U.S. GOVERNMENT PRINTING OFFICE

66–223 WASHINGTON : 2011

DEPARTMENT OF THE ARMY
OFFICE OF THE ASSISTANT SECRETARY
CIVIL WORKS
108 ARMY PENTAGON
WASHINGTON DC 20310-0108

APR 13 2011

Honorable John A. Boehner
Speaker of the House
of Representatives
U.S. Capitol Building, Room H-232
Washington, D.C. 20515-0001

Dear Mr. Speaker:

The Secretary of the Army recommends authorization of the Caloosahatchee River (C-43) West Basin Storage Reservoir project in Hendry County, Florida, for the purposes of ecosystem restoration and recreation. The project would be a major step in the modification of the Central and Southern Florida (C&SF) project to help restore, preserve, and protect the South Florida ecosystem, while providing for other water-related needs of the region. The project is described in the reports of the Chief of Engineers, dated March 11, 2010, and January 6, 2011, and the Integrated Project Implementation Report and Environmental Impact Statement, dated September 2007 (revised March 2010 and November 2010), which contain other pertinent documents. The views of the South Florida Water Management District (SFWMD), the State of Florida, the Department of the Interior, and the Environmental Protection Agency are set forth in the enclosed report.

The reports are submitted in accordance with Section 601(d) of the Water Resources Development Act (WRDA) of 2000, which requires the submission of a report and authorization of various features of the Comprehensive Everglades Restoration Plan (CERP). The recommended C-43 project is a feature of the CERP, which was approved by Section 601(b)(1) of the WRDA of 2000 as a framework for modifying the C&SF project. The Secretary of the Army plans to implement the C-43 project, as described herein, through the normal budget process at the appropriate time, considering national priorities, and the availability of funds.

The recommended C-43 project would significantly contribute to two CERP goals and objectives – improving habitat and functional quality, and improving native plant and animal species abundance and diversity. It would also contribute to the socioeconomic objective of providing incidental recreation and navigation opportunities. The reports identify the recommended ecosystem restoration improvements as an increment of a National Ecosystem Restoration (NER) Plan. We expect a future investigation of storage capabilities in the eastern portion of the watershed to incorporate the results of these reports and identify the NER Plan for the entire Caloosahatchee River watershed.

Printed on  Recycled Paper

The recommended project would improve the ecological function of the Caloosahatchee Estuary by capturing and storing excess surface water runoff from the Caloosahatchee River watershed and excess releases from Lake Okeechobee, and then releasing the stored water to augment inadequate flows during the dry season. These operations would reduce extreme changes in salinity in the estuary caused by extreme high and low flows in the river, and thereby create more stable aquatic habitat. The project is located on 10,700 acres of farm land near the Caloosahatchee River in Hendry County. The ecosystem restoration features include the construction of a 170,000 acre-foot reservoir within an embankment up to 37-feet high and a canal around the embankment perimeter. The new canal is necessary to continue operating existing canals at the site. Water would be moved by a 1500-cfs pump station and controlled by appurtenant spillways, culverts, outlets and other minor structures. Recreation features include a 12-mile-long trail on the embankment, a parking area, toilets, a kiosk, a boat ramp, a shade structure, fencing, and a foot bridge over the canal.

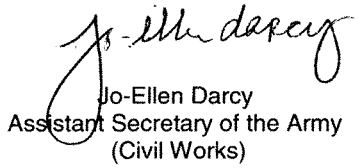
Based on October 2010 price levels, the estimated first cost of the recommended project is $579,599,000, which includes $576,643,000 for ecosystem restoration. In accordance with Section 601(e) of the WRDA of 2000, the Federal and non-Federal shares of the first cost for ecosystem restoration are $288,322,000 each. Based on a discount rate of 4.125 percent and a 40-year period of analysis, the equivalent average annual cost is $35,275,000, which includes the operation, maintenance, repair, rehabilitation, and replacement (OMRR&R) estimated at $3,160,000 annually. The OMRR&R estimate includes about $680,000 for monitoring water quality impacts. Ecological monitoring would be funded separately under the CERP Monitoring and Assessment Plan. In accordance with Section 601(e)(4), OMRR&R activities for ecosystem restoration are a non-Federal responsibility for implementation, but are cost shared equally between the Federal Government and the non-Federal sponsor. The estimated first cost of lands, easements, rights-of-way, relocations, and disposal areas for the recommended project is $84,650,000. The State of Florida has purchased 12,372 acres in the immediate area with funding provided by the Department of the Interior at a total cost of $32,800,000, of which about $27,567,000 was for acquiring lands required for this project. The latter amount is considered a Federal expenditure for cost sharing purposes since the funds were provided by the Federal government.

The project would also provide recreation opportunities incidental to ecosystem restoration. The estimated first cost of the recommended project includes $2,956,000 for recreation features. The Federal and the non-Federal shares of the first cost of the recreation features are $1,478,000 each in accordance with Section 103(c) of the WRDA of 1986. The equivalent average annual cost for recreation is $225,000, which includes $25,000 for annual OMRR&R. All of the OMRR&R for recreation is a non-Federal responsibility in accordance with Section 103(j) of WRDA 1986. The estimated average annual benefit for recreation is $384,000, resulting in net average annual benefits of about $159,000 and a benefit-to-cost ratio of about 1.7.

The estimated total Federal and non-Federal shares of the first cost of the project are $289,800,000 each. The total equivalent average annual cost is $35,500,000, which includes the total OMRR&R of about $3,185,000 annually.

Cost effectiveness and incremental cost analysis techniques were used to ensure that an appropriate ecosystem restoration plan was recommended. The recommended plan would improve the quality, quantity, and timing of flows in the lower Caloosahatchee River, which in turn would restore more natural hydrologic conditions and vegetative communities for fish and wildlife, including several endangered species, in the 71,000-acre Caloosahatchee Estuary. The plan would produce an average annual increase of 12,809 habitat units in the Caloosahatchee Estuary. As the next-added increment to CERP, the plan would deliver about 15,300 average annual habitat units. The ecosystem restoration first cost is about $8,200 for each acre of estuary restored.

The benefits to fish and wildlife habitat would be significant. The Caloosahatchee watershed and estuary are key components of the south Florida everglades ecosystem. The Everglades was designated as an International Biosphere Reserve (1976) and a World Heritage Site (1979) by the United Nations Educational, Scientific, and Cultural Organization (UNESCO), and a Wetland of International Importance (1987) in accordance with the Ramsar Convention. The portion of the Everglades ecosystem directly affected by the recommended plan, including the project site and the Caloosahatchee River and Estuary, provides habitat for 21 Federally-listed endangered or threatened species, including the Florida panther, Everglades snail kite, wood stork, manatee, eastern indigo snake, Audubon's crested caracara and five species of sea turtles.



The SFWMD would be the non-Federal project sponsor and is legally capable of fulfilling those responsibilities. In accordance with Sections 601(h)(4(A)((iii)((IV) and (V) of the WRDA of 2000, the SFWMD would be responsible for reserving available water and additional water made available by the project that would be necessary to achieve the project's restoration goals and objectives. The report states that the State of Florida will reserve or allocate for the natural system the additional water made available by the project. The project would not provide additional water for water supply or other water-related needs in the watershed. It also would not reduce levels of service for flood protection in accordance with Section 601(h)(5)(B) of the WRDA of 2000.

Section 601(e)(5)(B) of the WRDA of 2000 authorizes credit toward the non-Federal share for non-Federal design and construction work completed during the period of design or construction, subject to the execution of the design or project partnership agreement, and subject to a determination by the Secretary that the work is integral to the project. The non-Federal sponsor intends to design and construct portions of this project and seek credit under this authority. The sponsor executed a Pre-Partnership Credit Agreement with the Department of the Army on August 13, 2009, which enables credit for certain work completed prior to an authorization of the project by the Congress and the execution of a project partnership agreement. The actual

amount of credit to be afforded will be subject to audit and a determination that the work has been constructed in accordance with applicable Federal and State laws.

The Office of Management and Budget (OMB) advises that there is no objection to the submission of the report to Congress and concludes that the report recommendation is consistent with the policy and programs of the President. A copy of OMB's letter dated March 18, 2011, is enclosed. I am providing a copy of my letter to the House Committee on Appropriations' Subcommittee on Energy and Water Development, and the House Committee on Transportation and Infrastructure's Subcommittee on Water Resources and Environment. I am providing an identical letter to the President of the Senate.

Very truly yours,

Jo-Ellen Darcy
Assistant Secretary of the Army
(Civil Works)

REPLY TO
ATTENTION OF:
CECW-SAD (1105-2-10a)

MAR 11 2010

SUBJECT: Comprehensive Everglades Restoration Plan, Central and Southern Florida, Caloosahatchee River (C-43) West Basin Storage Reservoir Project, Hendry County, Florida

THE SECRETARY OF THE ARMY

1. I submit for transmission to Congress my report on ecosystem restoration improvements for the Caloosahatchee River (C-43) West Basin Storage Reservoir project, located in Hendry County, Florida. It is accompanied by the report of the district and division engineers. These reports are in response to Section 601 of the Water Resources Development Act (WRDA) of 2000, which authorized the Comprehensive Everglades Restoration Plan (CERP) as a framework for modifications and operational changes to the Central and Southern Florida Project that are needed to restore, preserve, and protect the South Florida ecosystem while providing for other water-related needs of the region, including water supply and flood protection. WRDA 2000 identified specific requirements for implementing components of the CERP, including development of a decision document known as a Project Implementation Report (PIR). The Caloosahatchee River (C-43) West Basin Storage Reservoir Project is a component of the CERP that was not specifically authorized in that Act. The authority for the preparation of the Caloosahatchee River (C-43) West Basin Storage Reservoir Project Implementation Report (PIR), one of a number of site-specific projects, is contained in Section 601(d) of WRDA 2000. Congress may authorize the project following review and approval of a PIR by the Secretary of the Army. The requirements of a PIR are addressed in this report. Preconstruction engineering and design activities for this Project will be continued under the existing CERP Design Agreement.

2. The PIR recommends a project that significantly contributes to two of the ecologic goals and objectives of the CERP: improving habitat and functional quality and improving native plant and animal species abundance and diversity. In addition, it contributes to the socioeconomic objective of providing recreational and navigation opportunities. Scientists have established that a mosaic of uplands, freshwater marsh, deep water sloughs, and estuarine habitats supporting a diverse community of fish and wildlife was one of the defining characteristics of the pre-drainage Everglades ecosystem. Currently in south Florida, habitat function and quality has significantly declined in remaining natural system areas due to water management projects and practices, resulting in a loss of suitable nesting, foraging, and fisheries habitat and a decline in native species diversity and abundance. The PIR confirms information in the CERP and provides project-level evaluation of costs and benefits associated with construction and operations of a reservoir. Constructing and operating a reservoir would reduce the extreme salinity changes in the Caloosahatchee Estuary by providing a more consistent flow of fresh water discharging at S-79 into the Caloosahatchee River Estuary. The extreme fresh water

fluctuations are due to fresh water flows from basin runoff and releases from Lake Okeechobee. Due to the advanced land acquisition activities conducted jointly by the Federal Government and the State of Florida, the Project can be implemented relatively quickly, significantly advancing the realization of project benefits in an area that has been degraded by past water management activities.

3. The reporting officers recommend implementing the Caloosahatchee River (C-43) West Basin Storage Reservoir to improve the ecological function of the Caloosahatchee Estuary by capturing and storing the excess surface water runoff from the Caloosahatchee River watershed (or C-43 Basin) and excess releases from Lake Okeechobee. Stored water will then be discharged to the estuary during the dry season to augment existing inadequate flows. The project site is located on farm land adjacent to the Caloosahatchee River (C-43) canal in Hendry County and totals approximately 10,700 acres. The reservoir will require approximately 10,480 acres of land in fee and 20 acres of perpetual channel easement. Approximately 200 additional acres will be required on a temporary basis during project construction for staging areas. Approximately 7,080 acres of project lands were acquired with a 50 percent Federal cost-share using funds appropriated via the 1996 Federal Farm Bill and the Land and Water Conservation Funds that were specifically designated for the acquisition of lands to restore the South Florida ecosystem. Major features of the reservoir include external (dam) embankments varying in height from 32-37 feet above existing grade, Soil-Bentonite slurry walls within and beneath the external embankments, an internal (dam) embankment separating the two reservoir cells with an approximate height of 31 feet above existing grade, an inflow pump station consisting of diesel-powered pumps with a total pumping capacity of 1,500 cfs, a perimeter canal, and pump station consisting of electric-powered pumps with a total pumping capacity of 195 cfs, and numerous spillways, culverts, perimeter canal structures, an internal cell balancing structure, and outlet structures. Recreational opportunities are also provided at the site within the project footprint.

4. The total first cost of the recommended plan from the Final PIR and Integrated EIS, dated September 2007, based on October 2009 price levels, is estimated to be $570,480,000. The fully funded cost, based on October 2009 price levels, is estimated to be $610,736,000. Project cost increases since the Central and Southern Florida Project Comprehensive Restudy Study Final Integrated Feasibility Report and Programmatic Environmental Impact Statement, April 1999, are primarily due to the fact that the recommended plan is a larger reservoir than originally envisioned (170,000 acre-feet of storage compared to 160,000 acre-feet in the Restudy), that design refinements were needed to incorporate current methods and criteria for addressing dam safety requirements, and that real estate costs increased. Project cost increases from the final PIR to present are due to revisions to the land valuation crediting policy for CERP.

5. In accordance with the cost-sharing requirements of Section 601(e) of the WRDA 2000, as amended, the Federal cost of the recommended plan would be $ 305,368,000 and the non-Federal cost would be $305,368,000. The estimated lands, easements, rights-of-way, and relocations costs for the recommended plan are $84,650,000 of which approximately

$27,566,500 (Rounded) has been provided to the State through the Federal Department of Interior Grant Funds. Based on October 2009 price levels, a 40-year period of economic evaluation and a 4.375 percent discount rate, the equivalent annual cost of the proposed project is estimated at $37,600,000, which includes operation, maintenance, repair, rehabilitation and replacement (OMRR&R), interest and amortization. The estimated annual costs for restoration OMRR&R are $3,100,000. The annual OMRR&R costs for recreation are estimated at $25,000. As a component of the CERP program, the interagency/interdisciplinary scientific and technical team, formed to ensure that system-wide goals are met, will participate in the annual monitoring to assess system-wide changes. In accordance with Sections 601(e)(4) and 601(e)(5)(D) of WRDA 2000 as amended, OMRR&R costs and adaptive assessment and monitoring costs will be shared equally between the Federal Government and the non-Federal sponsor. OMRR&R costs related to recreation features will be funded 100 percent by the non-Federal sponsor.

6. To ensure that an effective ecosystem restoration plan was recommended, cost effectiveness/incremental cost analysis techniques were used to evaluate alternative restoration plans. These techniques determined the selected alternative plan to be cost effective. The plan recommended for implementation is an increment of the National Ecosystem Restoration (NER) plan, it supports the adaptive management recommendations established by the National Research Council, and it meets the policy criteria established in U.S Army Corps of Engineers (USACE) guidance for planning in a collaborative environment. The recommended plan provides benefits by: 1) reducing harmful discharges to the Caloosahatchee Estuary by capturing a portion of high flow releases from Lake Okeechobee and basin runoff from the lower West Caloosahatchee River Basin during the wet season, 2) storing the water until needed in a reservoir, and 3) discharging stored water to supplement inadequate flows over S-79 to Caloosahatchee Estuary during the dry season, thereby reducing stress on the natural system. Hydrologic output comparisons were made between the flow frequency distribution of each alternative plan and the target frequency distribution for the combined monthly and weekly average freshwater inflows at S-79 for a nine year period of record. The nine years chosen out of the 36 year period of record contain three wet, three dry and three normal years. Biological outputs used to compare plans are based on several parameters that indicate the degree to which natural vegetative conditions and key indicator species are restored. The parameters for both hydrologic outputs and biological outputs are based on established peer-reviewed hydrologic and conceptual ecological models developed to guide the restoration of the South Florida ecosystem.

7. The recommended plan improves functional fish and wildlife habitat in the Caloosahatchee River Estuary. The Everglades has been designated an International Biosphere Reserve (1976) and a World Heritage Site (1979) by the United Nations Educational, Scientific, and Cultural Organization (UNESCO) and a Wetland of International Importance (1987) in accordance with the Ramsar Convention. The portion of the Everglades ecosystem directly affected by the Caloosahatchee River (C-43) West Basin Storage Reservoir, including the project site and the Caloosahatchee River and Estuary, provides habitat for 21 federally-listed endangered or threatened species, including the Florida panther, Everglades snail kite, wood stork, manatee, eastern indigo snake, Audubon's crested caracara and five species of sea turtles. In accordance

with the WRDA 2000 Section 601(f)(2), individual CERP projects shall be justified by the environmental benefits derived by the South Florida ecosystem. Similarly, Section 385.9(a) of the CERP Programmatic Regulations (33 CFR Part 385) requires that individual projects shall be formulated, evaluated, and justified based on their ability to contribute to the goals and purposes of the Plan and on their ability to provide benefits that justify costs on a next-added increment basis. The Caloosahatchee River (C-43) West Basin Storage Reservoir Project, operating in conjunction with other projects in the comprehensive plan produces an average annual increase of 12,809 habitat units in the Caloosahatchee River Estuary. On a next-added increment (NAI) basis (meaning adding the Caloosahatchee River (C-43) West Basin Storage Reservoir as the next project to be added to a system of projects) the Caloosahatchee River (C-43) West Basin Storage Reservoir project delivers about 15,300 average annual habitat units. Based on restoration first cost and the Caloosahatchee Estuary, the cost per acre benefited is about $8,034. On a next-added increment basis, the average annual cost per average annual habitat unit is approximately $2,825. Based on these parameters, the Caloosahatchee River (C-43) West Basin Storage Reservoir project is justified by the environmental benefits derived by the South Florida ecosystem and on a next-added increment basis. All NEPA compliance requirements have been completed. Final EIS coordination began on 21 September 2007 and concluded on 22 October 2007. No significant environmental changes have occurred since the EIS coordination was finalized in 2007.

8. Section 601(e)(5)(B) of the Water Resources Development Act of 2000, as amended by Section 6004 of the Water Resources Development Act of 2007, authorizes credit toward the non-Federal share for non-Federal design and construction work completed during the period of design or construction, subject to the execution of the design or project partnership agreement, and subject to a determination by the Secretary that the work is integral to the project. This project is included in the "Expedited Projects" formerly called Acceler8. The reporting officers recommend that the non-Federal sponsor be credited for all reasonable, allowable, necessary, auditable, and allocable costs applicable to The Caloosahatchee River (C-43) West Basin Storage Reservoir Project as may be authorized by law, including those incurred in advance of executing a project partnership agreement for this project, subject to authorization of the Project by law, a determination by the Assistant Secretary of the Army (Civil Works) or his/her designee that the In-kind work is integral to the Authorized CERP Project, that the costs are reasonable, allowable, necessary, auditable, and allocable, and that the In-kind work has been implemented in accordance with Government standards and applicable Federal and State laws.

9. Credits for non-Federal design and construction will be evaluated in accordance with the terms of the Master Agreement Between the Department of the Army and South Florida Water Management District for Cooperation in Constructing and Operating, Maintaining, Repairing, Replacing, and Rehabilitating Projects Authorized to be Undertaken Pursuant to the Comprehensive Everglades Restoration Plan, executed on 13 August 2009 (hereinafter "Master Agreement"). All documentation provided by the non-Federal sponsor will be thoroughly reviewed by USACE to determine reasonable, allowable, necessary, auditable, and allocable costs. Upon completion of this review, a financial audit will be conducted prior to granting final

credit. Coordination between USACE and the Sponsor will occur throughout design and construction via the USACE Regulatory process. The credit afforded to the non-Federal sponsor will be limited to the lesser of the following: (1) actual costs that are reasonable, allowable, necessary, auditable, and allocable to the Project; or (2) the USACE estimate of the cost of the work allocable to the Project had USACE performed the work. The non-Federal sponsor intends to implement this work using its own funds and would not use funds originating from other Federal sources unless the Federal granting agency verifies in writing that the expenditure of such funds is expressly authorized by statute and in accordance with Section 601 (e)(3) of WRDA 2000 as amended and the Master Agreement.

