation can vary +/- 90 degrees from the x-axis, analyses should be limited at most to +/-45 degrees from the x-axis. A sensitivity analysis conducted on wind angles indicated that wind blowing at a 45 degree angle (NW-SE) to the grid orientation (N-S) generally produced wave height results that were ~3-5% less than if both the wind and grid were oriented in the same direction. Though the critical fetches identified during preliminary design tend to be approximately +/-45 degrees from the developed grid orientation (N-S), given the theoretical nature of the analyses, it was assumed that the results would be within the range of acceptability.

To organize files and results, grid orientation and wind directions were labeled in a counterclockwise direction with north being considered zero degrees. (e.g. south would be 180 degrees, northeast would be 315 degrees)

4.4.2 Wave and Wind Data

The development of wave spectra based upon wave and wind data is greatly simplified by the fact that the reservoir does not have or require near shore wave or current information. The water surface of the reservoir is assumed to be smooth prior to the application of wind stress. Consequently, wave data is input to reflect no initial waves prior to the application of the wind speed.

The wind speed used for the final analyses is based upon the Case 1 100-year wind speed adjusted to the fetch limited duration wind speed. For all four fetches analyzed in manual freeboard calculations, the Case 1 adjusted fetch limited duration wind speed is 100 mph (44.7 m/s). Consequently, a 100 mph wind speed was used for all STWAVE Case 1 analyses for all wind directions.

4.4.3 STWAVE Results

Case 1 significant wave heights and wave periods estimated using STWAVE are provided in Appendix F.

4.5 ACES Analyses

ACES requires reservoir and embankment data such as water depth, embankment height, slope and roughness along with significant wave height and wave period data. In addition, calculations are dependent upon several empirically derived coefficients to account for slope roughness and to estimate overtopping rates.

4.5.1 Wave Runup

ACES estimates wave runup using a different methodology than the graphical method presented in the preliminary design manual calculations. The ACES rough slope wave runup calculations are based on an empirical equation derived by Ahrens and McCartney (ACES, 1992). The Ahrens and McCartney rough slope wave runup equation is:

$$R = H_i \frac{a\xi}{1 + b\xi}$$

Where:

H_i = incident wave height (feet)

a,b = empirical slope roughness coefficients associated with specific types of armor units (table provided in program)

ξ = $\dfrac{\tan\theta}{\sqrt{\dfrac{H_i}{L_o}}}$

θ = angle between structure seaward face and horizontal (a measure of structure slope)

L_o = deepwater wavelength

[Equation 1, ACES pg 5-2-3l]

Stepped slope embankments are not included in the slope roughness coefficient tables provided by the ACES program, therefore, the values for riprap, which provided the most conservative wave runup results of the available coefficient data was used.

4.5.2 Wave Overtopping

The calculation of wave overtopping is dependent upon empirically derived overtopping coefficients α and Q^*_o. An estimate for the coefficient α can be calculated automatically by ACES or by using the equation:

$$\alpha = 0.06 - 0.0143\ln(\sin\theta) \quad \textit{[Equation 7-13, SPM II, pg 7-54]}$$

Where:

α = an overtopping rate coefficient

θ = angle between structure seaward face and horizontal

While the overtopping coefficient α can readily be calculated, there is a great deal of uncertainty and limited available information on the how to best estimate Q^*_o. Figures for specific structure configurations provided in the Shore Protection Manual Volume II (Chapter 7) can potentially be used to estimate data pairs of α and Q^*_o based upon the relative wave height (d_s/H'_o) and wave steepness (H'_o/gT^2) ratios. These figures were generally considered not applicable due to either the embankment configuration and/or the lack of empirical data pairs within the range or even in close proximity to project calculations of wave height and wave steepness ratios.

However, Figure 7-34 of the Shore Protection Manual Vol. II does provide a means to estimate Q^*_o between waves conforming to cnoidal wave theory and linear wave theory (Figure 17). While this figure does not consider the configuration and slope of the embankment, it was considered the best available means to approximate the overtopping coefficient Q^*_o. Values of Q^*_o for a range of relative wave height (d_s/H'_o) and wave steepness (H'_o/gT^2) ratios were estimated from Figure 17. For d_s/H'_o exceeding 3.0, it was assumed that values would continue to follow the linear theory within the project range of H'_o/gT^2 values (generally from 0.010 to 0.016) as demonstrated by the d_s/H'_o =4.0 (assumed) line imposed on the graph in Figure 17.

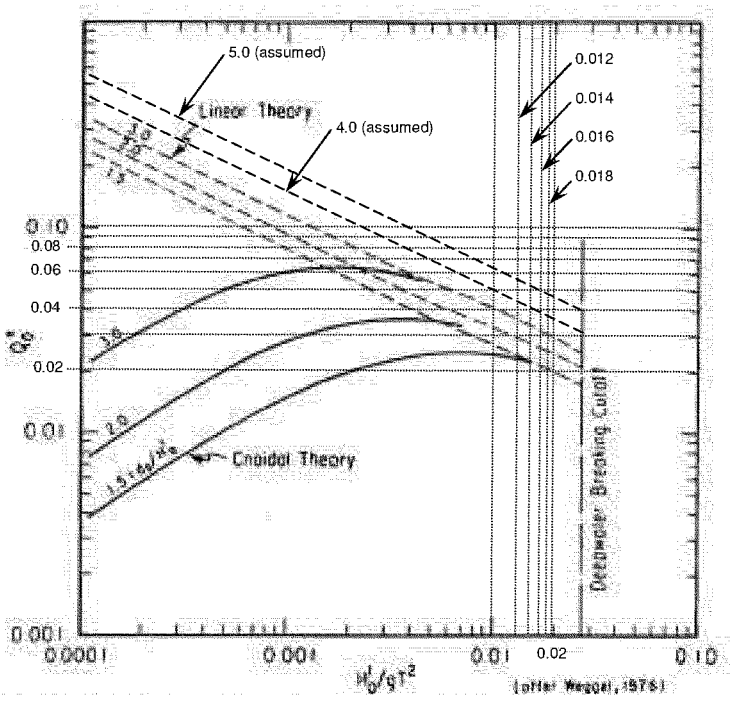

Figure 17: Variation of Q*o (Cnoidal vs. Linear Waves) [Figure 7-34, SPM Vol. II]

4.5.3 Summary of Manual Freeboard Calculations

Table 8 presents a summary comparison of the freeboard requirements based upon manual calculations. Supporting documentation is provided in Appendix C.

Table 8: Summary of Calculated Manual Freeboard Requirements

Description	Cell 1		Cell 2	
	Fetch 1A	Fetch 1B	Fetch 2A	Fetch 2B
Wave Runup (ft)	8.00	7.15	6.63	7.06
Flood Surcharge (ft)	4.13	4.13	4.13	4.13
Wind Setup (ft)	1.03	0.90	1.12	1.22
Required Freeboard (ft)	13.16	12.18	11.88	12.41
Average Normal Full Storage Level Depth[1] (ft)	20.36	20.22	17.51	17.06
Embankment Height (w/freeboard only) (ft)	33.52	32.40	29.39	29.47
Camber for Settlement (ft)	1.24	1.15	0.88	0.88
Embankment Height (ft) (w/freeboard and camber)	34.76	33.55	30.26	30.34
Proposed Embankment Elevation (NFSL=42.0) (ft)	56.40	55.33	54.75	55.28
Note: 1. Based the average depth along fetch determined in manual calculations.				

4.5.4 Summary of Wave Overtopping Analyses

The summary results of the overtopping analyses for Cell 1 and Cell 2 based upon STWAVE/ACES analyses are shown in Table 9. Detailed results and additional supporting documentation are provided in Appendix F.

Table 9: Summary of Cell 1 and Cell 2 Overtopping Analyses

Cell	Wind Direction (0=North)	Embankment Structure Height/Elevation at Overtopping Rate of							
		0.1 cfs/ft		0.01 cfs/ft		0.005 cfs/ft		0.001 cfs/ft	
		Ht (ft)	Elev. (ft)	Ht (ft)	Elev. (ft)	Ht (ft)	Elev. (ft)	Ht (ft)	Elev. (ft)
1	45 (Fetch 1A)	37.17	54.54	38.73	56.25	39.12	**56.64**	39.86	57.46
1	135 (Fetch 1B)	33.51	54.38	35.15	56.18	35.56	**56.59**	36.33	57.44
2	45 (Fetch 2A)	33.27	54.71	34.93	56.51	35.27	**56.72**	36.12	57.78
2	315 (Fetch 2B)	29.69	54.32	31.33	56.16	31.73	**56.56**	32.50	57.42

Note: 1. Elevation values include camber (see detailed results in Appendix F)

4.6 Internal Embankments

4.6.1 Internal Embankment Design Height

Table 10 provides a summary of the minimum internal embankment height based upon STWAVE/ACES analyses and an overtopping rate of 1.0 cfs/ft. Additional analyses including overtopping rates of 0.1 cfs/ft, 0.01 cfs/ft, 0.005 cfs/ft and 0.001 cfs/ft are provided and summarized in Appendix F.

Table 10: Summary of Internal Embankment Overtopping Analysis

Description	Wave		Embankment Toe			Embankment at 1.0 cfs/ft Overtopping		
	Ht (ft)	Period (s)	Elev. (ft)	Wind Setup (ft)	Water Depth (ft)	Height (ft)	Camber (ft)	Elev. (ft)
Wind blowing West (90 for Cell 2)	6.27	4.0	21.42	0.87	25.58	29.21	0.77	51.40
Wind blowing East (270 for Cell 1)	6.27	4.0	21.95	0.78	24.96	28.59	0.76	51.30

As previously discussed in Section 4.2.3, it is estimated that the maximum rise in the water surface elevation in Cell 1 and Cell 2 due to 1.0 cfs/ft overtopping for a duration of 1 hour is approximately 0.29 ft and 0.27 ft, respectively. Given the conservative approach taken in all aspects of the reservoir design and the amount of freeboard provided along the external embankments (~14 ft), it is not anticipated that such an increase in either cell would have any significant adverse impact that might compromise the integrity of the external embankments.

4.7 Summary of Embankment Design

Based upon the results of the STWAVE analyses, the external embankment height is dictated by the maximum overtopping criterion. To meet an overtopping rate criterion of 0.005 cfs/ft, a minimum external embankment elevation of 56.64 and 56.72 are required for Cell 1 and Cell 2, respectively.

For the internal embankment, an embankment elevation of 51.40 feet will meet the preliminary established criteria of limiting the internal embankment overtopping rate to less than 1.0 cfs/ft.

Reservoir Storm Hydrology

Reservoir Storm Hydrology

1. General

This section evaluates the following:

- Flood Routing for PMP storm events
- Location and capacity of spillway structure

2. Hydrologic Analyses

The flood routing analyses are based on the probable maximum precipitation (PMP) and associated probable maximum flood values (PMF) values according to the procedures given in the U.S. Department of Commerce/National Oceanic Atmospheric Administration (NOAA) Hydrometeorological Reports (HMR) 51, 52, and 53.

For the C-43 West Storage Reservoir (WSR), the PMF is taken as the PMP event multiplied by the contributing reservoir area, which includes the embankment crest, interior slopes (above water surface), and water surface area. DHI's MIKE SHE/MIKE 11 software (Abbott et al, 1986) was used to route the floods through the reservoir's outlet structures.

For the WSR Reservoir, the model results provide the following information:

- A design basis for sizing un-gated spillway structures
- The peak reservoir stage that occurs during the PMP design storm event.

3. Design Flood - Reservoir

The MIKE SHE/MIKE 11 model follows the routing scenarios outlined in Design Criteria Memorandum No. 2 (DCM-2). In DCM-2 (Acceler8, 2006), Case 1 is identified as a 100-year wind event in combination with the 72-hour PMP storm event.

The United States Army Corps of Engineers (USACE) generated the rainfall files used in the PMP. The 72-hour PMP storm event for the WSR was developed in accordance with HMR-51 (NOAA) and HMR-52 (NOAA).

The first step in this process was to determine the "all-season" PMP values for the 72-hour duration events based on a 10 square mile area using HMR-51. Figure 22 of HMR-51 indicates that the appropriate 72-hour event is equal to 55.7 inches of rain.

However, the area of the WSR is approximately 15 square miles, meaning the total rainfall distributed over the area should be less than 55.7 inches. The USACE used an internal program called "Probable Maximum Storm (HMR52)" to calculate an appropriate storm for this analysis. Key inputs into the program included the basin area of 14.8 square miles, the orientation of the storm isohytes at 270 degrees, and the storm

center coordinates centered over the reservoir. The result of the program run (WSR_T1.doc) is attached. This run calculated that the maximum precipitation applied to isohyet "A" would equal 54.95 inches over 72 hours. The results of the calculation are shown in Table 1.

The calculated maximum rainfall event was then normalized and broken down into 30-minute intervals (Table 2). This rainfall hyetograph is shown in Figure 1 and a cumulative rainfall hyetograph is shown in Figure 2.

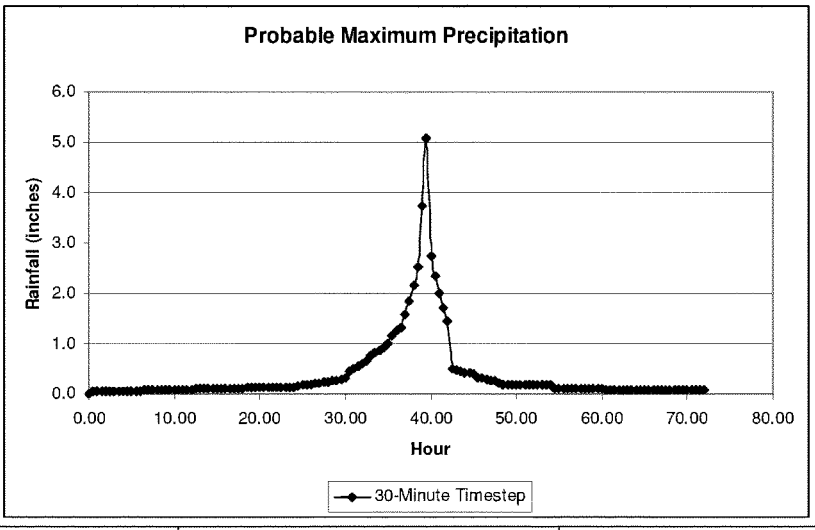

Figure 3 shows the distribution of rainfall isohyets over the freshwater Caloosahatchee River basin. The heaviest intensity of rainfall occurs in isohyets A and decreases away from the center of the storm. Table 1 shows the depth of rainfall calculated by the program for each of the isohyets within the watershed.

Table 1. Depth vs. Duration Relationships by length of PMP storm and Isohyet for distributed rainfall.

4. Flood Routing - Reservoir

For use in the MIKE SHE model, the 72-hour PMP storm event was built into a distributed, grid-based, model input file. First, isohyetal ellipses were built in GIS to define the distribution of the rainfall. The ellipses were then rotated and centered over the reservoir in accordance with HMR-52 results. The GIS ellipses were then converted into a MIKE SHE dfs2 grid file format. Finally this dfs2 file was then merged with the time series of the PMP event to generate spatially distributed precipitation files for use in the model. The spatial distribution of rainfall at the peak of the PMP storm event is shown in Figure 3. The rainfall amount applied to each isohyt is shown in Table 1.

	Probable Maximum Precipitation Peak Rainfall Intensity (in/hr)	Date March 30, 2007
		Figure **3**

The WSR is an "off-line" structure. Water enters the reservoir via pumping or direct precipitation. In addition to the groundwater and overland components, the MIKE SHE model includes the surface water network. This network includes the reservoir, multiple streams that route water around the reservoir, and multiple gates, pumps, and overflow spillways to manage water within the system. This system around the reservoir is shown in Figure 4.

	West Storage Reservoir Location	Date March 30, 2007
		Figure **4**

The Normal Full Surface Level (NFSL) is at elevation 42 feet, NAVD 88. The primary structures of concern in this task are the Service and Auxiliary spillways located in Cells 1 and 2 of the reservoir. Three different spillway configurations were considered during the design process. The alternatives are described as follows:

Alternative 1 Spillway Description:

In Alternative 1, the service spillways for Cells 1 and 2 consists of a 100-foot wide broad-crested weir at an elevation of 42.25 feet.

The auxiliary spillway for Cell 1 consists of a 250-foot wide broad-crested weir at an elevation of 42.75 feet. The auxiliary spillway for Cell 2 consists of a 125-foot wide broad-crested weir at an elevation of 42.75 feet.

Alternative 2 Spillway Description:

In Alternative 2, the Cell 1 service spillway consists of a double weir structure. The first is a notched weir with a 20-foot wide opening at an elevation of 42 feet, that opens an additional 250 feet at an elevation of 42.25 feet. This weir spills into a large box with a bottom elevation of approximately 35 feet. The second weir, width of 10 feet, is set at an elevation of 35.5 feet and controls flow out of the box structure. An identical structure would be located in Cell 2.

The auxiliary spillway in Cell 1 consists of a 180-foot long chimney drain (or similar weir structure) with a crest elevation of 42.75 feet. The Cell 2 auxiliary spillway consists of an 80-foot long chimney drain (or similar weir structure) with a crest elevation of 42.75 feet.

Alternative 3 Spillway Description:

In Alternative 3, the Cell 1 service spillway consists of a double weir structure. The first is a broad crested weir with a 54-foot wide opening at an elevation of 42 feet. This weir spills into a large box with a bottom elevation of approximately 37 feet. The second weir, width of 10 feet, is set at an elevation of 38 feet and controls flow out of the box structure. An identical structure would be located in Cell 2.

As specified by DCM-2, the governing conditions include the following two scenarios:

1. Routing starts at normal full storage level (uncontrolled spillway crest level),

    a. Route 30 percent of the 72-hour PMF (Time scale 0-hr to 72-hr): un-gated spillway flows, gated structures are in-operable.

    b. A 3-day dry interval with un-gated spillway flow, gated structures are operable (Time scale 72-hr to 144-hr).

    c. Route 100 percent of the 72-hour PMF (Time scale 144-hr to 216-hr): un-gated spillway flows, gated structures are in-operable.

    d. A 10-day dry interval with un-gated spillway flow, gated structures are operable (Time scale 216-hr to 456-hr).

    e. Route 30 percent of the 72-hour PMF (Time scale 456-hr to 528-hr): un-gated spillway flows, gated structures are in-operable.

2. Routing starts at normal full storage level (uncontrolled spillway crest level),

    a. Route 40 percent of the 72-hour PMF (Time scale 0-hr to 72-hr): un-gated spillway flows, gated structures are in-operable.

    b. A 5-day dry interval with un-gated spillway flow, gated structures are operable (Time scale 72-hr to 192-hr).

c. Route 100 percent of the 72-hour PMF (Time scale 192-hr to 264-hr): un-gated spillway flows, gated structures are in-operable.

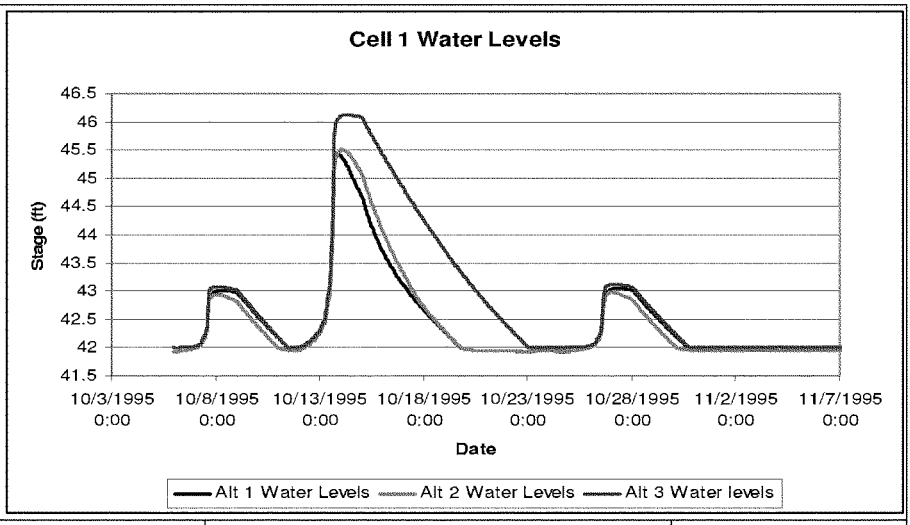
d. A 10-day dry interval with un-gated spillway flow, gated structures are operable (Time scale 264-hr to 504-hr).

e. Route 40 percent of the 72-hour PMF (Time scale 504-hr to 576-hr): un-gated spillway flows, gated structures are in-operable.

For these simulations, the PMP storm event was applied using initial conditions associated with the storm event of October 6, 1995. The 30- and 40-percent PMP series of storm events are shown in Figure 5. The reservoir water surface elevation started close to the NFSL for each simulation.

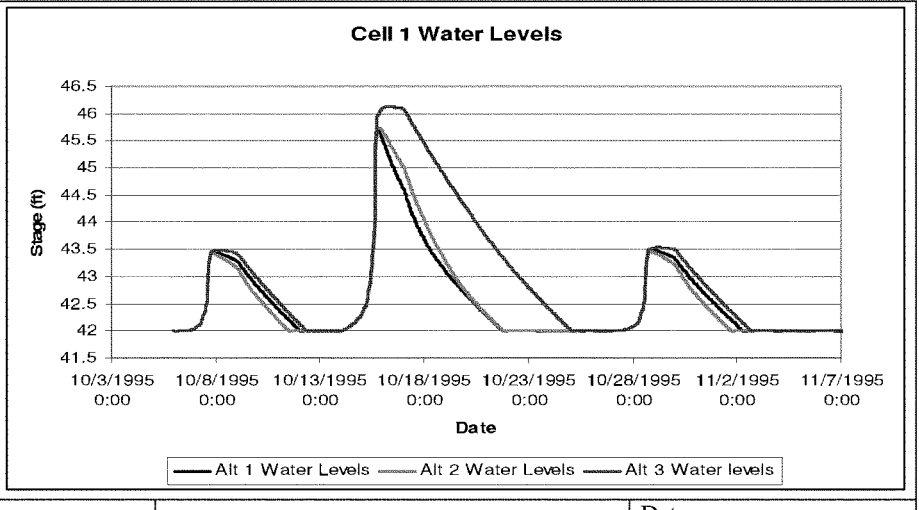
	30 Percent and 40 Percent Series of PMP Storm Events	Date March 30, 2007
		Figure **5**

4.1 **Routing Series of Storms**



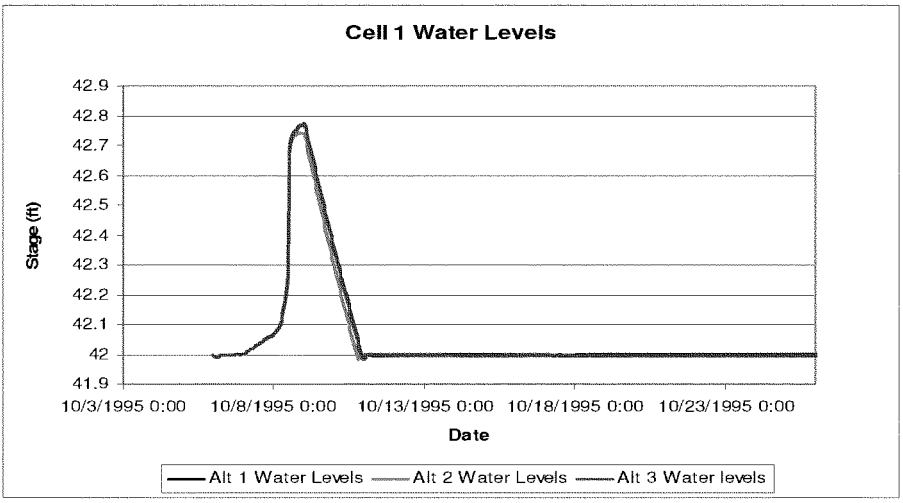
For each alternative spillway design, continuous rainfall events, developed to meet the Scenario 1 (30-percent PMP series of storms) and Scenario 2 (40-percent PMP series of storms) requirements were applied to the model. Initial conditions for the entire catchment were defined by the storm event of October 6, 1995. The beginning reservoir water surface

elevation was at an elevation of approximately 42 feet. In these simulations, the pumps and gated outlet structures were considered inoperable during rainfall periods and were allowed to operate during dry periods to bring the water surface elevation back to the NFSL. The only source of water into the reservoir was direct precipitation.



The rainfall was applied using the Scenario 1 and Scenario 2 series of storms and dry periods described above.

The results of these simulations are presented in Figures 6 – 19 and in Tables 4 – 6.



In addition to the 30- and 40-percent PMP series of storms, the 100-year storm was applied to each alternative design. These results are presented in Figures 20 – 26 and Table 7.

Appendix C: C-43 Manual Freeboard Calculations

Fetch 1A Analyses

Summary of Freeboard Analyses Case Scenarios Minimum Required Freeboard - Site C-43: Cell 1 (Fetch 1A)				
Freeboard Component	Case 1: PMP Combined with 100-Year Wind (ft)	Case 2: 100-Year Precip. Combined with Category 5 Winds (ft)	Case 3: Normal Full Storage Combined with Probable Max. Wind (ft)	Case 4: Hurricane Easy Storm Specific Wind and Precipitation (ft)
Design Precipitation **or** Flood Surge Depth (Routed Flood Event) =	4.13	0.77	0.00	3.77
Wind Setup =	1.03	1.86	3.21	1.03
Wave Height & Runup =	8.00	8.62	10.04	7.92
Waves Induced by Potential Landslides =	0.00	0.00	0.00	0.00
Provision for Malfunction of the Spillway or Discharge Structure =	0.00	0.00	0.00	0.00
Minimum Required Freeboard =	**13.16**	**11.26**	**13.25**	**12.72**
Camber or Embankment Settlement =	1.24	1.06	1.24	1.24
Minimum Required Freeboard with Camber =	**14.4**	**12.3**	**14.5**	**14.0**

Notes:
Minimum Required Freeboard rounded up to the next 0.01 foot.
Minimum Required Freeboard with Camber rounded up to the next 0.1 foot.
Case 1 - Surcharge depth is based upon routing of design storm event(s) through the reservoir.
Case 2 - Surcharge depth is based upon routing of design storm event through the reservoir.
Case 3 - Case 3 is to be used only for "sensitivity identification" and not as a selected design condition (pg 14 of 25, DCM-2)
Case 4 - Surcharge depth is assumed to be equal to the total precipitation of Hurricane Easy (45.2").

3/12/2007

Case 1: PMP Combined with 100-Year Wind
Design Wind Speed Analysis - Site C-43: Cell 1 (Fetch 1A)

Step 1: Select 50-Yr, 3-Sec Gust Wind Speed, $U_{50\text{-}yr,3\text{-}sec}$

Project Location =	C-43 Cell No. 1 (Fetch 1A)		
50-yr, 3-sec Gust Wind Speed, $U_{50\text{-}yr,3\text{-}sec}$ =	117.5	mph	*(Fig. 6-1b, ASCE 7-02)*

Step 2: Determine 100-Yr, 3-Sec Gust Wind Speed, $U_{100\text{-}yr,3\text{-}sec}$

$U_{50\text{-}yr,3\text{-}sec}$ =	117.5	mph	*(see Step 1)*
$U_{50\text{-}yr}$ to $U_{100\text{-}yr}$ Conversion Factor =	1.07		*(Table DCM 2-2, DCM-2)*
$U_{100\text{-}yr,3\text{-}sec} = U_{50\text{-}yr,3\text{-}sec}$ x Conversion Factor =	125.7	mph	

Step 3: Determine 100-Yr, 1-Hr Wind Speed, $U_{100\text{-}yr,1\text{-}hr}$

Initial wind speed duration, t =	3	sec.	*(based on Step 1 Data)*

Equations for ratio of wind speeds to 1-hour average wind speeds, U_t/U_{3600}

For $t \leq 3{,}600$: $U_t/U_{3600} = 1.277 + 0.296\tanh(0.9\log_{10}(45/t))$ =	applies		*(Eqn. 1, DCM-2)*
For $3{,}600 < t < 36{,}000$: $U_t/U_{3600} = -0.15\log_{10}(t)+1.5334$ =	does not apply		*(Eqn. 2, DCM-2)*
U_t/U_{3600} =	1.51		*(Eqn. 1, DCM-2)*
$U_t = U_{100\text{-}yr,\ 3\text{-}sec}$ =	125.73	mph	*(see Step 2)*
$U_{100\text{-}yr,\ 3600\text{-}sec} = U_{100\text{-}yr,\ 1\text{-}hr} = U_t/(U_t/U_{3600})$ =	83.3	mph	

Step 4: Determine 100-Yr, 1-Hr Wind Speed Over Water, $U_{100\text{-}yr,1\text{-}hr,water}$

Fetch Length (in miles), X =	3.51	miles	

Wind Speed Over Water to Wind Speed Over Land Ratio, U_{Water}/U_{Land}:

If initial data from Step 1 is over water wind speed, no conversion (Ratio = 1.0)	does not apply		*(Fig. II-2-20, CEM)*
For Fetch Length < 10 miles: U_{Water}/U_{Land} = 1.2 or 1.0	applies		*(Fig. II-2-20, CEM)*
For Fetch Length > 10 miles: See Figure II-2-7, CEM	does not apply		*(Fig. II-2-7, CEM)*
U_{water}/U_{land} =	1.2		*(Fig. II-2-20, CEM)*
$U_{100\text{-}yr,1\text{-}hr,land}$ =	83.3		*(see Step 3)*
$U_{100\text{-}yr,1\text{-}hr,water} = U_{100\text{-}yr,1\text{-}hr,land}$ x (U_{water}/U_{land}) =	100.0	mph	

Step 5: Estimate Fetch-Limited Wind Duration Time

Fetch Length (in miles), X =	3.51	miles	*(see Step 4)*
Wind Velocity (in mph), U =	100.0	mph	*(see Step 4)*
Fetch Limited Wind Duration Time, $t = 112(X^{0.67}/U^{0.34})$ =	54	min.	*(Eqn. 4, DCM-2)*
	3257	sec.	

Step 6: Estimate Ratio of Fetch Limited Duration Wind Speed and 1-Hour Wind Speed

Fetch Limited Wind Duration Time (in seconds), t =	3257	sec.	*(see Step 5)*

Equations for ratio of wind speeds to 1-hour average wind speeds, U_t/U_{3600}

For $t \leq 3{,}600$: $U_t/U_{3600} = 1.277 + 0.296\tanh(0.9\log_{10}(45/t))$ =	applies		*(Eqn. 1, DCM-2)*
For $3{,}600 < t < 36{,}000$: $U_t/U_{3600} = -0.15\log_{10}(t)+1.5334$ =	does not apply		*(Eqn. 2, DCM-2)*
Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.001		*(Eqn. 1, DCM-2)*

Step 7: Adjust 1-Hr Wind Speed (over water) to Equivalent Fetch Limited Duration Wind Speed

Fetch Limited Wind Duration (in minutes), t =	54	min.	*(see Step 5)*
100-Yr, 1-Hr Wind Speed Over Water, $U_{100\text{-}yr,1\text{-}hr,water}$ =	100.0	mph	*(see Step 4)*
Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.001		*(see Step 6)*
100-Yr, Fetch Limited Wind Speed Over Water = $U_{100\text{-}yr,1\text{-}hr,water}$ x U_t/U_{3600} =	100	mph	

Step 8: Stability Correction, Adjust Wind Speed for Boundary Layer Stability

Fetch Length (in miles), X =	3.51	miles	*(see Step 4)*
(If Fetch Length > 10 miles, else enter 0) Temperature of Air, T_a =	0	°C	
(If Fetch Length > 10 miles, else enter 0) Temperature of Sea, T_s =	0	°C	
Air-Sea Temperature Difference, ΔT_{as} $T_a - T_s$ =	0	°C	

Stability Correction Factor, R_T

For Fetch Length < 10 miles: $R_T = 1.0$	applies		*(pg. II-2-36, CEM)*
For Fetch Length > 10 miles: Based on ΔT_{as}, See Figure 3-14, SPM or in absence of temperature information, assume RT = 1.1	does not apply		*(Flg.3-14, SPM)* *(pg 3-30, SPM)*
$U_{100\text{-}yr,fetch\text{-}min,water}$ =	100	mph	*(see Step 7)*
Stability Correction Factor, R_T =	1		*(pg. II-2-36, CEM)*
$U_{100\text{-}yr,fetch\text{-}min,water,\ stability\ adjusted} = U_{100\text{-}yr,fetch\text{-}min,water}$ x R_T =	100	mph	*(Eqn. 3-27 SPM)*

Step 9. Compute Wind Stress Factor, U_A

$U_{100\text{-}yr,fetch\text{-}min,water,\ stability\ adjusted} = U$ =	100	mph	*(see Step 8)*
Wind Stress Factor, $U_A = 0.589U^{1.23}$ =	170	mph	*(Eqn. 3-28b SPM)*

Step 10. Wind Stress Factor in ft/s

Wind Stress Factor, U_A (ft/s) = $1.467U_A$ (mph) =	249	ft/sec	*(see Step 9)*

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 1: PMP Combined with 100-Year Wind
Wind Setup and Wave Properties Analysis - Site C-43: Cell 1 (Fetch 1A)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.51	miles	*(see Step 4)*
Fetch Length, F =	18,537	ft	
100-Yr, Fetch Limited Wind Speed Over Water = $U_{100-yr,fetch,over}$ =	100	mph	*(see Step 7)*
Wind Stress Factor, U_s (ft/s) =	249	ft/s	*(see Step 10)*

Step 11. Compute Deep-Water Significant Wave Height, H_{mo}

Deep-Water Significant Wave Height, $H_{mo} = (0.030282)U_s F^{1/2}$ = 9.67 feet *(Eqn. 3-33c, SPM)*

Step 12. Compute Deep-Water Wave Period, T_o

Deep-Water Wave Period, $T_o = 0.02825(U_s F)^{1/3}$ = 4.71 sec *(Eqn. 3-34c, SPM)*

Step 13. Compute Deep-Water Wave Length, L_o

Deep-Water Wave Length, $L_o = 5.12 T_o^2$ = 113 feet *(Eqn. 2-8b, SPM)*

Step 14. Compute Relative Depth, d/L_o

If $d/L_o \leq 0.5$, waves are classified as transitional or shallow water waves. *(pg 2-9, SPM)*
If $d/L_o > 0.5$, waves are classified as deep water. *(pg 2-9, SPM)*

	24.49	feet	
Relative Depth = d/L_o =	0.216		*(pg 2-9, SPM)*
Wave Classification =	Transitional/Shallow-Water		*(pg 2-9, SPM)*

Step 15. Compute Shallow-Water Wave Period, T *(Eqn. 3-40, SPM)*

Shallow-Water Wave Period, $T = 7.54 \tanh(A) \tanh(B/C)\, U_s/g$
where: F = Fetch Length (ft) (step 5) U_s = Wind Stress Factor (step 10) g = 32.2 ft/s²

$A = 0.833(gd/U_s^2)^{3/4}$ =	0.1619		
$B = 0.0379(gF/U_s^2)^{1/3}$ =	0.0806		
$C = \tanh(0.833(gd/U_s^2)^{3/4})$ =	0.1605		
Shallow-Water Wave Period, $T = 7.54 \tanh(A) \tanh(B/C)\, U_s/g$ =	3.34	sec	*(Eqn. 3-40, SPM)*

Step 16. Compute Shallow-Water Significant Wave Height, H *(Eqn. 3-39, SPM)*

Shallow-Water Significant Wave Height, $H = 0.283 \tanh(A) \tanh(B/C)\, U_s^2/g$
where: F = Fetch Length (ft) (step 5) U_s = Wind Stress Factor (step 10) g = 32.2 ft/s²

$A = 0.530(gd/U_s^2)^{3/4}$ =	0.0200		
$B = 0.00563(gF/U_s^2)^{1/2}$ =	0.0175		
$C = \tanh(0.530(gd/U_s^2)^{3/4})$ =	0.0200		
Shallow-Water Significant Wave Height, $H = 0.283 \tanh(A) \tanh(B/C)\, U_s^2/g$ =	7.70	feet	*(Eqn. 3-39, SPM)*

Step 17. Compute Zero Overwash Wave Height for Significant Wave Height

DCM-2 requires zero over wash as a design criteria for high and significant hazard dams. For purposes of the DCM-2, zero overwash wave height is defined as the wave height with a 2% occurrence frequency.

Significant Wave Height is either the Deep-Water or Shallow-Water Significant wave height Depending upon the Wave Classification (Step 14).

Significant Wave Height, H_s =	7.70	feet	*(see Step 11 or 16)*
Required probability of wave height being exceeded, m/N =	0.02		*(see Step 17 discussion)*
Root Mean Square Wave Height, $H_{rms} = 2^{1/2} H_s$ =	5.44	feet	*(Eqn. 3-16, SPM)*
Wave Height which is exceeded at given probability, $H^* = H_{rms}[-Ln(m/N)]^{1/2}$ =	10.65	feet	*(Eqn. 3-7, SPM)*

Step 18. Compute Wind Set-Up

Four different methods are calculated and considered in estimating wind setup.
Zeidler Zee Eqn: Widely used as applied to reservoirs but tends to overestimate wind setup for shallow impoundments (ave. depth<16 ft).
Sibul Eqn: Typically yields the lowest wind setup.
Ave. of Zeidler Zee & Sibul: Recommended for shallow impoundments (ave. depth<16 ft) when Bretschneider has no numeric solution.
Bretschneider Eqn: Recommend for shallow impoundments (average depth <16 ft).

Fetch Length, F =	3.51	miles	*(see Step 4)*
Fetch Length, F =	18,537	feet	
Average Wind Velocity, U = Wind Speed per Step 7 = $U_{100-yr,over}$ =	100	mph	*(pg A6, DCM-2)(see Step 7)*
Average Depth of Water along Fetch Line, D = Effective Depth =	24.49	feet	*(see Step 14)*
Zeidler Zee Eqn (Note: F=miles): Wind Set-Up, $S = U^2F/(1400D)$ =	1.03	feet	*(Eqn. 5, DCM-2)*
Sibul Eqn (Note: F=feet, g=32.2 ft/s²): $S = 0.0002244(F/d)^{1.25}(U^2/F_E)^{1.25(d/F)^{-0.375}}$ =	0.25	feet	*(Eqn. 7, DCM-2)*
Average of Zeidler Zee & Sibul: Wind Setup, $S = (S_{Zeidler\ Zee} + S_{Sibul})/2$ =	0.64	feet	
Bretschneider Eqn (Note: Calcs provided separately in Step 18a): $S = \Delta[(K_u F \Delta x)/(g d^2)]$ =	n/a	feet	*(Eqn. 6, DCM-2)(Step 18a)*
Equation Used for Wind Setup *(Enter Zeidler Zee, Sibul, Average, Bretschneider)* =	Zeidler Zee		
Computed Wind Set-Up, S =	1.03	feet	*(Eqn. 5, DCM-2)*

Step 19. Compute Water Depth at Toe of Structure

Water Depth at Toe of Structure, d_t = Effective Depth + Wind Set-Up = d + S = 25.52 feet *(pg. A6, DCM-2)*

Step 20. Check for Depth Limited Wave Breaking

See if wave height is limited due to breaking. After breaking, waves will tend to reform with lower heights within a few wave lengths. *(pg. 15-4, EM-1110-2-1420)*

Depth of interest is at Toe of Structure, $d_s = d_t$ =	25.52	feet	*(see Step 19)*
Wave Breaking Height, H_b (for depth d_s) = $d_s/1.28$ =	19.93	feet	*(Eqn. 2-91 & 3-50, SPM)*
Is max. wave height limited by breaking? (If H_b (step 20) $\leq H^*$ (step 17) then yes, else no) =	No		
(If no, wave height = H^* (step 17). If yes, conservatively assume wave height = H_b (step 20)) Maximum Wave Height =	10.65	feet	

Step 21. Estimate Ratio Between Deep-Water Wave Ht & Equivalent Deep-Water Ht

The value of H/Ho (shallow-water wave height/equivalent deep-water wave height) is estimated based on the value of d/L_o (effective depth / deep-water wave length) from Table C-1, SPM Vol II, Appendix C.

Effective Depth, d =	24.49	feet	*(see Step 14)*
Deep-Water Wave Length, L_o =	113	feet	*(see Step 13)*
Ratio of effective depth to deep-water wave length, d/L_o =	0.216		
H/H'_o =	0.9221		*(Table C-1, SPM Vol II)*

Step 22. Compute Equivalent Deep-Water Wave Height, H'_o

If wave classification is Deep-Water (Step 14), Significant Deep-Water Height is the Equivalent Deep-Water Height.
If wave classification is Transitional/Shallow-Water an adjustment is necessary.
If Wave Breaking Height (Step 20) is less than the Zero Overwash for Significant Wave Height (Step 17) then Equivalent Deep-Water Wave Height is Wave Braking Height (irregardless of wave classification).

Wave Breaking Height, H_b =	19.93	feet	*(see Step 20)*
Significant Wave Height, H_s =	10.65	feet	*(see Step 17)*
H/H'_o =	0.9221		*(see Step 21)*
If Shallow-Water: Equivalent Deep-Water Wave Height, $H'o = H/(H/H'o)$ =	11.55	feet	
If Deep Water: Equivalent Deep-Water Wave Height = Significant Deep-Water Height =	n/a	feet	
If Height Limited by Wave Breaking: Equiv. Deep-Water Wave Ht = Wave Breaking Ht. =	n/a	feet	
Equivalent Deep-Water Wave Height =	11.55	feet	

Step 23. Compute Depth at Toe of Structure to Equiv. Deep-Water Wave Ht, d_t/H'_o

Water Depth at Toe of Structure, d_t =	25.52	feet	*(see Step 19)*
Equivalent Deep-Water Wave Height, H'_o =	11.55	feet	*(see Step 22)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_t/H'_o =	2.21		

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 1: PMP Combined with 100-Year Wind
Wave Runup Analysis - Site C-43: Cell 1 (Fetch 1A)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.51	miles	*(see Step 4)*
Fetch Length, F =	18,537	feet	
100-Yr, Fetch Limited Wind Speed Over Water = $U_{100\text{-}yr,fetch\text{-}limit}$ =	100	mph	*(see Step 7)*
Wind Stress Factor, U_A (ft/s) =	249	ft/s	*(see Step 10)*

Wind Setup and Wave Properties Analysis - Summary Data

Wind Set-Up , S =	1.03	feet	*(see Step 19)*
Equivalent Deep-Water Wave Height, H'_o =	11.55	feet	*(see Step 22)*
Deep-Water Wave Period, T_o =	4.71	sec	*(see Step 12)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_s/H'_o =	2.21		*(see Step 23)*

Step 24. Compute Ratio of $H'_o/(g*T_o^2)$

Equivalent Deep-Water Wave Height, H'_o =	11.55	feet	*(see Step 22)*
Gravitational Constant, g =	32.2	ft/s^2	*(constant variable)*
Deep Water Wave Period, T_o =	4.71	sec	*(see Step 12)*
$H'_o/(g*T_o^2)$ =	0.016		

Steps 25 - 27. Estimate R/H'o *(Fig. 7-8 thru 7-20, SPM Vol. 2)*

Steps 25-27 are directed towards deriving the ratio of Wave Runup to the Equivalent Deep-Water Wave Height (R/H'_o) from graphs found in SPM Volume 2 (Fig. 7-8 thru 7-20). The graphs are based upon various designs of the runup face slope including the material, roughness, slope, and geometry the face slope. In addition the value of R/H'_o depends upon the values of d_s/H'_o and $H'_o/(gT^2)$. Determination of values will typically require an interpolation of values between graphs.

d_s/H'_o =	2.21		*(see Step 23)*
$H'_o/(g*T_o^2)$ =	0.016		*(see Step 24)*
Face Slope Material =	Step-Faced Slope		*Embankment Design*
Runup Face Slope (H:1V) =	3		*Embankment Design*
Runup Face Slope (Θ) =	18.4	degrees	
Figure used for Interpolation (Lower Interpolation Number) =	Fig. 7-11		*(SPM Vol. 2)*
Figure to used for Interpolation (Higher Interpolation Number) =	Fig. 7-12		*(SPM Vol. 2)*

Step 25. R/H'o from Fig. 7-11 with ds/H'o <= 2.21

$H'_o/(g*T_o^2)$ =	0.016		*(see Step 24)*
ds/H'o <=2.21 from Fig. 7-11 =	2		*(Fig. 7-11, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-11 =	0.84		*(Fig. 7-11, SPM Vol. 2)*

Step 26. R/H'o from Fig. 7-12 with ds/H'o >= 2.21

$H'_o/(g*T_o^2)$ =	0.016		*(see Step 24)*
ds/H'o >=2.21 from Fig. 7-12 =	3.0		*(Fig. 7-12, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-12 =	1.04		*(Fig. 7-12, SPM Vol. 2)*

Step 27. Estimated Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o

d_s/H'_o =	2.21		*(see Step 23)*
$H'_o/(g*T_o^2)$ =	0.016		*(see Step 24)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o =	0.88		*(Interpolated from Steps 25 & 26)*

Step 28. Compute Smooth Surface Wave Runup

Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'_o =	0.88		*(see Step 27)*
Equivalent Deep-Water Wave Height, H'_o =	11.55		*(see Step 22)*
Smooth Surface Wave Runup = R/H'_o x H'_o =	10.20	feet	

Step 29. If Applicable, Determine and Apply Wave Runup Correction Factor due to Scale Effects

This step applies if Figures 7-9 thru 7-12 or Figures 7-14 thru 7-19 were used to estimate R/H'_o in Steps 25-27. These figures summarize results for small-scale lab tests. Due to the inability to scale roughness effects in small-scale lab tests, the results are probably smaller than the runup on prototype structures. Figure 7-13 is used to adjust for this scale effect.

Smooth Surface Wave Runup = R/H'_o x H'_o =	10.20	feet	*(see Step 28)*
Scale Wave Runup Correction due to Scale Effects *(If Fig. 7-19 or 7-20 used, enter 1)* =	1.12		*(Fig. 7-13, SPM Vol. 2)*
Scale Corrected Wave Runup Height = (Smooth Surface Wave Runup)(Runup Correction) =	11.42	feet	

Step 30. Determine and Apply Correction Factor due to Dam Surface Roughness

Face Slope Material =	Step-Faced Slope		*(see Step 25)*
Surface Roughness Correction =	0.7		*(Table 7-2, SPM Vol 2) or (Table 2-2 EM1110-2-1614)*
Scale Corrected Wave Runup Height =	11.42	feet	*(see Step 29)*
Corrected Wave Runup = (Scale Corrected Wave Runup)(Surface Roughness Correction) =	8.00	feet	

Step 31. Correction Due to to Fetch Axis Not Being Normal to the Dam Axis

Angle Between Fetch Axis and Embankment Axis =	0	degrees	
Angle Correction Factor =	1.00		*(Fig. 8, ACER TM No. 11)*

Step 32. Adjusted Wave Runup

Corrected Wave Runup =	8.00		*(see Step 30)*
Angle Correction Factor =	1.00		*(see Step 31)*
Final Adjusted Wave Runup = (Corrected Wave Runup)(Angle Correction Factor) =	8.0	feet	

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

Case 2: 100-Year Precipitation Combined with Category 5 Hurricane Winds
Design Wind Speed Analysis - Site C-43: Cell 1 (Fetch 1A)

Steps 1-3: Adjustments not necessary for Case 2

Project Location =	C-43 Cell No. 1 (Fetch 1A)		
Category 5, Duration Adjusted Wind Speed (1-hr average), $U_{Cat5,1-hr}$ =	125.0	mph	*(Table DCM 2-3, DCM-2)*

The Category 5 wind speed from Table DCM 2-3, DCM-2 corresponds to an over-water wind speed per DCM-2 page 10.

Step 4: Determine Category 5, 1-Hr Wind Speed Over Water, $U_{Cat5,1-hr,water}$

Fetch Length (in miles), X =	3.51	miles	

Wind Speed Over Water to Wind Speed Over Land Ratio, U_{Water}/U_{Land}:

If initial data from Step 1 is over water wind speed, no conversion (Ratio = 1.0)	does not apply		*(Fig. II-2-20, CEM)*
For Fetch Length < 10 miles: U_{Water}/U_{Land} = 1.2 or 1.0	applies		*(Fig. II-2-20, CEM)*
For Fetch Length > 10 miles: See Figure II-2-7, CEM	does not apply		*(Fig. II-2-7, CEM)*
U_{water}/U_{land} =	1		*(Fig. II-2-20, CEM)*
$U_{Cat5,1-hr,land}$ =	-		*(see Step 3)*
$U_{Cat5,1-hr,water} = U_{Cat5,1-hr,land}$ x (U_{water}/U_{land}) =	125.0	mph	

Step 5: Estimate Fetch-Limited Wind Duration Time

	3.51	miles	*(see Step 4)*
Wind Velocity (in mph), U =	125.0	mph	*(see Step 4)*
Fetch Limited Wind Duration Time, $t = 112(X^{0.67}/U^{0.34})$ =	50	min.	*(Eqn. 4, DCM-2)*
	3019	sec.	

Step 6: Estimate Ratio of Fetch Limited Duration Wind Speed and 1-Hour Wind Speed

Fetch Limited Wind Duration Time (in seconds), t =	3019	sec.	*(see Step 5)*

Equations for ratio of wind speeds to 1-hour average wind speeds, U_t/U_{3600}

For $t \leq 3{,}600$: $U_t/U_{3600} = 1.277 + 0.296\tanh(0.9\log_{10}(4.5/t))$ =	applies		*(Eqn. 1, DCM-2)*
For $3{,}600 < t < 36{,}000$: $U_t/U_{3600} = -0.15\log_{10}(t)+1.5334$ =	does not apply		*(Eqn. 2, DCM-2)*
Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.002		*(Eqn. 1, DCM-2)*

Step 7: Adjust 1-Hr Wind Speed (over water) to Equivalent Fetch Limited Duration Wind Speed

Fetch Limited Wind Duration (in minutes), t =	50	min.	*(see Step 5)*
Category 5, 1-Hr Wind Speed Over Water, $U_{Cat5,1-hr,water}$ =	125.0	mph	*(see Step 4)*
Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.002		*(see Step 6)*
Category 5, Fetch Limited Wind Speed Over Water = $U_{Cat5,1-hr,water}$ x U_t/U_{3600} =	125	mph	

Step 8: Stability Correction, Adjust Wind Speed for Boundary Layer Stability

Fetch Length (in miles), X =	3.51	miles	*(see Step 4)*
(If Fetch Length > 10 miles, else enter 0) Temperature of Air, T_a =	0	°C	
(If Fetch Length > 10 miles, else enter 0) Temperature of Sea, T_s =	0	°C	
Air-Sea Temperature Difference, ΔT_{as} $T_a - T_s$ =	0	°C	

Stability Correction Factor, R_T

For Fetch Length < 10 miles: R_T = 1.0	applies		*(pg. II-2-36, CEM)*
For Fetch Length > 10 miles: Based on ΔT_{as}, See Figure 3-14, SPM or in absence	does not apply		*(Fig.3-14, SPM)*
of temperature information, assume RT = 1.1			*(pg 3-30, SPM)*
$U_{Cat5,fetch-min,water}$ =	125	mph	*(see Step 7)*
Stability Correction Factor, R_T =	1		*(pg. II-2-36, CEM)*
$U_{Cat5,fetch-min,water,\ stability\ adjusted} = U_{Cat5,fetch-min,water}$ x R_T =	125	mph	*(Eqn. 3-27 SPM)*

Step 9. Compute Wind Stress Factor, U_A

$U_{Cat5,fetch-min,water,\ stability\ adjusted} = U$ =	125	mph	*(see Step 8)*
Wind Stress Factor, $U_A = 0.589U^{1.23}$ =	224	mph	*(Eqn. 3-28b SPM)*

Step 10. Wind Stress Factor in ft/s

Wind Stress Factor, U_A (ft/s) = 1.467U_A (mph) =	329	ft/sec	*(see Step 9)*

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 2: 100-Year Precipitation Combined with Category 5 Hurricane Winds
Wind Setup and Wave Properties Analysis - Site C-43: Cell 1 (Fetch 1A)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.51	miles	*(see Step 4)*
Fetch Length, F =	18,537	ft	
Category 5, Fetch Limited Wind Speed Over Water = $U_{(Cat5,fetch-lim)}$ =	125	mph	*(see Step 7)*
Wind Stress Factor: U_* (ft/s) =	329	ft/s	*(see Step 10)*

Step 11. Compute Deep-Water Significant Wave Height, H_{mo}

Deep-Water Significant Wave Height, $H_{mo} = (0.000282)U_*F^{1/2}$ =	12.02	feet	*(Eqn. 3-33c, SPM)*

Step 12. Compute Deep-Water Wave Period, T_o

Deep-Water Wave Period, $T_o = 0.02825(U_*F)^{1/3}$ =	5.16	sec	*(Eqn. 3-34c, SPM)*

Step 13. Compute Deep-Water Wave Length, L_o

Deep-Water Wave Length, $L_o = 5.12T_o^2$ =	136	feet	*(Eqn. 3-8b, SPM)*

Step 14. Compute Relative Depth, d/L_o

If $d/L_o \leq 0.5$, waves are classified as transitional or shallow water waves. *(pg 2-8, SPM)*
If $d/L_o > 0.5$, waves are classified as deep water. *(pg 2-9, SPM)*

	21.13	feet	
Relative Depth = d/L_o =	0.155		*(pg 2-8, SPM)*
Wave Classification =	Transitional/Shallow-Water		*(pg 2-9, SPM)*

Step 15. Compute Shallow-Water Wave Period, T

Shallow-Water Wave Period, $T = 7.54\tanh(A)\tanh(B/C)\,U_*/g$ *(Eqn. 3-40, SPM)*

where: F = Fetch Length (ft) (step 5) U_* = Wind Stress Factor (step 10) $g = 32.2$ ft/s^2

$A = 0.833(gdU_*^{-2})^{0.375}$ =	0.1245		
$B = 0.0379(gF/U_*^2)^{1/3}$ =	0.6670		
$C = \tanh(0.833(gd/U_*^2)^{0.375})$ =	0.1239		
Shallow-Water Wave Period, $T = 7.54\tanh(A)\tanh(B/C)\,U_*/g$ =	4.71	sec	*(Eqn. 3-40, SPM)*

Step 16. Compute Shallow-Water Significant Wave Height, H

Shallow-Water Significant Wave Height, $H = 0.283\tanh(A)\tanh(B/C)\,U_*^2/g$ *(Eqn. 3-39, SPM)*

where: F = Fetch Length (ft) (step 5) U_* = Wind Stress Factor (step 10) $g = 32.2$ ft/s^2

$A = 0.530(gdU_*^{-2})^{0.75}$ =	0.0118		
$B = 0.00565(gF/U_*^2)^{0.5}$ =	0.0133		
$C = \tanh(0.530(gd/U_*^2)^{0.75})$ =	0.0118		
Shallow-Water Significant Wave Height, $H = 0.283\tanh(A)\tanh(B/C)\,U_*^2/g$ =	9.09	feet	*(Eqn. 3-39, SPM)*

Step 17. Compute Shallow-Water Wave Height for Zero Overwash

DCM-2 requires zero over wash as a design criteria for high and significant hazard dams. For purposes of the DCM-2, zero overwash wave height is defined as the wave height with a 2% occurrence frequency.

Significant Wave Height is either the Deep-Water or Shallow-Water Significant wave height depending upon the Wave Classification (Step 14).

Significant Wave Height, H_s =	9.09	feet	*(see Step 11 or 16)*
Required probability of wave height being exceeded, n/N =	0.02		*(see Step 17 discussion)*
Root Mean Square Wave Height, $H_{rms} = 2^{-1/2}H_s$ =	6.43	feet	*(Eqn. 3-10, SPM)*
Wave Height which is exceeded at given probability, $H^* = H_{rms}[-\ln(n/N)]^{1/2}$ =	12.57	feet	*(Eqn. 3-7, SPM)*

Step 18. Compute Wind Set-Up

Four different methods are calculated and considered in estimating wind setup.
Zeidler Zee Eqn: Widely used as applied to reservoirs but tends to overestimate wind setup for shallow impoundments (ave. depth<15 ft).
Sibul Eqn: Typically yields the lowest wind setup.
Ave. of Zeidler Zee & Sibul: Recommended for shallow impoundments (ave. depth<16 ft) when Bretschneider has no numeric solution.
Bretschneider Eqn: Recommend for shallow impoundments (average depth <16 ft).

Fetch Length, F =	3.51	miles	*(see Step 4)*
Fetch Length, F =	18,537	feet	
Average Wind Velocity, U = Wind Speed per Step 7 = $U_{(Cat5,fetch-lim)}$ =	125	mph	*(pg A6, DCM-2)(see Step 7)*
Average Depth of Water along Fetch Line, D = Effective Depth =	21.13	feet	*(see Step 14)*
Zeidler Zee Eqn (Note: F=miles): Wind Set-Up, $S = U^2F/(1400D)$ =	1.86	feet	*(Eqn. 5, DCM-2)*
Sibul Eqn (Note: F=feet, g=32.2 ft/s^2): $S = 0.0006244d(F/d)^{1.65}(U^2/Fg)^{1.65F^{0.07}/d^{0.07}}$ =	0.50	feet	*(Eqn. 7, DCM-2)*
Average of Zeidler Zee & Sibul: Wind Setup, $S = (S_{Zeidler\ Zee} + S_{Sibul})/2$ =	1.18	feet	
Bretschneider Eqn (Note: Calcs provided separately in Step 18a): $S = \Delta[(kU^2\Delta x)/(gd^2)]$ =	n/a	feet	*(Eqn. 6, DCM-2)(Step 18a)*
Equation Used for Wind Setup *(Enter Zeidler Zee, Sibul, Average, Bretschneider)* =	Zeidler Zee		
Computed Wind Set-Up, S =	1.86	feet	*(Eqn. 5, DCM-2)*

Step 19. Compute Water Depth at Toe of Structure

Water Depth at Toe of Structure, d_s = Effective Depth + Wind Set-Up = d + S =	22.99	feet	*(pg. A6, DCM-2)*

Step 20. Check for Depth Limited Wave Breaking

See if wave height is limited due to breaking. After breaking, waves will tend to reform with lower heights within a few wave lengths. *(pg. 15-4, EM-1110-2-1420)*

Depth of Interest is at Toe of Structure, $d_s = d_s$ =	22.99	feet	*(see Step 19)*
Wave Breaking Height, H_b (for depth d_s) = (d_s/1.28) =	17.96	feet	*(Eqn. 2-91 & 3-50, SPM)*
Is max. wave height limited by breaking? (If H_s [step 20] $\leq H^*$ [step 17] then yes, else no) =	No		
(If no, wave height = H^* (step 17). If yes, conservatively assume wave height = H_b (step 20)) Maximum Wave Height =	12.57	feet	

Step 21. Estimate Ratio Between Deep-Water Wave Ht & Equivalent Deep-Water Ht

The value of H/H'o (shallow water wave height/equivalent deep-water wave height) is estimated based on the value of d/L_o (effective depth / deep-water wave length) from Table C-1, SPM Vol II, Appendix C.

Effective Depth, d =	21.13	feet	*(see Step 14)*
Deep-Water Wave Length, L_o =	136	feet	*(see Step 13)*
Ratio of effective depth to deep-water wave length, d/L_o =	0.155		
H/H'_o =	0.9131		*(Table C-1, SPM Vol 2)*

Step 22. Compute Equivalent Deep-Water Wave Height, H'_o

If wave classification is Deep-Water (Step 14), Significant Deep Water Height is the Equivalent Deep-Water Height.
If wave classification is Transitional/Shallow-Water an adjustment is necessary.
If Wave Breaking Height (Step 20) is less than the Zero Overwash for Significant Wave Height (Step 17) then Equivalent Deep-Water Wave Height is Wave Breaking Height (irregardless of wave classification).

Wave Breaking Height, H_b =	17.96	feet	*(see Step 20)*
Significant Wave Height, H_s =	12.57	feet	*(see Step 17)*
H/H'_o =	0.9131		*(see Step 21)*
If Shallow-Water, Equivalent Deep-Water Wave Height, $H'o = H/(H/H'o)$ =	13.77	feet	
If Deep Water, Equivalent Deep Water Wave Height = Significant Deep-Water Height =	n/a	feet	
If Height Limited by Wave Breaking, Equiv. Deep-Water Wave Ht. = Wave Breaking Ht. =	n/a	feet	
Equivalent Deep-Water Wave Height =	13.77	feet	

Step 23. Compute Depth at Toe of Structure to Equiv. Deep-Water Wave Ht, d_s/H'_o

Water Depth at Toe of Structure, d_s =	22.99	feet	*(see Step 19)*
Equivalent Deep-Water Wave Height, H'_o =	13.77	feet	*(see Step 22)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_s/H'_o =	1.67		

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 2: 100-Year Precipitation Combined with Category 5 Hurricane Winds
Wave Runup Analysis - Site C-43: Cell 1 (Fetch 1A)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.51	miles	*(see Step 4)*
Fetch Length, F =	18,537	feet	
Category 5, Fetch Limited Wind Speed Over Water = $U_{CAT5,fetch-ltd}$ =	125	mph	*(see Step 7)*
Wind Stress Factor, U_A (ft/s) =	329	ft/s	*(see Step 10)*

Wind Setup and Wave Properties Analysis - Summary Data

Wind Set-Up , S =	1.86	feet	*(see Step 18)*
Equivalent Deep-Water Wave Height, H'_o =	13.77	feet	*(see Step 22)*
Deep-Water Wave Period, T_o =	5.16	sec	*(see Step 12)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_s/H'_o =	1.67		*(see Step 23)*

Step 24. Compute Ratio of $H'_o/(g*T_o^2)$

Equivalent Deep-Water Wave Height, H'_o =	13.77	feet	*(see Step 22)*
Gravitational constant, g =	32.2	ft/s^2	*(constant variable)*
Deep Water Wave Period, T_o =	5.16	sec	*(see Step 12)*
$H'_o/(g*T_o^2)$ =	0.016		

Steps 25 - 27. Estimate R/H'o *(Fig. 7-8 thru 7-20, SPM Vol. 2)*

Steps 25-27 are directed towards deriving the ratio of Wave Runup to the Equivalent Deep-Water Wave Height (R/H'_o) from graphs found in SPM Volume 2 (Fig. 7-8 thru 7-20). The graphs are based upon various designs of the runup face slope including the material, roughness, slope, and geometry the face slope. In addition the value of R/H'_o depends upon the values of d_s/H'_o and $H'_o/(gT^2)$. Determination of values will typically require an interpolation of values between graphs.

d_s/H'_o =	1.67	*(see Step 23)*
$H'_o/(g*T_o^2)$ =	0.016	*(see Step 24)*
Face Slope Material =	Stop-Faced Slope	*Embankment Design*
Runup Face Slope (H:1V) =	3	*Embankment Design*
Runup Face Slope (Θ) =	18.4 degrees	
Figure used for Interpolation (Lower Interpolation Number) =	Fig. 7-10	*(SPM Vol. 2)*
Figure to used for Interpolation (Higher Interpolation Number) =	Fig. 7-11	*(SPM Vol. 2)*

Step 25. R/H'o from Fig. 7-10 with ds/H'o <= 1.67

$H'_o/(g*T_o^2)$ =	0.016	*(see Step 24)*
ds/H'o <=1.67 from Fig. 7-10 =	0.6	*(Fig. 7-10, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-10 =	0.69	*(Fig. 7-10, SPM Vol. 2)*

Step 26. R/H'o from Fig. 7-11 with ds/H'o >= 1.67

$H'_o/(g*T_o^2)$ =	0.016	*(see Step 24)*
ds/H'o >=1.67 from Fig. 7-11 =	2.0	*(Fig. 7-11, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-11 =	0.84	*(Fig. 7-11, SPM Vol. 2)*

Step 27. Estimated Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o

d_s/H'_o =	1.67	*(see Step 23)*
$H'_o/(g*T_o^2)$ =	0.016	*(see Step 24)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o =	0.80	*(Interpolated from Steps 25 & 26)*

Step 28. Compute Smooth Surface Wave Runup

Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'_o =	0.80	*(see Step 27)*
Equivalent Deep-Water Wave Height, H'_o =	13.77	*(see Step 22)*
Smooth Surface Wave Runup = R/H'_o x H'_o =	11.00 feet	

Step 29. If Applicable, Determine and Apply Wave Runup Correction Factor due to Scale Effects

This step applies if Figures 7-8 thru 7-12 or Figures 7-14 thru 7-16 were used to estimate R/H'_o in Steps 25-27. These figures summarize results for small-scale lab tests. Due to the inability to scale roughness effects in small-scale lab tests, the results are probably smaller than the runup on prototype structures. Figure 7-13 is used to adjust for this scale effect.

Smooth Surface Wave Runup = R/H'_o x H'_o =	11.00	feet	*(see Step 28)*
Scale Wave Runup Correction due to Scale Effects *(If Fig. 7-13 or 7-20 used, enter 1)* =	1.12		*(Fig. 7-13, SPM Vol. 2)*
Scale Corrected Wave Runup Height = (Smooth Surface Wave Runup)(Runup Correction) =	12.32	feet	

Step 30. Determine and Apply Correction Factor due to Dam Surface Roughness

Face Slope Material =	Stop-Faced Slope		*(see Step 25)*
Surface Roughness Correction =	0.7		*(Table 7-2, SPM Vol 2) or (Table 2-2 EM1110-2-1614)*
Scale Corrected Wave Runup Height =	12.32	feet	*(see Step 29)*
Corrected Wave Runup = (Scale Corrected Wave Runup)(Surface Roughness Correction) =	8.62	feet	

Step 31. Correction Due to to Fetch Axis Not Being Normal to the Dam Axis

Angle Between Fetch Axis and Embankment Axis =	0	degrees	
Angle Correction Factor =	1.00		*(Fig. 8, ACER TM No. 11)*

Step 32. Adjusted Wave Runup

Corrected Wave Runup =	8.62		*(see Step 30)*
Angle Correction Factor =	1.00		*(see Step 31)*
Final Adjusted Wave Runup = (Corrected Wave Runup)(Angle Correction Factor) =	8.6	feet	

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 2: 100-Year Precipitation Combined with Category 5 Hurricane Winds
Minimum Required Freeboard - Site C-43: Cell 1 (Fetch 1A)

Step 33. Minimum Required Design Freeboard

Design Precipitation **or** Flood Surge Depth (Routed Flood Event) =	0.77	ft	*(based upon max. water surface elevation of routed storm event)*
Wind Setup =	1.86	ft	*(see Step 18)*
Wave Height & Runup =	8.62	ft	*(see Step 32)*
Waves Induced by Potential Landslides =	0.00	ft	*(not considered)*
Provision for Malfunction of the Spillway or Discharge Structure =	0.00	ft	*(not considered)*
Summation of all above Freeboard Components is Minimum Required Freeboard =	11.26	ft	*(rounded up to the next 0.01 foot)*

Step 34. Minimum Required Design Freeboard with Camber

Average Normal Full Storage Depth =	20.36	ft	*(Average Depth along Fetch based on NFSL = 42 ft El.)*
Minimum Required Freeboard =	11.26	ft	*(see Step 33)*
Minimum Embankment Height (not including camber) =	31.62	ft	*(summation of average normal full storage depth and freeboard)*
Minimum Required Freeboard =	11.26	ft	*(see Step 33)*
Embankment Settlement =	1.06	ft	*(see Technical Memorandum Table 3 or BODR Section 8E)*
Minimum Embankment Height (with camber) =	32.68	ft	*(minimum embankment height plus settlement)*
Minimum Required Design Freeboard with Camber =	12.32	ft	*(rounded up to the next 0.01 foot)*

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

3/12/2007

Case 3: Probable Maximum Wind Speed Combined with Normal Full Storage Level (Uncontrolled Spillway Level)
Design Wind Speed Analysis - Site C-43: Cell 1 (Fetch 1A)

Steps 1-2: Not necessary for Case 3

Project Location =	C-43 Cell No. 1 (Fetch 1A)		
Probable Maximum Wind (PMW) Speed, $U_{PMW,60\text{-}sec,water}$ =	200.0	mph	*(pg 13, DCM-2)*

For Case 3, the 200 mph assumed PMW corresponds to an over-water 1-minute average wind speed. *(pg 13, DCM-2)*

Step 3: Determine PMW, 1-Hr Wind Speed, $U_{PMW,1\text{-}hr}$

Initial wind speed duration, t =	60	sec.	*(based on Step 1 Data)*

Equations for ratio of wind speeds to 1-hour average wind speeds, U_t/U_{3600}

For $t \leq 3{,}600$: $U_t/U_{3600} = 1.277 + 0.296\tanh(0.9\log_{10}(45/t))$ =	applies		*(Eqn. 1, DCM-2)*
For $3{,}600 < t < 36{,}000$: $U_t/U_{3600} = -0.15\log_{10}(t)+1.5334$ =	does not apply		*(Eqn. 2, DCM-2)*
U_t/U_{3600} =	1.24		*(Eqn. 1, DCM-2)*
$U_t = U_{PMW,60\text{-}sec}$ =	200.00	mph	*(see Step 2)*
$U_{PMW,3600\text{-}sec} = U_{PMW,1\text{-}hr} = U_t/(U_t/U_{3600})$ =	160.8	mph	

Step 4: Determine PMW, 1-Hr Wind Speed Over Water, $U_{PMW,1\text{-}hr,water}$

Fetch Length (in miles), X =	3.51	miles	

If initial data from Step 1 is over water wind speed, no conversion (Ratio = 1.0)	does not apply		*(Fig. II-2-20, CEM)*
For Fetch Length < 10 miles: U_{Water}/U_{Land} = 1.2 or 1.0	applies		*(Fig. II-2-20, CEM)*
For Fetch Length > 10 miles: See Figure II-2-7, CEM	does not apply		*(Fig. II-2-7, CEM)*
U_{water}/U_{land} =	1		*(Fig. II-2-20, CEM)*
$U_{PMW,1\text{-}hr,land}$ =	-		*(see Step 3)*
$U_{PMW,1\text{-}hr,water} = U_{PMW,1\text{-}hr,land} \times (U_{water}/U_{land})$ =	160.8	mph	

Step 5: Estimate Fetch-Limited Wind Duration Time

Fetch Length (in miles), X =			
Wind Velocity (in mph), U =	160.8	mph	*(see Step 4)*
Fetch Limited Wind Duration Time, $t = 112(X^{0.67}/U^{0.34})$ =	46	min.	*(Eqn. 4, DCM-2)*
	2771	sec.	

Step 6: Estimate Ratio of Fetch Limited Duration Wind Speed and 1-Hour Wind Speed

Fetch Limited Wind Duration Time (in seconds), t =	2771	sec.	*(see Step 5)*

Equations for ratio of wind speeds to 1-hour average wind speeds, U_t/U_{3600}

For $t \leq 3{,}600$: $U_t/U_{3600} = 1.277 + 0.296\tanh(0.9\log_{10}(45/t))$ =	applies		*(Eqn. 1, DCM-2)*
For $3{,}600 < t < 36{,}000$: $U_t/U_{3600} = -0.15\log_{10}(t)+1.5334$ =	does not apply		*(Eqn. 2, DCM-2)*
Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.004		*(Eqn. 1, DCM-2)*

Step 7: Adjust 1-Hr Wind Speed (over water) to Equivalent Fetch Limited Duration Wind Speed

Fetch Limited Wind Duration (in minutes), t =	46	min.	*(see Step 5)*
PMW, 1-Hr Wind Speed Over Water, $U_{PMW,1\text{-}hr,water}$ =	160.8	mph	*(see Step 4)*
Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.004		*(see Step 6)*
PMW, Fetch Limited Wind Speed Over Water = $U_{PMW,1\text{-}hr,water} \times U_t/U_{3600}$ =	161	mph	

Step 8: Stability Correction, Adjust Wind Speed for Boundary Layer Stability

Fetch Length (in miles), X =	3.51	miles	*(see Step 4)*
(If Fetch Length > 10 miles, else enter 0) Temperature of Air, T_a =	0	o C	
(If Fetch Length > 10 miles, else enter 0) Temperature of Sea, T_s =	0	o C	
Air-Sea Temperature Difference, ΔT_{as} $T_a - T_s$ =	0	°C	

Stability Correction Factor, R_T

For Fetch Length < 10 miles: R_T = 1.0	applies		*(pg. II-2-36, CEM)*
For Fetch Length > 10 miles: Based on ΔT_{as}, See Figure 3-14, SPM or in absence of temperature information, assume RT = 1.1	does not apply		*(Fig.3-14, SPM)* *(pg 3-30, SPM)*
$U_{PMW,1\text{-}min,water}$ =	161	mph	*(see Step 7)*
Stability Correction Factor, R_T =	1		*(pg. II-2-36, CEM)*
$U_{PMW,fetch\text{-}min,water,\ stability\ adjusted} = U_{PMW,fetch\text{-}min,water} \times R_T$ =	161	mph	*(Eqn. 3-27 SPM)*

Step 9. Compute Wind Stress Factor, U_A

$U_{PMW,fetch\text{-}min,water,\ stability\ adjusted} = U$ =	161	mph	*(see Step 8)*
Wind Stress Factor, $U_A = 0.589U^{1.23}$ =	306	mph	*(Eqn. 3-28b SPM)*

Step 10. Wind Stress Factor in ft/s

Wind Stress Factor, U_A (ft/s) = $1.467U_A$ (mph) =	449	ft/sec	*(see Step 9)*

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 3: Probable Maximum Wind Speed Combined with Normal Full Storage Level (Uncontrolled Spillway Level)
Wind Setup and Wave Properties Analysis - Sta C-43: Cell 1 (Fetch 1A)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.51	miles	(see Step 5)
Fetch Length, F =	18,537	ft	
PMW, Fetch Limited Wind Speed Over Water = $U_{(F)(2)(3)(1.43)}$ =	161	mph	(see Step 7)
Wind Stress Factor, U_A (ft/s) =	449	ft/s	(see Step 10)

Step 11. Compute Deep-Water Significant Wave Height, H_{mo}

Deep-Water Significant Wave Height, H_{mo} = (0.000282)$U_A F^{1/2}$ =	17.23	feet	(Eqn. 3-33c, SPM)

Step 12. Compute Deep-Water Wave Period, T_o

Deep-Water Wave Period, T_o = 0.02825$(U_A F)^{1/2}$ =	5.72	sec	(Eqn. 3-34c, SPM)

Step 13. Compute Deep-Water Wave Length, L_o

Deep-Water Wave Length, L_o = 5.12T_o^2 =	168	feet	(Eqn. 2-8b, SPM)

Step 14. Compute Relative Depth, d/L_o

If $d/L_o \leq 0.5$, waves are classified as transitional or shallow water waves. (pg 2-9, SPM)
If $d/L_o > 0.5$, waves are classified as deep water. (pg 2-9, SPM)

	20.38	feet	
Relative Depth = d/L_o =	0.121		(pg 2-9, SPM)
Wave Classification =	Transitional/Shallow-Water		(pg 2-9, SPM)

Step 15. Compute Shallow-Water Wave Period, T

Shallow-Water Wave Period, T = 7.54 tanh(A) tanh(B/C) U_A/g (Eqn. 3-40, SPM)

where: F = Fetch Length (ft) (step 5) U_A = Wind Stress Factor (step 10) g = 32.2 ft/s^2

A = 0.493$(gd/U_A^2)^{0.75}$ =	0.0072		
B = 0.0379$(gF/U_A^2)^{0.75}$ =	0.0544		
C = tanh(0.833$(gd/U_A^2)^{0.375}$) =	0.0969		
Shallow-Water Wave Period, T = 7.54 tanh(A) tanh(B/C) U_A/g =	5.19	sec	(Eqn. 3-40, SPM)

Step 16. Compute Shallow-Water Significant Wave Height, H

Shallow-Water Significant Wave Height, H = 0.283 tanh(A) tanh(B/C) U_A^2/g (Eqn. 3-39, SPM)

where: F = Fetch Length (ft) (step 5) U_A = Wind Stress Factor (step 10) g = 32.2 ft/s^2

A = 0.530$(gd/U_A^2)^{0.75}$ =	0.0072		
B = 0.00565$(gF/U_A^2)^{0.5}$ =	0.0097		
C = tanh(0.530$(gd/U_A^2)^{0.375}$) =	0.0072		
Shallow-Water Significant Wave Height, H =0.283 tanh(A) tanh(B/C) U_A^2/g =	11.17	feet	(Eqn. 3-39, SPM)

Step 17. Compute Shallow-Water Wave Height for Zero Overwash

DCM-2 requires zero over wash as a design criteria for high and significant hazard dams. For purposes of the DCM-2, zero overwash wave height is defined as the wave height with a 2% occurrence frequency.

Significant Wave Height is either the Deep-Water or Shallow-Water Significant wave height Depending upon the Wave Classification (Step 14).

Significant Wave Height, H_s =	11.17	feet	(see Step 11 or 16)
Required probability of wave height being exceeded, n/N =	0.02		(see Step 17 discussion)
Root Mean Square Wave Height, $H_{rms} = 2^{-1/2} H_s$ =	7.90	feet	(Eqn. 3-10, SPM)
Wave Height which is exceeded at given probability, $H^* = H_{rms} [-\ln(n/N)]^{1/2}$ =	15.44	feet	(Eqn. 3-7, SPM)

Step 18. Compute Wind Set-Up

Four different methods are calculated and considered in estimating wind setup
Zeider Zee Eqn: Widely used as applied to reservoirs but tends to overestimate wind setup for shallow impoundments (ave. depth<16 ft).
Sibul Eqn: Typically yields the lowest wind setup.
Ave. of Zeider Zee & Sibul: Recommended for shallow impoundments (ave. depth<16 ft) when Bretschneider has no numeric solution.
Bretschneider Eqn: Recommend for shallow impoundments (average depth <16 ft).

Fetch Length, F =	3.51	miles	(see Step 5)
Fetch Length, F =	18,537	feet	
Average Wind Velocity, U = Wind Speed per Step 7 = $U_{(F)(2)(3)(1.43)}$ =	161	mph	(pg A6, DCM-2)(see Step 7)
Average Depth of Water along Fetch Line, D = Effective Depth =	20.38	feet	(see Step 14)
Zeider Zee Eqn: [Note: F=miles]: Wind Set-Up, S = $U^2F/(1400D)$ =	3.21	feet	(Eqn. 5, DCM-2)
Sibul Eqn (Note: Fetch, g=32.2 ft/s^2): S = $0.0000244d(F/d)^{0.67}(U^2/Fg)^{1/(2(0.67)-1.0)}$ =	0.96	feet	(Eqn. 7, DCM-2)
Average of Zeider Zee & Sibul: Wind Setup, S = $(S_{Zeider\ Zee} + S_{Sibul})/2$ =	2.09	feet	
Bretschneider Eqn [Note, Calcs provided separately in Step 18a]: S = $\Sigma^2[(kU^2/x)/(gd^2)]$ =	n/a	feet	(Eqn. 6, DCM-2)(Step 18a)
Equation Used for Wind Setup *(Enter Zeider Zee, Sibul, Average, Bretschneider)* =	Zeider Zee		
Computed Wind Set-Up, S =	3.21	feet	(Eqn. 5, DCM-2)

Step 19. Compute Water Depth at Toe of Structure

Water Depth at Toe of Structure, d_s = Effective Depth + Wind Set-Up = d + S =	23.57	feet	(pg. A6, DCM-2)

Step 20. Check for Depth Limited Wave Breaking

See if wave height is limited due to breaking. After breaking, waves will tend to reform with lower heights within a few wave lengths. (pg. 15-4, EM-1110-2-1420)

Depth of interest is at Toe of Structure, $d_i = d_s$ =	23.57	feet	(see Step 19)
Wave Breaking Height, H_b (for depth d_b) = (d_b/1.28) =	18.41	feet	(Eqn. 2-91 & 3-50, SPM)
Is max wave height limited by breaking? (If H_s (step 20) $\leq H^*$ (step 17) then yes, else no) =	No		
(If no, wave height = H^* (step 17). If yes, conservatively assume wave height = H_s (step 20)) Maximum Wave Height =	15.44	feet	

Step 21. Estimate Ratio Between Deep-Water Wave Ht & Equivalent Deep-Water Ht

The value of H/Ho (shallow-water wave height/equivalent deep-water wave height) is estimated based on the value of d/L_o (effective depth / deep-water wave length) from Table C-1, SPM Vol II, Appendix C.

Effective Depth, d =	20.38	feet	(see Step 14)
Deep-Water Wave Length, L_o =	168	feet	(see Step 13)
Ratio of effective depth to deep-water wave length, d/L_o =	0.121		
H/H'_o =	0.9200		(Table C-1, SPM Vol 2)

Step 22. Compute Equivalent Deep-Water Wave Height, H'_o

If wave classification is Deep-Water (Step 14), Significant Deep-Water Height is the Equivalent Deep-Water Height.
If wave classification is Transitional/Shallow-Water an adjustment is necessary.
If Wave Breaking Height (Step 20) is less than the Zero Overwash for Significant Wave Height (Step 17) then Equivalent Deep-Water Wave Height is Wave Braking Height (irregardless of wave classification).

Wave Breaking Height, H_b =	18.41	feet	(see Step 20)
Significant Wave Height, H_s =	15.44	feet	(see Step 17)
H/H'_o =	0.9200		(see Step 21)
If Shallow-Water: Equivalent Deep-Water Wave Height, H'o = H/(H/H'o) =	16.79	feet	
If Deep Water: Equivalent Deep-Water Wave Height = Significant Deep-Water Height =	n/a	feet	
If Height Limited by Wave Breaking: Equiv. Deep-Water Wave Ht. = Wave Breaking Ht. =	n/a		
Equivalent Deep-Water Wave Height =	16.79	feet	

Step 23. Compute Depth at Toe of Structure to Equiv. Deep-Water Wave Ht, d_s/H'_o

Water Depth at Toe of Structure, d_s =	23.57	feet	(see Step 19)
Equivalent Deep-Water Wave Height, H'_o =	16.79	feet	(see Step 22)
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_s/H'_o =	1.40		

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 3: Probable Maximum Wind Speed Combined with Normal Full Storage Level (Uncontrolled Spillway Level)
Wave Runup Analysis - Site C-43: Cell 1 (Fetch 1A)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.51	miles	*(see Step 5)*
Fetch Length, F =	18,537	feet	
PMW, Fetch Limited Wind Speed Over Water = $U_{PMW,fetch-min}$ =	161	mph	*(see Step 7)*
Wind Stress Factor, U_A (ft/s) =	449	ft/s	*(see Step 10)*

Wind Setup and Wave Properties Analysis - Summary Data

Wind Set-Up , S =	3.21	feet	*(see Step 18)*
Equivalent Deep-Water Wave Height, H'_o =	16.79	feet	*(see Step 22)*
Deep-Water Wave Period, T_o =	5.72	sec	*(see Step 12)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_s/H'_o =	1.40		*(see Step 23)*

Step 24. Compute Ratio of $H'_o/(g*T_o^2)$

Equivalent Deep-Water Wave Height, H'_o =	16.79	feet	*(see Step 22)*
Gravitational constant, g =	32.2	ft/s^2	*(constant variable)*
Deep Water Wave Period, T_o =	5.72	sec	*(see Step 12)*
$H'_o/(g*T_o^2)$ =	0.016		

Steps 25 - 27. Estimate R/H'o *(Fig. 7-8 thru 7-20, SPM Vol. 2)*

Steps 25-27 are directed towards deriving the ratio of Wave Runup to the Equivalent Deep-Water Wave Height (R/H'_o) from graphs found in SPM Volume 2 (Fig. 7-8 thru 7-20). The graphs are based upon various designs of the runup face slope including the material, roughness, slope, and geometry the face slope. In addition the value of R/H'_o depends upon the values of d_s/H'_o and $H'_o/(gT^2)$. Determination of values will typically require an interpolation of values between graphs.

d_s/H'_o =	1.40		*(see Step 23)*
$H'_o/(g*T_o^2)$ =	0.016		*(see Step 24)*
Face Slope Material =	Step-Faced Slope		*Embankment Design*
Runup Face Slope (H:1V) =	3		*Embankment Design*
Runup Face Slope (θ) =	18.4	degrees	
Figure used for Interpolation (Lower Interpolation Number) =	Fig. 7-10		*(SPM Vol. 2)*
Figure to used for Interpolation (Higher Interpolation Number) =	Fig. 7-11		*(SPM Vol. 2)*

Step 25. R/H'o from Fig. 7-10 with ds/H'o <= 1.4

$H'_o/(g*T_o^2)$ =	0.016		*(see Step 24)*
ds/H'o <=1.4 from Fig. 7-10 =	0.6		*(Fig. 7-10, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-10 =	0.69		*(Fig. 7-10, SPM Vol. 2)*

Step 26. R/H'o from Fig. 7-11 with ds/H'o >= 1.4

$H'_o/(g*T_o^2)$ =	0.016		*(see Step 24)*
ds/H'o >=1.4 from Fig. 7-11 =	2.0		*(Fig. 7-11, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-11 =	0.84		*(Fig. 7-11, SPM Vol. 2)*

Step 27. Estimated Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o

d_s/H'_o =	1.40		*(see Step 23)*
$H'_o/(g*T_o^2)$ =	0.016		*(see Step 24)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o =	0.77		*(Interpolated from Steps 25 & 26)*

Step 28. Compute Smooth Surface Wave Runup

Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'_o =	0.77		*(see Step 27)*
Equivalent Deep-Water Wave Height, H'_o =	16.79		*(see Step 22)*
Smooth Surface Wave Runup = R/H'_o x H'_o =	12.80	feet	

Step 29. If Applicable, Determine and Apply Wave Runup Correction Factor due to Scale Effects

This step applies if Figures 7-8 thru 7-12 or Figures 7-14 thru 7-18 were used to estimate R/H'_o in Steps 25-27. These figures summarize results for small-scale lab tests. Due to the inability to scale roughness effects in small-scale lab tests, the results are probably smaller than the runup on prototype structures. Figure 7-13 is used to adjust for this scale effect.

Smooth Surface Wave Runup = R/H'_o x H'_o =	12.80	feet	*(see Step 28)*
Scale Wave Runup Correction due to Scale Effects *(If Fig. 7-19 or 7-20 used, enter 1)* =	1.12		*(Fig. 7-13, SPM Vol. 2)*
Scale Corrected Wave Runup Height = (Smooth Surface Wave Runup)(Runup Correction) =	14.34	feet	

Step 30. Determine and Apply Correction Factor due to Dam Surface Roughness

Face Slope Material =	Step-Faced Slope		*(see Step 25)*
Surface Roughness Correction =	0.7		*(Table 7-2, SPM Vol 2) or (Table 2-2 EM1110-2-1614)*
Scale Corrected Wave Runup Height =	14.34	feet	*(see Step 29)*
Corrected Wave Runup = (Scale Corrected Wave Runup)(Surface Roughness Correction) =	10.04	feet	

Step 31. Correction Due to to Fetch Axis Not Being Normal to the Dam Axis

Angle Between Fetch Axis and Embankment Axis =	0	degrees	
Angle Correction Factor =	1.00		*(Fig. 8, ACER TM No. 11)*

Step 32. Adjusted Wave Runup

Corrected Wave Runup =	10.04		*(see Step 30)*
Angle Correction Factor =	1.00		*(see Step 31)*
Final Adjusted Wave Runup = (Corrected Wave Runup)(Angle Correction Factor) =	10.0	feet	

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 3: Probable Maximum Wind Speed Combined with Normal Full Storage Level (Uncontrolled Spillway Level)
Minimum Required Freeboard - Site C-43: Cell 1 (Fetch 1A)

Step 33. Minimum Required Design Freeboard

Design Precipitation **or** Flood Surge Depth (Routad Flood Event) =	0.00	ft	*(no surcharge, normal full storage level elevation assumed)*
Wind Setup =	3.21	ft	*(see Step 18)*
Wave Height & Runup =	10.04	ft	*(see Step 32)*
Waves Induced by Potential Landslides =	0.00	ft	*(not considered)*
Provision for Malfunction of the Spillway or Discharge Structure =	0.00	ft	*(not considered)*
Summation of all above Freeboard Components is Minimum Required Freeboard =	13.25	ft	*(rounded up to the next 0.01 foot)*

Step 34. Minimum Required Design Freeboard with Camber

Average Normal Full Storage Depth =	20.36	ft	*(Average Depth along Fetch based on NFSL = 42 ft El.)*
Minimum Required Freeboard =	13.25	ft	*(see Step 33)*
Minimum Embankment Height (not including camber) =	33.61	ft	*(summation of average normal full storage depth and freeboard)*
Minimum Required Freeboard =	13.25	ft	*(see Step 33)*
Embankment Settlement =	1.24	ft	*(see Technical Memorandum Table 3 or BODR Section 8E.)*
Minimum Embankment Height (with camber) =	34.85	ft	*(minimum embankment height plus settlement)*
Minimum Required Design Freeboard with Camber =	14.50	ft	*(rounded up to the next 0.01 foot)*

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

3/12/2007

Case 4: Hurricane Easy (125 mph, 3-sec Gust Wind Speed Combined With Both 24-hr (38.7") & 72 hr (45.2") Rainfall Durations)
Design Wind Speed Analysis - Site C-43: Cell 1 (Fetch 1A)

Step 1-2: Select EASY, 3-Sec Gust Wind Speed, $U_{EASY,3\text{-}sec}$

Project Location =	C-43 Cell No. 1 (Fetch 1A)		
EASY, 3-sec Gust Wind Speed, $U_{EASY,3\text{-}sec}$ =	125.0	mph	*(pg. 14, DCM-2)*

The Hurricane Easy, 125 mph, 3-sec gust wind speed is a storm specific case. Therefore, it is assumed that the Step 2 conversion factor adjustment is not relevant for this case.

Step 3: Determine EASY, 1-Hr Wind Speed, $U_{EASY,1\text{-}hr}$

Initial wind speed duration, t =	3	sec.	*(based on Step 1 Data)*

Equations for ratio of wind speeds to 1-hour average wind speeds, U_t/U_{3600}

For t ≤ 3,600:	$U_t/U_{3600} = 1.277 + 0.296\tanh(0.9\log_{10}(45/t))$ =	applies		*(Eqn. 1, DCM-2)*
For 3,600 < t < 36,000:	$U_t/U_{3600} = -0.15\log_{10}(t)+1.5334$ =	does not apply		*(Eqn. 2, DCM-2)*
	U_t/U_{3600} =	1.51		*(Eqn. 1, DCM-2)*
	$U_t = U_{EASY,3\text{-}sec}$ =	125.0	mph	*(see Step 2)*
	$U_{EASY,3600\text{-}sec} = U_{EASY,1\text{-}hr} = U_t/(U_t/U_{3600})$ =	82.8	mph	

Step 4: Determine EASY, 1-Hr Wind Speed Over Water, $U_{EASY,1\text{-}hr,water}$

Fetch Length (in miles), X =	3.51	miles	

Wind Speed Over Water to Wind Speed Over Land Ratio, U_{Water}/U_{Land}:

If initial data from Step 1 is over water wind speed, no conversion (Ratio = 1.0)		does not apply		*(Fig. II-2-20, CEM)*
For Fetch Length < 10 miles:	U_{Water}/U_{Land} = 1.2 or 1.0	applies		*(Fig. II-2-20, CEM)*
For Fetch Length > 10 miles:	See Figure II-2-7, CEM	does not apply		*(Fig. II-2-7, CEM)*
	U_{water}/U_{land} =	1.2		*(Fig. II-2-20, CEM)*
	$U_{Easy,1\text{-}hr,land}$ =	82.8		*(see Step 3)*
	$U_{EASY,1\text{-}hr,water} = U_{EASY,1\text{-}hr,land} \times (U_{water}/U_{land})$ =	99.4	mph	

Step 5: Estimate Fetch-Limited Wind Duration Time

Fetch Length (in miles), X =	3.51	miles	*(see Step 4)*
Wind Velocity (in mph), U =	99.4	mph	*(see Step 4)*
Fetch Limited Wind Duration Time, $t = 112(X^{0.67}/U^{0.34})$ =	54	min.	*(Eqn. 4, DCM-2)*
	3264	sec.	

Step 6: Estimate Ratio of Fetch Limited Duration Wind Speed and 1-Hour Wind Speed

Fetch Limited Wind Duration Time (in seconds), t =	3264	sec.	*(see Step 5)*

Equations for ratio of wind speeds to 1-hour average wind speeds, U_t/U_{3600}

For t ≤ 3,600:	$U_t/U_{3600} = 1.277 + 0.296\tanh(0.9\log_{10}(45/t))$ =	applies		*(Eqn. 1, DCM-2)*
For 3,600 < t < 36,000:	$U_t/U_{3600} = -0.15\log_{10}(t)+1.5334$ =	does not apply		*(Eqn. 2, DCM-2)*
	Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.001		*(Eqn. 1, DCM-2)*

Step 7: Adjust 1-Hr Wind Speed (over water) to Equivalent Fetch Limited Duration Wind Speed

Fetch Limited Wind Duration (in minutes), t =	54	min.	*(see Step 5)*
EASY-Yr, 1-Hr Wind Speed Over Water, $U_{EASY,1\text{-}hr,water}$ =	99.4	mph	*(see Step 4)*
Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.001		*(see Step 6)*
EASY, Fetch Limited Wind Speed Over Water = $U_{EASY,1\text{-}hr,water} \times U_t/U_{3600}$ =	99	mph	

Step 8: Stability Correction, Adjust Wind Speed for Boundary Layer Stability

Fetch Length (in miles), X =	3.51	miles	*(see Step 4)*
(If Fetch Length > 10 miles, else enter 0) Temperature of Air, T_a =	0	°C	
(If Fetch Length > 10 miles, else enter 0) Temperature of Sea, T_s =	0	°C	
Air-Sea Temperature Difference, ΔT_{as} $T_a - T_s$ =	0	°C	

Stability Correction Factor, R_T

For Fetch Length < 10 miles:	R_T = 1.0	applies		*(pg. II-2-36, CEM)*
For Fetch Length > 10 miles:	Based on ΔT_{as}, See Figure 3-14, SPM or in absence of temperature information, assume RT = 1.1	does not apply		*(Fig.3-14, SPM)* *(pg 3-30, SPM)*
	$U_{EASY,fetch\text{-}min,water}$ =	99	mph	*(see Step 7)*
	Stability Correction Factor, R_T =	1		*(pg. II-2-36, CEM)*
	$U_{EASY,fetch\text{-}min,water,\ stability\ adjusted} = U_{EASY,fetch\text{-}min,water} \times R_T$ =	99	mph	*(Eqn. 3-27 SPM)*

Step 9. Compute Wind Stress Factor, U_A

$U_{EASY,Fetch\text{-}min,water,\ stability\ adjusted} = U$ =	99	mph	*(see Step 8)*
Wind Stress Factor, $U_A = 0.589U^{1.23}$ =	169	mph	*(Eqn. 3-28b SPM)*

Step 10. Wind Stress Factor in ft/s

Wind Stress Factor, U_A (ft/s) = $1.467U_A$ (mph) =	248	ft/sec	*(see Step 9)*

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

Case 4: Hurricane Easy (125 mph, 3-sec Gust Wind Speed Combined With Both 24-hr (38.7") & 72 hr (45.2") Rainfall Durations)
Wind Setup and Wave Properties Analysis - Site C-43: Cell 1 (Fetch 1A)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.51	miles	*(see Step 4)*
Fetch Length, F =	18,537	ft	
EASY, Fetch Limited Wind Speed Over Water = $U_{(x)=U_{(10)}/R_L}$ =	99	mph	*(see Step 7)*
Wind Stress Factor, U_f, (ft/s) =	248	ft/s	*(see Step 10)*

Step 11. Compute Deep-Water Significant Wave Height, H_{mo}

Deep-Water Significant Wave Height, $H_{mo} = (0.0002821)U_f F^{1/2}$ = 9.61 feet *(Eqn. 3-33c, SPM)*

Step 12. Compute Deep-Water Wave Period, T_o

Deep-Water Wave Period, $T_o = 0.02825(U_f F)^{1/3}$ = 4.69 sec *(Eqn. 3-34c, SPM)*

Step 13. Compute Deep-Water Wave Length, L_o

Deep-Water Wave Length, $L_o = 5.12T_o^2$ = 113 feet *(Eqn. 2-4b, SPM)*

Step 14. Compute Relative Depth, d/L_o

If $d/L_o \leq 0.5$, waves are classified as transitional or shallow water waves. *(pg 2-9, SPM)*
If $d/L_o > 0.5$, waves are classified as deep water. *(pg 2-9, SPM)*

	24.13	feet	
Relative Depth = d/L_o =	0.214		*(pg 2-9, SPM)*
Wave Classification =	Transitional/Shallow-Water		*(pg 2-9, SPM)*

Step 15. Compute Shallow-Water Wave Period, T

Shallow-Water Wave Period, $T = 7.54 \tanh(A) \tanh(B/C)\, U_f/g$ *(Eqn. 3-40, SPM)*

where: F = Fetch Length (ft) (step 5) U_f = Wind Stress Factor (step 10) g = 32.2 ft/s²

$A = 0.833(gd/U_f^2)^{3/4}$ =	0.1619	
$B = 0.0379(gF/U_f^2)^{1/3}$ =	0.0809	
$C = \tanh(0.893(gd/U_f^2)^{3/4})$ =	0.1605	
Shallow-Water Wave Period, $T = 7.54 \tanh(A) \tanh(B/C)\, U_f/g$ =	4.33 sec	*(Eqn. 3-40, SPM)*

Step 16. Compute Shallow-Water Significant Wave Height, H

Shallow-Water Significant Wave Height, $H = 0.283 \tanh(A) \tanh(B/C)\, U_f^2/g$ *(Eqn. 3-39, SPM)*

where: F = Fetch Length (ft) (step 5) U_f = Wind Stress Factor (step 10) g = 32.2 ft/s²

$A = 0.530(gd/U_f^2)^{3/4}$ =	0.0200	
$B = 0.00565(gF/U_f^2)^{1/2}$ =	0.0176	
$C = \tanh(0.530(gd/U_f^2)^{3/4})$ =	0.0200	
Shallow-Water Significant Wave Height, $H = 0.283 \tanh(A) \tanh(B/C)\, U_f^2/g$ =	7.62 feet	*(Eqn. 3-39, SPM)*

Step 17. Compute Shallow-Water Wave Height for Zero Overwash

DCM-2 requires zero over wash as a design criteria for high and significant hazard dams. For purposes of the DCM-2, zero overwash wave height is defined as the wave height with a 2% occurrence frequency.

Significant Wave Height is either the Deep-Water or Shallow-Water Significant wave height Depending upon the Wave Classification (Step 14).

Significant Wave Height, H_s =	7.62	feet	*(see Step 11 or 16)*
Required probability of wave height being exceeded, n/N =	0.02		*(see Step 17 discussion)*
Root Mean Square Wave Height, $H_{rms} = 2^{1/2}H_s$ =	5.39	feet	*(Eqn. 3-16, SPM)*
Wave Height which is exceeded at given probability, $H^* = H_{rms}[-\ln(n/N)]^{1/2}$ =	10.54	feet	*(Eqn. 3-7, SPM)*

Step 18. Compute Wind Set-Up

Four different methods are calculated and considered in estimating wind setup.
Zeider Zee Eqn: Widely used as applied to reservoirs but tends to overestimate wind setup for shallow impoundments (ave. depth<16 ft).
Sibul Eqn: Typically yields the lowest wind setup.
Ave. of Zeider Zee & Sibul: Recommended for shallow impoundments (ave. depth<16 ft) when Bretschneider has no numeric solution.
Bretschneider Eqn: Recommend for shallow impoundments (average depth <16 ft).

Fetch Length, F =	3.51	miles	*(see Step 4)*
Fetch Length, F =	18,537	feet	
Average Wind Velocity, U = Wind Speed per Step 7 = $U_{(x)=U_{(10)}/R_L}$ =	99	mph	*(pg A6, DCM-2)(see Step 7)*
Average Depth of Water along Fetch Line, D = Effective Depth =	24.12666667	feet	*(see Step 14)*
Zeider Zee Eqn (Note: F=miles): Wind Set-Up, $S = U^2F/(1400D)$ =	1.03	feet	*(Eqn. 5, DCM-2)*
Sibul Eqn (Note: F=feet, g=32.2 ft/s²): $S = 0.0002244(F/d)^{1.06}(U^2F/g)^{0.25(F/d)^{-0.075}}$ =	0.25	feet	*(Eqn. 7, DCM-2)*
Average of Zeider Zee & Sibul: Wind Setup, $S = (S_{Zeider\ Zee} + S_{Sibul})/2$ =	0.64	feet	
Bretschneider Eqn (Note: Calcs provided separately in Step 18a): $S = 2.5[(kU^2/x)(gd^2)]$ =	n/a	feet	*(Eqn. 6, DCM-2)(Step 18a)*
Equation Used for Wind Setup *(Enter Zeider Zee, Sibul, Average, Bretschneider)* =	Zeider Zee		
Computed Wind Set-Up, S =	1.03	feet	*(Eqn. 5, DCM-2)*

Step 19. Compute Water Depth at Toe of Structure

Water Depth at Toe of Structure, d_t = Effective Depth + Wind Set-Up = d + S = 25.16 feet *(pg. A6, DCM-2)*

Step 20. Check for Depth Limited Wave Breaking

See if wave height is limited due to breaking. After breaking, waves will tend to reform with lower heights within a few wave lengths. *(pg. 15-4, EM-1110-2-1420)*

Depth of interest is at Toe of Structure, $d_s = d_t$ =	25.16	feet	*(see Step 19)*
Wave Breaking Height, H_b (for depth d_s) = $(d_s/1.28)$ =	19.65	feet	*(Eqn. 2-91 & 3-50, SPM)*
Is max. wave height limited by breaking? (If H_b (step 20) $\leq H^*$ (step 17) then yes, else no) =	No		
(If no, wave height = H^* (step 17). If yes, conservatively assume wave height = H_b (step 20)) Maximum Wave Height =	10.54	feet	

Step 21. Estimate Ratio Between Deep-Water Wave Ht & Equivalent Deep-Water Ht

The value of H/H'o (shallow-water wave height/equivalent deep water wave height) is estimated based on the value of d/L_o (effective depth / deep-water wave length) from Table C-1, SPM Vol II, Appendix C.

Effective Depth, d =	24.12666667	feet	*(see Step 14)*
Deep-Water Wave Length, L_o =	113	feet	*(see Step 13)*
Ratio of effective depth to deep-water wave length, d/L_o =	0.214		
H/H'_o =	0.9215		*(Table C-1, SPM Vol II)*

Step 22. Compute Equivalent Deep-Water Wave Height, H'_o

If wave classification is Deep-Water (Step 14), Significant Deep-Water Height is the Equivalent Deep-Water Height.
If wave classification is Transitional/Shallow-Water an adjustment is necessary.
If Wave Breaking Height (Step 20) is less than the Zero Overwash for Significant Wave Height (Step 17) then Equivalent Deep-Water Wave Height is Wave Braking Height (irregardless of wave classification).

Wave Breaking Height, H_b =	19.65	feet	*(see Step 20)*
Significant Wave Height, H_s =	10.54	feet	*(see Step 17)*
H/H'_o =	0.9215		*(see Step 21)*
If Shallow-Water: Equivalent Deep-Water Wave Height, $H'o = H/(H/H'o)$ =	11.44	feet	
If Deep Water: Equivalent Deep-Water Wave Height = Significant Deep-Water Height =	n/a	feet	
If Height Limited by Wave Breaking: Equiv. Deep-Water Wave Ht. = Wave Breaking Ht. =	n/a	feet	
Equivalent Deep-Water Wave Height =	11.44	feet	

Step 23. Compute Depth at Toe of Structure to Equiv. Deep-Water Wave Ht, d_t/H'_o

Water Depth at Toe of Structure, d_t =	25.16	feet	*(see Step 19)*
Equivalent Deep-Water Wave Height, H'_o =	11.44	feet	*(see Step 22)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_t/H'_o =	2.20		

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

Case 4: Hurricane Easy (125 mph, 3-sec Gust Wind Speed Combined With Both 24-hr (38.7") & 72 hr (45.2") Rainfall Durations)
Wave Runup Analysis - Site C-43: Cell 1 (Fetch 1A)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.51	miles	*(see Step 4)*
Fetch Length, F =	18,537	feet	
EASY, Fetch Limited Wind Speed Over Water = $U_{EASY,fetchmin}$ =	99	mph	*(see Step 7)*
Wind Stress Factor, U_A (ft/s) =	248	ft/s	*(see Step 10)*

Wind Setup and Wave Properties Analysis - Summary Data

Wind Set-Up , S =	1.03	feet	*(see Step 18)*
Equivalent Deep-Water Wave Height, H'_o =	11.44	feet	*(see Step 22)*
Deep-Water Wave Period, T_o =	4.69	sec	*(see Step 12)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_s/H'_o =	2.20		*(see Step 23)*

Step 24. Compute Ratio of $H'_o/(g*T_o^2)$

Equivalent Deep-Water Wave Height, H'_o =	11.44	feet	*(see Step 22)*
Gravitational constant, g =	32.2	ft/s^2	*(constant variable)*
Deep Water Wave Period, T_o =	4.69	sec	*(see Step 12)*
$H'_o/(g*T_o^2)$ =	0.016		

Steps 25 - 27. Estimate R/H'o *(Fig. 7-8 thru 7-20, SPM Vol. 2)*

Steps 25-27 are directed towards deriving the ratio of Wave Runup to the Equivalent Deep-Water Wave Height (R/H'_o) from graphs found in SPM Volume 2 (Fig. 7-8 thru 7-20). The graphs are based upon various designs of the runup face slope including the material, roughness, slope, and geometry the face slope. In addition the value of R/H'_o depends upon the values of d_s/H'_o and $H'_o/(gT^2)$. Determination of values will typically require an interpolation of values between graphs.

d_s/H'_o =	2.20		*(see Step 23)*
$H'_o/(g*T_o^2)$ =	0.016		*(see Step 24)*
Face Slope Material =	Step-Faced Slope		*Embankment Design*
Runup Face Slope (H:1V) =	3		*Embankment Design*
Runup Face Slope (Θ) =	18.4	degrees	
Figure used for Interpolation (Lower Interpolation Number) =	Fig. 7-11		*(SPM Vol. 2)*
Figure to used for Interpolation (Higher Interpolation Number) =	Fig. 7-12		*(SPM Vol. 2)*

Step 25. R/H'o from Fig. 7-11 with ds/H'o <= 2.2

$H'_o/(g*T_o^2)$ =	0.016		*(see Step 24)*
ds/H'o <=2.2 from Fig. 7-11 =	2		*(Fig. 7-11, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-11 =	0.84		*(Fig. 7-11, SPM Vol. 2)*

Step 26. R/H'o from Fig. 7-12 with ds/H'o >= 2.2

$H'_o/(g*T_o^2)$ =	0.016		*(see Step 24)*
ds/H'o >=2.2 from Fig. 7-12 =	3.0		*(Fig. 7-12, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-12 =	1.04		*(Fig. 7-12, SPM Vol. 2)*

Step 27. Estimated Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o

d_s/H'_o =	2.20		*(see Step 23)*
$H'_o/(g*T_o^2)$ =	0.016		*(see Step 24)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o =	0.88		*(Interpolated from Steps 25 & 26)*

Step 28. Compute Smooth Surface Wave Runup

Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'_o =	0.88		*(see Step 27)*
Equivalent Deep-Water Wave Height, H'_o =	11.44		*(see Step 22)*
Smooth Surface Wave Runup = R/H'_o x H'_o =	10.10	feet	

Step 29. If Applicable, Determine and Apply Wave Runup Correction Factor due to Scale Effects

This step applies if Figures 7-8 thru 7-12 or Figures 7-14 thru 7-18 were used to estimate R/H'_o in Steps 25-27. These figures summarize results for small-scale lab tests. Due to the inability to scale roughness effects in small-scale lab tests, the results are probably smaller than the runup on prototype structures. Figure 7-13 is used to adjust for this scale effect.

Smooth Surface Wave Runup = R/H'_o x H'_o =	10.10	feet	*(see Step 26)*
Scale Wave Runup Correction due to Scale Effects *(If Fig. 7-19 or 7-20 used, enter 1)* =	1.12		*(Fig. 7-13, SPM Vol. 2)*
Scale Corrected Wave Runup Height = (Smooth Surface Wave Runup)(Runup Correction) =	11.31	feet	

Step 30. Determine and Apply Correction Factor due to Dam Surface Roughness

Face Slope Material =	Step-Faced Slope		*(see Step 25)*
Surface Roughness Correction =	0.7		*(Table 7-2, SPM Vol 2) or (Table 2-2 EM1110-2-1614)*
Scale Corrected Wave Runup Height =	11.31	feet	*(see Step 29)*
Corrected Wave Runup = (Scale Corrected Wave Runup)(Surface Roughness Correction) =	7.92	feet	

Step 31. Correction Due to to Fetch Axis Not Being Normal to the Dam Axis

Angle Between Fetch Axis and Embankment Axis =	0	degrees	
Angle Correction Factor =	1.00		*(Fig. 8, ACER TM No. 11)*

Step 32. Adjusted Wave Runup

Corrected Wave Runup =	7.92		*(see Step 30)*
Angle Correction Factor =	1.00		*(see Step 31)*
Final Adjusted Wave Runup = (Corrected Wave Runup)(Angle Correction Factor) =	7.9	feet	

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

Waves Induced by Potential Landslides =	0.00	0.00	0.00	0.00
Provision for Malfunction of the Spillway or Discharge Structure =	0.00	0.00	0.00	0.00
Minimum Required Freeboard =	**12.18**	**10.01**	**11.72**	**11.74**
Camber or Embankment Settlement =	1.15	0.96	1.06	1.15
Minimum Required Freeboard with Camber =	**13.3**	**11.0**	**12.8**	**12.9**

Notes:
Minimum Required Freeboard rounded up to the next 0.01 foot.
Minimum Required Freeboard with Camber rounded up to the next 0.1 foot.
Case 1 - Surcharge depth is based upon routing of design storm event(s) through the reservoir.
Case 2 - Surcharge depth is based upon routing of design storm event through the reservoir.
Case 3 - Case 3 is to be used only for "sensitivity identification" and not as a selected design condition (pg 14 of 25, DCM-2)
Case 4 - Surcharge depth is assumed to be equal to the total precipitation of Hurricane Easy (45.2").

1997

3/12/2007

Case 1: PMP Combined with 100-Year Wind
Design Wind Speed Analysis - Site C-43: Cell 1 (Fetch 1B)

Step 1: Select 50-Yr, 3-Sec Gust Wind Speed, $U_{50\text{-}yr,3\text{-}sec}$

Project Location =	C-43 Cell No. 1 (Fetch 1B)		
50-yr, 3-sec Gust Wind Speed, $U_{50\text{-}yr,3\text{-}sec}$ =	117.5	mph	*(Fig. 6-1b, ASCE 7-02)*

Step 2: Determine 100-Yr, 3-Sec Gust Wind Speed, $U_{100\text{-}yr,3\text{-}sec}$

$U_{50\text{-}yr,3\text{-}sec}$ =	117.5	mph	*(see Step 1)*
$U_{50\text{-}yr}$ to $U_{100\text{-}yr}$ Conversion Factor =	1.07		*(Table DCM 2-2, DCM-2)*
$U_{100\text{-}yr,3\text{-}sec} = U_{50\text{-}yr,3\text{-}sec}$ x Conversion Factor =	125.7	mph	

Step 3: Determine 100-Yr, 1-Hr Wind Speed, $U_{100\text{-}yr,1\text{-}hr}$

Initial wind speed duration, t =	3	sec.	*(based on Step 1 Data)*

Equations for ratio of wind speeds to 1-hour average wind speeds, U_t/U_{3600}

For $t \leq 3{,}600$: $U_t/U_{3600} = 1.277 + 0.296\tanh(0.9\log_{10}(45/t))$ =	applies		*(Eqn. 1, DCM-2)*
For $3{,}600 < t < 36{,}000$: $U_t/U_{3600} = -0.15\log_{10}(t)+1.5334$ =	does not apply		*(Eqn. 2, DCM-2)*
U_t/U_{3600} =	1.51		*(Eqn. 1, DCM-2)*
$U_t = U_{100\text{-}yr,\ 3\text{-}sec}$ =	125.73	mph	*(see Step 2)*
$U_{100\text{-}yr,\ 3600\text{-}sec} = U_{100\text{-}yr,\ 1\text{-}hr} = U_t/(U_t/U_{3600})$ =	83.3	mph	

Step 4: Determine 100-Yr, 1-Hr Wind Speed Over Water, $U_{100\text{-}yr,1\text{-}hr,water}$

Fetch Length (in miles), X =	3.04	miles	

Wind Speed Over Water to Wind Speed Over Land Ratio, U_{Water}/U_{Land}:

If initial data from Step 1 is over water wind speed, no conversion (Ratio = 1.0)	does not apply		*(Fig. II-2-20, CEM)*
For Fetch Length < 10 miles: U_{Water}/U_{Land} = 1.2 or 1.0	applies		*(Fig. II-2-20, CEM)*
For Fetch Length > 10 miles: See Figure II-2-7, CEM	does not apply		*(Fig. II-2-7, CEM)*
U_{water}/U_{land} =	1.2		*(Fig. II-2-20, CEM)*
$U_{100\text{-}yr,1\text{-}hr,land}$ =	83.3		*(see Step 3)*
$U_{100\text{-}yr,1\text{-}hr,water} = U_{100\text{-}yr,1\text{-}hr,land}$ x (U_{water}/U_{land}) =	100.0	mph	

Step 5: Estimate Fetch-Limited Wind Duration Time

Fetch Length (in miles), X =	3.04	miles	*(see Step 4)*
Wind Velocity (in mph), U =	100.0	mph	*(see Step 4)*
Fetch Limited Wind Duration Time, $t = 112(X^{0.67}/U^{0.34})$ =	49	min.	*(Eqn. 4, DCM-2)*
	2957	sec.	

Step 6: Estimate Ratio of Fetch Limited Duration Wind Speed and 1-Hour Wind Speed

Fetch Limited Wind Duration Time (in seconds), t =	2957	sec.	*(see Step 5)*

Equations for ratio of wind speeds to 1-hour average wind speeds, U_t/U_{3600}

For $t \leq 3{,}600$: $U_t/U_{3600} = 1.277 + 0.296\tanh(0.9\log_{10}(45/t))$ =	applies		*(Eqn. 1, DCM-2)*
For $3{,}600 < t < 36{,}000$: $U_t/U_{3600} = -0.15\log_{10}(t)+1.5334$ =	does not apply		*(Eqn. 2, DCM-2)*
Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.003		*(Eqn. 1, DCM-2)*

Step 7: Adjust 1-Hr Wind Speed (over water) to Equivalent Fetch Limited Duration Wind Speed

Fetch Limited Wind Duration (in minutes), t =	49	min.	*(see Step 5)*
100-Yr, 1-Hr Wind Speed Over Water, $U_{100\text{-}yr,1\text{-}hr,water}$ =	100.0	mph	*(see Step 4)*
Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.003		*(see Step 6)*
100-Yr, Fetch Limited Wind Speed Over Water = $U_{100\text{-}yr,1\text{-}hr,water}$ x U_t/U_{3600} =	100	mph	

Step 8: Stability Correction, Adjust Wind Speed for Boundary Layer Stability

Fetch Length (in miles), X =	3.04	miles	*(see Step 4)*
(If Fetch Length > 10 miles, else enter 0) Temperature of Air, T_a =	0	°C	
(If Fetch Length > 10 miles, else enter 0) Temperature of Sea, T_s =	0	°C	
Air-Sea Temperature Difference, $\Delta T_{as} = T_a - T_s$ =	0	°C	

Stability Correction Factor, R_T

For Fetch Length < 10 miles: R_T = 1.0	applies		*(pg. II-2-36, CEM)*
For Fetch Length > 10 miles: Based on ΔT_{as}, See Figure 3-14, SPM or in absence of temperature information, assume RT = 1.1	does not apply		*(Fig.3-14, SPM)* *(pg 3-30, SPM)*
$U_{100\text{-}yr,fetch\text{-}min,water}$ =	100	mph	*(see Step 7)*
Stability Correction Factor, R_T =	1		*(pg. II-2-36, CEM)*
$U_{100\text{-}yr,fetch\text{-}min,water,\ stability\ adjusted} = U_{100\text{-}yr,fetch\text{-}min,water}$ x R_T =	100	mph	*(Eqn. 3-27 SPM)*

Step 9. Compute Wind Stress Factor, U_A

$U_{100\text{-}yr,fetch\text{-}min,water,\ stability\ adjusted} = U$ =	100	mph	*(see Step 8)*
Wind Stress Factor, $U_A = 0.589U^{1.23}$ =	170	mph	*(Eqn. 3-28b SPM)*

Step 10. Wind Stress Factor in ft/s

Wind Stress Factor, U_A (ft/s) = 1.467U_A (mph) =	250	ft/sec	*(see Step 9)*

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 1: PMP Combined with 100-Year Wind
Wind Setup and Wave Properties Analysis - Site C-43: Cell 1 (Fetch 1B)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.04	miles	*(see Step 4)*
Fetch Length, F =	16,048	ft	
100-Yr, Fetch Limited Wind Speed Over Water = $U_{100yr,fetch,over}$ =	100	mph	*(see Step 7)*
Wind Stress Factor, U_s (ft/s) =	259	ft/s	*(see Step 10)*

Step 11. Compute Deep-Water Significant Wave Height, H_{mo}

Deep-Water Significant Wave Height, $H_{mo} = (0.000282)U_s F^{1/2}$ =	8.62	feet	*(Eqn. 3-33c, SPM)*

Step 12. Compute Deep-Water Wave Period, T_o

Deep-Water Wave Period, $T_o = 0.02825(U_s F)^{1/2}$ =	4.48	sec	*(Eqn. 3-34c, SPM)*

Step 13. Compute Deep-Water Wave Length, L_o

Deep-Water Wave Length, $L_o = 5.12T_o^2$ =	103	feet	*(Eqn. 3-6b, SPM)*

Step 14. Compute Relative Depth, d/L_o

If $d/L_o \leq 0.5$, waves are classified as transitional or shallow water waves. *(pg 2-9, SPM)*
If $d/L_o > 0.5$, waves are classified as deep water. *(pg 2-9, SPM)*

Effective Depth, d =	24.35	feet	
Relative Depth = d/L_o =	0.236		*(pg 2-9, SPM)*
Wave Classification =	Transitional/Shallow-Water		*(pg 2-9, SPM)*

Step 15. Compute Shallow-Water Wave Period, T

Shallow-Water Wave Period, $T = 7.54\tanh(A)\tanh(B/C)\,U_s/g$ *(Eqn. 3-40, SPM)*

where: F = Fetch Length (ft) (step 5) U_s = Wind Stress Factor (step 10) g = 32.2 ft/s²

$A = 0.833(gd/U_s^2)^{3/4}$ =	0.1614	
$B = 0.037(gF/U_s^2)^{1/3}$ =	0.0767	
$C = \tanh(0.833(gd/U_s^2)^{3/4})$ =	0.1600	
Shallow-Water Wave Period, $T = 7.54\tanh(A)\tanh(B/C)\,U_s/g$ =	4.17 sec	*(Eqn. 3-40, SPM)*

Step 16. Compute Shallow-Water Significant Wave Height, H

Shallow-Water Significant Wave Height, $H = 0.283\tanh(A)\tanh(B/C)\,U_s^2/g$ *(Eqn. 3-39, SPM)*

where: F = Fetch Length (ft) (step 5) U_s = Wind Stress Factor (step 10) g = 32.2 ft/s²

$A = 0.530(gd/U_s^2)^{3/4}$ =	0.0139	
$B = 0.00565(gF/U_s^2)^{1/2}$ =	0.0163	
$C = \tanh(0.530(gd/U_s^2)^{3/4})$ =	0.0139	
Shallow-Water Significant Wave Height, $H = 0.283\tanh(A)\tanh(B/C)\,U_s^2/g$ =	7.35 feet	*(Eqn. 3-39, SPM)*

Step 17. Compute Zero Overwash Wave Height for Significant Wave Height

DCM-2 requires zero over wash as a design criteria for high and significant hazard dams. For purposes of the DCM-2, zero-overwash wave height is defined as the wave height with a 2% occurrence frequency.

Significant Wave Height is either the Deep-Water or Shallow-Water Significant wave height depending upon the Wave Classification (Step 14).

Significant Wave Height, H_s =	7.35	feet	*(see Step 11 or 16)*
Required probability of wave height being exceeded, n/N =	0.02		*(see Step 17 discussion)*
Root Mean Square Wave Height, $H_{rms} = 2^{-1/2}H_s$ =	5.20	feet	*(Eqn. 3-10, SPM)*
Wave Height which is exceeded at given probability, $H^* = H_{rms}[-\ln(n/N)]^{1/2}$ =	10.16	feet	*(Eqn. 3-7, SPM)*

Step 18. Compute Wind Set-Up

Four different methods are calculated and considered in estimating wind setup.
Zeider Zee Eqn: Widely used as applied to reservoirs but tends to overestimate wind setup for shallow impoundments (ave. depth<16 ft).
Sibul Eqn. Typically yields the lowest wind setup.
Ave. of Zeider Zee & Sibul: Recommended for shallow impoundments (ave. depth<16 ft) when Bretschneider has no numeric solution.
Bretschneider Eqn: Recommend for shallow impoundments (average depth <16 ft).

Fetch Length, F =	3.04	miles	*(see Step 4)*
Fetch Length, F =	16,048	feet	
Average Wind Velocity, U = Wind Speed per Step 7 = $U_{100yr,over}$ =	100	mph	*(pg A6, DCM-2)(see Step 7)*
Average Depth of Water along Fetch Line, D = Effective Depth =	24.35	feet	*(see Step 14)*
Zeider Zee Eqn (Note: F=miles): Wind Set-Up, $S = U^2F/(1400D)$ =	0.90	feet	*(Eqn. 5, DCM-2)*
Sibul Eqn (Note: F=feet, g=32.2 ft/s²): $S = 0.0000244(F/d)^{1.25}(U^2/g)^{2.5(F/d)^{-0.375}}$ =	0.23	feet	*(Eqn. 7, DCM-2)*
Average of Zeider Zee & Sibul: Wind Setup $S = (S_{Zeider\ Zee} + S_{Sibul})/2$ =	0.56	feet	
Bretschneider Eqn (Note: Calcs provided separately in Step 18a): $S = \Sigma[(KU^2Lx)/(gd^2)]$ =	n/a	feet	*(Eqn. 8, DCM-2)(Step 18a)*
Equation Used for Wind Setup *(Enter Zeider Zee, Sibul, Average, Bretschneider)* =	Zeider Zee		
Computed Wind Set-Up, S =	0.90	feet	*(Eqn. 5, DCM-2)*

Step 19. Compute Water Depth at Toe of Structure

Water Depth at Toe of Structure, d_s = Effective Depth + Wind Set-Up = d + S =	25.25	feet	*(pg. A6, DCM-2)*

Step 20. Check for Depth Limited Wave Breaking

See if wave height is limited due to breaking. After breaking, waves will tend to reform with lower heights within a few wave lengths. *(pg. 15-4, EM-1110-2-1420)*

Depth of interest is at Toe of Structure, $d_s = d_s$ =	25.25	feet	*(see Step 19)*
Wave Breaking Height, H_b (for depth d_s) = $(d_s/1.28)$ =	19.72	feet	*(Eqn. 2-91 & 3-50, SPM)*
Is max. wave height limited by breaking? (If H_s [step 20] $\leq H^*$ [step 17] then yes, else no) =	No		
(If no, wave height = H^* (step 17). If yes, conservatively assume wave height = H_b (step 20)) Maximum Wave Height =	10.16	feet	

Step 21. Estimate Ratio Between Deep-Water Wave Ht & Equivalent Deep-Water Ht

The value of H/Ho (shallow water wave height/equivalent deep water wave height) is estimated based on the value of d/L_o (effective depth / deep-water wave length) from Table C-1, SPM Vol II, Appendix C.

Effective Depth, d =	24.35	feet	*(see Step 14)*
Deep-Water Wave Length, L_o =	103	feet	*(see Step 12)*
Ratio of effective depth to deep-water wave length, d/L_o =	0.236		
H/H^*_o =	0.9279		*(Table C-1, SPM Vol 2)*

Step 22. Compute Equivalent Deep-Water Wave Height, H^*_o

If wave classification is Deep-Water (Step 14), Significant Deep-Water Height is the Equivalent Deep-Water Height.
If wave classification is Transitional/Shallow-Water an adjustment is necessary.
If Wave Breaking Height (Step 20) is less than the Zero Overwash for Significant Wave Height (Step 17) then Equivalent Deep-Water Wave Height is Wave Braking Height (irregardless of wave classification).

Wave Breaking Height, H_b =	19.72	feet	*(see Step 20)*
Significant Wave Height, H_s =	10.16	feet	*(see Step 17)*
H/H^*_o =	0.9279		*(see Step 21)*
If Shallow-Water: Equivalent Deep-Water Wave Height, $H^*o = H/(H/H^*o)$ =	10.95	feet	
If Deep Water: Equivalent Deep-Water Wave Height = Significant Deep-Water Height =	n/a	feet	
If Height Limited by Wave Breaking: Equiv. Deep-Water Wave Ht. = Wave Breaking Ht. =	n/a	feet	
Equivalent Deep-Water Wave Height =	10.95	feet	

Step 23. Compute Depth at Toe of Structure to Equiv. Deep-Water Wave Ht, d_s/H^*_o

Water Depth at Toe of Structure, d_s =	25.25	feet	*(see Step 19)*
Equivalent Deep-Water Wave Height, H^*_o =	10.95	feet	*(see Step 22)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_s/H^*_o =	2.30		

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 1: PMP Combined with 100-Year Wind
Wave Runup Analysis - Site C-43: Cell 1 (Fetch 1B)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.04	miles	*(see Step 4)*
Fetch Length, F =	16,048	feet	
100-Yr, Fetch Limited Wind Speed Over Water = $U_{(100\text{-}yr,fetch\text{-}ltd)}$ =	100	mph	*(see Step 7)*
Wind Stress Factor, U_A (ft/s) =	250	ft/s	*(see Step 10)*

Wind Setup and Wave Properties Analysis - Summary Data

Wind Set-Up , S =	0.90	feet	*(see Step 18)*
Equivalent Deep-Water Wave Height, H'_o =	10.95	feet	*(see Step 22)*
Deep-Water Wave Period, T_o =	4.49	sec	*(see Step 12)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_s/H'_o =	2.30		*(see Step 23)*

Step 24. Compute Ratio of $H'_o/(g*T_o^2)$

Equivalent Deep-Water Wave Height, H'_o =	10.95	feet	*(see Step 22)*
Gravitational Constant, g =	32.2	ft/s^2	*(constant variable)*
Deep Water Wave Period, T_o =	4.49	sec	*(see Step 12)*
$H'_o/(g*T_o^2)$ =	0.017		

Steps 25 - 27. Estimate R/H'o *(Fig. 7-8 thru 7-20, SPM Vol. 2)*

Steps 25-27 are directed towards deriving the ratio of Wave Runup to the Equivalent Deep-Water Wave Height (R/H'_o) from graphs found in SPM Volume 2 (Fig. 7-8 thru 7-20). The graphs are based upon various designs of the runup face slope including the material, roughness, slope, and geometry the face slope. In addition the value of R/H'_o depends upon the values of d_s/H'_o and $H'_o/(gT^2)$. Determination of values will typically require an interpolation of values between graphs.

d_s/H'_o =	2.30		*(see Step 23)*
$H'_o/(g*T_o^2)$ =	0.017		*(see Step 24)*
Face Slope Material =	Step-Faced Slope		*Embankment Design*
Runup Face Slope (H:1V) =	3		*Embankment Design*
Runup Face Slope (θ) =	18.4	degrees	
Figure used for Interpolation (Lower Interpolation Number) =	Fig. 7-11		*(SPM Vol. 2)*
Figure to used for Interpolation (Higher Interpolation Number) =	Fig. 7-12		*(SPM Vol. 2)*

Step 25. R/H'o from Fig. 7-11 with ds/H'o <= 2.3

$H'_o/(g*T_o^2)$ =	0.017		*(see Step 24)*
ds/H'o <=2.3 from Fig. 7-11 =	2		*(Fig. 7-11, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-11 =	0.78		*(Fig. 7-11, SPM Vol. 2)*

Step 26. R/H'o from Fig. 7-12 with ds/H'o >= 2.3

$H'_o/(g*T_o^2)$ =	0.017		*(see Step 24)*
ds/H'o >=2.3 from Fig. 7-12 =	3.0		*(Fig. 7-12, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-12 =	1.00		*(Fig. 7-12, SPM Vol. 2)*

Step 27. Estimated Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o

d_s/H'_o =	2.30		*(see Step 23)*
$H'_o/(g*T_o^2)$ =	0.017		*(see Step 24)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o =	0.85		*(Interpolated from Steps 25 & 26)*

Step 28. Compute Smooth Surface Wave Runup

Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'_o =	0.85		*(see Step 27)*
Equivalent Deep-Water Wave Height, H'_o =	10.95		*(see Step 22)*
Smooth Surface Wave Runup = R/H'_o x H'_o =	9.30	feet	

Step 29. If Applicable, Determine and Apply Wave Runup Correction Factor due to Scale Effects

This step applies if Figures 7-8 thru 7-12 or Figures 7-14 thru 7-18 were used to estimate R/H'_o in Steps 25-27. These figures summarize results for small-scale lab tests. Due to the inability to scale roughness effects in small-scale lab tests, the results are probably smaller than the runup on prototype structures. Figure 7-13 is used to adjust for this scale effect.

Smooth Surface Wave Runup = R/H'_o x H'_o =	9.30	feet	*(see Step 28)*
Scale Wave Runup Correction due to Scale Effects *(If Fig. 7-19 or 7-20 used, enter 1)* =	1.12		*(Fig. 7-13, SPM Vol. 2)*
Scale Corrected Wave Runup Height = (Smooth Surface Wave Runup)(Runup Correction) =	10.42	feet	

Step 30. Determine and Apply Correction Factor due to Dam Surface Roughness

Face Slope Material =	Step-Faced Slope		*(see Step 25)*
Surface Roughness Correction =	0.7		*(Table 7-2, SPM Vol 2) or (Table 2-2 EM1110-2-1614)*
Scale Corrected Wave Runup Height =	10.42	feet	*(see Step 29)*
Corrected Wave Runup = (Scale Corrected Wave Runup)(Surface Roughness Correction) =	7.29	feet	

Step 31. Correction Due to to Fetch Axis Not Being Normal to the Dam Axis

Angle Between Fetch Axis and Embankment Axis =	7	degrees	
Angle Correction Factor =	0.98		*(Fig. 8, ACER TM No. 11)*

Step 32. Adjusted Wave Runup

Corrected Wave Runup =	7.29		*(see Step 30)*
Angle Correction Factor =	0.98		*(see Step 31)*
Final Adjusted Wave Runup = (Corrected Wave Runup)(Angle Correction Factor) =	7.1	feet	

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 1: PMP Combined with 100-Year Wind
Minimum Required Freeboard - Site C-43: Cell 1 (Fetch 1B)

Step 33. Minimum Required Design Freeboard

Design Precipitation **or** Flood Surge Depth (Routed Flood Event) =	4.13	ft	*(based upon max. water surface elevation of routed storm event)*
Wind Setup =	0.90	ft	*(see Step 18)*
Wave Height & Runup =	7.15	ft	*(see Step 32)*
Waves Induced by Potential Landslides =	0.00	ft	*(not considered)*
Provision for Malfunction of the Spillway or Discharge Structure =	0.00	ft	*(not considered)*
Summation of all above Freeboard Components is Minimum Required Freeboard =	12.18	ft	*(rounded up to the next 0.01 foot)*

Step 34. Minimum Required Design Freeboard with Camber

Average Normal Full Storage Depth =	20.22	ft	*(Average Depth along Fetch based on NFSL = 42 ft El.)*
Minimum Required Freeboard =	12.18	ft	*(see Step 33)*
Embankment Height (not including camber) =	32.40	ft	*(summation of average normal full storage depth and freeboard)*
Minimum Required Freeboard =	12.18	ft	*(see Step 33)*
Embankment Settlement =	1.15	ft	*(see Technical Memorandum Table 3 or BODR Section 8E.)*
Minimum Embankment Height (with camber) =	33.55	ft	*(minimum embankment height plus settlement)*
Minimum Required Design Freeboard with Camber =	13.33	ft	*(rounded up to the next 0.01 foot)*

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

Case 2: 100-Year Precipitation Combined with Category 5 Hurricane Winds
Design Wind Speed Analysis - Site C-43: Cell 1 (Fetch 1B)

Steps 1-3: Adjustments not necessary for Case 2

Project Location =	C-43 Cell No. 1 (Fetch 1B)		
Category 5, Duration Adjusted Wind Speed (1-hr average), $U_{Cat5,1\text{-}hr}$ =	125.0	mph	*(Table DCM 2-3, DCM-2)*

The Category 5 wind speed from Table DCM 2-3, DCM-2 corresponds to an over-water wind speed per DCM-2 page 10.

Step 4: Determine Category 5, 1-Hr Wind Speed Over Water, $U_{Cat5,1\text{-}hr,water}$

Fetch Length (in miles), X =	3.04	miles	
Wind Speed Over Water to Wind Speed Over Land Ratio, U_{Water}/U_{Land}:			
If initial data from Step 1 is over water wind speed, no conversion (Ratio = 1.0)	does not apply		*(Fig. II-2-20, CEM)*
For Fetch Length < 10 miles: U_{Water}/U_{Land} = 1.2 or 1.0	applies		*(Fig. II-2-20, CEM)*
For Fetch Length > 10 miles: See Figure II-2-7, CEM	does not apply		*(Fig. II-2-7, CEM)*
U_{water}/U_{land} =	1		*(Fig. II-2-20, CEM)*
$U_{Cat5,1\text{-}hr,land}$ =	-		*(see Step 3)*
$U_{Cat5,1\text{-}hr,water} = U_{Cat5,1\text{-}hr,land} \times (U_{water}/U_{land})$ =	125.0	mph	

Step 5: Estimate Fetch-Limited Wind Duration Time

Fetch Length (in miles), X =	3.04	miles	*(see Step 4)*
Wind Velocity (in mph), U =	125.0	mph	*(see Step 4)*
Fetch Limited Wind Duration Time, $t = 112(X^{2.67}/U^{0.34})$ =	46	min.	*(Eqn. 4, DCM-2)*
	2741	sec.	

Step 6: Estimate Ratio of Fetch Limited Duration Wind Speed and 1-Hour Wind Speed

Fetch Limited Wind Duration Time (in seconds), t =	2741	sec.	*(see Step 5)*
Equations for ratio of wind speeds to 1-hour average wind speeds, U_t/U_{3600}			
For $t \leq 3{,}600$: $U_t/U_{3600} = 1.277 + 0.296\tanh(0.9\log_{10}(45/t))$ =	applies		*(Eqn. 1, DCM-2)*
For $3{,}600 < t < 36{,}000$: $U_t/U_{3600} = -0.15\log_{10}(t)+1.5334$ =	does not apply		*(Eqn. 2, DCM-2)*
Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.004		*(Eqn. 1, DCM-2)*

Step 7: Adjust 1-Hr Wind Speed (over water) to Equivalent Fetch Limited Duration Wind Speed

Fetch Limited Wind Duration (in minutes), t =	46	min.	*(see Step 5)*
Category 5, 1-Hr Wind Speed Over Water, $U_{Cat5,1\text{-}hr,water}$ =	125.0	mph	*(see Step 4)*
Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.004		*(see Step 6)*
Category 5, Fetch Limited Wind Speed Over Water = $U_{Cat5,1\text{-}hr,water} \times U_t/U_{3600}$ =	125	mph	

Step 8: Stability Correction, Adjust Wind Speed for Boundary Layer Stability

Fetch Length (in miles), X =	3.04	miles	*(see Step 4)*
(If Fetch Length > 10 miles, else enter 0) Temperature of Air, T_a =	0	°C	
(If Fetch Length > 10 miles, else enter 0) Temperature of Sea, T_s =	0	°C	
Air-Sea Temperature Difference, ΔT_{as} $T_a - T_s$ =	0	°C	
Stability Correction Factor, R_T			
For Fetch Length < 10 miles: R_T = 1.0	applies		*(pg. II-2-36, CEM)*
For Fetch Length > 10 miles: Based on ΔT_{as} See Figure 3-14, SPM or in absence of temperature information, assume RT = 1.1	does not apply		*(Fig.3-14, SPM)* *(pg 3-30, SPM)*
$U_{Cat5,fetch\text{-}min,water}$ =	125	mph	*(see Step 7)*
Stability Correction Factor, R_T =	1		*(pg. II-2-36, CEM)*
$U_{Cat5,fetch\text{-}min,water,\ stability\ adjusted} = U_{Cat5,fetch\text{-}min,water} \times R_T$ =	125	mph	*(Eqn. 3-27 SPM)*

Step 9. Compute Wind Stress Factor, U_A

$U_{Cat5,fetch\text{-}min,water,\ stability\ adjusted} = U$ =	125	mph	*(see Step 8)*
Wind Stress Factor, $U_A = 0.589U^{1.23}$ =	225	mph	*(Eqn. 3-28b SPM)*

Step 10. Wind Stress Factor in ft/s

Wind Stress Factor, U_A (ft/s) = $1.467U_A$ (mph) =	329	ft/sec	*(see Step 9)*

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 2: 100-Year Precipitation Combined with Category 5 Hurricane Winds
Wind Setup and Wave Properties Analysis - Site C-43; Cell 1 (Fetch 18)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.04	miles	*(see Step 4)*
Fetch Length, F =	16,048	ft	
Category 5, Fetch Limited Wind Speed Over Water = $U_{(F=5,fetch,over)}$ =	125	mph	*(see Step 7)*
Wind Stress Factor, U_* (ft/s) =	329	ft/s	*(see Step 10)*

Step 11. Compute Deep-Water Significant Wave Height, H_{mo}

Deep-Water Significant Wave Height, H_{mo} = (0.000282)$U_*F^{1/2}$ =	11.77	feet	*(Eqn. 3-33c, SPM)*

Step 12. Compute Deep-Water Wave Period, T_o

Deep-Water Wave Period, T_o = 0.02825$(U_*F)^{1/2}$ =	4.92	sec	*(Eqn. 3-34c, SPM)*

Step 13. Compute Deep-Water Wave Length, L_o

Deep-Water Wave Length, L_o = 5.12T_o^2 =	124	feet	*(Eqn. 2-6b, SPM)*

Step 14. Compute Relative Depth, d/L_o

If $d/L_o \leq 0.5$, waves are classified as transitional or shallow water waves. *(pg 2-9, SPM)*
If $d/L_o > 0.5$, waves are classified as deep water. *(pg 2-9, SPM)*

Effective Depth, d =	20.99	feet	
Relative Depth = d/L_o =	0.169		*(pg 2-9, SPM)*
Wave Classification =	Transitional/Shallow Water		*(pg 2-9, SPM)*

Step 15. Compute Shallow-Water Wave Period, T

Shallow-Water Wave Period, T = 7.54 tanh(A) tanh(B/C) U_*/g *(Eqn. 3-40, SPM)*

where: F = Fetch Length (ft) (step 5) U_* = Wind Stress Factor (step 10) g = 32.2 ft/s²

A = 0.833$(gd/U_*^2)^{3/4}$ =	0.1240		
B = 0.0379$(gF/U_*^2)^{1/3}$ =	0.0630		
C = tanh(0.833$(gd/U_*^2)^{3/4}$] =	0.1234		
Shallow-Water Wave Period, T = 7.54 tanh(A) tanh(B/C) U_*/g =	4.82	sec	*(Eqn. 3-40, SPM)*

Step 16. Compute Shallow-Water Significant Wave Height, H

Shallow-Water Significant Wave Height, H = 0.283 tanh(A) tanh(B/C) U_*^2/g *(Eqn. 3-39, SPM)*

where: F = Fetch Length (ft) (step 5) U_* = Wind Stress Factor (step 10) g = 32.2 ft/s²

A = 0.530$(gd/U_*^2)^{3/4}$ =	0.0118		
B = 0.00565$(gF/U_*^2)^{1/2}$ =	0.0123		
C = tanh(0.530$(gd/U_*^2)^{3/4}$] =	0.0118		
Shallow-Water Significant Wave Height, H = 0.283 tanh(A) tanh(B/C) U_*^2/g =	0.76	feet	*(Eqn. 3-39, SPM)*

Step 17. Compute Shallow-Water Wave Height for Zero Overwash

DCM-2 requires zero over wash as a design criteria for high and significant hazard dams. For purposes of the DCM-2, zero overwash wave height is defined as the wave height with a 2% occurrence frequency.

Significant Wave Height is either the Deep-Water or Shallow-Water Significant wave height
Depending upon the Wave Classification (Step 14).

Significant Wave Height, H_s =	0.76	feet	*(see Step 11 or 16)*
Required probability of wave height being exceeded, n/N =	0.02		*(see Step 17 discussion)*
Root Mean Square Wave Height, $H_{rms} = 2^{-1/2}H_s$ =	0.19	feet	*(Eqn. 3-10, SPM)*
Wave Height which is exceeded at given probability, $H^* = H_{rms}[-Ln(n/N)]^{1/2}$ =	12.11	feet	*(Eqn. 3-7, SPM)*

Step 18. Compute Wind Set-Up

Four different methods are calculated and considered in estimating wind setup:
Zeider Zee Eqn: Widely used as applied to reservoirs but tends to overestimate wind setup for shallow impoundments (ave. depth<16 ft).
Sibul Eqn: Typically yields the lowest wind setup.
Ave. of Zeider Zee & Sibul: Recommended for shallow impoundments (ave. depth<16 ft) when Bretschneider has no numeric solution.
Bretschneider Eqn: Recommend for shallow impoundments (average depth <16 ft).

Fetch Length, F =	3.04	miles	*(see Step 4)*
Fetch Length, F =	16,048	feet	
Average Wind Velocity, U = Wind Speed per Step 7 = $U_{(F=5,over)}$ =	125	mph	*(pg A6, DCM-2)(see Step 7)*
Average Depth of Water along Fetch Line, D = Effective Depth =	20.99	feet	*(see Step 14)*
Zeider Zee Eqn: (Note: F=miles): Wind Set-Up, S = $U^2F/(1400D)$ =	1.63	feet	*(Eqn. 5, DCM-2)*
Sibul Eqn (Note: F=feet, g=32.2 ft/s²): S = $0.0000244d(F/d)^{1.45}(U^2/g)^{(2.02F/d^{0.23})}$ =	0.45	feet	*(Eqn. 7, DCM-2)*
Average of Zeider Zee & Sibul: Wind Setup, S = $(S_{Zeider\ Zee} + S_{Sibul})/2$ =	1.04	feet	
Bretschneider Eqn (Note: Calcs provided separately in Step 18a): S = $\Sigma[(KU^2/\pi)(gd/\pi)]$ =	n/a	feet	*(Eqn. 6, DCM-2)(Step 18a)*
Equation Used for Wind Setup *(Enter Zeider Zee, Sibul, Average, Bretschneider)* =	Zeider Zee		
Computed Wind Set-Up, S =	1.63	feet	*(Eqn. 5, DCM-2)*

Step 19. Compute Water Depth at Toe of Structure

Water Depth at Toe of Structure, d_s = Effective Depth + Wind Set-Up = d + S =	22.62	feet	*(pg. A6, DCM-2)*

Step 20. Check for Depth Limited Wave Breaking

See if wave height is limited due to breaking. After breaking, waves will tend to reform with lower heights within a few wave lengths. *(pg. 15-4, EM-1110-2-1420)*

Depth of Interest is at Toe of Structure, d_s = d_s =	22.62	feet	*(see Step 19)*
Wave Breaking Height, H_b *(for depth d_s)* = $(d_s/1.28)$ =	17.67	feet	*(Eqn. 2-91 & 3-90, SPM)*
Is max. wave height limited by breaking? *(If H_s (step 20) $\leq H^*$ (step 17) then yes, else no)* =	No		
(If no, wave height = H^* (step 17). If yes, conservatively assume wave height = H_b (step 20)) Maximum Wave Height =	12.11	feet	

Step 21. Estimate Ratio Between Deep-Water Wave Ht & Equivalent Deep-Water Ht

The value of H/Ho (shallow-water wave height/equivalent deep-water wave height), is estimated based on the value of d/L_o (effective depth / deep-water wave length) from Table C-1, SPM Vol II, Appendix C.

Effective Depth, d =	20.99	feet	*(see Step 14)*
Deep-Water Wave Length, L_o =	124	feet	*(see Step 13)*
Ratio of effective depth to deep-water wave length, d/L_o =	0.169		
H/H'_o =	0.9133		*(Table C-1, SPM Vol 2)*

Step 22. Compute Equivalent Deep-Water Wave Height, H'_o

If wave classification is Deep-Water (Step 14), Significant Deep-Water Height is the Equivalent Deep-Water Height.
If wave classification is Transitional/Shallow-Water an adjustment is necessary.
If Wave Breaking Height (Step 20) is less than the Zero Overwash for Significant Wave Height (Step 17)
then Equivalent Deep-Water Wave Height is Wave Braking Height (irregardless of wave classification).

Wave Breaking Height, H_b =	17.67	feet	*(see Step 20)*
Significant Wave Height, H_s =	12.11	feet	*(see Step 17)*
H/H'_o =	0.9133		*(see Step 21)*
If Shallow-Water: Equivalent Deep-Water Wave Height, $H'o = H(H/H'o)$ =	13.26	feet	
If Deep Water: Equivalent Deep-Water Wave Height = Significant Deep-Water Height =	n/a	feet	
If Height Limited by Wave Breaking: Equiv. Deep-Water Wave Ht. = Wave Breaking Ht. =	n/a	feet	
Equivalent Deep-Water Wave Height =	13.26	feet	

Step 23. Compute Depth at Toe of Structure to Equiv. Deep-Water Wave Ht, d_s/H'_o

Water Depth at Toe of Structure, d_s =	22.62	feet	*(see Step 19)*
Equivalent Deep-Water Wave Height, H'_o =	13.26	feet	*(see Step 22)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_s/H'_o =	1.71		

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 2: 100-Year Precipitation Combined with Category 5 Hurricane Winds
Wave Runup Analysis - Site C-43: Cell 1 (Fetch 1B)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.04	miles	*(see Step 4)*
Fetch Length, F =	16,048	feet	
Category 5, Fetch Limited Wind Speed Over Water = $U_{CAT5,fetch-min}$ =	125	mph	*(see Step 7)*
Wind Stress Factor, U_A (ft/s) =	329	ft/s	*(see Step 10)*

Wind Setup and Wave Properties Analysis - Summary Data

Wind Set-Up , S =	1.63	feet	*(see Step 18)*
Equivalent Deep-Water Wave Height, H'_o =	13.26	feet	*(see Step 22)*
Deep-Water Wave Period, T_o =	4.92	sec	*(see Step 12)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_s/H'_o =	1.71		*(see Step 23)*

Step 24. Compute Ratio of $H'_o/(gT_o^2)$

Equivalent Deep-Water Wave Height, H'_o =	13.26	feet	*(see Step 22)*
Gravitational constant, g =	32.2	ft/s^2	*(constant variable)*
Deep Water Wave Period, T_o =	4.92	sec	*(see Step 12)*
$H'_o/(gT_o^2)$ =	0.017		

Steps 25 - 27. Estimate R/H'o *(Fig. 7-8 thru 7-20, SPM Vol. 2)*

Steps 25-27 are directed towards deriving the ratio of Wave Runup to the Equivalent Deep-Water Wave Height (R/H'_o) from graphs found in SPM Volume 2 (Fig. 7-8 thru 7-20). The graphs are based upon various designs of the runup face slope including the material, roughness, slope, and geometry the face slope. In addition the value of R/H'_o depends upon the values of d_s/H'_o and $H'_o/(gT^2)$. Determination of values will typically require an interpolation of values between graphs.

d_s/H'_o =	1.71		*(see Step 23)*
$H'_o/(gT_o^2)$ =	0.017		*(see Step 24)*
Face Slope Material =	Step-Faced Slope		*Embankment Design*
Runup Face Slope (H:1V) =	3		*Embankment Design*
Runup Face Slope (Θ) =	18.4	degrees	
Figure used for Interpolation (Lower Interpolation Number) =	Fig. 7-10		*(SPM Vol. 2)*
Figure to used for Interpolation (Higher Interpolation Number) =	Fig. 7-11		*(SPM Vol. 2)*

Step 25. R/H'o from Fig. 7-10 with ds/H'o <= 1.71

$H'_o/(gT_o^2)$ =	0.017		*(see Step 24)*
ds/H'o <=1.71 from Fig. 7-10 =	0.8		*(Fig. 7-10, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-10 =	0.63		*(Fig. 7-10, SPM Vol. 2)*

Step 26. R/H'o from Fig. 7-11 with ds/H'o >= 1.71

$H'_o/(gT_o^2)$ =	0.017		*(see Step 24)*
ds/H'o >=1.71 from Fig. 7-11 =	2.0		*(Fig. 7-11, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-11 =	0.78		*(Fig. 7-11, SPM Vol. 2)*

Step 27. Estimated Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o

d_s/H'_o =	1.71		*(see Step 23)*
$H'_o/(gT_o^2)$ =	0.017		*(see Step 24)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o =	0.74		*(Interpolated from Steps 25 & 26)*

Step 28. Compute Smooth Surface Wave Runup

Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'_o =	0.74		*(see Step 27)*
Equivalent Deep-Water Wave Height, H'_o =	13.26		*(see Step 22)*
Smooth Surface Wave Runup = R/H'_o x H'_o =	9.90	feet	

Step 29. If Applicable, Determine and Apply Wave Runup Correction Factor due to Scale Effects

This step applies if Figures 7-8 thru 7-12 or Figures 7-14 thru 7-16 were used to estimate R/H'_o in Steps 25-27. These figures summarize results for small-scale lab tests. Due to the inability to scale roughness effects in small-scale lab tests, the results are probably smaller than the runup on prototype structures. Figure 7-13 is used to adjust for this scale effect.