10. The plan recommended by the reporting officers is environmentally justified, technically sound, cost effective, and socially acceptable. The plan conforms to essential elements of the U.S. Water Resources Council's Economic and Environmental Principles and Guidelines for Water and Related Land Resources Implementation Studies and complies with other administration and legislative policies and guidelines. Also, the views of interested parties, including Federal, State and local agencies, have been considered.

State and Agency comments received during review of the Final PIR/EIS included concerns raised by the Florida Department of Agriculture and Consumer Services (FDACS) related to savings clause requirements and water reservations within the Caloosahatchee Basin. These concerns were addressed through several multi-agency meetings and ultimately resolved in a Headquarters, US Army Corps of Engineers (HQUSACE) response dated August 11, 2009. This letter stated that "all water to be protected for the natural system is a result of being able to capture and store excess Lake Okeechobee discharges to tide, and then delivering that water at the right time to meet estuary salinity targets. This project as simulated in the modeling, and as it will be operated, will not reduce the amount of water available from existing sources in the C-43 Basin or the amount available to existing legal users."

The U.S. Environmental Protection Agency, the Southwest Florida Regional Planning Council (SWFRPC), Lee County, and the City of Sanibel provided comments expressing water quality concerns associated with the construction and operations of the reservoir. In response, USACE and the non-Federal sponsor explained that the intent of this project is to focus on meeting salinity targets in the estuary. Future CERP planning efforts will focus on other problems, including water quality, identified in the Caloosahatchee River Basin. This project is permitted through the Florida Department of Environmental Protection (FDEP) and compliant with State water quality standards. The FDEP finds that there are reasonable assurances that "State water quality standards, including water quality criteria and moderating provisions, will be met." (FDEP letter to the Mayor of Sanibel dated April 30, 2007). USACE will require the permit holder to conduct limited algal monitoring. The primary purpose of monitoring for algae in the reservoir will be for the prevention of harmful algal bloom exposure to recreationists and users of the downstream potable water supply systems. This initial monitoring program will be assessed after two years to determine if modifications are needed. USACE also intends to require that the permit holder develop an Algal Monitoring and Management Plan for the

reservoir. This plan should include a long-term monitoring program as well as management plans should an algal bloom develop. Additionally, the non-Federal sponsor in conjunction with Lee County has acquired the Boma Property immediately east of S-78 along the Caloosahatchee River for the construction of a water quality treatment facility targeting nitrogen removal. Plans for this facility are being developed as part of the Northern Everglades Program, Caloosahatchee River Watershed Protection Plan, a cooperative State effort between the non-Federal sponsor, FDEP, and FDACS.

The SWFRPC additionally expressed concerns with the intended use of the Picayune Strand Restoration Project lands as mitigation for Florida panther habitat impacted by the construction and operation of the Caloosahatchee River (C-43) West Basin Storage Reservoir. In response, USACE stated that the USFWS has lead responsibility for programmatic tracking of Florida panther habitat losses and gains associated with CERP projects. Although individual projects may cause some panther habitat loss, this loss is being evaluated in the context of the conservation of the species range-wide. Acquisition of lands for this project and other CERP projects has resulted in preservation of important lands that may have otherwise been used for development. A majority of Florida panther habitat to be preserved is associated with the nearby Picayune Strand Restoration Project (PSRP), which is adjacent to other large tracts of natural and preserved lands including Fakahatchee Strand Preserve State Park and Big Cypress National Preserve. Acquisition and preservation of lands in the Caloosahatchee River (C-43) West Basin Storage Reservoir study area are consistent with the USFWS' goal to locate, preserve, and restore tracts of lands containing sufficient area and appropriate land cover types to ensure the long-term survival of the Florida panther.

11. The Project complies with the following requirements of WRDA 2000 as amended:

a. Project Implementation Report (PIR). The requirements of a PIR as defined by Section 601(h)(4)(A).

b. Water Reservations. Sections 601(h)(4)(A)(iii)(IV) and (V) require identification of the appropriate quantity, timing, and distribution of water dedicated and managed for the natural system and the amount of water to be reserved or allocated for the natural system. Additional water delivered to and retained in natural areas was identified and will be reserved or allocated by the State of Florida.

c. Elimination or Transfer of Existing Legal Sources of Water. Section 601(h)(5)(A) states that existing legal sources of water shall not be eliminated or transferred until a new source of water supply of comparable quantity and quality is available to replace the water to be lost as a result of the Plan. Implementation of the Caloosahatchee River (C-43) West Basin Storage Reservoir project will not result in a transfer or elimination of sources of water to meet agricultural and urban demand in the Caloosahatchee River (C-43 Canal) Basin (remaining the same as before the project). Sources of water for the Seminole and Miccosukee Tribes and Everglades National Park are influenced by the regional water management system (C&SF

Project, including Lake Okeechobee), and will not be affected by this project. Therefore, there will be no elimination or transfer as a result of this project on existing legal sources of supply for: agricultural or urban water supply, allocation or entitlement to the Seminole Indian Tribe of Florida under Section 7 of the Seminole Indian Land Claims Settlement Act of 1987 (25 U.S.C. 1772e), the Miccosukee Tribe of Florida, water supply for Everglades National Park, or water supply for fish and wildlife.

d. Maintenance of Flood Protection. Section 601 (h)(5)(B) states that CERP shall not reduce levels of service for flood protection that are in existence on the date of enactment of this Act and in accordance with applicable law. Potential effects of the storage reservoir on water levels on adjacent lands were evaluated. In response to these evaluations, the Project includes a seepage management system, consisting of a seepage cut-off wall, seepage canal, and pump to ensure that adjacent lands in the immediate vicinity of the project are not adversely affected. The operations of this project will not change the operations of the Caloosahatchee River (C-43 Canal); therefore, there will be no system-wide effects on flood protection that will impact the regional basin as a result of the Project.

12. Agency technical reviews (ATR) of the Caloosahatchee River (C-43) West Basin Storage Reservoir document were carried out through collaboration with the National Ecosystem Restoration Planning Center of Expertise (PCX) in compliance with guidance at the time of Final PIR completion (2007). Extensive external scientific peer review through the National Academy of Science (NAS) has been conducted at the CERP programmatic level and will continue throughout the planning and implementation of the CERP program through the NAS biennial reports to Congress. In particular, the NAS promoted the use of traditional water storage technologies and the use of adaptive management principles within the formulation process. Both of these comments have been integrated into the formulation and design of the C-43 project. No further IEPR was deemed necessary or recommended for the study. In addition, no further IEPR is needed in response to WRDA 2007, since C-43 studies had been initiated and alternatives identified more than two years prior to its enactment and the final report had been submitted for approval prior to its passage.

13. I generally concur with the findings, conclusions, and recommendations of the reporting officers. The Caloosahatchee River (C-43) West Basin Storage Reservoir Project requires specific authorization by Congress in accordance with Section 601(d) of the WRDA 2000. Accordingly, I recommend that the plan described herein for ecosystem restoration be authorized for implementation as a Federal Project, with such modifications as in the discretion of the Chief of Engineers may be advisable, and subject to cost-sharing, financing, and other applicable requirements of Section 601 of WRDA 2000 as amended. In addition, I recommend that the non-Federal sponsor be authorized to receive credit for work accomplished prior to the execution of a Project Partnership Agreement (PPA) for this Project, in accordance with Section 601 of WRDA 2000, as amended, and the terms of the Master Agreement.

CECW-SAD
SUBJECT: Comprehensive Everglades Restoration Plan, Central and Southern Florida, Caloosahatchee River (C-43) West Basin Storage Reservoir project, Hendry County, Florida

Further, this recommendation is subject to the non-Federal sponsor agreeing to comply with all applicable Federal laws and agreeing to perform the following items of local cooperation:

a. Provide 50 percent of total project costs consistent with the provisions of Section 601(e) of the Water Resources Development Act of 2000 as amended including authority to perform design and construction of project features consistent with Federal law and regulation;

b. Provide all lands, easements, and rights-of-way, including suitable borrow and dredged or excavated material disposal areas, and perform or assure the performance of all relocations that the Government and the Non-Federal Sponsor jointly determine to be necessary for the construction, operation, maintenance, repair, replacement and rehabilitation of the Project and valuation will be in accordance with the Master Agreement;

c. Shall not use the ecosystem restoration features or lands, easements, and rights-of-way required for such features as a wetlands bank or mitigation credit for any other projects.

d. Give the Government a right to enter, at reasonable times and in a reasonable manner, upon land that the non-Federal sponsor owns or controls for access to the Project for the purpose of inspection, and, if necessary, for the purpose of completing, operating, maintaining, repairing, replacing, or rehabilitating the Project;

e. Assume responsibility for operating, maintaining, repairing, replacing, and rehabilitating (OMRR&R) the Project or completed functional portions of the Project, including mitigation features, in a manner compatible with the Project's authorized purposes and in accordance with applicable Federal and State laws and specific directions prescribed in the OMRR&R manuals and any subsequent amendments thereto. Cost sharing for OMRR&R will be in accordance with Section 601 of WRDA 2000 as amended;

f. The non-Federal Sponsor shall operate, maintain, repair, replace and rehabilitate the recreation features of the Project with responsibility for 100 percent of the cost;

g. Keep the recreation features, and access roads, parking areas, and other associated public use facilities, open and available to all on equal terms;

h. Unless otherwise provided for in the statutory authorization for this Project, comply with Section 221 of Public Law 91-611, Flood Control Act of 1970, as amended, and Section 103 of the WRDA of 1986, Public Law 99-662, as amended, which provides that the Secretary of the Army shall not commence the construction of any water resources project or separable element thereof, until the non-Federal sponsor has entered into a written agreement to furnish its required cooperation for the Project or separable element;

i. Hold and save the Government free from all damages arising from construction, operation, maintenance, repair, replacement and rehabilitation of the Project and any project-related

betterments, except for damages due to the fault or negligence of the Government or the Government's contractors;

j. Keep and maintain books, records, documents, and other evidence pertaining to costs and expenses incurred pursuant to the Project to the extent and in such detail as will properly reflect total project costs and comply with the provisions of the Master Agreement;

k. Perform, or cause to be performed, any investigations for hazardous substances that are determined necessary to identify the existence and extent of any hazardous substances regulated under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), 42 USC 9601-9675, that may exist in, on, or under lands, easements or rights-of-way necessary for the construction, operation, and maintenance of the Project; except that the non-Federal sponsor shall not perform such investigations on lands, easements, or rights-of-way that the Government determines to be subject to the navigation servitude without prior specific written direction by the Government;

l. Assume complete financial responsibility for all necessary cleanup and response costs of any CERCLA-regulated materials located in, on, or under lands, easements, or rights-of-ways that the Government determines necessary for construction, operation, maintenance, repair, replacement and rehabilitation;

m. As between the Government and the non-Federal Sponsor, the non-Federal Sponsor shall be considered the operator of the Project for purposes of CERCLA liability. To the maximum extent practicable, the non-Federal Sponsor shall operate, maintain, repair, replace, and rehabilitate the Project in a manner that will not cause liability to arise under CERCLA;

n. Prevent obstructions or encroachments on the project (including prescribing and enforcing regulations to prevent such obstructions or encroachments) such as any new developments on project lands, easements, and rights-of-way or the addition of facilities which might reduce the outputs produced by the ecosystem restoration features, hinder operation and maintenance of the project, or interfere with the project's proper function;

o. Comply with the applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public law 91-646, as amended by title IV of the Surface Transportation and Uniform Relocation Assistance Act of 1987 (Public Law 100-17), and the Uniform Regulations contained in 49 CFR part 24, in acquiring lands, easements, and rights-of-way, and performing relocations for construction, operation, and maintenance of the Project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said act;

p. Comply with all applicable Federal and State laws and regulations, including, but not limited to, Section 601 of the Civil Rights Act of 1964, Public Law 88-352 (42 U.S.C. 2000d) and Department of Defense Directive 5500.11 issued pursuant thereto; Army Regulation 600-7,

entitled "Nondiscrimination on the Basis of Handicap in Programs and Activities Assisted or Conducted by the Department of the Army;" and all applicable Federal labor standards requirements including, but not limited to, 40 U.S.C. 3141-3148 and 40 U.S.C. 3701-3708[revising, codifying and enacting without substantive change the provisions of the Davis-Bacon Act (formerly 40 U.S.C. 276a et seq.), the Contract Work Hours and Safety Standards Act (formerly 40 U.S.C. 327 et seq.) and the Copeland Anti-Kickback Act (formerly 40 U.S.C. 276c)];

q. Comply with Section 106 of the National Historic Preservation Act in completion of all consultation with the Florida State Historic Preservation Officer, and as necessary, the Advisory Council on Historic Preservation, prior to construction as part of the preconstruction engineering and design phase of the project;

r. Provide 50 percent of that portion of total cultural resource preservation mitigation and data recovery costs attributable to the Project that are in excess of one percent of the total amount authorized to be appropriated for the Project;

s. Do not use Federal funds to meet the non-Federal sponsor's share of total project costs unless the Federal granting agency verifies in writing that the expenditure of such funds is expressly authorized and in accordance with Section 601 (e)(3) of the WRDA of 2000, as amended, and in accordance with the Master Agreement;

t. The Non-Federal Sponsor agrees to participate in and comply with applicable Federal floodplain management and flood insurance programs consistent with its statutory authority.

(1) Not less than once each year the Non-Federal Sponsor shall inform affected interests of the extent of protection afforded by the Project.

(2) The Non-Federal Sponsor shall publicize flood plain information in the area concerned and shall provide this information to zoning and other regulatory agencies for their use in preventing unwise future development in the flood plain and in adopting such regulations as may be necessary to prevent unwise future development and to ensure compatibility with protection levels provided by the Project.

(3) The Non-Federal Sponsor shall comply with Section 402 of WRDA 1986, as amended (33 U.S.C. 701b-12), which requires a non-Federal interest to have prepared, within one year after the date of signing a PPA for the Project, a floodplain management plan. The plan shall be designed to reduce the impacts of future flood events in the project area, including but not limited to, addressing those measures to be undertaken by non-Federal interests to preserve the level of flood protection provided by the Project. As required by Section 402, as amended, the non-Federal interest shall implement such plan not later than one year after completion of construction of the Project. The Non-Federal Sponsor shall provide an information copy of the plan to the Government upon its preparation.

(4) The Non-Federal Sponsor shall prescribe and enforce regulations to prevent obstruction of or encroachment on the Project or on the lands, easements, and rights-of-way determined by the Government to be required for the construction, operation, maintenance, repair, replacement, and rehabilitation of the Project, that could reduce the level of protection the Project affords, hinder operation or maintenance of the Project, or interfere with the Project's proper function.

u. The overarching objective of the Plan is the restoration, preservation, and protection of the South Florida ecosystem while providing for other water-related needs of the region, including water supply and flood protection. The Federal Government and the non-Federal sponsor are committed to the protection of the appropriate quantity, quality, timing, and distribution of water to ensure the restoration, preservation, and protection of the natural system as defined in Section 601 of WRDA 2000, for so long as the project remains authorized. This quantity, quality, timing, and distribution of water shall meet applicable water quality standards and be consistent with the natural system restoration goals and objectives of the CERP, as the Plan is defined in the Programmatic Regulations. The non-Federal sponsor will protect the water for the natural system by taking the following actions to achieve the overarching natural system objectives of the Plan:

(1) Ensure, through appropriate and legally enforceable means under Florida law, that the quantity, quality, timing, and distribution of existing water that the Federal Government and the non-Federal sponsor have determined in this Project Implementation Report is available and beneficial to the natural system, will be available at the time the Project Partnership Agreement for the project is executed and will remain available for so long as the Project remains authorized.

(a) Prior to the execution of the Project Partnership Agreement, reserve or allocate for the natural system the necessary amount of water that will be made available by the project that the Federal Government and the non-Federal sponsor have determined in this Project Implementation Report.

(b) After the Project Partnership Agreement is signed and the project becomes operational, make such revisions under Florida law to this reservation or allocation of water that the non-Federal sponsor determines, as a result of changed circumstances or new information, is necessary for the natural system.

(2) For so long as the Project remains authorized, notify and consult with the Secretary of the Army should any revision in the reservation of water or other legally enforceable means of protecting water be proposed by the non-Federal sponsor, so that the Federal Government can assure itself that the changed reservation or legally enforceable means of protecting water conform with the non-Federal sponsor's commitments under paragraphs 1 and 2. Any change to

CECW-SAD
SUBJECT: Comprehensive Everglades Restoration Plan, Central and Southern Florida, Caloosahatchee River (C-43) West Basin Storage Reservoir project, Hendry County, Florida

a reservation of water made available by the project shall require an amendment to the Project Partnership Agreement.

14. The recommendation contained herein reflects the information available at this time and current Departmental policies governing formulation of individual projects. It does not reflect program and budgeting priorities in the formulation of a national Civil Works construction program or the perspective of higher review levels within the executive branch. Consequently, the recommendation may be modified before it is transmitted to the Congress as a proposal for authorization and implementation funding.

R. L. VAN ANTWERP
Lieutenant General, US Army
Chief of Engineers

DEPARTMENT OF THE ARMY
OFFICE OF THE CHIEF OF ENGINEERS
WASHINGTON, D.C. 20314-1000

JAN 0 6 2011

CECW-SAD (1105-2-10a)

SUBJECT: Comprehensive Everglades Restoration Plan, Central and Southern Florida, Caloosahatchee River (C-43) West Basin Storage Reservoir Project, Hendry County, Florida - Supplemental

THE SECRETARY OF THE ARMY

1. I submit for transmission to Congress this supplement to my report on ecosystem restoration and recreation for the Caloosahatchee River (C 43) West Basin Storage Reservoir project, located in Hendry County, Florida, dated March 11, 2010. The purpose of this supplement is to clarify the authority for cost sharing of the recreational features recommended for the project.

2. In accordance with the Federal Water Project Recreation Act of 1965, full consideration was given to opportunities the project affords for recreation. The recommended C-43 West Basin Storage Reservoir project contains approximately $3,000,000 of recreation features, including a 12-mile multi-purpose trail and associated parking and toilet facilities, information kiosk, canoe/kayak launch facility, a shade structure, traffic control fencing, and a pedestrian footbridge to provide public access to the reservoir. These recreation features have been justified in accordance with policy.

3. Although cost sharing of the ecosystem restoration features for this project is governed by Section 601 of the Water Resources Development Act (WRDA) of 2000, as amended, cost sharing of the recreation features is governed by Section 103 of the WRDA 1986, as amended. In particular, in accordance with Section 103(j) of WRDA 1986, 100 percent of the cost of operation, maintenance, repair, replacement, and rehabilitation of the recreation features is the non-Federal sponsor's responsibility. In addition, Section 601(e)(5)(B) of WRDA 2000, as amended, governs credit for non-Federal sponsor design and construction work on the ecosystem restoration features of the project, whereas Section 221(a)(4) of the Flood Control Act of 1970, as amended (42 U.S.C. 1962d-5b(a)(4)) governs credit for non-Federal sponsor design and construction work on the recreation features of the project.

4. As part of this supplement, the costs of the project have been escalated and updated to October 2010 price levels and the reporting format has been changed from fully funded costs to initial investment. The total first cost of the recommended plan from the Final Project Implementation Report and Integrated Environmental Impact Statement, dated September 2007, based on October 2010 price levels, is estimated to be $579,599,000, including $576,643,000 for ecosystem restoration and $2,956,000 for recreation. In accordance with Section 601 of the

CECW-SAD (1105-2-10a)
SUBJECT: Comprehensive Everglades Restoration Plan, Central and Southern Florida, Caloosahatchee River (C-43) West Basin Storage Reservoir Project, Hendry County, Florida - Supplemental

WRDA 2000, as amended, for the ecosystem restoration features of the recommended plan, the estimated Federal cost is $288,321,500 and the estimated non-Federal cost is $288,321,500. In accordance with Section 103(c) of the WRDA 1986, as amended, for the recreational features of the recommended plan, the estimated Federal cost of $1,478,000; and the non-Federal cost is $1,478,000. The estimated lands, easements, rights-of-way, and relocations costs for the recommended plan are $84,650,000 of which approximately $27,567,000 has been provided to the State through the Federal Department of Interior Grant Funds. Based on October 2010 price levels, a 40-year period of economic evaluation and a 4.12 percent discount rate, the equivalent annual cost of the proposed project is estimated at $35,500,000, which includes operation, maintenance, repair, rehabilitation and replacement (OMRR&R), interest and amortization. The estimated annual OMRR&R costs for ecosystem restoration are $3,160,000. The annual OMRR&R costs for recreation are estimated at $25,000. In accordance with Section 601 of WRDA 2000 as amended, OMRR&R costs and adaptive assessment and monitoring costs for ecosystem restoration will be shared equally between the Federal Government and the non-Federal sponsor. In accordance with Section 103(j) of the WRDA 1986, as amended, OMRR&R costs related to recreation features will be funded 100 percent by the non-Federal sponsor.

Respectfully,

R. L. VAN ANTWERP
Lieutenant General, US Army
Chief of Engineers

SOUTH FLORIDA WATER MANAGEMENT DISTRICT

PROJ 04.N.2.9

November 6, 2009

Colonel Alfred A. Pantano, Jr.
District Engineer Jacksonville District
U.S. Army Corps of Engineers
P.O. Box 4970
Jacksonville, FL 32232-0019

Dear Colonel Pantano:

Subject: Letter of Support for the November 2009 Update of the Caloosahatchee River (C-43) West Basin Storage Reservoir Project Implementation Report

The purpose of this letter is to express the South Florida Water Management District's (District) continuing support for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project consistent with the Governing Board resolution approving submittal of the Letter of Support (August 9, 2007). We appreciate the U.S. Army Corps of Engineers' (Corps) efforts to work with the State of Florida and resolve the outstanding real estate valuation and crediting concerns. The Final Project Implementation Report, including the revision to project cost estimates to reflect use of the Corps' nationwide policy for valuation and crediting of lands, is the result of a collaborative effort over the last five years. The Recommended Plan will provide improved timing of freshwater deliveries to the Caloosahatchee Estuary which will help to restore habitat function and quality in the Estuary, resulting in improved plant and animal species abundance and diversity.

The successful development of the Recommended Plan outlined in this Project Implementation Report was dependent upon its many contributors. The Corps and the District played key leadership roles. However, the Recommended Plan was significantly enhanced through contributions from the Florida Department of Environmental Protection, the Florida Fish and Wildlife Conservation Commission and the U.S. Department of the Interior, as well as numerous other state, federal and local agencies.

As you know, the District has completed detailed design for this project in collaboration with the Corps' Jacksonville Engineering Division. It is anticipated that minor refinements in the plans and specifications may be necessary prior to solicitation of construction bids. We fully intend to collaborate with the Corps to accomplish any necessary refinements. It is our hope and expectation that this project will be authorized for construction in the 2010 Water Resources Development Act.

The District is proud to share a partnership with the Corps on this vital and exciting project.

Sincerely,

Carol Ann Wehle

Carol Ann Wehle
Executive Director
South Florida Water Management District

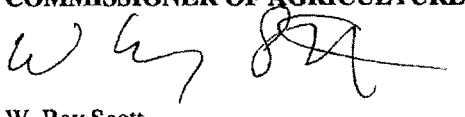
Florida Department of Agriculture and Consumer Services' Comments on the Caloosahatchee River (C-43) West Basin Storage Reservoir Project Final Integrated Project Implementation Report and Environmental Impact Statement

The Florida Department of Agriculture and Consumer Services (FDACS) appreciates the opportunity to comment and requests the following concerns be addressed in the review of the Corps' Caloosahatchee River (C-43) West Basin Storage Reservoir (BSR) Project Final Integrated Project Implementation Report (PIR) and Environmental Impact Statement (EIS). FDACS has submitted comments formally at the agency level and to the Project Delivery Team (PDT) throughout the project development process and during public review periods. The review issues that we consider as remaining to be addressed are summarized below and detailed in the "FDACS Staff Comments" attachment.

The Final PIR and EIS do not acknowledge the Yellow Book's original "source switch" function for the C-43 reservoir project, rather it rewrites the project's conceptual history to match the current outcome. An accurate account should be included of the original plan to switch basin irrigation demand from Lake Okeechobee to the basin run-off captured in the proposed C-43 reservoir as opposed to the current PIR's plan to capture excess basin run-off and Lake Okeechobee regulatory releases for estuary use exclusively. This change has implications beyond this particular project because other CERP projects use planning conditions based on the original concept of restricting Lake Okeechobee irrigation releases for agricultural water demand in the C-43 Basin. The Final PIR/EIS Annex B – Draft PIR Comment Matrix (page B-82) responds to an earlier FDACS comment on this issue, but merely confirms the change: "The reservoir proposed in this project allows estuary demands to be supplemented by reservoir storage during the dry season, thus relieving some dry-season demands on Lake Okeechobee allowing more water within the lake to be used system wide." While not stating that these system wide uses include C-43 basin irrigation demand, it is not apparent how the irrigation demand would otherwise be met.

Annex C contains an analysis that identifies the volume of water made available by the project for the natural system. The amount identified under the Initial Operating Regime (IOR) is anticipated to be substantially more than the amount that will ultimately be available for the natural system as identified in the Next Added Increment (NAI) analysis. Under the driest conditions, the IOR amount is approximately 50% greater than the NAI amount (Table C-3: Identification of the Volume of Water (Ac-Ft/Year) Made Available for the Natural System to Achieve the Benefits of the Project, Page C-24, Annex C, Caloosahatchee River (C-43) West Basin Storage Reservoir (BSR) Project Final Integrated PIR and EIS). The larger amount identified in the IOR is recommended to be reserved for the natural system under Florida law. The recently released "Revised Final Draft CERP Guidance Memoranda - GM #4: Identifying Water Made Available for the Natural System and for Other Water Related Needs" refers to changing water reservations in response to changing conditions as more CERP projects are completed. The language of GM #4 appears to address the incorporation of additional water made available and not subsequent reductions in water made available. FDACS is concerned that it may be difficult to maintain an accurate accounting of the water made available for the natural system by the Caloosahatchee (C-43) West BSR relative to reductions in that amount that result when other projects are implemented. Moreover, the prospect of "rolling back" an already established reservation raises some significant legal questions, and underscores the need to carefully account for "water made available" by this project and to consider how the potential future reductions in "water made available" will be dealt with. The USACE did not provide a response in the Final PIR/EIS Annex B – Draft PIR Comment Matrix to an earlier FDACS comment that raised this issue.

Our remaining concern is the lack of an evaluation tool to determine if the Caloosahatchee (C-43) West BSR will create a greater demand on the Caloosahatchee River with an associated greater demand on Lake Okeechobee during drought years. Consequently, meeting the Savings Clause requirements for an existing legal source as of December 11, 2000, consistent with Federal law, is still an open question for the Caloosahatchee River (C-43) West BSR Project Final Integrated PIR and EIS. While we agree with the USACE that the possibility of significant negative impacts to existing users in the area of the project is minimal, we are not convinced that an adequate analysis of impacts to water supply during drought years has been performed or that the methodology described in "Revised Final Draft CERP Guidance Memoranda GM #3: Savings Clause Requirements" has been followed. It is not clear whether the system wide effect of an additional demand on Lake Okeechobee was considered at all. We believe that the information and analyses provided do not address this issue and are not adequate to provide the assurances required by state or federal law.



The underlying issue for all our concerns is that the modeling conducted for the Caloosahatchee (C-43) West BSR relied upon delivery of a specific volume of water from Lake Okeechobee, and it is not clear what system wide impacts this demand on the lake will have, particularly under drought conditions. First, there is a potential conflict with the original Yellow Book assumption that the project would restrict deliveries to the C-43 basin and consequently with the planning assumptions for other CERP projects.

Second, the apparent anomaly between the water made available under the IOR scenario and the NAI scenario likely hinges on the discrepancy between potentially competing water demands from Lake Okeechobee. Finally, we are less concerned with Savings Clause assurances in the immediate project area than with a potential reduction in water supply availability outside the project area if the reservoir creates an additional demand on Lake Okeechobee. The enclosed attachment, "FDACS Staff Comments," provides additional details regarding our concerns.

Again, we appreciate the opportunity to comment on the Caloosahatchee River (C-43) West BSR Project Final Integrated PIR and EIS. Our level of concern with the issues we raise here is heightened by current system conditions, and we believe that a better understanding of the effect of this project under such conditions is needed. Moreover, we do not believe that the Savings Claus analysis adequately addresses potential impacts outside the area of the project, nor do the PIR and EIS provide sufficient information to provide the assurances required under Florida law. If you should have questions regarding FDACS' comments, please contact Ray Scott at (850) 410-6714.

Sincerely,

CHARLES H. BRONSON
COMMISSIONER OF AGRICULTURE

W. Ray Scott
Conservation & Water Policy
Federal Program Coordinator

FDACS STAFF COMMENTS:

Review Comments for the Caloosahatchee River (C-43) West BSR Project Final Integrated PIR and EIS

The Yellow Book's Original " Source Switching" Conceptual Plan for the C-43 Reservoir has been Omitted from the Project's Background Information

During development of the conceptual plan for the Restudy, one of the main concepts of the regional storage components was to provide additional storage for water supply in the Caloosahatchee, St. Lucie and Kissimmee Basins which should ultimately reduce irrigation demands on Lake Okeechobee. Water could then be conserved in the lake and would be "...available for sustaining the health of lake and downstream natural areas ..." (Sections 6.4.2 and 6.4.1.2). The source for agricultural irrigation demands would be "switched" to the reservoirs as much as possible and be supplemented as needed by the lake. More lake water would be available for natural system needs.

Since the only purpose of the C-43 reservoir is now to meet estuary demands, and not to "switch sources" for local irrigation demands, that change from the Yellowbook concept needs to be acknowledged and the planning conditions for other projects need to be updated based on that change. At this time, urban and agricultural demands have all been removed from the alternative evaluation. How does this fit into the regional plan as developed by CERP for the capture of local basin run-off to meet existing demands in the "reservoir" basins (Caloosahatchee, St. Lucie, and EAA basins) and retaining Lake Okeechobee water for natural system needs. How will the difference in concepts be accommodated going forward?

FDACS maintains that the difference in the Lake Okeechobee boundary condition used by the Caloosahatchee River (C-43) West Basin Storage Reservoir and that used by other CERP projects is problematic and should be acknowledged in the PIR and addressed in the appropriate forum. The following examples from the Final PIR/EIS document illustrate the point.

In Appendix C on pages C-75 and C-76, nutrient load reductions of 29% to 38% are projected "due to the reduction in flow resulting from the implementation of CERP components other than the C-43 West Reservoir." It is inconsistent to evaluate the nutrient removal potential of Alternatives combined with implementation of the rest of CERP while ignoring how reductions in flows resulting CERP's full CERP implementation will impact water supply for existing legal users in the C-43 Basin.

NAI performance is 28% greater than the CERP System-wide Analyses performance. The NAI performance to CERP system-wide performance evaluation compares the benefits of the Caloosahatchee River (C-43) West Basin Storage Reservoir as a stand alone project to the performance achieved by the system-wide conditions anticipated by CERP implementation. The Final PIR/EIS, Section 7, page 7-25, describes some

potential reasons for this difference including "The first and most influential of these results from the rest of CERP's impact on the overall water budget provided to the Caloosahatchee River (C-43) basin. The system-wide analysis has a lower water budget than the NAI analysis, leading to diminished dry season conditions."

The full implementation of CERP predicts that the Lake Okeechobee releases will be minimal and that the C-43 Basin will be "off the lake". Phase I has not restricted the use of Lake Okeechobee water for irrigation. If this assumption changes to what is currently being used in all other CERP projects (restricted deliveries of Lake Okeechobee water to C-43), access to water currently available for existing legal users would be compromised and a Savings Clause violation for the full project implementation would occur in Phase II. The version of the model used during the Restudy used a surface water run-off volume in the C-43 Basin that has been determined to be too high. The Yellow Book C-43 project relied on the higher basin run-off to meet agricultural irrigation demands. This assumption has resulted in restrictions on deliveries to meet irrigation demands from Lake Okeechobee in current CERP modeling.

Initial Operating Regime (IOR) Water Availability is Greater than Next Added Increment (NAI) Water Availability and the Greater Amount is Being Reserved

Annex C contains an analysis showing the identification of water made available by the project for the natural system. The amount identified under the IOR is anticipated to be more than the amount identified in the NAI, and the IOR amount is recommended to be reserved for the natural system under Florida law. FDACS is concerned it will be very difficult to maintain an accurate accounting of how much of the "C-43 project reservation amount" is included in the natural system amounts made available by other projects (e.g., the EAA Reservoir). The recently released "Revised Final Draft CERP Guidance Memoranda - GM #4: Identifying Water Made Available for the Natural System and for Other Water Related Needs" refers to changing water reservations in response to changing conditions as more CERP projects are completed. However, the wording indicates that this is to incorporate additional water made available and not to account for reductions in water made available.

One explanation for using the larger IOR volume for natural system reservation is that even if future operations divert water from the Caloosahatchee estuary and degrades the performance of the reservoir, that would be acceptable because the environmental benefits realized system wide by CERP would off-set the loss of benefits in the Caloosahatchee Estuary. Making this case to advocates for the Caloosahatchee Estuary will be difficult and sets the stage for water availability competition among CERP projects and potential legal complications related to the transfer of beneficial water to another basin.

Basin-wide and System-wide Savings Clause Analyses Not Performed According to Draft CERP Guidance Memoranda GM #3: Savings Clause Requirements Due to Inadequate Evaluation Tools

FDACS is concerned that the extensive changes in groundwater seepage and surface water dynamics resulting from the Caloosahatchee River (C-43) West Basin Storage Reservoir has the potential to impact water quantity and water quality in ways that may not be evident at the Pilot Test Cell scale. Construction and operation of the C-43 Part I Phase I Reservoir on the Berry Groves site will create a substantial change in the hydrodynamic interactions between groundwater, surface water, and water use in the vicinity of the reservoir that could impact water availability for existing legal users dependent upon the C-43 Canal and Lake Okeechobee for water supply.

The slurry wall will prevent seepage currently flowing north from properties south of the reservoir site from reaching the C-43 Canal along the historic path under the reservoir site. The C-43 Canal and the properties between the reservoir and the C-43 Canal will no longer be supplied by the historic groundwater seepage source. The C-43 Part I Phase I Reservoir operating plan uses perimeter canal seepage to maintain groundwater levels and water supply to existing legal users in the vicinity of the reservoir. Water will be pumped from the C-43 Canal to maintain the perimeter canal water levels and seepage during dry conditions when the reservoir can no longer be used to supply the perimeter canal.

An analysis comparing pre project and post project water volumes associated with "replacing" the historic ground water seepage flows into the C-43 Canal along the length of the reservoir and maintaining surface water levels of the perimeter canal throughout the period of record is needed. Ideally, a sub regional evaluation tool would be used to compare the pre project and post project water budget performance over the period of record between S-77 and S-79 using a time step not exceeding one month.

According to the Restoration Coordination and Verification (RECOVER) report provided in Annex E, the type of data needed to evaluate project alternatives for the system-wide performance measure "WS-1- Lake Okeechobee Service Area (LOSA) Water Supply" was not available and the water supply evaluation was incomplete. The RECOVER report (Section E.5.2) states, "In order to determine the full extent of predicted water supply impacts in the C-43 Basin, the severity and duration of any water restrictions above those that might be expected when drought levels exceed a 1 in 10 condition needs to be reviewed. In order to perform the Supply Side Management (SSM) based review, raw data or post-processed data that will allow the determination of monthly demand volume, number of days per month with cutbacks (demands not met), and volume of cutbacks (demand not met) per each month is required. Since this data is not readily available from MIKE SHE output, annual average volumes (AAV) were evaluated. It is important to note that the average annual number will not allow for a determination of differences in alternative performance regarding water supply deliveries."

SFWMD had intended to use the MIKE SHE Freshwater Caloosahatchee Model throughout the model's nine year Period of Record (POR) to determine the pre and post project water budget in response to FDACS' concerns about water supply assurances for existing legal users. Volumes between pre and post project when reservoir operations draw water from the C-43 for water supply purposes during dry conditions were to be

compared to determine if there is a reasonable assurance that existing users will not be adversely impacted by water supply demands via the perimeter canal operations. The results were to be included in the final State Compliance Report. However, because this pre and post volume comparison for water supply withdrawals was not made, no results were available and this information was not included in the report.

SFWMD in partnership with their consultant, DHI, worked diligently to provide FDACS with other additional information and analyses to demonstrate that the water supply assurances required under Florida law are being provided for existing legal users. While recognizing the minimal likelihood of significant adverse impacts within the area of the project, we remained unconvinced that an adequate analysis of impacts to water supply during drought years had been conducted. It was not clear whether the system wide effect of an additional demand on Lake Okeechobee was considered at all. In addition, a volume probability curve for the Caloosahatchee Basin, consistent with the methodology described in "Revised Final Draft CERP Guidance Memoranda GM #3: Savings Clause Requirements" was not provided. We believe that the information and analyses provided do not fully address the issue and are inadequate to provide the assurances required by state or federal law.

Information provided by SFWMD to FDACS but not included as part of the Final State Compliance Report Caloosahatchee River (C-43) West Basin Storage Reservoir Project submitted to the Florida Department of Environmental protection (FDEP) or in the Caloosahatchee River (C-43) West BSR Project Final Integrated PIR and EIS Annex C are:

* Spreadsheet Model Results prepared for the draft PIR
* DHI Report on Analysis of MIKE-SHE results
* Acceler8 C-43 Water Storage Reservoir 60% design submittal – 30 May 07
* Stanley Consultants Technical memorandum – Townsend Canal Impacts for Various Pumping Scenarios at C43PS-1
* DHI Technical Memorandum – Comparison of Irrigation Applications in the C-43 Basin and C-43 Reservoir – FDACS Request

None of these provided a reliable quantification of the pre and post project water supply volumes for reasons detailed below.

Spreadsheet Model Results prepared for the draft PIR - The Spreadsheet Model only predicts flows over the S-79 Structure based on C-43 West BSR operations.

DHI Report on Analysis of MIKE-SHE results -The MIKE-SHE Model analysis only addresses flows over the S-79 Structure based on C-43 West BSR operations.

Acceler8 C-43 Water Storage Reservoir 60% design submittal – 30 May 07 - The 60% design submittal does not address water supply in drought conditions.

Stanley Consultants Technical memorandum – Townsend Canal Impacts for Various Pumping Scenarios at C43PS-1 - This modeling analysis only addresses canal flows and groundwater levels in the vicinity of the C-43 West BSR.

DHI Technical Memorandum – Comparison of Irrigation Applications in the C-43 Basin and C-43 Reservoir – FDACS Request - This technical memorandum provided two model evaluations for review. One identified Irrigation Command Areas (ICAs) throughout the basin and compared pre and post project irrigation delivery results. The other graphed Townsend Canal pumping rates pre and post project. The FDACS analysis of the results yielded no clear conclusion regarding basin-wide or system-wide impacts to water supply during drought years.

Irrigation Command Center Results

We have no confidence that the "Irrigation Command Areas (ICA)" data provided by the South Florida Management District from DHI, is of sufficient quality to allow for any meaningful conclusions.

The main reason for the lack of confidence is the perplexing result of impacts far away from the reservoir where no difference should be occurring. There is no mechanism-based process to explain why the ICAs away from the reservoir show any difference. The SFWMD technical explanation provided is that this is "within the model confidence limits" but the results are questionable and indicate poorly understood sub routines within the model.