Smooth Surface Wave Runup = R/H'_o x H'_o =	9.90	feet	*(see Step 28)*
Scale Wave Runup Correction due to Scale Effects *(If Fig. 7-19 or 7-20 used, enter 1)* =	1.12		*(Fig. 7-13, SPM Vol. 2)*
Scale Corrected Wave Runup Height = (Smooth Surface Wave Runup)(Runup Correction) =	11.09	feet	

Step 30. Determine and Apply Correction Factor due to Dam Surface Roughness

Face Slope Material =	Step-Faced Slope		*(see Step 25)*
Surface Roughness Correction =	0.7		*(Table 7-2, SPM Vol 2) or (Table 2-2 EM1110-2-1614)*
Scale Corrected Wave Runup Height =	11.09	feet	*(see Step 29)*
Corrected Wave Runup = (Scale Corrected Wave Runup)(Surface Roughness Correction) =	7.76	feet	

Step 31. Correction Due to to Fetch Axis Not Being Normal to the Dam Axis

Angle Between Fetch Axis and Embankment Axis =	7	degrees	
Angle Correction Factor =	0.98		*(Fig. 8, ACER TM No. 11)*

Step 32. Adjusted Wave Runup

Corrected Wave Runup =	7.76		*(see Step 30)*
Angle Correction Factor =	0.98		*(see Step 31)*
Final Adjusted Wave Runup = (Corrected Wave Runup)(Angle Correction Factor) =	7.6	feet	

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 2: 100-Year Precipitation Combined with Category 5 Hurricane Winds
Minimum Required Freeboard - Site C-43: Cell 1 (Fetch 1B)

Step 33. Minimum Required Design Freeboard

Design Precipitation **or** Flood Surge Depth (Routed Flood Event) =	0.77	ft	*(based upon max. water surface elevation of routed storm event)*
Wind Setup =	1.63	ft	*(see Step 18)*
Wave Height & Runup =	7.61	ft	*(see Step 32)*
Waves Induced by Potential Landslides =	0.00	ft	*(not considered)*
Provision for Malfunction of the Spillway or Discharge Structure =	0.00	ft	*(not considered)*
Summation of all above Freeboard Components is Minimum Required Freeboard =	10.01	ft	*(rounded up to the next 0.01 foot)*

Step 34. Minimum Required Design Freeboard with Camber

Average Normal Full Storage Depth =	20.22	ft	*(Average Depth along Fetch based on NFSL = 42 ft El.)*
Minimum Required Freeboard =	10.01	ft	*(see Step 33)*
Embankment Height (not including camber) =	30.23	ft	*(summation of average normal full storage depth and freeboard)*
Minimum Required Freeboard =	10.01	ft	*(see Step 33)*
Embankment Settlement =	0.96	ft	*(see Technical Memorandum Table 3 or BODR Section 8E.)*
Minimum Embankment Height (with camber) =	31.19	ft	*(minimum embankment height plus settlement)*
Minimum Required Design Freeboard with Camber =	10.97	ft	*(rounded up to the next 0.01 foot)*

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

Case 3: Probable Maximum Wind Speed Combined with Normal Full Storage Level (Uncontrolled Spillway Level)
Design Wind Speed Analysis - Site C-43: Cell 1 (Fetch 1B)

Steps 1-2: Not necessary for Case 3

Project Location =	C-43 Cell No. 1 (Fetch 1B)		
Probable Maximum Wind (PMW) Speed, $U_{PMW,60\text{-}sec,water}$ =	200.0	mph	*(pg 13, DCM-2)*

For Case 3, the 200 mph assumed PMW corresponds to an over-water 1-minute average wind speed. *(pg 13, DCM-2)*

Step 3: Determine PMW, 1-Hr Wind Speed, $U_{PMW,\ 1\text{-}hr}$

Initial wind speed duration, t =	60	sec.	*(based on Step 1 Data)*

Equations for ratio of wind speeds to 1-hour average wind speeds, U_t/U_{3600}

For $t \leq 3{,}600$: $U_t/U_{3600} = 1.277 + 0.296\tanh(0.9\log_{10}(45/t))$ =	applies		*(Eqn. 1, DCM-2)*
For $3{,}600 < t < 36{,}000$: $U_t/U_{3600} = -0.15\log_{10}(t)+1.5334$ =	does not apply		*(Eqn. 2, DCM-2)*
U_t/U_{3600} =	1.24		*(Eqn. 1, DCM-2)*
$U_t = U_{PMW,\ 60\text{-}sec}$ =	200.00	mph	*(see Step 2)*
$U_{PMW,\ 3600\text{-}sec} = U_{PMW,\ 1\text{-}hr} = U_t/(U_t/U_{3600})$ =	160.8	mph	

Step 4: Determine PMW, 1-Hr Wind Speed Over Water, $U_{PMW,1\text{-}hr,water}$

Fetch Length (in miles), X =	3.04	miles	

Wind Speed Over Water to Wind Speed Over Land Ratio, U_{Water}/U_{Land}:

If initial data from Step 1 is over water wind speed, no conversion (Ratio = 1.0)	does not apply		*(Fig. II-2-20, CEM)*
For Fetch Length < 10 miles: U_{Water}/U_{Land} = 1.2 or 1.0	applies		*(Fig. II-2-20, CEM)*
For Fetch Length > 10 miles: See Figure II-2-7, CEM	does not apply		*(Fig. II-2-7, CEM)*
U_{water}/U_{land} =	1		*(Fig. II-2-20, CEM)*
$U_{PMW,1\text{-}hr,land}$ =	-		*(see Step 3)*
$U_{PMW,1\text{-}hr,water} = U_{PMW,1\text{-}hr,land} \times (U_{water}/U_{land})$ =	160.8	mph	

Step 5: Estimate Fetch-Limited Wind Duration Time

Fetch Length (in miles), X =			
Wind Velocity (in mph), U =	160.8	mph	*(see Step 4)*
Fetch Limited Wind Duration Time, $t = 112(X^{0.67}/U^{0.34})$ =	42	min.	*(Eqn. 4, DCM-2)*
	2516	sec.	

Step 6: Estimate Ratio of Fetch Limited Duration Wind Speed and 1-Hour Wind Speed

Fetch Limited Wind Duration Time (in seconds), t =	2516	sec.	*(see Step 5)*

Equations for ratio of wind speeds to 1-hour average wind speeds, U_t/U_{3600}

For $t \leq 3{,}600$: $U_t/U_{3600} = 1.277 + 0.296\tanh(0.9\log_{10}(45/t))$ =	applies		*(Eqn. 1, DCM-2)*
For $3{,}600 < t < 36{,}000$: $U_t/U_{3600} = -0.15\log_{10}(t)+1.5334$ =	does not apply		*(Eqn. 2, DCM-2)*
Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.005		*(Eqn. 1, DCM-2)*

Step 7: Adjust 1-Hr Wind Speed (over water) to Equivalent Fetch Limited Duration Wind Speed

Fetch Limited Wind Duration (in minutes), t =	42	min.	*(see Step 5)*
PMW, 1-Hr Wind Speed Over Water, $U_{PMW,1\text{-}hr,water}$ =	160.8	mph	*(see Step 4)*
Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.005		*(see Step 6)*
PMW, Fetch Limited Wind Speed Over Water = $U_{PMW,1\text{-}hr,water} \times U_t/U_{3600}$ =	162	mph	

Step 8: Stability Correction, Adjust Wind Speed for Boundary Layer Stability

Fetch Length (in miles), X =	3.04	miles	*(see Step 4)*
(If Fetch Length > 10 miles, else enter 0) Temperature of Air, T_a =	0	o C	
(If Fetch Length > 10 miles, else enter 0) Temperature of Sea, T_s =	0	o C	
Air-Sea Temperature Difference, ΔT_{as} $T_a - T_s$ =	0	°C	

Stability Correction Factor, R_T

For Fetch Length < 10 miles: R_T = 1.0	applies		*(pg. II-2-36, CEM)*
For Fetch Length > 10 miles: Based on ΔT_{as}, See Figure 3-14, SPM or in absence of temperature information, assume RT = 1.1	does not apply		*(Fig.3-14, SPM)* *(pg 3-30, SPM)*
$U_{PMW,1\text{-}min,water}$ =	162	mph	*(see Step 7)*
Stability Correction Factor, R_T =	1		*(pg. II-2-36, CEM)*
$U_{PMW,fetch\text{-}min,water,\ stability\ adjusted} = U_{PMW,fetch\text{-}min,water} \times R_T$ =	162	mph	*(Eqn. 3-27 SPM)*

Step 9. Compute Wind Stress Factor, U_A

$U_{PMW,fetch\text{-}min,water,\ stability\ adjusted} = U$ =	162	mph	*(see Step 8)*
Wind Stress Factor, $U_A = 0.589U^{1.23}$ =	307	mph	*(Eqn. 3-28b SPM)*

Step 10. Wind Stress Factor in ft/s

Wind Stress Factor, U_A (ft/s) = $1.467U_A$ (mph) =	450	ft/sec	*(see Step 9)*

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 3: Probable Maximum Wind Speed Combined with Normal Full Storage Level (Uncontrolled Spillway Level)
Wind Setup and Wave Properties Analysis - Site C-43: Cell 1 (Fetch 1B)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.04	miles	*(see Step 5)*
Fetch Length, F =	16,048	ft	
PMW, Fetch Limited Wind Speed Over Water = $U_{PMW(fetch-lim)}$ =	162	mph	*(see Step 7)*
Wind Stress Factor, U_* (ft/s) =	450	ft/s	*(see Step 10)*

Step 11. Compute Deep-Water Significant Wave Height, H_{mo}

Deep-Water Significant Wave Height, $H_{mo} = [0.0002821]U_*F^{1/2}$ = 16.07 feet *(Eqn. 3-33c, SPM)*

Step 12. Compute Deep-Water Wave Period, T_o

Deep-Water Wave Period, $T_o = 0.02825(U_*F)^{1/2}$ = 5.46 sec *(Eqn. 3-34c, SPM)*

Step 13. Compute Deep-Water Wave Length, L_o

Deep-Water Wave Length, $L_o = 5.12T_o^2$ = 153 feet *(Eqn. 3-8b, SPM)*

Step 14. Compute Relative Depth, d/L_o

If $d/L_o \leq 0.5$, waves are classified as transitional or shallow water waves. *(pg 2-9, SPM)*
If $d/L_o > 0.5$, waves are classified as deep water. *(pg 2-9, SPM)*

Effective Depth, d =	20.22	feet	
Relative Depth = d/L_o =	0.132		*(pg 2-9, SPM)*
Wave Classification =	Transitional/Shallow-Water		*(pg 2-9, SPM)*

Step 15. Compute Shallow-Water Wave Period, T

Shallow-Water Wave Period, $T = 7.54 \tanh(A) \tanh(B/C)\, U_*/g$ *(Eqn. 3-40, SPM)*

where: F = Fetch Length (ft) (step 5) U_* = Wind Stress Factor (step 10) g = 32.2 ft/s²

$A = 0.833(gd/U_*^2)^{3/8}$ =	0.0659
$B = 0.0379(gF/U_*^2)^{1/3}$ =	0.9510
$C = \tanh(0.833(gd/U_*^2)^{3/8})$ =	0.0665
Shallow-Water Wave Period, $T = 7.54 \tanh(A) \tanh(B/C)\, U_*/g$ =	4.99 sec *(Eqn. 3-40, SPM)*

Step 16. Compute Shallow-Water Significant Wave Height, H

Shallow-Water Significant Wave Height, $H = 0.283 \tanh(A) \tanh(B/C)\, U_*^2/g$ *(Eqn. 3-39, SPM)*

where: F = Fetch Length (ft) (step 5) U_* = Wind Stress Factor (step 10) g = 32.2 ft/s²

$A = 0.530(gd/U_*^2)^{3/4}$ =	0.0072
$B = 0.00565(gF/U_*^2)^{1/2}$ =	0.0690
$C = \tanh(0.530(gd/U_*^2)^{3/4})$ =	0.0072
Shallow-Water Significant Wave Height, $H = 0.283 \tanh(A) \tanh(B/C)\, U_*^2/g$ =	10.84 feet *(Eqn. 3-39, SPM)*

Step 17. Compute Shallow-Water Wave Height for Zero Overwash

DCM-2 requires zero over wash as a design criteria for high and significant hazard dams. For purposes of the DCM-2, zero overwash wave height is defined as the wave height with a 2% occurrence frequency.

Significant Wave Height is either the Deep-Water or Shallow-Water Significant wave height
Depending upon the Wave Classification (Step 14).

Significant Wave Height, H_s =	10.84	feet	*(see Step 11 or 16)*
Required probability of wave height being exceeded, risk =	0.02		*(see Step 17 discussion)*
Root Mean Square Wave Height, $H_{rms} = 2^{-1/2}H_s$ =	7.67	feet	*(Eqn. 3-10, SPM)*
Wave Height which is exceeded at given probability, $H^* = H_{rms}[-\ln(risk)]^{1/2}$ =	14.99	feet	*(Eqn. 3-7, SPM)*

Step 18. Compute Wind Set-Up

Four different methods are calculated and considered in estimating wind setup
Zeider Zee Eqn: Widely used as applied to reservoirs but tends to overestimate wind setup for shallow impoundments (ave. depth<16 ft).
Sibul Eqn: Typically yields the lowest wind setup.
Ave. of Zeider Zee & Sibul: Recommended for shallow impoundments (ave. depth<16 ft) when Bretschneider has no numeric solution.
Bretschneider Eqn: Recommend for shallow impoundments (average depth <16 ft).

Fetch Length, F =	3.04	miles	*(see Step 5)*
Fetch Length, F =	16,048	feet	
Average Wind Velocity, U = Wind Speed per Step 7 = $U_{PMW(fetch-lim)}$ =	162	mph	*(pg A6, DCM-2)(see Step 7)*
Average Depth of Water along Fetch Line, D = Effective Depth =	20.22	feet	*(see Step 14)*
Zeider Zee Eqn (Note: F=miles): Wind Set-Up, $S = U^2F/(1400D)$ =	2.81	feet	*(Eqn. 5, DCM-2)*
Sibul Eqn (Note: F=feet, g=32.2 ft/s²): $S = 0.0600244e(F/g)^{4/5}(U^2/g)^{2.02(F/g)^{-0.225}}$ =	0.67	feet	*(Eqn. 7, DCM-2)*
Average of Zeider Zee & Sibul: Wind Setup, $S = (S_{Zeider\ Zee} + S_{Sibul})/2$ =	1.64	feet	
Bretschneider Eqn (Note: Calcs provided separately in Step 18a): $S = 3.5[(kU^2/s)^2/(gF)^2]$ =	n/a	feet	*(Eqn. 6, DCM-2)(Step 18a)*
Equation Used for Wind Setup *(Enter Zeider Zee, Sibul, Average, Bretschneider)* =	Zeider Zee		
Computed Wind Set-Up, S =	2.81	feet	*(Eqn. 5, DCM-2)*

Step 19. Compute Water Depth at Toe of Structure

Water Depth at Toe of Structure, d_s = Effective Depth + Wind Set-Up = d + S = 23.03 feet *(pg. A6, DCM-2)*

Step 20. Check for Depth Limited Wave Breaking

See if wave height is limited due to breaking. After breaking, waves will tend to reform with lower heights within a few wave lengths. *(pg. 15-4, EM-1110-2-1420)*

Depth of interest is at Toe of Structure, $d_i = d_s$ =	23.03	feet	*(see Step 19)*
Wave Breaking Height, H_b (for depth d_s) = $(d_s/1.28)$ =	17.99	feet	*(Eqn. 2-91 & 3-30, SPM)*
Is max. wave height limited by breaking? (If H_b [step 20] $\leq H^*$ [step 17] then yes, else no) =	No		
(If no, wave height = H^* (step 17). If yes, conservatively assume wave height = H_b (step 20)) Maximum Wave Height =	14.99	feet	

Step 21. Estimate Ratio Between Deep-Water Wave Ht & Equivalent Deep-Water Ht

The value of H/H'o (shallow-water wave height:equivalent deep water wave height) is estimated based on the value of d/L_o (effective depth / deep-water wave length) from Table C-1, SPM Vol II, Appendix C.

Effective Depth, d =	20.22	feet	*(see Step 14)*
Deep-Water Wave Length, L_o =	153	feet	*(see Step 13)*
Ratio of effective depth to deep-water wave length, d/L_o =	0.132		
H/H'_o =	0.9164		*(Table C-1, SPM Vol II)*

Step 22. Compute Equivalent Deep-Water Wave Height, H'_o

If wave classification is Deep-Water (Step 14), Significant Deep-Water Height is the Equivalent Deep-Water Height.
If wave classification is Transitional/Shallow-Water an adjustment is necessary.
If Wave Breaking Height (Step 20) is less than the Zero Overwash for Significant Wave Height (Step 17) then Equivalent Deep-Water Wave Height is Wave Braking Height (irregardless of wave classification).

Wave Breaking Height, H_b =	17.99	feet	*(see Step 20)*
Significant Wave Height, H_s =	14.99	feet	*(see Step 17)*
H/H'_o =	0.9164		*(see Step 21)*
If Shallow-Water: Equivalent Deep-Water Wave Height, $H'o = H/(H/H'o)$ =	16.36	feet	
If Deep Water: Equivalent Deep-Water Wave Height = Significant Deep-Water Height =	n/a	feet	
If Height Limited by Wave Breaking: Equiv. Deep-Water Wave Ht. = Wave Breaking Ht. =	n/a	feet	
Equivalent Deep-Water Wave Height =	16.36	feet	

Step 23. Compute Depth at Toe of Structure to Equiv. Deep-Water Wave Ht, d_s/H'_o

Water Depth at Toe of Structure, d_s =	23.03	feet	*(see Step 19)*
Equivalent Deep-Water Wave Height, H'_o =	16.36	feet	*(see Step 22)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_s/H'_o =	1.41		

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 3: Probable Maximum Wind Speed Combined with Normal Full Storage Level (Uncontrolled Spillway Level)
Wave Runup Analysis - Site C-43: Cell 1 (Fetch 1B)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.04	miles	*(see Step 5)*
Fetch Length, F =	16,048	feet	
PMW, Fetch Limited Wind Speed Over Water = $U_{PMW,fetch-min}$ =	162	mph	*(see Step 7)*
Wind Stress Factor, U_A (ft/s) =	450	ft/s	*(see Step 10)*

Wind Setup and Wave Properties Analysis - Summary Data

Wind Set-Up , S =	2.81	feet	*(see Step 18)*
Equivalent Deep-Water Wave Height, H'_o =	16.36	feet	*(see Step 22)*
Deep-Water Wave Period, T_o =	5.46	sec	*(see Step 12)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_s/H'_o =	1.41		*(see Step 23)*

Step 24. Compute Ratio of $H'_o/(g*T_o^2)$

Equivalent Deep-Water Wave Height, H'_o =	16.36	feet	*(see Step 22)*
Gravitational constant, g =	32.2	ft/s^2	*(constant variable)*
Deep Water Wave Period, T_o =	5.46	sec	*(see Step 12)*
$H'_o/(g*T_o^2)$ =	0.017		

Steps 25 - 27. Estimate R/H'o *(Fig. 7-8 thru 7-20, SPM Vol. 2)*

Steps 25-27 are directed towards deriving the ratio of Wave Runup to the Equivalent Deep-Water Wave Height (R/H'_o) from graphs found in SPM Volume 2 (Fig. 7-8 thru 7-20). The graphs are based upon various designs of the runup face slope including the material, roughness, slope, and geometry the face slope. In addition the value of R/H'_o depends upon the values of d_s/H'_o and $H'_o/(gT^2)$. Determination of values will typically require an interpolation of values between graphs.

d_s/H'_o =	1.41		*(see Step 23)*
$H'_o/(g*T_o^2)$ =	0.017		*(see Step 24)*
Face Slope Material =	Stone-Faced Slope		*Embankment Design*
Runup Face Slope (H:1V) =	3		*Embankment Design*
Runup Face Slope (θ) =	18.4	degrees	
Figure used for Interpolation (Lower Interpolation Number) =	Fig. 7-10		*(SPM Vol. 2)*
Figure to used for Interpolation (Higher Interpolation Number) =	Fig. 7-11		*(SPM Vol. 2)*

Step 25. R/H'o from Fig. 7-10 with ds/H'o <= 1.41

$H'_o/(g*T_o^2)$ =	0.017		*(see Step 24)*
ds/H'o <=1.41 from Fig. 7-10 =	0.8		*(Fig. 7-10, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-10 =	0.63		*(Fig. 7-10, SPM Vol. 2)*

Step 26. R/H'o from Fig. 7-11 with ds/H'o >= 1.41

$H'_o/(g*T_o^2)$ =	0.017		*(see Step 24)*
ds/H'o >=1.41 from Fig. 7-11 =	2.0		*(Fig. 7-11, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-11 =	0.78		*(Fig. 7-11, SPM Vol. 2)*

Step 27. Estimated Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o

d_s/H'_o =	1.41		*(see Step 23)*
$H'_o/(g*T_o^2)$ =	0.017		*(see Step 24)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o =	0.71		*(Interpolated from Steps 25 & 26)*

Step 28. Compute Smooth Surface Wave Runup

Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'_o =	0.71		*(see Step 27)*
Equivalent Deep-Water Wave Height, H'_o =	16.36		*(see Step 22)*
Smooth Surface Wave Runup = R/H'_o x H'_o =	11.60	feet	

Step 29. If Applicable, Determine and Apply Wave Runup Correction Factor due to Scale Effects

This step applies if Figures 7-8 thru 7-12 or Figures 7-14 thru 7-18 were used to estimate R/H'_o in Steps 25-27. These figures summarize results for small-scale lab tests. Due to the inability to scale roughness effects in small-scale lab tests, the results are probably smaller than the runup on prototype structures. Figure 7-13 is used to adjust for this scale effect.

Smooth Surface Wave Runup = R/H'_o x H'_o =	11.60	feet	*(see Step 28)*
Scale Wave Runup Correction due to Scale Effects *(If Fig. 7-19 or 7-20 used, enter 1)* =	1.12		*(Fig. 7-13, SPM Vol. 2)*
Scale Corrected Wave Runup Height = (Smooth Surface Wave Runup)(Runup Correction) =	12.99	feet	

Step 30. Determine and Apply Correction Factor due to Dam Surface Roughness

Face Slope Material =	Stone-Faced Slope		*(see Step 25)*
Surface Roughness Correction =	0.7		*(Table 7-2, SPM Vol 2) or (Table 2-2 EM1110-2-1614)*
Scale Corrected Wave Runup Height =	12.99	feet	*(see Step 29)*
Corrected Wave Runup = (Scale Corrected Wave Runup)(Surface Roughness Correction) =	9.09	feet	

Step 31. Correction Due to to Fetch Axis Not Being Normal to the Dam Axis

Angle Between Fetch Axis and Embankment Axis =	7	degrees	
Angle Correction Factor =	0.98		*(Fig. 8, ACER TM No. 11)*

Step 32. Adjusted Wave Runup

Corrected Wave Runup =	9.09		*(see Step 30)*
Angle Correction Factor =	0.98		*(see Step 31)*
Final Adjusted Wave Runup = (Corrected Wave Runup)(Angle Correction Factor) =	8.9	feet	

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 3: Probable Maximum Wind Speed Combined with Normal Full Storage Level (Uncontrolled Spillway Level)
Minimum Required Freeboard - Site C-43: Cell 1 (Fetch 1B)

Step 33. Minimum Required Design Freeboard

Design Precipitation **or** Flood Surge Depth (Routad Flood Event) =	0.00	ft	*(no surcharge, normal full storage level elevation assumed)*
Wind Setup =	2.61	ft	*(see Step 18)*
Wave Height & Runup =	8.91	ft	*(see Step 32)*
Waves Induced by Potential Landslides =	0.00	ft	*(not considered)*
Provision for Malfunction of the Spillway or Discharge Structure =	0.00	ft	*(not considered)*
Summation of all above Freeboard Components is Minimum Required Freeboard =	11.72	ft	*(rounded up to the next 0.01 foot)*

Step 34. Minimum Required Design Freeboard with Camber

Average Normal Full Storage Depth =	20.22	ft	*(Average Depth along Fetch based on NFSL = 42 ft El.)*
Minimum Required Freeboard =	11.72	ft	*(see Step 33)*
Embankment Height (not including camber) =	31.94	ft	*(summation of average normal full storage depth and freeboard)*
Minimum Required Freeboard =	11.72	ft	*(see Step 33)*
Embankment Settlement =	1.06	ft	*(see Technical Memorandum Table 3 or BODR Section 8E)*
Minimum Embankment Height (with camber) =	33.00	ft	*(minimum embankment height plus settlement)*
Minimum Required Design Freeboard with Camber =	12.78	ft	*(rounded up to the next 0.01 foot)*

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

Case 4: Hurricane Easy (125 mph, 3-sec Gust Wind Speed Combined With Both 24-hr (38.7") & 72 hr (45.2") Rainfall Durations)
Design Wind Speed Analysis - Site C-43: Cell 1 (Fetch 1B)

Step 1-2: Select EASY, 3-Sec Gust Wind Speed, $U_{EASY,3\text{-}sec}$

Project Location =	C-43 Cell No. 1 (Fetch 1B)		
EASY, 3-sec Gust Wind Speed, $U_{EASY,3\text{-}sec}$ =	125.0	mph	*(pg. 14, DCM-2)*

The Hurricane Easy, 125 mph, 3-sec gust wind speed is a storm specific case. Therefore, it is assumed that the Step 2 conversion factor adjustment is not relevant for this case.

Step 3: Determine EASY, 1-Hr Wind Speed, $U_{EASY,\ 1\text{-}hr}$

Initial wind speed duration, t =	3	sec.	*(based on Step 1 Data)*

Equations for ratio of wind speeds to 1-hour average wind speeds, U_t/U_{3600}

For t ≤ 3,600:	$U_t/U_{3600} = 1.277 + 0.296\tanh(0.9\log_{10}(45/t))$ =	applies		*(Eqn. 1, DCM-2)*
For 3,600 < t < 36,000:	$U_t/U_{3600} = -0.15\log_{10}(t)+1.5334$ =	does not apply		*(Eqn. 2, DCM-2)*
	U_t/U_{3600} =	1.51		*(Eqn. 1, DCM-2)*
	$U_t = U_{EASY,\ 3\text{-}sec}$ =	125.0	mph	*(see Step 2)*
	$U_{EASY,\ 3600\text{-}sec} = U_{EASY,\ 1\text{-}hr} = U_t/(U_t/U_{3600})$ =	82.8	mph	

Step 4: Determine EASY, 1-Hr Wind Speed Over Water, $U_{EASY,1\text{-}hr,water}$

Fetch Length (in miles), X =	3.04	miles	

Wind Speed Over Water to Wind Speed Over Land Ratio, U_{Water}/U_{Land}:

If initial data from Step 1 is over water wind speed, no conversion (Ratio = 1.0)		does not apply		*(Fig. II-2-20, CEM)*
For Fetch Length < 10 miles:	U_{Water}/U_{Land} = 1.2 or 1.0	applies		*(Fig. II-2-20, CEM)*
For Fetch Length > 10 miles:	See Figure II-2-7, CEM	does not apply		*(Fig. II-2-7, CEM)*
	U_{water}/U_{land} =	1.2		*(Fig. II-2-20, CEM)*
	$U_{EASY,1\text{-}hr,land}$ =	82.8		*(see Step 3)*
	$U_{EASY,1\text{-}hr,water} = U_{EASY,1\text{-}hr,land} \times (U_{water}/U_{land})$ =	99.4	mph	

Step 5: Estimate Fetch-Limited Wind Duration Time

Fetch Length (in miles), X =	3.04	miles	*(see Step 4)*
Wind Velocity (in mph), U =	99.4	mph	*(see Step 4)*
Fetch Limited Wind Duration Time, $t = 112(X^{0.67}/(U^{0.34})$ =	49	min.	*(Eqn. 4, DCM-2)*
	2963	sec.	

Step 6: Estimate Ratio of Fetch Limited Duration Wind Speed and 1-Hour Wind Speed

Fetch Limited Wind Duration Time (in seconds), t =	2963	sec.	*(see Step 5)*

Equations for ratio of wind speeds to 1-hour average wind speeds, U_t/U_{3600}

For t ≤ 3,600:	$U_t/U_{3600} = 1.277 + 0.296\tanh(0.9\log_{10}(45/t))$ =	applies		*(Eqn. 1, DCM-2)*
For 3,600 < t < 36,000:	$U_t/U_{3600} = -0.15\log_{10}(t)+1.5334$ =	does not apply		*(Eqn. 2, DCM-2)*
	Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.003		*(Eqn. 1, DCM-2)*

Step 7: Adjust 1-Hr Wind Speed (over water) to Equivalent Fetch Limited Duration Wind Speed

Fetch Limited Wind Duration (in minutes), t =	49	min.	*(see Step 5)*
EASY-Yr, 1-Hr Wind Speed Over Water, $U_{EASY,1\text{-}hr,water}$ =	99.4	mph	*(see Step 4)*
Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.003		*(see Step 6)*
EASY, Fetch Limited Wind Speed Over Water = $U_{EASY,1\text{-}hr,water} \times U_t/U_{3600}$ =	100	mph	

Step 8: Stability Correction, Adjust Wind Speed for Boundary Layer Stability

Fetch Length (in miles), X =	3.04	miles	*(see Step 4)*
(If Fetch Length > 10 miles, else enter 0) Temperature of Air, T_a =	0	°C	
(If Fetch Length > 10 miles, else enter 0) Temperature of Sea, T_s =	0	°C	
Air-Sea Temperature Difference, ΔT_{as} $T_a - T_s$ =	0	°C	

Stability Correction Factor, R_T

For Fetch Length < 10 miles:	R_T = 1.0	applies		*(pg. II-2-36, CEM)*
For Fetch Length > 10 miles:	Based on ΔT_{as}, See Figure 3-14, SPM or in absence of temperature information, assume RT = 1.1	does not apply		*(Fig.3-14, SPM)* *(pg 3-30, SPM)*
	$U_{EASY,fetch\text{-}min,water}$ =	100	mph	*(see Step 7)*
	Stability Correction Factor, R_T =	1		*(pg. II-2-36, CEM)*
	$U_{EASY,fetch\text{-}min,water,\ stability\ adjusted} = U_{EASY,fetch\text{-}min,water} \times R_T$ =	100	mph	*(Eqn. 3-27 SPM)*

Step 9. Compute Wind Stress Factor, U_A

$U_{EASY,Fetch\text{-}min,water,\ stability\ adjusted} = U$ =	100	mph	*(see Step 8)*
Wind Stress Factor, $U_A = 0.589U^{1.23}$ =	169	mph	*(Eqn. 3-28b SPM)*

Step 10. Wind Stress Factor in ft/s

Wind Stress Factor, U_A (ft/s) = $1.467U_A$ (mph) =	248	ft/sec	*(see Step 9)*

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 4: Hurricane Easy (125 mph, 3-sec Gust Wind Speed Combined With Both 24-hr (34.7") & 72 hr (45.2") Rainfall Durations)
Wind Setup and Wave Properties Analysis - Stn C-43: Cell 1 (Fetch 1B)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.04	miles	*(see Step 4)*
Fetch Length, F =	16,048	ft	
EASY, Fetch Limited Wind Speed Over Water = $U_{(EASY,Fetch,Max)}$ =	100	mph	*(see Step 7)*
Wind Stress Factor, U_s (ft/s) =	248	ft/s	*(see Step 10)*

Step 11. Compute Deep-Water Significant Wave Height, H_{mo}

Deep-Water Significant Wave Height, $H_{mo} = (0.000282)U_s F^{1/2}$ =	3.86	feet	*(Eqn. 3-33c, SPM)*

Step 12. Compute Deep-Water Wave Period, T_o

Deep-Water Wave Period, $T_o = 0.02825(U_s F)^{1/3}$ =	4.48	sec	*(Eqn. 3-34c, SPM)*

Step 13. Compute Deep-Water Wave Length, L_o

Deep-Water Wave Length: $L_o = 5.12 T_o^2$ =	103	feet	*(Eqn. 2-4b, SPM)*

Step 14. Compute Relative Depth, d/L_o

If $d/L_o \leq 0.5$, waves are classified as transitional or shallow water waves. *(pg 2-9, SPM)*
If $d/L_o > 0.5$, waves are classified as deep water. *(pg 2-9, SPM)*

Effective Depth, d =	23.86	feet	
Relative Depth = d/L_o =	0.234		*(pg 2-9, SPM)*
Wave Classification =	Transitional/Shallow-Water		*(pg 2-9, SPM)*

Step 15. Compute Shallow-Water Wave Period, T

Shallow-Water Wave Period: $T = 7.54 \tanh(A) \tanh(B/C) U_s/g$ *(Eqn. 3-40, SPM)*
where: F = Fetch Length (ft) (step 5) U_s = Wind Stress Factor (step 10) $g = 32.2$ ft/s^2

$A = 0.530(gd/U_s^2)^{3/4}$ =	0.1613		
$B = 0.0379(gF/U_s^2)^{1/2}$ =	0.0770		
$C = \tanh(0.833(gd/U_s^2)^{3/8})$ =	0.1599		
Shallow-Water Wave Period, $T = 7.54 \tanh(A) \tanh(B/C) U_s/g$ =	3.16	sec	*(Eqn. 3-40, SPM)*

Step 16. Compute Shallow-Water Significant Wave Height, H

Shallow-Water Significant Wave Height, $H = 0.283 \tanh(A) \tanh(B/C) U_s^2/g$ *(Eqn. 3-39, SPM)*
where: F = Fetch Length (ft) (step 5) U_s = Wind Stress Factor (step 10) $g = 32.2$ ft/s^2

$A = 0.530(gd/U_s^2)^{3/4}$ =	0.0199		
$B = 0.00565(gF/U_s^2)^{1/2}$ =	0.0184		
$C = \tanh(0.530(gd/U_s^2)^{3/8})$ =	0.0199		
Shallow-Water Significant Wave Height, $H = 0.283 \tanh(A) \tanh(B/C) U_s^2/g$ =	7.26	feet	*(Eqn. 3-39, SPM)*

Step 17. Compute Shallow-Water Wave Height for Zero Overwash

DCM-2 requires zero over wash as a design criteria for high and significant hazard dams. For purposes of the DCM-2, zero overwash wave height is defined as the wave height with a 2% occurrence frequency.

Significant Wave Height is either the Deep-Water or Shallow-Water Significant wave height
Depending upon the Wave Classification (Step 14).

Significant Wave Height, H_s =	7.26	feet	*(see Step 11 or 16)*
Required probability of wave height being exceeded, n/N =	0.02		*(see Step 17 discussion)*
Root Mean Square Wave Height, $H_{rms} = 2^{1/2} H_s$ =	5.15	feet	*(Eqn. 3-10, SPM)*
Wave Height which is exceeded at given probability, $H^* = H_{rms} [-\ln(n/N)]^{1/2}$ =	10.07	feet	*(Eqn. 3-7, SPM)*

Step 18. Compute Wind Set-Up

Four different methods are calculated and considered in estimating wind setup
Zeider Zee Eqn: Widely used as applied to reservoirs but tends to overestimate wind setup for shallow impoundments (ave. depth<16 ft).
Sibul Eqn: Typically yields the lowest wind setup.
Ave. of Zeider Zee & Sibul: Recommended for shallow impoundments (ave. depth<16 ft) when Bretschneider has no numeric solution.
Bretschneider Eqn: Recommend for shallow impoundments (average depth <16 ft).

Fetch Length, F =	3.04	miles	*(see Step 4)*
Fetch Length, F =	16,048	feet	
Average Wind Velocity, U = Wind Speed per Step 7 = $U_{(EASY,Fetch,Max)}$ =	100	mph	*(pg A6, DCM-2)(see Step 7)*
Average Depth of Water along Fetch Line, D = Effective Depth =	23.86666667	feet	*(see Step 14)*
Zeider Zee Eqn (Note: F=miles): Wind Set-Up, $S = U^2 F/(1400D)$ =	0.00	feet	*(Eqn. 5, DCM-2)*
Sibul Eqn (Note: F=feet, $g=32.2$ ft/s^2): $C = 0.0000244 d(F/d)^{1.25}(U^2/g)^{2.5(F/d)^{-0.375}}$ =	0.23	feet	*(Eqn. 7, DCM-2)*
Average of Zeider Zee & Sibul, Wind Setup, $S = (S_{Zeider\ Zee} + S_{Sibul})/2$ =	0.56	feet	
Bretschneider Eqn (Note: Coles provided separately in Step 18a): $S = 2[(kU^2/g)(g/\sigma)]$ =	n/a	feet	*(Eqn. 6, DCM-2)(Step 18a)*
Equation Used for Wind Setup: *(Enter Zeider Zee, Sibul, Average, Bretschneider)* =	Zeider Zee		
Computed Wind Set-Up, S =	0.00	feet	*(Eqn. 5, DCM-2)*

Step 19. Compute Water Depth at Toe of Structure

Water Depth at Toe of Structure, d_s = Effective Depth + Wind Set-Up = d + S =	24.89	feet	*(pg. A6, DCM-2)*

Step 20. Check for Depth Limited Wave Breaking

See if wave height is limited due to breaking. After breaking, waves will tend to reform with lower heights within a few wave lengths. *(pg. 15-4, EM-1110-2-1420)*

Depth of Interest is at Toe of Structure, $d_i = d_s$ =	24.89	feet	*(see Step 19)*
Wave Breaking Height, H_b (for depth d_b) = $(d_b/1.28)$ =	19.44	feet	*(Eqn. 2-91 & 3-30, SPM)*
Is max. wave height limited by breaking? (If H_b [step 20] $\leq H^*$ [step 17] then yes, else no) =	No		
(If no, wave height = H^* (step 17). If yes, conservatively assume wave height = H_b (step 20)) Maximum Wave Height =	10.07	feet	

Step 21. Estimate Ratio Between Deep-Water Wave Ht & Equivalent Deep-Water Ht

The value of H/H'o (shallow-water wave height/equivalent deep-water wave height) is estimated based on the value of L_o (effective depth / deep-water wave length) from Table C-1, SPM Vol II, Appendix C.

Effective Depth, d =	23.86666667	feet	*(see Step 14)*
Deep-Water Wave Length, L_o =	103	feet	*(see Step 13)*
Ratio of effective depth to deep-water wave length, d/L_o =	0.234		
H/H'_o =	0.9273		*(Table C-1, SPM Vol 2)*

Step 22. Compute Equivalent Deep-Water Wave Height, H'_o

If wave classification is Deep-Water (Step 14), Significant Deep-Water Height is the Equivalent Deep-Water Height.
If wave classification is Transitional/Shallow-Water an adjustment is necessary.
If Wave Breaking Height (Step 20) is less than the Zero Overwash for Significant Wave Height (Step 17) then Equivalent Deep-Water Wave Height is Wave Breaking Height (irregardless of wave classification).

Wave Breaking Height, H_b =	19.44	feet	*(see Step 20)*
Significant Wave Height, H_s =	10.07	feet	*(see Step 17)*
H/H'_o =	0.9273		*(see Step 21)*
If Shallow-Water, Equivalent Deep-Water Wave Height, $H'o = H/(H/H'o)$ =	10.85	feet	
If Deep Water, Equivalent Deep-Water Wave Height = Significant Deep-Water Height =	n/a	feet	
If Height Limited by Wave Breaking, Equiv. Deep-Water Wave Ht. = Wave Breaking Ht. =	n/a	feet	
Equivalent Deep-Water Wave Height =	10.85	feet	

Step 23. Compute Depth at Toe of Structure to Equiv. Deep-Water Wave Ht, d_s/H'_o

Water Depth at Toe of Structure, d_s =	24.89	feet	*(see Step 19)*
Equivalent Deep-Water Wave Height, H'_o =	10.85	feet	*(see Step 22)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_s/H'_o =	2.29		

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 4: Hurricane Easy (125 mph, 3-sec Gust Wind Speed Combined With Both 24-hr (38.7") & 72 hr (45.2") Rainfall Durations)
Wave Runup Analysis - Site C-43: Cell 1 (Fetch 1B)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.04	miles	*(see Step 4)*
Fetch Length, F =	16,048	feet	
EASY, Fetch Limited Wind Speed Over Water = $U_{EASY,fetch-ltd}$ =	100	mph	*(see Step 7)*
Wind Stress Factor, U_A (ft/s) =	248	ft/s	*(see Step 10)*

Wind Setup and Wave Properties Analysis - Summary Data

Wind Set-Up , S =	0.90	feet	*(see Step 18)*
Equivalent Deep-Water Wave Height, H'_o =	10.85	feet	*(see Step 22)*
Deep-Water Wave Period, T_o =	4.48	sec	*(see Step 12)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_s/H'_o =	2.29		*(see Step 23)*

Step 24. Compute Ratio of $H'_o/(g*T_o^2)$

Equivalent Deep-Water Wave Height, H'_o =	10.85	feet	*(see Step 22)*
Gravitational constant, g =	32.2	ft/s^2	*(constant variable)*
Deep Water Wave Period, T_o =	4.48	sec	*(see Step 12)*
$H'_o/(g*T_o^2)$ =	0.017		

Steps 25 - 27. Estimate R/H'o *(Fig. 7-8 thru 7-20, SPM Vol. 2)*

Steps 25-27 are directed towards deriving the ratio of Wave Runup to the Equivalent Deep-Water Wave Height (R/H'_o) from graphs found in SPM Volume 2 (Fig. 7-8 thru 7-20). The graphs are based upon various designs of the runup face slope including the material, roughness, slope, and geometry the face slope. In addition the value of R/H'_o depends upon the values of d_s/H'_o and $H'_o/(gT^2)$. Determination of values will typically require an interpolation of values between graphs.

d_s/H'_o =	2.29		*(see Step 23)*
$H'_o/(g*T_o^2)$ =	0.017		*(see Step 24)*
Face Slope Material =	Step-Faced Slope		*Embankment Design*
Runup Face Slope (R:1V) =	3		*Embankment Design*
Runup Face Slope (θ) =	18.4	degrees	
Figure used for Interpolation (Lower Interpolation Number) =	Fig. 7-11		*(SPM Vol. 2)*
Figure to used for Interpolation (Higher Interpolation Number) =	Fig. 7-12		*(SPM Vol. 2)*

Step 25. R/H'o from Fig. 7-11 with ds/H'o <= 2.29

$H'_o/(g*T_o^2)$ =	0.017		*(see Step 24)*
ds/H'o <=2.29 from Fig. 7-11 =	2		*(Fig. 7-11, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-11 =	0.78		*(Fig. 7-11, SPM Vol. 2)*

Step 26. R/H'o from Fig. 7-12 with ds/H'o >= 2.29

$H'_o/(g*T_o^2)$ =	0.017		*(see Step 24)*
ds/H'o >=2.29 from Fig. 7-12 =	3.0		*(Fig. 7-12, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-12 =	1.00		*(Fig. 7-12, SPM Vol. 2)*

Step 27. Estimated Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o

d_s/H'_o =	2.29		*(see Step 23)*
$H'_o/(g*T_o^2)$ =	0.017		*(see Step 24)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o =	0.84		*(Interpolated from Steps 25 & 26)*

Step 28. Compute Smooth Surface Wave Runup

Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'_o =	0.84		*(see Step 27)*
Equivalent Deep-Water Wave Height, H'_o =	10.85		*(see Step 22)*
Smooth Surface Wave Runup = R/H'_o x H'_o =	9.20	feet	

Step 29. If Applicable, Determine and Apply Wave Runup Correction Factor due to Scale Effects

This step applies if Figures 7-8 thru 7-12 or Figures 7-14 thru 7-16 were used to estimate R/H'_o in Steps 25-27. These figures summarize results for small-scale lab tests. Due to the inability to scale roughness effects in small-scale lab tests, the results are probably smaller than the runup on prototype structures. Figure 7-13 is used to adjust for this scale effect.

Smooth Surface Wave Runup = R/H'_o x H'_o =	9.20	feet	*(see Step 28)*
Scale Wave Runup Correction due to Scale Effects *(If Fig. 7-19 or 7-20 used, enter 1)* =	1.12		*(Fig. 7-13, SPM Vol. 2)*
Scale Corrected Wave Runup Height = (Smooth Surface Wave Runup)(Runup Correction) =	10.30	feet	

Step 30. Determine and Apply Correction Factor due to Dam Surface Roughness

Face Slope Material =	Step-Faced Slope		*(see Step 25)*
Surface Roughness Correction =	0.7		*(Table 7-2, SPM Vol 2) or (Table 2-2 EM1110-2-1614)*
Scale Corrected Wave Runup Height =	10.30	feet	*(see Step 29)*
Corrected Wave Runup = (Scale Corrected Wave Runup)(Surface Roughness Correction) =	7.21	feet	

Step 31. Correction Due to to Fetch Axis Not Being Normal to the Dam Axis

Angle Between Fetch Axis and Embankment Axis =	7	degrees	
Angle Correction Factor =	0.98		*(Fig. 8, ACER TM No. 11)*

Step 32. Adjusted Wave Runup

Corrected Wave Runup =	7.21		*(see Step 30)*
Angle Correction Factor =	0.98		*(see Step 31)*
Final Adjusted Wave Runup = (Corrected Wave Runup)(Angle Correction Factor) =	7.1	feet	

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

Fetch 2A Analyses

Summary of Freeboard Analyses Case Scenarios Site C-43: Cell 2 (Fetch 2A)				
Freeboard Component	Case 1: PMP Combined with 100-Year Wind (ft)	Case 2: 100-Year Precip. Combined with Category 5 Winds (ft)	Case 3: Normal Full Storage Combined with Probable Max. Wind (ft)	Case 4: Hurricane Easy Storm Specific Wind and Precipitation (ft)
Design Precipitation **or** Flood Surge Depth (Routed Flood Event) =	4.13	0.77	0.00	3.77
Wind Setup =	1.12	2.09	3.61	1.13
Wave Height & Runup =	6.63	7.62	8.82	6.56
Waves Induced by Potential Landslides =	0.00	0.00	0.00	0.00
Provision for Malfunction of the Spillway or Discharge Structure =	0.00	0.00	0.00	0.00
Minimum Required Freeboard =	**11.89**	**10.48**	**12.44**	**11.46**
Camber or Embankment Settlement =	0.88	0.67	0.88	0.78
Minimum Required Freeboard with Camber =	**12.8**	**11.2**	**13.3**	**12.2**

Notes:
Minimum Required Freeboard rounded up to the next 0.01 foot.
Minimum Required Freeboard with Camber rounded up to the next 0.1 foot.
Case 1 - Surcharge depth is based upon routing of design storm event(s) through the reservoir.
Case 2 - Surcharge depth is based upon routing of design storm event through the reservoir.
Case 3 - Case 3 is to be used only for "sensitivity identification" and not as a selected design condition (pg 14 of 25, DCM-2)
Case 4 - Surcharge depth is assumed to be equal to the total precipitation of Hurricane Easy (45.2").

2015

3/12/2007

Case 1: PMP Combined with 100-Year Wind
Design Wind Speed Analysis - Site C-43: Cell 2 (Fetch 2A)

Step 1: Select 50-Yr, 3-Sec Gust Wind Speed, $U_{50\text{-}yr,3\text{-}sec}$

Project Location =	C-43 Cell No. 2		
50-yr, 3-sec Gust Wind Speed, $U_{50\text{-}yr,3\text{-}sec}$ =	117.5	mph	*(Fig. 6-1b, ASCE 7-02)*

Step 2: Determine 100-Yr, 3-Sec Gust Wind Speed, $U_{100\text{-}yr,3\text{-}sec}$

$U_{50\text{-}yr,3\text{-}sec}$ =	117.5	mph	*(see Step 1)*
$U_{50\text{-}yr}$ to $U_{100\text{-}yr}$ Conversion Factor =	1.07		*(Table DCM 2-2, DCM-2)*
$U_{100\text{-}yr,3\text{-}sec} = U_{50\text{-}yr,3\text{-}sec}$ x Conversion Factor =	125.7	mph	

Step 3: Determine 100-Yr, 1-Hr Wind Speed, $U_{100\text{-}yr,1\text{-}hr}$

Initial wind speed duration, t =	3	sec.	*(based on Step 1 Data)*

Equations for ratio of wind speeds to 1-hour average wind speeds, U_t/U_{3600}

For $t \leq 3{,}600$:	$U_t/U_{3600} = 1.277 + 0.296\tanh(0.9\log_{10}(45/t))$ =	applies		*(Eqn. 1, DCM-2)*
For $3{,}600 < t < 36{,}000$:	$U_t/U_{3600} = -0.15\log_{10}(t)+1.5334$ =	does not apply		*(Eqn. 2, DCM-2)*
	U_t/U_{3600} =	1.51		*(Eqn. 1, DCM-2)*
	$U_t = U_{100\text{-}yr,\ 3\text{-}sec}$ =	125.73	mph	*(see Step 2)*
	$U_{100\text{-}yr,\ 3600\text{-}sec} = U_{100\text{-}yr,\ 1\text{-}hr} = U_t/(U_t/U_{3600})$ =	83.3	mph	

Step 4: Determine 100-Yr, 1-Hr Wind Speed Over Water, $U_{100\text{-}yr,1\text{-}hr,water}$

Fetch Length (in miles), X =	3.40	miles	

Wind Speed Over Water to Wind Speed Over Land Ratio, U_{Water}/U_{Land}:

If initial data from Step 1 is over water wind speed, no conversion (Ratio = 1.0)		does not apply		*(Fig. II-2-20, CEM)*
For Fetch Length < 10 miles:	U_{Water}/U_{Land} = 1.2 or 1.0	applies		*(Fig. II-2-20, CEM)*
For Fetch Length > 10 miles:	See Figure II-2-7, CEM	does not apply		*(Fig. II-2-7, CEM)*
	U_{water}/U_{land} =	1.2		*(Fig. II-2-20, CEM)*
	$U_{100\text{-}yr,1\text{-}hr,land}$ =	83.3		*(see Step 3)*
	$U_{100\text{-}yr,1\text{-}hr,water} = U_{100\text{-}yr,1\text{-}hr,land}$ x (U_{water}/U_{land}) =	100.0	mph	

Step 5: Estimate Fetch-Limited Wind Duration Time

Fetch Length (in miles), X =	3.40	miles	*(see Step 4)*
Wind Velocity (in mph), U =	100.0	mph	*(see Step 4)*
Fetch Limited Wind Duration Time, $t = 112(X^{0.67}/U^{0.34})$ =	53	min.	*(Eqn. 4, DCM-2)*
	3187	sec.	

Step 6: Estimate Ratio of Fetch Limited Duration Wind Speed and 1-Hour Wind Speed

Fetch Limited Wind Duration Time (in seconds), t =	3187	sec.	*(see Step 5)*

Equations for ratio of wind speeds to 1-hour average wind speeds, U_t/U_{3600}

For $t \leq 3{,}600$:	$U_t/U_{3600} = 1.277 + 0.296\tanh(0.9\log_{10}(45/t))$ =	applies		*(Eqn. 1, DCM-2)*
For $3{,}600 < t < 36{,}000$:	$U_t/U_{3600} = -0.15\log_{10}(t)+1.5334$ =	does not apply		*(Eqn. 2, DCM-2)*
	Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.001		*(Eqn. 1, DCM-2)*

Step 7: Adjust 1-Hr Wind Speed (over water) to Equivalent Fetch Limited Duration Wind Speed

Fetch Limited Wind Duration (in minutes), t =	53	min.	*(see Step 5)*
100-Yr, 1-Hr Wind Speed Over Water, $U_{100\text{-}yr,1\text{-}hr,water}$ =	100.0	mph	*(see Step 4)*
Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.001		*(see Step 6)*
100-Yr, Fetch Limited Wind Speed Over Water = $U_{100\text{-}yr,1\text{-}hr,water}$ x U_t/U_{3600} =	100	mph	

Step 8: Stability Correction, Adjust Wind Speed for Boundary Layer Stability

Fetch Length (in miles), X =	3.40	miles	*(see Step 4)*
(If Fetch Length > 10 miles, else enter 0) Temperature of Air, T_a =	0	°C	
(If Fetch Length > 10 miles, else enter 0) Temperature of Sea, T_s =	0	°C	
Air-Sea Temperature Difference, ΔT_{as} $T_a - T_s$ =	0	°C	

Stability Correction Factor, R_T

For Fetch Length < 10 miles:	$R_T = 1.0$	applies		*(pg. II-2-36, CEM)*
For Fetch Length > 10 miles:	Based on ΔT_{as}, See Figure 3-14, SPM or in absence of temperature information, assume RT = 1.1	does not apply		*(Fig.3-14, SPM)* *(pg 3-30, SPM)*
	$U_{100\text{-}yr,fetch\text{-}min,water}$ =	100	mph	*(see Step 7)*
	Stability Correction Factor, R_T =	1		*(pg. II-2-36, CEM)*
	$U_{100\text{-}yr,fetch\text{-}min,water,\ stability\ adjusted} = U_{100\text{-}yr,fetch\text{-}min,water}$ x R_T =	100	mph	*(Eqn. 3-27 SPM)*

Step 9. Compute Wind Stress Factor, U_A

$U_{100\text{-}yr,1\text{-}min,water,\ stability\ adjusted} = U$ =	100	mph	*(see Step 8)*
Wind Stress Factor, $U_A = 0.589U^{1.23}$ =	170	mph	*(Eqn. 3-28b SPM)*

Step 10. Wind Stress Factor in ft/s

Wind Stress Factor, U_A (ft/s) = 1.467U_A (mph) =	249	ft/sec	*(see Step 9)*

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 1: PMP Combined with 100-Year Wind
Wind Setup and Wave Properties Analysis - Site C-43: Cell 2 (Fetch 2A)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.40	miles	*(see Step 4)*
Fetch Length, F =	17,944	ft	
100-Yr, Fetch Limited Wind Speed Over Water = $U_{100-yr,fetch,over}$ =	100	mph	*(see Step 7)*
Wind Stress Factor, U_* (ft/s) =	249	ft/s	*(see Step 10)*

Step 11. Compute Deep-Water Significant Wave Height, H_{mo}

Deep-Water Significant Wave Height, $H_{mo} = (0.000282)U_*F^{0.5}$ = 9.42 feet *(Eqn. 3-33c, SPM)*

Step 12. Compute Deep-Water Wave Period, T_o

Deep-Water Wave Period, $T_o = 0.02825(U_*F)^{0.5}$ = 8.66 sec *(Eqn. 3-34c, SPM)*

Step 13. Compute Deep-Water Wave Length, L_o

Deep-Water Wave Length, $L_o = 5.12T_o^2$ = 111 feet *(Eqn. 3-4b, SPM)*

Step 14. Compute Relative Depth, d/L_o

If $d/L_o \leq 0.5$, waves are classified as transitional or shallow water waves. *(pg 2-8, SPM)*
If $d/L_o > 0.5$, waves are classified as deep water. *(pg 2-9, SPM)*

Effective Depth, d =	21.64	feet	
Relative Depth = d/L_o =	0.195		*(pg 2-8, SPM)*
Wave Classification =	Transitional/Shallow-Water		*(pg 2-9, SPM)*

Step 15. Compute Shallow-Water Wave Period, T

Shallow-Water Wave Period, $T = 7.54\ \tanh^{A}(A)\ \tanh^{(B/C)}(U_*/g$ *(Eqn. 3-40, SPM)*

where: F = Fetch Length (ft) (step 5) U_* = Wind Stress Factor (step 10) g = 32.2 ft/s²

$A = 0.833(gd/U_*^2)^{0.5}$ =	0.1546	
$B = 0.0379(gF/U_*^2)^{0.5}$ =	0.0797	
$C = \tanh(0.833(gd/U_*^2)^{0.5})$ =	0.1533	
Shallow-Water Wave Period, $T = 7.54\ \tanh(A)\ \tanh(B/C)\ U_*/g$ =	4.29 sec	*(Eqn. 3-40, SPM)*

Step 16. Compute Shallow-Water Significant Wave Height, H

Shallow-Water Significant Wave Height, $H = 0.283\ \tanh(A)\ \tanh(B/C)\ U_*^2/g$ *(Eqn. 3-39, SPM)*

where: F = Fetch Length (ft) (step 5) U_* = Wind Stress Factor (step 10) g = 32.2 ft/s²

$A = 0.530(gd/U_*^2)^{0.5}$ =	0.0182	
$B = 0.0565(gF/U_*^2)^{0.5}$ =	0.0172	
$C = \tanh(0.530(gd/U_*^2)^{0.5})$ =	0.0182	
Shallow-Water Significant Wave Height, $H = 0.283\ \tanh(A)\ \tanh(B/C)\ U_*^2/g$ =	7.35 feet	*(Eqn. 3-39, SPM)*

Step 17. Compute Zero Overwash Wave Height for Significant Wave Height

DCM-2 requires zero over wash as a design criteria for high and significant hazard dams. For purposes of the DCM-2, zero overwash wave height is defined as the wave height with a 2% occurrence frequency.

Significant Wave Height is either the Deep-Water or Shallow-Water Significant wave height Depending upon the Wave Classification (Step 14).

Significant Wave Height, H_s =	7.35	feet	*(see Step 11 or 16)*
Required probability of wave height being exceeded, n/N =	0.02		*(see Step 17 discussion)*
Root Mean Square Wave Height, $H_{rms} = 2^{-0.5}H_s$ =	5.20	feet	*(Eqn. 3-10, SPM)*
Wave Height which is exceeded at given probability, $H^* = H_{rms}[-Ln(n/N)]^{0.5}$ =	10.17	feet	*(Eqn. 3-7, SPM)*

Step 18. Compute Wind Set-Up

Four different methods are calculated and considered in estimating wind setup
Zeider Zee Eqn: Widely used as applied to reservoirs but tends to overestimate wind setup for shallow impoundments (ave. depth<16 ft).
Sibul Eqn: Typically yields the lowest wind setup.
Ave. of Zeider Zee & Sibul: Recommended for shallow impoundments (ave. depth<16 ft) when Bretschneider has no numeric solution.
Bretschneider Eqn: Recommend for shallow impoundments (average depth <16 ft).

Fetch Length, F =	3.40	miles	*(see Step 4)*
Fetch Length, F =	17,944	feet	
Average Wind Velocity, U = Wind Speed per Step 7 = $U_{100-yr,over}$ =	100	mph	*(pg A6, DCM-2)(see Step 7)*
Average Depth of Water along Fetch Line, D = Effective Depth =	21.64	feet	*(see Step 14)*
Zeider Zee Eqn: (Note: F=miles): Wind Set-Up, $S = U^2F/(1400D)$ =	1.12	feet	*(Eqn. 5, DCM-2)*
Sibul Eqn (Note: F=feet, g=32.2 ft/s²): $S = 0.0000244(F/d)^{0.67}(U^2/g)^{1.23\cdot(d/F)^{0.25}}$ =	0.28	feet	*(Eqn. 7, DCM-2)*
Average of Zeider Zee & Sibul: Wind Setup, $S = (S_{Zeider\ Zee} + S_{Sibul})/2$ =	0.70	feet	
Bretschneider Eqn (Note: Calcs provided separately in Step 18a): $S = \Sigma[(KU^2/x)(gd^2)]$ =	n/a	feet	*(Eqn. 6, DCM-2)(Step 18a)*
Equation Used for Wind Setup *(Enter Zeider Zee, Sibul, Average, Bretschneider)* =	Zeider Zee		
Computed Wind Set-Up, S =	1.12	feet	*(Eqn. 5, DCM-2)*

Step 19. Compute Water Depth at Toe of Structure

Water Depth at Toe of Structure, d_t = Effective Depth + Wind Set-Up = d + S = 22.76 feet *(pg. 6, DCM-2)*

Step 20. Check for Depth Limited Wave Breaking

See if wave height is limited due to breaking. After breaking, waves will tend to reform with lower heights within a few wave lengths. *(pg. 1-5, EM-1110-2-1420)*

Depth of Interest is at Toe of Structure, $d_i = d_t$ =	22.76	feet	*(see Step 19)*
Wave Breaking Height, H_b (for depth d_i) = $(d_i/1.28)$ =	17.78	feet	*(Eqn. 2-91 & 2-90, SPM)*
Is max. wave height limited by breaking? *(If H_s (step 20) $\leq H^*$ (step 17) then yes, else no)* =	No		
(If no, wave height = H^* (step 17). If yes, conservatively assume wave height = H_b (step 20)) Maximum Wave Height =	10.17	feet	

Step 21. Estimate Ratio Between Deep-Water Wave Ht & Equivalent Deep-Water Ht

The value of H/Ho (shallow-water wave height/equivalent deep-water wave height) is estimated based on the value of d/L_o (effective depth / deep-water wave length) from Table C-1, SPM Vol II, Appendix C.

Effective Depth, d =	21.64	feet	*(see Step 14)*
Deep-Water Wave Length, L_o =	111	feet	*(see Step 13)*
Ratio of effective depth to deep-water wave length, d/L_o =	0.195		
H/H^*_o =	0.917		*(Table C-1, SPM Vol 2)*

Step 22. Compute Equivalent Deep-Water Wave Height, H^*_o

If wave classification is Deep-Water (Step 14), Significant Deep-Water Height is the Equivalent Deep-Water Height.
If wave classification is Transitional/Shallow-Water an adjustment is necessary.
If Wave Breaking Height (Step 20) is less than the Zero Overwash for Significant Wave Height (Step 17) then Equivalent Deep-Water Wave Height is Wave Breaking Height (irregardless of wave classification).

Wave Breaking Height, H_b =	17.78	feet	*(see Step 20)*
Significant Wave Height, H_s =	10.17	feet	*(see Step 17)*
H/H^*_o =	0.9170		*(see Step 21)*
If Shallow-Water: Equivalent Deep-Water Wave Height, $H^*o = H/(H/H^*o)$ =	11.09	feet	
If Deep Water: Equivalent Deep-Water Wave Height = Significant Deep-Water Height =	n/a	feet	
If Height Limited by Wave Breaking: Equiv. Deep-Water Wave Ht. = Wave Breaking Ht. =	n/a	feet	
Equivalent Deep-Water Wave Height =	11.09	feet	

Step 23. Compute Depth at Toe of Structure to Equiv. Deep-Water Wave Ht, d_t/H^*_o

Water Depth at Toe of Structure, d_t =	22.76	feet	*(see Step 19)*
Equivalent Deep-Water Wave Height, H^*_o =	11.09	feet	*(see Step 22)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_t/H^*_o =	2.05		

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 1: PMP Combined with 100-Year Wind
Wave Runup Analysis -Site C-43: Cell 2 (Fetch 2A)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.40	miles	*(see Step 4)*
Fetch Length, F =	17,944	feet	
100-Yr, Fetch Limited Wind Speed Over Water = $U_{(100-yr,fetch-ltd)}$ =	100	mph	*(see Step 7)*
Wind Stress Factor, U_A (ft/s) =	249	ft/s	*(see Step 10)*

Wind Setup and Wave Properties Analysis - Summary Data

Wind Set-Up , S =	1.12	feet	*(see Step 18)*
Equivalent Deep-Water Wave Height, H'_o =	11.09	feet	*(see Step 22)*
Deep-Water Wave Period, T_o =	4.66	sec	*(see Step 12)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_s/H'_o =	2.05		*(see Step 23)*

Step 24. Compute Ratio of $H'_o/(g*T_o^2)$

Equivalent Deep-Water Wave Height, H'_o =	11.09	feet	*(see Step 22)*
Gravitational Constant, g =	32.2	ft/s^2	*(constant variable)*
Deep Water Wave Period, T_o =	4.66	sec	*(see Step 12)*
$H'_o/(g*T_o^2)$ =	0.016		

Steps 25 - 27. Estimate R/H'o *(Fig. 7-8 thru 7-20, SPM Vol. 2)*

Steps 25-27 are directed towards deriving the ratio of Wave Runup to the Equivalent Deep-Water Wave Height (R/H'_o) from graphs found in SPM Volume 2 (Fig. 7-8 thru 7-20). The graphs are based upon various designs of the runup face slope including the material, roughness, slope, and geometry the face slope. In addition the value of R/H'_o depends upon the values of d_s/H'_o and $H'_o/(gT^2)$. Determination of values will typically require an interpolation of values between graphs.

d_s/H'_o =	2.05	*(see Step 23)*
$H'_o/(g*T_o^2)$ =	0.016	*(see Step 24)*
Face Slope Material =	Step-Faced Slope	*Embankment Design*
Runup Face Slope (H:1V) =	3	*Embankment Design*
Runup Face Slope (Θ) =	18.4 degrees	
Figure used for Interpolation (Lower Interpolation Number) =	Fig. 7-11	*(SPM Vol. 2)*
Figure to used for Interpolation (Higher Interpolation Number) =	Fig. 7-12	*(SPM Vol. 2)*

Step 25. R/H'o from Fig. 7-11 with ds/H'o <= 2.05

$H'_o/(g*T_o^2)$ =	0.016	*(see Step 24)*
ds/H'o <=2.05 from Fig. 7-11 =	2.0	*(Fig. 7-11, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-11 =	0.84	*(Fig. 7-11, SPM Vol. 2)*

Step 26. R/H'o from Fig. 7-12 with ds/H'o >= 2.05

$H'_o/(g*T_o^2)$ =	0.016	*(see Step 24)*
ds/H'o >=2.05 from Fig. 7-12 =	3.0	*(Fig. 7-12, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-12 =	1.04	*(Fig. 7-12, SPM Vol. 2)*

Step 27. Estimated Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o

d_s/H'_o =	2.05	*(see Step 23)*
$H'_o/(g*T_o^2)$ =	0.016	*(see Step 24)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o =	0.95	*(Interpolated from Steps 25 & 26)*

Step 28. Compute Smooth Surface Wave Runup

Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'_o =	0.85		*(see Step 27)*
Equivalent Deep-Water Wave Height, H'_o =	11.09		*(see Step 22)*
Smooth Surface Wave Runup = R/H'_o x H'_o =	9.40	feet	

Step 29. If Applicable, Determine and Apply Wave Runup Correction Factor due to Scale Effects

This step applies if Figures 7-8 thru 7-12 or Figures 7-14 thru 7-18 were used to estimate R/H'_o in Steps 25-27. These figures summarize results for small-scale lab tests. Due to the inability to scale roughness effects in small-scale lab tests, the results are probably smaller than the runup on prototype structures. Figure 7-13 is used to adjust for this scale effect.

Smooth Surface Wave Runup = R/H'_o x H'_o =	9.40	feet	*(see Step 28)*
Scale Wave Runup Correction due to Scale Effects *(If Fig. 7-19 or 7-20 used, enter 1)* =	1.12		*(Fig. 7-13, SPM Vol. 2)*
Scale Corrected Wave Runup Height = (Smooth Surface Wave Runup)(Runup Correction) =	10.53	feet	

Step 30. Determine and Apply Correction Factor due to Dam Surface Roughness

Face Slope Material =	Step-Faced Slope		*(see Step 25)*
Surface Roughness Correction =	0.7		*(Table 7-2, SPM Vol 2) or (Table 2-2 EM1110-2-1614)*
Scale Corrected Wave Runup Height =	10.53	feet	*(see Step 29)*
Corrected Wave Runup = (Scale Corrected Wave Runup)(Surface Roughness Correction) =	7.37	feet	

Step 31. Correction Due to to Fetch Axis Not Being Normal to the Dam Axis

Angle Between Fetch Axis and Embankment Axis =	42	degrees	
Angle Correction Factor =	0.90		*(Fig. 8, ACER TM No. 11)*

Step 32. Adjusted Wave Runup

Corrected Wave Runup =	7.37		*(see Step 30)*
Angle Correction Factor =	0.90		*(see Step 31)*
Final Adjusted Wave Runup = (Corrected Wave Runup)(Angle Correction Factor) =	6.6	feet	

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.

3/12/2007

Case 1: PMP Combined with 100-Year Wind
Minimum Required Freeboard - Site C-43: Cell 2 (Fetch 2A)

Step 33. Minimum Required Design Freeboard

Design Precipitation **or** Flood Surge Depth (Routed Flood Event) =	4.13	ft	*(based upon max. water surface elevation of routed storm event)*
Wind Setup =	1.12	ft	*(see Step 18)*
Wave Height & Runup =	6.63	ft	*(see Step 32)*
Waves Induced by Potential Landslides =	0.00	ft	*(not considered)*
Provision for Malfunction of the Spillway or Discharge Structure =	0.00	ft	*(not considered)*
Summation of all above Freeboard Components is Minimum Required Freeboard =	11.89	ft	*(rounded up to the next 0.01 foot)*

Step 34. Minimum Required Design Freeboard with Camber

Average Normal Full Storage Depth =	17.51	ft	*(Average Depth along Fetch based on NFSL = 42 ft El.)*
Minimum Required Freeboard =	11.89	ft	*(see Step 33)*
Embankment Height (not including camber) =	29.40	ft	*(summation of average normal full storage depth and freeboard)*
Minimum Required Freeboard =	11.89	ft	*(see Step 33)*
Embankment Settlement =	0.88	ft	*(see Technical Memorandum Table 3 or BODR Section 8E.)*
Minimum Embankment Height (with camber) =	30.28	ft	*(minimum embankment height plus settlement)*
Minimum Required Design Freeboard with Camber =	12.77	ft	*(rounded up to the next 0.01 foot)*

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

Case 2: 100-Year Precipitation Combined with Category 5 Hurricane Winds
Design Wind Speed Analysis - Site C-43: Cell 2 (Fetch 2A)

Steps 1-3: Adjustments not necessary for Case 2

Project Location =	C-43 Cell No. 2		
Category 5, Duration Adjusted Wind Speed (1-hr average), $U_{Cat5,1\text{-}hr}$ =	125.0	mph	*(Table DCM 2-3, DCM-2)*

The Category 5 wind speed from Table DCM 2-3, DCM-2 corresponds to an over-water wind speed per DCM-2 page 10.

Step 4: Determine Category 5, 1-Hr Wind Speed Over Water, $U_{Cat5,1\text{-}hr,water}$

Fetch Length (in miles), X =	3.40	miles	

Wind Speed Over Water to Wind Speed Over Land Ratio, U_{Water}/U_{Land}:

If initial data from Step 1 is over water wind speed, no conversion (Ratio = 1.0)	does not apply		*(Fig. II-2-20, CEM)*
For Fetch Length < 10 miles: U_{Water}/U_{Land} = 1.2 or 1.0	applies		*(Fig. II-2-20, CEM)*
For Fetch Length > 10 miles: See Figure II-2-7, CEM	does not apply		*(Fig. II-2-7, CEM)*
U_{water}/U_{land} =	1		*(Fig. II-2-20, CEM)*
$U_{Cat5,1\text{-}hr,land}$ =	-		*(see Step 3)*
$U_{Cat5,1\text{-}hr,water} = U_{Cat5,1\text{-}hr,land} \times (U_{water}/U_{land})$ =	125.0	mph	

Step 5: Estimate Fetch-Limited Wind Duration Time

Fetch Length (in miles), X =	3.40	miles	*(see Step 4)*
Wind Velocity (in mph), U =	125.0	mph	*(see Step 4)*
Fetch Limited Wind Duration Time, $t = 112(X^{0.67}/U^{0.34})$ =	49	min.	*(Eqn. 4, DCM-2)*
	2954	sec.	

Step 6: Estimate Ratio of Fetch Limited Duration Wind Speed and 1-Hour Wind Speed

Fetch Limited Wind Duration Time (in seconds), t =	2954	sec.	*(see Step 5)*

Equations for ratio of wind speeds to 1-hour average wind speeds, U_t/U_{3600}

For $t \leq 3{,}600$: $U_t/U_{3600} = 1.277 + 0.296\tanh(0.9\log_{10}(4.5/t))$ =	applies		*(Eqn. 1, DCM-2)*
For $3{,}600 < t < 36{,}000$: $U_t/U_{3600} = -0.15\log_{10}(t)+1.5334$ =	does not apply		*(Eqn. 2, DCM-2)*
Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.003		*(Eqn. 1, DCM-2)*

Step 7: Adjust 1-Hr Wind Speed (over water) to Equivalent Fetch Limited Duration Wind Speed

Fetch Limited Wind Duration (in minutes), t =	49	min.	*(see Step 5)*
Category 5, 1-Hr Wind Speed Over Water, $U_{Cat5,1\text{-}hr,water}$ =	125.0	mph	*(see Step 4)*
Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.003		*(see Step 6)*
Category 5, Fetch Limited Wind Speed Over Water = $U_{Cat5,1\text{-}hr,water} \times U_t/U_{3600}$ =	125	mph	

Step 8: Stability Correction, Adjust Wind Speed for Boundary Layer Stability

Fetch Length (in miles), X =	3.40	miles	*(see Step 4)*
(If Fetch Length > 10 miles, else enter 0) Temperature of Air, T_a =	0	o C	
(If Fetch Length > 10 miles, else enter 0) Temperature of Sea, T_s =	0	o C	
Air-Sea Temperature Difference, ΔT_{as} $T_a - T_s$ =	0	°C	

Stability Correction Factor, R_T

For Fetch Length < 10 miles: R_T = 1.0	applies		*(pg. II-2-36, CEM)*
For Fetch Length > 10 miles: Based on ΔT_{as} See Figure 3-14, SPM or in absence of temperature information, assume RT = 1.1	does not apply		*(Fig.3-14, SPM)* *(pg 3-30, SPM)*
$U_{Cat5,fetch\text{-}min,water}$ =	125	mph	*(see Step 7)*
Stability Correction Factor, R_T =	1		*(pg. II-2-36, CEM)*
$U_{Cat5,fetch\text{-}min,water,\ stability\ adjusted} = U_{Cat5,fetch\text{-}min,water} \times R_T$ =	125	mph	*(Eqn. 3-27 SPM)*

Step 9. Compute Wind Stress Factor, U_A

$U_{Cat5,fetch\text{-}min,water,\ stability\ adjusted} = U$ =	125	mph	*(see Step 8)*
Wind Stress Factor, $U_A = 0.589U^{1.23}$ =	224	mph	*(Eqn. 3-28b SPM)*

Step 10. Wind Stress Factor in ft/s

Wind Stress Factor, U_A (ft/s) $= 1.467U_A$ (mph) =	329	ft/sec	*(see Step 9)*

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 2: 100-Year Precipitation Combined with Category 5 Hurricane Winds
Wind Setup and Wave Properties Analysis - Stn C-43: Cell 2 (Fetch 2A)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.40	miles	*(see Step 4)*
Fetch Length, F =	17,944	ft	
Category 5, Fetch Limited Wind Speed Over Water = $U_{Cat5,fetch-ltd}$ =	125	mph	*(see Step 7)*
Wind Stress Factor, U_* (ft/s) =	329	ft/s	*(see Step 10)*

Step 11. Compute Deep-Water Significant Wave Height, H_{mo}

Deep-Water Significant Wave Height, $H_{mo} = (0.000282)U_*F^{1/2}$ =	12.42	feet	*(Eqn. 3-33c, SPM)*

Step 12. Compute Deep-Water Wave Period, T_p

Deep-Water Wave Period, $T_p = 0.02825(U_*F)^{1/2}$ =	5.11	sec	*(Eqn. 3-34c, SPM)*

Step 13. Compute Deep-Water Wave Length, L_o

Deep-Water Wave Length, $L_o = 5.12T_p^2$ =	133	feet	*(Eqn. 2-6b, SPM)*

Step 14. Compute Relative Depth, d/L_o

If $d/L_o \leq 0.5$, waves are classified as transitional or shallow water waves. *(pg 2-9, SPM)*
If $d/L_o > 0.5$, waves are classified as deep water. *(pg 2-9, SPM)*

Effective Depth, d =	18.28	feet	
Relative Depth = d/L_o =	0.137		*(pg 2-9, SPM)*
Wave Classification =	Transitional/Shallow-Water		*(pg 2-9, SPM)*

Step 15. Compute Shallow-Water Wave Period, T

(Eqn. 3-40, SPM)

Shallow-Water Wave Period, $T = 7.54\ \tanh(A)\ \tanh(B/C)\ U_*/g$
where: F = Fetch Length (ft) (step 5) U_* = Wind Stress Factor (step 10) g = 32.2 ft/s²

$A = 0.833(gd/U_*^2)^{3/4}$ =	0.1179	
$B = 0.037(gF/U_*^2)^{1/3}$ =	0.0663	
$C = \tanh(0.833(gd/U_*^2)^{3/4})$ =	0.1174	
Shallow-Water Wave Period, $T = 7.54\ \tanh(A)\ \tanh(B/C)\ U_*/g$ =	4.62 sec	*(Eqn. 3-40, SPM)*

Step 16. Compute Shallow-Water Significant Wave Height, H

(Eqn. 3-39, SPM)

Shallow-Water Significant Wave Height, $H = 0.283\ \tanh(A)\ \tanh(B/C)\ U_*^2/g$
where: F = Fetch Length (ft) (step 5) U_* = Wind Stress Factor (step 10) g = 32.2 ft/s²

$A = 0.530(gd/U_*^2)^{3/4}$ =	0.0106	
$B = 0.00565(gF/U_*^2)^{1/2}$ =	0.0131	
$C = \tanh(0.530(gd/U_*^2)^{3/4})$ =	0.0106	
Shallow-Water Significant Wave Height, $H = 0.283\ \tanh(A)\ \tanh(B/C)\ U_*^2/g$ =	0.51 feet	*(Eqn. 3-39, SPM)*

Step 17. Compute Shallow-Water Wave Height for Zero Overwash

DCM-2 requires zero over wash as a design criteria for high and significant hazard dams. For purposes of the DCM-2, zero overwash wave height is defined as the wave height with a 2% occurrence frequency.

Significant Wave Height is either the Deep-Water or Shallow-Water Significant wave height
Depending upon the Wave Classification (Step 14).

Significant Wave Height, H_s =	6.51	feet	*(see Step 11 or 16)*
Required probability of wave height being exceeded, n/N =	0.02		*(see Step 17 discussion)*
Root Mean Square Wave Height, $H_{rms} = 2^{-1/2}H_s$ =	6.01	feet	*(Eqn. 3-10, SPM)*
Wave Height which is exceeded at given probability, $H^* = H_{rms}\ [-Ln(n/N)]^{1/2}$ =	11.76	feet	*(Eqn. 3-7, SPM)*

Step 18. Compute Wind Set-Up

Four different methods are calculated and considered in estimating wind setup:
Zeider Zee Eqn: Widely used as applied to reservoirs but tends to overestimate wind setup for shallow impoundments (ave. depth<16 ft).
Sibul Eqn. Typically yields the lowest wind setup.
Ave. of Zeider Zee & Sibul: Recommended for shallow impoundments (ave. depth<16 ft) when Bretschneider has no numeric solution.
Bretschneider Eqn: Recommend for shallow impoundments (average depth <16 ft).

Fetch Length, F =	3.40	miles	*(see Step 4)*
Fetch Length, F =	17,944	feet	
Average Wind Velocity, U = Wind Speed per Step 7 = $U_{Cat5,fetch-ltd}$ =	125	mph	*(pg A6, DCM-2)(see Step 7)*
Average Depth of Water along Fetch Line, D = Effective Depth =	18.28	feet	*(see Step 14)*
Zeider Zee Eqn: (Note: F=miles): Wind Set-Up, $S = U^2F/(1400D)$ =	2.09	feet	*(Eqn. 5, DCM-2)*
Sibul Eqn (Note: F=feet, g=32.2 ft/s²): $S = 0.0000244d(F/d)^{1.65}(U^2/[g])^{2.0(0.57\ to\ 0.75)}$ =	0.57	feet	*(Eqn. 7, DCM-2)*
Average of Zeider Zee & Sibul: Wind Setup, $S = (S_{Zeider\ Zee} + S_{Sibul})/2$ =	1.33	feet	
Bretschneider Eqn (Note: Calcs provided separately in Step 18a): $S = \Sigma[(KU^2\Delta x)/(gd^*)]$ =	n/a	feet	*(Eqn. 6, DCM-2)(Eqn 18a)*
Equation Used for Wind Setup *(Enter Zeider Zee, Sibul, Average, Bretschneider)* =	Zeider Zee		
Computed Wind Set-Up, S =	2.09	feet	*(Eqn. 5, DCM-2)*

Step 19. Compute Water Depth at Toe of Structure

Water Depth at Toe of Structure, d_t = Effective Depth + Wind Set-Up = d + S =	20.37	feet	*(pg. 6, DCM-2)*

Step 20. Check for Depth Limited Wave Breaking

See if wave height is limited due to breaking. After breaking, waves will tend to reform with lower heights within a few wave lengths. *(pg. 15-4, EM-1110-2-1420)*

Depth of interest is at Toe of Structure, $d_s = d_t$ =	20.37	feet	*(see Step 19)*
Wave Breaking Height, H_b (for depth d_s) = $(d_s/1.28)$ =	15.91	feet	*(Eqn. 2-91 & 3-50, SPM)*
Is max. wave height limited by breaking? (If H_b [step 20] $\leq H^*$ [step 17] then yes, else no) =	No		
(If no, wave height = H^* (step 17). If yes, conservatively assume wave height = H_b (step 20)) Maximum Wave Height =	11.76	feet	

Step 21. Estimate Ratio Between Deep-Water Wave Ht & Equivalent Deep-Water Ht

The value of H/Ho (shallow-water wave height/equivalent deep-water wave height), is estimated based on the value of d/L_o (effective depth / deep-water wave length) from Table C-1, SPM Vol II, Appendix C.

Effective Depth, d =	18.28	feet	*(see Step 14)*
Deep-Water Wave Length, L_o =	133	feet	*(see Step 13)*
Ratio of effective depth to deep-water wave length, d/L_o =	0.137		
H/H^*_o =	0.9152		*(Table C-1, SPM Vol 2)*

Step 22. Compute Equivalent Deep-Water Wave Height, H^*_o

If wave classification is Deep-Water (Step 14), Significant Deep-Water Height is the Equivalent Deep-Water Height.
If wave classification is Transitional/Shallow-Water an adjustment is necessary.
If Wave Breaking Height (Step 20) is less than the Zero Overwash for Significant Wave Height (Step 17)
then Equivalent Deep-Water Wave Height is Wave Braking Height (irrespective of wave classification).

Wave Breaking Height, H_b =	15.91	feet	*(see Step 20)*
Significant Wave Height, H_s =	11.76	feet	*(see Step 17)*
H/H^*_o =	0.9152		*(see Step 21)*
If Shallow-Water: Equivalent Deep-Water Wave Height, $H^*o = H/(H/H^*o)$ =	12.85	feet	
If Deep Water: Equivalent Deep-Water Wave Height = Significant Deep-Water Height =	n/a	feet	
If Height Limited by Wave Breaking: Equiv. Deep-Water Wave Ht. = Wave Breaking Ht. =	n/a	feet	
Equivalent Deep-Water Wave Height =	12.85	feet	

Step 23. Compute Depth at Toe of Structure to Equiv. Deep-Water Wave Ht, d_t/H^*_o

Water Depth at Toe of Structure, d_t =	20.37	feet	*(see Step 19)*
Equivalent Deep-Water Wave Height, H^*_o =	12.85	feet	*(see Step 22)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_t/H^*_o =	1.59		

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 2: 100-Year Precipitation Combined with Category 5 Hurricane Winds
Wave Runup Analysis - Site C-43: Cell 2 (Fetch 2A)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.40	miles	*(see Step 4)*
Fetch Length, F =	17,944	feet	
Category 5, Fetch Limited Wind Speed Over Water = $U_{CAT5,fetch-ltd}$ =	125	mph	*(see Step 7)*
Wind Stress Factor, U_A (ft/s) =	329	ft/s	*(see Step 10)*

Wind Setup and Wave Properties Analysis - Summary Data

Wind Set-Up , S =	2.09	feet	*(see Step 18)*
Equivalent Deep-Water Wave Height, H'_o =	12.85	feet	*(see Step 22)*
Deep-Water Wave Period, T_o =	5.11	sec	*(see Step 12)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_s/H'_o =	1.58		*(see Step 23)*

Step 24. Compute Ratio of $H'_o/(gT_o^2)$

Equivalent Deep-Water Wave Height, H'_o =	12.85	feet	*(see Step 22)*
Gravitational constant, g =	32.2	ft/s^2	*(constant variable)*
Deep Water Wave Period, T_o =	5.11	sec	*(see Step 12)*
$H'_o/(gT_o^2)$ =	0.015		

Steps 25 - 27. Estimate R/H'o *(Fig. 7-8 thru 7-20, SPM Vol. 2)*

Steps 25-27 are directed towards deriving the ratio of Wave Runup to the Equivalent Deep-Water Wave Height (R/H'_o) from graphs found in SPM Volume 2 (Fig. 7-8 thru 7-20). The graphs are based upon various designs of the runup face slope including the material, roughness, slope, and geometry the face slope. In addition the value of R/H'_o depends upon the values of d_s/H'_o and $H'_o/(gT^2)$. Determination of values will typically require an interpolation of values between graphs.

d_s/H'_o =	1.58		*(see Step 23)*
$H'_o/(gT_o^2)$ =	0.015		*(see Step 24)*
Face Slope Material =	Stop-Faced Slope		*Embankment Design*
Runup Face Slope (H:1V) =	3		*Embankment Design*
Runup Face Slope (Θ) =	18.4	degrees	
Figure used for Interpolation (Lower Interpolation Number) =	Fig. 7-10		*(SPM Vol. 2)*
Figure to used for Interpolation (Higher Interpolation Number) =	Fig. 7-11		*(SPM Vol. 2)*

Step 25. R/H'o from Fig. 7-10 with ds/H'o <= 1.58

$H'_o/(gT_o^2)$ =	0.015		*(see Step 24)*
ds/H'o <=1.58 from Fig. 7-10 =	0.8		*(Fig. 7-10, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-10 =	0.75		*(Fig. 7-10, SPM Vol. 2)*

Step 26. R/H'o from Fig. 7-11 with ds/H'o >= 1.58

$H'_o/(gT_o^2)$ =	0.015		*(see Step 24)*
ds/H'o >=1.58 from Fig. 7-11 =	2.0		*(Fig. 7-11, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-11 =	0.89		*(Fig. 7-11, SPM Vol. 2)*

Step 27. Estimated Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o

d_s/H'_o =	1.58		*(see Step 23)*
$H'_o/(gT_o^2)$ =	0.015		*(see Step 24)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o =	0.84		*(Interpolated from Steps 25 & 26)*

Step 28. Compute Smooth Surface Wave Runup

Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'_o =	0.84		*(see Step 27)*
Equivalent Deep-Water Wave Height, H'_o =	12.85		*(see Step 22)*
Smooth Surface Wave Runup = R/H'_o x H'_o =	10.80	feet	

Step 29. If Applicable, Determine and Apply Wave Runup Correction Factor due to Scale Effects

This step applies if Figures 7-8 thru 7-12 or Figures 7-14 thru 7-18 were used to estimate R/H'_o in Steps 25-27. These figures summarize results for small-scale lab tests. Due to the inability to scale roughness effects in small-scale lab tests, the results are probably smaller than the runup on prototype structures. Figure 7-13 is used to adjust for this scale effect.

Smooth Surface Wave Runup = R/H'_o x H'_o =	10.80	feet	*(see Step 28)*
Scale Wave Runup Correction due to Scale Effects *(If Fig. 7-19 or 7-20 used, enter 1)* =	1.12		*(Fig. 7-13, SPM Vol. 2)*
Scale Corrected Wave Runup Height = (Smooth Surface Wave Runup)(Runup Correction) =	12.10	feet	

Step 30. Determine and Apply Correction Factor due to Dam Surface Roughness

Face Slope Material =	Stop-Faced Slope		*(see Step 25)*
Surface Roughness Correction =	0.7		*(Table 7-2, SPM Vol 2) or (Table 2-2 EM1110-2-1614)*
Scale Corrected Wave Runup Height =	12.10	feet	*(see Step 29)*
Corrected Wave Runup = (Scale Corrected Wave Runup)(Surface Roughness Correction) =	8.47	feet	

Step 31. Correction Due to to Fetch Axis Not Being Normal to the Dam Axis

Angle Between Fetch Axis and Embankment Axis =	42	degrees	
Angle Correction Factor =	0.90		*(Fig. 8, ACER TM No. 11)*

Step 32. Adjusted Wave Runup

Corrected Wave Runup =	8.47		*(see Step 30)*
Angle Correction Factor =	0.90		*(see Step 31)*
Final Adjusted Wave Runup = (Corrected Wave Runup)(Angle Correction Factor) =	7.6	feet	

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 2: 100-Year Precipitation Combined with Category 5 Hurricane Winds
Minimum Required Freeboard - Site C-43: Cell 2 (Fetch 2A)

Step 33. Minimum Required Design Freeboard

Design Precipitation **or** Flood Surge Depth (Routed Flood Event) =	0.77	ft	*(based upon max. water surface elevation of routed storm event)*
Wind Setup =	2.09	ft	*(see Step 18)*
Wave Height & Runup =	7.62	ft	*(see Step 32)*
Waves Induced by Potential Landslides =	0.00	ft	*(not considered)*
Provision for Malfunction of the Spillway or Discharge Structure =	0.00	ft	*(not considered)*
Summation of all above Freeboard Components is Minimum Required Freeboard =	10.48	ft	*(rounded up to the next 0.01 foot)*

Step 34. Minimum Required Design Freeboard with Camber

Average Normal Full Storage Depth =	17.51	ft	*(Average Depth along Fetch based on NFSL = 42 ft El.)*
Minimum Required Freeboard =	10.48	ft	*(see Step 33)*
Embankment Height (not including camber) =	27.99	ft	*(summation of average normal full storage depth and freeboard)*
Minimum Required Freeboard =	10.48	ft	*(see Step 33)*
Embankment Settlement =	0.67	ft	*(see Technical Memorandum Table 3 or BODR Section 8E.)*
Minimum Embankment Height (with camber) =	28.66	ft	*(minimum embankment height plus settlement)*
Minimum Required Design Freeboard with Camber =	11.15	ft	*(rounded up to the next 0.01 foot)*

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

Case 3: Probable Maximum Wind Speed Combined with Normal Full Storage Level (Uncontrolled Spillway Level)
Design Wind Speed Analysis - Site C-43: Cell 2 (Fetch 2A)

Steps 1-2: Not necessary for Case 3

Project Location =	C-43 Cell No. 2		
Probable Maximum Wind (PMW) Speed, $U_{PMW,60\text{-}sec,water}$ =	200.0	mph	*(pg 13, DCM-2)*

For Case 3, the 200 mph assumed PMW corresponds to an over-water 1-minute average wind speed. *(pg 13, DCM-2)*

Step 3: Determine PMW, 1-Hr Wind Speed, $U_{PMW,\ 1\text{-}hr}$

Initial wind speed duration, t =	60	sec.	*(based on Step 1 Data)*

Equations for ratio of wind speeds to 1-hour average wind speeds, U_t/U_{3600}

For t ≤ 3,600: $U_t/U_{3600} = 1.277 + 0.296\tanh(0.9\log_{10}(45/t))$ =	applies		*(Eqn. 1, DCM-2)*
For 3,600 < t < 36,000: $U_t/U_{3600} = -0.15\log_{10}(t)+1.5334$ =	does not apply		*(Eqn. 2, DCM-2)*
U_t/U_{3600} =	1.24		*(Eqn. 1, DCM-2)*
$U_t = U_{PMW,\ 60\text{-}sec}$ =	200.00	mph	*(see Step 2)*
$U_{PMW,\ 3600\text{-}sec} = U_{PMW,\ 1\text{-}hr} = U_t/(U_t/U_{3600})$ =	160.8	mph	

Step 4: Determine PMW, 1-Hr Wind Speed Over Water, $U_{PMW,1\text{-}hr,water}$

Fetch Length (in miles), X =	3.40	miles	

Wind Speed Over Water to Wind Speed Over Land Ratio, U_{Water}/U_{Land}:

If initial data from Step 1 is over water wind speed, no conversion (Ratio = 1.0)	does not apply		*(Fig. II-2-20, CEM)*
For Fetch Length < 10 miles: U_{Water}/U_{Land} = 1.2 or 1.0	applies		*(Fig. II-2-20, CEM)*
For Fetch Length > 10 miles: See Figure II-2-7, CEM	does not apply		*(Fig. II-2-7, CEM)*
U_{water}/U_{land} =	1		*(Fig. II-2-20, CEM)*
$U_{PMW,1\text{-}hr,land}$ =	-		*(see Step 3)*
$U_{PMW,1\text{-}hr,water} = U_{PMW,1\text{-}hr,land} \times (U_{water}/U_{land})$ =	160.8	mph	

Step 5: Estimate Fetch-Limited Wind Duration Time

Fetch Length (in miles), X =			
Wind Velocity (in mph), U =	160.8	mph	*(see Step 4)*
Fetch Limited Wind Duration Time, $t = 112(X^{0.67}/U^{0.34})$ =	45	min.	*(Eqn. 4, DCM-2)*
	2711	sec.	

Step 6: Estimate Ratio of Fetch Limited Duration Wind Speed and 1-Hour Wind Speed

Fetch Limited Wind Duration Time (in seconds), t =	2711	sec.	*(see Step 5)*

Equations for ratio of wind speeds to 1-hour average wind speeds, U_t/U_{3600}

For t ≤ 3,600: $U_t/U_{3600} = 1.277 + 0.296\tanh(0.9\log_{10}(45/t))$ =	applies		*(Eqn. 1, DCM-2)*
For 3,600 < t < 36,000: $U_t/U_{3600} = -0.15\log_{10}(t)+1.5334$ =	does not apply		*(Eqn. 2, DCM-2)*
Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.004		*(Eqn. 1, DCM-2)*

Step 7: Adjust 1-Hr Wind Speed (over water) to Equivalent Fetch Limited Duration Wind Speed

Fetch Limited Wind Duration (in minutes), t =	45	min.	*(see Step 5)*
100-Yr, 1-Hr Wind Speed Over Water, $U_{100\text{-}yr,1\text{-}hr,water}$ =	160.8	mph	*(see Step 4)*
Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.004		*(see Step 6)*
PMW, t-min Wind Speed Over Water = $U_{PMW,1\text{-}hr,water} \times U_t/U_{3600}$ =	161	mph	

Step 8: Stability Correction, Adjust Wind Speed for Boundary Layer Stability

Fetch Length (in miles), X =	3.40	miles	*(see Step 4)*
(If Fetch Length > 10 miles, else enter 0) Temperature of Air, T_a =	0	o C	
(If Fetch Length > 10 miles, else enter 0) Temperature of Sea, T_s =	0	o C	
Air-Sea Temperature Difference, ΔT_{as} $T_a - T_s$ =	0	° C	

Stability Correction Factor, R_T

For Fetch Length < 10 miles: R_T = 1.0	applies		*(pg. II-2-36, CEM)*
For Fetch Length > 10 miles: Based on ΔT_{as}, See Figure 3-14, SPM or in absence	does not apply		*(Fig.3-14, SPM)*
of temperature information, assume RT = 1.1			*(pg 3-30, SPM)*
$U_{PMW,fetch\text{-}min,water}$ =	161	mph	*(see Step 7)*
Stability Correction Factor, R_T =	1		*(pg. II-2-36, CEM)*
$U_{PMW,fetch\text{-}min,water,\ stability\ adjusted} = U_{PMW,fetch\text{-}min,water} \times R_T$ =	161	mph	*(Eqn. 3-27 SPM)*

Step 9. Compute Wind Stress Factor, U_A

$U_{PMW,fetch\text{-}min,water,\ stability\ adjusted} = U$ =	161	mph	*(see Step 8)*
Wind Stress Factor, $U_A = 0.589U^{1.23}$ =	306	mph	*(Eqn. 3-28b SPM)*

Step 10. Wind Stress Factor in ft/s

Wind Stress Factor, U_A (ft/s) = $1.467U_A$ (mph) =	449	ft/sec.	*(see Step 9)*

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 3: Probable Maximum Wind Speed Combined with Normal Full Storage Level (Uncontrolled Spillway Level)
Wind Setup and Wave Properties Analysis - Stie C-43: Cell 2 (Fetch 2A)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.40	miles	*(see Step 5)*
Fetch Length, F =	17,944	ft	
PMW, Fetch Limited Wind Speed Over Water = $U_{PMW(Fetch-Ltd)}$ =	161	mph	*(see Step 7)*
Wind Stress Factor, U_s (ft/s) =	448	ft/s	*(see Step 10)*

Step 11. Compute Deep-Water Significant Wave Height, H_{mo}

Deep Water Significant Wave Height, $H_{mo} = (0.0002821)U_s F^{1/2}$ =	16.96	feet	*(Eqn. 3-33c, SPM)*

Step 12. Compute Deep-Water Wave Period, T_o

Deep-Water Wave Period, $T_o = 0.02825(U_s F)^{1/2}$ =	5.86	sec	*(Eqn. 3-34c, SPM)*

Step 13. Compute Deep-Water Wave Length, L_o

Deep-Water Wave Length, $L_o = 5.12 T_o^2$ =	164	feet	*(Eqn. 2-8b, SPM)*

Step 14. Compute Relative Depth, d/L_o

If $d/L_o \leq 0.5$, waves are classified as transitional or shallow water waves. *(pg 2-8, SPM)*
If $d/L_o > 0.5$, waves are classified as deep water. *(pg 2-8, SPM)*

Effective Depth, d =	17.51	feet	
Relative Depth = d/L_o =	0.107		*(pg 2-8, SPM)*
Wave Classification =	Transitional/Shallow Water		*(pg 2-8, SPM)*

Step 15. Compute Shallow-Water Wave Period, T

Shallow-Water Wave Period, $T = 7.54 \tanh(A) \tanh(B/C)\, U_s/g$ *(Eqn. 3-40, SPM)*
where: F = Fetch Length (ft) (step 5) U_s = Wind Stress Factor (step 10) $g = 32.2$ ft/s^2

$A = 0.833(gd/U_s^2)^{3/8}$ =	0.0918		
$B = 0.0379(gF/U_s^2)^{1/3}$ =	0.0930		
$C = \tanh(0.853(gd/U_s^2)^{0.65})$ =	0.0916		
Shallow-Water Wave Period, $T = 7.54 \tanh(A) \tanh(B/C)\, U_s/g$ =	5.39	sec	*(Eqn. 3-40, SPM)*

Step 16. Compute Shallow-Water Significant Wave Height, H

Shallow-Water Significant Wave Height, $H = 0.283 \tanh(A) \tanh(B/C)\, U_s^2/g$ *(Eqn. 3-39, SPM)*
where: F = Fetch Length (ft) (step 5) U_s = Wind Stress Factor (step 10) $g = 32.2$ ft/s^2

$A = 0.530(gd/U_s^2)^{3/4}$ =	0.0964		
$B = 0.0565(gF/U_s^2)^{1/3}$ =	0.0996		
$C = \tanh(0.530(gd/U_s^2)^{0.75})$ =	0.0963		
Shallow-Water Significant Wave Height, $H = 0.283 \tanh(A) \tanh(B/C)\, U_s^2/g$ =	13.33	feet	*(Eqn. 3-39, SPM)*

Step 17. Compute Shallow-Water Wave Height for Zero Overwash

DCM-2 requires zero over wash as a design criteria for high and significant hazard dams. For purposes of the DCM-2, zero overwash wave height is defined as the wave height with a 2% occurrance frequency.

Significant Wave Height is either the Deep-Water or Shallow-Water Significant wave height
Depending upon the Wave Classification (Step 14).

Significant Wave Height, H_s =	10.20	feet	*(see Step 11 or 16)*
Required probability of wave height being exceeded, n/N =	0.02		*(see Step 17 discussion)*
Root Mean Square Wave Height, $H_{rms} = 2^{-1/2} H_s$ =	7.29	feet	*(Eqn. 3-10, SPM)*
Wave Height which is exceeded at given probability, $H^* = H_{rms} [-\ln(n/N)]^{1/2}$ =	14.25	feet	*(Eqn. 3-7, SPM)*

Step 18. Compute Wind Set-Up

Four different methods are calculated and considered in estimating wind setup
Zeider Zee Eqn: Widely used as applied to reservoirs but tends to overestimate wind setup for shallow impoundments (ave. depth<16 ft).
Sibul Eqn: Typically yields the lowest wind setup.
Ave. of Zeider Zee & Sibul: Recommended for shallow impoundments (ave. depth<16 ft) when Bretschneider has no numeric solution.
Bretschneider Eqn: Recommend for shallow impoundments (average depth <16 ft).

Fetch Length, F =	3.40	miles	*(see Step 5)*
Fetch Length, F =	17,944	feet	
Average Wind Velocity, U = Wind Speed per Step 7 = $U_{PMW(Fetch-Ltd)}$ =	161	mph	*(pg A6, DCM-2)(see Step 7)*
Average Depth of Water along Fetch Line, D = Effective Depth =	17.51	feet	*(see Step 14)*
Zeider Zee Eqn: (Note: F=miles): Wind Set-Up, $S = U^2F/(1400D)$ =	3.61	feet	*(Eqn. 5, DCM-2)*
Sibul Eqn (Note: F=feet, g=32.2 ft/s^2): $S = 0.0002444(F/d)^{1/3}(U^2F/g)^{0.5[(F/d)^{1/3}-0.277d]}$ =	1.06	feet	*(Eqn. 7, DCM-2)*
Average of Zeider Zee & Sibul: Wind Setup, $S = (S_{Zeider\ Zee} + S_{Sibul})/2$ =	2.35	feet	
Bretschneider Eqn (Note: Calcs provided separately in Step 18a): $S = \Sigma[(kU^2\Delta x)/(gd^2)]$ =	n/a	feet	*(Eqn. 8, DCM-2)(Step 18a)*
Equation Used for Wind Setup *(Enter Zeider Zee, Sibul, Average, Bretschneider)* =	Zeider Zee		
Computed Wind Set-Up, S =	3.61	feet	*(Eqn. 5, DCM-2)*

Step 19. Compute Water Depth at Toe of Structure

Water Depth at Toe of Structure, d_t = Effective Depth + Wind Set-Up = d + S =	21.12	feet	*(pg. 6, DCM-2)*

Step 20. Check for Depth Limited Wave Breaking

See if wave height is limited due to breaking. After breaking, waves will tend to reform with lower heights within a few wave lengths. *(pg. 15-4, EM-1110-2-1420)*

Depth of interest is at Toe of Structure, $d_t = d_t$ =	21.12	feet	*(see Step 19)*
Wave Breaking Height, H_b (for depth d_t) = $(d_t/1.28)$ =	16.50	feet	*(Eqn. 2-91 & 3-50, SPM)*
Is max. wave height limited by breaking? (If H_b (step 20) $\leq H^*$ (step 17) than yes, else no) =	No		
(If no, wave height = H^* (step 17). If yes, conservatively assume wave height = H_b (step 20)) Maximum Wave Height =	14.25	feet	

Step 21. Estimate Ratio Between Deep-Water Wave Ht & Equivalent Deep-Water Ht

The value of H/Ho (shallow-water wave height/equivalent deep-water wave height) is estimated based on the value of d/L_o (effective depth / deep-water wave length) from Table C-1, SPM Vol II, Appendix C.

Effective Depth, d =	17.51	feet	*(see Step 14)*
Deep-Water Wave Length, L_o =	164	feet	*(see Step 13)*
Ratio of effective depth to deep-water wave length, d/L_o =	0.107		
H/H'_o =	0.9276		*(Table C-1, SPM Vol 2)*

Step 22. Compute Equivalent Deep-Water Wave Height, H'_o

If wave classification is Deep-Water (Step 14), Significant Deep-Water Height is the Equivalent Deep-Water Height.
If wave classification is Transitional/Shallow-Water an adjustment is necessary.
If Wave Breaking Height (Step 20) is less than the Zero Overwash for Significant Wave Height (Step 17)
then Equivalent Deep-Water Wave Height is Wave Breaking Height (irregardless of wave classification).

Wave Breaking Height, H_b =	16.50	feet	*(see Step 20)*
Significant Wave Height, H_s =	14.25	feet	*(see Step 17)*
H/H'_o =	0.9276		*(see Step 21)*
If Shallow-Water, Equivalent Deep-Water Wave Height, $H'o = H/(H/Ho)$ =	15.37	feet	
If Deep Water: Equivalent Deep-Water Wave Height = Significant Deep-Water Height =	n/a	feet	
If Height Limited by Wave Breaking, Equiv. Deep-Water Wave Ht. = Wave Breaking Ht. =	n/a	feet	
Equivalent Deep-Water Wave Height =	15.37	feet	

Step 23. Compute Depth at Toe of Structure to Equiv. Deep-Water Wave Ht, d_t/H'_o

Water Depth at Toe of Structure, d_t =	21.12	feet	*(see Step 19)*
Equivalent Deep-Water Wave Height, H'_o =	15.37	feet	*(see Step 22)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_t/H'_o =	1.37		

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 3: Probable Maximum Wind Speed Combined with Normal Full Storage Level (Uncontrolled Spillway Level)
Wave Runup Analysis - Site C-43: Cell 2 (Fetch 2A)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.40	miles	*(see Step 5)*
Fetch Length, F =	17,944	feet	
PMW, Fetch Limited Wind Speed Over Water = $U_{PMW,fetch-min}$ =	161	mph	*(see Step 7)*
Wind Stress Factor, U_A (ft/s) =	449	ft/s	*(see Step 10)*

Wind Setup and Wave Properties Analysis - Summary Data

Wind Set-Up , S =	3.61	feet	*(see Step 18)*
Equivalent Deep-Water Wave Height, H'_o =	15.37	feet	*(see Step 22)*
Deep-Water Wave Period, T_o =	5.66	sec	*(see Step 12)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_s/H'_o =	1.37		*(see Step 23)*

Step 24. Compute Ratio of $H'_o/(g*T_o^2)$

Equivalent Deep-Water Wave Height, H'_o =	15.37	feet	*(see Step 22)*
Gravitational constant, g =	32.2	ft/s^2	*(constant variable)*
Deep Water Wave Period, T_o =	5.66	sec	*(see Step 12)*
$H'_o/(g*T_o^2)$ =	0.015		

Steps 25 - 27. Estimate R/H'o *(Fig. 7-8 thru 7-20, SPM Vol. 2)*

Steps 25-27 are directed towards deriving the ratio of Wave Runup to the Equivalent Deep-Water Wave Height (R/H'_o) from graphs found in SPM Volume 2 (Fig. 7-8 thru 7-20). The graphs are based upon various designs of the runup face slope including the material, roughness, slope, and geometry the face slope. In addition the value of R/H'_o depends upon the values of d_s/H'_o and $H'_o/(gT^2)$. Determination of values will typically require an interpolation of values between graphs.

d_s/H'_o =	1.37		*(see Step 23)*
$H'_o/(g*T_o^2)$ =	0.015		*(see Step 24)*
Face Slope Material =	Stop-Faced Slope		*Embankment Design*
Runup Face Slope (H:1V) =	3		*Embankment Design*
Runup Face Slope (Θ) =	18.4	degrees	
Figure used for Interpolation (Lower Interpolation Number) =	Fig. 7-10		*(SPM Vol. 2)*
Figure to used for Interpolation (Higher Interpolation Number) =	Fig. 7-11		*(SPM Vol. 2)*

Step 25. R/H'o from Fig. 7-10 with ds/H'o <= 1.37

$H'_o/(g*T_o^2)$ =	0.015		*(see Step 24)*
ds/H'o <=1.37 from Fig. 7-10 =	0.8		*(Fig. 7-10, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-10 =	0.75		*(Fig. 7-10, SPM Vol. 2)*

Step 26. R/H'o from Fig. 7-11 with ds/H'o >= 1.37

$H'_o/(g*T_o^2)$ =	0.015		*(see Step 24)*
ds/H'o >=1.37 from Fig. 7-11 =	2.0		*(Fig. 7-11, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-11 =	0.89		*(Fig. 7-11, SPM Vol. 2)*

Step 27. Estimated Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o

d_s/H'_o =	1.37		*(see Step 23)*
$H'_o/(g*T_o^2)$ =	0.015		*(see Step 24)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o =	0.82		*(Interpolated from Steps 25 & 26)*

Step 28. Compute Smooth Surface Wave Runup

Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'_o =	0.82		*(see Step 27)*
Equivalent Deep-Water Wave Height, H'_o =	15.37		*(see Step 22)*
Smooth Surface Wave Runup = R/H'_o x H'_o =	12.50	feet	

Step 29. If Applicable, Determine and Apply Wave Runup Correction Factor due to Scale Effects

This step applies if Figures 7-8 thru 7-12 or Figures 7-14 thru 7-16 were used to estimate R/H'_o in Steps 25-27. These figures summarize results for small-scale lab tests. Due to the inability to scale roughness effects in small-scale lab tests, the results are probably smaller than the runup on prototype structures. Figure 7-13 is used to adjust for this scale effect.

Smooth Surface Wave Runup = R/H'_o x H'_o =	12.50	feet	*(see Step 28)*
Scale Wave Runup Correction due to Scale Effects *(If Fig. 7-19 or 7-20 used, enter 1)* =	1.12		*(Fig. 7-13, SPM Vol. 2)*
Scale Corrected Wave Runup Height = (Smooth Surface Wave Runup)(Runup Correction) =	14.00	feet	

Step 30. Determine and Apply Correction Factor due to Dam Surface Roughness

Face Slope Material =	Stop-Faced Slope		*(see Step 25)*
Surface Roughness Correction =	0.7		*(Table 7-2, SPM Vol 2) or (Table 2-2 EM1110-2-1614)*
Scale Corrected Wave Runup Height =	14.00	feet	*(see Step 29)*
Corrected Wave Runup = (Scale Corrected Wave Runup)(Surface Roughness Correction) =	9.80	feet	

Step 31. Correction Due to to Fetch Axis Not Being Normal to the Dam Axis

Angle Between Fetch Axis and Embankment Axis =	42	degrees	
Angle Correction Factor =	0.90		*(Fig. 8, ACER TM No. 11)*

Step 32. Adjusted Wave Runup

Corrected Wave Runup =	9.80		*(see Step 30)*
Angle Correction Factor =	0.90		*(see Step 31)*
Final Adjusted Wave Runup = (Corrected Wave Runup)(Angle Correction Factor) =	8.8	feet	

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 3: Probable Maximum Wind Speed Combined with Normal Full Storage Level (Uncontrolled Spillway Level)
Minimum Required Freeboard - Site C-43: Cell 2 (Fetch 2A)

Step 33. Minimum Required Design Freeboard

Design Precipitation **or** Flood Surge Depth (Routed Flood Event) =	0.00	ft	*(no surcharge, normal full storage level elevation assumed)*
Wind Setup =	3.61	ft	*(see Step 18)*
Wave Height & Runup =	8.82	ft	*(see Step 32)*
Waves Induced by Potential Landslides =	0.00	ft	*(not considered)*
Provision for Malfunction of the Spillway or Discharge Structure =	0.00	ft	*(not considered)*
Summation of all above Freeboard Components is Minimum Required Freeboard =	12.44	ft	*(rounded up to the next 0.01 foot)*

Step 34. Minimum Required Design Freeboard with Camber

Average Normal Full Storage Depth =	17.51	ft	*(Average Depth along Fetch based on NFSL = 42 ft El.)*
Minimum Required Freeboard =	12.44	ft	*(see Step 33)*
Embankment Height (not including camber) =	29.95	ft	*(summation of average normal full storage depth and freeboard)*
Minimum Required Freeboard =	12.44	ft	*(see Step 33)*
Embankment Settlement =	0.88	ft	*(see Technical Memorandum Table 3 or BODR Section 8E)*
Minimum Embankment Height (with camber) =	30.83	ft	*(minimum embankment height plus settlement)*
Minimum Required Design Freeboard with Camber =	13.32	ft	*(rounded up to the next 0.01 foot)*

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

Case 4: Hurricane Easy (125 mph, 3-sec Gust Wind Speed Combined With Both 24-hr (38.7") & 72 hr (45.2") Rainfall Durations)
Design Wind Speed Analysis - Site C-43: Cell 2 (Fetch 2A)

Step 1-2: Select EASY, 3-Sec Gust Wind Speed, $U_{EASY,3\text{-}sec}$

Project Location =	C-43 Cell No. 2		
EASY, 3-sec Gust Wind Speed, $U_{EASY,3\text{-}sec}$ =	125.0	mph	*(pg. 14, DCM-2)*

The Hurricane Easy, 125 mph, 3-sec gust wind speed is a storm specific case. Therefore, it is assumed that the Step 2 conversion factor adjustment is not relevant for this case.

Step 3: Determine EASY, 1-Hr Wind Speed, $U_{EASY,1\text{-}hr}$

Initial wind speed duration, t =	3	sec.	*(based on Step 1 Data)*

Equations for ratio of wind speeds to 1-hour average wind speeds, U_t/U_{3600}

For t ≤ 3,600:	$U_t/U_{3600} = 1.277 + 0.296\tanh(0.9\log_{10}(45/t))$ =	applies		*(Eqn. 1, DCM-2)*
For 3,600 < t < 36,000:	$U_t/U_{3600} = -0.15\log_{10}(t)+1.5334$ =	does not apply		*(Eqn. 2, DCM-2)*
	U_t/U_{3600} =	1.51		*(Eqn. 1, DCM-2)*
	$U_t = U_{EASY,3\text{-}sec}$ =	125.00	mph	*(see Step 2)*
	$U_{100\text{-}yr,\ 3600\text{-}sec} = U_{100\text{-}yr,\ 1\text{-}hr} = U_t/(U_t/U_{3600})$ =	82.8	mph	

Step 4: Determine EASY, 1-Hr Wind Speed Over Water, $U_{EASY,1\text{-}hr,water}$

Fetch Length (in miles), X =	3.40	miles	

Wind Speed Over Water to Wind Speed Over Land Ratio, U_{Water}/U_{Land}:

If initial data from Step 1 is over water wind speed, no conversion (Ratio = 1.0)		does not apply		*(Fig. II-2-20, CEM)*
For Fetch Length < 10 miles:	U_{Water}/U_{Land} = 1.2 or 1.0	applies		*(Fig. II-2-20, CEM)*
For Fetch Length > 10 miles:	See Figure II-2-7, CEM	does not apply		*(Fig. II-2-7, CEM)*
	U_{water}/U_{land} =	1.2		*(Fig. II-2-20, CEM)*
	$U_{Easy,1\text{-}hr,land}$ =	82.8		*(see Step 3)*
	$U_{EASY,1\text{-}hr,water} = U_{EASY,1\text{-}hr,land} \times (U_{water}/U_{land})$ =	99.4	mph	

Step 5: Estimate Fetch-Limited Wind Duration Time

Fetch Length (in miles), X =	3.40	miles	*(see Step 4)*
Wind Velocity (in mph), U =	99.4	mph	*(see Step 4)*
Fetch Limited Wind Duration Time, $t = 112(X^{0.67}/(U^{0.34})$ =	53	min.	*(Eqn. 4, DCM-2)*
	3193	sec.	

Step 6: Estimate Ratio of Fetch Limited Duration Wind Speed and 1-Hour Wind Speed

Fetch Limited Wind Duration Time (in seconds), t =	3193	sec.	*(see Step 5)*

Equations for ratio of wind speeds to 1-hour average wind speeds, U_t/U_{3600}

For t ≤ 3,600:	$U_t/U_{3600} = 1.277 + 0.296\tanh(0.9\log_{10}(45/t))$ =	applies		*(Eqn. 1, DCM-2)*
For 3,600 < t < 36,000:	$U_t/U_{3600} = -0.15\log_{10}(t)+1.5334$ =	does not apply		*(Eqn. 2, DCM-2)*
	Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.001		*(Eqn. 1, DCM-2)*

Step 7: Adjust 1-Hr Wind Speed (over water) to Equivalent Fetch Limited Duration Wind Speed

Fetch Limited Wind Duration (in minutes), t =	53	min.	*(see Step 5)*
EASY, 1-Hr Wind Speed Over Water, $U_{EASY,1\text{-}hr,water}$ =	99.4	mph	*(see Step 4)*
Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.001		*(see Step 6)*
EASY, Fetch Limited Wind Speed Over Water = $U_{EASY,1\text{-}hr,water} \times U_t/U_{3600}$ =	100	mph	

Step 8: Stability Correction, Adjust Wind Speed for Boundary Layer Stability

Fetch Length (in miles), X =	3.40	miles	*(see Step 4)*
(If Fetch Length > 10 miles, else enter 0) Temperature of Air, T_a =	0	o C	
(If Fetch Length > 10 miles, else enter 0) Temperature of Sea, T_s =	0	o C	
Air-Sea Temperature Difference, ΔT_{as} $T_a - T_s$ =	0	°C	

Stability Correction Factor, R_T

For Fetch Length < 10 miles:	R_T = 1.0	applies		*(pg. II-2-36, CEM)*
For Fetch Length > 10 miles:	Based on ΔT_{as}, See Figure 3-14, SPM or in absence of temperature information, assume RT = 1.1	does not apply		*(Fig.3-14, SPM) (pg 3-30, SPM)*
	$U_{EASY,fetch\text{-}min,water}$ =	100	mph	*(see Step 7)*
	Stability Correction Factor, R_T =	1		*(pg. II-2-36, CEM)*
	$U_{EASY,fetch\text{-}min.water,\ stability\ adjusted} = U_{EASY,fetch\text{-}min,water} \times R_T$ =	100	mph	*(Eqn. 3-27 SPM)*

Step 9. Compute Wind Stress Factor, U_A

$U_{EASY,fetch\text{-}min.water,\ stability\ adjusted} = U$ =	100	mph	*(see Step 8)*
Wind Stress Factor, $U_A = 0.589U^{1.23}$ =	168	mph	*(Eqn. 3-28b SPM)*

Step 10. Wind Stress Factor in ft/s

Wind Stress Factor, U_A (ft/s) = $1.467U_A$ (mph) =	248	ft/sec	*(see Step 9)*

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 4: Hurricane Easy (125 mph, 3-sec Gust Wind Speed Combined With Both 24-hr (36.7") & 72-hr (46.2") Rainfall Durations)
Wind Setup and Wave Properties Analysis - Site C-43: Cell 2 (Fetch 2A)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.40	miles	*(see Step 4)*
Fetch Length, F =	17,944	ft	
EASY, Fetch Limited Wind Speed Over Water = $U_{(EASY,F=Fetch)}$ =	100	mph	*(see Step 7)*
Wind Stress Factor, U_* (ft/s) =	246	ft/s	*(see Step 10)*

Step 11. Compute Deep-Water Significant Wave Height, H_{mo}

Deep-Water Significant Wave Height, $H_{mo} = (0.000282)U_*F^{1/2}$ =	9.36	feet	*(Eqn. 3-33a, SPM)*

Step 12. Compute Deep-Water Wave Period, T_o

Deep-Water Wave Period, $T_o = 0.02825(U_*F)^{1/2}$ =	4.64	sec	*(Eqn. 3-34c, SPM)*

Step 13. Compute Deep-Water Wave Length, L_o

Deep-Water Wave Length, $L_o = 5.12T_o^2$ =	110	feet	*(Eqn. 2-6b, SPM)*

Step 14. Compute Relative Depth, d/L_o

If $d/L_o \leq 0.5$, waves are classified as transitional or shallow water waves. *(pg 2-9, SPM)*
If $d/L_o > 0.5$, waves are classified as deep water. *(pg 2-9, SPM)*

Effective Depth, d =	21.28	feet	
Relative Depth = d/L_o =	0.193		*(pg 2-9, SPM)*
Wave Classification =	Transitional/Shallow-Water		*(pg 2-9, SPM)*

Step 15. Compute Shallow-Water Wave Period, T

Shallow-Water Wave Period, $T = 7.54 \tanh(A) \tanh(B/C)\, U_*/g$ *(Eqn. 3-40, SPM)*
where: F = Fetch Length (ft) (step 5) U_* = Wind Stress Factor (step 10) $g = 32.2$ ft/s^2

$A = 0.833(gd/U_*^2)^{3/8}$ =	0.1544	
$B = 0.0379(gF/U_*^2)^{1/3}$ =	0.0009	
$C = \tanh(0.833(gd/U_*^2)^{3/8})$ =	0.1532	
Shallow-Water Wave Period, $T = 7.54 \tanh(A) \tanh(B/C)\, U_*/g$ =	4.26 sec	*(Eqn. 3-40, SPM)*

Step 16. Compute Shallow-Water Significant Wave Height, H

Shallow-Water Significant Wave Height, $H = 0.283 \tanh(A) \tanh(B/C)\, U_*^2/g$ *(Eqn. 3-39, SPM)*
where: F = Fetch Length (ft) (step 5) U_* = Wind Stress Factor (step 10) $g = 32.2$ ft/s^2

$A = 0.530(gd/U_*^2)^{3/8}$ =	0.0192	
$B = 0.0565(gF/U_*^2)^{1/2}$ =	0.0179	
$C = \tanh(0.530(gd/U_*^2)^{3/8})$ =	0.0182	
Shallow-Water Significant Wave Height, $H = 0.283 \tanh(A) \tanh(B/C)\, U_*^2/g$ =	7.27 feet	*(Eqn. 3-39, SPM)*

Step 17. Compute Shallow-Water Wave Height for Zero Overwash

DCM-2 requires zero over wash as a design criteria for high and significant hazard dams. For purposes of the DCM-2, zero overwash wave height is defined as the wave height with a 2% occurrence frequency.

Significant Wave Height is either the Deep-Water or Shallow-Water Significant wave height Depending upon the Wave Classification (Step 14).

Significant Wave Height, H_s =	7.27	feet	*(see Step 11 or 16)*
Required probability of wave height being exceeded, n/N =	0.02		*(see Step 17 discussion)*
Root Mean Square Wave Height, $H_{rms} = 2^{-1/2}H_s$ =	5.14	feet	*(Eqn. 3-10, SPM)*
Wave Height which is exceeded at given probability, $H^* = H_{rms}[-\ln(n/N)]^{1/2}$ =	10.06	feet	*(Eqn. 3-7, SPM)*

Step 18. Compute Wind Set-Up

Four different methods are calculated and considered in estimating wind setup
Zeider Zee Eqn: Widely used as applied to reservoirs but tends to overestimate wind setup for shallow impoundments (ave. depth<15 ft).
Sibul Eqn. Typically yields the lowest wind setup.
Ave. of Zeider Zee & Sibul: Recommended for shallow impoundments (ave. depth<15 ft) when Bretschneider has no numeric solution.
Bretschneider Eqn: Recommend for shallow impoundments (average depth <15 ft).

Fetch Length, F =	3.40	miles	*(see Step 4)*
Fetch Length, F =	17,944	feet	
Average Wind Velocity, U = Wind Speed per Step 7 = $U_{(EASY,F=Fetch)}$ =	100	mph	*(pg A6, DCM-2)(see Step 7)*
Average Depth of Water along Fetch Line, D = Effective Depth =	21.27666667	feet	*(see Step 14)*
Zeider Zee Eqn: [Note: F=miles]: Wind Set-Up, $S = U^2F/(1400D)$ =	1.13	feet	*(Eqn. 5, DCM-2)*
Sibul Eqn (Note: F=feet, g=32.2 ft/s^2): $S = 0.0000244(F/g)^{0.50}(U^2/g)^{1.23(F/g)^{-0.333}}$ =	0.29	feet	*(Eqn. 7, DCM-2)*
Average of Zeider Zee & Sibul: Wind Setup, $S = (S_{Zeider\ Zee} + S_{Sibul})/2$ =	0.70	feet	
Bretschneider Eqn [Note: Calcs provided separately in Step 12a]: $S = \Sigma[(kU^2/\sigma)x]/(gd^*)$ =	n/a	feet	*(Eqn. 8, DCM-2)(Step 18A)*
Equation Used for Wind Setup *(Enter Zeider Zee, Sibul, Average, Bretschneider)* =	Zeider Zee		
Computed Wind Set-Up, S =	1.13	feet	*(Eqn. 5, DCM-2)*

Step 19. Compute Water Depth at Toe of Structure

Water Depth at Toe of Structure, d_s = Effective Depth + Wind Set-Up = d + S =	22.41	feet	*(pg. 6, DCM-2)*

Step 20. Check for Depth Limited Wave Breaking

See if wave height is limited due to breaking. After breaking, waves will tend to reform with lower heights within a few wave lengths. *(pg. 15-4, EM-1110-2-1420)*

Depth of Interest is at Toe of Structure, $d_i = d_s$ =	22.41	feet	*(see Step 19)*
Wave Breaking Height, H_b (for depth d_i) = $(d_i/1.28)$ =	17.51	feet	*(Eqn. 2-91 & 3-50, SPM)*
Is max. wave height limited by breaking? (If H_s [step 20] $\leq H^*$ [step 17] then yes, else no) =	No		
(If no, wave height = H^* (step 17). If yes, conservatively assume wave height = H_b, (step 20)) Maximum Wave Height =	10.06	feet	

Step 21. Estimate Ratio Between Deep-Water Wave Ht & Equivalent Deep-Water Ht

The value of H/Ho (shallow water wave height/equivalent deep-water wave height) is estimated based on the value of d/L_o (effective depth / deep-water wave length) from Table C-1, SPM Vol II, Appendix C.

Effective Depth, d =	21.27666667	feet	*(see Step 14)*
Deep-Water Wave Length, L_o =	110	feet	*(see Step 13)*
Ratio of effective depth to deep-water wave length, d/L_o =	0.193		
H/H^*_o =	0.9167		*(Table C-1, SPM Vol 2)*

Step 22. Compute Equivalent Deep-Water Wave Height, H^*_o

If wave classification is Deep-Water (Step 14), Significant Deep-Water Height is the Equivalent Deep-Water Height.
If wave classification is Transitional/Shallow-Water an adjustment is necessary.
If Wave Breaking Height (Step 20) is less than the Zero Overwash for Significant Wave Height (Step 17) then Equivalent Deep-Water Wave Height is Wave Braking Height (irregardless of wave classification).

Wave Breaking Height, H_b =	17.51	feet	*(see Step 20)*
Significant Wave Height, H_s =	10.06	feet	*(see Step 17)*
H/H^*_o =	0.9167		*(see Step 21)*
If Shallow-Water: Equivalent Deep-Water Wave Height, $H^*_o = H/(H/H^*o)$ =	10.97	feet	
If Deep Water: Equivalent Deep-Water Wave Height = Significant Deep-Water Height =	n/a	feet	
If Height Limited by Wave Breaking: Equiv. Deep-Water Wave Ht. = Wave Breaking Ht. =	n/a	feet	
Equivalent Deep-Water Wave Height =	10.97	feet	

Step 23. Compute Depth at Toe of Structure to Equiv. Deep-Water Wave Ht, d_s/H^*_o

Water Depth at Toe of Structure, d_s =	22.41	feet	*(see Step 19)*
Equivalent Deep-Water Wave Height, H^*_o =	10.97	feet	*(see Step 22)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_s/H^*_o =	2.04		

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 4: Hurricane Easy (125 mph, 3-sec Gust Wind Speed Combined With Both 24-hr (38.7") & 72 hr (45.2") Rainfall Durations)
Wave Runup Analysis - Site C-43: Cell 2 (Fetch 2A)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.40	miles	*(see Step 4)*
Fetch Length, F =	17,944	feet	
EASY, Fetch Limited Wind Speed Over Water = $U_{EASY,fetch-ltd}$ =	100	mph	*(see Step 7)*
Wind Stress Factor, U_A (ft/s) =	248	ft/s	*(see Step 10)*

Wind Setup and Wave Properties Analysis - Summary Data

Wind Set-Up , S =	1.13	feet	*(see Step 18)*
Equivalent Deep-Water Wave Height, H'_o =	10.97	feet	*(see Step 22)*
Deep-Water Wave Period, T_o =	4.64	sec	*(see Step 12)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_s/H'_o =	2.04		*(see Step 23)*

Step 24. Compute Ratio of $H'_o/(gT_o^2)$

Equivalent Deep-Water Wave Height, H'_o =	10.97	feet	*(see Step 22)*
Gravitational constant, g =	32.2	ft/s^2	*(constant variable)*
Deep Water Wave Period, T_o =	4.64	sec	*(see Step 12)*
$H'_o/(gT_o^2)$ =	0.016		

Steps 25 - 27. Estimate R/H'o *(Fig. 7-8 thru 7-20, SPM Vol. 2)*

Steps 25-27 are directed towards deriving the ratio of Wave Runup to the Equivalent Deep-Water Wave Height (R/H'_o) from graphs found in SPM Volume 2 (Fig. 7-8 thru 7-20). The graphs are based upon various designs of the runup face slope including the material, roughness, slope, and geometry the face slope. In addition the value of R/H'_o depends upon the values of d_s/H'_o and $H'_o/(gT^2)$. Determination of values will typically require an interpolation of values between graphs.

d_s/H'_o =	2.04		*(see Step 23)*
$H'_o/(gT_o^2)$ =	0.016		*(see Step 24)*
Face Slope Material =	Stone-Faced Slope		*Embankment Design*
Runup Face Slope (H:1V) =	3		*Embankment Design*
Runup Face Slope (Θ) =	18.4	degrees	
Figure used for Interpolation (Lower Interpolation Number) =	Fig. 7-11		*(SPM Vol. 2)*
Figure to used for Interpolation (Higher Interpolation Number) =	Fig. 7-12		*(SPM Vol. 2)*

Step 25. R/H'o from Fig. 7-11 with ds/H'o <= 2.04

$H'_o/(gT_o^2)$ =	0.016		*(see Step 24)*
ds/H'o <=2.04 from Fig. 7-11 =	2		*(Fig. 7-11, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-11 =	0.84		*(Fig. 7-11, SPM Vol. 2)*

Step 26. R/H'o from Fig. 7-12 with ds/H'o >= 2.04

$H'_o/(gT_o^2)$ =	0.016		*(see Step 24)*
ds/H'o >=2.04 from Fig. 7-12 =	3		*(Fig. 7-12, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-12 =	1.04		*(Fig. 7-12, SPM Vol. 2)*

Step 27. Estimated Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o

d_s/H'_o =	2.04		*(see Step 23)*
$H'_o/(gT_o^2)$ =	0.016		*(see Step 24)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o =	0.85		*(Interpolated from Steps 25 & 26)*

Step 28. Compute Smooth Surface Wave Runup

Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'_o =	0.85		*(see Step 27)*
Equivalent Deep-Water Wave Height, H'_o =	10.97		*(see Step 22)*
Smooth Surface Wave Runup = R/H'_o x H'_o =	9.30	feet	

Step 29. If Applicable, Determine and Apply Wave Runup Correction Factor due to Scale Effects

This step applies if Figures 7-8 thru 7-12 or Figures 7-14 thru 7-16 were used to estimate R/H'_o in Steps 25-27. These figures summarize results for small-scale lab tests. Due to the inability to scale roughness effects in small-scale lab tests, the results are probably smaller than the runup on prototype structures. Figure 7-13 is used to adjust for this scale effect.

Smooth Surface Wave Runup = R/H'_o x H'_o =	9.30	feet	*(see Step 28)*
Scale Wave Runup Correction due to Scale Effects *(If Fig. 7-19 or 7-20 used, enter 1)* =	1.12		*(Fig. 7-13, SPM Vol. 2)*
Scale Corrected Wave Runup Height = (Smooth Surface Wave Runup)(Runup Correction) =	10.42	feet	

Step 30. Determine and Apply Correction Factor due to Dam Surface Roughness

Face Slope Material =	Stone-Faced Slope		*(see Step 25)*
Surface Roughness Correction =	0.7		*(Table 7-2, SPM Vol 2) or (Table 2-2 EM1110-2-1614)*
Scale Corrected Wave Runup Height =	10.42	feet	*(see Step 29)*
Corrected Wave Runup = (Scale Corrected Wave Runup)(Surface Roughness Correction) =	7.29	feet	

Step 31. Correction Due to to Fetch Axis Not Being Normal to the Dam Axis

Angle Between Fetch Axis and Embankment Axis =	42	degrees	
Angle Correction Factor =	0.90		*(Fig. 8, ACER TM No. 11)*

Step 32. Adjusted Wave Runup

Corrected Wave Runup =	7.29		*(see Step 30)*
Angle Correction Factor =	0.90		*(see Step 31)*
Final Adjusted Wave Runup = (Corrected Wave Runup)(Angle Correction Factor) =	6.6	feet	

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 4: Hurricane Easy (125 mph, 3-sec Gust Wind Speed Combined With Both 24-hr (38.7") & 72 hr (45.2") Rainfall Durations)
Minimum Required Freeboard - Site C-43: Cell 2 (Fetch 2A)

Step 33. Minimum Required Design Freeboard

Design Precipitation **or** Flood Surge Depth (Routed Flood Event) =	3.77	ft	*(conservatively assumed to be total EASY precipitation of 45.2")*
Wind Setup =	1.13	ft	*(see Step 18)*
Wave Height & Runup =	6.56	ft	*(see Step 32)*
Waves Induced by Potential Landslides =	0.00	ft	*(not considered)*
Provision for Malfunction of the Spillway or Discharge Structure =	0.00	ft	*(not considered)*
Summation of all above Freeboard Components is Minimum Required Freeboard =	11.46	ft	*(rounded up to the next 0.01 foot)*

Step 34. Minimum Required Design Freeboard with Camber

Average Normal Full Storage Depth =	17.51	ft	*(Average Depth along Fetch based on NFSL = 42 ft El.)*
Minimum Required Freeboard =	11.46	ft	*(see Step 33)*
Embankment Height (not including camber) =	28.97	ft	*(summation of average normal full storage depth and freeboard)*
Minimum Required Freeboard =	11.46	ft	*(see Step 33)*
Embankment Settlement =	0.78	ft	*(see Technical Memorandum Table 3 or BODR Section 8E)*
Minimum Embankment Height (with camber) =	29.75	ft	*(minimum embankment height plus settlement)*
Minimum Required Design Freeboard with Camber =	12.24	ft	*(rounded up to the next 0.01 foot)*

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

Fetch 2B Analyses

Summary of Freeboard Analyses Case Scenarios Site C-43: Cell 2 (Fetch 2B)				
Freeboard Component	Case 1: PMP Combined with 100-Year Wind (ft)	Case 2: 100-Year Precip. Combined with Category 5 Winds (ft)	Case 3: Normal Full Storage Combined with Probable Max. Wind (ft)	Case 4: Hurricane Easy Storm Specific Wind and Precipitation (ft)
Design Precipitation **or** Flood Surge Depth (Routed Flood Event) =	4.13	0.77	0.00	3.77
Wind Setup =	1.22	2.27	3.94	1.23
Wave Height & Runup =	7.06	7.62	9.53	6.99
Waves Induced by Potential Landslides =	0.00	0.00	0.00	0.00
Provision for Malfunction of the Spillway or Discharge Structure =	0.00	0.00	0.00	0.00
Minimum Required Freeboard =	**12.41**	**10.67**	**13.47**	**11.98**
Camber or Embankment Settlement =	0.88	0.67	0.98	0.78
Minimum Required Freeboard with Camber =	**13.3**	**11.3**	**14.5**	**12.8**

Notes:
Minimum Required Freeboard rounded up to the next 0.01 foot.
Minimum Required Freeboard with Camber rounded up to the next 0.1 foot.
Case 1 - Surcharge depth is based upon routing of design storm event(s) through the reservoir.
Case 2 - Surcharge depth is based upon routing of design storm event through the reservoir.
Case 3 - Case 3 is to be used only for "sensitivity identification" and not as a selected design condition (pg 14 of 25, DCM-2)
Case 4 - Surcharge depth is assumed to be equal to the total precipitation of Hurricane Easy (45.2").

2033

3/12/2007

Case 1: PMP Combined with 100-Year Wind
Site C-43: Cell 2 (Fetch 2B)

Step 1: Select 50-Yr, 3-Sec Gust Wind Speed, $U_{50\text{-}yr,3\text{-}sec}$

Project Location =	C-43 Cell No. 2		
50-yr, 3-sec Gust Wind Speed, $U_{50\text{-}yr,3\text{-}sec}$ =	117.5	mph	*(Fig. 6-1b, ASCE 7-02)*

Step 2: Determine 100-Yr, 3-Sec Gust Wind Speed, $U_{100\text{-}yr,3\text{-}sec}$

$U_{50\text{-}yr,3\text{-}sec}$ =	117.5	mph	*(see Step 1)*
$U_{50\text{-}yr}$ to $U_{100\text{-}yr}$ Conversion Factor =	1.07		*(Table DCM 2-2, DCM-2)*
$U_{100\text{-}yr,3\text{-}sec} = U_{50\text{-}yr,3\text{-}sec}$ x Conversion Factor =	125.7	mph	

Step 3: Determine 100-Yr, 1-Hr Wind Speed, $U_{100\text{-}yr,1\text{-}hr}$

Initial wind speed duration, t =	3	sec.	*(based on Step 1 Data)*

Equations for ratio of wind speeds to 1-hour average wind speeds, U_t/U_{3600}

For $t \leq 3{,}600$:	$U_t/U_{3600} = 1.277 + 0.296\tanh(0.9\log_{10}(45/t))$ =	applies		*(Eqn. 1, DCM-2)*
For $3{,}600 < t < 36{,}000$:	$U_t/U_{3600} = -0.15\log_{10}(t)+1.5334$ =	does not apply		*(Eqn. 2, DCM-2)*
	U_t/U_{3600} =	1.51		*(Eqn. 1, DCM-2)*
	$U_t = U_{100\text{-}yr,\ 3\text{-}sec}$ =	125.73	mph	*(see Step 2)*
	$U_{100\text{-}yr,\ 3600\text{-}sec} = U_{100\text{-}yr,\ 1\text{-}hr} = U_t/(U_t/U_{3600})$ =	83.3	mph	

Step 4: Determine 100-Yr, 1-Hr Wind Speed Over Water, $U_{100\text{-}yr,1\text{-}hr,water}$

Fetch Length (in miles), X =	3.62	miles	

Wind Speed Over Water to Wind Speed Over Land Ratio, $U_{W\text{-}Site}/U_{Land}$:

If initial data from Step 1 is over water wind speed, no conversion (Ratio = 1.0)		does not apply		*(Fig. II-2-20, CEM)*
For Fetch Length < 10 miles:	U_{Water}/U_{Land} = 1.2 or 1.0	applies		*(Fig. II-2-20, CEM)*
For Fetch Length > 10 miles:	See Figure II-2-7, CEM	does not apply		*(Fig. II-2-7, CEM)*
	U_{water}/U_{land} =	1.2		*(Fig. II-2-20, CEM)*
	$U_{100\text{-}yr,1\text{-}hr,land}$ =	83.3		*(see Step 3)*
	$U_{100\text{-}yr,1\text{-}hr,water} = U_{100\text{-}yr,1\text{-}hr,land}$ x (U_{water}/U_{land}) =	100.0	mph	

Step 5: Estimate Fetch-Limited Wind Duration Time

Fetch Length (in miles), X =	3.62	miles	*(see Step 4)*
Wind Velocity (in mph), U =	100.0	mph	*(see Step 4)*
Fetch Limited Wind Duration Time, $t = 112(X^{0.67}/U^{0.34})$ =	55	min.	*(Eqn. 4, DCM-2)*
	3323	sec.	

Step 6: Estimate Ratio of Fetch Limited Duration Wind Speed and 1-Hour Wind Speed

Fetch Limited Wind Duration Time (in seconds), t =	3323	sec.	*(see Step 5)*

Equations for ratio of wind speeds to 1-hour average wind speeds, U_t/U_{3600}

For $t \leq 3{,}600$:	$U_t/U_{3600} = 1.277 + 0.296\tanh(0.9\log_{10}(45/t))$ =	applies		*(Eqn. 1, DCM-2)*
For $3{,}600 < t < 36{,}000$:	$U_t/U_{3600} = -0.15\log_{10}(t)+1.5334$ =	does not apply		*(Eqn. 2, DCM-2)*
	Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.001		*(Eqn. 1, DCM-2)*

Step 7: Adjust 1-Hr Wind Speed (over water) to Equivalent Fetch Limited Duration Wind Speed

Fetch Limited Wind Duration (in minutes), t =	55	min.	*(see Step 5)*
100-Yr, 1-Hr Wind Speed Over Water, $U_{100\text{-}yr,1\text{-}hr,water}$ =	100.0	mph	*(see Step 4)*
Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.001		*(see Step 6)*
100-Yr, Fetch Limited Wind Speed Over Water = $U_{100\text{-}yr,1\text{-}hr,water}$ x U_t/U_{3600} =	100	mph	

Step 8: Stability Correction, Adjust Wind Speed for Boundary Layer Stability

Fetch Length (in miles), X =	3.62	miles	*(see Step 4)*
(If Fetch Length > 10 miles, else enter 0) Temperature of Air, T_a =	0	°C	
(If Fetch Length > 10 miles, else enter 0) Temperature of Sea, T_s =	0	°C	
Air-Sea Temperature Difference, ΔT_{as} $T_a - T_s$ =	0	°C	

Stability Correction Factor, R_T

For Fetch Length < 10 miles:	R_T = 1.0	applies		*(pg. II-2-36, CEM)*
For Fetch Length > 10 miles:	Based on ΔT_{as}, See Figure 3-14, SPM or in absence of temperature information, assume RT = 1.1	does not apply		*(Fig.3-14, SPM)* *(pg 3-30, SPM)*
	$U_{100\text{-}yr,fetch\text{-}min,water}$ =	100	mph	*(see Step 7)*
	Stability Correction Factor, R_T =	1		*(pg. II-2-36, CEM)*
	$U_{100\text{-}yr,fetch\text{-}min,water,\ stability\ adjusted} = U_{100\text{-}yr,fetch\text{-}min,water}$ x R_T =	100	mph	*(Eqn. 3-27 SPM)*

Step 9. Compute Wind Stress Factor, U_A

$U_{100\text{-}yr,1\text{-}min,water,\ stability\ adjusted} = U$ =	100	mph	*(see Step 8)*
Wind Stress Factor, $U_A = 0.589U^{1.23}$ =	170	mph	*(Eqn. 3-28b SPM)*

Step 10. Wind Stress Factor in ft/s

Wind Stress Factor, U_A (ft/s) = 1.467U_A (mph) =	249	ft/sec	*(see Step 9)*

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

3/12/2007

Case 1: PMP Combined with 100-Year Wind
Site C-43: Cell 2 (Fetch 2B)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.62	miles	*(see Step 4)*
Fetch Length, F =	19,097	ft	
100-Yr, Fetch Limited Wind Speed Over Water = $U_{100-yr,fetch,over}$ =	100	mph	*(see Step 7)*
Wind Stress Factor, U_s (ft/s) =	249	ft/s	*(see Step 10)*

Step 11. Compute Deep-Water Significant Wave Height, H_{mo}

Deep-Water Significant Wave Height, $H_{mo} = (0.000282)U_s F^{1/2}$ =	9.71	feet	*(Eqn. 3-33c, SPM)*

Step 12. Compute Deep-Water Wave Period, T_o

Deep-Water Wave Period, $T_o = 0.02825(U_s F)^{1/3}$ =	4.75	sec	*(Eqn. 3-34c, SPM)*

Step 13. Compute Deep-Water Wave Length, L_o

Deep-Water Wave Length, $L_o = 5.12 T_o^2$ =	116	feet	*(Eqn. 2-6b, SPM)*

Step 14. Compute Relative Depth, d/L_o

If $d/L_o \leq 0.5$, waves are classified as transitional or shallow water waves. *(pg 2-8, SPM)*
If $d/L_o > 0.5$, waves are classified as deep water. *(pg 2-9, SPM)*

	21.19	feet	
Relative Depth = d/L_o =	0.183		*(pg 2-9, SPM)*
Wave Classification =	Transitional/Shallow-Water		*(pg 2-9, SPM)*

Step 15. Compute Shallow-Water Wave Period, T

Shallow-Water Wave Period, $T = 7.54 \tanh(A) \tanh(B/C)\, U_s/g$ *(Eqn. 3-40, SPM)*

where: F = Fetch Length (ft) (step 5) U_s = Wind Stress Factor (step 10) g = 32.2 ft/s²

$A = 0.833(gd/U_s^2)^{3/4}$ =	0.1534		
$B = 0.0379(gF/U_s^2)^{1/3}$ =	0.0014		
$C = \tanh(0.833(gd/U_s^2)^{3/4})$ =	0.1522		
Shallow-Water Wave Period, T = 7.54 tanh(A) tanh(B/C) U_s/g =	4.34	sec	*(Eqn. 3-40, SPM)*

Step 16. Compute Shallow-Water Significant Wave Height, H

Shallow-Water Significant Wave Height, $H = 0.283 \tanh(A) \tanh(B/C)\, U_s^2/g$ *(Eqn. 3-39, SPM)*

where: F = Fetch Length (ft) (step 5) U_s = Wind Stress Factor (step 10) g = 32.2 ft/s²

$A = 0.530(gd/U_s^2)^{3/4}$ =	0.0150		
$B = 0.0565(gF/U_s^2)^{1/3}$ =	0.0178		
$C = \tanh(0.530(gd/U_s^2)^{3/4})$ =	0.0150		
Shallow-Water Significant Wave Height, $H = 0.283 \tanh(A) \tanh(B/C)\, U_s^2/g$ =	7.43	feet	*(Eqn. 3-39, SPM)*

Step 17. Compute Zero Overwash Wave Height for Significant Wave Height

DCM-2 requires zero over wash as a design criteria for high and significant hazard dams. For purposes of the DCM-2, zero overwash wave height is defined as the wave height with a 2% occurrence frequency.

Significant Wave Height is either the Deep-Water or Shallow-Water Significant wave height
Depending upon the Wave Classification (Step 14).

Significant Wave Height, H_s =	7.43	feet	*(see Step 11 or 16)*
Required probability of wave height being exceeded, n/N =	0.02		*(see Step 17 discussion)*
Root Mean Square Wave Height, $H_{rms} = 2^{-1/2} H_s$ =	5.25	feet	*(Eqn. 3-10, SPM)*
Wave Height which is exceeded at given probability, $H^* = H_{rms}[-\ln(n/N)]^{1/2}$ =	10.28	feet	*(Eqn. 3-7, SPM)*

Step 18. Compute Wind Set-Up

Four different methods are calculated and considered in estimating wind setup
Zeider Zee Eqn: Widely used as applied to reservoirs but tends to overestimate wind setup for shallow impoundments (ave. depth<16 ft).
Sibul Eqn: Typically yields the lowest wind setup.
Ave. of Zeider Zee & Sibul: Recommended for shallow impoundments (ave. depth<16 ft) when Bretschneider has no numeric solution.
Bretschneider Eqn: Recommend for shallow impoundments (average depth <16 ft).

Fetch Length, F =	3.62	miles	*(see Step 4)*
Fetch Length, F =	19,097	feet	
Average Wind Velocity, U = Wind Speed per Step 7 = $U_{100-yr,over}$ =	100	mph	*(pg A6, DCM-2)(see Step 7)*
Average Depth of Water along Fetch Line, D = Effective Depth =	21.19	feet	*(see Step 14)*
Zeider Zee Eqn: (Note: F=miles): Wind Set-Up, $S = U^2F/(1400D)$ =	1.22	feet	*(Eqn. 5, DCM-2)*
Sibul Eqn (Note: F=feet, g=32.2 ft/s²): $S = 0.0000244(F/d)^{1.45}(U^2/Fg)^{2.02(d/L)^{-0.218}}$ =	0.30	feet	*(Eqn. 7, DCM-2)*
Average of Zeider Zee & Sibul: Wind Setup, $S = (S_{Zeider\ Zee} + S_{Sibul})/2$ =	0.76	feet	
Bretschneider Eqn (Note: Calcs provided separately in Step 18a): $S = \Sigma[(\Delta U^2 \Delta x)/(gd^*)]$ =	n/a	feet	*(Eqn. 6, DCM-2)(Step 18a)*
Equation Used for Wind Setup *(Enter Zeider Zee, Sibul, Average, Bretschneider)* =	Zeider Zee		
Computed Wind Set-Up, S =	1.22	feet	*(Eqn. 5, DCM-2)*

Step 19. Compute Water Depth at Toe of Structure

Water Depth at Toe of Structure, d_t = Effective Depth + Wind Set-Up = d + S =	22.41	feet	*(pg. 6, DCM-2)*

Step 20. Check for Depth Limited Wave Breaking

See if wave height is limited due to breaking. After breaking, waves will tend to reform with lower heights within a few wave lengths. *(pg. 15-3, EM-1110-2-1420)*

Depth of Interest is at Toe of Structure, $d_s = d_t$ =	22.41	feet	*(see Step 19)*
Wave Breaking Height, H_b (for depth d_s) = $(d_s/1.28)$ =	17.51	feet	*(Eqn. 2-91 & 3-50, SPM)*
Is max. wave height limited by breaking? (If H_b (step 20) $\leq H^*$ (step 17) then yes, else no) =	No		
(If no, wave height = H^* (step 17). If yes, conservatively assume wave height = H_b (step 20)) Maximum Wave Height =	10.28	feet	

Step 21. Estimate Ratio Between Deep-Water Wave Ht & Equivalent Deep-Water Ht

The value of H/Ho (shallow-water wave height/equivalent deep-water wave height) is estimated based on the value of d/L_o (effective depth / deep-water wave length) from Table C-1, SPM Vol II, Appendix C.

Effective Depth, d =	21.19	feet	*(see Step 14)*
Deep-Water Wave Length, L_o =	116	feet	*(see Step 13)*
Ratio of effective depth to deep-water wave length, d/L_o =	0.183		
H/H^*_o =	0.9149		*(Table C-1, SPM Vol 2)*

Step 22. Compute Equivalent Deep-Water Wave Height, H^*_o

If wave classification is Deep-Water (Step 14), Significant Deep-Water Height is the Equivalent Deep-Water Height.
If wave classification is Transitional/Shallow-Water an adjustment is necessary.
If Wave Breaking Height (Step 20) is less than the Zero Overwash for Significant Wave Height (Step 17) then Equivalent Deep-Water Wave Height is Wave Braking Height (irregardless of wave classification).

Wave Breaking Height, H_b =	17.51	feet	*(see Step 20)*
Significant Wave Height, H_s =	10.28	feet	*(see Step 17)*
H/H^*_o =	0.9149		*(see Step 21)*
If Shallow-Water: Equivalent Deep-Water Wave Height, $H^*o = H/(H/H^*o)$ =	11.23	feet	
If Deep Water: Equivalent Deep-Water Wave Height = Significant Deep-Water Height =	n/a	feet	
If Height Limited by Wave Breaking: Equiv. Deep-Water Wave Ht = Wave Breaking Ht =	n/a	feet	
Equivalent Deep-Water Wave Height =	11.23	feet	

Step 23. Compute Depth at Toe of Structure to Equiv. Deep-Water Wave Ht, d_t/H^*_o

Water Depth at Toe of Structure, d_t =	22.41	feet	*(see Step 19)*
Equivalent Deep-Water Wave Height, H^*_o =	11.23	feet	*(see Step 22)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_t/H^*_o =	2.00		

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 1: PMP Combined with 100-Year Wind
Site C-43: Cell 2 (Fetch 2B)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.62	miles	*(see Step 4)*
Fetch Length, F =	19,097	feet	
100-Yr, Fetch Limited Wind Speed Over Water = $U_{(100-yr,fetch-ltd)}$ =	100	mph	*(see Step 7)*
Wind Stress Factor, U_A (ft/s) =	249	ft/s	*(see Step 10)*

Wind Setup and Wave Properties Analysis - Summary Data

Wind Set-Up , S =	1.22	feet	*(see Step 18)*
Equivalent Deep-Water Wave Height, H'_o =	11.23	feet	*(see Step 22)*
Deep-Water Wave Period, T_o =	4.75	sec	*(see Step 12)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_s/H'_o =	2.00		*(see Step 23)*

Step 24. Compute Ratio of $H'_o/(g*T_o^2)$

Equivalent Deep-Water Wave Height, H'_o =	11.23	feet	*(see Step 22)*
Gravitational Constant, g =	32.2	ft/s^2	*(constant variable)*
Deep Water Wave Period, T_o =	4.75	sec	*(see Step 12)*
$H'_o/(g*T_o^2)$ =	0.015		

Steps 25 - 27. Estimate R/H'o *(Fig. 7-8 thru 7-20, SPM Vol. 2)*

Steps 25-27 are directed towards deriving the ratio of Wave Runup to the Equivalent Deep-Water Wave Height (R/H'_o) from graphs found in SPM Volume 2 (Fig. 7-8 thru 7-20). The graphs are based upon various designs of the runup face slope including the material, roughness, slope, and geometry the face slope. In addition the value of R/H'_o depends upon the values of d_s/H'_o and $H'_o/(gT^2)$. Determination of values will typically require an interpolation of values between graphs.

d_s/H'_o =	2.00		*(see Step 23)*
$H'_o/(g*T_o^2)$ =	0.015		*(see Step 24)*
Face Slope Material =	Step-Faced Slope		*Embankment Design*
Runup Face Slope (H:1V) =	3		*Embankment Design*
Runup Face Slope (θ) =	18.4	degrees	
Figure used for Interpolation (Lower Interpolation Number) =	Fig. 7-10		*(SPM Vol. 2)*
Figure to used for Interpolation (Higher Interpolation Number) =	Fig. 7-11		*(SPM Vol. 2)*

Step 25. R/H'o from Fig. 7-10 with ds/H'o <= 2

$H'_o/(g*T_o^2)$ =	0.015		*(see Step 24)*
ds/H'o <=2 from Fig. 7-10 =	0.8		*(Fig. 7-10, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-10 =	0.75		*(Fig. 7-10, SPM Vol. 2)*

Step 26. R/H'o from Fig. 7-11 with ds/H'o >= 2

$H'_o/(g*T_o^2)$ =	0.015		*(see Step 24)*
ds/H'o >=2 from Fig. 7-11 =	2.0		*(Fig. 7-11, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-11 =	0.89		*(Fig. 7-11, SPM Vol. 2)*

Step 27. Estimated Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o

d_s/H'_o =	2.00		*(see Step 23)*
$H'_o/(g*T_o^2)$ =	0.015		*(see Step 24)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o =	0.89		*(Interpolated from Steps 25 & 26)*

Step 28. Compute Smooth Surface Wave Runup

Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'_o =	0.89		*(see Step 27)*
Equivalent Deep-Water Wave Height, H'_o =	11.23		*(see Step 22)*
Smooth Surface Wave Runup = R/H'_o x H'_o =	10.00	feet	

Step 29. If Applicable, Determine and Apply Wave Runup Correction Factor due to Scale Effects

This step applies if Figures 7-8 thru 7-12 or Figures 7-14 thru 7-18 were used to estimate R/H'_o in Steps 25-27. These figures summarize results for small-scale lab tests. Due to the inability to scale roughness effects in small-scale lab tests, the results are probably smaller than the runup on prototype structures. Figure 7-13 is used to adjust for this scale effect.