Also, interpretation of results is ambiguous. Even between the FDACS reviewers there is a difference of opinion on whether more irrigation applications indicate a better or worse scenario for water users during water shortage conditions. As detailed below, there is a definite difference for the modeled irrigation applications pre and post project in drought years for ICAs near the reservoir. The implication of these differences is unknown.

The results as modeled and presented by DHI indicate that overall the irrigation applications between the with and without project scenarios is very similar throughout 1978 to 1985 with the exception of an increase in irrigation applications from the Caloosahatchee River in the '81-'82 drought years for ICA 122 and ICA 44. ICA 122 lies off the NE corner of the C-43 Reservoir, an area that will be supplied by the PS-4 via the perimeter canal when the reservoir is dry. ICA 44 lies just south of the C-43 Reservoir.

The increase in irrigation applications are significant for '81-'82 is because most of the ICAs and years modeled show the "with project" scenario as having less irrigation applications where as the ICA 122 and 44 drought applications go in the opposite direction. ICA 122 shows a 19 % (4.1") increase in '81 and a 12% (1.54") increase in '82. ICA 44 shows a 13% (2.43") increase in '81 and only a 1% (0.14") increase in '82.

Townsend Canal Pumping Results – no water volume quantification available

The Berry Grove Pump will be replaced by both the C-43 West BSR PS-1 and PS-4 pumps. The PS-4 is not directly comparable to the Berry Groves Pump. PS-4 is only used when the reservoir is dry to convey water from the Townsend Canal into the perimeter canal for water supply purposes.

The difficulty encountered is that the units reported are a withdrawal rate (cfs) and not a volume. The Berry Groves pump shows a much greater variety of pumping rates than the Duda Pump or PS-4 throughout the dry year of '78 and the '81-'82 drought. Visual inspection of the pumping rate graph was the only information available. This did not provide for a pre and post water supply volume comparison. The most relevant results for a determination of water supply impacts is the "without project" combined Berry Groves Pump and Duda Pump volumes compared to the "with project" combined PS-4 and Duda Pump volumes for each month in '78, '81 and '82. Volume information was requested, but the SFWMD was not able to provide that information.

RE: Department of the Army, Jacksonville District Corps of Engineers – Final Integrated Project Implementation Report and Environmental Impact Statement for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project – Hendry County, Florida.
SAI # FL200709193767C (Reference SAI # FL200704263301C)

Dear Mr. Waters:

The Florida State Clearinghouse, pursuant to Presidential Executive Order 12372, Gubernatorial Executive Order 95-359, the Coastal Zone Management Act, 16, U.S.C. §§ 1451-1464, as amended, and the National Environmental Policy Act, 42 U.S.C. §§ 4231, 4331-4335, 4341-4347, as amended, has coordinated a review of the Final Integrated Project Implementation Report and Environmental Impact Statement (FPIR/EIS).

The Florida Department of Environmental Protection (DEP) fully supports the construction of the Comprehensive Everglades Restoration C-43 West Basin Reservoir Project. The DEP also commends the U.S. Army Corps of Engineers for working with staff to develop additional water quality analyses to address reasonable assurance that the project will not "cause or contribute" to water quality violations. Staff will continue to work closely with the Corps of Engineers and the South Florida Water Management District to facilitate permit issuance and implement the Comprehensive Everglades Restoration Plan.

The Florida Department of Agriculture and Consumer Services (FDACS) appreciates the opportunity to review the FPIR/EIS and requests that the document include information regarding the original plan to switch basin irrigation demand from Lake

Okeechobee to the basin run-off captured in the proposed C-43 reservoir as opposed to the current PIR plan to capture excess basin run-off and Lake Okeechobee regulatory releases for estuary use exclusively. FDACS has also expressed concerns that it may be difficult to maintain an accurate accounting of the water made available for the natural system by the C-43 reservoir relative to reductions in that amount that result when other projects are implemented. In addition, staff is less concerned with Savings Clause assurances in the immediate project area than with a potential reduction in water supply availability outside the project area if the reservoir creates additional demands on Lake Okeechobee. FDACS advises that the information and analyses provided do not address this issue sufficiently and are not adequate to provide the assurances required by state or federal law. Please refer to the enclosed FDACS memorandum for further details.

The Southwest Florida Regional Planning Council (SWFRPC) supports the components of the project that will benefit Caloosahatchee River area hydrology, water quality, wetlands, and wildlife and notes concerns regarding the acquisition of lands in Picayune Strand State Forest to off-set the loss of Florida panther habitat; the exclusion of the Oyster Restoration Plan for the Tidal Caloosahatchee in the FPIR/EIS; and utilization of water quality stations significantly downstream from the C-43 reservoir to monitor its water quality benefits. Staff continues to strongly recommend that the PIR incorporate: a water quality treatment component in the design of the reservoir project; plans for construction of littoral areas at the corners of the seepage canal; the planting of native shade tree species where new trees are proposed; an Oyster Restoration Plan for the Tidal Caloosahatchee; and a recalculation of the available mitigation credits created by habitat restoration within Picayune Strand State Forest to determine the real net benefit to the Florida panther. Though the SWFRPC supports the concept and implementation of the C-43 reservoir project, water quality protections should not be deferred in development of the project. Please refer to the enclosed SWFRPC letter for additional comments and recommendations.

Based on the information contained in the FPIR/EIS and the enclosed state agency comments, the state has determined that, at this stage, the proposed activities are consistent with the Florida Coastal Management Program (FCMP). The concerns identified by our reviewing agencies must be addressed prior to project implementation. The state's continued concurrence with the project will be based, in part, on the adequate resolution of issues identified during this and subsequent reviews. The state's final review of the project's consistency with the FCMP will be conducted during the environmental permitting stage.

Thank you for the opportunity to review the proposed project. Should you have any questions regarding this letter, please contact Ms. Lauren P. Milligan at (850) 245-2170.

Yours sincerely,

Sally B. Mann

Project:	FL200709193767C
Comments Due:	10/23/2007
Letter Due:	11/02/2007
Description:	DEPARTMENT OF THE ARMY, JACKSONVILLE DISTRICT CORPS OF ENGINEERS - FINAL INTEGRATED PROJECT IMPLEMENTATION REPORT (PIR) AND ENVIRONMENTAL IMPACT STATEMENT FOR THE CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR PROJECT - HENDRY COUNTY, FLORIDA
Keywords:	ACOE - FIPIR/EIS CALOOSAHATCHEE RIVER C-43 WEST BASIN STORAGE RESERVOIR - HENDRY
CFDA #:	99.997

Agency Comments:

TRANSPORTATION - FLORIDA DEPARTMENT OF TRANSPORTATION

The Florida Department of Transportation (FDOT) has concluded its review of the Final Integrated Project Implementation Report (PIR) and Environmental Impact Statement (EIS) for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project in Hendry County and offers the following comments: If the applicant performs excavation in FDOT right-of-way, any asbestos-containing material (ACM) encountered must be properly handled in accordance with all local, state and federal regulations. In no case shall ACM be crushed and buried within FDOT right-of-way. If this proposal results in impacts to FDOT roadways, all necessary permits must be obtained from the District One Operations Center prior to construction activities occurring within the state road right-of-way. Any contaminated soil that must be excavated in order to install utility features should be properly handled and disposed of and contaminated effluent from dewatering operations should be properly treated and discharged. All necessary worker safety precautions should be followed.

AGRICULTURE - FLORIDA DEPARTMENT OF AGRICULTURE AND CONSUMER SERVICES

The FDACS appreciates the opportunity to review the FPIR/EIS and requests that the document include information regarding the original plan to switch basin irrigation demand from Lake Okeechobee to the basin run-off captured in the proposed C-43 reservoir as opposed to the current PIR's plan to capture excess basin run-off and Lake Okeechobee regulatory releases for estuary use exclusively. This change has implications beyond the current project because other CERP projects use planning conditions based on the original concept of restricting Lake Okeechobee irrigation releases for agricultural water demand in the C-43 Basin. FDACS has also expressed concerns that it may be difficult to maintain an accurate accounting of the water made available for the natural system by the C-43 reservoir relative to reductions in that amount that result when other projects are implemented. There is a need to carefully account for "water made available" by this project and to consider how the potential future reductions in that water will be handled. In addition, staff are less concerned with Savings Clause assurances in the immediate project area than with a potential reduction in water supply availability outside the project area if the reservoir creates additional demands on Lake Okeechobee. FDACS advises that the information and analyses provided do not address this issue sufficiently and are not adequate to provide the assurances required by state or federal law.

SUBJECT: United States Army Corps of Engineers, Jacksonville District - Final Integrated Project Implementation Report and Environmental Impact Statement for the Caloosahatchee River West Basin Storage Reservoir Project - Hendry County, Florida

SAI #: FL07-3767C

Background:

The purpose of the Caloosahatchee River (C-43) West Basin Storage Reservoir project is to contribute to the restoration of the Caloosahatchee Estuary as part of the Comprehensive Everglades Restoration Plan (CERP) established by the 2000 Water Resources Development Act. The tentatively selected plan, Alternative 3B, consists of a 170,000 acre-ft. above-ground storage reservoir, a 1500 cfs pump station, external and internal embankments, internal control and outflow water control structures, and environmentally responsible design features to provide fish and wildlife habitat such as littoral areas in the perimeter canal and deep water refugia within the reservoir.

Comments:

The Florida Department of Environmental Protection commends the U.S. Army Corps of Engineers for working with us to develop the additional water quality analysis to address reasonable assurance that the project will not "cause or contribute" to water quality violations. The Department will continue to work closely with the Corps of Engineers and the South Florida Water Management District (SFWMD) to facilitate permit issuance.

We look forward to continuing our relationship with the Corps of Engineers and the SFWMD as we move forward with implementing the Comprehensive Everglades Restoration Plan. If you have any questions regarding these comments, please feel free to contact Greg Knecht at (850) 245-2088.

SUBJECT: Comments on the Caloosahatchee River (C-43) West Basin Storage Reservoir Project Final Integrated Project Implementation Report and Environmental Impact Statement

---

The Florida Department of Agriculture and Consumer Services (FDACS) appreciates the opportunity to comment and requests the following concerns be addressed in the review of the Corps' Caloosahatchee River (C-43) West Basin Storage Reservoir (BSR) Project Final Integrated Project Implementation Report (PIR) and Environmental Impact Statement (EIS). FDACS has submitted comments formally at the agency level and to the Project Delivery Team (PDT) throughout the project development process and during public review periods. The review issues that we consider as remaining to be addressed are summarized below.

The Final PIR and EIS do not acknowledge the Yellow Book's original "source switch" function for the C-43 reservoir project. Rather, it rewrites the project's conceptual history to match the current outcome. An accurate account should be included of the original plan to switch basin irrigation demand from Lake Okeechobee to the basin run-off captured in the proposed C-43 reservoir as opposed to the current PIR's plan to capture excess basin run-off and Lake Okeechobee regulatory releases for estuary use exclusively. This change has implications beyond this particular project because other CERP projects use planning conditions based on the original concept of restricting Lake Okeechobee irrigation releases for agricultural water demand in the C-43 Basin. The Final PIR/EIS Annex B – Draft PIR Comment Matrix (page B-82) responds to an earlier FDACS comment on this issue, but merely confirms the change: "The reservoir proposed in this project allows estuary demands to be supplemented by reservoir storage during the dry season, thus relieving some dry-season demands on Lake Okeechobee allowing more water within the lake to be used system wide." While not stating that these system wide uses include C-43 basin irrigation demand, it is not apparent how the irrigation demand would otherwise be met.

Annex C contains an analysis that identifies the volume of water made available by the project for the natural system. The amount identified under the Initial Operating Regime (IOR) is anticipated to be substantially more than the amount that will ultimately be available for the natural system as identified in the Next Added Increment (NAI) analysis. Under the driest conditions, the IOR amount is approximately 50% greater than the NAI amount (Table C-3: Identification of the Volume of Water (Ac-Ft/Year) Made Available for the Natural System to Achieve the Benefits of the Project, Page C-24, Annex C, Caloosahatchee River (C-43) West Basin Storage Reservoir (BSR) Project Final Integrated PIR and EIS).

The larger amount identified in the IOR is recommended to be reserved for the natural system under Florida law. The recently released "Revised Final Draft CERP Guidance Memoranda - GM #4: Identifying Water Made Available for the Natural System and for Other Water Related Needs" refers to changing water reservations in response to changing conditions as more CERP projects are completed. The language of GM #4 appears to address the incorporation of additional water made available and not subsequent reductions in water made available. FDACS is concerned that it may be difficult to maintain an accurate accounting of the water made available for the natural system by the Caloosahatchee (C-43) West BSR relative to reductions in that amount that result when other projects are implemented. Moreover, the prospect of "rolling back" an already established reservation raises some significant legal questions, and underscores the need to carefully account for "water made available" by this project and to consider how the potential future reductions in "water made available" will be dealt with. The USACE did not provide a response in the Final PIR/EIS Annex B – Draft PIR Comment Matrix to an earlier FDACS comment that raised this issue.

Our remaining concern is the lack of an evaluation tool to determine if the Caloosahatchee (C-43) West BSR will create a greater demand on the Caloosahatchee River with an associated greater demand on Lake Okeechobee during drought years. Consequently, meeting the Savings Clause requirements for an existing legal source as of December 11, 2000, consistent with Federal law, is still an open question for the Caloosahatchee River (C-43) West BSR Project Final Integrated PIR and EIS. While we agree with the USACE that the possibility of significant negative impacts to existing users in the area of the project is minimal, we are not convinced that an adequate analysis of impacts to water supply during drought years has been performed or that the methodology described in "Revised Final Draft CERP Guidance Memoranda GM #3: Savings Clause Requirements" has been followed. It is not clear whether the system wide effect of an additional demand on Lake Okeechobee was considered at all. We believe that the information and analyses provided do not address this issue and are not adequate to provide the assurances required by state or federal law.

The underlying issue for all our concerns is that the modeling conducted for the Caloosahatchee (C-43) West BSR relied upon delivery of a specific volume of water from Lake Okeechobee, and it is not clear what system wide impacts this demand on the lake will have, particularly under drought conditions. First, there is a potential conflict with the original Yellow Book assumption that the project would restrict deliveries to the C-43 basin and consequently with the planning assumptions for other CERP projects. Second, the apparent anomaly between the water made available under the IOR scenario and the NAI scenario likely hinges on the discrepancy between potentially competing water demands from Lake Okeechobee. Finally, we are less concerned with Savings Clause assurances in the immediate project area than with a potential reduction in water supply availability outside the project area if the reservoir creates an additional demand on Lake Okeechobee.

Again, we appreciate the opportunity to comment on the Caloosahatchee River (C-43) West BSR Project Final Integrated PIR and EIS. Our level of concern with the issues we raise here is heightened by current system conditions, and we believe that a better understanding of the effect of this project under such conditions is needed. Moreover, we do not believe that the Savings Claus analysis adequately addresses potential impacts outside the area of the project, nor do the PIR and EIS provide sufficient information to provide the assurances required under Florida law.

If you should have questions regarding FDACS' comments, please contact me at (850) 410-6714.

Re: IC&R 2007-059
SAI#FL 200709193767C
Hendry County, Caloosahatchee River (C-43) West Basin Storage Reservoir, Final Integrates Project Implementation Report (PIR) and Final Environmental Impact Statement (EIS), Permit 3005-5958(IP-TKW)

Dear Ms. Mann:

The Southwest Florida Regional Planning Council (SWFRPC) has reviewed the Final Integrated Project Implementation Report (PIR) and Final Environmental Impact Statement (EIS) for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project, and has the following comments:

The request dated, September 19, 2007 was received for our review on September 21, 2007.

The proposed project has the potential to effect hydrology, water quality, wetlands, and wildlife within one of the largest manmade canal systems and watersheds within the southwest Florida region.

There are several components of the Final Integrated Project Implementation Report (PIR) that will have environmental benefits including:

- Construction of a 170,000 acre-feet reservoir with the expressed purpose of reducing the number and duration of extreme hydrologic events at S-79 locks on the Caloosahatchee River.
- Reduction in the number and duration of high flow (>4500 cfs) and low flow (<450 cfs) events in the Caloosahatchee River.
- Adopting and implementing targets of 0 flows below 450 cfs and above 4,500 cfs for the Caloosahatchee River.

TO: Ms. Sally B. Mann

DATE: October 25, 2007

PAGE: Two

RE: IC&R 2007-059 - SAI#FL 200709193767C

- Commitment to use the water quality prediction tools currently in development, such as reservoir and estuary water quality models, to optimize the reservoir operations with the goal of improving downstream water quality. (reference: Page C-83)
- Commitment to 5 years of water quality monitoring associated with design and initial operations of the reservoir.

A component of the Draft Final Integrated Project Implementation Report (PIR) that would have had environmental benefits that has been removed and/or are not included in the PIR including:

- An Oyster Restoration Plan for the Tidal Caloosahatchee that anticipated an increase from 3.02 acres of oyster reef habitat in 2004 to 30 acres of oyster reef habitat within 10 to 15 years. With the ultimate addition of hard, suitable substrate the target of oyster reef habitat increases to 100 acres. (References: Page 5-36 of the PIR. Page C-67)

There are several components of the Final Integrated Project Implementation Report (PIR) that are questionable in conception and execution including:

- The use of the acquisition of lands in the Picayune Strand State Forest as mitigative off-site to the loss of Florida panther habitat accrued by the C-43 project flooding of Florida panther habitat area. The issue is compounded by the mixed sources of funding that were used to acquire the land that today constitutes the Picayune Strand State Forest. The forest was variously acquired by direct federal fund allocations that did not specify that the land acquisition constituted a mitigation bank or mitigation area, State funds from the CARL and Florida Forever funding sources that are not bonded as mitigation banks or areas, private conservation entity acquired lands donated to the State, already existing mitigation sites utilized as off-sets to other listed species impacts including Florida panther and red-cockaded woodpecker project impacts for private developments, and other donated lands. It is therefore questionable to ex post facto utilize and existing public conservation land set aside by funding sources that did not envision or specify that this land was to constitute mitigation for impacts to federal listed species habitat elsewhere. Following this train of thought all existing State and federal lands not previously debited could be considered mitigation banks against future projects. In addition, many areas of the Picayune State Forest will be negatively impacted and rendered useless for Florida panther habitat by construction features and upland flooding caused by the construction activities of the restoration project including spreader

TO: Ms. Sally B. Mann

PAGE: Three
RE: IC&R 2007-059 - SAI#FL 200709193767C

berm/swale and pump station construction and higher water discharges across upland and short hydroperiod wetland systems.

- The use of water quality monitoring stations significantly downstream of the C-43 reservoir as a monitoring surrogate of the water quality benefits to the Caloosahatchee estuary of the discharge from the reservoir is questionable in large part since a significant number of other factors in the main line of the River and contributions to the river from downstream and in-stream water sources will swamp out the water quality content and volume effects of the reservoir. Since there are many other water quality improvement projects that will be occurring concurrent with the C-43 reservoir project including reductions in domestic fertilizer use, restorations of tributary creeks downstream of the C-43 structure, and improvements to wastewater treatment plants, it will not be possible to identify the source of water quality improvement to the Caloosahatchee River and thereby attribute it to the reservoir's project.

The SWFRPC strongly recommends incorporation of the following into the PIR:

1) A water quality treatment component needs to be included in the design of the reservoir project. The need for a water quality treatment component was identified early in the process of alternative development review by federal, state, regional, and local agency participants of the PDT in the development of the PIR. It was deferred from consideration by the SFWMD and the USACOE. We understand that this reservoir project is the only reservoir design currently under consideration for CERP funding that does not have a water quality treatment feature. Based upon materials posted on the CERP web-site, east coast reservoirs have water quality treatment features included in their design. It is important that the current project design not preclude the necessary water quality treatment features. It is important that land not be surplused from the project footprint before necessary water quality treatment features are planned and constructed. Addressing hydrology without including water quality improvement is insufficient in protecting the estuary and aquatic resources of the Caloosahatchee River and the nationally recognized Outstanding Florida Waters estuaries at its confluence. H.R. 1816, the "Restoring the Caloosahatchee River: A Legacy for Florida" Act, was introduced by Congressman Connie Mack and the State of Florida Appropriations Bill delivered to Governor Crist includes funding a water quality component for the C-43 Reservoir project. The TSP should include water quality treatment features with sufficient space for their construction.