Smooth Surface Wave Runup = R/H'_o x H'_o =	10.00	feet	*(see Step 28)*
Scale Wave Runup Correction due to Scale Effects *(If Fig. 7-19 or 7-20 used, enter 1)* =	1.12		*(Fig. 7-13, SPM Vol. 2)*
Scale Corrected Wave Runup Height = (Smooth Surface Wave Runup)(Runup Correction) =	11.20	feet	

Step 30. Determine and Apply Correction Factor due to Dam Surface Roughness

Face Slope Material =	Step-Faced Slope		*(see Step 25)*
Surface Roughness Correction =	0.7		*(Table 7-2, SPM Vol 2) or (Table 2-2 EM1110-2-1614)*
Scale Corrected Wave Runup Height =	11.20	feet	*(see Step 29)*
Corrected Wave Runup = (Scale Corrected Wave Runup)(Surface Roughness Correction) =	7.84	feet	

Step 31. Correction Due to to Fetch Axis Not Being Normal to the Dam Axis

Angle Between Fetch Axis and Embankment Axis =	45	degrees	
Angle Correction Factor =	0.90		*(Fig. 8, ACER TM No. 11)*

Step 32. Adjusted Wave Runup

Corrected Wave Runup =	7.84		*(see Step 30)*
Angle Correction Factor =	0.90		*(see Step 31)*
Final Adjusted Wave Runup = (Corrected Wave Runup)(Angle Correction Factor) =	7.1	feet

3/12/2007

Case 1: PMP Combined with 100-Year Wind
Site C-43: Cell 2 (Fetch 2B)

Step 33. Minimum Required Design Freeboard

Design Precipitation **or** Flood Surge Depth (Routed Flood Event) =	4.13	ft	*(based upon max. water surface elevation of routed storm event)*
Wind Setup =	1.22	ft	*(see Step 18)*
Wave Height & Runup =	7.06	ft	*(see Step 32)*
Waves Induced by Potential Landslides =	0.00	ft	*(not considered)*
Provision for Malfunction of the Spillway or Discharge Structure =	0.00	ft	*(not considered)*
Summation of all above Freeboard Components is Minimum Required Freeboard =	12.41	ft	*(rounded up to the next 0.01 foot)*

Step 34. Minimum Required Design Freeboard with Camber

Average Normal Full Storage Depth =	17.06	ft	*(Average Depth along Fetch based on NFSL = 42 ft El.)*
Minimum Required Freeboard =	12.41	ft	*(see Step 33)*
Embankment Height (not including camber) =	29.47	ft	*(summation of average normal full storage depth and freeboard)*
Minimum Required Freeboard =	12.41	ft	*(see Step 33)*
Embankment Settlement =	0.88	ft	*(see Technical Memorandum Table 3 or BODR Section 8E)*
Minimum Embankment Height (with camber) =	30.35	ft	*(minimum embankment height plus settlement)*
Minimum Required Design Freeboard with Camber =	13.29	ft	*(rounded up to the next 0.01 foot)*

3/12/2007

Case 2: 100-Year Precipitation Combined with Category 5 Hurricane Winds
Site C-43: Cell 2 (Fetch 2B)

Steps 1-3: Adjustments not necessary for Case 2

Project Location =	C-43 Cell No. 2		
Category 5, Duration Adjusted Wind Speed (1-hr average), $U_{Cat5,1-hr}$ =	125.0	mph	*(Table DCM 2-3, DCM-2)*

The Category 5 wind speed from Table DCM 2-3, DCM-2 corresponds to an over-water wind speed per DCM-2 page 10.

Step 4: Determine Category 5, 1-Hr Wind Speed Over Water, $U_{Cat5,1-hr,water}$

Fetch Length (in miles), X =	3.62	miles	

Wind Speed Over Water to Wind Speed Over Land Ratio, U_{Water}/U_{Land}:

If initial data from Step 1 is over water wind speed, no conversion (Ratio = 1.0)	does not apply		*(Fig. II-2-20, CEM)*
For Fetch Length < 10 miles: U_{Water}/U_{Land} = 1.2 or 1.0	applies		*(Fig. II-2-20, CEM)*
For Fetch Length > 10 miles: See Figure II-2-7, CEM	does not apply		*(Fig. II-2-7, CEM)*
U_{water}/U_{land} =	1		*(Fig. II-2-20, CEM)*
$U_{Cat5,1-hr,land}$ =	-		*(see Step 3)*
$U_{Cat5,1-hr,water} = U_{Cat5,1-hr,land}$ x (U_{water}/U_{land}) =	125.0	mph	

Step 5: Estimate Fetch-Limited Wind Duration Time

	3.62	miles	*(see Step 4)*
Wind Velocity (in mph), U =	125.0	mph	*(see Step 4)*
Fetch Limited Wind Duration Time, $t = 112(X^{0.67}/U^{0.34})$ =	51	min.	*(Eqn. 4, DCM-2)*
	3080	sec.	

Step 6: Estimate Ratio of Fetch Limited Duration Wind Speed and 1-Hour Wind Speed

Fetch Limited Wind Duration Time (in seconds), t =	3080	sec.	*(see Step 5)*

Equations for ratio of wind speeds to 1-hour average wind speeds, U_t/U_{3600}

For $t \leq 3{,}600$: $U_t/U_{3600} = 1.277 + 0.296\tanh\{0.9\log_{10}(4.5/t)\}$ =	applies		*(Eqn. 1, DCM-2)*
For $3{,}600 < t < 36{,}000$: $U_t/U_{3600} = -0.15\log_{10}(t)+1.5334$ =	does not apply		*(Eqn. 2, DCM-2)*
Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.002		*(Eqn. 1, DCM-2)*

Step 7: Adjust 1-Hr Wind Speed (over water) to Equivalent Fetch Limited Duration Wind Speed

Fetch Limited Wind Duration (in minutes), t =	51	min.	*(see Step 5)*
Category 5, 1-Hr Wind Speed Over Water, $U_{Cat5,1-hr,water}$ =	125.0	mph	*(see Step 4)*
Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.002		*(see Step 6)*
Category 5, Fetch Limited Wind Speed Over Water = $U_{Cat5,1-hr,water}$ x U_t/U_{3600} =	125	mph	

Step 8: Stability Correction, Adjust Wind Speed for Boundary Layer Stability

Fetch Length (in miles), X =	3.62	miles	*(see Step 4)*
(If Fetch Length > 10 miles, else enter 0) Temperature of Air, T_a =	0	o C	
(If Fetch Length > 10 miles, else enter 0) Temperature of Sea, T_s =	0	o C	
Air-Sea Temperature Difference, ΔT_{as} $T_a - T_s$ =	0	°C	

Stability Correction Factor, R_T

For Fetch Length < 10 miles: $R_T = 1.0$	applies		*(pg. II-2-36, CEM)*
For Fetch Length > 10 miles: Based on ΔT_{as}, See Figure 3-14, SPM or in absence of temperature information, assume RT = 1.1	does not apply		*(Fig.3-14, SPM)* *(pg 3-30, SPM)*
$U_{Cat5,fetch-min,water}$ =	125	mph	*(see Step 7)*
Stability Correction Factor, R_T =	1		*(pg. II-2-36, CEM)*
$U_{Cat5,fetch-min,water,\ stability\ adjusted} = U_{Cat5,fetch-min,water}$ x R_T =	125	mph	*(Eqn. 3-27 SPM)*

Step 9. Compute Wind Stress Factor, U_A

$U_{Cat5,fetch-min,water,\ stability\ adjusted}$ = U =	125	mph	*(see Step 8)*
Wind Stress Factor, $U_A = 0.589U^{1.23}$ =	224	mph	*(Eqn. 3-28b SPM)*

Step 10. Wind Stress Factor in ft/s

Wind Stress Factor, U_A (ft/s) = 1.467U_A (mph) =	329	ft/sec	*(see Step 9)*

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 2: 100-Year Precipitation Combined with Category 5 Hurricane Winds
Site C-43: Cell 2 (Fetch 2B)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.02	miles	*(see Step 4)*
Fetch Length, F =	19,057	ft	
Category 5, Fetch Limited Wind Speed Over Water = $U_{(cat5,fetch,obt)}$ =	125	mph	*(see Step 7)*
Wind Stress Factor, U_* (ft/s) =	329	ft/s	*(see Step 10)*

Step 11. Compute Deep-Water Significant Wave Height, H_{mo}

Deep-Water Significant Wave Height, H_{mo} = (0.000282)$U_A F^{1/2}$ =	12.61	feet	*(Eqn. 3-33c, SPM)*

Step 12. Compute Deep-Water Wave Period, T_o

Deep-Water Wave Period, T_o = 0.02825$(U_A F)^{1/2}$ =	5.21	sec	*(Eqn. 3-34c, SPM)*

Step 13. Compute Deep-Water Wave Length, L_o

Deep-Water Wave Length, $L_o = 5.12 T_o^2$ =	139	feet	*(Eqn. 2-8b, SPM)*

Step 14. Compute Relative Depth, d/L_o

If $d/L_o \leq 0.5$, waves are classified as transitional or shallow water waves. *(pg 2-9, SPM)*
If $d/L_o > 0.5$, waves are classified as deep water. *(pg 2-9, SPM)*

	17.83	feet	
Relative Depth = d/L_o =	0.128		*(pg 2-9, SPM)*
Wave Classification =	Transitional/Shallow-Water		*(pg 2-9, SPM)*

Step 15. Compute Shallow-Water Wave Period, T

Shallow-Water Wave Period, $T = 7.54 \tanh(A) \tanh(B/C)\, U_A/g$ *(Eqn. 3-40, SPM)*

where: F = Fetch Length (ft) (step 5) U_A = Wind Stress Factor (step 10) g = 32.2 ft/s^2

$A = 0.833(gd/U_A^2)^{3/4}$ =	0.1169	
$B = 0.0379(gF/U_A^2)^{1/3}$ =	0.0677	
$C = \tanh(0.833(gd/U_A^2)^{3/8})$ =	0.1164	
Shallow-Water Wave Period, $T = 7.54 \tanh(A) \tanh(B/C)\, U_A/g$ =	4.69 sec	*(Eqn. 3-40, SPM)*

Step 16. Compute Shallow-Water Significant Wave Height, H

Shallow-Water Significant Wave Height, $H = 0.283 \tanh(A) \tanh(B/C)\, U_A^2/g$ *(Eqn. 3-39, SPM)*

where: F = Fetch Length (ft) (step 5) U_A = Wind Stress Factor (step 10) g = 32.2 ft/s^2

$A = 0.530(gd/U_A^2)^{3/4}$ =	0.0104	
$B = 0.00565(gF/U_A^2)^{1/2}$ =	0.0135	
$C = \tanh(0.530(gd/U_A^2)^{3/8})$ =	0.0104	
Shallow-Water Significant Wave Height, $H = 0.283 \tanh(A) \tanh(B/C)\, U_A^2/g$ =	8.51 feet	*(Eqn. 3-39, SPM)*

Step 17. Compute Shallow-Water Wave Height for Zero Overwash

DCM-2 requires zero over wash as a design criteria for high and significant hazard dams. For purposes of the DCM-2, zero overwash wave height is defined as the wave height with a 2% occurrence frequency.

Significant Wave Height is either the Deep-Water or Shallow-Water Significant wave height depending upon the Wave Classification (Step 14).

Significant Wave Height, H_s =	8.51	feet	*(see Step 11 or 16)*
Required probability of wave height being exceeded, n/N =	0.02		*(see Step 17 discussion)*
Root Mean Square Wave Height, $H_{rms} = 2^{-1/2} H_s$ =	6.02	feet	*(Eqn. 3-10, SPM)*
Wave Height which is exceeded at given probability, $H^* = H_{rms}[-\ln(n/N)]^{1/2}$ =	11.78	feet	*(Eqn. 3-7, SPM)*

Step 18. Compute Wind Set-Up

Four different methods are calculated and considered in estimating wind setup:
Zeitler Zee Eqn: Widely used as applied to reservoirs but tends to overestimate wind setup for shallow impoundments (ave. depth<15 ft).
Sibul Eqn: Typically yields the lowest wind setup.
Ave. of Zeitler Zee & Sibul: Recommended for shallow impoundments (ave. depth≤16 ft) when Breitschneider has no numeric solution.
Breitschneider Eqn: Recommend for shallow impoundments (average depth <16 ft).

Fetch Length, F =	3.62	miles	*(see Step 4)*
Fetch Length, F =	19,057	feet	
Average Wind Velocity, U = Wind Speed per Step 7 = $U_{(cat5,fetch)}$ =	125	mph	*(pg A6, DCM-2)(see Step 7)*
Average Depth of Water along Fetch Line, D = Effective Depth =	17.83	feet	*(see Step 14)*
Zeitler Zee Eqn: (Note: F=miles); Wind Set-Up, $S = U^2F/(1400D)$ =	2.27	feet	*(Eqn. 5, DCM-2)*
Sibul Eqn (Note: F=feet, g=32.2 ft/s^2): $S = 0.0000244(F/d)^{4/5}(U^2/F)^{2.0/3.0}(F/g)^{1.0/3.0}$ =	0.61	feet	*(Eqn. 7, DCM-2)*
Average of Zeitler Zee & Sibul: Wind Setup, $S = (S_{Zeitler\ Zee} + S_{Sibul})/2$ =	1.44	feet	
Breitschneider Eqn (Note: Calcs provided separately in Step 18a): $S = \Sigma[(KU^2/gX)(gd/U^2)]$ =	n/a	feet	*(Eqn. 6, DCM-2)(Step 18a)*
Equation Used for Wind Setup *(Enter Zeitler Zee, Sibul, Average, Breitschneider)* =	Zeitler Zee		
Computed Wind Set-Up, S =	2.27	feet	*(Eqn. 5, DCM-2)*

Step 19. Compute Water Depth at Toe of Structure

Water Depth at Toe of Structure, d_s = Effective Depth + Wind Set-Up = d + S =	20.10	feet	*(pg. 6, DCM-2)*

Step 20. Check for Depth Limited Wave Breaking

See if wave height is limited due to breaking. After breaking, waves will tend to reform with lower heights within a few wave lengths. *(pg. 15-4, EM-1110-2-1420)*

Depth of Interest is at Toe of Structure, $d_i = d_s$ =	20.10	feet	*(see Step 19)*
Wave Breaking Height, H_b (for depth d_b) = (d_b/1.28) =	15.71	feet	*(Eqn. 2-91 & 3-50, SPM)*
Is max. wave height limited by breaking? (If H_b [step 20] ≤ H^* [step 17] then yes, else no) =	No		
(If no, wave height = H^* (step 17). If yes, conservatively assume wave height = H_b (step 20)) Maximum Wave Height =	11.78	feet	

Step 21. Estimate Ratio Between Deep-Water Wave Ht & Equivalent Deep-Water Ht

The value of H/Ho (shallow-water wave height/equivalent deep-water wave height) is estimated based on the value of d/L_o (effective depth / deep-water wave length) from Table C-1, SPM Vol II, Appendix C.

Effective Depth, d =	17.83	feet	*(see Step 14)*
Deep-Water Wave Length, L_o =	139	feet	*(see Step 13)*
Ratio of effective depth to deep-water wave length, d/L_o =	0.128		
H/H^*_o =	0.9175		*(Table C-1, SPM Vol 2)*

Step 22. Compute Equivalent Deep-Water Wave Height, H^*_o

If wave classification is Deep-Water (Step 14), Significant Deep-Water Height is the Equivalent Deep-Water Height.
If wave classification is Transitional/Shallow-Water an adjustment is necessary.
If Wave Breaking Height (Step 20) is less than the Zero Overwash for Significant Wave Height (Step 17) then Equivalent Deep-Water Wave Height is Wave Braking Height (irregardless of wave classification).

Wave Breaking Height, H_b =	15.71	feet	*(see Step 20)*
Significant Wave Height, H_s =	11.78	feet	*(see Step 17)*
H/H^*_o =	0.9175		*(see Step 21)*
If Shallow-Water: Equivalent Deep-Water Wave Height, $H^*o = H/(H/H^*o)$ =	12.83	feet	
If Deep Water: Equivalent Deep-Water Wave Height = Significant Deep-Water Height =	n/a	feet	
If Height Limited by Wave Breaking: Equiv. Deep-Water Wave Ht. = Wave Breaking Ht. =	n/a	feet	
Equivalent Deep-Water Wave Height =	12.83	feet	

Step 23. Compute Depth at Toe of Structure to Equiv. Deep-Water Wave Ht, d_s/H^*_o

Water Depth at Toe of Structure, d_s =	20.10	feet	*(see Step 19)*
Equivalent Deep-Water Wave Height, H^*_o =	12.83	feet	*(see Step 22)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_s/H^*_o =	1.57		

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 2: 100-Year Precipitation Combined with Category 5 Hurricane Winds
Site C-43: Cell 2 (Fetch 2B)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.62	miles	*(see Step 4)*
Fetch Length, F =	19,097	feet	
Category 5, Fetch Limited Wind Speed Over Water = $U_{CAT5,fetch-ltd}$ =	125	mph	*(see Step 7)*
Wind Stress Factor, U_A (ft/s) =	329	ft/s	*(see Step 10)*

Wind Setup and Wave Properties Analysis - Summary Data

Wind Set-Up , S =	2.27	feet	*(see Step 18)*
Equivalent Deep-Water Wave Height, H'_o =	12.83	feet	*(see Step 22)*
Deep-Water Wave Period, T_o =	5.21	sec	*(see Step 12)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_s/H'_o =	1.57		*(see Step 23)*

Step 24. Compute Ratio of $H'_o/(gT_o^2)$

Equivalent Deep-Water Wave Height, H'_o =	12.83	feet	*(see Step 22)*
Gravitational constant, g =	32.2	ft/s^2	*(constant variable)*
Deep Water Wave Period, T_o =	5.21	sec	*(see Step 12)*
$H'_o/(gT_o^2)$ =	0.015		

Steps 25 - 27. Estimate R/H'o *(Fig. 7-8 thru 7-20, SPM Vol. 2)*

Steps 25-27 are directed towards deriving the ratio of Wave Runup to the Equivalent Deep-Water Wave Height (R/H'_o) from graphs found in SPM Volume 2 (Fig. 7-8 thru 7-20). The graphs are based upon various designs of the runup face slope including the material, roughness, slope, and geometry the face slope. In addition the value of R/H'_o depends upon the values of d_s/H'_o and $H'_o/(gT^2)$. Determination of values will typically require an interpolation of values between graphs.

d_s/H'_o =	1.57		*(see Step 23)*
$H'_o/(gT_o^2)$ =	0.015		*(see Step 24)*
Face Slope Material =	Step-Faced Slope		*Embankment Design*
Runup Face Slope (H:1V) =	3		*Embankment Design*
Runup Face Slope (Θ) =	18.4	degrees	
Figure used for Interpolation (Lower Interpolation Number) =	Fig. 7-10		*(SPM Vol. 2)*
Figure to used for Interpolation (Higher Interpolation Number) =	Fig. 7-11		*(SPM Vol. 2)*

Step 25. R/H'o from Fig. 7-10 with ds/H'o <= 1.57

$H'_o/(gT_o^2)$ =	0.015		*(see Step 24)*
ds/H'o <=1.57 from Fig. 7-10 =	0.8		*(Fig. 7-10, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-10 =	0.75		*(Fig. 7-10, SPM Vol. 2)*

Step 26. R/H'o from Fig. 7-11 with ds/H'o >= 1.57

$H'_o/(gT_o^2)$ =	0.015		*(see Step 24)*
ds/H'o >=1.57 from Fig. 7-11 =	2.0		*(Fig. 7-11, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-11 =	0.89		*(Fig. 7-11, SPM Vol. 2)*

Step 27. Estimated Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o

d_s/H'_o =	1.57		*(see Step 23)*
$H'_o/(gT_o^2)$ =	0.015		*(see Step 24)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o =	0.84		*(Interpolated from Steps 25 & 26)*

Step 28. Compute Smooth Surface Wave Runup

Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'_o =	0.84		*(see Step 27)*
Equivalent Deep-Water Wave Height, H'_o =	12.83		*(see Step 22)*
Smooth Surface Wave Runup = R/H'_o x H'_o =	10.80	feet	

Step 29. If Applicable, Determine and Apply Wave Runup Correction Factor due to Scale Effects

This step applies if Figures 7-8 thru 7-12 or Figures 7-14 thru 7-18 were used to estimate R/H'_o in Steps 25-27. These figures summarize results for small-scale lab tests. Due to the inability to scale roughness effects in small-scale lab tests, the results are probably smaller than the runup on prototype structures. Figure 7-13 is used to adjust for this scale effect.

Smooth Surface Wave Runup = R/H'_o x H'_o =	10.80	feet	*(see Step 28)*
Scale Wave Runup Correction due to Scale Effects *(If Fig. 7-19 or 7-20 used, enter 1)* =	1.12		*(Fig. 7-13, SPM Vol. 2)*
Scale Corrected Wave Runup Height = (Smooth Surface Wave Runup)(Runup Correction) =	12.10	feet	

Step 30. Determine and Apply Correction Factor due to Dam Surface Roughness

Face Slope Material =	Step-Faced Slope		*(see Step 25)*
Surface Roughness Correction =	0.7		*(Table 7-2, SPM Vol 2) or (Table 2-2 EM1110-2-1614)*
Scale Corrected Wave Runup Height =	12.10	feet	*(see Step 29)*
Corrected Wave Runup = (Scale Corrected Wave Runup)(Surface Roughness Correction) =	8.47	feet	

Step 31. Correction Due to to Fetch Axis Not Being Normal to the Dam Axis

Angle Between Fetch Axis and Embankment Axis =	45	degrees	
Angle Correction Factor =	0.90		*(Fig. 8, ACER TM No. 11)*

Step 32. Adjusted Wave Runup

Corrected Wave Runup =	8.47		*(see Step 30)*
Angle Correction Factor =	0.90		*(see Step 31)*
Final Adjusted Wave Runup = (Corrected Wave Runup)(Angle Correction Factor) =	7.6	feet	

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 2: 100-Year Precipitation Combined with Category 5 Hurricane Winds
Site C-43: Cell 2 (Fetch 2B)

Step 33. Minimum Required Design Freeboard

Design Precipitation **or** Flood Surge Depth (Routed Flood Event) =	0.77	ft	*(based upon max. water surface elevation of routed storm event)*
Wind Setup =	2.27	ft	*(see Step 18)*
Wave Height & Runup =	7.62	ft	*(see Step 32)*
Waves Induced by Potential Landslides =	0.00	ft	*(not considered)*
Provision for Malfunction of the Spillway or Discharge Structure =	0.00	ft	*(not considered)*
Summation of all above Freeboard Components is Minimum Required Freeboard =	10.67	ft	*(rounded up to the next 0.01 foot)*

Step 34. Minimum Required Design Freeboard with Camber

Average Normal Full Storage Depth =	17.06	ft	*(Average Depth along Fetch based on NFSL = 42 ft El.)*
Minimum Required Freeboard =	10.67	ft	*(see Step 33)*
Embankment Height (not including camber) =	27.73	ft	*(summation of average normal full storage depth and freeboard)*
Minimum Required Freeboard =	10.67	ft	*(see Step 33)*
Embankment Settlement =	0.67	ft	*(see Technical Memorandum Table 3 or BODR Section 8E)*
Minimum Embankment Height (with camber) =	28.40	ft	*(minimum embankment height plus settlement)*
Minimum Required Design Freeboard with Camber =	11.34	ft	*(rounded up to the next 0.01 foot)*

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

Case 3: Probable Maximum Wind Speed Combined with Normal Full Storage Level (Uncontrolled Spillway Level)
Site C-43: Cell 2 (Fetch 2B)

Steps 1-2: Not necessary for Case 3

Project Location =	C-43 Cell No. 2		
Probable Maximum Wind (PMW) Speed, $U_{PMW,60\text{-}sec,\ water}$ =	200.0	mph	*(pg 13, DCM-2)*

For Case 3, the 200 mph assumed PMW corresponds to an over-water 1-minute average wind speed. *(pg 13, DCM-2)*

Step 3: Determine PMW, 1-Hr Wind Speed, $U_{PMW,\ 1\text{-}hr}$

Initial wind speed duration, t =	60	sec.	*(based on Step 1 Data)*

Equations for ratio of wind speeds to 1-hour average wind speeds, U_t/U_{3600}

For t ≤ 3,600: $U_t/U_{3600} = 1.277 + 0.296\tanh(0.9\log_{10}(45/t))$ =	applies		*(Eqn. 1, DCM-2)*
For 3,600 < t < 36,000: $U_t/U_{3600} = -0.15\log_{10}(t)+1.5334$ =	does not apply		*(Eqn. 2, DCM-2)*
U_t/U_{3600} =	1.24		*(Eqn. 1, DCM-2)*
$U_t = U_{PMW,\ 60\text{-}sec}$ =	200.00	mph	*(see Step 2)*
$U_{PMW,\ 3600\text{-}sec} = U_{PMW,\ 1\text{-}hr} = U_t/(U_t/U_{3600})$ =	160.8	mph	

Step 4: Determine PMW, 1-Hr Wind Speed Over Water, $U_{PMW,1\text{-}hr,water}$

Fetch Length (in miles), X =	3.62	miles	
If initial data from Step 1 is over water wind speed, no conversion (Ratio = 1.0)	does not apply		*(Fig. II-2-20, CEM)*
For Fetch Length < 10 miles: U_{Water}/U_{Land} = 1.2 or 1.0	applies		*(Fig. II-2-20, CEM)*
For Fetch Length > 10 miles: See Figure II-2-7, CEM	does not apply		*(Fig. II-2-7, CEM)*
U_{water}/U_{land} =	1		*(Fig. II-2-20, CEM)*
$U_{PMW,1\text{-}hr,land}$ =	-		*(see Step 3)*
$U_{PMW,1\text{-}hr,water} = U_{PMW,1\text{-}hr,land} \times (U_{water}/U_{land})$ =	160.8	mph	

Step 5: Estimate Fetch-Limited Wind Duration Time

Fetch Length (in miles), X =			
Wind Velocity (in mph), U =	160.8	mph	*(see Step 4)*
Fetch Limited Wind Duration Time, $t = 112(X^{0.67}/U^{0.34})$ =	47	min.	*(Eqn. 4, DCM-2)*
	2827	sec.	

Step 6: Estimate Ratio of Fetch Limited Duration Wind Speed and 1-Hour Wind Speed

Fetch Limited Wind Duration Time (in seconds), t =	2827	sec.	*(see Step 5)*

Equations for ratio of wind speeds to 1-hour average wind speeds, U_t/U_{3600}

For t ≤ 3,600: $U_t/U_{3600} = 1.277 + 0.296\tanh(0.9\log_{10}(45/t))$ =	applies		*(Eqn. 1, DCM-2)*
For 3,600 < t < 36,000: $U_t/U_{3600} = -0.15\log_{10}(t)+1.5334$ =	does not apply		*(Eqn. 2, DCM-2)*
Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.003		*(Eqn. 1, DCM-2)*

Step 7: Adjust 1-Hr Wind Speed (over water) to Equivalent Fetch Limited Duration Wind Speed

Fetch Limited Wind Duration (in minutes), t =	47	min.	*(see Step 5)*
100-Yr, 1-Hr Wind Speed Over Water, $U_{100\text{-}yr,1\text{-}hr,water}$ =	160.8	mph	*(see Step 4)*
Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.003		*(see Step 6)*
PMW, t-min Wind Speed Over Water = $U_{PMW,1\text{-}hr,water} \times U_t/U_{3600}$ =	161	mph	

Step 8: Stability Correction, Adjust Wind Speed for Boundary Layer Stability

Fetch Length (in miles), X =	3.62	miles	*(see Step 4)*
(If Fetch Length > 10 miles, else enter 0) Temperature of Air, T_a =	0	o C	
(If Fetch Length > 10 miles, else enter 0) Temperature of Sea, T_s =	0	o C	
Air-Sea Temperature Difference, ΔT_{as} $T_a - T_s$ =	0	° C	

Stability Correction Factor, R_T

For Fetch Length < 10 miles: R_T = 1.0	applies		*(pg. II-2-36, CEM)*
For Fetch Length > 10 miles: Based on ΔT_{as}, See Figure 3-14, SPM or in absence of temperature information, assume RT = 1.1	does not apply		*(Fig.3-14, SPM)* *(pg 3-30, SPM)*
$U_{PMW,fetch\text{-}min,water}$ =	161	mph	*(see Step 7)*
Stability Correction Factor, R_T =	1		*(pg. II-2-36, CEM)*
$U_{PMW,fetch\text{-}min,water,\ stability\ adjusted} = U_{PMW,fetch\text{-}min,water} \times R_T$ =	161	mph	*(Eqn. 3-27 SPM)*

Step 9. Compute Wind Stress Factor, U_A

$U_{PMW,fetch\text{-}min,water,\ stability\ adjusted} = U$ =	161	mph	*(see Step 8)*
Wind Stress Factor, $U_A = 0.589U^{1.23}$ =	306	mph	*(Eqn. 3-28b SPM)*

Step 10. Wind Stress Factor in ft/s

Wind Stress Factor, U_A (ft/s) = $1.467U_A$ (mph) =	449	ft/sec	*(see Step 9)*

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

Case 3: Probable Maximum Wind Speed Combined with Normal Full Storage Level (Uncontrolled Spillway Level)
Site C-43: Cell 2 (Fetch 2B)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.62	miles	*(see Step 5)*
Fetch Length, F =	19,097	ft	
PMW, Fetch Limited Wind Speed Over Water = $U_{PMW,Fetch,Lim}$ =	161	mph	*(see Step 7)*
Wind Stress Factor, U_s (ft/s) =	446	ft/s	*(see Step 10)*

Step 11. Compute Deep-Water Significant Wave Height, H_{mo}

Deep Water Significant Wave Height, $H_{mo} = (0.000282)U_s F^{1/2}$ = 17.46 feet *(Eqn. 3-33c, SPM)*

Step 12. Compute Deep-Water Wave Period, T_o

Deep-Water Wave Period, $T_o = 0.02825(U_s F)^{1/3}$ = 5.76 sec *(Eqn. 3-34c, SPM)*

Step 13. Compute Deep-Water Wave Length, L_o

Deep-Water Wave Length, $L_o = 5.12 T_o^2$ = 171 feet *(Eqn. 2-8b, SPM)*

Step 14. Compute Relative Depth, d/L_o

If $d/L_o \leq 0.5$, waves are classified as transitional or shallow water waves. *(pg 2-6, SPM)*
If $d/L_o > 0.5$, waves are classified as deep water *(pg 2-6, SPM)*

	17.06	feet
Relative Depth = d/L_o =	0.1	*(pg 2-6, SPM)*
Wave Classification =	Transitional/Shallow-Water	*(pg 2-6, SPM)*

Step 15. Compute Shallow-Water Wave Period, T

Shallow-Water Wave Period, $T = 7.54 \tanh(A) \tanh(B/C) U_s/g$ *(Eqn. 3-40, SPM)*
where: F = Fetch Length (ft) (step 5) U_s = Wind Stress Factor (step 10) g = 32.2 ft/s²

$A = 0.833(gd/U_s^2)^{3/8}$ =	0.0910	
$B = 0.0379(gF/U_s^2)^{1/3}$ =	0.0550	
$C = \tanh(0.833(gd/U_s^2)^{3/8})$ =	0.0908	
Shallow-Water Wave Period, $T = 7.54 \tanh(A) \tanh(B/C) U_s/g$ =	5.16 sec	*(Eqn. 3-40, SPM)*

Step 16. Compute Shallow-Water Significant Wave Height, H

Shallow-Water Significant Wave Height, $H = 0.283 \tanh(A) \tanh(B/C) U_s^2/g$ *(Eqn. 3-39, SPM)*
where: F = Fetch Length (ft) (step 5) U_s = Wind Stress Factor (step 10) g = 32.2 ft/s²

$A = 0.530(gd/U_s^2)^{3/4}$ =	0.0063	
$B = 0.00565(gF/U_s^2)^{1/2}$ =	0.0099	
$C = \tanh(0.530(gd/U_s^2)^{3/4})$ =	0.0063	
Shallow-Water Significant Wave Height, $H = 0.283 \tanh(A) \tanh(B/C) U_s^2/g$ =	19.25 feet	*(Eqn. 3-39, SPM)*

Step 17. Compute Shallow-Water Wave Height for Zero Overwash

DCM-2 requires zero over wash as a design criteria for high and significant hazard dams. For purposes of the DCM-2, zero overwash wave height is defined as the wave height with a 2% occurrence frequency.

Significant Wave Height is either the Deep-Water or Shallow-Water Significant wave height
Depending upon the Wave Classification (Step 14).

Significant Wave Height, H_s =	19.25	feet	*(see Step 11 or 16)*
Required probability of wave height being exceeded, n/N =	0.02		*(see Step 17 discussion)*
Root Mean Square Wave Height, $H_{rms} = 2^{-1/2} H_s$ =	7.25	feet	*(Eqn. 3-10, SPM)*
Wave Height which is exceeded at given probability, $H^* = H_{rms} [-\ln(n/N)]^{1/2}$ =	14.18	feet	*(Eqn. 3-7, SPM)*

Step 18. Compute Wind Set-Up

Four different methods are calculated and considered in estimating wind setup.
Zeidler Zee Eqn: Widely used as applied to reservoirs but tends to overestimate wind setup for shallow impoundments (ave. depth< 16 ft).
Sibul Eqn: Typically yields the lowest wind setup.
Ave. of Zeidler Zee & Sibul: Recommended for shallow impoundments (ave. depth< 16 ft) when Bretschneider has no numeric solution.
Bretschneider Eqn: Recommend for shallow impoundments (average depth <16 ft).

Fetch Length, F =	3.62	miles	*(see Step 5)*
Fetch Length, F =	19,097	feet	
Average Wind Velocity, U = Wind Speed per Step 7 = $U_{PMW,Fetch,Lim}$ =	161	mph	*(pg A6, DCM-2)(see Step 7)*
Average Depth of Water along Fetch Line, D = Effective Depth =	17.06	feet	*(see Step 14)*
Zeidler Zee Eqn (Note: F=miles): Wind Set-Up, $S = U^2 F/(1400D)$ =	3.94	feet	*(Eqn. 5, DCM-2)*
Sibul Eqn (Note: F=feet, g=32.2 ft/s²): $S = 0.0002444(F/g)^{1/3}(U^2/g)^{2(F/g)^{-0.0375}}$ =	1.16	feet	*(Eqn. 7, DCM-2)*
Average of Zeidler Zee & Sibul: Wind Setup, $S = (S_{Zeidler\ Zee} + S_{Sibul})/2$ =	2.55	feet	
Bretschneider Eqn (Note: Calcs provided separately in Step 18a): $S = \frac{3}{4}[(kU^2/gx)(gF/g)$ =	n/a	feet	*(Eqn. 6, DCM-2)(Step 18a)*
Equation Used for Wind Setup *(Enter Zeidler Zee, Sibul, Average, Bretschneider)* =	Zeidler Zee		
Computed Wind Set-Up, S =	3.94	feet	*(Eqn. 5, DCM-2)*

Step 19. Compute Water Depth at Toe of Structure

Water Depth at Toe of Structure, d_t = Effective Depth + Wind Set-Up = d + S = 21.00 feet *(pg. 6, DCM-2)*

Step 20. Check for Depth Limited Wave Breaking

See if wave height is limited due to breaking. After breaking, waves will tend to reform with lower heights within a few wave lengths. *(pg. 1B-4, EM-1110-2-1420)*

Depth of interest is at Toe of Structure, $d_x = d_t$ =	21.00	feet *(see Step 19)*
Wave Breaking Height, H_b (for depth d_x) = $(d_x/1.28)$ =	16.41	feet *(Eqn. 2-91 & 3-50, SPM)*
Is max. wave height limited by breaking? (If H_s (step 20) $\leq H^*$ (step 17) than yes, else no) =	No	
(If no, wave height = H^* (step 17). If yes, conservatively assume wave height = H_s (step 20))		
Maximum Wave Height =	14.18 feet	

Step 21. Estimate Ratio Between Deep-Water Wave Ht & Equivalent Deep-Water Ht

The value of H/Ho (shallow-water wave height/equivalent deep water wave height) is estimated based on the value of d/L_o (effective depth / deep-water wave length) from Table C-1, SPM Vol II, Appendix C.

Effective Depth, d =	17.06	feet *(see Step 14)*
Deep-Water Wave Length, L_o =	171	feet *(see Step 13)*
Ratio of effective depth to deep-water wave length, d/L_o =	0.1	
H/H'_o =	0.9327	*(Table C-1, SPM Vol 2)*

Step 22. Compute Equivalent Deep-Water Wave Height, H'_o

If wave classification is Deep-Water (Step 14), Significant Deep-Water Height is the Equivalent Deep-Water Height.
If wave classification is Transitional/Shallow-Water an adjustment is necessary.
If Wave Breaking Height (Step 20) is less than the Zero Overwash for Significant Wave Height (Step 17)
then Equivalent Deep-Water Wave Height is Wave Breaking Height (irregardless of wave classification).

Wave Breaking Height, H_b =	16.41	feet	*(see Step 20)*
Significant Wave Height, H_s =	14.18	feet	*(see Step 17)*
H/H'_o =	0.9327		*(see Step 21)*
If Shallow-Water, Equivalent Deep-Water Wave Height, $H'o = H/(H/Ho)$ =	15.20	feet	
If Deep Water, Equivalent Deep-Water Wave Height = Significant Deep-Water Height =	n/a	feet	
If Height Limited by Wave Breaking, Equiv. Deep-Water Wave Ht. = Wave Breaking Ht. =	n/a	feet	
Equivalent Deep-Water Wave Height =	15.20	feet	

Step 23. Compute Depth at Toe of Structure to Equiv. Deep-Water Wave Ht, d_t/H'_o

Water Depth at Toe of Structure, d_t =	21.00	feet *(see Step 19)*
Equivalent Deep-Water Wave Height, H'_o =	15.20	feet *(see Step 22)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_t/H'_o =	1.38	

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 3: Probable Maximum Wind Speed Combined with Normal Full Storage Level (Uncontrolled Spillway Level)
Site C-43: Cell 2 (Fetch 2B)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.62	miles	*(see Step 5)*
Fetch Length, F =	19,097	feet	
PMW, Fetch Limited Wind Speed Over Water = $U_{PMW,fetch-min}$ =	161	mph	*(see Step 7)*
Wind Stress Factor, U_* (ft/s) =	449	ft/s	*(see Step 10)*

Wind Setup and Wave Properties Analysis - Summary Data

Wind Set-Up , S =	3.94	feet	*(see Step 18)*
Equivalent Deep-Water Wave Height, H'_o =	15.20	feet	*(see Step 22)*
Deep-Water Wave Period, T_o =	5.78	sec	*(see Step 12)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_s/H'_o =	1.38		*(see Step 23)*

Step 24. Compute Ratio of $H'_o/(g*T_o^2)$

Equivalent Deep-Water Wave Height, H'_o =	15.20	feet	*(see Step 22)*
Gravitational constant, g =	32.2	ft/s^2	*(constant variable)*
Deep Water Wave Period, T_o =	5.78	sec	*(see Step 12)*
$H'_o/(g*T_o^2)$ =	0.014		

Steps 25 - 27. Estimate R/H'o *(Fig. 7-8 thru 7-20, SPM Vol. 2)*

Steps 25-27 are directed towards deriving the ratio of Wave Runup to the Equivalent Deep-Water Wave Height (R/H'_o) from graphs found in SPM Volume 2 (Fig. 7-8 thru 7-20). The graphs are based upon various designs of the runup face slope including the material, roughness, slope, and geometry the face slope. In addition the value of R/H'_o depends upon the values of d_s/H'_o and $H'_o/(gT^2)$. Determination of values will typically require an interpolation of values between graphs.

d_s/H'_o =	1.38		*(see Step 23)*
$H'_o/(g*T_o^2)$ =	0.014		*(see Step 24)*
Face Slope Material =	Stop-Faced Slope		*Embankment Design*
Runup Face Slope (H:1V) =	3		*Embankment Design*
Runup Face Slope (Θ) =	18.4	degrees	
Figure used for Interpolation (Lower Interpolation Number) =	Fig. 7-10		*(SPM Vol. 2)*
Figure to used for Interpolation (Higher Interpolation Number) =	Fig. 7-11		*(SPM Vol. 2)*

Step 25. R/H'o from Fig. 7-10 with ds/H'o <= 1.38

$H'_o/(g*T_o^2)$ =	0.014		*(see Step 24)*
ds/H'o <=1.38 from Fig. 7-10 =	0.8		*(Fig. 7-10, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-10 =	0.82		*(Fig. 7-10, SPM Vol. 2)*

Step 26. R/H'o from Fig. 7-11 with ds/H'o >= 1.38

$H'_o/(g*T_o^2)$ =	0.014		*(see Step 24)*
ds/H'o >=1.38 from Fig. 7-11 =	2.0		*(Fig. 7-11, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-11 =	0.96		*(Fig. 7-11, SPM Vol. 2)*

Step 27. Estimated Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o

d_s/H'_o =	1.38		*(see Step 23)*
$H'_o/(g*T_o^2)$ =	0.014		*(see Step 24)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o =	0.89		*(Interpolated from Steps 25 & 26)*

Step 28. Compute Smooth Surface Wave Runup

Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'_o =	0.89		*(see Step 27)*
Equivalent Deep-Water Wave Height, H'_o =	15.20		*(see Step 22)*
Smooth Surface Wave Runup = R/H'_o x H'_o =	13.50	feet	

Step 29. If Applicable, Determine and Apply Wave Runup Correction Factor due to Scale Effects

This step applies if Figures 7-8 thru 7-12 or Figures 7-14 thru 7-16 were used to estimate R/H'_o in Steps 25-27. These figures summarize results for small-scale lab tests. Due to the inability to scale roughness effects in small-scale lab tests, the results are probably smaller than the runup on prototype structures. Figure 7-13 is used to adjust for this scale effect.

Smooth Surface Wave Runup = R/H'_o x H'_o =	13.50	feet	*(see Step 28)*
Scale Wave Runup Correction due to Scale Effects *(If Fig. 7-19 or 7-20 used, enter 1)* =	1.12		*(Fig. 7-13, SPM Vol. 2)*
Scale Corrected Wave Runup Height = (Smooth Surface Wave Runup)(Runup Correction) =	15.12	feet	

Step 30. Determine and Apply Correction Factor due to Dam Surface Roughness

Face Slope Material =	Stop-Faced Slope		*(see Step 25)*
Surface Roughness Correction =	0.7		*(Table 7-2, SPM Vol 2) or (Table 2-2 EM1110-2-1614)*
Scale Corrected Wave Runup Height =	15.12	feet	*(see Step 29)*
Corrected Wave Runup = (Scale Corrected Wave Runup)(Surface Roughness Correction) =	10.58	feet	

Step 31. Correction Due to to Fetch Axis Not Being Normal to the Dam Axis

Angle Between Fetch Axis and Embankment Axis =	45	degrees	
Angle Correction Factor =	0.90		*(Fig. 8, ACER TM No. 11)*

Step 32. Adjusted Wave Runup

Corrected Wave Runup =	10.58		*(see Step 30)*
Angle Correction Factor =	0.90		*(see Step 31)*
Final Adjusted Wave Runup = (Corrected Wave Runup)(Angle Correction Factor) =	9.5	feet	

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 3: Probable Maximum Wind Speed Combined with Normal Full Storage Level (Uncontrolled Spillway Level)
Site C-43: Cell 2 (Fetch 2B)

Step 33. Minimum Required Design Freeboard

Design Precipitation **or** Flood Surge Depth (Routed Flood Event) =	0.00	ft	*(no surcharge, normal full storage level elevation assumed)*
Wind Setup =	3.94	ft	*(see Step 18)*
Wave Height & Runup =	9.53	ft	*(see Step 32)*
Waves Induced by Potential Landslides =	0.00	ft	*(not considered)*
Provision for Malfunction of the Spillway or Discharge Structure =	0.00	ft	*(not considered)*
Summation of all above Freeboard Components is Minimum Required Freeboard =	13.47	ft	*(rounded up to the next 0.01 foot)*

Step 34. Minimum Required Design Freeboard with Camber

Average Normal Full Storage Depth =	17.06	ft	*(Average Depth along Fetch based on NFSL = 42 ft El.)*
Minimum Required Freeboard =	13.47	ft	*(see Step 33)*
Embankment Height (not including camber) =	30.53	ft	*(summation of average normal full storage depth and freeboard)*
Minimum Required Freeboard =	13.47	ft	*(see Step 33)*
Embankment Settlement =	0.98	ft	*(see Technical Memorandum Table 3 or BODR Section 8E)*
Minimum Embankment Height (with camber) =	31.51	ft	*(minimum embankment height plus settlement)*
Minimum Required Design Freeboard with Camber =	14.45	ft	*(rounded up to the next 0.01 foot)*

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

Case 4: Hurricane Easy (125 mph, 3-sec Gust Wind Speed Combined With Both 24-hr (38.7") & 72 hr (45.2") Rainfall Durations)
Site C-43: Cell 2 (Fetch 2B)

Step 1-2: Select EASY, 3-Sec Gust Wind Speed, $U_{EASY,3\text{-}sec}$

Project Location =	C-43 Cell No. 2		
EASY, 3-sec Gust Wind Speed, $U_{EASY,3\text{-}sec}$ =	125.0	mph	*(pg. 14, DCM-2)*

The Hurricane Easy, 125 mph, 3-sec gust wind speed is a storm specific case. Therefore, it is assumed that the Step 2 conversion factor adjustment is not relevant for this case.

Step 3: Determine EASY, 1-Hr Wind Speed, $U_{EASY,\ 1\text{-}hr}$

Initial wind speed duration, t =	3	sec.	*(based on Step 1 Data)*
Equations for ratio of wind speeds to 1-hour average wind speeds, U_t/U_{3600}			
For $t \leq 3{,}600$: $U_t/U_{3600} = 1.277 + 0.296\tanh(0.9\log_{10}(45/t))$ =	applies		*(Eqn. 1, DCM-2)*
For $3{,}600 < t < 36{,}000$: $U_t/U_{3600} = -0.15\log_{10}(t)+1.5334$ =	does not apply		*(Eqn. 2, DCM-2)*
U_t/U_{3600} =	1.51		*(Eqn. 1, DCM-2)*
$U_t = U_{EASY,3\text{-}sec}$ =	125.00	mph	*(see Step 2)*
$U_{100\text{-}yr,\ 3600\text{-}sec} = U_{100\text{-}yr,\ 1\text{-}hr} = U_t/(U_t/U_{3600})$ =	82.8	mph	

Step 4: Determine EASY, 1-Hr Wind Speed Over Water, $U_{EASY,1\text{-}hr,water}$

Fetch Length (in miles), X =	3.62	miles	
Wind Speed Over Water to Wind Speed Over Land Ratio, U_{Water}/U_{Land}:			
If initial data from Step 1 is over water wind speed, no conversion (Ratio = 1.0)	does not apply		*(Fig. II-2-20, CEM)*
For Fetch Length < 10 miles: U_{Water}/U_{Land} = 1.2 or 1.0	applies		*(Fig. II-2-20, CEM)*
For Fetch Length > 10 miles: See Figure II-2-7, CEM	does not apply		*(Fig. II-2-7, CEM)*
U_{water}/U_{land} =	1.2		*(Fig. II-2-20, CEM)*
$U_{Easy,1\text{-}hr,land}$ =	82.8		*(see Step 3)*
$U_{EASY,1\text{-}hr,water} = U_{EASY,1\text{-}hr,land} \times (U_{water}/U_{land})$ =	99.4	mph	

Step 5: Estimate Fetch-Limited Wind Duration Time

Fetch Length (in miles), X =	3.62	miles	*(see Step 4)*
Wind Velocity (in mph), U =	99.4	mph	*(see Step 4)*
Fetch Limited Wind Duration Time, $t = 112(X^{0.57}/U^{0.34})$ =	55	min.	*(Eqn. 4, DCM-2)*
	3329	sec.	

Step 6: Estimate Ratio of Fetch Limited Duration Wind Speed and 1-Hour Wind Speed

Fetch Limited Wind Duration Time (in seconds), t =	3329	sec.	*(see Step 5)*
Equations for ratio of wind speeds to 1-hour average wind speeds, U_t/U_{3600}			
For $t \leq 3{,}600$: $U_t/U_{3600} = 1.277 + 0.296\tanh(0.9\log_{10}(45/t))$ =	applies		*(Eqn. 1, DCM-2)*
For $3{,}600 < t < 36{,}000$: $U_t/U_{3600} = -0.15\log_{10}(t)+1.5334$ =	does not apply		*(Eqn. 2, DCM-2)*
Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.001		*(Eqn. 1, DCM-2)*

Step 7: Adjust 1-Hr Wind Speed (over water) to Equivalent Fetch Limited Duration Wind Speed

Fetch Limited Wind Duration (in minutes), t =	55	min.	*(see Step 5)*
EASY, 1-Hr Wind Speed Over Water, $U_{EASY,1\text{-}hr,water}$ =	99.4	mph	*(see Step 4)*
Ratio of Fetch Limited Duration Wind Speed to 1-Hour Wind Speed, U_t/U_{3600} =	1.001		*(see Step 6)*
EASY, Fetch Limited Wind Speed Over Water = $U_{EASY,1\text{-}hr,water} \times U_t/U_{3600}$ =	99	mph	

Step 8: Stability Correction, Adjust Wind Speed for Boundary Layer Stability

Fetch Length (in miles), X =	3.62	miles	*(see Step 4)*
(If Fetch Length > 10 miles, else enter 0) Temperature of Air, T_a =	0	o C	
(If Fetch Length > 10 miles, else enter 0) Temperature of Sea, T_s =	0	o C	
Air-Sea Temperature Difference, ΔT_{as} $T_a - T_s$ =	0	°C	
Stability Correction Factor, R_T			
For Fetch Length < 10 miles: R_T = 1.0	applies		*(pg. II-2-36, CEM)*
For Fetch Length > 10 miles: Based on ΔT_{as}, See Figure 3-14, SPM or in absence of temperature information, assume RT = 1.1	does not apply		*(Fig.3-14, SPM)* *(pg 3-30, SPM)*
$U_{EASY,fetch\text{-}min,water}$ =	99	mph	*(see Step 7)*
Stability Correction Factor, R_T =	1		*(pg. II-2-36, CEM)*
$U_{EASY,fetch\text{-}min,water,\ stability\ adjusted} = U_{EASY,fetch\text{-}min,water} \times R_T$ =	99	mph	*(Eqn. 3-27 SPM)*

Step 9. Compute Wind Stress Factor, U_A

$U_{EASY,fetch\text{-}min,water,\ stability\ adjusted} = U$ =	99	mph	*(see Step 8)*
Wind Stress Factor, $U_A = 0.589U^{1.23}$ =	169	mph	*(Eqn. 3-28b SPM)*

Step 10. Wind Stress Factor in ft/s

Wind Stress Factor, U_A (ft/s) = $1.467U_A$ (mph) =	247	ft/sec	*(see Step 9)*

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 4: Hurricane Easy (125 mph, 3-sec Gust Wind Speed Combined With Both 24-hr (36.7") & 72-hr (46.2") Rainfall Durations)
Site C-43: Cell 2 (Fetch 2B)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.62	miles	*(see Step 4)*
Fetch Length, F =	19,097	ft	
EASY, Fetch Limited Wind Speed Over Water = $U_{EASY(fetch-ltd)}$ =	99	mph	*(see Step 7)*
Wind Stress Factor, U_* (ft/s) =	247	ft/s	*(see Step 10)*

Step 11. Compute Deep-Water Significant Wave Height, H_{mo}

Deep-Water Significant Wave Height, $H_{mo} = (0.000282)U_*F^{1/2}$ =	9.64	feet	*(Eqn. 3-33a, SPM)*

Step 12. Compute Deep-Water Wave Period, T_o

Deep-Water Wave Period, $T_o = 0.02825(U_*F)^{1/2}$ =	4.74	sec	*(Eqn. 3-34c, SPM)*

Step 13. Compute Deep-Water Wave Length, L_o

Deep-Water Wave Length, $L_o = 5.12T_o^2$ =	115	feet	*(Eqn. 3-4b, SPM)*

Step 14. Compute Relative Depth, d/L_o

If $d/L_o \leq 0.5$, waves are classified as transitional or shallow water waves. *(pg 2-9, SPM)*
If $d/L_o > 0.5$, waves are classified as deep water. *(pg 2-9, SPM)*

	20.83	feet	
Relative Depth = d/L_o =	0.181		*(pg 2-9, SPM)*
Wave Classification =	Transitional/Shallow-Water		*(pg 2-9, SPM)*

Step 15. Compute Shallow-Water Wave Period, T

Shallow-Water Wave Period, $T = 7.54\tanh(A)\tanh(B/C)\,U_*/g$ *(Eqn. 3-40, SPM)*

where: F = Fetch Length (ft) (step 5) U_* = Wind Stress Factor (step 10) g = 32.2 ft/s²

$A = 0.833(gd/U_*^2)^{3/4}$ =	0.1533	
$B = 0.0379(gF/U_*^2)^{1/3}$ =	0.0818	
$C = \tanh(0.833(gd/U_*^2)^{3/8})$ =	0.1521	
Shallow-Water Wave Period, $T = 7.54\tanh(A)\tanh(B/C)\,U_*/g$ =	4.33 sec	*(Eqn. 3-40, SPM)*

Step 16. Compute Shallow-Water Significant Wave Height, H

Shallow-Water Significant Wave Height, $H = 0.283\tanh(A)\tanh(B/C)\,U_*^2/g$ *(Eqn. 3-39, SPM)*

where: F = Fetch Length (ft) (step 5) U_* = Wind Stress Factor (step 10) g = 32.2 ft/s²

$A = 0.530(gd/U_*^2)^{3/4}$ =	0.0179	
$B = 0.00565(gF/U_*^2)^{1/2}$ =	0.0179	
$C = \tanh(0.530(gd/U_*^2)^{3/8})$ =	0.0179	
Shallow-Water Significant Wave Height, $H = 0.283\tanh(A)\tanh(B/C)\,U_*^2/g$ =	7.35 feet	*(Eqn. 3-39, SPM)*

Step 17. Compute Shallow-Water Wave Height for Zero Overwash

DCM-2 requires zero over wash as a design criteria for high and significant hazard dams. For purposes of the DCM-2, zero-overwash wave height is defined as the wave height with a 2% occurrence frequency.

Significant Wave Height is either the Deep-Water or Shallow-Water Significant wave height depending upon the Wave Classification (Step 14).

Significant Wave Height, H_s =	7.35	feet	*(see Step 11 or 16)*
Required probability of wave height being exceeded, n/N =	0.02		*(see Step 17 discussion)*
Root Mean Square Wave Height, $H_{rms} = 2^{1/2}H_s$ =	5.19	feet	*(Eqn. 3-10, SPM)*
Wave Height which is exceeded at given probability, $H^* = H_{rms}[-Ln(n/N)]^{1/2}$ =	10.16	feet	*(Eqn. 3-7, SPM)*

Step 18. Compute Wind Set-Up

Four different methods are calculated and considered in estimating wind setup
Zeidler Zee Eqn: Widely used as applied to reservoirs but tends to overestimate wind setup for shallow impoundments (ave. depth<15 ft).
Sibul Eqn: Typically yields the lowest wind setup.
Ave. of Zeidler Zee & Sibul: Recommended for shallow impoundments (ave. depth<15 ft) when Bretschneider has no numeric solution.
Bretschneider Eqn: Recommend for shallow impoundments (average depth <15 ft).

Fetch Length, F =	3.62	miles	*(see Step 4)*
Fetch Length, F =	19,097	feet	
Average Wind Velocity, U = Wind Speed per Step 7 = $U_{EASY(fetch-ltd)}$ =	99	mph	*(pg A6, DCM-2)(see Step 7)*
Average Depth of Water along Fetch Line, D = Effective Depth =	20.82666667	feet	*(see Step 14)*
Zeidler Zee Eqn (Note: F=miles): Wind Set-Up, $S = U^2F/(1400D)$ =	1.23	feet	*(Eqn. 5, DCM-2)*
Sibul Eqn (Note: F=feet, g=32.2 ft/s²): $S = 0.0000144d(Fd)^{1.65}(U^2/Fg)^{(1/2)(0.57d_{0.25}-0.57d_0)}$ =	0.30	feet	*(Eqn. 7, DCM-2)*
Average of Zeidler Zee & Sibul: Wind Setup, $S = (S_{Zeidler\ Zee} + S_{Sibul})/2$ =	0.76	feet	
Bretschneider Eqn (Note: Calcs provided separately in Step 18a): $S = \Box[(kU^2\Box x)/(gd^2)]$ =	n/a	feet	*(Eqn. 6, DCM-2)(Step 18a)*
Equation Used for Wind Setup *(Enter Zeidler Zee, Sibul, Average, Bretschneider)* =	Zeidler Zee		
Computed Wind Set-Up, S =	1.23	feet	*(Eqn. 5, DCM-2)*

Step 19. Compute Water Depth at Toe of Structure

Water Depth at Toe of Structure, d_o = Effective Depth + Wind Set-Up = d + S =	22.05	feet	*(pg. 6, DCM-2)*

Step 20. Check for Depth Limited Wave Breaking

See if wave height is limited due to breaking. After breaking, waves will tend to reform with lower heights within a few wave lengths. *(pg. 15-4, EM-1110-2-1420)*

Depth of interest is at Toe of Structure, $d_x = d_o$ =	22.05	feet	*(see Step 19)*
Wave Breaking Height, H_b *(for depth d_b)* = $(d_b/1.28)$ =	17.23	feet	*(Eqn. 2-91 & 2-92, SPM)*
Is max. wave height limited by breaking? *(If H_s [step 20] $\leq H^*$ [step 17] then yes, else no)* =	No		
(If no, wave height = H^* (step 17). If yes, conservatively assume wave height = H_b (step 20)) Maximum Wave Height =	10.16	feet	

Step 21. Estimate Ratio Between Deep-Water Wave Ht & Equivalent Deep-Water Ht

The value of H/Ho (shallow-water wave height/equivalent deep-water wave height) is estimated based on the value of d/L_o (effective depth / deep-water wave length) from Table C-1, SPM Vol II, Appendix C.

Effective Depth, d =	20.82666667	feet	*(see Step 14)*
Deep-Water Wave Length, L_o =	115	feet	*(see Step 12)*
Ratio of effective depth to deep-water wave length, d/L_o =	0.181		
H/H'_o =	0.9146		*(Table C-1, SPM Vol 2)*

Step 22. Compute Equivalent Deep-Water Wave Height, H'_o

If wave classification is Deep-Water (Step 14), Significant Deep-Water Height is the Equivalent Deep-Water Height.
If wave classification is Transitional/Shallow-Water an adjustment is necessary.
If Wave Breaking Height (Step 20) is less than the Zero Overwash for Significant Wave Height (Step 17) then Equivalent Deep-Water Wave Height is Wave Braking Height (irregardless of wave classification).

Wave Breaking Height, H_b =	17.23	feet	*(see Step 20)*
Significant Wave Height, H_s =	10.16	feet	*(see Step 17)*
H/H'_o =	0.9146		*(see Step 21)*
If Shallow-Water: Equivalent Deep-Water Wave Height, $H'o = H(H/H'o)$ =	11.11	feet	
If Deep Water: Equivalent Deep-Water Wave Height = Significant Deep-Water Height =	n/a	feet	
If Height Limited by Wave Breaking: Equiv. Deep-Water Wave Ht. = Wave Breaking Ht. =	n/a	feet	
Equivalent Deep-Water Wave Height =	11.11	feet	

Step 23. Compute Depth at Toe of Structure to Equiv. Deep-Water Wave Ht, d_o/H'_o

Water Depth at Toe of Structure, d_o =	22.05	feet	*(see Step 19)*
Equivalent Deep-Water Wave Height, H'_o =	11.11	feet	*(see Step 22)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_o/H'_o =	1.98		

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

3/12/2007

Case 4: Hurricane Easy (125 mph, 3-sec Gust Wind Speed Combined With Both 24-hr (38.7") & 72 hr (45.2") Rainfall Durations)
Site C-43: Cell 2 (Fetch 2B)

Design Wind Analysis - Summary Data

Fetch Length, F =	3.62	miles	*(see Step 4)*
Fetch Length, F =	19,097	feet	
EASY, Fetch Limited Wind Speed Over Water = $U_{EASY,fetch-ltd}$ =	99	mph	*(see Step 7)*
Wind Stress Factor, U_A (ft/s) =	247	ft/s	*(see Step 10)*

Wind Setup and Wave Properties Analysis - Summary Data

Wind Set-Up , S =	1.23	feet	*(see Step 18)*
Equivalent Deep-Water Wave Height, H'_o =	11.11	feet	*(see Step 22)*
Deep-Water Wave Period, T_o =	4.74	sec	*(see Step 12)*
Ratio of Water Depth at Toe of Structure to Equivalent Deep-Water Wave Height, d_s/H'_o =	1.99		*(see Step 23)*

Step 24. Compute Ratio of $H'_o/(g*T_o^2)$

Equivalent Deep-Water Wave Height, H'_o =	11.11	feet	*(see Step 22)*
Gravitational constant, g =	32.2	ft/s^2	*(constant variable)*
Deep Water Wave Period, T_o =	4.74	sec	*(see Step 12)*
$H'_o/(g*T_o^2)$ =	0.015		

Steps 25 - 27. Estimate R/H'o *(Fig. 7-8 thru 7-20, SPM Vol. 2)*

Steps 25-27 are directed towards deriving the ratio of Wave Runup to the Equivalent Deep-Water Wave Height (R/H'_o) from graphs found in SPM Volume 2 (Fig. 7-8 thru 7-20). The graphs are based upon various designs of the runup face slope including the material, roughness, slope, and geometry the face slope. In addition the value of R/H'_o depends upon the values of d_s/H'_o and $H'_o/(gT^2)$. Determination of values will typically require an interpolation of values between graphs.

d_s/H'_o =	1.99		*(see Step 23)*
$H'_o/(g*T_o^2)$ =	0.015		*(see Step 24)*
Face Slope Material =	Step-Faced Slope		*Embankment Design*
Runup Face Slope (H:1V) =	3		*Embankment Design*
Runup Face Slope (Θ) =	18.4	degrees	
Figure used for Interpolation (Lower Interpolation Number) =	Fig. 7-10		*(SPM Vol. 2)*
Figure to used for Interpolation (Higher Interpolation Number) =	Fig. 7-11		*(SPM Vol. 2)*

Step 25. R/H'o from Fig. 7-10 with ds/H'o <= 1.99

$H'_o/(g*T_o^2)$ =	0.015		*(see Step 24)*
ds/H'o <=1.99 from Fig. 7-10 =	0.6		*(Fig. 7-10, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-10 =	0.75		*(Fig. 7-10, SPM Vol. 2)*

Step 26. R/H'o from Fig. 7-11 with ds/H'o >= 1.99

$H'_o/(g*T_o^2)$ =	0.015		*(see Step 24)*
ds/H'o >=1.99 from Fig. 7-11 =	2		*(Fig. 7-11, SPM Vol. 2)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o from Fig. 7-11 =	0.89		*(Fig. 7-11, SPM Vol. 2)*

Step 27. Estimated Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o

d_s/H'_o =	1.99		*(see Step 23)*
$H'_o/(g*T_o^2)$ =	0.015		*(see Step 24)*
Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'o =	0.89		*(Interpolated from Steps 25 & 26)*

Step 28. Compute Smooth Surface Wave Runup

Ratio of Wave Runup to Equivalent Deep-Water Wave Height, R/H'_o =	0.89		*(see Step 27)*
Equivalent Deep-Water Wave Height, H'_o =	11.11		*(see Step 22)*
Smooth Surface Wave Runup = R/H'_o x H'_o =	9.90	feet	

Step 29. If Applicable, Determine and Apply Wave Runup Correction Factor due to Scale Effects

This step applies if Figures 7-8 thru 7-12 or Figures 7-14 thru 7-18 were used to estimate R/H'_o in Steps 25-27. These figures summarize results for small-scale lab tests. Due to the inability to scale roughness effects in small-scale lab tests, the results are probably smaller than the runup on prototype structures. Figure 7-13 is used to adjust for this scale effect.

Smooth Surface Wave Runup = R/H'_o x H'_o =	9.90	feet	*(see Step 28)*
Scale Wave Runup Correction due to Scale Effects *(If Fig. 7-19 or 7-20 used, enter 1)* =	1.12		*(Fig. 7-13, SPM Vol. 2)*
Scale Corrected Wave Runup Height = (Smooth Surface Wave Runup)(Runup Correction) =	11.09	feet	

Step 30. Determine and Apply Correction Factor due to Dam Surface Roughness

Face Slope Material =	Step-Faced Slope		*(see Step 25)*
Surface Roughness Correction =	0.7		*(Table 7-2, SPM Vol 2) or (Table 2-2 EM1110-2-1614)*
Scale Corrected Wave Runup Height =	11.09	feet	*(see Step 29)*
Corrected Wave Runup = (Scale Corrected Wave Runup)(Surface Roughness Correction) =	7.76	feet	

Step 31. Correction Due to to Fetch Axis Not Being Normal to the Dam Axis

Angle Between Fetch Axis and Embankment Axis =	45	degrees	
Angle Correction Factor =	0.90		*(Fig. 8, ACER TM No. 11)*

Step 32. Adjusted Wave Runup

Corrected Wave Runup =	7.76		*(see Step 30)*
Angle Correction Factor =	0.90		*(see Step 31)*
Final Adjusted Wave Runup = (Corrected Wave Runup)(Angle Correction Factor) =	7.0	feet	

Note: The analyses based upon methodologies presented in the SFWMD Design Criteria Manual DCM-2.

The cells that required input.
The cells with analysis output.

BASIC WIND SPEED – EASTERN GULF OF MEXICO AND SOUTHEASTERN US HURRICANE COASTLINE

Step 1

Minimum Design Loads for Buildings and Other Structures

Reference:
ASCE Standard
Minimum Design Loads for
Buildings and Other
Structures. SEI/ASCE 7-02

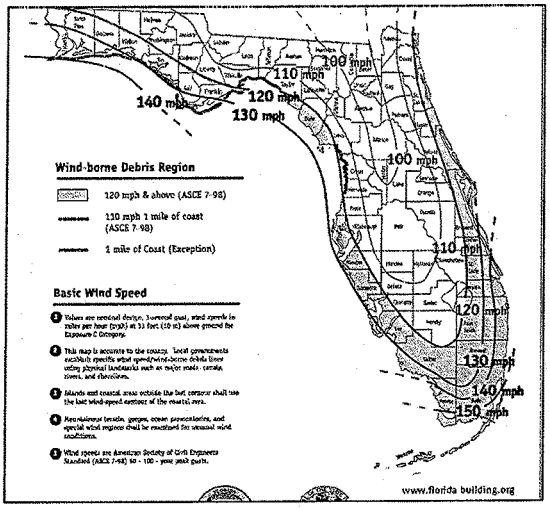

Figure DCM 2-2: Florida 50-Year to 100-Year Gust Wind Speeds (mph) (ref. ASCE 7-02, Figure 6-1b; Florida Building Code, Figure 1606)

The conservative assumption is to assume that the wind speeds on **Figure DCM 2-2** represent 50-year wind speeds and convert the values to 100-year wind speeds, as shown below. The equivalent 100-year wind speeds listed in **Table DCM 2-2**, use a factor of 1.07 to convert hurricane wind speeds from a 50-year to a 100-year return (from the standard structural design reference of the American Society of Civil Engineers (ASCE) Table C 6-3, ASCE 2003). For example, if an area with a 125-mph wind speed is selected from **Figure DCM 2-2**, the corresponding 3-second gust 100-year wind speed would be 134 mph.

Table DCM 2-2: Wind Speed Conversion Factors by Return Period

Return Period (years)	Conversion Factor
500	1.23
200	1.14
100	1.07
50	1.00
25	0.88

The 3-second gust wind speeds shown on **Figure DCM 2-2** are of an insufficient duration to fully develop significant waves. Specifically, the wind speed duration of 3 seconds is insufficient to develop the wave height, which would occur due to the traction of a constant wind at this speed and propagate the wave across the reservoir. Therefore, wind speed adjustments appropriate for developing significant reservoir waves are to be developed as shown below.

ASCE Figure 6-1b (ASCE, 2003) shows the same wind speeds as Figure 1606 in the Florida Building Code. Figures 6-1a, 6-1b, and 6-1c (ASCE, 2003) cover the Gulf and Atlantic coasts from southern Texas to Florida to North Carolina and to Maine. The figures provide "smoothed" contours of wind speed and are based on a substantial amount of data and analysis. It would be impractical for CERP dam design consultants to duplicate the scope of data analysis used in developing the ASCE figures and is generally not necessary. Use of these figures provides reliable and consistent data from location to location. The analysis of local wind speed gage data, even from first-order stations, would provide unreliable and inconsistent results from location to location because of routine gage malfunctions at extreme wind speeds and the "hit and miss" nature of hurricanes relative to data recording stations. Freeboard criteria for CERP reservoirs, therefore, will be based on Figure 1606 of the Florida Building Code for wind speed data, rather than developing wind speeds based on local gage data, with the appropriate adjustments described below. Figure 1606, which is identified as being based on 50-year to 100-year wind speeds, will be conservatively interpreted as representing 50-year wind speeds for application to freeboard determination.

2.1.1.2 Duration Adjustment of Wind Speeds

When evaluating wave generation in water bodies of different sizes, different wind speed averaging intervals are appropriate. The current Coastal Engineering Manual notes that if extreme wind speeds are being considered, wind speed should be adjusted from the averaging time of the observation (3-second on **Figure DCM 2-2**) to an averaging time appropriate for wave prediction (USACE, 2003, pg. II-2-34). To adjust the wind speeds for duration, the Coastal Engineering Manual references a figure on page II-2-4, which also includes the defining equations? The following equations (USACE, 2003, pg. II-2-4) show the calculation adjustments for the ratio of wind speeds by various durations, to 1-hour average wind speeds.

For $t \le 3{,}600$: $$\frac{U_t}{U_{3,600}} = 1.277 + 0.296 \tanh\left(0.9 \log_{10}\left(\frac{45}{t}\right)\right)$$ Eqn. 1

For $3{,}600 < t < 36{,}000$: $$\frac{U_t}{U_{3,600}} = -0.15 \log_{10} t + 1.5334$$ Eqn. 2

where:

t = time (seconds)

U_t = wind speed (mph) at time t (seconds)

$U_{3,600}$ = 1-hour average wind speed (mph)

This document provides working level guidance to assist in the implementation of projects and project features under the Comprehensive Everglades Restoration Plan (CERP) program implemented by the South Florida Water Management District, the Florida Department of Environmental Protection, and the U.S. Army Corps of Engineers. The guidance does not supersede existing or future federal or state regulation, does not constitute policy for any of these agencies, and does not create authority beyond that granted to any agency member carrying out their duties.

Step 3 [redacted]

Reference: DCM-2

Necessary only if Fetch length, F > 10 miles

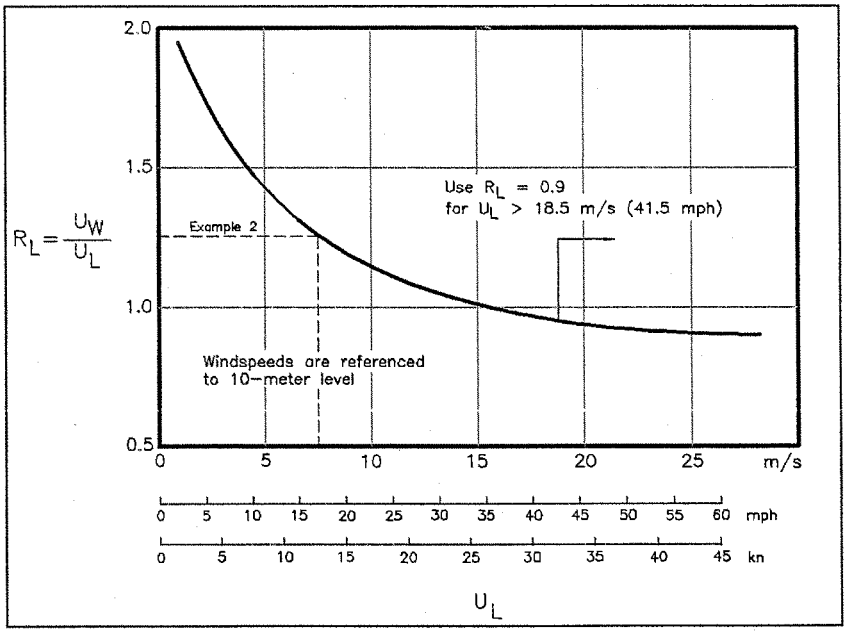

Figure II-2-7. Ratio R_L of windspeed over water U_W to windspeed over land U_L as a function of windspeed over land U_L (after Resio and Vincent (1977))

marine boundary layer and winds from other directions fall within a land boundary layer. In areas such as this, a land-to-sea transform (similar to that shown in Figures II-2-7 and II-2-8) can be used for all angles coming from the land. Depending on the distance to the water and the elevation of the measurement site, winds coming from the direction of open water may or may not still be representative of a marine boundary layer. Guidance for determining the effects of fetch on wind speed modifications can be found in Resio and Vincent (1977) and Smith (1983). These studies indicate that fetch effects wind speeds significantly only at locations within about 16 km (10 miles) of shore.

(e) Wind speed transition from land to water. The net effect of wind speed variation with fetch is to provide a smooth transition from the (generally lower) wind speed over land to the (generally higher) wind speed over water. Thus, wind speeds tend to increase with fetch over the first 10 miles or so after a transition from a land surface. The exact magnitude and characteristics of this transition depend on the roughness characteristics of the terrain and vegetation and on the stability of the air flow. A very simplistic approximation to this wind speed variation for the Resio and Vincent curves used here could be obtained by fitting a logarithmic curve to the asymptotic overland and overwater wind speed values. However, for most design and engineering purposes, it is probably adequate to simply use the long-fetch values with the recognition that they are somewhat conservative. The one situation that should cause some concern would be if overwater wind speed measurements are taken near the upwind end of a fetch. These winds could be considerably lower than wind speeds at the end of the fetch and underconservative values for wave conditions could result from the use of such (uncorrected) winds in a predictive scheme.

Step 4

Reference:
CEM, USACE
EM 1110-2-1100

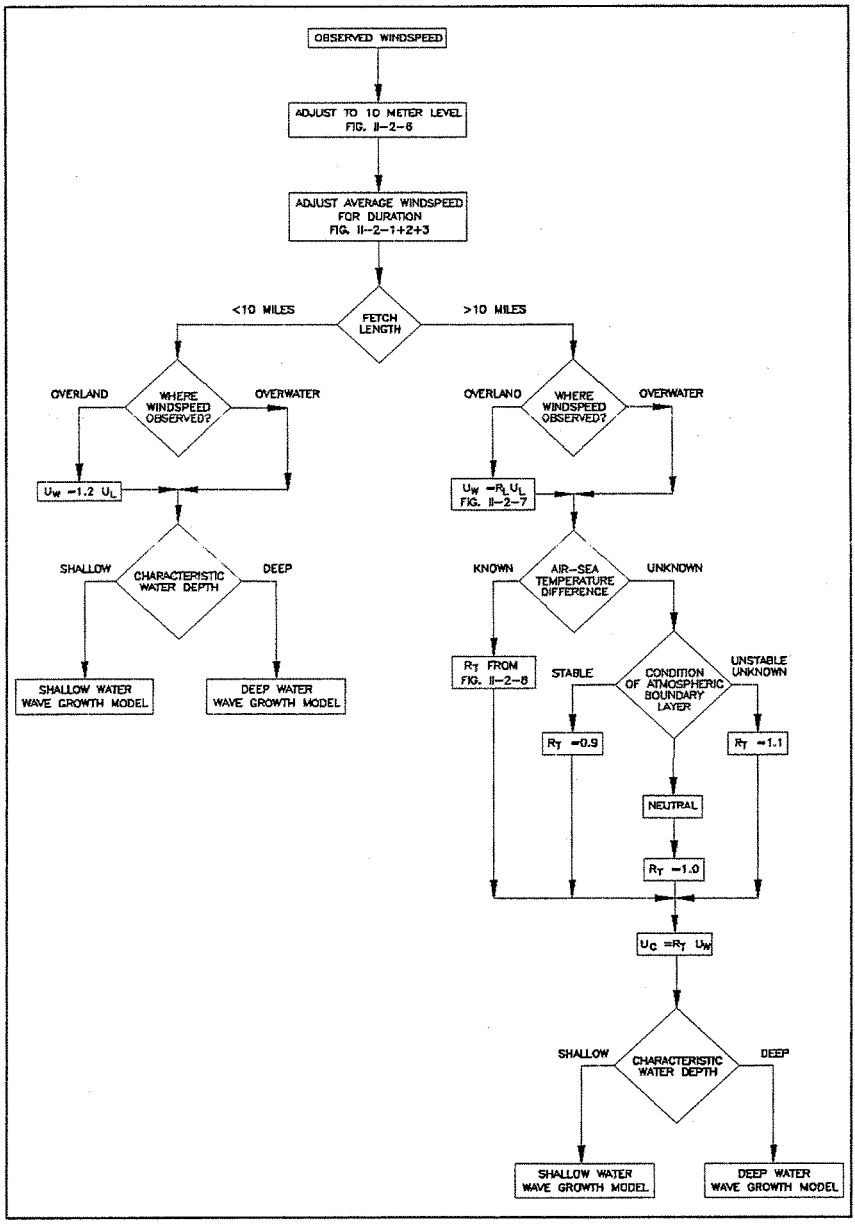

Figure II-2-20. Logic diagram for determining wind speed for use in wave hindcasting and forecasting models

Reference: CEM, USACE EM 1110-2-1100

Step 4.

For a given wind speed and fetch, there is an associated wind duration that, if exceeded, cannot increase the wave size because of the limiting effects of the fetch and depth. The following equation (USACE, 2003, Eqn. II-2-35) can be used to determine whether or not waves in a particular situation can be categorized as fetch limited.

$$t_{x,u} = 77.23\frac{X^{0.67}}{u^{0.34} g^{0.33}} \qquad \text{Eqn. 3}$$

where:

t = wind duration time (seconds)

X = fetch length (meters)

u = wind velocity (meters/sec)

g = gravitational constant (meters/sec^2)

In English units, the above equation would be:

$$t = 112\frac{X^{0.67}}{u^{0.34}} \qquad \text{Eqn. 4}$$

where:

t = wind duration time (minutes)

X = fetch length (miles)

u = wind velocity (mph)

The above Eqn. 4 is also presented in a current publication on freeboard analysis (Holler, 2004). An example can clarify the procedure for determining the 100-year wind speed that would be coincident with the PMP.

2.1.1.3 Example Wind Speed Adjustments

The following wind speed determination generally follows the example procedure for estimating winds for wave prediction provided in the Coastal Engineering Manual beginning on page II-2-34 (USACE, 2003).

1. Assume the reservoir is in an area where the gust-wind is 125 mph based on the Florida Building Code (**Figure DCM 2-2**).

2. Adjust the 50-year, 3-second wind speed to an equivalent 100-year wind speed:

   (125 mph) * 1.07 = 134 mph

This document provides working level guidance to assist in the implementation of projects and project features under the Comprehensive Everglades Restoration Plan (CERP) program implemented by the South Florida Water Management District, the Florida Department of Environmental Protection, and the U.S. Army Corps of Engineers. The guidance does not supersede existing or future federal or state regulation, does not constitute policy for any of these agencies, and does not create authority beyond that granted to any agency member carrying out their duties.

Step 5

Reference: DCM-2

The 3-second gust wind speeds shown on **Figure DCM 2-2** are of an insufficient duration to fully develop significant waves. Specifically, the wind speed duration of 3 seconds is insufficient to develop the wave height, which would occur due to the traction of a constant wind at this speed and propagate the wave across the reservoir. Therefore, wind speed adjustments appropriate for developing significant reservoir waves are to be developed as shown below.

ASCE Figure 6-1b (ASCE, 2003) shows the same wind speeds as Figure 1606 in the Florida Building Code. Figures 6-1a, 6-1b, and 6-1c (ASCE, 2003) cover the Gulf and Atlantic coasts from southern Texas to Florida to North Carolina and to Maine. The figures provide "smoothed" contours of wind speed and are based on a substantial amount of data and analysis. It would be impractical for CERP dam design consultants to duplicate the scope of data analysis used in developing the ASCE figures and is generally not necessary. Use of these figures provides reliable and consistent data from location to location. The analysis of local wind speed gage data, even from first-order stations, would provide unreliable and inconsistent results from location to location because of routine gage malfunctions at extreme wind speeds and the "hit and miss" nature of hurricanes relative to data recording stations. Freeboard criteria for CERP reservoirs, therefore, will be based on Figure 1606 of the Florida Building Code for wind speed data, rather than developing wind speeds based on local gage data, with the appropriate adjustments described below. Figure 1606, which is identified as being based on 50-year to 100-year wind speeds, will be conservatively interpreted as representing 50-year wind speeds for application to freeboard determination.

2.1.1.2 Duration Adjustment of Wind Speeds

When evaluating wave generation in water bodies of different sizes, different wind speed averaging intervals are appropriate. The current Coastal Engineering Manual notes that if extreme wind speeds are being considered, wind speed should be adjusted from the averaging time of the observation (3-second on **Figure DCM 2-2**) to an averaging time appropriate for wave prediction (USACE, 2003, pg. II-2-34). To adjust the wind speeds for duration, the Coastal Engineering Manual references a figure on page II-2-4, which also includes the defining equations? The following equations (USACE, 2003, pg. II-2-4) show the calculation adjustments for the ratio of wind speeds by various durations, to 1-hour average wind speeds.

For $t \le 3{,}600$: $$\frac{U_t}{U_{3,600}} = 1.277 + 0.296 \tanh\left(0.9 \log_{10}\left(\frac{45}{t}\right)\right)$$ Eqn. 1

For $3{,}600 < t < 36{,}000$: $$\frac{U_t}{U_{3,600}} = -0.15 \log_{10} t + 1.5334$$ Eqn. 2

where:

t = time (seconds)

U_t = wind speed (mph) at time t (seconds)

$U_{3,600}$ = 1-hour average wind speed (mph)

Step [redacted] 6

Reference: DCM-2

be considered. When the observed wind is given in terms of the fastest mile, Figure II-2-2 can be used to convert to an equivalent averaging time.

(c) Overland or overwater. When the observation was collected overwater (within the marine boundary layer), this adjustment is not needed. When the observation was collected overland and the fetch is long enough for full development of a marine boundary layer (longer than about 16 km or 10 miles), the observed wind speed should be adjusted to an overwater wind speed using Figure II-2-7 (see Example Problem II-2-4). Otherwise (for overland winds and fetches less than 16 km), wave growth occurs in a transitional atmospheric boundary layer, which has not fully adjusted to the overwater regime. In this case, wind speeds observed overland must be increased to better represent overwater wind speeds. A factor of 1.2 is suggested here, but no simple method can accurately represent this complex case. In relation to all of these adjustments, the term overland implies a measurement site that is predominantly characterized as inland. If a measurement site is directly adjacent to the water body, it may, for some wind directions, be equivalent to overwater.

(d) Stability. For fetches longer than 16 km, an adjustment for stability of the boundary layer may also be needed. If the air-sea temperature difference is known, Figure II-2-8 can be used to make the adjustment. When only general knowledge of the condition of the atmospheric boundary layer is available, it should be categorized as stable, neutral, or unstable according to the following:

Stable - when the air is warmer than the water, the water cools air just above it and decreases mixing in the air column ($R_T = 0.9$).

Neutral - when the air and water have the same temperature, the water temperature does not affect mixing in the air column ($R_T = 1.0$).

Unstable - when the air is colder than the water, the water warms the air, causing air near the water surface to rise, increasing mixing in the air column ($R_T = 1.1$).

When the boundary layer condition is unknown, an unstable condition, $R_T = 1.1$, should be assumed.

(4) Procedure for adjusting winds from synoptic weather charts. As discussed earlier, synoptic weather charts are maps depicting isobars at sea level. The free air, or geostrophic, wind speed is estimated from these sea level pressure charts. Adjustments or corrections are then made to the geostrophic wind speed. Pressure chart estimations should be used only for large areas, and the estimated values should be compared with observations, if possible, to verify their accuracy.

(a) Geostrophic wind speed. To estimate geostrophic wind speed, Equation II-2-10 or Figure II-2-12 should be used (see Example Problem II-2-5).

(b) Level and stability. Wind speed at the 10-m level should be estimated from the geostrophic wind speed using Figure II-2-13. The resulting speed should then be adjusted for stability effects as needed using Figure II-2-8.

(c) Duration. Wind duration estimates are also needed. Since synoptic weather charts are prepared only at 6-hr intervals, it may be necessary to use interpolation to determine duration. Linear interpolation is adequate for most cases. Interpolation should not be used if short-duration phenomena, such as frontal passages or thunderstorms, are present.

(5) Procedure for estimating fetch. Fetch is defined as a region in which the wind speed and direction are reasonably constant. Fetch should be defined so that wind direction variations do not exceed 15 deg and wind speed variations do not exceed 2.5 m/s (5 knots) from the mean. A coastline upwind from the point of interest always limits the fetch. An upwind limit to the fetch may also be provided by curvature, or spreading,

 Step 8

Reference:
CEM, USACE
EM 1110-2-1100

method may be applied to obtain a 3-hour average; however, the assumption of constant wind again may not be valid.

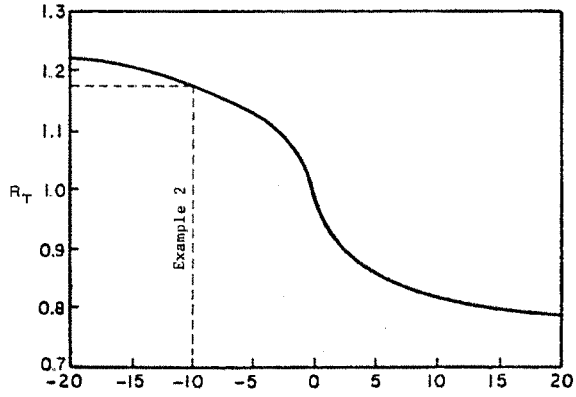
If thunderstorms or other brief, severe winds are included in the data, the method may overestimate results; but often there are no other data available.

c. Stability Correction. If the air-sea temperature difference $\Delta T_{as} = T_a - T_s$ is zero, the boundary layer has neutral stability and no windspeed correction is necessary. If ΔT_{as} is negative, the boundary layer is unstable and the windspeed is more effective in causing wave growth. If ΔT_{as} is positive, the boundary layer is stable and the windspeed is less effective. The correction factor, R_T, is a function of ΔT_{as} and was defined by Resio and Vincent (1977b) to account for this effect. An effective windspeed is obtained by

$$U = R_T \, U(10) \tag{3-27}$$

where R_T is read from Figure 3-14. This correction can be substantial. For example, if the winds are estimated for a ΔT_{as} of $+10^{o}$ C and ΔT_{as} is actually -10^{o} C, the error in $U*$ is 50 percent. ΔT_{as} may vary seasonally. In the fall a lake's water may still be warm, but cold winds may blow across it; in the spring, the reverse may be true. Investigation of the values of T_{as} is usually warranted, and the a priori assumption of a neutrally stable boundary layer should be questioned. In the absence of temperature information, $R_T = 1.1$ should be assumed.

d. Location Effects. Often overwater wind data are not available, but data from nearby land sites are. It is possible to translate overland winds to overwater winds if they are the result of the same pressure gradient and the only major difference is the surface roughness (Resio and Vincent, 1977b). For first-order airport weather stations around the Great Lakes, the relationship between overwater winds to nearby overland winds is given for neutral stability by R_L in Figure 3-15; this can be used as an approximation for other areas unless the landscape roughness characteristics are markedly different. The land anemometer site should be close enough to the body of water so that the winds are caused by the same atmospheric pressure gradient. Thunderstorms and squall lines are small-scale phenomena and violate the assumption that overland winds and overwater winds are from the same pressure gradient. If the anemometer site is adjacent to shore, winds blowing off the water require no adjustment for location effects; i.e., $R_L = 1$. A stability adjustment R_T should be used, however.



e. Coefficient of Drag. The wave growth formulas and nomograms are expressed in terms of wind-stress factor U_A (adjusted windspeed). After the appropriate windspeed conversions are made, the windspeed is converted to a wind-stress factor by either of the following formulas:

$$U_A = 0.71 \, U^{1.23} \quad (U \text{ in m/s}) \tag{3-28a}$$

$$U_A = 0.589 \, U^{1.23} \quad (U \text{ in mph}) \tag{3-28b}$$

Step 11, 12

and

$$L_o = \frac{gT^2}{2\pi} = 5.12T^2 \text{ ft} \tag{2-8b}$$

If equations (2-7a) and (2-7b) are used to compute wave celerity when the relative depth is d/L = 0.25, the resulting error will be about 9 percent. It is evident that a relative depth of 0.5 is a satisfactory boundary separating deepwater waves from waves in water of transitional depth. If a wave is traveling in *transitional* depths, equations (2-2) and (2-3) must be used without simplification. Care should be taken to use equations (2-2) and (2-3) when necessary; i.e., when the relative depth is between one-half and one-twenty-fifth.

When the relative water depth becomes shallow, i.e., $2\pi d/L < 1/4$ or $d/L < 1/25$, equation (2-2) can be simplified to

$$C = \sqrt{gd} \tag{2-9}$$

This relation, attributed to Lagrange, is of importance when dealing with long-period waves, often referred to as long waves. Thus, when a wave travels in shallow water, wave celerity depends only on water depth.

b. The Sinusoidal Wave Profile. The equation describing the free surface as a function of time t and horizontal distance x for a simple sinusoidal wave can be shown to be

$$\eta = a \cos\left(\frac{2\pi x}{L} - \frac{2\pi t}{T}\right) = \frac{H}{2} \cos\left(\frac{2\pi x}{L} - \frac{2\pi t}{T}\right) \tag{2-10}$$

where η is the elevation of the water surface relative to the SWL, and H/2 is one-half the wave height equal to the wave amplitude a. This expression represents a periodic, sinusoidal, progressive wave traveling in the positive x-direction. For a wave moving in the negative x-direction, the minus sign before $2\pi t/T$ is replaced with a plus sign. When $(2\pi x/L - 2\pi t/T)$ equals $0, \pi/2, \pi, 3\pi/2$, the corresponding values of η are H/2, 0, -H/2, and 0, respectively.

c. Some Useful Functions. It can be shown by dividing equation (2-3) by equation (2-6), and equation (2-4) by equation (2-8) that

$$\frac{C}{C_o} = \frac{L}{L_o} = \tanh\left(\frac{2\pi d}{L}\right) \tag{2-11}$$

If both sides of equation (2-11) are multiplied by d/L, it becomes

$$\frac{d}{L_o} = \frac{d}{L} \tanh\left(\frac{2\pi d}{L}\right) \tag{2-12}$$

The term d/L_o has been tabulated by Wiegel (1954) as a function of d/L and is presented in Appendix C, Table C-1. Table C-2 includes d/L as a function

Step 13

Reference:
SPM Vol I

Equation (2-4b) explicitly gives L in terms of wave period T and is sufficiently accurate for many engineering calculations. The maximum error of 5 percent occurs when $2\pi d/L \approx 1$.

Gravity waves may also be classified by the water depth in which they travel. The following classifications are made according to the magnitude of d/L and the resulting limiting values taken by the function tanh $(2\pi d/L)$:

Classification	d/L	$2\pi d/L$	tanh $(2\pi d/L)$
Deep water	$> 1/2$	$> \pi$	≈ 1
Transitional	1/25 to 1/2	1/4 to π	tanh $(2\pi d/L)$
Shallow water	$< 1/25$	$< 1/4$	$\approx 2\pi d/L$

In deep water, tanh $(2\pi d/L)$ approaches unity and equations (2-2) and (2-3) reduce to

$$C_o = \sqrt{\frac{gL_o}{2\pi}} = \frac{L_o}{T} \tag{2-5}$$

and

$$C_o = \frac{gT}{2\pi} \tag{2-6}$$

Although *deep water* actually occurs at an infinite depth, tanh $(2\pi d/L)$, for most practical purposes, approaches unity at a much smaller d/L. For a relative depth of one-half (i.e., when the depth is one-half the wavelength), tanh $(2\pi d/L) = 0.9964$.

Thus, when the relative depth d/L is greater than one-half, the wave characteristics are virtually independent of depth. Deepwater conditions are indicated by the subscript o as in L_o and C_o. The period T remains constant and independent of depth for oscillatory waves; hence, the subscript is omitted (Ippen, 1966b, pp. 21-24). If units of meters and seconds are specified, the constant $g/2\pi$ is equal to 1.56 meters per second squared and

$$C_o = \frac{gT}{2\pi} = \frac{9.8}{2\pi} T = 1.56T \text{ m/s} \tag{2-7a}$$

and

$$L_o = \frac{gT^2}{2\pi} = \frac{9.8}{2\pi} T^2 = 1.56T^2 \text{ m} \tag{2-8a}$$

If units of feet and seconds are specified, the constant $g/2\pi$ is equal to 5.12 feet per second squared and

$$C_o = \frac{gT}{2\pi} = 5.12T \text{ ft/s} \tag{2-7b}$$

Step 14

VI. WAVE FORECASTING FOR SHALLOW WATER

1. Forecasting Curves.

Water depth affects wave generation. For a given set of wind and fetch conditions, wave heights will be smaller and wave periods shorter if generation takes place in transitional or shallow water rather than in deep water. Several forecasting approaches have been made, including the method given by Bretschneider as modified using the results of Ijima and Tang (1966). Bretschneider and Reid (1953) consider bottom friction and percolation in the permeable sea bottom.

There is no single theoretical development for determining the actual growth of waves generated by winds blowing over relatively shallow water. The method presented here is based on successive approximations in which wave energy is added due to wind stress and subtracted due to bottom friction and percolation. This method uses deepwater forecasting relationships (Chapter 3, Section V) to determine the energy added due to wind stress. Wave energy lost due to bottom friction and percolation is determined from the relationships developed by Bretschneider and Reid (1953). Resultant wave heights and periods are obtained by combining the above relationships by numerical methods. The basic assumptions applicable to development of deepwater wave generation relationships as well as development of relationships for bottom friction loss (Putnam and Johnson, 1949) and percolation loss (Putnam, 1949) apply. The duration should be considered approximate.

These shallow-water forecasting curves (Fig. 3-27 through 3-36) represent an interim method for wave forecasting in shallow water. Modifications to the shallow-water forecasting equations were made to provide a transition between the revised deepwater forecasting equations and the shallow-water forecasting model. Research is underway that may revise the shallow-water forecasting model. Until the results of this new research are available, the curves should be used. The curves are plotted from the following equations:

$$\frac{gH}{U_A^2} = 0.283 \tanh\left[0.530\left(\frac{gd}{U_A^2}\right)^{3/4}\right] \tanh\left\{\frac{0.00565\left(\frac{gF}{U_A^2}\right)^{1/2}}{\tanh\left[0.530\left(\frac{gd}{U_A^2}\right)^{3/4}\right]}\right\} \qquad (3\text{-}39)$$

$$\frac{gT}{U_A} = 7.54 \tanh\left[0.833\left(\frac{gd}{U_A^2}\right)^{3/8}\right] \tanh\left\{\frac{0.0379\left(\frac{gF}{U_A^2}\right)^{1/3}}{\tanh\left[0.833\left(\frac{gd}{U_A^2}\right)^{3/8}\right]}\right\} \qquad (3\text{-}40)$$

Reference: SPM Vol I

Step 15, 16

i.e., made dimensionless by dividing each observed height by H_{rms} data from all observations may be combined into a single plot. Points from scaled 15-minute samples are superimposed on Figure 3-3 to show the scatter to be expected from analyzing individual observations in this manner.

Data from 72 scaled 15-minute samples representing 11,678 observed waves have been combined in this manner to produce Figure 3-4. The theoretical height appears to be about 5 percent greater than the observed height for a probability of 0.01 and 15 percent greater at a probability of 0.0001. It is possible that the difference between the actual and the theoretical heights of highest waves is due to breaking of the highest waves before they reach the coastal wave gages. Hence the Rayleigh distribution may be taken as an approximate distribution in shallow water, but is probably conservative.

Equation (3-1) can be established rigorously for restrictive conditions and empirically for a much wider range of conditions. If equation (3-1) is used, the probability density function can be obtained in the form

$$f[(\hat{H} - \Delta H) \leq H \leq (\hat{H} + \Delta H)] = \left(\frac{2}{H_{rms}^2}\right) H\, e^{-\left(\frac{\hat{H}}{H_{rms}}\right)^2} \tag{3-6}$$

The height of the wave with any given probability n/N of being exceeded may be determined approximately from curve a in Figure 3-5 or from the equation

$$\frac{\hat{H}}{H_{rms}} = \left[-\mathrm{Ln}\left(\frac{n}{N}\right)\right]^{1/2} \tag{3-7}$$

The average height of all waves with heights greater than $\hat{H}$, denoted $\overline{H}(\hat{H})$ can be obtained from the equation

$$\overline{H}(\hat{H}) = \frac{\int_{\hat{H}}^{\infty} H^2\, e^{-\left(\frac{H}{H_{rms}}\right)^2} dH}{\int_{\hat{H}}^{\infty} H\, e^{-\left(\frac{H}{H_{rms}}\right)^2} dH} \tag{3-8}$$

Alternatively, the ratio $\overline{H}(\hat{H})/H_{rms}$ can be estimated from curve b in Figure 3-5, where P is the probability of $\hat{H}$ being exceeded. By setting $\hat{H} = 0$, all waves are considered and it is found that the average wave height is given by

$$\overline{H} = 0.886\, H_{rms} \tag{3-9}$$

and the significant wave height is given by

$$H_s = 1.416 H_{rms} \approx \sqrt{2}\, H_{rms} \tag{3-10}$$

In the analysis system used by CERC from 1960 to 1970, and whenever digital recordings cannot be used, the average period of a few of the best formed waves is selected as the significant wave period. An estimated number of

Army Engineer Research and Development Center. An example of the fetch length radials used for wind-wave generation calculations in the ACES program is shown on **Figure DCM 2-2.**

Wave fields include monochromatic (regular) waves and irregular waves. The irregular waves are to be used to evaluate wave fields to determine wave height for freeboard determination. Thorough understanding of the freeboard design process and the basis of the various factors to be applied is critical to effective use of these computer programs. Adequate training and access to technical support is recommended. The programs should not be used for specific project circumstances that are beyond the limitations of the programs.

The traditional spreadsheet/hand calculations using primarily the Coastal Engineering Manual – CEM (USACE, 2003) and the Shore Protection Manual - SPM (USACE, 1984) can be used for analysis of various alternatives. Although the Coastal Engineering Manual is the most current document, the Shore Protection Manual is referenced for wave runup calculations since that portion of the Coastal Engineering Manual is in Draft form at this time. Wave heights from the CEM/SPM utilize Rayleigh Distribution to evaluate wave fields for structures (e.g. significant wave, 2 percent frequency wave, 5 percent frequency wave etc.). Irregular waves in STWAVE and ACES are similarly used to evaluate wave fields for structures.

The results of final computer-generated parameters are also to be compared with the traditional hand calculation methods for the final selected configuration. A direct one-to-one comparison may not result in an exact match. However, order of magnitude agreement should result. An example of the hand calculation method for developing wind speed, wave height and runup for freeboard determination is presented in **Attachment A.** The example computation is presented for **Case 1** condition, and would be repeated in a similar manner for **Cases 2, 3 and 4** in the determination of the controlling freeboard condition and the required dam crest level.

2.5 Wind Setup

Wind setup is one of the required components in the determination of freeboard. On the shallowest CERP impoundments, wind setup is a particularly important component of freeboard, and may even exceed the wave runup component in magnitude. Three methods are available for determining wind setup. The most widely used wind setup equation as applied to reservoirs is probably the Zeider Zee equation, which normally results in the highest wind setup determination of the three methods. The Zeider Zee equation (USACE, 1997, pg. 15-3) is expressed as:

$$S = \frac{U^2 F}{1400d} \qquad \text{Eqn. 5}$$

Where:

S = wind setup (feet) above the stillwater level

U = average wind velocity (miles per hour) over the fetch

F = fetch length (miles)

Step 18

Reference: DCM-2

d = average depth (feet) of water generally along the fetch line

Although the Zeider Zee equation is commonly suggested for determining wind setup in reservoirs, typical reservoirs in the U.S. are substantially deeper than the typical CERP impoundments. Because the Zeider Zee equation may yield results that excessively over-estimate wind setup at average reservoir water depths that are more typical of CERP impoundments, guidance is provided in this section to recommended alternative wind setup methods.

The recommended alternative to the Zeider Zee equation at lower impoundment depths (average stillwater depth less than 16 feet including surcharge depth), is the Bretschneider method (Bretschneider, 1966). The Bretschneider method normally results in wind setup heights that approach the mean value of results for the Zeider Zee and Sibul equations. For an enclosed reservoir of regular or somewhat irregular shape, an effective stress parameter in the Bretschneider method is presented in an integrated form as follows:

$$\frac{\kappa U^2 F}{g d^2} = \sum_{i=1}^{i=M} \left(\frac{\kappa U^2 \Delta x}{g (d_i)^2} \right) \qquad \text{Eqn. 6}$$

where:

κ = a constant equal to 3.3 x 10^{-6} (dimensionless)

U = average wind velocity (feet per second) over the fetch

F = fetch length (feet)

g = the gravitational constant (32.17 ft/sec^2)

d = average depth (feet) of water generally along the fetch line

i = section number

x = horizontal distance (feet)

The effective stress parameter is used for determining the wind setup (S in feet) as a function of S/d with Tables 5.2 and 5.3 as provided by Bretschneider (1966). The method accounts for wind conditions that may create a partially exposed reservoir bottom along the fetch line.

The Sibul equation (Brater and King, 1976) generally yields the lowest wind setup values of the three wind setup equations. The Sibul equation is expressed as:

$$\frac{S}{d} = 2.44 \times 10^{-5} \left(\frac{F}{d} \right)^{1.66} \left(\frac{U^2}{Fg} \right)^{2.02 \left(\frac{F}{d} \right)^{-0.0768}} \qquad \text{Eqn. 7}$$

where:

Step 18

Reference: DCM-2

S = wind setup (feet) above the stillwater level

d = average depth (feet) of water generally along the fetch line

F = fetch length (feet)

U = average wind velocity (feet per second) over the fetch

g = the gravitational constant (32.17 ft/sec^2)

The Bretschneider method is recommended for shallow impoundments with average depths less than 16 feet. Under conditions where the Bretschneider method does not have a numerical solution, the wind setup for the more shallow reservoirs can be computed as the average of the wind setup results for the Zeider Zee and the Sibul equations. For the deeper impoundments, with average depths greater or equal to 16 feet, the Zeider Zee equation is recommended because the equation provides a continuous solution without excessive over-estimation of wind setup.

3. Summary

The state-of-the-practice for freeboard determination includes consideration of combinations of reservoir level/precipitation and wind conditions that are reasonably expected to occur simultaneously. Additional considerations include: settlement, waves induced by landslides or malfunction of the spillway and/or outlet works. At a minimum, freeboard determination for design of high and significant hazard potential impoundments will include the precipitation and wind combinations for **Cases 1** through **4** described in this memorandum, as well as settlement, and malfunction of the spillway and/or outlet works for freeboard determination. Freeboard determination will be based on zero over-wash or over-wash that is not of such magnitude and duration as to threaten the safety of the dam. The Rayleigh Distribution (irregular wave field) will be used for the wave analysis. The recommended method for assessing the over-wash potential is an evaluation of the over-wash rate versus embankment height, in conjunction with an analysis of the probability of exceedance of the precipitation plus wind condition (residual risk based on hydrologic conditions) versus a selected embankment height. A methodology for analysis of mixed populations (e.g. precipitation and wind conditions) is included in USACE EM 1110-2-1415.

Considering information in standard references for freeboard and discussions at the Acceler8 Design Criteria Workshop (Dec. 2004), it is most appropriate to determine freeboard for each impoundment for the four cases of combined precipitation and wind events, at a minimum. The most likely controlling case for freeboard would be for a reservoir level resulting from the PMP for the critical condition, combined with a 100-year wind speed – **Case 1**. The 100-year wind speed will be developed for the specific site location using the Florida Building Code and **Table DCM 2-2** (ASCE, 2003), and with the fetch length of the reservoir. The figures, which are identified as being based on 50-year to 100-year wind speeds, will be conservatively interpreted as representing 50-year wind speeds. Calculation of wind set-up and wave run-up will be in accordance with the applicable portions of the USACE Coastal Engineering Manual, with the adjustments shown above. Bretschneider's and Zeider-Zee equations will be used for wind setup analysis. **Cases 2, 3** and **4** will also be evaluated for each impoundment

This document provides working level guidance to assist in the implementation of projects and project features under the Comprehensive Everglades Restoration Plan (CERP) program implemented by the South Florida Water Management District, the Florida Department of Environmental Protection, and the U.S. Army Corps of Engineers. The guidance does not supersede existing or future federal or state regulation, does not constitute policy for any of these agencies, and does not create authority beyond that granted to any agency member carrying out their duties.

Step 1B

Reference: DCM-2

Step 17: Compute shallow-water wave height for zero over-wash
The freeboard height that results in zero over-wash is the design criteria for high and significant hazard dams, for wave runup conditions and freeboard determination due to the erosive nature of embankment material (see **DCM-2**, Section 2 discussion). A wave height with a 2% frequency will be used to analyze a "low probability of over-wash" condition, to evaluate alternative embankment sections. In addition, the 2% frequency wave height will be used for a manual check of the STWAVE generated value.

The shallow-water wave height in Step 16 is the significant wave height. Using Equations 3-7 and 3-10 in the SPM, the 2% wave height ($H_{2\%}$) is calculated as 1.40 times the significant wave height. Therefore, the maximum wave height would be 10.95 ft (7.82 ft. in Step 16 multiplied by 1.40). Note: If deep-water wave length conditions are determined, Steps 15 through 17 would use deep water equations.

Step 18: Compute wind set-up
Based on the effective depth of 16.47 ft, fetch distance of 6.97 miles, and effective wind speed of 104 mph, the wind set-up is then computed using Eqn. 15-1 (USACE EM 1110-2-1420), as 3.31 ft. It should be noted that the effective wind speed (U) in Step 7 is used to compute the wind set-up not the wind stress factor (U_A) in Step 9 (Note, for average stillwater depth less than 16 feet, the Bretschneider method would be used. See Section 2.5, **DCM – 2**).

Step 19: Compute water depth at toe of the structure (dam)
The water depth at the toe of the structure (d_s) would be 19.78 ft, which is the sum of the effective depth of 16.47 ft plus wind set-up of 3.31 ft in Step 18.

Step 20: Check for depth limited wave breaking
Based on SPM Eqn. 2-91 and 3-50, the depth limited wave breaking height is 0.78 times depth. The depth limited wave height is 15.43 feet (0.78 multiplied by 19.78 ft from Step 19). Therefore, the maximum wave height of 10.95 feet from Step 17 is not limited by wave breaking.

Step 21: Estimate ratio between deep-water wave height and equivalent deep water wave height
Runup curves were developed in reference to equivalent deepwater wave heights. The relative depth calculated in Step 14 is less than 0.5. Therefore, an equivalent deep water wave height (H'_o) needs to be computed. The value of H/H'_o (shallow-water wave height / equivalent deep water wave height) is estimated based on the value of d/L_o (effective depth / deep water wave length). The relationship between d/L_o and H/H'_o is listed in Table C-1 of SPM Vol. II, Appendix C. Based on d/L_o of 0.089 in Step 14, the H/H'_o would be 0.9433.

Step 22: Compute equivalent deep-water wave height
The equivalent deep-wave wave height (H'_o) would be 11.61 ft (10.95 ft in Step 17 divided by 0.9433 in Step 18).

This document provides working level guidance to assist in the implementation of the projects and project features under the Comprehensive Everglades Restoration Plan (CERP) program implemented by the South Florida Water Management District, the Florida Department of Environmental Regulation, and the U.S. Army Corps of Engineers. The guidance does not supersede existing or future federal or state regulation, does not constitute policy for any of these agencies, and does not create authority beyond that granted to any agency member carrying out their duties.

Step 18, 19
Reference: DCM-12

becomes shallow enough to initiate breaking; this depth is usually denoted as d_b and termed the breaking depth. Munk (1949) derived several relationships from a modified solitary wave theory relating the breaker height H_b, the breaking depth d_b, the unrefracted deepwater wave height H'_o, and the deepwater wavelength L_o. His expressions are given by

$$\frac{H_b}{H'_o} = \frac{1}{3.3(H'_o/L_o)^{1/3}} \tag{2-90}$$

and

$$\frac{d_b}{H_b} = 1.28 \tag{2-91}$$

The ratio H_b/H'_o is frequently termed the breaker height index. Subsequent observations and investigations by Iversen (1952, 1953) Calvin (1969), and Goda (1970) among others, have established that H_b/H'_o and d_b/H_b depend on beach slope and on incident wave steepness. Figure 2-72 shows Coda's empirically derived relationships between H_b/H'_o and H_o/L_o for several beach slopes. Curves shown on the figure are fitted to widely scattered data; however they illustrate a dependence of H_b/H'_o on the beach slope. Empirical relationships derived by Weggel (1972) between d_b/H_b and H_b/gT^2 for various beach slopes are presented in Figure 2-73. It is recommended that Figures 2-72 and 2-73 be used, rather than equations (2-90) and (2-91), for making estimates of the depth at breaking or the maximum breaker height in a given depth since the figures take into consideration the observed dependence of d_b/H_b and H_b/H'_o on beach slope. The curves in Figure 2-73 are given by

$$\frac{d_b}{H_b} = \frac{1}{b-(aH_b/gT^2)} \tag{2-92}$$

where a and b are functions of the beach slope m, and may be approximated by

$$a = 43.75(1 - e^{-19m}) \tag{2-93}$$

$$b = \frac{1.56}{(1 + e^{-19.5m})} \tag{2-94}$$

Breaking waves have been classified as spilling, plunging, or surging depending on the way in which they break (Patrick and Wiegel, 1955), and (Wiegel, 1964). Spilling breakers break gradually and are characterized by *white water* at the crest (see Fig. 2-74). Plunging breakers curl over at the crest with a plunging forward of the mass of water at the crest (see Fig. 2-75). Surging breakers build up as if to form a plunging breaker but the base of the wave surges up the beach before the crest can plunge forward (see Fig. 2-76). Further subdivision of breaker types has also been proposed. The term collapsing breaker is sometimes used (Calvin, 1968) to describe breakers in the transition from plunging to surging (see Fig. 2-77). In actuality, the

Step 20

Reference:
CEM, USACE
EM 1110-2-1100

$$\alpha_r = \frac{1 - K_{fa}}{1 - K_{f.01}} \tag{3-47}$$

and, for a decaying wave,

$$F_a = \alpha_r \, \Delta x \tag{3-48}$$

b. Wave Growth. For any given water depth, windspeed, and fetch length, a maximum significant wave height H_{sm} which is generated can be defined from Figure 3-21. If the initial wave height H_i at the seaward or beginning edge of the fetch segment is less than H_{sm}, it is assumed that the wave will increase in height.

To find the wave growth, first determine an equivalent fetch length F_e for the initial wave (obtained directly from Figure 3-21 using the given wave height, windspeed, and water depth). Secondly, the adjusted fetch F_a as discussed in Chapter 3, Section IV,2,a is determined using equations (3-45) and (3-46) and Figure 3-38. The total fetch is then given as

$$F = F_e + F_a \tag{3-49}$$

Reentering Figures 3-21 and 3-22 with the fetch length F and the adjusted windspeed factor U_A and water depth d the wave height and period at the end of the fetch segment, H_f and T, are determined.

c. Wave Decay. If the initial significant wave height H_i at the seaward or beginning edge of a segment of fetch exceeds the maximum significant wave height H_{sm} for the given water depth of the segment of fetch and the given windspeed, it may be assumed that the effects of the bottom friction will exceed the effects of the wind stress. Therefore, the wave will decay, will lose height, and over a long distance will approach a wave height equal to the maximum significant wave height.

The following steps are used to predict the decay of a wave:

(a) At the seaward end of fetch segment determine the maximum significant wave height Hem that would be generated for a given wind speed and water depth, assuming an unlimited fetch and using Figure 3-21.

(b) Determine the maximum stable wave height H_m at the seaward edge of the fetch segment, where

$$H_m = 0.78 \, d \tag{3-50}$$

(c) Determine the fractional reduction R_i at the seaward edge of the segment of fetch under consideration. This is given by

$$R_i = \frac{H_m - H_i}{H_m - H_{sm}} \tag{3-51}$$

(d) Determine an equivalent initial wave height H_{ie}, assuming that fractional wave growth is proportional to fractional wave decay, by

Step 29

$$r = \frac{R \text{ (rough slope)}}{R \text{ (smooth slope)}} = \frac{R/H_o' \text{ (rough slope)}}{R/H_o' \text{ (smooth slope)}} \tag{7-7}$$

Table 7-2 indicated the range of values of r for various slope characteristics.

This roughness and porosity correction factor is also considered applicable) as a first approximation, in the analysis of wave runup on slopes having surface materials with two or more different roughness values, r. Until more detailed guidance is available, it is suggested that the percentage of the total slope length, ℓ , subjected to wave runup of each roughness value be used to develop an adjusted roughness correction value. This is expressed by the equation

$$r \text{ (adjusted)} = \frac{\ell_1}{\ell} r_1 + \frac{\ell_2}{\ell} r_2 + \frac{\ell_3}{\ell} r_3 + \cdots \tag{7-8}$$

where ℓ is the total slope length, ℓ_1 is the length of slope where the roughness value r_2 applies, ℓ_2 is the length of slope where the roughness value r_2 applies, and so on. This procedure has obvious deficiencies as it does not account for location of the roughness on the structure and the varying interaction of slope roughness characteristics to the depth of water jet running up the structure slope.

Table 7-2. Value of r for various slope characteristics (after Battjes, 1974).

Slope Surface Characteristics	Placement	r
Smooth, impermeable	------	1.00
Concrete blocks	Fitted	0.90
Basalt blocks	Fitted	0.85 to 0.90
Gobi blocks	Fitted	0.85 to 0.90
Grass	-------	0.85 to 0.90
One layer of quarrystone (impermeable foundation)	Random	0.80
Quarrystone	Fitted	0.75 to 0.80
Rounded quarrystone	Random	0.60 to 0.65
Three layers of quarrystone (impermeable foundation)	Random	0.60 to 0.65
Quarrystone	Random	0.50 to 0.55
Concrete armor units (~ 50 percent void ratio)	Random	0.45 to 0.50

The use of the figures to estimate wave runup is illustrated by the following example.

STEP 30

REFERENCE: SPM, Vol II

Table 2-2
Rough Slope Runup Correction Factors (Carstea et al. 1975b)

Armor Type	Slope (cot θ)	Relative Size H / K_r[a,b]	Correction Factor r
Quarrystone	1.5	3 to 4	0.60
Quarrystone	2.5	3 to 4	0.63
Quarrystone	3.5	3 to 4	0.60
Quarrystone	5	3	0.60
Quarrystone	5	4	0.68
Quarrystone	5	5	0.72
Concrete Blocks[c]	Any	6[b]	0.93
Stepped slope with vertical risers	1.5	$1 \le H_o'/K_r$[d]	0.75
Stepped slope with vertical risers	2.0	$1 \le H_o'/K_r$[d]	0.75
Stepped slope with vertical risers	3.0	$1 \le H_o'/K_r$[d]	0.70
Stepped slope with rounded edges	3.0	$1 \le H_o'/K_r$[d]	0.86
Concrete Armor Units			
Tetrapods random two layers	1.3 to 3.0	-	0.45
Tetrapods uniform two layers	1.3 to 3.0	-	0.51
Tribars random two layers	1.3 to 3.0	-	0.45
Tribars uniform one layer	1.3 to 3.0	-	0.50

[a] K_r is the characteristic height of the armor unit perpendicular to the slope. For quarrystone, it is the nominal diameter; for armor units, the height above the slope.
[b] Use H_o' for $d_s/H_o' > 3$; and the local wave height, H_s for $d_s/H_o' \le 3$.
[c] Perforated surfaces of Gobi Blocks, Monoslaps, and concrete masonry units placed hollows up.
[d] K_r is the riser height.

Note:
1. Depth at Elevation 46.13 is the water depth at the embankment toe with the surcharge elevation of 46.13 plus the wind setup.
2. Due to a software bug, the station (X,Y) coordinates in the graphical output is shown backwards as (Y,X). The results, however, appear OK. The station coordinates in this spreadsheet are the correct coordinates (so they are the reverse of what is shown in the graphical output data).

Wind Setup Calculations

Compute Wind Set-Up Cell 1

Four different methods are calculated and considered in estimating wind setup

Zeider Zee Eqn: Widely used as applied to reservoirs. Tends to overestimate wind setup for shallow impoundments (depth<16 ft).

Sibul Eqn: Typically yields the lowest wind setup.

Ave. of Zeider Zee & Sibul: Recommended for shallow impoundments (depth<16 ft) when Bretschneider has no numeric solution.

Bretschneider Eqn: Recommend for shallow impoundments (average depth <16 ft).

Fetch Length, F =	2.65	miles	
Fetch Length, F =	14000	feet	
Average Wind Velocity, U = Wind Speed per Step 7 = $U_{100\text{-}yr,t\text{-}min}$ =	100	mph	
NFSL Elevation + Surcharge =	46.13	feet	
Average Fetch Elevation =	21.79	feet	
Average Depth of Water along Fetch Line, D = Effective Depth =	24.34	feet	
Zeider Zee Eqn {Note: F=miles}: Wind Set-Up, $S = U^2F/(1400D)$ =	0.78	feet	*(Eqn. 5, DCM-2)*
Sibul Eqn {Note: F=feet, g=32.2 ft/s²}: $S = 0.0000244d(F/d)^{1.66}(U^2/Fg)^{2.02(F/d)^{\wedge}-0.0768}$ =	0.20	feet	*(Eqn. 7, DCM-2)*
Average of Zeider Zee & Sibul: Wind Setup, $S = (S_{Zeider\ Zee} + S_{Sibel})/2$ =	0.49	feet	
Bretschneider Eqn {Note: Calcs provided separately in Step 18a}: $S = \Sigma\{(kU^2\Delta x)/(gd^2)\}$ =	-	feet	
Equation Used for Wind Setup *(Enter Zeider Zee, Sibul, Average, Bretschneider)* =	Zeider Zee		
Computed Wind Set-Up, S =	0.78	feet	*(Eqn. 5, DCM-2)*

Appendix G:
C-43 WSR Overwash Rate Memo

MEMO

TO: LuAnn McVicker, PhD, PE
Project Manager
C-43 West Storage Reservoir

DATE: March 7, 2007

FROM: Dave Grounds

SUBJECT: C-43 WSR Overwash Rate

An overtopping rate of 0.001 cfs/LF of dam was used for the C-43 West Storage Reservoir (C-43 WSR) 30% design submittal before the overwash tests were performed. This overtopping rate was based on DCM-2 and the example analysis contained in DCM-2 as well as discussions with USACE and A8 staff. This overtopping rate was chosen for the C-43 WSR site primarily due to the highly erodible "fine sand and silt" that will be used to construct the dam. In addition, a dam-break analysis was conducted to determine the hazard classification of the C-43 WSR and to determine the potential flooding effects on the adjacent properties. According to the classification system in the SFWMD Design Criteria Manual DCM-1, the proposed C-43 WSR has been classified as a high hazard potential impoundment.

The highly erodible on-site soil conditions were further documented during the construction of the C-43 Test Cell Project. Very minimal project rain events produced deep "gulley" erosion on the dam slope as well as the Perimeter Canal slopes. The erosion potential was greatly increased by the lack of vegetative cover and/or concentrated run-off flows.

As you know, overwash tests were completed on vegetated portions of the test cell embankment during the week of December 18, 2006. On Wednesday December 20, 2006 the overwash test used a flow rate of 0.01 cubic feet per linear foot of embankment (cfs/LF). For the first 3.5 hours, no significant erosion was observed. At 3 hours and 35 minutes into the test, a gully began forming rapidly at the center of the slope. The soil appeared to be saturated and began to quickly erode into the gully. Once the gully began to form, the erosion rate increased to the point where the major gully was incised into the embankment slope to a depth of over four feet.

The "washouts" created by 0.01 cfs/LF at the C-43 Test Cell are not acceptable for the long-term integrity of the dam. These washouts would be even more pronounced with the C-43 WSR dam crest at elevation 56.6 feet, instead of the crest elevation 42.0 feet at the Test Cell Project. At a minimum, this overwash rate would likely require substantial maintenance and repair of the downstream embankment slope and could result in "cutting back" into the filter blanket and toe drain system. If the C-43 WSR embankment is exposed to the 0.01 cfs/LF overwash rate for a sustained amount of time, the erosion would be uncontrolled and could threaten the embankment integrity.

Based on the results of the C-43 Test Cell overwash tests, it was determined that an overwash rate of 0.005 cfs/LF would be acceptable and would be used for final design or the C-43 WSR. However, after construction is completed, it would require that a good maintenance program be implemented and maintained for the life of the C-43 WSR. This long-term maintenance must ensure that the vegetative cover will be maintained in at least the same condition as the C-43 Test Cell Project was at the time it was tested. It is our opinion that this vegetative condition is reasonable to expect in the long-term with a good maintenance program.

The overwash test on the C-44 WSR Project indicated that if the reservoirs were properly sodded and maintained as a sodded "lawn", then an overwash rate of 0.01 cfs/LF could be used. In our meeting of March 1, 2007, it was

the consensus among the Operations and Maintenance staff that this sod condition would not last after 5 to 10 years and from that point forward the exterior of the reservoirs would most likely be represented by the C-43 Overwash Test.

The condition of the C-43 Test Cell turf at the time of the overwash test is comparable to and resembles the current turf condition of the dam around Lake Okeechobee. The Lake Okeechobee dam is representative of what can be expected after 5 to 10 years of maintenance. At some point during a period of drought and long after the results of this overwash test are forgotten, the vegetative cover of the C-43 WSR is expected to be no better than the Lake Okeechobee dam and would be representative of the turf condition during the C-43 Test Cell overwash test. Therefore, the C-43 WSR's safety will be compromised with any overwash rate exceeding 0.005 cfs/LF. It is simply too optimistic to assume that the exterior of the C-43 WSR will be maintained as a lawn for the next 50+ years.

By using an overwash rate of 0.01 cfs/LF when compared to a rate of 0.005 cfs/LF, the project savings for the C-43 WSR is approximately $2.3 million. Although this amount is significant, it is very small (less than 1%) when compared to an overall project cost of $334 million and certainly does not justify using the higher overwash rate.

Other considerations for safety at the C-43 WSR site include its close proximity to existing development and in the future will probably be bordered by development on the north, east and south sides. If any type of failure were to occur, very significant loss of life could result. The C-43 WSR is also within 3,000 feet of SR-80, which is a hurricane evacuation route and can not be compromised.

To follow the design criteria as described in DCM-2, "the designer must apply engineering judgment in analyzing the risk and acceptable over-wash rate that is selected for each embankment." Based on the overwash test results, site investigations, risk analysis and intensive overtopping rate modeling analyses, Stanley is responsible and is in the best position to select an acceptable over-wash rate for the C-43 WSR Project.

In summary, it is Stanley's position that an overwash rate of 0.005 cfs/LF is correct for the C-43 WSR Project for the long-term safety and integrity of the C-43 WSR and this rate will be used for final design.

A.13 TECHNICAL MEMORANDUM – TOWNSEND CANAL IMPACTS FOR VARIOUS PUMPING SCENARIOS AT C43PS-1

TECHNICAL MEMORANDUM

TO: ACCELR8
South Florida Water Management District
3301 Gun Club Road
West Palm Beach, Florida 33406

DATE: January 19, 2007

West Palm beach, Florida 33406

SUBJECT: **Work Order C-C10401P-WO 09, Revision 1: Task 4.3** – Townsend Canal Impacts for Various Pumping Scenarios at C43PS-1

INTRODUCTION:

The following technical memorandum summarizes the evaluation, findings and proposed improvements from HEC-RAS modeling of the Townsend Canal for various pumping scenarios. The evaluation examines impacts to the Townsend Canal, S.R. 80 Bridge and Duda Pump Station, (Duda PS), from the addition and operation of Pump Station No. 1, (C43PS-1) of the proposed C-43 Reservoir. Additionally, the capacity or limitations, from the Townsend Canal Weir and Gated Orifice Structure, (Townsend Canal Structure), was considered in the analysis.

The HEC-RAS simulations of the Townsend Canal consisted of modeling the following pumping scenarios, with indicated conditions, to establish existing parameters and predict proposed water surface profiles:

1. **Existing canal geometry, including Townsend Canal Structure**, for pumping **600 cfs** from the Caloosahatchee River (C-43) to Berry Groves Pump Station (300 cfs) and the Duda PS (300 cfs).
2. **Existing canal geometry** and proposed **1,500 cfs pump** station at C43PS-1 with the **Townsend Canal Structure removed**, and **300 cfs** to the Duda PS
3. **Proposed canal geometry** (e.g. canal cross-section improvements), **1,500 cfs pump** at C43PS-1 with **Townsend Canal Structure in place** and **300 cfs** to Duda PS.
4. **Proposed canal geometry, 1,500 cfs pump** at C43PS-1 with the **Townsend Canal Structure removed** and **300 cfs** to Duda PS.
5. **Proposed canal geometry, 2,000 cfs pump** at C43PS-1 with the **Townsend Canal Structure removed** and **300 cfs** to Duda PS.

6. **Proposed canal geometry, 2,500 cfs pump** at C43PS-1 with the **Townsend Canal Structure removed** and **300 cfs** to Duda PS.
7. **Proposed canal geometry, 3,800 cfs pump** at C43PS-1 with the **Townsend Canal Structure removed** and **300 cfs** to Duda PS.

For reference, it should be noted, under natural flow conditions or when pumps are not "ON", the Townsend Canal flows northerly to the Caloosahatchee River. Therefore the Caloosahatchee River is the downstream receiving water body for the Townsend Canal. For all natural flow conditions, the flow rate is controlled by the weir portion of the Townsend Canal Structure, which is a 70.4 linear-foot broad-crested weir with a crest elevation of 2.37' North American Vertical Datum, (NAVD). For the purposes of discussion and consistency in the memorandum the Caloosahatchee River will always be referred to as "downstream" with respect to the Townsend Canal. However, during pumping operations the direction of flow reverses and the Caloosahatchee River becomes "upstream" with respect the flow within the Townsend Canal.

The Townsend Canal Structure was analyzed for existing conditions with 'Head vs. Discharge' curves to determine the level of influence, on flow conditions at the mouth of the Townsend Canal. When the pumps are on the pump induced flow into the Townsend Canal from the Caloosahatchee River is controlled by 10-6'x6' orifices with flap gates, in the Townsend Canal Structure. The 10 orifices are positioned linearly below the 70.4-foot weir crest and cut directly through the Townsend Canal Structure. Each orifice has a common flow-line elevation of -5.2' NAVD. When the water surface elevation exceeds 2.37' NAVD in the Caloosahatchee River, flow passes over the 70.4-foot weir of the Townsend Canal Structure in addition to the orifice flow. The orifices permit flow, in one direction, from the Caloosahatchee River to the Townsend Canal due to the flap gates positioned on the southern face of the Townsend Canal Structure. The flap gates are closed over the orifice openings during natural flow conditions, but open when the flow direction is reversed from existing pump activation. The orifices with flap gates induce head loss; and the elevation, dimensions and physical configuration of the Townsend Canal Structure with respect to common water surface elevations, in both the Townsend Canal and Caloosahatchee River create limiting flow conditions. This presents one of the main obstacles to overcome for the proposed pumping scenarios.

APPROACH:

The Townsend Canal was modeled using the U.S. Army Corps of Engineers, (USACE), HEC-RAS software, Version 3.1.3. The analysis examines the Canal in two sections, the Northern Section, which is considered to be from the mouth of the Townsend Canal at the Caloosahatchee River to the proposed "Junction" point in the Townsend Canal. The "Junction" branches to the Intake Canal of the C-43 Reservoir and provides conveyance to the primary C-43 Reservoir Pump Station; C43PS-1. The C43PS-1 structure lies approximately 1,050 feet east of the Townsend Canal. The second or Southern Section of the Townsend Canal is from the "Junction" point, south to the Duda PS. Refer to Attachment 'A' for the Townsend Canal Orientation Plan.

All model runs were performed until a constant water surface elevation, (WSEL), of 2.00 NAVD in the Caloosahatchee River was obtained for each scenario. The WSEL of 2.00 NAVD was selected as a baseline elevation for proposed conditions. The benefit of obtaining a constant WSEL in the Caloosahatchee River allows for direct comparisons of the water surface profile conditions, between the various pumping scenarios. The modeled Townsend Canal section from the Caloosahatchee River to the Duda PS is 3.18 miles long, with incremental distances of; 0.41 miles from the Caloosahatchee River to the S.R. 80 Bridge, 0.98 miles from the Caloosahatchee River to the proposed Junction at the Intake Canal to C43PS-1.

The Existing Condition Geometry includes original Townsend Canal cross-sections determined from survey information. The Existing Condition Geometry, HEC-RAS model runs include a 600 cfs flow rate through the Townsend Canal Structure with 300 cfs diverting to the existing Berry Groves Pump station and the remaining 300 cfs continuing to the Duda PS. This run mimics the current pumping scenario and establishes the WSEL at the Duda PS. A second model was run using the Existing Condition Geometry, the Townsend Canal Structure removed and a flow of 1,800 cfs (1,500 cfs for C43PS-1 and 300 cfs for the Duda PS). The result from this run indicated considerable losses in the North Section and demonstrated the need for improvements to the canal to accommodate the proposed flows and to maintain the pre-reservoir WSEL in the canal at the Duda PS.

Both Existing Condition Geometry model runs indicate that the existing cross-sections of the Townsend Canal from the Junction point south to the Duda PS as having sufficient capacity for 300 cfs. As a result, all proposed geometry changes or improvements should occur only in the North Section of the Townsend Canal.

The initial improvements to the North Section Geometry examine 1,800 cfs through the improved Townsend Canal with the Townsend Canal Structure in place. The losses through the structure for 1,800 cfs correlate to 1.1 feet of head, which is directly subtracted from the water surface elevation of 2.00' NAVD at the Caloosahatchee River. This forces the WSEL at the Duda PS to be significantly lower than existing conditions in order to produce a WSEL at the mouth of the Townsend Canal 0.9' NAVD. Therefore, all Proposed Condition model runs are performed with the Townsend Weir Structure removed, varying C43PS-1 pump rates and 300 cfs continuing to the Duda PS.

All proposed improvement HEC-RAS model runs for the various pumping rates include expanding or reshaping only the North Section canal geometry. Proposed improvements at the SR-80 Bridge include reshaping the canal side-slopes, re-armoring (rip-rap) the side-slopes and adding armor to the canal bottom. Based on the surveyed cross-sections, the canal bottom at the SR 80 Bridge has already scoured beyond the scour depth anticipated during the bridge design. For that reason the proposed improvements do not include lowering the canal flow-line within approximately 100-feet north and south of the SR 80 Bridge.

The physical criteria for cross-sectional improvements and design goals for all pumping conditions consisted of the following:

- Provide a water surface elevation at Duda PS of approximately 1.0 NAVD
- Limit flow velocity near the S.R. 80 Bridge to 3.0 fps
- Limit flow velocity in the Townsend canal to less than 2.5 fps
- Avoid over-excavation of the canal bottom to eliminate undermining of the existing side-slopes
- Avoid over-excavating of the canal bottom on either side of the bridges to eliminate significant fluctuations in the canal bottom profile which might create critical velocity conditions.
- Increase cross-sectional area by expanding the canal width
- Limit Townsend Canal improvements to within the existing right-of-way

RESULTS:

Each of the HEC-RAS, water surface profile model run simulations is summarized below:

Existing Canal Geometry, 600 cfs – with Townsend Canal Structure (Table 1)

This HEC-RAS model run examines the existing canal geometry and a total flow rate of 600 cfs through the Townsend Canal Structure which introduces 0.15 feet of head loss. At approximately the midpoint of the canal, 300 cfs diverts to the Berry Groves Pump Station and the remaining 300 cfs continues to the Duda PS. This evaluation establishes a baseline for the WSEL and velocities.

Table 1: HEC-RAS Profile Summary

Townsend Canal Location	Flow Rate (cfs)	Channel Velocity (fps)	Water Surface Elevation (NAVD)
C-43 & Townsend	600	0.74	1.85 (2.00-0.15)
S.R. 80 Bridge	600	1.17	1.70
Junction for C43PS-1	600	0.74	1.63
Duda PS	300	0.65	1.24

Existing Canal Geometry, 1,800 cfs – without Townsend Canal Structure (Table 2)

This HEC-RAS model run examines conditions and impacts from a 1,500 cfs pump flow at C43PS-1 along with the 300 cfs at the Duda PS. The purpose is to examine the impact and determine the capacity or capability of the existing Townsend Canal geometry, without the Townsend Canal Structure, but with respect to proposed pump flow. The results clearly identify considerable losses in the North Section. This indicates that without canal improvements, the WSEL (-3.00) at the Duda PS is not acceptable. The WSEL of 2.10 at the connection between the Townsend Canal and the Caloosahatchee River is the limiting WSEL prior to incurring a critical velocity flow regime. Critical velocities of approximately 10 fps are unacceptable for the Townsend Canal.

Table 2: HEC-RAS Profile Summary

Townsend Canal Station	Flow Rate (cfs)	Channel Velocity (fps)	Water Surface Elevation (NAVD)
C-43 & Townsend	1,800	2.14	2.10
S.R. 80 Bridge	1,800	4.30	0.41
Junction for C43PS-1	1,800	3.74	-0.75
Duda PS	300	1.84	-3.00

North Section Improvements, 1,800 cfs – with Townsend Canal Structure (Table 3)

This HEC-RAS model run simulates improvements to the Townsend Canal cross-sections in the North Section. Additional armoring and bank protection is proposed at the SR 80 Bridge location, which allows for higher velocities through the bridge opening. The purpose of this modeling scenario is to examine the impact the Townsend Canal Structure has on higher flow rates due to pumping conditions, with Townsend Canal improvements for increased capacity. The results indicate a head loss of 1.1 feet through the Townsend Canal Structure. This loss reduces the water surface elevation at the mouth of the Townsend Canal which reduces the cross-sectional flow area, and consequently the water surface at the Duda PS is well below the elevation that was determined for current flow conditions. The results indicate that the Townsend Canal Structure introduces losses that create conditions incapable of conveying the various proposed pumping scenario flow rates.

Table 3: HEC-RAS Profile Summary

Townsend Canal Location	Flow Rate (cfs)	Channel Velocity (fps)	Water Surface Elevation (NAVD)
C-43 & Townsend	1,800	1.92	0.93 (2.00-1.07)
S.R. 80 Bridge	1,800	3.09	0.56
Junction for C43PS-1	1,800	2.84	-0.61
Duda PS	300	1.35	-2.00

North Section Improvements, 1,800 cfs – without Townsend Canal Structure (Table 4)

This HEC-RAS model run proposes cross section improvements along the entire North Section of the Townsend Canal. The improvements consist of streamlining the bottom elevation to reduce obstructions and re-grading the eastern bank side-slope. Additional modifications include configuring the cross-sections at the S.R. 80 Bridge to 1:1 side-slope and armoring the side-slopes and canal bottom. The improvements provide minor increases in the cross-sectional flow area, but primarily eliminate inconsistencies in the bottom elevation of the canal and reduce losses. The final modification consists of removing the Townsend Canal Structure. No modifications are proposed for the Townsend Canal south of the Junction for conveyance of 300 cfs to the Duda PS.

Table 4: HEC-RAS Profile Summary

Townsend Canal Location	Flow Rate (cfs)	Channel Velocity (fps)	Water Surface Elevation (NAVD)
C-43 & Townsend	1,800	2.15	2.01
S.R. 80 Bridge	1,800	2.83	1.64
Junction for C43PS-1	1,800	2.23	1.28
Duda PS	300	0.67	1.00

Refer to Attachment 'B' for cross-sections showing improvements at the SR 80 Bridge corresponding to the 1,500 cfs, 2,000 cfs, 2,800 cfs and 3,800 cfs pumping scenarios.

North Section Improvements, 2,300 cfs – without Townsend Canal Structure (Table 5)

This model run proposes cross section improvements along the entire North Section of the Townsend Canal. The improvements consist of streamlining and excavating the bottom elevation to reduce obstructions and excavating the eastern bank side slope. Additional modifications include configuring the cross-sections at the S.R. 80 Bridge to 1:1 side-slope and armoring the side-slopes and canal bottom. Additionally, the improvements include beginning the 1:1 side-slopes at a higher elevation which effectively increases the bottom width. The improvements provide an increase in the cross-sectional flow area, and eliminate inconsistencies in the bottom elevation of the canal and reduce losses. The final modification consists of removing the Townsend Canal Structure. No modifications are proposed for the Townsend Canal, south of the Junction, for conveyance of 300 cfs to the Duda PS.

Table 5: HEC-RAS Profile Summary

Townsend Canal Location	Flow Rate (cfs)	Channel Velocity (fps)	Water Surface Elevation (NAVD)
C-43 & Townsend	2,300	2.14	2.01
S.R. 80 Bridge	2,300	3.33	1.63
Junction for C43PS-1	2,300	2.35	1.30
Duda PS	300	0.67	1.03

North Section Improvements, 2,800 cfs – without Townsend Canal Structure (Table 6)

This HEC-RAS model run proposes cross section improvements along the entire North Section of the Townsend canal. The improvements consist of excavating the bottom elevation to the same depth as the 2,300 cfs pump scenario with additional expansion or widening to the eastern bank side-slope. Additional modifications include configuring the cross-sections at the S.R. 80 Bridge to 1:1 side-slope, armoring the side-slopes, canal bottom and constructing an additional bridge span to accommodate the wider cross-section. The improvements provide a significant increase in the cross-sectional flow area, and eliminate inconsistencies in the bottom elevation of the canal and reduce losses. The final modification consists of removing the Townsend Canal Structure. No modifications are proposed for the South Section of the Townsend Canal, which conveys the 300 cfs to the Duda PS. The widening of the Townsend Canal North Section requires additional right-of-way to accommodate the required maintenance berm.

Table 6: HEC-RAS Profile Summary

Townsend Canal Location	Flow Rate (cfs)	Channel Velocity (fps)	Water Surface Elevation (NAVD)
C-43 & Townsend	2,800	2.23	2.00
S.R. 80 Bridge	2,800	3.02	1.66
Junction for C43PS-1	2,800	2.40	1.33
Duda PS	300	0.66	1.06

North Section Improvements, 4,100 cfs – without Townsend Canal Structure (Table7)

This HEC-RAS model run proposes cross section improvements along the entire North Section of the Townsend Canal. The improvements consist of further excavating the bottom and additional expansion or widening of the cross-sections. The proposed widening is configured to fit within the extent of the canal right-of-way however; additional right-of-way is required to accommodate the required maintenance berm. Additional modifications include configuring the cross-sections at the S.R. 80 Bridge to 1:1 slope, stabilizing the side slope and canal bottom and constructing two additional bridge spans to accommodate the wider cross-section. The improvements provide a significant increase in the cross-sectional flow area, and eliminate inconsistencies in the bottom elevation of the canal to reduce losses. The final modification consists of removing the Townsend Canal Structure. No modifications are proposed for the Townsend Canal south of the Junction for conveyance of 300 cfs to the Duda PS.

Table 7: HEC-RAS Profile Summary

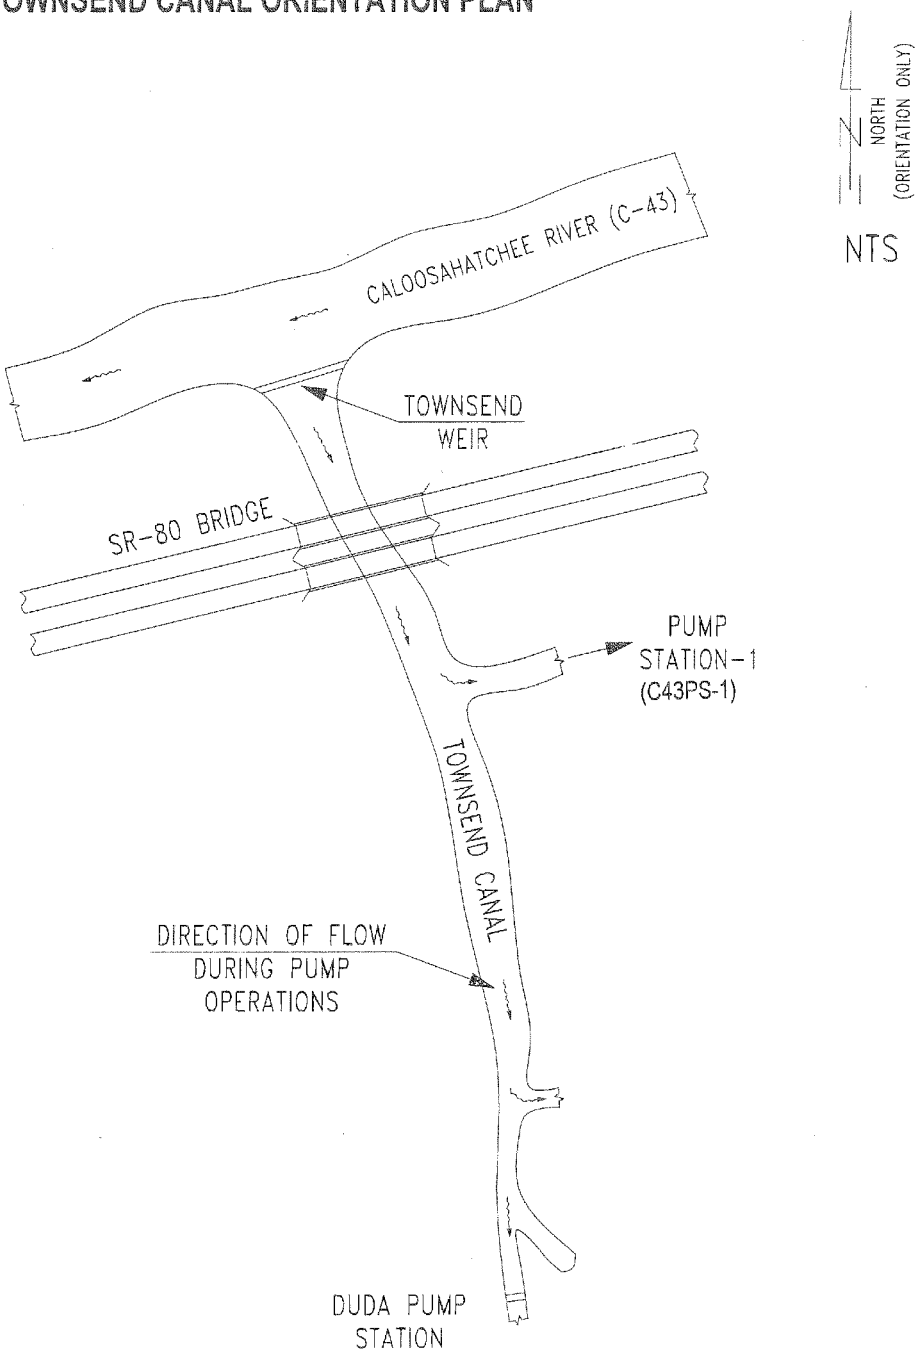
Townsend Canal Location	Flow Rate (cfs)	Channel Velocity (fps)	Water Surface Elevation (NAVD)
C-43 & Townsend	4,100	2.31	2.00
S.R. 80 Bridge	4,100	3.01	1.68
Junction for C43PS-1	4,100	2.53	1.38
Duda PS	300	0.66	1.12

CONCLUSION:

The model runs determined the following:

- For the existing pumping conditions (600cfs), the WSEL at the Duda PS was determined from the model to be 1.24' NAVD. This established a baseline elevation at the Duda PS for analyzing proposed pump-flow scenarios.
- The proposed pumping scenarios without any canal improvements create erosive velocities and lower the WSEL at the Duda PS significantly below the baseline elevation. Therefore canal improvements are necessary.

The goal was to quantify the impacts to the canal from the proposed pumping scenarios, determine necessary improvements for acceptable flow conditions in the canal and estimate the improvement costs associated with each pumping scenario.



As previously indicated, all improvements are proposed within the North Section of the Townsend Canal. They include removal of the Townsend Canal Structure, providing erosion protection (rip-rap armoring) along the side-slopes and the canal bottom at the S.R. 80 Bridge and re-grading the Townsend Canal cross-section (earthwork increases as the pump flows increase). These improvements are considered the necessary minimum, and are recommended for all proposed pumping scenarios.

Based on the FDOT Bridge Hydraulics Sheet and canal surveys, the Townsend Canal at the S.R. 80 Bridge has exceeded the anticipated scour. Therefore, minimal excavation is proposed in the canal adjacent to the Bridges and erosion protection is proposed for the side slopes and bottom to eliminate further scouring. Velocity rates around the S.R. 80 Bridge have been limited to values around 3.0 fps.

To assist in the selection of a pump station size, costs were assigned to the various pumping scenario improvements. Refer to attachment 'C' for the C43PS-1 Pump Station Capacity Comparison table.

Total Costs				**$1,477,440**		**$12,735,376**		**$25,002,751**		**$35,367,990**

SUMMARY								
Total PDR Cost Estimate:		$334,298,000		$334,298,000		$334,298,000		$334,298,000
Revised Cost Estimate:		**$335,775,440**		**$347,033,376**		**$359,300,751**		**$369,665,990**

NOTES:

1) The cost summary spread sheet indicates the cost impacts to the Townsend Canal, Townsend Canal Weir Structure, and the SR 80 Bridge for the various C43PS-1 capacity runs. The Townsend Canal improvements for all the runs are north of the C43PS-1 Pump Station. There are no Townsend Canal improvements between Duda's pump station and C43PS-1.

2) Only the major items have been included in the estimate. The unit prices used, contingency of 25%, and an escalation of 17.5% were the same as used in the PDR (30%) submittal.

3) The estimated cost for C43PS-1 (1500 cfs capacity) included in the PDR is $59, 817,000.

4) The maximum velocity in the Townsend Canal of 2.5 f/s was used for all the pump capacity runs. A maximum velocity of 3.0 f/s was used at the SR-80 bridge. A bridge typical section for each run will be provided as soon as they are developed. In general, the slopes at each abutment was steepened for the 1500 cfs and the 2000 cfs runs. For the 2500 cfs run the SR-80 bridge was lengthened by 30 ft. (one span). For the 3800 cfs run, the SR-80 bridge was lengthened by 60 ft. (two spans).

5) We have contacted FDOT to discuss the potential improvements to the SR 80 Bridge used in our cost analysis. FDOT will not make any commitment to accept any of the assumed improvements until a formal bridge hydraulics report and designs are submitted for their review

6) It should be noted that the Townsend Canal improvements north or the SR 80 bridge for the 3800 cfs C43PS-1 will not fit within the existing 200 ft. canal easement. This is probably true for the 2500 cfs run also. No additional cost for purchasing a wider canal easement has been included.

7) HACRAS pumping assumptions for the various capacity runs includes: C43PS-4 not pumping; Duda's pump station pumping 300 cfs; all water pumped from the C-43.

B.0 COST ESTIMATES

B.1 GENERAL INFORMATION

Corps of Engineers cost estimates for planning purposes are prepared in accordance with the following guidance:

- Engineer Instructions (EI) 01D010, Construction Cost Estimates, 1 September 1997 (also known as Unified Facilities Criteria 3-700-02A)
- Engineer Regulation (ER) 1110-1-1300, Cost Engineering Policy and General Requirements, 26 March 1993
- ER 1110-2-1302, Civil Works Cost Engineering, 31 March 1994
- ER 1110-2-1150, Engineering and Design For Civil Works Projects, 31 August 1999
- ER 1105-2-100, Planning Guidance Notebook, 22 April 2000, as amended
- Engineer Manual (EM) 1110-2-1304 (Tables revised 30 March 2007), Civil Works Construction Cost Index System, 31 March 2000

In addition, the set of plan formulation cost estimates used for plan selection rely on construction feature unit pricing and are prepared in Civil Works Breakdown Structure (CWBS) format to the subfeature level. The cost estimate supporting the National Ecosystem Restoration plan (Selected Alternative Plan) is prepared in MCACES/MII format to the CWBS subfeature level. This estimate is supported by the preferred labor, equipment, materials and crew/production breakdown. In addition, a fully funded (escalated for inflation through project completion) cost estimate, the Baseline Cost Estimate or Total Project Cost Summary, has been developed. A risk analysis was prepared that addresses uncertainties in Selected Alternative Plan cost items both qualitatively and quantitatively. The risk analysis is included at the end of this appendix. The goal of the cost estimating for the C-43 Reservoir study is to produce a final product (cost estimate) that is reliable and accurate and that defines the Government's and the non-Federal sponsor's obligations. The final product is also intended to support project authorization.

A 30 percent Preliminary Design Level Cost Estimate was developed for the project by Stanley Consultants for the South Florida Water Management District's Acceler8 program. This cost estimate was reviewed by Jacksonville District and used as the basis for the direct costs in the preparation of the plan formulation cost estimates and of the MCACES cost estimate for the Selected Alternative Plan. For this reason the MCACES cost estimate for the Selected Alternative Plan shows User Created Cost items in lieu of the traditional Labor, Materials and Equipment breakdown. The Labor, Materials and Equipment breakdown is found in Stanley Consultants cost estimate. The 30 percent cost estimate was prepared by Stanley Consultants using MCACES Gold 5.31 software. It is dated 31 May 2006. R.S. Means' 2006 database adjusted by the

Engineering News Record index was used as the basis for Stanley Consultants' crew based estimate. Vendors and equipment manufacturers were contacted by Stanley Consultants to confirm costs for specific items. Certain mechanical equipment was estimated using the Richardson (2004) guides as the database. Labor rates used in the 30 percent design cost estimate are the Davis Bacon Union Shop Labor Rates for Fort Meyers, Florida

First, the cost estimate for the Selected Alternative Plan was prepared by transcribing the direct costs from the Acceler8 contractor's estimate to the MII software. Markups and contractor/subcontractor structure consistent with Jacksonville District practices/conventions/history were added. A printout was made of the total project costs including unit pricing. Then, the unit pricing was used to prepare the plan formulation cost estimates. Finally, the Total Project Cost Summary was prepared using the estimate for the Selected Alternative Plan as its basis.

B.1.1 Selected Alternative Plan

The scope of work for the Selected Alternative Plan is found in Appendix A, Engineering. The MCACES/MII cost estimate for the Selected Alternative Plan (Section B.3, below) is based on that scope and is formatted in the Civil Works Breakdown Structure. In addition, it includes both construction and non-construction costs. The construction costs fall under the following feature codes:

- 02 Relocations
- 03 Reservoirs
- 04 Dams
- 09 Channels and Canals
- 13 Pumping Plant
- 14 Recreation Facilities
- 15 Floodway Control-Diversion Structures

The non-construction costs fall under the following feature codes:

- 01 Lands and Damages
- 30 Planning, Engineering and Design
- 31 Construction Management

Construction Costs. Direct costs for the construction features were taken from the 30% design cost estimate as described above. These direct costs are reported in the MCACES/MII estimate as 'User Defined' costs and are the sum of the labor, equipment and materials direct costs from the 30% design cost estimate. Sales tax of 7% is added in the 30% design cost estimate to material and

equipment costs and is therefore considered a direct cost. To the direct costs were added the following contractor markups:

* Job Office Overhead at 8%, running (4% on subcontracted work)
* Home Office Overhead at 5%, running (3% on subcontracted work)
* Bonds and Insurance at 1.5%, running (1.5% on subcontracted work)
* Contractor's profit at 8.55% (8.55% on subcontracted work)

Profit was determined using the weighted profit guidelines. Table 1 summarizes the prime contractor profit calculation. Separate profit percentages were calculated for each subcontractor, using the weighted profit guidelines.

TABLE 1. WEIGHTED PROFIT GUIDELINES CALCULATION-PRIME CONTRACTOR

	Value X	Weight =	Percentage
Risk	0.09	20	1.8
Difficulty	0.1	15	1.5
Size	0.03	15	0.45
Period	0.12	15	1.8
Contractor's Investment	0.07	5	0.35
Assistance by Government	0.07	5	0.35
Subcontracting	0.092	25	2.3
TOTAL		100	8.55

The indicator, 'running' means the cost is calculated based on the percentage entered (computed as shown in the table, above) multiplied by the running total. The running total is the sum of the direct costs (labor, equipment and materials, plus any sub-bid or user-defined items) and the values of any categories appearing above the present category in the hierarchy of the MII program, for this case, job office overhead, home office overhead, profit and bonds, in that order.

Also added are the following owner markups:

Contingency at 25%
Escalation at 2.79%

The contingency is a deviation from the guidance contingency of 20% for projects at the feasibility level with an expected cost greater then $10,000,000 (ER 1110-2-1302, Appendix D, Page 9). This is for cost consistency with Comprehensive

Everglades Restoration Program guidance DCM-7. In addition, certain features were assigned a contingency of 30% due to design uncertainties. These are primarily structures associated with the dam, whose exact designs have not yet been described.

Escalation was added to bring the direct costs, dated 31 May 2006, to fiscal year 2007 price levels (1 October 2007). Only the direct costs taken from Stanley Consultants' cost estimate are escalated (for use in the plan formulation cost estimates and the MCACES/MII cost estimate for the Selected Alternative Plan). Costs derived by other means are already in fiscal year 2007 price levels and therefore not escalated. Civil Works Construction Cost Indexing System composite yearly factors were used to determine the escalation rate. For fiscal year 2006 the factor is 641.50 and for fiscal year 2007 the factor is 659.42; therefore, costs in the 2006 price level are multiplied by 659.42/641.50 to arrive at costs in the 2007 price level.

It is assumed that the construction work will be performed under one contract. Subcontractors are identified as follows:

- Landscaping subcontractor
- Demolition subcontractor
- Structures subcontractor (with a Pumping Equipment subcontractor)
- Clearing and Grubbing subcontractor
- Instruments/Controls subcontractor

Subcontractor markups are defined as follows:

- Job Office Overhead at 8%, running (4% on subcontracted work)
- Home Office Overhead at 5%, running (3% on subcontracted work)
- Bonds and Insurance at 1.5%, running (1.5% on subcontracted work)
- Contractor's profit as determined using the weighted profit guidelines (same percentage on subcontracted work)

Non-construction Costs. Real Estate costs were provided by Real Estate Division. These costs are best described in the Real Estate Appendix, Appendix D. They include lands costs and administrative costs and are distinguished as non-Federal sponsor costs or government costs. Contingencies are applied as indicated in the Real Estate Appendix and vary by component.

Planning, Engineering and Design costs are broken down into Preconstruction, Engineering and Design (PED), or preparation of contract plans and specifications; Engineering During Construction (EDC); and the Project Implementation Report. PED costs were solicited from Engineering Division via the Project Manager, as suggested by the guidance. Ten percent of the total

construction cost is used as the total rate for engineering costs through construction, as is customary in Jacksonville District's Cost Branch. This percentage is broken down into eight percent of construction costs for PED and two percent for EDC. The cost for the PIR was provided to Cost Branch via the Project Manager and represents funds spent to date plus funds expected to be spent through report completion.

Construction Management costs were solicited from Construction-Operations Division via the Project Manager, again as suggested by the guidance. Seven and six-tenths percent is used as the rate for Construction Management costs for the cost estimate for the Selected Alternative Plan. This percentage is based on actual funds spent for construction management on past contracts. When this cost is calculated for planning projects it is itemized to show amounts allocated for each task anticipated to occur during construction.

B.1.2 Plan Formulation Cost Estimates

To iterate, unit prices for each major or variable construction element were taken from the cost estimate developed for the Selected Alternative Plan. These unit prices were entered into spreadsheets that differentiated each plan by the quantities required to construct the plans. The spreadsheets are included in this appendix (Section B.2). The spreadsheets are formatted according to the Civil Works Breakdown Structure and include construction and non-construction costs. Quantities for the construction elements were provided to Cost Branch by the Engineering Technical Lead. Real Estate costs were provided by Real Estate Division. Preconstruction, Engineering and Design costs and Construction Management costs were calculated using percentages; at this level of estimating they are assumed to be ten percent and eight percent, respectively. During ITR, slight adjustments were made to the Selected Alternative Plan cost estimate, but these tables were not updated, in order to keep the comparison of costs across the alternatives consistent. The selected plan cost went down due to changes in profit percentages. The cost change should not affect plan selection.

Section 5 of the main report describes the costed alternative plans in detail. They include the following:

- Plan 2; 100,000 acre-foot reservoir with 1,500 cubic feet per second pumping capacity
- Plan 3B; 170,000 acre-foot reservoir with 1,500 cubic feet per second pumping capacity
- Plan 3C; 170,000 acre-foot reservoir with 3,800 cubic feet per second pumping capacity
- Plan 4; 220,000 acre-foot reservoir with 3,800 cubic feet per second pumping capacity

The C-43 alternative plans include pump stations of 150 cubic feet per second (cfs), 1,500 cfs and 3,800 cfs. The 150 and 1,500 cfs pump stations are included in the Acceler8 30% design cost estimate so their direct costs are applied as described above in the project costing. The 3,800 cfs pump station was costed independently of the Acceler8 30 % design. Cost engineering guidance allows for use of historic pricing at this phase of a planning study. Historic bid data was collected from contracts awarded by Jacksonville District since 2000. This data was summarized in a total cfs/cost per cfs chart as well as a total cfs/total cost chart. Curves were fit to these charts/data points, equations determined for the curves, and predictions made for other cfs pump station costs based on these equations. For this analysis, all costs were indexed using the Corps Civil Works Construction Cost Indexing System (CWCCIS) to Fiscal Year 2007 levels. Note that the pump stations constructed since 2000 are lower head pump stations, of about ten feet static head. The pump stations for the plan formulation have static heads of about 30 and 40 feet (27 feet for the 150 cfs station and 42 feet for the 1,500 and 3,800 cfs stations). A second set of curves was superimposed on the first set to allow for additional pumping equipment costs to account for the higher head. This set of curves relies on the direct costs prepared by Stanley Consultants for the Acceler8 program of South Florida Water Management District. For the lower head pump station, costs were added of $3,800,000 and for the higher head pump stations, costs were added of $46,300,000. Shifting the historic curves upward in cost by these additional amounts is intended to account for the greater pumping equipment costs and possibly greater building costs for the higher head stations.

TABLE 2. HISTORIC PUMP STATION DATA

Pump Station	Date Awarded	Total Cost	Cost FY 07$	No of Pumps	Pump Size	Total cfs	Cost/Pump FY 07$	Cost/cfs FY 07$
361	4/19/2001	$2,170,000	$3,043,598	3	3e/25 cfs	75	$1,014,533	$40,581
9A	9/19/2000	$5,915,495	$8,370,163	4	2d/175 cfs, 2e/75 cfs	500	$2,092,541	$16,740
357	9/20/2005	$10,388,921	$11,306,565	5	4d/125 cfs,1e/75 cfs	575	$2,261,313	$19,664
362	9/30/2000	$29,109,915	$41,189,239	7	3d/960 cfs, 2d/550 cfs, 2e/110 cfs	4200	$5,884,177	$9,807
319	3/30/2000	$27,283,338	$38,604,714	5	3d/960 cfs, 2d/550 cfs	3980	$7,720,943	$9,700
385	5/17/2004	$3,988,583	$4,340,891	4	4e/40 cfs	160	$1,085,223	$27,131
382	9/26/2003	$9,617,529	$12,805,389	3	3d/160 cfs, 160 cfs, 60 cfs	380	$4,268,463	$33,698
383	9/26/2003	$1,012,371	$1,347,936	2	2e/15 cfs, 25 cfs	40	$673,968	$33,698

Notes: 1.)Under 'pump size', 'e' is for electric and 'd' for diesel. 2.)CFS is cubic feet per second.

TABLE 3. CURVE ADJUSTMENT CALCULATION

Size/cfs	Higher Head Cost	Lower Head Cost	Difference
150	$9,000,000	$5,200,000	$3,800,000
1500	$25,700,000	$29,500,000	
3800	$48,900,000	$52,700,000	
1500	$72,000,000	$25,700,000	$46,300,000
3800	$95,200,000	$48,900,000	
	$9,000,000 from a preliminary C-43 TSP estimate using Corps' markups.		
	$72,000,000 from a preliminary C-43 TSP estimate using Corps' markups.

Time: 14:21:33
Title Page

This estimate is for the Selected Alternative Plan, Alternative 8B, a 170,000 acre-foot storage reservoir with 1,500 cubic feet per second pump capacity.

Estimated by: USACE- SAJ and Stanley Consultants/Accelar8/SFWMD
Designed by: Stanley Consultants/Accelar8/SFWMD
Prepared by: Milton Swiatasek
Preparation Date: 10/20/2009
Effective Date of Pricing: 10/20/2009
Estimated Construction Time: 1,825 Days

Jacksonville District Cost report

Date	Author	Note
5/18/2007	T Leeser	Project Name:C43 Project Number: 114458 Project Type (e.g., Reconnaissance, Feasibility, Bid): PIR (Study Authority is the Water Resources Development Act of 2000) Scope of Work: Alternative B as described in the PIR, Appendix A, Engineering Authorized Cost (if any): Not yet authorized. Contingency Amount (if any): 25%. This is a variation from Corps' guidance to allow for uncertainties in the design of the embankment and auxiliary structures. Some features have 30% contingency. Contingency on real estate is 25% on Federal administrative costs and 7% on non-Federal administrative costs, zero on RE Fee costs (per RE e-mail from A.Ayuso dated 6/18/07.) PED Amount (if any): 19% S&A Amount (if any): 7.5% Backup itemized and provided by CO. Sales Tax: 7% Job Office Overhead: 8% Home Office Overhead: 5% Profit: 10.1% Computed by weighted guidelines method. Bonds and Insurance: 1.5% Estimated Contract Award Date (mo/yr): Based on A&SFWMD schedule (see below) as described in e-mail from LuAnn McVicar, SFWMD, to Gia Hightower, USACE, dated 14 May 2007. 1) Clearing & Grubbing contract - contract award 12 July 07. 2) Embankment Structure Pre-load contract - advertise week of 13 August 07; contract award 11 October 07. 3) Reservoir & Pump Stations contract (main contract) - Release RFP's on 18 September 07 (to pre-qualified group of contractors); Release RFBs (to RFP short-listed group of contractors) on 19 December 07; award contract on 14 February 08. Estimated Construction Start Date (mo/yr): 8/2007 (see above) Estimated Construction Midpoint Date (mo/yr): 2/2009 Estimated Construction Complete Date (mo/yr): Based on 1,026 days (per Stanley Consultants' 30% design cost estimate) this is 3 years or 8/2010. CWCCIS Indices used: Engineer Manual 1110-2-1304 dated 30 Mar 2007 Subfeature Date Index Published Index Composite 10/05 641.50 Composite 10/05 658.42 Estimate revised to reflect Tentatively Selected Plan, Alternative 3B. This estimate relies on the MCACES Gold cost estimate prepared by Stanley Consultant's for the Accelerate Program (A3)/South Florida Water Management District dated 5/31/06. Stanley Consultant's estimate uses the labor/equipment/materials makeup for costs and is crew/productivity based. The direct costs in Stanley Consultant's estimate are the basis of the unit costs in this estimate, for all cost items except as noted. The estimate is dated 5/31/06 so these costs are escalated to FY 2007 price levels. In addition, Stanley Consultants prepared a Technical Memorandum for the SFWMD/A3 program on the Townsend Canal Improvements. The TM included a cost summary; the costs are used herein. These costs are also escalated since the cost table in the TM equates the costs to their previous cost estimate and adds the two to obtain a revised total cost. Scope of Work: Taken from Draft Project Implementation Report dated April 2007, Engineering Appendix, beginning on page A-56. A two-cell 176,000 acre-foot above ground storage reservoir, a 1,500 cubic feet per second pumping station and a selection of water control structures. The reservoir project site would consist of approximately 10,500 acres. Site preparation: Clearing and grubbing the entire site to eight inches depth. Site work and access road: Maintenance of existing paved entrance road during construction and construction of a new entrance road after construction of the reservoir. Townsend Canal improvements: Widen channel bottom, add scour protection across entire channel width. Embankment: 14-foot wide crest (including soil cement protection), 3 horizontal to 1 vertical side slopes. Cell One elevation is +55 feet, NAVD, and Cell Two elevation is +84 feet. Construction material is random fill with the borrow area on-site. Upstream slope protection and an interior drain are included, as well as a soil-bentonite wall. Downstream of the embankment is a 100-foot wide bench with a 24-foot access road. There is an interior embankment separating Cells One and Two, with a crest elevation of +50 feet, NAVD, also covered in soil-cement. Side slopes: To be seeded and sodded.

Project Notes Page 4

Date	Author	Note
5/16/2007	T. Leeser	Relocations: Of electric and water utilities. Structures: Two pump stations, two outlet structure sluice gates, three perimeter canal structures (roller, slide and weir gates), two crested spillways, one balancing structure sluice gate and eight gated culverts (slide and weir gates). Demolition: Of two existing pump stations. Recreation features: A major recreation attraction of the C-43 Storage Reservoir. Part 1 will be an approximately 12-mile multi-purpose trail loop atop the levee constructed as part of the project. Recreation facilities proposed include: parking and toilet facilities (olivas multrum waterless vault toilets), information kiosk, canoe/kayak launch facility, a shade structure, traffic-control fencing and a pedestrian footbridge bridge over the perimeter canal to provide public access to the reservoir.
6/15/2007	T. Leeser	Revised estimate to remove four structures to be built by others, S-16 through S-19, per e-mail PM to EN-C (B. Marlowe to T. Leeser) on 15 June 2007. Changed real estate costs per e-mail from RE (A. Ayusc) dated 6/18/07.
6/27/2007	T. Leeser	Revised estimate to incorporate change in scope of work that raises dam/embankment height. Per DP e-mail on scope change and as coordinated through EN/ETL, increased quantities for random fill/embankment from 19,772,438 to 22,011,438 cy and for soil cement from 789,659 to 824,659 cubic yards. Also as directed through EN/ETL, increased contingency on other features expected to change slightly in design, by a corresponding amount (22,011,438/19,772,438=1.11), to 30% (25% X 1.11 = 28%, used 30%). Also per EN/ETL e-mail dated 26 June 2007, added manatee gate.
7/18/2007	T. Leeser	As a result of Independent Technical Review, profit on the prime contractor was changed by adjusting the weighted profit guidelines computation to better reflect project conditions. Also, separate profits were calculated for each subcontractor using the weighted profit guidelines (per EI 010010). As a result, the non-construction costs 'Planning, Engineering and Design' and 'Construction Management' were revised. The cost book was changed to Region III and cost factors were updated (e.g., fuel) to reflect current pricing.
10/20/2009	Switanek	Revised Estimate to reflect current 2008 cost book and escalated by Cost Growth Index (USACE) to 2010 dollars as of 20 Oct 09. Also included $84,554,000 real estate cost without escalation and contingency. Because escalation and contingency was already included in Real- Estates cost estimate.

B.4 TOTAL PROJECT COST SUMMARY

The Total Project Cost Summary includes escalation through project completion. The cost estimate for the Selected Alternative Plan is prepared with an identified price level date. Inflation factors are used to adjust the pricing to the project schedule. This estimate is known as the Fully Funded Cost Estimate or Total Project Cost Summary. It includes all Federal and non-Federal costs: Lands, Easements, Rights of Way and Relocations; construction features; Preconstruction Engineering and Design; Construction Management; Contingency; and Inflation. The summary is shown in the following table.

WBS 4 C-43 Basin Aquifer Storage Reservoir – Part 1 Project													
FY 2009 Fully Funded Estimate													
(Amounts in Thousands of Dollars)

B.5 RISK AND UNCERTAINTY ANALYSIS

B.5.1 Risk analysis methods

A study was made of risk associated with the C-43 reservoir construction costs. The MCACES/MII cost estimate for the Selected Alternative Plan was used as the basis for the risk study. Only the construction costs were examined for the risk study; Real Estate, Preconstruction, Engineering and Design and Construction Management Costs were not included. First, references were gathered that describe risk analysis as might be applied to Corps of Engineers projects. These references are the following:

1. Memorandum For Commander, Jacksonville District, From James C. Dalton, P.E., Subject: Risk Analysis in Construction Cost Estimates for Projects $10 Million and Greater, dated 23 April 2007
2. Risk Analysis Framework For Cost Estimation, Institute For Water Resources Report 00-R-9, December 2000

Then, a qualitative description of risk was prepared using the references as a guide. Finally, a quantitative description of risk was made using EXCEL software with the Crystal Ball add-in. The qualitative and quantitative descriptions of risk are presented below. The report from the Crystal Ball simulation is provided with this write-up, showing the level of detail of the quantitative assessment and the results of the assessment.

B.5.2 Qualitative description of risk

In order to identify and mitigate risk, the qualitative description of risk addresses risk assessment, risk management and risk communication, as follows:

1. Risk Assessment-Quantify and describe

- What can go wrong?
- How can it happen?
- How likely is it?
- What is the magnitude of the bad event should it happen?

2. Risk Management-Identify risk reducing actions

- What can be done to reduce the impact of the risk described?
- What can be done to reduce the likelihood of the risk described?
- What are the trade-offs of the available options?
- What is the best way to address the described risk?

3. Risk Communication

- With whom to communicate?
- How to get both the information that is needed and the information others have?
- How to convey the information to be communicated?
- When to communicate?

With a cost estimate, one of the worst things that can go wrong is that the cost can be greatly underestimated. On a Corps of Engineers construction project, the cost is truly known at the time of closeout, when all claims and modifications are submitted, negotiated, approved and paid. This can be several years after physical completion of the project, and many, many years after planning and authorization. Underestimating the cost of a construction project can happen in a myriad of ways, from differing site conditions to lower actual productivity rates to higher actual labor, equipment and material rates. On the surface, it is very likely that the point estimate of the total construction cost generated for a planning study is not dead on. At a deeper level, the question to be asked is, How far off could that point estimate be?

In investigating the range of uncertainty in a planning-level cost estimate one uncovers ideas about how to reduce the likelihood and the impact of underestimating the construction cost. Perhaps this takes the form of more geotechnical field investigations, increased hydrologic modeling, or further research into the current cost of certain construction materials or products. Sometimes a planner or engineer must choose between accepting risk in the long run and spending additional funds and time in the short run. Often when risk is identified at the planning stage it is accommodated with a higher cost contingency and addressing the risk is left for a later stage in the project life-cycle.

Risk may be a topic that members of a project delivery team do not prefer to discuss. However, risk does need to be communicated with all those on the project delivery team, and especially with those who have the authority to make decisions about managing the risk and on adapting to the risk. Including a risk analysis in a planning document is a first step toward sharing information about the uncertainty in a project. Of course, the identification of uncertainty is only helpful if that risk assessment is carried through and modified as the project progresses.

Potential sources of uncertainty in the cost estimate for the C-43 West Basin Reservoir project Selected Alternative Plan are listed below:

- Contractor's home office overhead
- Contractor's job office overhead
- Contractor's profit
- Contractor's bond
- Subcontractors' markups
- Subcontracting scheme
- Contracting scheme/multiple contracts
- Labor rates
- Crew makeup
- Equipment rates
- Equipment makeup
- Materials costs
- Productivity rates
- Construction duration
- Design parameters/quantities/sizes
- Fuel cost
- Weather
- Overtime
- Cost of money/cost of money discount
- Electricity rates
- Shipping costs
- Mobilization/demobilization cost
- Demolition cost
- Relocation cost
- Clearing and grubbing cost
- Stripping cost
- Blanket drain cost
- Toe drain cost
- Toe drain outfall end treatment cost
- Random fill cost
- Chimney drain cost
- Slurry wall cost
- Soil cement cost
- Select fill cost
- Sodding cost
- Cell instruments and controls cost
- Access road construction cost
- Vehicle barrier gate cost
- Floating safety barrier cost
- Floating weed barrier cost
- Silt fence cost
- CS-1 cost
- CS-2 cost
- C43S-1 cost

- C43S-8 cost
- C43S-12 cost
- C43S-3 cost
- C43S-10 cost
- C43S-11 cost
- C43S-7 cost
- C43S-9 cost
- C43S-14 cost
- C43S-15 cost
- C43P-1 cost pumping equipment
- C43P-1 cost trash rack and screen
- C43P-1 cost sitework and equipment building
- C43P-1 cost pump station building
- C43P-4 cost pumping equipment
- C43P-4 cost trash rack and screen
- C43P-4 cost sitework and equipment building
- C43P-4 cost pump station building
- Double lane boat ramp cost
- Vehicle gate cost
- Shade trees cost
- Footbridge cost
- Shade shelter cost
- Canoe launch cost
- Information kiosk
- Parking area/handicap access cost
- Waterless vault toilet facility

Potential sources of certainty are the following:

- Sales tax on materials
- Escalation
- Materials makeup

Sales tax on materials is included in this list since sales tax is charged on materials in Florida at the given rate prescribed by the County in which the construction will occur. Escalation, although arguable, is a source of certainty in that the indexing factors used to bring the direct costs prepared by the Acceler8 contractor from fiscal year 2006 to fiscal year 2007 prices are well-documented. These are the Civil Works Construction Cost Index System factors published twice a year by the Corps of Engineers. Materials makeup is a source of certainty at this level of planning in a relative sense due to the great detail with which the Acceler8 contractor's cost estimate is prepared. This cost estimate is the basis for the direct costs used in the estimate for the Selected Alternative Plan. For a feasibility level/project implementation report, the detailed cost

estimate goes well beyond what would be regularly prepared to meet Corps guidance.

Following the cost estimator's rule of thumb that 80% of the cost is in 20% of the line items, the items in the C-43 cost estimate with the greatest cost are the following:

- Embankment
- Pump Station (1,500 cubic feet per second)

On a qualitative basis, total cost consists of quantity and unit pricing. The quantity of the materials needed for the embankment is function of the embankment height, width and cross-sectional shape as well as factors such as shrink and swell. The unit pricing of the embankment is a function of, among many factors, equipment and labor employed, production rates (including from how far away the material must come and bad weather), and whether material must be purchased.

As for the pump station, again the quantity of the materials needed is a function of the design, which in turn relies on hydrologic modeling. The unit pricing is a function of materials purchased, including the pumping equipment and concrete with which to construct the buildings, production rates, and equipment needed and labor employed.

B.5.3 Quantitative description of risk

Purposes of quantifying risk include to identify a range of probable costs, to provide an assessment of the probability of completing the project at any given cost level within the identified range, to identify project variables which could contribute most significantly to cost overruns, and to allow for inclusion of the costs identified to mitigate these risks and reflect market conditions (that is, to set contingency).

The quantification of risk for the C-43 Selected Alternative Plan cost estimate is intended to meet the purposes of identifying a range of probable costs and providing an assessment of completing the project at a given cost level. Quantifying risk to set contingency is outside of the realm of this analysis.

The EXCEL add-in 'Crystal Ball' was used to define probability distributions for each variable cost component (quantity and unit cost), thereby describing the uncertainty in the numbers used in the cost estimate. A forecast of each cost component is then made using Monte Carlo simulation to show the entire range of possible cost outcomes and the likelihood of achieving each of them. By including Total Construction Cost as one of the components forecast, a range of

costs can be calculated as well as the certainty of achieving a total cost within a given range.

A list was made of the cost items in the Selected Alternative Plan cost estimate (see table below). For each item, the quantity, unit of measure, unit cost and project cost were extracted from the cost estimate. Note the exact costs used in the risk analysis vary slightly from the Selected Alternative Plan cost estimate. This is because the Selected Alternative Plan cost estimate was revised after the Independent Technical Review; altering the Contractors' profit values. The general results of the risk analysis remain, therefore, the risk analysis was not revised after the Independent Technical Review. Where the quantity varied, a minimum and maximum quantity were calculated, as 10% minus or plus the point estimate or most likely quantity value. Ten percent was used since the level of effort to determine and check these quantities was significant and therefore the quantities are not expected to vary much in the final design/bid documents. To account for unit cost variations, the minimum unit cost was taken to be the most likely cost without added contingency (varying from 25 to 30%) and the maximum cost to be the most likely cost with twice the contingency. The exception to the unit cost rule is the pumping stations, where vendor quotes were obtained for cost components such as the pumping equipment. For the pumping stations, the minimum and maximum were calculated at 10% of and 110% of the most likely cost.

Therefore, the variable quantities and unit costs were assumed to have triangular distributions, that is, ranging from a minimum value to a most likely value, to a maximum value. Further details of the distribution determinations are provided in the attached Crystal Ball report.

Forecasts of project cost were made using the distributions defined coupled with Monte Carlo simulation. The forecasts are described via graphs and statistics and are provided in the attached Crystal Ball report.

TABLE 8: INPUT FOR MONTE CARLO SIMULATION

CONSTRUCTION COST								Quantity		Unit Cost	
Feature Description	Subfeature	Item	Quantity	Unit Of Measure	Unit Cost	Project Cost	Percent of Total Cost	Minimum	Maximum	Minimum	Maximum

TOTAL CONSTRUCTION COST						**$319,839,429.00**	0.985				

2247

The range in the total construction cost is from $287,000,000 to $354,000,000. Recall the total construction cost reported in the cost estimate for the Selected Alternative Plan is $320,000,000. The following two figures show the bounds of the range of costs. The certainty that the total construction cost will lie within $10,000,000 of the cost reported in the Selected Alternative Plan estimate is 66%. The certainty that the total construction cost will lie within $20,000,000 of the cost reported in the Selected Alternative Plan estimate is 94%.

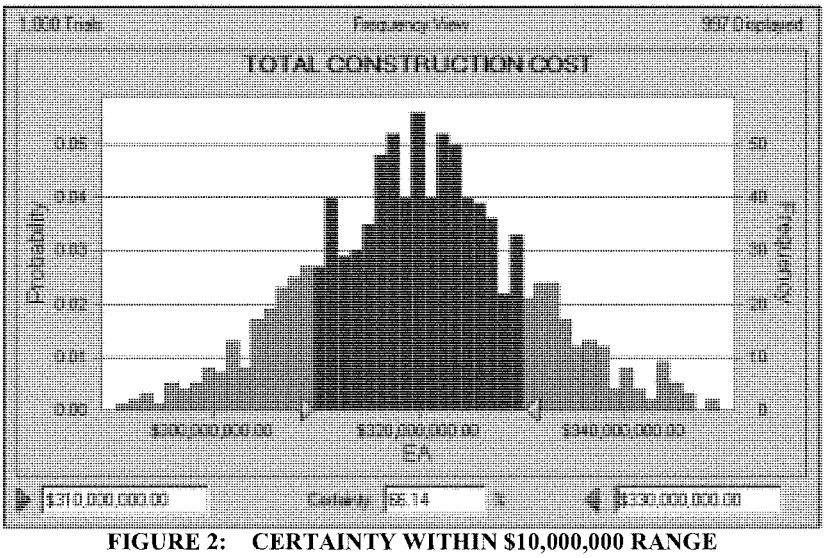

FIGURE 2: CERTAINTY WITHIN $10,000,000 RANGE

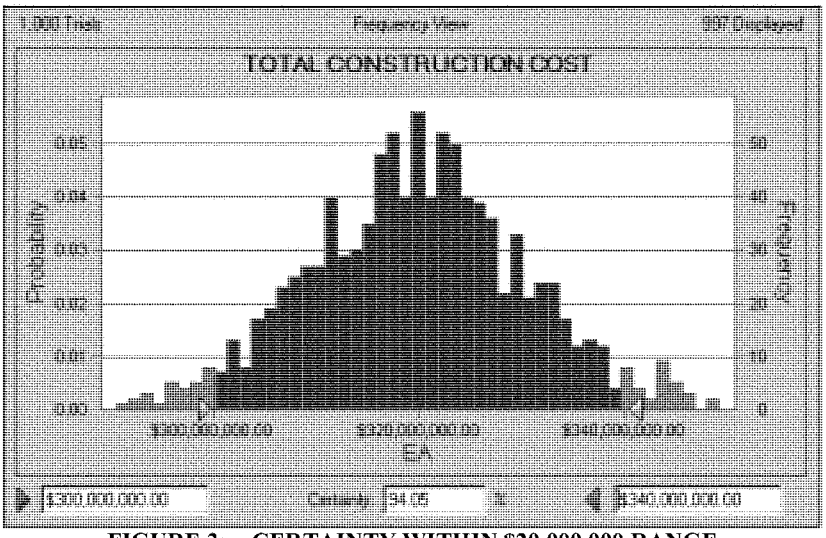

FIGURE 3: CERTAINTY WITHIN $20,000,000 RANGE

B.5.4 Monte Carlo Simulation Results

The report from the Monte Carlo simulation is provided in the following pages. Forecasts with statistics are provided for each cost component studied. Assumptions are documented, including probability distributions. No overlay charts were created. Finally, a sensitivity chart is given for the Total Construction Cost, showing the influence of the cost components. This chart confirms that the embankment/random fill item is the most influential.

C.0 ENVIRONMENTAL INFORMATION

C.1 ECOLOGICAL ANALYSIS–SYSTEM FORMULATION (LAST ADDED INCREMENT)

C.1.1 Background

This project is expected to primarily benefit the Caloosahatchee Estuary. However, because Comprehensive Everglades Restoration Plan (CERP) projects are required to be selected and justified based on their system-wide benefits, the following analysis conducted for the plan selection process is based on a system formulation approach in which the Caloosahatchee River (C-43) West Basin Storage Reservoir project benefits would coincide with the rest of CERP being constructed. An additional analysis will be conducted to determine the difference between the average annual habitat unit lift for the Last Added Increment (LAI) and the Next Added Increment (NAI), to justify the stand-alone benefits of the project.

The environmental evaluation process used for plan selection was based on five attributes:

- Average habitat suitability indices (HSI) for oyster–based on all seasons of dry years and all seasons of wet years
- Average HSI for *Vallisneria*–based on dry seasons of dry years
- Average HSI for seagrass–based on wet seasons of wet years
- Extreme events–average HSI of oyster, *Vallisneria*, and seagrass during the three driest months and three wettest months in the period of record.
- EST05–This attribute reflects the percentage of weeks each alternative matches the target flow (EST05). EST05 is a time series of flow developed to maximize beneficial conditions for a suite of organisms in the Caloosahatchee River (C-43) Estuary. EST05 was adopted as the system-wide performance measure for the Caloosahatchee Estuary (NE-03) by the Restoration Coordination and Verification (RECOVER) team.

Scoring each of the attributes above resulted in a quality index number (HSI or percent) for each alternative. Those quality index numbers were then combined using a Habitat Unit Combination Method (HUCM) in order to arrive at one total Habitat Unit (HU) number for each alternative.

Table C-1 summarizes the five attributes and quality index calculations for the 2000 base case, 2050 future without project, and each of the alternatives.

TABLE C-1: TOTAL QUALITY INDEX NUMBERS, SYSTEM FORMULATION

Condition	Oyster	*Vallisneria*	Seagrass	Extreme Event	EST05

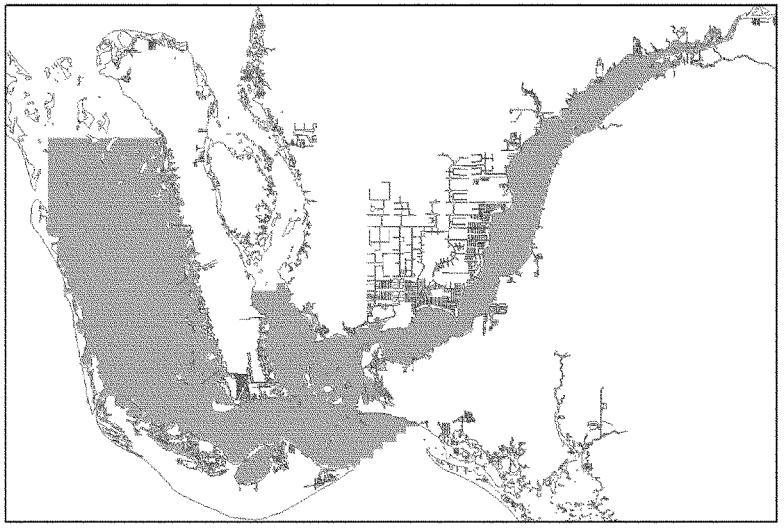
Alternative 3c	16,397
Alternative 4	15,907



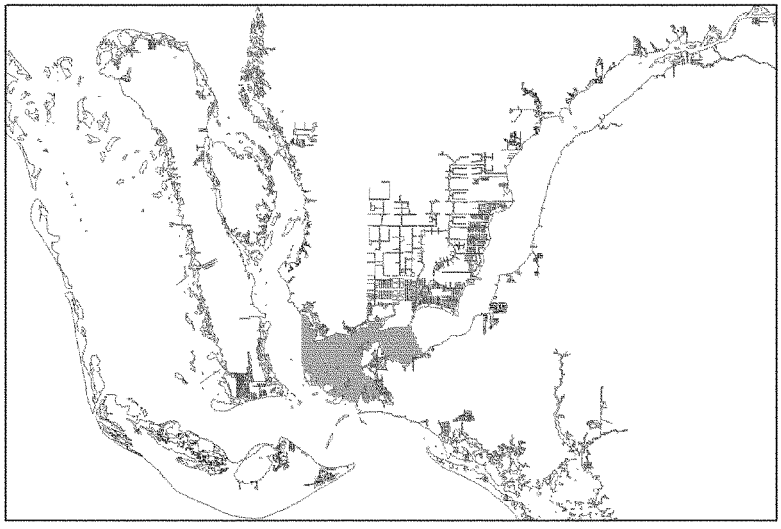
C.1.2 Geographic scope

The purpose of the Caloosahatchee River (C-43) West Basin Storage Reservoir project is to restore more natural timing, volume, and duration of freshwater flows to the Caloosahatchee Estuary, and to provide a more appropriate range of salinity conditions by reducing extreme salinity fluctuations. The proposed alternatives may improve conditions for estuarine and marine resources throughout most of Lower Charlotte Harbor, including the Caloosahatchee Estuary, San Carlos Bay (Shell Point to Pine Island Sound), Pine Island Sound, and Matlacha Pass. Additionally, the Gulf-side of Fort Myers Beach and Sanibel Island near Point Ybel may also benefit from the proposed alternatives. However, calculation of habitat benefits achieved by each of the proposed alternatives was restricted to portions of the estuary where changes in salinity in relation to freshwater flows at S-79 could reasonably be predicted (***Figure C-1***).

The SFWMD has a record of monitored salinity levels at 19 stations throughout the estuary from S-79 downstream to San Carlos Bay, south to Point Ybel, north to Masters Landing in Matlacha Pass, and west and north to Useppa Island in Pine Island Sound. That data was used to predict changes in salinity based on flows at S-79 through regression analysis for the geographic extent of the estuary monitored (i.e., 71,095 acres). The resulting salinity model grid was then refined to 70,979 acres based on additional model input data, including

geographical information system (GIS) coverages of existing seagrasses, *Vallisneria,* and oyster distributions. This acreage is within the navigable waters of the United States and within the navigational servitude of the United States.

FIGURE C-1: TOTAL AREA OF BENEFIT



The species selected for modeling differ in their habitat requirements and range of tolerable conditions. Thus, the portion of the estuary for which the HSI models assessed habitat suitability changes resulting from each alternative varied according to the species or group of species being portrayed. For each species, the primary area of impact was used to determine total benefits. The ecological subteam determined these areas based on best professional judgment as well as model limitations. The total area of ecological benefit (used for Extreme Event and EST05) reflects total area covered by the HSI models. This is the best estimate available at the time of acreage impacted, and is therefore used as the total area benefited; although in reality, a larger area is probably impacted by Caloosahatchee flows, and will accrue benefits from this project.

C.1.2.1 Oysters–5,8 99 Acres

Oysters are sessile and are best suited for the middle portions of the estuary. Thus, the core oyster population and target area for recovery is limited to the San Carlos Bay area from Shell Point to Merwyn Key and Fisherman's Key, and habitat suitability changes for oysters were only assessed in that geographic area ***Figure C-2.***

FIGURE C-2: MAP OF OYSTERS

C.1.2.2 *Vallisneria*- 4,129 Acres

Vallisneria (tape grass or wild celery) is limited to the upper or fresher portions of the estuary extending from S-79 to Iona Cove and habitat suitability changes for *Vallisneria* were only assessed in that geographic area (***Figure C-3***).

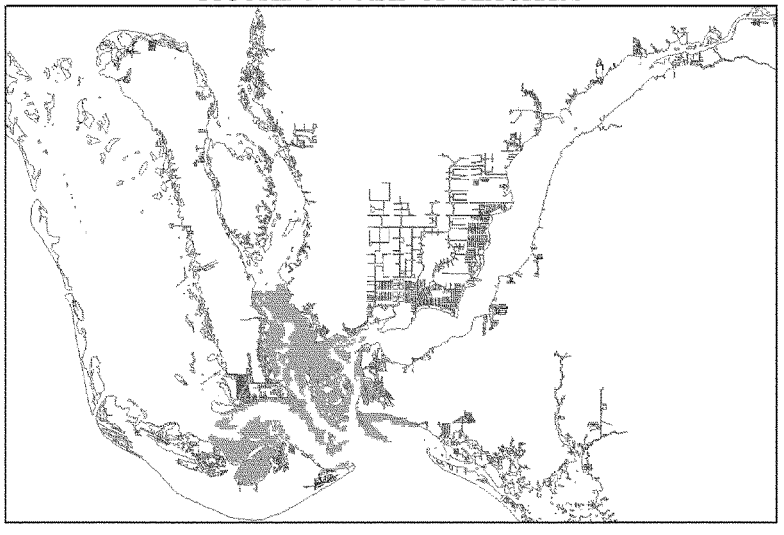


FIGURE C-3: MAP OF VALLISNERIA

C.1.2.3 Seagrasses –12,547 Acres

Habitat suitability changes for seagrasses were assessed separately for three contiguous geographic areas based on 1) species composition and their depth and salinity tolerance ranges, and on 2) the spatial differences in the frequency of exposure to extreme variation or fluctuations in salinity levels from freshwater flows at S-79 (***Figure C-4***). The furthest upstream seagrass area is Iona Cove and is dominated by *Halodule wrightii. Halodule* tolerates lower salinity levels than *Thalassia testudinum*, and as a result, is the only seagrass that occurs upstream of Shell Point in the Iona Cove area. The San Carlos Bay seagrass area is downstream from Shell Point and contains both *Halodule* and *Thalassia.* Habitat suitability changes in the San Carlos Bay area were modeled separately because the bay is at the mouth of the Caloosahatchee River. Thus, the bay may experience frequent extreme fluctuations in salinity during high freshwater flow events during the wet season (i.e., July through November) particularly of wet years. Both seagrass species also occur in the Pine Island Sound area. However, that area is the farthest area downstream of the primary freshwater source (i.e., S-79) and experiences few extreme variations in salinity. Likewise, the effects of the alternatives on seagrass habitat suitability in Pine Island sound were modeled separate from the Iona Cove and San Carlos Bay areas. Although all of these areas were modeled using the HSIs, the San Carlos Bay area was used for the HU calculations. The team decided that this area was most representative, as it contains both *Halodule* and *Thalassia*, and best reflects the impacts of differing alternatives.

FIGURE C-4: MAP OF SEAGRASS

C.1.3 HSI Overview

The purpose of this habitat suitability model for the Caloosahatchee River (C-43) West Basin Storage Reservoir project is to portray species response to changes in environmental variables resulting from restoration activities spatially and temporally to facilitate policy decisions. The intent of the habitat suitability model is not to simulate the life-cycles of the species. Rather, the intent is to estimate number of HUs to serve as a relative basis for comparing management alternatives.

Complete documentation on the oyster, *vallisneria*, and seagrass HSI models are available in this Appendix..

C.1.3.1 HSI species

Species selected for modeling (focal species) are ecologically, recreationally or economically important and have a well established linkage to stressors of management interest. They may also make good focal species because they engage the public in caring about the outcome of restoration projects. The habitat suitability models (HSI) were developed by choosing specific life stages of each species with the most limited, restricted, or tightest range of suitable conditions, to capture the highest sensitivities of the organisms to the environmental changes associated with the planned restoration activities.

The project team originally decided to use seven species–eastern oysters, blue crabs, *Vallisneria*, seagrass (*Halodule* and *Thalassia*), spotted seatrout, decapod larvae, and zooplankton. Once all models were run on all alternatives, the team decided to narrow down the full analysis to three species–oysters, *Vallisneria* and seagrass. It was useful to run all of the species models, as they affirmed that all species showed an improvement over base conditions. However, it was determined that some species would be dropped for purposes of quantification for the final analysis because:

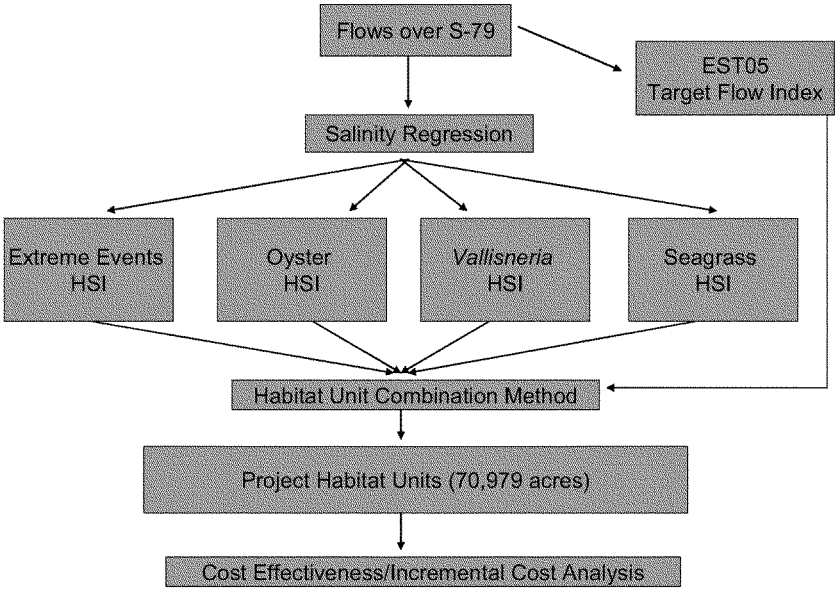
- they were less sensitive to changes between alternatives
- they were redundant and added little additional value
- the team decided to focus on habitats rather than individual species

The chosen species also cover a full range of both temporal and spatial attributes–oysters are found in the middle estuary and are impacted by both wet and dry season, seagrass are found in the lower estuary and are most impacted by the wet season, and *Vallisneria* is found in the upper estuary and is most impacted by the dry season.

C.1.3.2 Importance of Seasonality for This Project

Upon review of the data, there is little value in averaging all HSIs for all seasons of all years. The purpose of the Caloosahatchee River (C-43) West Basin Storage Reservoir project is to help moderate flows–reduce flows during high flow periods and augment flows during low flow periods. Therefore, in order to present benefits, the impact must be determined during those periods of time. Thus the benefits were calculated using the appropriate seasons to reflect when species are most impacted. Wet years analyzed include 1979, 1982, and 1983. Dry years include 1980, 1981, and 1985. The wet season was defined as June through November. The dry season was defined as December through May.

C.1.3.3 HSI Assumptions



The following is a list of assumptions for the HSI models:

- Linear relationship between the index and individual habitat parameter
- Positive relationship between the index and habitat carrying capacity
- Time scales are appropriate to capture change
- Spatial scale appropriate to capture change
- Variables strongly correlated with habitat quality and can be quantified by the model
- Habitat quality for selected species is a good indicator of habitat quality for other estuarine species
- Input data used to create HSI curves are reliable
- Where local data is lacking, data is from other regions/estuaries are applied to models.

C.1.3.4 Summary of Benefits

The following sub-sections describe the quality index scores for the five attributes studied (three single species, extreme events, and hydrology). Ecological benefit index scores were then combined using a HU combination methodology to produce a single project habitat unit lift. A detailed description of the HSI model for each species, as well as the method for calculation of HUs, can be found later in this appendix. ***Figure C-5*** displays the integration of the indicators in order to calculate HUs.

FIGURE C-5: INTEGRATION OF HSI INDICATORS

C.1.3.4.1 Eastern Oyster Background and Habitat Suitability Index Scores

In the Caloosahatchee Estuary, oysters have been identified as a valued ecosystem component (VEC). Oysters are natural inhabitants of southern estuaries and were documented to be abundant in the system. The Eastern oyster is important for providing reef habitat that serves as areas of concentration (Wells, 1961; Bahr and Lanier, 1981) and as food (Burrell, 1986) for numerous estuarine species including gastropod mollusks, polychaete worms, decapod crustaceans, various boring sponges, fish, and birds, including the endangered oyster catcher. The Eastern oyster is the dominant species in the oyster reef community. There may be over 40 species of macrofauna living in oyster beds with the total number of species exceeding 300 (Wells, 1961).

Salinity, temperature, depth, substrate, and high flow frequency have been chosen as the particular requirements for determining habitat suitability for the Eastern oyster in the Caloosahatchee Estuary. Specific requirements have been pulled from scientific literature for both adults and larval oysters. For the purpose of alternative selection for the C43 West Basin Reservoir Project, depth and substrate have been turned off or removed from the model. This is because the depth within the model boundaries does not exceed three meters, except for within navigation channels, which are not available areas for restoration.

Including substrate in the model application limits restoration benefits to areas where oysters are already present, as that is the only hard substrate data available to the model. The addition of hard substrate to areas with high habitat suitability would be ideal, but is not part of the recommended plan for this project.

To determine benefits for the oyster, both wet and dry seasons of wet and dry years were considered. Wet periods can impact the oyster by flushing out the larvae. Dry periods make the oyster more susceptible to predation and disease. The oyster is this study's "middle estuary (mesohaline to euhaline)" indicator (***Table C-3***).

Alternative 3c	.61
Alternative 4	.61

C.1.3.4.2 *Vallisneria* Background and Habitat Suitability Index Scores

Vallisneria americana (tape grass) is a salt-tolerant freshwater submerged aquatic vegetation (SAV) species that is located in the fresh, oligohaline, and mesohaline portion of estuaries in the eastern United States. Beds of tape grass can occur in the Caloosahatchee Estuary up to 30 kilometers (km) downstream of S-79 near the Mid-Point Bridge, but grow most luxuriantly upstream of the US-41 Bridges, especially where their greatest coverage occurs around Beautiful Island (Chamberlain and Doering 1998). When conditions are favorable, tape grass exhibits a seasonal pattern of growth, with highest biomass achieved in the late summer, flowering in the late summer-early fall, and a winter decline in biomass (Bortone and Turpin, 2000). Tape grass in the Caloosahatchee does not completely die back in the winter as it does in more temperate northern climates (Dawes and Lawrence, 1989). Laboratory experiments using Caloosahatchee plants determined that tape grass can grow throughout the year provided appropriate salinity and water quality conditions are available. Therefore, freshwater discharge commensurate with a suitable salinity for growth need not separately account for different seasonal or spatial salinity preferences or tolerances (Doering et al., 1999).

Previous condition, salinity, temperature, and light availability have been chosen as the particular requirements for determining habitat suitability for *Vallisneria* in the Caloosahatchee Estuary. "Previous condition" means that the

current month's suitability also depends on the how well the grass was doing last month.

To determine benefits for *Vallisneria*, the team looked at the dry season of dry years. *Vallisneria* prefers freshwater, so when the estuary does not receive enough flow and high salinities move into the upper estuary, the *Vallisneria* will suffer (***Table C-4)***.

Alternative 3c	.35
Alternative 4	.35

C.1.3.4.3 Seagrass Background and Habitat Suitability Index Scores

Beds of SAV are important to the ecology of shallow estuarine and marine environments. These beds provide habitat for many benthic and pelagic organisms, function as nurseries for juveniles and other early life stages, stabilize sediments, improve water quality, and can form the basis of a detrital food web (Kemp et al., 1984; Fonseca and Fisher, 1986; Carter et al., 1988; Killgore et al., 1989; Lubber et al. 1990). Because of their importance, estuarine restoration initiatives often focus on SAV (Batiuk et al., 1992; Johansson and Greening, 2000; Virnstein and Morris, 2000). SAV are commonly monitored to gauge the health of estuarine systems (Tomasko et al., 1996) and their environmental requirements can form the basis for water quality goals (Dennison et al., 1993; Stevenson et al., 1993).

In the Caloosahatchee Estuary, field and laboratory research was conducted by South Florida Water Management District (SFWMD) over a wide range of flows and salinities. This information, along with the results from researchers in other systems is used to estimate maximum freshwater inflow limits and associated water quality requirements to protect and restore *Halodule wrightii* (shoal grass) and *Thalassia testudinum* (turtle grass). Previous condition, salinity, temperature, and light availability have been chosen as the particular requirements for determining habitat suitability for seagrasses in the Caloosahatchee Estuary. "Previous condition" means that the current month's suitability also depends on the how well the grass was doing last month. This reflects the extended recovery period for seagrasses.

To determine benefits for seagrass, the team considered wet seasons of wet years. Seagrass is a marine organism that prefers high salinity conditions. When excess fresh water is flushed through the estuary, the salinity dips extremely low, stressing the seagrasses in the lower estuary (***Table C-5***).

C.1.3.5 Extreme Events Background and Habitat Suitability Index Scores

The extreme event attribute is perhaps the best indicator of how the reservoir alternatives will perform during high and low flow events. This calculation indicates the lift in benefits for Eastern oyster (wet and dry months), *Vallisneria* (dry months), and seagrass (wet months) during the three most extreme (wettest and driest) events for the nine-year period of record analyzed. This benefit is calculated by averaging the HSI for the most stressful months (based on highest and lowest average monthly flows during model runs for 2050 without project conditions) in the period of record for each of the three species. The months and years used were as follows:

- Wet October 82, March 83, April 83
- Dry March 81, April 81, May 81

After a score is calculated for each species during the extreme events, the HSI of the three species is averaged for a final extreme event HSI score (***Table C-6***).

TABLE C-6: EXTREME EVENTS HSI SCORES

Alternative 4	.45

C.1.3.6 EST05 Background and Quality Index Scores

EST05 is a hydrologic target for a suite of estuarine organisms. Because it represents a time series/flow range necessary for an ecological balance within the estuary, it may not reflect the optimal hydrology for any one species. Because all of the species indicators are also somewhat dampened by the effect of averaging over months, seasons, spatially, the team thought it would be beneficial to have at least one benefit stream that depicts a more accurate picture of how well each alternative is matching this target flow. This is why a benefit stream has been derived by the percentage of fit to EST05. This time series of flows was initially created to benefit the ecology of the estuary and as a result, an alternative that can most closely mimic this time series would be most beneficial to the estuary as a whole.

A method for evaluating flows associated with the Caloosahatchee River (C-43) West Basin Storage Reservoir project was developed to easily compare potential project flows (cubic feet/second) with the percent distribution of the target flows from S-79 for any time period (one year or longer). The resulting index scale (0-1) reflects the relative amount that the project related flows move toward the target flows (score of 1) from the base condition (score of 0) for the period being evaluated. For application purposes, the Caloosahatchee River (C-43) West Basin Storage Reservoir project used the year 1982 as the base condition to calculate the TFI BC (target flow index base condition) for the representative years 1978-1986 that were evaluated by the project. This year represents the worst single year regarding flows that exceed EST05 on both the dry and wet extremes (***Table C-7***). This score can then be expressed as the percent toward achieving the target flows (percent of target achieved, or PTA). See TFI documentation for more information.

Alternative 4	.79

C.1.3.7 Habitat Unit Combination Methodology

After a quality index was determined for each benefit stream, these were combined to calculate a total project HU score. This was done with the HUCM. Please refer to ***Figure C-6*** below.

FIGURE C-6: HABITAT UNIT COMBINATION METHODOLOGY

In order to use the HUs for the project in further comparisons (such as cost effectiveness/incremental cost analysis [CE/ICA]), it is useful to produce one single HU number for the project. Therefore a HUCM was created. The basis of the HUCM is that the total quality index values in any one area are summed and then divided by the total number of quality index scores for that area to find an average quality score for the area. Then that score is multiplied by the number of acres for that area. Two of the attributes cover the entire area of benefit (extreme event and EST05). Therefore, all areas have at least those two scores in addition to any species specific HSI values. For example, the only species specific HSI calculated for the area in red in ***Figure C-6*** was for oysters. To calculate the HUCM, the oyster score would be added to the extreme event score and the EST05 score, and the total would be divided by three. That value would then be multiplied by the number of acres in red. The HUs calculated for each area are then added together to quantify the total HUs for the project. By using this method, there is no "double counting" of benefits, even where scores have been calculated for overlapping attributes.

Based on ***Figure C-6*** above, the equation to calculate the total HUs for the Caloosahatchee River (C-43) West Basin Storage Reservoir project using the HUCM is as follows:

Total Project Habitat Units =
((*Vallisneria* score + Extreme Event score + EST05 score)/3) x 4130) +

((Oyster score + Extreme Event score + EST05 score)/3 x 2392) +
((Seagrass score + Extreme Event score + EST05 score)/3 x 9041) +
((Seagrass score + Oyster score + Extrem e Event score + E ST05 score)/4 x 3506) +
((Extreme Event score + EST05 score)/2 x 51910)

See ***Table C-8*** for the total average annual HUs for each alternative calculated using HUCM.

TABLE C-8: TOTAL AVERAGE ANNUAL HABITAT UNITS SCORES

Alternative	Average Annual Project Habitat Units
Alternative 2	10,628
Alternative 3B	12,809
Alternative 3C	16,397
Alternative 4A	15,907

C.1.3.8 Conclusions

Because of the complex, three dimensional nature of this ecosystem, there is no one benefit stream which tells the full story. The team used the HUCM to calculate a total project HU lift. Based on the methodology described in this section, the team has concluded that Alternative 3C has the highest number of HUs and therefore shows the most improvement to the estuary.

C.2 NAI ENVIRONMENTAL BENEFIT ANALYSIS

The system-wide formulation was conducted to determine the input for the CE/ICA and assist in the selection of the recommended plan. An additional analysis was also conducted to use in justifying and describing the benefits of the Caloosahatchee River (C-43) West Basin Storage Reservoir as a stand-alone project without the system-wide benefits attributed to other CERP projects, otherwise known as the NAI analysis.

An identical method was used for the NAI as was used for the system formulation (LAI). As described in the LAI analysis, five attributes were studied to determine system response. Oysters, *Vallisneria*, seagrasses, extreme events and EST05 were all measured and compared to 2050 in order to determine the benefit lift for the Selected Alternative Plan (SAP) (***Table C-9***). This methodology is described in the environmental benefits evaluation section.

Although the NAI and LAI are listed below, this is not a valid comparison due to different sources of data for the two analyses. Therefore, even though the HSIs are similar, the total project average annual HUs are based on different 2050

model conditions, resulting in a larger lift for the NAI analysis. The NAI analysis reflects 28 percent more benefits than the system-wide formulation. There are several variables which could explain the higher benefits with the NAI approach. The first and most influential of these results from the rest of CERP's impact on the overall water budget provided to the Caloosahatchee River (C-43) Basin. The system-wide analysis has a lower water budget than the NAI analysis, leading to diminished dry season conditions. The other variances may stem from differing models being utilized for the benefit analysis. The system-wide analysis utilized the MIKESHE model and the NAI run utilized spreadsheet flow models.

TABLE C-9: COMPARISON OF NAI AND LAI SCORES

Alternative	Oyster	Vallisneria	Seagrass	Extreme Events	EST05	Total Projec t Average Annual Habitat Units
3B LAI	.60	.33	.59	.43	.70	12,809
3B NAI	.59	.33	.52	.24	.70	15380

C.2.1 Conclusions

Both the system formulation (LAI) and the NAI evaluations of the selected plan demonstrate significant ecological benefits due to implementation of the Caloosahatchee River (C-43) West Basin Storage Reservoir project.

C.3 HABITAT SUITABILITY INDEX PROCESS

C.3.1 Background

The forecasting model used to evaluate alternatives for the Caloosahatchee River (C-43) West Basin Storage Reservoir project consisted of a set of stressor-response (habitat suitability) models for individual species. These HSI models were developed from scientific literature, expert knowledge, and available field data. The HSIs portray each stressor variable spatially and temporally across the study area at a scale appropriate to the organism or community being portrayed. HSI models were incorporated into a GIS to describe responses spatially and temporally for the selection of restoration alternatives for each project.

Models were created for species of ecological, recreational, or economic importance, or because they engage the public in caring about the outcome of restoration projects. The models include the Eastern oyster (*Crassostrea virginica*), blue crab (*Callinectes sapidus*), spotted seatrout (*Cynoscion nebulosus*), wild celery (*Vallisneria americana*), turtle grass (*Thalassia testudinum*), shoal grass (*Halodule wrightii*), and selected species of zooplankton. Additionally, each model has a well-established linkage to

stressors of management interest. Habitat suitability for each species was determined using specific life stages of the organism with the most limited, restricted, or tightest range of suitable conditions. By doing this, the highest sensitivities of the organisms to environmental changes associated with the planned restoration activities are captured. For the Eastern oyster, habitat suitability is modeled for both adult and larvae life stages because of the tighter range of suitable conditions necessary for larval success. The adult blue crab tolerates a very wide range of salinity conditions, so the limiting conditions for successful blue crab habitat are the more restricted conditions necessary for blue crab recruitment. As a result, the blue crab HSIs are focused on the megalopae larvae and spawning female life stages. Spotted seatrout require specific conditions for forage and spawning, including suitable habitat and the proximity of that habitat to deeper refugia. Flow is important, as large inputs of freshwater can cause spotted seatrout eggs to sink, reducing survival of the larvae. Therefore, the spotted seatrout model will include forage and spawn components.

Each HSI model describes a response surface of habitat suitability values between 0 (unsuitable) and 1 (most suitable) that varies spatially according to stressor levels throughout the estuary and temporally according to temporal patterns in stressor variables. Much of the temporal variation is a result of temporal cycling of important stressor inputs, such as salinity. The models calculate habitat suitability monthly as the weighted geometric mean of the environmental variables identified as important for each model. The geometric mean is derived from the product of the variables rather than the sum (as in the arithmetic mean), and has the appropriate property that if any of the individual variables are unsuitable for species success (i.e., the value of the variable is zero) then the entire index goes to zero. This HSI value was then multiplied by the area within each grid cell and the grid cell values added to calculate HUs for each species. ***Figure C-5*** represents how the various HSIs were combined to generate HU scores and support the CE/ICA effort.

C.3.2 HSI Formulas

Where "w" is a weight between 0 and 1 assigned to each variable and where "previous" means that the current month's suitability also depends on the how well the grass was doing last month (previous score) (e.g. Previous = previous_month_HSI + 0.05 (not to exceed 1.0); this allows for growth from month to month if other conditions are suitable).

C.3.2.1 Spotted Seatrout

Spotted Seatrout HIS $_{(May–October)}$ = MAX (ForageComponent, SpawnComponent)
Spotted Seatrout HSI $_{(November–April)}$ = ForageComponent

Forage Component Index = (HabitatwSeagrass%Cover * Salinity^{w} * Temperature^{w})
Spawn Component Index = (HabitatwDropoff&SeagrassProximity ^{w}* Salinity^{w})
Spawning is May - October

C.3.2.2 Eastern Oyster

Eastern Oyster HIS $_{(May\text{-}November)}$ = MIN (LarvaeComponentIndex, AdultComponentIndex)
Eastern Oyster HIS $_{(December\text{-}April)}$ = (AdultComponentIndex)
LarvalComponentIndex = (Salinity^{w} * Temperature^{w} * Flow^{w})
AdultComponentIndex = (Salinity^{w} * Temperature^{w})

C.3.2.3 Blue Crab

Blue Crab HIS $_{(June\text{-}October)}$ = (LarvaeComponentIndex^{w} + SpawningFemaleComponentIndex^{w})
Blue Crab HIS $_{(March\text{-}May,\ Nov,\ Dec)}$ = (SpawningFemaleComponentIndex)
LarvalComponentIndex = (Salinity^{w} * Temperature^{w} * Flow^{w})
Spawning FemaleComponentIndex = (Salinity^{w} * Temperature^{w})

C.3.2.4 Seagrass

Seagrass HSI = (Previous^{w} * Salinity^{w} * Temperature^{w} * LightAvailability^{w})

C.3.2.5 Vallisneria

Vallisneria HSI = (Previous^{w} * Salinity^{w} * Light Availability^{w} * Temperature^{w})

C.4 HABITAT UNIT CALCULATIONS METHODOLOGY-JANUARY 2007

C.4.1 Habitat Unit Methodology/Rules

This section describes an approach to calculating HUs that was applied in January 2007.

1. Flows over S-79 are calculated using a spreadsheet model or MIKESHE model.
2. These flows are then run through a salinity regression model which outputs a salinity grid for the full area of benefit.
3. These salinities (along with other parameters) are then used as input for the oyster, V*allisneria*, and seagrass HSI models.
4. The following rules were applied to the HSI models (some new model rules, some post processing rules):
   I. Oyster
      i. Mask the core area with no temperature variable

ii. If HSI is less than or equal to .1 in any given month, then the following month is also scored at less than or equal to .1 (this represents the recovery lag)
iii. Include Iona Cove in the potential habitat area
iv. Consider all seasons of three wet years (79, 82, 83) and dry years (80, 81, 85)

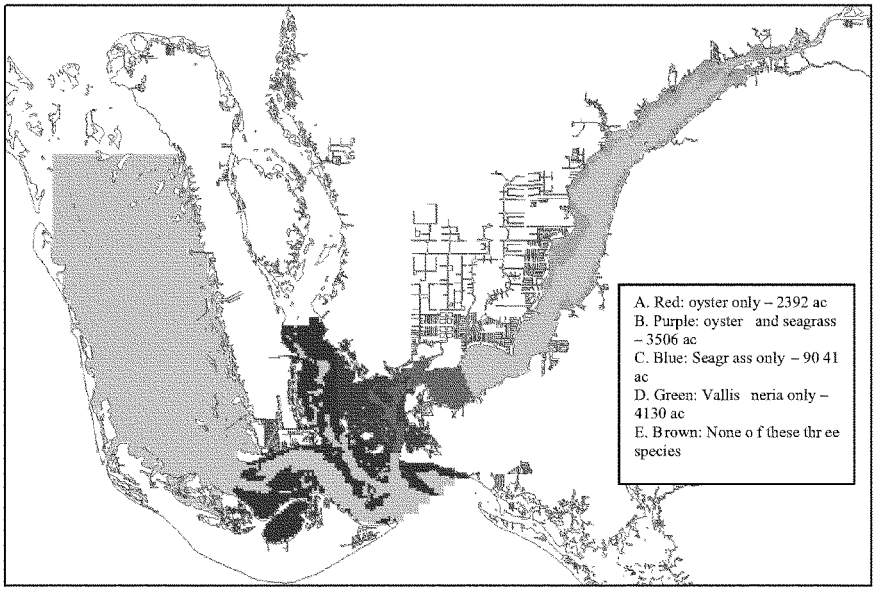
II. Seagrass
i. Apply mask to core area and calculate HSI for San Carlos Bay only, as this is the area with the highest potential for improvement
ii. Establish a lower depth threshold of seven feet in San Carlos Bay
iii. If HSI is less than or equal to .1 in any month, then the HSI stays at less than or equal to .1 for the remainder of that season
iv. Consider wet seasons (June–November) only of three wet years (79, 82, 83)

III. *Vallisneria*
i. Establish a lower depth threshold of five feet
ii. If HSI is less than or equal to .2 for one month, then HSI is less than or equal to .2 for the remainder of that season
iii. If HSI is less than or equal to .1 in any month, then HSI = 0 for 12 subsequent months
iv. Consider dry seasons (December–May) only of three dry years (80, 81, 85)

5. Two additional quality indices were calculated. Those are as follows:

I. Extreme Event
i. This is calculated by averaging the HSI for the most stressful months (based on model runs for 2050 without project conditions) in the period of record for each of the three species. The months and years used were as follows:
ii. Oysters – (wet)Oct 82, March 83, April 83
iii. Oysters - (dry) March 81, April 81, May 81
iv. Vallisneria-March 81, April 81, May 81
v. Seagrasses–Oct 82, March 83, April 83
vi. After each species is averaged, the HSI of the three species is averaged for a final extreme event HSI number.

II. EST05
i. The team wanted to present an accurate picture of how well each alternative was matching the EST05 time series of flows over S-79, as this flow is considered ideal for the overall health of the estuary ecosystem.
ii. A method for evaluating flows associated with the Caloosahatchee River (C-43) West Basin Storage Reservoir project was developed to easily compare potential project flows



(cubic feet/second) with the percent distribution of the target flows from S-79 for any time period (one year or longer). The resulting index scale (0-1) reflects the relative amount that the project related flows move toward the target flows (score of 1) from the base condition (score of 0) for the period being evaluated. For application purposes, the Caloosahatchee River (C-43) West Basin Storage Reservoir project uses the year 1982 as the base condition to calculate the TFI BC for the representative years 1978-1986 that were evaluated by the project. This year represents the worst single year regarding flows that exceed EST05 on both the dry and wet extremes. This score can then be expressed as the percent toward achieving the target flows (percent of target achieved [PTA]). See TFI documentation for more information

C.4.2 Habitat Unit Combination Methodology

After a quality index was determined for each benefit stream, these were combined to calculate a total project HU score. This was done with the HUCM. Please refer to ***Figure C-7*** below.

In order to use the HUs for the project in further comparisons (such as CE/ICA), it is useful to produce one single HU number for the project. Therefore a HUCM was created. The basis of the HUCM is that the total quality index values in any one area are summed and then divided by the total number of quality index scores for that area to find an average quality score for the area. Then that score is multiplied by the number of acres for that area. Two of the attributes cover the entire area of benefit (extreme event and EST05). Therefore, all areas have at least those two scores in addition to any species specific HSI values. For example, the only species specific HSI calculated for the area in red in ***Figure C-7*** was for oysters. To calculate the HUCM, the oyster score would be added to the extreme event score and the EST05 score, and the total would be divided by three. That value would then be multiplied by the number of acres in red. The HUs calculated for each area are then added together to quantify the total HUs for the project. By using this method, there is no "double counting" of benefits, even where scores have been calculated for overlapping attributes.

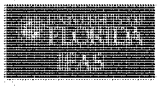


FIGURE C-7: HABITAT UNIT COMBINATION METHODOLOGY JANUARY 2007

Based on ***Figure C-7*** above, the equation to calculate the total HUs for the Caloosahatchee River (C-43) West Basin Storage Reservoir project using the HUCM is as follows:

Total Project Habitat Units =
((*Vallisneria* score + Extreme Event score + EST05 score)/3) x 4130) +
((Oyster score + Extreme Event score + EST05 score)/3 x 2392) +
((Seagrass score + Extreme Event score + EST05 score)/3 x 9041) +
((Seagrass score+ Oyster score+ Extreme Event score + EST05 score)/4 x 3506) + ((Extreme Event score + EST05 score)/2 x 51910)

STRESSOR RESPONSE MODEL FOR THE EASTERN OYSTER, *CRASSOSTREA VIRGINICA*

By Frank J. Mazzotti, Leonard G. Pearlstine, Tomma Barnes, Aswani Volety, Kevin Chartier, Alicia M. Weinstein, and Donald DeAngelis

Introduction

A key component in adaptive management of Comprehensive Everglades Restoration Plan (CERP) projects is evaluating alternative management plans. Regional hydrological and ecological models will be applied to evaluate restoration alternatives and the results will be applied to modify management actions.

Objective

The purpose of this habitat suitability model for the C-43 West Basin Reservoir and Southwest Florida Feasibility Study projects is to portray species responses to changes in environmental variables resulting from restoration activities spatially and temporally to facilitate policy decisions. The intention of the habitat suitability model is not to simulate the life-cycles of the species. Rather, the intent is to estimate numbers of habitat units to serve as a relative basis for comparing management alternatives.

Southwest Florida Feasibility Study

The Southwest Florida Feasibility Study (SWFFS) is a component of the Comprehensive Everglades Restoration Plan (CERP). The SWFFS is an independent but integrated implementation plan for CERP projects and was initiated in recognition that there were additional water resource issues (needs, problems, and opportunities) within Southwest Florida that was not being addressed directly by CERP. The SWFFS identifies, evaluates, and compares alternatives that address those additional water resource issues in Southwest Florida. An adaptive assessment strategy is being developed that will create a system-wide monitoring program to measure and interpret ecosystem responses. The SWFFS provides an essential framework to address the health and sustainability of aquatic systems. This includes a focus on water quantity and quality, flood protection, and ecological integrity.

C43 West Reservoir

The purpose of the C43 Basin Storage Reservoir project is to improve the timing, quantity, and quality of freshwater flows to the Caloosahatchee River estuary. The project includes an above ground reservoir with a total storage capacity of approximately 197 million

cubic meters (160,000 acre-feet) and will be located in the C-43 Basin in Hendry, Glades, or Lee Counties. The initial design of the reservoir assumed 8094 hectares (20,000 acres) with water levels fluctuating up to 2.4 meters (8 feet) above grade. The final size, depth and configuration of this facility will be determined through more detailed planning and design.

Forecasting Models

Forecasting models bring together research and monitoring to ecosystems of Southwest Florida and place them into an adaptive management framework for the evaluation of alternative plans. There are two principle ways to structure adaptive management: (1) *passive* by which policy decisions are made based on a forecasting model and the model is revised as monitoring data become available, and (2) *active* by which management activities are implemented through statistically valid experimental design to better understand how and why natural systems respond to management (Wilhere 2002).

In an integrated approach that includes both passive and active-adaptive management, a forecasting model simulates system response and is validated by monitoring programs to measure actual system response. Monitoring can then provide information for passive-adaptive management for recalibration of the forecasting model. Directed research, driven by model uncertainties, is an active-adaptive management strategy for learning and the reduction of uncertainties in the model.

The forecasting models for the C-43 West Reservoir Project and the Southwest Florida Feasibility Study consist of a set of stressor response (habitat suitability) models for individual species. These stressor response models have been developed principally with literature, expert knowledge, and currently available field data.

Habitat Suitability Indices

Habitat Suitability Indices (HSI) models were developed with each stressor variable portrayed spatially and temporally across systems of the study area at scales appropriate to the organism or community being portrayed. The HSI models have been incorporated into a GIS to portray responses spatially and temporally to facilitate policy decisions. That is, the model describes a response surface of habitat suitability values that vary spatially according to stressor levels throughout the estuary and temporally according to temporal patterns in stressor variables. Much of the temporal variation is a result of temporal cycling of important stressor inputs, such as water temperature and salinity. Temporal change for other important variables may not be cyclical, such as rising sea level and increasing land use and fresh water demands in the region. Areas predicted to be suitable and those predicted to be less suitable or disturbed should be targeted for additional sampling as part of the model validation and adaptive management process.

Species selected for modeling (focal species) are ecologically, recreationally or economically important and have a well established linkage to stressors of management interest. They may also make good focal species because they engage the public in caring about the outcome of restoration projects. The habitat suitability models (HSI) were developed by choosing specific life stages of each species with the most limited, restricted, or tightest range of suitable conditions, to capture the highest sensitivities of the organisms to the environmental

2

changes associated with the planned restoration activities. Values used in the models are listed in Table 1.

The models calculate habitat suitability monthly as the weighted arithmetic mean of the environmental variables identified as important for each model.

Ecology of the Eastern Oyster

The eastern oyster is a bivalve in the family Ostreidae. It is important both commercially and recreationally in fisheries along the Atlantic and Gulf of Mexico coasts of North America. It requires a proper substrate and suitable salinity conditions for existence. Due to its sedentary nature, the Eastern oyster is susceptible to undesirable natural and artificial environmental changes, as well as pollution within its habitat. Environmental disruptions are responsible for reducing oyster populations and their traditional habitats (Cake 1983).

Eastern oysters live in estuaries and behind barrier islands from the Gulf of St. Lawrence, Canada, through the Gulf of Mexico to the Bay of Campeche, Mexico, and into the West Indies. They exist in every major bay system within their range but are not evenly distributed among or within bays. The availability of clean, firm substrate sites for attachment restricts the distribution of Eastern oyster. The Eastern oyster is most abundant in the Gulf of Mexico, Chesapeake Bay, and Long Island Sound (Stanley and Sellers 1986).

Eastern oysters filter feed for planktonic organisms and detritus. They are prey to protozoan, anemones, coelenterates, helminths, mollusks, crustaceans, and fish (Berrigan et al.1991; Tolley et al. 2005). In the Gulf of Mexico, Eastern oysters typically reach about 3" long in 18–24 months and 5.9" long in 5 or 6 years. They can live as long as 25 to 30 years and reach a maximum size of 11.8". Eastern oysters are protandrous hermaphrodites, but can become alternate hermaphrodites after an initial male state, even alternating sex within a spawning season (Galtsoff 1964). Maturity is reached in as little as 4 weeks after setting.

The eastern oyster in the Gulf of Mexico spawns between March and November (Butler 1954). Locally oyster spawning begins late March and continues through October, with most larvae present May through November specifically in the Caloosahatchee estuary between March or April and October (Volety per. com. 2004). Gametogenesis and spawning are initiated and maintained when water temperatures reach about 20 °C with mass spawning at temperatures above 25°C in the Gulf of Mexico (Stauber 1950, Schlesselman 1955, Hopkins 1931, Ingle 1951, Menzel 1955, Hayes and Menzel 1981), and locally between 26°C and 28°C (Savarese et al. 2003, 2004, Volety et al. 2003). Optimal salinity for spawning is 10‰-30‰ (Menzel 1951). Males are usually the first to spawn, and their spermatozoa and gamones stimulate other males and females to spawn. Eggs and sperms are released directly into the water column and fertilization is external (Galtsoff 1964). Mature oysters spawn numerous times through the spawning season but peaks are in late spring when water temperatures increase and in fall when water temperatures begin to drop (Pollard 1973). Each female produces 23 to 86 million eggs per spawning (Davis and Chanley 1955). The egg hatches 6 hours after fertilization at water temperatures near 24°C (Loosanoff 1965, Berrigan et al. 1991).

Oyster larvae are meroplankton and develop in the water column within the estuary. At the larval stage, the Eastern oyster is able to withstand a wide range of salinities and salinity tolerance depends on the salinity at which the parents were held during gametogenesis (Davis 1958). Hopkins (1931) monitored abundances of larvae and spat in Texas and found that even

3.

though the water was well populated with larvae, they would not attain setting stage unless salinities reaches 20‰ to 21‰. In Louisiana, setting occurred at 10‰ to 22‰ with a peak at 20‰ to 22‰ (Chatry et al 1983). Other authors say that metamorphosing oyster larvae will set at salinities between 5‰ and 35‰ with optimal setting occurring between 10‰ and 30‰ and peaks at 18‰ to 22‰ (Carriker 1951, Davis 1958, Calabrese and Davis 1970, Chantry and Dugus (MS). Locally, optimal salinities for oyster larvae appear to be between 10‰ to 30‰ and the most favorable being between 15‰ and 25‰ (Savarese et al. 2003, 2004, Volety et al. 2003).

Water temperatures that are above or below seasonal norms shorten or lengthen, respectively, the normal 2 week larval development period (Cake 1983). Under laboratory conditions larvae held at 30°C began to settle 10-12 days after fertilization, larvae held at 24°C set after 24-26 days, but few larvae held at 20°C set within 35 days (Loosanoff and Davis 1963). Optimal water temperatures for growth range from about 20°C to 30°C (Stanley and Sellers 1986). In Southwest Florida, favorable temperatures tend to be slightly higher at 26° to 30°C (Savarese et al. 2003, 2004, Volety et al. 2003).

Oyster larvae must settle on a relatively clean, sediment-free, stable surface that is not heavily fouled with other encrusting organisms (Cake 1983) in areas with stable salinities (Stanley and Sellers 1986). It will attach to a variety of materials including occupied or empty oyster shells, calcareous remains of other mollusks, wooden materials, rocks, gravel, and solid refuse (Hedgpeth 1953, Butler 1954, Lunz 1958, Galtsoff 1964, Gunter and Demoran 1971, Mackenzie 1977, 1981, 1983). Optimal cultch material includes shells of live or recently dead oysters and calcareous remains of other estuarine mollusks (Butler 1054, Galtsoff 1964, Gunter and Demoran 1971, Mackenzie 1977, 1981, 1983). Successful colonies occur at depths from 0.3 m (1 ft) above mean low water to 12m (40 ft) (Butler 1954). Optimal depth in the Gulf of Mexico estuaries is .5 m to 3 m (Volety pers. com. 2003).

Adult oysters are sessile. Their distribution depends on where the larvae set and on the subsequent survival of the spat. Oysters are filter feeders and may filter 1500 times their body volume in and hour (Loosanoff and Nomejko 1946). Adult oysters typically live in clumps called reefs, beds, or bars. Most growth occurs during the first 3 months of life and is influenced by temperature, salinity, intertidal exposure, turbidity, food, and position and density in the oyster reef (Stanley and Sellers 1986). The Eastern oyster is the dominant species in the oyster reef community, with over 40 additional macrofaunal species or groups living in oyster beds (Bahr and Lanier 1981; Savarese et al. 2003, 2004, Tolley et al. 2005). Predators, diseases, and parasites can affect oyster populations and limit the abundance of oysters.

American oysters in the Gulf of Mexico have a normal salinity range of 10‰ to 30‰ but can survive in salinities from 5‰ to 40‰ (Gunder and Geyer 1955, Butler 1954, Galtsoff 1964, Stenzel 1971). Optimal salinity ranges for physiological purposes, food abundance, and stenohaline predator avoidance is 10‰ to 20‰ (Butler 1954, Eleuterius 1977). Larval settlement and growth is decreased at low salinities and peaks at 25‰ – 29‰ (Menzel et al. 1966, Chatry et al. 1983) and 20‰ -22‰ (Castagna and Chanley 1973), respectively.

Oysters can tolerate ambient water temperatures from 1°C to 49°C (Galtsoff 1964), but typically stop feeding at 6°-7°C and at 42°C most physiological processes stop or are greatly reduced (Galtsoff 1964). Optimal water temperatures for growth, reproduction, and survival range from about 20°C to 30°C (Stanley and Sellers 1986). In the Gulf of Mexico, oysters

cannot withstand freezing temperatures or temperatures above 37°C (Copeland and Hoese 1966, Cake 1983). In South Florida, cold temperatures are not a problem for oysters but high temperatures often can be. Local studies show that adult oysters do best at temperatures between 20°C and 32°C and peak at between 23°C and 30°C (Savarese et al. 2003, 2004, Volety et al. 2003).

HSI for the Eastern Oyster

In the Caloosahatchee Estuary, oysters have been identified as a Valued Ecosystem Component (VEC). Oysters are natural components of southern estuaries and were documented to be abundant in the system. The Eastern oyster is important for providing reef habitat that serves as areas of concentration (Wells 1961, Bahr and Lanier 1981) and as food (Burrell 1986) for numerous estuarine species including gastropod mollusks, polychaete worms, decapod crustaceans, various boring sponges, fish, and birds, including the endangered oyster catcher. The Eastern oyster is the dominant species in the oyster reef community. There may be over 40 species of macrofauna living in oyster beds with the total number of species exceeding 300 (Wells 1961).

Salinity, temperature, depth, substrate, and high flow frequency have been chosen as the particular requirements for determining habitat suitability for the Eastern oyster in the Caloosahatchee Estuary. Specific requirements have been pulled from scientific literature are listed, along with their source, in the table below for both adults and larval oysters. For the purpose of alternative selection for the C43 West Basin Reservoir Project, depth and substrate have been turned off or removed from the model. This is because the depth within the model boundaries does not exceed 3 meters, except for within navigation channels, which are not available areas for restoration. Including substrate in the model application limits restoration benefits to areas where oysters are already present, as that is the only hard substrate data available to the model. The addition of hard substrate to areas with high habitat suitability will be included as part of the restoration plan.

A user interface for running coastal southwestern Florida HSI models is documented in Mazzotti *et al.* (2006).

HSI Formula

Oyster

Calculated monthly

Component Indices are the weighted geometric mean of the variables. The final HSI is an arithmetic mean of the larval and adult component indices.

Eastern Oyster *LarvalComponentIndex* = (Salinity^{w} * Temperature^{w} * Flow^{w})

Eastern Oyster *AdultComponentIndex* = (Salinity^{w} * Temperature^{w})

$HSI_{May\text{-}November}$ = MIN (*LarvaeComponentIndex* + *AdultComponentIndex*)

$HSI_{December\text{-}April}$ = (*AdultComponentIndex*) where:

The default weight, $w = 1/(number\ of\ variables)$. The weight can take on different values for the different variables, however, the sum of the weights must be equal to one.

Temperature values used in model are average monthly water temperatures and do not change with hydrologic alternatives.

STRESSOR RESPONSE MODEL FOR *Vallisneria americana*

By Frank J. Mazzotti, Leonard G. Pearlstine, Robert H. Chamberlain, Melody J. Hunt, Tomma Barnes, Kevin Chartier, and Donald DeAngelis

Introduction

A key component in adaptive management of Comprehensive Everglades Restoration Plan (CERP) projects is evaluating alternative management plans. Regional hydrological and ecological models will be applied to evaluate restoration alternatives and the results will be applied to modify management actions.

Southwest Florida Feasibility Study

The Southwest Florida Feasibility Study (SWFFS) is a component of the Comprehensive Everglades Restoration Plan (CERP). The SWFFS is an independent but integrated implementation plan for CERP projects and was initiated in recognition that there were additional water resource issues (needs, problems, and opportunities) within Southwest Florida not being addressed directly by CERP. The SWFFS identifies, evaluates, and compares alternatives that address those additional water resource issues in Southwest Florida. An adaptive assessment strategy is being developed that will create a system-wide monitoring program to measure and interpret ecosystem responses. The SWFFS provides an essential framework to address the health and sustainability of aquatic systems. This includes a focus on water quantity and quality, flood protection, and ecological integrity.

C43 West Reservoir

The purpose of the C43 Basin Storage Reservoir project is to improve the timing, quantity, and quality of freshwater flows to the Caloosahatchee River estuary. The project's initial phase includes an above-ground reservoir with a total water storage capacity of approximately 170,000 acre-feet and will be located in the C-43 Basin in Lee County. The initial design of the reservoir assumed 8094 hectares (20,000 acres) with water levels fluctuating up to 2.4 meters (8 feet) above grade. The final size, depth and configuration of this facility will be determined through more detailed planning and design.

Forecasting Models

Forecasting models bring together research and monitoring to ecosystems of Southwest Florida and place them into an adaptive management framework for the evaluation of alternative plans. There are two principle ways to structure adaptive management: (1) *passive* by which policy decisions are made based on a forecasting model and the model is revised as monitoring data

become available, and (2) *active* by which management activities are implemented through statistically valid experimental design to better understand how and why natural systems respond to management (Wilhere 2002).

In an integrated approach that includes both passive and active-adaptive management, a forecasting model simulates system response and is validated by monitoring programs to measure actual system response. Monitoring can then provide information for passive-adaptive management for recalibration of the forecasting model. Directed research, driven by model uncertainties, is an active-adaptive management strategy for learning and the reduction of uncertainties in the model.

The forecasting models for the C-43 West Reservoir Project and the Southwest Florida Feasibility Study consist of a set of stressor response (habitat suitability) models for individual species. These stressor response models have been developed principally with literature, expert knowledge, and currently available field data.

Habitat Suitability Indices

Habitat Suitability Index (HSI) models were developed with each stressor variable portrayed spatially and temporally across systems of the study area at scales appropriate to the organism or community being portrayed. The HSI models have been incorporated into a GIS to portray responses spatially and temporally to facilitate policy decisions. That is, the model describes a response surface of habitat suitability values that vary spatially according to stressor levels throughout the estuary and temporally according to temporal patterns in stressor variables. Much of the temporal variation is a result of temporal cycling of important stressor inputs, such as water temperature and salinity. Temporal change for other important variables may not be cyclical, such as rising sea level and increasing land use and fresh water demands in the region. Areas predicted to be suitable and those predicted to be less suitable or disturbed should be targeted for additional sampling as part of the model validation and adaptive management process.

Species selected for modeling (focal species) are ecologically, recreationally or economically important and have a well-established linkage to stressors of management interest. They may also make good focal species because they engage the public in caring about the outcome of restoration projects. The habitat suitability models (HSI) models were developed by choosing specific life stages of each species with the most limited, restricted, or tightest range of suitable conditions, to capture the highest sensitivities of the organisms to the environmental changes associated with the planned restoration activities. Values used in the models are listed in Table 1.

The models calculate habitat suitability monthly as the weighted geometric mean of the environmental variables identified as important for each model. Because the geometric mean is derived from the product of the variables rather than the sum (as in the arithmetic mean) and has the appropriate property that if any of the individual variables are unsuitable for species success (i.e., the value of the variable is zero) then the entire index goes to zero.

Ecology of *Vallisneria americana*

One of the factors contributing to high productivity in estuaries has been the historic abundance of submerged aquatic vegetation (SAV). SAV also provide food for waterfowl and are critical habitat for shellfish and finfish. In addition, submerged plants affect nutrient cycling, sediment stability, and water clarity (Batiuk et al. 1992). Because SAV beds provide habitat for

benthic and pelagic organisms, many of their water chemistry requirements overlap, including preferred salinity and temperature ranges. However, SAV also serve well as indicators of water clarity and nutrient levels. Habitat requirements developed for fish and birds do not normally incorporate these conditions. In addition, "many of the restoration goals for fish and birds involve changes in both environmental quality and management of human harvesting activities" (Dennison et al. 1993). In contrast, SAV goals can more directly be linked to environmental and water quality, thus providing for more direct establishment of targets and protection goals in areas of the estuary where SAV are located (Batiuk et al. 1992, Dennison et al. 1993, Doering et al. 2002).

Tape grass, *Vallisneria americana*, is a salt-tolerant freshwater SAV species that is located in the fresh, oligohaline, and mesohaline portion of estuaries in the eastern United States. Beds of tape grass can occur in the Caloosahatchee Estuary up to 30 km downstream of S-79 (near Area 4: Figure 1), but grow most luxuriantly upstream of Area 3, especially where their greatest coverage occurs around Area 2 and Beautiful Island (Chamberlain and Doering 1998a, and b). Like other populations in Florida (Dawes and Lawrence 1989), tape grass in the Caloosahatchee does not completely die back in the winter as it does in more temperate northern clines. Field observations indicate that mature plants can be found year round that probably are of a sufficient height and density to provide habitat for other organisms. Field observations also indicate that canopy height and shoot density (Figure 2; SFWMD 2003) begin to decline as salinity rises above 10‰ (Chamberlain and Doering 1998a, Bortone and Turpin 2000). When conditions are favorable, tape grass exhibits a seasonal pattern of growth, with highest biomass achieved in the late summer (Figure 3, SFWMD 2006), flowering in the late summer-early fall, and a winter decline in biomass (Bortone and Turpin 2000). Laboratory experiments using Caloosahatchee plants also determined that tape grass can grow throughout the year (Figure 4; SFWMD 2003) provided that conducive salinity and sufficient light are available (Barko et al. 1984, Bortone and Turpin 2000). Therefore, freshwater discharge commensurate with a suitable salinity and clarity need not separately account for different seasonal or spatial tolerances (Doering et al. 1999).

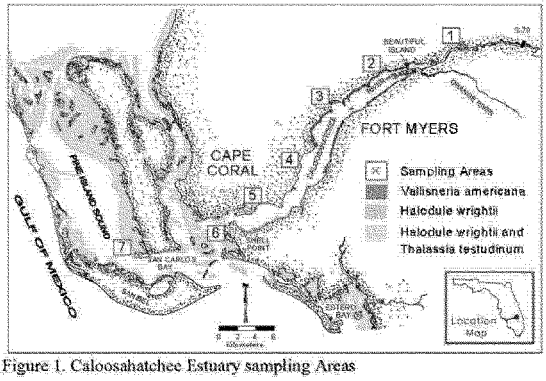

Figure 1. Caloosahatchee Estuary sampling Areas

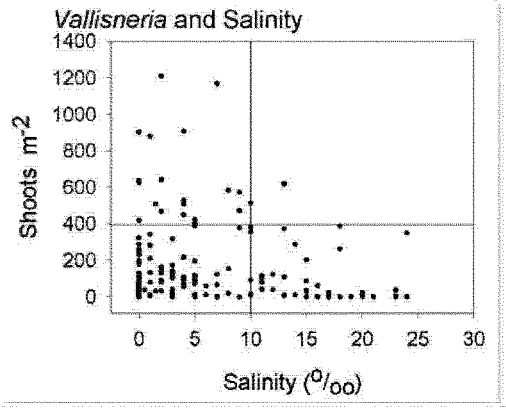

Figure 2. Field survey results of shoot counts vs. salinity (SFWMD 2003).

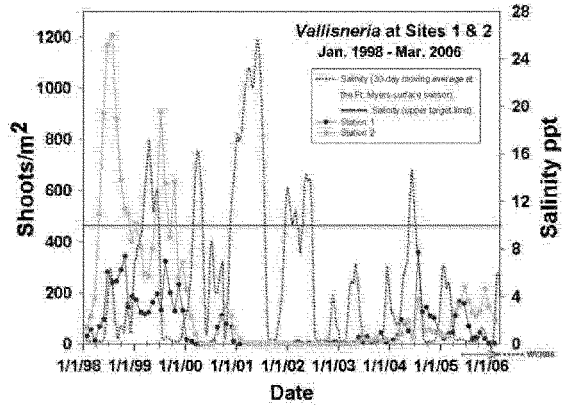

Figure 3. Tape grass (*Vallisneria americana*) shoot density in the upper Caloosahatchee Estuary (Sites 1 and 2 in Area 2, Figure 1). Recent data are from stations monitored by the Sanibel-Captiva Conservation Foundation and Mote Marine Laboratory (SFWMD 2006).

4

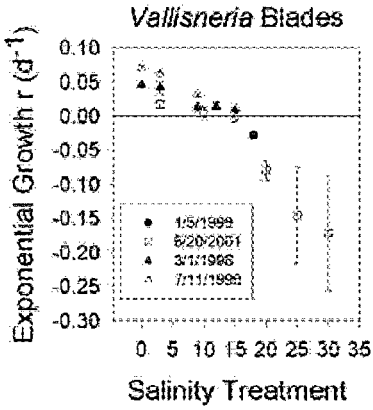

Figure 4. Laboratory experimental results of growth rate vs. salinity (SFWMD 2003).

General non-quantitative observations of tape grass during 1956-1989 found that relative abundance greatly varied annually throughout its range (Chamberlain et al. 1995) and indicated that healthy plants during the winter dry season lead to good coverage, taller plants, and reproduction during the peak summer growing months. Quantitative sampling since 1998 confirms this observation (Bortone and Turpin 2000).

In the upper estuary, temporal and spatial fluctuation in salinity and other important water quality parameters are largely driven by freshwater discharge at S-79. During periods of high discharge, usually during the summer wet season, the system turns fresh. During periods of low discharge during the winter and spring, salt water intrudes up the estuary.

Literature information, field studies, and laboratory investigations of tape grass salinity tolerance (SFWMD 2003) was used to establish hydrologic targets for developing the Minimum Flow and Level Rule (as per Florida Administrative Code, Section 40E-8.021(24)). After analysis of historical salinity records from the estuary along with an initial salinity model, a flow of 300 cfs from S-79 (Figure 5) was identified as the average minimum flow needed (SFWMD 2003) to support tape grass growth in the critical region of the estuary where it has historically been most abundant (Figure 1; Area 2). This designated flow volume, along with about 200 cfs input from the tidal tributaries and ground water, should maintain salinity at $\leq$ 10‰ under average conditions and support tape grass growth. The MFL rule includes two salinity criteria measured near the Ft. Myers Yacht Basin (near Area 3, Figure 1). An MFL exceedance occurs if: (1) the 30-day moving average salinity rises above 10‰ or (2) a single daily average salinity rises above 20‰. The first criterion recognizes that tape grass in the critical region (Figure 1; Area 2) grows well at salinity below 10‰. The second accounts for the effect of exposure to high salinity for short time periods. Upon additional consideration and analysis (Chamberlain 2005, Chamberlain and Doering 2004), a

minimum flow of 450 cfs is now promoted to better insure tape grass protection during very dry conditions when the tidal tributary flow contribution is diminished well below the required 200 cfs.

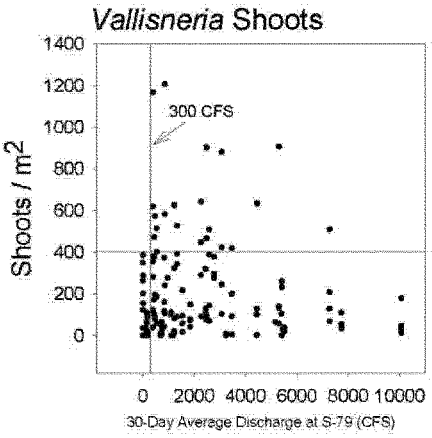

Figure 5. Field survey results of shoot counts vs. inflow from S-79 (Doering et al. 2002, SFWMD 2003).

Although viable rosettes (short immature plants) are almost always present, total denuding of the bottom and loss of all plants can occur. This situation became evident after the year 2000 drought (Figure 3). Plants did not return in appreciable numbers after 2 years, thus confirming significant harm to this portion of the estuary as defined by the MFL Rule (SFWMD 2003).

Doering et al. (1999) reported decreasing growth of tape grass as salinity increased (Figure 3) whereby positive growth became zero when salinity exceeded 10‰. Doering et al. (1999) also found that tape grass survived at 15‰ for over 40 days under ample light conditions and mortality was observed at 18‰, with a few viable plants persisting after 70 days (Doering et al., 2001). Analysis of long-term records reveals saltwater intrusion into the upper estuary that results in salinity of ≥10‰ may last for over 100 days, but almost always is less than 70 days. Median durations are 5-12 days. Therefore, approximately 50% of the intrusion events that occur may last long enough to impact tape grass growth. Peak salinities during these intrusion average 13-14‰, which is near the tape grass limit for growth, but approximately 25% of the peak salinities are ≥18‰, which can severely reduced coverage and bed morphometrics (Kraemer et al. 1999, Doering et al. 2001). During a field experiment in the Caloosahatchee Estuary, Kraemer et al (1999) found that exposure to salinities approaching 18‰ for longer than 2 weeks - 1 month resulted in tape grass mortality from which plants did not recover. Based on the results of studies and information

6

discussed above, the HSI curve in Figure 6 was formulated for a model described in Hunt and Doering (2005).

Both long term and short term exposures (if repeated) during the late winter may result in tape grass not fulfilling its growth potential needed to provide habitat during the spring and summer season. In addition, other growth parameters, such as water clarity and temperature can also influence contiguous plant coverage and recovery after population declines. Therefore, rules were developed (Table 2) for applying to the HSI model, in order to insure previous conditions are considered when determining the new HSI value each month.

Research to date indicates that the flow distributions specified by Chamberlain and Doering (2004) should promote good water quality (Doering and Chamberlain 1998, Chamberlain et al. 2003) in the ranges suggested by Dennison et al. (1993). The numeric tape grass model developed by Hunt and Doering (2005) uses salinity, light attenuation, and temperature as independent variables to predict tape grass density. The model confirms that light is an important variable for tape grass growth in the Caloosahatchee. Even though high flows are not a concern for tape grass regarding salinity, they are associated with reduced plant density (Figure 5). Water clarity decreases during increased flows due to suspended solids, color and in some cases increased incident of algal blooms. These factors may contribute to a decrease in tape grass growth, recovery, distribution along the estuary, and the depth it can survive.

Batiuk et al. (1992) and Dennison et al. (1993) reviewed water quality requirements for SAV that are found in estuaries and suggested guideline values for water clarity, suspended solids, nutrients, and chlorophyll-a for tape grass (Table 1). In the field transplant studies by Kraemer et al. (1999), salinity tolerances appeared lower than in laboratory experiments, and it was suggested that other factors, particularly light co-varying with salinity can influence the distributional limits. Further evidence of the importance of light in this ecosystem was reported by Bortone and Turpin (2000). In a field study, they found *V. americana* biomass to be significantly associated with six factors: location, temperature, depth, secchi depth, TSS and color – making four of the six factors associated with light conditions. Additional laboratory mesocosm experiments were conducted to quantify the effects of light stress at different salinities (Hunt et al, 2003; 2004). Photosynthesis/ Irradiance (P/I) curves were developed and showed that light utilization varies with salinity. Based on this work by Hunt et al. (2003; 2004), two HSI curves were developed for different ranges of salinity. Figure 7 and 8 depict the index values for tape grass response to average daily bottom light (ADBL) when salinity is < 9.5‰ and ≥9.5‰, respectively. Figure 9 provides the formula for calculating ADBL, which requires knowing (1) incident light in the PAR (Photosynthetic Active Radiation) spectral range; (2) water column light attenuation (K); and (3) depth. Average monthly incident PAR for the Caloosahatchee is depicted in Figure 10 and was calculated from a daily average PAR dataset, recorded by a continuous sensor during 1998-2004, located in the nearby Estero Bay Watershed. Light attenuation was calculated based on freshwater inflow from S-79 (resulting regression line-Figure 11). This relationship was determined from analysis that predicted secchi disk readings (dependent variable) from the 30-day average S-79 flow volume (cfs). Average daily flow is recorded by the USGS since structure 1965 and the secchi disk data to support the regression analysis came from field measurements collected intermittently since 1986. Light attenuation (K) is calculated form the predicted secchi value by the formula, -1.65/secchi (Batiuk et al. 1992). Depth was determined from bathymetry surveys of the Caloosahatchee Estuary and the resulting information supplied in a GIS data file that matched the grid cell points of the model.

7

Table 1. Summary of freshwater inflow and water quality requirements for *Vallisneria americana* in the Caloosahatchee Estuary.

Estuary Area	Value	Source
Throughout its range	Water Quality: (1) Light for *Val* to 1m: (a) atten (K_d)= 1.5-2.0 m^{-1} (b) Secchi Disk depth = 0.85 to 1.1m (c) Light saturatn ~150-200µE/m^2s (d) Minimum (model) ~ 17 µE/m^2s (2) Chlorophyll –a = 15 µg/l (3) Tot.Susp.Solids=15 mg/l (4) Dissolved Inorg. N = 0.15 mg/l (5) Dissolved Inorg. P = 0.07 mg/l (6)Temperature: (a) Estimated Min.(model) ~14-16°C (b) Optimum (model) ~ 34°C (b) Est'd Max (model) >34 °C, < 50°C	(1, 2, 3, 4, 5) - Batiuk et al. 1992, Dennison et al. 1993, Chamberlain et al. 2003 (1, 6) - Hunt and Doering 2005, Hunt et al. 2003, 2004
Throughout its range	Salinity: (1) Optimum growth @ 0-3 ‰ (2) Net month growth if: (a) < 10‰ (b) Exposure @ 18‰ ≤ 5 days (3) Growth/day cessation ~10-15‰ (4) No net growth in month following 18‰ for 11-20 days. (5) Plant growth/day decline as approach ~15‰ (6) Month growth potential decreased after 1 day @ 18‰ (7) ~40% mortality after 20 days @ 18‰ (8) Lethal limit @ ~ 18‰ ~2-4 weeks	(1, 2, 3, 5, 6, 5, 7) - Doering et al. 1999, 2001, 2002 (2) - Chamberlain et al. 1995a,b (8) - Kraemer et al. 1999
Target Area2 - Beautiful Isl.	Salinity targets: (1) Monthly average < 10‰ (2) 1 day peak ≤ 18‰	SFWMD 2003
Ft.MyersBridge Salinity Probe	Salinity targets (MFL): (1) Monthly average ≤ 10‰ (2) 1 day peak ≤ 20‰	SFWMD 2003
Target Area2 - Beautiful Isl.	Hydrologic (flow) Targets: (1) Minimum flow (a) 450 cfs avg monthly flow @ S-79 (b) combined 500 cfs avg monthly flow S-79 & tidal basin (near & upstrm Ft.Myers Bridges) (2) Max flows consistent to protect downstrm SAV (2800-4500 cfs) will prevent exceedence of WQ guidelines.	(1) - Chamberlain 2005, Chamberlain et al. 1995, Chamberlain and Doering 2004 (2) - Doering and Chamberlain 1998

8

	(3) Defined preferred flow distribution (EST05) that maximizes flows (75%) in 450-800 cfs range will maximize WQ for growth	(3) – Chamberlain et al. 2003
Target Area2 - Beautiful Isl.	Target Plant Morphometricts (June-Sept growing season): (1) Minimum 20% of average potential shoot density (~200-300 shoots/m^2 of potential > 1,000 shts/m^2). (2) Minimum avg. blade length 15cm (3) Most years $\geq$ 300-600 shts/m^2 (4) Most years-plant reproduction (sexual) (5) Run tape grass model to evaluate/select preferred flows	(1, 2) Chamberlain 2005, Chamberlain et al. 2003 (3) - SFWMD 2006 (4) - Doering et al. 1999, 2002 (5) - Hunt et al. 2003, 2004, 2005

Temperature is an additional factor that may influence tape grass growth. In general, temperature changes primarily influence growth of SAV over predictable seasonal cycles. In northern environments there is a distinct seasonal growth pattern involving the production of vegetative tubers and winter dormancy period during the cold winter months. Different temperature growth ranges have been reported for *V. americana* in populations growing in different climates and under different environmental conditions. Titus and Adams (1979) report a temperature optimum for *V. americana* obtained from University Bay, Madison, WI. of 32.6°C. In the Detroit River, *V. americana* grew at water temperatures ranging from 19 to 31.5 °C (Hunt 1963). Barko et al. (1982, 1984) reported growth of commercially obtained juvenile plants was severely restricted below 20°C.

Consistent with the southern ecotype of *V. americana* reported by Smart and Dorman (1993), no over-wintering buds or tubers have been reported in the Caloosahatchee Estuary. The acute limits or effects of the colder winter water temperatures on the growth and survival in Florida is not known. Water temperatures in the upper Caloosahatchee Estuary over the period 1998-2005 have varied between 14°C in the winter to 34°C in the summer. Inter-annual variation in seasonal high and low water temperatures are also apparent over this time period. Lower water temperature during some years may adversely impact tape grass. High freshwater inflow that increases water color may result in dark water that absorbs solar energy and raises water temperature near tape grass tolerance limits. Given the span in water temperatures in the Caloosahatchee Estuary, ranging from potentially above optimal conditions to below tolerance levels in any given year and the importance of over-wintering survival, water temperature may be an important variable that influences *V. americana* survival

A habitat suitability temperature curve (Figure 12) was developed for tape grass in the Caloosahatchee based on an equation of O'Neill et al. (1972). Input values for the lower lethal, optimum, and upper lethal limits came from general literature values (not specific to Florida) and calibrated based on a growth model described by Hunt and Doering (2005). Non-linear regression was employed to predict daily average temperature in the Caloosahatchee Estuary using historical data collected by continuous sensors since 1992 (Figure 13). Note, that as a daily average data set predicted from historical records, it does not reflect the high or low conditions that might be expected in any given year.

9

HSI for *Vallisneria americana*

HSI Formula

Calculated monthly:

$HSI = (Previous^{W} * Salinity^{W} * Light\ Availability * Temperature^{W})$

Previous
"Previous" variable included because current month's HSI score should depend on the how well the grass was doing last month (previous score).
Previous = previous_month_HSI score + 0.05 (not to exceed 1.0), in order to allow for growth from month to month if other conditions are suitable.

Table 2. Changes to HSI model's spatial boundaries (A) and post-processing routines (B and C) for adjusting the final HSI ecological model scores to better reflect long-term impacts of severe reduction in *Vallisneria americana* density due to low HSI scores of environmental variables (salinity, light and temperature in above model formula).

Routine	Model output criteria	Model score adjustment
A.	Establish a lower depth threshold of 5 ft	Model areas > 5 feet are not scored
B.	If HSI score $\leq$ 0.2 for one month,	Than HSI remains $\leq$0.2 for remainder of the season
C.	If HSI score $\leq$ 0.1 for one month,	Than HSI = 0 for 12 subsequent months

Adjustments were agreed to by ecological benefits sub-team (6/14/06)

HSI Curves and Application (for determining input values to HSI model formula)

Salinity

The freshwater inflow associated with base conditions and management alternatives serve as input for the hydrodynamic model (CH3D with regression routine) that estimates salinity concentration at key locations in the estuary. An immolator program used the salinity output to further estimate salinity at the remaining model grid cells. This salinity was compared to the curve in Figure 6 to determine the HSI score for that grid cell and input to the model formula.

10

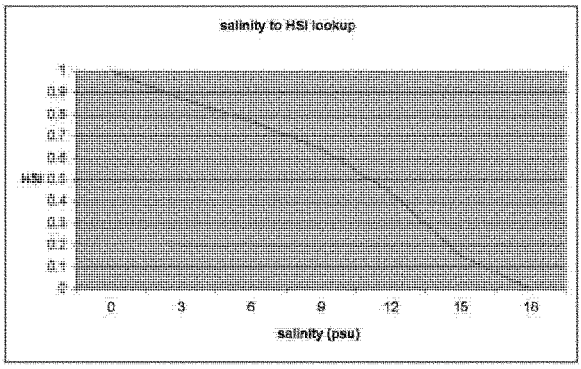

Figure 6. HSI value for *Vallisneria americana* in response to salinity (formulated from Doering et al. 1999; Hunt and Doering 2005).

Light

The formula in Figure 9 was employed to calculate the average daily bottom light (ABDL) during the month. The average incident PAR component of this formula, for the month of interest, is supplied by the data values associated with Figure 10. The light attenuation (K) component was supplied by the data values associated with Figure 11, which depends on the average flow for the month. Depth data was supplied from a GIS file with survey data that matched the model grid cell points. Once the ADBL value is determined for the month, it is used to estimate the index score as depicted in Figures 7 or 8, depending on the salinity value for the model cell during the month.

11

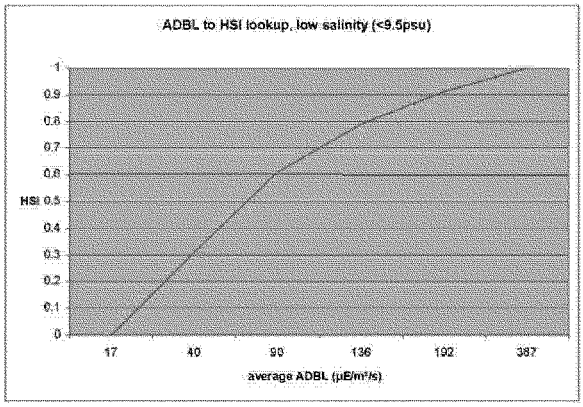

Figure 7. HSI value for *Vallisneria* response to average daily bottom light in low salinity range (<9.5psu) conditions (Hunt et al. 2004 and 2003; Hunt and Doering, 2005).

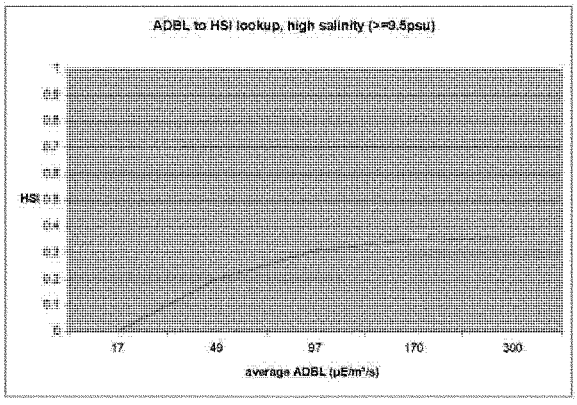

Figure 8. HSI value for *Vallisneria* response to average daily bottom light in low salinity range (≥9.5psu) conditions (Hunt et al. 2004 and 2003; Hunt and Doering, 2005).

12

$$ADBL = (average\ monthly\ incident\ PAR)*(1-surface\ reflectance)*e^{-K*depth},$$

$$surface\ reflectance = 0.9 * incident\ PAR$$

Figure 9. Equation to determine ADBL

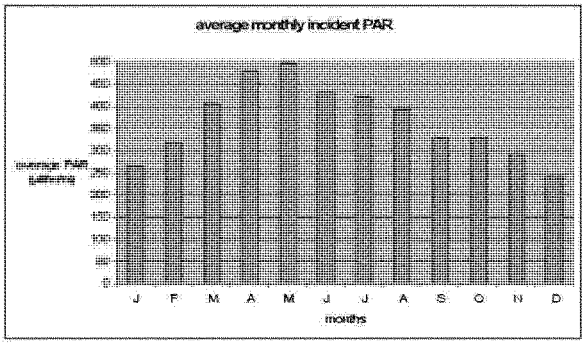

Figure 10. Average monthly Incident PAR (calculated form daily average PAR measurements collected during 1998-2004 at a continuous recording station in the Estero Bay watershed).

13

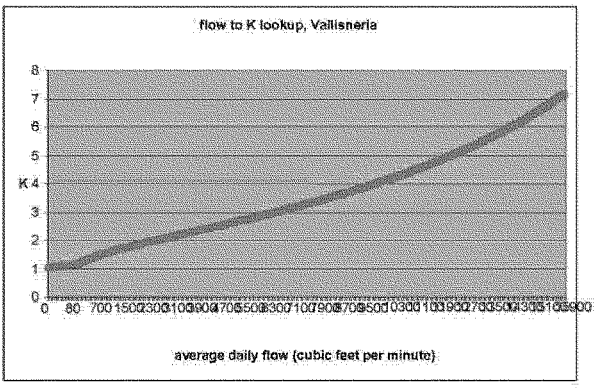

Figure 11. HSI relationship between average daily flow and light attenuation (K values).

Temperature

Daily average temperature was estimated from continuous in-water recorders that have been measuring near surface temperature since 1992. Depending on the HSI model requirements, these daily values (Figure 13) can be averaged over the time period of interest (e.g., monthly average). The resulting temperature is then used to determine the index value in Figure 12 for input to the HSI model formula.

C.7 TARGET FLOW INDEX (EST05) METHOD

C.7.1 Background

A method for evaluating flows associated with the Caloosahatchee River (C-43) West Basin Storage Reservoir project was developed to easily compare potential project flows (cubic feet/second) with the percent distribution of the target flows from S-79 for any time period (one year or longer). The resulting index scale (0-1) reflects the relative amount that the project related flows move toward the target flows (score of 1) from the base condition (score of 0) for the period being evaluated. This score can then be expressed as the percent toward achieving the target flows (PTA).

C.7.2 Target Flow Index Calculation

The 36 year period of record (1965-2000) target flows (EST05) is depicted in ***Table C-10*** and should be the reference target flow condition for comparing project flows.

TABLE C-10: TARGET FREQUENCY DISTRIBUTION (EST05) OF MEAN MONTHLY FLOWS FROM S-79 FOR THE 1965-2000 PERIOD OF RECORD (CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR-CALOOSAHATCHEE ESTUARY HYDROLOGIC EVALUATION PERFORMANCE MEASURES, 2005)

Discharge Range (cfs) From S-79	Percent Distribution Of Flows From S-79
0 to 450	0%
450 to 500	42.8%
500 to 800	31.7%
800 to1500	19.2%
1500 to 2800	5.6%
2800 to 4500	0.7%
>4500	0%

The TFI evaluation method calculates a score for each of the ***Table C-10*** flow categories using the target percent distribution (frequency) compared with the percent frequency of the project flows being evaluated. The formulas for calculating the score are identified in column 3 of ***Table C-11***. The flows above (>4500 cfs) and below (<450 cfs) the target distribution are each divided into three additional categories to account for increasing adverse environmental impacts the farther the evaluated flows are from the target flows. Each of these three additional categories is progressively weighted (3 to 5), with the flows farthest from the target having the greatest multiplication weight of 5. Using the same weighting at both ends of the distribution avoids favoring the upper estuary or lower estuary. The range of flows in each category is also spatially

based. For example, in the upper estuary, as flows decrease below 450 cfs, tape grass (*Vallisneria americana*) productivity declines due to increasing salinity and this decline increases farther upstream as flows tend toward 0 cfs. As flows increase in each category above 4500 cfs, oyster mortality increases and impacts on seagrass becomes more severe in eastern San Carlos Bay, to the western side, and up into lower Pine Island Sound.

Ideally, most of the flows (~75%) should fall into the 450–800 cfs range. Therefore, a fractional based score is calculated to most heavily penalize the proposed project related flows that fall short in these two categories. A governor is included for these two categories to avoid falsely rewarding a proposed project if more then the desired flow frequency is provided, such that if the category score exceeds 0, then the category score will be set at 0.

Flows in the three categories covering the range between 800 cfs and 4500 cfs are differential based in their comparison. The absolute value of the difference between the evaluated and target flows is multiplied by a weight that equally increases (by 0.83) with each added flow category, because harm also increases to downstream ecosystem components as flows differ from the target in each increasing category.

TABLE C-11: TARGET FLOW-RANGE CATEGORIES, THE ASSOCIATED TARGET FREQUENCY, AND THE FORMULA FOR SCORING FLOW SCENARIOS WITHIN EACH CATEGORY.

Target Flows Ranges	Frequency of Target Flows	Calculation formulas to compare target flows (**Q**) with frequency (*f*) of Project **Q** (f_{PQ})
0-150	0	$(0 - f_{PQ}) * 5$
150 -300	0	$(0 - f_{PQ}) * 4$
300 – 450	0	$(0 - f_{PQ}) * 3$
450 – 500	0.428	$(f_{PQ} / 0.428)$ **-1**: If >0, then = 0
500 – 800	0.317	$(f_{PQ} / 0.317)$ **-1:** If >0, then = 0
800 – 1500	0.192	**I** $(0.192 - f_{PQ})$ **I** * (- 0.83)
1500 – 2800	0.056	**I** $(0.056 - f_{PQ})$ **I** * (- 1.67)
2800 – 4500	0.007	**I** $(0.007 - f_{PQ})$ **I** * (- 2.50)
4500 – 5500	0	$(0 - f_{PQ}) * 3$
5500 – 6500	0	$(0 - f_{PQ}) * 4$
>6500	0	$(0 - f_{PQ}) * 5$

The score for each category is summed to calculate a total score for the project related flows being evaluated. Any flows different from the target flows will

produce a negative score, which becomes more negative as the flows tend toward the two tails. An example is provided in ***Table C-12*** that uses the actual flow distribution from S-79 during 1978-1986, which encompasses a period of very high, very low and average flows. The total score for this period is - 4.047.

TABLE C-12: EXAMPLE OF USING THE TARGET FLOW INDEX-TABLE COLUMN DEPICT THE TARGET FLOW-RANGE CATEGORIES, ASSOCIATED TARGET FREQUENCY, THE ACTUAL FLOW DISTRIBUTION FREQUENCY OF S-79 FLOWS DURING 1978-1986, AND THE RESULTING CATEGORY SCORES USING THE FORMULAS IN TABLE C-11.

Target Flows Ranges (cfs)	Frequency Of Target Flows	Frequency Distribution of S-79 flows during 1978-1986	Category Score of 1978-1986 flows
0-150	0	0.157	- 0.787
150 -300	0	0.130	- 0.519
300 – 450	0	0.046	-0.139
450 – 500	0.428	0.037	- 0.913
500 – 800	0.317	0.093	- 0.708
800 – 1500	0.192	0.130	- 0.052
1500 – 2800	0.056	0.157	- 0.169
2800 – 4500	0.007	0.148	- 0.353
4500 – 5500	0	0.028	- 0.083
5500 – 6500	0	0.046	- 0.185
>6500	0	0.028	- 0.139
Total	1.000	1.000	**- 4.047**

To compare TFI scores, a base condition must first be identified. This based condition should represent the flow distribution without project components during the period of record being evaluated. The TFI score for the base condition (TFI_{BC}) can then be used as the bottom of the range for comparison to the project flow scores (TFI_P) for the same period of record. Since the target flows (***Table C-11***) are based on the 36 year period of record (1965-2000), then using a smaller period of record may not have the same frequency distribution of flows (e.g., a period of record that disproportionately contains drought years or tropical storm years). Therefore, the 36 year target flows (***Table C-11***) should be adjusted by calculating a target TFI (TFI_T) using the actual target flow distribution for the same period of record being evaluated.

These three TFI values are then combined to determine a flow comparison index (FCI) value, with a scale from 0 to 1, which indicates the relative amount that the flow distribution associated with a project alternative moves toward

achieving the target flow distribution (score of 1) for the period of record being evaluated. The formula for calculating the FCI is as follows:

$$\mathbf{FCI} = (1 - [(TFI_P - TFI_T) / (TFI_{BC} - TFI_T)])$$

For example purposes, assume the period of record being evaluated is 1978-1986, the base condition TFI_{BC} = -4.047 (from ***Table C-12***), the expected target flow TFI_T = -0.8, and the alternative project flow TFI_P score is -3.0. Therefore, inserting these values into the formula provides an alternative's flow FCI value of 0.323. Multiplying this value by 100 indicates the percent toward the target flows that is achieved (e.g., PTA = 32.3%) by a project alternative when compared to the base condition for the period of record being evaluated.

For application purposes, the Caloosahatchee River (C-43) West Basin Storage Reservoir project uses the year 1982 as the base condition to calculate the TFI_{BC} for the representative years 1978-1986 that were evaluated by the project. This year represents the worst single year regarding flows that exceed EST05 on both the dry and wet extremes.

C.8 OYSTER REEF RESTORATION PLAN

C.8.1 Oyster Reef Restoration is Not Part of the Recommended Plan

Although an oyster reef restoration plan is included in this document, it is not part of the recommended plan. The team feels it would be a valuable addition to the Caloosahatchee Estuary and encourages other organizations to implement this restoration. The plan is included for information purposes only.

C.8.2 Introduction

The Eastern oyster, *Crassostrea virginica* is important both commercially and recreationally in fisheries along the Atlantic Ocean and Gulf of Mexico coasts of North America. While this role of oysters as a fishery is well known, their ecological significance remains under-appreciated and under-studied (Coen et al. 1999a). Individual oysters filter 4-34 liters of water per hour, removing phytoplankton, particulate organic carbon, sediments, pollutants, and microorganisms from the water column. This filtration results in greater light penetration immediately downstream, promoting growth of SAV. Although oysters assimilate most of the organic matter that they filter, the remainder is deposited on the bottom where it provides food for benthic organisms. Furthermore, the oyster's ability to form large biogenic reefs (Coen et al. 1999b) qualifies it as a keystone species.

Oysters and the complex, three-dimensional, reef structure they form, attract numerous species of invertebrates and fishes (Ingle & Smith 1956, Woodburn 1965, McDonald 1982, Peters 1981, Meyer 1994). To date, over 300 species have

been identified as depending, either directly or indirectly, on oyster reefs (Tolley and Volety 2005). Many of these organisms in turn serve as forage for important fisheries species (Marshall 1958, Tabb and Manning 1961, Fore and Schmidt 1973, Gilmore et al. 1983, Peters and McMichael 1987, McMichael and Peters 1989).

Due to its sedentary nature, the Eastern oyster is susceptible to natural and artificial ecosystem changes. Environmental disruptions are responsible for reducing oyster populations and their traditional habitats (Cake 1983). Although not currently harvested in the Caloosahatchee Estuary, oysters have been identified in this area as a VEC (Chamberlain and Doering 1998a, 1998b). Historical records indicate that oyster reefs were once significant features of Gulf of Mexico estuaries, including the Caloosahatchee Estuary and adjacent San Carlos Bay. However, populations have declined (Volety et al. unpublished results).

Based on 2004 surveys, there are presently only 3.02 acres of Eastern oysters in the Caloosahatchee Estuary. Most of this possible habitat is located in the Shell Point region of the estuary. A preliminary target for the aerial extent of oysters in the lower estuary with the proper changes in salinity and flow is a 30-acres increase over the next 10-15 years. With the addition of hard substrate over the next ten years, this target can be increased to 100 acres of oyster reefs. This substantial increase in the oyster population will not only provide essential habitat for many species, thus providing a food source for larger estuarine dependent organisms such as game fishes and birds, but will additionally contribute to better water quality.

In the last five years, 23 small-scale oyster reefs have been constructed locally by volunteers lead by investigators from Florida Gulf Coast University (FGCU) and SFWMD (and other local agencies). FGCU has a network of local volunteers including middle school, high school and undergraduate students, environmental and civic organizations, and local media, which have aided in these restoration efforts. Involving the public not only makes them aware of the SFWMD and U.S. Army Corps of Engineers (USACE) efforts in restoration, but also enhances environmental education and creates vested interest in the water quality in the estuary and become local stewards.

C.8.3 Methods

C.8.3.1 Volunteer recruitment

Community volunteer involvement should be a critical and integral component of this project. FGCU, a state university with excellent community collaborations on various projects, will aid with coordination of the restoration efforts including volunteer recruitment. It is also home to the local public

television and radio stations, WGCU and FM 90.1 and 89.9, respectively. Through FGCU volunteer list and recruitment over television and radio stations, investigators in southwest (SW) Florida were able to recruit over 200 community volunteers per year for reef restoration and oyster gardening activities in our previous four to five years. Volunteers have been willing to participate in the project including donating time and boat resources.

C.8.3.2 Reef Construction

Recycled and fossil oyster shell and stabilizing mesh (where needed) will be used to establish suitable substrate for oyster recruitment. This approach has been initiated in South Carolina and successfully implemented in SW Florida. Previous studies indicate that mesh laid over the top of deployed shell and anchored at the edges with rebar significantly decreases subsequent loss due to boat wakes and waves, while unprotected shell washes away in a matter of days. Once recruitment of oysters and other stabilizing organisms such as mussels occurs, the deployed shell becomes stabilized and the mesh may be removed or becomes part of the reef.

Each year, reefs of approximately two acres total area will be constructed with recycled and fossil oyster shell in the Caloosahatchee Estuary. Each reef will be created with shell bags at the periphery to prevent erosion and filled with shell in the middle. Shells will be loaded into bundles of wire-mesh bags and will then be placed into the water to form a reef. Given the large scale nature of the reef, while community volunteers will assist in the shell bags and reef construction, loose shell will be transported to the sites via barges and shell deposited in the water using high pressure hose systems. Reef construction will be done in early spring to maximize the recruitment of new spat onto the constructed reefs. In order to speed up reef creation, seeding of the constructed reefs with reproductively mature adult oysters will also be considered. Appropriate permits (Florida Department of Environmental Protection [FDEP], USACE) will be secured prior to the construction of the reefs. As part of the permit requirements, aerial photographs of the constructed reefs and monitoring of the reefs for success needs to be provided to the USACE.

C.8.3.3 Yearly Costs

Shell and transportation to the location:	$30,000
Barge, winch, crane costs:	$10,000
Personnel:	$25,000
Chopper and monitoring:	$7,000

Indirect costs (approx)	$10,000
Miscellaneous:	$20,000
Total:	**$102,000**

These figures represent a cost estimate and not exact pricing. The cost is estimated to be between $100,000 and $150,000 per year.

C.9 WATER QUALITY ANALYSIS FOR PLAN FORMULATION

C.9.1 Background

The construction and operation of the Caloosahatchee River (C-43) West Basin Storage Reservoir will affect the quality and quantity of water released at S-79 and the resulting change will impact the downstream Caloosahatchee Estuary. As stated in other places within this document, the primary ecological goals of the project are to improve the quantity and timing of water delivered to the estuary at S-79. While water quality improvement is a not a primary goal of the project, changes to water quality conditions that result from the project must be estimated as part of the benefit assessment. In addition, since the USACE will be obtaining a water quality certificate from the FDEP, the USACE will also have to demonstrate that the reservoir does not cause degradation of water quality conditions downstream of the project.

The project delivery team (PDT) and the FDEP have identified the following five issues as the primary measures of the acceptability of the project in terms of water quality:

1. The quality of the water discharged from the reservoir should be no worse than the quality of the water pumped into the reservoir. This is measured in terms of projected flow-weighted nutrient concentrations at the reservoir.
2. Operation of the reservoir should not result in an increase in the frequency of wet or dry season high nutrient loading periods. This is measured as the number of times monthly Total Nitrogen (TN) loading exceeds the critical load estimates developed for the FDEP by Janicki in 2003. These critical loading thresholds are 190 tons of TN in the dry season and 350 tons of TN in the wet season.
3. Operation of the reservoir should not result in an increase in the frequency in which annual nutrient loads exceed a previously defined threshold quantity. The critical annual loading threshold is 3000 tons of TN per year.
4. Operation of the reservoir should not result in an increase in the total nutrient load discharged into the estuary at the S-79 structure.
5. The operation of the reservoir should not result in a substantial shift of nutrient loading from the wet season to the dry season.

The FDEP has focused on nutrient concentration and loading as the primary indicators of the project's impact. This approach recognizes the direct role that nutrients play in the ecological health of the river and estuary in terms of dissolved oxygen concentrations, as well as water clarity (i.e., chlorophyll-a concentration, secchi depth, photosynthetically available radiation or PAR). Other water quality constituents such as pesticides and metals play an

important role in the health of the Caloosahatchee River and Estuary; however, these are not expected to be adversely affected by the construction of the reservoir since 12,000 acres of agricultural land which contribute these pollutants will be taken out of production. While it is possible that some contaminants become mobilized from the reservoir sediments into the water column, low concentrations of these contaminants in the sediments and high volumes of flow through the reservoir will not result in violations of water quality standards for these pollutants. A discussion of the effects of soil contamination is found in the hazardous, toxic and radioactive waste (HTRW) section of the report.

C.9.2 Methodology

This water quality assessment is focused on nitrogen and phosphorus nutrient loading and concentrations calculated using a mass balance approach. Estimates of future nutrient concentrations and loads were prepared using measured TN and total phosphorus (TP) concentrations at S-79 coupled with simulated reservoir and S-79 flows from the Caloosahatchee River (C-43) Basin MIKESHE model. Given that the Caloosahatchee River (C-43) West Basin Storage Reservoir project as a stand-alone project and as an element of CERP significantly changes the S-79 hydrograph, reliable predictions of the impact of the project on water quality at S-79 can be made using a mass-balance water quality assessment approach used in conjunction with simple reservoir pollutant removal assumptions.

C.9.3 Results

The FDEP has stated that the USACE has to demonstrate that the construction and operation of the reservoir will not cause or contribute to degradation of water quality within the Caloosahatchee River or downstream of the S-79 structure in the estuary. The analysis below presents the water quality impact of several reservoir configurations.

C.9.3.1 Annual TP and TN Loading at S-79

C.9.3.1.1 Scenario 1: No Removal in Reservoir

Table C-13 shows the predicted average monthly TP and TN loading at S-79 for future conditions with and without the reservoir project. The results shown in this table are computed under the assumption that the reservoir pollutant removal effectiveness factor for TP and TN is 0.0. (The reservoir pollutant removal effectiveness factor is defined as the fraction of pollutant that is removed and retained in the reservoir.).

C.9.3.1.1.1 Project vs. 2050 Future Without Project Conditions

Compared to the future (Project versus 2050 Future Without Project), the installation of any of the proposed reservoir/pump combinations will result in an average annual reduction in TP load at S-79 ranging from 29 to 34 percent. For TN, the reduction will range from 28 to 33 percent. From these results it appears that neither significant increases in either the pump size or reservoir size results in markedly reduced nutrient loads at S-79. More than doubling the reservoir size provides only four percent more TP removal and three percent more TN removal, while increasing the pump size from 1500 to 3800 cfs provides about three percent more nutrient removal. A comparison of the results for Alternative 3A and Alternative 3B which have identical reservoir sizes and pump capacities shows that the operation scheme used to control inflow to and outflow from the reservoir may have a significant impact on the amount of nutrients that are sent to S-79.

The comparison of 2050 with and without project flow conditions shows that the overall CERP project will reduce flows at S-79 by an estimated 28 to 33 percent. The projected flow reduction for each alternative is very close to the projected reduction in TN and TP loads. This is expected since nutrient loading at S-79 is highly correlated to flows.

TABLE C-13: ESTIMATES OF ANNUAL TP AND TN LOADING AT S-79 FOR 1978-1986 USING MIKESHE CALOOSAHATCHEE RIVER (C-43) HYDROLOGY. RESERVOIR EFFECTIVENESS FACTOR = 0.0[1]

Alternatives VS 2050 Conditions						
Alternative Name	2050 FWO	ALT2	ALT3A	ALT3B	ALT3C	ALT4B
Reservoir Size (ac-ft)	0	100,000	170,000	170,000	170,000	220,000

TP Average Annual Load (tons)	136	95	87	97	92	90
TP % Reduction VS 2050*	0%	30%	36%	29%	32%	34%
TN Average Annual Load (tons)	1,516	1,069	1,015	1,089	1,049	1,037
TN % Reduction VS 2050*	0%	29%	33%	28%	31%	32%
FLOW % Reduction VS 2050	0%	30%	33%	28%	31%	31%

C.9.3.1.2 Scenario 2: Nutrient Removal by Reservoir

[1] All nutrient reduction estimates presented here are calculated as the difference between loads expected without any CERP implementation and the loads expected with a given C-43 alternative combined with the rest of CERP implemented. Nutrient load reduetion due solely to the C-43 West Reservoir Project is much less than that shown in this table.

Error! Reference source not found. shows the impact of various reservoir effectiveness estimates on TP and TN loads at S-79. For TP, the net reduction in load at S-79 is shown for reservoir effectiveness factors of 0.4, 0.6, and 0.9. For TN, the net change in load at S-79 is shown for reservoir effectiveness factors of 0.2 0.4, -0.5 and -1.0. The highest reduction factor for TP represents optimal removal possibly through the addition of a stormwater treatment area (STA) or other downstream water quality treatment feature. The prediction of the concentration of TN in the reservoir discharge is not as straight forward as that for phosphorus since a mass-balance approach for calculating TN must take into account the possibility of the fixation of atmospheric nitrogen by blue-green algae. These algae normally fix atmospheric nitrogen into ammonia which is released back into the water column upon death. Under optimal conditions, the removal of TN from natural waters through treatment in wetland systems is constrained to a lower limit of approximately one milligram per liter (mg/L) TN. This minimal TN concentration is composed of the less bio-available organic nitrogen fraction which is not removed from the water column as readily as nitrate or ammonia. Given these constraints, the effect of the reservoir on S-79 TN loads was tested using removal effectiveness factors of 0, 0.20, 0.40, -0.50, and -1.0. The two negative removal rates, -0.50 and -1.0 test the effect of algal blooms in the reservoir on loads and concentrations of TN at S-79. Although algal blooms are extremely unlikely to occur continuously within the reservoir, the calculations presented here conservatively apply the negative removal rates on a continuous basis in order to test worse-case conditions.

C.9.3.1.2.1 Project versus 2050 Future Without Project Conditions

If pollutant removal occurs in the reservoir, relative to future conditions (2050 Future Without Project), the installation of the ALT3B and the rest of CERP would result in a reduction of 29% to 38% of the TP load at S-79 (From ***Table C-14***). Most of this removal is due to the reduction in flow resulting from the implementation of CERP components other than the C43 West Reservoir component; however, up to an additional 9% of load reduction can be achieved if the reservoir provides 90% removal of TP. The highest potential removal rate of 90% would occur with a large reservoir coupled with a STA that provides optimal treatment of all reservoir discharges. However, given that future nutrient loading to the basin is expected to decrease (as a result of urbanization and Best Management Practices implementation) and that an STA would likely not fully treat all of the reservoir discharges, the maximum removal is likely to be less than that predicted here.

Compared to future conditions (2050 Future Without Project), Alt3B could be expected to provide a reduction in annual expected TN load of 18% to as much as 32% if nitrogen removal was to occur in a reservoir or a downstream STA. Given that nitrogen loading to the basin is expected to decrease as a result of urbanization and that a STA would be unlikely to treat all reservoir discharges,

the maximum decrease in TN load attributable to reservoir treatment would likely be less than that predicted here.

As part of the Acceler8 design efforts, two test cells of approximately four acres in size were constructed in early 2006 on the project lands to primarily test seepage conditions on the site. Water quality monitoring of nutrients, algae, physical parameters and toxics was performed on a monthly basis for a period of 12 months at the test cells. The intent of the test cell water quality study was to supplement the desktop evaluation of future reservoir water quality conditions. The significant observations and potential implications of the test cell water quality data to the full-scale reservoir are listed below.

1. Low dissolved oxygen conditions developed in the lower depths of the test cells during the summer season. The full-scale reservoir can be operated such that the discharge of low dissolved oxygen water is avoided by releasing water from the upper portion of the reservoir water column.
2. The pH of the water in the test cells frequently exceeded the 8.5 pH Class III surface water quality standard. This increase in pH is thought to be related to algal growth. Increased pH will also occur in the full-scale reservoir but to a lesser extent. Since the inflow to the full-scale reservoir will be 0.4 pH units less than that observed in the test cell inflow, it is much less likely that the Class III pH water quality standard will be regularly exceeded in the full scale reservoir.
3. The observed chlorophyll-a concentration in the test cells was less than that observed in the inflow water and also less than the estuary target of 11 ug/l recommended by the DEP. However, the chlorophyll-a concentration within the test cells was still trending up at the conclusion of the study. This is an indication that the average chlorophyll—a concentration in the reservoir is likely to be higher than that observed in the test cells.
4. Nutrient concentrations (TN and TP) were reduced in the test cells relative to the inflow concentrations. This indicates that some nutrient removal will likely occur within the full-scale reservoir.
5. Water column light transmittance in the test cells was increased relative to the inflow water. This is likely to also occur within the full-scale reservoir.

While this study is useful, it is not prudent to base the prediction of future reservoir water quality entirely upon the results of the test cell water quality study because of the large differences in size and operations between the test cell and full-scale reservoir. The small scale of the test cells limited the potential for wind induced mixing conditions which would reduce the tendency of the reservoir to thermally stratify. The likely difference between test cell operations

and full-scale reservoir operations means that water quality processes that are affected by hydraulic residence time, such as nutrient removal, would behave differently in the full-scale reservoir as compared to that observed in the test cells. While the test cell study lasted 12 months, it is probable that water quality conditions within the full-scale reservoir will continue to stabilize over a multi-year period. Thus, the test cell data is perhaps a useful predictor of the water quality conditions within the reservoir directly after construction rather than an indication of long-term conditions once the reservoir has matured.

C.10.11 Algae Production in the Reservoir

Like the Caloosahatchee Estuary and Lake Okeechobee, algal production will occur in the full-scale reservoir as a result of excess nutrient concentrations and favorable temperature conditions. Algal production will be limited to the upper portion of the reservoir water column which experiences adequate light transmittance for photosynthesis. Some mixing of the upper portions of the water column that contain the algal growth will occur as a result of wind induced mixing; however, given the depth of the reservoir and the low velocity wind conditions typically experienced in the project area, it is not likely that elevated chlorophyll-a concentrations which are a result of algal production will be found at all depths of the reservoir. In the test cell water quality study, chlorophyll-a was found to average around 6 ug/l which is less than the 11 ug/l target concentration recommended by the DEP for the Caloosahatchee Estuary. Because the chlorophyll-a concentrations within the test cells were trending upward at the conclusion of the study, it is likely that the full-scale reservoir would experience higher chlorophyll-a concentrations that that observed in the test cells once the reservoir has operated for several years. The draft test cell water quality report (WSI, Inc, 2007) used four different predictive equations to estimate the potential chlorophyll-a concentration in the upper portion of the reservoir water column for each month of the year. The average predicted annual average concentration of chlorophyll was between 12.2 and 24 ug/l. The predictive equations were all developed for Florida lakes which differ from the proposed reservoir in that they are generally much shallower and likely have a significantly higher average hydraulic residence time. Given these differences, the average chlorophyll-a concentrations as predicted by these equation are probably higher than that which will occur in the reservoir. When the reservoir periodically does generate algae such that chlorophyll-a concentrations exceed the target of 11 ug/L, discharges can then be made from lower depths of the reservoir which will likely have a chlorophyll-a concentration below the target. Other treatment options such as aeration or wetland treatment will be considered in the future in the event that careful management of discharges does not largely control the release of water containing elevated concentrations of algae and its byproducts.

TABLE C-14: TOTAL PHOSPHORUS AND TOTAL NITROGEN LOADING AND PERCENT REDUCTION UNDER VARIOUS RESERVOIR PHOSPHORUS REMOVAL FACTORS, WHERE RF IS THE FRACTION OF THE POLLUTANT REMOVED BY THE RESERVOIR.

RF = -1.0		20%	25%	18%	18%	19%

C.9.3.1.3 Effect of Reservoir Seepage on S-79 Concentrations

One proposal for the construction of the reservoir involves the installation of a sub-surface slurry wall to reduce seepage losses from the reservoir pool. In the original calculations, seepage was assumed to have different water quality characteristics than reservoir structure discharges. To test the effect of a seepage barrier configuration on nutrient loading at S-79, the original water quality calculations were redone using the assumption that all reservoir outflows (seepage and structure discharge) have the same water quality. This assumption reduced the effective removal percentage of TP by about three percent. For TN, the calculations indicate that the average load is not affected by the presence or absence of a seepage wall. This is largely because in the original calculations, the concentration of TN was assumed to be minimally changed as it seeps from the reservoir.

C.9.3.2 Wet/Dry Season Nitrogen Loading

The downstream estuary has historically been affected by nutrient loads coming from the S-79 structure. A study by ERD (2003) found that discharge from S-79 contributes from 90 to 95 percent of the mean annual mass of TN and TP to the tidal Caloosahatchee River. The next largest contributor to the tidal Caloosahatchee River was the Orange River with 1.1 to 3.8 percent of the daily mass of TN and TP. Due to the naturally occurring high levels of phosphorus in the watershed, it is generally believed that nitrogen is the limiting nutrient in the downstream Caloosahatchee Estuary. The FDEP (Janicki 2003) determined that the nitrogen/chlorophyll-a relationship was the best means of predicting nutrient impairment in the estuary. The FDEP (Janicki 2003) report has identified two preliminary seasonal threshold loads for TN loading to the estuary from releases at S-79 in order to achieve a chlorophyll-a concentration limit of 11 ug/L in the estuary:

1. Dry season monthly load less than 190 tons/month, and
2. Wet season monthly load less than 350 tons/month.

Controlling nitrogen loading from upstream of the S-79 structure will positively impact the downstream estuary by reducing the frequency and magnitude of algal blooms. The net impact of the reservoir project on monthly nitrogen loading threshold exceedance events is shown in ***Table C-15***. In this table, the net change in the number of wet and dry season monthly nitrogen load threshold exceedance events is shown relative to 2050 Future Without Project condition.

C.9.3.2.1 Project versus 2050 Future Without Project Conditions

In ***Table C-15***, regardless of whether TN concentrations fall by 40 percent or increase by 50 percent, the reservoir project will reduce the number of dry

season target (> 190 tons/month) exceedances from seven to one or two over the nine year simulation period when compared to the 2050 future without condition. For the wet season, the number of monthly TN threshold (350 tons/month) exceedance events falls from six to two or fewer regardless of how TN concentrations are changed by the reservoir. The number of exceedance events for the dry and wet season thresholds (190 and 350 tons/month) are not substantially affected by the sizes of the pumps and reservoirs. However, at lower loading thresholds such as 100 tons/month, the effect of reservoir operations influence the number of exceedance events (comparison of Alternative 3A to Alternative 3B).

TABLE C-15: FREQUENCY OF EXCEEDING MONTHLY TN THRESHOLD LOADS FOR VARIOUS RESERVOIR REMOVAL EFFICIENCIES

Estimated TN Removal Rate =>	**0.00**					
DRY SEASON						
RANGE	2050	ALT2	ALT3a	ALT3b	ALT3c	ALT4
Number of Months < 100 Tons	49	55	60	56	56	56

C.9.3.3 Annual Nitrogen Loading

In addition to seasonal nitrogen threshold loads, the FDEP (Janicki 2003) identified an annual maximum nitrogen threshold load for flows at S-79. The target of 3000 tons/year of TN is based on the desire to achieve a chlorophyll-a concentration limit of 11 ug/L. ***Table C-16*** shows the annual TN load and the number of times that the annual TN threshold load of 3000 tons/year is exceeded during the 1978-1986 simulation period for various nitrogen removal scenarios. Compared to 2050 future without conditions, it appears that the number of annual TN load exceedance events will fall from one to zero regardless of the impact of the reservoir on TN concentrations.

C.9.3.4 Flow-weighted Nutrient Concentrations

The operation of the reservoir is likely to alter the average flow-weighted TN and TP concentrations as measured at S-79. The long-term average flow-weighted TP concentration at the reservoir outfall will most likely be less than the long-term flow-weighted average inflow TP concentration. It is possible that reservoir releases made during periods of reduced storage will have elevated TP concentrations. The potential for these high TP release events can be minimized through modifications to the design and operation of the reservoir (minimum pool maintenance, for instance). A water quality modeling tool such as -Dynamic Model for Stormwater Treatment Areas-2 (DMSTA) could be used to optimize reservoir operations for TP reduction.

As discussed earlier, the prediction of TN concentration within the reservoir is difficult given the possibility of fixation of atmospheric nitrogen by certain algal species. While it is possible that TN concentrations might increase as a result of seasonal algal blooms, these events will not be continuous. If TN concentrations in the reservoir increased by 50 percent as a result of algal blooms, then relative to the present condition, the project would not result in an increase in the annual average TN flow-weighted concentration. However, with algal blooms increasing reservoir TN concentrations by 50 percent, the project would increase the annual average TN flow-weighted concentration at S-79 by as much as 0.20 mg/L (or 11 percent) when compared to 2050 Future Without Project conditions.

C.9.4 Risk and Uncertainty Analysis

As with any prediction of the future it is impossible to determine its accuracy. The assumptions that are employed in any analysis can increase or decrease the confidence that decision makers have in the results. A risk and uncertainty discussion of the water quality analysis methodology is found in the Environmental Effects chapter of the integrated EIS.

C.9.5 Conclusion

The methodology and assumptions used in this analysis were not intended to predict daily water quality concentrations but rather to provide an estimate of the impact of the Caloosahatchee River (C-43) West Basin Storage Reservoir project on average nutrient loads and concentrations at S-79. Under the conservative assumption that no water quality treatment occurs in the reservoir, Alternative 3B including the rest of CERP will reduce TP and TN loading at S-79 by approximately 30 percent in comparison to the future without condition. If critical components of CERP such as EAA Storage or ASR are not implemented, the ability to reduce lake discharges and S-79 flows will limit the overall reduction in nutrient load predicted here. While it is possible that nitrogen fixation within the reservoir will result in short-term increases in TN loading to

S-79, the average annual TN load at S-79 will most likely be reduced. The project should result in an improvement in overall average water quality conditions at S-79 as well as downstream in the estuary. Given the uncertainty in the threshold chlorophyll-a concentration required for the restoration of the ecological function of the estuary, the degree to which the reservoir project will improve downstream water quality is unknown at this time. Based on the evidence presented here, and in the Supplemental Water Quality Analysis in Chapter 11 of Appendix C, it appears that the project will not cause or contribute to water quality degradation under future conditions. During the development of follow on CERP projects within the Caloosahatchee Basin, more sophisticated water quality prediction tools such as reservoir and estuary water quality models should be developed and used to optimize the reservoir operations with the goal of improving downstream water quality.

C.10 WATER QUALITY EFFECTS FOR THE NEXT ADDED INCREMENT ANALYSIS

C.10.1 Background

The NAI analysis is used to measure the benefits of the project in the absence of the implementation of any other CERP project. While the with-project hydrologic conditions for the alternative assessment analysis included CERP features other than the Caloosahatchee River (C-43) West Basin Storage Reservoir project, the with-project hydrologic conditions for the NAI analysis include only the Caloosahatchee River (C-43) West Basin Storage Reservoir project. Since the FDEP will be considering the water quality impact of the Caloosahatchee River (C-43) West Basin Storage Reservoir project in the absence of any other CERP project, the comparison provided by a NAI analysis is the most appropriate for determining the water quality impact of the project prior to the implementation of the remainder of CERP.

The construction and operation of the Caloosahatchee River (C-43) West Basin Storage Reservoir will affect the quality and quantity of water released at S-79 and the resulting change will impact the downstream Caloosahatchee Estuary. As stated in other places within this document, the primary ecological goals of the project are to improve the quantity and timing of water delivered to the estuary at S-79. While water quality improvement is a not a primary goal of the project, the USACE will have to obtain a water quality certificate from the FDEP. For the water quality certificate, the USACE will have to demonstrate that the reservoir does not cause degradation of water quality conditions downstream of the project. The PDT and the FDEP have identified the following five issues as the primary measures of the acceptability of the project in terms of water quality:

1. The quality of the water discharged from the reservoir should be no worse than the quality of the water pumped into the reservoir.
2. Operation of the reservoir should not result in an increase in the frequency of wet or dry season high nutrient loading periods. This is measured as the number of times monthly TN loading exceeds the critical load estimates developed for the FDEP by Janicki in 2003. These critical loading thresholds are 190 tons of TN in the dry season and 350 tons of TN in the wet season.
3. Operation of the reservoir should not result in an increase in the frequency in which annual nutrient loads exceed a previously defined threshold quantity. The critical annual loading threshold is 3000 tons of TN per year.
4. Operation of the reservoir should not result in an increase in the TN load discharged into the estuary at the S-79 structure.
5. The operation of the reservoir should not result in a substantial shift of nutrient loading from the wet season to the dry season.

The FDEP has focused on nutrient concentration and loading as the primary indicators of the project's impact. This approach recognizes the direct role that nutrients play in the ecological health of the river and estuary in terms of dissolved oxygen concentrations, as well as water clarity (chlorophyll-a concentration, secchi depth, PAR). Other water quality constituents such as pesticides and metals play an important role in the health of the Caloosahatchee River and Estuary; however, these are not expected to be adversely affected by the construction of the reservoir.

C.10.2 Methodology

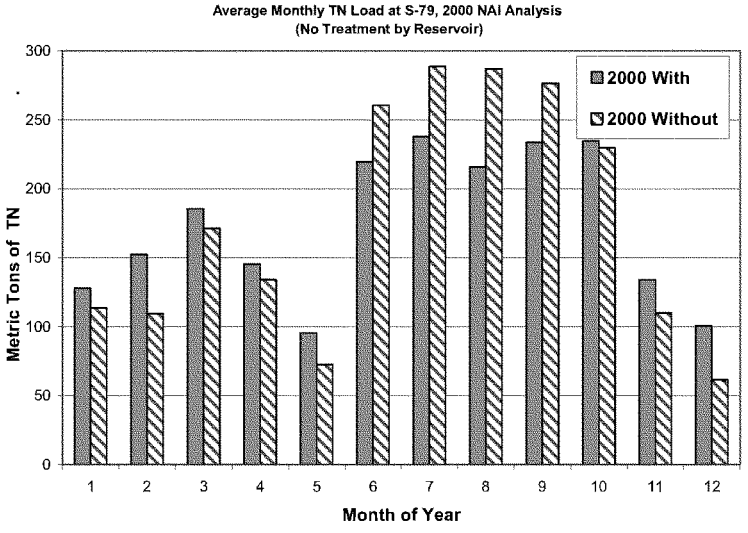
Two different approaches were used to predict the impact of the reservoir on downstream water quality. The first approach was to create a simple mass balance model of TN loads at S-79. The second approach was to use the DMSTA-2 model to predict the net removal of phosphorus in the reservoir. The mass balance approach is a sufficient method to calculate the effect of the reservoir on nutrient loads at S-79 since less than 20 percent of the total flow at S-79 is expected to be routed through the reservoir. The mass balance approach tracks the load into and out of the reservoir and the impact of this routing on the timing and magnitude of nutrient loads at S-79. Estimates of with and without project nutrient concentrations and loads were prepared using measured TN and TP concentrations at S-79 coupled with simulated reservoir and S-79 flows from the Caloosahatchee River (C-43) West Basin Storage Reservoir project spreadsheet model. Since the Caloosahatchee River (C-43) West Basin Storage Reservoir project spreadsheet model simulates the period from 1965 through 2000 and that water quality data is available at S-79 for the period from 1981 through the present, the period of analysis used for the NAI water quality assessment was from 1981 through 2000.

Two comparison datasets were available from the spreadsheet hydrology model, the 2000 With Project and the 2000 Without Project conditions. Using these datasets, water quality mass balance calculations were performed using TN and TP concentrations and loads at S-79. The effect of the reservoir on nutrient loads at S-79 was estimated using the simplified approach of reducing or increasing the concentration of reservoir discharges by a set percentage. The simplified assumptions resulted in similar predictions of impacts to TN and TP in terms of load and concentration at S-79. Given similar results for both parameters and the fact that FDEP has focused on TN loading within the estuary, mass balance results only for TN are presented here.

C.10.3 Impact of Reservoir on Average Monthly TN Load at S-79

The impact of the reservoir on monthly average TN loads at S-79 is shown in ***Figure C-8*** and ***Figure C-9***. ***Figure C-8*** shows that average monthly TN loads in the dry season will be greater with the project than without the project given 2000 hydrology conditions. The increase in dry season loading is a direct result of holding wet season water in the reservoir and releasing it in the dry season when normally there is little flow. Without treatment, the average monthly TN load in the wet season will be reduced by as much as ten percent for some months. ***Figure C-9*** shows the impact on S-79 loads if the reservoir provides 60 percent removal of TN. Under this scenario, it appears that the average monthly load during the dry season for the with-project condition is nearly the same as the without project condition. The actual rate of TN removal is probably somewhere between 0 and 60 percent depending upon operating conditions.