TO: Ms. Sally B. Mann

DATE: October 25, 2007

PAGE: Four

RE: IC&R 2007-059 - SAI#FL 200709193767C

2) The littoral areas proposed at the corners of the seepage canal as part of the project should be constructed. We concur with the Florida Fish & Wildlife Conservation Commission that these littoral areas will provide habitat benefits and potential water quality benefits.

3) All shade trees proposed on the outside area of the north rim canal adjacent to parking areas should be native to the Caloosahatchee basin. Past selection and planting of exotic tree species in USACOE projects has led to damage to reservoir banks and project canal banks resulting in expensive removal programs and the need to construction repairs.

4) An Oyster Restoration Plan for the Tidal Caloosahatchee which anticipates an increase from 3.02 acres of oyster reef habitat in 2004 to 30 acres of oyster reef habitat within 10 to 15 years. With the ultimate addition of hard, suitable substrate the target of oyster reef habitat increases to 100 acres.

5) The use of the past acquisition of existing conservation lands as Florida panther habitat impact mitigation for new projects such as the C-43 reservoir needs to be seriously reconsidered. The balance of mitigation created by such a practice will ultimately lead to net significant habitat loss for the Florida panther as each new project is "offset " by the existence of already protected conservation lands that add no new net increase in habitat extents for the species. In any case, lands that are impacted by project activities on the Picayune State Forest that will render land useless as Florida panther habitat should not be utilized as mitigation credits. Similarly, lands that were acquired by funding sources other than those specifically intended to serve as mitigation banks should not be utilized to generate mitigation credits from the acquisition itself. Only the net lift in panther habitat improvement created by a new restoration plan for panther habitat should be considered as available mitigation credits to be utilized for the C-43 project and similar future CERP projects. Therefore, we recommend a recalculation of the available mitigation credits that are created by habitat restoration within the Picayune State Forest based upon the current version of the restoration plan and then an audited accounting of the post-restoration project habitat restoration outcomes to determine the real net positive effects for the Florida panther of that restoration effort. The subsequent balance should then be addressed if the mitigative lift is less than the level of impact accrued by the C-43 project.

RE: IC&R 2007-059 - SAI#FL 200709193767C

The SWFRPC supports the concept and development of the C-43 reservoir project to reduce the negative hydrologic discharges to the Caloosahatchee River, restoration of base flows for the Caloosahatchee River, and improvement in water quality of the Caloosahatchee River. Our staff has participated cooperatively in the development of the PIR and EIS. We did not and do not agree; however, that water quality protections should be deferred in development of this project.

We look forward to cooperating with the applicant and other relevant agencies to resolve the issues that we have identified in this letter in order to ensure consistency with the Coastal Zone Management Act/Florida Coastal Management Program and to ensure that the PIR proceeds in a fashion that minimizes impacts to water quality, hydrology, and fish and wildlife resources in the Southwest Florida Region. Please feel free to call me if you would like to coordinate further discussion of these issues; I will be glad to facilitate any such efforts. If you have specific questions about the content of this letter, please contact Mr. Jim Beever directly at (239) 338-2550 ext 224 or by e-mail jbeever@swfrpc.org.

Sincerely,

SOUTHWEST FLORIDA REGIONAL PLANNING COUNCIL

DEPARTMENT OF THE ARMY
U.S. ARMY CORPS OF ENGINEERS
WASHINGTON, D.C. 20314-1000

AUG 11 2009

South Atlantic Division
Regional Integration Team

Charles H. Bronson, Commissioner
Florida Department of Agriculture and Consumer Services
The Capitol
Tallahassee, FL 32399-0800

Dear Commissioner Bronson:

Thank you for your letter dated October 19, 2007 on the Caloosahatchee Basin Storage Reservoir Project Final Project Implementation Report. Since that time, there have been several productive meetings with your staff and contracted consultants, as well as with the South Florida Water Management District, Florida Department of Environmental Protection, and Corps of Engineers, Jacksonville District staff to clarify and better understand the Department's concerns. In addition, several national policy concerns were reviewed as required pending final assessment of the report and have been a reason for the postponement of response until this date. We appreciate your staff's willingness to identify issues of concern and possible resolutions, and we would like to offer the following information and explanations in response to your letter based on staff discussions and policy review.

Project-Specific Objectives and System-wide Issues
Your letter states on page one:

> *"An accurate accounting should be included of the original plan to switch basin irrigation demand from Lake Okeechobee to the basin run-off captured in the proposed C-43 reservoir as opposed to the current PIR's plan to capture excess basin run-off and Lake Okeechobee regulatory releases for estuary use exclusively."*

It is true that the objectives for this project were updated since the original formulation of the C-43 reservoir feature in the 1999 Comprehensive Review Study. Changed conditions in the C-43 basin and an updated analysis of the availability of excess basin runoff that could be captured and back-pumped to Lake Okeechobee, along with the acquisition of the Berry Groves site and uncertainties about the feasibility of implementing the aquifer storage and recovery (ASR) project that was associated with the reservoir, caused the project delivery team to recommend new project objectives, evaluation criteria, and reservoir operations focused on restoring the Caloosahatchee Estuary.

These changed conditions and the basis for changing project goals and objectives were discussed and presented at several key milestones during project planning, and were documented in the Draft (April 2007) and Final (September 2007) Project Implementation Reports (PIRs). At those milestone meetings and in written comments on the Draft and Final PIRs, Department staff

duly noted their concerns about the modified project objectives and deferring consideration of additional water supply to future planning efforts. Nevertheless, in the interest of finalizing planning, approval, and authorization of a key component of the CERP for which the State of Florida had already acquired a significant portion of project lands, leaders at the South Florida Water Management District and the Corps of Engineers made a collective decision to proceed with preparing and finalizing a project implementation report focusing on the reservoir and restoration of the Caloosahatchee Estuary.

The Department's concerns about potential project impacts on water available for agricultural water supply and deferring planning efforts addressing agricultural water supply issues in the Caloosahatchee Basin are easily understood, especially considering that South Florida has recently experienced unprecedented drought conditions and record low water levels in Lake Okeechobee. But it must be emphasized that the goal of the Caloosahatchee (C-43) West Basin Storage Reservoir project is to create additional capability to manage water resources to meet ecosystem restoration objectives in the Caloosahatchee Estuary by capturing excess (flood control) releases from Lake Okeechobee, without impacting municipal or agricultural supplies elsewhere in the basin.

Furthermore, the reservoir project was not formulated to address other system-wide objectives outside the C-43 basin (e.g., increase the amount of water available in Lake Okeechobee to meet regional irrigation demands). Other CERP projects and operational planning efforts (for example, EAA Storage Reservoir, Site 1 Impoundment, and Broward County Water Preserve Areas, System Operating Manual) have been or will be formulated to increase the amount of water available from both project and system-wide operations to meet restoration targets and provide water for other water-related needs, including irrigation. We strongly encourage your Department's participation in the initial formulation and evaluation of those other CERP efforts to ensure that your agency's concerns are fully incorporated in project planning, including modeling and analysis and preparation of draft project operating manuals.

Modeling

The Department raised concerns about modeling conducted for the analyses presented in the PIR and assumptions supporting that modeling. Although we and SFWMD acknowledge that the basin-level modeling and the water budget for the reservoir is based on an assumption about in-flows from Lake Okeechobee, that assumption is consistent with the policies and procedures in the current draft "Six Program-Wide Guidance Memoranda" (July 2007) proposed by the agencies responsible for implementing the CERP. These policies and procedures address how projects will be formulated and justified, how compliance with the Savings Clause is to be analyzed, and how water is quantified to be reserved or allocated by the State of Florida.

We also understand that basin-scale modeling performed by the SFWMD to design the project prompted additional requests for more information than what was presented in the project implementation report to demonstrate compliance with the Savings Clause. Additional comparison analysis of dry season monthly pumping was conducted by Jacksonville District staff and shared with the Department's staff and contracted consultants (MacVicar, Federico, and Lamb). The comparison of monthly pumping volumes from the Caloosahatchee River by the Berry Groves

pump (historical condition) and the proposed PS4 pump (future with project condition) during the dry season over a 9-year period of record confirmed that the project would not create an additional demand on the River or Lake Okeechobee to maintain the proposed perimeter canal surrounding the reservoir. In fact, the analysis showed that, in comparison to the Berry Groves pump as previously operated, the project's PS 4 pump would pull only approximately 25% of the water that the Berry Groves pump did over the entire1978-1986 period of analysis. In many years the PS 4 pump would not even be needed, because the reservoir contains sufficient water to maintain the perimeter canal in the dry season. In only two months over the period of record would the PS 4 pump pull slightly more water than the Berry Groves pump, and this is far outweighed by the much lower demand over the entire period.

This analysis also demonstrated that the reservoir and its cut-off walls will not affect water availability north of the reservoir or to the C-43 Canal. The perimeter canal, which is outside of the cutoff wall, will intercept groundwater flow and route it north, making water available to properties north of the reservoir and C-43.

Water Reservations or Allocations

Your letter correctly notes that the Initial Operating Regime (IOR) model simulation indicates that there is more water to be protected by the State of Florida than is generated by the NAI model simulation; however, the current policy of the State of Florida which is consistent with the Draft Guidance Memoranda is to protect water based on an analysis of the IOR. As you know, reservation or allocation of CERP project water for the natural system by the State of Florida is through adoption of an administrative rule. If conditions change, particularly as a result of implementation of other CERP projects, it is expected that the SWFMD would seek to modify a reservation or allocation to be consistent with the analyses performed for in future CERP PIRs. Updates of the reservation or allocation rules would be consistent with CERP Programmatic Regulations which contemplated the need for updates. The Department will have ample opportunity to address the technical aspects of the initial and subsequent rule-making efforts through the State of Florida's administrative process.

For this project, a key point is that all of the water to be protected for the natural system is a result of being able to capture and store excess Lake Okeechobee discharges to tide in the reservoir, and then delivering that water at the right time to meet estuary salinity targets. This project as simulated in the modeling, and as it will be operated, will not reduce the amount of water available from existing sources in the C-43 basin or the amount available to existing legal users.

We trust that the above information and explanations, together with the actions generated by the discussions that have occurred since your original letter, sufficiently address your concerns. If you would like to discuss these issues further, please contact Ms. Beth Marlowe, our Jacksonville District Project Manager, at 904-232-2074.

Sincerely,

Steven L. Stockton, P.E.
Director of Civil Works

CESAJ-DR-PE 03 June 2008

MEMORANDUM FOR THE RECORD

SUBJECT:	Conference Call regarding C-43 West Basin Storage Reservoir Concerns Raised by Florida Department of Agriculture and Consumer Services (FDACS)
CALL DATE:	May 13, 2008
ATTENDEES:	Rebecca Elliott, FDACS Steve Lamb, Contractor to FDACS Brenda Mills, South Florida Water Management District (SFWMD) Allen Hall, SFWMD Brian Cornwell, US Army Corps of Engineers (USACE) Beth Marlowe, USACE

Brenda opened the meeting with acknowledgement of FDACS concerns raised in their October 19, 2007 letter in response to Corps HQ request for State and Agency review comments on the Caloosahatchee (C-43) West Basin Storage Reservoir Final Project Implementation Report and draft proposed Chief's Report. The group discussed two outstanding technical questions raised regarding the effects of the reservoir on regional water supply.

Issue 1: Will the PS4 pump associated with the C-43 reservoir pull enough water from the C-43 (and ultimately Lake Okeechobee) during dry times to become, in effect, a regional water user?

FDACS agrees that, intuitively, it should not be, but they are looking for appropriate quantification on paper to confirm the intuitive argument, so that five years from now everyone understands and can remember what was agreed to, and so that performance can be tracked in future years and compared to expectations.

Brian Cornwell clarified where withdrawals are occurring now, and how water would be routed around the proposed reservoir to maintain water supply to properties to the east of the proposed reservoir. The Paul property historically has pulled surface water from the LPDD header canal during the dry season. This canal depended on pumping of surface water from the Townsend and C-43 canals by the Berry Groves pump. In the future with project water will be supplied from the reservoir unless it is dry, in which case water will be supplied from the reservoir perimeter canal, which pulls from the Townsend Canal, and ultimately, from the C-43. Brian prepared a comparison analysis of monthly dry season pumping of the Berry Groves pump and the proposed PS4 pump during the dry season over a 9-year period of record. The results show cumulative pumping from the C-43 would decrease significantly in the future with project condition. There would be no significant increase in pumping in any single month, compared to Berry Groves pump. The PS4 pump is not expected to create a new demand on the C-43 or Lake Okeechobee during the dry season. See attachment 1 for details.

Rebecca Elliott and Steve Lamb agreed that the quantitative analysis provided addressed their concerns. The group agreed that the issue resolution would be documented by preparation of this meeting summary, and an explanation of the data files used and how the analysis was conducted. In addition, a short summary of the issue and its resolution will be included in the USACE response letter to the October 19, 2007 FDACS letter of concern.

Issue 2: What effect will the proposed reservoir's cut-off wall have on groundwater flow?

Brenda explained that in general, the perimeter canal will replace any groundwater lost to existing users with surface water. The perimeter canal will capture groundwater flow outside the cut-off wall. The group agreed that the monthly pumping volume chart prepared by Brian to address Issue 1 largely answers the second question because it shows all pull from the C-43 to the perimeter canal. The group determined it was not worth it to create more complicated analyses because we can extract the answers needed from what we have.

The group asked if there were any other potential concerns that needed to be addressed. Rebecca Elliott asked about any potential concerns in moderate events, and whether water quality would be different because of the change in source. The group responded that data will be collected early to identify any changes and make any necessary adjustments. The consensus was this issue has been resolved.

The conference call was then adjourned.

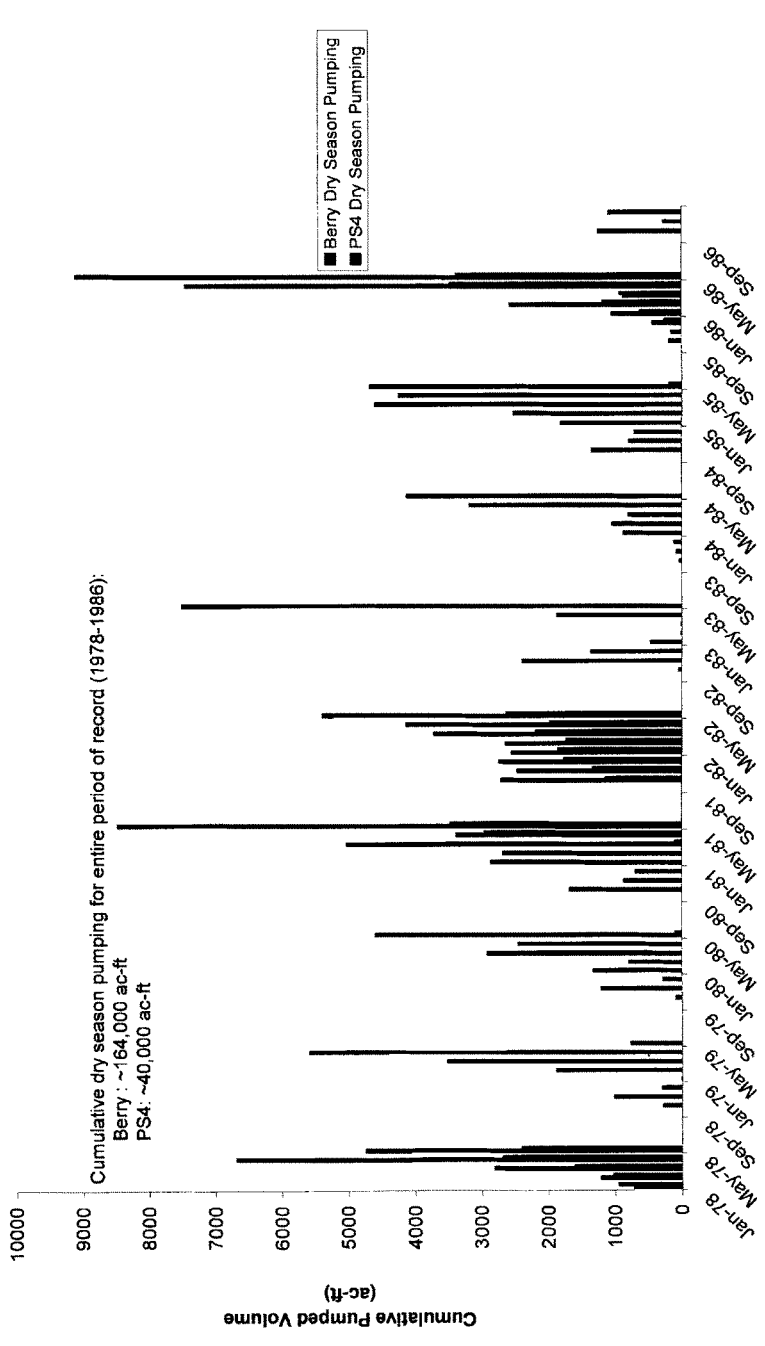
Attachment 1:
Comparison of Monthly Dry Season Pumping Volumes from the Berry Groves and Proposed PS4 Pumps

The Caloosahatchee River (C-43) West Basin Storage Reservoir is planned to be constructed at the current Berry Groves site. The reservoir embankment will contain a slurry wall to reduce seepage out of the reservoir as well as a perimeter canal, located outside of the slurry wall. In addition to intercepting any potential seepage, the perimeter canal will maintain existing groundwater levels and deliver surface water that currently is conveyed by the LPDD Header Canal to properties east of the reservoir.

During normal wet season operations, the PS1 pump station will pump excess flows from the C-43 into the reservoir. During the dry season, this reservoir water is released into the perimeter canal, then into the Townsend Canal, Fort Simmons Branch, and Banana Branch, and ultimately into the C-43 to augment low flows to the Caloosahatchee Estuary.

The perimeter canal will also deliver surface water that is currently conveyed by the LPDD Header Canal to properties east of the reservoir. When water is available in the reservoir, releases are made via the S-8 structure into the perimeter canal. When there is no water in the reservoir, the PS-4 pump station will pump water from the Townsend Canal, into the perimeter canal to maintain existing water supply.

In addition to intercepting any potential seepage, the perimeter canal will also serve the purpose of maintaining existing groundwater levels and gradients in the local vicinity of the project. Users who rely on groundwater will not be impacted by the slurry cutoff wall due to the fact that the perimeter canal will provide a relatively constant water level outside the slurry wall.



Concerns have been raised that the maintenance of water levels in the perimeter canal could create a new demand on the C-43, and ultimately on the Lake Okeechobee Service Area. An analysis was conducted using the integrated surface water-groundwater model MIKE SHE, comparing the pre-project existing condition to the with-project condition. In accordance with the Savings Clause (WRDA 2000), the analysis was conducted using the 2000 land use condition for with project and without project conditions.

The data is presented as monthly volume pumped by the PS-4 pump station (with-project), compared to the monthly volume of water pumped by the Berry Groves pump station (existing condition). Since water is pumped by the PS-4 pump station only in extremely dry times when the reservoir is empty, the data has been simplified by only showing dry season pumping, conservatively assumed to be from October 1 through May 31.

As shown in Figure 1, the with-project condition introduces no significant increase in pumping for any individual month and actually shows a very significant reduction in cumulative dry season pumping for the period 1978 through 1986.

This analysis illustrates that, when compared to existing conditions, the perimeter canal will not create a new demand on the C-43 or Lake Okeechobee.