FIGURE C-8: AVERAGE MONTHLY TN LOAD AT S-79 ASSUMING 2000 HYDROLOGY AND NO TREATMENT BY RESERVOIR



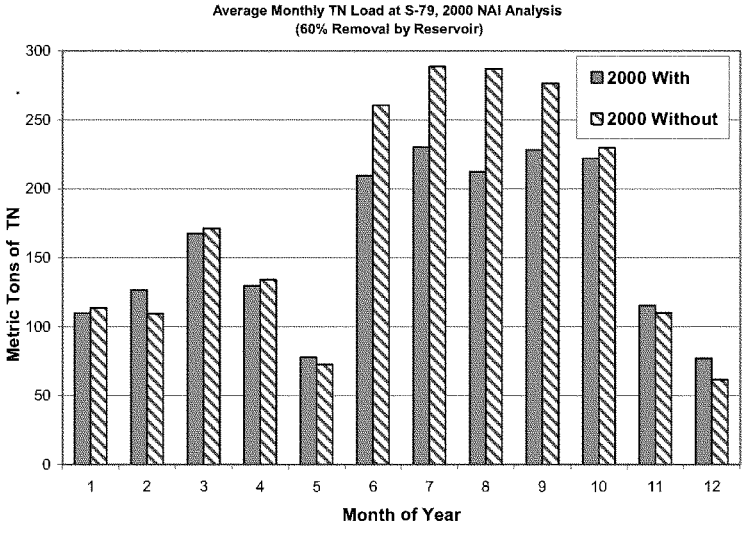


FIGURE C-9: AVERAGE MONTHLY TN LOAD AT S-79 ASSUMING 2000 HYDROLOGY AND 60% REMOVAL BY RESERVOIR

C.10.4 Impact of Reservoir on Seasonal Nutrient Load at S-79

The FDEP is concerned that the reservoir project may cause a significant shift in TN load from the wet season to the dry season. In 2003, the FDEP developed dry season and wet season threshold loads for TN load at S-79. The dry season threshold is 190 tons/month. The wet season threshold is 350 tons/month. A project that resulted in an increase in the frequency of exceeding these threshold loads may be considered by the FDEP to cause water quality degradation. To test whether the project might cause a significant seasonal load shift, the frequency of monthly TN loads at S-79 for with- and without project conditions was estimated using the 2000 NAI hydrology for the period from 1981 through 2000. These calculations were done using two conservative assumptions. The first assumption is that the reservoir provides no pollutant removal. The second tested assumption is that the fixation of nitrogen by algal blooms within the reservoir causes TN concentrations in the daily discharge to increase by 100 percent over the daily average flow-weighted reservoir concentration. The results for the no pollutant removal assumption, shown in ***Table C-17***, lists the number of months that the total TN load falls within ten different bins. In the dry season it appears that the without project condition results in more than half of the months having less than 50 tons of TN. The number of dry season months with less than 50 tons of TN for the with project condition is less than 25

percent. The dry season frequency of monthly loads between 50 and 100 tons is much greater for the with project condition than for the without project condition. However, the number of month where the load exceeds the FDEP threshold load of 190 tons/month is somewhat less (29 versus 31) for the with project condition than for the without project condition. For the wet season, the number of months exceeding the FDEP threshold of 300 tons/month is 20 for the with project condition and is 28 for the without project condition. Based on these results it appears that with little or no pollutant removal within the reservoir, the number of times that the dry season or wet season TN threshold loads are exceeded will decrease as a result of the implementation of the project.

TABLE C-17: FREQUENCY OF DRY AND WET SEASON MONTHLY TN LOADING AT S-79 FOR 2000 NAI HYDROLOGIC CONDITIONS ASSUMING NO POLLUTANT REMOVAL IN RESERVOIR

Frequency Analysis of Monthly Total Nitrogen Load at S-79					
DRY SEASON			WET SEASON		
BINS (Monthly Tons of TN)	2000 With	2000 Without	BINS (Monthly Tons of TN)	2000 With	2000 With out
0 to 10	7	61	0 to 10	1	5
10 to 25	7	12	10 to 25	4	5
25 to 50	15	17	25 to 50	3	5
50 to 100	68	8	50 to 100	20	11
100 to 190	14	11	100 to 190	29	19
190 to 250	8	7	190 to 250	7	13
250 to 350	8	9	250 to 350	16	13
350 to 500	7	9	350 to 500	10	13
500 to 700	2	2	500 to 700	6	11
700 to 1000	4	4	700 to 1000	4	5
Number of Months > 190	29	31	Number of Months > 350	20	29

The results of the frequency of monthly nutrient loads calculated using the assumption that TN concentrations in reservoir discharge will increase by 100 percent is shown in ***Table C-18***. These results show that with project condition increases the number of dry season threshold exceedance events by two months over the without project condition. These results indicate that even under the conservative assumption that TN discharge concentrations double as a result of nitrogen fixation by algal blooms, the net increase in dry season threshold exceedance events will be moderate (from 31 to 33 months out of 140). Given that it is not likely that algal blooms would occur on a continuous basis, it is unlikely that the frequency of exceeding the dry season TN threshold load would increase as predicted in this extreme scenario.

TABLE C-18: FREQUENCY OF DRY AND WET SEASON MONTHLY TN LOADING AT S-79 FOR 2000 NAI HYDROLOGIC CONDITIONS ASSUMING 100 PERCENT INCREASE IN RESERVOIR TN CONCENTRATIONS

Frequency Analysis of Monthly Total Nitrogen Load at S-79					
DRY SEASON			WET SEASON

1000	4	4	1200	5	5
Number of Months > 190	**33**	**31**	**Number of Months > 350**	**20**	**28**

C.10.5 Assessment of Annual TN Load

The FDEP has determined that exceeding an annual load of 3000 tons of TN at S-79 is undesirable. The reservoir could potentially change the frequency of exceeding the 3000 tons/year threshold by either providing substantial removal of TN or by causing an increase in TN load by serving as an incubator of nitrogen fixing algae. To test the maximum impact of the reservoir on annual TN loading at S-79, the reservoir was assumed to provide either 100 percent removal of TN or increase discharge concentrations of TN by 100 percent over inflow concentrations. The frequency of exceeding the 3000 tons/year threshold under these various assumptions was estimated using the 2000 NAI hydrology conditions. With no project, the 3000 tons/year threshold was exceeded four times over the 1981 to 2000 period. Under the impossible assumption that the reservoir provides 100 percent removal of TN before discharge, the frequency of exceeding the threshold would not change from the without project condition given 2000 NAI hydrology. With 100 percent removal effectiveness by the reservoir, the net decrease in total TN load at S-79 would be approximately ten percent.

If nitrogen fixation by algal blooms in the reservoir resulted in an increase of 100 percent in discharge TN concentrations relative to the flow-weighted inflow concentration, the number of times that the annual TN threshold load of 3,000

tons/year would be exceeded would increase from four to five. The total TN load at S-79 would increase by ten percent under this scenario. While this scenario shows an increase in the number of annual load target exceedances, the probability that reservoir discharges would consistently have TN concentrations twice the inflow flow-weighted concentrations is limited since severe algal blooms within the reservoir are not likely to occur continuously.

C.10.6 Nutrient Removal Within Reservoir

The DMSTA 2, (Walker 2005) was used to estimate the net reduction in phosphorus load achieved by the reservoir. The 2000 NAI hydrologic conditions from the Caloosahatchee River (C-43) West Basin Storage Reservoir Spreadsheet Hydrology Model were input into DMSTA. The default parameters recommended by the DMSTA developer for a reservoir were used in the simulation. A partial list of input parameters is shown in ***Table C-19***. A partial list of the model output is shown in ***Table C-20***. In ***Table C-20***, it appears that the reservoir will reduce the phosphorus loads in the discharge by 22percent in comparison to the inflow phosphorus load. The flow-weighted TP concentration in the outflow will be approximately 135 parts per billion (ppb) in comparison to the flow-weighted inflow concentration of 179 ppb. The reliability of these DMSTA results are somewhat compromised by the simulation error message indicating that the average water depth for the simulation period was 4.1 meters which exceeds the upper bound of the DMSTA reservoir calibration range of 3.04 meters.

Although a STA is not planned as part of this project, the impact of constructing and operating a 3,000 acre STA in conjunction with the reservoir was simulated with DMSTA. The results of this simulation indicate that a combination of the reservoir and a STA will reduce TP load from the reservoir discharges by around 39 percent.

The net impact on S-79 loads from the reservoir and the reservoir/STA combination can be estimated using the results of the DMSTA simulations. Since the reservoir may remove up to 22 percent of the load from the 20 percent of total S-79 flows will pass through the reservoir, the net decrease in total TP load at S-79 will be approximately four percent. In terms of the total annual TP load for the estuary, the net reduction resulting from the operation of the reservoir would be around three percent since 25 to 30 percent of the total estuary load is from below S-79. If a reservoir/STA combination was to remove 39 percent of the load from the 20 percent of S-79 flow, the net result would be an eight percent reduction in TP load at S-79.

C.10.7 Assessment of Reservoir Dissolved Oxygen

Anoxic conditions at depth within the reservoir are most likely to occur if the reservoir becomes thermally stratified. Thermal stratification in reservoirs tends to set up during the summer months. By itself, wind/wave mixing at the reservoir is not likely to be extensive enough to prevent thermal stratification at depth. In Cell 1, inflows to the reservoir are likely to disrupt the vertical

stratification process at least near the pump station discharge. Fortunately, most reservoir inflows will occur during the summer months when stratification is most likely to setup. Flow into Cell 2 will also disrupt stratification in this cell however to a lesser extent than for the pump induced mixing of Cell 1. It might be possible that periodic operation of the inflow pumps and discharge structures can be scheduled to disrupt thermal stratification and reduce the potential for the formation of anoxic deep waters.

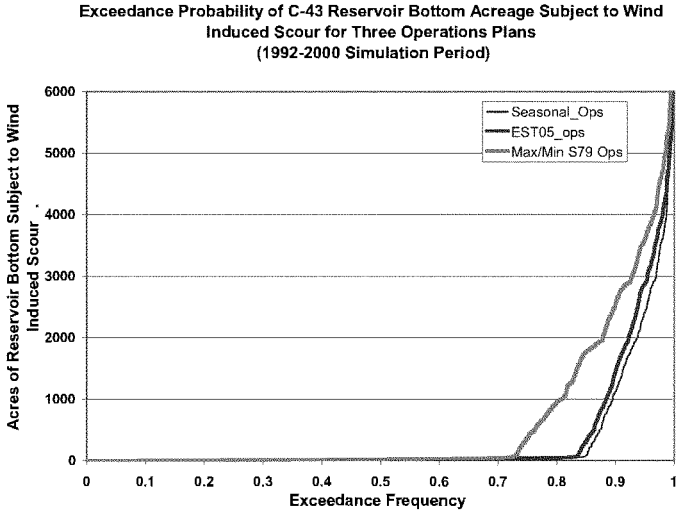
Regardless of whether thermal stratification occurs at the lower depths of the reservoir, the concentration of DO in the upper portion of the reservoir water column is expected to typically meet or exceed the state standard of 5 mg/L. The concentration of dissolved oxygen in the discharge water will be heavily influenced by how the outfall structures are operated. The outfall structures in Cell 1 and Cell 2 are designed such that the water can be withdrawn from the reservoir at three elevations (Cell 1: 18 ft, 25 ft, 32 ft, Cell 2: 21 ft, 26 ft, 33 ft). Discharge water can be released from two or more elevations so that high DO water from the upper water column is blended with reduced DO water from the lower water column.

It is difficult to predict with any certainty the actual dissolved oxygen dynamics of the reservoir at this time given the lack of sufficient water quality data. However, modeling just thermal stratification instead of a complete list of water quality constituents can be done in the near future without having operational water quality data. Since thermal stratification plays a big role in reservoir water quality dynamics, this type of modeling will provide some indication of future reservoir water quality. Such a modeling effort can be done during the construction and initial operations phases of the project as part of developing a refined operations plan. Models that might be applied in this manner include CE-QUAL-R1 or EFDC (Environmental Fluid Dynamics Code).

C.10.8 Accumulation of Reservoir Sediments

Sediments will accumulate in the reservoir over time. The total amount of sediments that could accumulate in the reservoir can be estimated by multiplying the average total suspended solids (TSS) content by the total flow that passes through the reservoir over the simulation period from 1965 to 2000. The average TSS concentration at S79 over the last 25 years is 2.1 mg/L. If it is assumed that this average concentration will be as high as 10 mg/L, that the reservoir will retain all suspended solids, and that the accumulated material will contain 2% solids and 98% water, the total amount of accumulated material is 310 acre-feet in volume over the 35 year simulation period. This is equivalent to approximately ½ inch of material spread out over the entire reservoir bottom surface. Another source of material accumulation is decayed aquatic vegetation. Since the reservoir will be fairly deep and constantly varying in depth, only floating aquatic vegetation is likely to thrive in the absence of a control program.

Given the limited quantity of sediments carried in the inflow water and the implementation of an aquatic vegetation control program, sediments and decayed material should not accumulate such that a material removal effort is required for many years to come.



C.10.9 Potential for Re-Suspension of Bottom Sediments

Several of the important factors that control wind induced sediment re-suspension are the depth of water within the reservoir, the strength of the wind and the longest fetch for wave buildup. The depth of wind induced wave mixing is typically calculated as one-half of the wavelength. For this analysis, the relationship between wind speed, fetch length and depth of wave mixing was taken from Table 4-1, of Section 4 of the Institute of Food and Agricultural Sciences (IFAS) document, entitled "Wind, Waves, and Water Mixing in Lakes". This table was combined with daily stage, and storage data from the IMC's C-43 Reservoir Spreadsheet Modeling effort. The available wind velocity data was not accompanied with directional data. This did not present a problem since the C-43 West Reservoir is composed of two nearly square cells which mean that the maximum and minimum fetch lengths would be essentially identical regardless of wind direction. The potential surface area of wind induced re-suspension was assumed to be evenly distributed between five fetch zones within each cell. Using the fetch lengths and the daily wind velocity, a maximum depth of mixing was calculated for each zone for each day. The elevation of the bottom of the mixing layer was calculated for each of the five fetch zones by subtracting the depth of wave mixing from the daily predicted reservoir stage from the IMC model output. The surface area where re-suspension would occur on a given day was calculated by subtracting the surface area for the elevation of the bottom of the mixing layer for that day from the surface area for the elevation of the reservoir stage for that day.

The attached ***Figure C-10*** shows the exceedance frequency curve for bottom acreage potentially subject to sediment re-suspension for the ESTO5 operations, Seasonal Stage Criteria Operations, or the Min/Max S79 Operations as simulated by the IMC's spreadsheet model of the reservoir. From ***Figure C-10*** it appears that the frequency and extent of bottom area potentially exposed to wind/wave scour will depend upon the final operations plan. For the Max/Min S79 Operations, during 80% of the time less than 1000 acres are subject to wind induced re-suspension. For the ESTO5 or Seasonal Operations plans, during 90% of the time less than 1000 acres are subject to wind induced re-suspension. Overall, depending upon the operation plan in place, between 3.6% and 7% of the bottom area on average would be subject to wind forces that might induce re-suspension of sediments or muck.

While there may be times when wind induced scour re-suspends bottom sediments, the amount of bottom area subjected to wave induced scour is relatively small in comparison to the total reservoir surface area regardless of the selected operations plan.

FIGURE C-10. EXCEEDANCE PROBABILITY CURVES FOR RESERVOIR BOTTOM AREA SUBJECT TO WIND/WAVE SCOUR (SEDIMENT RE-SUSPENSION).

C.10.10 Summary of Test Cell Water Quality Testing

As part of the Acceler8 design efforts, two test cells of approximately four acres in size were constructed in early 2006 on the project lands to primarily test seepage conditions on the site. Water quality monitoring of nutrients, algae, physical parameters and toxics was performed on a monthly basis for a period of 12 months at the test cells. The intent of the test cell water quality study was to supplement the desktop evaluation of future reservoir water quality conditions. Results of the test cell water quality monitoring program are described in a report prepared by Wetland Solutions, Inc., for Stanley Consultants (Wetland Solutions, Inc., 2007, C-43 West Storage Reservoir Test Cell Water Quality Summary, Draft Report, July 2007, Prepared for Stanley Consultants, Inc.). Significant observations and potential implications of the test cell water quality data to the full-scale reservoir are listed below.

1. Low dissolved oxygen conditions developed in the lower depths of the test cells during the summer season. The full-scale reservoir can be operated such that the discharge of low dissolved oxygen water is avoided by releasing water from the upper portion of the reservoir water column.
2. The pH of the water in the test cells frequently exceeded the 8.5 pH Class III surface water quality standard. This increase in pH is thought to be related to algal growth. Increased pH will also occur in the full-scale reservoir but to a lesser extent. Since the inflow to the full-scale reservoir will be 0.4 pH units less than that observed in the test cell inflow, it is much less likely that the Class III pH water quality standard will be regularly exceeded in the full scale reservoir.
3. The observed chlorophyll-a concentration in the test cells was less than that observed in the inflow water and also less than the estuary target of 11 ug/l recommended by the DEP. However, the chlorophyll-a concentration within the test cells was still trending up at the conclusion of the study. This is an indication that the average chlorophyll—a concentration in the reservoir is likely to be higher than that observed in the test cells.
4. Nutrient concentrations (TN and TP) were reduced in the test cells relative to the inflow concentrations. This indicates that some nutrient removal will likely occur within the full-scale reservoir.
5. Water column light transmittance in the test cells was increased relative to the inflow water. This is likely to also occur within the full-scale reservoir.

Limited groundwater quality testing was also performed at the test cells. The results of this testing indicated high levels of total dissolved solids, aluminum, arsenic, and iron, in the groundwater directly adjacent to the slurry cutoff wall installed in test cell #2. The source or cause of this limited contamination is not known at this time. Additionally, since the metals analyses were done using unfiltered samples, it is not known what fraction of the metals detected are particulate or dissolved. If it is determined that the elevated concentrations are a result of particulate matter, then it is possible that sampling methods or monitoring well construction contributed to the elevated metals concentrations. However, elevated dissolved metals concentrations would indicate that levee construction methods should be carefully reviewed in terms of minimizing its effects on near field groundwater chemistry.

While this study is useful, it is not prudent to base the prediction of future reservoir water quality entirely upon the results of the test cell water quality study because of the large differences in size and operations between the test cell and full-scale reservoir. The small scale of the test cells limited the potential for wind induced mixing conditions which would reduce the tendency of the reservoir to thermally stratify. The likely difference between test cell

operations and full-scale reservoir operations means that water quality processes that are affected by hydraulic residence time, such as nutrient removal, would behave differently in the full-scale reservoir as compared to that observed in the test cells. While the test cell study lasted 12 months, it is probable that water quality conditions within the full-scale reservoir will continue to stabilize over a multi-year period. Thus, the test cell data is perhaps a useful predictor of the surface water quality conditions within the reservoir directly after construction rather than an indication of long-term conditions once the reservoir has matured. Given the results of the test cell groundwater quality monitoring, a review of reservoir construction methods and materials should be done prior to the initiation of construction. Additionally, groundwater quality testing at the existing reservoir piezometers should be performed during and after construction of the reservoir.

C.10.11 Algae Production in the Reservoir

Like the Caloosahatchee Estuary and Lake Okeechobee, algal production will occur in the full-scale reservoir as a result of excess nutrient concentrations and favorable temperature conditions. Algal production will be limited to the upper portion of the reservoir water column which experiences adequate light transmittance for photosynthesis. Some mixing of the upper portions of the water column that contain the algal growth will occur as a result of wind induced mixing; however, given the depth of the reservoir and the low velocity wind conditions typically experienced in the project area, it is not likely that elevated chlorophyll-a concentrations which are a result of algal production will be found at all depths of the reservoir. In the test cell water quality study, chlorophyll-a was found to average around 6 ug/l which is less than the 11 ug/l target concentration recommended by the DEP for the Caloosahatchee Estuary. Because the chlorophyll-a concentrations within the test cells were trending upward at the conclusion of the study, it is likely that the full-scale reservoir would experience higher chlorophyll-a concentrations that that observed in the test cells once the reservoir has operated for several years. The draft test cell water quality report (WSI, Inc, 2007) used four different predictive equations to estimate the potential chlorophyll-a concentration in the upper portion of the reservoir water column for each month of the year. The average predicted annual average concentration of chlorophyll was between 12.2 and 24 ug/l. The predictive equations were all developed for Florida lakes which differ from the proposed reservoir in that they are generally much shallower and likely have a significantly higher average hydraulic residence time. Given these differences, the average chlorophyll-a concentrations as predicted by these equation are probably higher than that which will occur in the reservoir. When the reservoir periodically does generate algae such that chlorophyll-a concentrations exceed the target of 11 ug/L, discharges can then be made from lower depths of the reservoir which will likely have a chlorophyll-a concentration below the target. Given the possibility of algal blooms occurring within the reservoir, the final

OMM&R plan should include monitoring and posting of health warnings, per the WHO (World Health Organization) guidelines for recreational contact with algae. In the event that careful management of discharges does not largely control the release of water containing elevated concentrations of algae and its byproducts, other treatment options such as aeration or wetland treatment will be considered.

C.10.12 Risk and Uncertainty Analysis of Water Quality Predictions

As with any prediction of the future it is impossible to determine its accuracy. The assumptions that are employed in any analysis can increase or decrease the confidence that decision makers have in the results. Several of the key assumptions used in this water quality assessment are discussed below in order to characterize the risk and uncertainty inherent in the results presented here.

C.10.13 Use of Historic Data

As is typically done, the past history of TP and TN concentrations measured at S-79 are used in the prediction of future water quality conditions. The use of historic data to predict long-term water quality conditions can result in error particularly when future conditions are expected to be substantially different from past conditions. Within the Caloosahatchee River (C-43) Basin there are substantial changes anticipated over the 50-year design period that will significantly affect water quality. For instance, the reduction in flow from the lake is expected to reduce nutrient loads at S-79 but might also result in an increase in flow-weighted nutrient concentrations since lake water is generally cleaner than basin runoff. Future implementation of best management practices and the conversion of agricultural lands to urban uses will likely result in a reduction of basin nutrient loads. Given the anticipated changes in the basin, the use of historical data to predict future water quality conditions appears in this case to be a conservative assumption given that most of the anticipated changes result in reduced nutrient loading and concentrations at S-79.

C.10.14 Use of Caloosahatchee River (C-43) West Basin Storage Reservoir Spreadsheet Model Flows

The Caloosahatchee River (C-43) West Basin Storage Reservoir spreadsheet model output used in this water quality assessment may differ significantly from actual reservoir operations in terms of the timing and magnitude of reservoir inflows and outflows. The actual reservoir operations might result in a somewhat different shifting of seasonal nutrient load than that predicted using the spreadsheet hydrology if seepage losses are significant in terms of the total water pumped into the reservoir. The effect of reservoir seepage on water quality should improve the average nutrient concentration in the discharge and also somewhat attenuate the predicted seasonal shift in nutrient load.

C.10.15 Use of Mass Balance Calculations

This water quality assessment did not attempt to predict a time history of nutrient concentrations at the reservoir outfall. Instead a simple mass-balance approach was coupled with various estimates of long-term nutrient removal rates. This approach is predicated on the assumption that project related increased nutrient loading causes a overall decrease in estuary water quality conditions while project related decreased nutrient loading causes an overall improvement in estuary water quality conditions. Coupled hydrodynamic/water quality models of the reservoir and estuary would be capable of integrating the effect of seasonal shifts in flow and load and predicting daily trends in water quality indicators such as dissolved oxygen and chlorophyll-a concentration. These tools are best used after project implementation when actual water quality data are available for model calibration and verification.

C.10.16 Use of FDEP Threshold Loads

Threshold loads used in this analysis were taken from the FDEP (Janicki, 2003). In this document, the FDEP developed chlorophyll-a concentration targets at S-79 using two approaches, the standards/rules based approach and the reference site approach. The reference site approach provided a target of 3.8 ug/L chlorophyll-a. The standards/rules based approach provided a target of 11 ug/L. The FDEP has decided to use the 11 ug/L chlorophyll-a target, which results in TN thresholds of 190 tons/month dry-season, 350 tons/month wet-season, and 3000 tons/year. These thresholds were used in this analysis and the results indicated that the project would decrease the number of times that the seasonal and annual TN thresholds were exceeded. If it turns out that the reference site value of 3.8 ug/L chlorophyll-a is a more realistic restoration threshold, the TN thresholds would be zero (0) tons/month dry-season, 43 tons/month wet-season, and 210 tons/year. A comparison of seasonal and annual TN loads against these lower thresholds would show that the project does not decrease the number of exceedance events because all of the predicted monthly and annual loads are much greater than these lower thresholds. Realistically, the low wet and dry season TN thresholds that correspond to the 3.8 ug/L chlorophyll-a are not achievable unless S-79 flows are greatly reduced from present levels. For the dry season, a drastic reduction in flow is undesirable since this would result in increased estuarine salinity downstream of S-79.

C.10.17 Summary of Water Quality Impacts of Reservoir

The analysis presented here shows that the reservoir is unlikely to cause or contribute to water quality degradation downstream of the project site. (Supplemental water quality analysis is presented in Chapter 11 of this appendix.) While some shift in nutrient load from the wet season to the dry

season will occur as expected, the frequency of exceeding the FDEP's threshold for dry season monthly load of 190 tons/month is unlikely to increase as a result of the project. The frequency of exceeding the wet season monthly TN threshold load will be reduced by approximately 25 percent. The project is not unlikely to increase the average annual TN load at S-79 nor is it likely to increase the frequency of exceeding the threshold of 3,000 tons/year of TN. Based on the results of a DMSTA-2 model run, it appears that the reservoir would remove approximately 20 percent of the TP load that passes through the reservoir.

Although the proposed reservoir reduces the expected annual average nutrient load at S-79 and is expected to improve overall average water quality conditions, there will be limited periods in which the project may cause some downstream water quality degradation. It is possible that on a periodic basis the water quality conditions within the reservoir will result in the occurrence of algal blooms. While it is likely that algal blooms will occur in the reservoir, the possibility that the reservoir will serve as a key source of algal seed is less likely given that water quality conditions within the Caloosahatchee River (C-43) and upstream in Lake Okeechobee already provide substantial quantities of algal material to the estuary.

It is possible that during some periods of the year, the reservoir may become thermally stratified and anoxic at depth. This was shown in the test cell water quality data. These adverse water quality conditions can be mitigated to a great extent through operational schemes that induce vertical mixing of the reservoir water column. Dissolved oxygen levels in the discharge water can be manipulated by using multiple discharge ports that draw off water from the upper and lower water column.

Given the low suspended sediment content of the inflow water, the reservoir is unlikely to accumulate enough sediment such that it will have to be removed in the foreseeable future. Periodic dry down events can be used to consolidate low density sediments and limit re-suspension into the water column. The potential for wind driven re-suspension of sediment is limited given the average operating depth of the reservoir and the low velocity winds typical of Southwest Florida.

The addition of an STA to the reservoir project has been considered and rejected by the PDT at this time. It is apparent from the expected hydrologic flow conditions that the reservoir will not process enough of the Caloosahatchee River (C-43) flows to result in more than a ten percent reduction in the total nutrient load at S-79. Furthermore, the addition of an STA to the project would result in less operational flexibility in meeting the desired flow regime at S-79 and thus potentially reduce overall project benefits. A comprehensive water quality study of the basin should be done once the reservoir is built to determine if adding an STA is the most cost-effect means of improving basin water quality or if non-

structural measures are more cost effective. In addition to reservoir outflows being of equal or better quality than inflows, the reservoir is expected to achieve state water quality standards.

While it can be demonstrated that overall nutrient loading at S-79 will decrease as a result of this project, the magnitude of improvement in water quality conditions within the estuary cannot be predicted with certainty at this time. Given that the primary ecological benefit of the Caloosahatchee River (C-43) West Basin Storage Reservoir project is to improve the timing and quantity of freshwater flow to the estuary, the risk that this project may not be able to markedly improve water quality in the estuary should not be seen as a critical flaw.

C.11 SUPPLEMENTAL WQ ASSESSMENT BY USACE AND FDEP PREPARED JUNE 2007

Supplemental Analysis of C-43 West Reservoir Effects on Dry Season Water Quality Downstream of S-79

Mark Shafer, USACE
Ken Weaver FDEP

June 4, 2007

1.0 Introduction

The Corps C-43 West Reservoir draft Project Implementation Report (PIR) includes an assessment of the nitrogen load shift that results from holding wet season flows and discharging them to the dry season. The assessment clearly shows that the average monthly total nitrogen (TN) during the dry season months will increase as a result of the project. This shift of nutrient load from the wet season to the dry season is an unavoidable result of operating the project as intended. The analysis presented in the draft PIR demonstrates that even though a shift of nutrient load to the dry season occurs, the project does not increase the frequency in which the recommended 190 tons/month dry season and the 350 tons/month wet season targets are exceeded. Given that the recommended loading targets were developed for the entire estuary, additional analysis is warranted to demonstrate that the project will not "cause or contribute" to water quality degradation downstream of S-79. The results of four additional assessments are presented below.

2.0 Flow-Weighted Average Nutrient Concentrations

The potential impact of shifting nutrient loads from the wet season to the dry season has been assessed by comparing the with- and without project flow-weighted average nutrient concentrations at S-79. This analysis was done using historical WQ data coupled with spreadsheet hydrology results (IMC) for the period 1981 through 2001. Table 1 shows the wet and dry season TN and TP flow weighted average concentrations for without project conditions compared to with project conditions. This table shows that the with-project dry season and wet season flow-weighted TN concentrations are less than the without project condition. There is a slight increase in the flow-weighted TP concentration for the with project condition when assuming no treatment by the reservoir; however, if 20% removal is achieved by the reservoir as predicted by the DMSTA-2 model run done for the PIR, there would be no increase.

Table 2 shows the monthly TN and TP flow-weighted average concentrations for with- and without project conditions. Under the conservative assumption that the reservoir provides no removal of TN, the with-project condition provides insignificant increases to the February and March average monthly flow-weighted TN concentrations in comparison to the without project condition. The projected increases are well within the accuracy limits of the water quality data. With no TP removal, several of the months

show an increase in the average flow-weighted concentrations. Under the assumption that the reservoir provides approximately 20% removal of TP (as predicted by DMSTA-2), the average monthly flow-weighted TP concentrations for the with-project condition are similar to the without project condition.

3.0 Exceedance Probability Curves of Nutrient Concentrations

The potential impact of shifting nutrient loads from the wet season to the dry season has been assessed by comparing the exceedance probability curves of estimated daily nutrient concentrations for the with- and without project conditions. Figures 1 through 4 show the dry and wet season exceedance probability curves for TN and TP. These curves were developed using the spreadsheet hydrology model and historic S79 water quality data. The comparison of dry season TN concentration exceedance probability curves shown in Figure 1 indicates that the with-project condition provides a slight improvement above the 60% exceedance probability under the assumption that no TN removal occurs in the reservoir. The comparison of dry season TP concentration exceedance probability curves shown in Figure 2 indicates that the with-project condition provides increased TP concentration above the 20% exceedance probability under the assumption of no treatment. Using a reasonable assumption that the reservoir removes 20% of the TP (as estimated by DMSTA-2 modeling), the with-project condition provides TP concentration return frequencies for the dry season equivalent to the without project condition. Figures 3 and 4 show that the wet season TN concentration return frequency for the with-project condition are slightly improved over the without project condition; however, for TP it appears that the project will result in an increase in the frequency of higher concentrations during the wet season. As above, if 20% TP removal is assumed in the reservoir, the project will not cause an increase in the frequency of higher TP concentrations at S-79 during the wet season.

4.0 Temporal Changes in 30-Day Total TN Loads

The project will shift flows and nutrient loads from the wet season to the dry season. Within the dry season itself, periods of low flow and load under the without project condition will be supplemented by releases from the reservoir under the with project condition. Conversely, periods of high flow and load that occur under the without project condition will be reduced by pumping C-43 flows into the reservoir. Figures 5 shows the number of days where the 30-day running total TN load exceeds TN load thresholds. In this figure, it is apparent that the with project condition results in a doubling of the number of days in which the 30-day total TN load is approximately 80 tons. However, above the 150 ton TN threshold, the with project frequency of days exceeding a given threshold load is slightly reduced relative to the without project condition. Figure 6 shows the relationship between the net difference of with and without project 30-day running total TN loads as compared to the without project 30-day running total TN loads. This plot shows that for without project days where the 30-day running total TN load is less than 30 tons, the corresponding with project days tend to result in 50 to 100

additional tons over the preceding 30-day period. Based on the data presented in Figures 5 and 6, it appears that whether the project causes and contributes to water quality degradation due to an increase in dry season loads is dependant upon the effect of shifting the dry season TN load frequency distribution from one dominated by monthly loads in the 0 to 10 tons/30-days range to one dominated by loads between 50 and 80 tons/30 days. The effect of shifting the dry season load frequency distribution can be determined by examining the existing relationship between nutrient loading at S-79 and downstream water quality conditions.

5.0 Relationship Between S-79 TN Loads and Chlorophyll-a.

There have been several attempts to link nutrient discharges at S79 with estuary water quality conditions downstream. Janicki Environmental (2003), under contract with FDEP, developed dry and wet season TN loading targets using historic estuary chlorophyll-a data and S-79 TN loads. This study was cited in the PIR as the source of recommended dry season, wet season, and annual loading targets for TN discharged from S-79. The Janicki recommendation for nitrogen loading to maintain a chlorophyll-a target of 11 µg/l is based an analysis of chlorophyll-a data from the entire estuary. However, since the state's 303(d) listings for the estuarine portions of the Caloosahatchee are based on multiple segments rather than an average condition of the entire estuary, the Janicki targets may not be protective of all portions of the estuary, particularly those where the median concentrations are substantially less than 11 µg/l. (The 11 µg/l concentration is the default threshold concentration used by the DEP's Impaired Water Rule (IWR) as an indication of water quality degradation in coastal estuaries.)

Doering and Chamberlain (2005) described current median chlorophyll-a conditions in four sections of the estuary (upper, mid, lower estuary above Shell Pt, and in San Carlos Bay). The median values calculated by Doering and Chamberlain for the upper (10.7 µg/L) and mid (12.7 µg/L) estuary are at or above the 11 µg/L default threshold used in the IWR; therefore, it can be reasonably assumed that Janicki's critical loads which are based on 11 µg/L would be protective of the existing condition in these two portions of the estuary. However, the existing median chlorophyll-a concentration within San Carlos Bay is 4.2 µg/L and in the lower estuary is (5.3 µg/L). Since Janicki's threshold loads are based on 11 µg/L chlorophyll-a, these loads are not likely low enough to ensure that no water quality degradation occurs in the lower estuary or San Carlos Bay.

5.1 Dry Season S79 Load versus Chlorophyll-a

The comparison of chlorophyll-a concentrations and the dry season 30-day total TN load at S79 is shown for each estuary zone in Figures 7 through 10. Regression equations were fit to each set of data. In general, these equations are not robust predictors of chlorophyll-a concentrations; however, they can be used as an indication of the effect of increasing dry season nutrient loads. For instance, in Figure 7, it appears that for the upper estuary, increased TN load may result in reduced chlorophyll-a concentration since

the slope of the best fit equation is negative. For the middle and lower estuary and San Carlos Bay (Figures 8 through 10), the fitted polynomial equations indicate that increasing TN loading up to approximately 450 tons/month may result in an increase in chlorophyll-a. Given the low regression coefficient (r-squared) for the fitted equations, another analytical method not dependent upon strong correlation between chlorophyll-a and TN load is required before drawing final conclusions regarding the impact of the project caused seasonal load shift.

5.2 Conditional Probability Analysis of TN load versus Chlorophyll-a

The final test to determine the probable effect of the project on dry season chlorophyll-a concentrations in the estuary is a conditional probability analysis. Conditional probability analysis was proposed by Paul and McDonald (2005) as a method of developing geographically specific water quality criteria in the absence of a demonstrably strong relationship between the discharge of a pollutant and a measured biological response to that discharge. Conditional probability is the probability of an event occurring once a preceding event has occurred. In this analysis, the test is whether the increased dry season loads will significantly increase the probability of exceeding the chlorophyll-a threshold concentrations relative to the existing condition. For this analysis, the threshold chlorophyll-a concentration of interest for the upper and middle estuary is the Impaired Water Rule's default 11 µg/L since the median chlorophyll-a concentrations for these two estuary zones are approximately 11 µg/L. For waters where the median concentration is below 11 µg/L such as the lower estuary and San Carlos Bay, the Impaired Water Rule (IWR) specifies listing as impaired these water bodies "if data indicate annual mean chlorophyll a values have increased by more than 50% over historical values". Using this logic, the determination of whether the project causes or contributes to water quality degradation as a result of the shift of nutrient loads to the dry season can be made by testing to see if the project is likely to increase median chlorophyll-a concentrations by 50% over existing conditions within the lower estuary and San Carlos Bay.

Based on Figures 5 and 6, it appears that the project condition is dominated by loads in the 50-100 ton range while the existing condition is dominated by loads less than 10 tons per preceding 30-day periods. If it can be demonstrated that the expected increased dry season loads, particularly in the 30-day 50 to 100 ton range, will not significantly increase existing chlorophyll-a levels by more than the default 11 µg/L in the upper and middle estuary and by no more than 50 percent over present conditions in the lower estuary and San Carlos Bay then it can be concluded that the project will not cause or contribute to water quality degradation downstream of S-79. A significant increase in the conditional probability can be determined based on non-overlapping 90% confidence intervals; that is, the load at which the lower 90% confidence interval is greater than the chlorophyll-a threshold exceedance probability associated with a 0 ton load. Use of a 0 ton baseline represents a conservative assumption, since the baseline dry season condition is dominated by loads in the 0 to 10 ton range.

Figure 11 shows the probability of observing chlorophyll-a concentrations greater than 11 µg/L in the (A) upper and (B) mid estuary segments if specific 30-day TN loads are exceeded. The solid blue line and dashed red lines are the conditional probability distribution and the 90 percent confidence intervals of the conditional probability distribution, respectively. The location of the horizontal dashed line is determined by the upper 90 percent confidence interval associated with a 0 30-day TN load. Since the lower confidence interval lines for the upper and middle estuary segments do not exceed the horizontal dashed lines set at the probability of the 0 ton baseline condition, the expected increase in dry season nutrient loads associated with the project will not result in a statistically significant increase in the median chlorophyll-a concentrations for the upper and middle estuary. Thus, by this measure it is demonstrated that the project will not cause or contribute to water quality degradation in these two upper estuary segments.

Figure 12, shows the probability of observing chlorophyll-a concentrations greater than (A) 5.3 µg/L, (B) 7.95 µg/L, and (C) 11 µg/L in the lower estuary segment if specific 30-day TN loads are exceeded. The solid blue line and dashed red lines are the conditional probability distribution and the 90 percent confidence intervals of the conditional probability distribution, respectively. The horizontal dashed line is placed at the upper 90 percent confidence interval probability associated with a 0 30-day TN load at the S-79. Since the lower confidence interval lines for the lower estuary segments does exceed the horizontal dashed line set at the probability of the 0 ton baseline condition, in the top graph ($P(Chla > 5.3ug/L|X \geq X_o)$), the expected increase in dry season nutrient loads associated with the project will result in a statistically significant increase in the median chlorophyll-a concentrations for the lower estuary. However, using the IWR logic, the critical test in this case is whether the project will result in a 50% increase in the median chlorophyll-a concentration (or 7.95 µg/L). The middle graph of Figure 12 shows that for $P(Chla > 7.95ug/L|X \geq X_o)$, the lower confidence interval line does not exceed the horizontal dashed line set at the upper confidence interval probability of the 0 ton baseline condition. Thus, the expected increase in dry season nutrient loads associated with the project will not result in a statistically significant increase in the probability that chlorophyll-a will exceed 150% of the existing median concentration in the lower estuary. By this measure it is demonstrated that the project will not cause or contribute to water quality degradation in the lower estuary segment.

Figure 13, shows the Probability of observing chlorophyll-a concentrations greater than (A) 4.2 µg/L, (B) 6.3 µg/L, and (C) 11 µg/L in San Carlos Bay if specific 30-day TN loads are exceeded. The solid blue line and dashed red lines are the conditional probability distribution and the 90 percent confidence intervals of the conditional probability distribution, respectively. The horizontal dashed line is placed at the upper 90 percent confidence interval probability associated with a 0 30-day TN load at the S-79. Since the lower confidence interval lines for San Carlos Bay does exceed the horizontal dashed line set at the probability of the 0 ton baseline condition, in the top graph (A) ($P(Chla > 4.2ug/L|X \geq X_o)$), the expected increase in dry season nutrient loads associated with the project may result in an increase in the median chlorophyll-a

concentrations in San Carlos Bay. (The potential increase is not statistically significant since the lower 90% confidence interval remains below the horizontal dashed line.) Again, the critical test in this case is whether the project will result in a 50% increase in the median chlorophyll-a concentration which for San Carlos Bay is 6.3 µg/L. The middle graph (B) of Figure 13 shows that for $P(Chla > 6.3ug/L | X \geq X_o)$, the lower confidence interval line does not exceed the horizontal dashed line set at the upper confidence interval probability of the 0 ton baseline condition. Thus, the expected increase in dry season nutrient loads associated with the project will not result in a statistically significant increase in the probability that chlorophyll-a exceeds 150% of median concentration in San Carlos Bay. By this measure it is demonstrated that the project will not cause or contribute to water quality degradation in San Carlos Bay.

6.0 Conclusions

To assist in the review of the tables and figures presented in the paper, short summary statements are included below:

1.) The project will not result in an increase in the frequency of dry season or wet season exceedances of the targets presented in Janicki (2003) (Draft PIR, April 2007).
2.) The shift in nutrient load will not increase dry season flow-weighted TN concentrations (Table 1)
3.) The shift in nutrient load will not result in a significant increase in the average monthly TN concentrations (Table 2).
4.) The daily flow-weighted TN concentrations for the with-project condition is very similar to the without project condition) with the exception that at higher TN concentrations the project provides a slight improvement in return frequencies (Figures 1 and 3).
5.) The daily flow-weighted TP concentrations for the with-project condition is somewhat higher than without project conditions if no removal by reservoir is assumed. Under a reasonable assumption that 20% TP removal can be achieved within the reservoir, the with project flow-weighted TP return frequency matches the without project conditions (Figures 2 and 4).
6.) Project will result in an increase in the frequency of dry season 30-day loads in the 50 to 100 ton range while decreasing the frequency of dry season 30-day loads in the 0 to 10 ton range and 150 plus tons range (Figure 5).
7.) The project will result in an increase in 30-day loads by approximately 50 to 100 tons for those days when without project conditions provide 30-day loads less than approximately 150 tons. At the same time, the project will reduce 30-day loads by approximately 50 to 100 tons for those days when without project conditions provide 30-day loads in excess of 150 tons. Above 30-day loads of 400 tons under without project conditions, the project will generally not result in an increase or decrease in 30-day loads (Figure 6).

8.) During the dry season, increased flow tends to result in reduced chlorophyll-a concentrations in the upper estuary (Figure 7).
9.) During the dry season, increased TN load tends to result in increased chlorophyll-a concentrations in the middle, lower estuary and San Carlos Bay when 30-day preceding loads are less than less than 450 tons TN (Figure 8-10).
10.) Shifting TN loads during the dry is not expected to have a significant effect on the probability (frequency) of high chlorophyll-a events (>11 µg/L) in the upper or mid estuary (Figures 11A and 11B).
11.) The project may reduce the probability of high chlorophyll events in the upper estuary (Figure 11A), most likely related to increased flushing of the estuary associated with higher flows during the dry season.
12.) There is a potential for an increase in the median chlorophyll-a concentration within the lower estuary at TN loads greater than 64 tons (Figure 12A). However, the increase is expected to be less than 50% (Figure 12B); therefore, it would not be considered a violation of the IWR requirements nor would it be expected to result in a noticeable or deleterious change to the system.
13.) Increased frequency of monthly loads in the 50 to 100 ton range may potentially increase the median chlorophyll-a levels slightly in San Carlos Bay (Figure 13A), although the change in the probability of exceedance is not significant. Furthermore, the increase in median chlorophyll-a concentration is expected to be less than 50% (Figure 13B).

In summary, given the evidence presented in this paper, it is reasonable and prudent to conclude that the project is not expected to have significant negative effects on dry season chlorophyll-a conditions in the four segments of the estuary, i.e., it is not expected to cause or contribute to nutrient response violations in downstream waters.

Table 1. Comparison of Historic Seasonal TN and TP Concentrations Against Estimated Seasonal Flow-Weighted TN and TP Concentrations At S-79 Assuming 0 to 30% Removal by Reservoir

SEASON	Historic Without Project, S79 TN Concentration (mg/L)	No Removal by Reservoir, Flow-Weighted TN Concentration at S79 (mg/L)	10% Removal by Reservoir, Flow-Weighted TN Concentration at S79 (mg/L)	20% Removal by Reservoir, Flow-Weighted TN Concentration at S79 (mg/L)	30% Removal by Reservoir, Flow-Weighted TN Concentration at S79 (mg/L)

DATE: December 6, 2004

SUBJECT: Recommended Flow Distribution for S-79

As per your request, we have discussed which distribution of S-79 flows is currently preferred for the Caloosahatchee Estuary. We have decided that EST05 will best promote estuarine health and meet the adopted Minimum Flows and Levels (MFL) requirements. There have been a number of proposed flow distributions during the last decade. We thought it would benefit the project team to briefly review these iterations in order to reduce confusion and also to explain why we recommend EST05.

During the mid-1990s we were charged with providing an estimate of the optimum freshwater inflows to the estuary, based on the results of our previously conducted research (Chamberlain and Doering 1995, 1998a, and 1998b). As part of this analysis, we made the first attempts to define a preferred distribution of flows from S-79 that would better support the estuary's biotic resources. We began by evaluating the inflows that had occurred during the 25 year period 1966-1990. These flows were obviously skewed toward the very low end of the range (Figure 1 and 2a), which routinely threatened the low salinity zone of the estuary where the submerged plant *Vallisneria americana* provides important habitat when allowed to flourish. A distribution of inflows that has the greatest frequency range from 300 to 1,500 cfs, with a peak between 300-800 cfs was determined to be the most beneficial to the range of species evaluated. However, we also recognized that a percent of flows outside the preferred range is an important component of the natural variability inherent in estuaries. An optimization program was employed as a first attempt to define the percent of acceptable violations (Labadie 1995: Otero et al 1995). The desired inflow ranges (limits for biota) were input variables to the model, along with the natural periodicity of violations of the upper and lower limits (estimated from the 1966-1990 historic data). For the Caloosahatchee, 20.5% violation of the low flow limit created inflows that emulated the natural variability established from the rainfall during 1966-1990. In addition to natural variation, this original frequency distribution (Figure 2b) generated by the model revealed that (1) the appropriate inflows limits were attained (300-2,800 cfs); and (2) the greatest frequency of inflows were within the range from 300-1,300 cfs, with a peak of inflows between

300-800 cfs. This original frequency distribution was reported as provisional, with the intent to update it as more information became available about the salinity requirements of key biota.

More resent modeling efforts use a 2000 Base condition (Figure 3a), which have approximate 51% of the flows falling below 300 cfs. Additional field and laboratory research since the Chamberlain and Doering (1998b) publication indicates that *Vallisneria* is more sensitive to water quality conditions related to high salinity during low flows, as well as poor water clarity during excessive discharges. The last major drought constituted significant harm to the *Vallisneria* beds, which have still not fully recovered after 4 years. Subsequent hydrologic modeling work related to the RESTUDY, the Caloosahatchee Water Management Plan, and the development of MFLs produce less low flow violations than the original 20.5% and will better protect *Vallisneria*. Two flow distributions were created during this time: (1) EST01 with 14% of the flows $\leq$ 300 cfs, represented the best determination of a "safe" redistribution of existing non-tidal Caloosahatchee water deliveries; and (2) EST02 (Figure 3b), was based on improving minimum deliveries at S-79. A primary purpose of the C-43 Project is to modify existing watershed runoff so that it falls within the flow envelope for the estuary. EST02 is more likely to achieve this goal. It also is the best available estimate of pre-development delivery. EST05 (Figure 3c) was developed specifically to addresses *Existing Legal Sources for the Caloosahatchee Estuary at S-79*. It is similar to EST02, except that mean monthly inflows at S-79 are maintained above 300 cfs. Therefore, EST05 provides a slightly higher level of protection (against lower salinity) in the upper estuary than the other two time series.

For the accelerated C-43 Project, we recommend using EST05. Although EST02 flows are probably more representative of pre-development conditions, the reality is that permanent alterations have occurred. Addition of a base flow in EST05 recognizes the estuary has been modified, especially by installation of S-79, which truncated the salinity gradient, preventing upstream migration of low salinity water during the dry season, thus eliminating the dry season oligohaline low salinity zone that historically existed. EST05 is consistent with the 300 cfs minimum flow threshold established for the Caloosahatchee Estuary at S-79 (Doering et al. 2002) and is commensurate with the MFL and the recovery strategy for MFL that C-43/CERP needs to provide. Even with EST05's additional protection against low flow conditions, there will be instances of high salinity above the MFL criteria, in part due to low tidal basin inflow. Also, the alternatives to be considered will likely not always produce flows $\geq$ 300, so there will still be occurrences of very low flow consistent with the natural variability of estuarine systems.

C.13 CHAMBERLAIN AND DOERING PAPER

PRELIMINARY ESTIMATE OF OPTIMUM FRESHWATER INFLOW TO THE CALOOSAHATCHEE ESTUARY: A RESOURCE-BASED APPROACH

R.H. Chamberlain[1]
P.H. Doering[1]

ABSTRACT

In the Caloosahatchee Estuary, establishing a suitable salinity environment is the most basic prerequisite for promoting estuarine biota in this system. The South Florida Water Management District has adopted a resource-based research strategy with the intent of prescribing an acceptable freshwater discharge distribution within the salinity tolerance range of key estuarine species. To test this approach, submerged aquatic vegetation were selected as key species. This paper presents preliminary results and recommends a provisional inflow distribution.

INTRODUCTION

The Caloosahatchee River (canal C-43) and estuary (Figure 1) have been drastically altered to convey more basin runoff and regulatory releases from Lake Okeechobee (Chamberlain and Doering, this proceedings). These changes have caused large fluctuations in: freshwater inflow volume; frequency of inflow events; timing of discharges; and water quality in the downstream estuary. Therefore, the South Florida Water Management District (SFWMD) initiated a long-term research program in 1985 to quantify the impacts of freshwater inflow from Franklin Lock and Dam (structure S-79) on downstream estuarine organisms. Chamberlain and Doering (this proceedings) described the resource-based management approach of this program and explained that it seeks to define limits for freshwater inflow which provide a suitable salinity and water quality environment for key species. To test this research strategy, submerged vascular plants have been selected as key species.

One aspect of the estuarine research has been field monitoring of water quality and biota during a wide range of discharge events. The purpose of this paper is to report preliminary results of the relationship between freshwater inflow, salinity, submerged aquatic vegetation (SAV) and other estuarine species. These results are based on analysis of field monitoring efforts, in order to: (1) establish provisional limits for the quantity of freshwater discharged to the estuary via S-79, and (2) examine one of the major assumptions of the resource-based approach: that environmental conditions suitable for key species also will be suitable for other important biota.

METHODS

A computational salinity model developed by Bierman (1993) for the Caloosahatchee Estuary (CE) was employed to mathematically define the influence of various freshwater inflows on salinity at every 2 kilometers upstream from Shell Point to S-79. Modeling results compared freshwater inflow influence on the preferred salinity and distribution of SAV and other biota, which were determined from field sampling and the literature. The model also determined that salinity downstream to Shell Point is dependent (97%) on inflow from S-79 and that during average inflow conditions (~1,000 cfs) the hydraulic residence time averages about one month. Therefore, for this report, freshwater discharge to the estuary is considered in terms of mean monthly inflow from S-79.

[1]South Florida Water Management District, Ecosystem Restoration Department, 3301 Gun Club Road, West Palm Beach, FL 33406

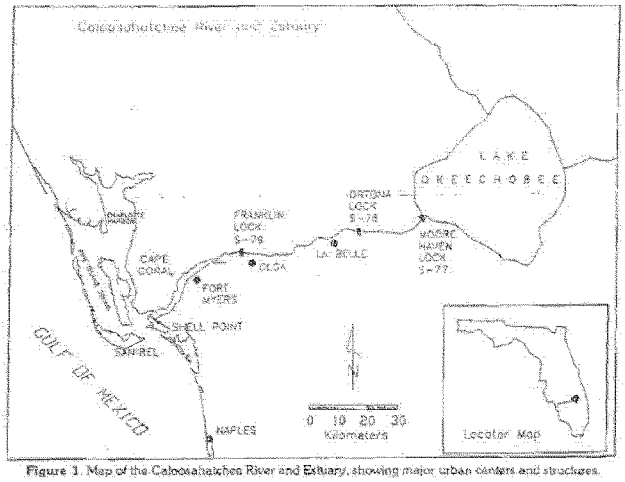

Figure 1. Map of the Caloosahatchee River and Estuary, showing major urban centers and structures.

Field observations of *Vallisneria americana* by Hoffacker (1994), the authors of this paper, and others (Gunter and Hall 1962; Phillips and Springer 1960), served to establish a qualitative abundance index for comparison with salinity at the time of observation. Information from Hoffacker (1994) and the SFWMD were combined to produce a map of SAV distribution upstream of Shell Point (Figure 2).

Monthly water quality and biota sample collections occurred in three phases: phase 1 ran from 1986 into 1989 when S-79 inflows were usually low to moderate; phase 2 was conducted during 1994–1996 when discharges were often large; and two follow-up sample trips (phase 3) to evaluate seagrass recovery were conducted in 1997. Sampling centered around seven locations in phase 1 (Figure 2), areas 1–6 in phase 2, and only location 6 in 1997.

Repetitive random samples of the seagrasses *Halodule wrightii* and *Thalassia testudinum* were collected at locations 5–7 during phase 1 and area 6 in the remaining two phases. For this report, only the photosynthetic blades that were collected within 0.1 m^2 quadrat samples, then dried and weighed, were analyzed (dry weight biomass).

For this preliminary analysis, the effects of freshwater discharge on zooplankton, ichthyoplankton, and benthic macroinvertebrates were evaluated using the data obtained during phase 1 of the SFWMD field monitoring. All data that were not normally distributed were logarithmically transformed. The biota from each station were separated into flow categories (factor levels). A simple one-factor analysis of variance (ANOVA) was

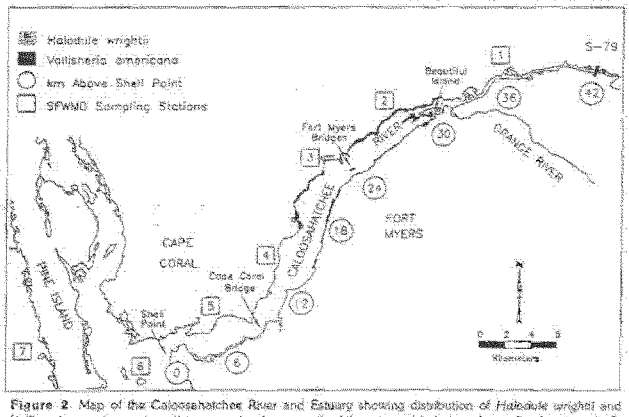

Figure 2. Map of the Caloosahatchee River and Estuary showing distribution of *Halodule wrightii* and *Vallisneria americana*, river distances in km from mouth of the estuary (circles), and sampling locations (1–7, squares).

calculated to test for statistical difference between the mean monthly inflow categories ($p<0.05$). A hierarchy evaluation (Scheffe multiple range test) for mean density between inflow categories was performed to determine which inflow levels were associated with significantly more or less biota. Because adult finfish, crabs, and shrimp were not sampled, we relied on literature information from the CE and other Florida estuaries to estimate desired inflow conditions for these biota.

RESULTS AND DISCUSSION

Salinity And Freshwater Inflow

The salinity model results (Bierman 1993) indicate that more than half the estuary upstream of Shell Point will become nearly freshwater and, salinity will be reduced drastically downstream during even moderate mean monthly discharges of 2,000 cfs (Figure 3). Inflows greater than 4,000 cfs will cause most of the estuary upstream of Shell Point to become freshwater and depress salinity (<15 ppt)in portions of San Carlos Bay. At the other extreme, prolonged low to no flow (<100 cfs) results in salinity conditions near S-79 that exceed 15 ppt, eliminating any tidal freshwater or oligohaline zone within the estuary.

V. americana longitudinal distribution is about 18 km during ideal growing conditions and stretches from its upstream limit at 32 km, as measured from Shell Point, to its downstream limit at 14 km (Figure 2). Based on this distribution, we estimated that over 80% of the total area covered by moderate to dense stands of *V. americana* under favorable growing conditions are in the first 4 km (28–32) of its upstream limit.

Literature information indicates that *V. americana* growth steadily declines with increasing salinity until it ceases at approximately 8–9 ppt, but it can tolerate salinity (survive) up to 11–13 ppt (Day et al.

Chamberlain, Doering

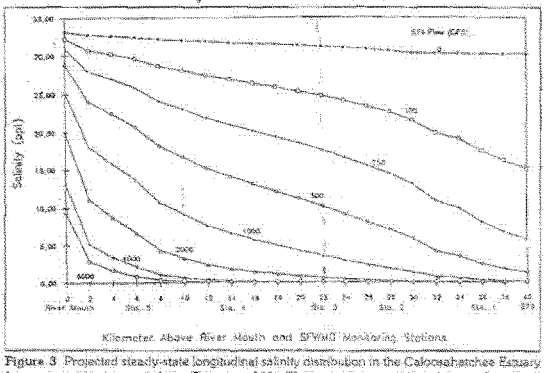

Figure 3. Projected steady-state longitudinal salinity distribution in the Caloosahatchee Estuary for a range of freshwater inflows (Bierman 1993). The x-axis corresponds to distance from Shell Point (km).

1989, Twilley and Barko 1990). The qualitative information assembled from observations in the CE (Figure 4) is consistent with these limits and indicates that density declines where salinity is above 10 ppt. A similar plot of biomass vs. temperature reveals no trend, suggesting little influence of temperature on *V. americana* distribution in this system.

Employing the results of the model by Bierman (1993; Figure 3), it appears that at least a 300 cfs mean monthly discharge from S-79 is required to maintain *V. americana* in the system. Analysis of historical S-79 discharges determined that attaining the 300 cfs minimum inflow will be a concern only during the November–May dry season. Therefore augmentation of flow should be considered during this time. Discharges that approach 400–500 cfs will provide salinity conditions of <10 ppt within the portion of the estuary that support most of the total *V. americana* coverage. To provide salinity conducive for *V. americana* throughout its entire 18 km range will require mean monthly discharges of approximately 800 cfs.

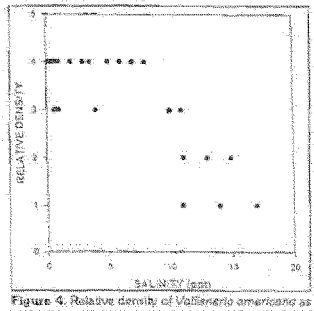

Figure 4. Relative density of *Vallisneria americana* as a function of salinity in the Caloosahatchee Estuary. Density ranks equate to following: 1 = absent; 2 = absent to sparse; 3 = moderately dense; 4 = dense. Each circle corresponds to one observation (Phillips and Springer 1960; Gunter and Hall 1962; Hoffacker 1994; SFWMD).

H. wrightii is the only seagrass species consistently found around station 5, upstream of Shell Point, until it mixes downstream with *T. testudinum* in San Carlos Bay (Figures 5a and b). *H. wrightii* has a much smaller distribution upstream of Shell Point than *V. americana*. It ranges only from 2–10 km upstream of Shell Pt., with the greatest coverage per 2-km segment within the 4-6 km area.

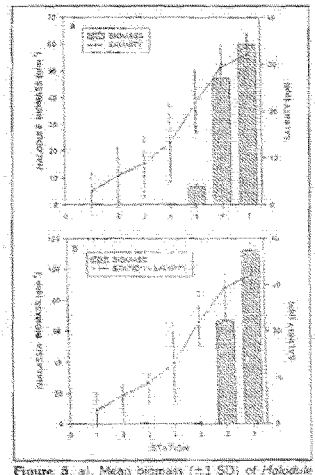

Figure 5. a). Mean biomass (±1 SD) of *Halodule wrightii* (dry weight) and salinity (±1 SD) at each sampling station for all seasons combined, and (b) mean biomass (±1 SD) of *Thalassia testudinum* (dry weight).

H. wrightii is reported to have a wide salinity tolerance by McMahan (1968). It does not survive below 3.5 ppt and prefers salinity as high as 44 ppt. This wide tolerance is probably why it is the only true seagrass species encountered inside the CE at station 5, although high discharges probably limit its productivity. The lowest biomass occurs inside the estuary where salinity is also lowest and most variable. Graphically and statistically, biomass of *H. wrightii* is greater when salinity is above 20 ppt (Figure 6). Statistically, the greatest biomass occurs when salinity is >28 ppt.

Literature summarized by Zieman and Zieman (1989) indicates that the optimum salinity range for *T. testudinum* is 24–35 ppt, with maximum photosynthetic activity occurring at 35 ppt and decreasing linearly with declining salinity. *T. testudinum* does not normally grow in areas where salinity is below 17 ppt. These literature values are consistent with preliminary monitoring results for the CE (Figure 5b). *T. testudinum* does not exist inside the estuary (in Iona Cove: area 5), where salinity during sampling was more variable, with a standard deviation that extended below 20 ppt due to long periods below 10 ppt. Like *H. wrightii*, the biomass of *T. testudinum* is statistically greater when salinity is above 20 ppt, regardless of season.

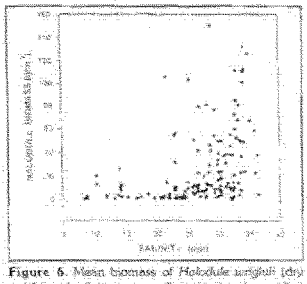

Figure 6. Mean biomass of *Halodule wrightii* (dry weight) and salinity per sampling trip at each sampling station for all seasons combined.

According to the Bierman model and statistical analysis, the 400–600 cfs needed to support over 80% of the *V. americana*, will not lower salinity below that preferred by *H. wrightii* (>20 ppt) anywhere in its current range. Salinity begins to approach the reported mortality limit of *H. wrightii* (3.5 ppt) in area 5 when average discharges approach 3,000 cfs for more than a month. Both *H. wrightii* and *T. testudinum* biomass are statistically greatest throughout their respective distributions when mean monthly inflow is less than about 800 cfs for more than two months. In San Carlos Bay, mean monthly inflows >4,500 for two or more months are statistically associated with the least biomass for both species.

Finfish

At least 75% of Florida's recreational fishes depend on estuaries for at least a portion of their life. The most important role of estuarine systems is as a nursery area for juvenile stages (Seaman 1988). In the upper CE, Gunter and Hall (1962) reported the greatest catches in seines consisted of juveniles, during midwinter inflows that reduced salinity in the inner estuary to 1–5 ppt (station 2 area). Seine catches in the outside water (San Carlos Bay area) were greatest when salinity was high. Therefore, establishment of a minimum inflow for *V. americana* should generally benefit the finfish of the estuary by providing a salinity gradient that includes desired low salinity conditions upstream for juveniles. Maintenance of this minimum flow is apparently most critical during the winter dry season. However, year round high maximum inflow limits that maintain salinity downstream of Shell Point also appear beneficial.

Bay anchovy (*Anchoa mitchilli*) juveniles and adults were the third most abundant fish collected by Gunter and Hall (1962), with 94% of the fish caught upstream of Shell Point. Most of the juveniles they caught were from near zero salinity water at stations close to *V. americana* beds at Beautiful Island and the Ft. Myers bridges. This is consistent with Jones et al. (1978), who reported that juveniles often ascend rivers above brackish waters. Therefore, inflows within the optimum range for SAV (300–800 cfs) should not adversely impact bay anchovies, and should provide better conditions for their development and food production.

Redfish (*Sciaenops ocellata*) are an important game fish in Florida. Spawning occurs seaward of estuary passes during late summer and fall. Seaman (1988) reported that seagrass meadows are primary habitat for young redfish. Once in the estuary, juveniles feed on benthic organisms from October to February and later on small fish and shrimp. Collections of redfish in the CE (Phillips and Springer 1960; Gunter and Hall 1962) were almost exclusively inside the estuary with salinity ranging from 0.2–14 ppt. Therefore, promoting dry season inflows conducive for SAV also will provide salinity and habitat for redfish recruitment and development.

Ichthyoplankton

Anchoa spp. comprised 76% of the SFWMD ichthyoplankton samples during 1986–1989 (unpublished data). The greatest density occurred during April–July, followed by the period of December through March. During the dry season, when inflows will need to be augmented for *V. americana*, high inflows >2,500 cfs were associated with the lowest mean ichthyoplankton density, regardless of location in the estuary. Mean density within the flow category of 300–600 cfs were at least the second highest at all stations, and therefore represented the optimum overall flow category.

The presence of developing fish eggs provides a good indication of the spawning location and recruitment success of fish in an

estuary. Statistical analysis of eggs within ichthyoplankton samples during the dry season found significant differences existed among inflow categories: inflows in the range of 150–600 cfs were associated with the highest mean egg density at stations 1–4; and density decreased as inflows increased above this category. In fact, no eggs were ever collected during this season at stations 1–5 when inflows were >2,500 cfs and substantially fewer eggs were collected at station 6. Reduced egg density during high inflows are assumed to be related to a 'flush-out' effect, so similar impacts probably exist during the wet season.

Zooplankton

Zooplankton provide a crucial link in the estuarine food web when they consume free-floating microscopic plants (phytoplankton) and transfer plant energy to higher trophic levels. Dominant forage fishes such as bay anchovy, as well as juvenile stages of most estuarine fish species, depend on zooplankton as a food source.

Within each season, mean zooplankton density increased with increasing salinity and distance from S-79. In general, zooplankton density was greatest during April–July. Collections during this time period appeared sensitive to high flows. Inflows greater than 1,500 cfs resulted in the lowest mean density at all stations. Evaluation of dry season inflow (November–May) revealed significant lower density with flows >1,200 cfs. Zooplankton mean density associated with inflows between 300–600 cfs were consistently among the greatest encountered at each station.

Invertebrates

In the Little Manatee River (southwest Florida), Peebles and Flannery (1992) reported that transfer of the estuary's food source to juvenile fish appeared to occur largely through their feeding on benthic organic material. Therefore, the density of benthic organisms can strongly influence the survival of many higher trophic species. The SFWMD benthic macroinvertebrate survey (unpublished data) found that the CE supports a large number of species (519). The majority of these are sessile and can't relocate to a more favorable location when water quality deteriorates. CE inflows within the optimum range for *V. americana* appear conducive for supporting a wide range of benthic infauna. Statistical analysis of dry season data indicate that peak benthic macroinvertebrate density at stations 1–4 was associated with inflows (150–600 cfs) that establish salinity in approximately the mesohaline range (5–18 ppt). This same preliminary analysis also indicated that mean monthly discharges >3,000 cfs are associated with the lowest densities at stations 1–4.

Penaeid shrimp probably represent the most economically important fishery in Florida (Seaman 1988). Mating and spawning occurs offshore and the postlarvae migrate into the estuary and seek shallow areas with vegetation and/or abundance of organic detritus. The loss of SAV directly reduces fishery yields (Seaman 1988). Gunter and Hall (1962) indicated pink shrimp (*Penaeus duorarum*) were common in seine and net samples in the CE. Haunert (1987) reported pink shrimp abundance increased after inflows increased in the St. Lucie Estuary, but decreased when inflows caused salinity to decline to oligohaline conditions (<5 ppt), which are not tolerated well by pink shrimp (McFarland and Lee 1963; Gunter et al. 1964). Therefore, in the CE, minimum and maximum inflows that promote SAV at both the inner estuary and the Iona Cove–San Carlos Bay regions should provide ideal salinity for pink shrimp and support bottom vegetation habitat important for postlarvae development.

The CE supports a year-round commercial

Chamberlain, Doering

and sport fishery for blue crabs (*Callinectes sapidus*). This species also is an important source of food for many fish. The first development stages are planktonic, which prefer 30 ppt and will perish if exposed to salinity <20 ppt (Millikin and Williams 1984). After settling out of the plankton, each subsequent juvenile phase of both sexes is concentrated in progressively lower salinity because of their continuing migration up the estuary (Millikin and Williams 1984). Juvenile and adult blue crabs also occur in much

Table 1. Provisional recommended inflows (cubic feet/second) for promoting the health of selected taxa in the Caloosahatchee Estuary.

Snook	300	300–1,500	3,000	late dry season — PIR; all year (esp. late dry season) — UIL
Larval fish		300–600	2,500	dry season (esp. spring–early summer)
Fish eggs		150–600	2,500	all year
Pink shrimp	300	300–800	3,000	all year
Blue crabs	300	300–800	3,000	all year (esp. Feb–Jul)
Zooplankton		300–600; <1,500	2,500	all year
Shrimp and crab larvae		<1,300	2,500	all year (esp. spring–Jul)
Benthic macro-invertebrates		300–800	3,000	all year
Oysters		300–800	3,000	all year

-128-

higher densities in areas covered by vegetation. Therefore, inflows in the range of 300–800 will be beneficial for blue crabs because of their salinity requirements throughout the CE, as well as the SAV habitat that these flows promote in both the inner and outer estuary.

ESTIMATE OF OPTIMUM INFLOW

Table 1 recommends provisional inflow ranges and timing for maintaining the health of the important taxa discussed above and others. The preliminary analysis suggests that a minimum inflow of 300 cfs for *V. americana* during the dry season will not be harmful, but inflows greater than about 2,500–3,000 cfs may be detrimental to other biota anytime of the year. Therefore, a distribution of inflows that has the greatest frequency range from 300 to <1,500 cfs, with a peak of 300–800 cfs, should be generally beneficial to all the biota evaluated.

Beyond identifying the optimal timing and distribution of inflow, we also must consider that freshwater inflow varies naturally as a function of rainfall. Inclusion of this natural variation is important to insuring a diverse composition of estuarine biota. Ultimately, this will mean a defined percent of violations should be allowed for both the high and low discharge limits. As a first attempt to define this environmentally sensitive distribution of S-79 discharges, a optimization program (computer model) was employed (Labadie 1995; Otaro et al. 1995). The program utilized historic watershed runoff data during 1966–1990 (without Lake Okeechobee releases). The desired inflow ranges (limits for the biota) are input variables to the model, along with the natural periodicity of violations of the upper and lower limits (estimated from the 1966–1990 historic data). For the Caloosahatchee Estuary, 20.5% violation of the lower limit and 5.5% violations of the upper limit created inflows that emulated the natural variability established from rainfall during 1966–1990. In addition to natural variation, the resulting frequency distribution generated by the model (Table 2) reveals that: (1) the appropriate inflow limits were attained (300–2,800 cfs); and (2) the greatest frequency of inflows were within the range from 300–1300 cfs, with a peak of inflows between 300–800 cfs.

Table 2. Proposed frequency distribution of freshwater inflows to the Caloosahatchee Estuary for 1966–1990 generated by the optimization model.

FREQUENCY OF OCCURRENCE (%)	DISCHARGE RANGE (from S-79; cfs)
20.5	0–300
44.3	301–800
15.7	801–1300
5.5	1301–1800
4.8	1801–2300
3.9	2301–2800
5.5	>2801

The above-recommended optimum flow distribution is provisional, based on the data currently evaluated, preliminary model results, and our best professional judgement. A final distribution will be established after a better understanding of the salinity tolerances of seagrass and other species is determined. This will be accomplished by conducting a more detailed evaluation of the field data than provided in this summary, and by completing field and lab experiments, which have already begun.

ACKNOWLEDGMENTS

The resource-based strategy was based on peer reviewed guidelines developed by Mote Marine Laboratory for SFWMD estuarine research, and applied in the St. Lucie Estuary. Mote Marine Laboratory also identified and enumerated the organisms contained in the Caloosahatchee samples. The field work, sample processing, and data management depended on the effort of many SFWMD staff, most notably Dan Crean and Kathy Haunert.

C.14 EXISTING LEGAL SOURCES OF WATER FOR THE CALOOSAHATCHEE ESTUARY

Existing Legal Sources for the Caloosahatchee Estuary At the Franklin Lock and Dam (S-79)

Coastal Ecosystems Division

Southern Restoration Department

May 2003

1

Introduction:

The Water Resources Development Act of 2000 (WRDA 2000) assures the protection of existing legal sources of water as of the date of enactment, December 2000. CERP projects cannot eliminate or transfer an existing legal source of water unless a new source of water supply of comparable quantity and quality is available to replace water lost as a result of the Plan.

Legal sources are defined as follows:

> *The quantity of water available from all locations of which there was a dependence as of December 2000, consistent with federal and State law for: 1) urban and agricultural existing legal uses, including those uses exempt from permitting requirements; 2) non-consumptive uses, including regional surface water deliveries and groundwater seepage for resource protection; 3) meeting the entitlement rights of the Seminole tribe of Florida; 4) the Miccosukee Tribe; 5) federal and state requirements for Everglades National Park; and 6) protection of fish and wildlife.*

It is proposed to spatially separate the major regions or user basins of the C&SF project to properly determine the dependence of each basin on existing legal sources. Within this context, estuaries may be viewed as "user basins" that have existing legal sources of freshwater for the protection of fish and wildlife. The task at hand is to quantify the volume of water currently delivered to estuaries that is beneficial (=protects) to fish and wildlife and sustains healthy populations.

Beneficial Discharges to Estuaries:

No standard methods exist to quantify the beneficial discharge of freshwater to an estuary. Freshwater discharge affects many aspects of the estuarine environment including circulation, water chemistry, salinity, residence time, and biological

2

productivity. In turn changes in any of these parameters can affect estuarine fish and wildlife. Thus, the "benefits" to fish and wildlife of a particular discharge event may be defined in terms of any of these parameters. In general, the approach used here has been to examine the effects of freshwater discharge on salinity and in turn the effects of salinity on selected estuarine organisms. A discharge is beneficial if it produces a salinity regime that allows estuarine organisms to successfully reproduce and survive. A salinity-based definition was chosen because historically, salinity has been identified as the environmental variable that primarily controls the performance, composition, distribution and abundance of estuarine flora and fauna (Bulger et al. 1993, Emery et al. 1957, Gunter 1961).

Another important aspect of freshwater discharge to estuaries is that it varies. The natural component of this variability in discharge is primarily a function of temperature and rainfall. Although there are exceptions, freshwater discharge accounts for much of the variation in estuarine salinity at seasonal and inter-annual time scales (Peterson et al. 1995). This kind of natural variability can cause dramatic changes in the composition and distribution of estuarine biota (Tyler 1986, Nichols, 1985). Despite the noticeable effects that it may have, beneficial discharges should allow for natural variability. Ideally, a beneficial discharge rate should not be viewed as a single constant value but as a long-term average derived from a time-series that follows a natural periodicity.

In order to quantify this beneficial volume or discharge, two pieces of information are required. First, we need to know the quantity of water delivered as of Dec. 2000. Output from the South Florida Water Management Model (SFWMM) 2000 will serve as an estimate of "current water delivery". Second, a "beneficial discharge target" must be defined and quantified. In the best case, both the "current water delivery" and the "beneficial discharge target" will be defined as a climate driven time-series of daily flows. Once the two are known, the "beneficial deliveries" as of Dec 2000 can be calculated by a straightforward subtraction of the "current water delivery" from the "beneficial discharge target".

3

South Florida Water Management Model:

The South Florida Water Management Model (SFWMM) is a regional-scale computer model that simulates the hydrology and the management of the water resources system from Lake Okeechobee to Florida Bay. It covers an area of 7600 square miles using a mesh of 2 mile x 2 mile cells. In addition, the model includes inflows from Kissimmee River, and runoff and demands in the Caloosahatchee River and St. Lucie canal basins. The model simulates the major components of the hydrologic cycle in south Florida including rainfall, evapotranspiration, infiltration, overland and groundwater flow, canal flow, canal-groundwater seepage, levee seepage and groundwater pumping. It incorporates current or proposed water management control structures and current or proposed operational rules. The ability to simulate water shortage policies affecting urban, agricultural, and environmental water uses in South Florida is a major strength of this model. The SFWMM simulates hydrology on a daily basis using climatic data for the 1965-2000 period which includes many droughts and wet periods. The model has been calibrated and verified using water level and discharge measurements at hundreds of locations distributed throughout the region within the model boundaries. The 2000 Base run, which serves as an estimate of current water delivery, simulates the 36-year period from 1965 – 2000 on a daily basis, assuming land uses as they were in 2000. The "beneficial discharge target" also will simulate the same period on a daily basis.

Since the literature concerning beneficial discharges to estuaries is not well developed, there are no accepted methods for quantification. Several possible approaches are described below.

Flow Range Approach:

In general, the South Florida Water Management District has applied a resource-based approach to water management issues in estuaries. Water quantity issues (e.g. minimum, maximum, and optimum flows) have been addressed by (1) identifying important resources and their location in an estuarine system (e.g. oysters, Submerged Aquatic Vegetation), (2) determining the salinity tolerances of these resources, (3) determining

the relationship between freshwater inflow and the distribution of salinity within in the estuary and (4) determining the freshwater discharge that produces overlap between a resource and its tolerable salinity. The salinity tolerance information can be used to identify a salinity envelope (with an upper bound and lower bound) within which these keystone resources can successfully complete their entire life cycle. The relationship between salinity and fresh water discharge can in turn be used to identify a range of freshwater inflows (with a lower bound and an upper bound) that maintains salinity within the prescribed envelope at appropriate locations in the estuary. These flows are beneficial and protect fish and wildlife. In general, the salinities employed in these envelopes are those which can be tolerated by indicator organisms for about a month or longer. The flows associated with these envelopes are therefore mean monthly flows.

In the simplest application, an upper limit to beneficial flows is identified such that higher flows are not considered beneficial. Flows in the output from the SFWMM model that fall below this critical level are considered beneficial. Because they fall below minimum flows, excessively low flows, while not harmful, provide essentially no ecological benefit. The counter argument, employed in this method is that some flow, however small, is more beneficial than none at all. The procedure is illustrated in Figure 1.

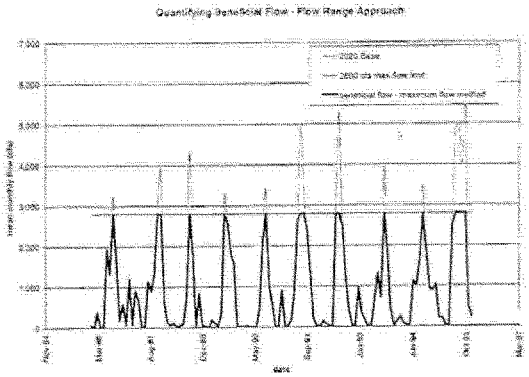

Figure 1. Beneficial Flow based on maximum acceptable flow

Flow Distribution Approach:

The flow distribution is an extension of the flow range approach described above. The salinity or flow envelope approach specifies a range of acceptable flows and limits that can be used to define a "beneficial volume". However, these limits are constant, containing no signature of natural variability. Runoff events outside the norm occur with some frequency. While it is not known precisely what frequencies are beneficial or harmful to an estuary, it is generally accepted that elimination of naturally occurring "extreme" events would be detrimental. Therefore, a distribution with most flows occurring inside the envelope and higher or lower flows occurring outside the envelope with some lower frequency is more natural and desirable.

The problem is to identify the shape of the "beneficial" frequency distribution. A flow frequency distribution is composed of a number of contiguous flow ranges and a frequency of occurrence for each. A contiguous series of flow intervals can be defined by the different levels of physiological or demographic performance that occur at different levels of flow or salinity. A qualitative impression of the relative frequency of each interval can be based on the number and quality of physiological or demographic functions supported by each interval (Figure 2). For example, in Figure 2, the frequencies of flows in the 500 to 700 cfs and 700 – 900 cfs intervals are highest because these support the best adult survival, growth and reproduction and the highest population abundances and instances of occurrence.

The resulting distribution is a qualitative representation of a hydropattern that is ecologically favorable for biota in the Caloosahatchee estuary. Climate driven hydrologic modeling is then used to create a hydrologic pattern that is both consistent with the species driven hydropattern and the statistical characteristics of river discharge to an estuary (log-normal mean monthly flows). The final hydropattern is a 36 year (1965 – 2000) time series of daily discharge for S-79 that produces a frequency distribution of mean monthly flows that is log-normal and includes natural variability.

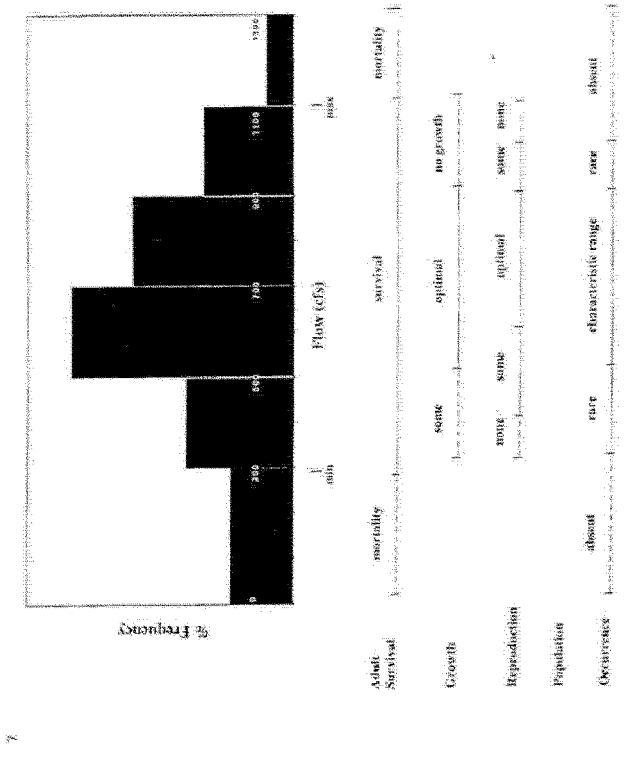

Figure 2. Conceptual derivation of an ecologically based distribution of freshwater inflow

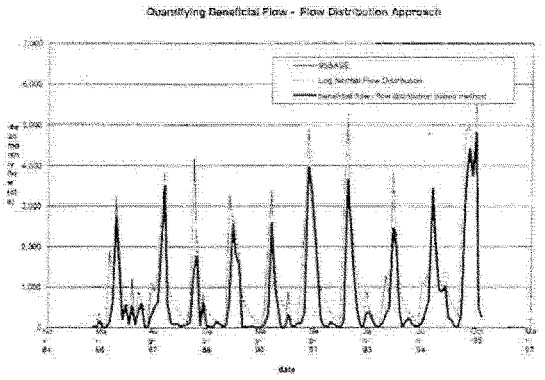

Figure 3. Beneficial Flow based on flow distributions.

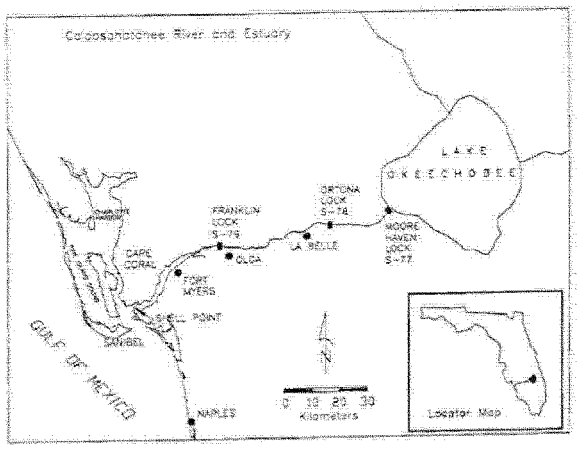
Pre-Development Flow Approach:

For some estuarine systems it may not be possible to use the resource-based approach described above. This may occur because important resources have not been identified or their salinity tolerances are unknown. This may also occur because other water quality parameters (aside from salinity) may be better indicators of beneficial or detrimental water volumes (e.g. nutrients). An analysis of natural inflows provides an alternative approach. This method assumes that the pattern and magnitude of natural freshwater inputs are "good" for estuarine receiving waters. Estimates of "natural" inflows can be derived from historic measurements that occurred before the system was impaired or from models such as a natural systems model.

The Caloosahatchee Estuary:

Study Area:

The Caloosahatchee River and Estuary are located on the southwest coast of Florida (Figure 4). The Caloosahatchee River runs from Lake Okeechobee to the Franklin Lock and Dam (S-79) where it empties into the estuary which is some 40 kilometers long and terminates at Shell Point. The Caloosahatchee River is the major source of freshwater to the estuary. Enough water enters the estuary at S-79 to fill its volume over 8 times per year (Doering and Chamberlain 1999).



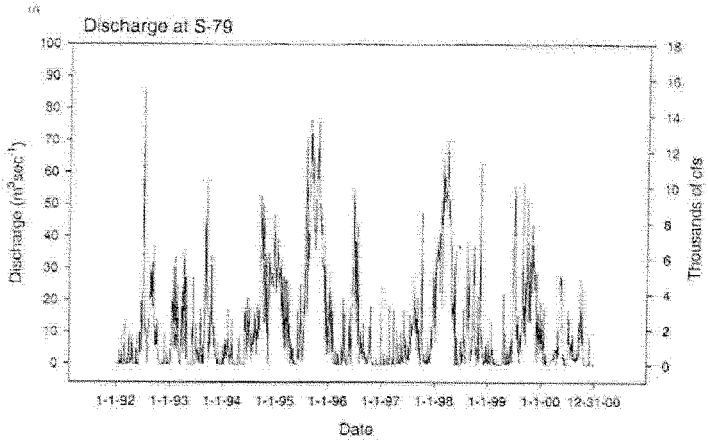


Figure 4. The location of the Caloosahatchee estuarine system

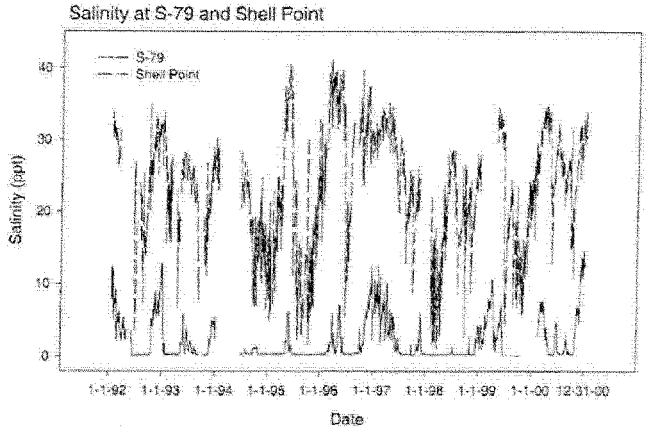

Figure 5. Daily freshwater discharge at S-79 and corresponding salinity at S-79 and Shell Point

The hydrology of the Caloosahatchee system has been altered over time. The river has been permanently connected to Lake Okeechobee and about 20% of the water entering the estuary now comes from the Lake mainly as regulatory releases to maintain the Lake at a prescribed water level. The river has also been straightened, deepened and three water control structures have been added. The last, Structure S-79, was completed in 1966 to act, in part, as a salinity barrier (Flaig and Capece, 1993). The result is that freshwater delivery has been altered and the salinity gradient is variable and often truncated. Long-term records of salinity at the head (S-79) and mouth (Shell Point) illustrate this high variability and truncation of the salinity gradient (Figure 5). During periods of low freshwater discharge, salt water regularly intrudes all the way to the structure, often exceeding 10 ‰. By contrast, high freshwater discharge can cause salinity to drop below 5 ‰ at the mouth. The transition between the two states can be rapid, sometimes requiring less than a week. The fluctuations observed at the head and mouth of the estuary exceed the salinity tolerances of oligohaline and marine species.

Figure 5. Daily freshwater discharge at S-79 and corresponding daily average salinity at S-79 at the head of the estuary and at Shell Point near its mouth.

Ecological Basis for Beneficial Deliveries to the Caloosahatchee:

The South Florida Water Management District recognized the need to identify a range of discharges from S-79 that will protect the system and began a research program in 1985 (Chamberlain and Doering 1998a). The research program included field sampling to establish relationships between major ecosystem components (seagrass, zooplankton, fish larvae, benthic macroinfauna) and inflow at S-79 (Chamberlain and Doering 1998b). An extensive literature review was conducted to summarize salinity tolerance information for other organisms found in the Caloosahatchee but not sampled by the District. The District began a series of laboratory experiments in 1995 to establish cause and effect salinity tolerances of submerged aquatic angiosperms (SAV) found in the Caloosahatchee (Doering et al. 1999, Doering and Chamberlain 2000, Doering et al. 2001). More recently, the District has funded research on the relationship between flow, salinity and autecology of the oyster (Volety and Tolley 2003).

12

The results of this research form the basis of our understanding of the ecological response of the Caloosahatchee to freshwater discharge at S-79. In the next section the derivation of the flow envelope is presented first, followed by the derivation of the flow distribution.

Derivation of a Flow Range for the Caloosahatchee:

A combination of the Valued Ecosystem Component Approach (USEPA, 1987) and the habitat overlap concept of Browder and Moore (1981) was used to establish minimum and maximum inflow estimates. Conceptually, flows below the minimum are considered too low to support an adequate biotic structure and function of the low salinity zone in an estuary. Inflows above the maximum cause loss of biotic structure and functionality in areas of higher salinity. Inflow estimates and their derivation have been published in the peer-reviewed literature (Chamberlain and Doering 1998b; Doering et al. 2002). A brief description of the approach is given here.

The Valued Ecosystem Component Approach (VEC) is the general name given to a method developed by the U.S. Environmental Protection Agency (USEPA, 1987) to guide monitoring programs in the National Estuary Program. The approach has been modified to focus on providing critical estuarine habitat. In some cases that habitat might be physical, such as an open water oligohaline zone. In other cases the habitat is biological and typified by one or more prominent species (e.g. an oyster bar). For the Caloosahatchee, beds of submerged angiosperm grasses (SAV) have been identified as a VEC.

The overlap concept of Browder and Moore (1981) forms the basis for relating freshwater discharge to VEC or other estuarine resources (Sklar and Browder, 1998). The concept of static and dynamic habitat overlap (Browder and Moore, 1981) is based on the ideas of Gunter (1961) that (a) estuaries serve a nursery function and (b) salinity determines the distribution of species within an estuary, and indeed different life stages of the same species. In addition, the concept recognizes the importance of the appropriate physical or static habitat to the nursery function and

15

ability of the estuary to support diverse and abundant biotic populations. Freshwater inflow positions favorable salinities relative to important stationary habitat factors such as shoreline, water depth, and bottom type (Browder and Moore, 1981). In the present application, ecologically supportive freshwater inflows produce a temporal and spatial overlap between grass beds and physiologically tolerable salinity (Figure 6).

In order to estimate minimum and maximum flows, using the overlap approach, the relationship between the spatial distribution of salinity in the estuary and discharge at S-79 must be known. Statistical regression and steady state numerical modeling were used for this purpose (Doering et al. 2002). The location of overlap of tolerable salinity and SAV in the estuary must also be known.

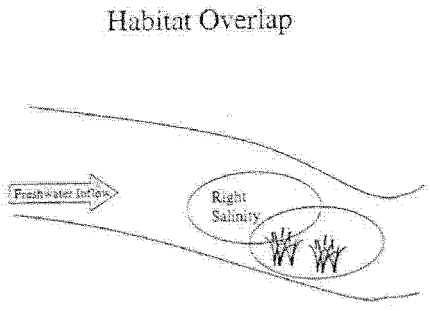

Figure 6. Illustration of the habitat overlap concept. Freshwater inflow positions favorable salinity over grass bed.

The distribution of SAV in the Caloosahatchee is given in Figure 7. The salt tolerant freshwater species *Vallisneria americana* is found at the head of the estuary. Under good growing conditions, *V. americana* can cover about 405 hectares (1000 acres), primarily along the shore. Appreciable densities of plants begin about 32 km upstream of Shell Point and extended to about 12 km upstream of Shell Point. About 60 % of the total area that can be covered by *V. americana* is located between 24 km and 32 km, upstream of the Ft. Myers Bridges (Figure 2). *Halodule wrightii* is the only seagrass found upstream of Shell Point. Further downstream in San Carlos Bay mixed beds of *Thalassia testudinum* and *H. wrightii* occur. Under good growing conditions, some 121 hectares (300 acres) of *H. wrightii* can be found between 2 km and 10 km upstream of Shell Point. About 75% of this area is located between km 2 and km 6 (Chamberlain and Doering 1998b).

15

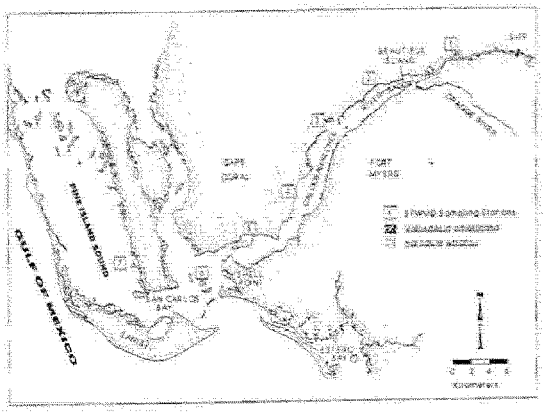

Figure 7. Distribution of submerged aquatic vegetation in the Caloosahatchee Estuary. Numbers refer to areas sampled for zooplankton, ichthyoplankton and other biota.

Although *V. americana* is considered a freshwater species, it is salt tolerant. Salinity tolerances of *V. americana* reported in the literature vary (Doering et al. 1999). Bourn (1932; 1934) found that growth declined with increasing salinity until it ceased at 8.4 ‰. Haller et al. (1974) reported growth at 3.33 ‰ , no growth at 6.66 ‰ or 10 ‰ and death at 13.3 ‰ . After 5 weeks, Twilley and Barko (1990) found no effect of salinity on growth over the range 0 ‰ to 12 ‰. Our laboratory results suggest that for *V. americana* from the Caloosahatchee, growth is low or nil in the 10 ‰ - 15 ‰ range with mortality occurring at salinities greater that 15 ‰ (Doering et al. 1999; Doering et al. 2002). This agrees well with transplant experiments conducted in the Caloosahatchee that indicated mortality at salinities greater than 15 ‰ (Kraemer et al. 1999). Adair et al. (1994) found the distribution of *V. americana* in Trinity Bay,

16

Texas limited to salinities less than 10 $^{o}/_{oo}$. In outdoor mesocosm experiments, French (2001) observed minimal growth of Vallisneria from the Chesapeake Bay at 10 $^{o}/_{oo}$ and 15 $^{o}/_{oo}$. The combination of results from field monitoring and laboratory experiments conducted by District and other investigators agree that 10 $^{o}/_{oo}$ is a critical threshold salinity for growth.

Halodule wrightii apparently tolerates a wide range of salinity. Upper survival limits range from 52.5 $^{o}/_{oo}$ to 80 $^{o}/_{oo}$ (McMillan and Moseley 1967; MacMahon 1968; McMillan 1974). Estimates of the lower bound for survival also vary. MacMahon (1968) observed death at 0 $^{o}/_{oo}$ and 3.5 $^{o}/_{oo}$ and survival at 9 $^{o}/_{oo}$ after 3 weeks exposure. McMillan (1974) observed green tissue at 0 $^{o}/_{oo}$ and 5 $^{o}/_{oo}$ after two weeks exposure. Zimmerman and Livingston (1976) reported a characteristic salinity range of 17 $^{o}/_{oo}$ – 36 $^{o}/_{oo}$ for *H. wrightii* in Florida estuaries, with a lower limit of 6 $^{o}/_{oo}$.

Both our field density data and our laboratory growth results agree with the characteristic salinity range reported by Zimmerman and Livingston (1976). Although variable, our laboratory results indicate that growth declines at salinities less than 18 $^{o}/_{oo}$ and mortality can begin at 6 $^{o}/_{oo}$ (Doering et al. 2002).

The minimum flow estimate (mean monthly flow at S-79 of about 300cfs) is based on maintaining a tolerable salinity (<10 ppt) for *Vallisneria americana* upstream of Km 24 as measured from Shell Point. This location is consistent with the recently established Minimum Flow and Level for the Caloosahatchee Estuary. The maximum inflow estimate of 2800 cfs is based on avoiding mortality of *Halodule wrightii* at low salinity (< 6 ppt) downstream of Km 6 as measured from Shell Point (see Doering et al. 2002, Appendix 1).

Ecologically Based Flow Distribution:

So far a flow envelope for the Caloosahatchee Estuary down to Shell Point has been identified. The overlap concept can be extended to seagrasses located further down stream in San Carlos Bay. The concept also can be extended to other organisms in the Caloosahatchee: identifying the

17

flows associated with maximum abundances in different areas of the system. This analysis begins to identify optimal or preferred ranges of flow within the flow envelope and quantifies preferred and maximum flows for the more marine portion of the system located in San Carlos Bay.

Table 1. Flow tolerances for biota in the Caloosahatchee Estuary. Flows refer to mean monthly discharge at S-79. * for locations see Figure 7.

SPECIES	General Area	Locations*	Preferred Flow Range (cfs)	Upper Inflow Limit (cfs)
Fish (general)	Estuary	2 - 5	300 – 2800	3,000
Bay Anchovy	Upper Estuary	2 - 4	300 - 800	3,000
Silver Perch	Upper Estuary	2 - 4	300 - 800	3,000
Redfish	Estuary	2 - 5	300 - 800	3,000
Snook	Estuary	2 - 5	300 – 1,500	3,000
Wild Celery	Upper Estuary	2-3	300 - 800	None
Zooplankton	Estuary	2 – 3	150 – 600	2,500
Shrimp/Crab Larvae	Iona Cove	5	1,200 – 1,500	>1,500
	San Carlos Bay	6	2,500 – 3,000	>3,000
Ichthyoplankton	Upper Estuary	2 - 4	< 600	2,500
	Iona Cove	5	600 - 800	2,500
Benthic Macro - Invertebrates	Upper Estuary	1 - 4	150 - 600	3,000
Oysters	Lower Estuary San Carlos Bay	4 - 6	500 – 2000	> 2000
Blue Crabs	Estuary-San Carlos	1 - 6	300 - 800	> 3000
Seagrass				
Halodule	Iona Cove	5	< 800	2,800
Halodule/Thalassia	San Carlos Bay	6	< 2,500	< 4,500

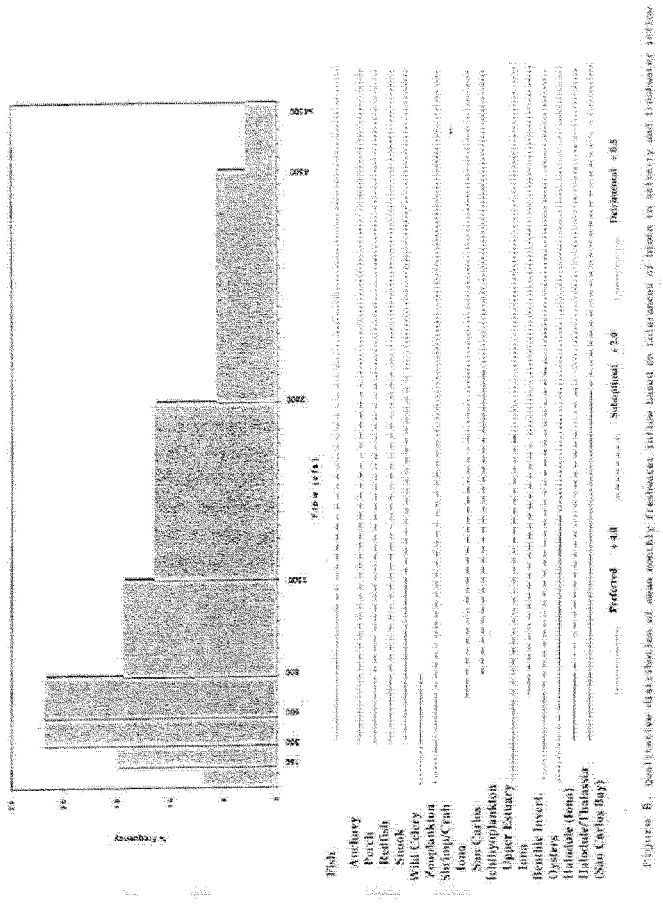

Table 1 summarizes statistical analyses of the effects of freshwater discharge at S-79 on the abundances of various organisms found in the Caloosahatchee (Chamberlain and Doering

18

1998b). Details of the statistical analyses may be found in Chamberlain et al. (1995), SFWMD 2003 (MFL update appendix) and Volety and Tolley 2003. From this summary a qualitative flow distribution was derived.

For each organism or group of organisms, preferred, suboptimal and detrimental ranges of flow were identified (Figure 8). Initial flow ranges for the frequency distribution were selected based on the clustering of preferred, suboptimal and detrimental flows within specific ranges. Most preferred flows, associated with high abundance, occurred in the 150 – 800 cfs ranges, most suboptimal in the 800 – 2000 cfs range and most detrimental at flows greater than 3000 cfs. These gross flow ranges were further subdivided to provide more detail in the distribution.

A score was derived for each flow range based on the number of organisms for which that flow range was preferred, suboptimal or detrimental. In derivation of the score, the number of organisms that preferred the range were given highest weight (4), while the number for which the flow range was detrimental were given the least (0.5). The number for which the flow range was suboptimal was given an intermediate weight (2). Weighted numbers were summed for each flow range and normalized to the total number of organisms used to calculate the score. Normalized scores were expressed as a percentage of the sum of normalized scores. For example, the total score for the 300 – 500 cfs interval was 46 based on 12 organisms. The normalized score was 3.8 which was 22 % of the sum of normalized scores. The resulting qualitative frequency distribution (Figure 8) has a peak in the 300 – 800 cfs range. This is consistent with the conclusions of Chamberlain and Doering (1998b).

Beneficial Deliveries to the Caloosahatchee:

This section of the report describes the development of Beneficial Delivery Targets for the Caloosahatchee Estuary. Since the tidal watershed (downstream of S-79) is unmonitored and outside of the SFWMD management area, environmental deliveries are only defined for the freshwater portion of the Caloosahatchee Watershed, the area upstream of S-79. Furthermore, regulatory discharges from Lake Okeechobee are not considered in this analysis, which deals only with runoff from the Caloosahatchee watershed delivered to the estuary at S-79.

Owing to development in the watershed, the Caloosahatchee Estuary suffers from stresses associated with inflows that are too high at times and inflows that are too low at times. Restoration targets were developed during the Caloosahatchee Water Management Plan and the RESTUDY. These targets were long-term monthly flow distributions. Two distributions were created during that process (EST01, EST02) and a third (EST05) was created especially for this project. EST01 was based on a redistribution of existing water deliveries at S-79; EST02 was based on minimal deliveries at S-79; EST05 was similar to EST02 except that mean monthly inflow at S-79 was never allowed to fall below 300 cfs. EST02, the minimal delivery time-series, was intended to be equivalent to deliveries from the pre-development watershed. The base flow of 300 cfs in EST05 was added to protect fish and wildlife from the detrimental effects of low flow, which is consistent with the Minimum Flow and Level for the Caloosahatchee. All three distributions have a peak in the 300 – 800 cfs range and are thus commensurate with the qualitative, species driven flow distribution derived earlier. These distributions are shown in Table 2.

Table 2. Monthly Flow Distributions at S-79

Flow Range	2020 Base	Est01	Est02	Est05
0 to 150 cfs	25%	0%	0%	0%
150 to 300 cfs	6%	14%	7%	0%
300 to 500 cfs	6%	24%	38%	43%
500 to 800 cfs	8%	24%	30%	32%
800 to 1500 cfs	13%	21%	19%	19%
1500 to 2800 cfs	11%	12%	6%	6%
2800 to 4500 cfs	9%	4%	1%	1%
>4500 cfs	23%	1%	0%	0%

22

Each distribution has a long-term average flow. Table 3 shows the average annual flows corresponding to the distributions of Table 2. Note that EST01 has about the same runoff (688,000 acre-feet) as current conditions (668,000 acre-feet). Runoff for EST02 (496,000 acre-feet) is almost 200,000 acre-feet less than current conditions. This difference in runoff relates to the decrease in evaporation that occurred when the watershed was drained and land use shifted away from hydric vegetation. Addition of a base flow (300 cfs) in EST05 adds 30,000 acre-feet to EST02.

Table 3. Average Annual Flows (acre-foot per year) at S-79

2000 Base	Est01	Est02	Est05
668,186	687,963	493,672	524,849

In order to calculate Existing Legal Sources, a time series with a daily time step, consistent with the SFWMM is required. A linear reservoir model (LINRES) was selected for this effort. Linear reservoir models are an old form of watershed model that includes HSPF and the Stanford Watershed models. This type of model is process driven, requires few parameters, and can be easily fitted to the flow distribution pattern of EST02. Like other CERP hydrologic models it is continuous and long-term and operates on a daily time step using spatially distributed rainfall and potential evapotranspiration (See Appendix 2).

Evaluation of Beneficial Deliveries:

Three Beneficial Delivery times series or Targets have been developed for use in calculation of Existing Legal Sources: EST01, EST02 and EST05. Undoubtedly, there are numerous ways to quantify and compare the "benefit" afforded to the Caloosahatchee Estuary by each of these flow distributions. We have examined the salinity produced in the estuary by each of these 35-year daily discharge scenarios. Specifically, we have examined the ability of each scenario to meet salinity requirements of the MFL in the upper estuary and salinity requirements of maximum inflows in the lower estuary.

Regression models, based on output from a numerical, hydrodynamic model have been used to estimate salinity in the estuary (Appendix 3). EST01, EST02 and EST05 define

33

beneficial freshwater deliveries at S-79. Freshwater also enters the estuary downstream (or west) of S-79. In modeling salinity in the estuary, these downstream inflows also have been considered (Appendix 2).

Comparison of EST01, EST02, and EST05:

Table 4. Frequency analysis of 30-day moving average salinity for EST01 and EST02 at various locations in the Caloosahatchee Estuary. The 30-day moving average salinity is used because it is an MFL performance measure.

30-day moving average salinity (ppt)	Ft. Myers			Shell Point		
	EST01	EST02	EST05	EST01	EST02	EST05
	% of days	% of days	% of days	% of days	% of days	% of days
0-5	34	27	28	0	0	0
5-10	29	33	41	0	0	0
10-13	23	32	32	2	1	1
13-15	13	9	0	2	2	2
15-20	1	0	0	10	6	6
20-25	0	0	0	17	14	14
25-30	0	0	0	59	70	77
30-35	0	0	0	11	7	6

The volume of water in EST01 exceeds that in EST02 by some 200,000 acre-feet annually (Table 3). Yet, the distribution of salinities produced in the estuary differ only slightly (Table 4.) Minimum flow criteria (≤ 10 ppt at Ft. Myers) are exceeded 37 % of the time in EST01 and 41 % of the time in EST02. Adding a 300 cfs base flow to EST02, as in EST05, produces slightly lower salinity at Ft. Myers but still exceeds MFL criteria at a frequency (32 %) comparable to the other two flow distributions (Table 4). Neither of the three time series causes salinity to drop below 6 ppt in the lower estuary. EST02 is preferred over EST01 as a Beneficial Delivery Target since it is our best approximation of predevelopment conditions and since the extra water required by EST01 does not achieve any further benefit within the estuary according to the criteria

24

employed. EST05 provides a slightly higher level of protection (lower salinity) in the upper estuary than the other two time series.

While EST02 and EST05 yield similar results, they are fundamentally different and the decision to use one or the other in the calculation of an Existing Legal Source for the Caloosahatchee must be a matter of policy. As stated earlier, EST02 is our best available estimate of pre-development delivery of freshwater to the Caloosahatchee. Using EST02 in the calculation assumes that flows equivalent to those entering the system before it was modified are adequate to protect fish and wildlife under current conditions. However, since permanent alteration has occurred, this assumption may be unreasonable. Addition of a base flow in EST05 recognizes that the estuary has been modified, especially by installation of S-79 which truncates the salinity gradient, preventing upstream migration of low salinity water during the dry season and hence eliminating the oligohaline zone that historically existed. EST05 is consistent with the 300 cfs minimum flow established for the Caloosahatchee Estuary at S-79 (Doering et al. 2002). The definition of "beneficial" underlying EST05 views inflows below a 300 cfs threshold as being just as detrimental as no flow at all because in either case, there is no oligohaline zone in the estuary. EST02 assumes that any flow, even if below the 300 cfs threshold, is better than no flow at all.

Figure 9 shows the average position in the estuary of the 10 ppt isohaline during the dry season under the EST02 and EST05. The mean position of this critical isohaline under EST05 occurs at Ft. Myers. Thus, on average, EST05 provides a level of protection commensurate with the Caloosahatchee Estuary MFL. It should be noted however, that given the error involved in prediction of isohaline position, the mean position of the 10 ppt isohaline could also occur at Ft. Myers under EST02.

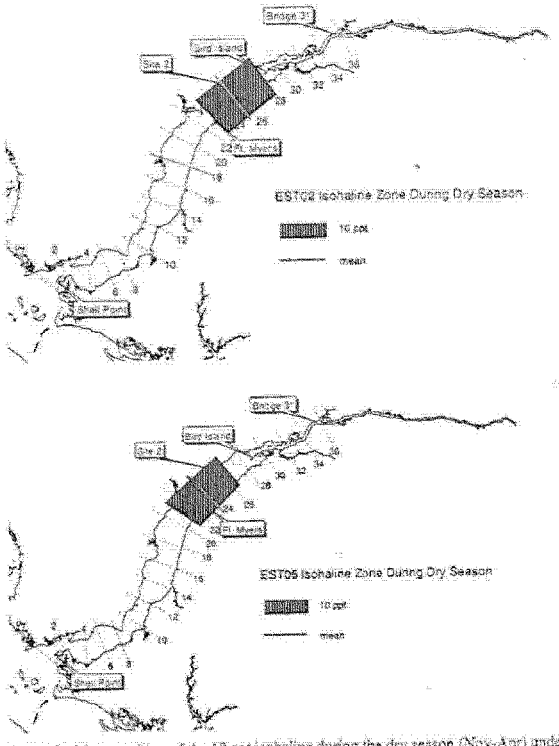

Figure 9. Mean position of the 10 ppt isohaline during the dry season (Nov-Apr) under EST02 and EST05. Box indicates error in estimate of isohaline position.

26

Existing Legal Sources for the Caloosahatchee Estuary:

Existing Legal Sources can be calculated by comparing a particular hydrology against the Beneficial Delivery Target hydrology. The Beneficial Delivery Target describes a hydrology that protects fish and wildlife in the estuary. Since it is a target, it exists in theory only. Existing Legal Source Deliveries are a subset of beneficial deliveries; they are the beneficial deliveries occurring today. They are calculated by comparing "2000 Base" hydrology against the Beneficial Delivery Target hydrology.

Table 5 shows how Existing Legal Sources for 2000 Base change when based on different Beneficial Delivery Targets. Existing Legal Sources are calculated using two methods – one based on daily flows and the other based on monthly flows. The daily definition shows current deliveries to be about 45,000 acre-feet per year less than the monthly definition.

Not surprisingly, the choice of a Beneficial Delivery Target has a significant effect on Existing Legal Sources. Using EST01 instead of EST02 would result in a difference of 160,000 acre-feet per year. EST02 is preferred over EST01 as a Target since it is our best approximation of pre-development conditions and since the extra water required by EST01 does not achieve any known benefit within the estuary.

Using EST02 as the Target, only 250,000 acre-feet of the total 668,000 acre-feet of "2000 Base" runoff is delivered at a time that is beneficial to the estuary. Including a base flow of 300 cfs in the Beneficial Delivery Target (EST05) does not significantly change the total volume of the Existing Legal Source Delivery.

27

Table 3: Average Annual Existing Legal Source Deliveries (acre-foot per year) at S-79 for 2000 Base - based on different Beneficial Delivery Targets

	Ex01	Ex02	Ex03
Defined daily	441,704	280,199	283,397
Defined monthly	493,658	326,038	328,829

C.15 FINAL CALOOSAHATCHEE RIVER (C-43) BASIN ECOLOGICAL PERFORMANCE MEASURES

6/28/05 SWFFS DRAFT C
Text: Bob Chamberlain (rchamber@sfwmd.gov)

Summary Form (4 pages)

C-43 Basin Storage Reservoir Project - Caloosahatchee Estuary Hydrologic Evaluation Performance Measures

Name of Performance Measures Document : S-79, Shell Point, and San Carlos Bay Freshwater Inflow

Status: Date this 4 page summary created/revised – 28 June 2005
For 6/28/05 DRAFT of full Performance Measures Document (attached). Previous Draft 5/12/05

Category: Hydrologic – (Water Levels, **Flow Volumes**)

Justification: The Caloosahatchee River is the major source of freshwater for the Caloosahatchee Estuary and southern Charlotte Harbor aquatic environment. The river bisects its watershed and now functions as a primary canal (C-43) that conveys both runoff from the Caloosahatchee watershed and regulatory releases from Lake Okeechobee. The C-43 has undergone numerous physical changes to facilitate increased freshwater discharge for flood protection and meet water supply demands. Together, these physical changes and alterations of the natural freshwater inflow to the Caloosahatchee Estuary have caused unnatural large scale fluctuations in the salinity and water quality within the area above Shell Point, as well as reduction in environmental stability for the San Carlos Bay area. The area's biotic richness and significant economic value are threatened by long-term shifts in water quantity and quality.

Description of Performance Measure: Reduce the high variability in freshwater inflow to the Caloosahatchee Estuary, thereby restoring the full range of salinity along its longitudinal axis required to support naturally occurring conditions for estuarine biota. This can be accomplished by: (1) reduction of wet season high flow from the watershed, capturing and storing this water, and then releasing it during the dry season in a more environmentally sensitive and beneficial manner to estuarine resources; and (2) reducing discharges from Lake Okeechobee to the Caloosahatchee Estuary.

SWFFS/CERP Targets & Current Condition:
Ecological Performance targets
1. (a) Maintain a 30-day moving average salinity ≤ 10 ppt during the dry season at the Ft. Myers continuous salinity sensor (near the surface at the Ft. Myers Yacht Basin), such that *Vallisneria americana* (tape grass) in the Beautiful Island area does not decrease below 20% coverage and blade length is ≥ 10 cm (values are provisional and may be adjusted after current research (MML 2004 and 2007 reports) are evaluated); (b) Daily average salinity shall not exceed 20 ppt at Ft. Myers more than once every two years, and neither shall the 30-day moving average salinity of 10 ppt (MFL Rule: SFWMD 2000); (c) Limit the occurrence of average monthly salinity <15 ppt at the Cape Coral Bridge sensor, so salinity ≥ 20 ppt is promoted in Iona Cove (Bierman 1993), which is supportive of minimum seagrass density (coverage ≥ 30% at 1 meter water depth and average blade length ≥ 10 cm - values are provisional and may be adjusted upon further research); and (d) Maintain daily salinity at Piney Point > 5 ppt, so that minimum conditions are provided for the recruitment, survival, and growth of juvenile oysters upstream of Shell Point during March – October (juvenile oyster growth ≥ 2.5 mm a month; recruitment ≥ 3 spats per substrate shell a month; and mortality < 20% per month - values are based on information interpreted from Volety et al. 2003).
2) Maintain an average monthly salinity ≥ 25 ppt, as measured at the Sanibel Causeway Bridge near surface continuous sensor, so that historical seagrass density and coverage in the San Carlos Bay area (as determined from previous surveys, hydroacoustic monitoring, and aerial photography) is protected and restored to a previous condition (at least circa Harris et al. 1983) that includes reestablishment of continuous coverage at deeper depths in the San Carlos Bay area between Shell Point and the Sanibel Causeway.

Hydrologic performance targets to achieve the Ecological targets
1a) For each alternative, compare the number of times that the combined mean monthly inflows from the Caloosahatchee watershed and Lake Okeechobee fall below a low-flow limit of **450** cfs, measured at S-79, during October to July . The alternative with the fewest number of times that monthly average flows fall below **450 cfs** will be considered better for protecting aquatic vegetation, oysters, and fish communities.

1

6/28/05 SWFFS DRAFT C
Text: Bob Chamberlain (rchamber@sfwmd.gov)

1b). For each alternative, compare the frequency that the combined mean monthly low-flow limit of **450** cfs through S-79 was not met for just one month (not followed by another month below the this low-flow limit), as well as the frequency for 2, 3, 4... etc. consecutive months. The water management alternative with the fewest number of consecutive months below the **450** cfs will be considered better for protecting estuarine aquatic resources.
1c). For each alternative, compare the frequency that the combined mean monthly low-flow limit of **450** cfs through S-79 from the watershed and Lake Okeechobee was not met for just one year (not followed by another year with months below **450** cfs), as well as the frequency for 2, 3, 4... etc. consecutive years. The water management alternative with the fewest number of years and consecutive years with average monthly flow occurrences below **450** cfs will be considered better for protecting estuarine aquatic resources.

2a). For each management alternative, compare the number of times that the combined mean monthly inflow from the watershed and Lake Okeechobee exceeds 2,800 cfs at S-79. The alternative with the fewest number of times that this criterion is exceeded at any time of year will be considered better for protecting both SAV and juvenile oysters at Shell Point and upstream. Additionally, a better ranking will be given to the alternative with the least number of discharges above this limit during March through October, in order to limit critically low salinity conditions from occurring both upstream and downstream of Shell Point, which threatens estuarine resources, including SAV and juvenile oyster recruitment and survival.
2b). For each alternative, compare the frequency that the combined mean monthly inflow from the watershed and Lake, measured at S-79, exceeds 2,800 cfs for just one month (not followed by another month above this limit), as well as the frequency for 2, 3, 4... etc. consecutive months. The alternative with the fewest consecutive months that violate this criterion throughout the year will be considered better for protecting estuarine resources, including juvenile oyster recruitment and survival. Additionally, a better ranking will be given to the alternative with the least number of discharges above this limit during March through October, in order to limit critically low salinity conditions from occurring both upstream and downstream of Shell Point, which threatens estuarine resources, including SAV and juvenile oyster recruitment and survival

3a). For each alternative, compare the number of times that the combined mean monthly inflow from the watershed and Lake Okeechobee exceed 4,500 cfs at S-79. The alternative with the least number of times flows exceed these limits will be considered better for protecting the estuarine resources, including those downstream in the San Carlos Bay region. Additionally, a better ranking will be given to the alternative with the least number of discharges above this limit during March through October, in order to limit critically low salinity conditions from occurring both upstream and downstream of Shell Point, which threatens estuarine resources, including SAV and juvenile oyster recruitment and survival.
3b). For each alternative, compare the frequency that the combined mean monthly inflows from the watershed and Lake, measured at S-79, exceeds 4,500 cfs for just one month (not followed by another month above this limit), as well as the frequency for 2, 3, 4... etc. consecutive months. The alternative with the fewest number of consecutive months that violate this criterion will be considered better for protecting aquatic resources, including juvenile oysters. Additionally, a better ranking will be given to the alternative with the least number of consecutive discharge periods above this limit during March through October, in order to limit critically low salinity conditions from occurring both upstream and downstream of Shell Point, which threatens estuarine resources, including SAV and juvenile oyster recruitment and survival.

4). For the C-43 BSR Project, in combination with other CERP infrastructure alternatives, compare the number of days that regulatory discharges from Lake Okeechobee are made to the Caloosahatchee River. The management alternative with the least daily discharge volume, the fewest number of total days of discharge, and the fewest number of consecutive days will be preferred. Special consideration will be provided for pulse releases that may benefit the estuary.

5). For each alternative, compare the frequency distribution of the combined monthly average freshwater inflows through S-79 from the watershed and Lake Okeechobee for the entire period of record being evaluated. The alternative with the frequency distribution of inflows that best approaches the range defined in the main Performance Measures Document will be considered better for protecting estuarine resources, while further promoting biotic diversity. Specifically, the alternative that maximizes up to 75% of flows

2

6/28/05 SWFFS DRAFT C
Text: Bob Chamberlain (rchamber@sfwmd.gov)

from S-79 in the **450 to 800** cfs and almost all the remaining flows in the 800-2800 cfs range will be considered the most desirable. The preferred flow distribution may change as more information is provided regarding: predevelopment flow and salinity conditions; natural variation; what salinity conditions were naturally (historically) associated with droughts and flood events; and what flows are needed to protect and restore the biotic features in the current and future developed system.
Rationale: The Caloosahatchee River is the major source of freshwater for the Caloosahatchee Estuary and southern Charlotte Harbor aquatic environment. The Caloosahatchee Estuary and downstream region supports a wide diversity of estuarine organism of environmental and commercial value. Alteration to the natural freshwater inflow to the estuary have caused unnatural large scale fluctuations in the salinity and water quality within the area above Shell Point, as well as reduction in environmental stability for the San Carlos Bay area. The resulting impacts to seagrass, oysters, benthic invertebrates, and fishes can be dramatic and long lasting. It is the goal of the C-43 BSR and CERP to reduce the high variability in freshwater inflow to the Caloosahatchee Estuary, so to restore a full range of salinity along its longitudinal axis that is supportive of naturally occurring estuarine biota. This goal can be accomplished by: (1) reducing high flows during the wet season, capturing and storing this water, then releasing it in a more environmentally sensitive manner that is beneficial to estuarine resources during the dry season; and (2) minimizing regulatory (non discretionary) discharges form Lake Okeechobee to the Caloosahatchee Estuary.
Modeling Evaluation Protocol: Regional and subregional models will be used to simulate historical (base) conditions and predicted flows to the estuary with and without CERP project features for each alternative considered. Natural system flows to the Caloosahatchee Estuary from its watershed and tidal basins may also be considered in order to compare flows associated with the developed basins. Output (flows) from the above model runs will be used to evaluate the level that hydrologic targets are achieved for each alternative and base condition. Model output will be used as input for the estuarine salinity model to further assess changes in salinity. To help evaluate if ecological goals will be met, the estimated salinity will be used to assess the impact on key biota by employing habitat suitability indices related to salinity.
Monitoring Assessment Protocol: 1). Define and assess appropriate attributes (specific species and/or community values) to ascertain if this project's ecological goals are attained and there is a discernable positive impact on the estuary, specifically including SAV, oyster, and fish as follows: a). Routinely (at seasonally important intervals) monitor SAV coverage, density, and canopy height to at least 1.5-2.0 m depth at key species locations. b). Routinely monitor (at seasonally important intervals) oyster survival and recruitment at key locations. c). Routinely monitor (seasonally) water quality, including temperature, D.O., salinity, nutrients, chlorophyll, suspended solids, and water clarity along the longitudinal axis of the estuary (S-79 - Sanibel Causeway and into lower Pine Island Sound and Matlacha Pass). d). Monitor routinely (at appropriate seasonal intervals) species and biotic groups of concern as separately defined in performance measure documents and the CE conceptual model. At a minimum, insure the Monitoring Assessment Plan (MAP) effort within RECOVER is being fulfilled. 2). Scientifically assess and publicly agree what constitutes desirable natural variability (predevelopment conditions) related to salinity and causal freshwater inflow from S-79 and the tidal basin. 3). Install and monitor flow gages in downstream tidal tributaries to begin assembling a long term data set to: verify model predictions of flows; determine actual amount and timing of tidal tributary flows related to MFL requirements for achieving the salinity criteria; and to help assess flow impacts on biota being monitored for CERP (RECOVER). 4). Monitor S-79 and S-77discharges for adherence to the selected alternative flow distribution. 5). Continue to maintain and monitor existing 7 salinity recorders and other permanent sensors in the Caloosahatchee Estuary. Install new sensors to monitor salinity and other water quality parameters of concern at key locations for VEC. Suggest additional sensors be located in western San Carlos Bay, lower Pine Island Sound, and Matlacha Pass. 6). Assess limits of SAV morphology for providing suitable habitat as a VEC and its relationship to flow, salinity, and water quality conditions. 7). Finish development of the: tape grass model; Caloosahatchee Hydrodynamic/Salinity Model; a water quality model component; habitat suitability models; and a seagrass model for the lower estuary.

S-79, SHELL POINT, AND SAN CARLOS BAY
FRESHWATER INFLOW PERFORMANCE MEASURES

INTRODUCTION

BACKGROUND

The Caloosahatchee River is the major source of freshwater for the Caloosahatchee Estuary and southern Charlotte Harbor aquatic environment. The river bisects its watershed and now functions as a primary canal (C-43) that conveys both runoff from the Caloosahatchee watershed and regulatory releases from Lake Okeechobee. The canal has undergone a number of alterations to facilitate this increased freshwater discharge and flood protection. These alterations include: channel enlargement; bank stabilization; the development of an intricate network of canals within the watershed; and the addition of three lock and dams. The final downstream structure, Franklin Lock and Dam (S-79), demarcates the beginning of the estuary, and acts as a barrier to salinity and tidal action, which historically extended to nearly the LaBelle area.

ISSUES

The above alterations to the Caloosahatchee River and watershed have resulted in a drastic change in freshwater inflow to the downstream ecosystem. The resulting large fluctuation of salinity and water quality can adversely impact estuarine biota (Chamberlain and Doering 1998a; Sklar and Browder 1998).

An important upper estuarine feature is the freshwater-brackish submerged grass, *Vallisneria americana* (tape grass), which when present is located near the shoreline in the upper estuary to a depth of about 1.0 m (Figure 1). Its greatest coverage occurs from Beautiful Island to just past the Ft. Myers bridges (Hoffacker et al. 1994; Chamberlain and Doering 1998b). During times of extended low inflow conditions, when salinity is too high, this grass becomes very sparse and can disappear completely (Chamberlain et al. 1995; Doering et al. 2002; SFWMD 2000)

Downstream, sparse beds of the seagrass *Halodule wrightii* (shoal grass) extend up from San Carlos Bay to nearly the Cape Coral Bridge (Hoffacker et al. 1994; Chamberlain and Doering 1998b). Like tape grass, it is restricted to the shoreline margins (Figure 1) and historically represented a valued ecosystem component of the estuary. Oysters also exist near the mouth at Shell Point and historical accounts of the river indicate that oysters were once a more prominent feature in the area upstream (Sackett 1888). Both shoal grass and oysters in this area of the estuary are sensitive to high freshwater inflows from S-79 (Chamberlain and Doering 1998b; Doering et al. 2002; Volety et al. 2003).

The dominant biological features in the San Carlos Bay area are its numerous mangrove islands and many kilometers of mangrove shoreline, which are often closely associated with oysters and large meadows of seagrass (Figure 1). Because of its biotic richness and aesthetic appeal, San Carlos Bay supports a wide variety of recreational and fishery activities with significant economic value. The natural resources of this area are also impacted by large freshwater

releases and are threatened by long-term shifts in water quantity and quality (Chamberlain and Doering 1998b; Doering et al. 2002; Volety et al. 2003).

Recent environmental investigations in the Caloosahatchee Estuary (CE) have resulted in an estimate of the optimum quantity of water needed by the Caloosahatchee Estuary to protect key biota. These species, or Valued Ecosystem Components (VECs), help sustain the ecological structure and function of the estuary by providing food, living space, and foraging sites for other naturally occurring estuarine species. Oysters and submerged aquatic vegetation (SAV) represent VECs in the Caloosahatchee Estuary. Limits on water quantity and related water quality, such as salinity, will protect these species and should lead to a healthy and diverse estuarine ecosystem.

Research results reported by Chamberlain et al. 1995, Doering et al. 1999 and 2001, Doering and Chamberlain 2000, and Kraemer et al. 1999 were used to determine optimum salinity (envelope) for SAV in the Caloosahatchee Estuary. A steady-state salinity model (Scarlatos 1988; Bierman 1993 Figure 2) and a statistical model of salinity (SFWMD 2000) were used to estimate mean monthly flows from S-79 that will establish a desirable salinity range in the geographic locations of SAV, without adverse impacts to benthic invertebrates, ichthyoplankton, and zooplankton (Chamberlain et al. 1995, 1999, 2001; Chamberlain and Doering 1998b; Doering et al. 2002; SFWMD 2000 and 2002). An upgraded, fully hydrodynamic model has been developed and is under refinement. An early version of this model (Figure 3) has been used to verify and improve estimates of inflow requirements based on model prediction of salinity distribution in the estuary. For the CE, a mean monthly inflow of at least 300 ft^3/sec (cfs) is needed from S-79 to ensure that the average monthly salinity at Ft. Myers (Yacht Basin) is $\leq$ 10 ppt (target maximum salinity for tape grass) and daily average salinity does not exceed 20 ppt more than once in two consecutive years. This estimated minimum flow level (MFL) depends on about 200 cfs of additional flow from the downstream tidal basin between S-79 and Ft. Myers. However, violations of the salinity criteria commonly occurs during dryer than normal periods in the dry season when the combined tidal tributary flows are < 200 cfs. Therefore, a minimum flow of 300 from S-79 is not enough. A greater frequency of flows are needed from S-79 that approaches 500 cfs in order to achieve the intended salinity goals associated with the MFL and prevent MFL salinity violations during these very dry conditions.

At the other extreme, mean monthly flows that exceed 2,800 cfs should be minimized, because greater flows cause more than half the estuary upstream of Shell Point to become freshwater and salinity near Shell Point drops to levels that threaten many of the species in this region. Mean monthly inflows greater than 4,500 cfs from S-79 causes: salinity and other water quality parameters in San Carlos Bay to decline below desired levels; and the entire estuary upstream of Shell Point to approach freshwater conditions.

Research results reported by Volety et al. (2003) further demonstrated the importance of oysters as a VEC. They found that a greater abundance of decopds and fishes were associated with clusters of live oyster compared to dead-articulated clusters, while the structure provided by both living and dead

oysters shells supported a greater abundance than no shells. Species richness and dominance were higher for samples with oyster clusters (dead or live) compared to controls with no oyster shell. This study points out that, "perhaps the real significance of living oysters to habitat value lies not only in creating a three-dimensional structure, but also in maintaining this structure of clusters through time." Individual oysters may die, leaving empty compartments for reef residents, but "mass mortality within a cluster results in the disarticulation of the oysters shell."

Volety et al. (2003) in their field and lab research evaluated the survival of oyster adults and juveniles, as well as oyster health, the prevalence and intensity of disease, and oyster recruitment success. The results were compared to environmental factors, including salinity and freshwater flow from S-79. Oysters grow best at a salinity of 14 to 28 parts per thousand (ppt). Infection by the oyster pathogen, *Perkinsus marinus*, increases during higher salinity and temperature. Field studies during this research determined that the prevalence of infection was high, but disease intensity was low, because temperature and salinity act antagonistically (i.e., high summer temperature occurs during the wet season and lower salinity). Therefore, freshwater releases to diminish *Perkinsus marinus* are generally not advised during warm summer months because of the potential threat to oyster populations from further lowering salinity.

The greatest oyster growth and recruitment occurs during the wet season, but slower growth, poor spat production, and excessive valve closure occurs at salinities below 14 ppt. During their study, salinity conditions were best suited for oyster growth just upstream of Shell Point. However, this upstream area is also the most vulnerable to high mortality when large releases cause salinity to fall below threshold tolerance, sometimes for prolonged periods. The Volety et al (2003) report suggests, "that while adult oysters are tolerant, salinities of 5 ppt or lower will result in > 95% mortality of juvenile oysters." High juvenile mortality can occur when exposed to this salinity for just a week. Experimental results indicate that adults are able to tolerate salinities as low as 5 ppt up to 8 weeks, but can not tolerate salinities lower than 3 ppt, which can occur upstream of Shell Point when S-79 discharges exceed 4,000 cfs. Therefore, high discharges can limit population survival and abundance in this region where they were historically present. As a restoration note, Volety et al. (2003) indicated that because of high spat recruitment at intermediate salinities, along with good growth rates and low disease, it is very feasible to develop oyster reefs upstream of Shell Point by strategically placing oyster clutch in suitable areas, if provided the ability to control current [high] freshwater inflows.

Oysters in southwest Florida spawn continuously, with peak recruitment (spat settlement) occurring during May to November. Recruitment near Shell Point and possibly upstream begins to peak in March, a full 3 months earlier than in San Carlos Bay, thus making these newly settled juveniles vulnerable to large releases from S-79, which have often occurred during this period to regulate Lake Okeechobee water level for flood protection. Large freshwater flows at this time and during the summer also expose oyster larvae to lethal low salinities, or

flush the larvae to more downstream locations where there may not be suitable substrate for settlement.

In their conclusions, Volety et al. (2003) recommended freshwater inflows for the protection and enhancement of oyster recruitment and survival around Shell Point and San Carlos Bay, which are consistent with the flows outlined above for SAV. "Flows between 500 and 2000 cfs would result in salinities of 16-28 ppt at all stations, conditions that are favorable to sustain and enhance oyster populations in the Caloosahatchee Estuary." Under current water management practices, oysters in the Caloosahatchee are not stressed by low flows of < 300 cfs from S-79. However, complete cessation of discharges during the winter will increase salinities in areas normally associated with lower salinity, and result in the migration of marine predators and pests. They further speculate that oyster spat that recruit to downstream areas also will be exposed to higher salinity and heavy predation pressure resulting in very little survival. However, the greatest threat to oysters under current water management practices is due to high flows that exceed 3,000 cfs for extended periods (2-4 weeks). This is especially true for summer months during peak spawning, juvenile recruitment, and oyster growth. Volety et al. (2003) recommends that when freshwater releases are necessary, repeated pulses of < 1 week duration during winter months be made instead of sustained releases of freshwater during summer or winter months. Interpretation of these results also indicates that such pulses would be least damaging during December through February, before increased spawning and recruitment begins at upstream locations.

PERFORMANCE MEASURES

Physical changes to the estuary in combination with alteration of the natural freshwater inflow to the estuary have caused unnatural large scale fluctuations in the salinity and water quality within the area above Shell Point, as well as reduction in environmental stability for the San Carlos Bay area. The resulting impacts to seagrass, oysters, benthic invertebrates, and fishes can be dramatic and long lasting. It is the goal of the C-43 Basin Storage Reservoir (BSR) Project and Comprehensive Everglades Restoration Plan (CERP) to reduce the high variability in freshwater inflow to the Caloosahatchee Estuary, so to provide a full range of salinity along its longitudinal axis that is supportive of naturally occurring estuarine biota. This goal can be accomplished by: (1) reducing high flows from the watershed during the wet season, capturing and storing this water, then releasing it in a more environmentally sensitive manner that is beneficial to estuarine resources during the dry season; and (2) minimizing (non discretionary) regulatory discharges form Lake Okeechobee to the Caloosahatchee Estuary.

ECOLOGICAL PERFORMANCE TARGETS:

ET 1. (a) Maintain a 30-day moving average salinity ≤ 10 ppt during the dry season at the Ft. Myer's continuous salinity sensor (at 20% of water

6/28/05 SWFFS DRAFT C
Text: Bob Chamberlain (rchamber@sfwmd.gov)

depth), such that salinity in the Beautiful Island area remains <10 ppt, tape grass in this area does not decrease below 20% coverage, and blade length is ≥ 10 cm (values are provisional and may be adjusted after current and planned research (MML 2004 and 2007 reports) are evaluated); (b) Daily average salinity shall not exceed 20 ppt at Ft. Myers more than once every two years, and neither shall the 30-day moving average salinity of 10 ppt (MFL Rule: SFWMD 2000); (c) Limit the occurrence of average monthly salinity <15 ppt at the Cape Coral Bridge sensor, so salinity ≥20 ppt is promoted in Iona Cove (Bierman 1993), which is supportive of restoring at least continuous minimum seagrass density in the Iona Cove area (coverage ≥ 30% at 1 meter water depth and average blade length ≥ 10 cm – values are provisional and may be adjusted upon further research); and (d) Maintain daily salinity at Piney Point > 5 ppt, so that minimum conditions are provided for the recruitment, survival, and growth of juvenile oysters upstream of Shell Point during March – October (juvenile oyster growth ≥ 2.5 mm a month; recruitment 3 spats per substrate shell a month; and mortality < 20% per month – values are based on information interpreted from Volety et al. 2003).

ET 2. Maintain an average monthly salinity ≥ 25 ppt, as measured at the Sanibel Causeway near surface continuous sensor, so that historical seagrass density and coverage in the San Carlos Bay area is protected (as determined from previous surveys and areal photography) and restored to a previous condition (at least circa Harris et al. 1983), which includes reestablishment of continuous coverage at deeper depths in the San Carlos Bay area between Shell Point and the Sanibel Causeway.

HYDROLOGIC PERFORMANCE TARGETS TO ACHIEVE THE ECOLOGICAL TARGETS

Freshwater inflow:

HT 1a. For each alternative, compare the number of times that the combined mean monthly inflows from the Caloosahatchee watershed and Lake Okeechobee fall below a low-flow limit of **450** cfs at S-79 during October to July. The alternative with the fewest number of times that flows fall below **450** cfs will be considered better for protecting aquatic vegetation, oysters, and fish communities.

HT 1b. For each alternative, compare the frequency that the combined mean monthly low-flow limit of **450** cfs through S-79 was not met for just one month (not followed by another month below **450** cfs), as well as the frequency for 2, 3, 4…etc. consecutive months. The water management alternative with the fewest number of consecutive months with average flows below **450** cfs will be considered better for protecting estuarine aquatic resources.

HT 1c. For each alternative, compare the frequency that the combined mean monthly low-flow limit of **450** cfs through S-79 from the watershed

8

6/28/05 SWFFS DRAFT C
Text: Bob Chamberlain (rchamber@sfwmd.gov)

and Lake Okeechobee was not met for just one year (not followed by another year with months below **450** cfs), as well as the frequency for 2, 3, 4...etc. consecutive years. The water management alternative with the fewest number years and consecutive years with average monthly flow occurrences below **450** cfs will be considered better for protecting estuarine aquatic resources

HT 2a. For each management alternative, compare the number of times that the combined mean monthly inflow from the watershed and Lake Okeechobee exceed 2,800 cfs at S-79. The alternative with the fewest number of times that this criterion is exceeded at any time of year will be considered better for protecting both SAV and juvenile oysters at Shell Point and upstream. Additionally, a better ranking will be given to the alternative with the least number of discharges above this limit during March through October, in order to limit critically low salinity conditions from occurring both upstream and downstream of Shell Point, which threatens estuarine resources, including SAV and juvenile oyster recruitment and survival.

HT 2b. For each alternative, compare the frequency that the mean the combined monthly inflow from the watershed and Lake, measured at S-79, exceeds 2,800 cfs for just one month (not followed by another month above this limit), as well as the frequency for 2, 3, 4... etc. consecutive months. The alternative with the fewest consecutive months that violate this criterion throughout the year will be considered better for protecting estuarine resources, including juvenile oyster recruitment and survival. Additionally, a better ranking will be given to the alternative with the least number of discharges above this limit during March through October, in order to limit critically low salinity conditions from occurring both upstream and downstream of Shell Point, which threatens estuarine resources, including SAV and juvenile oyster recruitment and survival.

HT 3a. For each alternative, compare the number of times that the combined mean monthly inflows from the watershed and Lake Okeechobee exceed 4,500 cfs at S-79. The alternative with the least number of times flows exceed this limit will be considered better for protecting the estuarine resources, including those downstream in the San Carlos Bay region. Additionally, a better ranking will be given to the alternative with the least number of discharges above this limit during March through October, in order to limit critically low salinity conditions from occurring both upstream and downstream of Shell Point, which threatens estuarine resources, including SAV and juvenile oyster recruitment and survival.

Text: Bob Chamberlain (rchamber@sfwmd.gov)

> ***HT 3b***. For each alternative, compare the frequency that the combined mean monthly inflows from the watershed and Lake, measured at S-79, exceeds 4,500 cfs for just one month (not followed by another month above this limit), as well as the frequency for 2, 3, 4...etc. consecutive months. The alternative with the fewest number of consecutive months that violate this criterion will be considered better for protecting aquatic resources, including juvenile oysters. Additionally, a better ranking will be given to the alternative with the least number of consecutive discharge periods above these limits during March through October, in order to limit critically low salinity conditions from occurring both upstream and downstream of Shell Point, which threatens estuarine resources, including SAV and juvenile oyster recruitment and survival.

As part of the South Florida Restudy, water management alternatives were evaluated that incorporated a range of infrastructure changes. The adopted plan (CERP) when built is predicted to reduce drastically the number of regulatory discharges from Lake Okeechobee that elevates freshwater inflow to the CE.

> ***HT 4***. For the C-43BSR Project, in combination with other CERP infrastructure alternatives, compare the number of days that regulatory discharges from Lake Okeechobee are made to the Caloosahatchee River. The management alternative with the least daily discharge volume, the fewest number of total days of discharge, and the fewest number of consecutive days will be preferred. Special consideration will be provided for pulse releases that may benefit the estuary

The optimum range and timing of freshwater discharges is best achieved by identifying a frequency distribution of desirable inflows, which also considers that freshwater inflows vary naturally as a function of rainfall. An optimum inflow range that includes natural variation in salinity is important to insuring a diverse composition of estuarine biota (Sklar and Browder 1998). As a first attempt to define this environmentally sensitive distribution of S-79 discharges, an optimization model was employed (Labadie 1995; Otero et al. 1995). The model utilized historic watershed runoff data during 1966-1990 (without regulatory Lake Okeechobee discharges). The desired inflow ranges were input variables to the model, along with the natural periodicity of violations based on rainfall cycles. However, this initial distribution and allowable violations did not fully account for: the physical changes in the Caloosahatchee Estuary, such as the truncating effect of installing S-79; and the adverse biotic impacts from the violations that cause unnatural salinity conditions and extremes within this physically changed environment. Therefore, the initial distribution frequencies (Chamberlain et al. 1995; Chamberlain and Doering 1998b) were further refined during the Restudy to consider MFL requirements for achieving estuarine resource protection. Most recently, estimates of tidal tributary inflows were added to better assess total estuarine inflows related to salinity distribution targets, which lead to the selection of EST05 as the preferred distribution.

10

6/28/05 SWFFS DRAFT C
Text: Bob Chamberlain (rchamber@sfwmd.gov)

The current proposed frequency distribution of mean monthly inflows to the CE from S-79 (estuary demand time series EST05: Caloosahatchee Freshwater Watershed delivery volume to the estuary ~ 524,000 af/yr) was chosen from several CERP options because it best meets the range of flows from S-79 that are needed for achieving estuarine protection and restoration goals by: providing flows that do not fall below the limit that achieves the MFL salinity based rules; reducing mean monthly flows greater than 2,800 cfs; and maintaining a full estuarine salinity gradient that is not unnaturally compressed. Most importantly, a flow distribution that provides S-79 flows below the 450 cfs EST05 low-flow limit will not achieve the protection defined in the MFL rule (SFWMD 2000 and 2002).

The frequency distribution of flows from S-79 associated with EST05 (without tidal basin contribution) are identified in the following table.

Discharge Range (cfs) From S-79	Percent Distribution Of Flows From S-79
0 to 450	0%
450 to 500	42.8%
500 to 800	31.7%
800 to1500	19.2%
1500 to 2800	5.6%
2800 to 4500	0.7%
>4500	0%

HT 5. For each alternative, compare the frequency distribution of the combined monthly average freshwater inflows through S-79 from the watershed and Lake Okeechobee for the entire period of record being evaluated. The alternative with the frequency distribution of inflows that best approaches the range defined in the above table will be considered better for protecting and restoring estuarine resources, while further promoting biotic diversity. Specifically, the alternative that maximizes, up to 75% of the flows from S-79 in the **450-800** cfs range and almost all the remaining inflow in the 800 to 2800 cfs range will be considered the most desirable.

In order to better achieve the CERP project and MFL restoration goals, the EST05 distribution provides no allowances of monthly average discharges from S-79 that are less than **450** cfs. However, salinity violations are allowed under the MFL rule once every two years for the moving monthly average and daily salinity criteria. Therefore, the C-43 BSR Project can still achieve estuarine protection and restoration success if the final selected alternative has flow occurrences beyond the distribution limits, including those below 450 cfs. The degree of achievement will be in part demonstrated by comparing performance measure targets and habitat units between base conditions and the alternative.

11

6/28/05 SWFFS DRAFT C
Text: Bob Chamberlain (rchamber@sfwmd.gov)

As discussed earlier, the preferred flow distributions have changed periodically during the course of this project. The proposed EST05 flow distribution may also change as more information is provided regarding: predevelopment flow and salinity conditions; natural variation; what salinity conditions were naturally (historically) associated with droughts and flood events; and what flows are needed to protect and restore the biotic features in the current and future developed system. This is consistent with the adaptive management strategy adopted for this project.

INFORMATION NEEDS AND RECOMMENDED ASSESSMENT STUDIES

1. Define and assess appropriate attributes (specific species and/or community values) to ascertain if this project's ecological goals are attained and there is a discernable positive impact on the estuary, specifically including SAV, oyster, and fish as follows:
   (a) Routinely (at seasonally important intervals) monitor SAV coverage, density, and canopy height to at least 1.5-2.0 m depth at key species locations.
   (b) Routinely monitor (at seasonally important intervals) oyster survival and recruitment at key locations.
   (c) Routinely monitor (seasonally) water quality, including temperature, D.O., salinity, nutrients, chlorophyll, suspended solids, and water clarity along the longitudinal axis of the estuary (S-79 – Sanibel Causeway and into lower Pine Island Sound and Matlacha Pass).
   (d) Monitor routinely (at appropriate seasonal intervals) species and biotic groups of concern as separately defined in performance measure documents and the CE conceptual model. At a minimum, insure the Monitoring Assessment Plan (MAP) effort within RECOVER is being fulfilled.
2. Scientifically assess and publicly agree what constitutes desirable natural variability (predevelopment conditions) related to salinity and causal freshwater inflow from S-79 and the tidal basin.
3. Install and monitor flow gages in downstream tidal tributaries to begin assembling a long term data set to: verify model predictions of flows; determine actual amount and timing of tidal tributary flows related to MFL requirements for achieving the salinity criteria; and to help assess flow impacts on biota being monitored for CERP (RECOVER).
4. Monitor S-79 and S-77discharges for adherence to the selected alternative flow distribution.
5. Continue to maintain and monitor existing 7 salinity recorders and other permanent sensors in the Caloosahatchee Estuary. Install new sensors to monitor salinity and other water quality parameters of concern at key locations for VEC. Suggest additional sensors be

12

located in western San Carlos Bay, lower Pine Island Sound, and Matlacha Pass.

6. Assess limits of SAV morphology for providing suitable habitat as a VEC and its relationship to flow, salinity, and water quality conditions.
7. Finish development of the: tape grass model; Caloosahatchee Hydrodynamic/Salinity Model; a water quality model component; habitat suitability models; and a seagrass model for the lower estuary.

STRESSOR RESPONSE MODEL FOR THE SEAGRASSES, *Halodule wrightii* and *Thalassia testudinum*

By Frank J. Mazzotti, Leonard G. Pearlstine, Robert Chamberlain, Tomma Barnes, Kevin Chartier, and Donald DeAngelis

Introduction

A key component in adaptive m anagement of Comprehensive Everglad es Restoration Plan (CERP) projects is evaluating alternative management plans. Regional hydrological and ecological models will be applie d to evalua te resto ration alte rnatives and the re sults will b e applied to modify management actions.

Southwest Florida Feasibility Study

The Southwest Florida Feasibility Study (SW FFS) is a com ponent of the Co mprehensive Everglades Restoratio n Plan (CERP). The SWFFS is an independent but integrate d implementation plan f or CERP projects and wa s initia ted in recog nition tha t there wer e additional w ater resource issues (needs, problem s, and opportunitie s) within Southwest Florida that were not being addressed directly by CERP. The SWFFS identifies, evaluates, and compares alternatives that address those additional water resource issues in Southwest Florida. An adaptive assessment strategy is being deve loped tha t w ill cre ate a syst em-wide m onitoring program to measure and interpret ecosystem responses. T he SWFFS provides an esse ntial fram ework to address the health and s ustainability of aquatic s ystems. This includes a focus on water quantity and quality, flood protection, and ecological integrity.

C43 West Reservoir

The purpose of the C43 Basin Storage Reservoir project is to im prove the tim ing, quantity, and quality of fr eshwater flows to the Caloosahatch ee River estuary. The project includes an above-ground reservoir with a total stor age capacity of approxim ately (170,000 acre-feet) and will be located in the C-43 Basin in Hendr y, Glades, or Lee Counties. The initial design of the reservoir assumed 8094 hectares (20,000 acres) with water levels fluctuati ng up to 2.4 m eters (8 feet) above grade. The final size, depth and configura tion of this facility wi ll be determ ined through more detailed planning and design.

Forecasting Models

Forecasting models brin g togeth er research and monitoring to ecosystems of Southwest Flo rida and place th em into an adaptive m anagement framework for the evaluation of altern ative plans. There are two princip le ways to structure adap tive m anagement: (1) *passive,* by which policy

decisions are made based on a forecasting model and the model is revised as monitoring data become available, and (2) *active,* by which management activities are implemented through statistically valid experimental design to better understand how and why natural systems respond to management (Wilhere 2002).

In an integrated approach that includes both passive and active-adaptive management, a forecasting model simulates system response and is validated by monitoring programs to measure actual system response. Monitoring can then provide information for passive-adaptive management for recalibration of the forecasting model. Directed research, driven by model uncertainties, is an active-adaptive management strategy for learning and the reduction of uncertainties in the model.

The forecasting models for the C-43 West Reservoir Project and the Southwest Florida Feasibility Study consist of a set of stressor response (habitat suitability) models for individual species. These stressor response models have been developed principally with literature, expert knowledge, and currently available field data.

Habitat Suitability Indices

Habitat Suitability Indices (HSI) models were developed with each stressor variable portrayed spatially and temporally across systems of the study area at scales appropriate to the organism or community being portrayed. The HSI models have been incorporated into a GIS to portray responses spatially and temporally to facilitate policy decisions. That is, the model describes a response surface of habitat suitability values that vary spatially according to stressor levels throughout the estuary and temporally according to temporal patterns in stressor variables. Much of the temporal variation is a result of temporal cycling of important stressor inputs, such as water temperature and salinity. Temporal change for other important variables may not be cyclical, such as rising sea level and increasing land use and fresh water demands in the region. Areas predicted to be suitable and those predicted to be less suitable or disturbed should be targeted for additional sampling as part of the model validation and adaptive management process.

Species selected for modeling (focal species) are ecologically, recreationally or economically important and have a well established linkage to stressors of management interest. They may also make good focal species because they engage the public in caring about the outcome of restoration projects. The habitat suitability models (HSI) were developed by choosing specific life stages of each species with the most limited, restricted, or tightest range of suitable conditions, to capture the highest sensitivities of the organisms to the environmental changes associated with the planned restoration activities. Values used in the models are listed in Table 1.

The models calculate habitat suitability monthly as the weighted geometric mean of the environmental variables identified as important for each model. Because the geometric mean is derived from the product of the variables rather than the sum (as in the arithmetic mean) and has the appropriate property that if any of the individual variables are unsuitable for species success (i.e., the value of the variable is zero) then the entire index goes to zero.

Ecology of Seagrasses

Beds of submerged aquatic vegetation (SAV) are important to the ecology of shallow estuarine and marine environments. These beds provide habitat for many benthic and pelagic organisms,

function as nurseries for juveniles and other early life stages, stabilize sediments, improve water quality, and can form the basis of a detrital food web (Kemp et al. 1984; Fonseca and Fisher 1986; Carter et al. 1988; Killgore et al. 1989; Lubber et al. 1990). Because of the importance of these beds, estuarine restoration initiatives often focus on SAV (Batiuk et al. 1992; Johansson and Greening 2000; Virnstein and Morris 2000). SAV are commonly monitored to gauge the health of estuarine systems, (Tomasko et al. 1996) and their environmental requirements can form the basis for water quality goals (Dennison et al. 1993; Stevenson et al. 1993).

In the Caloosahatchee Estuary, field and laboratory research has been conducted by the South Florida Water Management District (SFWMD, associated contractors, and non-government organizations over a wide range of flows and salinities. This information, along with the results from researchers in other systems, is used to estimate maximum freshwater inflow limits and associated water quality requirements to protect and restore *Halodule wrightii* (shoal grass) and *Thalassia testudinum* (turtle grass).