Monthly Dry Season Pumping for Berry Groves and PS4

revd 10118107

United States Department of the Interior

OFFICE OF THE SECRETARY
Washington, D.C. 20240

Oct 15, 2007

Honorable John Paul Woodley
Assistant Secretary of the Army
U.S. Department of the Army
Office of the Assistant Secretary Civil Works
108 Army Pentagon
Washington, DC 20310-0108

Dear Mr. Secretary:

Thank you for the opportunity to review and provide comments on the *Chief of Engineers Proposed Report on the Comprehensive Everglades Restoration Plan, Central and Southern Florida Project, Caloosahatchee River (C-43) West Basin Storage Reservoir, Final Project Implementation Report, Hendry County, FL* (Chief's Report). The Department of the Interior (Department) provided funds for the purchase of lands utilized in this project.

The Department supports the Chief's Report on the recommended plan for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project, as described in the *Central and Southern Florida Project Comprehensive Everglades Restoration Plan Caloosahatchee River (C-43) West Basin Storage Reservoir Project Final Integrated Project Implementation Report and Final Environmental Impact Statement, September 2007.*

The Caloosahatchee River and Estuary is at the head of a vast estuarine and marine ecosystem that includes aquatic preserves managed by the state of Florida, the federally designated Charlotte Harbor National Estuary and the J.N. "Ding" Darling National Wildlife Refuge. Currently, there is not enough storage capacity in the regional water management system to minimize or prevent the harmful periodic excessive discharges of freshwater to the Caloosahatchee Estuary. Conversely, during dry periods, there are many times when there is not enough freshwater available in the regional system to maintain desirable salinity levels in the estuary. The combined result of too much or too little freshwater flowing to the Caloosahatchee Estuary is a degraded estuarine ecological community. Restoration of a healthy and productive aquatic ecosystem in the Caloosahatchee River is essential to maintaining the ecological integrity in these publicly owned and managed areas. The recommended plan provides benefits by reducing harmful discharges to the Caloosahatchee Estuary by capturing a portion of damaging high flows in the Caloosahatchee River, storing the water until needed in a reservoir and discharging the stored water to supplement inadequate flows to the Caloosahatchee Estuary during the dry season.

The portion of the Everglades ecosystem directly affected by the Caloosahatchee River (C-43) West Basin Reservoir, including the project site, the Caloosahatchee River and Estuary and the lower West Caloosahatchee River Basin, provides habitat for 21 federally listed endangered or threatened species, including the endangered Florida panther, Everglades snail kite, wood stork, manatee, eastern indigo snake, and Audubon's crested caracara. The Department is pleased that there will be monitoring of project effects on the endangered eastern indigo snake and Audubon's crested caracara. The Department looks forward to working with you to monitor the effects of reservoir operations on endangered species, such as the Florida panther, and to manage adaptively to maximize benefits on all fish and wildlife resources.

Sincerely,

Terrence C. Salt
Director of Everglades Restoration Initiatives

Subject: EPA NEPA Review of the COE "Final Caloosahatchee River (C-43) West Basin Storage Reservoir Project" (September 2007); Hendry County, FL; CEQ# 20070394; ERP# COE-E39068-FL

Dear Mr. Waters:

In accordance with our responsibilities under Section 102(2)(C) of the National Environmental Policy Act (NEPA) and Section 309 of the Clean Air Act, the U.S. Environmental Protection Agency (EPA) has reviewed the referenced U.S. Army Corps of Engineers (COE) Final Environmental Impact Statement (FEIS) for the proposed C-43 Basin Storage Reservoir (BSR). This proposed project is a major component of the Comprehensive Everglades Restoration Plan (CERP) and therefore was reviewed as a project implementing the overall goals and objectives of Everglades restoration.

EPA provided comments on the draft EIS (DEIS) to the COE Jacksonville District in a letter dated June 7, 2007. EPA continues to support the COE's expedited approval and implementation of the Caloosahatchee C-43 Reservoir to provide additional water storage along the Okeechobee Waterway. We offer our continued technical water quality assistance as appropriate.

EPA focused its NEPA review of the FEIS on the COE's responses to our comment letter on the DEIS found in Annex B (pp. B-73 to B-81). As noted below, we find this section to be generally responsive to our comments on the DEIS but not always organized in a user-friendly manner. We offer the following response-specific and general comments:

* General Responses – Several responses were generic, indicating that the FEIS will be modified or that the COE agrees/concurs with the comment, as opposed to what volume, section or page of the FEIS was modified and/or a synopsis of that modification. To the extent feasible, we request that the responses in future COE NEPA documents be more specific to facilitate the public review, although we realize that this is a six-volume

document and draft documents often change until publication, such that section numbers and page numbers may be difficult to identify.

* Response 9 (Project Sizing) – We are pleased to find that additional water storage along the Caloosahatchee River is planned via another storage reservoir project (Caloosahatchee Watershed Project).

* Response 11 (Wetlands) – The EPA comment for this response was incorrectly transferred in the Annex. Page 8 of our DEIS letter indicated that page 20 of the DEIS stated that "[t]here will be no mitigation for wetlands as a result of the federal project" while page B-76 of Annex B stated that "[t]here will be mitigation for wetlands as a result of the federal project".

* Locating Responses – For future COE NEPA documents, we suggest that locating the COE's responses to agency/public comments be facilitated. Although Section 9.35.1 of the main document is titled as *Comments Received and Responses*, it refers the reader to Annex B. Annex B then refers to *Agency Correspondence* (B.3.3) and *Public Correspondence* (B.3.4) and could have been improved to read agency and public correspondence "with COE responses". In addition, it is unclear why EPA's comments are included under public rather than agency correspondence. In general, a six-volume document should be made as user-friendly as possible for public review.

In addition to the responses section, we are pleased to note that modifications in FEIS were also made. We particularly note that Appendix C (*Environmental Information*: pp. C-72 to C-119) addressed most of our water quality concerns. We appreciate this summary. Beyond this write-up, however, we encourage the Jacksonville COE to annually provide our EPA Region 4 South Florida Office with the C-43 BSR water quality monitoring program analysis. Coordination with downstream users such as Lee County and City of Sanibel is also recommended. We have also reviewed the *Draft Project Operating Plan* in Annex D and generally find it acceptable for water quality. EPA wishes to participate in the reservoir operations team and will await a schedule of events from the COE.

Although the above responses and sections were generally well done, we wish to offer a few comments on the *Water Quality Management Plan* (WQMP) in Annex D (pg. D-76). We have two main concerns with the WQMP: 1) identification of the project category and 2) water quality monitoring of the reservoir. Regarding our first concern, Section 1 of the WQMP defines the C-43 BSR Project as a Category "C" project instead of a Category "B" project (which are projects designed to achieve water quality improvement even though they do not contain water quality improvement features). Accordingly, we recommend that the C-43 BSR Project be re-characterized as a Category "B" project in the COE's Record of Decision (ROD). Regarding our second concern, we continue to request that the project include warm-weather monitoring of the reservoir (in addition to the proposed monitoring of chlorophyll-*a* at the discharge structures). Specifically, reservoir monitoring should entail sampling for blue-green algae from April to October at 1-ft below the surface. Along with algal sampling, monitoring should also

include taking *in situ* water quality profiles for reservoir temperature and dissolved oxygen during these months to document reservoir water quality and determine any thermal stratification. We recommend that the COE's ROD provide a commitment for such warm-weather monitoring of the reservoir (if such a commitment is not forthcoming, the ROD should fully substantiate how the monitoring of chlorophyll-*a* would serve as a surrogate for the recommended reservoir monitoring). Given the project's intent to improve the downstream water quantity and quality concerns associated with the current water releases from Lake Okeechobee, we find it essential to maintain the water quality of the reservoir and to determine the water quality prior to releases downstream to the lower Caloosahatchee River and Estuary at S-79. The water quality of the C-43 BSR release waters should be no worse than – and preferably better than – the ambient waters of the Caloosahatchee. Such monitoring data should also be of interest to the reservoir operations team.

Should you have questions regarding our comments, feel free to contact Chris Hoberg of my staff for NEPA-related issues (404/562-9619 or hoberg.chris@epa.gov) or Eric Hughes in our EPA Water Management Division (located in the Jacksonville District office) for technical issues (904/232-2464 or hughes.eric@epa.gov).

Sincerely,

Heinz J. Mueller, Chief
NEPA Program Office
Office of Policy and Management

Dear Ms. Darcy:

As required by Executive Order 12322, the Office of Management and Budget completed its review of your recommendation for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project in Hendry County, Florida.

Based on our review of the project, we concluded that your recommendation is consistent with the policy and programs of the President. The Office of Management and Budget does not object to you submitting this report to Congress for authorization.

Sincerely,

Richard A. Mertens

CENTRAL AND SOUTHERN FLORIDA PROJECT
CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR
FINAL INTEGRATED
PROJECT IMPLEMENTATION REPORT
AND
ENVIRONMENTAL IMPACT STATEMENT
ADDENDUM A

Addendum Purpose:

The purpose of this Addendum is to document changes to project costs as presented in the Final Integrated Project Implementation Report and Environmental Impact Statement of July 2007, based on a revised project real estate cost completed in accordance with CECW-SAD memorandum dated July 30, 2009 signed by the Director of Civil Works, U.S. Army Corps of Engineers. The current guidance for the CERP, Land Valuation and Crediting is as follows:

a. Consistent with long-standing USACE practice, and as supported by the unique land credit provision for CERP contained in Section 601 (e)(5)(A) of WRDA 2000, tracts acquired by the SFWMD that are acquired and provided in furtherance of a CERP project should be valued and credited as individual tracts regardless of whether the acquisition was prior to or after execution of the Project Partnership Agreement (PPA) for that project. This general principle would not apply where the SFWMD acquired contiguous tracts that are required for a CERP project but it acquired such tracts prior to the PPA for a reason and use other than for implementation of the CERP project. A determination that a tract was acquired "in furtherance of a CERP project" should be supported by documentation existing at the time of acquisition.

b. The unique statutory land credit provision for CERP projects is clear that the non-Federal sponsor will be afforded credit for the value of lands, or interests in lands, that it provides in accordance with a PIR "regardless of the date of acquisition." *See* Section 601 (e)(5)(A) of WRDA 2000. To effectuate the clear intent of Congress reflected in this credit provision, land use restrictions imposed in furtherance of a CERP project after acquisition of a tract by the SFWMD should not be considered in valuing that tract for crediting purposes.

c. For the same reasons as expressed in subparagraph b. above, demolition of improvements after a tract was acquired in furtherance of a CERP project should not change the approach to value from that applicable at the time of acquisition. Accordingly, the tract should be valued for crediting purposes as it was improved when acquired by the SFWMD. To accomplish this result, the contributory value of the improvements, as of the date of the SFWMD's acquisition, should be added to the market value of the land on the date it is provided for the project as appraised in accordance with its highest and best use on the date of acquisition.

3. Incidental Costs. The SFWMD has requested that it be afforded credit for the costs incurred by other non-Federal governmental entities incidental to acquisition of project lands by such entities. The wording of Section 601 (e)(5)(A) is clear that credit may be afforded only for "incidental costs for land acquired by a non-Federal sponsor." Credit may be afforded for traditional incidental acquisition costs that are incurred by SFWMD (such as appraisal costs, mapping costs, or relocation assistance benefits) as well as costs actually incurred by SFWMD in obtaining the required real property rights from other non-Federal governmental entities. However, to be eligible for credit to be afforded to the SFWMD for incidental acquisition costs, SFWMD must have, in fact, incurred those costs. This Addendum is consistent with that guidance memorandum. This Addendum includes documentation and page number references for all edits to information contained in the Final PIR/EIS. This Addendum, as approved by CECW, will be appended to the Chief's Report and forwarded with it and the Final PIR/EIS to ASA (CW) for approval and transmission to Congress.

The increase in real estate costs does not affect alternative selection or site selection for the Caloosahatchee River (C-43) West Basin Storage Reservoir. Each alternative includes the same project footprint. As a result, the increase in real estate costs are the same for each of the four alternatives evaluated for this project. The change increases total project costs for all alternatives by the identical dollar amount and thus all alternatives maintain the same relative differences for the sake of comparison and alternative selection.

The Final Caloosahatchee River (C-43) West Basin Storage Reservoir PIR recommends 170,000 ac-ft of storage on approximately 10,700 ac with pump capacity of 1500 cfs. Originally estimated at FY07 (October 2006) price levels, the fully funded cost estimate was $565,700,000. This addendum reflects changes in the project costs due to revised project real estate costs. In addition, all project costs have been escalated to FY10 (October 2009) price levels, resulting in a revised fully funded cost estimate of $610,736,000.

Edits are organized by Final PIR section following the structure of the table of contents. This Addendum, as approved by CECW, will be appended to the Final PIR/EIS and forwarded with the Chief's Report to ASA(CW) for approval and transmission to Congress.

MAIN REPORT

The following revisions to the original text are proposed for the Main Report:

Executive Summary

1. Page xv, fourth paragraph, fifteenth line, change $2,740 to $2,825.

2. Page xvi, first paragraph, second line, change $7,146 to $8,035.

3. Page xx, third paragraph, fourth line, change $507,241,000 to $570,480,000.

4. Page xxi, replace Table ES-1 with the following table:

TABLE ES-1: CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR COSTS OCTOBER 2009 PRICE LEVELS (INITIAL COSTS ROUNDED TO THE NEAREST $10,000)

Ecosystem Restoration Elements	TOTALS
Construction	
02 Relocations	$1,180,000
03 Reservoir	$12,780,000
04 Dams (embankments, slurry wall, drains, soil cement, perimeter canal, spillways, structures, etc.)	$278,780,000
09 Channels and Canals	$5,180,000
13 Pumping Plants	$83,300,000
14 Recreation	$2,930,000
15 Floodway Control-Diversion Structures	$18,430,000
Sub-Total Construction Cost	**$402,580,000**
Non-Construction	
01 Lands and Damages	$84,650,000
30 Planning, Engineering, and Design	$51,880,000
31 Construction Management	$31,370,000
Sub-Total Non-Construction Cost	**$167,900,000**
TOTAL INITIAL COST	**$570,480,000**

*The costs in this table are MII costs and can be found in the MII report in Appendix B Cost Estimates.

5. Page xxi, first paragraph, first sentence, change $3,000,000 to $3,100,000.

Section 1.0 Introduction

1. Page 1-11, last paragraph, change to read:

Storage of water within the C-43 Basin had been established as one of the primary management measures contributing to the goals and purposes of the Restudy. Based on these findings, the SFWMD originally acquired approximately 12,372 acres (including easements) using State funds and Federal funds. SFWMD exchanged approximately 541 acres of this previously acquired land for approximately 600 acres adjacent to the

property originally acquired. As the PIR development process was initiated, there was an effort to identify early opportunities to obtain system-wide benefits by utilizing readily available lands. One of these opportunities was the evaluation of a potential reservoir located in the western Caloosahatchee River Basin on lands acquired by SFWMD with both Department of Interior (DOI) and SFWMD funds (please see Real Estate Appendix D, section D1.10.2 for more information).

2. Page 1-21, paragraph 1.9, change to read as follows:

1.9 LAND ACQUISITION ACTIVITIES

As described previously, storage of water within the Caloosahatchee Basin has been established as one of the primary management measures contributing to the goals and purposes of the Restudy. The SFWMD and others have been very proactive in acquiring lands needed for CERP implementation. Based on the findings of the Restudy and CWMP, which both call for a storage reservoir in the Caloosahatchee Basin, the SFWMD, Department of Interior and the U.S. Army Corps of Engineers, Jacksonville District participated in the selection of the site for acquisition of the Berry Grove lands. An opportunity arose in October 2000 to acquire over 12,000 acres of grove land which was determined by SFWMD and the U.S. Army Corps of Engineers, Jacksonville District to be an ideal location for a reservoir for the C-43 reservoir project approved in the Central and Southern Florida Project, Comprehensive Review Study, Final Integrated Feasibility Report and Programmatic Environmental Impact Statement, April 1999. The Federal funds used for this project were appropriated to the DOI and a Grant Agreement entitled Everglades Watershed Restoration-Grant Number LWCF-1 was executed to acquire south Florida ecosystem restoration project lands in the C-43 Basin. The Florida Division of State Lands, in cooperation with the staff of the SFWMD, reached an agreement that allowed the SFWMD to acquire the Berry Groves. In addition the South Florida Water Management District acquired adjacent properties as a key component for Everglades restoration (February 2000). To date the State of Florida has purchased a total of 12,372 acres in the immediate area in anticipation of reservoir construction with Federal funding provided by the DOI at a total of approximately $32,800,000, a portion of which ($27,566,669) will be credited to the Federal government towards the acquisition of lands required for this project. SFWMD exchanged approximately 541 acres of this previously acquired land for approximately 600 acres adjacent to the property originally acquired. The revised total land would be approximately 12,430 acres. Of this approximately 12,430 acres, the Caloosahatchee River (C-43) West Basin Storage Reservoir project will require approximately 10,700 acres, of which approximately 10,480 acres will be required in fee, approximately 20 acres will be required in perpetual channel easement and approximately 200 acres will be required in temporary easements for staging areas.

Section 2.0 Existing Conditions/Affected Environment
No proposed edits

Section 3.0 Future Without Project Conditions
No proposed edits

Section 4.0 Identification of Problems and Opportunities
No proposed edits

Section 5.0 Formulation of Alternative Plans

1. Page 5-34, replace the first paragraph with the following language:

The costs in this section are ROM costs for consistent comparison of alternatives. These costs will not match the MII project costs.

Section 6.0 Environmental Effects of the Selected Alternative Plan
No proposed edits

Section 7.0 The Selected Alternative Plan

1. Page 7-12, second paragraph, first line, replace $2,519,000 with $2,930,000.

2. Page 7-12, second paragraph, third line, replace $2,972,000 with $3,457,000.

3. Page 7-13, first paragraph, fifth line, replace 4 7/8 with 4 3/8.

4. Page 7-13, replace Table 7-1 with the following table:

TABLE 7-1: SUMMARY OF RECREATION COSTS AND BENEFITS (OCTOBER 2009 PRICE LEVEL)

Recreation Construction Costs	**$2,930,000**
PED & S/A (18%)	$527,400
Total Recreation Construction	**$3,457,000**
Construction Duration	12 months
Interest During Construction Costs	$75,000
Total Recreation Investment	**$3,532,000**
Period of Analysis	40 years
Annualized Cost	$189,000
OMRR&R	$25,000
Average Annual Costs	**$214,000**
Annual Benefits	
User Day Value	$7.27
Daily Use	145
Annual Use	52,925
Average Annual Benefit	**$384,700**

5. Page 7-13, second paragraph, second line, replace $160,000 with $170,700.

6. Page 7-13, last paragraph, fifth line, replace October 2006 with October 2009.

7. Page 7-14, replace Table 7-2 with the following table:

TABLE 7-2: PROJECT COSTS FOR THE SELECTED ALTERNATIVE PLAN (OCTOBER 2009 PRICE LEVEL) (Initial cost rounded to the nearest $10,000)

Ecosystem Restoration Elements	TOTALS
Construction	
02 Relocations	$1,180,000
03 Reservoir	$12,780,000
04 Dams (embankments, slurry wall, drains, soil cement, perimeter canal, spillways, structures, etc.)	$278,780,000
09 Channels and Canals	$5,180,000
13 Pumping Plants	$83,300,000
14 Recreation	$2,930,000
15 Floodway Control-Diversion Structures	$18,430,000
Sub-Total Construction Cost	**$402,580,000**
Non-Construction	
01 Lands and Damages	$84,650,000
30 Planning, Engineering, and Design	$51,880,000
31 Construction Management	$31,370,000
Sub-Total Non-Construction Cost	**$167,900,000**
TOTAL INITIAL COST	**$570,480,000**

*The costs in this table are MII costs and can be found in the MII report in Appendix B Cost Estimates.

8. Page 7-14, first paragraph, second line, replace October 2006 with October 2009.

9. Page 7-15, replace Table 7-3 with the following table:

TABLE 7-3: COMPARISON OF YELLOW BOOK AND SELECTED ALTERNATIVE PLAN FIRST COST FOR CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR PROJECT (OCT 2009 PRICE LEVEL)

Component	Yellow Book	Project First Cost	Fully Funded Cost
Caloosahatchee River (C-43) West Basin Storage Reservoir	$400,000,000	$570,480,000	$610,736,000*

* revised fully funded cost estimate based upon revised land valuation and crediting policy.

10. Page 7-15, first paragraph, second line, change $35,100,000 to $36,200,000

11. Page 7-15, first paragraph, fourth line, change $160,000 to $170,700.

12. Page 7-15, first paragraph, fifth line, change $2,740 to $2,825.

13. Page 7-17, last paragraph, first line, change $$27,567,669 to $27,566,659.

14. Page 7-18, Section 7.5.3, first paragraph, change first two sentences to read:

The existing conditions section of this document (Section 2) includes a summary of the Phase I/II Environmental Site Assessment (ESA) studies done on the properties originally acquired (totaling approximately 12,372 acres) and property the later acquired in an exchange (totaling approximately 600 acres) for the reservoir project. These are the Berry Groves tract composed of approximately 9,000 acres, the Bryan Paul Grove tract composed of approximately 600 acres, the MG Enterprises LLC property composed of approximately 2,399 acres, and the Griffin property composed of approximately 954 acres.

15. Page 7-22, third paragraph, eighth line, change $3,000,000 to $3,100,000.

Section 8.0 Plan Implementation

1. Page 8-2, revised values for the "Total Cost" column in Table 8-1 are listed below. The federal and non-federal cost share break-down has been updated using the revised numbers.

TABLE 8-1: COST APPORTIONMENT TABLE FOR THE CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR (OCTOBER 2009 PRICE LEVEL ROUNDED TO THE NEAREST $10,000)

Item	Non-Federal Cost	Federal Cost	Total Cost
PED	$25,940,000	$25,940,000	$51,880,000
Lands & Damages*	$56,810,000	$27,840,000	$84,650,000
Construction Management**	$15,685,000	$15,685,000	$31,370,000
Construction Total	$186,805,000	$215,775,000	$402,580,000
Total	$285,240,000	$285,240,000	$570,480,000

* The numbers in this table are consistent with the revised MCACES cost report included in this Addendum in edits to Appendix B.

Section 9 Summary of Coordination
No proposed edits

Section 10.0 Recommendations
The recommendations section contains several changes to the 2007 report, to include an update of costs and several items of local cooperation. The costs were updated to reflect October 2009 price levels. The items of local cooperation were updated to include standard ecosystem restoration clauses, standard language regarding floodplain management and flood insurance programs, as well as changes reflecting the Master Agreement executed with the South Florida Water Management District in 2009.

The recommendations section of the July 2007 Final PIR shall be replaced by the following:

The Caloosahatchee River (C-43) West Basin Storage Reservoir project will provide an above-ground storage reservoir (including pump stations and water control structures) and associated conveyance canals as a cost-effective solution to achieving estuarine restoration benefits in the Caloosahatchee Estuary, which is integral to achieving system-wide benefits in the south Florida ecosystem. The Project will help reduce wet season high volume flows from Lake Okeechobee and contributing basin runoff from the lower West Caloosahatchee River Basin by capturing and storing a portion of these flows in the reservoir. Then during the dry season when water levels are at their lowest, water will be released from the reservoir to the Caloosahatchee River (C-43 Canal) to promote a healthy salinity balance in the estuary, thereby reducing saltwater migration into the freshwater portion of the estuary. In addition, the plan achieves the benefits of the Project as previously developed for the CERP.

This Project is integral to achieving restoration in the Caloosahatchee Estuary and plays an important role in meeting the CERP system-wide ecosystem restoration goals and objectives and other water-related needs of the region. Fish and wildlife habitat benefits of the Caloosahatchee River (C-43) West Basin Storage Reservoir project includes improving the timing of water deliveries to the estuary thereby providing a salinity range

suitable for a healthy ecosystem and reestablishment of natural hydropatterns within existing natural areas, improvement in seagrass beds in the estuary, and increase habitat for the eastern oyster, blue crab, and other fish and marine organisms. The Project is expected to produce a total of 12,809 average annual habitat units (HUs). Further, this Project is a critical building block upon which a subsequent study will be able to evaluate and achieve broader ecosystem restoration objectives in the Caloosahatchee River Watershed (includes the East Caloosahatchee River (upper) and West Caloosahatchee River (lower) fresh water river basin and the tidal basin).

I find that the Caloosahatchee River (C-43) West Basin Storage Reservoir project, located in western Hendry County, is an integral part of CERP. The Caloosahatchee River (C-43) West Basin Storage Reservoir project Recommended Plan features a reservoir with a storage capability of 170,000 ac-ft, a normal pool storage depth between 15 and 25 feet feet with a footprint of approximately 10,700 acres (of which approximately 10,480 acres are required in fee, approximately 20 acres will be perpetual easements, and approximately 200 acres will be used on a temporary basis for staging area).. The reservoir includes an individual inflow pump station of 1500 cfs capacity, discharge structures, emergency overflow spillways, and seepage control canals with associated structures. The reservoir may also provide opportunities to increase flood damage reduction capabilities through operational changes to the C&SF Project and local drainage systems. However, these opportunities are considered incidental and are not claimed as benefits. Additionally, the reservoir may provide some water quality improvements in the Townsend, Banana Branch and Ft. Simmons Branch canals and other areas. Again, these opportunities are considered incidental and are not claimed as benefits.

Therefore, I recommend that the Caloosahatchee River (C-43) West Basin Storage Reservoir project as described in the section of the report entitled "The Selected Plan", with such modifications that may be deemed advisable at the discretion of the Chief of Engineers, be authorized for construction. The total estimated first cost for the Caloosahatchee River (C-43) West Basin Storage Reservoir project is $570,480,000 (October 2009 price level).The total first cost for the Caloosahatchee River (C-43) West Basin Storage Reservoir project includes recreation features totaling $2,930,000. The estimated total annual cost of OMRR&R of the ecosystem restoration elements is $3,100,000 with an estimated Federal annual OMRR&R cost of $1,550,000 and an estimated non-Federal OMRR&R cost of $1,550,000. The estimated cost for OMRR&R of the recreation elements is $25,000 which is 100 percent non-Federal.

The above recommendations are made with the provision that the non-Federal sponsor and the Secretary of the Army shall enter into a binding agreement defining the terms and conditions of cooperation for implementing the Project, and that the non-Federal sponsor agrees to perform the following items of local cooperation:

a. Provide 50 percent of total project costs consistent with the provisions of Section 601(e) of the Water Resources Development Act of 2000 as amended including

authority to perform design and construction of project features consistent with Federal law and regulation.

b. Provide all lands, easements, and rights-of-way, including suitable borrow and dredged or excavated material disposal areas, and perform or assure the performance of all relocations that the Government and the Non-Federal Sponsor jointly determine to be necessary for the construction, operation, maintenance, repair, replacement and rehabilitation of the Project and valuation will be in accordance with the Master Agreement.

c. Shall not use the ecosystem restoration features or lands, easements, and rights-of-way required for such features as a wetlands bank or mitigation credit for any other projects.

d. Give the Government a right to enter, at reasonable times and in a reasonable manner, upon land that the non-Federal sponsor owns or controls for access to the Project for the purpose of inspection, and, if necessary, for the purpose of completing, operating, maintaining, repairing, replacing, or rehabilitating the Project;

e. Assume responsibility for operating, maintaining, repairing, replacing, and rehabilitating (OMRR&R) the Project or completed functional portions of the Project, including mitigation features, in a manner compatible with the Project's authorized purposes and in accordance with applicable Federal and State laws and specific directions prescribed in the OMRR&R manuals and any subsequent amendments thereto. Cost sharing for OMRR&R will be in accordance with Section 601 of WRDA 2000 as amended;

f. The non-Federal Sponsor shall operate, maintain, repair, replace and rehabilitate the recreation features of the Project with responsibility for 100 percent of the cost;

g. Keep the recreation features, and access roads, parking areas, and other associated public use facilities, open and available to all on equal terms;

h. Unless otherwise provided for in the statutory authorization for this Project, comply with Section 221 of Public Law 91-611, Flood Control Act of 1970, as amended, and Section 103 of the WRDA of 1986, Public Law 99-662, as amended, which provides that the Secretary of the Army shall not commence the construction of any water resources project or separable element thereof, until the non-Federal sponsor has entered into a written agreement to furnish its required cooperation for the Project or separable element;

i. Hold and save the Government free from all damages arising from construction, operation, maintenance, repair, replacement and rehabilitation of the Project and

any project-related betterments, except for damages due to the fault or negligence of the Government or the Government's contractors;

j. Keep and maintain books, records, documents, and other evidence pertaining to costs and expenses incurred pursuant to the Project to the extent and in such detail as will properly reflect total project costs and comply with the provisions of the Master Agreement;

k. Perform, or cause to be performed, any investigations for hazardous substances that are determined necessary to identify the existence and extent of any hazardous substances regulated under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), 42 USC 9601-9675, that may exist in, on, or under lands, easements or rights-of-way necessary for the construction, operation, and maintenance of the Project; except that the non-Federal sponsor shall not perform such investigations on lands, easements, or rights-of-way that the Government determines to be subject to the navigation servitude without prior specific written direction by the Government;

l. Assume complete financial responsibility for all necessary cleanup and response costs of any CERCLA regulated materials located in, on, or under lands, easements, or rights-of-ways that the Government determines necessary for construction, operation, maintenance, repair, replacement and rehabilitation;

m. As between the Government and the non-Federal Sponsor, the non-Federal Sponsor shall be considered the operator of the Project for purposes of CERCLA liability. To the maximum extent practicable, the non-Federal Sponsor shall operate, maintain, repair, replace, and rehabilitate the Project in a manner that will not cause liability to arise under CERCLA;

n. Prevent obstructions or encroachments on the project (including prescribing and enforcing regulations to prevent such obstructions or encroachments) such as any new developments on project lands, easements, and rights-of-way or the addition of facilities which might reduce the outputs produced by the ecosystem restoration features, hinder operation and maintenance of the project, or interfere with the project's proper function;

o. Comply with the applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public law 91-646, as amended by title IV of the Surface Transportation and Uniform Relocation Assistance Act of 1987 (Public Law 100-17), and the Uniform Regulations contained in 49 CFR part 24, in acquiring lands, easements, and rights-of-way, and performing relocations for construction, operation, and maintenance of the Project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said act;

p. Comply with all applicable Federal and State laws and regulations, including, but not limited to, Section 601 of the Civil Rights Act of 1964, Public Law 88-352 (42

U.S.C. 2000d) and Department of Defense Directive 5500.11 issued pursuant thereto; Army Regulation 600-7, entitled "Nondiscrimination on the Basis of Handicap in Programs and Activities Assisted or Conducted by the Department of the Army;" and all applicable Federal labor standards requirements including, but not limited to, 40 U.S.C. 3141-3148 and 40 U.S.C. 3701-3708[revising, codifying and enacting without substantive change the provisions of the Davis-Bacon Act (formerly 40 U.S.C. 276a et seq.), the Contract Work Hours and Safety Standards Act (formerly 40 U.S.C. 327 et seq.) and the Copeland Anti-Kickback Act (formerly 40 U.S.C. 276c)];

q. Comply with Section 106 of the National Historic Preservation Act in completion of all consultation with the Florida State Historic Preservation Officer, and as necessary, the Advisory Council on Historic Preservation, prior to construction as part of the preconstruction engineering and design phase of the project;

r. Provide 50 percent of that portion of total cultural resource preservation mitigation and data recovery costs attributable to the Project that are in excess of one percent of the total amount authorized to be appropriated for the Project;

s. Do not use Federal funds to meet the non-Federal sponsor's share of total project costs unless the Federal granting agency verifies in writing that the expenditure of such funds is expressly authorized and in accordance with Section 601 (e)(3) of the WRDA of 2000, as amended, and in accordance with the Master Agreement;

t. The Non-Federal Sponsor agrees to participate in and comply with applicable Federal floodplain management and flood insurance programs consistent with its statutory authority.

1. Not less than once each year the Non-Federal Sponsor shall inform affected interests of the extent of protection afforded by the Project.

2. The Non-Federal Sponsor shall publicize flood plain information in the area concerned and shall provide this information to zoning and other regulatory agencies for their use in preventing unwise future development in the flood plain and in adopting such regulations as may be necessary to prevent unwise future development and to ensure compatibility with protection levels provided by the Project.

3. The Non-Federal Sponsor shall comply with Section 402 of WRDA 1986, as amended (33 U.S.C. 701b-12), which requires a non-Federal interest to have prepared, within one year after the date of signing a PPA for the Project, a floodplain management plan. The plan shall be designed to reduce the impacts of future flood events in the project area, including but not limited to, addressing those measures to be undertaken by non-Federal interests to preserve the level of flood protection provided by the Project. As required by Section 402, as

amended, the non-Federal interest shall implement such plan not later than one year after completion of construction of the Project. The Non-Federal Sponsor shall provide an information copy of the plan to the Government upon its preparation.

4. The Non-Federal Sponsor shall prescribe and enforce regulations to prevent obstruction of or encroachment on the Project or on the lands, easements, and rights-of-way determined by the Government to be required for the construction, operation, maintenance, repair, replacement, and rehabilitation of the Project, that could reduce the level of protection the Project affords, hinder operation or maintenance of the Project, or interfere with the Project's proper function.

u. The overarching objective of the Plan is the restoration, preservation, and protection of the South Florida ecosystem while providing for other water-related needs of the region, including water supply and flood protection. The Federal Government and the non-Federal sponsor are committed to the protection of the appropriate quantity, quality, timing, and distribution of water to ensure the restoration, preservation, and protection of the natural system as defined in Section 601 of WRDA 2000, for so long as the project remains authorized. This quantity, quality, timing, and distribution of water shall meet applicable water quality standards and be consistent with the natural system restoration goals and objectives of the CERP, as the Plan is defined in the Programmatic Regulations. The non-Federal sponsor will protect the water for the natural system by taking the following actions to achieve the overarching natural system objectives of the Plan:

1. Ensure, through appropriate and legally enforceable means under Florida law, that the quantity, quality, timing, and distribution of existing water that the Federal Government and the non-Federal sponsor have determined in this Project Implementation Report is available and beneficial to the natural system, will be available at the time the Project Partnership Agreement for the project is executed and will remain available for so long as the Project remains authorized.

2. (a) Prior to the execution of the Project Partnership Agreement, reserve or allocate for the natural system the necessary amount of water that will be made available by the project that the Federal Government and the non-Federal sponsor have determined in this Project Implementation Report.

   (b) After the Project Partnership Agreement is signed and the project becomes operational, make such revisions under Florida law to this reservation or allocation of water that the non-Federal sponsor determines, as a result of changed circumstances or new information, is necessary for the natural system.

3. For so long as the Project remains authorized, notify and consult with the Secretary of the Army should any revision in the reservation of water or other legally enforceable means of protecting water be proposed by the non-Federal sponsor, so that the Federal Government can assure itself that the changed reservation or legally enforceable means of protecting water conform with the non-Federal sponsor's commitments under paragraphs 1 and 2. Any change to a reservation of water made available by the project shall require an amendment to the Project Partnership Agreement.

Section 601(e)(5)(B) of the WRDA 2000 authorizes the Secretary of the Army to provide credit to the non-Federal sponsor for work completed by it during the period of construction pursuant to a PCA and a determination by the Secretary that the work is integral to the CERP. As part of its initiative for early implementation of certain expedited CERP projects, formerly known as the "Acceler8 Program", the non-Federal sponsor has stated that it may construct portions of the Caloosahatchee River (C-43) West Basin Storage Reservoir project consistent with this report, in advance of Congressional authorization and the signing of a PCA. The non-Federal sponsor is exploring alternative project delivery methods to expedite implementation of the Project. Such delivery methods may include public-private partnerships in which the non-Federal sponsor contracts with a private or not-for-profit entity for services that may include designing, building, operating or financing these components. I believe that it would be in the public interest for this Project to be implemented expeditiously due to the early benefits to the surrounding habitat, as well as hydrologic benefits to Federal lands and estuaries in other portions of the south Florida ecosystem. Therefore, I recommend that should the non-Federal sponsor construct portions of the Caloosahatchee River (C-43) West Basin Storage Reservoir project prior to the execution of a PAC for this Project, the non-Federal sponsor be credited for such construction costs at the time the PAC for the Caloosahatchee River (C-43) West Basin Storage Reservoir project is executed. Such credit would be applied toward the non-Federal sponsor's share of the costs associated with the implementation of the CERP as authorized by Section 601(e)(5)(C) of WRDA 2000, shall not include cash reimbursements, and shall be subject to: a) the authorization of the Caloosahatchee River (C-43) West Basin Storage Reservoir project by law; b) a determination by the Secretary of the Army that the activities are integral to the CERP restoration project; c) a certification by the District Engineer that the costs are reasonable, allowable, necessary, auditable, and allocable; and d) a certification by the District Engineer that the activities have been implemented in accordance with USACE design and construction standards and applicable Federal and State laws.

The recommendations contained herein reflect the information available at this time and current Departmental policies governing formulation of individual projects. They do not reflect program and budgeting priorities inherent in the formulation of a national Civil Works construction program nor the perspective of higher review levels within the Executive Branch. Consequently, the recommendations may be modified before they are transmitted to the Congress as proposals for authorization and implementation funding.

However, prior to transmittal to the Congress, the Sponsor, the State, interested Federal agencies, and other parties will be advised of any modifications and will be afforded an opportunity to comment further.

Alfred A. Pantano
Colonel, Corps of Engineers
District Engineer

ANNEXES AND APPENDIXES

No revisions to Annexes A-F are necessary as a result of renegotiated real estate costs or escalated (October 2009) project costs.

Appendix A Engineering

1. Page A-62, section A.5.6.3, second line, replace $3,360,000 with $3,100,000.

Appendix B Cost Estimates

1. Page B-16 through B-28, replace the 2007 MCACES with the revised enclosed MCACES.

2. Page B-30 through B-32, replace the 2007 Fully Funded Cost Estimate with the revised enclosed Fully Funded Cost Estimate.

Time 14:21:33
Title Page

This estimate is for the Selected Alternative Plan, Alternative 3B, a 170,000 acre-foot storage reservoir with 1,500 cubic feet per second pump capacity.