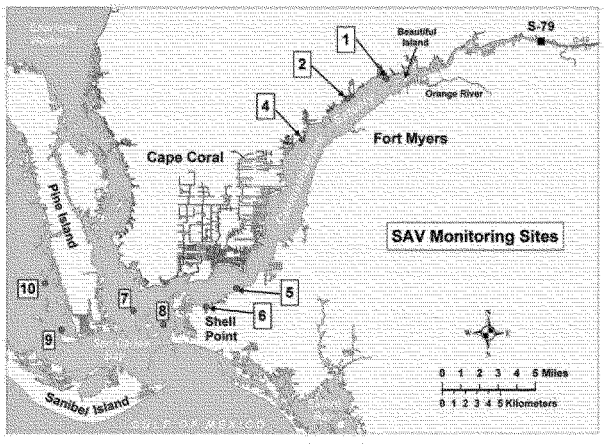
McNulty et al. (1972) and Harris et al. (1983) mapped SAV in the lower estuary upstream of Shell Point, as well as throughout the outer embayments. *Halodule* is the only seagrass species consistently located upstream of Shell Point (Figure 1: Stations 5 and 6) until it mixes downstream with *Thalassia* and other less common species in San Carlos Bay (Stations 7 and 8) and Pine Island Sound (Stations 9 and 10). *Halodule* has a wide salinity tolerance (McMahan 1968). It does not survive below 3.5 ppt and prefers salinity as high as 44 ppt (Zieman and Zieman 1989). This wide tolerance is probably why it is the only true seagrass species encountered upstream of Shell Point. Monitoring results (Figure 2a) indicate that, of all areas where *Halodule* is present, the lowest biomass is found upstream, where salinity is more diluted and most variable (Chamberlain et al 1995, Chamberlain and Doering 1998b, Doering et al. 2002). The greatest biomass occurs when salinity is above 20 ppt. Figure 2a also depicts seasonal growth patterns that can be influenced by high freshwater inflow that cause decreasing salinity (as occurred in the Water Year 2006) due to tropical storms during 2004 and 2005.

Literature summarized by Zieman and Zieman (1989) indicates that the optimum salinity range for *Thalassia* is 24-35 ppt. The maximum photosynthetic activity of *Thalassia* occurs in euhaline seawater and decreases proportionately with decreasing salinity. *Thalassia* does not grow in areas with salinity normally below 17 ppt and will suffer significant leaf loss when exposed to lower salinity. *Thalassia* does not exist upstream of Shell Point where salinity during the SFWMD study was more variable. Recent monitoring results (Figure 2b) also depict a declining density below normal at the end of WY 2006 from discharge related to tropical storms during 2004 and 2005.

Comparison of map coverage by Harris et al. (1983) determined substantial loss in seagrass during the mid-later 20th century. This loss was in part due to changes in freshwater flow patterns (salinity variability), physical alteration in the estuary and watershed, as well as changes in water management practices (Chamberlain and Doering 1998a). Harris et al. (1983) reported that the greatest loss appeared to be from deeper beds, which indicates that a change in water clarity has occurred, in part probably due to the increased freshwater inflow reaching the downstream beds and associated decreased water quality (i.e., increased water color).

In general, as flows increase, the water quality constituents (primarily color) that inhibit light penetration also increase. Therefore, as light attenuation increases, the depth at which the seagrass can survive decreases. SFWMD monitoring data indicates that average monthly flows

from S-79 that exceed 4,000 cfs are associated with light penetration below that necessary to support plants at 1 m depth in San Carlos Bay. Lower mean monthly discharges that approach 3,000 cfs are associated with the same problem for *Halodule* upstream of Shell Point. At deeper depths (e.g., 1.5m) plant coverage is considerably more sensitive to the freshwater inflow (Figure 3).



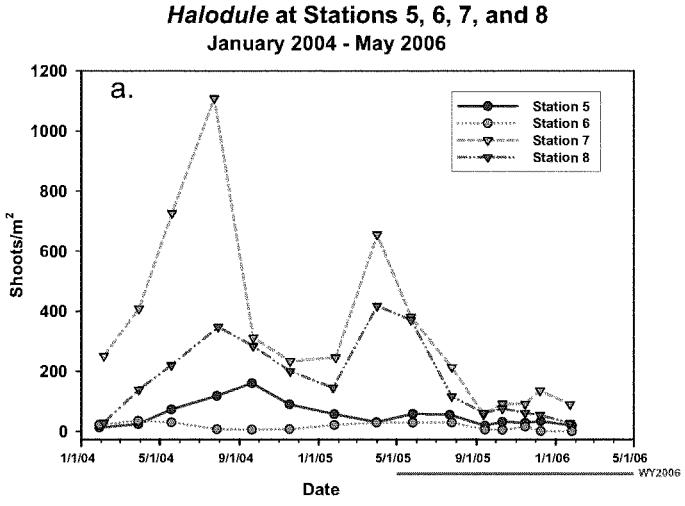


Figure 1. Caloosahatchee Estuary SAV monitoring stations for *Vallisneria americana* is found at stations 1-3, *Halodule wrightii* at stations 5-10, *Thalassia testudinum* at stations 8-10.

Based on the literature identified in Table 1, along with SFWMD laboratory and field research, the HSI curve in Figure 4 was formulated to represent relative *Halodule* and *Thalassia* response to salinity values generated during model runs.

Although there are species-specific variations, generally speaking, SAV distributions are limited by four environmental factors: light, salinity, temperature, and nutrients (Dennison et al. 1993, Kemp et al. 2004). In the Caloosahatchee, as indicated above, studies have documented that SAV distribution and subsequently its functionality, is strongly related to limits on their physiological response to salinity and light. Except at the distribution margins, plant location in the estuary generally depends on salinity, while growth characteristics controlling plant height and depth strongly relates to light attenuation within salinity tolerant zones.

The average daily bottom light (ADBL) required by SAV, which helps determine the depth to which plants exist, is measured in the photosynthetic active radiation (PAR) spectrum of 400-700 nanometers during the entire 24 hour day (not just daylight or peak light periods). ADBL for shoal grass can be divided into stressed environments like in Iona Cove, and more desirable areas as in San Carlos Bay (as evidenced in the results of Dunton 1994 and 1996 from Texas). Dunton and Tomasko (1991) and Dunton (1996) also determined light requirements during winter and summer seasons. Based primarily on their results, the minimum range of ADBL in Iona Cove is estimated to be about 50-60 micro-Einsteins (uE = micromoles/m^2/sec) and saturation is 220-

300uE, depending on the season . In San Carlos Bay, the m inimum and saturation levels of ADBL equates to about, 75-100uE, and 225-325uE, respectively.

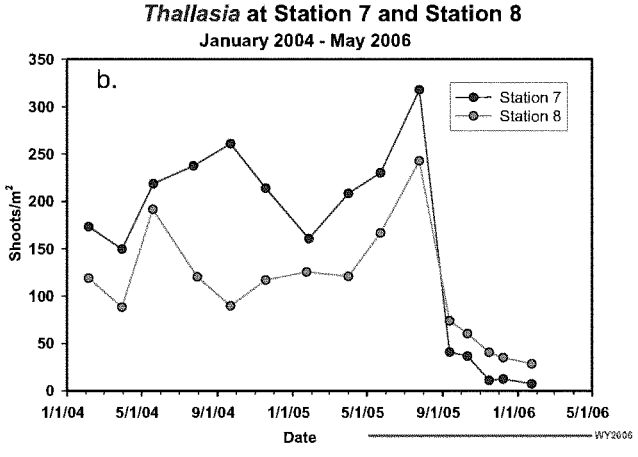

Figure 2. Time series density of seagrass: (a.) *Halodule wrightii;* and (b) *Thalassia testudinum* (turtle grass) in the Caloosahatchee Estuary and San Carlos Bay, with the time period of a Water Year indicated (WY: May 1 –April 30). Data collected by the Sanibel-Captiva Conservation Foundation.

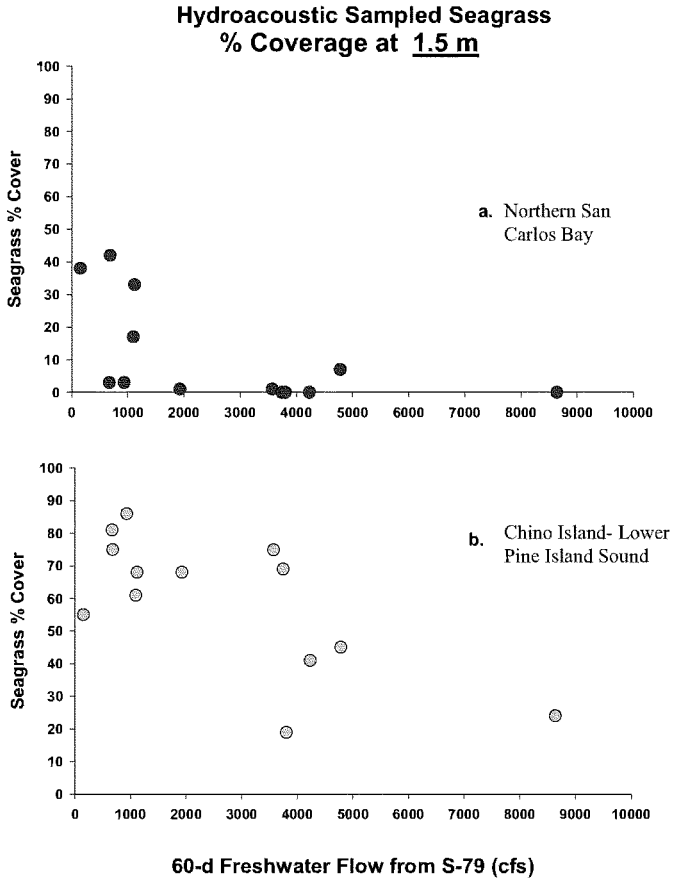

Figure 3. Seagrass coverage at two locations downstream of the Caloosahatchee River (a. Site 7; and b. Site 9-in Figure 1) compared to 60-day average freshwater inflow from S-79 prior to sampling.

These estimates can be put on a relative HSI scale from 0 to 1 as reflected in Figure 5. However, this scale better reflects the qua lity of habitat (e.g. plant growth potential and health), not the amount of c overage (acres), which is one of the HSI modeling objectives. For exa mple, a HSI =1.0 or 0.5 both represent an area with plant cove rage that is sustaina ble between months. To address this issue, a "50% Approach" was a dopted, whereby a single linear line from the minimum ADBL during the winter in Iona C ove to the PAR level of 150uE is used that represents 50% of saturation during the summer growing season in San Carlos Bay (Figure 5).

Table 1. Habitat Requirements for the Seagrasses, *Halodule* and *Thalassia*. The following table summarizes S-79 inflow criteria (mean monthly cubic feet per second), important salinity ranges, and water quality requirements for the protection and support of *Halodule* and *Thalassia* in the Caloosahatchee Estuary.

Variable	Estuary Area	Value	Source
Halodule and *Thalassia*	Throughout their range	Light to 1m: 1) Min. 20-25% of Subsurface irradiance 2) Minimum attenuation Coef -1.5 3) Most important during warm growing season 4) Recovery goal: Deeper, 2m? 5) Optimal Productivity at 300 mE	Kenworthy and Haunert 1991 Tomasko and Hall 1999 Dixon and Leverone 1995 Herzka and Dunton 1997 Fong et al. 1997
Halodule	Throughout its range	Salinity: 1) 3.5ppt - minimum tolerance; duration of tolerance 1-2 months; Recovery 1 year (following winter and spring) of preferred salinity 2) Prefers > 20ppt, below which productivity declines 3) Optimum, seawater ~ 35ppt 4) Location requirements – long term average salinity >20ppt, std. dev. < 10ppt	Zieman and Zieman 1989 McMahan 1968 Chamberlain and Doering 1998b Chamberlain (Pers. field/lab obs) 2004
		Temperature: 1) Greatest productivity during March – September (Possibly a magnitude more biomass in shallow areas of Area 6) 2) Optimum 22-26°C	Chamberlain (Pers. field/lab obs/analysis) 2004 Fong et al. 1997
Area	5	Flow (to achieve above salinity and light limits): 1) Max < 3,000 cfs 2) Preferred < 1000 cfs 3) Optimum < 500 cfs	Chamberlain and Doering 1998b Doering et al. 2002
Thalassia	Throughout its range	Salinity: 1) ~ 6ppt - minimum tolerance; duration tolerance 1-2 months; Recovery 1 year (following winter and spring) of preferred salinity;	Chamberlain and Doering 1998b Doering and Chamberlain 2000 Doering et al. 2002 Zieman and Zieman 1989 Zieman et al 1999 Chamberlain (Pers. field/lab obs/analysis) 2004

		Mortality when 0 ppt for ≥ 3 weeks – no recovery 2) Prefers > 20ppt, < 17ppt productivity declines 3) Optimum, 24-35ppt 4) Location requirements – long term average salinity >20-25ppt, std. dev. ≤ 5ppt	
		Temperature: 1) Greatest productivity during March – September 2) Optimum when ~ 30°C 3) Decreased productivity @ < 20 °C 4) Stressful when water temp < 15 °C (winter) 5) Mortality - month>36°C	Chamberlain (Pers. field/lab obs/analysis) 2004 Dawes et al. 1997 Koch and Erskine 2001 Miller 2000
Halodule and Thalassia	Area 6	Flow (to achieve above salinity and light limits): 1) Max 4,500 efs 2) Preferred < 2,500 cfs 3) Optimum < 1,000 cfs	Chamberlain and Doering 1998b Chamberlain 1995 Doering et al. 2002

The for mula for calculating ADBL is based on the Lambert-Beer equa tion, which requires knowing: (1) surface incident light in the PAR sp ectral range; (2) water co lumn light attenuation (K); and (3) depth. Average monthly incident PAR for the Caloosahatchee is depicted in Figure 6 and was calculated from a daily average PAR da taset, recorded by a continuous sensor during 1998-2004, located in the nearby Estero Bay W atershed. Light attenuation was calculated based on the curv ilinear rela tionships of salin ity and simultaneous light atte nuations m easurements (Figure 7) at stations upstream and downstream of Shell Point (Figure 8). Depth was determ ined from bathymetry surveys of the Caloosahatchee Estuary and the resulting information supplied in a GIS data file that matched the grid cell points of the model.

Seasonal patterns are an indicati on of the influence and im portance of temperature o n seagrass, with th e be st gr owth o ccurring between the 22 and 30 °C range. In addition, tem perature will affect photosynthesis by altering th e rate of biochem ical reactions of photosynthesis. Therefore, ecological models of seagrass in clude tem perature as a variab le governing seagrass growth predictions (Fong et al. (1887). Based on these literature results and those identified in Table 1, a HSI temperature curve was developed (Figure 9) that indicates th e relative importance and input value to the HSI model, as per the estimated daily average (ambient) temperature (Figure 10).

HSI for the Seagrass, *Halodule wrightii* and *Thalassia testudinum*

HSI Variables and Summary Formula

Habitat suitability for the combined grasses *Halodule wrightii* and *Thalassia testudinum* is calculated monthly as a geometric mean:

HSI = (Previous^{w} * Salinity^{w} * Temperature^{w} * LightAvailability^{w})

Where w = the weight for each variable and the sum of $w = 1$. In the accepted model, each of the variables has been weighed equally, so $w = 0.25$.

Previous
"Previous" variable included because current month's HSI score should depend on the how well the grass was doing last month (previous score). In the model application, Previous = previous_month_HSI score + 0.05, (not to exceed 1.0), in order to allow for growth from month to month, if other conditions are suitable.

Table 2. Changes to HSI model's spatial boundaries (A and B) and post-processing routines (C) for adjusting the final HSI ecological model scores to better reflect long-term impacts of severe reduction in seagrass coverage due to low HSI scores of environmental variables (salinity, light and temperature in above model formula).

Routine	Model output criteria	Model score adjustment
A.	Apply new masks for the three areas of the estuary (Pine Island, San Carlos Bay, and Iona Cove	Consider them separately and evaluate the spread across them
B.	Establish a lower depth threshold of 5 ft and 7ft in San Carlos Bay and Pine Island Sound	Model areas > depth thresholds are not scored
C.	If HSI score $\leq$ 0.1 for one month,	Than HSI = 0.1 for remainder of season

Adjustments were agreed to by ecological benefits sub-team (6/14/06)

HSI Curves and Application (for determining HSI variable input values)

Salinity

HSI Calculation – Values based on the literature identified in Table 1, along with SFWMD laboratory and field research, which resulted in the curvilinear relationship between HSI values and salinity depicted below in Figure 4.

Data Source - Freshwater inflows are estimated for S-79 and from the tidal basin using hydrologic models. Flows are generated for each base-case and proposed alternative.

These flows are input for the CH3D hydrodynamic salinity model and associated regression routine, which calculates salinity at fixed locations in the estuary. Using a spatial interpolation program, salinity is then calculated throughout the estuary at each GIS cell point where a HSI value is determined.

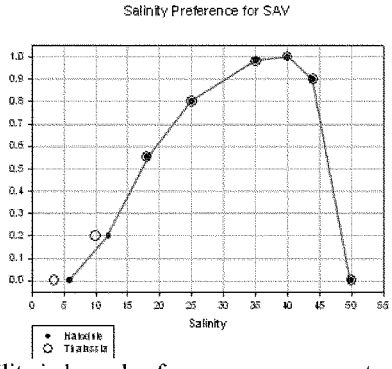

Figure 4. Habitat suitability index value for seagrass response to salinity.

Available light at Depth (based on *Halodule wrightii* requirements)

HSI Calculation – Literature provided estimates of the light needed by *Halodule*, ranging from the minimum requirements to the maximum a plant can utilize. Since this project is interested in estimating the area of coverage and not the density, a 50% line was used to estimate HSI related to potential for presence (Figure 5).

Data Source

a) Depth - Recent bathymetry data provided in GIS format to match HSI cells.
b) Available incident light at the surface (surface irradiance = SI)) - Daily average value estimated from a continuous sensor (7 year period of record, 1998-2004: Figure 6).
c) Light attenuation (K) - Amount of Photosynthetic Active Radiation (PAR) lost with increasing water depth. Field measured values were correlated with simultaneous field measurements of salinity from upstream of Shell Point (Iona Cove area) and downstream (San Carlos Bay and Pine Island Sound) using non-linear regression (Figures 7 and 8).
d) Amount of light at depth (ADBL) for each HSI cell – Determined using the Lambert-Beer equation ($[(0.9*SI)*e^{-K*depth}]$) , which requires input of the incident light just below the water surface (.90(SI)), the attenuation coefficient (K), and depth of each GIS cell.

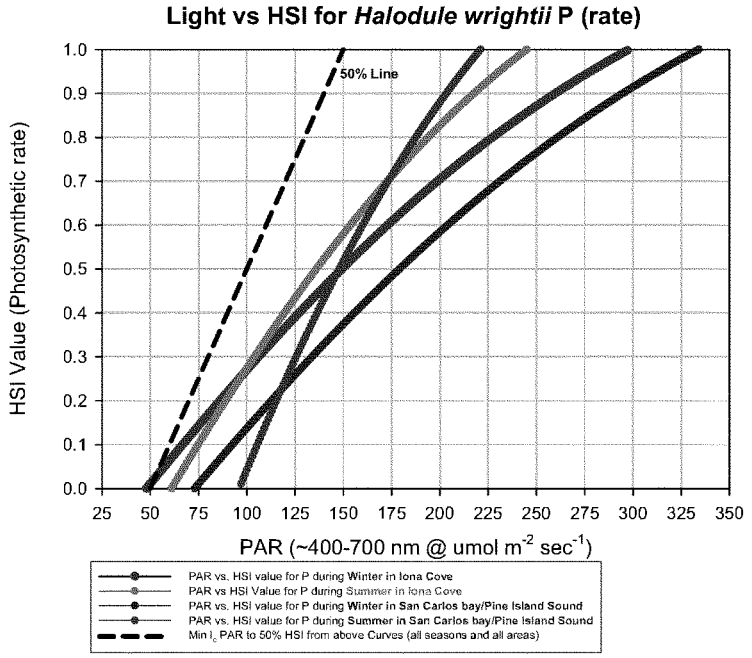

Figure 5. Habitat suitability index value for seagrass response to light. HSI values represent the relative amount of average daily light required by *Halodule wrightii*. The 50% line was used in the model to indicate relative light vs. plant's need to maintain presence

Available Light at the Surface

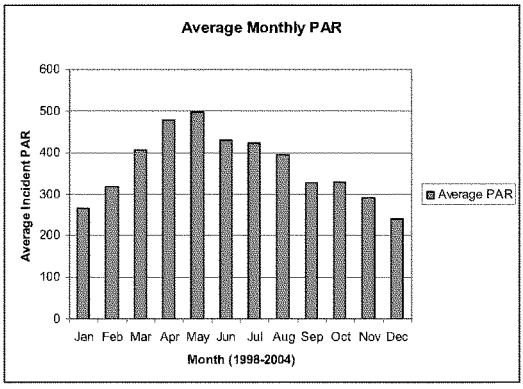

Figure 6. Average Monthly Photosynthetic Active Radiation (PAR)

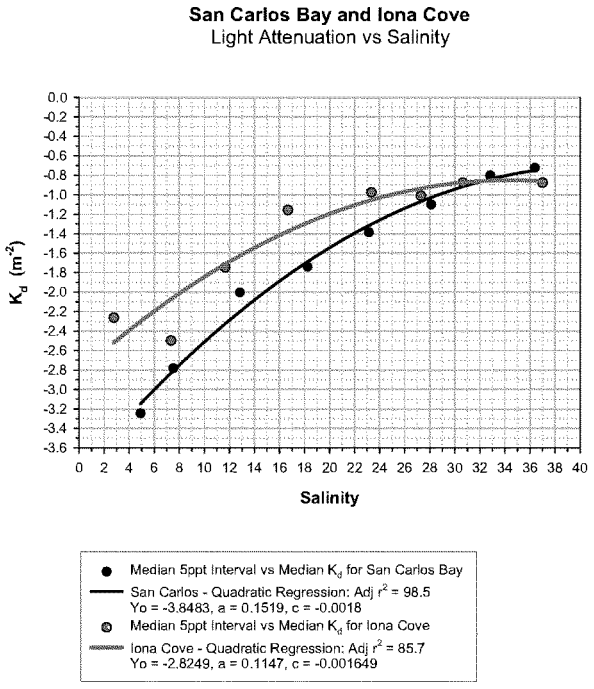

Figure 7. Light attenuation vs. Salinity in seagrass areas.

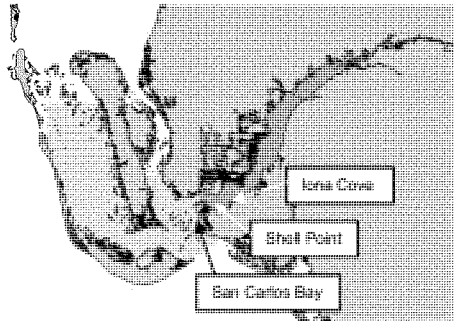

Figure 8. Light attenuation regions. The m odel uses Iona Cove light attenuation relationships for areas east of S hell Po int and San Carlos Bay light attenuation relationships for areas west of Shell Point.

Temperature

HSI Calculation – Preferred temperature range of seagrass (Figure 9) based on literature values (Dawes et al. 1997, Koch and Erskine 2001, Miller 2000).

Data Source – HSI uses a monthly average estimated water temperature. The single monthly value is estimated by fitting a non-linear regression line to daily temperature vs. day of the year (Period of record beginning in 1993), so each day has about 13 temperature values (Figure 10).

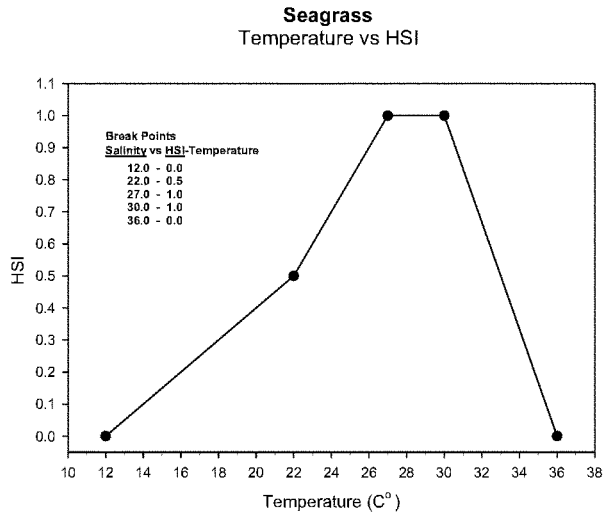

Figure 9. Habitat suitability index value for seagrass response to temperature.

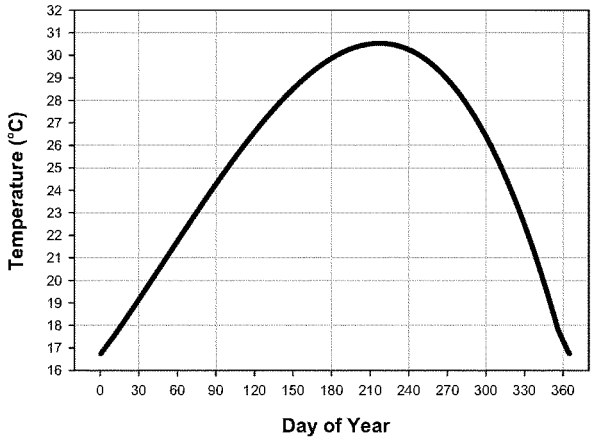

Figure 10. Estimated water temperature in the Caloosahatchee Estuary adjacent to seagrass area.

D.0 REAL ESTATE

D.1 STATEMENT OF PURPOSE OF THE REAL ESTATE PLAN (REP)

The purpose of this Real Estate Plan (REP) is to present the overall real estate requirements, costs, acquisition schedules, and other real estate requirements necessary and in support of the Final Project Implementation Report (FPIR) for the Central and Southern Florida, Comprehensive Everglades Restoration Plan, Caloosahatchee River (C-43) West Basin Storage Reservoir project. This Real Estate Plan is tentative in nature and both the final real property acquisition lines and estimates of value are subject to change after approval of the decision document to which this Plan is appended.

D.2 DESCRIPTION OF PRIOR REP PREPARED FOR THE PROJECT

The Caloosahatchee River (C-43) West Basin Storage project was discussed in the Central and Southern Florida Project, Comprehensive Review Study (Restudy), Appendix "F," Real Estate Plan; dated April 1999, page F-32.

D.3 PROJECT AUTHORIZATION

Along with the Central and Southern Florida Comprehensive Review Study, and the Water Resources Development Act of 2000, Section 601the C-43 West Basin Storage Reservoir Project PIR is authorized by Section 309(l) of the Water Resources Development Act of 1992 (Public Law 102-580) which states:

"(1) CENTRAL AND SOUTHERN FLORIDA. -- The Chief of Engineers shall review the report of the Chief of Engineers on central and southern Florida, published as House Document 643; 80th Congress, 2nd Session, and other pertinent reports, with a view to determining whether modifications to the existing project are advisable at the present time due to significantly changed physical, biological, demographic, or economic conditions, with particular reference to modifying the project or its operation for improving the quality of the environment, improving protection of the aquifer, and improving the integrity, capability, and conservation of urban water supplies affected by the project or its operation."

This study is also authorized by two resolutions of the Committee on Transportation and Infrastructure, United States House of Representatives, dated September 24, 1992. The first resolution states:

"Resolved by the Committee on Public Works and Transportation of the United States House of Representatives, That the Board of Engineers for Rivers and Harbors, is requested to review the report of the Chief of Engineers on Central and Southern Florida, published as House Document 643, Eightieth Congress, Second Session, and other pertinent reports, to determine whether modifications

of the recommendations contained therein are advisable at the present time, in the interest of environmental quality, water supply and other purposes."

The second resolution states:

"Resolved by the Committee on Public Works and Transportation of the United States House of Representatives, That the Board of Engineers for Rivers and Harbors, is requested to review the report of the Chief of Engineers on Central and Southern Florida, published as House Document 643, Eightieth Congress, Second Session, and other pertinent reports, to determine whether modifications of the recommendations contained therein are advisable at the present time, in the interest of environmental quality, water supply and other purposes for Florida Bay, including a comprehensive, coordinated ecosystem study with hydrodynamic modeling of Florida Bay and its connections to the Everglades, the Gulf of Mexico, and the Florida Keys Coral Reef ecosystem."

The Water Resources Development Act of 1996 was enacted on October 12, 1996. Section 528 of the Act (Public Law 104-303) entitled "Everglades and South Florida Ecosystem Restoration" authorizes a number of ecosystem restoration activities and also provides specific direction and guidance for the CERP.

(b) RESTORATION ACTIVITIES-
(1) COMPREHENSIVE PLAN-
(A) DEVELOPMENT-
(i) PURPOSE- The Secretary shall develop, as expeditiously as practicable, a proposed Comprehensive Plan for the purpose of restoring, preserving, and protecting the South Florida ecosystem. The Comprehensive Plan shall provide for the protection of water quality in, and the reduction of the loss of fresh water from, the Everglades. The Comprehensive Plan shall include such features as are necessary to provide for the water-related needs of the region, including flood control, the enhancement of water supplies, and other objectives served by the Central and Southern Florida Project.
(ii) CONSIDERATIONS- The Comprehensive Plan shall—
(I) Be developed by the Secretary in cooperation with the non-Federal project sponsor and in consultation with the Task Force; and
(II) Consider the conceptual framework specified in the report titled "Conceptual Plan for the Central and Southern Florida Project Restudy," published by the Commission and approved by the Governor.
(B) SUBMISSION- Not later than July 1, 1999, the Secretary shall—
(i) Complete the feasibility phase of the Central and Southern Florida Project comprehensive review study as authorized by section 309(l) of the Water Resources Development Act of 1992 (106 Statue. 4844), and by two resolutions of the Committee on Public Works and Transportation of the House of Representatives, dated September 24, 1992; and

(ii) Submit to Congress the plan developed under subparagraph (A)(i) consisting of a feasibility report and a programmatic environmental impact statement covering the proposed Federal action set forth in the plan.
(C) ADDITIONAL STUDIES AND ANALYSES- Notwithstanding the completion of the feasibility report under subparagraph (B), the Secretary shall continue to conduct such studies and analyses as are necessary, consistent with subparagraph (A)(i).

A design agreement to perform project engineering and design (PED) activities including adaptive assessment and monitoring in support of CERP was executed on May 12, 2000 between the U.S. Army Corps of Engineers (Corps) and South Florida Water Management District (SFWMD). This agreement provides for the SFWMD to receive in-kind credit for design work. A Master Program Management Plan (MPMP) for the CERP was executed on August 24, 2000, outlining the protocols and procedures by which project management plans for all projects included in the agreement would be completed. This document conforms to the guidance provided within the MPMP.

In Section 601 of the Water Resources Development Act of 2000 (PL 106-541), Congress approved the Central and Southern Florida (C&SF) Project Comprehensive Review Study Integrated Feasibility Report and Programmatic Environmental Impact Statement (known as the "Yellow Book"), which describes and outlines the Comprehensive Everglades Restoration Plan (CERP):

(b) Comprehensive Everglades Restoration Plan –
(1) Approval -
(A) IN GENERAL. —Except as modified by this section, the Plan is approved as a framework for modifications and operational changes to the Central and Southern Florida Project that are needed to restore, preserve, and protect the South Florida ecosystem while providing for other water-related needs of the region, including water supply and flood protection. The Plan shall be implemented to ensure the protection of water quality in, the reduction of the loss of fresh water from, and the improvement of the environment of the South Florida ecosystem and to achieve and maintain the benefits to the natural system and human environment described in the Plan, and required pursuant to this section, for as long as the project is authorized.
A Project Implem entation Report must be co mpleted for C-43 Basin Storage Reservoir project, as set forth in Section 601(b)(2)(D) of WRDA 2000.

(i)PROJECT IMPLEMENTATION REPORTS.—Before implementation of a project described in any of clauses (i) through (x) of subparagraph (C), the Secretary shall review and approve for the project a project implementation report prepared in accordance with subsections (f) and (h).
(ii) SUBMISSION OF REPORT. —The Secretary shall submit to the Committee on Transportation and Infra-structure of the House of Representatives and the

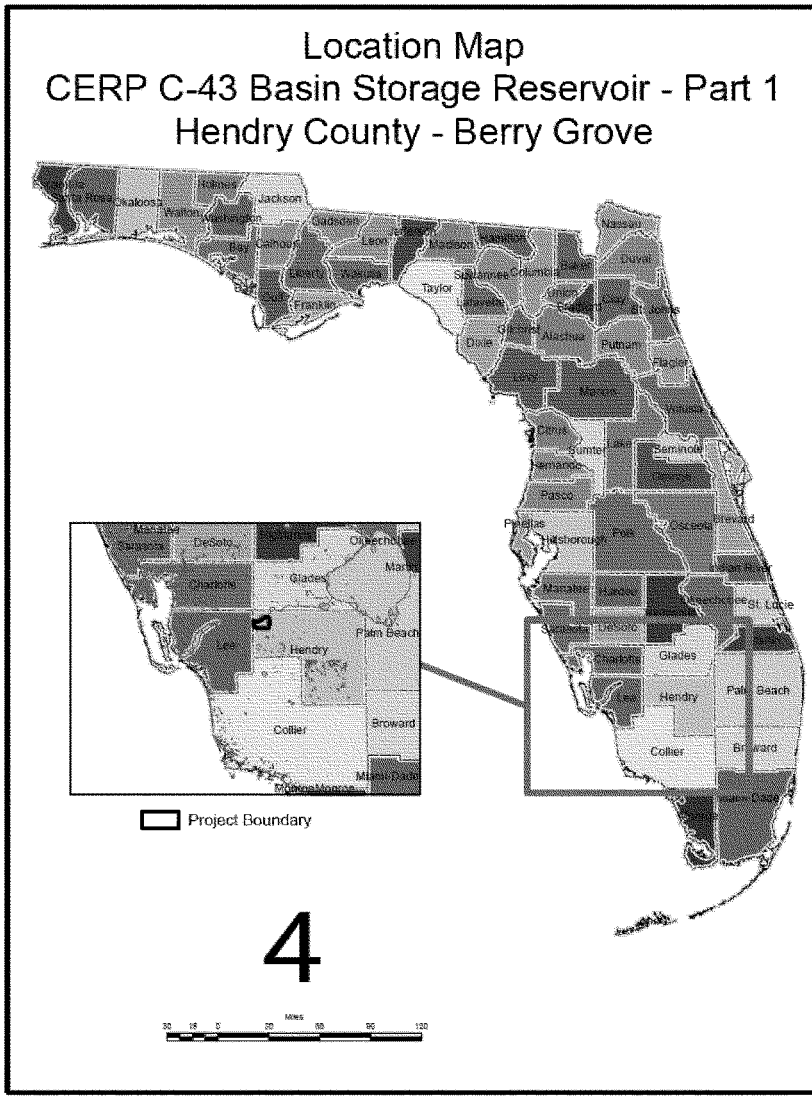
Committee on Environment and Public Works of the Senate the project implementation report required by sub-sections (f) and (h) for each project under this paragraph (including all relevant data and information on all costs).
(iii) FUNDING CONTINGENT ON APPROVAL. —No appropriation shall be made to construct any project under this paragraph if the project implementation report for the project has not been approved by resolutions adopted by the Committee on Transportation and Infrastructure of the House of Representatives and the Committee on Environment and Public Works of the Senate.

Finally, Section 601(h)(4) of WRDA 2000 further requires that PIRs document:

(4) PROJECT-SPECIFIC ASSURANCES-
(A) PROJECT IMPLEMENTATION REPORTS-
(i) IN GENERAL- The Secretary and the non-Federal sponsor shall develop project implementation reports in accordance with section 10.3.1 of the Plan.
(ii) COORDINATION- In developing a project implementation report, the Secretary and the non-Federal sponsor shall coordinate with appropriate Federal, State, tribal, and local governments.
(iii) REQUIREMENTS- A project implementation report shall--
(I) be consistent with the Plan and the programmatic regulations promulgated under paragraph (3);
(II) describe how each of the requirements stated in paragraph (3)(B) is satisfied;
(III) comply with the National Environmental Policy Act of 1969 (42 U.S.C. 4321 et seq.);
(IV) identify the appropriate quantity, timing, and distribution of water dedicated and managed for the natural system;
(V) identify the amount of water to be reserved or allocated for the natural system necessary to implement, under State law, subclauses (IV) and (VI);
(VI) comply with applicable water quality standards and applicable water quality permitting requirements under subsection (b)(2)(A)(ii);
(VII) be based on the best available science; and
(VIII) include an analysis concerning the cost-effectiveness and engineering feasibility of the project.

D.4 PROJECT PURPOSE

The purpose of the Caloosahatchee River (C-43) West Basin Storage Reservoir project is to address the declining health of the Caloosahatchee River and estuarine ecosystem by improving water deliveries to the estuary. The project will increase availability of water for the estuarine system during the dry season, while reducing excessive high flows during the wet season. This will result in providing a downstream salinity range suitable for a healthy ecosystem that promotes estuarine habitat, increased fish and wildlife and biological diversity. Once the demands of the estuary are met, additional water resource benefits could be achieved by providing supplemental water resources for



agriculture and urban users resulting in a reduction of demands placed on existing surface and ground water resources such as the Caloosahatchee River (C-43 Canal) and Lake Okeechobee.

D.5 PROJECT LOCATION AND DESCRIPTION

D.5.1 Project Location

The Caloosahatchee River (C-43) West Basin Storage Reservoir project area encompasses approximately 10,700 acres consisting of approximately 10,480 acres in fee, approximately 20 acres of perpetual channel easement, and 200 acres in temporary easement that lie within approximately 12,430 acres owned or being acquired by SFWMD. The lands are located in northwestern portion of Hendry County, Florida within Township 43 South, Range 28 East in Sections 30, 31, 32, 33, 34, 35 and 36; in Township 44 South, Range 28 East in Sections 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, and 12; in a portion of Section 31, Township 43 South, Range 29 East; and in a portion of Section 6, Township 44 South, Range 29 East. Reservoir access from State Road 80 will be located in Section 27, Township 43 South, Range 28 East. Portions of Sections 25, 26, 27 28, 29 and 30, Township 43 South, Range 28 East will be used as staging areas. The (C-43) West Basin Storage Reservoir project is situated approximately 36 miles west of the city of Clewiston and approximately 6 mile west from the Hendry County seat of LaBelle, Florida. It parallels State Road 80 (SR80) which lies to the North. To the Northeast and east the Project adjoins the Bob Paul (Bob Paul) property. To the south and southeast the Project adjoins the A. Duda and Sons, Inc. property (Duda). The East side adjoins State Road 29 (SR 29). On the west side of the Project is the Townsend Canal. See ***Figure D-1*** below.

FIGURE D-1: LOCATION MAP

The Reservoir currently under consideration will be constructed on property formerly owned by J&H Grove Holdings, L.C. (Berry Groves), the Griffin Family Limited Partnership, the MG Enterprises, L.L.C and the Bryan Paul Citrus.. All these lands are currently owned in fee by the SFWMD except the Bryan Paul

Citrus parcel that will be an exchange of 541.31 acres of SFMWD ownership in exchange for 600.17 acres of the Bryan Paul Citrus property.

Agricultural lands are prevalent in Hendry County; pastureland and crops (primarily citrus but also sugarcane and others) comprise the majority of the agricultural industry. Remaining natural areas include pine flatwoods (upland communities dominated by pine and saw palmetto) and a variety of wetland communities. Land use within the project boundary reflects the land use of the surrounding county.

The Duda pump station, located at the "bend" in the Townsend Canal west of the southwest corner of the Griffin property, lifts water from the Townsend Canal into the Townsend Canal south of the pump station and feeds a series of canals within the Duda property.

In addition to the Townsend canal, other water systems that exist within the vicinity of the project include the Northeast Rim Ditch, the Roberts Canal, the Crawford Canal, the Banana Branch, and the Fort Simmons Branch. Such water systems including canals, streams, and ponds are common and serve as watershed conveyance systems and tributaries to the Caloosahatchee River (C-43 Canal).

Prior to site preparation by SFWMD, Berry Groves' citrus plant was situated north of the project footprint along SR 80. The Duda citrus plant is east of the project footprint along SR 29. A large FP&L transmission line is located parallel and borders the entire northern boundary of the project footprint. This FP&L transmission line will not be impacted by the project.

D.5.2 Project Description – Selected Alternative Plan (Alt 3B)

The Selected Alternative Plan (SAP) consists of a two-cell impoundment with a "normal pool" storage capacity of 170,000 acre-feet. This SAP comes closest to approximating the Restudy C-43 Reservoir recommended volume of approximately 160,000 acre-feet of storage and is the size evaluated and currently being designed by the SFWMD under their Acceler8 program. The project footprint for the SAP encompasses approximately 10,480-acres in fee, approximately 20 acres of perpetual channel easement, and 200 acres in temporary easement for total project footprint of 10,700 acres. It consists of major features and components to include a two-cell reservoir with armoring, cutoff walls, and embankments. Other features are Pump Stations, spillways with emergency overflow and vertical lifts, drawdown structures, culverts, canals, earthwork artificial habitat creation, and recreational features. The reservoir design includes a pump station with 1,500 cfs capacity to pump water from the Townsend Canal to fill the Reservoir.

Each cell is designed to discharge independently through separate discharge structures. Cell 1 will discharge via the S-1 structure into the Townsend Canal. Cell 2 will discharge via S-8 structure into the Perimeter Canal. These structures will be designed for incremental operation allowing required flows to be released to the Caloosahatchee River (C-43 Canal) during periods of low flow. These structures could also serve as design storm control structures for releases prior to and during a storm event. The storm releases must be balanced with the targeted maximum flow allowed over S-79, which is 4,500 cfs. An emergency spillway with a crest elevation based on retaining the 25-year, 72-hour storm event is to be provided within each cell's discharge structure. The 25-year, 72-hour storm captured in the reservoir would be a "control release" after the storm event in order to restore the water surface to the normal pool elevation while not exceeding the maximum flow of 4,500 cfs at S-79.

D.5.3 Project Features

A discussion of the project features and major components along with the acreage, and estate follows. See Table D-1 "Main Project Features and ***Figure D-2***: "Caloosahatchee River (C-43) West Basin Storage Reservoir Site Plan." below.

D.5.3.1 Reservoir Impoundment

The Reservoir is an earthen impoundment consisting of approximately 9,220 acres of interior storage that is to be constructed above the existing ground. It will consist of an approximate 170,000 acre-feet two-cell reservoir. Water will be pumped from the Caloosahatchee River (C-43 Canal) and into the Reservoir by utilizing the existing Townsend Canal and a new pump station (C43PS-1) located in the northwest corner of the project. See ***Figure D-2*** below.

Water will be discharged from the Reservoir through gravity discharge structures in each cell that discharge into a Perimeter Canal. Both flows into and out of the Reservoir will be controlled by monitoring flows at S-79.

TABLE D-1: MAIN PROJECT FEATURES

Project Features/Components	Approximate Acreage Rounded	Proposed Estate (SAP)	Total Acres for SAP
Reservoir (interior)	9220	Fee	
Seepage Canals	244	Fee	
Reservoir Embankment	774	Fee	
Pump Structures PS-1 and PS-4	17	Fee	
Townsend Canal	106	Fee	
Access Road from State Road 80	4	Fee	
Perimeter Access and Buffer Area	115	Fee	10,480®
Townsend Canal (Northern and Middle Canal)	20	Perpetual Channel Easement	
Temporary W ork Area/Stockpile and Staging	200	Temporary Easement	
Relocation	0		
Recreation	0		
Borrow/Disposal	0		
Total Project LERRD Proposed			10,700®

D.5.3.2 Canals

The existing Townsend Canal, located along the west perimeter of the Reservoir, would serve as the west Perimeter Canal. The existing spoil piles along the east side of the Townsend Canal would be removed as part of the project. Drainage improvements are proposed outside of the project boundary and would include new or replacement culverts in the header canal east of the project. Improvements to or the relocation of the existing weir structure located at the mouth of the Townsend canal are included.

The Perimeter Canal is a man-made canal that collects seepage from Cells 1 and 2 of the Reservoir, re-routes and conveys flow from the Roberts Canal to the Banana Branch Canal and conveys irrigation flows, cell discharge flows, and flood routing. The Perimeter Canal is vital in assisting with the regulation and stabilization of stormwater runoff, regulatory releases from Lake Okeechobee and improving the salinity balance for the Caloosahatchee estuary. The Perimeter Canal also provides flow releases to the downstream portions of the Roberts Canal (Banana Branch), Fort Simmons Branch and the Townsend Canal. The Perimeter Canal has three discharge structures that help facilitate with the flow control measures described above identified as C43S-3, C43S-10, and C43S-11. The Perimeter Canal design includes littoral shelves along the exterior slope that are intended to promote wetland vegetation, fisheries and recreation activities.

D.5.3.3 Embankments

The perimeter embankment would have an external geometry that includes a 12-foot wide crest (14 foot Crest Width including the soil cement protection) and 3 horizontal to 1 vertical side slopes. Crest elevations have been established at +55 and +54 feet NAVD for Cell 1 and Cell 2, respectively. The embankment would be constructed largely of random fill, but would also include a low permeability soil-bentonite (SB) wall, an internal drain, and upstream slope protection. The SB wall would extend from an elevation 5 feet above the normal pool elevation to 5 feet below the top of a clay layer which underlies the project site at depths generally in the range of 10 to 25 feet below existing surface grades.

A few structures pass through the perimeter embankment. At these locations, the above ground portion of the SB wall would be replaced with select fill. In addition, a roughly 100-foot wide bench with a 24-foot access road would be constructed above the existing ground surface immediately downstream of the perimeter embankment. A Perimeter Canal would be located on the outside of the bench.

The Interior Dam between Cells 1 and 2 would be a homogenous embankment with a crest elevation of +50 feet NAVD. It would not include any SB wall or internal drain. The side slopes of the separator dam would be covered on both sides with soil-cement. Typical Sections of the proposed embankments are provided on Plates C-2 through C-4.

D.5.3.4 C43CS-1 and C43CS-2 Crest Spillway Structures

C43CS-1 is located on the west side of Cell 1 and discharges to the Townsend Canal. C43CS-2 is located just east of C43S-8 in the northwest corner of Cell 2 and discharges to the Perimeter Canal. The design objective of the crest spillway structures is to minimize the surcharge storage of the reservoir without exceeding the allowable discharge. Each cell of the reservoir has an uncontrolled crest spillway structure to manage flood flows.

D.5.3.5 Pumping Station C43PS-1

Pump Station C43PS-1 will consist of a 1500 cfs pump station 252' long and 84' wide with intake located on the Townsend Canal and an over-the embankment arrangement for discharge to the Reservoir. The facility will house four main pumps. Two pumps will be 500 cfs capacity each, and two will be 250 cfs capacity each. The pump station building will consist of an operating floor at El 25.0 for the placement of most pump station machinery and a two-story steel structure above El 25.0 housing the control room, break room and workshop.

D.5.3.6 Pumping Station C43PS-4

The purpose of the C43PS-4 pump station is for water supply to the neighboring landowners and maintenance of stage in the Perimeter Canal for seepage control. The station site is situated at the Southwest corner of the Reservoir at the southern limit of the District's property. The. pump station will be designed to pump water from the Townsend Canal into the Perimeter Canal at a maximum 150 cfs rated capacity. The station discharge will be conveyed to the Perimeter Canal a distance of 1500 to 2000 feet via a conveyance canal paralleling the toe of slope of the Reservoir embankment.

The Townsend Canal provides flood conveyance for the citrus operations south of the Reservoir and irrigation water during the dry season. The normal canal stage upstream of the existing pump station is maintained for the farm operations at 23.5 feet NAVD. The Townsend Canal stage varies with the Caloosahatchee River.

D.5.3.7 Gated Culvert Structure C43S-3

C43S-3 consists of a Double Barrel 10'x10' Box Culvert. Each barrel will have an independent intake structure, consisting of a 10'x10' sluice gate and a 10'x10' weir gate with allowance for a 5 foot high weir opening Should there be a demand for irrigation by the Bob Paul Grove, C43PS-4 will introduce 150 cfs into the Perimeter Canal. This flow will ultimately be conveyed through the Perimeter Canal to C43S-3 at which time it will be pumped into the LPDD Canal and used for irrigation for the Bob Paul Grove.

D.5.3.8 Culvert Structure C43S-7

Structure C43S-7 is located at the intersection of the upstream end of the Banana Branch Canal and the Perimeter Canal. The structure will provide a hydraulic connection between the perimeter canal and the Banana Branch Canal. It consists of a double 10'W x 10' H box culvert with one (1) sluice gate and one (1) weir gate. The reservoir bisects the Roberts/Banana Branch Canal thus flow from the Roberts Canal is re-routed through the Perimeter Canal and discharged to the Banana Branch Canal via Structure C43S-7.

D.5.3.9 Culvert Structure C43S-9

Structure C43S-9 is a double 6'W x 6'H box culvert that conveys flow from the Perimeter Canal through to the Fort Simmons Branch Canal which discharges into the Caloosahatchee River.

D.5.3.10 Gated Spillway Structure C43S-10

Structure C43S-10 consists of one 14'x10' Vertical Roller Gate and two (2) 10'x10' weir gates. The structure will consist of a reinforced concrete spillway with one (1) Vertical Roller Gate and two (2) Weir Gates to control flow through the Perimeter Canal. Design flow received by the Perimeter Canal from the Roberts Canal would be conveyed and discharged into the Banana Branch Canal prior to C43S-10. The flow from the Roberts Canal will be bypassed through the project site using the Perimeter Canal and outlet to the Banana Branch Canal

D.5.3.11 Gated Spillway Structure C43S-11

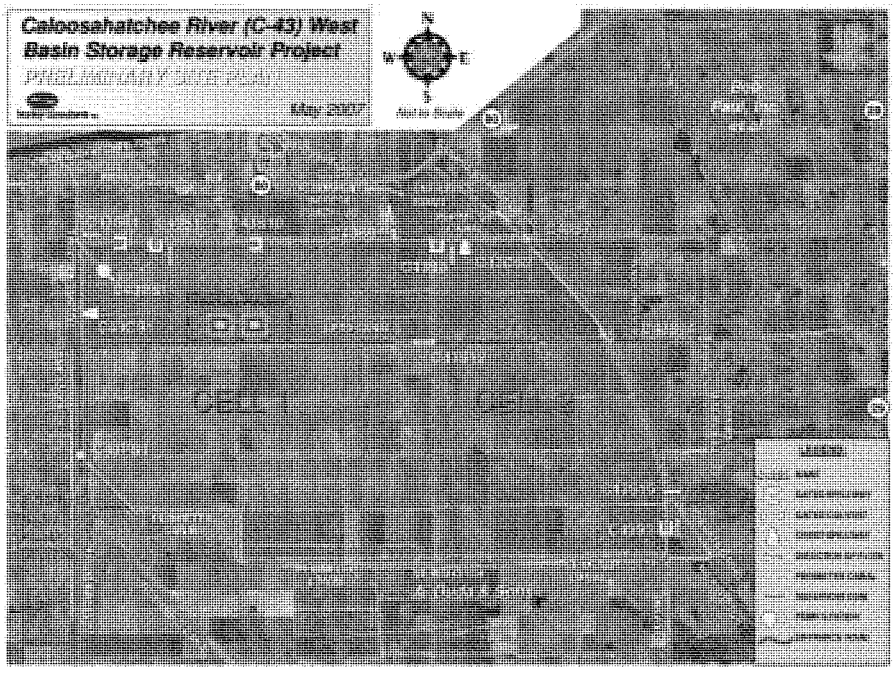
C43S-11 is the largest of the Perimeter Canal structures which consists of a reinforced concrete spillway with two (2) 14'W x 8' H Vertical Roller Gates and two (2) 10'W x 8'H weir gates to control flow through the Perimeter Canal ultimately to the Townsend Canal.

D.5.3.12 C43S-1 and C43S-8 - Gated Outlet Structures

C43S-1 and C43S-8 are the main outlets for Cell 1 and Cell 2 respectively. Both outlets discharge into the north Perimeter Canal with C43S-1 discharging four feet lower than C43S-8.

D.5.3.13 Balancing Outlet Structure C43S-12

C43S-12 is located on the interior dam between Cells 1 and 2 of the reservoir. The primary function of the structure is to convey water between the cells and allow the cells to operate independently if needed. If one of the cells needs to be dewatered for maintenance C43S-12 may be closed to isolate the cells.



D.5.3.14 Culvert Structure C43S-14

Structure C43S-14 is a 10'Wx6'H box culvert that connects the Header Canal to the Perimeter Canal. This structure will convey water from the Perimeter Canal, into the Header Canal. This culvert structure will provide a hydraulic connection between the perimeter canal and the Header Canal.

D.5.3.15 Culvert Structure C43S-15

This culvert structure will provide a hydraulic connection between the perimeter canal and the Roberts Canal. The Roberts Canal discharges into the Perimeter Canal located downstream of Structure C43S-3. Flow from the Roberts Canal is conveyed through Structure C43S-15. The structure, which consists of a double 10'x8' box culvert with an independently operated sluice gate and weir gate.

FIGURE D-2: CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR SITE PLAN

D.6 ANALYSIS OF ESTATES REQUIRED FOR PROJECT

The Programmatic Regulations for the CERP, 33 CFR 385, Part 385.5, require the development of Six Program-Wide Guidance Memorandum. The April 2005 draft in Section 1.9.3 and the November 2006 draft in Section 1.10.3 of the Six Program-Wide Guidance Memoranda provide that an analysis to determine the estates required for implementation of a project should be determined using the following guidelines.

D.6.1 Estates Required for CERP Projects

For all lands determined to be required for CERP Projects, the interests required for implementation generally will be fee simple, based on assumptions that all or a significant portion of the rights in the land will be required for project purposes. Although fee acquisition should be the standard estate for CERP projects, lesser estates such as flowage or conservation easements should be considered, as appropriate, if the benefits of the project can still be achieved with the lesser estate. The PIR should provide the rationale for such lesser estates.

To verify the appropriateness of fee simple acquisition or less than fee acquisition, the PIR must include the following analysis and the conclusions must be reflected in the appropriate report sections. The level of detail required for the analysis will vary depending on the project feature involved.

D.6.1.1 Determine the Rights that Are Required to Construct and Perform Operation, Maintenance, Repair, Rehabilitation, And Replacement (OMRR&R) for the Project:

- *Identify the affirmative rights on the land that are required to implement the project.*
- *In addition to affirmative rights that may be required, identify restrictions on use (restrictive covenants) by the fee owner that are required so as not to interfere with project purposes and outputs.*
- *Identify the length of time that the affirmative rights or restrictive covenants are needed for the project.*
- *Determine whether constructed project features may need to be modified over time due to uncertainties in science, formulation, or design (adaptive management).*
- *Determine whether project land, or portions thereof, will be open for public use (either active or passive uses).*

D.6.1.2 Other Factors to be Considered:

- *Compare the cost/value of specific types of easements to fee value.*
- *Assess potential for severance damages from fee acquisition.*
- *Determine whether public owners have legal capability to convey fee.*
- *Assess stewardship/OMRR&R considerations regarding the risk and consequences of encroachment on project land by adjacent owners; the risk and consequences of violation of easement terms by fee owners; and monitoring and enforcement capabilities of Sponsor.*
- *Assess negative perception by public of private benefits or gain due to landowner reservations where easements are selected.*
- *Assess whether State Marketable Title Act requires re-recording of easement instruments.*

D.6.2 Estates for Components

For the analysis, the estates for each of the three project components were determined independently utilizing not only the factors set forth above but Engineering Regulation 405-1-12, Chapter 12, paragraph 12-9 because of the nature of the components. The Caloosahatchee River (C-43) West Basin Storage Reservoir project includes approximately 10,
700 acres, with approximately 9,220 acres of interior storage area, approximately 244 acres required for the north, south and east seepage canals,

approximately 774 acres of embankment, approximately 106 acres required for the Townsend Canal approximately 17 acres required for the two pump stations, approximately 4 acres required for the access road from State Road 80 to the project site, approximately 115 acres required for the perimeter road and berm area on the north, south and east sides of the project, and approximately 200 acres for temporary construction area staging and stock pile area. All of the lands are owned in fee or will be acquired in fee by the SFWMD, except for approximately 20 acres within the Townsend Canal over which SFWMD has an easement sufficient for project purposes.

D.6.2.1 Reservoir and Embankments

The Reservoir embankments comprising approximately 774 acres have been determined to be a dam with the embankments on all four sides having to meet dam safety criteria. Chapter 12, paragraph 12-9 of ER 405-1-12 requires fee title for dam sites. While a standard estate such as a flowage easement (permanent flooding) for the interior areas of the Reservoir might be sufficient, the estimated value of the easement over this approximately 9,220 acres would exceed 95 percent of the fee value of the property. Access to the interior of the Reservoir must also be restricted. The following activities will have to be prohibited:

a) commercial or industrial activities;
b) construction of any kind within the reservoir;
c) dumping of refuse, wastes, sewage, or other debris;
d) harvesting wood products;
e) commercial recreational activities;
f) activities detrimental to flood damage reduction, water management, conservation, environmental restoration, water storage, erosion control, soil conservation, reclamation, fish and wildlife habitat preservation, and allied purposes,
g) any mining or alteration of the surface of the land, including any substance that must be quarried or removed by methods that will consume or deplete the surface, including, but not limited to, the removal of topsoil, sand, gravel, rock, and peat; any use or activity that causes or is likely to cause significant pollution of any surface, and
h) prohibition of all agricultural activity.

Leaving rights outstanding in third parties would also inhibit future operational changes in the Reservoir and the other facilities associated with the Reservoir. All these lands for construction of the Reservoir are required in fee.

D.6.2.2 Pump Stations

The lands required for the pump stations (permanent structures) approximately 17 acres would be required in fee.

D.6.2.3 Perimeter Canals

For the land required for the perimeter canals and structures in and around perimeter canals (south, north and east side) comprised approximately 244 acres and the Townsend Canal (west side) comprised of approximately 126 acres, a permanent canal easement could be the estate required for these lands. However, the estimated value of this easement would exceed 90 percent of the fee value of the property. Therefore fee title is the recommended estate for the lands required for the Townsend Canal, except for approximately 20 acres located adjacent to and running just south of the Caloosahatchee River (C-43 Canal) over which SFWMD has acquired a perpetual canal easement, which contains language identical to the standard perpetual channel easement, which is sufficient for project purposes.

D.6.2.4 Main Access Road

An access road will run from SR80 to the Project site to provide ingress and egress for both project operation and maintenance and the general public for recreation purposes at the site. The standard road easement could be the estate required for these lands, comprised of approximately 4 acres. However, the estimated value of this easement would exceed 80 percent of the fee value of the property. Therefore fee title is the recommended estate.

D.6.2.5 Perimeter Access and Buffer Area

There are approximately 115 acres located between the exterior edge of the perimeter canals on which permanent maintenance access roads will be constructed and maintained. These roads will provide access not only for project operation and maintenance but for public access for recreation purposes. While a modified standard estate such as a modified road easement might be sufficient, the estimated value of the easement over this land would exceed 80 percent of the fee value of the property. In addition, the following activities will have to be prohibited:

a) commercial or industrial activities;
b) construction of any kind within this area;
c) dumping of refuse, wastes, sewage, or other debris;
d) harvesting wood products;
e) commercial recreational activities;
f) activities detrimental to flood damage reduction, water management, conservation, environmental restoration, water storage, erosion control, soil conservation, reclamation, fish and wildlife habitat preservation, and allied purposes,
g) any mining or alteration of the surface of the land, including any substance that must be quarried or removed by methods that will

consume or deplete the surface, including, but not limited to, the removal of topsoil, sand, gravel, rock, and peat; any use or activity that causes or is likely to cause significant pollution of any surface, and

h) prohibition of all agricultural activity.

All these lands are required in fee.

D.6.2.6 Temporary Work/Stockpile/Staging Areas

During the construction of the Reservoir Project, the contractor may need approximately 200 acres for temporary work areas, temporary stockpile areas and temporary staging areas. A temporary easement for the period of construction will be required over this approximately 200 acres. SFWMD owns fee title to lands directly to the north of the Reservoir project which will be used for these temporary work/stockpile/staging areas.

D.6.3 Facility, Utility Relocations

Preliminary Attorney's Opinions of Compensability have been completed and used for the purpose of completing the study. Final Attorney's Opinions of Compensability and final relocation determinations will be completed as required by Engineering Regulation (ER) 405-1-12, chapter 12, paragraph 12-22 prior to completion of the PCA or 100% design of the reservoir by SFWMD.

D.6.3.1 Florida Power and Light Company (FP&L)

FP&L owns a limited right of way easement 140 feet in width that runs through the East ½ of Section 31 and into Sections 32, 33, 34, 35 and 36, Township 43 South, Range 28 East for construction of electric transmission and distribution power lines and towers recorded in ORB 4 page 14 of the records of Hendry County. These power lines will not be impacted by the project. Therefore no relocation of this line will be necessary for the project.

FP&L owns an easement 15 foot wide in Sections 7 and 8, Township 44 South, Range 28 East for construction of overhead and underground electric utility facilities (including wires, poles, guys, cables, conduits and appurtenant equipment) recorded in Official Record Book 428 page 870 of the records of Hendry County. As modified and superseded by an easement 15 foot wide in Sections 5, 7 and 8, Township 44 South, Range 28 East for construction of overhead and underground electric utility facilities (including wires, poles, guys, cables, conduits and appurtenant equipment) recorded in Official Record Book 460 page 37 of the records of Hendry County. This powerline easement runs along side the LPDD drainage canal and will be relocated to the north of the project area. It was determined that FP&L has a compensable interest in this area.

FP&L owns an easement 10 foot wide in Sections 30, 31, 32, 33, 34, 35 and 36, Township 43 South, Range 28 East and Sections 31, 32 and 33, Township 43 South, Range 29 East for construction of overhead and underground electric utility facilities (including wires, poles, guys, cables, conduits and appurtenant equipment) recorded in Official Record Book79 Page 231 of the records of Hendry County. Some of this easement is within the right of way of the Townsend Canal. It is anticipated that only one power pole will have to be relocated. Other minor utility lines run throughout the project area and will be abandoned or removed by the utility company. It was determined that FP&L has a compensable interest in this area.

"ANY CONCLUSION OR CATEGORIZATION CONTAI NED IN THIS REPORT THAT AN ITEM IS A UTILI TY OR FACILITY RE LOCATION TO BE PERFORMED BY THE NON-FEDERAL SP ONSOR AS PART OF ITS LE RRD RES PONSIBILITIES IS PRELIMINARY ONLY. THE GOVE RNMENT W ILL MAKE A FINAL DETERMINATION OF THE RELOCA TIONS NECESSARY FOR THE CONSTRUCTION, OPERATION, OR MAI NTENANCE OF T HE PROJE CT AFTE R FURTHER ANALYSIS AND COMPL ETION AND APP ROVAL OF FINAL ATTORNEY'S OPINIONS OF C OMPENSABILITY FOR EACH OF THE IMPACTED UTILITIES AND FACILITIES."

Final Attorney's Opinions of Compensability and final relocation determinations will later occur as required by Engineering Regulation (ER) 405-1-12, chapter 12, paragraph 12-22.

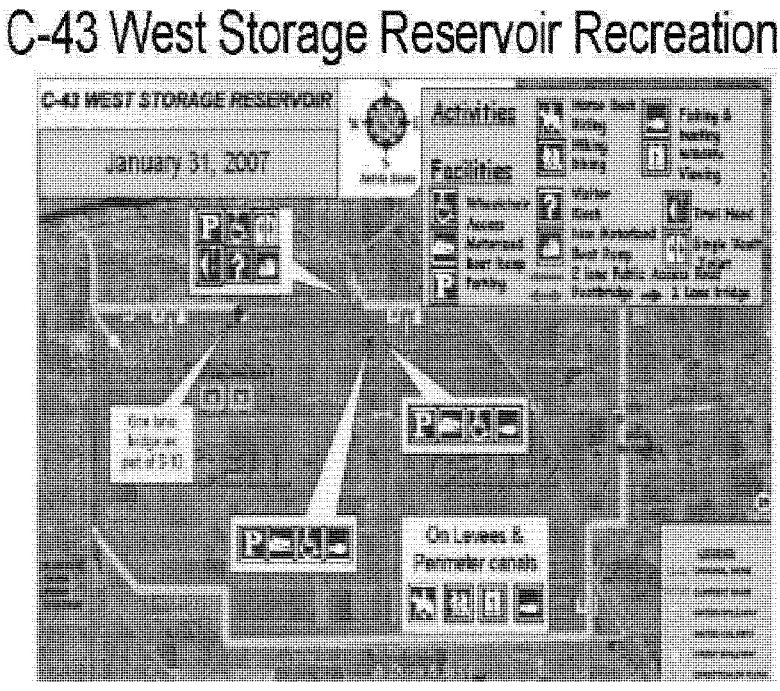
D.6.4 TEMPORARY WORK AREAS

Preliminary analysis indicates that all required temporary staging and stockpile areas will occur within the lands and right of way owned or controlled by SFWMD. Therefore, no additional LER is anticipated to be required for such purposes.

D.6.5 BORROW AND DISPOSAL SITES

D.6.5.1 Borrow

Based on the Geotechnical analysis, it was determined that sufficient quantities of suitable borrow material, within the project footprint, will be made available for construction of the embankment and for other purposes. (See Engineering Appendix). Therefore, no off-site borrow or disposal sites will be required.



D.6.5.2 Disposal

It is proposed that excavated material from the construction site will be utilized for borrow material; therefore, no additional disposal material or borrow site will be required.

D.6.6 RECREATION FEATURES

Recreational features being considered for construction lie within the approximately 10,480 acres to be provided in fee and will be constructed within the footprint of the project. Therefore, no addition LER is required for recreational purposes. The recreational features being proposed may include a nature study, multi-use trail atop the embankment, equestrian use, boat and bank fishing, canoeing/kayaking, motor boating and hunting which will fit with the project purposes as managed by the SFWMD. A major recreation attraction of the Caloosahatchee River (C-43) West Basin Storage Reservoir will be an approximately 12-mile multi-purpose trail loop atop the embankment constructed as part of the project. Recreation facilities proposed include parking and toilet facilities (clivas multrum waterless vault toilets), information kiosk, canoe/kayak launch facility, a shade structure, traffic-control fencing and a pedestrian footbridge bridge over the perimeter canal to provide public access to the reservoir. Two handicapped accessible, double-lane public boat ramps would be provided. Vehicle access will be over the single-lane bridge over C43S-10. The ramps are proposed within the reservoirs on the north embankment. A paved two-lane public road will provide vehicular access to a one-lane bridge across the perimeter canal. A two-lane crushed shell road up the embankment and to the ramps is proposed. Boat traffic control buoys would keep boaters clear of the reservoir structures. Signage would post warnings. The canoe/kayak launch facility would be on the perimeter canal. Littoral areas are proposed at the corners of the seepage canal as part of the project and would provide ideal bank fishing locations outside the levee perimeter. The Florida Fish & Wildlife Conservation Commission (FWC) has endorsed the littoral shelf concept for habitat benefit and potential water quality benefits. Shades trees are proposed on the outside area of the north rim canal adjacent to parking areas. Ample public parking will be developed outside of the north levee and perimeter canal in the general area of the construction staging location. See ***Figure D-3*** and the Appendix H - Recreation of this report for further discussion.

FIGURE D-3: CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR RECREATION FEATURES

D.6.7 ACCESS TO THE PROJECT AREA

Access to the site would be from State Road 80 along the existing access road to the Field Office. Other access roads would be added as required for both construction and operation and maintenance activities. Therefore, ingress and egress will be via Federal, State, municipal, county roads, and roads and rights of way available to the non-Federal sponsor for project purposes. No additional LER are required.

D.7 EXISTING FEDERAL PROJECTS

There are no known Federal projects that lie fully or partially within the LER required for the project.

D.8 FEDERALLY OWNED LANDS

There are no known federally owned lands within the project area.

D.9 NON-FEDERAL SPONSOR OWNED LANDS AND CREDITING

The SFWMD records indicate that they currently own approximately 12,352 acres in fee and approximately 20 acres in easement for a total of 12,372 acres (***Figure D-4*** entitled "SFWMD Parcel Acquisition Map, and, ***Table D-2*** entitled "Acreage and Interest Owned by SFWMD). The approximately 20 acres of easement is situated at the northwest corner of SFWMD's fee ownership, and it connects the Townsend Canal to the Caloosahatchee River. A review of the SFWMD easements indicated that they currently have sufficient interest for the construction, maintenance, repair, replacement and operation for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project. The estate proposed for this approximately 20 acres of Townsend Canal is the standard channel improvement easement for the project. SFWMD is currently in negotiation to exchange 541.31 acres within its ownership for 600.17 acres owned by Bryan Paul Citrus and identified on the map and table as GX100-008 and GX100-009 respectively. Such an exchange would add an additional approximately 58 acres for a estimated total of 12,430 acres for SFWMD ownership in fee and easement that would be available and sufficient interest for project purposes. Within the approximately 12,372 acres presently owned by SFWMD, approximately 9,003 acres were acquired from J&H Grove Holdings, Inc. (area referred to as the Berry Groves) with both Federal (DOI) and State funds. Only approximately 7,080 acres of this approximately 9,003 acres acquired with both Federal and State funds will be used for the Project. The remainder of the approximately 3,620 acres required for the project was acquired with State funds.

A breakdown of the acreages and costs are as follows:

- SFWMD's total land acquisition consists of approximately 12,372 acres including approximately 20 acres of easement.
- SFWMD will exchange approximately 541 of these acres for approximately 600 acres owned by Bryan Paul Citrus for a new total of approximately 12,340 acres.
- Total project footprint for LER requirements is estimated at approximately 10,700 acres that consists of approximately 10,480 acres in fee, approximately 20 acres in perpetual easement, and approximately 200 acres in temporary easements.
- Federal (DOI) and State funds contribution for acquiring 9,003 acres of J&H Grove Holdings L.C.(Berry Grove) property consist of *$32,800,000 of Federal funds and $38,668,403 of State funds for a total of *$71,500,000®. Such figures are based on information provided by SFWMD.
- Land acquired with Federal and State funds to be used for project purposes is approximately 7,080 acres.

- Federal Fund contribution for approximately 7.080 acres is estimated at $27,502,294 for land cost and $64,375 for acquisition cost for an estimated total of $27,566,669.
- Federal administrative costs for 10,700 acres is an estimated amount of $424,219® with 25% contingency.
- Total estimated Federal cost share *$27,930,000.
- State funds contribution for both the 7,080 acres as well as the remaining 3,620 acres is an estimated amount of $50,990,270 for land cost and an estimated amount of $1,504,585® for acquisition cost with 7% contingency included.
- Total estimated real estate costs for the 10,700 acres required for the project are the sum of $27,502,294 Federal + $424,219 Federal + $50,990,270 non-Federal + $1,504,585 non-Federal which amounts to *$80,420,000.00 (Rounded Down).

*Note costs in $x1000

The amount of the Federal share may be increased or decreased based on a more detailed analysis which will occur during the crediting review process after approval of the Project, execution of a Project Cooperation Agreement, and certification of the land by SFWMD. See ***Figure D-4*** entitled "SFWMD Parcel Acquisition", ***Table D-2*** entitled "Acreage and Interest Owned by SFWMD", and ***Table D-3*** entitled "Summary of Baseline Cost Estimate".

FIGURE D-4: SFWMD PARCEL ACQUISITION MAP

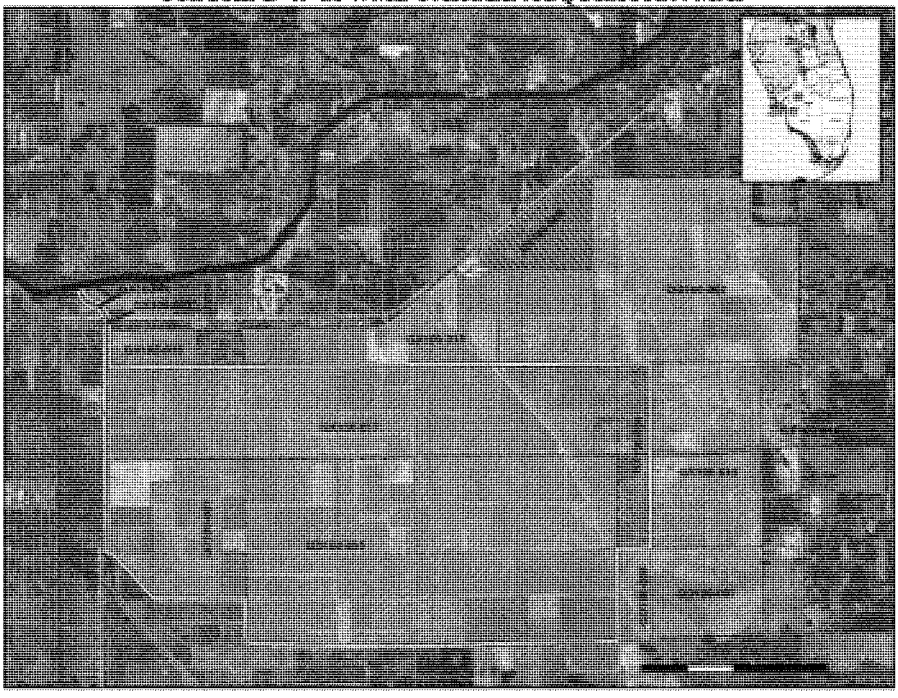


TABLE D-2: ACREAGE AND INTEREST OWNED BY SFWMD

Landowner Name	Acres Acquired	Land Purchase Price	Land Associated Costs	Total Acquisition Costs	District/State Funded	Locally Funded	Federally Funded
Berry, Paul & Duda (GX 100-002) easement	10.28	$0.00	$4,940.04	$4,940.04	$4,940.04	$0.00	$0.00
Berry Groves (GX100-003) easement	5.99	$0.00	$5,946.87	$5,946.87	$5,946.87	$0.00	$0.00
SFWMD (GX100-008*) fee	541.31	$0.00	$0.00	$0.00	$0.00	$0.00	$0.00
J&H Grove Holdings, L.C. (GX100-001) fee	8,121.52	$63,010,622	$854,434.62	$63,865,056.62	$32,359,745.62	$0.00	$31,505,311
J&H Grove Holdings, L.C. (GX100-004) fee	338.98	$7,510,988	$80,358.67	$7,591,346.67	$6,296,657.67	$0.00	$1,294,689
Griffin Family LMTD Partnership (QD 100-001) fee	954.89	$4,620,000	$105,588.50	$4,725,588.50	$4,725,588.50	$0.00	$0.00
MG Enterprises LLC (QD 100-005) fee	2,399.11	$13,875,000	$58,995.28	$13,933,995.28	$13,933,995.28	$0.00	$0.00
Sub-Total Acres currently acquired	12,372.08	$89,016,610	$1,099,377.07	$90,115,987.07	$57,315,987.07	$0.00	**$32,800,000
SFWMD (GX100-008*) fee to be conveyed to Bryan Paul Citrus	541.31	$0.00	$0.00	$0.00	$0.00	$0.00	$0.00
Sub total after conveyance to Bryan Paul	11,830.77						
Bryan Paul Citrus (GX100-009) fee to be acquired by SFWMD in exchange for GX100-008	600.17			$0.00	$0.00	$0.00	$0.00
FINAL TOTAL ACRES OWNED BY SFWMD	**12,430.94**						

* Note GX-100-008 (Cerp Id=04) was exchanged for GX-100-009 (Cerp Id=04A); no dollar impact
** Note these figures had not yet been verified but will be verified during crediting and certification of lands.

D.9.1 Crediting Considerations

This report takes into consideration for crediting purposes the Congressional Authority, the Programmatic Regulations, Six Program-Wide Guidance Memoranda, dated February 2006, and the DOI and SFWMD Grant Agreement entitled Everglades Watershed Restoration-Grant Number LWCF-1.

The CERP Congressional Authority - the CERP Congressional Authority which reads, in part, as follows: "Regardless of the date of acquisition, the value of lands or interests in land acquired by non-Federal interests for any activity described in subsection (b) shall be included in the total cost of the activity and credited against the non-Federal share of the cost of the activity. Such value shall be determined by the Secretary."

"IN GENERAL- Notwithstanding section 528(e)(4) of the Water Resources Development Act of 1996 (110 Stat. 3770) and regardless of the date of acquisition, the value of lands or interests in lands and incidental costs for land acquired by a non-Federal sponsor in accordance with a project implementation report for any project included in the Plan and authorized by Congress shall be-- (i) included in the total cost of the project; and (ii) credited toward the non-Federal share of the cost of the project.

Draft Programmatic Regulations, Six Program-Wide Guidance Memoranda, dated February 2006 - States that credit will be afforded to the Sponsor based on the actual cost of the land needed for a project instead of what the land is worth at the time of a Project Cooperation Agreement signing. Consequently, the Project Delivery Team (PDT) should use actual acquisition costs in plan formulation, cost estimating, and crediting, subject to those costs being reasonable, allocable, and allowable." Therefore, credit for LERRD provided by SFWMD will be based on actual cost of the land, the administrative cost to purchase the lands, and the incidental cost for acquiring the LERRD for the project.

D.9.2 Department of Interior Grant Number LWCF-1, Addendum 3, Land and Water Conservation Act Funds

In June 1999, the DOI and SFWMD executed a Grant Agreement entitled Everglades Watershed Restoration-Grant Number LWCF-1, in which DOI provided $38,900,000 in Federal funds to the SFWMD for the acquisition of land in the East Coast Buffer/WPA and Southern Corkscrew Regional Ecosystem Watershed Project. SFWMD matched the Federal share with a State share of $38,900,000, making the total expenditures on land acquisition at $77,800,000. This Grant contained language to allow SFWMD to manage these acquired lands during an Interim Period defined as "...the period of time: 1) commencing a) with respect to Grant Lands, the date of purchase or date of possession under

condemnation, as appropriate, and b) with respect to Match Lands, the effective date of the Grant Agreement as defined below, and 2) ending a) sixty (60) days prior to the issuance of a notice to proceed with construction of the respective phase of the District/Corps Project, at which time the Grant Land or Match Land is deemed to be 'Incorporated into a District/Corps Project', or b) on the date of receipt by Interior of written notice from the Corps or the District that the particular Grant Land or Match Land is not to be included within a District/Corps Project, or c) such other date agreed to by Interior and the District." .... "Upon incorporation of each Grant Land or Match Land into a District/Corps Project, such Grant Land or Match Land shall be managed in accordance with Corps approved water management and control plans and operation and maintenance manuals for the project so long as the project remains authorized."

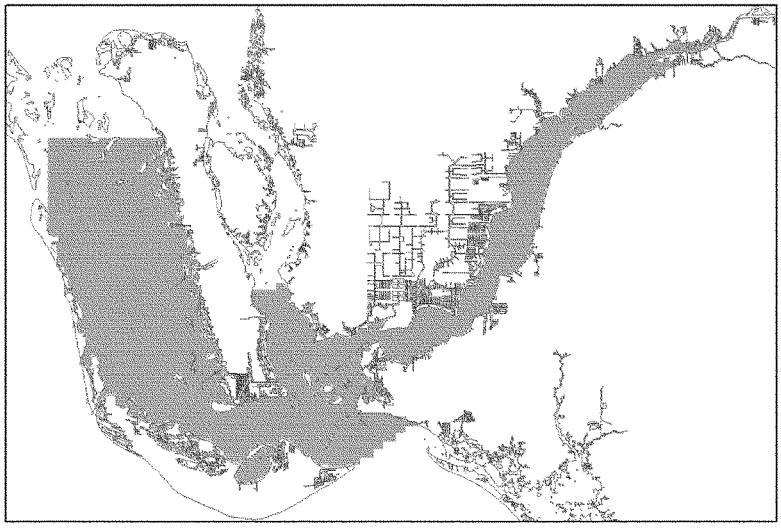
This Grant was amended December 1999 to add an additional $13,900,000 from each of the parties bringing the total to $105,600,000. The Grant was amended again in April 2000 to add an additional $18,900,000 from each of the parties bringing the total to $143,000,000. This additional $37,800,000 was to be used to purchase the Berry Groves property (Caloosahatchee River (C-43) West Basin Storage Reservoir project). The DOI's additional $18,900,000 in funding came from Land and Water Conservation Funds provided to the DOI by Congress. The last amendment to this Grant was executed in June 2001 with each party contributing an additional $5,974,000 bringing the total State and Federal funding under the Grant to $155,348,000. Not all the lands covered in this Grant Agreement are within the footprint of the Caloosahatchee River (C-43) West Basin Storage Reservoir project.

D.9.2.1 Certification and Crediting for Actual and Incidental Costs Acquired under the Department of Interior Grants

Pursuant to the terms and conditions of the Department of Interior Grant Agreement, SFWMD submitted and Department of Interior reviewed and approved the actual acquisition costs and SFWMD's administrative/incidental costs, (excluding SFWMD's staff costs) for the acquisition of J&H Grove Holdings, L.C. (Berry Grove) properties consisting of approximately 9,003 acres in the amount of $71,500,000®, of which $32,800,000 were Federal funds. Of the approximately 7,080 acres of the approximately 9,003 acres required for the project, the Federal share would be approximately $27,566,670® as shown in ***Table D-2***, ***Table D-3***, and ***Table D-4***. These figures may be increased or decreased based on a more detailed analysis during the crediting review process after approval of the Project, execution of a Project Cooperation Agreement and certification of the land.

The sum of $27,566,670 will be credited towards the Federal share of total project cost. This would avoid the review of the same information by two

Federal Agencies and would be consistent with the terms of the Framework Agreement as stated above. The value of real estate acquired pursuant to this Article will be the actual acquisition cost of such real property for credit purposes under applicable cost-sharing principles." This proposal would also reduce future administrative costs.



D.10 UNIFORM RELOCATION ASSISTANCE ACT, PL 91-646

Information provided by SFWMD indicates that there were no persons displaced from acquisition of the project lands by SFWMD. SFWMD's purchase contracts indicated that PL 91-646 was considered, but as part of the acquisition, the landowners waived their rights to relocation claims in the negotiated contracts. SFWMD will be required to provide proof of such waiver prior too or provide such proof as part of the crediting package for LERRD crediting.

D.11 NAVIGATIONAL SERVITUDE AND OTHER LANDS

Approximately 71,000 acres of the Caloosahatchee River and Caloosahatchee estuary from the tidal Caloosahatchee River (i.e., downstream of S-79 to Shell Point) to San Carlos Bay (Shell Point to Pine Island Sound), and areas within Pine Island Sound and Matlacha Pass will be available for use for the environmental benefits for the project. These acres are within the navigable waters of the United States and within the navigation servitude of the Untied States. See ***Figure D-5*** below. See Environmental Appendix for further discussion on the subject matter.

FIGURE D-5: ENVIRONMENTAL LANDS MAP

D.12 INDUCED FLOODING

An analysis will be completed to address the Savings Clause Provisions established by the Water Resources Development Act of 2000 (WRDA 2000) that was signed into law by the President of the United States (Public Law No. 106-541, of the 106th Congress). Section 601(h)(5) contains a Savings Clause that provides protection for existing legal sources of water that will be eliminated or transferred due to project implementation and for no significant and adverse reduction in the level of service for flood protection that was in existence on the date of enactment and in accordance with applicable law. The Programmatic Regulations for the Everglades (33 CFR §§ 385.5 and 385.35-37) require a programmatic guidance memorandum on existing legal sources of water, and a determination of the pre-CERP baseline conditions and direction about what constitutes "levels of service for flood protection ... in accordance with applicable law" existing on date of enactment of WRDA 2000.

To ensure the levels of service of flood protection will not be diminished by this project, hydrologic and hydraulic analyses are being performed using surface water and groundwater modeling. The results of the analyses indicate that the project is not expected to result in stage increase in canal systems adjacent to the project site. The modeling analysis indicates that no flooding will occur outside the project due to the construction or the operation and maintenance of the project. The analysis also indicates that any seepage from the reservoir will be captured in the seepage canals; however, additional analyses will be

undertaken after project construction to ensure that the level of service of flood protection in areas adjacent to the project site is maintained.

D.13 MINERAL AND TIMBER ACTIVITIES

Preliminary investigations indicate that there are no known present or anticipated mineral activities in the vicinity of the proposed project that may affect construction, operation, or maintenance of the project.

D.14 NON-FEDERAL AUTHORITY TO PARTICIPATE IN THE PROJECT

The SFWMD was created by virtue of Florida Statutes, Chapter 373, Section .069 to further the State policy of flood damage prevention, preserve natural resources of the State including fish and wildlife and to assist in maintaining the navigability of rivers and harbors. (There are other enumerated purposes but they are not directly applicable to this project). See Exhibit "C".

D.15 PROPOSED ESTATES

Based on the analysis set forth in paragraph D.1.7.1 above, the following estates will be required:

D.15.1 Standard Estates

D.15.1.1 Standard Estate – Fee

The fee simple title to (the land described in Schedule A), subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

D.15.1.2 Channel Improvement Easement

A perpetual and assignable right and easement to construct, operate, and maintain channel improvement works on, over and across (the land described in Schedule A) for the purposes as authorized by the Act of Congress approved (ADD APPROPRIATE WRDA AUTHORIZATION), including the right to clear, cut, fell, remove and dispose of any and all timber, trees, underbrush, buildings, improvements and/or other obstructions there from; to excavate, dredge, cut away, and remove any or all of said land and to place thereon dredge or spoil material; and for such other purposes as may be required in connection with said work of improvement; reserving, however, to the owners, their heirs and assigns, all such rights and privileges as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

D.15.1.3 Temporary Work Area and/or Disposal Area Easement

A temporary easement and right-of-way in, on, over and across (the land described in Schedule A), for a period not to exceed ADD APPROPRIATE TERM OF YEARS AREA IS REQUIRED FOR CONSTRUCTION PURPOSES) _____, beginning with date possession of the land is granted to the United States, for use by the United States, its representatives, agents, and contractors as a (borrow area) (work area), including the right to borrow and/or deposit fill, spoil and waste material thereon) (move, store and remove equipment and supplies, and erect and remove temporary structures on the land and to perform any other work necessary and incident to the construction of the Caloosahatchee River (C-43) West Basin Storage Reservoir Project, together with the right to trim, cut, fell and remove therefrom all trees, underbrush, obstructions, and any other vegetation, structures, or obstacles within the limits of the right-of-way; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

D.16 ZONING ORDINANCES

Preliminary investigation indicates that no enactments of zoning ordinances are proposed in lieu of, or to facilitate, acquisition in connection with the project.

D.17 ACQUISITION SCHEDULES

It is anticipated that SFWMD currently owns, or will own or control the lands required for construction, operations, and maintenance of the project. Following execution of the Project Cooperation Agreement (PCA), the Federal Government will provide SFWMD with general written descriptions, including maps as appropriate, of the LER and the facility/utility relocations that the Government has determined the non-Federal sponsor must provide and perform for the construction, operation, and maintenance of the project. The LER descriptions will include the required estate, acreage, location, and schedule requirements in detail sufficient to enable the SFWMD to fulfill its obligations to provide the LER in a timely fashion. If relocation is required then the descriptions will include sufficient detail so as to enable the non-Federal sponsor to perform its relocation responsibilities in a timely fashion. In addition, a written notice to proceed with acquisition of such additional LER will be provided to SFWMD.

D.18 HAZARDOUS, TOXIC OR RADIOLOGICAL WASTE (HTRW)

The existing conditions portion of the HTRW document includes a summary of the Phase I/II Environmental Site Assessment (ESA) studies done on the four

properties acquired for the reservoir project. In the course of these studies, over 50 point source sites with potential HTRW contamination were identified. At this time, most if not all of these potential contamination sites have been either remediated or further investigated to characterize the sites and prepare remediation plans. The project sponsor, the SFWMD has made a commitment to the Corps and FWS that after it takes control of the properties from the present lessees and begins construction of the reservoir, all of the outstanding point source remediation efforts will be completed. In addition to the point source contamination sites, the SFWMD also identified distributed soil contamination in portions of the cultivated areas on all of the acquired properties. The remediation of the cultivated soil sites involves the placement of these soils into the core of the reservoir dam. This will isolate the contaminated soils from benthic organisms that serve as food for higher level organisms and thus reduce the potential for bioaccumulation of contaminants by fish and wildlife.

The FWS service has reviewed all of the SFWMD's remediation plans and indicated that they believe that the efforts will sufficiently reduce the risk of harm to fish and wildlife in those areas where the remediation will be performed. The FWS has also stated that moderate levels of copper and other contamination of the cultivated areas are believe to not pose a direct threat to species of concern; however, they believe that an indirect effect may occur since widespread low-level soil contamination may reduce the population of benthic organisms upon which the species of concern normally feed.

Despite the diligent work performed by the SFWMD and FWS to reduce the risk to environmental resources, it is possible that once the reservoir is built, bioaccumulation of soil contaminants does result in harm to one or more species of interest. If this does happen, additional remediation efforts, such as more extensive removal of the reservoir bottom sediments could be done to further reduce the exposure of benthic organisms to nearsurface soil contamination. The cost of additional remediation, if necessary, would be the responsibility of the non-federal sponsor. If such remediation is necessary, the reservoir would be at least partially out of service for several months while the work is conducted.

Most of the contamination at the point source sites has been delineated and much of it remediated. The remaining sites are expected to be remediated prior to certification of the lands and are not likely to cause a project delay. See main body of report for a full discussion of the HTRW.

The non-Federal sponsor shall be responsible for ensuring that the development and execution of Federal, State, and/or locally required HTRW response actions area accomplished at 100 percent non-project cost. No cost sharing credit will be given for the cost of response actions.

D.19 PROJECT SUPPORT

No real estate issues relevant to planning, designing or implementing are anticipated. No real estate issues that may impact the project schedules, budgets, PCA, or quality of the deliveries are anticipated since these lands are currently owned by SFWMD.

There is no known or anticipated opposition to the project by landowners in the project area or any known or anticipated ownership concerns that could impact the project since SFWMD already owns, controls, or will control the lands that are required for project purposes.

D.20 BASELINE COST ESTIMATES AND MCACES COST ESTIMATES

The actual acquisition costs and administrative costs provided by SFWMD were considered in the final computation. SFWMD cost towards the land and incidental cost is estimated at $52,400,056.39 without contingency and $52,494,855.94 with contingency. A seven percent contingency was added to the Sponsor's estimated administrative/incidental costs due to risk and uncertainty. The federal cost amounted to $27,926,512.75, which includes the Federal share of the land costs as well as future federal administrative costs. The total real estate cost with contingency is estimated at $80,421,000. These figures are subject to modification and verification during the crediting review process.

D.21 BASELINE COST ESTIMATES AND MCACES COST ESTIMATES

The actual acquisition costs and administrative costs provided by SFWMD were considered in the final computation. SFWMD cost towards the land and incidental cost is estimated at $52,494,855.94. A seven percent contingency was added to the Sponsor's estimated costs due to risk and uncertainty. The Federal cost amounted to $27,930,000®. The total real estate cost with contingency is estimated at $80,420,000 (Rounded Down). (***Table D-3***)

D.23 EXHIBITS

EXHIBIT "A"
SEC. 390. EVERGLADES ECOSYSTEM RESTORATION

(a) IN GENERAL.--On July 1, 1996, out of any funds in the Treasury not otherwise appropriated, the Secretary of the Treasury shall provide $200,000,000 to the Secretary of the Interior to carry out this section.

(b) ENTITLEMENT.--The Secretary of the Interior (referred to in this section as the "Secretary")--

(1) shall be entitled to receive the funds made available under subsection (a);

(2) shall accept the funds; and

(3) shall use the funds to--

(A) conduct restoration activities in the Everglades ecosystem in South Florida, which shall include the acquisition of real property and interests in real property located within the Everglades ecosystem; and

(B) fund resource protection and resource maintenance activities in the Everglades ecosystem.

(c) SAVINGS PROVISION.--Nothing in this subsection precludes the Secretary from transferring funds to the Army Corps of Engineers, the State of Florida, or the South Florida Water Management District to carry out subsection (b)(3).

(d) DEADLINE.--The Secretary shall use the funds made available under subsection (a) for restoration activities referred to in subsection (b)(3) not later than December 31, 1999.

(e) REPORT TO CONGRESS.--For each of calendar years 1996 through 1999, the Secretary shall submit an annual report to Congress describing all activities carried out under subsection (b)(3).

(f) SEPARATE AND ADDITIONAL EVERGLADES RESTORATION ACCOUNT.--

(1) ESTABLISHMENT.--There is established in the Treasury a special account (to be known as the "Everglades Restoration Account"), which shall consist of such funds as may be deposited in the account under paragraph (2). The account shall be separate, and in addition to, funds deposited in the Treasury under subsection (a).

(2) SOURCE OF FUNDS FOR ACCOUNT.--

(A) PROCEEDS FROM SURPLUS PROPERTY.--

(i) IN GENERAL.--Subject to subparagraph (B), the Administrator shall deposit in the special account all funds received by the Administrator, on or after the date of enactment of this Act, from the disposal pursuant to the Federal Property and Administrative Services Act of 1949 (40 U.S.C. 471 et seq.) of surplus real property located in the State of Florida.

ii) AVAILABILITY AND DISPOSITION OF FEDERAL LAND.--

(I) IDENTIFICATION.--Any Federal real property located in the State of Florida (excluding lands under the administrative jurisdiction of the Secretary that are set aside for conservation purposes) shall be identified for disposal or exchange under this subsection and shall be presumed available for purposes of this

subsection unless the head of the agency controlling the property determines that there is a compelling program need for any property identified by the Secretary.
(II) AVAILABILITY.--Property identified by the Secretary for which there is no demonstrated compelling program need shall, not later than 90 days after a request by the Secretary, be reported to the Administrator and shall be made available to the Administrator who shall consider the property to be surplus property for purposes of the Federal Property and Administrative Services Act of 1949 (40 U.S.C. 471 et seq.).
(III) PRIORITIZATION OF DISPOSITION.—The Administrator may prioritize the disposition of property made available under this subparagraph to permit the property to be sold as quickly as practicable in a manner that is consistent with the best interests of the Federal Government.
(B) LIMIT ON TOTAL AMOUNT OF DEPOSITS.--The total amount of funds deposited in the special account under subparagraph (A) shall not exceed $100,000,000.
(C) EFFECT ON CLOSURE OF MILITARY INSTALLATIONS.--Nothing in this section alters the disposition of any proceeds arising from the disposal of real property pursuant to a base closure law.
(3) USE OF SPECIAL ACCOUNT.--Funds in the special account shall be available to the Secretary until expended under this paragraph. The Secretary shall use funds in the special account to assist in the restoration of the Everglades ecosystem in South Florida through--
(A) subject to paragraph (4), the acquisition of real property and interests in real property located within the Everglades ecosystem; and
(B) the funding of resource protection and resource maintenance activities in the Everglades ecosystem.
(4) STATE CONTRIBUTION.--The Secretary may not expend any funds from the special account to acquire a parcel of real property, or an interest in a parcel of real property, under paragraph (3)(A) unless the Secretary obtains, or has previously obtained, a contribution from the State of Florida in an amount equal to not less than 50 percent of the appraised value of the parcel or interest to be acquired, as determined by the Secretary.
(5) DEFINITIONS.--In this subsection:
(A) ADMINISTRATOR.--The term "Administrator" means the Administrator of General Services.
(B) BASE CLOSURE LAW.--The term "base closure law" means each of the following:
(i) The Defense Base Closure and Realignment Act of 1990 (part A of title XXIX of Public Law 101-510; 10 U.S.C. 2687 note).
(ii) Title II of the Defense Authorization Amendments and Base Closure and Realignment Act (Public Law 100-526; 10 U.S.C. 2687 note).
(iii) Section 2687 of title 10, United States Code.
(iv) Any other similar law enacted after the date of enactment of this Act.

(C) EVERGLADES ECOSYSTEM.--The term "Everglades ecosystem" means the Florida Everglades Restoration area that extends from the Kissimmee River basin to Florida Bay.
(D) EXCESS PROPERTY.--The term "excess property" has the meaning provided in section 3 of the Federal Property and Administrative Services Act of 1949 (40 U.S.C. 472).
(E) EXECUTIVE AGENCY.--The term "executive agency" has the meaning provided in section 3 of the Federal Property and Administrative Services Act of 1949 (40 U.S.C. 472).
(F) SPECIAL ACCOUNT.--The term "special account" means the Everglades Restoration Account established under paragraph (1).
(G) SURPLUS PROPERTY.--The term "surplus property" has the meaning provided in section 3 of the Federal Property and Administrative Services Act of 1949 (40 U.S.C. 472).
(g) REPORT TO DETERMINE THE FEASIBILITY OF ADDITIONAL LAND ACQUISITION AND RESTORATION ACTIVITIES.--
*(1) IN GENERAL.--The Secretary shall conduct an investigation to determine what, if any, unreserved and unappropriated Federal lands (or mineral interests in any such lands) under the administrative jurisdiction of the Secretary are suitable *1025 for disposal or exchange for the purpose of conducting restoration activities in the Everglades region.*
(2) CONSERVATION LANDS.--No lands under the administrative jurisdiction of the Secretary that are set aside for conservation purposes shall be identified for disposal or exchange under this subsection.
(3) FLORIDA.--In carrying out this subsection, the Secretary shall, to the maximum extent practicable, determine which lands and mineral interests located within the State of Florida are suitable for disposal or exchange before making the determination for eligible lands or interests in other States.
(4) PUBLIC ACCESS.--In carrying out this subsection, the Secretary shall consider that in disposing of lands, the Secretary shall retain such interest in the lands as may be necessary to ensure that the general public is not precluded from reasonable access to the lands for purposes of fishing, hunting, or other recreational uses.
(5) REPORT.--Not later than 1 year after the date of enactment of this Act, the Secretary shall submit a report to the Committee on Resources of the House of Representatives and the Committee on Energy and Natural Resources of the Senate describing the results of the investigation conducted under this subsection. The report shall describe the specific parcels identified under this subsection, establish the priorities for disposal or exchange among the parcels, and estimate the values of the parcels.

Exhibit "B"
SECTION 601 (E)(3) OF THE WATER RESOURCES DEVELOPMENT ACT OF 2000, (PL 106-541)
(e) COST SHARING.
(3) FEDERAL ASSISTANCE.
(A) IN GENERAL.--The non-Federal sponsor with respect to a project authorized by subsection (b), (c), or (d) may use Federal funds for the purchase of any land, easement, rights-of-way, or relocation that is necessary to carry out the project if any funds so used are credited toward the Federal share of the cost of the project.
(B) AGRICULTURE FUNDS.--Funds provided to the non-Federal sponsor under the Conservation Restoration and Enhancement Program (CREP) and the Wetlands Reserve Program (WRP) for projects in the Plan shall be credited toward the non-Federal share of the cost of the Plan if the Secretary of Agriculture certifies that the funds provided may be used for that purpose. Funds to be credited do not include funds provided under section 390 of the Federal Agriculture Improvement and Reform Act of 1996 (110 Stat.1022).

Exhibit "C"
FLORIDA STATUTES
TITLE XXVIII. NATURAL RESOURCES; CONSERVATION, RECLAMATION, AND USE CHAPTER 373. WATER RESOURCES
PART I. STATE WATER RESOURCE PLAN
373.1501. South Florida Water Management District as local sponsor
(1) As used in this section and s. 373.026(8), the term:
(b) "Department" means the Department of Environmental Protection.
(c) "District" means the South Florida Water Management District.
(f) "Project" means the Central and Southern Florida Project.
(g) "Project Component" means any structural or operational change, resulting from the restudy, to the Central and Southern Florida Project as it existed and was operated as of January 1, 1999.
(h) "Restudy" means the Comprehensive Review Study of the Central and Southern Florida Project, for which federal participation was authorized by the federal Water Resources Development Acts of 1992 and 1996 together with related Congressional resolutions and for which participation by the South Florida Water Management District is authorized by this section. The term includes all actions undertaken pursuant to the aforementioned authorizations which will result in recommendations for modifications or additions to the Central and Southern Florida Project.
(2) The Legislature finds that the restudy is important for restoring the Everglades ecosystem and sustaining the environment, economy, and social wellbeing of South Florida. It is the intent of the Legislature to facilitate and support the restudy through a process concurrent with Federal Government review and Congressional authorization. Nothing in this section is intended in any way to limit federal agencies or Congress in the exercise of their duties and

responsibilities. It is further the intent of the Legislature that all project components be implemented through the appropriate processes of this chapter and be consistent with the balanced policies and purposes of this chapter, specifically s. 373.016.
(4) The district is authorized to act as local sponsor of the project for those project features within the district as provided in this subsection and subject to the oversight of the department as further provided in s. 373.026. The district may:
(a) Act as local sponsor for all project features previously authorized by Congress;
(b) Continue data gathering, analysis, research, and design of project components, participate in preconstruction engineering and design documents for project components, and further refine the Comprehensive Plan of the restudy as a guide and framework for identifying other project components;
(c) Construct pilot projects that will assist in determining the feasibility of technology included in the Comprehensive Plan of the restudy; and
(d) Act as local sponsor for project components.
(5) In its role as local sponsor for the project, the district shall comply with its responsibilities under this chapter and implement project components through appropriate provisions of this chapter. In the development of project components, the district shall:
(a) Analyze and evaluate all needs to be met in a comprehensive manner and consider all applicable water resource issues, including water supply, water quality, flood protection, threatened and endangered species, and other natural system and habitat needs;
(b) Determine with reasonable certainty that all project components are feasible based upon standard engineering practices and technologies and are the most efficient and cost-effective of feasible alternatives or combination of alternatives, consistent with restudy purposes, implementation of project components, and operation of the project; (c) Determine with reasonable certainty that all project components are consistent with applicable law and regulations, and can be permitted and operated as proposed. For purposes of such determination:
1. The district shall convene a pre-application conference with all state and federal agencies with applicable regulatory jurisdiction;
2. State agencies with applicable regulatory jurisdiction shall participate in the pre-application conference and provide information necessary for the district's determination; and
3. The district shall request that federal agencies with applicable regulatory jurisdiction participate in the pre-application conference and provide information necessary for the district's determination;
(d) Consistent with this chapter, the purposes for the restudy provided in the Water Resources Development Act of 1996, and other applicable federal law, provide reasonable assurances that the quantity of water available to existing legal users shall not be diminished by implementation of project components so as to adversely impact existing legal users, that existing levels of service for flood protection will not be diminished outside the geographic area of the project

component, and that water management practices will continue to adapt to meet the needs of the restored natural environment.
(e) Ensure that implementation of project components is coordinated with existing utilities and public infrastructure and that impacts to and relocation of existing utility or public infrastructure are minimized.
(6) The department and the district shall expeditiously pursue implementation of project modifications previously authorized by Congress or the Legislature, including the Everglades Construction Project. Project components should complement and should not delay project modifications previously authorized.
(7) Notwithstanding any provision of this section, nothing herein shall be construed to modify or supplant the authority of the district or the department to prevent harm to the water resources as provided in this chapter.
(8) Final agency action with regard to any project component subject to s. 373.026(8)(b) shall be taken by the department. Actions taken by the district pursuant to subsection (5) shall not be considered final agency action. Any petition for formal proceedings filed pursuant to ss. 120.569 and 120.57 shall require a hearing under the summary hearing provisions of s. 120.574, which shall be mandatory. The final hearing under this section shall be held within 30 days after receipt of the petition by the Division of Administrative Hearings.

E.0 AGENCY/PUBLIC COORDINATION

Public outreach efforts for the Caloosahatchee River (C-43) West Basin Storage Reservoir project began early in the project formulation process. Due to the intense public, political, and media interest in restoration of the south Florida ecosystem, public participation has been a critical component of the development of this Project Implementation Report (PIR).

E.1 PUBLIC INVOLVEMENT PROGRAM

Public involvement is a process by which interested and affected individuals, organizations, agencies, and governmental entities are consulted and participate in the decision-making. Public involvement in the Caloosahatchee River (C-43) West Basin Storage Reservoir project has two main functions: to inform the public about what the project team is planning and to generate input on key issues and concerns critical to resolving the challenges involved in the planning effort.

This project has been developed with strong cooperation from the US Fish and Wildlife Service (USFWS), US Department of Agriculture (USDA), Natural Resources Conservation Service (NRCS), US Environmental Protection Agency (USEPA), National Oceanic and Atmospheric Administration (NOAA), US Geologic Survey (USGS), Florida Fish and Wildlife Conservation Commission (FFWCC), and Florida Department of Environmental Protection (FDEP), as well as Hendry and Lee counties. The South Florida Water Management District (SFWMD) is a cost-sharing partner in the study and had been a fully active participant in the formulation of this project and creation of the project report. USEPA, USFWS, and USGS have staffers located in the Planning sections of U.S. Army Corps of Engineers (USACE), Jacksonville District; these staffers aid in interagency coordination for Comprehensive Everglades Restoration Plan (CERP) projects. There has also been local participation in the project from Lee and Hendry counties.

E.2 SCOPING FOR THE CALOOSAHATCH EE RI VER (C-43) WEST BASIN STORAGE RESERVOIR PROJECT

A Notice of Intent (NOI) to produce an integrated Caloosahatchee River (C-43) West Basin Storage Reservoir Draft PIR and Environmental Impact Statement (EIS) was published in the Federal Register in March 2003. A Scoping Letter asking for agency and public comment on the proposed Caloosahatchee River (C-43) West Basin Storage Reservoir PIR was sent out March 18, 2003

An official letter inviting USFWS, USEPA, Everglades National Park (ENP), FFWCC and FDEP to be cooperating agencies (as defined by the National Environmental Policy Act or NEPA) was sent in September 2006. These

agencies were chosen because of their special expertise on the area. The selection of these agencies to be invited as cooperating agencies does not exclude any other agencies from full participation in the project. Although none of these agencies accepted the invitation, their input will continue to be valued and solicited for the project.

E.3 OTHER REQUIRED COORDINATION

In addition to the scoping required by the NEPA, coordination required by other Federal laws and regulations has been conducted with the following agencies:

E.3.1 U.S. Fish and Wildlife Service

Two Planning Aid Letters, dated August 13, 2003 and March 29, 2005 were received from the USFWS as part of the process for developing alternative plans. A Draft Fish and Wildlife Coordination Act Report (DCAR) report was issued in March 2007. A Final CAR was issued on July 13, 2007. The letters and report can be reviewed in ***Annex A***. This information has been incorporated by the project team into the Caloosahatchee River (C-43) West Basin Storage Reservoir PIR plan formulation process. The USFWS is a member of the project team.

The USFWS also identified critical fish and wildlife habitat and threatened and endangered species in a letter dated April 11, 2002, and provided scoping comments in a letter dated June 10, 2003 (see ***Annex A***). The USACE asked for formal consultation with the USFWS due to potential adverse impacts to the endangered Florida panther (*Felis concolor coryi*), threatened Audubon's crested caracara (*Polyborus plancus audubonii*), and threatened eastern indigo snake (*Drymarchon corais couperi*). This letter was sent by the USACE on January 10, 2007. The USFWS concurred with the Corps determinations and completed the formal consultation by a BO dated 20 July 2007.

E.3.2 National Marine Fisheries Service

Public law 104-208 reflects the Secretary of Commerce and Fishery Management Council authority and responsibilities for the protection of Essential Fish Habitat (EFH). Federal agencies that fund, permit, or carry out activities that may adversely impact EFH are required to consult with the National Marine Fisheries Service (NMFS) regarding potential effects of their actions on EFH and Federally managed fisheries. This PIR/EIS served as an EFH assessment and was coordinated with NMFS. NMFS has also completed their consultation for Section 7 of the Endangered Species Act (ESA) by concurring with the "may affect but not likely to adversely affect" determination for sea turtles and smalltooth sawfish by letter dated March 28, 2007. NMFS reviewed the draft EIS and stated in an email dated 30 May 2007 that "NOAA's National Marine Fisheries Service, Southeast Region, Habitat Conservation Division, has

reviewed the Department of the Army permit application listed below. We anticipate that any adverse effects that might occur on marine and anadromous fishery resources would be minimal and, therefore, do not object to issuance of the permit." The permit application referred to used this draft EIS as the NEPA document, and therefore NMFS agreed with the Corps determination of beneficial effects to EFH and fishery resources.

E.3.3 Florida Fish and Wildlife Conservation Commission

No Planning Aid Letters have been received from the Florida Fish and Wildlife Conservation Commission (FWC), though FWC has participated in the project team. FWC submitted comments dated 8 June 2007 on the draft PIR/EIS through the Florida Clearinghouse. Those comments along with the Corps' response are summarized in the draft PIR comment matrix in Annex A.

E.3.4 Florida State Historic Officer

Coordination with the State Historic Preservation Officer (SHPO) in accordance with the procedure of the Advisory Council on Historic Preservation is complete. An archaeological and historical survey of the project area revealed one site potentially eligible for listing in the National Register of Historic Places. It was the opinion of Janus Research, contractor to the SFWMD, that the site would not be adversely impact by project activities. Janus recommended no further archaeological or historical investigations in the project area. The SHPO concurred with Janus' opinion and recommendation by a letter sent October 5, 2006.

E.4 ENVIRONMENTAL JUSTICE

Executive Order 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations, requires the Federal government to achieve environmental justice by identifying and addressing disproportionately high adverse effects of its activities on minority and low-income populations. It requires the analysis of information such as the race, national origin, and income level for areas expected to be impacted by environmental actions. It also requires Federal agencies to identify the need to ensure the protection of populations relying on subsistence consumption of fish and wildlife, through analysis of information on such consumption patterns and communication to the public of associated risk. Environmental justice analysis is included in this report in the environmental impacts section as well as the agency coordination section.

E.5 REVIEW OF THE DRAFT AND FINAL PIR/EIS

A Notice of Availability was published in the Federal Register on 27 April 2007 when this document was released for public and agency review. Comments received were addressed and are included in Annex B.

A Notice of Availability of the Final PIR/EIS will be published in the Federal Register, and the final report will be sent to numerous local, state and Federal agencies, private interest groups and interested public for review and comment in accordance with the Council on Environmental Quality's NEPA regulations and related USACE guidance. Comments received during the review will be considered in preparing the final study documents and by subsequent reviewers and decision-makers in the Washington-level Federal review process. The agencies, groups and individuals listed in Annex B will be sent copies of the Final PIR.

E.5.1 Comments Received and Responses

The Final PIR will be made available to the public and other agencies. After the 30-day review period, comments received from state, Federal and local agencies, Native American Tribes, non-governmental organizations and concerned individuals will be reviewed. The comment letters received will be on file in the USACE, Jacksonville District at the address shown on the cover page of this document.

F.0 PLAN FORMULATION

F.1 PLAN FORMULATION AND ALTERNATIVE EVALUATION

F.1.1 Background and Introduction

Extreme changes in salinity in the Caloosahatchee Estuary due to either excessive or little to no freshwater discharges over the Franklin Lock & Dam (S-79) have resulted in an ecosystem in decline. Ecological and water quality problems will continue into the future unless restorative actions are taken. Large regulatory releases from Lake Okeechobee along with discharges of substantial amounts of excess stormwater runoff from the basin during the wet season have had negative impacts on the Caloosahatchee River & estuary. Since rainfall cannot be controlled, it is necessary to store the excess stormwater to prevent its rapid conveyance to the estuary. Historically in South Florida, storage was achieved through extensive wetland systems that once dominated the landscape, and provided for the attenuation and filtering of the stormwater runoff resulting from rainfall events.

The purpose of the Caloosahatchee River (C-43) West Basin Storage Reservoir project is to improve water deliveries to the estuary, provide for dry season flows, restore downstream salinity levels to those supportive of key estuarine species, and ensure the availability of water for the natural system needs of the Caloosahatchee estuarine system. Improvements in the distribution of water should result in improvements to the timing, quality and quantity of water deliveries to the inland ecosystems. Additional water resource benefits could provide supplemental water resources for agriculture and urban users resulting in a reduction of demands placed on existing surface and ground water resources such as the Caloosahatchee Rive (C-43 Canal) and Lake Okeechobee.

The Restudy provided the initial scope of the project as determined during the creation of CERP. The screening and evaluation of plan components proposed in the Restudy made the determination that above ground water storage provided the most cost effective alternative for freshwater attenuation (CERP, Volume 1, Section 7.2). The CERP project scope included a description of the project as follows:

"This feature includes above-ground reservoir(s) with a total storage capacity of approximately 160,000 acre-feet located in the Caloosahatchee River (C-43) Basin in Hendry, Glades, or Lee Counties. The initial design of the reservoir(s) assumed 20,000 acres with water levels fluctuating up to 8 feet above grade. The final size, depth and configuration of this facility will be determined through more detailed planning and design."

Reservoir storage became a starting point of the Caloosahatchee River (C-43) West Basin Storage Reservoir study. Improvements in the timing, distribution, and magnitude of water deliveries to the estuary should result from improvements in the distribution of surface storage. Further improvements from additional in-basin storage, other potential recommendations to supplement water uses in the study area, and provide dry season flows to the estuarine systems are anticipated benefits.

In 1997, significant amendments were made to the Florida Water Resources Act of 1972 (Chapter 373, Florida Statutes) regarding regional water supply planning. These changes required the SFWMD to prepare a District-wide Water Supply Assessment (DWSA) and to prepare water supply plans for regions that were anticipated to have the potential of demand outstripping available supply by the year 2020. The SFWMD in 1998 had undertaken a water supply planning initiative to ensure prudent management of South Florida's water resources. As a result of this initiative, the SFWMD released in 2000 the Caloosahatchee Water Management Plan (CWMP). The CWMP analysis determined that the projected surface water needs of the Caloosahatchee River and Estuary can be met during a 1-in-10 drought condition with the development of water management and storage infrastructure that effectively captures and stores surface water flows in the basin. The CWMP determined that improved management for surface water through storage could increase freshwater availability in the region and reduce potential impacts resulting from water use.

Both the Restudy and the CWMP therefore arrived at a similar conclusion: above ground water storage areas were the most cost affective and appropriate method for attenuation of freshwater runoff and capture of Lake Okeechobee inflows in the Caloosahatchee River (C-43) West Basin Storage Reservoir project area.

During completion of the CERP Master Program Management Plan (MPMP) in August of 2000, the project was divided into two parts, Part I: The Caloosahatchee River (C-43) Basin Storage Reservoir Project (C-43 BSRP), and Part II: The Caloosahatchee River (C-43) Basin ASR Project. The projects were separated to accommodate the inclusion of the findings of the Caloosahatchee ASR Pilot Project into the full ASR project without delaying the implementation of the reservoir aspect of the project. The Caloosahatchee River (C-43) Basin Storage Reservoir Project (Part I) was subsequently divided into two separate PIRs, with the first PIR being known as Caloosahatchee River (C-43) West Basin Storage Reservoir.

The Caloosahatchee River (C-43) West Basin Storage Reservoir PIR addresses formulation, evaluation, and justification of a separable reservoir project by

reaffirming that a reservoir in the West Caloosahatchee River (lower) basin will achieve the benefits of the Restudy for the Caloosahatchee River (C-43) Basin in a cost-effective manner, demonstrate that a reservoir has been optimized, and acknowledge that the project is part of a more comprehensive plan for the Caloosahatchee River (C-43) Basin. Since the Caloosahatchee River (C-43) West Basin Storage Reservoir project is located in the lower portion of the West Caloosahatchee River (C-43) Basin, the PIR is focused on estuary restoration and has limited capability to provide additional water to meet water supply demands in the East Caloosahatchee River (upper) basin. A subsequent second PIR will address the water supply needs and water quality issues of the East Caloosahatchee River (upper) basin and will also address any additional restoration needs and demands in the West Caloosahatchee River (lower) basin not met by the Caloosahatchee River (C-43) West Basin Storage Reservoir project.

Storage of water within the Caloosahatchee River (C-43) Basin had been established as one of the primary management measures contributing to the goals and purposes of the Restudy. Based on these findings, the SFWMD acquired approximately 12,372 acres using State and Federal funds appropriated to the Department of Interior under the authority of the 1996 Farm Bill (Federal Agriculture Improvement and Reform Act of 1996, Public Law 104-127, 110 Stat. 1022). As the PIR development process was initiated, there was an effort to identify early opportunities to obtain system-wide benefits by utilizing readily available lands. One of these opportunities was the Caloosahatchee River (C-43) West Basin Storage Reservoir evaluating a potential reservoir in the western Caloosahatchee River Basin on lands acquired by SFWMD with DOI Farm Bill and SFWMD funds.

Draft Programmatic Regulations Guidance Memoranda # 1 and #2 instruct project teams to affirm and optimize the component identified in the Restudy unless conditions or planning objectives have changed, or if the component no longer meets the purposes outlined in the Restudy, to formulate new alternatives. Additionally, for projects where the non-Federal sponsor has already acquired lands, formulation of alternative plans using other sites will be minimized if the intended project purposes can be achieved and no more cost-effective sites are identified during formulation. Additional management measures to address the new circumstances should be developed and screening should occur based on the project's evaluation criteria and performance measures. As stated in CERP Guidance Memorandum 2:

Reaffirmation: If the project as described in the Plan is reaffirmed, then the Project Delivery Team's efforts will focus on development of design alternatives and optimization of the project features, cost-effectiveness, satisfaction of programmatic regulations requirements for PIRs, Micro-Computer Aided Cost

Engineering System (MCACES) cost estimates, and the integrated National Environmental Policy Act (NEPA) documentation to supplement the information contained in the Programmatic Environmental Impact Statement for the Plan, in accordance with the concept of tiering under NEPA.

Reformulation: When the project described in the Plan no longer achieves the benefits of the project as described in the Plan, additional formulation will be required prior to initiating detailed design of the selected alternative plan. However, the formulation completed and described in the Plan will provide the foundation for the Project Delivery Team to formulate additional alternatives. The new or changed circumstances requiring additional formulation should be documented.

The plan formulation for this project focuses on reaffirming that above-ground storage reservoirs in the Caloosahatchee River (C-43) Basin continue to meet the goals, objectives, and purposes for the project as described in the Restudy. Accordingly, in reviewing the findings of the Restudy, the team has determined that based on the current conditions, the project as described in the Restudy still achieves the benefits of the project in a cost-effective manner. As a result, the team has determined that the plan formulation process entails optimization of the project described in the Restudy.

F.1.2 Plan Formulation and Evaluation Process

The Caloosahatchee River (C-43) West Basin Storage Reservoir project has developed evaluation criteria and performance measures consistent with planning objectives that were used during the formulation process. More specifically, performance measures were utilized during for plan formulation, and a full suite of evaluation criteria were utilized for comparison of alternative plans and selection of the recommended plan. Benefit and impact analyses conducted for this study will be accomplished at both the local and system-wide scale consistent with the CERP draft guidance memorandum on Plan Formulation and Evaluations Procedures.

F.1.3 System-Wide Perspective

The Caloosahatchee River (C-43) West Basin Storage Reservoir project is related to the balance of CERP through the Caloosahatchee River (C-43 Canal), which connects the Caloosahatchee Estuary to Lake Okeechobee and its watershed. From a system-wide perspective, freshwater releases made through the Caloosahatchee River (C-43 Canal) to the Caloosahatchee estuary are based on management of Lake Okeechobee for the benefit of the entire Central and Southern Florida Project system, which includes providing flood protection and water supply for natural, urban and agricultural areas. These management decisions have not traditionally been made on the basis of maintaining a healthy

ecosystem within the Caloosahatchee estuary system as their primary objective. However, they have resulted in significant adverse effects, such as oyster die-off and seagrass bed deterioration, in the receiving water bodies when discharges are made for extended periods of time at high rates of flow. The Restudy analysis recognized this effect and sought means to reduce the high flow events from Lake Okeechobee through the Caloosahatchee River (C-43 Canal). CERP includes various storage projects around the lake to reduce the need to make such damaging discharges into the Caloosahatchee River (C-43 Canal). The combination of storage options reduces the volume stored in Lake Okeechobee that contributes to higher lake levels, therefore reducing the potential future discharge to the estuary.

F.1.4 Local Perspective

The primary C&SF canal (C-43) along with the secondary and agricultural canal systems which drain into the primary canal (C-43) provide the conveyance for freshwater and nutrients to the receiving water bodies in the Caloosahatchee estuary as well as promote drainage of historic watershed wetlands. Therefore, solutions that address these specific problems will be formulated and evaluated within the Caloosahatchee River (C-43) Basin.

F.1.5 Development of Alternative Plans

The following sections describe the methodology used to develop the Caloosahatchee River (C-43) West Basin Storage Reservoir project alternative plans; locate appropriate sites for the various components; and describe the details of each alternative developed.

The CERP identified a conceptual project that served as a starting point of 160,000 acre-feet of above ground storage for environmental restoration for the Caloosahatchee River and estuary. This storage amount was established through various previously completed modeling techniques. Under the CERP analysis of the sub-region, an acceptable salinity range for the estuarine ecosystem was established that translated to mean monthly freshwater inflows of 300 cfs to 2800 cfs at S-79. This included the need for low flow augmentation and minimizing high flow discharge events to improve estuarine water quality and to protect and restore estuarine habitat and biota. This flow target at S-79 helped produce modeling results indicating the most efficient size for determining the storage capacity of reservoirs to capture local basin and Lake Okeechobee inflows.

F.1.6 Formulation of Alternative Plans

Alternative plans were formulated to identify specific ways to achieve planning objectives within constraints, so as to solve the problems and realize the

opportunities that were identified in the first steps of the planning process. An alternative plan consists of a system of structural and /or nonstructural measures, strategies, or programs formulated to meet, fully or partially, the identified study planning objectives subject to the planning constraints. A management measure is a feature or an activity that can be implemented at a specific geographic site to address one or more planning objectives. Management measures are the building blocks of alternative plans and are categorized as structural and nonstructural. An alternative plan is a set of one or more management measures functioning together to address one or more objectives.

F.1.7 Components/Management Measures Considered by Alternative Development Sub-team

As described in the above section, the plan formulation process begins with a group of ideas that are developed and refined by the team to address specific planning goals and objectives of the project. These ideas become the building blocks of the components that will eventually be combined to form the different alternative plans. The following section provides a description of each component type considered by the team for use in further plan formulation activities, how it could meet planning objectives, and reasons for its retention or exclusion from the plan formulation process. The components described are reservoirs, stormwater treatment areas, natural storage and water quality treatment areas, oxbow restoration, operations of reservoirs, and Best Management Practices (BMPs).

F.1.7.1 Reservoir Storage Areas

The CERP Restudy project scope included a description of the Caloosahatchee River (C-43) West Basin Storage Reservoir project as follows: "This feature includes above-ground reservoir(s) with a total storage capacity of approximately 160,000 acre-feet located in the Caloosahatchee River (C-43) Basin in Hendry, Glades, or Lee Counties." As previously stated, reservoir storage became the starting point of the Caloosahatchee River (C-43) West Basin Storage Reservoir study. Draft Programmatic Regulations Guidance Memoranda # 1 and #2 instruct PDT's to optimize the component identified in the Comprehensive Plan, unless conditions have changed, planning objectives have changed, or the component no longer meets the purposes outlined in the Restudy. The PDT's focus was therefore to formulate using surface storage reservoirs to the extent practicable to meet planning objectives, but to consider other management measures as needed if reservoirs did not meet the full suite of planning objectives in a cost effective manner.

Above ground reservoirs were considered and evaluated as a means for capturing, confining and storing excess stormwater runoff generated by the drainage basin. These reservoirs will essentially be large water storage areas

surrounded by perimeter levees constructed from excavating soil from the interior of the reservoir adjacent to the levee locations. Deeper reservoirs will require extended side slopes to provide structural stability and seepage control. Excess soil excavated as a result of the increase in depth will be compacted into thin layers to form the levees and extended side slopes. The maximum sustained depth of water in the reservoir is usually less than 15 feet above the existing ground surface, with the maximum levee height (top of levee) being above that of the operating pool of stored water. This is to protect the levee against wind or rain driven overtopping.

Water will be pumped from adjacent canals into the reservoirs when the flow rates in the canals begin to contribute excess deliveries of water to the Caloosahatchee River. To improve water quality, water stored in the reservoirs may be conveyed through a stormwater treatment cell before it is released to the Caloosahatchee River. Water may also be released back to the adjacent source canals when required for maintenance purposes or when it is advantageous to supplement water supply. Water surface levels within the reservoirs will vary over a large range. In general, it is expected that water levels will gradually increase during the rainy season, approaching maximum levels near the beginning of the dry season. As the dry season's end approaches, water levels in the reservoir may drop to near the existing ground surface (as a result of evapotranspiration and water withdrawals).

The reservoir will not be specifically designed to provide in situ habitat or be considered a habitat due to the expected seasonal fluctuations in water levels. However it is probable that fish colonization will occur in the reservoirs. To allow for the survival of fish populations during times when water levels are low, it may prove practical to excavate deeper regions within reservoirs that can act as fish refugia. Any habitat function derived from the reservoirs is incidental. Reservoirs will be sited on already cultivated agricultural lands.

F.1.7.2 Restoration of Natural Storage Areas

Reservoir storage was identified in the Restudy as the key component for the restoration of the Caloosahatchee River and estuary. The Restudy did not explore the use of natural areas as an alternative to reservoir storage. However, some natural areas were considered by the PDT as management measures that could contribute to the goal of reducing the amount of stormwater reaching the canal systems, river, and estuary through the natural retention of stormwater runoff.

The Alternative Development Sub-team looked at lands where the retention of stormwater was both practical and possible. These lands were then identified and considered as possible sites for restoration because of their ability in providing additional water storage within the Caloosahatchee River (C-43)

Basin. Those sites that did not contribute to addressing problems in the Caloosahatchee estuary (i.e., stand alone or hydrologically separate sites) but were ideal candidates for restoration, were to be considered through the planning process for the Southwest Florida Feasibility Study (SWFFS). Information on other restoration sites within the Caloosahatchee River (C-43) Basin will be transferred to the SWFFS project delivery team for evaluation and potential implementation. Specifically, Lake Hicpochee, Telegraph Swamp, Lake Flirt and Graham Marsh were all evaluated. From this original list, it was determined that Graham Marsh fell outside of the West Basin Storage Reservoir study boundary, so that site was dropped. Telegraph Swamp was also dropped from consideration, due to threatened and endangered species issues, which could be adversely effected by potential restoration efforts. Lake Hicpochee and Lake Flirt are still being considered as alternative sites for natural area restoration in this study.

Finally, incorporation of the use of natural areas as a storage option introduces an opportunity to re-hydrate and restore historic wetland and lacustrine areas and upland areas that have been altered due to urban and agricultural encroachments. This would address the "enhance ecological values" objective of the potential alternative plan by, in addition to improving habitat quality in the estuary through storage of basin runoff, also increasing the spatial extent of watershed wetlands and lake habitats through restoration.

F.1.7.3 Stormwater Treatment Areas

Stormwater Treatment Area or STAs are designed and built to capture and treat stormwater runoff from the drainage basin, then release it back to the receiving water body. Their primary function is to reduce nutrient loadings and remove suspended sediments dissolved in the water column. STAs are usually shallow water bodies created by constructing small levees six to seven feet in height above the surrounding ground surface. The depth of water flowing through the STAs will usually range from one to three feet in depth. The general design of STAs is to divide it into a number of cells in which the water depth and rate of flow can be controlled. Water enters the STA through a distribution canal in a controlled manner to induce shallow and slow flow over a surface that is covered with dense vegetation. The vegetated cells are designed to uptake nutrients and remove suspended sediments from the water column. Discharge from an STA will usually be directed toward the primary receiving water body such as the Caloosahatchee River.

More than 75% of the nitrogen and phosphorus load sent to the Caloosahatchee Estuary comes from sources upstream of S-79. Within the estuary, the impact of the S-79 pollutant load is evident from tidal river water body segments downstream of S-79 that are impaired for chlorophyll-a and/or biological integrity. FDEP examined the potential nutrient impairment problems in the

estuary. Their study used regression equations to describe the relationships between chlorophyll-a concentration and nitrogen loading, and between chlorophyll-a concentration and phosphorus loading. Their findings indicated that due to the naturally occurring high levels of phosphorus in the watershed, nitrogen, rather than phosphorus, was the limiting nutrient, and high nitrogen loads were responsible for the elevated chlorophyll-a concentrations in the Caloosahatchee estuary. Vegetated STAs are designed to remove at least 80% of the incoming phosphorus load in water captured by the reservoirs. STAs recently constructed in South Florida have been designed to optimize phosphorus removal, but are not as effective at the removal of nitrogen. The long-term efficacy of total nitrogen removal in South Florida STAs awaits further empirical evaluation. Because STA's are more effective at removing phosphorus than nitrogen and because the excess nutrient problem in the Caloosahatchee estuary is related to nitrogen, the need for STA's as part of the project was questioned by the PDT. The PDT decided to consider STA's not as stand-alone management measures, but as potential treatment cells within storage reservoirs. Furthermore, the design and operation of reservoirs themselves would be examined as a promising means of reducing nitrogen loads to the estuary.

F.1.7.4 Aquifer Storage and Recovery

The CERP Restudy project scope included a description of the 44 Aquifer Storage and Recovery (ASRs) wells within the Caloosahatchee Basin, each having an injection or withdrawal capacity of five million gallons per day with chlorination for pre-treatment and aeration for post-treatment. The ASR wells will be located at the reservoirs locations and are to be either adjacent to or connected to the surface reservoir. When the reservoirs are filled to capacity, water is to be pumped into the ASR well for storage (at a specific capacity). When water levels are low in the reservoir, water is then pumped from the ASR well back into the reservoir. It was assumed for the Restudy that the recovery efficiency would be 70% of water injected.

The ASR wells are proposed in order to maximize the benefits associated with the Caloosahatchee Basin storage reservoirs. For example, due to high ET rates in the study area, it would be difficult to store enough water in surface reservoirs to provide minimum dry season flows to the estuary over more than one dry season. Since water storage in the aquifer is protected from the high ET rates, ASR's are an attractive management measure for storing water to meet minimum downstream flows over multiple years and during drought events. However, a pilot project for ASR wells is necessary to identify the most suitable sites of the ASR wells in the vicinity of the reservoirs and to determine the optimum configuration of those wells. The pilot project will provide information regarding the characteristics of the aquifer system within the Caloosahatchee River Basin as well as determine the hydrogeological and geotechnical

characteristics of the upper Floridan Aquifer. The pilot project will also determine the specific water quality characteristics of water to be injected, the specific water quality characteristics and the amount of water recovered from the aquifer, and the water quality characteristics of water within the receiving aquifer. The level and extent of treatment and the number of ASRs wells needed may be modified based upon the finding s from the ASR pilot project.

While the Caloosahatchee River Basin ASR pilot project is under way, the findings are not yet available for use. Recognizing that more information regarding the feasibility and performance of ASR's was necessary from the pilot projects before ASR's could be designed and implemented in the Caloosahatchee Basin, in 2000 the Master Program Management Plan (MPMP) for CERP separated the Caloosahatchee River (C-43) Basin Storage Reservoir and Aquifer Storage and Recovery Projects as described in the Restudy into Part 1 (Caloosahatchee River (C-43) Basin Storage Reservoir Project) and Part 2 (Caloosahatchee River (C-43) Basin ASR Project). The projects were separated to accommodate the inclusion of the findings of the Caloosahatchee ASR Pilot Project without delaying the implementation of the reservoir. Therefore this PIR focuses only on the storage reservoir portion, while a subsequent PIR focusing on implementation of the ASR project will be undertaken between 2015-2020, according to the current Master Implementation Sequencing Plan (MISP).

F.1.7.5 Backpumping with Stormwater Treatment

Backpumping with Stormwater Treatment was identified in the CERP Restudy project scope as a feature to capture excess Caloosahatchee River (C-43) Basin runoff, which would then be used to augment the regional system water supply.

This feature includes pump stations and a stormwater treatment area with a total capacity of approximately 20,000 acre-feet located in the Caloosahatchee River (C-43) Basin in Glades and Hendry Counties. The initial design of the stormwater treatment area assumed 5000 acres with the water level fluctuating up to 4 feet above grade. The final size, depth and configuration of this facility will be determined through more detailed planning and design. This feature operates after the estuary and agricultural/urban demands have been met in the basin and when water levels in the storage reservoir exceed 6.5 feet above grade. Lake Okeechobee must also be considered to have available storage. When these conditions are met, a series of pump stations will backpump excess water from the reservoir and the Caloosahatchee River (C-43) Basin to Lake Okeechobee after treatment through a stormwater treatment area.

While this feature was included in the Restudy, subsequent analyses from the 2000 Caloosahatchee Water Management Plan (SFWMD 2000) determined that the Caloosahatchee River (C-43) Basin, even with the Restudy's 160,000 acre-feet of additional storage, has insufficient water supply to meet all future

environmental, agricultural, and urban demands. Backpumping water from the Caloosahatchee River (C-43) Basin to Lake Okeechobee therefore does not make sense. The study area has a water shortage, not a water surplus to be exported to other basins.

F.1.7.6 Oxbow Restoration

As a result of natural changes to the course of the Caloosahatchee River over the years, a number of oxbows have formed along the banks of the Caloosahatchee River. An oxbow is a crescent shape lake that forms when the course of the river changes at a bend in the river and over a period of time, sedimentation builds up and closes the bend off from the river. There are approximately 35 of these oxbows located along the Caloosahatchee River from the S-79 structure to the City of LaBelle. Some of these oxbows have connections to the river with some water flowing through them. Water quality is poor in all of the oxbows; all have dissolved oxygen problems due to decaying vegetation and sediment buildup. Oxbows offer little storage value, but could provide habitat within the river. Currently, restoration of the Caloosahatchee River Oxbows is being addressed under the Army Corps of Engineers' Section 206 Continuing Authorities program for small ecosystem restoration projects.

F.1.7.7 Operation of Reservoirs

Nutrient loading and suspended sedimentation have been identified as secondary issues affecting the health of the Caloosahatchee River and Estuary. The Caloosahatchee River (C-43) West Basin Storage Reservoir project alternatives will focus on the capture and release of basin runoff through the use of reservoirs that will alter the timing and quantity of nutrients delivered to the estuary through S-79 Structure. This will have an effect on other water quality parameters such as dissolved oxygen and Chlorophyll-a. A nutrient loading analysis of reservoir operations conducted by FDEP determined that with an available storage of 228,000 acre-feet of storage, the project would capture approximately 500 tons/year of TN. Depending upon the design and operation of the reservoir system, settling and some biological uptake will remove between 20% and 30% of the TN load captured by the reservoirs. With ASR, the total load of nitrogen removed from the system would increase by 50% to approximately 150 to 200 tons/year. This is approximately 6% to 9% of the present annual nitrogen load (roughly 3,000 tons per year) to the estuary.

F.1.7.8 Best Management Practices (BMPs)

The Florida Watershed Restoration Act provided for FDACS to develop water quality BMPs for agricultural non-point sources. The FDACS BMP program adopts BMPs developed by growers through workshops as the most effective and practicable on-location means to improve water quality from agricultural

discharges. The focus of the BMP effort is to reduce the nutrient and pollutant content of runoff from all major agricultural commodity groups (i.e., citrus, sugarcane, cattle, and row crops). The status and likely effects of agricultural BMP implementation will be taken into account in the assessment of water quality conditions. Participation is self-implementing in that a grower chooses to participate. Benefits of participation include a mechanism for "presumption of compliance" with state water quality standards and a waiver of liability.

All agricultural sectors within the Caloosahatchee Basin have joined to develop a Caloosahatchee BMP Manual for adoption by FDACS for their BMP Program in 2005. The program also includes cost-share funds for growers to implement BMPs as part of the Florida Forever Act Amendments. FDEP acts as a partner in the monitoring of the FDACS BMP program as part of the TMDL Program. A watershed is considered successful once 80 percent of the agricultural acres in the watershed are enrolled in the FDACS BMP program. For the purpose of this study, the study team will develop conservative estimates for future BMPs based on input from USDA and other local governments responsible for monitoring the program.

SFWMD will expand its Urban BMP Program into the urban areas within the next year. The concept behind the BMP program is to identify and establish effective measures to prevent polluted stormwater from entering the receiving water bodies. The program includes education for homeowners and landscape professionals.

Many of the local governments in the Caloosahatchee Basin, including Lee County have implemented and funded stormwater management programs. Cities such as Ft. Myers have similar programs. These cities and counties have similar goals that strive to ultimately improve urban drainage problems, while at the same time providing a means to clean surface water runoff from entering in the Caloosahatchee River/estuary.

The BMP programs described above are considered as part of the future without project conditions for the Caloosahatchee River (C-43) West Basin Storage Reservoir project and will not be considered as management measures in the formulation of Caloosahatchee River (C-43) West Basin Storage Reservoir project's alternative plans.

F.2 PROJECT SITING ANALYSIS

F.2.1 Development and Application of Project Siting Criteria

When the Alternative Development Group started the process of evaluating potential site locations in the Caloosahatchee River (C-43) Basin, all suggestions were recognized and included in the site screening analysis. The first step of the

process was to determine potential site locations for project components. Potential sites locations had been identified earlier during the development of the CERP Restudy and in the Caloosahatchee Water Management Plan, which became the starting point for the Alternative Development Group. Additional potential sites locations were also identified early on in PDT meetings, with input from the public and stakeholders providing additional information on potential site locations.

In sorting through the long list of potential site locations, the Alternative Development Group quickly realized the need to develop a process that could rate parcels of land against a variety of criteria and screen for suitability for use in this project. In October 2002, an Alternative Development/Site Screening Sub-Team began development of a screening criteria and application process for use in conducting a preliminary site screening of these potential sites for the project. The purpose of the Site Screening process is to screen a site for its potential use in the development of alternative plan management measures to meet the goals of the project. If the list of potential sites included locations that are inappropriate for use as management measures, the screening process is an early and efficient method to identify and eliminate these inappropriate sites. Some of the factors that went into developing the criteria were:

- Land use and land cover
- Proximity to primary canal or existing canal conveyance networks
- Soils suitability and recharge potential
- Potential contributions to the watershed
- Potential storage capacity
- Potential restoration value
- Hydrologic network distance from the estuary
- Land elevations

Once screened, the more suitable land parcels will be further evaluated for those land parcels which best fits into the overall plan for the project. This will save time and resources by avoiding detailed planning and early engineering activities on sites that are incompatible with the project purpose. The following sections contain a description of the project siting process evaluation criteria, and conclusions derived during the project component siting effort.

F.2.2 List of Potential Sites

Information on potential sites locations were compiled and organized for the project. This information included the names of the land parcel(s), description (including current land use and conditions of the site that were compatible with the project), land parcel(s) size, county, sub-basin, and the rationale for choosing the site. From this information, a site/basin map was then developed that clearly identifies each site. (***Table F-1***and ***Figure F-1***).

The original list of potential site locations for this project included several natural areas that could potentially be restored as well as provide additional water storage within the Caloosahatchee River (C-43) drainage basin. The intent was to identify natural areas that specifically contributed to or had an effect on the health of the estuary through hydrologic connections.

The identified land parcel(s) were evaluated for their potential suitability for use in the development of alternative plan management measures. Potential sites were scored for two sets of objectives:

1. Meeting the storage requirements of the project
2. Potential incorporation into a restoration plan.

The siting criteria were divided into two categories:

1. Gate Criteria
2. General Criteria

The Gate Criteria are the first look at the suitability of a potential land parcel for the project. Once a potential land parcel(s) is screened and has passed the Gate Criteria, a second screening application is applied to the site. The General Criteria are applied to the more suitable land parcel(s) for further evaluation to determine those land parcels which best fits into the overall plan for the project. A more detail explanation of the Gate and General Criteria is provided in the subsequent paragraphs below. All of the Screening Criteria included a name and number assignment, a screening level and category designation. The criterion sheets included a criteria description, Storage and Restoration Scoring Rationale, Methodology (identifying the tools to be used to score the sites), and any applicable comments that included the author's name and date the criteria was accepted by the sub-team (Appendix F).

TABLE F-1: LIST OF SITING INFORMATION FOR PROJECT LOCATIONS

Site Id. Number	Site Name	General Description	Size	County	Sub-Basin	Rational
P1	Berry Grove	The Berry Groves parcel has been used as a citrus grove since the early 1960' s. Its' location in the basin is at a point along the Caloosahatchee River (Caloosahatchee Riv er (C-43 Canal)) that approx. 83% of basin runoff could be captured. In addition, its' proximity to the rive r as well as its' current in frastructure (Townsend Canal connection to C-43, Header Canal for internal distribution, Roberts Canal for inflows from southeast), were strong indicators in the determination to ac quire th e property. Other considerations included th e size as well as the number of owners.	8640 acres	Hendry	WCB	Site was analyzed during the Restudy and the CWMP and subsequently acquired for use in the Caloosahatchee River (C-43) W est Basin Storage Reservoir Project.

2637

Site Id. Number	Site Name	General Description	Size	County	Sub-Basin	Rational
P1+A	Berry Gro ve + Griffin	The Berry Groves is generally described in P1 above. The additional parcel, Griffin, has been used as a citrus grove as well since the early 1960' s. In c onjunction with Berry Groves its' location, proximity to water source and current infrastructure is conducive to storage. The addition of the Griffin parcel would not significantly increas e th e tim e and resources required for the analysis and potentially the design and construction of a reservoir on this combined site. Other considerations in cluded the s ize as well as the number of owners.	9594 acres	Hendry	WCB	Site was analyzed during the Restudy and the CWMP and has recently been acquired for use in the Caloosahatch ee River (C-43) W est Basin Storage Reservoir Project. Site adds 954 acres.

2638

Site Id. Number	Site Name	General Description	Size	County	Sub-Basin	Rational
P1+A+B	Berry Gro ve + Griffin + Metlife	The Berry Groves and Griffin parcels are generally described in P1 and P1+A above. The additional parcel, Metlife, has been used as a citrus grove as well sinee the early 1960' s. In c onjunction with Berry Groves and Griffin, its' location, proximity to water source and current infrastructure is conducive to storage. T he addition of the Metlife parcel would improve the regularity of the site (minimize the num ber of parcel corners and obtuse an gle sizes) while not s ignificantly increas ing the time and resources required for the ana lysis and pote ntially th e design and construction of a reservoir o n this com bined site. Other considerations included the size as we ll as the num ber of owners.	11,954 acres	Hendry	WCB	Site was analyzed during the Restudy and the CWMP and has recently been acquired for use in the Caloosahatchee River (C-43) Basin Storage R eservoir Project. Site adds 2360 acres.
A	Griffin	Griffin, has been used as a citrus grove as well since the early 1960's. Its' location, proxim ity to water so urce and curren t infrastructure is conducive to storage.	954 acres	Hendry	WCB	

2639

Site Id. Number	Site Name	General Description	Size	County	Sub-Basin	Rational
B	Metlife	Metlife, has been used as a citrus grove as well since the early 1960's. Its' location, proximity to water source and current infrastructure is conducive to storage.	2360 acres	Hendry	WCB	
P2	Lake Hicpochee	Lake Hicpochee was historically a lake and wetland system that had no sustained connection to Lake Okeechobee. Lake Hicpochee was bisected when the Caloosahatchee River was channelized and has been over drained and greatly impacted by invasive plant species since then. The Florida Fish and Wildlife Conservation Commission has developed restoration plans for Lake Hicpochee in the past, but due to funding they have not been implemented. Although, the two halves of Lake Hicpochee could never be re-connected due to navigational requirements for the C-43, the lake could be surrounded by low leves and the water level could be restored.	4600 acres	Glades	ECB	Site was suggested by Graham Story and supported by multiple environmental agencies for low-level storage and restoration. The State of Florida (TIITF) owns the majority of the historical footprint of Lake Hicpochee.

2640

Site Id. Number	Site Name	General Description	Size	County	Sub-Basin	Rational
P2+C	Lake Hicpochee + River Groves	See Lake Hicpochee in P2 above. River Grov es is curren tly p lanted in citrus an d has a co nnection at the northe astern corn er to Lake Hicpochee. It is s ituated in Glade s County, and is adjacent to the C-43.	7,160 acres	Glades	ECB	Current landowners presented the site as an option for deeper storage to be used in the restoration of Lake Hicpochee and the Caloosahatchee. Site adds 2560 acres.
P2+D	Lakc Hicpochee + Duda Farms	See Lake Hicpochee in P2 above. Duda is curren tly planted in sugarcane and has a connection at the on the east sid e to the C-19 Canal which connects to Lake Hicpochee, which flows into the C-43. It is situated in Glades County. Duda = 2880 acres, Peeples = 2080 acres and Bronson = 960 acres	10,520 acres	Glades	ECB	Current landowners presented the site as an option for deeper storage to be used in the restoration of Lake Hicpochee and the Caloosahatchee. Sites add 5920 acres.
P2+C+D	Lake Hicpoehee + River Gro ves + Duda Farms	See P2, P2+C and P2+D above.	17,680 acres	Glades	ECB	See the comments from P2, P2+C and P2+D above.
C	River Groves	River Groves is curren tly p lanted in citrus an d has a co nnection at the northe astern corn er to Lake Hicpochee. It is s ituated in Glade s County, and is adjacent to the C-43.	2,560 acres	Glades	ECB	

2641

Site Id. Number	Site Name	General Description	Size	County	Sub-Basin	Rational
D	Duda Farms	Duda is currently planted in sugarcane and has a connection at the on the east side to the C-19 Canal which connects to Lake Hicpochee, which flows into the C-43. It is situated in Glades County. Duda = 2880 acres	2,880 acres	Glades	ECB	
P2E		The site is located to the east of Lake Hicpochee between Duda and River Groves. See P2, P2+C and P2+D above.	2,830 acres	Glades	ECB	See the comments from P2, P2+C and P2+D above.
P3	Central Distributed Reservoir (Baron WCD Canal No. 1)	Two different approaches for the distributed reservoir concept have been presented to the Caloosahatchee River (C-43) Basin Storage Reservoir Team, 1, utilizes an existing canal, which is controlled at the downstream end, widened and used as storage, 2, utilizes an existing agricultural retention/irrigation storage area to reduce agricultural reliance on the C-43. This site falls under the first category. It is located near the river along a major Drainage/Irrigation Canal that has the potential for modifications to would provide storage.	1,650 acres	Glades	WCB	This approach was suggested by Bruce Boler of EPA and the area was identified by looking at the existing drainage/irrigation infrastructure for potential application.

2642

Site Id. Number	Site Name	General Description	Size	County	Sub-Basin	Rational
P3E	Eastern Distributed Reservoir (Flagpole Canal)	Two differe nt approaches for the distributed reservoir concept have been presented to the Caloosahatchee River (C-43) Basin Storage Reservoir Team, 1, utilizes an existin g canal, which is controlled at the downstream end, widened and used as storage, 2, utilizes an existing agricu ltural retention/irrigation s torage area to reduce ag ricultural re liance on the C-43. This site falls under the firs t category, as well, and is located in the cas tern basin alon g a m ajor Drainage/Irrigation Canal that has the potential for m odifications to would provide storage.	5,120 acres	Hendry	ECB	This approach was suggested by Bruce Boler of EPA and the area was identified by looking at the existing drainage/irrigation infrastructure f or potential application.

2643

Site Id. Number	Site Name	General Description	Size	County	Sub-Basin	Rational
PWC-4	Western Dispersed Reservoir Four Corners	Two distinct approaches for the dispersed reservoir concept have been presented in the Caloosahatchee River (C-43) Basin Storage Reservoir Feasibility Study. 1. utilizes an existing canal which is controlled at the downstream end, widened and used as storage. 2. utilizes an existing agricultural retention/detention storage area to reduce agricultural acreage on the C-43. This site falls under the first category as well and is located in the western basin along the Prairie Drainage/Irrigation Canal that has the potential for on site retention as it would provide storage. In addition, the Four Corners intersection of Charlotte, Glades, Hendry, and Lee Counties had been identified as an area in need of an upland water management system to	23,040 acres	Glades	WCB	This suggestion came from the problems and opportunities development of this project as well as the Southwest Florida Feasibility Study.

Site Id. Number	Site Name	General Description	Size	County	Sub-Basin	Rational
F5	Campaign Security Road Site	This site was identified by Jacobs as a potential for providing flow attenuation for the Cumberland Reservoir. It is located on the Chattahoochee River, just downstream of the Cobb County Water Treatment Plant.	2,000	Cobb	Upper Chattahoochee	This site was not carried forward because it is a duplicate of site F6.
F6	Lower Powers Ferry Road Site	This site was identified by Jacobs as a potential for providing flow attenuation for the Cumberland Reservoir. It is located on the Chattahoochee River, just downstream of the Cobb County Water Treatment Plant.	2,000	Cobb	Upper Chattahoochee	This site was not carried forward because it is a duplicate of site F5.
F7	Lower Roswell Road Site	This site was identified by Jacobs as a potential for providing flow attenuation for the Cumberland Reservoir. It is located on the Chattahoochee River, just downstream of the Cobb County Water Treatment Plant.	2,000	Cobb	Upper Chattahoochee	This site was not carried forward because it is a duplicate of site F5.
F8	Lower Roswell Road Site	This site was identified by Jacobs as a potential for providing flow attenuation for the Cumberland Reservoir. It is located on the Chattahoochee River, just downstream of the Cobb County Water Treatment Plant.	2,000	Cobb	Upper Chattahoochee	This site was not carried forward because it is a duplicate of site F5.
F9	Lower Roswell Road Site	This site was identified by Jacobs as a potential for providing flow attenuation for the Cumberland Reservoir. It is located on the Chattahoochee River, just downstream of the Cobb County Water Treatment Plant.	2,000	Cobb	Upper Chattahoochee	This site was not carried forward because it is a duplicate of site F5.
F10	Lower Roswell Road Site	This site was identified by Jacobs as a potential for providing flow attenuation for the Cumberland Reservoir. It is located on the Chattahoochee River, just downstream of the Cobb County Water Treatment Plant.	2,000	Cobb	Upper Chattahoochee	This site was not carried forward because it is a duplicate of site F5.

Site Id. Number	Site Name	General Description	Size	County	Sub-Basin	Rational
P7	Graham Marsh	Graham Marsh is located just south of the northeastern basin boundary. Graham Marsh is an undisturbed significant wetland. Currently used as an paved pasture/prime area. May fall outside of the Caloosahatchee River (C-43) Watershed as specified from Graham Marsh provides water to system. Is also a 4 cells. Has minimal infrastructure and great distance for use in the Caloosahatchee River (C-43)	24,320 acres	Hendry	N/A	Location contributed by Hugh English as having potential for control storage to managed by current use. Assessed by Bob Hercamp as well.
P8	Alico Devil's Garden	Description: Located south of the Alico Devil's Garden is for used outside the Caloosahatchee River (C-43) Watershed along CR833 in eastern Hendry. Currently used as improved pasture/current area.	6,000 acres	Hendry	N/A	Location contributed by Hugh English
P9	Montura Ranch Estates Reservoir	Currently used as reservoir retention for the Montura Ranch Estates development in eastern Hendry County. Basin improves subareas that lie east of the hills outside the Caloosahatchee River (C-43) Watershed.	2,560 acres	Hendry	N/A	Location contributed by "Buck" Abergonis, Hendry County Engineer

Site Id. Number	Site Name	General Description	Size	County	Sub-Basin	Rational
P104	SR29 Infrastructure Changes	Infrastructure changes along SR29 as part of alleviating flooding south of Labelle, while enabling the diversion of flows to a reservoir site.	n/a	Hendry	WCD	Location contributed by "Rock" Aboagnale, Hendry County Engineer
P105	Felda Infrastructure Changes	Infrastructure changes in north of Felda as part of alleviating flooding in Felda, while enabling the diversion of flows to a reservoir site.	n/a	Hendry	WCD	Location contributed by "Rock" Aboagnale, Hendry County Engineer
P106	Railroad Grade Infrastructure Changes	Infrastructure changes: Canal 1 at Labelle to be used in alleviating flooding south and east of Labelle, while enabling the diversion of flows to the Caloosahatchee River (C-43) for capture in a reservoir.	n/a	Hendry	WCD	Location contributed by "Rock" Aboagnale, Hendry County Engineer
P107	Hendry or Dog Canal Infrastructure Changes	Infrastructure changes along the Townsend Dog Canal in Hendry County to be used in alleviating flooding in Lehigh Acres, while enabling the diversion of flows to a reservoir site.	n/a	Lee	WCD	Location contributed by "Rock" Aboagnale, Hendry County Engineer, Lee County Water Control District, Craig Benscoter, local stakeholder
P108	S-79 / G-Lock	Construction of a new lock at the western end of the Franklin Lake Flow-through. The water by-passed in the Caloosahatchee River (C-43) could be cleaned as it makes its way from S-78 to S-79. [7]	2,500 acres	Glades	WCD	Location developed during the CWMP, and suggested by Graham Stacy

Site Id. Number	Site Name	General Description	Size	County	Sub-Basin	Rational
P11	Osteen Lykes Brothers	This parcel is located directly north of Osteen. The site currently includes planted pine and unimproved pasture as well as a natural system with flows to the C-32. In addition, site contains an existing sand track pit.	11,200 acres	Glades	WCD 55-01	Location is identified as the Collins or Lykes Brothers tract on sort at a Project Delivery Team Meeting as a site for consideration as a public private partnership.
P12	Nocatee Slough	Nocatee Slough is located south of Fisheating Creek and the Herbert Hoover Dike and adjacent to the SFWMD owned Nocatee or Slough Recreation Area. The site contains the remnants of the slough and is used for improved pasture.	14,200 acres	Glades	FCD	Location is identified as the Collins or Lykes Brothers tract on sort at a Project Delivery Team Meeting as a site for consideration as a public private partnership.

Site Id. Number	Site Name	General Description	Size	County	Sub-Basin	Rational
P13	South-Central	This site is located south of the C-43, east of LaBelle, and is bounded by two major drainage canals on the east and west. The site may be divided into two sections due to the number of landowners located on the northern half. The existing land use includes citrus and improved pasture.	9,700 acres	Hendry	WCB/ECB	During the completion of the site screening criteria, the Project Delivery Team initiated a basin wide review for any potential additions to the list of sites already under consideration. This site was identified as having potential for storage due to its' size, location in the basin as regards runoff, no known significant existing wetlands, current land use, proximity to source and threatened and endangered species sightings. P13A (north) = 9600 acres, P13B (south) = 15360 acres, P13B1 (south and east of Canal No. 2) = 9700 acres
F	Paul	This site is located immediately east of P1 (Berry Groves) and could contribute to the placement of a significant portion of the required storage in one contiguous reservoir. The existing use includes citrus and although there are several owners, they are all from the same family. Review the discussions in P1, P1+A, P1+B, and P1+A+B above.	5,120 acres	Hendry	WCB	Recently suggested by staff at SFWMD as having potential.

2649

Site Id. Number	Site Name	General Description	Size	County	Sub-Basin	Rational
P14	Berry Grov es + Griffin + Metlif e + Paul	This site is com posed of site P1 (Berry Gro ves), A (Griffin), B (Metlife) an d site F (P aul). The existing use includes citrus.	17,074 acres	Hendry	WCB	Recently suggested by staff at SFWMD as having potential.
P15	Telegraph Swamp East	This site is located to the eas t of Telegraph Swa mp. The existing use includes agricultural.	3,475 acres	Lee	WCB	Site exis ts to the eas t of P5 (which did not pass GO).

Shaded sites were screened from further consideration.

Sub Basins: ECB = East Caloosahatchee Basin
WCB = West Caloosahatchee Basin
TSB = Telegraph Swamp Basin

2650

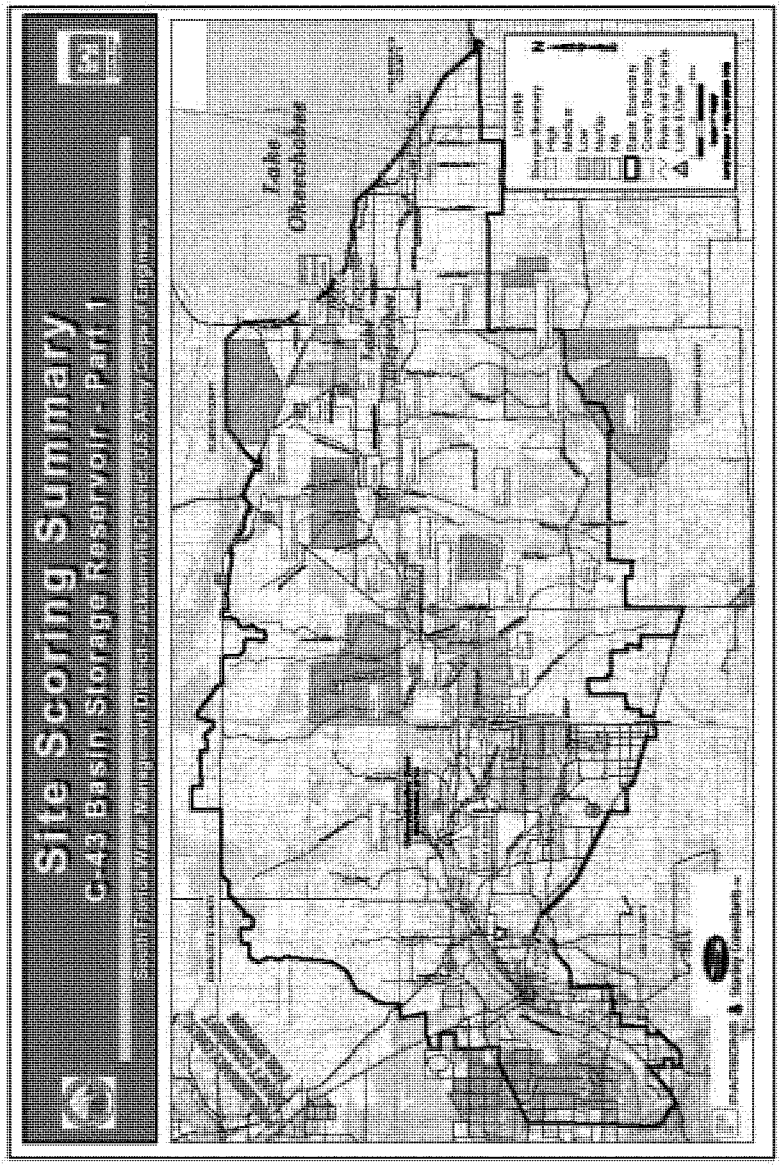

FIGURE F-1: LOCATIONS OF POTENTIAL SITES

F.3 SCREENING

F.3.1 Gate Criteria

As stated in the above paragraph, the Gate Criteria is the first look at the suitability of a potential land parcel for the project. The Gate Criteria consist of six criteria. The first six criteria included:

- Threatened and Endangered Species/Habitat
- Significant Wetlands
- Known Significant Cultural Resources
- Known Superfund Sites
- Safety Impacts
- Basin Location

Rating of the land parcel(s) was based on a simple rating of either Go or No Go. A site that was known to violate one or more of these criteria received a "No Go" rating and would not be considered for further analysis.

F.3.2 General Criteria

Once a site has passed the Gate Criteria, a second further screening application is applied to evaluate the potential suitability of the land parcel. The additional sitting criteria followed six general categories. They are:

- Utilities
- Use and Density Factors
- Regulatory or Legal Factors
- Transportation Impacts
- Land Condition
- Other Considerations (Environmental Justice and Recreation)

From these six general categories, 33 criteria were developed to rate the suitability of the site using a simple rating system of –1, 0, or +1. These sites were then rated for each of the 33 criteria, resulting in a -1, 0, or +1 score being assigned to the site for the specific criteria. These scores would then be tallied, with a total overall score being determined for each site. Each site's total score would give an indication of its' relative strength or weakness for use as a management measure in the development of alternative plans.

F.3.3 Results of Application of Screening Criteria

Approximately twenty land parcels were identified as potential sites for the location of future project components. These twenty sites were screened using both the Gate and General Criteria to evaluate their suitability as potential site locations for future project components (reservoirs, etc.). The Gate Criteria were first applied to the twenty sites, as the first screen to determine which sites

would be suitable for the location of project components. Using the Gate Criteria, potential sites were rated for storage capabilities (able to be best utilized for placement of storage reservoirs) and for restoration potential. The storage rational was based on the fact that the site used as a storage facility, did not have an adverse impact on the Gate Criteria. The restoration rational was base on whether the site implements recovery plan goals or the site either alone or combined with other sites resulted in restoration goals being met (as defined by the project goals and objectives) without having a negative impact on the Gate Criteria. ***Table F-2*** shows those sites that did not pass the Gate Criteria for storage capacity. Next, again using the Gate Criteria, the twenty sites were evaluated for their restoration potential.

Table F-3 shows those sites that did not pass the Gate Criteria for the sites' restoration potential. It should be noted that when some of the sites which passed the Gate Criteria for restoration potential but did not pass the Gate Criteria for storage capacity, were combined with adjacent sites, these sites then did received a passing grade for storage capacity. Therefore, those sites (P2-Lake Hicpochee) then were passed on along with the other passing sites to be screened using the site screening criteria. Although P3-WCD Canal No. 1 did not pass one of the Gate Criteria, further review of the site determined that with some redesign of the storage component, the site was still a viable option and was therefore passed on to be screened further.

TABLE F-2: POTENTIAL SITES BASED ON STORAGE CAPACITY

Gate Criteria GO / NO GO	Potential Sites Based on Storage Capacity								
	P2	P3	P5	P6	P7	P8	P9	P11	P12
T&E Species/ Habitat	No Go	No Go	No Go	No Go	No Go			No Go	No Go
Significant Wetlands	No Go	Go	Go	No Go	No Go			Go	Go
Known Significant Cultural Resources	Go	Go	Go	Go				Go	Go
Known Superfund Sites	Go	Go	Go					Go	Go
Safety Impacts	Go	Go	Go					Go	Go
Basin Location	Go	Go	Go	Go	No Go	No Go	No Go	Go	Go

TABLE F-3: POTENTIAL SITES BASED ON RESTORATION POTENTIAL

Gate Criteria GO / NO GO	Potential Sites Based on Restoration Potential		
	P****	P****	P&P**
T&E Species / Habitat	Go	Go	Go
Significant Wetlands	Go	Go	Go
Known Significant Cultural Resources			
Known Superfund Sites		Go	Go
Safety Impacts		Go	Go
Basin Location	No Go	No Go	No Go

After passing the Gate Criteria, each site or combination of sites were rated using the site screening criteria to further narrow down the selection of potential sites locations. Again these sites were rated for both storage capacity and restoration potential based on the site screening criteria. As stated in the previous section, these sites were given a rating of +1, 0, or –1 depending on how it was scored for each individual screening category. These scores were then added up to determine an overall score for the site based on both storage capacity and restoration potential. Each sites or group of sites individual scores were then added up for both storage capacity and restoration potential. The potential maximum score that a site could receive was a score of 33 points, assuming that a site scored a +1 for each of the 33 individual site screening criteria. Those sites that had a score of +12 or above were selected as locations to place storage components (***Table F-4*** and ***Table F-5***). Additionally, the following sites were rejected for the following reasons even though some of these sites received a favorable rating:

P3W/P4	Land was unavailable
P5	Land was unavailable
P6	Site was located in a known panther corridor
P7	Not located in the Caloosahatchee River (C-43) Basin
P8	Not located in the Caloosahatchee River (C-43) Basin
P9	Not located in the Caloosahatchee River (C-43) Basin
P10A-D	Canal improvements, provided no storage or restoration value
10E	Lake Flirt Lock (cost prohibited)
P11	Land was not available
P12	Significant Cultural Impacts from storage use
F-Paul	Traded for MetLife property on Berry Grove Site

From a list of twenty potential sites, eleven sites were identified as suitable locations for project components (See Appendix F, Siting Criteria).

TABLE F-4: CALOOSAHATCHEE RIVER (C43) WEST BASIN STORAGE RESERVOIR SITE SCREENING SCORES–STORAGE SUMMARY

Site	Score (33 max)	Comment
High Scores (18+)		
P1	20

Each of the parcels shown on ***Figure F-2*** met the requirements of the site screening criteria for selections to various degrees. When the siting criteria were prioritized and weighted (high, medium and low) out of the approximately twenty parcels screened, eleven sites met the requirements of the screening

criteria for storage and restoration. The follow sites will be used for developing preliminary design for reservoirs:

- P1 Berry Grove
- A Griffin Parcel
- B Metlife Parcel
- P2 Lake Hicpochee
- P2E Parcel on west side of Lake Hicpochee
- C River Grove Parcel
- D-Duda Duda Parcel
- D-Peeples Peeples Parcel
- D-Bronson Bronson Parcel
- P3 WCD Canal No. 1
- P3E Flagpole Canal
- P13 South Central Parcel
- P15 Parcel located on southwest corner of Four Corners (Intersection of Lee, Hendry, Charlotte and Glades County)

Further analysis on each of these sites for their use as locations of project component will be conducted when preliminary designs of reservoirs are developed which look at utilize the site to its fullest potential.

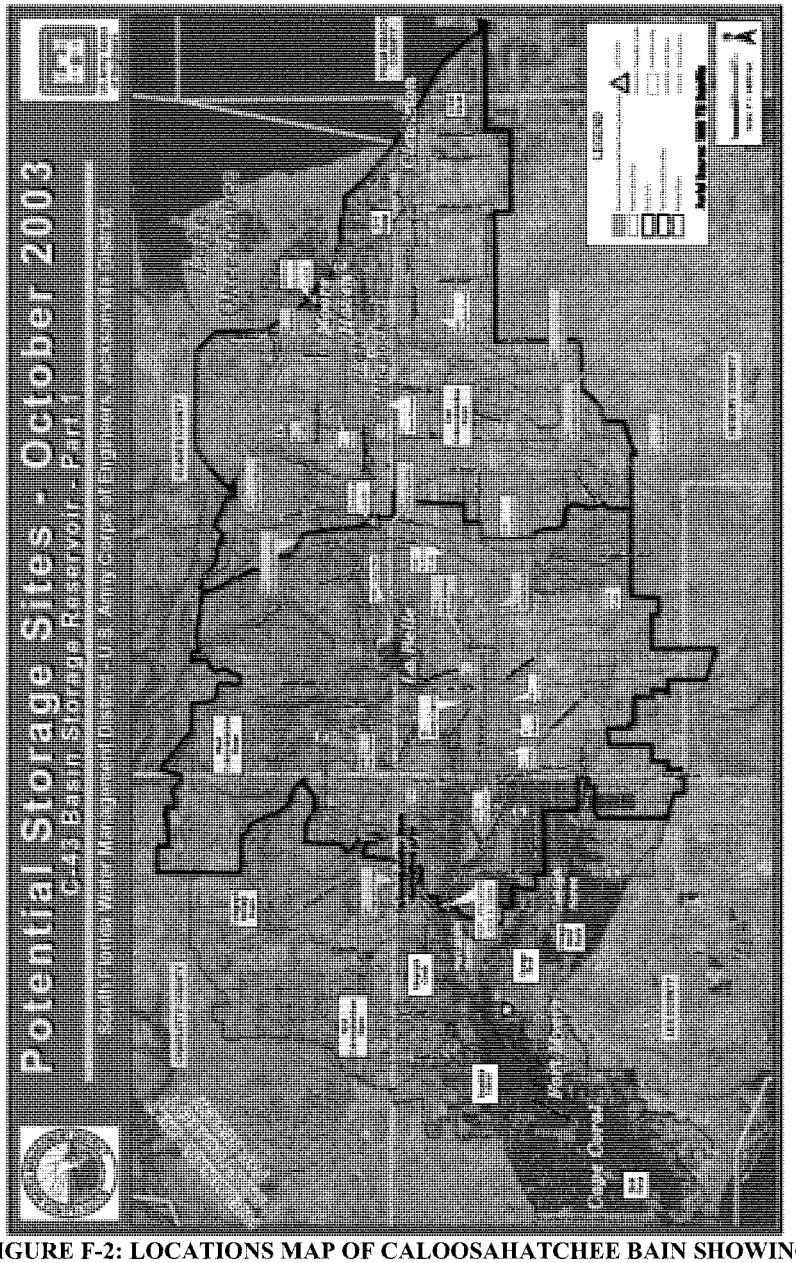

FIGURE F-2: LOCATIONS MAP OF CALOOSAHATCHEE BAIN SHOWING LOCATIONS OF PARCELS THAT HAVE PASSED SITE SCREENING CRITERIA

F.3.4 Level 1 Gate Criteria

Caloosahatchee River (C43) West Basin Storage Reservoir Site Screening Criteria

Criterion Name: THREATENED AND ENDANGERED SPECIES / HABITAT	SSG –1.0.1
Level:	**1 - Gate Criteria**
Category:	**Not Applicable**

Description:
Endangered and Threatened Species – those animal and plant species defined by federal and/or state regulations to be endangered or threatened.

Habitats of Endangered and Threatened Species – defined as areas indicated on geographic information system maps of the USFWS and the FWC that contain habitats of endangered and threatened species including the zones established in the Florida Panther protection and Recovery Plan.

Storage Rationale:	**Restoration Rationale:**
GO: Not likely to adversely effect threatened or endangered species or their habitat. **NO GO :** Likely to adversely effect threatened or endangered species or their habitat	**GO:** Site implements recovery plan goals OR Site (either alone or when combined with other sites) results in the restoration goals being met (as defined in the projects "Goals and Objectives") **NO GO:** Site (either alone or in rational combination with other sites) does not reasonably aid in meeting the project's restoration goals or is contrary to species recovery plan goals.
Storage Methodology: Direct impacts – GIS analysis Secondary impacts – GIS analysis Native habitats shall be avoided as well as known nesting areas for these species on sites under consideration for storage.	**Restoration Methodology:** Direct impacts – GIS analysis Secondary impacts – GIS analysis Additional source material – South Florida Multi-species Recovery Plan, other adopted recovery plans and guidelines. Using a site that has been identified as habitat for threatened and endangered species for restoration would result in a Go rating.

Comments:
There are several threatened and endangered species found in the Caloosahatchee Basin, including the Florida panther (*Felis concolor coryi*), wood stork (*Mycteria americana*), Florida grasshopper sparrow (*Ammodramus savannarum floridanus*), West Indian manatee (*Trichechus manatus*), red-cockaded woodpecker (*Picoides borealis*), Florida scrub-jay (*Aphelocoma coerulescens*), Everglade snail kite (*Rostrhamus sociabilis plumbeus*), Audubon's crested caracara (*Polyborus plancus audubonii*), Bald eagle (*Haliaeetus leucocephalus*), Okeechobee gourd (*Cucurbita okeechobeensis*), Beautiful pawpaw (*Deeringothamnus pulchellus*). In addition, the Everglades snail kite has designated critical habitat.

GIS materials include layers provided by USFWS and FWC associated with South Florida Multi-Species Recovery Plan, Southwest Florida Regional Wildlife Habitat Plan, and Closing the Gaps in Florida's Wildlife Habitat Conservation System.

Accepted by Project Delivery Team.

Author(s): Jim Beever / FWC, beever@fwc.state.fl.us, and Stephanie Brady USFWS, Stephanie_Brady@fws.gov

Criterion Name: SIGNIFICANT WETLANDS	SSG –1.0.2
Level: 1 – Gate Criteria	
Category: **Not Applicable**	

Description:

Wetlands – those areas defined by federal and/or state regulations to be wetlands, in accordance with the regulation-prescribed hydrology, vegetation and soils criteria.

Significant Wetlands – defined as one or a combination of the following:
Wetlands of regional or state importance as defined by FAC 62-302. Wetlands, which also constitute headwaters. Wetlands, which if affected (positively or negatively), would result in substantial secondary impacts (which may also be positive or negative). Wetlands, which if negatively affected, could not be mitigated.

Storage Rationale:	**Restoration Rationale:**
GO: Site results in no to minimal negative wetland impacts to significant wetlands.	**GO:** Site allows for wetland restoration benefits to target wetland types and an approximation of the original wetland function (either alone or when combined with other sites) results in some of the restoration goals being met (as defined in the projects "Goals and Objectives")
NO GO: Site results in more than minimal impacts to significant wetlands.	**NO GO:** Site, alone or in ratio nal combination with other sites, does not reasonably aid in meeting the project's restoration goals.
Storage Methodology: Direct impacts – GIS analysis of NWI data Direct = within footprint	**Restoration Methodology:** Direct impacts – GIS analysis of NWI data

Comments:

GIS layers include EPA/FWC Wetlands of Significance to Listed Species and the Regionally Significant Wetlands Maps Developed in the Southwest Florida EIS and the LWCWSP (J. Beever 11/8/02). Secondary impacts will be considered in screening criteria.
Further detailed screening will occur during Alternatives evaluation.

Accepted by Project Delivery Team.

Author(s): Sandy Scheda / SEA-Project Consultant / sscheda@scheda.com

Criterion Name: KNOWN SIGNIFICANT CULTURAL RESOURCES	SSG –1.0.3
Level:	**1 – Gate Criteria**
Category:	**Not Applicable**

Description:
Cultural resources – any prehistoric or historic district, site, building, structure, or object found in, or eligible for inclusion in the National Register of Historic Places (NRHP) (as defined by the National Historic Preservation Act of 1966-as amended).

Storage Rationale:	**Restoration Rationale:**
GO: Site results in no negative impacts to significant resources, or impacts, which can be practicably mitigated. **NO GO:** Site results in negative impacts to significant resources, which cannot be practicably mitigated.	**GO:** Site results in no negative impacts to significant resources, or impacts, which can be practicably mitigated. **NO GO:** Site results in negative impacts to significant resources, which cannot be practicably mitigated.
Storage Methodology: Utilizing existing and publicly available information.	**Restoration Methodology:** Same

Comments:
More detailed analysis will occur in future phases.

Site results in area being rehydrated to its historic aesthetic appearance, OR site results in the preservation of known wooden or other organic artifacts whose condition has been degraded by dehydration.

Accepted by Project Delivery Team.

Author(s): Sandy Scheda & Bill Burger / SEA-Consultant, sscheda@scheda.com

Criterion Name: KNOWN SUPERFUND SITES		SSG –1.0.4
Level:	**1 - Gate Criteria**	
Category:	**Not Applicable**	
Description: This criterion is based on whether or not a site is known to be on the USEPA Superfund hazardous waste sites list.		
Storage Rationale: **GO:** Site is not listed as a Superfund site. **NO GO:** Site is listed as a Superfund Site.	**Restoration Rationale:** **GO:** Site is not listed as a Superfund site. **NO GO:** Site is listed as a Superfund Site.	
Storage Methodology: Compare the list of proposed sites to the list of sites on the Superfund cleanup list. (Note: There are no Superfund listed sites in Glades or Hendry Counties.	**Restoration Methodology:** Compare the list of proposed sites to the list of sites on the Superfund cleanup lis t. (Note: T here a re no Superfund listed sites in Glades or Hendry Counties	
Comments: There are no superfund sites in Glades or Hendry counties. Accepted by Project Delivery Team.		
Author(s): Gordon Romeis, FDEP, Gordon.romeis@dep.state.fl.us		

Criterion Name: SAFETY IMPACTS	**SSG –1.0.5**
Level:	**1 – Gate Criteria**
Category:	**Not Applicable**
Description: Initial review of the measures that will have to be taken to avoid or prevent the risks to human life, health, and safety by utilizing the site under review.	
Storage Rationale: **NO GO:** The site violates the criteria for dam/levee design currently utilized by the US ACOE standards or higher state standards. **GO:** The facility at the site can be designed to comply with the criteria for dam/levee design currently utilized by the US ACOE standards or higher state standards.	**Restoration Rationale:** N/A
Storage Methodology: GIS Assessment that identifies inhabited areas, and general topographic relief, with sites overlaid. Distance to habited sites, and topographic assessment, can be evaluated. Utilizing the design criteria identified above to perform an initial evaluation of suitability.	**Restoration Methodology:** N/A
Comments: General JPEG File provided by SWFRPC. Sites identified as having a probability for loss of life enter intensive screening for Mitigation requirements; should such requirements not be able to be met, the site becomes removed from further consideration. Federal law PL 91-646 will be followed in the event of displacement of landowners. It is a requirement of CERP to maintain the existing level of flood protection in accordance with WRDA 2000 and applicable State regulations. **It is recogniz ed that the projec t will be designed to USACE standards or higher state standards for public safety or the criteria being specifically adopted for the Comprehensive Everglades Restoration Plan, the more stringent of the criteria.** This Gate Criterion relates to the following Screening Criterion: Buffers/Setbacks; and the Land Condition subgroup criteria of Current Land Use, Soils, Topographic Relief, and Configuration Complexity. Accepted by Project Delivery Team.	
Author(s): Wayne Daltry, Lee County BOCC, wdaltry@leegov.com	

Criterion Name: BASIN LOCATION	**SSG –1.0.6**
Level: 1 – Gate Criteria	
Category: **Not Applicable**	
Description: This criterion is based on whether or not a site is known to be in the contributing watershed for the Caloosahatchee River (C-43) Basin.	
Storage Rationale: **GO :** Site is in the Caloosahatchee River (C-43) Basin **NO GO :** Site is not in the Caloosahatchee River (C-43) Basin	**Restoration Rationale:** Same
Storage Methodology: Compare the location of the proposed sites to the Caloosahatchee River (C-43) Basin Map.	**Restoration Methodology:** Same
Comments: To be accepted by the PDT

F.3.5 Level 2 General Screening Criteria

Caloosahatchee River (C43) West Basin Storage Reservoir Site Screening Criteria

Criterion Name: UTILITY IMPACTS		SSC –2.1.1
Level:	**2 - General Screening Criteria**	
Category:	**Utility**	

Description:

Utility Impacts include existing, authorized, and potential utility facilities and/or corridors that are/may be located within, across, and/or adjacent to a proposed project site. Utilities include above ground and underground electric power, telephone, cable, fiber optic cable, water, sewer, and similar lines and related facilities such as sub stations, switching stations, etc. Authorized facilities include those that have been permitted, but are not yet constructed and/or operational. Potential facilities/corridors include those for which land has been acquired by easement and/or fee but which have not yet been permitted for a specific use.

Storage Rationale:

Positive (+ 1): No existing utility lines, facilities, easements or fee corridors within or immediately adjacent to the proposed project site that would need to be relocated and/or incorporated into the project design. Local power distribution lines available to provide power during construction and for operational purposes upon project implementation without major relocation or connection costs.

Neutral (0): Existing utility lines, facilities, easements, etc. can be avoided and/or incorporated into the proposed project design with minimal impacts to the existing utility lines, facilities, easements, etc. and/or the project design or timetable and/or relocated at a minimal cost.

Negative (-1): Existing utility lines, facilities, easements, etc. cannot be incorporated into the proposed project design and must be relocated at a significant cost in order to locate the project on the proposed site, including project construction and operational needs for power. This value may also be impacted by the number and type of utility lines, facilities, etc. that may need to be relocated.

Restoration Rationale:

Positive (+ 1): No existing utility lines, facilities, easements or fee corridors within or immediately adjacent to the proposed project site that would need to be relocated and/or incorporated into the project design. Local power distribution lines available to provide power during construction and for operational purposes upon project implementation without major relocation or connection costs.

Neutral (0): Existing utility lines, facilities, easements, etc. can be avoided and/or incorporated into the proposed project design with minimal impacts to the existing utility lines, facilities, easements, etc. and/or the project design or timetable and/or relocated at a minimal cost.

Negative (-1): Existing utility lines, facilities, easements, etc. cannot be incorporated into the proposed project design and must be relocated at a significant cost in order to locate the project on the proposed site, including project construction and operational needs for power. This value may also be impacted by the number and type of utility lines, facilities, etc. that may need to be relocated.

Methodology:

Use a combination of existing land use information, GIS mapping information, utility information, Sunshine State Utility Locator Service, planning documents, and on-site visits to identify existing, permitted, and proposed utility lines, facilities, and corridors and specific information about each including the size of the line and/or facility, whether it is a local or regional type line and/or facility, etc.

The number and type (local versus regional service) of existing, permitted, and proposed lines and/or facilities will be evaluated to determine whether a positive, neutral or negative valne will be assigned.

Comments:

Existing or proposed utility lines and/or other utility facilities on and/or adjacent to a proposed project site may impact the design and/or implementation of the proposed project. In some cases, depending on the type of project proposed and the type of existing or proposed lines and/or facilities, it is possible to design the project in such a way that it avoids or minimizes impacts to the existing and/or proposed lines and/or facilities. In other cases, it may not

be possible to build the project without relocating and/or modifying the lines and/or facilities. Power needs during construction and/or operation of the proposed project may also be a consideration depending on the location, size and type of proposed project. Depending on the type of lines and/or facilities involved, the relocation and/or modification costs could significantly impact the cost of the project and the time required to complete the project. An additional consideration for utilities that have acquired lands by easement or fee for future lines and/or facilities, but have not yet applied for or received permits for those lines and/or facilities, is the extent to which those lands are part of their overall network for providing service within their service area and how that would impact their ability to meet their service requirements in the future. A related consideration is maintenance of access to these facilities during as well as post construction of the proposed project.

Reviewed and accepted by the sub team, pending full PDT concurrence with this recommendation.

Criterion Name: WETLAND HABITAT	SSC -2.2.1
Level: 2	- General Screening Criteria
Category:	Use & Density Factors

Description:
Wetlands – those areas defined by federal and/or state regulations to be wetlands, in accordance with the regulation-prescribed hydrology, vegetation and soils criteria.

"Wetlands" means those areas that are inundated or saturated by surface water or groundwater at a frequency and duration sufficient to support, and under normal circumstances does support, a prevalence of vegetation typically adapted for life in saturated soils. Soils present in wetlands are generally classified as hydric or alluvial, and possess characteristics that are associated with reducing soil conditions. The prevalent vegetation in wetlands generally consists of facultative or obligate hydrophytic macrophytes that are typically adapted to areas having soil conditions described above. These species, due to morphological, physiological, or reproductive adaptation, have the ability to grow, reproduce, or persist in aquatic environments or anaerobic soil conditions. Florida wetlands generally include swamps, marshes, bayheads, bogs, cypress domes and strands, sloughs, wet prairies, riverine swamps and marshes, hydric seepage slopes, tidal marshes, mangrove swamps, and other similar areas. Florida wetlands generally do not include longleaf or slash pine flatwoods, with an understory dominated by saw palmetto.

(Taken from FAC Chapter 40E-4.021, Definitions)

Storage Rationale:	Restoration Rationale:
Positive (+1): Potential site use results in no or low level negative wetland impacts, impacts are to lower quality wetland, impacts are mitigatable. **Neutral (0)**: Potential site use results in a low to moderate level of negative wetland), impacts may also be to average quality wetlands, impacts are mitigatable. **Negative (-1)**: Potential site use results in high level of negative wetland impacts, impacts may also be to high quality wetland, impacts are difficult to mitigate.	**Positive (+ 1)**: Site attains designated wetland restoration benefits Site potentially may increase the spatial extent of functional wetlands. **Neutral (0)**: Site (either alone or when combined with other sites) results in some of the restoration goals being met (as defined in the projects "Goals and Objectives"). **Negative (-1)**: Site does not reasonably aid in meeting the project's restoration goals.
Storage Methodology: Direct impacts – GIS analysis Secondary impacts – GIS analysis Uses other appropriate mapping resources such as smaller scale aerials to complete preliminary review of accuracy of GIS databases	**Restoration Methodology:** Same

Comments:
Best professional analysis by team members with ecological expertise that identifies both isolated and interconnected systems that impact the site or are impacted by the site. Adjacent lands that can contribute to the restoration of or preservation of wetlands.

The screening for this item takes this into further detail than gate criteria.

Author(s): Sandy Scheda, SEA-Project Consultant, sscheda@scheda.com

Criterion Name: PROTECTED SPECIES/WILDLIFE/HABITAT	SSC –2.2.2
Level: 2 - General Screening Criteria	
Category: **Use & Density Factors**	

Description:
Protected Species. Those animal and plant species defined by federal and state regulations to be endangered, threatened, or species of special concern.

Habitats of Protected Species and Wildlife. These areas are defined and maintained in geographic information system by both the USFWS and the FWC. These databases contain habitats of these species.

Storage Rationale:	**Restoration Rationale:**
Positive (+1): Site location results in no adverse impacts to protected species, other wildlife, or their habitats. **Neutral (0):** Site location results in a slight adverse impact to protected species, other wildlife, or their habitats. **Negative (-1):** Site location results in low to high level of adverse impacts to protected species, other wildlife, or their habitats, or site would require a review for potential take.	**Positive (+1):** Restoration site implements goals to recover or restore protected species, wildlife, and their habitats **Neutral (0):** Restoration site (either alone or when combined with other sites) results in the restoration goals being met. **Negative (-1):** Restoration site (either alone or in rational combination with other sites) is contrary to the recovery or restoration of protected species, wildlife or their habitats.
Storage Methodology: Direct impacts - GIS analysis Secondary impacts - GIS analysis	**Restoration Methodology:** Direct impacts - GIS analysis Secondary impacts - GIS analysis Additional source material - South Florida Multi-species Recovery Plan, other adopted recovery plans and guidclines.

Comments:
GIS materials inclnde layers provided by USFWS and FWC associated with South Florida Multi-Species Recovery Plan, Southwest Florida Regional Wildlife Habitat Plan, and Closing the Gaps in Florida's Wildlife Habitat Conservation System

Criterion Name: CULTURAL RESOURCES	SSC –2.2.3
Level:	**2 - General Screening Criteria**
Category:	**Use & Density Factors**

Description:
Cultural resources – any prehistoric or historic district, site, building, structure, or object found in, or eligible for inclusion in the National Register of Historic Places (NRHP) (as defined by the National Historic Preservation Act of 1966-as amended)

Storage Rationale:	Restoration Rationale:
Positive (+1): Site con sists of less t han 10 % high probability area o r kno wu cultural reso urce sites, which can be mitigated. **Neutral (0):** Si te co nsists o f 10-20% hi gh probability area o r con tains one to three rep orted cultural reso urces, wh ich can b e mitigated cost-effectively. **Negative (-1):** Site consists of 20% or greater h igh probability areas or co ntains m ore th an three reported cultu ral resou rces or any cultural resource listed o n or determined elig ible for th e National Register of Hi storic Places, whi ch cannot be mitigated cost-effectively.	**Positive (+1):** Site results in no adverse effect or p rovides a beneficial effect to eligible historic properties. **Neutral (0):** Site resu lts in n egative im pacts to Natio nal Register Listed /Eligible resou rces, wh ich can b e m itigated cost-effectively. **Negative (-1):** Site resu lts in negative imp acts to National Register Listed/Eligible resources, which cannot be mitigated cost-effectively.
Storage Methodology:	**Restoration Methodology:**
Analysis wo uld be conducted usi ng the re sults of Probability M apping for belo wground resou rces. Considers location o f k nown above-ground resources	Same

Comments:
High Probability Areas are areas lo cated by the confluence of creeks and larger bodies of water, and high areas in marshy areas.

In accordance with Section 106 of the National Historic Preservation Act of 1966, as amended, all adverse affects to cultural resources will be avoided or mitigated in consultation with the State Historic Preservation Officer.

Author(s): Grady Caulk, Corps, Sandy Scheda & Bill Burger, SEA-Consultant, sscheda@scheda.com

Criterion Name: CONSERVATION LANDS	SSC –2.2.4
Level:	**2 - General Screening Criteria**
Category:	**Not Applicable**

Description:

Conservation Lands – those lands and waters in conservation and preservation protection defined by federal, state, regional local government or private conservation ownership, including conservation easements.

Proposed Conservation Lands – those lands and waters in conservation and preservation protection defined by federal, state, regional local government or private conservation ownership, including conservation easements that are on official listings or documents for acquisition in fee or less-than-fee.

Storage Rationale:	**Restoration Rationale:**
Positive (+1): Site results in no negative impacts to conservation lands or proposed conservation lands. **Neutral (0)**: Site results have the potential to secondarily negatively impact the acquisition of proposed conservation lands either by physical or appraisal effects. **Negative (-1)**: Site results in negative impacts to existing conservation lands or proposed conservation lands by direct effects in preventing conservation uses or preventing acquisition for conservation purposes.	**Positive (+1):** Site implements conservation use or acquisition goals **Neutral (0):** Site (either alone or when combined with other Sites) results in some of the restoration goals being met (as defined in the projects "Goals and Objectives") **Negative (-1):** Site (either alone or in rational combination with other Sites) does not reasonably aid in meeting the project's restoration goals or is contrary to conservation goals on existing and proposed lands.
Storage Methodology: Direct impacts – GIS analysis Secondary impacts – GIS analysis Additional material- official land acquisition proposal lists and documents	**Restoration Methodology:** Direct impacts – GIS analysis Secondary impacts – GIS analysis Additional material Conservation Lands Management Plans, other adopted restoration plans and guidelines.

Comments:

There are several conservation lands and on-going conservation lands acquisition projects in the Caloosahatchee Basin, including the Florida panther Ecoscape project.

The screening criteria shall prohibit the selection of sites that will not contribute to the protection of existing conservation lands or interfere with on-going conservation land acquisition in-fee or less-than-fee simple.

GIS materials include layers provided by USFWS, FWC, FDEP, SFWMD, and UF associated with land acquisition programs including Florida Forever, Save Our Rivers, lee County 2020, Southwest Florida Regional Wildlife Habitat Plan, and Closing the Gaps in Florida's Wildlife Habitat Conservation System.

Reviewed and accepted by the sub team, pending full PDT concurrence with this recommendation.

Author(s): Jim Beever, FWC, beever@fwc.state.fl.us

Criterion Name: COMPREHENSIVE L AND USE PLAN & Z ONING COMPLIANCE	SSC -2.3.1
Level:	**2 - General Screening Criteria**
Category:	**Regulatory or Legal Factors**

Description:
Identify and consider impacts on the future use of the site resulting from the existing land use and other applicable designation(s) in the local government Comprehensive Land Use Plan (CLUP) and Zoning Code that govern the use of this site and adjacent lands.

Storage Rationale:	Restoration Rationale:
Positive (+1): No changes or special approvals under the existing CLUP & Z oning designation for the site are required to implement the proposed project. **Neutral (0):** The proposed use is compatible with the current CLUP for the site, but requires a special approval under the CLUP process or a zoning change in order to be implemented. These approvals can likely be obtained within the next 6 months due to the timing of the local government's next open application filing period for CLUP approvals. **Negative (-1):** The proposed use requires a change in the current CLUP designation for the site and corresponding zoning changes to implement the proposed project and/or it will likely take at least a year to process the request due to the timing of the local government's next open application filing period for CLUP changes.	**Positive (+1):** No changes or special approvals under the existing CLUP & Z oning designation for the site are required to implement the proposed project. **Neutral (0):** The proposed use is compatible with the current CLUP for the site, but requires a special approval under the CLUP process or a zoning change in order to be implemented. These approvals can likely be obtained within the next 6 months due to the timing of the local government's next open application filing period for CLUP approvals. **Negative (-1):** The proposed use requires a change in the current CLUP designation for the site and corresponding zoning changes to implement the proposed project and/or it will likely take at least a year to process the request due to the timing of the local government's next open application filing period for CLUP changes.

Methodology:
Identify: (1) the applicable local government CLUP and Zoning Code designations which apply to the proposed site; (2) the applicable CLUP and Zoning designations and special overlays or approvals required that apply to the proposed site; (3) whether or not a CLUP amendment or special approval or zoning classification change by the local government is required to implement the project; (4) if a CLUP amendment or special approval or zoning change is required, the ability to prepare and file that request in a timely manner with in the designated application filing periods.

Comments:
If the proposed use would require an amendment to the applicable CLUP or Zoning District in order for the site to be used, this could significantly impact the timetable for and cost of implementing the proposed project due to the amount of time that it typically takes to process a CLUP amendment and/or Zoning classification time. Local governments only allow amendments to their CLUP to be filed during a designated annual or bi-annual filing period, unless they are filed in conjunction with a Development of Regional Impact (DRI) application. It is unlikely that this project would qualify as a DRI. It usually takes several months to a year to process a CLUP amendment. Zoning change requests can typically be filed on a monthly basis, but can still take several months to process depending on the complexity of the proposed project and the issues involved.

There may some situations where: (1) a proposed use, such a reservoir, may be incompatible with an existing CLUP or zoning classification or overlay provision, such as preservation, without modifying the existing CLUP or zoning code designation or overlay; or (2) a proposed use may be allowed within an existing CLUP or Zoning Code designation, but only by special approval and subject to additional special conditions.

Reviewed and accepted by the sub team, pending full PDT concurrence with this recommendation.

Author(s): Susan Coughanour, SFWMD, scoughanour@sfwmd.gov

Site Screening Criteria: Pending Rule/ Regulatory Compliance	SSC –2.3.2
Level:	**2 - General Evaluation Criteria**
Category:	**Regulatory or Legal Factors**

Description:

Identify and consider the extent to which the proposed use of the site may be affected by: (1) rules that have recently been adopted but whose implementation is officially scheduled for a specific future date; and/or (2) proposed and/or on-going rule making activities. These rule making activities may be undertaken by local governments, regional agencies (water management district/regional planning council/ other), state agencies, federal agencies, and/or Indian tribes.

Storage and Restoration Rationale:

Positive (+1): No recently adopted rules and/or pending rule-making activities that could affect how the site could be used for the proposed project.

Neutral (0): Recently adopted rules and/or on-going rule making activities will have minimal impacts on how the site will be used for the proposed project since: (1) the content of the rule changes is such that it is not expected to significantly impact the project design; (2) the effective date of the adopted/proposed rules is far enough in the future that permits for the proposed project can likely be obtained prior to the rule changes going into effect.

Negative (-1): Recently adopted and/or proposed rule making activities address content areas likely to substantially affect the use of the site for the proposed project, particularly in terms of project design. Proposed rules and/or rule making activities are currently embroiled in extended legal proceedings regarding their validity.

Storage and Restoration Methodology:

Identify all recently adopted rules and/or pending rule making activities by the applicable local, regional, state, and/or federal agencies and/or Indian Tribes that could affect how the site is used for the proposed project;

Review the content of the recently adopted/pending rules to identify potential impacts on project design and/or location;

Review adopted/proposed implementation dates for potential impacts on permit application process and project timetables.

Comments:

Depending on the extent to which proposed, on-going and/or recently adopted rules/rule changes affect a project design, they could have a corresponding impact on the construction timetable and implementation date for the proposed project. When new rules or rule changes are proposed or adopted, they typically specify a future effective date. They also specify whether the new rules are applicable to new applications only and/or to applications that have not yet been found to be complete by the reviewing agency by a specific implementation date. The content of the rule changes could also affect the proposed project design. Consequently, depending on the status of any permit applications already under review or being prepared, the implementation date of the new rules/rule changes, and/or the cout ent of the proposed/adopted rules, the project design, as well as the construction timetable, could be impacted.

Compliance with permit conditions is presumed to be addressed under the Permitting Criteria.

Reviewed and accepted by the sub team, pending full PDT concurrence with this recommendation.

Author(s): Susan Coughanour, SFWMD, scoughanour@sfwmd.gov

Criterion Name: MITIGATION / CONS ERVATION E ASEMENT / DEED RESTRICTIONS	SSC –2.3.3
Level:	**2 - General Screening Criteria**
Category:	**Regulatory or Legal Factors**

Description:

Identify and co nsider impacts o n t he fu ture u se of th e site resu lting from ex isting mitigation areas, co nservation easements, deed restrictions, or other legal limitations (by permit condition, land use designation, or other) on the use of the site.

Storage and Restoration Rationale:

Positive (+1): No existing conservation or other types of easements or deed rest rictions on t he property that would limit the proposed use of the property.

Neutral (0): Limitations associated with the existing conservation or other types of easements or deed restrictions on the property can be incorporated into the proj ect design without significantly impacting the ability of the project to meet project goals.

Negative (-1): Limitations associated with the existing conservation or other types of easements or deed restrictions on the property will significantly limit the ability of the site to be used for the proposed project design and/or be time consuming and costly to address.

Storage and Restoration Methodology:

Identify: (1) all existing conservation easements and/or deed restrictions on all or part of the proposed site; (2) any other legally protected (by permit, land use designation, or other method) areas on all or part of the proposed site; (3) all li mitations o n allo wable lan d uses and /or land use practices, water levels, clea ring practices, ope ration a nd maintenance practices, including exotic control, special uses such as hunting/fishing, etc., contained in the easements, deed restrictions, and/or any other legally limiting documents that could impact the project design; (4) the ability to incorporate t he li mitations co ntained i n th e ex isting ease ments, d eed restrictio ns, and/or other l egally li miting documents into the project design.

Comments:

It is assu med th at m itigation land s, and o ften st ormwater m anagement areas, a re typically encum bered by conservation easements and/or some type of deed restrictions. Conservation easements, deed restrictions and/or other types of l egal restrictions on land use m ay limit the use of t he property and/or impact t he design of t he proposed project or facil ity as a result of restrictions on allowable land uses, land practices, water levels, control elevations, etc. Due t o t he nat ure o f m ost mitigation areas, c onservation o r ot her types of ea sements/deed rest rictions will typically limit water levels on that portion of the property covered by the easement/restriction and/or mitigation area and disallow its use as a deep water storage area. Additional design features/costs may also be required to use areas adjacent to conservation easement/mitigation lands for deep water storage purposes. Restoration projects can often be designed consistent with existing mitigation/conservation easements.

It is assu med that impacts to natural wetland functions will be evaluated under separate criteria. The existence of these types of encumbrances on the property will influence property values. This issue will be addressed in the Gross Appraisal.

Criterion Name: CONSTRUCTION / O&M ACCESS	SSC –2.4.1
Level:	**2 - General Screening Criteria**
Category:	**Transportation Impacts**
Description: This screening criteria will provide an evaluation of each site for temporary ease of construction and permanent O&M access both to the site as well as existing internal roads and bridges which can be used during construction and/or built upon for future use. In addition, staging areas for construction and O&M would be included in the screening.	
Storage and Restoration Rationale: **Positive (+1)**: If significant access is available. **Neutral (0)**: If existing is not adequate for construction access. **Negative (-1)**: If impediments or costly improvements are required.	
Storage and Restoration Methodology: By utilizing aerial photography and GIS -review existing on-site transportation infrastructure.	
Comments: Ingress & Egress to site (distance to and condition of existing roads & bridges) as well as internal infrastructure will impact the costs of construction as well as minimizing the impacts to surrounding areas during construction of the project hauling routes. Capability of the existing roads and bridges to accommodate construction vehicles, equipment, and large components of the projects i.e. HS25 loading capability for bridges. Reviewed and accepted by the sub team, pending full PDT concurrence with this recommendation.

Criterion Name: PUBLIC LANDS	SSC -2.5.1
Level:	**2 - General Screening Criteria**
Category:	**Land Condition**

Description:
Public lands include those lands that are owned by the federal, state or local government, including sovereign and submerged lands. Sovereign lands include all lands under bodies of navigable water and tidelands within the territorial limits of the State of Florida. Conservation lands are not included in this description since they are described in SSC 2.2.4. Public lands include those lands that may have been acquired or designated for a variety of public uses, including stormwater mauagement, recreation, public facilities, preservation or other public uses.

Storage Rationale:	Restoration Rationale:
Positive (+ 1): Storage on site is consistent with the existing or intended use of this public site. **Neutral (0)**: Storage on site is not contrary to the existing or intended use of this public site. **Negative (-1)**: Storage on site is not consistent with the existing or intended use of this public site.	**Positive (+1)**: Restoration on site is consistent with the existing or intended use of the public site. Land is adjacent to restoration corridors being identified and utilized in other public projects. **Neutral (0)**: Restoration on site is not contrary to the existing or intended use of this public site. **Negative (-1)**: Restoration on site is not consistent with the existing or intended use of this public site.
Storage Methodology: Hendry, Lee & Glades County Plat Books; County Comprehensive Plan & Zoning Maps; Save our Rivers Maps; GIS analysis of FLUCFCS LU/LC data	**Restoration Methodology:** Same

Comments:
The ability to use public lands for the proposed project may be impacted by (1) the purpose for which the land was originally acquired, including funding sources; (2) existing and/or planned public uses of the land; and (3) the extent to which waterways, tidelands, and riparian lands are publicly and/or privately owned and/or controlled. Additional approvals and/or permits may be required to use public lands for a purpose that is different than the purpose for which it was originally acquired and/or what is allowed under the funding source used to acquire the property. If applicable to the site selected, sovereign lands will be addressed in the Gross Appraisal Report for the selected plan.

Reviewed and accepted by the sub team, pending full PDT concurrence with this recommendation.

Criterion Name: STORAGE CAPACITY	**SSC –2.5.10**
Level:	**2 - General Screening Criteria**
Category:	**Land Condition**

Description:
This screening criterion will provide an evaluation of each site for the volume of storage capacity.

Storage Rationale:	**Restoration Rationale:**
Positive (+1): If site could store greater than 10,000 ac-ft. **Neutral (0)**: If site could store 5,000 to 10,000 ac-ft. **Negative (-1)**: If site could store < 5,000 ac-ft.	**Positive (+1)**: Depths and hydroperiods appropriate for the maintenance of the natural community can be achieved. **Neutral (0)**: Uncertain **Negative (-1)**: Depths and hydroperiods appropriate for the maintenance of the natural community are not likely to be achieved.

Methodology:
Utilize GIS information and NRCS Soil Surveys to determine the best possible site location.

Comments:
Minimizing the number of reservoir locations reduces the design and construction costs as well. Managing land costs – smaller sites with greater depth – lower costs.

CERP assumed a storage depth of 8 feet for planning purposes, however, a storage depth of greater than 8 feet could yield a larger volume per acre ratio.

Level:	**2 - General Screening Criteria**
Category:	**Land Condition**
Description: This screening criterion will provide an evaluation of each site for ease of water management, arrangement of cells, gravity flow, maintenance of adjacent existing water management systems, and distribution of flows.	
Storage Rationale: **Positive (+ 1)**: Little to no modification to existing hydrologic infrastructure is necessary to convey water to and from the storage feature. **Neutral (0)**: Some modification or addition to existing hydrologic infrastructure. **Negative (-1)**: Major modifications to existing or construction of new hydrologic infrastructure are necessary to convey water to and from the storage feature.	**Restoration Rationale:** **Positive (+ 1)**: Little to no modification to existing hydrologic infrastructure is necessary to convey water to and from the restoration feature. **Neutral (0)**: Some modification or addition to existing hydrologic infrastructnre. **Negative (- 1)**: Major modifications to existing or construction of new hydrologic infrastructure are necessary to convey water to and from the restoration feature.
Methodology: GIS/H&H exercise to determine the hydrologic infrastructure.	
Comments: Reviewed and accepted by the sub team, pending full PDT concurrence with this recommendation.	
Author(s): Agnes Ramsey/Shawn Waldeck, SFWMD aramsey@sfwmd.gov, Stanley Consultants, Inc, waldeckshawn@stanleygroup.com	

Criterion Name:	**GROUNDWATER RECHARGE**	**SSC –2.5.12**
Level:	**2 - General Screening Criteria**	
Category:	**Land Condition**	

Description:

For the purposes of the se screening cr iteria, ground waters are cha racterized and re gulated in accordance with t he definitions and regulations provided in F ederal and St ate law. It is noted that when ground wat er recharge is the likely result of any specific feature, s pecial attention and po tential protective measures may be necessary to protect the quality of those ground waters and/or their uses. Federal and State regulations restrict the permitting/construction of pr ojects th at m ay cau se or co ntribute to th e degradation of groundwater resources and /or adv erse im pacts to existing legal users and sonrces of water. Impoundment of pollutant runoff from surface waters for a reservoir could result in the introduction of these contaminants to surficial aquifers (ground water).

Storage Rationale:

Positive (+ 1): Min imal p otential for grou nd water recharge.
Neutral (0): Mo derate p otential fo r grou nd water recharge.
(0*) Available in formation i s in sufficient to m ake a determination
Negative (-1): Co nsiderable p otential fo r ground water recharge.

Restoration Rationale:

Positive (+ 1): Co nsiderable p otential for g round water recharge.
Neutral (0): Moderate potential for ground water recharge.
(0*) Available in formation is in sufficient to m ake a determination.
Negative (- 1): Min imal p otential fo r ground water recharge.

Methodology:

Based on available soils, geological maps, recharge maps, well field protection maps, and/or other readily available literature, the degree of surface water and ground water interaction/connection at the site will be assessed.

Comments:

Storage Methodology: The objective is to minimize ground water and surface water interactions. The ability to store water in a reservo ir/impoundment is improved if ground water recharge rates at the site ar e minimal. The goal is to hold water in the reservoir/impoundment and minimize uncontrollable outflow.

Restoration Methodology: The objective is to provide for ground water and surface water in teractions. Th e ability recharge ground water near an aquifer recharge area a nd/or a wet land wi th ground water dom inated hydrology i s improved if ground w ater r echarge r ates at the site are c onsiderable. The go al is to in crease groun d water lev els and/or aquifer recharge rates by impounding water on t he site to enhance the quantity of ground water resources. If restoration is desired, special attention should be afforded to the quality water to be impounded.

Reviewed and accepted by the sub team, pending full PDT concurrence with this recommendation.

Author(s): Shawn Komlos, EPA / komlos.shawn@epamail.epa.gov

Criterion Name: SURFACE WATER	**SSC –2.5.13**
Level:	**2 - General Screening Criteria**
Category:	**Land Condition**

Description:
Surface waters are classified by public use criteria (Class I is potable, Class II is shellfish harvesting, and Class III is fishable/swimmable). Surface waters in Florida are considered "impaired" or degraded based upon water quality standards associated with these classifications and evaluative procedures established by the State in the "Impaired Waters Rule." Federal and State regulations restrict and in some cases preclude the permitting of projects in surface waters identified as failing to meet public use requirements.

Storage Rationale:	**Restoration Rationale:**
Positive (+1): Source water is not impaired or degraded. **Neutral (0):** Available information is insufficient to make a determination **Negative (-1):** Source water is impaired or degraded.	**Positive (+1):** Source water is not impaired or degraded. **Neutral (0):** Available information is insufficient to make a determination **Negative (-1):** Source water is impaired or degraded.

Methodology:
Maps and lists of waters classified as "impaired" or degraded according to the federal 303(d) list, State 305(b) list, or by other federal environmental assessments, i.e., EA, NEPA, and EIS. etc. will be reviewed to determine if the site is likely to receive from or discharge to water bodies with recognized water quality problems.

Comment:
Storage Comment: The objective is to allow for the capture and detention of as much water as is possible, while maximizing flexibility in storage feature operation. If tributaries that contribute water to the site have been identified as having water quality problems (i.e., excessive concentrations and /or loads of pollutants), future options for the correction of such problems may be reduced via the construction of the storage feature. It is recognized that STAs or other treatment may be needed to meet TMDLs once they are established.

Restoration Comment: If tributaries that contribute water to the site have been identified as having water quality problems (i.e., excessive concentrations and/or loads of pollutants), future options for the correction of such problems could be improved and/or expanded via the construction and/or incorporation of water quality treatment/enhancement features. However, for the purposes of restoration of on-site ecological conditions the goal is to import as little polluted water as possible onto the site to be restored.

This screening criterion is looking at on-site conditions and on-site habitat and the impacts that source water quality could have on those. The project should avoid point sources and not impair water bodies.

Author(s): Shawn Komlos, EPA/ komlos.shawn@epamail.epa.gov

Criterion Name: Hydraulic Differential	**SSC -2.5.14**
Level:	**2 - General Screening Criteria**
Category:	**Land Condition**

Description:
This screening criterion will provide an evaluation of each site for difference between that elevation and the elevation of the water source available for storage.

Storage Rationale:	**Restoration Rationale:**
Positive (+1): Less than 10 feet of difference. **Neutral (0)**: 10 to 20 feet of difference. **Negative (-1):** Greater than 20 feet of difference.	Same.

Methodology:
Utilizing existing topographic maps to determine the differential between the known elevations of the source water and the existing site ground elevation.

Comments:
The average elevation of the site and the difference between that elevation and the elevation of the water source available for storage is a factor to consider in selection of a desirable facility, be it reservoir or restoration. The greater the difference between the elevation at a site and the elevation in the C-43 or other identified source water body, the higher the lift required to move the water into storage; and potentially an increase in pumping cost or number of pumping stages. It is desirable to have a low a lift as necessary and sites with low average elevation relative to the reach on the C-43 will be ranked higher.
The proposed ranking scale is presented below, and takes into consideration the elevations of the water pools in the C-43.

Source Elevation in C-43 between S-79 and S-78, approximately 3 feet ngvd
Source Elevation in C-43 between S-78 and S-77, approximately 11 feet ngvd
Source Elevation in other source water bodies will be determined on a CBC basis.

Note
The criteria is not based on the actual average elevation but on a difference, sites in the East or West basin may have same elevation but differ in ranking due to difference in water level in the C-43 in either basin.
Higher cost associated with additional pumping is the primary undesirable factor
Less than 2 feet difference may necessitate pumping for both filling or releasing from project

Reviewed and accepted by the sub team, pending full PDT concurrence with this recommendation.

Author(s): Alternative Development Sub Team

Criterion Name: Degree of Topographic Relief	**SSC –2.5.15**
Level: 2 - General Screening Criteria	
Category: **Land Condition**	

Description:
The degree of topographic relief on the site is a measure of elevation gradient across the site. A relatively flat site would have little change in elevation between its highest region and its lowest region. In the converse, a site with high topographic relief would have a large difference between the elevation at the highest region and elevation at the lowest region. We have used region in place of point in this definition to distinguish the effect of a local and isolated through or knoll (or mound) from that of a more widespread and extensive topographic feature.

Storage Rationale:	**Restoration Rationale:**
Positive (+1): Minimal differences in relief. Less than 2 feet of difference across the section. **Neutral (0)**: 2 to 6 feet of difference across the section. **Negative (-1):** Greater than 6 feet of difference across the section.	N/A

Methodology:
USGS Digital Elevation Maps

Comments:
Sites with high topographic relief would require significant earthwork and may limit design of a project by requiring sectioning /partitioning of the site where a single unpartitioned project might have been desirable. In the case of a reservoir, additional pumping / infrastructure may be required to move water between partitioned cells. It is desirable to have as low a topographic relief on the site as possible and sites with low topographic relief will be ranked higher.

A section refers to a one-mile area.

Criterion: SITE SIZE	**SSC –2.5.2**
Level:	**2 - General Screening Criteria**
Category:	**Land Conditions**
Description:	
This screening criterion will provide an evaluation of each site for site size and ability to acquire adjacent sites if the site is less than one section or 640 acres	
Storage Methodology: **Positive (+1)**: If site is greater than 640 acres. **Neutral (0)**: If site is less than 640 acres and adjacent sites may be available for a cumulative total greater than 640 acres. **Negative (- 1)**: If site is less than 640 acres and no adjacent sites are available	**Restoration Methodology:** Not Applicable
Methodology: Utilize existing county plat maps as well as the County Property Appraiser's Offices website to determine site size.	
Comments: Size assumption is that one section/ 640 acres/ one square mile is capable of storing approximately. 5,000 ac-ft at a depth of approximately 8 feet.	
Author(s): Draft Approved by Site Selection Sub-Team 11/21/02	

Criterion Name: TAX BASED IMPACTS	**SSC –2.5.20**
Level:	**2 - General Screening Criteria**
Category:	**Land Condition**

Description:
Land use of industrial, commercial, residential, agricultural areas provide the tax base necessary for the counties to provide essential services. Conversion from these units will have an impact on the tax base.

Storage Rationale:	**Restoration Rationale:**
Positive (+1): Barren, vacant or abandoned lands when have been impacted. **Neutral (0)**: Unimproved or natural areas. **Negative (-1)**: Improved lands.	**Positive (+1)**: Barren, vacant or abandoned lands when have been impacted. **Neutral (0)**: Unimproved or natural areas. **Negative (-1)**: Improved lands.
Storage Methodology: GIS analysis of FLUCFCS LU/LC data	**Restoration Methodology:** Same

Comments:
Economic impacts are addressed under other criteria.
Improved land is defined as existing industrial, residential or commercial land.

Reviewed and accepted by the sub team, pending full PDT concurrence with this recommendation.

Author(s): Sandy Scheda, SEA – Consultant, sscheda@scheda.com

Criterion Name: SOIL CHEMISTRY SUITABILITY	SSC –2.5.21
Level:	**2 - General Screening Criteria**
Category:	**Land Condition**

Description:
This screening criterion will provide a potential contaminant evaluation of each site for suitability of in-situ soil conditions for the pre-construction and operation of storage features.

Storage Rationale:	**Restoration Rationale:**
Positive (+ 1): If soils are chemically suitable for construction of a storage feature with nominal likelihood for mitigation (or small degree of mitigation) or cleanup. **Neutral (0)**: Minimal chemical impacts and/or moderate likelihood for mitigation (or moderate degree of mitigation) or cleanup. **Negative (-1)**: Extensive chemical mitigation and/or considerable likelihood for mitigation (or considerable degree of mitigation) or cleanup.	**Positive (+1)**: If soils are suitable for restoration, minimal likelihood for cleanup. **Neutral (0)**: Unknown or moderate likelihood for cleanup. **Negative (-1)**: Considerable likelihood for cleanup.

Methodology:
Utilizing the IFAS/USDA/FDEP/local/or other databases and resources to identify the current and historical land uses for potential contaminant evaluation. Readily ascertainable databases.
This will not necessarily capture historical hazardous waste incidents, which are captured in the site criterion SSG 1.0.4 Known Superfund Sites.

Comments:
The degrees to which on-site soils may be potentially contaminated due to historical land use practices (such as agricultural, industrial, and/or former military) will likely affect project costs associated with on-site soil quality characterization and/or cleanup/remediation.

If contamination is found on a proposed site location, the private landowner must pay for the clean-up/remediation prior to handing it over to the Caloosahatchee River (C-43) Basin Storage Reservoir Project. However, if the land is under public ownership the Project will have to pay for the clean-up/remediation, which could increase the project costs.

Reviewed and accepted by the sub team, pending full PDT concurrence with this recommendation.

Author(s): Agnes Ramsey/Shawn Waldeck, SFWMD aramsey@sfwmd.gov, Stanley Consultants, Inc, waldeckshawn@stanleygroup.com

Criterion Name: CURRENT LAND USE	SSC –2.5.3
Level:	**2 - General Screening Criteria**
Category:	**Land Condition**

Description:
Land use is categorized into industrial (planned or completed), commercial (planned or completed), residential (planned or completed), agricultural (row-crops, citrus, cane and pasture), unimproved natural areas or recreational areas.

Storage Rationale:	**Restoration Rationale:**
Positive (+ 1): Conversion of site's current land including agricultural crops, vacant residential, commercial or industrial, barren lands, and abandoned mines to storage facility results in a net positive affect. **Neutral (0)**: Conversion of site's land from improved pasture to storage facility results in no negative affects **Negative (-1)**: Conversion of site's land from unimproved natural areas, existing industrial, residential or commercial to storage facility results in net negative affect	**Positive (+ 1)**: Conversion of site's unimproved natural/native use to restored condition results in a net positive affect **Neutral (0)**: Conversion of site's cane, citrus, or seasonal row-crop or vacant residential, commercial or industrial, barren lands, abandoned mines use to restored condition results in no negative affects **Negative (- 1)**: Conversion of urban, industrial, commercial, or residential use to restoration facility results in net negative affect
Storage Methodology: GIS analysis of FLUCFCS LU/LC data	**Restoration Methodology:** Same

Comments:
Economic impacts are addressed under other criteria.

The conversions of certain land use types to storage facilities result in less environmental and social impacts to natural systems and local human populations. Areas that have been previously legally cleared without significant human infrastructure are predisposed for storage uses. The elimination of native habitats for man-made storage facilities can result in significant environmental impacts.

In contrast, restoration of existing degraded natural areas is easier to achieve, with less cost, using current restoration technologies. Areas developed in cane, citrus, seasonal row-crop, vacant lands, and old mines have been and can be restored using current restoration technologies but at a greater cost. Restoring existing urban, industrial, and commercial or residential land to natural conditions has not been demonstrated to be successful and has not been attempted in many cases due to economic and social costs.

Reviewed and accepted by the sub team, pending full PDT concurrence with this recommendation.

Author(s): Sandy Scheda / SEA – Consultant, sscheda@scheda.com

Criterion Name: NUMBER OF LAND OWNERS	**SSC –2.5.4**
Level: 2	**– General Screening Criteria**
Category:	**Land Condition**

Description:
Identify the number of parcels, including primary residences (permanent, year-round homes) and/or businesses that may need to be acquired in order to assemble a large enough site to implement the proposed project.

Storage and Restoration Rationale:
Positive (+1): Proposed site has only one landowner; strong potential for willing seller; no homeowners, tenants, and/or businesses who will need to be relocated in order to use the property.

Neutral (0): Less than five landowners; little possibility that condemnation will be necessary to acquire the required parcels; less than five homeowners, tenants, and/or businesses who will need to be relocated in order to use the property.

Negative (-1): Many land owners; strong possibility that condemnation will be necessary to acquire at least some of the required parcels; multiple homeowners, tenants, and/or businesses who will need to be relocated in order to use the property.

Storage and Restoration Methodology:
County Tax Assessor's records, including Tract and Property Ownership data.

Comments:
Dealing with conglomerates, corporations, and/or more than one individual landowner for the purchase of their property may add to the complexity and schedule for acquiring the property needed for the proposed project. If the property must be acquired through condemnation, rather than from willing seller(s), and/or there are property owners who are eligible for relocation, this could significantly impact the acquisition schedule and potentially impact the construction start date. This issue will be addressed more thoroughly in the Gross Appraisal for the selected plan. The target is to minimize the total number of primary residences and businesses that may need to be acquired to implement the proposed project.

A willing seller is defined as a landowner who has offered a potential site to the project.

Reviewed and accepted by the sub team, pending full PDT concurrence with this recommendation.

Criterion Name: EXISTING LAND COVER	SSC –2.5.5
Level:	**2 - General Screening Criteria**
Category:	**Land Condition**

Description:
Conversion of land cover types to storage or restoration facilities may result in less environmental impacts to natural systems and listed species.

Storage Rationale:	**Restoration Rationale:**
Positive (+1): Conversion of Site's current land cover to storage facility results in a net positive affect. **Neutral (0)**: Conversion of Site's land cover to storage facility results in no negative affects, or impacts can be mitigated to equal the same result **Negative (-1)**: Conversion of Site's land cover to storage facility results in net negative affect.	Same
Storage Methodology: GIS analysis of FLUCFCS LU/LC, and NWI data	**Restoration Methodology:** Same

Comments:

The conversions of certain land cover types to storage facilities result in less environmental impacts to natural systems and listed species that depend upon these habitats. Some areas that are legally cleared have no negative impacts since the land cover is predisposed for storage uses. The elimination of some land cover types such as invasive exotic vegetation can result in net positive environmental impacts.

In contrast restoration of existing degraded natural areas is easier to achieve, with less cost, using current restoration technologies. Areas developed in cane, citrus, seasonal row-crop, vacant lands, and old mines have been and can be restored using current restoration technologies but at a greater cost. Restoring existing urban, industrial, and commercial or residential land to natural conditions has not been demonstrated to be successful and has not been attempted in many cases due to economic and social costs.

Reviewed and accepted by the sub team, pending full PDT concurrence with this recommendation.

Criterion Name: PROXIMITY TO WATER RESOURCES	**SSC –2.5.6**
Level: 2 - General Screening Criteria	
Category: Land Condition	
Description: This screening criterion will provide an evaluation of the site and proximity to the available sources or receiving waters.	
Storage Rationale: **Positive (+1)**: If the project is hydraulically connected to the source or receiving body. **Neutral (0)**: If within 1 mile of source or receiving body based on the size of the overall project. **Negative (-1)**: If project is more than 1 mile from the source or receiving body based on the size of the overall project.	**Restoration Rationale:** Same
Storage Methodology: Utilize Land Use maps and GIS information.	**Restoration Methodology:** Same
Comments: Costs and reductions in losses of discharges based upon greater distances from the source as well as the topography differences in this basin, which would require multiple pump stations. In addition, additional land acquisition would be required for the construction of connections between the source and the project. Higher O&M costs and head losses for greater distance, system response to rain events or droughts. Reviewed and accepted by the sub team, pending full PDT concurrence with this recommendation.

Criterion Name:	GEOTECHNICAL SOIL SUITABILITY	SSC –2.5.7
Level:	2 - General Screening Criteria	
Category:	Land Condition	

Description:
This screening criterion will provide a structural evaluation of each site for suitability of in-situ soil conditions for the construction and operation of storage features and suitability of soils for seepage control.

Storage Rationale:	Restoration Rationale:
Positive (+ 1): If soils are structurally suitable for construction of a reservoir with nominal likelihood for structural or seepage mitigation (or small degree of mitigation). **Neutral (0)**: Minimal structural or seepage impacts and/or moderate likelihood for mitigation (or moderate degree of mitigation). **Negative (- 1)**: Extensive structural or seepage mitigation and/or considerable likelihood for mitigation (or considerable degree of mitigation).	**Positive (+1)**: If soils are structurally suitable for restoration and/or groundwater recharge. **Neutral (0)**: Unknown. **Negative (- 1)**: Soils not suitable for restoration and/or groundwater recharge.
Storage Methodology: Utilize USGS and NRCS/USDA Soil Survey Information.	**Restoration Methodology:**

Comments:
Suitability for use in construction – structural fill for levees & roads, STA/wetland species, slope dressing, and seepage containment.

For Storage, minimizing seepage losses will improve the project efficiency. For Restoration, seepage will improve the groundwater table and water quality, potentially improving natural habitat. Seepage control costs will vary per site due to local geology and fill materials. Seepage issues are more inflammatory in urban/suburban areas.

Reviewed and accepted by the sub team, pending full PDT concurrence with this recommendation.

Criterion Name: SITE LOCATION IN THE CONTRIBUTING WATERSHED – WATER QUANTITY	SSC –2.5.8
Level:	**2 - General Screening Criteria**
Category:	**Land Condition**

Description:
The storage screening criterion will provide an evaluation of each site's location within the watershed for the capture of runoff from watershed (S-77 to S-79).
The restoration screening criterion is tailored toward the ability to provide potential passive/natural storage in the upper tributary.

Storage Rationale:	**Restoration Rationale:**
Positive (+1): If site could capture watershed runoff from >/= 75% of watershed area. **Neutral (0)**: If site could capture watershed runoff from 50 to 75% watershed area. **Negative (-1)**: If site captures watershed runoff of < 50% watershed area.	**Positive (+1)**: Upper tributary floodplain. Storage scheme supports natural hydroperiods. **Neutral (0)**: Location between upper tributary and tail water floodplains. **Negative (-1)**: Tail water floodplain.

Methodology:
Utilize the existing Caloosahatchee watershed map, other existing maps and GIS information.

Comments:
A sites ability to capture a significant amount of water would increase the overall project benefit to the estuary by reducing the impacts of runoff and providing the captured flows during dry periods. Amount of capture, % of basin runoff & volume. Dependent upon other sites under consideration.
Lake O releases can be caught anywhere in the Caloosahatchee River (C-43 Canal) and is therefore not location dependent.

Reviewed and accepted by the sub team, pending full PDT concurrence with this recommendation.

Criterion Name: SITE CONTRIBUTION TO LOAD	SSC 2.5.9
Level:	**2 - General Screening Criteria**
Category:	**Land Condition**

Description:
Does the site land use contribute degrading water quality constituents to the watershed, river, and estuary? By placing a storage or restoration feature within the watershed the load from runoff can be reduced in-place, and reduce the capacity / area needed for project features required for storage or water quality treatment needed for the project as a whole by removing a contributing source of load.

Storage Rationale:	**Restoration Rationale:**
Positive (+1): The land use conversion results in long-term load reduction. **Neutral (0)**: No positive or negative effects to long-term load reduction. **Negative (-1)**: Land use conversion could contribute to downstream water quality degradation.	**Positive (+1)**: Land use conversion results in long-term load reduction. **Neutral (0)**: No positive or negative effects to long-term load reduction. **Negative (-1)**: Land use conversion results in on-site loading.
Storage Methodology:	**Restoration Methodology:**
Urban and Agricultural - i.e. crops high contribution to loads in runoff Pasture – Low to Medium loads Natural Areas – Minimally contributes to loads, or does not contribute to loads.	Urban and Agricultural - i.e. crops high contribution to loads in runoff Pasture – Low to Medium loads Natural Areas – Minimally contributes to loads, or does not contribute to loads.

Comments:
Land use is categorized as Urban, Agricultural/Crops, Pasture and Natural. Other categories can be added as needed.

Reviewed and accepted by the sub team, pending full PDT concurrence with this recommendation.

Criterion Name: IDENTIFY ENVIRONMENTAL JUSTICE	SSC – 2.6.1
Level: 2 - General Screening Criteria	
Category: Other Considerations	
Description: This screening criterion will provide an evaluation of each site for negative impacts to low income and minority populations.	
Storage and Restoration Rationale: **Positive (+1)**: If no displacement **Neutral (0)**: If no significant displacement **Negative (-1):** If significant displacement is likely to occur.	
Storage and Restoration Methodology: Utilize census data, collective team knowledge, community-based information, and any additional information sources, such as major employers of low income and minority populations in the region of the proposed site location.	
Comments: The area considered should evaluate those who live, frequent or rely on the resources of the affected area. There may be impacts to those living near the storage site. This is a preliminary evaluation for typical or foreseeable conditions and does not complete the analysis related to any specific selected site. Where subsistence-fishing opportunities are interrupted the impact warrants consideration. Where bank fishing is known to occur the assumption that subsistence-fishing opportunities exist is a reasonable assumption. When the displacement of subsistence-fishing opportunities occurs, the value may be neutral if these can be replaced. Census data is limited to the housing information on-site. Therefore, the census data would indicate where the population resides but would not indicate what activities are present and where they are located, such as subsistence fishing and work on agricultural lands. Census data where housing is displaced may be indicative if tract and site data match. Census data in rural areas is often not indicative, as tracts are large. Jobs will be related to economic activities that employ individuals affected by the site changes. Reviewed and accepted by the sub team, pending full PDT concurrence with this recommendation. Further evaluation will be made for construction and O&M access as alternatives are further developed.	
Author(s): Jerry Krenz, SFWMD, jkrenz@sfwmd.gov	

Criterion: RECREATION	**SSC – 2.6.2**
Level: 2 - General Screening Criteria	
Category: Other Considerations	
Description: This screening criterion will provide an evaluation of each site for displacement to public recreation and access.	
Storage and Restoration Rationale: **Positive (+1):** If no displacement or potential enhancement. **Neutral (0):** If no significant displacement. **Negative (-1):** If significant displacement is likely to occur.	
Storage and Restoration Methodology: Utilize land use maps and GIS information. As this is a preliminary evaluation no formal assessment process is expected. Utilize a visual assessment for evidence of boat ramps or other facilities and inquiry of local knowledge from known community leaders or SFWMD service center staff.	
Comments: Recreation includes passive hiking, wildlife viewing and other activities that may not easily be evidenced through this preliminary process. This is preliminary evaluation related to typical or foreseeable conditions and does not complete the analysis related to any specific selected site. Where displacement of activities occurs the value may be neutral if these can be replaced. A positive impact may occur if no passive recreation or access is present but it is likely to be gained. Reviewed and accepted by the sub team, pending full PDT concurrence with this recommendation. Further evaluation will be made for construction and O&M access as alternatives are further developed.

TABLE F-8: SITING METHODOLOGY SUMMARY

SCORING METHODOLOGY SUMMARY - GENERAL

* This document summarizes methodologies utilized, the site scoring process. Use this document with the scoring notes for storage and restoration

			Storage Rationale	Restoration Rationale	Storage Methodology:	Restoration Methodology:	
	Information Obtained	Description					Comments
THREATENED AND ENDANGERED SPECIES / HABITAT	GIS layers: T&E species	Endangered and Threatened Species – those animal and plant species defined by federal and/or state regulations to be endangered or threatened.	GO: Not likely to adversely affect threatened or endangered species or their habitat.	GO: Site implements recovery plan goals OR Site (either alone or when combined with other sites) results in the restoration goals being met (as defined in the projects "Goals and Objectives")	Direct impacts – GIS analysis	Direct impacts – GIS analysis	There are several threatened and endangered species found in the Caloosahatchee Basin, including the Florida panther (Felis concolor coryi), wood stork (Mycteria americana), Florida grasshopper sparrow (Ammodramus savannarum floridanus), West Indian manatee (Trichechus manatus), red-cockaded woodpecker (Picoides borealis), Florida scrub-jay (Aphelocoma coerulescens), Everglade snail kite (Rostrhamus sociabilis plumbeus), Audubon's crested caracara (Polyborus plancus audubonii), Bald eagle (Haliaeetus leucocephalus), Okeechobee gourd (Cucurbita okeechobeensis), Beautiful pawpaw (Deeringothamnus pulchellus). In addition, the Everglades snail kite has designated critical habitat.
	Known nesting areas: scrub	Habitat of Endangered and Threatened Species – defined as areas indicated on geographic information system maps of the USFWS and the FWC that contain habitats of endangered and threatened species including the zones established in the Florida Panther protection and Recovery Plan.	NO GO: Likely to adversely affect threatened or endangered species or their habitat	NO GO: Site (either alone or in rational combination with other sites) does not reasonably aid in meeting the project's restoration goals or is contrary to species recovery plan goals.	Secondary impacts – GIS analysis	Secondary impacts – GIS analysis	GIS materials include layers provided by USFWS and FWC associated with South Florida Multi-Species Recovery Plan, Southwest Florida Regional Wildlife Habitat Plan, and Closing the Gaps in Florida's Wildlife Habitat Conservation System.
	Native habitat: from National Wetlands Inventory (NWI) data				Native habitats shall be avoided as well as known nesting areas for these species on sites under consideration for storage.	Reference source material – South Florida Multi-species Recovery Plan, other adopted recovery plans and guidelines. Using a site that has been identified as habitat for threatened and endangered species for	
	T&E Species list for area						
	SW FL Regional Wildlife Habitat Plan						
SSG- SIGNIFICANT 1.02 WETLANDS	National Wetlands Inventory (NWI) data	Wetlands – those areas defined by federal and/or state regulations to be wetlands, in accordance with the regulation-prescribed hydrology, vegetation and soils criteria.	GO: Site results in no to minimal negative wetland impacts to significant wetlands.	GO: Site allows for wetland restoration benefits to target wetland types and an approximation of the original wetland function (either alone or when combined with other sites) results in some of the restoration goals being met (as defined in the project "Goals and Objectives")	Direct impacts – GIS analysis of NWI data	Direct impacts – GIS analysis of NWI data	1. GIS layers include EEA/FWC Wetlands of Significance or Listed Species and the Regionally Significant Wetlands Maps Developed in the Southwest Florida EIS and the LOCWSS (J. Beever 11/8/02). Secondary impacts will be considered in screening criteria.
	Wetland layers	Significant Wetlands – defined as one or a combination of the following:	NO GO: Site results in more than minimal impacts to significant wetlands.	NO GO: Site, alone or in rational combination with other sites, does not reasonably aid in meeting the project's restoration goals.	Direct - within footprint		2. Further detailed screening will occur during Alternatives evaluation.
	Wetlands of Significance list, Species and Regionally Significant Wetlands Maps	Wetlands of regional or state importance as defined by FAC 62-302. Wetlands, which also constitutes headwaters.					

2705

			Storage Rationale	Resources Rationale	Storage Methodology:	Resources Methodology:	
	Information Obtained	Description					Comment:
	Quad sheets for Caloosahatchee Basin	Wetlands, which if affected (positively or negatively), would result in substantial secondary impacts (which may also be positive or negative). Wetlands, which if negatively affected, could not be mitigated.					
	SW Florida EIS						
	NRCS Soil Survey Glades, Hendry, Lee County survey maps						
	GIS layers from SFA/USC						
SSC-1.83	KNOWN SIGNIFICANT CULTURAL RESOURCES	List of Historical Sites	Cultural resources – any prehistoric or historic district, site, building, structure, or object found in,	GO: Site results in no negative impacts to significant resources, or impacts, which can be practicably mitigated.	GO: Site results in no negative impacts to significant resources, or impacts, which can be practicably mitigated.	Utilizing existing and publicly available information.	Some	More detailed analysis will occur in future phases
		List of Cemeteries	or eligible for inclusion in the National Register of Historic Places (NRHP) (as defined by the National Historic Preservation Act of 1966, as amended).	NO GO: Site results in negative impacts to significant resources, which cannot be practicably mitigated.	NO GO: Site results in negative impacts to significant resources, which cannot be practicably mitigated.			Site results in area being rehydrated so its historic aesthetic appearance, OR site results in the preservation of human wooden or other organic artifacts whose condition has been degraded by dehydration.
		Nearby Archeological Sites						
		Existing Publicly available information						
SSC-1.84	KNOWN SUPERFUND SITES	Not Required	This criterion is based on whether or not a site is known as for on the USEPA Superfund hazardous waste sites list.	GO: Site is not listed as a Superfund site.	GO: Site is not listed as a Superfund site.	Compare the list of proposed sites to the list of sites on the Superfund cleanup list. (Note: There are no Superfund listed sites in Glades or Hendry Counties	Compare the list of proposed sites to the list of sites on the Superfund cleanup list. (Note: There are no Superfund listed sites in Glades or Hendry Counties	There are no superfund sites in Glades or Hendry counties.
		Site in Lee County is not in area being studied		NO GO: Site is listed as a Superfund Site.	NO GO: Site is listed as a Superfund Site.			
SSC-1.85	SAFETY IMPACTS	GIS maps	Initial review of the measures that will have to be taken to avoid or prevent the risks to human life, health, and safety by utilizing the site under review	NO GO: The site violates the criteria for dam/levee design currently utilized by the US ACOE standards or higher state standards.	N/A	GIS Assessment that identifies inhabited areas, and general topographic relief, with sites overlaid.	N/A	General JPEG file provided by SWFRPC. Sites identified as having a probability for loss of life enter intensive screening for Mitigation requirements; should such requirements not be able to be met, the site becomes removed from further consideration.
		Census Statistics		GO: The facility at the site can be designed to comply with the criteria for dam/levee design currently utilized by the US ACOE standards or higher state standards.		Distance to habited sites, and topographic assessment, can be evaluated.		Federal law PL 91-646 will be followed in the event of displacement of landowners.

2706

			Storage Rationale	Restoration Rationale	Storage Methodology:	Restoration Methodology:	
	Information Obtained	Description					Comment
					Utilizing the design criteria identified above to perform an initial evaluation of suitability.		It is a requirement of CERP to maintain the existing level of flood protection in accordance with WRDA 2000 and applicable State regulations.
							It is recognized that the project will be designed to USACOE standards or higher state standards for public safety or the criteria being specifically adopted for the Comprehensive Everglades Restoration Plan, the more stringent of the criteria. This Gate Criterion relates to the following Screening Criterion: Buffer/Setbacks; and the Land Condition subgroup criteria of Current Land Use, Soils, Topographic Relief, and Configuration Complexity.

27707

	Information Obtained	Description	Storage Rationale	Extraction Rationale	Storage Methodology:	Extraction Methodology:	Comment
SSC- BASIN 1.06 LOCATION		This criterion is based on whether or not a site is known to be in the contributing watershed for the C-43 Basin.	GO : Site is in the C-43 Basin	Same	Compare the location of the proposed sites to the C-43 Basin Map	Same	To be accepted by the PDT
			NO GO : Site is not in the C-43 Basin				
SSC- UTILITY 2.1.3 IMPACTS - 11/15	Utilities maps	Utility Impacts include existing, authorized, and potential utility facilities and/or corridors that are/may be located within, across, and/or adjacent to a proposed project site.	Positive (+2): No existing utility lines, facilities, easements or fee corridors within or immediately adjacent to the proposed project site that would need to be relocated and/or incorporated into the project design.	Same	Use a combination of existing land use information, GIS mapping information, utility information, Sunshine State Utility Locator Service, planning documents, and on-site visits to identify existing, permitted,	Same	Existing or proposed utility lines and/or other utility facilities on and/or adjacent to a proposed project site may impact the design and/or implementation of the proposed project. In some cases, depending on the type of project proposed and the type of existing or proposed lines and/or facilities, it is possible to design the project in such a way that it avoids or minimizes impacts to the existing and/or proposed lines and/or facilities. In other cases, it may not be possible to build the project without relocating and/or modifying the lines and/or facilities. Power needs during construction and/or operation of the proposed project may also be a consideration depending on the location, size and type of proposed project. Depending on the type of line and/or facility,
	*Glades County- this information must be obtained directly from county	Utilities include above ground and underground electric power, telephone, cable, fiber optic cable, water, sewer, and similar lines and related facilities such as substations, switching stations, etc.	Local power distribution lines available to provide power during construction and for operational purposes upon project implementation without major relocation or connection costs. Neutral (0):		and proposed utility lines, facilities, and corridors and specific information about each including the size of the line and/or facility, whether it is a local or regional type line and/or facility, etc.		An additional consideration for utilities that have acquired lands by easement or fee for future lines and/or facilities, but have not yet applied for or received permits for those lines and/or facilities, is the extent to which those lands are part of their overall network for providing service within their service area and how they would impact their ability to meet their service requirements in the future. A related consideration is maintenance of access to these facilities during as well as post construction of the proposed project.
	Existing Land Use Information	Authorized facilities include those that have been permitted, but are not yet constructed and/or operational. Potential facilities/corridors include those for which land has been acquired by easement and/or fee but which have not yet been permitted for a specific use.	Existing utility lines, facilities, easements, etc. can be avoided and/or incorporated into the proposed project design with minimal impacts to the existing utility lines, facilities, easements, etc. and/or the project design or timetable and/or relocated at a minimal cost.Negative (-1): Existing utility lines, facilities, easements, etc.		The number and type (local versus regional service) of existing, permitted, and proposed lines and/or facilities will be evaluated to determine whether a positive, neutral or negative value will be assigned.		
	Utility Plans; Sunshine State Utility Locator Service		cannot be incorporated into the proposed project design and must be relocated at a significant cost in order to locate the project on the proposed site, including project construction and operational needs for power. This value may also be impacted by the number and type of utility lines, facilities, etc. that may need to be relocated.				

			Storage Rationale	Restoration Rationale	Storage Methodology:	Restoration Methodology:	
	Information Obtained	Description					Comments
KSC- WETLAND 2.2.1 HABITAT	GIS maps		Positive (+1): Potential site use results in no or low level negative wetland impacts, impacts are to lower quality wetland, impacts are mitigatible. Neutral (0): Potential site use results in a low to moderate level of negative wetland), impacts may also be to average quality wetlands, impacts are mitigatable.	Positive (+1): Site contains designated wetland restoration benefits Site potentially may increase the spatial extent of functional wetlands. Neutral (0): Site (either alone or when combined with other sites) results in some of the restoration goals being met (as defined in the projects "Goals and Objectives"). Negative (-1): Site does not reasonably aid in meeting the project's restoration goals.	Direct impacts – GIS analysis Secondary impacts – GIS analysis Uses other appropriate mapping resources such as smaller scale aerials to complete preliminary review of accuracy of GIS database	Same	
	Quad sheets		"Wetlands" means those areas that are inundated or saturated by surface water or groundwater at a frequency and duration sufficient to support, and under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soils. Soils present in wetlands are generally classified as hydric or alluvial, and possess characteristics that are associated with reducing soil conditions.	Negative (-1): Potential site use results in high level of negative wetland impacts, impacts may also be to high quality wetland, impacts are difficult to mitigate.	Uses other appropriate mapping resources such as smaller scale aerials to complete preliminary review of accuracy of GIS database		Best professional analysis by team members with ecological expertise that identifies both isolated and interconnected systems that impact the site or are impacted by the site. Adjacent lands that can contribute to the restoration of or preservation of wetlands..
	GIS layers from USFWS, FWC	(Taken from FAC Chapter 62E-4.021, Definitions)	The prevalent vegetation in wetlands generally consists of facultative or obligate hydrophytic macrophytes that are typically adapted to areas having soil conditions desc These species, due to morphological, physiological, or reproductive adaptation, have the ability to grow, reproduce, or persist in aquatic environments or anaerobic soil conditions.				The screening for this item takes this into further detail than gate criteria.
			Florida wetlands generally include swamps, marshes, hardwoods, bogs, cypress domes and strands, sloughs, wet prairies, riverine swamps and marshes, hydric seepage slopes, tidal marshes, mangrove swamps, and other similar areas. Florida wetlands generally do not include longleaf or slash pine flatwoods, with an understory dominated by saw palmetto, cited above.				

27709

	Information Obtained	Description	Storage Rationale	Restoration Rationale	Storage Methodology	Restoration Methodology	Comment
PROTECTED SPC- SPECIES / 2.2.2 WILDLIFE / HABITAT	GIS maps	Protected Species. These animal and plant species defined by federal and state regulations to be endangered, threatened, or species of special concern.	Positive (+1): Site location results in no adverse impacts to protected species, other wildlife, or their habitats.	Positive (+1): Restoration site implements goals to recover or restore protected species, wildlife, and their habitats	Direct impacts - GIS analysis	Direct impacts - GIS analysis	GIS materials include layers provided by USFWS and FWC associated with South Florida Multi-Species Recovery Plan, Southwest Florida Regional Wildlife Habitat Plan, and Closing the Gaps in Florida's Wildlife Habitat Conservation System
	FWC	Habitats of Protected Species and Wildlife. These areas are defined and maintained in geographic information system by both the USFWS and the FWC. These databases contain habitats of these species.	Neutral (0): Site location results in a slight adverse impact to protected species, other wildlife, or their habitats.	Neutral (0): Restoration site (either alone or when combined with other sites) results in the restoration goals being met.	Secondary impacts - GIS analysis	Secondary impacts - GIS analysis	
	GIS layer from USFWS, FWC		Negative (-1): Site location results in low to high level of adverse impacts to protected species, other wildlife, or their habitats, or site would require a review for potential take.	Negative (-1): Restoration site (either alone or in rational combination with other sites) is contrary to the recovery or restoration of protected species, wildlife or their habitats.		Additional source material - South Florida Multi-species Recovery Plan, other adopted recovery plans and guidelines.	
SSC- CULTURAL 2.2.3 RESOURCES	List of Historical Sites	Cultural resources – any prehistoric or historic district, site, building, structure, or object found in, or eligible for inclusion in the National Register of Historic Places (NRHP) (as defined by the National Historic Preservation Act of 1966 as amended)	Positive (+1): Site consists of less than 10% high probability areas or known cultural resource sites, which can be mitigated.	Positive (+1): Site results in no adverse effect or provides a beneficial effect to eligible historic properties.	Analysis would be conducted using the results of Probability Mapping for belowground resources. Considers location of known above-ground resources	Same	High Probability Areas are areas located by the confluence of creeks and larger bodies of water, and high areas in marshy areas.
	Probability Mapping		Neutral (0): Site consists of 10-20% high probability areas or contains one to three reported cultural resources, which can be mitigated cost-effectively.	Neutral (0): Site results in negative impacts to National Register Listed/Eligible resources, which can be mitigated cost-effectively.			In accordance with Section 106 of the National Historic Preservation Act of 1966, as amended, all adverse effects to cultural resources will be avoided or mitigated in consultation with the State Historic Preservation Officer.
			Negative (-1): Site consists of 20% or greater high probability areas or contains more than three reported cultural resources or any cultural resource listed on or determined eligible for the National Register of Historic Places, which cannot be mitigated cost-effectively.	Negative (-1): Site results in negative impacts to National Register Listed/Eligible resources, which cannot be mitigated cost-effectively.			
SSC- CONSERVATIO 2.2.4 N LANDS	GIS layer from USFWS, FWC/FDEP, SFWMD, and UF	Conservation Lands – those lands and waters in conservation and preservation protection defined by federal, state, regional local government or private conservation ownership, including conservation easements.	Positive (+1): Site results in no negative impacts to conservation lands or proposed conservation lands.	Positive (+1): Site implements conservation land or acquisition goals	Direct impacts – GIS analysis	Direct impacts – GIS analysis	There are several conservation lands and on-going conservation lands acquisition projects in the Caloosahatchee Basin, including the Florida panther Ecotone project.
	CARL 1999 layer	Proposed Conservation Lands – those lands and waters in conservation and preservation protection defined by federal, state, regional local government or private conservation ownership, including conservation easements that are on official listing or documents for acquisition in fee or less-than-fee.	Neutral (0): Site results have the potential to secondarily negatively impact the acquisition of proposed conservation lands either by physical or appraisal effects.	Neutral (0): Site (either alone or when combined with other sites) results in some of the restoration goals being met (as defined in the projects "Goals and Objectives")	Secondary impacts – GIS analysis	Secondary impacts – GIS analysis	The screening criteria shall prohibit the selection of sites that will not contribute to the protection of existing conservation lands or interfere with on-going conservation land acquisition in-fee or less-than-fee simple.

2710

			Storage Rationale	Restoration Rationale	Storage Methodology:	Restoration Methodology:	
	Information Obtained	Description					Comments
	Caloosahatchee Ecoscape		Negative (-1): Site results in negative impacts to existing conservation lands or proposed conservation lands by direct effects or preventing conservation areas or preventing acquisition for conservation purposes.	Negative (-1): Site (either alone or in combination with other Sites) does not reasonably aid in meeting the project's restoration goals or is contrary to conservation goals on existing and proposed	Additional material- official land acquisition proposal lists and documents	Additional material Conservation Lands Management Plans, other adopted restoration plans and guidelines.	GIS materials include layers provided by USFWS, FWC, FDEP, SFWMD, and LN associated with land acquisition programs including Florida Forever, Save Our Rivers, Lee County 2020, Southwest Florida Regional Wildlife Habitat Plan, and Closing the Gaps in Florida's Wildlife Habitat Conservation System.

COMPREHENSIVE 95C- VE LAND USE 2.5.1 PLAN & ZONING COMPLIANCE	Future Land Use - Lee County	Identify and consider impacts on the future use of the site resulting from the existing land use and other applicable designations(s) in the local government Comprehensive Land Use Plan (CLUP) and Zoning Code that govern the use of this site and adjacent lands.	Positive (+2): No changes or special approvals under the existing CLUP & Zoning designation for the site are required to implement the proposed project.	Same	Identify: (1) the applicable local government CLUP and Zoning Code designations which apply to the proposed site; (2) the applicable CLUP and Zoning designations and special overlays or approvals required that apply to the proposed site;		If the proposed use would require an amendment to the applicable CLUP or Zoning District in order for the site to be used, this could significantly impact the timetable for and cost of implementing the proposed project due to the amount of time that it typically takes to process a CLUP amendment and/or Zoning classification time. Local governments only allow amendments to their CLUP to be filed during a designated annual or bi-annual filing period, unless they are filed in conjunction with a Development of Regional Impact (DRI) application. It is unlikely that this project would qualify as a DRI. It usually takes several months to a year to process a CLUP amendment. Zoning change requests can typically
	Comp Plans		Neutral (0): The proposed use is compatible with the current CLUP for the site, but requires a special approval under the CLUP process or a zoning change in order to be implemented. These approvals can likely be obtained within the next 6 months due to the timing of the local government's next open application filing period for CLUP approvals.		(3) whether or not a CLUP amendment or special approval or zoning classification change by the local government is required to implement the project; (4) if a CLUP amendment or special approval or zoning change is required, the ability to prepare and file that request in a timely manner within the designated application filing periods.		There may some situations where: (1) a proposed use, such a reservoir, may be incompatible with an existing CLUP or zoning classification or overlay provision, such as preservation, without modifying the existing CLUP or zoning code designation or overlay; or (2) a proposed use may be allowed within an existing CLUP or Zoning Code designation, but only by special approval and subject to additional special conditions.
	CLUP/Zoning Districts		Negative (-1): The proposed use requires a change in the current CLUP designation for the site and corresponding zoning changes to implement the proposed project and/or it will likely take at least a year to process the request due to the timing of the local government's next open application filing period for CLUP changes.				
	DRI Applicants for area

SSC- PENDING RULE 3.3.2 / REGULATORY	List of recently adopted rules/changes affecting project	Identify and consider the extent to which the proposed use of the site may be affected by: (1) rules that have recently been adopted but whose implementation is officially scheduled for a specific future date; and/or (2) proposed and/or on-going rule making activities. These rule making activities may be undertaken by local government, regional agencies (water management district/regional planning council/ other), state agencies, federal agencies, and/or Indian tribes.	Positive (+1): No recently adopted rules and/or pending rule-making activities that could affect how the site could be used for the proposed project. Neutral (0): Recently adopted rules and/or on-going rule making activities will have minimal impacts on how the site will be used for the proposed project since:	Same	(1) Identify all recently adopted rules and/or pending rule making activities by the applicable local, regional, state, and/or federal agencies and/or Indian Tribes that could affect how the site is used for the proposed project;	Same	Depending on the extent to which proposed, on-going and/or recently adopted rules/rule changes affect a project design, they could have a corresponding impact on the construction timetable and implementation dates for the proposed project. When new rules or rule changes are proposed or adopted, they typically specify a future effective date. They also specify whether the new rules are applicable to new applications only and/or to applications that have not yet been found to be complete by the reviewing agency by a specific implementation date. The content of the rule changes could also affect the proposed project design. Consequently, depending on the status of any permit applications already under review or
			(2) the content of the rule changes is such that it is not expected to significantly impact the project design; (2) the effective date of the adopted/proposed rules is far enough in the future that permits for the proposed project can likely be obtained prior to the rule changes going into effect.		(2) Review the content of the recently adopted/pending rules to identify potential impacts on project design and/or location;		
			Negative (-1): Recently adopted and/or proposed rule making activities address content areas likely to substantially affect the use of the site for the proposed project, particularly in terms of project design. Proposed rules and/or rule making activities are currently embroiled in extended legal proceedings regarding their validity.		(3) Review adopted/proposed implementation dates for potential impacts on permit application process and project timetables.		
SSC- MITIGATION / CONSERVATION EASEMENT / DEED RESTRICTIONS 3.3.2	Identify exist conservation easement/deed restrictions	Identify and consider impacts on the future use of the site resulting from existing mitigation areas, conservation easement, deed restrictions, or other legal limitations (by permit condition, land use designation, or other) on the use of the site.	Positive (+1): No existing conservation or other types of easements or deed restrictions on the property that would limit the proposed use of the property.		Identify: (1) all existing conservation easement and/or deed restrictions on all or part of the proposed site; (2) any other legally protected (by permit, land use designation, or other method) areas on all or part of the proposed site; (3) all limitations on allowable land uses and/or land use practices, water levels, clearing practices, operation and maintenance practices, including exotic control,	Same	It is assumed that mitigation lands, and other conservation management areas, are typically encumbered by conservation easement and/or some type of deed restrictions. Conservation easement, deed restrictions and/or other types of legal restrictions on land use may limit the use of the property and/or impact the design of the proposed project or facility as a result of restrictions on allowable land uses, land practices, water levels, control elevations, etc. Due to the nature of most mitigation areas, conservation or other types of easements/deed restrictions will typically limit water levels on that portion of the property covered by the easement/restriction and/or mitigation area and disallow its use as a
	legally protected lands		Neutral (0): Limitations associated with the existing conservation or other types of easements or deed restrictions on the property can be incorporated into the project design without significantly impairing the ability of the project to meet project goals.				It is assumed that impacts to natural wetland functions will be evaluated under separate criteria. The existence of these types of encumbrances on the property will influence property values. This issue will be addressed in the Green Appraisal.

2712

EFFECTS TO EXISTING NAVIGATION AND TRANSPORTATION INFRASTRUCTURE SSC-2.4.2		This screening criterion will provide an evaluation of each site for impacts to existing navigation and transportation facilities, that are adjacent to the site and would be impacted by the construction and operation of the project. In addition, use of the existing transportation systems by heavy construction traffic may have impacts or be limited by the size and condition of the system.	Positive (+2): If project is compatible.		Utilize existing maps of navigational and highway transportation systems and GIS information.	Same	The navigation and transportation systems adjacent to the site may be impacted by the construction activities and by changes to the existing facilities in order to accommodate the project may impact the costs of construction. Capability of the existing locks, roads and bridges to accommodate construction vehicles, equipment and large components of the project; i.e. HS25 loading capability for bridges. Suitability for traffic detours if needed, future acoustic and road widening.
			Neutral (0): n/a				
			Negative (-2): If project is not compatible with the existing navigation and transportation systems.				
SSC-2.5.1 PUBLIC LANDS	GIS analysis	Public lands include those lands that are owned by the federal, state or local government, including sovereign and submerged lands. Sovereign lands include all lands under bodies of navigable water and tidelands within the territorial limits of the State of Florida. Conservation lands are not included in this description since they are described in SSC 2.2.4. Public lands include those lands that may have been acquired or designated for a variety of public uses, including stormwater management, recreation, public facilities, conservation or other	Positive (+2): Storage on site is consistent with the existing or intended use of this public site.	Positive (+1): Restoration on site is consistent with the existing or intended use of this public site. Land is adjacent to restoration corridors being identified and utilized in other public projects.	Hendry, Lee & Glades County Plat Books, Save our Rivers Maps GIS analysis of FLUCFCS LULC data	Same	The ability to use public lands for the proposed project may be impacted by (1) the purpose for which the land was originally acquired, including funding sources;
	Proposed Land Acquisition Plan		Neutral (0): Storage on site is not contrary to the existing or intended use of this public site.	Neutral (0): Restoration on site is not contrary to the existing or intended use of this public site.			(2) existing and/or planned public uses of the lands; and
	Grant Appraisal Report		Negative (-2): Storage on site is not consistent with the existing or intended use of this public site.	Negative (-1): Restoration on site is not consistent with the existing or intended use of this public site.			(3) the extent to which waterways, tidelands, and riparian lands are publicly and/or privately owned and/or controlled.
	Water and Surface Water Permits						Additional approvals and/or permits may be required to use public lands for a purpose that is different than the purpose for which it was originally acquired and/or what is allowed under the funding source used to acquire the property. If applicable to the site selected, sovereign lands will be addressed in the Grant Appraisal Report for the selected plan.
	Permit search

	County Plat Books						
SSC-2.5.2 SITE SIZE	Legal Descriptions	This screening criterion will provide an evaluation of each site for parcel size and ability to acquire adjacent parcels if the site is less than one section or 640 acres	Positive (+2): If site is greater than 640 acres.	Not Applicable	Utilize existing county plat maps as well as the Count Property Appraiser's Office website to determine parcel size.		Size assumption is that one section (640 acres) / one square mile is capable of storing approximately 3,000 ac-ft at a depth of approximately 5 feet.
			Neutral (0): If site is less than 640 acres and adjacent parcels may be available for a cumulative total greater than 640 acres.				

			Storage Rationale	Restoration Rationale	Storage Methodology:	Restoration Methodology:	
	Information Obtained	Description					Comment:
			Negative (-1): If site is less than 640 acres and no adjacent parcels are available				
SSC- CURRENT 2.5.3 LAND USE	Future Land Use Maps	Land use is categorized into industrial (planned or completed), commercial (planned or completed), residential (planned or completed), agricultural (row-crops, citrus, cane and pasture), unimproved natural areas or recreational areas.	Positive (+1): Conversion of site's current land including agricultural crops, vacant residential, commercial or industrial, barren lands, abandoned mines to storage facility results in a net positive effect.	Positive (+1): Conversion of site's unimproved natural native use to restored condition results in a net positive effect	GIS analysis of FLUCFCS LU/LC data	Same	Ecological impacts are restoration under current criteria. The conversions of certain land use types to storage facilities result in less environmental and social impacts to natural systems and local human populations. Areas that have been previously legally cleared without significant human infrastructure are predisposed for storage uses. The elimination of native habitats for man-made storage facilities can result in significant environmental impacts. In contrast, restoration of existing degraded natural areas is easier to achieve, with less cost,
	Existing Comp Plans		Neutral (0): Conversion of site's land from improved pasture to storage facility results in no negative effects	Neutral (0): Conversion of site's cane, citrus, or seasonal row-crop or vacant residential, commercial or industrial, barren lands, abandoned mines use to restored condition results in no negative effects			
			Negative (-1): Conversion of site's land from unimproved natural areas, existing industrial, residential or commercial to storage facility results in net negative effect	Negative (-1): Conversion of urban, industrial, commercial, or residential use to restoration facility results in net negative effect			
SSC- NUMBER OF 2.5.4 LAND OWNERS	West Coast Land Management Region Map	Identify the number of parcels, including primary residences (permanent, year-round homes) and/or businesses that may need to be acquired in order to assemble a large enough site to implement the proposed project.	Positive (+1): Proposed site has only one landowner; strong potential for willing seller; no homeowners, tenants, and/or businesses who will need to be relocated in order to use the property.		County Tax Assessor's records, including Tract and Property Ownership data.		Dealing with conglomerates, corporations, and/or more than one individual landowner for the purchase of their property may add to the complexity and schedule for acquiring the property needed for the proposed project. If the property must be acquired through condemnation rather than from willing seller(s), and/or there are property owners who are eligible for relocation, this could significantly impact the acquisition schedule and potentially impact the construction start date. This issue will be addressed more thoroughly in the Grant Appraisal for the selected plan. The target is to minimize the total number of primary residences and businesses that may need to be acquired to implement the proposed project.
	County Tax Assessor Information		Neutral (0): Less than five landowners; little possibility that condemnation will be necessary to acquire the required parcels; less than five homeowners, tenants, and/or businesses who will need to be relocated in order to use the property.		5		A willing seller is defined as a landowner who has offered a potential site to the project.
			Negative (-1): Many landowners; strong possibility that condemnation will be necessary to acquire at least some of the required parcels; multiple homeowners, tenants, and/or businesses who will need to be relocated in order to use the property.				

2715

	Information Obtained	Description	Storage Rationale	Restoration Rationale	Storage Methodology	Restoration Methodology	Comment
SSC- EXISTING LS.5 LAND COVER	GIS analysis of FLUCFCS/LULC	Conversion of land cover types to storage or restoration facilities may result in less environmental impacts to natural systems and listed species.	Positive (+1): Conversion of Site's current land cover to storage facility results in a net positive effect.	Same	GIS analysis of FLUCFCS, LULC, and NWI data	Same	The conversions of certain land cover types to storage facilities result in less environmental impacts to natural systems and listed species that depend upon these habitats. Some areas that are legally cleared have no negative impacts since the land cover is predisposed for storage uses. The elimination of some land cover types such as invasive exotic vegetation can result in net positive environmental impacts.
	NWI data		Neutral (0): Conversion of Site's land cover to storage facility results in no negative effects, or impacts can be mitigated to equal the same result				In contrast restoration of existing degraded natural areas is easier to achieve, with less cost, using current restoration technologies. Areas developed in cane, citrus, seasonal row-crop, vacant lands, and old mines have been and can be restored using current restoration technologies but at a greater cost. Restoring existing urban, industrial, and commercial or residential land to natural conditions has not been demonstrated to be successful and has not been attempted in many cases due to economic and social costs.
			Negative (-1): Conversion of Site's land cover to storage facility results in net negative effect.				
SSC- PROXIMITY TO LS.6 WATER RESOURCES	Land Use Maps	This screening criterion will provide an evaluation of the site and proximity to the available sources or receiving waters.	Positive (+1): If the project is hydraulically connected to the source or receiving body.	Same	Utilize Land Use maps and GIS information.	Same	Costs and reductions in losses of discharges based upon greater distances from the source as well as the topography differences in this basin, which would require multiple pump stations. In addition, additional land acquisition would be required for the construction of connection between the source and the project. Higher O&M costs and head losses for greater distance, system response to rain events or droughts.
	GIS		Neutral (0): If within 1 mile of source or receiving body based on the size of the overall project.				
SSC- GEOTECHNICA LS.7 L/SOIL SUITABILITY	Geotechnical Report - Hendry County	This screening criterion will provide a structural evaluation of each site for suitability of in-situ soil conditions for the construction and operation of storage features, and suitability of soils for seepage control.	Positive (+1): If soils are structurally suitable for construction of a reservoir with nominal likelihood for structural or seepage mitigation (or small degree of mitigation).	Positive (+1): If soils are structurally suitable for restoration and/or groundwater recharge.	Utilize USGS and NRCS/USDA Soil Survey Information.		Suitability for use in construction – structural fill for levees & roads, STA/wetland species, slope dressing, and seepage containment.
	USGS quad Sheets		Neutral (0): Minimal structural or seepage impacts and/or moderate likelihood for mitigation (or moderate degree of mitigation).	Neutral (0): Unknown.			For Storage, minimizing seepage losses will improve the project efficiency. For Restoration, seepage will improve the groundwater table and water quality, potentially improving natural habitat. Seepage control costs will vary per site due to local geology and fill materials. Seepage issues are more inflammatory in urban/suburban areas.
			Negative (-1): Extensive structural or seepage mitigation and/or considerable likelihood for mitigation (or considerable degree of mitigation).	Negative (-1): Soils not suitable for restoration and/or groundwater recharge

	Information Obtained	Description					Comments
SSC-2.5.5 SITE CONTRIBUTION - WATERSHED - WATER QUANTITY	Used infrared map coverage with coverage of project sites provided by Schedo on 01/13/05. Need topo map provided by ACE. Not available at time of this screening.	The storage screening criterion will provide an evaluation of each site's location within the watershed for the capture of runoff from watershed (See 77 on S-79).	Positive (+1): If site could capture watershed runoff from >= 75% of watershed area.	Positive (+1): Upper tributary floodplain. Storage scheme supports natural hydroperiods.	Utilize the existing Caloosahatchee watershed map, other existing maps and GIS information.		A sites ability to capture a significant amount of water would increase the overall project benefit to the estuary by reducing the impacts of runoff and providing the captured flows during dry periods. Amount of capture, % of basin runoff & volume. Dependent upon other sites under consideration.
	Caloosahatchee Watershed Map	The restoration screening criterion is tailored toward the ability to provide potential passive/natural storage in the upper tributary.	Neutral (0): If site could capture watershed runoff from 50 to 75% watershed area.	Neutral (0): Location between upper tributary and tail water floodplains.			Lake O releases can be caught anywhere in the C-43 Canal and is therefore not location dependent.
			Negative (-1): If site captures watershed runoff of < 50% watershed area.	Negative (-1): Tail water floodplain.			Reviewed and accepted by the sub team, pending full PDT concurrence with this recommendation.
SSC-2.5.6 SITE CONTRIBUTION TO LOAD	Pump station data	Does the site land use contribute degrading water quality constituents to the watershed, river, and estuary? By placing a storage or restoration feature within the watershed the land from runoff can be reduced in-place, and reduce the capacity / area needed for project features required for storage or water quality treatment needed for the project as a whole by removing a contributing source of load.	Positive (+1): The land use conversion results in long-term load reduction.	Positive (+1): Land use conversion results in long-term load reduction.	Urban and Agricultural - i.e. crops high contribution to loads in runoff	Urban and Agricultural - i.e. crops high contribution to loads in runoff	Land use is categorized as: Urban, Agricultural/Crops, Pasture and Natural. Other categories can be added as needed.
	Land runoff Data		Neutral (0): No positive or negative effects to long-term load reduction.	Neutral (0): No positive or negative effects to long-term load reduction.	Pasture – Low to Medium loads	Pasture – Low to Medium loads	
			Negative (-1): Land use conversion could contribute to downstream water quality degradation.	Negative (-1): Land use conversion results in on-site loading.	Natural Areas – Minimally contributes to loads, or does not contribute to loads.	Natural Areas – Minimally contributes to loads, or does not contribute to loads.	
SSC-2.5.1 0 STORAGE CAPACITY	GIS analysis	This screening criterion will provide an evaluation of each site for the volume of storage capacity.	Positive (+1): If site could store greater than 10,000 ac-ft.	Positive (+1): Depths and hydroperiods appropriate for the maintenance of the natural community can be achieved.	Utilize GIS information and NRCS Soil Surveys to determine the best possible site location.		Minimizing the number of reservoir locations reduces the design and construction costs as well. Managing land costs – smaller sites with greater depth – lower costs.
	NRCS Soil Surveys		Neutral (0): If site could store 5,000 to 10,000 ac-ft.	Neutral (0): Uncertain.			CERP assumed a storage depth of 8 feet for planning purposes, however, a storage depth of greater than 8 feet could yield a larger volume per acre ratio.
			Negative (-1): If site could store < 5,000 ac-ft.	Negative (-1): Depths and hydroperiods appropriate for the maintenance of the natural community are not likely to be achieved.

WSG-2.5.1 GROUNDWATER RECHARGE	Soils and Geological Maps	For the purposes of these screening criterion, ground waters are characterized and regulated in accordance with the definitions and regulations provided in Federal and State law. It is noted that when ground water recharge is the likely result of any specific feature, special attention and potential protective measures may be necessary to protect the quality of these ground waters and/or their use. Federal and State regulations restrict the permitting/construction of projects that may cause or contribute to the [illegible]	Positive (+1): Minimal potential for ground water recharge.	Positive (+1): Considerable potential for ground water recharge.	Based on available soils, geological maps, recharge maps, well field protection maps, and/or other readily available literature, the degree of surface water and ground water interaction/connection at the site will be	Some	Storage Methodology: The objective is to minimize ground water and surface water interactions. The ability to store water in a reservoir/impoundment is improved if ground water recharge rates at the site are minimal. The goal is to hold water in the reservoir/impoundment and minimize unaccountable outflow.
			Neutral (0): Moderate potential for ground water recharge.	Neutral (0): Moderate potential for ground water recharge.	Based on available soils, geological maps, recharge maps, well field protection maps, and/or other readily available literature, the degree of surface water and ground water interaction/connection at the site will be assessed.		Restoration Methodology: The objective is to provide for ground water and surface water interactions. The ability recharge ground water near an aquifer recharge area and/or a wetland with ground water dominated hydrology is improved if ground water recharge rates at the site are considerable. The goal is to increase ground water levels and/or aquifer recharge rates by impounding water on the site to enhance the quantity of ground water recourses. If restoration is desired, special attention should be afforded to the quality water to be impounded.
			(0*) Available information is insufficient to make a determination	(0*) Available information is insufficient to make a determination.			
			Negative (-1): Considerable potential for ground water recharge.	Negative (-1): Minimal potential for ground water recharge.			
WSC-2.5.3 SURFACE WATER		Surface waters are classified by public use criteria (Class I is potable, Class II is shellfish harvesting, and Class III is fishable/swimmable). Surface waters in Florida are considered "impaired" or degraded based upon water quality standards associated with these classifications and evaluative procedures established by the State in the "Impaired Waters Rule." Federal and State regulations restrict and in some cases preclude the permitting of projects in surface waters identified as failing to meet public use requirements	Positive (+1): Source water is not impaired or degraded. Neutral (0): Available information is insufficient to make a determination Negative (-1): Source water is impaired or degraded.	Positive (+1): Source water is not impaired or degraded. Neutral (0): Available information is insufficient to make a determination Negative (-1): Source water is impaired or degraded.	Maps and lists of waters classified as "impaired" or degraded according to the federal 303(d) list, State 303(b) list, or by other federal environmental assessments, i.e., EA, NEPA, EIS, etc. will be reviewed to determine if the site is likely to receive from or discharge to water bodies with recognized water quality problems.	Some	Storage Comment: The objective is to allow for the capture and detention of as much water as is possible, while maximizing flexibility in storage feature operation. If tributaries that contribute water to the site have been identified as having water quality problem (i.e., excessive concentrations and/or loads of pollutants), future options for the correction of such problems may be reduced via the construction of the storage feature. It is recognized that NPAs or other treatment may be needed to meet TMDLs once they are established.
							Restoration Comment: If tributaries that contribute water to the site have been identified as having water quality problems (i.e., excessive concentrations and/or loads of pollutants), future options for the correction of such problems could be improved and/or expanded via the construction and/or incorporation of water quality treatment/enhancement features. However, for the purposes of restoration of on-site ecological conditions the goal is to import as little polluted water as possible onto the site to be restored.

2719

			Storage Rationale	Restoration Rationale	Storage Methodology:	Restoration Methodology:	
	Information Obtained	Description					Comment
							This screening criterion is looking at on-site conditions and on-site habitat and the impacts that source water quality could have on those. The project should avoid point sources and not impair water bodies.
SSC-2.5.1.4	HYDRAULIC DIFFERENTIAL						
	Used coverage of project sites provided by Scheda on 02/13/03. Not available at time of this screening				Utilizing existing topographic maps to determine the differential between the known elevations of the source water and the existing site ground elevation.	Same	The average elevation of the site and the difference between that elevation and the elevation of the water source available for storage is a factor to consider in selection of a desirable facility, be it reservoir or restoration. The greater the difference between the elevation at a site and the elevation in the C-43 or other identified source water body, the higher the lift required to move the water into storage; and potentially an increase in pumping cost or number of pumping stages. It is desirable to have as low a lift as necessary and sites with low average elevation relative to the reach on the C-43 will be ranked higher.
	USGS Topographical maps						The proposed ranking scale is presented below, and takes into consideration the elevations of the water pools in the C-43.
							Source Elevation in C-43 between S-79 and S-78, approximately 5 feet msvd
							Source Elevation in C-43 between S-78 and S-77, approximately 11 feet msvd
							Source Elevation in other source water bodies will be determined on a CBC basis.
							Note
							(1) The criteria is not based on the actual average elevation, but on a difference, sites in the East or West basin may have same elevation but differ in ranking due to difference in water level in the C-43 in either basin.
							(2) Higher cost associated with additional pumping is the primary undesirable factor
							(3) Less than 2 feet difference may necessitate pumping for both filling or releasing from

			Storage Rationale	Restoration Rationale	Storage Methodology:	Restoration Methodology:	
	Information Obtained	Description					Comments
SWSC-2.5.3.5 DEGREE OF TOPOGRAPHIC RELIEF	USGS Maps	The degree of topographic relief on the site is a measure of elevation gradient across the site. A relatively flat site would have little change in elevation between its highest region and its lowest region. In the converse, a site with high topographic relief would have a large difference between the elevation at the highest region and elevation at the lowest region. We have used region in place of point in this definition to distinguish the effect of a local and isolated through or knoll (or mound) from that of a	Positive (+1): Minimal differences in relief. Less than 2 feet of difference across the section.	N/A	USGS Digital Elevation Maps		Sites with high topographic relief would require significant earthwork and may limit design of a project by requiring sectioning /partitioning of the site where a single unpartitioned project might have been desirable. In the case of a reservoir, additional pumping / infrastructure may be required to move water between partitioned cells. It is desirable to have as low a topographic relief on the site as possible and sites with low topographic relief will be ranked higher.
			Neutral (0): 2 to 6 feet of difference across the section.				A section refers to a one-mile area.
SSC-2.5.1.6 WATER SUPPLY SEEPAGE ISSUES	GIS/ Coverage of the process of developing freshness potential maps and defining areas of potential recharge for C-43 watershed. Freshness potential maps developed for south of C-43 canal as part of SWFS. (Map 22) in GPD/cubic foot. Used infrared map coverage with coverage of project sites provided by Schada on 03/13/03.	This screening criterion will provide an evaluation of each site for effects of seepage on local water supply wells.	Positive (+1): Potential for supplying water via seepage losses, criteria value.	Same	Utilize a standard engineering approach for controlling seepage, i.e. seepage collection, which would result in a positive 1 rating versus seepage cutoff, which would result in a negative1 rating.		Much of the study area (S-77 to S-79) residential water supply is provided by seepage from the agricultural irrigation seepage. This project must maintain that type of supply or provide alternative sources for human consumption. Ability to get seepage where and when needed, proximity to people and water supply intakes.
			Neutral (0): n/a.				
			Negative (-1): Inability to supply water via seepage losses.				
SSC-2.5.1.7 UNIQUE NATURAL AND MANMADE FEATURES		This criterion captures unique natural and manmade features that are not listed or eligible for listing on the National Register of Historic Places (NRHP). These would include areas of local and regional importance such as cemeteries, monuments, structures, geological features, significant trees, natural springs, etc.	Positive (+1): No involvement, or site results in a positive impact to such features.	Same	Data sources would include Chambers of Commerce, County Historians, collective team knowledge, available maps, and/or reports regarding these types of features within the C-43 Basin.	Same	Items included on the NRHP or eligible for listing fall under the Site Screening Criteria 2.2.3 Cultural Resources.
			Neutral (0): Site results in no negative impacts.				
			Negative (-1): Site results in negative impacts to identified features.

SSC-2.5.4 UNDESIRABLE ADJACENT LAND USE INFLUENCES	GIS	This screening criterion will provide an evaluation of each site for: landfills, fuel depots (gas stations), incinerators, water/wastewater treatment or supply facilities, mining, industrial/manufacturing facilities, and airports.	Positive (+1): No potential for land, groundwater, or airborne contamination.	Positive (+1): No potential for land, groundwater, or airborne contamination.	Utilize land use maps and GIS information to determine adjacent land use and determine potential contamination based on collective team knowledge.	Same	Not to put the reservoir in areas that could be potentially contaminated and therefore spread the pollutants in the estuary. Recognize the sensitivity of exported water supply.
	Land Use maps		Neutral (0):	Neutral (0):			
			Negative (-1): Potential contamination.	Negative (-1): Potential contamination.			
SSC-2.5.5 CONFIGURATION COMPLEXITY	Topographical Maps	This screening criterion will provide an evaluation of each site for the potential design and construction complexity based upon site geometry.	Positive (+1): If site consists of regularly shaped geometry, four sides/corners approx. 90 degree inside angles.		Assessing the shape/configuration of each site on a case-by-case basis for overall shape as well as internal configuration utilizing county maps and GIS information.		A site's shape will have a great impact upon the cost of design and construction as well as the utility/functionality of the site.
			Neutral (0): If site consists of non-regular shape, 5 – 6 corners, no inside corner angles less than 65 degrees.				
			Negative (-1): If site consists of very irregular shape, > 6 corners, inside corner angles of extreme size.				

2722

SSC-2.5.2 TAX BASED IMPACTS	GIS of FLUCCS/LULC data	Land use of industrial, commercial, residential, agricultural areas provide the tax base necessary for the counties to provide essential services. Conversion from these units will have an impact on the tax base.	Land use of industrial, commercial, residential, agricultural areas provide the tax base necessary for the counties to provide essential services. Conversion from these units will have an impact on the tax base.	Positive (+1): Barren, vacant or abandoned land: when have been impacted.	GIS analysis of FLUCFCS/LULC data	GIS analysis of FLUCFCS/LULC data	Economic impacts are addressed under another criteria.
				Neutral (0): Unimproved or natural areas.			Improved land is defined as existing industrial, residential or commercial land.
SSC-2.5.3.1 SOIL CHEMISTRY SUITABILITY	DEAS/USDA/FDEP local or other database	This screening criterion will provide a potential contaminant evaluation of each site for suitability of in-situ soil conditions for the pre-construction and operation of storage features.	Positive (+1): If soils are chemically suitable for construction of a storage feature with minimal likelihood for mitigation (or small degree of mitigation) or cleanup.	Positive (+1): If soils are suitable for restoration, minimal likelihood for cleanup.	Utilizing the DEAS/USDA/FDEP/local/or other databases and resources to identify the current and historical land uses for potential contaminant evaluation. Readily ascertainable databases.		The degree to which on-site soils may be potentially contaminated due to historical land use practices (such as agricultural, industrial, and/or former military) will likely affect project costs associated with on-site soil quality characteristics and/or cleanup/remediation.
			Neutral (0): Minimal chemical impacts and/or moderate likelihood for mitigation (or moderate degree of mitigation) or cleanup.	Neutral (0): Unknown or moderate likelihood for cleanup.	This will not necessarily capture historical hazardous waste incidents, which are captured in the site criterion SSC 1.3.4 Known Superfund Sites.		If contamination is found on a proposed site location, the private landowner must pay for the clean-up/remediation prior to handing it over to the C-43 Basin Storage Reservoir Project. However, if the land is under public ownership the Project will have to pay for the clean-up/remediation, which could increase the project cost.
			Negative (-1): Extensive chemical mitigation and/or considerable likelihood for mitigation (or considerable degree of mitigation) or cleanup.	Negative (-1): Considerable likelihood for cleanup.			
SSC-2.6.1 IDENTIFY ENVIRONMENTAL JUSTICE	Census data	This screening criterion will provide an evaluation of each site for negative impacts to low income and minority populations.	Positive (+1): If no displacement	Same	Utilize census data, collective team knowledge, community-based information, and any additional information sources, such as major employers of low income and minority populations in the region of the proposed site location.	Same	The area considered should evaluate those who live, frequent or rely on the resources of the affected area. There may be impacts to those living near the storage site.
			Neutral (0): If no significant displacement				This is a preliminary evaluation for typical or foreseeable conditions and does not complete the analysis related to any specific selected site. When subsistence-fishing opportunities are interrupted the impact warrants consideration. Where bank fishing is known to occur the assumption that subsistence-fishing opportunities exist is a reasonable assumption. When the displacement of subsistence-fishing opportunities occurs, the value may be neutral if these can be replaced.

2723

			Storage Rationale	Restoration Rationale	Storage Methodology:	Restoration Methodology:	
	Information Obtained	Description					Comment
			Negative (-1): If significant displacement is likely to occur.				Census data is limited to the housing information on-site. Therefore, the census data would indicate where the population resides but would not indicate what activities are present and where they are located, such as subsistence fishing and work on agricultural lands. Census data where housing is displaced may be indicative if exact and site data match. Census data in rural areas is often not indicative, as tracts are large. Jobs will be related to economic activities that employ individuals affected by the site changes.
							Further evaluation will be made for construction and O&M screen as alternatives are further developed.
3SC-2.6.1 RECREATION	Aerials	This screening criterion will provide an evaluation of each site for displacement to public recreation and access.	Positive (+1): If no displacement or potential enhancement.	Same	As this is a preliminary evaluation no formal assessment process is expected. Utilize a visual assessment for evidence of boat ramps or other facilities and inquiry of local knowledge from known community leaders or SFWMD service center staff.	Same	Recreation includes passive hiking, wildlife viewing and other activities that may not easily be evidenced through this preliminary process.
	List of Parks and Recreation Areas		Neutral (0): If no significant displacement.				This is preliminary evaluation related to typical or foreseeable conditions and does not complete the analysis related to any specific selected site.
			Negative (-1): If significant displacement is likely to occur.				Where displacement of activities occurs the value may be neutral if these can be replaced. A positive impact may occur if no passive recreation or access is present but it is likely to be gained.
							Further evaluation will be made for construction and O&M screen as alternatives are further developed.

G.0 ECONOMIC AND SOCIAL CONSIDERATIONS

G.1.1 Introduction

The Caloosahatchee River (C-43) West Basin Storage Reservoir Project recommended plan is an important piece of the south Florida ecosystem improvement efforts that together make up the overall Comprehensive Everglades Restoration Plan (CERP). This part of the project report is concerned with the socio-economic issues of plan implementation. The primary effects of the project are the costs of implementation, and the ecosystem restoration and improvement effects. The net national project cost (National Economic Development [NED] cost) represents the largest monetarily expressed impact of plan implementation. Project costs have regional impact dimensions as well, as expenditures on the project can cause changes in local and regional earnings, sales, and employment, due to the ripple effect of project spending throughout the regional economy. The most significant beneficial effect of the project is the ecosystem improvement expected to result from the plan. This major benefit is not expressed in monetary terms, in accordance with policy. A Cost Effectiveness/Incremental Cost Analysis (CE/ICA) is utilized to determine the alternative that provides least unit cost per unit of benefits.

G.1.2 Purpose of this Investigation

This investigation assesses the economic effects of the alternative ecosystem restoration plans formulated in the feasibility phase of the Caloosahatchee River (C-43) West Basin Storage Reservoir Project. The economic evaluation of the alternative restoration plans includes five principal elements:

Socio-economic Profile of the Study Area: This profile includes population and economic forecasts for the region, as well as projections of future water demand.

Anticipated Effects of Alternative Plans on the National Economic Development (NED) Account: Alternative plans could result in positive or negative effects on net national economic efficiency due to project-induced impacts on the following economic activities in south Florida:

- Agricultural water supply
- Municipal and industrial (M&I) water supply
- Flooding potential
- Recreation
- Commercial and recreational fishing

Evaluation of Project Costs: Project costs include all expenditures required to implement the alternative plans. The Federal government and the State of Florida will share these costs. Project costs include those for initial construction; lands; relocations; rights of way; rehabilitation, replacement, and repair; and operations and maintenance (O&M) (including the costs of post-construction monitoring and adaptive management).

Regional Economic Development (RED) Effects: The potential RED effects of the Selected Alternative Plan (SAP) include changes in income, employment, or economic output of the region.

Other Social Effects (OSE): The potential social effects of the SAP include effects on minority, elderly, and disadvantaged groups, population displacement, and effects on community cohesion.

The economic analysis for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project was conducted consistent with Federal statutes and U.S. Army Corps of Engineers (USACE) policy. Procedures for estimating NED and RED effects are specified in the Economic and Environmental Principles and Guidelines for Water and Related Land Resources Implementation Studies (U.S. Water Resources Council, 10 May 1983), Engineering Regulation (ER) 1105-2-100 (22 April 2000), and other USACE guidance.

G.1.3 Methodology

A number of factors were considered prior to developing the methodologies used to evaluate the economic effects of the alternative restoration plans. These factors include: available analytical tools, economic theory, Federal policy, obtainable data, and time and budgetary constraints. These factors are discussed below.

G.1.3.1 Without-Plan and With-Plan Conditions

Proper definition of the without and with-plan conditions are critical to the planning process. The without-plan condition is the most likely condition expected to exist in the future in the absence of a proposed project. The future without plan condition (2050) is the benchmark against which alternative future with-plans are evaluated. National and regional socio-economic parameters considered include income, employment, population, and other aggregate projections such as land use trends, water supply, and water demand. Comparisons of conditions with the implementation of alternative plans to future without-plan conditions were performed to identify the beneficial and adverse effects of the proposed plans. Depending on the alternative and the type of economic impact changes resulting from implementation of a restoration plan, it may be desirable or undesirable when compared to the future without-plan

condition. For example, alternatives that include modifications to the current system to provide additional water storage areas may result in fewer economic losses associated with agricultural (irrigation) water shortages. This would be a desirable ancillary benefit of restoration.

G.1.3.2 Sources and Causes of Economic Effects

The potential economic impacts of the alternative restoration plans are secondary consequences of the environmental improvements and hydrologic changes that are expected to result from the proposed structural and operational modifications to the Caloosahatchee River (C-43) West Basin Storage Reservoir Storage Reservoir project study area. These projected impacts are contingent upon the successful implementation and operation of restoration plans and subsequent outputs and therefore, subject to the uncertainties inherent in those ecosystem restoration activities. Due to the challenges inherent in quantifying National Ecosystem Restoration (NER) benefits, quantifying the resulting NED benefit is also a challenge. Nonetheless, there are methods for evaluating the economic efficiencies of alternative restoration plans.

G.1.3.3 Methodology for Conducting Economic Analysis

Consistent with USACE Guidance, a benefit-cost analysis is not required for NER plans. For ecosystem restoration projects, a plan that reasonably maximizes ecosystem restoration benefits compared to costs, consistent with the Federal objective shall be selected. The methodologies used to conduct economic analysis studies for the project were based on a combination of factors, including: economic theory, USACE's ecosystem restoration and economic evaluation policies, and the characteristics of methodologies used by economists to value ecosystem benefits. For this study, the alternative restoration plans were compared using information in monetary and non-monetary units. The economic analysis of Caloosahatchee River (C-43) West Basin Storage Reservoir Storage Reservoir alternative restoration plans include: (1) the NED costs (in monetary terms), (2) the anticipated environmental benefits resulting from restoration measures (in non-monetary terms), (3) the NED benefits and impacts attributable to the following: agricultural water supply, municipal and industrial (M&I) water supply, commercial navigation, recreation, and commercial fishing (in monetary and non-monetary terms) and (4) the positive and adverse regional economic effects (RED) resulting from project implementation.

This section of the report addresses items (1), (3), and (4) above. The economic basis for making policy decisions about whether to invest public funds in ecosystem restoration for this project is comparing monetary costs and non-monetary benefits in order to determine whether the expenditure is justified and

to select the plan which minimizes the cost of obtaining ecosystem benefits. The costs of ecosystem restoration projects include: initial construction costs; major rehabilitation and repair costs; operations and maintenance (O&M) costs; post construction monitoring costs; and adverse NED effects. Typically, these costs can be expressed in monetary (i.e., dollar) terms.

The principal challenge of ecosystem restoration economics is estimating the value of restoration benefits. The primary purpose of each alternative plan is ecosystem restoration. The benefits of ecosystem restoration are usually expressed by ecologists in non-monetary units, such as acres of specific habitat created, indices of biological productivity associated with habitat improvement, or increased abundance and/or diversity of particular species of plants or animals. For decision-making purposes, it would be desirable to express ecosystem restoration benefits in monetary terms, in order to compare them with project costs. Expressing the costs and benefits of alternatives in a common, monetary metric would facilitate selection of the best restoration plan for a given site. However, calculating the monetary value of environmental amenities is both difficult and controversial. Environmental amenities are public goods that are generally not exchanged in the marketplace. For marketable commodities (i.e., items that people buy and sell), the demand and prices paid for these goods can be used as "proxies" for determining their value to consumers. In the absence of data on consumers' expenditures for environmental amenities, resource economists have attempted to develop techniques that can be used to estimate their value using indirect indicators of consumers' "willingness to pay" for ecosystem restoration. For goods and services that are not purchased in the marketplace, non-market valuation approaches must be used to infer their value to the public. There are direct and indirect use values for these goods and services. Use values refer to the value consumers obtain from using a good that is related to an environmental amenity. For example, recreational fishermen obtain direct use value from the freshwater fisheries. The fishermen also obtain indirect use values from the ecosystem, since it provides ecological functions that contribute to the productivity of the fisheries. Use values can be either consumptive or non-consumptive. Consumptive use values refer to the cases for which the good is consumed by the user and is no longer available to others, such as waterfowl hunting. Non-consumptive use values refer to the value obtained by a user in cases for which the good remains to be used by others in the future, such as catch-and-release fishing or bird watching. It is reasonable to expect that the alternative restoration plans will generate additional use values to the public. Non-market activities that would benefit from restoration plans include recreational fishing, subsistence activities, and a variety of eco-tourism related activities (e.g., bird watching, hiking and canoeing).

Non-use values include the values the public obtains from simply knowing that the good or resource is available, even if they have not used it previously.

Individuals may value a good simply from knowing it exists (existence value) or because they may want to have the opportunity to use it at some future time (option value). Again, it is reasonable to expect that the alternative restoration plans will generate additional non-use values to the public. The tremendous interest in and support for ecosystem restoration, not just in south Florida but throughout the country (and the world), is an indication that a broad segment of society values the ecosystem, even though most have never experienced the area first hand.

Theoretically, it should be possible to determine the value of restoring the Caloosahatchee River and Estuary ecosystem by asking people what they would be willing to pay for different levels and types of restoration projects, or by observing what they spend on ancillary costs (e.g., travel, subsistence, equipment) when they engage in these non-market experiences. Economists have developed a variety of techniques to estimate society's willingness to pay for these types of non-marketable environmental amenities. These economic valuation techniques include market-based, surrogate market, and non-market methodologies (see Freeman, 1993). Market-based approaches estimate the value of environmental resources using information generated in the marketplace. These approaches include changes in factors of production, valuation of complimentary goods and services, defensive expenditures, and market valuation of the next best alternative. Surrogate-market techniques estimate value based on preferences revealed in surrogate markets. These techniques include the travel cost method and hedonic valuation. The contingent valuation method (CVM) is the most widely accepted non-market valuation methodology. CVM is perceived as the most effective technique to determine society's willingness to pay for environmental protection and/or restoration and is the only technique able to estimate non-use (i.e., option and existence) values. This method is based on carefully designed surveys that solicit respondent's willingness to pay for a specific environmental resource in a given condition. The survey is intended to reveal both users' and non-users' willingness to pay for the resource.

Unfortunately, these surrogate-market techniques, including CVM, have significant shortcomings that lead to concerns about their reliability and validity. They are especially problematic in cases for which respondents are unfamiliar with the environmental amenity, when the issue is controversial, or where it generates strong reactions, based on ethical, rather than economic motivations. Most importantly for the Caloosahatchee River (C-43) West Basin Storage Reservoir effort, the reliability and validity of these techniques are especially questionable in situations in which the actual changes that would result from the restoration efforts are difficult to precisely describe or visualize. Finally, stated preference methods, such as CVM, can be expensive to implement, especially when multiple alternatives are being evaluated.

As specified in USACE's ecosystem restoration policy (EC 1105-2-210: Ecosystem Restoration in the Civil Works Program), ecosystem restoration projects are not subject to traditional benefit-cost analyses. An ecosystem restoration proposal must still be justified by comparing the monetary costs and non-monetary benefits of restoring degraded ecosystems. USACE ecosystem restoration evaluation procedures focus on the non-monetary benefits of restoration, comparing these benefits to monetary costs using CE/ICA procedures.

G.1.4 Prior Studies

This study relied on the use of prior studies and other secondary information to the extent possible. These studies are contained in the reference list presented at the end of this appendix. The South Florida Water Management District (SFWMD) has previously conducted a wide variety of studies that directly or indirectly support this investigation. Interviews with SFWMD staff and review of SFWMD reports have contributed greatly to this investigation.

G.1.5 Organization of Appendix

The sections that follow evaluate the economic impacts of the alternative restoration plans. Section G.2 develops a socio-economic profile for the region, and Section G.3 contains the water demand forecasts for the region. The following sections develop the basis for critical physical and socio-economic effects of the future conditions, with-plan and without-plan. The costs and the incremental analysis of the alternative plans are presented in Sections G.7 and G.8. The regional economic effects and other social effects (OSE) of the alternative plans are explored in Sections G.9 and G.10 respectively.

G.2 POPULATION AND ECONOMY

G.2.1 Overview

This section of the appendix includes a description of the local economy and demographics of the study area. This descriptive information provides insight into the study area's socio-economic characteristics, and provides part of the basis for different facets of the economic impact evaluation work in the rest of this appendix.

The people who live in the study area, and the economic activity, in which they are engaged, comprise important components of the area's total environment. In addition to the direct use of this data for the water use projections and OSE mentioned above, residents of the study area represent the socio-economic environment for the other impact topics of flooding, water use shortages, fishing, recreation, and navigation.

Any course of action forthcoming from this study will have effects throughout an economic system as well as the natural ecosystem(s), the health and sustenance of which are the impetus for this investigation. The economic system is connected with the natural ecosystem and in general is ultimately dependent upon it for survival. This connection is especially strong in the study area. Adverse changes in the health and condition of the natural system can cause severe negative impacts on the economic system, particularly in the study area for this feasibility study. Conversely, in this study area, beneficial changes to the natural system are expected to have a strong positive effect on the economic system. It is significant, therefore, to describe and understand the general economic and social environment within which such changes could take place. Although the main focus of economic impact evaluation efforts undertaken for this study has been to describe the economic impacts and benefits of alternatives being considered for implementation, describing the broader context for these evaluation efforts is also necessary and important.

G.2.2 Economic and Social Well–Being Problems and Opportunities

As a result of the C&SF project, by providing flood protection and an available supply of drinking water, the population of south Florida has grown from approximately 900,000 as reported in 1950 to a population of over 5.5 million in 1995. By the year 2050, the population of south Florida is projected to grow to 11.6 million. Lee County has one of the fastest growing populations in both south Florida and in the state. The increased growth in population can be attributed to an inflow of retirees and not as a result of high birth rates for this area. The coastal areas in these counties have become highly urbanized. As a result, this urbanization has caused development to move westward into areas that were once agricultural or natural.

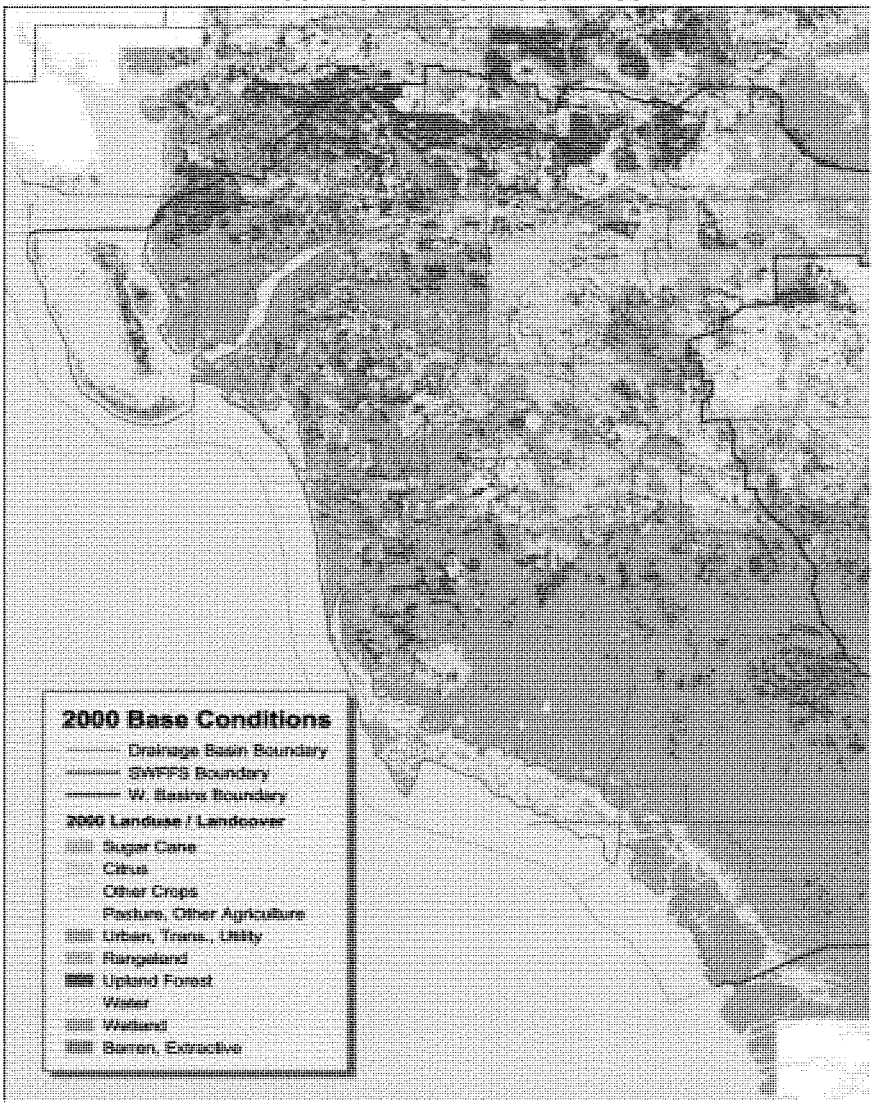
The Governor's Commission for a Sustainable South Florida identified agriculture and tourism as "critical industries" for maintaining the economy in the southern part of the state. In Lee and Hendry counties, agriculture is a major industry and citrus production predominates. A rapidly expanding human population demanding more developable lands and advancing agricultural development now threatens the relatively pristine natural areas. The tourism industry is also dependent upon the region's ability to sustain its economy and its quality of life through management of its resources. Agriculture and tourism depend on a system that can provide vital water supply needs and flood protection.

Competition for regional water resources has intensified with the increase in population and agriculture industry growth. This places a strain on existing resources, which will eventually surpass the readily available sources. When the needs of the natural system are then factored in, demands become greater and conflicts among competing water users will become even more severe. While

most people recognize the need for a healthy ecosystem to support the region's economy and jobs, many people are concerned that restoration projects will displace farms and other businesses, limit development, reduce available water supply and reduce job opportunities. By contrast, continued degradation of the south Florida ecosystem will adversely affect the tourism and recreational industry that are important to the regional economy.

G.2.3 Study Area

Located on Florida's lower southwest coast, the Caloosahatchee River region extends approximately 70 miles from Lake Okeechobee to the lower Charlotte Harbor Basin at San Carlos Bay. The Caloosahatchee River Region is the northern portion of the SFWMD's Lower West Coast (LWC) planning area. The Caloosahatchee River region is divided into seven drainage basins according to hydrologic characteristics. These basins are the C-21, East Caloosahatchee and West Caloosahatchee Basin, Orange River, S-236, Telegraph Swamp Basin and the Tidal Caloosahatchee Basin (SFWMD, 1995), (Figure 1-2). These basins include parts of Charlotte, Glades, Hendry, and Lee counties and extend slightly into Collier County. There are three municipalities located within the study area. They are:



Clewiston
LaBelle
Moore Haven

G.2.4 Existing and Forecasted Land Use

G.2.4.1 Existing Land Use

Figure G-1 depicts the 2000 land use map for the southwest Florida Region. This map was generated for the southwest Florida Feasibility Study and includes the Caloosahatchee River (C-43) West Basin Storage Reservoir Storage Reservoir study area.

FIGURE G-1: EXISTING LAND USE

Much of the land use/cover change occurring in southwest Florida over the past several years can be categorized as either the creation of new developments in previously natural or agricultural areas, or the change in the types of agriculture practiced. Most of the new development appears to be in golf course/residential

areas concentrated near Interstate 75 in Lee County. A majority of these residential areas and small reservoirs were associated with new golf course communities.

Table G-1 presents the number of acres associated with existing golf courses.

TABLE G-1 GOLF COURSE ACREAGE

County	Year	Acreage
Lee	2000	8,962
Hendry	2000	120
Glades	2000	220
Charlotte	2000	460

The agricultural areas are inland from the urban areas and the Gulf Coast. They are being encroached upon by the urban areas and undergoing conversion within agricultural types. Much of Lee County is being converted from cattle farms to citrus, and there is a great deal of conversion year to year between pasture and row crops.

G.2.4.2 Existing Agricultural Land Use

The study area continues to experience growth in irrigated agricultural acreage, especially citrus. The irrigated crops in this region are citrus, sugarcane, vegetables, sod, and greenhouse/nursery. The project footprint is an active citrus grove. Growth in citrus acreage is usually on land that was formerly pastureland. Descriptions of the agricultural acreage in each county are included in ***Table G-2***.

TABLE G-2: TOTAL LAND AND FARM ACREAGE

Item	Florida	Charlotte	Glades	Hendry	Lee
Total Land Acreage	34,513,162	443,907	495,123	737,622	514,323
Farms	44,081	284	231	456	643
Farm Acreage	10,414,877	191,529	379,278	606,839	134,649

Source: USDA, NASS, 2002 Census of Agriculture

The following acreage by specific crop types was obtained from the Lower West Coast Water Supply Plan (LWCWSP) and pertains to acreage in 1995. The study area does not coincide exactly with the LWCWSP study area, but falls within the study area. Citrus is by far the dominant agricultural crop in the LWC study area, and occupies approximately one-half of agricultural acreage in

the region. Between 1968 and 1980 acreage remained at about the same level. From about 1984 until about 1992, acreage grew rapidly, associated with the inter-regional movement of citrus acreage southward from Central Florida following several severe winter freezes in the mid-1980s. Since approximately 1992, citrus growth has slowed in the area. Tropical fruits (primarily avocados and mangos) and nuts are produced only in Lee County. In 1995, there were 1,930 acres of tropical fruits and nuts in Lee County. Vegetable crops grown in the study area include cucumbers, peppers, tomatoes, squash, eggplant, watermelons, Latin vegetables, snap beans, and potatoes. Different types of vegetables are often grown interchangeably, and in 1995 there were 44,231 acres of land used for vegetable production.

Hendry and Glades county areas are the only parts of the study area where sugarcane is produced. As a result of the cultivation practices used for sugarcane, 25 percent of the land used for sugarcane production is fallow in any given year. In 1995, a total of 35,443 acres of sugarcane were produced in the Hendry County area. The seed corn production in southeastern Charlotte County varies from year to year, based primarily on the demand for seed corn, which in turn is dependent on seed corn production in other parts of the country. This variation in production is more a fluctuation than a trend. The estimate for seed corn production is 2,100 acres and 1,000 acres for soybeans. While fluctuations are anticipated, the magnitude of this acreage is typical. Rice in southern Glades County is grown during the summer months in rotation with sugarcane or winter vegetables, and takes place on land that would otherwise be fallow. Rice acreage in southern Glades County was assessed at 200 acres in 1995. In 1995, there were a total of 650 acres of irrigated sod production in the LWC Planning Area. In 1995, there were 6,089 acres of greenhouse/nursery operations in the LWC Planning Area, and this is projected to increase to 10,627 acres by the year 2020.

G.2.4.3 Future Land Use

Future land use projections in the Caloosahatchee Basin were updated as part of the larger regional Southwest Florida Feasibility Study (SWFFS). These regional preliminary draft projections will serve as a starting point for describing the West Basin Storage Reservoir project study area's land use. These projections have been reviewed by agricultural and governmental interests in the study area and will be used as the most likely future scenario. These have been incorporated into all project modeling effort. The draft projections resulting from the SWFFS update apply to 2025 and 2050 conditions. For the Caloosahatchee River (C-43) West Basin Storage Reservoir study area, the 2025 land uses have been extended to reflect expected 2050 conditions. It is not anticipated that the agricultural acreages will increase or decrease substantially

between 2025 and 2050, but the total urban acreages will increase in area and increase in density to account for the increase in population.

G.2.4.3.1 Methodology

In order to support the hydrologic modeling effort, the spatial distribution of land use was estimated for 2025 and 2050 conditions. These estimates are by necessity based on best professional judgment, due to the large uncertainties in predicting trends in population, economics, government policies, and other factors for an area experiencing rapid growth. The assumptions and methodology used to estimate future land uses are described below.

Land Use Data

Land-use patterns have been mapped for all of southern Florida using 1995 aerial photography, according to the Florida Land Use, Cover and Forms Classification System (FLUCCS) adopted by the Florida Department of Transportation. The 1995 database was updated using 2000 aerial photography and other sources to create a 2000-base coverage of land use. This 2000-base land use provides a reference point for a variety of modeling and analyses.

Public and Conservation Lands

A spatial database of public and conservation lands was compiled from a variety of sources. These lands were grouped into three broad categories: lands already acquired as public and/or conservation land, lands formally proposed for acquisition (through such programs as Conservation and Recreation Lands (CARL), Save our Rivers program (SOR), or Florida Forever Board of Trustees land (FFBOT)), or lands informally identified as desirable for acquisition.

Golf Courses

Because of the unique water-use patterns of golf courses in urbanized areas, a database of some 160 golf courses was compiled for southwestern Florida. The golf courses were correlated to existing water-use permits. The best estimate is that the irrigated area of golf courses will grow from 18,500 acres to 28,000 acres by about 2030, with an average of 120 acres per 18-hole course. Using existing patterns of urban development and the locations of water-use permits, both existing and proposed likely locations for about 80 new golf courses were mapped.

County Future Land Plans

The most-recent future-growth plans at the county level were obtained in digital format from Charlotte, Glades, Hendry, Lee, and Collier counties. The planning horizon varies from county to county. Some plans are for 2010, some extend to

2020, and some are simply designated "future." Each county has developed its own classification system for future land use. Because the models require a single, consistent classification, for each county a "crosswalk" table was developed to convert the county-based categories into FLUCCS categories. Meetings were held with county and municipal planners to refine the crosswalk tables and include recent changes to future-growth plans. For residential areas, population densities (in dwelling units per acre) were estimated for 2025 and 2050.

Agriculture

Under previous county land use plans, the accepted estimate for future agriculture was that the Caloosahatchee, S-4, and S-236 basins would have 125,000 acres of sugar cane and 125,000 acres of citrus in 2020. Compared to the 2000-base land use, this represents approximately 25,000 acres of additional sugar cane and 25,000 acres of additional citrus. These numbers were adopted as target values for 2025. In addition, representatives of the agricultural community estimated that 10,000 acres of new vegetable-crop or sod lands would be developed between 2000 and 2025. Likely areas for conversion of pasture/ranges lands to the more intensive agricultural use were identified.

General Rules for Distributing Future Land Use

Using geographic-information-systems (GIS) database structures and software, all of these spatial databases, or layers, were combined for analysis. A few simple rules were developed in order to resolve the combination of layers into a spatial pattern for future land use. The basic rules are:

1) Development is defined as a change of FLUCCS code to a more intensive land use. Examples include conversion of rangeland to citrus or vegetable crops to residential.
2) Some types of land can be developed; some cannot.
3) Lands that can be developed include pasture, rangeland, agriculture, upland forest, mining/gravel operations, open land, transitional land, and barren land.
4) Lands that cannot be developed include wetlands, open water, agricultural water-retention areas, and most existing urban land (including commercial, industrial, institutional, recreational, and utilities).
5) Existing conservation lands cannot be developed. Lands proposed for acquisition are allowed to be developed.
6) Most existing urban use remains constant. Residential areas can develop to higher density.
7) Urban development takes precedence over agriculture, in most cases. Every urban use, with the possible exception of low-density residential (see below), will "trump" agriculture.

Estimation of 2025 and 2050 Land Use

Additional rules were applied in order to differentiate between 2025 and 2050 conditions. For the 2025 estimate, a threshold density was applied for residential lands. If the 2025 density was expected to be two or more dwellings per acre, the land was developed as residential. Otherwise it remained as non-urban. For the 2050 estimate, all lands identified as residential were converted to urban, regardless of density.

It is recognized that these rules are arbitrary and limited by the nature of the source data, and that all estimates of future land use are highly uncertain. It is quite possible that urban growth will exceed these estimates. Because agriculture requires more water than any urban use, however, it is not likely that the future water demands will exceed the demands that are computed from these results. This "conservative" approach to estimating growth helps to ensure that future water demands will not be underestimated.

G.2.4.3.2 Results of Future Scenarios

Land use in the Caloosahatchee Basin is split between agricultural land use, urban/metropolitan land and conservation land. In the eastern portion of the Caloosahatchee Basin, Hendry, Charlotte, and Glades counties have been predominantly agriculture and rural in nature, while in the western portion of the basin, Lee County is more urban and supports industrial and commercial development. The land use, as described by the Southwest Florida Regional Planning Council (SWFRPC), details Hendry County as remaining largely agricultural, with urbanized areas in Clewiston to the east and La Belle to the west, and intermittent preserves and wetlands throughout. Additionally there are two main industrial concerns in Hendry County, one west of Clewiston and one near the Lee County border. Like Hendry County, Glades County remains largely agricultural in 2025, with some urbanized areas (La Belle's northern reaches and Moore Haven on Lake Okeechobee) and preserves and wetlands throughout. Within the study area, Charlotte County will remain vastly agricultural with some preserves and wetlands areas.

The predominant land use in the Caloosahatchee Basin is agricultural, and is expected to remain so in the future. The study area continues to experience growth in irrigated agricultural acreage. The irrigated crops in this region are citrus (the dominant irrigated crop), sugarcane, vegetables, sod, and greenhouse/nursery. Over the past two decades, southwest Florida has had the fastest growing citrus acreage in the state. Growth in citrus acreage is usually on land that was formerly pastureland. Sugarcane closely follows citrus in dominance in terms of crops grown in the Caloosahatchee Basin. It is produced in the Caloosahatchee Basin in close vicinity to Lake Okeechobee (in Hendry and Glades counties). Sugarcane acreage has continued to increase since 1995, and

is expected to continue to increase in the future. Irrigation is typically applied from the surface water sources in the Caloosahatchee Basin and consequently, subsidence is not a significant problem due to the soils being generally sandy, rather than organic.

In terms of urban and industrial development, Lee County is the most populous part of the study area. The Fort Myers /Cape Coral Metropolitan Statistical Area (MSA), unincorporated areas of Lehigh Acres, Buckingham, North Fort Myers, South Fort Myers, and East Fort Myers constitute the bulk of the population in the western portion of the Caloosahatchee Basin (see ***Table G-3*** in Existing Conditions section on population estimates by county). Urban growth in Lee County has the potential to impact the region's environmental and water resources. Drainage of wetlands caused by urban expansion, loss of natural surface water storage areas, and contamination from urban land use is the major water related issues in the urban areas. Growth in this part of the basin generally follows the I-75 corridor, with the greatest portion of the population being located west of the W.P. Franklin Lock and Spillway (S-79). Much of the projected urban growth in this part of the basin is located to the east of I-75 toward the S-79. Much of this development contains a mixture of single family/multifamily dwellings, commercial and industrial facilities, some mining operations and preserves/wetlands. ***Figure G-2*** presents a map of the 2050 future land use conditions in the Caloosahatchee River (C-43) West Basin Storage Reservoir study area. ***Figure G-3*** presents a map showing changes between existing (2000) conditions and future without project conditions. ***Table*** G-3 shows changes to land use for the 2025 and 2050 conditions.

There are a number of areas where urban development, agriculture, and/or proposed conservation areas compete for the same land. While these competing areas are not large compared to the entire area being modeled, they are significant. There were two most likely scenarios that were determined to be applicable to the Caloosahatchee River (C-43) West Basin Storage Reservoir study area. The first of these scenarios corresponds to land use in 2025, the second to land use in 2050. The first scenario has agriculture out-competing or "trumping" new low-density residential urban use, agriculture develops in areas proposed for conservation (not existing conservation lands, however), and marginal urban land has not developed yet. The second scenario, or 2050 conditions, also has agriculture trumping new low-density residential urban, agriculture is allowed to develop in areas proposed for conservation, but marginal urban land has now developed.

From the following table and figures, general characterizations of the study area can be determined which lead to the belief that in the future, urban lands and agriculture will increase in acreage, resulting in a decrease in natural areas. Within the greater Caloosahatchee River (C-43) West Basin Storage Reservoir study area, urban lands are expected to increase from 47,000 acres in 2000 to

114,000 acres in 2025 and 127,000 acres in 2050. Sugar cane is expected to increase to 116,000 acres in 2025 and decline slightly to 113,000 acres in 2050. Acreages for citrus are 118,000 in 2025 and 110,000 in 2050. Vegetable crops and sod production are expected to increase by 10,000 acres by 2025. Given the high probability that urbanization will meet or exceed the counties' current future-growth plans within the next 20 years, it may be difficult for the agricultural community to meet its 2025 goals.

FIGURE G-2: 2050 LAND USE

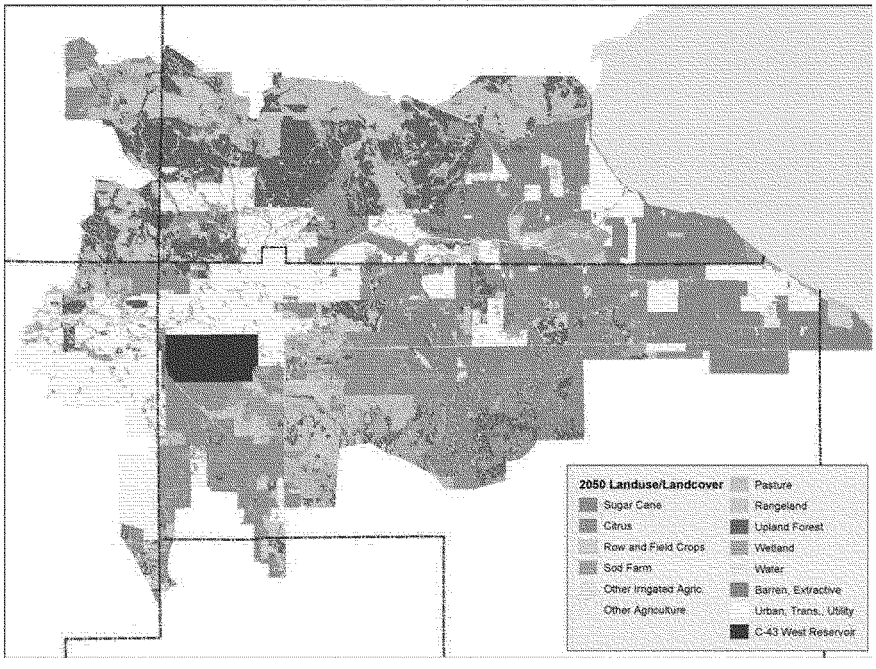


FIGURE G-3: DIFFERENCE BETWEEN 2000 AND 2050 LAND USE

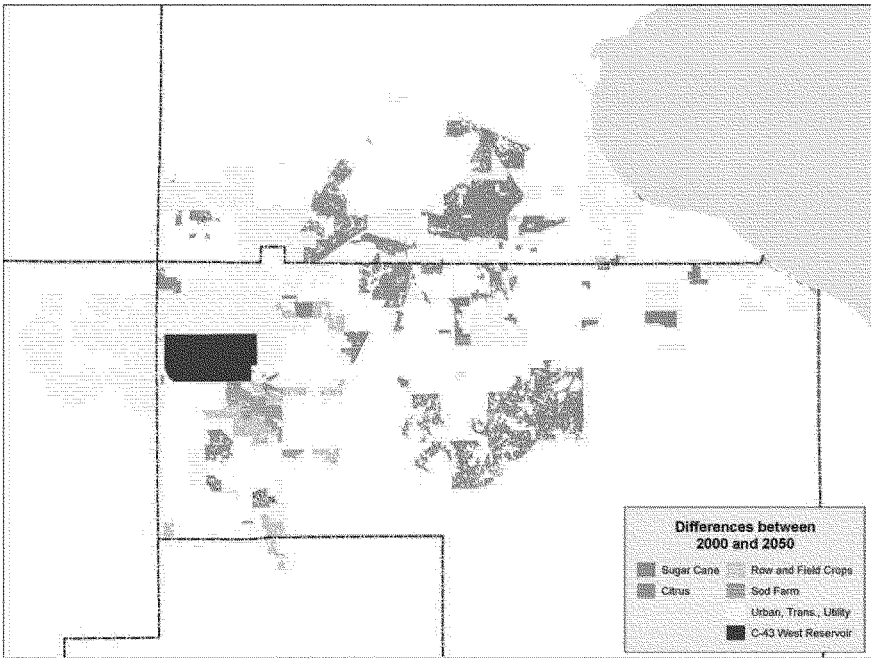

TABLE G-3: CHANGE IN LAND USE FROM 2000-2050

Land Use Category	2000 LAND USE	2025 LAND USE	Change from 2000 to 2025	2050 LAND USE	Change from 2000 to 2050	Change from 2025 to 2050

G.2.5 General

Socioeconomic and demographic data for the study area indicate higher than average income when compared to the rest of the state and nation, and much greater economic and population growth than for the rest of the nation. Additional characteristics of the study area include a strong service sector, fishing, tourism, and recreation. Florida's economy is generally characterized by strong wholesale and retail trade, government and service sectors. Florida's warm weather and extensive coastline attract vacationers and other visitors and helps to make the State a significant retirement destination for people from all over the country. Easily developed land, accessible water supply, abundant natural resources, and the aesthetic beauty of the region are the fundamental building blocks of the local economy. Relative to the national economy, the manufacturing sector has played less of a role in Florida, including the study area. However, high technology manufacturing has begun to emerge as a significant sector in the State over the last decade.

G.2.6 Population

G.2.6.1 Population: Historic Trends and Existing Condition

Population for the four counties in the study area (Charlotte, Glades, Lee and Hendry County) increased at a high growth rate during the period from 1990 to 2000. Charlotte increased at 27.6 percent, Lee at 31.6 percent, Glades at 39.3 percent and Hendry at 40.5 percent. The population of Florida and the United States increased 23.5% and 13.1% respectively over the same period.

TABLE G-4: POPULATION OF COUNTIES AND CENSUS TRACTS

		Race							
	Population, 2000	**White**	**%**	**Black**	**%**	**Hispanic**	**%**	**Other**	**%**
Florida	15,982,378	12,466,255	78.0%	2,333,427	14.6%	2,685,040	16.8%	1,182,696	7.4%
Charlotte County	141,627	131,147	92.6%	6,232	4.4%	4,674	3.3%	4,249	3.0%
Census Tract 101	3556	2,916	82.0%	525	14.8%	191	5.4%	115	3.2%
Glades County	10,786	8,305	77.0%	1,133	10.5%	1,629	15.1%	1,348	12.5%
Census Tract 1	2018	1,975	97.9%	2	0.1%	21	1.0%	41	2.0%
Census Tract 2	5669	4,590	81.0%	415	7.3%	1,353	23.9%	664	11.7%
Census Tract 3	2889	1,577	54.6%	697	24.1%	220	7.6%	615	21.3%
Lee County	475,639	417,135	87.7%	31,392	6.6%	45,186	9.5%	27,112	5.7%
Fort Meyers MSA	440888	386,598	87.7%	29,035	6.6%	42,042	9.5%	25,255	5.7%
Hendry County	36,210	23,935	66.1%	5,323	14.7%	14,339	39.6%	7,083	19.6%
Census Tract 1	6567	4,973	75.7%	729	11.1%	2,655	40.4%	41	0.6%
Census Tract 2	7506	3,750	50.0%	2,898	38.6%	2,007	26.7%	664	8.8%
Census Tract 3	6926	4,222	61.0%	132	1.9%	4,256	61.4%	615	8.9%
Census Tract 4	11066	8,503	76.8%	802	7.2%	3,738	33.8%	1,761	15.9%

Hendry County has a large percentage of people that claim Hispanic origin. Of the 36,210 residents in the county during the year 2000, almost 40 percent (14,339 persons) are of Hispanic origin. Glades, Charlotte and Lee counties all have lower proportions of persons of Hispanic origin than does the state.

Florida's African-American population is 2,333,427, which is 14.6percent of the State's total population. Hendry County has a total African-American population that is slightly higher than that of the state total. There are also three census tracks in the study area that have a higher African-American representation than that of the state.

The Native-American population of the study area represents less than one percent of the aggregate population of the study area.

G.2.6.2 Population: Projections

According to the population projection derived from the Florida Bureau of Economic and Business Resources (BEBR), population in Charlotte County is expected to increase over 83 percent from 2000 to 2050; in Glades County, to increase by 74 percent; Hendry County, to increase by 96 percent; and Lee County, to grow by 97 percent. Florida as a whole is projected to grow 86 percent by 2050. The projected growth of the south Florida Nine-County area is anticipated to be 78 percent over the same 50-year period. These estimated population increases are reflected in future without project condition water demands and land use patterns.

TABLE G-5: CHARLOTTE, GLADES, HENDRY AND LEE COUNTIES, POPULATION ESTIMATES 2000-2050 (1,000S) (BEBR PROJECTIONS, US CENSUS (2000))

Area	2000	2010	2020	2030	2040	2050
Florida	15,982.4	18,866.7	21,792.6	24,528.6	27,118.7	29,714.5
Charlotte County	141.6	169.5	198.9	225.9	242.8	259.8
Glades County	10.6	12.4	14.2	16	17.2	18.4
Hendry County	36.2	44.4	53.3	61.8	66.4	71.1
Lee County	440.9	546.8	653.3	753.9	810.3	866.9

G.2.7 Economy

Generally, a strong wholesale and retail trade, government and service sectors characterize Florida's economy. Florida's warm weather and extensive coastline attracts vacationers and other visitors and helps make the state a significant retirement destination for people all over the country. Agricultural production is also an important sector of the state's economy, and is especially significant to portions of the study area. Compared to the national economy, the manufacturing sector has played less of a role in Florida, but high technology manufacturing has begun to emerge as a significant sector in the State over the last decade.

TABLE G-6: INCOME AND EMPLOYMENT FOR COUNTIES AND CENSUS TRACTS

	Income					Employment	
	Median Household, 1999	Personal Per Capita, 1999	Persons Below Poverty Level	% Below Poverty Level	Average Household Size	In Labor Force (+16 yrs old)	Unemployed
Florida	38,819	21,806	1,997,797	12.5%	2.46	7,407,458	412,411
Charlotte County	36,379	21,557	11,613	8.2%	2.18	52,512	1,822
Census Tract 101	41274	17,560	165	4.6%	2.47	1,176	27
Glades County	38,819	15,338	1,639	15.2%	2.51	3,677	357
Census Tract 1	27604	17,216	374	18.5%	2.47	1,873	29
Census Tract 2	31170	14,597	938	16.5%	2.72	4,268	256
Census Tract 3	34091	15,471	175	6.1%	2.62	2,324	72
Lee County	40,319	24,542	46,137	9.7%	2.31	186,417	7,234
Fort Myers MSA	40139	24,542	42,316	9.6%	2.31	3,120	230
Hendry County	33,592	13,663	8,727	24.1%	3.09	14,579	1,235
Census Tract 1	37210	15,460	1,197	18.2%	2.92	3,120	230
Census Tract 2	31760	13,047	2,034	27.1%	3.15	3,318	420
Census Tract 3	34250	12,315	1,894	27.3%	3.55	3,512	237
Census Tract 4	33022	15,417	2,492	22.5%	2.87	4,425	280

As can be noted in ***Table G-6***, the unemployment rate for Florida is 5.1 percent (2003), which is greater than that of Lee (four percent) and Charlotte (4.4 percent) counties. Hendry and Glades counties had unemployment rates that were much greater than the state total, with Glades' unemployment rate at 8.7 percent and Hendry County's unemployment rate at 11.7 percent.

Personal per capita income in Florida is $21,806 (1999), but is somewhat lower in Charlotte County at $21,557, and substantially lower in Glades County at $15,338 and Hendry at $13,663. Lee County experiences higher per capita income than that of the state average. Every rural census tract associated with the study area has lower than the state average per capita income.

In 1999 it was reported that 12.5 percent of Florida's population lived below the poverty level, while 24.1 percent of Hendry County's and 15.2 percent of Glades County lived below the poverty level. Charlotte County and the census tracts associated with it are both below the state poverty level figures. All census tracts in Hendry County are above the state poverty level.

G.2.8 Agriculture Economy

Agriculture is a significant contributor to the economies of the counties in the study area. Measures of relative significance presented here include: number and average size of farms, number of acres under cultivation, total market value of production, property taxes, and impacts on seasonal employment.

Total production of the four-county study area accounts for more than half a billion dollar total revenue. Of this total amount, Hendry County accounts for more than 60 percent of the total output of the study area, and is the nation's second largest producer of sugarcane, the third largest producer of oranges, and the sixth largest producer of grapefruit.

TABLE G-7: SUMMARY STUDY AREA AGRICULTURAL STATISTICS– BY COUNTY (2002)*

	Number of farms	Average size (acres)	Total acres used for farmland	Market Value of Production
Charlotte	284	674	191,529	$ 42,632,000
Glades	231	1,766	407,950	$ 72,064,000
Hendry	456	1,211	552,352	$ 357,076,000
Lee	643	197	126,484	$ 109,147,000
Total	1,614	792	1,278,315	$ 580,919,000

*NASS, 2002 Census of Agriculture, County Profile

Table G-7, above, presents statistics of county and study area based agricultural activity for 2002. To isolate general trends in agricultural land use so that impacts of the project on agricultural may be represented; statistics for 1997 are presented in ***Table G-8.***

TABLE G-8: SUMMARY STUDY AREA AGRICULTURAL STATISTICS- BY COUNTY (1997)

	Number of farms	Average size (acres)	Total acres used for farmland
Charlotte	287	1,018	292,053
Glades	253	1,499	379,278
Hendry	507	1,197	606,839
Lee	725	186	134,649
Total	1,772	797	1,412,819

In the five years that differentiate ***Table G-7*** and ***Table G-8***, all Charlotte, Hendry and Lee counties in the study area experienced a decrease in the number of farms and the number of acres under cultivation. In Charlotte County the

number of farms declined by one percent. While the number of farms in Charlotte County has not demonstrated a precipitous decline, the number of acres under cultivation decreased by more than thirty percent and the average size of farms also decreased by more than thirty percent. In Lee County the area under cultivation and the number of farms decreased by six percent and 11 percent from 1997 to 2002 while the average farm size increased by six percent for the same period. In Hendry County the area under cultivation and the number of farms decreased by nine and ten percent from 1997 to 2002 while the average farm size increased by one percent for the same period. While Lee County exceeds Hendry County in absolute number of farms, only 16 percent of Lee County farms have sales greater than $50,000 per annum versus 36 percent of Hendry County farms having sales exceeding $50,000. Glades County is the only county in the study area that realized an increase in the number of acres under cultivation. The amount of land in farms increased eight percent with the average size of the farms increasing 18 percent, while the total number of farms decreased by nine percent. Hendry and Glades counties had large increases in the average per farm market value of production, with Hendry increasing 29 percent and Glades increasing 35 percent.

TABLE G-9: MILLAGE RATE, ASSESSED VALUE AND PROPORTION OF AGRICULTURAL REVENUE-BY COUNTY FOR 2004* ($1,000)

	Millage Rate	Agricultural Assessment	Agricultural Revenue	Total Assessment	Total Revenue	Agriculture's Percentage of Total Revenue
Charlotte	15.4667	$99,670	$1,542	$12,296,175	$190,181	0.81%
Glades	24.1233	$143,670	$3,466	$385,736	$9,305	37.25%
Hendry	25.3923	$491,034	$12,468	$1,299,494	$32,997	37.79%
Lee	16.852	$204,340	$3,444	$46,978,992	$791,690	0.43%
Total		$938,714	$20,919	$60,960,397	$1,024,174	1.54%

*State of Florida, Department of Revenue, 2004 Florida Property Valuations and Tax Data

Property taxes on agricultural land add almost $21 million into local reserves. This accounts for approximately one and a half percent of the four county study area. On a per county level, the predominately rural agricultural counties of Glades and Hendry realize about 37 percent of their *ad valorem* taxes coming from agricultural property.

TABLE G-10: AGRICULTURE PRODUCTION CROPS: AVERAGE MONTHLY PRIVATE REPORTING UNITS, EMPLOYMENT, AND PAYROLL COVERED BY UNEMPLOYMENT COMPENSATION LAW*
(NAICS code 111)

	Number of Reporting Units	Number of Employees	Payroll ($1,000)
Charlotte	13	377	$512

Hendry	52	2299	$2,814
Lee	N/A	N/A	N/A
Total	**68**	**$2,475**	**$3,204**

*Florida Statistical Abstract 2004

The agricultural industry provides the area with numerous monthly employment positions and income. Activity depicted in ***Table G-10*** is for agricultural production of crops, and ***Table G-11*** is for agricultural support services.

This analysis demonstrates the importance of agriculture to the study area economy. It also suggests some conclusions on the impact a reduction in study area agriculture will have on local government, landowners and workers. The market price of most agricultural commodities demonstrates a highly elastic behavior; the removal or reduction of a single supplier will not affect the market price greatly. As a result the impact of this removal will be highly localized; a reduction in output will result in a primary reduction in seasonal employment and property tax receipts and a smaller secondary reduction in support services employment and revenue.

The unique nature and market recognition of the Florida agriculture industry might mitigate some of the impacts to total revenue and local tax revenue. Given the dominance of agriculture in Glades and Hendry counties, it is anticipated that any impacts resulting in a reduction of agriculture will be more

pronounced in these two counties. It is apparent that agriculture plays a significant role in contributions to tax revenues of the counties located in the study area. Total *ad valorem* property taxes levied on agriculture lands in the Caloosahatchee River (C-43) West Basin Storage Reservoir study area accounts for over $20 million. More significantly, agriculture property taxes may represent over 37 percent of the total revenue of Glades and Hendy counties. Local government fiscal balances of these counties are contingent on the continuation and proliferation of the success of agriculture in these areas.

G.3 MUNICIPAL AND INDUSTRIAL WATER DEMAND

The Comprehensive Review Study for the C&SF project, known as the Restudy, recommended the development of a feasibility study to identify southwest Florida water resource conditions, and to develop potential solutions to any problems that may be identified. This M&I Water Use Forecast is part of the overall SWFFS, but includes Lee County, most of Collier and Henry counties and portions of Charlotte, Glades and Monroe counties, and the Caloosahatchee River Basin which correspond to the Caloosahatchee River (C-43) West Basin Storage Reservoir study area. The water use sectors for which forecasts were developed include public and self-supply domestic (residential), commercial, industrial, government, and unaccounted-for water loss. Water use in agriculture, mining, and power generation were not addressed as part of the M&I forecast. The purpose of the M&I water use forecast was to estimate existing water use and to develop water use projections for the SWFFS area.

An M&I forecast is required as input to modeling that will be the basis for planning and optimally designing the Caloosahatchee River (C-43) West Basin Storage Reservoir project. The planning horizon is the year 2050. Water use estimates from the present to 2050 for natural area environmental purposes, agricultural irrigation purposes, M&I use, and other purposes are needed. The results of the IWR-MAIN effort are a set of projections through the year 2050 for M&I use only.

The M&I water use forecasts were developed using the IWR-MAIN Water Demand Management Suite, a computerized water resource planning tool that allows the development of water use forecasts and the evaluation of water conservation programs. The IWR-MAIN software allows water use forecasts to be developed based on existing water use patterns and existing or forecast socioeconomic parameters and then allows the impact of water conservation measures on those water uses to be evaluated. To maintain consistency with the water use forecasts developed for the Initial CERP Update (ICU), the water use models developed for the western portion of the study area in that analysis will be used in this analysis. In the ICU, residential water use was forecast using a multiplicative forecast model and nonresidential water use was forecast using a constant use rate model.

Golf course irrigation requirements were based on a model developed by the SFWMD and previously used in projecting water use in the LWC WSP. The SFWMD model consisted of using multiple regression analysis to project future golf course acreage, then applying irrigation requirements to those acreages based on the Agricultural Field Scale Irrigation Requirements Simulation (AFSIRS) model. Golf course acreage was projected for the period of analysis using multiple regression analysis. Multiple regression analysis evaluates the past relationships between a dependent end variable and independent variables. Once this relationship was described through equations, the equations were used to project future golf course acreage, based on projected population. Irrigation requirements from AFSIRS, based on a representative irrigation system/rainfall station/soil type combination for each county, were then applied to the projected golf course acreage to develop projected golf course irrigation requirements. Consistent population projections are critical to the development of M&I water use because they are used to directly project housing and employment counts, the main drivers of the IWR-MAIN water use models. Therefore, considerable time and effort was expended on developing reasonable, acceptable, and defendable projections.

The population projections from 2000 to 2050 were based on population projections produced by the BEBR. BEBR generates low, medium, and high sets of population projections for each county in Florida for 2005 through 2030. The medium population projections are believed by BEBR to most likely provide an accurate forecast of future county populations. The high and low population projections were developed to indicate the uncertainty concerning the medium set of projections, based on past population forecast error.

Three population projection scenarios were developed for this analysis. The BEBR medium projections were the basis for the medium or most-likely scenario for all counties except Collier County, and the BEBR high and low population projections were the basis for the high and low scenarios, respectively. Collier County has formalized an alternative method for projecting population for planning purposes, based on the BEBR high scenario growth rates. Collier County projects the medium population based on the BEBR high growth rate for the first five years (2000-2005). Projections for 2005 to 2030 were based on 95 percent of BEBR high growth rate. In order to develop projections to 2050, the growth rate exhibited in the national population projections from 2030 to 2050 was applied to the projected 2030 BEBR population for each county.

The IWR-MAIN models were calibrated to local water use patterns using the most recent data available (2000), then used to estimate water use for 2000 and project water use, in five-year intervals, to 2050. Four sets of forecasts were developed. Three were based on differing population projection scenarios, and

one was based on one-in-ten year drought conditions. Projection of future water use included the implementation of all reasonable conservation measures.

The use of the calibrated IWR-MAIN forecast models resulted in the development of baseline water use estimates, assuming that future water use patterns will continue into the future. These baseline forecasts are conditional water use forecasts that exclude the potential impacts of existing water conservation programs that may result in a reduction in the average water use per housing unit or employee over time. The SFWMD requires the development of water conservation plans prior to issuing a water use permit. These conservation plans incorporate passive water conservation measures that include an increasing block rate structure, the required use of ultra-low flow water fixtures on new construction or renovation of existing structures, restrictions on lawn watering, requiring rain sensors on automatic sprinkler systems, a leak detection program, and public education concerning water conservation measures. IWR-MAIN was used to forecast water use for each study area assuming that passive water conservation measures would be implemented.

IWR-MAIN employs an end use model to distribute forecast water demand to end-uses (i.e., toilets, showers, washing machines, lawn irrigation) and allows the planner to evaluate the impact of conservation measures on those end uses. The conservation measures incorporated into this analysis can be broadly classified as ultra-low volume plumbing fixture requirement ordinances, irrigation ordinances, and rain sensor switch ordinances. Other requirements such as conservation water rate structure, utility leak detection and repair, and public education programs are addressed in the baseline IWR-MAIN forecast. The water use, by end-use fixture for each conservation level category is presented in ***Table G-12***.

TABLE G-12: WATER USE BY END-USE FIXTURE, BY CONSERVATION LEVEL CATEGORY

End-Use Water Fixture	Unit of Measure	Conservation Level Category		
		Non-Conserving	Conserving	Ultra-Conserving
Toilets	Gallons per flush	5.0	3.5	1.6
Showerheads	Gallons per minute	3.8	3.0	2.5
Faucets	Gallons per minute	3.5	2.5	2.0
Dishwashers	Gallons per load	14.0	9.3	6.0
Clothes washing	Gallons per load	55.0	42.0	24.0
Urinals	Gallons per flush	1.5	1.5	1.0
Lawn irrigation	Percent savings	0.0	10.0	10.0

According the U.S. Geological Survey (USGS) in 2000, estimates of annual water withdraws (***Table G-13***), total public-supply water use for the region is

estimated at 110 million gallons a day (MGD), and from the IWR-MAIN model (***Table G-14***), the total M&I water use is estimated at 177.5 MGD. The addition of 776 MGD of agricultural water use increases total water demand for the region to 951 approximately MGD. Agricultural water use accounts for 81 percent of the total use, and public-supply water use accounts for 12 percent and recreational self-supply accounting for about five percent.

TABLE G-13: USGS ESTIMATED TOTAL WATER USE, FOR SELECTED COUNTIES, 2000 (EXCLUDING MINING AND POWER GENERATION)

	Municipal and Industrial							
		Self-Supply						
County	Public Supply	Domestic	Commercial	Industrial	Recreation	Sub Total	Agriculture	**Grand Total**
Charlotte	14.21	3.55	0.11	0	3.48	21.35	47.19	**68.54**
Glades	0.55	0.61	0.04	0	0.42	1.62	69.02	**70.64**
Hendry	4.72	1.67	0.21	0.51	1.09	8.2	503.91	**512.11**
Lee	52.37	8.86	0.46	0.09	22.66	84.4	60.51	**144.95**
Total	**71.85**	**14.69**	**0.82**	**0.6**	**27.65**	**115.57**	**680.63**	**796.24**

On the county-level, the largest total water user in the study area in 2000 was Hendry County, mainly because of agricultural water use. Hendry County used a total of 512.11 MGD, or 51 percent, of the total regional water use. Of this amount, 503.91 MGD (or 98 percent) was agricultural use and 4.72 MGD was public-supply M&I water use. Collier and Lee counties' public-supply water use were fairly equivalent at about 52 MGD. However, because of high agricultural water use, Collier County had the second highest total water use in the five-county area, at 224.42 MGD, which accounted for over 64 percent of the county's total water use. Lee County's total water use was 144.95 MGD, the third highest in the region. Lee County had the highest self-supply domestic water use in the region at 8.86 MGD. Collier and Lee counties also had high recreational water use, with Lee County having the highest use in the region at 26.17 MGD and Lee County using 22.66 MGD.

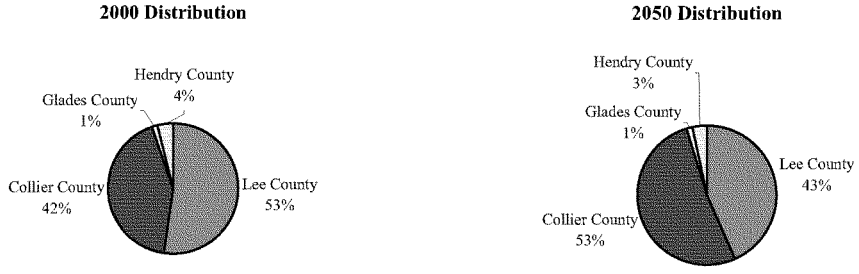

Table G-14 represents the conservation-adjusted, most likely population scenario, water use forecast and the percent of total water use associated with each county or county area in the study area, for 2000, 2025, and 2050. Lee County accounted for 52.2 percent of all M&I water use in the study area in 2000, while Collier County accounted for 42.4 percent. By 2025, Collier County was the largest water user, accounting for 50 percent of all water use in the SWFFS area. By 2050, Collier County is projected to account for 52.2 percent, with Lee County accounting for 43.2 percent of all water use. The percent of total M&I water consumed in Collier County is projected to increase over the period of analysis because of the projected increase in population in Collier County compared to the rest of the study area. Collier County population is

projected to increase by 215 percent from 2000 to 2050, while the population of Lee County is projected to increase by 97 percent over the same time period. The Glades County Area generates the smallest use, at slightly more than one percent of the total regional water use over all time periods. Due to the small population in the Charlotte County portion of the study area, the water use totals for Charlotte County are incorporated into those of Glades County and therefore the USGS 2000 baseline totals do not exactly equal the IWR-MAIN 2000 totals.

TABLE G-14: CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR STUDY AREA, M&I CONSERVATION-ADJUSTED WATER USE AND DISTRIBUTION, BY COUNTY AREA MOST-LIKELY POPULATION SCENARIO, 2000, 2025, AND 2050

	2000		2025		2050	
Area	MGD	Percent of Total	MGD	Percent of Total	MGD	Percent of Total
Lee County	92.7	52.2%	129.5	45.2%	148.0	43.2%
Collier County	75.2	42.4%	143.5	50.0%	178.6	52.2%
Glades County Area	2.4	1.4%	4.0	1.4%	4.5	1.3%
Hendry County Area	7.1	4.0%	9.7	3.4%	11.2	3.3%

FIGURE G-6: M&I CONSERVATION-ADJUSTED FORECAST OF WATER USE BY SECTOR FOR THE MOST LIKELY SCENARIO

G.3.1 Agricultural Water Demands

G.3.1.1 Introduction

The SFWMD calculated agricultural water demands as part of the Caloosahatchee Water Management Plan (CWMP), in April 2000. These water demand calculations are the most current demands available for the Caloosahatchee River (C-43) West Basin Storage Reservoir study area and are a sufficient base point for demonstrating future demands and trends for the planning horizon.

The following section contains the data collected and presented in the CWMP. The land use information in the following section does not coincide exactly with the acreage counts for sugarcane as presented in the land use section (Section G-2.4), but the general trend in land use changes are similar. The citrus acreage is consistent with what was modeled in the CWMP. The agricultural water demands for sugarcane will be updated to reflect current land use projections, after the land use projections are finalized and adopted. Upon completion of the water demands update, a lower agricultural water demand than was projected

for the CWMP is expected, due to current land use projections showing a smaller increase in agricultural acreage.

G.3.1.2 Land Use

An important factor in accurately estimating agricultural water use is determining the location and acreage of crops. Agricultural water use depends on the crops that are grown in the basin and on how those crops are managed and irrigated. Land use in the CWMP planning area is predominantly agricultural and is expected to remain so in the future. For the CWMP, land use from the 1995 Land Use Coverage was utilized. This 1995 Land Use Coverage has been updated to 2000 since the CWMP was completed, but the projections from 1995 were used in the water demand estimate for the CWMP.

At the time of the CWMP, citrus was the dominant irrigated crop in the basin and occupied more than 91,000 acres, according to the SFWMD's 1995 Land Use Coverage. During the past two decades, southwest Florida has had the fastest growing citrus acreage in the state. This growth is associated with the movement of citrus southward from Central Florida following several severe winter freezes in the early-1980s. Sugarcane, with an estimated 75,000 acres, according to the SFWMD's 1995 Land Use Coverage, closely follows citrus in dominance of land area. Sugarcane is primarily grown in close vicinity to the Everglades Agricultural Area (EAA), in Hendry and Glades counties, where transportation costs to sugar mills can be minimized. Sugarcane acreage has continued to increase since 1995, and is expected to continue in the future. The increase in acres of sugarcane and citrus is not expected to cause expansion of the Lake Okeechobee Service Area (LOSA) but it does assume all development of undeveloped lands in LOSA would rely on Caloosahatchee River (C-43 Canal) waters. The increase in irrigated agriculture stems mainly from a decrease in pasture.

G.3.1.3 MIKESHE Modeling

The Integrated Surface Water/Ground Water Model (ISGM), MIKESHE, includes a module for estimating irrigation requirements based upon land use, soil type, crop type, rainfall and evapotranspiration. It has the capability to utilize a vast amount of raw and processed data to estimate crop needs. These data can be summarized under irrigated crop, irrigated area, and water use.

G.3.1.3.1 Irrigated Crop

The different crop types within the basin that are irrigated are specified within the MIKESHE model. Three major crops are included in the vegetation classification as requiring irrigation. These are sugarcane, citrus, and truck

crops (vegetables). A fourth, improved pasture may or may not be irrigated and is assumed not irrigated in the analyses.

G.3.1.3.2 Irrigated Area

The maximum expanse or extent of irrigated areas needed to be explicitly specified in the MIKESHE model. The MIKESHE model determines what portion of the specified irrigated area requires irrigation at each model time step. The determination is based on soil moisture that is affected by rainfall, soil type, and other factors that are specified in the model. The irrigated areas are specified using 1995 land use maps and the SFWMD water-use permit coverages.. Acreage that is permitted but not cropped is therefore excluded from the analyses.

G.3.1.3.3 Water Use

The actual irrigation practices within the basin vary from farm to farm, at different periods of the year, from crop to crop, and at different stages of crop growth. Irrigation practices by individual users are largely unknown and can not be modeled. In general however, all practices ensure that crop losses through evapotranspiration can be minimized with irrigation. Using this premise, the MIKESHE model computes irrigation demands based on estimates of actual evapotranspiration for each crop and growth stage. The computation of evapotranspiration is based on leaf area index, root depth, soil characteristics of the root zone, and potential evaporation.

The MIKESHE model requires the distribution of irrigation demands not only in space over the basin but in time as well. The result is a process that can be replicated for any time period once the input data such as the crop type, soil type, and land area is known. This was considered desirable for estimating future irrigation requirements within the CWMP planning area. The MIKESHE model was calibrated using ground water levels and river discharges at S-79 and S-78 on the Caloosahatchee River (C-43 Canal). MIKESHE output for inflow and outflow from the basin was used to estimate basin excesses and deficits.

Table G-15 summarizes the water use allocation for major agricultural land use categories for the CWMP area based on the ISGM.

TABLE G-15: SUMMARY OF 1995 WATER USE DEMAND BASED ON THE ISGM FOR MAJOR AGRICULTURAL LAND USE CATEGORIES.

Crop	Water Use (1,000 acre-feet/year)
Citrus	143
Sugarcane	110
Vegetables	36
Total	290

Note: Based on 1995 land use, MIKESHE results indicate an additional 30,000 acre-ft/year of irrigation in addition to citrus, sugarcane and vegetables.

G.3.2 Future Agricultural Demands

G.3.2.1 Land Use

The SWFRPC has estimated that total agricultural acreage will increase between three and seven percent between 1995 and 2020, while citrus acreage will increase between 54 and 81 percent and sugarcane between 62 and 190 percent. The increase in citrus and sugarcane acreage is due in a large part to conversion of existing irrigated acreage that is in other crop types to citrus and sugarcane. Based upon representation from the agricultural industry and CAC discussion and concurrence, a 2020 citrus acreage of 112,500 and sugarcane acreage of 125,000 were modeled. This represented a reduction from the SWFRPC estimate but an increase from the SFWMD *District wide Water Supply Assessment* (DWSA) completed by the SFWMD in July 1998.

A scientific procedure that considered existing land use, ownership, suitability for crop use, and proximity to existing agricultural lands was used to adjust the 1995 land use map to the 2020 land use projections. An explanation summarizing the steps involved in development of the 2020 land use coverage is included in the Land Use section. Based on the 2020 land use map MIKESHE was used to estimate future agricultural demands.

G.3.2.2 2020 Demands Based on MIKESHE

The MIKESHE model developed for the CWMP was used to estimate the future demands by incorporating the 2020 land use information and modifying irrigated areas within the model to match the new land use. The MIKESHE model, unlike the AFSIRS model, was used to simulate demand using an eight-year period (1988-1995). The selected period represents a combination of wet, dry, and average years representative of variations within the Caloosahatchee Basin. The resulting demands for the 2020 Base Case using the MIKESHE methodology therefore represents probable demands based on 2020 land use and hydrologic data corresponding to an eight-year period. The resulting demands

for the entire planning area, including both the LOSA and non-LOSA portions of the basin, were obtained.

Table G-16 summarizes the simulated 2020 irrigation demand for major agricultural land use categories for the CWMP area based on the MIKESHE model.

TABLE G-16: SUMMARY OF 2020 WATER USE DEMAND BASED ON THE MIKESHE FOR MAJOR AGRICULTURAL LAND USE CATEGORIES.

Crop	Water Use (1,000 acre-feet/year)
Citrus	242
Sugarcane	181
Vegetables	27
Total	450

The MIKESHE estimate of demand is 47 percent greater than the AFSIRS estimates of net basin demand. The difference is attributed to the difference in the demand estimated by both methods. While the AFSIRS methodology estimates a net basin demand that adjusts field scale demands by runoff occurring within the same basin, MIKESHE computed irrigation requirement in excess of precipitation. Analyses of output from AFSIRS indicate that field scale demand estimates are between 15 and 70 percent greater than net basin demand estimates for the major crop types within the planning area.

G.4 FLOOD DAMAGE REDUCTION IMPACTS OF SELECTED ALTERNATIVES

A key design criterion and goal throughout the development of the project components has been that flooding of developed areas will remain the same or improved with the plan implemented as compared to without the plan. No flooding of residential or commercial properties will be caused by implementation of the plan. See Appendix A for a detailed analysis of flooding impacts.

G.5 COMMERCIAL NAVIGATION

Navigation will not be negatively impacted by the implementation of the Caloosahatchee River (C-43) West Basin Storage Reservoir project. Existing flows will be maintained in the Caloosahatchee River and the local marinas and boat ramps will not be impacted by lower stages.

G.5.1 Commercial and Recreational Fishing

G.5.1.1 Introduction and Existing Conditions

A profile of commercial and recreational fishing in the Caloosahatchee Estuary can be constructed using field information and data in national and state fishing databases. Much of the available information about commercial and recreational fishing in the estuary is contained in studies and data sets for larger geographic areas.

There is some commercial fishing in the Caloosahatchee Estuary. The Florida Statistical Abstract (FSA) estimates the direct employment in fishing in Lee County. According to the FSA, the fishing industry in Lee County involves an estimated 40 businesses (FSA, 1997), with 180 employees, and an estimated annual payroll of $3.54 million. The use of cast nets in the estuary is reported to be common. In addition, there is reported to be substantial crabbing activity in the estuary. In Lee County, there are 638 saltwater products licenses and 267 permits for blue crab fishing.

The Caloosahatchee Estuary has important ecological connections with offshore commercial fish stocks. As described in Nelson (1992), many commercial finfish and invertebrate species use estuaries for critical stages of their development. ***Table G-17*** presents commercial landings, trips, and value data collected by the Florida Department of Environmental Protection (DEP) for the Pine Island Sound/San Carlos Bay area. As indicated in this table, in 1997 the value of the commercial landings from this area was approximately $1.7 million. The finfish and bait shrimp fisheries account for most of the landings and value. Although the shrimp landings in ***Table G-17*** are small, there is a significant offshore pink shrimp fishery that is based on Sanibel Island. This fishery is reflected in 1997 pink shrimp landings data for Lee County, which totaled 4,033,537 pounds. The Caloosahatchee Estuary and the area affected by freshwater releases from Lake Okeechobee comprise part of the nursery habitat for this fishery. The finfish and bait shrimp poundage, trips, and value data vary widely from year to year. This is due to changes in the fish population dynamics, fishing conditions, and fishing effort.

The data in ***Table G-17*** are complemented by the information in ***Table G-18***. ***Table G-18*** contains 1997 landings data from nearby Charlotte Harbor (to the north) and Estero Bay (to the south). As indicated in ***Table G-18***, the finfish fishery in Charlotte Harbor is substantially larger than that of the Pine Island/San Carlos Bay area. ***Table G-19*** contains 2002 annual landings summary for the coastal counties associated with the study area.

TABLE G-17: COMMERCIAL LANDINGS, TRIPS AND VALUE PINE ISLAND SOUND/SAN CARLOS BAY, 1993-1997

YEAR	CATEGORY	POUNDS	TRIPS	VALUE
1993	Finfish	1,084,476	4,853	$629,297
	Invertebrates	1,484	11	$1,435
	Shrimp	2,017	9	$6,250
	Bait Shrimp	89,165	1,762	$213,630
1994	Finfish	174,582	783	$134,862
	Invertebrates	1,864	13	$1,299

	Invertebrates	888,664
	Shrimp	2,928,307
	Bait Shrimp	82,602

The Caloosahatchee Estuary also supports guided sport fishing and recreational fisheries. Nelson (1992) described the following recreational species as "highly abundant", "abundant", or "common" in the Caloosahatchee Estuary: tarpon, sea catfish, snook, crevalle jack, silver perch, pinfish, spotted seatrout, red drum, black drum, and stripped mullet.

G.5.2 Expected Conditions

G.5.2.1 Lake Okeechobee Releases to the Caloosahatchee Estuary

Stages in Lake Okeechobee are managed to keep lake levels from being too high at the beginning of the wet season (June) to provide flood and hurricane

protection; and to keep levels from dropping during the dry season (November to May) for water supply purposes. Lake Okeechobee has four principal outlets for discharging inflows received from its tributary waterways:

1. evaporation, which in the south Florida climate accounts for 70 percent of the lake's water loss
2. distributary canals that convey water southward to the Lower East Coast and the Everglades
3. Atlantic Ocean via the St. Lucie canal
4. Gulf of Mexico via the Caloosahatchee River

The quantity, quality, and timing of the releases to the Caloosahatchee Estuary are critical determinants of the diversity and productivity of those ecosystems. Management of Lake Okeechobee and the ecological effects on the estuarine ecosystems resulting from the hydrologic changes induced by the alternative restoration plans are described below. The purpose of this discussion is to aid in interpreting the economic consequences of the alternative restoration plans on the Caloosahatchee Estuary.

G.5.2.2 Management of Lake Okeechobee

Water levels in Lake Okeechobee are managed through regulatory (flood control) and non-regulatory releases. Regulatory releases are made according to the regulation schedule established by the USACE in conjunction with the SFWMD to ensure that the integrity of the levee system surrounding the lake is not compromised by high water levels. Non-regulatory releases are made to meet:

1. environmental water supply requirements of the Everglades ecosystem
2. water supply requirements of the Lower East Coast
3. agricultural irrigation water demands in the LOSA
4. environmental needs in the St. Lucie and Caloosahatchee estuaries

Non-regulatory releases from Lake Okeechobee to the two estuaries are made in response to particular circumstances throughout the year. In general, releases are made during low flow periods to provide sufficient freshwater inflows into the estuaries to maintain ecologically desirable salinity levels.

As described in Hall (1992), the regulatory releases from Lake Okeechobee are intended to control high lake stages. The releases are controlled by the regulation schedule, which has management zones that specify outlets and release rates according to the time of year and prevailing lake stage. Although the regulatory discharges can have negative effects on the Caloosahatchee Estuary due to excessive freshwater flows into these ecosystems, the releases are necessary during high lake stages to avoid loss of life and property associated with hurricane-generated rainfall and waves.

The current regulation schedule provides for pulse releases to these estuaries during periods of rising lake stage. The pulse releases are designed to avoid the adverse ecological effects of higher releases over more concentrated periods. Pulse releases mimic natural hydrology following rainfall events. The receiving estuaries are able to absorb the pulses without prolonged salinity or ecological effects. While the pulses are effective for moderate regulatory releases, the prospect or occurrence of prolonged high lake stages can necessitate continuous releases from Lake Okeechobee into the estuaries.

The regulatory releases from Lake Okeechobee are directed southward toward the Water Conservation Areas (WCAs) (and the Everglades ecosystem) to the fullest extent possible. When the need for regulatory releases exceeds the receiving capacity of the WCAs, releases are made to the estuary. Maximum non-harmful releases will be made to the Caloosahatchee Estuary when the lake stage is rising.

G.5.2.3 Effects on Estuarine Ecology

The Caloosahatchee Estuary is a highly productive ecosystem that exists at the interface between freshwater and seawater. The Caloosahatchee Estuary is part of the southern portion of Charlotte Harbor, which includes the estuary, San Carlos Bay, Pine Island Sound, and Matlacha Pass. The estuary extends 29 miles from the W.P. Franklin Lock and Dam near Alva to Shell Point at its mouth in San Carlos Bay. San Carlos Bay, which is bounded by Sanibel Island and Pine Island, is located at the confluence of the river, Pine Island Sound, Matlacha Pass, and the Gulf of Mexico. The freshwater released into the estuary is controlled by the Franklin Lock and Dam, which also serve as a barrier to salinity and tidal influences upstream.

The quantity, timing, and quality of freshwater inputs to estuaries are critical determinants of the structure and function of these ecosystems (Bulger et al., 1990). Freshwater flows provide critical functions and materials for estuaries, including:

- nutrients for estuarine biota
- protection from predation by mature life stages that are intolerant of lower salinities or that are unable to find prey in naturally turbid estuarine waters
- a range of salinity conditions for a variety of organisms with different requirements for growth and development
- transportation of many estuarine-dependent larvae

Relative to natural conditions, the releases from Lake Okeechobee and changes in their watersheds have adversely affected the structure and function of these

sensitive ecosystems. In general, the peak flows from Lake Okeechobee to these estuaries are higher than those under natural conditions, and the low flows are lower.

The changes in freshwater inputs to the estuaries have short-term and long-term effects on these ecosystems. The most immediate effect of these changes is the magnification of the natural fluctuations of salinity in these estuaries. Estuarine species evolved under conditions of naturally fluctuating salinity levels, but excessive fluctuations can stress these ecosystems. As described by Bulger et al. (1990), excessive salinity fluctuations can keep estuarine biota in constant flux between organisms that favor higher salinity and those that favor lower salinity. If the fluctuations are extreme, appropriate salinity conditions do not last long enough for organisms to complete their life cycle, and the diversity of organisms is reduced to those few species that can tolerate the dramatic salinity fluctuations. Even moderate releases (such as in Zone B of the regulation schedule) can transform these estuarine systems into freshwater habitats after a few weeks of sustained releases. The estuarine species are displaced or expire during extended periods of low or high salinity. In addition, continuous flow releases tend to create critically low benthic oxygen levels at the transition zone between freshwater and seawater. These ecosystem perturbations affect more than just estuarine species, since estuaries provide important nursery habitat for marine (offshore) finfish and invertebrate species.

In general, when regulatory releases are terminated, the salinity levels in these estuaries return to the normal range, and the ecosystems begin to recover. The estuarine species that were displaced or extirpated return or are replaced. The recovery period is commensurate with the rate and duration of the freshwater inputs to the estuaries. Other longer-term effects of the regulatory releases from Lake Okeechobee on the Caloosahatchee Estuary include sediment and nutrient effects. Both effects are related to the quality of the water releases from Lake Okeechobee, which contain suspended silt, clay, and organic material. Much of the suspended material settles onto the bottom of the Caloosahatchee River during modest, non-regulatory releases. However, during regulatory releases–particularly the high release levels of Zone B and Zone A–this material is re-suspended and carried into the estuaries during the first few days of the release period. Suspended material increases the turbidity of the water in the estuaries and blocks sunlight to seagrass communities in these estuaries. The suspended material smothers some seagrass communities as it settles in the low energy environment of the estuaries. Other seagrass communities are affected by the reduction in sunlight that results from increased turbidity. Nutrient effects result from the nitrates and phosphorus contained in the lake water that are re-suspended by the release flows and stimulate primary production in the estuaries. Releases can imbalance nutrient cycling in these ecosystems, leading

to algae blooms and subsequent declines in dissolved oxygen and further increases in turbidity.

The short- and long-term ecological problems in these estuaries are not entirely attributable to the Lake Okeechobee regulatory water releases, however. These estuaries have perturbations from other sources that contribute to the stresses on these ecosystems. For instance, other estuarine tributaries deposit freshwater, sediments, and nutrients in these ecosystems, including heavy metals that are associated with agricultural pesticide use in the contributing watersheds.

G.5.2.4 Fishing Effects in the Estuaries

The above mentioned ecological effects of the freshwater releases to the estuaries can lead to commercial and recreational fishing impacts. The challenge in estimating the economic effects on commercial and recreational fishing in the Caloosahatchee Estuary is complicated by the need to differentiate between the with- and without-project future conditions. The determination of a dollar value of the loss to commercial and recreation fishing is not feasible due to the inability to quantify the decrease in fish numbers and accurately measure the decrease in fish yields. It is safe to reason that as fish populations decrease due to degraded conditions in the estuary, restrictions will be placed on certain species of fish, the supply of fish will decrease and greater distances will have to be traveled for commercial fishing vessels who in turn will realize smaller catches, all leading to a decrease in economic activity.

G.6 RECREATION

This section examines the potential effects of the SAP on outdoor recreation in the study area. Outdoor recreation in Florida includes many different activities. A common way of differentiating outdoor recreation activities is to classify them based as "user-oriented" or "resource-based" activities. User-oriented activities, such as individual and team sports, are not dependent on any natural resource setting and can be located, space permitting, on any open site. These facilities are provided for the convenience of the user. For example, a basketball court can be added to a playground. Resource-based activities, such as hunting and fishing, depend on the existence and quality of supporting natural or historical resources. The economic value of resource-based recreation is determined by the users' willingness to pay for a recreation occasion. The willingness of current and potential users to pay for resource-based recreation of specific quantity and quality constitutes the demand for that type of recreation. The interaction of demand with the quantity and quality of recreation resources available determines the recreation use or "participation" levels for that resource-based activity. When the quantity or quality of recreation resources is modified by a

project, such as the alternative restoration plans, the change in value of resource-based recreation is based on the difference in the willingness of users to pay under the with- and without-project conditions.

The Caloosahatchee River (C-43) West Basin Storage Reservoir provides a unique and extensive natural resource-based recreational resource. The restoration of the ecosystem could potentially have important impacts on the value of outdoor recreation in the study area. The hydrologic changes associated with the alternative restoration plans have been designed to improve the structure and function of the ecosystems. These improvements can be expected to provide resource-based recreational opportunities compatible with the protection of the natural systems. Many tourists and residents recreate in the natural areas surrounding the study area. If the alternative restoration plans improve the ecology of the study area, the quality of the study area related recreation and/or the number of people who participate in study area related recreation could increase as well. Consequently, the value of outdoor recreation in the study area could also substantially increase.

However, precisely estimating the future value of recreation in the study area is problematic, and anticipating the incremental changes in value associated with restoration is even more challenging. There are four principal uncertainties that challenge forecasting the future quantity and quality of outdoor recreation under with- and without project conditions. Perhaps the most important uncertainty concerns the timing and character of the ecological changes that are expected to result from the alternative restoration plans. At this time, the outcomes of the restoration actions cannot be predicted. Consequently, secondary effects, such as associated changes in recreation patterns and the resulting effect on industries supporting recreation (e.g., marine industry) cannot be accurately quantified.

Another uncertainty regarding the future value of recreation is the marketing of tourism and study area related recreation. If the restored ecosystem is used to market tourism and recreation in the study area, the value of recreation could change dramatically relative to the without-project future conditions.

A third uncertainty is the degree to which recreational facilities and recreational access would be developed as part of a restoration plan. Recreation facilities and access, such as visitor centers, scenic overlooks, nature trails, and roads, can greatly affect participation levels.

Finally, there are a variety of economic factors at the national level that can influence tourist and resident recreation demand. These factors include the health of the national economy, levels of disposable income, and the availability and costs of competing recreation opportunities. As described in the 2000

Florida Statewide Comprehensive Outdoor Recreation Plan (SCORP) (Draft): "The states 1996 tourist population (44.7 million) is expected to increase to 57 million visitors, a 25 percent increase, by 2005. However, Florida tourism and its economic implications are sensitive to national economic and energy policies. The dynamic nature of the industry causes uncertainty in tourism forecasting, making it difficult to accurately project visitation levels for more than one or two years at a time" (Florida DEP, 2000). As evidence of the challenges of tourism and recreation forecasting, the Florida Tourism and Industry Marketing Corporation limits its tourism forecasts to three years, and the most recent SCORP (2000) used a ten-year forecast horizon (to the year 2010).

G.6.1 Recreation Resources

The SCORP is the best source of information on recreation demand and supply at the state and regional scales. It divides the state into 11 planning regions, each with clusters of counties. As indicated in ***Table G-20,*** Region 9 is the planning region that encompasses the study area.

TABLE G-20: COUNTIES WITHIN SCORP PLANNING REGIONS POTENTIALLY AFFECTED BY ALTERNATIVE RESTORATION PLANS

Region	Counties
Region 9	Collier
	Glades
	Hendry
	Lee
	Sarasota
	Charlotte

Source: Florida Department of Environmental Protection, 2000.

The SCORP organizes outdoor recreation in Florida into 47 categories that encompass a variety of recreation activities including team sports (e.g., basketball and baseball), individual sports (e.g., golf and tennis), hunting, fishing, swimming, and boating. ***Table G-21*** presents descriptive information on the recreation facilities in SCORP Region 9 for study area specific recreation categories. These resource-based categories were selected as those that could potentially be affected by the hydrologic changes or ecological changes associated with the alternative restoration plans. This table also includes percentages of the statewide totals for the recreation categories.

G.6.1.1 Recreation Demand

Profiles of existing and future recreation demand in the study area can be developed by drawing on a variety of information at the national, state, regional, and local levels. In general, the variety of recreational interests in the United States appears to be increasing along with recreational participation rates. As future recreation needs and interests develop, it is important to recognize that participation in specific types of recreational activities is often linked to demographic factors such as age and income. For example, participation in activities requiring vigorous exercise is considerably higher for young people than for senior citizens. However, the elderly population has increasing recreation participation because of the growing awareness of the importance of physical fitness. Participation in most activities is low for those with family incomes below $25,000 per year. Interestingly, participation is also low for those with family incomes greater than $100,000 per year. Most outdoor recreational activities appear to be enjoyed largely by the middle class, those with family incomes between $25,000 and $75,000 per year.

G.6.1.2 Regional Recreation Demand

Recreation demands were developed for the SCORP through surveys of residents and tourists. The Division of Recreation and Parks conducts periodic surveys of resident and tourist participation in recreation activities to estimate outdoor recreation in Florida. The recreation participation information was derived from the 2000 surveys conducted by the University of Florida, Department of Recreation, Parks, and Tourism. Participation in outdoor recreation activities is expressed in terms of user-occasions, which occur each time an individual participates in a single outdoor recreation activity. The number of user-occasions was calculated for each planning region as well as the entire state by type of activity. Demand was estimated for 1997, 2000, 2005 and 2010 by applying the per capita participation rates to population projections.

Table G-21 presents 1997 and projected 2010 demands for the selected recreation activities in SCORP Planning Region 9. This table includes user-occasions as well as facility/resource needs. As part of the without-project conditions, all of the regions are expected to have significant increases in demands for the selected recreation activities with a commensurate need to increase development of the regions' recreation resources and facilities.

TABLE G-21: DEMAND AND FACILITY NEEDS (1997 AND 2010) FOR SELECTED RECREATION ACTIVITIES SOUTHWEST REGION (SCORP REGION 9)

Activity	Units	Demand (user-occasions)		Resources / Facility Needs	
		1997	2010	1997	2010
Hunting	Acres	108,131	139,247	0	0
RV / Trailer Camping	Camp Sites	1, 501,713	2,386127	0	0
Tent Camping	Camp Sites	155,069	204,538	0	0
Hiking	Miles	1,299,375	2,011,069	223	517
Freshwater Fishing	Feet	543,125	779,561	0	0
Nature Study	Miles	2,146,713	3,073,615	10.87	56.8
Bicycle Riding	Miles	11,761,917	16,675,164	771.33	1,177.08

Source: Florida Department of Environmental Protection, 2000.

In summation, the Southwest Region (Region 9) ecosystems support a significant amount of outdoor recreation in the LEC of Florida. A significant portion of the expenditures comes from tourists. As can be seen from the table above, the activities that have a lack of supply for recreation purposes are hiking, biking and nature study. These are resources that could potentially be increased through the construction of the Caloosahatchee River (C-43) West Basin Storage Reservoir.

G.6.2 National Recreation Trends

National trends in recreation may help to identify potential or expected changes in the demand for Florida recreation as the result of ecosystem restoration. Two recent national surveys of outdoor recreation have particular relevance for this investigation.

G.6.2.1 National Survey of Recreation and the Environment

The Outdoor Recreation Coalition of America conducted a National Survey of Recreation and the Environment in 1994 and 1995. Approximately 17,000 Americans were interviewed in a random sample telephone survey, providing information regarding their participation in 62 recreational activities organized into 13 broad categories.

Table G-22 presents 1994-1995 participation rates for 26 of the 62 surveyed recreational activities. The activities in this table were selected as those that potentially could be affected by the SAP. Of the selected activities, the three

most popular groups of activities were outdoor viewing, fitness activities, and outdoor social activities that had participation rates of 76.2 percent, 68.3 percent and 67.8 percent, respectively. Walking was identified as the most popular activity with approximately 134 million participating (66.7 percent of the population). Approximately 124 million recreationists (62.1 percent) enjoy visiting a beach or other waterside and gathering outdoors with family. Sightseeing also had a high level of participation (56.6 percent). Other very popular activities include hiking and backpacking, fishing, boating and camping.

The Outdoor Recreation Coalition conducted a similar national survey of recreation and the environment in 1983-1984. (***Table G-23).*** ***Table G-24*** compares the results of the two surveys. The categories are somewhat different due to differences in the surveys.

TABLE G-22: PARTICIPATION RATES FOR SELECTED RECREATIONAL ACTIVITIES BY U.S. POPULATION 16 YEARS OR OLDER, 1994-1995

Recreational Activity	Participants (millions)	Percent of U.S. Population
Fitness	136.9	68.3%
Walking	133.7	66.7%

Table G-23 contains numbers of participants, not participation rates. As indicated in this table, there has been an increase in the number of participants for almost all activities. The 11.4 percent increase in United States. population during this period explains some of the change in the number of participants. However, some activities are clearly undergoing an increase in participation rates. For example, bird watching has the largest increase (155 percent) in number of participants from 1984 to 1995. Hiking and backpacking also

experienced large increases in participation, 93.5 and 72.7 percent respectively. Walking activity increased 42 percent from 94 million to 134 million participants. Also, since 1984 there has been an increasing interest in specialized outdoor adventure activities such as orienteering, mountain climbing, rock climbing, caving, and special types of wildlife viewing.

In general, the variety of recreational interests in the United States appears to be increasing along with recreational participation rates. As future recreation needs and interests develop, it is important to recognize that participation in specific types of recreational activities is often linked to demographic factors such as age and income. For example, participation in activities requiring vigorous exercise is considerably higher for young people than for senior citizens. However, the elderly population has increasing recreation participation because of the growing awareness of the importance of physical fitness. Participation in most activities is low for those with family incomes below $25,000 per year. Interestingly, participation is also low for those with family incomes greater than $100,000 per year. Most outdoor recreational activities appear to be enjoyed largely by the middle class, those with family incomes between $25,000 and $75,000 per year.

G.6.2.2 National Survey of Fishing, Hunting, and Wildlife-Associated Recreation

The U.S. Fish and Wildlife Service conducted the National Survey of Fishing, Hunting, and Wildlife-Associated Recreation in 1996. As part of this survey, 22,578 anglers and hunters and 11,759 wildlife watchers were interviewed. The purpose of the survey was to gather information regarding participation and expenditures for wildlife-related activities, including fishing, hunting, and wildlife watching. National participation and expenditure data for sportsmen and wildlife watchers are presented in ***Table G-24*** . The survey revealed that 77 million Americans aged 16 or older (40 percent of the adult population) enjoyed some form of wildlife-related recreation in 1996 with total expenditures exceeding $101 billion.

Wildlife watching activities primarily included observing, photographing and feeding wildlife for two types of participants: residential and nonresidential. The residential category included those activities that occurred within one mile of the residents' homes, while the nonresidential group included those who took trips or outings for the primary purpose of observing, photographing, or feeding wildlife. Based on the National Survey of Fishing, Hunting, and Wildlife-Associated Recreation, in 1996 over 62.9 million people in the United States participated in wildlife watching. This figure is consistent with the 1995 participation of 62.6 million wildlife watchers reported in the National Survey of Recreation and the Environment.

TABLE G-24: TOTAL U.S. WILDLIFE WATCHING PARTICIPATION, 1996

Category	Participants	Expenditures
Residential	60.8 million	
Nonresidential	23.7 million	
Total*	62.9 million	$29 billion

Source: U.S. Fish and Wildlife Service, 1996.

The sum of residential and nonresidential subcategories does not equal the total due to an overlap in participation. ***Table G-25*** presents residential and nonresidential participation in various wildlife-watching activities. Among all wildlife-watching participants, 97 percent (60.8 million) watched wildlife within one mile of their home (residential). The most popular residential activities included feeding and observing wildlife, 54.1 and 44.1 million participants, respectively. Approximately 23.7 million people (38 percent of all wildlife-watchers) spent 314 million days in 1996 taking trips for the primary purpose of enjoying wildlife. Of all nonresidential wildlife watchers, 68 percent participated only within their home state, 13 percent traveled only to other states and 19 percent took wildlife watching trips in both their state of residence as well as in other states. Survey results indicated that wildlife-watching trips were evenly distributed among male and female participants. The types of sites visited by nonresidential wildlife watchers included woodlands (77 percent), lakes or streamside (69 percent), open field (63 percent), brush covered (59 percent), wetland marsh or swamp (44 percent), manmade area (39 percent) and oceanside (27 percent). Of the 23.7 million nonresidential participants, 22.9 million enjoyed observing wildlife. Observing birds and land mammals was favored by 75 percent of wildlife observers.

TABLE G-25: U.S. WILDLIFE WATCHING ACTIVITY, 1996

Category	Participants (millions)	Average Days / Year (millions)	Average Days / Participant
Total Wildlife Watching*	62.9 (100%)		
Residential*	60.8 (97% of total)		
Observed Wildlife	44.1		
Photographed Wildlife	16.0		
Fed Wildlife	54.1		
Maintained Plantings/Natural Areas	13.4		
Visited Public Areas	11.0		
Nonresidential*	23.7 (38% of total)	314	13.2

The National Survey of Fishing, Hunting, and Wildlife-Associated Recreation also contains state-level information on recreation participation and expenditures. In 1996, approximately 3,642,000 of Florida's 11,239,000

residents (32 percent) participated in wildlife-related recreation with the following distribution: 2,840,000 wildlife watching (25 percent of the state population) and 1,988,000 hunting/fishing (18 percent of the state's population). According to the survey, 79 percent of the time spent wildlife watching by Florida residents is spent within the State of Florida.

As indicated in ***Table G-27***, there were an estimated 1,846,000 participants in wildlife-watching activities in Florida in 1996. Approximately 1,050,000 (57 percent) of these participants were Florida residents and the remainder (796,000 or 43 percent) was from outside the state. Together, the in-state and out-of-state participants spent a total of 14,658,000 days watching wildlife in Florida.

TABLE G-27: PARTICIPANTS IN WILDLIFE-RELATED RECREATION IN FLORIDA, 1996

Participant	Residents	% of Total	Non-residents	% of Total	Total
Anglers	1,878,000	(66%)	986,000	(34%)	2,864,000
Hunters	170,000	(92%)	14,000	(8%)	184,000
Wildlife Watchers	1,050,000	(57%)	796,000	(43%)	1,846,000

Source: U.S. Fish and Wildlife Service, 1996.

Table G-28 presents estimated expenditures associated with wildlife watching in Florida during 1996. As indicated in this table, in-state and out-of-state participants spent over $1.6 billion in 1996 on wildlife watching. This includes trip-related expenditures and equipment expenditures. Wildlife watching equipment includes binoculars, film, bird food, and special clothing. Auxiliary equipment expenditures accounted for items such as tents and backpacking equipment. Other expenditures include magazines and books, membership dues and contributions, land leasing and ownership, and plantings.

TABLE G-28: FLORIDA WILDLIFE WATCHING EXPENDITURES, 1996

Expenditure Category	Total Expenditures (millions)	% of Total
TOTAL EXPENDITURES	$ 1,677.2	100%
Trip-Related Expenditures	$ 754.7	45%
Food and Lodging	$ 439.7	26%
Transportation	$ 189.4	11%
Other Trip Costs	$ 125.6	7%
Total Equipment Expenditures	$ 767.6	46%
Wildlife-Watching Equipment	$ 286.9	17%
Auxiliary Equipment	$ 65.4	4%
Other Expenditures	$ 154.8	9%

G.6.2.3 State Recreation Trends

The Florida SCORP supplements the results of the two national recreation surveys described above with estimates of current and future recreation demand at the state and regional scales. Recreation demands were developed for the SCORP through surveys of residents and tourists. The Division of Recreation and Parks conducts periodic surveys of resident and tourist participation in recreation activities to estimate outdoor recreation in Florida. The Division of Recreation and Parks did not have funds to conduct a new participation survey for the latest SCORP so the recreation participation information was derived from the 1992-1993 surveys conducted by the University of Florida, Department of Recreation, Parks, and Tourism. Participation in outdoor recreation activities is expressed in terms of user-occasions, which occur each time an individual participates in a single outdoor recreation activity. The number of user-occasions was calculated for each planning region as well as the entire state by type of activity. Demand was estimated for 1997, 2000, 2005 and 2010 by applying the per capita participation rates to population projections.

Table G-29 presents 1992 statewide resident and tourist demand in Florida for selected outdoor recreation activities. The activities were chosen based on their potential for being affected by the alternative restoration plans. As indicated in this table, over 45 million residents and tourists participated in these activities in 1992. Hiking, recreational vehicle (RV) camping, and nature study were popular with residents and tourists. With the exception of RV camping, participation by residents outnumbered tourist participation.

TABLE G-29: DEMAND FOR SELECTED RECREATION ACTIVITIES IN FLORIDA USER-OCCASIONS (THOUSANDS), 1992

Activity	Resident	Tourist	Resident & Tourist	% of Total
Hunting	1,656	34	1,690	4%
RV Camping	2,992	5,659	8,651	19%
Tent Camping	1,260	825	2,086	5%
Hiking	5,220	3,668	8,887	20%
Horseback Riding	3,155	491	3,647	8%
Nature Study	4,645	2,215	6,859	15%
Canoeing	846	555	1,401	3%
Total	27,235	18,271	45,506	100%

Source: Florida Department of Environmental Protection, 1994.

Table G-30 presents participation rates for the same set of recreation activities during 1985 and 1992. In general, residents have higher participation rates than tourists, and participation rates for both groups have declined from 1985 to 1992.

TABLE G-30: PARTICIPATION RATES FOR SELECTED RECREATIONAL ACTIVITIES (1985, 1992)

	% of Residents Participating		% of Tourists Participating	
Activity	1985	1992	1985	1992
Hunting	11%	2%	0%	0%
RV/Trailer Camping	8%	3%	4%	5%
Tent Camping	10%	3%	1%	1%
Hiking	10%	6%	3%	3%

G.6.2.4 State Tourism Trends

As described in the SCORP, 49 million domestic and international visitors to Florida per year comprise a significant portion of the overall demand for outdoor recreation resources in Florida. Their participation in resource-based recreation and their relatively high incomes (compared to resident recreationists) make tourists a significant component of project-related recreation in the study area. The Comprehensive Review Study detailed the importance of tourism on the recreation in Florida.

G.6.2.5 Potential Changes in Value of Recreation

The Caloosahatchee River (C-43) West Basin Storage Reservoir can support a significant amount of outdoor recreation in the Florida LEC, with a significant portion of expenditures coming from tourists. Based on the recent adverse effects related to environmental damage of the ecosystem, it may be concluded that improving the environmental quality of the Caloosahatchee River and Estuary ecosystem will substantially support and sustain local recreation-based businesses. Given the potential levels of expenditures and consumer surplus in the future, a small percentage increase in the quantity or quality of project-related recreation could represent an increase in recreation value.

There are potential recreation resources that will be associated directly with the construction of the impoundment. The uses presently considered compatible with resource protection and passive recreation include: freshwater fishing, horseback riding, hiking, off-road bicycling, wildlife viewing and nature study.

G.6.3 Recreation Benefits

The recreation appendix (Appendix H) for the Caloosahatchee River (C-43) West Basin Storage Reservoir project contains a description of the conceptual plan

that is being proposed for recreation purposes. Recreation features are being planned in the Caloosahatchee River (C-43) West Basin Storage Reservoir project as an incidental project benefit. These recreation benefits will not be used in the justification of the recommended plan. Order of magnitude costs have been included as provided by the SFWMD cost estimators and gleaned from other approved reports after updating. Costs have been updated by using the USACE, Jacksonville District, Broward County Water Preserve Areas recreation MCACES costs. SFWMD will be O&M the Caloosahatchee River (C-43) West Basin Storage Reservoir project recreational features. Adjustments may be made to the dollars spent depending on project design. As shown in Appendix H, Recreation, the costs for proposed recreation features would be $2,519,000. An additional ten percent for PED, and an additional eight percent for construction supervision and administration bring the estimated total costs for recreation to $2,972,000.

The NED benefit evaluation procedures contained in ER 1105-2-100 (22 Apr 00), Appendix E, Section VII, include three methods of evaluating the beneficial and adverse NED effects of project recreation: travel cost method (TCM), CVM, and unit day value (UDV) method.

The UDV method was selected for estimating recreation benefits associated with the creation of the Caloosahatchee River (C-43) West Basin Storage Reservoir. The UDV approach in recreation benefit analysis consists of two parts: determining value per visit and estimating visitation. Application of the selected value to estimate annual use over the project life, in the context of the with and without-project framework of analysis, provides the estimate of recreation benefits.

The without project condition in this analysis has no recreation value since the Caloosahatchee River (C-43) West Basin Storage Reservoir would not exist and the land would not be open to the public. It is presumed that the impoundment must be open to the public in order to realize the recreation benefits being claimed. The with-project condition will be the expected value of the recreational activity based on the UDV method.

Economic justification is determined by examining the benefit to cost ratio and net benefits of the proposed recreation sites. The economic justification of the proposed recreation sites can be examined by comparing the equivalent average annual costs with the estimate of the equivalent average annual benefits that would be realized over the period of analysis. These average annual recreation benefits and costs are summarized in

ER 1105-2-100 (The Planning Guidance Notebook) provides economic evaluation procedures to be used in all Federal water resources planning studies. The

guidelines specified in the ER 1105-2-100 dated 22 April 2000 were observed in preparing this cost analysis. The (FY) 2007 federally mandated project evaluation interest rate of 4.875 percent, an economic period of analysis of 40 years and FY 2007 prices were used to evaluate the economic feasibility of the project recreation sites.

The value of a day of general recreation was computed at $6.79. The number of visits per year was estimated at 52,925. Average annual benefits were estimated at $359,000. Average annual cost was estimated at $199,000. A summary of the economic feasibility is shown in ***Table G-31***.

TABLE G-31: SUMMARY OF RECREATION COSTS AND BENEFITS

Recreation Construction Costs	**$2,519,000**
PED & S/A (18%)	$453,000
Total Recreation Construction	**$2,972,000**
Construction Duration	12 months
Interest During Construction Costs	$72,000
Total Recreation Investment	**$3,044,000**
Period of Analysis	40 years
Annualized Cost	$174,000
OMRR&R	$25,000
Total Annual Costs	**$199,000**
Annual Benefits	
User Day Value	$6.79
Daily Use	145
Annual Use	52,925
Average Annual Benefit	**$359,000**

A sensitivity analysis was done to further reinforce expected benefits and provide additional justification for proposed recreation features (***Table G-32***). Minimum and SCORP expected benefits have been provided for comparison with the proposed Caloosahatchee River (C-43) West Basin Storage Reservoir recreation benefits. This economic analysis suggests there would be ample benefits to conservatively justify the proposed recreation facility construction for the Caloosahatchee River (C-43) West Basin Storage Reservoir project.

TABLE G-32: SENSITIVITY ANALYSIS USING MULTIPLE SCENARIOS

Scenario	Annual Users	Daily Users	Annual Benefit
Most Likely	52,925	145	$160,000.00
Worst Case	32,850	90	$24,000.00
SCORP Guidelines	464,280	1,272	$2,953,000.00

A benefit to cost ratio of 1.8 to 1 and net annual benefits equaling $160,000 were calculated based on the conceptual plan.

G.7 COSTS

Data for initial construction/implementation, land acquisition, monitoring, and periodically recurring costs for operation, maintenance, repair, replacement, and rehabilitation (O&MRR&R), have been developed through engineering design and cost estimation, and real estate appraisal efforts. Details of that data development are explained and discussed elsewhere in this report. The main issues requiring economic evaluation attention include equivalent time basis calculations, price levels, and timing of project spending.

For purposes of this report and analysis, NED costs (as defined by Federal and USACE policy), are expressed in October 2006 price levels, and are based on costs estimated to be incurred over a 40 year period of analysis. Costs of a plan represent the value of goods and services required to implement and operate and maintain the selected alternative plan.

The following table displays the costs associated with the alternatives. The costs presented in ***Table G-33*** are preliminary rough order of magnitude (ROM) estimates and include total initial costs of construction features, recreation features, real estate, Interest During Construction (IDC), and total average annual costs for each alternative. These costs were used to formulate and evaluate plans to identify the SAP. The costs for the SAP were further refined based on additional engineering and environmental evaluations, as noted in the main report and can be found in the MCACES cost estimates The O&M cost is an annual estimate for fully implemented components.

TABLE G-33: ESTIMATED NED COSTS FOR ALTERNATIVES

	Alt 2	Alt 3B	Alt 3C	Alt 4
Cost Component				
Construction	$285,800,000	$316,900,000	$368,000,000	$464,300,000
S/A	$18,400,000	$20,400,000	$23,700,000	$29,800,000
PED	$23,000,000	$25,500,000	$29,600,000	$37,300,000
Lands	$80,507,000	$80,507,000	$80,507,000	$80,507,000
Initial Cost	**$407,707,000**	**$443,307,000**	**$501,807,000**	**$611,907,000**
Interest During Construction				
Construction	$26,600,000	$29,500,000	$34,000,000	$43,000,000
Lands	$13,500,000	$13,500,000	$13,000,000	$13,000,000
Total IDC	**$40,100,000**	**$43,000,000**	**$47,000,000**	**$56,000,000**
Total Project Investment	**$447,807,000**	**$486,307,000**	**$548,807,000**	**$667,907,000**
Average Annual Cost				
Interest & Amortization	**$25,700,000**	**$27,900,000**	**$31,400,000**	**$38,300,000**
Operation & Maintenance	$3,265,000	$3,358,000	$5,267,000	$5,556,000
Total Average Annual Cost	**$28,965,000**	**$31,258,000**	**$36,667,000**	**$43,856,000**

* Recreation costs are not included in the NED costs for alternatives
* The costs in this table are preliminary costs and are not exactly equivalent to the costs used in the main report which are detailed costs.

The timing of a plan's costs is important. Construction and other initial implementation for component costs cannot simply be added to periodically recurring costs for project operation, maintenance, and monitoring. Also, construction costs incurred in a given year of the project can not simply be added to construction costs incurred in other years if meaningful and direct comparisons of the costs of the different components are to be made. A common practice of equating sums of money across time with their equivalent at an earlier single point in time is the process known as discounting. Through this mathematical process, which involves the use of an interest rate (or discount rate) officially prescribed by Federal policy for use in water resource planning analysis (4.875 percent per year at the time of analysis), the cost time stream for the alternative plans were mathematically translated into a equivalent time basis value.

There is some admitted uncertainty as to how the plan, if approved and adopted, would be implemented. It is recognized that the plan would likely be implemented over a considerable period of time, little by little. For purposes of this evaluation, construction costs are assumed to be incurred on an equal monthly basis during the implementation of the alternative plan as defined.

ER 1105-2-100 requires that IDC be computed which represents the opportunity cost of capital incurred during the construction period. Interest was computed

for construction and PED costs from the middle of the month in which the expenditures were incurred until the first of the month following the estimated construction completion date. Interest during construction was computed for both real estate and construction costs. Interest during construction was computed for the total real estate cost starting from the month prior to construction commencing.

The cost of a project is the investment incurred up to the beginning of the period of analysis. The investment cost at that time is the sum of construction and other initial cost such as real estate and PED cost plus interest during construction. ***Table G-33*** summarizes the total investment cost and total annual equivalent costs of each alternative plan.

G.8 COST EFFECTIVENESS AND INCREMENTAL COST ANALYSIS

Plan formulation and evaluation actions for this project focused on management measures and plans developed in prior Everglades ecosystem restoration studies. All of the prior studies with similar planning objectives (to restore fish and wildlife habitat functions in the remaining estuaries and rivers) concluded that additional storage to supplement the regional water management system was needed at the Caloosahatchee River (C-43) West Basin Storage Reservoir location, and an aboveground impoundment was the most cost-effective management measure for creating additional storage.

The initial and final arrays of alternative plans for this project consisted of aboveground impoundments (a single management measure) of varying storage volumes and pump sizes. All other management measures were screened from further consideration as a result of prior studies. Since all of the plans in the final array of alternative plans consisted of the same cost effective management measure, an incremental cost analysis (ICA) was performed to determine the incremental costs of the benefits produced by the remaining four structural plans. ICA of the system-wide effects of the final array of plans was performed using IWR Plan software for the eight remaining alternative plans.

Cost effectiveness analysis begins with a comparison of the costs and outputs of alternative plans to identify the least cost plan for every level of output considered. Alternative plans are compared to identify those that would produce greater levels of output at the same cost, or at a lesser cost, as other alternative plans. Alternative plans identified through this comparison are the cost effective alternative plans. Next, through ICA, the cost effective alternative plans are compared to successively identify the alternative plans with the least additional cost per additional output that is, the "Best Buy" alternative plans that produce the "biggest bang for the buck." Cost effective plans are compared by examining the additional (incremental) costs for the additional (incremental) amounts of

output produced by successively larger cost effective plans. The plans with the lowest incremental costs per unit of output for successively larger levels of output are the best buy plans. The results of these calculations and comparisons of costs and outputs between alternative plans provide a basis for addressing the decision question "Is it worth it?" i.e., are the additional outputs worth the costs incurred to achieve them?

This analysis is based on and follows guidance from the USACE Institute for Water Resources publication, Evaluation of Environmental Investment Procedures Manual, Interim: Cost Effectiveness and Incremental Analyses, May 1995, IWR Report #95-R-1. Costs are based initially on a ROM and include PED and construction costs, Interest During Construction, as well as O&M costs after construction. The most feasible cost effective plans reflect estimates based on ROM quantities

G.8.1 Types of Benefits Analyzed

In practice, USACE ecosystem restoration studies typically measure the ecosystem benefits of alternative plans in terms of physical dimensions (number of acres of wetlands, for example), or population counts (number of wading birds, for example), or various habitat-based scores ("habitat units" based on the U.S. Fish & Wildlife Service's *Habitat Evaluation Procedures*, or "HEP", for example). The evaluation consisted of many performance measures to ascertain how well each of the alternative plans performed on various criteria indicative of ecosystem restoration, and habitat units (HU) were derived from these performance measures and selected by the project delivery team (PDT) as the metric that best integrated information regarding the quality and quantity of improved hydrologic and ecologic function within the study area.

The purpose of the habitat suitability model for the Caloosahatchee River (C-43) West Basin Storage Reservoir project is to portray species response to changes in environmental variables resulting from restoration activities spatially and temporally to facilitate policy decisions. The intent of the habitat suitability model is not to simulate the life-cycles of the species. Rather, it is to estimate the number of HUs to serve as a relative basis for comparing management alternatives.

Habitat Suitability Indices (HSI) models were developed with each stressor variable portrayed spatially and temporally across the study area at scales appropriate to the organism or community being portrayed. The HSI models have been incorporated into a GSI to portray responses spatially and temporally to facilitate policy decisions. That is, the model describes a response surface of habitat suitability values that vary spatially according to stressor levels

throughout the estuary and temporally according to temporal patterns in stressor variables.

Species selected for modeling (focal species) are ecologically, recreationally or economically important and have a well established linkage to stressors of management interest. They may also make good focal species because they engage the public in caring about the outcome of restoration projects. The HSI models were developed by choosing specific life stages of particular species with the most limited, restricted, or tightest range of suitable conditions, to capture the highest sensitivities of the organisms to the environmental changes associated with the planned restoration activities.

The project team originally decided to use seven species–eastern oysters, blue crabs, *Vallisneria,* seagrass (*Halodule and Thalassia)*, spotted seatrout, decapod larvae, and zooplankton. Once all models were run on all alternatives, the team decided to narrow the full analysis to three species–oysters, *Vallisneria* and seagrass.

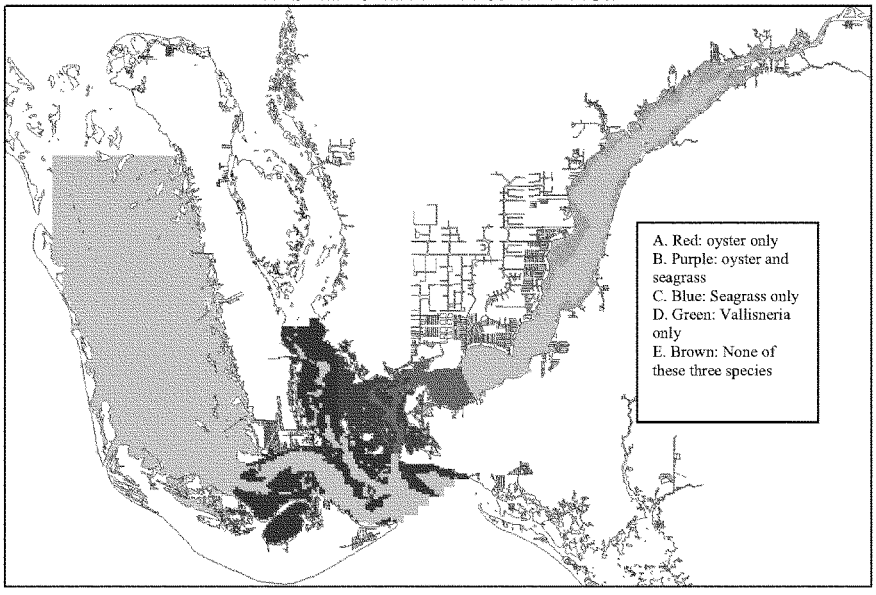
The following sub-sections describe the annualized ecological benefits for the five attributes studied (three single species/habitats, extreme events, and Restoration Coordination and Verification [RECOVER] Performance Measure). Ecological benefit index scores were then multiplied by the acreage of the affected area to obtain HUs. A detailed description of the HSI model for each species, as well as the method for calculation of HUs is contained in the environmental appendix of the final PIR.

Three of the chosen benefit streams are indicators of the health of certain habitats within the estuary. Although these are single species, they represent habitat for hundreds of individual species which live, feed and breed in these areas. Therefore, although the habitat suitability scores were multiplied by the modeled area to estimate total ecological benefits, the ecological benefits are actually applicable to a much larger area because other species also directly and indirectly benefit from the habitat improvement.

Two of our benefit streams are indicators of whole estuary health. The Extreme Events benefit stream is an average of two habitats and reflects how these habitats react to extreme events. Although only two habitats were considered, the team felt it was appropriate to apply this to the full estuarine acreage, as this is perhaps the best indicator of how the entire estuary would react to differing alternatives during extreme events. NE-03 RECOVER PM based on a flow created to maximize whole estuary ecological health.

Table G-34 includes a list of the raw HSI scores for each of the alternatives and the existing and future without project condition. The details behind the calculations can be seen in the environmental appendix.

TABLE G-34: HSI SCORES FOR ALTERNATIVE CONDITIONS



Indicator	2000	2050	ALT2	ALT3B	ALT3C	ALT4
Vallisneria	0.16	0.20	0.31	0.33	0.35	0.35
Seagrass	0.51	0.54	0.59	0.59	0.59	0.59
Oysters	0.48	0.52	0.60	0.60	0.61	0.61
Extreme Events	0.28	0.30	0.42	0.43	0.45	0.45
EST05	0.38	0.43	0.64	0.70	0.80	0.79

G.8.2 Habitat Unit Combination Methodology

Sometimes it is difficult to summarize the results of CE/ICA when the analyses are performed separately on HUs for distinct species or communities. This phenomenon often occurs simply because different management measures or alternative plans "do" different things, provide different types of output, and provide benefits to different biological communities. Therefore, the CE/ICA was performed on the combined HUs for all the performance indicators.

Once the HSI scores were calculated, the five streams of AAHUs were then converted into one project AAHU number. This was done with the Habitat Unit Combination Methodology (HUCM) (***Figure G-7***).

FIGURE G-7: CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR AREA OF IMPACT

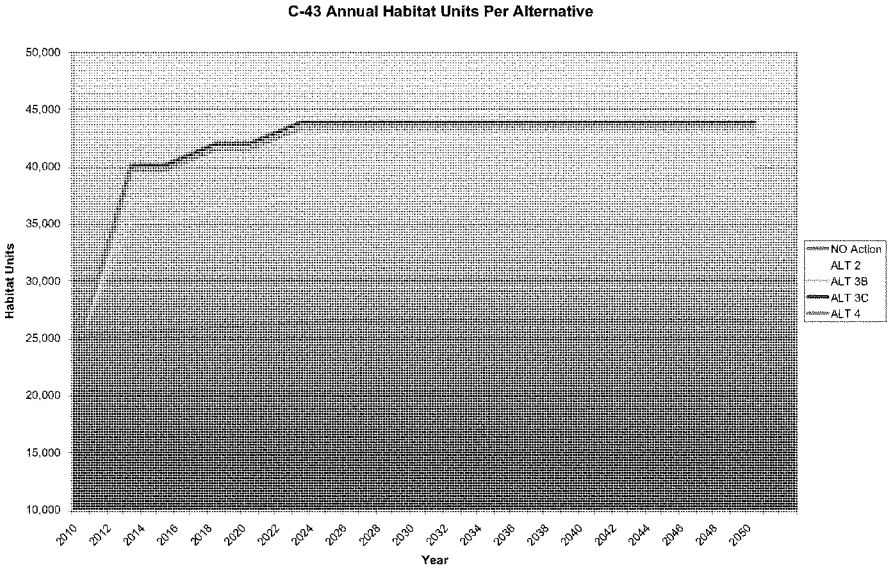
The basis of the HUCM is that the total HSI values in any one area are summed and then divided by the total number of HSI scores for that area to find an average HSI for the area. Then that score is multiplied by the number of acres for that area. There are two HSI scores which are calculated for the entire area of benefit (extreme event and EST05). Therefore, all areas have at least those two scores in addition to any species specific HSI values. So, for example, if one area has oysters as the only species specific HSI calculated, the HUCM would add the oyster HSI plus the extreme event and EST05 HSI, then divide by three. That value would then be multiplied by the number of acres for the area. Once there is a value for each area, those values are added together to get the total HUs for the project.

Based on ***Figure G-7*** above, the equation for HUCM for the Caloosahatchee River (C-43) West Basin Storage Reservoir is as follows:

Total Project Habitat Units = ((V + EE +ES)/3) x 4,130) + ((O +EE + ES)/3 x 2,392) + ((S + EE + ES)/3 x 9,041) + ((S + O + EE + ES)/4 x 3,506) + ((EE +ES)/2 x 51,910)
Where:
V = Vallisneria HSI
EE = Extreme Event HSI

ES = EST05 HSI
O = Oyster HSI
S = Seagrass HSI

G.8.3 Average Annual Benefits



CE/ICA requires a comparison of average annual costs and average annual benefits. In an ecosystem restoration project, the analysis compares the alternative plans' average annual costs against the appropriate average annual HU estimates. The average annual outputs were calculated as the difference between with- and without-plan conditions over the period of analysis (through year 2050). Costs used for CE/ICA are displayed in ***Table G-35***. Note that the output values shown reflect the differences between without project and with project on an average annual basis (i.e., ecological "lift" provided by each of the alternatives).

Figure G-8: A graphically represents the average annual benefits for the combined HUs. There is a plot of the future without condition HUs, and a plot of the future with project HUs. The period of analysis for benefit annualization that was utilized is 40 years. The base year, or the first year benefits begin to accrue, is in 2010. The alternatives that took longer to have benefits begin accruing had costs annualized over 39 years and the 2010 present worth of the annualization calculated. In order to account for the discrepancy in annual benefit period of analysis, the benefits were annualized over 40 years (which is consistent with the cost annualization); with a year of zero lift being included in the average. Any year on this chart can be picked to represent the HUs created in any particular period. The average annual HU lift is calculated as subtracting the future without project HUs from the future with project HUs for each year and averaging over the life of the project, which in this case is 40 years.

The analysis of ecological response times for large, diverse ecosystems is extremely difficult to calculate. For example, when analyzing an estuarine system, certain attributes will have to be examined when predicting the response to changes in salinity. Oysters will generally provide responses within a year of salinity change towards normal conditions. Seagrasses will also normally respond fairly quickly, but these responses are difficult to measure since there will be relocation of certain populations in response to specific currents and salinity concentrations. Small invertebrate and fish species should also respond fairly quickly; however, large vertebrate species of fish will take longer to increase as they take longer to mature and reach reproductive ages. As such, the team took a linear approach to predict ecological response time, and the consensus was 80 percent of the benefits would be realized three years from start of construction, 90 percent within five years after that, 100 percent of the

lift would be realized within ten years of construction. The future without condition would experience a gradual improvement for 15 years at which point the ecosystem would stabilize.

FIGURE G-8: ANNUAL HABITAT UNIT LIFT

G.8.4 Cost Effectiveness Analysis

The results will be demonstrated in the various following charts and graphs. In summary, CE/ICA was performed using a combination of the following five metrics to represent various ecosystem outputs of the project alternatives:

- Vallisneria
- Oyster
- Seagrass
- EST05
- Extreme Event

CE/ICAs were conducted for each of the project alternative plans. The analyses compared the alternative plans' average annual costs against the appropriate average annual HU estimates. The average annual outputs were calculated as the difference between with- and without-plan conditions over the period of analysis (through year 2050). A summary of the average annual lift calculations

and average annual costs used in the CE/ICA analysis are provided in ***Table G-36***.

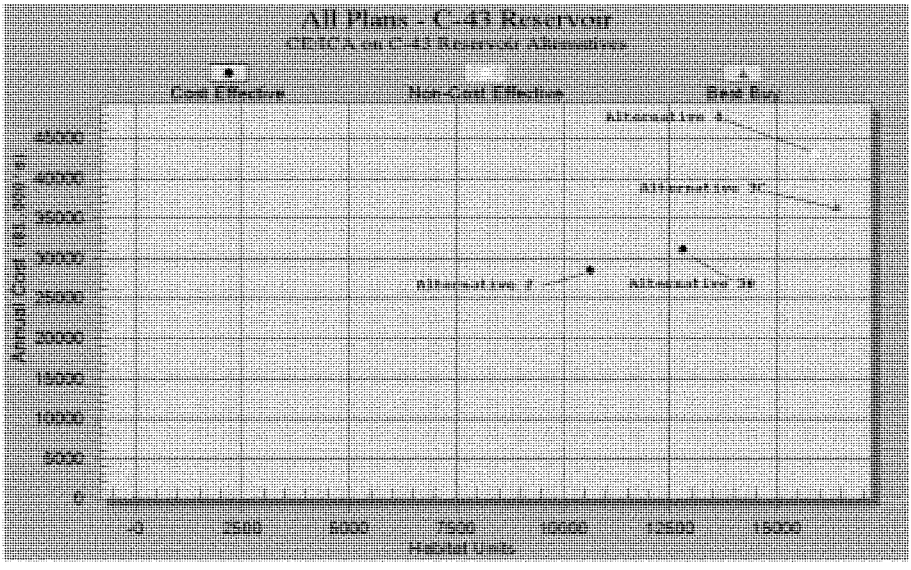
The total cost of CERP is not included in this CE/ICA. The cost of the balance of the CERP features, those not included in the project alternatives, is the same for all the alternatives. As such, including it in this analysis does not bring any additional insight or differentiation between alternatives. For this analysis, the difference between the alternatives can be shown through a display of the outputs and costs of each alternative without the cost of the other CERP features.

All of the environmental outputs were calculated on an average annual basis to account for the fact that several years may be required for full attainment of the functional capacities to be realized. This was performed for the expected future with and without project HUs, which were used to calculate the average annual benefits for each ecosystem output.

TABLE G-35: COSTS AND OUTPUTS USED IN COST EFFECTIVENESS AND INCREMENTAL COST ANALYSES
(VALUES FOR ALTERNATIVES ARE DIFFERENCES BETWEEN WITHOUT PLAN AND WITH PLAN ON AN AVERAGE ANNUAL BASIS)

	Alternative 2	Alternative 3B	Alternative 3C	Alternative 4
Annual Cost	**$28,965,000**	**$31,258,000**	**$36,667,000**	**$43,856,000**
Average Annual Habitat Units	**10,628**	**12,809**	**16,397**	**15,907**

Note: Values assume system benefits (ecosystem outputs that would accrue to the West Basin Storage Reservoir study area if rest of CERP is constructed).



G.8.4.1 Cost Effectiveness Analysis

Table G-36 and ***Figure G-9*** show that Alternatives 2, 3B and 3C are all cost effective alternatives. Alternative 3C provides the greatest habitat lift of all the alternatives, and this alternative also has the lowest average annual cost per unit of output.

TABLE G-36: RESULTS OF COST EFFECTIVENESS ANALYSIS: ALL PLANS AND COST EFFECTIVE PLANS ARRAYED BY INCREASING OUTPUT FOR EACH OUTPUT CATEGORY

	Average Annual Cost ($1,000)	Output (Annual Lift)	Average Annual Cost Per Output	Cost Effective?
Plans	**Freshwater Wetland Habitat Units (HU)**			
Without Plan	$0	0	N/A	
Alternative 2	$28,965	10,628	$2,725	YES
Alternative 3B	$31,258	12,809	$2,440	YES
Alternative 4	$43,856	15,907	$2,757	NO
Alternative 3C	$36,667	16,397	$2,236	YES

FIGURE G-9: CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR ALTERNATIVE PLANS

G.8.4.2 Incremental Cost Analysis

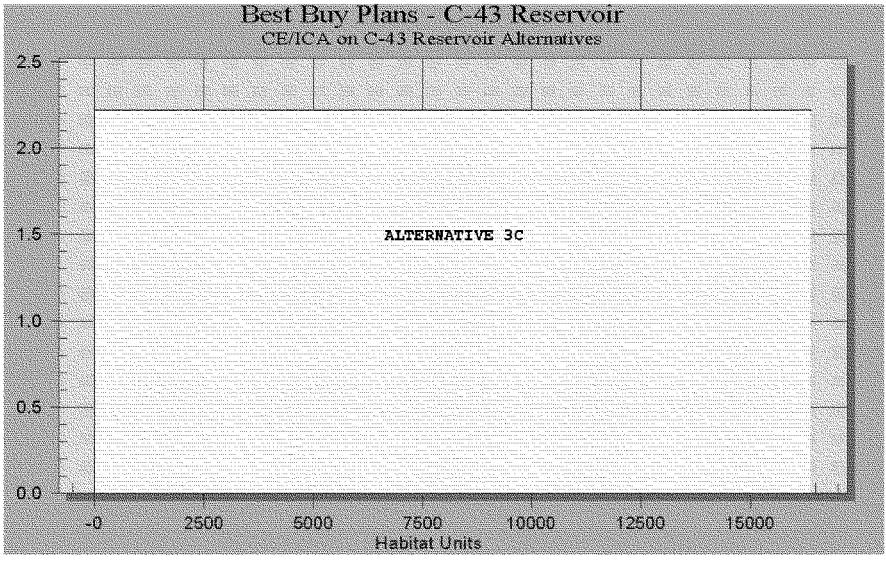


Table G-37 and ***Figure G-10*** present the results of ICA for the alternative plans for respective ecological zones. Typically, the cost effective plans are arrayed by increasing output to clearly show changes in cost (i.e., increments of cost) and changes in output (i.e., increments of output) of each cost effective alternative plan compared to the without plan condition. The plan with the lowest incremental costs per unit of output of all plans is the first best buy plan. After the first best buy plan is identified, all larger cost effective plans are compared to the first best buy plan in terms of increases in (increments of) cost and increases in (increments of) output. The alternative plan with the lowest incremental cost per unit of output (for all cost effective plans larger than the first best buy plan) is the second best buy plan.

These tables and figures show that there is only one best buy plan for the Caloosahatchee River (C-43) West Basin Storage Reservoir project. Alternative 3C provides the greatest HU lift while having the lowest cost per unit of output and is the NER plan which is the plan that reasonably maximizes ecosystem benefits when compared to costs.

TABLE G-37: RESULTS OF INCREMENTAL COST ANALYSIS: COST EFFECTIVE AND BEST BUY PLANS ARRAYED BY INCREASING OUTPUT

	Average Annual Cost ($1000)	Output	Average Cost Per Output ($1,000)	Incremental Average Annual Cost ($1,000)	Incremental Output	Incremental Cost Per Output	Best Buy?
(Habitat Units)							
Without Plan	$0	0	N/A	N/A	N/A	N/A	
Alternative 3C	$36,667	16,397	$2,236	$36,667	16,397	$2,236	Best Buy

FIGURE G-10: BEST BUY PLANS

G.8.5 Selected Alternative Plan

The P&G states: "the alternative plan with the greatest net economic benefit consistent with protecting the Nation's environment (NED Plan is to be selected paragraph 1.10.2)." There is no similar rule for plan selection where outputs are not measured in dollars, as in the case of ecosystem restoration analyses. While the CE/ICA does not provide a discrete decision rule for plan selection, it does provide the types of information to support an informed decision regarding ecosystem restoration. Information about the acceptability, completeness, efficiency and effectiveness can also providing valuable support in making an informed decision in answering the question: "Is it worth it?"

TABLE G-38: SUMMARY OF ALTERNATIVE PLANS

Alternative 2	Alternative 3B	Alternative 3C	Alternative 4
Cost Effective	**Cost Effective**	**Cost Effective and Best Buy**	**Not Cost Effective**

The final array of alternatives was evaluated using the Planning P&G evaluation criteria. These are:

- Acceptability,
- Completeness,
- Efficiency, and
- Effectiveness.

Acceptability is the workability and viability of the alternative plan with respect to acceptance by state and local entities and the public and compatibility with existing laws, regulations, and public policies.

Completeness is the extent to which a given alternative plan provides and accounts for all necessary investments or other actions to ensure the realization of the planned effects.

Efficiency is the extent to which an alternative plan is the most cost-effective means of alleviating the specified problems and realizing the specified opportunities, consistent with protecting the nation's environment.

Effectiveness is the extent to which an alternative plan alleviates the specified problems and achieves the specified opportunities.

In ***Table G-39*** each plan, except the No Action Alternative, was rated on a scale of 0 to 2 on the ability of each plan to meet the specified criteria (0 = does not meet; 1 = partially meets; 2 = fully meets).

TABLE G-39: P&G EVALUATION CRITERIA

	2	3B	3C	4A
Acceptability	1	2	1	1
Completeness	1	1	1	1
Efficiency	1	1	2	0
Effectiveness	1	2	2	1

Alternative 3B is the only alternative that fully meets the P&G evaluation criteria and has therefore been identified as the SAP. The No Action Alternative does not meet any of the P&G criteria.

G.8.6 Next Added Increment Justification

Section 385.26 of the CERP Programmatic Regulations requires that the selected plan be "justified on a next-added increment (NAI) basis." The regulations further require a series of programmatic guidance memoranda be developed, including guidance for performing plan formulation and evaluation process and NAI justification. Initial drafts of the six programmatic guidance memoranda were completed and made available for public and agency review and comment on 26 April 2005.

G.8.6.1 Next Added Increment Benefits

The evaluation of the NAI formulation was completed using the Habitat Unit Combination Methodology (HUCM) approach on the five performance measures for the SAP (Alternative 3B). The NAI was performed by calculating the total NER benefits attributable to the Caloosahatchee River (C-43) West Basin Storage Reservoir Project resulting from the incremental implementation of the project. The NAI analysis demonstrates that the SAP without any other CERP project would produce 15,308 total HUs.

It was determined through this analyses that there are benefits associated with the NAI analyses that was completed for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project. Overall, the project design is consistent with attaining project goals and objectives. Operational flexibility will lead to increased benefits by further minimizing potential high flows to the estuary as well as by minimizing discharges (and associated sediment loads).

In comparing the NAI benefits with the system-wide analysis it can be noted that there is a perception of more benefits realized in the NAI analysis. There were approximately 12,800 average annual HUs calculated for the system-wide analysis compared to the 15,300 average annual HUs in the NAI analysis. In reality the NAI and system-wide HSI scores are relatively close. ***Table G-40*** presents a summary of the raw HSI scores for both the NAI and system-wide calculations.

TABLE G-40: SUMMARY OF RAW HSI SCORES

	SYSTEM WIDE FORMULATION			NAI ANALYSIS		
	2000	2050	ALT 3B	2000	2050	ALT 3B
Vallisneria	0.16	0.20	0.33	0.03	0.08	0.60
Seagrasses	0.51	0.54	0.59	0.49	0.51	0.52
Oysters	0.48	0.52	0.60	0.52	0.52	0.23
Extreme Events	0.28	0.30	0.43	0.22	0.24	0.24
EST05	0.38	0.43	0.70	0.20	0.21	0.71

G.9 REGIONAL ECONOMIC IMPACTS

G.9.1 Overview

This chapter examines the potential effects of the SAP on the RED account. The RED account registers indirect and secondary effects to the region that are expected to result from the direct economic effects of the alternative plans. Direct economic effects represent the impacts of economic stimuli in terms of changes in regional industrial output, earnings, or employment. Indirect economic impacts represent the resultant economic changes in the industries that support and rely upon the industries directly affected by the stimuli. In addition, induced economic impacts are those impacts experienced by all local industries as direct and indirect effects alter household income and ultimately change local household spending patterns.

G.9.2 Methodology

A regional input-output model, *IMPLAN*, was used to estimate the RED effects of the Caloosahatchee River (C-43) West Basin Storage Reservoir SAP. Regional input-output (I-O) analysis provides the classic tool for tracing economic impacts throughout the regional economy. Based on the region's industrial structure, I-O analysis tracks the expected inter-industry flow of goods and services. For the RED analysis, the regional economy was defined as encompassing four southwest Florida counties (Glades, Lee, Hendry and Charlotte) using *IMPLAN*. Using county-level economic data, which was procured from the software vendor, the model was used to estimate the economic effects of the SAP on wages, employment, and industrial output. Specifically, *IMPLAN* was employed in a four-part methodology to: (1) describe the study area economy, (2) create economic scenarios, (3) introduce economic changes, and (4) estimate resulting direct, indirect, and induced economic effects.

The total construction expenditures are listed in ***Table G-33***.

G.9.3 IMPLAN Regional Economic Effects Results

In ***Table G-41***, the direct economic effects and aggregated indirect and induced economic effects are presented for the selected alternative plan. RED effects have only been calculated for construction expenditures and not for changes resulting from impacts to navigation, water usage, flood control or real estate expenditures. Economic impacts to total industry output and employee compensation are expected to persist through each year of construction. Wages include salaries, non-wage compensation, and benefits. Employment is measured as the number of jobs, not necessarily full-time equivalents.

Table G-41 and ***Table G-42*** present the *IMPLAN* output for direct, indirect, and induced impacts of the SAP, and ***Table G-43*** is and provides an indicator of the employment effects of the construction expenditures. These impacts account for less than one percent of total economic activity in each of the different output categories.

TABLE G-41: DIRECT, INDIRECT AND INDUCED IMPACTS ON EMPLOYEE COMPENSATION AS A RESULT OF IMPLAN MODEL RUNS (2006 DOLLARS)

	Direct	Indirect	Induced	Total
Alternative 3B	$30,804,000	$7,764,000	$24,298,000	$62,866,000

TABLE G-42: DIRECT, INDIRECT AND INDUCED IMPACTS ON REGIONAL OUTPUT AS A RESULT OF IMPLAN MODEL RUNS (2006 DOLLARS)

	Direct	Indirect	Induced	Total
Alternative 3B	$183,067,000	$23,225,000	$66,625,000	$272,917,000

TABLE G-43: DIRECT, INDIRECT AND INDUCED IMPACTS ON EMPLOYMENT AS A RESULT OF IMPLAN MODEL RUNS (2006 DOLLARS)

	Direct	Indirect	Induced	Total
Alternative 3B	956	269	786	2,011

G.10 OTHER SOCIAL EFFECTS

G.10.1 Overview

The OSE account considers the effects of alternative plans in areas that are not already contained in the NED and RED accounts. The categories of effects contained within the OSE account include:

- Urban and community impacts;
- Life, health, and safety factors;
- Displacement;

- Long-term productivity; and
- Energy requirements and energy conservation.

The Caloosahatchee River (C-43) West Basin Storage Reservoir Project alternative restoration plan could result in beneficial and adverse OSE within the study area. As is evident throughout this appendix, a variety of positive and adverse NED impacts on water supply, flood damage reduction and recreation are expected to result from the Caloosahatchee River (C-43) West Basin Storage Reservoir construction. Similarly, the alternative restoration plans could have positive or adverse OSE impacts on the study area associated with (1) plan implementation, including land acquisition, project construction, and O&M activities, and (2) operation of the modified C&SF system. As in the case of the NED effects, the OSE account is concerned with the net effects of the alternative plans (i.e., the differences between the with- and without-project future conditions).

Some of the potential OSE impacts would occur primarily at the regional scale, and others would have more localized effects. At both scales, there may be some individuals and communities that are positively affected by project implementation, some that are adversely affected, and many that are not affected at all. Relative to the size of the regional or local economies, the OSE effects may be minimal. However, if these effects occur predominantly within a limited geographic area, or affect a relatively small or vulnerable population, then the impacts can be disproportionately large. Therefore, the purposes of OSE analysis include not only determining the total magnitude of potential impacts, but also identifying the population (and its characteristics) that would be affected by any proposed action.

Some of the categories of effects typically included in the OSE account do not pertain to the alternative restoration plans. For example, the alternative plans are not expected to affect energy use or energy conservation in the study area. As will be noted, other categories of potential OSE impacts have been addressed previously in this appendix.

G.10.2 Potential Urban and Community Impacts

An urban and community impact is the principal category of potential OSE impacts associated with the alternative restoration plans. This category of impacts includes effects on income distribution, employment distribution, population distribution and composition, and quality of community life. Some urban and community impacts have previously been addressed in this appendix. For example, regional income effects and fiscal impacts were discussed in the RED analysis. In addition, the impacts of agricultural water supply and M&I water supply were discussed in detail in earlier sections. The OSE assessment

of urban and community impacts considers both the potential for exposure to the effects of the alternative restoration plans and the degree of vulnerability to potential impacts. Exposure refers to whether an individual or community is subject to the OSE of the alternative plans. Vulnerability refers to the ability of that individual or community to respond or adjust to those effects.

Potential urban and community impacts of the alternative restoration plans could result from: (1) land acquisition and potential relocation of populations for reservoir and other project construction features, (2) reduced agricultural activity associated with taking the reservoir lands out of cultivation, and (3) construction activity associated with plan implementation. In general, construction activity is considered to have positive impacts. At the local scale, construction and O&M activities associated with the alternative restoration plans can have positive effects to local residents and communities by providing jobs, increasing local wages, increasing local sales, increasing tax revenues and generally benefiting the local economy.

There are a variety of social and economic factors that are important determinants of an individual or community's ability to cope with adversity. One of the most important economic factors in the ability of individuals and groups to respond is the number of employment alternatives available locally. The ability to find another job depends on the education and training of the work force as well as the needs of local economic concerns, such as other farms, agricultural-related services, or some other local business. The socio-economic makeup of the community is also an important consideration of the ability of individuals and the community at large to cope with the adverse effects of large-scale agricultural land conversion. Some groups in society are recognized as having less opportunity to respond to adversity. These groups include ethnic and racial minorities, the elderly, and the poor. ***Table G-44*** presents a socio-economic vulnerability profile for the local counties. This profile contains information that indicates the ability of the county population to respond to social and economic adversity. It is important to recognize that the county scale may not accurately reflect the ability of any given community or groups within a community to accommodate potential changes associated with the alternative restoration plans.

Table G-44 contains the racial/ethnic mix of each county in the study area, as well as population over 65 years of age, 2000 unemployment, per capita income, and the expected changes in employment and income.

The surrounding counties have a wide range of ethnic compositions, proportions of elderly population, unemployment rates, and per capita incomes. These socio-economic characteristics suggest that the rural counties of the study area– those that are expected to provide locations for new storage reservoirs– are areas that are least able to accommodate the associated economic and social effects on local

communities. However, in these rural areas the affected populations should be relatively small.

Although the restoration of the estuaries and construction of the reservoir is a unique undertaking, there have been other projects and programs with similar goals and socio-economic contexts. One study conducted by the U.S. Department of the Interior assessed the national and regional economic impacts of not allowing timber harvests in certain old-growth forests in Oregon in order to protect the northern spotted owl. One aspect of this study investigated the re-employment of timber workers who had been displaced by the cessation of local logging activities. Surveys of displaced loggers suggested that they found that 57 percent of displaced workers reported post-displacement wages equal to or above their previous wages. According to the bureau of labor statistics, 92 percent of displaced workers find new jobs within one year, and the remaining eight percent find jobs within two years.

TABLE G-44: 2005 CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR SURROUNDING COUNTIES SOCIO-ECONOMIC VULNERABILITY PROFILE

	Asian	White	Black	American Indian	Hispanic	Population Over 65 (2000)	Unemployment Rate (2000)	2000 Per Capita Income**	Percent of Population Below Poverty Level
Charlotte County	1.1	92.7	5.3	0.2	4.2	33.7	N/A	N/A	9.3
Glades County	0.4	83.6	10.5	4.9	17.6	20.7	5.3	17,434	13.1

G.11 ENVIRONMENTAL JUSTICE

EO 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations, requires the Federal government to achieve environmental justice by identifying and addressing high, adverse and disproportionate effects of its activities on minority and low-income populations. E.O. 12898, Environmental Justice, states that the proposed action would not result in adverse human health or environmental effects. Any impacts of the action would not be disproportionate towards any minority or low-income population. The activity does not (a) exclude persons from participation in, (b) deny persons the benefits of, or (c) subject persons to discrimination because of their race, color, or national origin. The activity would not impact "subsistence consumption of fish and wildlife." It requires the analysis of information such as the race, national origin, and income level for areas expected to be impacted by

environmental actions. It also requires Federal agencies to identify the need to ensure the protection of populations relying on subsistence consumption of fish and wildlife, through analysis of information on such consumption patterns, and the communication of associated risks to the public.

The Caloosahatchee River (C-43) West Basin Storage Reservoir project will provide benefits to quality of life by improving the natural environment. The project features of wetland restoration and improved water discharge are by design in locations remote from urban populations such that negative impacts are eliminated for all communities. The Caloosahatchee River (C-43) West Basin Storage Reservoir is a Congressionally approved project funded with Federal and State dollars to make improvements to hydrology for people and the environment.

In public outreach efforts to date, only one potential environmental justice issue has been identified: the loss of jobs for low income and minority workers as a result of acquiring agricultural land for the construction of the reservoir. The expected loss in employment will occur to seasonal and/or temporary migrant workers, and as can be noted in the future land use section agricultural acreage in the surrounding study area and counties is expected to increase. The Caloosahatchee River (C-43) West Basin Storage Reservoir Project provides an opportunity to somewhat alleviate this potential problem by providing jobs within and during construction of the project, some of which could provide seasonal and temporary employment. In addition, it is anticipated that adjacent lands will continue to support agricultural operations.

The reservoir site is located based upon hydrologic characteristics, land availability and interconnection to existing canals and structures to optimize operations. Furthermore, in the consideration of the project site, urban areas are avoided to eliminate the negative impacts typically associated with site location of large projects. Through "willing seller agreements" a variety of land rights have been or will be acquired that allow the use of land for the resulting improvements to the human quality of life and the intended environmental benefits intended by the impoundment.

These environmental benefits provide quality of life improvements to all people and primarily to people in the communities within the study area. By the nature of design, this operating procedure will maintain if not improve flood damage reduction. This will improve the quality of human life by providing increased wildlife activity; a special bonus for those who appreciate seeing increases in fish and bird populations. This logically translates to the increased benefits in enjoyment, aesthetics, and economics for recreational activities.

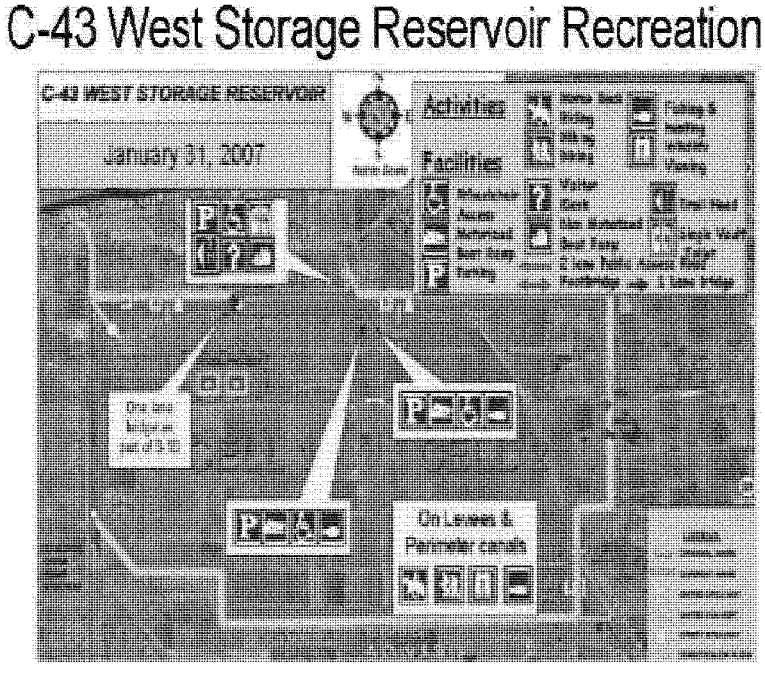
H.0 ECONOMIC AND SOCIAL CONSIDERATIONS

H.1 AUTHORIZATION

The Comprehensive Everglades Restoration Plan (CERP), authorized by the Water Resources Development Act of 2000 (WRDA 2000), will involve modifying the Central and Southern Florida (C&SF) Project, which was constructed with extensive Congressional authorizations from the 1944 Flood Control Act to the WRDA of 1996. The Federal Water Project Recreation Act (Public Letter [P.L]. 89-72) and the WRDA of 1986 (P.L. 99-662) provide additional guidance. Further specific CERP design guidance was signed on 12 May 2000, in the form of the Department of the Army and South Florida Water Management District (SFWMD) Design Agreement for Everglades and South Florida Ecosystem Restoration Project.

Additional authorization and guidance for the proposed ancillary recreation resources development is contained in CECW-AG, 11 June 1998 Memorandum, Policy Guidance Letter No. 59, Recreation Development at Ecosystem Restoration Projects and EP 1165-2-502. Despite austere budgets and policy requirements, recreational developments can and do contribute to community health and well being (CECW, 1998). The recreation resources that are being proposed as part of the CERP Caloosahatchee River (C-43) West Basin Storage Reservoir project will comply with the philosophy and inclusion of the CESAD-PD-J 15 September 2004 Memorandum, are economically justified, and fall within the ten percent rule.

H.2 INTRODUCTION TO RECREATION FOR THE CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR



H.2.1 Proposed Recreation Overview

The recreation appendix for the Caloosahatchee River (C-43) West Basin Storage Reservoir project contains a description of the conceptual plan that is being proposed for recreation purposes. The recreation concept map is shown in ***Figure H-1***. Recreation features are being planned in the Caloosahatchee River (C-43) West Basin Storage Reservoir project as an incidental project benefit. These recreation benefits will not be used in the justification of the recommended plan. Order of magnitude costs have been included as provided by the SFWMD cost estimators and gleaned from other approved reports after updating. Costs have been updated using the U.S. Army Corps of Engineers (USACE), Jacksonville District, Broward County water preserve area (WPA) recreation MCACES costs. A determination of recreation facility design standards to meet USACE and local building code requirements is under way. SFWMD will be operating and maintaining the Caloosahatchee River (C-43) West Basin Storage Reservoir project recreational features. Adjustments may be made to the dollars spent depending on project design. The costs for proposed recreation features would be $2,519,000. An additional ten percent for planning, engineering and design (PED), and an

additional eight percent for construction supervision and administration (S/A) bringing the estimated total costs for recreation to $2,972,000.

The Caloosahatchee River (C-43) West Basin Storage Reservoir project will consist of two large reservoir cells that total approximately 170,000 acre-feet of above ground water storage, on approximately 10,500 acres, approximately 10,480 acres of fee land. Perimeter seepage canals will encircle the above ground impoundment areas that are adjacent to each other and share a common levee wall. The scale of the proposed impoundment cells, potential fishing and boating opportunities, could attract users from points across south Florida. Project operations will be undertaken for a couple years to ensure boating access will be safe per water regulation schedules. A tentative boating schedule will be tied to the water schedule. For example, boating will be allowed during the wet season when there is ample water in the reservoir. Boating may not be allowed during the dry season when less water is available. As available adjacent lands become developed, the local draw of visitors to the Caloosahatchee River (C-43) West Basin Storage Reservoir would increase and the impoundment would experience both regional and local visitation. An international draw of visitors may be experienced.

FIGURE H-1: CONCEPTUAL RECREATION PLAN

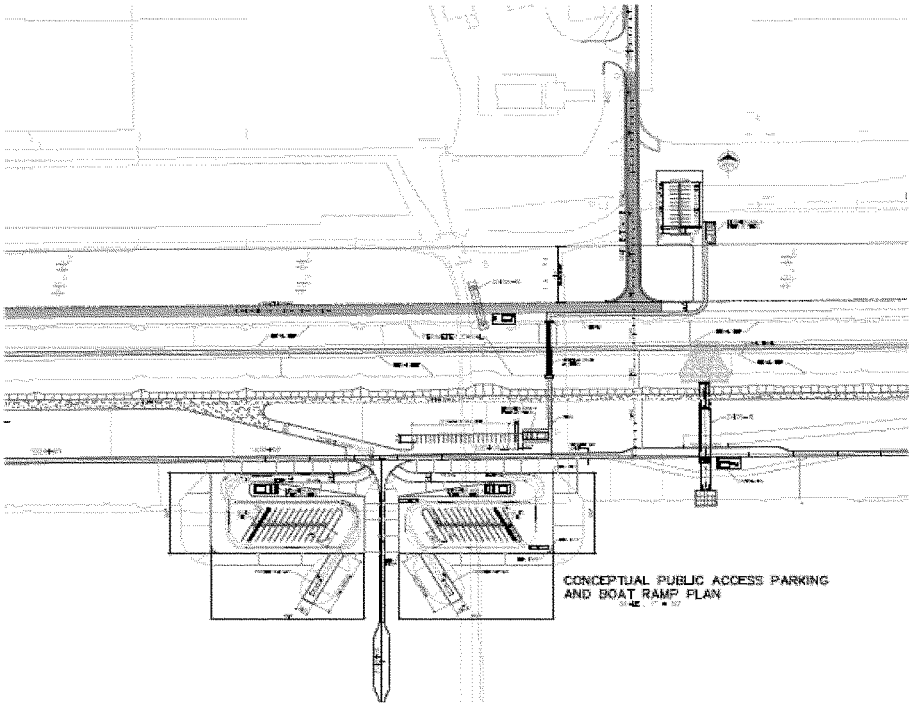
No additional real estate will be required since all the proposed recreation features will be located on project fee title lands. All features will be compatible with the environmental purposes of the impoundment, and will not detract from the environmental or socioeconomic benefits being generated by the project.

The recreation activities proposed for the Caloosahatchee River (C-43) West Basin Storage Reservoir include: nature study, multi-use trail atop the levee, equestrian use, boat and bank fishing, canoeing/kayaking, motor boating and hunting which will fit with the project purposes as managed by the SFWMD (***Figure H-1***). A major recreation attraction of the Caloosahatchee River (C-43) West Basin Storage Reservoir will be an approximately 12-mile multi-purpose trail loop atop the levee constructed as part of the project. Recreation facilities proposed include: parking and toilet facilities (clivas multrum waterless vault toilets), information kiosk, canoe/kayak launch facility, a shade structure, traffic-control fencing and a pedestrian footbridge bridge over the perimeter canal to provide public access to the reservoir.

Two handicapped accessible, double-lane public boat ramps would be provided; one into each of the two reservoir cells. Vehicle access will be via the single-lane bridge over S-10. The ramps are proposed within the reservoirs on the north levee. A paved two-lane public road will provide vehicular access to a one-lane bridge across the perimeter canal. A two-lane crushed shell road up the levee and to the ramps is proposed. Boat traffic control buoys would keep boaters clear of the reservoir structures. Signage would post warnings. The canoe/kayak launch facility would be on the perimeter canal.

Littoral areas are proposed at the corners of the seepage canal as part of the project and would provide ideal bank fishing locations outside the levee perimeter. The Florida Fish and Wildlife Conservation Commission (FWC) has endorsed the littoral shelf concept for habitat benefit and potential water quality benefits. Shades trees are proposed on the outside area of the north rim canal adjacent to parking areas. Ample public parking will be developed outside of the north levee and perimeter canal in the general area of the construction staging location.

H.2.2 Recreation Facilities Management Overview



The SFWMD would be responsible for 100 percent of the recreation operations, maintenance, repair, rehabilitation and replacement (OMRR&R) as outlined in Engineering Regulation (ER) 1105-2-100, April 2000, page E-286, the Agreement of May 2000 and the 29 September 2005 OMRR&R USACE Memorandum.

Public access for motorized and non motorized boats is planned for the Caloosahatchee River (C-43) West Basin Storage Reservoir project. A variety of concerns have been expressed regarding the potential of the affect of boating within this and other water resource projects.

The local sponsor, SFWMD, through their rulemaking authority has created rule 40E-7 F.A.C. with enforcement provisions by the FWC officers or other law enforcement officers. This rule has general language applicable to all SFWMD lands and several special provisions for different types of land. Rules allow SFWMD to address hours of public access, the ability to allow or prohibit different activities in different areas or at different times and the overall ability to close public access at any time there are emergencies, pending storms or routine operations and management needs or ongoing protection of the land itself.

The section titled, 40E-7.5384 Special Provisions for Impoundment Areas of the District Open to the Public, has further language that applies to impoundments and boat operation. The rule allows SFWMD to specify boat types, engine types and sizes, operating speeds and areas of operation. Personal watercraft are specifically prohibited while air boats may be allowed where designated. The rules can be adjusted through the posting of signs. This allows SFWMD to adjust rules as necessary to ensure that the projects intended purposes are served, to manage conflicts between users or adjust public use at different water levels, or for other factors. This set of rules allows SFWMD to adjust the boating controls at each impoundment so that the different character of each water body can be enjoyed in a proper manner by the public. The rules are posted on the SFWMD web site through this link
<https://my.sfwmd.gov/pls/portal/docs/PAGE/PG_GRP_SFWMD_LANDRESOURCES/PORTLET_RECREATIONALUSE/TAB1576034/407-E%20RULE%20%20FAC%20%20CHAPTER%2040.PDF>

FIGURE H-2: BOAT RAMP SCHEMATIC

H.3 BENEFIT CATEGORIES

H.3.1 Study Area Recreation Background.

The study area for the recreation benefit analysis for this project includes the counties of Lee, Collier, Hendry, Glades and portions of Charlotte county; approximately the same geographical extent as Region 9 of Statewide Comprehensive Outdoor Recreation Plan (SCORP). The 2000 Florida SCORP identifies the proposed project area as part of Region 9 comprised of Charlotte, Collier, Lee, Sarasota, Glades and Hendry counties. Recreation deficits identified by the SCORP for this region include; bicycle riding, tent camping, hiking, nature study and saltwater beach activities. A statewide need assessment through 2010 identifies these deficits and the unit need for each (miles of trail, camp sites) is provided in SCORP 2000.

Some existing recreational facilities within the Caloosahatchee Basin provide opportunity to hike, boat, fish and camp. Existing recreation facilities near the project site include Ortona Lock Recreation Area, Caloosahatchee Regional Park, and WP Franklin Lock Recreational Area that are used by residents and tourists alike. The Caloosahatchee is used as a boating corridor between the east and west coasts of Florida, boat traffic is moderately heavy with boating and fishing occurring on the river. The banks of the Caloosahatchee are too steep to be useful for bank fishing. Access for boat launch is provided at the three USACE lock structures located along the river. The FWC provides ramps at Wayside Park in Hendry County and at the intersection of State Road (SR) 80 and Highland, east of Ft. Myers, in Lee County. All are well used.

The population growth of south Florida will only add to the calculated existing recreation deficits. ***Table H-1*** shows projected county, State and US population growth per Census 2000.

TABLE H-1: STUDY AREA POPULATION THROUGH 2050 (1000'S)

	2005	2010	2020	2025	2030	2040	2050
Charlotte	159	175	206	221	234	252	270

US growth rate		0.91%	0.83%	0.83%	0.79%	0.78%	0.71%

H.3.2 Project Entrance and Perimeter Canal Area

The majority of the project recreation facilities are proposed on the north side of the project perimeter canal, south of SR 80. Public access via the construction access road would be finalized once the construction access route is confirmed. General parking, paved handicapped parking, paved path to an information kiosk and waterless toilet facilities are proposed on the north side of the perimeter canal. A pedestrian bridge across the exterior canal is also proposed. Equestrian use would be staged in this area, allowed on the project lands but not on the levees.

These facilities would be in open view as the project lands are accessed from SR 80 along the construction access route for visual security. The proposed recreation high-use area would utilize the former reservoir project staging area for parking. Once the project staging area is determined the recreation plan will be completed. Shade structures, shade trees, canoe/kayak launching facilities and fencing would also be located along the north side of the perimeter canal. A single-lane operations vehicle bridge is proposed to span the perimeter canal near S-10. The bridge would provide access, for public boating inside the Caloosahatchee River (C-43) West Basin Storage Reservoir, over the perimeter canal to the north levee. The expected boat ramp use falls within USACE road and access guidance in Engineering Manual (EM) 1110-2-400, 1982. The bridge proposal has been coordinated with the Hendry County EMT. No additional recreation costs are proposed for the levee-top trail system. The preliminary cost estimate for the entrance and perimeter canal recreation area is estimated at $504,000 as shown in ***Table H-2***.

TABLE H-2: ENTRANCE AND PERIMETER CANAL RECREATION FEATURES

Features	Quantity	Unit Cost	Total Cost
Shade Trees	200	$250	$50,000
Footbridge	1	$135,000*	$135,000
Shade Shelter 10' x 20'	3	$25,000**	$75,000
Canoe Launch	1	$39,000*	$39,000
Information Kiosk	1	$15,000*	$15,000
Parking Area Handicap Access	15 Spaces	$50,000*	$50,000
Waterless Vault Toile t Facility	2 units	$90,000*	$90,000
Traffic Control Fencing	Lump Sum	$50,000*	$50,000
Entrance and Perimeter Canal Site Total			**$504,000**

*Corps of Engineers, Broward County WPA Nov 06 Provided Costs, ** SFWMD provided costs.

H.3.3 Levee Crown and Reservoir Impoundment Areas

The levee crown and reservoir impoundments will be accessed by the one-lane operation bridge over the perimeter canal near S43-10. A paved two-lane access road would lead to the bridge. A two-lane, crushed shell road would provide access from the bridge over the north levee and into the reservoir impoundment area for the public boat ramp facilities. Paved parking for both boat ramps is proposed. The Caloosahatchee River (C-43) West Basin Storage Reservoir impoundment boat ramp concept would include a handicapped accessible, double-lane boat ramp with parking for each reservoir cell. Boat ramp parking facilities are proposed at the foot of the north levee. If needed, additional parking would be available on the north side of the perimeter canal (see ***Figure H-2***).

A footbridge is proposed to provide pedestrian access across the perimeter canal and up the levee separate from vehicular traffic. Two to five acres of grassed parking for vehicle and trailers is proposed. Pedestrian and bicyclist access to the levee trail would be via the pedestrian bridge and crushed shell road to the north levee crown. Vehicle fencing along the north side of the perimeter canal would keep vehicles out of the canal and off the levee. A vehicle gate would be placed across the paved road

at the base of the levee to secure the area when needed. The preliminary cost estimate for this site is $2,015,000 as shown in ***Table H-3***.

TABLE H-3: LEVEE AND RESERVOIR IMPOUNDMENT RECREATION FEATURES

Feature	Quantity	Unit Cost	Total Cost
Double-lane boat ramp (linear feet)	2	$1,000,000**	$2,000,000
Finger Pier (handicapped accessible)	1	Included in boat ramp	
Vehicle Gate	1	$15,000**	$15,000
Paved road from bridge up levee and down to boat ramp	LF	Included in project costs	$0
Levee and Reservoir Impoundment Site Total			**$2,015,000**

H.4 RECREATION BENEFITS

H.4.1 National Perspective

The national economic development (NED) benefit evaluation procedures contained in ER 1105-2-100 (22 April 2000), Appendix E, Section VII, include three methods of evaluating the beneficial and adverse NED effects of project recreation: travel cost method (TCM), contingent valuation method (CVM), and unit day value (UDV) method.

The UDV method was selected for estimating recreation benefits associated with the creation of the Caloosahatchee River (C-43) West Basin Storage Reservoir. When the UDV method is used for economic evaluations, planners will select a specific value from the range of values provided annually. Application of the selected value to estimate annual use over the project life, in the context of the with- and without-project framework of analysis, provides the estimate of recreation benefits.

The without project condition analysis has no recreation value since without the Caloosahatchee River (C-43) West Basin Storage Reservoir project there would be no public access. The with-project condition will be the expected value of the recreational activity based on the UDV method. ***Table H-4*** illustrates the method of assigning a point rating to a particular general recreation activity. The table also shows the point values assigned based on measurement standards described for the five criteria of activities, facilities, relative scarcity, ease of access, and aesthetic factors.

TABLE H-4: GUIDELINES FOR ASSIGNING POINTS FOR GENERAL RECREATION

Criteria	Judgment factors				
Recreation experience[1] Total Points: 30 Point Value: 14	Two general activities[2] 0-4	Several general activities 5-10	Several general activities: one high quality value activity[3] 11-16	Several general activities; more than one high quality high activity 17-23	Numerous high quality value activities; some general activities 24-30
Availability of opportunity[4] Total Points: 18 Point Value: 6	Several within 1 hr. travel time; a few within 30 min. travel time 0-3	Several within 1 hr. travel time; none within 30 min. travel time 4-6	One or two within 1 hr. travel time; none within 45 min. travel time 7-10	None within 1 hr. travel time 11-14	None within 2 hr. travel time 15-18
Carrying capacity[5] Total Points: 14 Point Value: 8	Minimum facility for development for public health and safety 0-2	Basic facility to conduct activity(ies) 3-5	Adequate facilities to conduct without deterioration of the resource or activity experience 6-8	Optimum facilities to conduct activity at site potential 9-11	Ultimate facilities to achieve intent of selected alternative plan 12-14
Accessibility Total Points: 18 Point Value: 10	Limited access by any means to site or within site 0-3	Fair access, poor quality roads to site; limited access within site 4-6	Fair access, fair road to site; fair access, good roads within site 7-10	Good access, good roads to site; fair access, good roads with in site 11-14	Good access, high standard road to site; good access within site 15-18
Environmental Total Points: 20 Point Value: 8	Low esthetic factors[6] that significantly lower quality[7] 0-2	Average esthetic quality; factors exist that lower quality to minor degree 3-6	Above average esthetic quality; any limiting factors can be reasonably rectified 7-10	High esthetic quality; no factors exist that lower quality 11-15	Outstanding esthetic quality; no factors exist that lower quality 16-20

Point value assignments for ***Table H-4*** above are based on Economic Guidance Memorandum (EGM) 07-03. The Criteria and Judgment Factors for General Recreation were used as the basis of the estimated point values for the proposed recreation area. Judgment factors were reviewed after conducting site visits and coordination with local agencies. The following selection factors were used for the criteria outlined in ***Table H-4***.

- The Caloosahatchee River (C-43) West Basin Storage Reservoir proposed recreation resources would provide an area specific, unique recreation opportunity afforded by the project setting and the project levees. The site offers solitude and panoramic views outside a growing metropolitan region, and would provide specific recreation amenities (as outlined in ***Table H-1***) for expanding regional populations that would increase demands. Levee crown walking, biking and nature study use would also experience the panoramic viewshed. The point value rating is estimated in the middle end of the judgment factor scale because of the general activities that would sustain a regional use in the Hendry County area.
- The availability of opportunity rating is based upon current local recreation facilities near the project area within the proposed recreation resource location. At the high end of the scale are those recreational facilities which are a geographical rarity; these are sites for which there is no close substitute within two hours. For example, two hours of drive time is sufficient for an east west transit across the lower part of Florida. For this study let us assume that two hours is sufficient to travel approximately 80 miles (non-interstate travel). With exception of jogging and walking activity and equestrian trails, alternative facilities exist for all other classifications. Scores for this judgment factor are therefore expected to be mid to low scale. One note; with the exception of equestrian activity the proposed recreation resources will help provide facilities necessary to alleviate both current and projected SCORP Region 9 deficits in those activities.
- The proposed Caloosahatchee River (C-43) West Basin Storage Reservoir, project recreation resources carrying capacity point values are estimated to improve with the recreation component construction. The general recreation values are based on the optimum use of the site potential, without overuse of the proposed recreation resources. Good water resources and access to them for non-boat fishing, multi-use trail and environmental observation comprise a large part of the projected recreation resources use. Peak use is conservatively projected to occur during half of the calendar year.
- The accessibility rating is based upon the availability of local highways, roads and streets in good condition that would provide access to the proposed recreation facilitates. Direct routes from the east on paved roads provide good access.
- The environmental quality rating is based upon the existing aesthetic values of the proposed Caloosahatchee River (C-43) West Basin Storage Reservoir Area recreation resource facilities and the ease of correcting any limiting aesthetic factors. The proposed site would possess panoramic views. The best aesthetics of the proposed project area are views from the Caloosahatchee River (C-43) West Basin Storage Reservoir levees to the west during a sunset.

The value of a day of general recreation at the proposed Caloosahatchee River (C-43) West Basin Storage Reservoir Area Project was determined for each project activity using the guidelines for assigning points for the general recreation in ***Table H-4***. The points were then converted to dollar values using conversion factors included in the EGM 07-03, UDVs for Recreation, 2006, which is based on ER 1105-2-100.

The Outdoor Recreation Coalition of America notes the trend in walking and bird watching has increased 42 percent and 155 percent from the 1984 survey to the 1995 survey. The U.S. Fish and Wildlife Service, National Survey of Fishing, Hunting and Wildlife-Associated Recreation shows a 98 percent and 38 percent increase in residential and non-residential wildlife watching in the State of Florida (Restudy, 1999). Recreation trends show increased usage of existing facilities and a need to develop new facilities. With ensuing development in the project area, and the increase in population projections for the State of Florida, the study team believes there would be ample use of the proposed recreation facilities.

Table H-5 displays the point value conversion to a UDV fiscal year (FY) 2007 dollar amount. The 46 points generated a user day value of $6.79. Estimation of the annual use over the project life is next.

TABLE H-5: CONVERSION OF POINTS TO DOLLAR VALUES

General Recreation Point Values	General Recreation Dollar Values
0	$3.32
10	3.95
20	4.36
30	4.98
40	6.23
50	7.06
60	7.68
70	8.10
80	8.93
90	9.55
100	9.97

H.4.2 State of Florida Perspective

The State of Florida's Department of Environmental Protection, Division of Recreation and Parks (DEP) developed the SCORP for 2000. The SCORP was used to obtain state regional recreation participation rates. The SCORP also provides

recreation user day guidelines for resource based outdoor recreation activities listed in ***Table H-6***. These guidelines are based on maximum carrying capacity levels developed by the DEP. The Caloosahatchee River (C-43) West Basin Storage Reservoir is a geographically large inland body of freshwater in an area of the state where state based recreation resources are mainly environmental/ecological or riverine in nature.

Using the guidelines available from the SCORP, reasonable user rate projections can be determined. Due to the Caloosahatchee River (C-43) West Basin Storage Reservoir rural location and rustic/minimal recreation features planned, it was determined that a conservative usage rate would be used. The projected Caloosahatchee River (C-43) recreation use rates referenced the resource needs and guidelines published by the SCORP, but use rates developed were substantially lower than the SCORP published rates. It is expected that recreation use within the study area would be reduced during reservoir dry periods. The probability that only the two miles on either side of the access points will be used for the multi-use trail and perimeter canal paddle boating was factored into the recreation use scenario.

In many areas, even where water bodies are accessible, they are unusable due to the lack of facilities. As previously noted, the regional level needs assessments in this plan (SCORP) are not capable of identifying local needs. Nonetheless, it is well known that there is a need to fund development of access facilities such as boat ramps, canoe launches, docks, catwalks and piers, as well as support facilities such as bathhouses, restrooms, and parking areas. Federal, state and local governments should work together to fund construction of these facilities in all areas where there is sufficient access to water bodies suitable for recreation. (SCORP, 2000).

H.4.3 Regional Perspective

The current SCORP indicates regional recreation demands not met for the year 2010 for three activities associated with the proposed Caloosahatchee River (C-43) West Basin Storage Reservoir recreation. In the current or existing without project condition miles of hiking, nature trail and biking trail are needed to fill projected regional demand. Analysis of supply and demand within Region 9 indicates that future demand for equestrian trails will overcome supply sometime between 2010 and 2015.

The use guidelines for designated bicycle, hiking and nature study trails were based on carrying capacity guidelines adopted by the SCORP and used by the state park system (see ***Table H-6***). Since SCORP provides no guidelines for boat ramp or bank fishing use, the SFWMD and USACE provided use rates of ten per weekday and 15 per weekend day. The Caloosahatchee River (C-43) West Basin Storage Reservoir consists of approximately 12 miles of trails and canals that are available for use. Only four miles of trails and canals were used to determine daily usage

rates because it is expected that two miles to either side of the access point and parking will be used most often.

A balanced mix of ecosystem compatible recreation use and facilities are proposed for the Caloosahatchee River (C-43) West Basin Storage Reservoir. The proposed recreation would help to fill existing and projected SCORP 2000 recreation deficits for Region 9. Even though SCORP 2000 shows no projected shortage of boat ramps in the region by the year 2010, the Caloosahatchee River (C-43) West Basin Storage Reservoir recreation proposal is planning to provide these public use facilities to accommodate and facilitate use of the site by the boating public.

The Florida Fish and Wildlife Conservation Commission (FWCC) provided the Everglades Restoration Program a letter (23 February 2007–Addendum I) that discusses the need for boat ramps in the south Florida area. The letter also states that the Florida SCORP does not identify boat ramp deficits or future needs in Florida. FWC stated freshwater boat access for fishing is consistently voiced by their stakeholders. The CERP Master Recreation Plan, Public Outreach Summary Report (January 2007) lists boat access needs as the third most heard public comment.

The DEP Office of Park Planning who authors the SCORP has also provided the Everglades Restoration Program a letter that supports the need for south Florida boat ramps (March 1, 2007 letter, Addendum II). FDEP's letter explains why SCORP does not quantify need for some water related activities including boat ramps and directs the team to a quote currently within SCORP on that subject. Further DEP cited Florida legislative documents that also concur that Florida needs boat ramps.

Since 1994, recreational vessel registration in Florida has increased by 36 percent but public boating facilities have not kept pace. In response, the 2005 Florida Legislature enacted and Governor Bush signed HB 955 directing the Florida DEP to evaluate recreational boating access in Florida State Parks. The document, *Recreational Boating Access in Florida State Parks* (Jan 2006) identified boating access needs and summarized potential for providing new and expanded facilities to increase public boating access.

TABLE H-6: MOST LIKELY RECREATION PARTICIPATION USER DAY PROJECTION SCENARIO

Activity	Units Provided	SCORP Maximum Area Requirements	SCORP Turn over Rates	SCORP Capacity Guidelines	SCORP Region 9 Resource Needs (2010)		Caloosahatchee River (C-43) Projected Expected Users
					User Occasions	Units	
Bicycling Jogging Walking	12 miles/ 4 utilized	10-20 users Per Mile	4/day	40-80 users per mile per day	16,675,164	1,177 miles	20 20 20
Equestrian Trails	12 miles/ 4 utilized	2-8 groups/mile-4/ group	3/day	24–96 equestrians/ trail mi/ day	204,592	0 miles	15
Canoeing / kayaking	2 miles of canals and Impoundment	1-2 users per canoe	2/day	1-2 canoes per acre or mile	N/A	N/A	25
Nature Study	12 miles/ 4 utilized	5-20 groups per mile	4/day	40-160 users per mile of trail/day	3,073,615	56.80 miles	20
Bankfishing†	50 mi of canal & reservoir banks	10 Linear Feet/ fisherman	2/day				10/day (wkday/wkend average)
Freshwater Motorboat Access†	2-double-lane paved boat ramp				NA	4	15/day (wkday/wkend average)
General Recreation Total							145 users per day

† = signifies conservative user rates developed between by Corps and SFWMD recreation planning POCs after SCORP review.

H.5 ECONOMIC JUSTIFICATION OF RECREATION

The justification of incurring additional costs for recreation features is derived by utilizing a benefit to cost ratio. The tangible economic justification of the proposed project can be ascertained by comparing the equivalent average annual charges with the estimate of the equivalent average annual benefits, which would be realized over the period of analysis. These average annual recreation benefits and costs are summarized in ***Table H-7***.

ER 1105-2-100 (The Planning Guidance Notebook) provides economic evaluation procedures to be used in all Federal water resources planning studies. The guidelines specified in the ER 1105-2-100 dated 22 April 2000 were observed in preparing this cost analysis. The Federally mandated project evaluation interest rate of 4 7/8 percent, an economic period of analysis of 40 years and current prices were used to evaluate economic feasibility.

TABLE H-7: SUMMARY OF RECREATION COSTS AND BENEFITS

Recreation Construction Costs	**$2,519,000**
PED & S/A (18%)	$453,000
Total Recreation Construction	**$2,972,000**
Construction Duration	12 months
Interest During Construction Costs	$72,000
Total Recreation Investment	**$3,044,000**
Period of Analysis	40 years
Annualized Cost	$174,000
OMRR&R	$25,000
Total Annual Costs	**$199,000**
Annual Benefits	
User Day Value	$6.79
Daily Use	145
Annual Use	52,925
Average Annual Benefit	**$359,000**

The benefit to cost ratio for the proposed recreation features is approximately 1.80, with net annual benefits equaling approximately $160,000.

A sensitivity analysis was done to further reinforce expected benefits and provide additional justification for proposed recreation features (***Table H-8***). Minimum and SCORP expected benefits have been provided for comparison with the proposed Caloosahatchee River (C-43) recreation benefits. This economic analysis suggests there would be ample benefits to conservatively justify the proposed recreation facility construction for the Caloosahatchee River (C-43) West Basin Storage Reservoir project.

TABLE H-8: SENSITIVITY ANALYSIS USING MULTIPLE SCENARIOS

Scenario	Annual Users	Daily Users	Annual Benefit
Most Likely	52,925	145	$160,000.00
Worst Case	32,850	90	$24,000.00
SCORP Guidelines	464,280	1,272	$2,953,000.00

February 23, 2007

Dennis Duke, Chief of Everglades Restoration
U.S. Army Corps of Engineers
701 San Marco Boulevard
Jacksonville, FL 32207-8175

Dear Mr. Duke:

The purpose of this letter is to convey a regional need for boat ramp access in south Florida. It has come to our attention that Florida's Statewide Comprehensive Outdoor Recreation Plan (SCORP), the primary tool being used to quantify recreational needs for CERP projects, does not quantify the needs for more boat ramps in south Florida. We think that the regional overview generated by SCORP may not address Florida's growing public boat access needs.

There are more than one million registered boats in Florida. Additionally, we average around 400,000 boats from other states that frequently visit Florida. Our waterways increasingly show the strains of congestion as each year brings more residents and visitors to use our water resources. There are approximately 1,300 publicly managed boat ramps in the state, 200 of which are maintained by the Florida Fish and Wildlife Conservation Commission (FWC). South Florida has the fewest number of freshwater boat ramps in the state, but has the majority of the State's population. As south Florida becomes increasingly urban, access to public waters becomes more of an issue.

The need for additional access to freshwaters in south Florida for recreational boating and fishing is an issue that we consistently hear voiced by our stakeholders. We view many of the above ground storage impoundments that are being planned as suitable for boat ramps, to provide access to newly created freshwaters. We currently have staff working alongside the Corps and the South Florida Water Management District on the Master Recreation Plan, as well as other CERP projects.

It is our opinion that there is a need for additional boat ramps in south Florida, that SCORP does not adequately evaluate this need, and that certain CERP/Acelle8 project offer an opportunity to address this need. We look forward to continuing to work on this issue with you. Thank you very much.

Sincerely,

Chuck Collins, Regional Director
South Region
Florida Fish & Wildlife Conservation Commission

Dear Mr. Krenz:

This letter will follow up on our conversation of last week regarding the need for boat ramps within the CERP project area.

How best to identify needs for outdoor recreation resources and facilities has been a much discussed topic in recreation planning for many years. In Florida, state government's role has been to identify needs that exist at a statewide and broad regional level through a statewide outdoor recreation plan. Since that level of planning is not well suited to assessing needs on a local or site-specified scale, assessments at those levels are most appropriately done by regional, county or municipal agencies.

We recognize that many water-related recreational activities are difficult to quantify, especially in Florida which has a myriad of water features and a wide range of activities that take place in and around them. It is clear to us that Florida needs additional boat ramps and related facilities that are suitable for public outdoor recreation. The following excerpt from the currently approved state outdoor recreation plan reflects this recognition:

> In many areas, even where water bodies are accessible, they are unusable due to the lack of facilities. As previously noted, the regional level assessments in this plan are not capable of identifying local needs. Nonetheless, it is well known that there is a need to fund development of access facilities such as boat ramps, canoe launches, docks, catwalks and piers, as well as support facilities such as bathhouses, restrooms and parking areas. Federal state and local governments should work together to fund construction of these facilities in all areas where there is insufficient access to water bodies suitable for recreation. (Source: *Outdoor Recreation in Florida-2000*, Chapter 6-10.)

The Florida Legislature has also recognized the state's increasing need for boat ramps and associated facilities. In November 2004, the Senate Committee on Community Affairs released a report entitled Working Waterfronts, which urged the Legislature to expand programs to preserve recreational working waterfronts and expand public access through boat ramps. The report noted that boater registrations in Florida increased by 61 percent between 1987 and 2003, while the number of boat ramps grew by only 14 percent during roughly the same period. Also in 2006, the Department of Environmental Protection, in cooperation with the Florida Fish and Wildlife Conservation Commission, prepared a report on boating access in Florida's state parks. That report, Recreational Boating Access to Florida State Parks, identifies substantial needs for improvements and new facilities in every one of the five state park regions.

We appreciate this opportunity to discuss the need for additional boat ramps in Florida and clarify our role in identifying these needs. I hope this information will be helpful in explaining the need for boat ramp facilities as part of the CERP project. If we can be of any further assistance, please do not hesitate to let me know.

Sincerely,

Albert Gregory, Chief
Office of Park Planning
Division of Recreation and Parks