Estimated by USACE- SAJ and Stanley Consultants/Acceler8/SFWMD
Designed by Stanley Consultants/Acceler8/SFWMD
Prepared by Milton Switanek
Preparation Date 10/20/2009
Effective Date of Pricing 10/20/2009
Estimated Construction Time 1,025 Days

Jacksonville District Cost report

Date	Author	Note
5/16/2007	T. Leeser	Project Name:C43 Project Number: 114458 Project Type (e.g., Reconnaissance, Feasibility, Bid): PIR (Study Authority is the Water Resources Development Act of 2000) Scope of Work: Alternative B as described in the PIR, Appendix A, Engineering. Authorized Cost (if any): Not yet authorized. Contingency Amount (if any): 25%. This is a variation from Corps' guidance to allow for uncertainties in the design of the embankment and auxiliary structures. Some features have 30% contingency. Contingency on real estate is 25% on Federal administrative costs and 7% on non-Federal administrative costs, zero on RE Fee costs (per RE e-mail from A.Ayuso dated 6/19/07.) PED Amount (if any): 10% S&A Amount (if any): 7.6% Backup itemized and provided by CO. Sales Tax: 7% Job Office Overhead: 8% Home Office Overhead: 5% Profit: 10.1% Computed by weighted guidelines method. Bonds and Insurance: 1.5% Estimated Contract Award Date (mo/yr): Based on A8/SFWMD schedule (see below) as described in e-mail from LuAnn McVicar, SFWMD, to Gin Hightower, USACE, dated 14 May 2007. 1) Clearing & Grubbing contract - contract award 12 July 07. 2) Embankment Structure Pre-load contract - advertise week of 13 August 07; contract award 11 October 07. 3) Reservoir & Pump Stations contract (main contract) - Release RFPs on 18 September 07 (to pre-qualified group of contractors); Release RFBs (to RFP short-listed group of contractors) on 19 December 07; award contract on 14 February 08. Estimated Construction Start Date (mo/yr): 8/2007 (see above) Estimated Construction Midpoint Date (mo/yr): 2/2009 Estimated Construction Complete Date (mo/yr): Based on 1,025 days (per Stanley Consultants' 30% design cost estimate) this is 3 years or 8/2010. CWCCIS Indices used: Engineer Manual 1110-2-1304 dated 30 Mar 2007 Subfeature Date Index Published Index Composite 10/05 641.50 Composite 10/06 659.42 Estimate revised to reflect Tentatively Selected Plan, Alternative 3B. This estimate relies on the MCACES Gold cost estimate prepared by Stanley Consultant's for the Accelerate Program (A8)/South Florida Water Management District dated 5/31/06. Stanley Consultant's estimate uses the labor/equipment/materials makeup for costs and is crew/productivity based. The direct costs in Stanley Consultant's estimate are the basis of the unit costs in this estimate, for all cost items except as noted. The estimate is dated 5/31/06 so these costs are escalated to FY 2007 price levels. In addition, Stanley Consultants prepared a Technical Memorandum for the SFWMD/A8 program on the Townsend Canal Improvements. The TM included a cost summary; the costs are used herein. These costs are also escalated since the cost table in the TM equates the costs to their previous cost estimate and adds the two to obtain a revised total cost. Scope of Work: Taken from Draft Project Implementation Report dated April 2007, Engineering Appendix, beginning on page A-56. A two-cell 170,000 acre-foot above ground storage reservoir, a 1,500 cubic feet per second pumping station and a selection of water control structures. The reservoir project site would consist of approximately 10,500 acres. Site preparation: Clearing and grubbing the entire site to eight inches depth. Site work and access road: Maintenance of existing paved entrance road during construction and construction of a new entrance road after construction of the reservoir. Townsend Canal improvements: Widen channel bottom, add scour protection across entire channel width. Embankment: 14-foot wide crest (including soil cement protection), 3 horizontal to 1 vertical side slopes. Cell One elevation is +55 feet, NAVD, and Cell Two elevation is +54 feet. Construction material is random fill, with the borrow area on-site. Upstream slope protection and an interior drain are included, as well as a soil-bentonite wall. Downstream of the embankment is a 100-foot wide bend with a 24-foot access road. There is an interior embankment separating Cells One and Two, with a crest elevation of +50 feet, NAVD, also covered in soil-cement. Side slopes: To be seeded and sodded.

Project Notes Page ii

Date	Author	Note
5/16/2007	T. Leeser	Relocations: Of electric and water utilities. Structures: Two pump stations, two outlet structure sluice gates, three perimeter canal structures (roller, slide and weir gates), two crested spillways, one balancing structure sluice gate and eight gated culverts (slide and weir gates). Demolition: Of two existing pump stations. Recreation features: A major recreation attraction of the C-43 Storage Reservoir, Part 1 will be an approximately 12-mile multi-purpose trail loop atop the levee constructed as part of the project. Recreation facilities proposed include: parking and toilet facilities (clivas multrum waterless vault toilets), information kiosk, canoe/kayak launch facility, a shade structure, traffic-control fencing and a pedestrian footbridge bridge over the perimeter canal to provide public access to the reservoir.
6/18/2007	T. Leeser	Revised estimate to remove four structures to be built by others, S-16 through S-19, per e-mail PM to EN-C (B. Marlowe to T. Leeser) on 15 June 2007. Changed real estate costs per e-mail from RE (A. Ayuso) dated 6/18/07.
6/27/2007	T. Leeser	Revised estimate to incorporate change in scope of work that raises dam/embankment height. Per DP e-mail on scope change and as coordinated through EN/ETL, increased quantities for random fill/embankment from 19,772,438 to 22,011,438 cy and for soil cement from 789,659 to 824,659 cubic yards. Also as directed through EN/ETL, increased contingency on other features expected to change slightly in design , by a corresponding amount (22,011,438/19,772,438=1.11), to 30% (25% X 1.11 = 28%, used 30%). Also per EN/ETL e-mail dated 28 June 2007, added manatee gate.
7/18/2007	T. Leeser	As a result of Independent Technical Review, profit on the prime contractor was changed by adjusting the weighted profit guidelines computation to better reflect project conditions. Also, separate profits were calculated for each subcontractor using the weighted profit guidelines (per EI 01D010). As a result, the non-construction costs 'Planning, Engineering and Design' and 'Construction Management' were revised. The cost book was changed to Region III and cost factors were updated (e.g., fuel) to reflect current pricing.
10/20/2009	Switanek	Revised Estimate to reflect current 2008 cost book and escalated by Cost Growth Index (USACE) to 2010 dollars as of 20 Oct 09. Also included $84,654,000 real estate cost without escalation and contigency. Because escalation and contigency was already included in Real- Estates cost estimate.

Appendix C Environmental Information
No proposed edits

Appendix D Real Estate

The Real Estate Appendix is up-dated in accordance with CECW-SAD memorandum dated July 30, 2009 signed by the Director of Civil Works, U.S. Army Corps of Engineers. The current guidance for the CERP, Land Valuation and Crediting is as follows:

a. Consistent with long-standing USACE practice, and as supported by the unique land credit provision for CERP contained in Section 601 (e)(5)(A) of WRDA 2000, tracts acquired by the SFWMD that are acquired and provided in furtherance of a CERP project should be valued and credited as individual tracts regardless of whether the acquisition was prior to or after execution of the PPA for that project. This general principle would not apply where the SFWMD acquired contiguous tracts that are required for a CERP project but it acquired such tracts prior to the PPA for a reason and use other than for implementation of the CERP project. A determination that a tract was acquired "in furtherance of a CERP project" should be supported by documentation existing at the time of acquisition.

b. The unique statutory land credit provision for CERP projects is clear that the non-Federal sponsor will be afforded credit for the value of lands, or interests in lands, that it provides in accordance with a PIR "regardless of the date of acquisition." *See* Section 601 (e)(5)(A) of WRDA 2000. To effectuate the clear intent of Congress reflected in this credit provision, land use restrictions imposed in furtherance of a CERP project after acquisition of a tract by the SFWMD should not be considered in valuing that tract for crediting purposes.

c. For the same reasons as expressed in subparagraph b. above, demolition of improvements after a tract was acquired in furtherance of a CERP project should not change the approach to value from that applicable at the time of acquisition. Accordingly, the tract should be valued for crediting purposes as it was improved when acquired by the SFWMD. To accomplish this result, the contributory value of the improvements, as of the date of the SFWMD's acquisition, should be added to the market value of the land on the date it is provided for the project as appraised in accordance with its highest and best use on the date of acquisition.

3. Incidental costs. The SFWMD has requested that it be afforded credit for the costs incurred by other non-federal governmental entities incidental to acquisition of project lands by such entities. the wording of section 601 (e)(5)(a) is clear that credit may be afforded only for "incidental costs for land acquired by a non-federal sponsor." credit may be afforded for traditional incidental acquisition costs that are incurred by SFWMD (such as appraisal costs, mapping costs, or relocation assistance benefits) as well as costs actually incurred by SFWMD in obtaining the required real property rights from other non-federal governmental entities. however, to be eligible for credit to be afforded to the SFWMD for incidental acquisition costs, SFWMD must have, in fact, incurred those costs.

1. Page D-7, Paragraph D.5.1, first paragraph, first sentence change to read as follows:

The Caloosahatchee River (C-43) West Basin Storage Reservoir project area encompasses approximately 10,700 acres consisting of approximately 10,480 acres in fee, approximately

20 acres of perpetual channel easement, and 200 acres in temporary easement that lie within approximately 12,430 acres owned by SFWMD.

2. Pages D-8 and D-9, last paragraph, change to read as follows:

The Reservoir currently under consideration will be constructed on property formerly owned by J&H Grove Holdings, L.C. (Berry Groves), the Griffin Family Limited Partnership, the MG Enterprises, L.L.C and the Bryan Paul Citrus. All these lands are currently owned in fee by the SFWMD.

3. Page D-23, Section D.9, first paragraph, fourth sentence, eleventh through seventeenth line, change sentence to read as follows:

SFWMD exchanged 541.31 acres within its ownership for 600.17 acres owned by Bryan Paul Citrus and identified on the map and table as GX100-008 and GX100-009 respectively. The exchange added an additional approximately 58 acres for an estimated total of 12,430 acres for SFWMD ownership in fee and easement that is available and sufficient interest for project purposes.

4. Page D-23, Section D.9, second paragraph, first and second bullets, change to read:
   - SFWMD's total initial land acquisition consisted of approximately 12,372 acres including approximately 20 acres of easement.
   - SFWMD exchanged approximately 541 of these acres for approximately 600 acres owned by Bryan Paul Citrus for a new total of approximately 12,430 acres.

5. Page D-24 first, second, third, fourth and fifth bullets, change to read as follows and Delete Note: *Note Costs in $x1000:

   - Federal Fund contribution for approximately 7,080 acres is estimated at $27,502,294 for land cost and $64,375 for acquisition cost for an estimated total of $27,566,669.
   - Federal administrative costs for 10,700 acres is an estimated amount of $273,000 with 30% contingency.
   - Total estimated Federal cost share $27,840,000.
   - State funds contribution for both the 7,080 acres as well as the remaining 3,620 acres is an estimated amount of $54,970,000 for land cost and an estimated amount of $1,840,000 for administrative/acquisition costs with contingencies included.
   - Total estimated real estate costs for the 10,700 acres required for the project are the sum of $27,566,669 Federal + $273,000 Federal +$54,970,000 non-Federal + $1,840,000 non-Federal which amounts to $84,650,000.00 (Rounded).

6. Page D-27 fourth paragraph should read:

In accordance with CECW-SAD memorandum dated July 30, 2009 signed by the Director of Civil Works, U.S. Army Corps of Engineers. The current guidance for the CERP, Land Valuation and Crediting is as follows:

a. Consistent with long-standing USACE practice, and as supported by the unique land credit provision for CERP contained in Section 601 (e)(5)(A) of WRDA 2000, tracts acquired by the SFWMD that are acquired and provided in furtherance of a CERP project should be valued and credited as individual tracts regardless of whether the acquisition was prior to or after execution of the PPA for that project. This general principle would not apply where the SFWMD acquired contiguous tracts that are required for a CERP project but it acquired such tracts prior to the PPA for a reason and use other than for implementation of the CERP project. A determination that a tract was acquired "in furtherance of a CERP project" should be supported by documentation existing at the time of acquisition.

b. The unique statutory land credit provision for CERP projects is clear that the non-Federal sponsor will be afforded credit for the value of lands, or interests in lands, that it provides in accordance with a PIR "regardless of the date of acquisition." *See* Section 601 (e)(5)(A) of WRDA 2000. To effectuate the clear intent of Congress reflected in this credit provision, land use restrictions imposed in furtherance of a CERP project after acquisition of a tract by the SFWMD should not be considered in valuing that tract for crediting purposes.

c. For the same reasons as expressed in subparagraph b. above, demolition of improvements after a tract was acquired in furtherance of a CERP project should not change the approach to value from that applicable at the time of acquisition. Accordingly, the tract should be valued for crediting purposes as it was improved when acquired by the SFWMD. To accomplish this result, the contributory value of the improvements, as of the date of the SFWMD's acquisition, should be added to the market value of the land on the date it is provided for the project as appraised in accordance with its highest and best use on the date of acquisition.

3. Incidental costs. The SFWMD has requested that it be afforded credit for the costs incurred by other non-federal governmental entities incidental to acquisition of project lands by such entities. the wording of section 601 (e)(5)(a) is clear that credit may be afforded only for "incidental costs for land acquired by a non-federal sponsor." credit may be afforded for traditional incidental acquisition costs that are incurred by SFWMD (such as appraisal costs, mapping costs, or relocation assistance benefits) as well as costs actually incurred by SFWMD in obtaining the required real property rights from other non-federal governmental entities. However, to be eligible for credit to be afforded to the SFWMD for incidental acquisition costs, SFWMD must have, in fact, incurred those costs.

However, the national valuation and crediting policy will not apply to any lands acquired for any project utilizing Federal funds, (Farm Bill and/or Land and Conservation Act funds), provided to any non-Federal Sponsor. The actual acquisition costs of SFWMD or any other non-Federal Sponsor will be utilized in the plan formulation, cost estimating, evaluation, and crediting in accordance with the terms and conditions of any Department of Interior Grant as well as the Framework Agreement executed 3 October 1996 by and between the United States Department of Interior, the United States Department of the Army, the State of Florida, Department of Environmental Protection, and the South Florida Water Management District. This will be applicable to all lands included or described in any Department of Interior (DOI) Grant Agreement.

The approximately 3,620 acres acquired by SFWMD with only State/SFWMD funds were acquired in May and June 2003 after April 30, 1999 the date the C&SF Comprehensive Review Study, Final Integrated Feasibility Report and Programmatic Impact Statement (PEIS) - April 1999.

7. Page D-28 paragraph D.9.2.1 Certification and Crediting for Actual and Incidental Costs Acquired under the Department of Interior Grants should be changed to read as follows:

Pursuant to the terms and conditions of the Department of Interior Grant Agreement, SFWMD submitted and Department of Interior reviewed and approved the actual acquisition costs and SFWMD's administrative/incidental costs, (excluding SFWMD's staff costs) for the acquisition of J&H Grove Holdings, L.C. (Berry Grove) properties consisting of approximately 9,003 acres in the amount of $71,500,000, of which $32,800,000 were Federal funds. Of the approximately 7,080 acres of the approximately 9,003 acres required for the project, the Federal share for the lands would be approximately $27,566,669 as shown in ***Table D-2***, ***Table D-3***, and ***Table D-4***. These figures may be increased or decreased based on a more detailed analysis during the crediting review process after approval of the Project, execution of a Project Cooperation Agreement and certification of the land.

8. Page D-34, paragraphs D.20 & D.21 should be changed to read as follows:

D.20 BASELINE COST ESTIMATE (*Table D-3)* AND MCACES COST ESTIMATE (*Table D-4)*

The actual acquisition costs and administrative costs provided by SFWMD were considered in the final computation. SFWMD cost towards the land and incidental costs is estimated at $56,810,000 (Rounded) with contingency. The Federal cost is estimated at $27,840,000 (Rounded), which includes the Federal share of the land costs as well as future federal administrative costs. The total real estate cost with contingency is estimated at $84,650,000 (Rounded). These figures are subject to modification and verification during the crediting review process.

D.21 BASELINE COST ESTIMATE (*Table D-3*) AND MCACES COST ESTIMATE (*Table D-4)*

The actual acquisition costs and administrative costs provided by SFWMD were considered in the final computation. The total real estate cost with contingency is estimated at $84,650,000 (Rounded).

CENTRAL AND SOUTHERN FLORIDA PROJECT
CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR
FINAL INTEGRATED
PROJECT IMPLEMENTATION REPORT
AND
ENVIRONMENTAL IMPACT STATEMENT
ADDENDUM B

Addendum Purpose:

The purpose of this Addendum is intended to serve as a response to comments received in May and June 2010 from the Assistant Secretary of the Army's (ASA) review of the Final Caloosahatchee River (C-43) West Basin Storage Reservoir Project Final Integrated Project Implementation Report and Environmental Impact Statement of July 2007. Comments received focus on challenges encountered with the hydrologic modeling and implications thereof on plan selection.

Project Status:

The Final Caloosahatchee River (C-43) West Basin Storage Reservoir Project Implementation Report (PIR) and Environmental Impact Statement successfully underwent a Civil Works Review Board briefing in August 2007. The project Chief's Report was signed on 11 March 2010 following a two and half year delay resulting from programmatic level decision making regarding land valuation and crediting. In April 2010, the Caloosahatchee River (C-43) West Basin Storage Reservoir Final PIR was submitted to the office of the ASA. The Final PIR was slated for transmittal to the Office of Management and Budget (OMB) for review on 16 July 2010. Transmittal is currently delayed pending resolution of ASA comments.

ASA Comments:

Initial comments were received from the ASA's office in May 2010. After an initial response, the US Army Corps of Engineers received a second round of comments from the ASA in late June 2010. This second round of comments expands upon a single remaining unresolved comment regarding challenges in the hydrologic modeling and its role in plan selection as described in the Final PIR. A summary of these comments follows:

1. The PIR lacks complete and valid feasibility-level engineering analyses to support project justification.
2. The PIR had an incomplete description of project's Hydraulic and Hydrologic (H&H) performance.
    - Failed to characterize the recommended plan's impacts on downstream flows, estuary conditions, or reservoir operations.

- The PIR did not indicate amount of storage that would likely be beneficial for this basin, i.e. a target for restoring the estuary.

3. The report does not sufficiently assure that the right plan is recommended or that the plans would achieve their respective intended outputs to warrant Federal investment.
4. There is no indication that the Corps reviewed the H&H modeling. The modeling and analyses need to be revised and subjected to ATR and model review guidance.

Project Modeling and Plan Selection:

The hydrologic modeling completed for the Caloosahatchee River (C-43) West Basin Storage Reservoir project utilized an iterative and prudent methodology compliant with USACE plan formulation guidance in place at that time (2006-2007). The initial modeling of alternatives and plan selection was completed using the MIKESHE model. MIKESHE is an industry standard model developed by the Danish Hydrologic Institute and is a USACE certified engineering model approved for use on CERP projects. During the team level QA/QC review of the MIKESHE model output, it was recognized that errors existed in the model runs. The impact of the error on the outcome of each alternative was uncertain. As a result, a determination of the impact if any on the ranking/order of the benefits (environmental lift) of the alternatives could not be ascertained. In order to validate the plan selection and address the MIKESHE output errors, the Interagency Modeling Center (IMC) developed a spreadsheet analysis. This analysis was used in addition to the MIKESHE model to calculate flow at the S-79 structure (**FIGURE 1**) (see Engineering Appendix A, Attachment A: IMC Technical Memorandum for the Caloosahatchee River (C-43) West Basin Storage Reservoir Spreadsheet Model for Alternative Evaluation, pg. 124, for detailed hydrologic output including flow frequency and duration data).

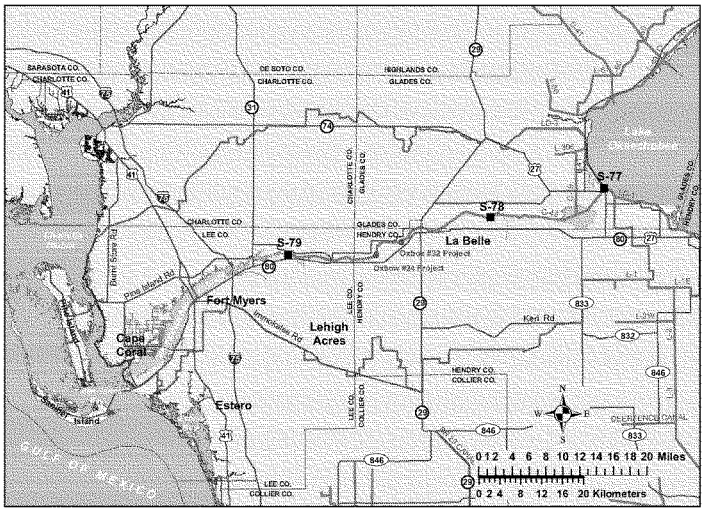

FIGURE 1: CALOOSAHATCHEE WATERSHED

The results were then used to conduct a Next Added Increment (NAI) analysis on each of the final alternatives. This Spreadsheet analysis served as a parallel alternative analysis approach to verify plan selection, although the MIKESHE model remained the model on record for use in ranking the project alternatives. A brief summary of the final alternatives is provided in the table below (**TABLE 1**).

TABLE 1: SUMMARY OF FINAL ARRAY OF COST EFFECTIVE ALTERNATIVES

Alternative 1	No Action (Future-Without Project)
Alternative 2	100,000 ac-ft reservoir, 1,500 cfs pump capacity
Alternative 3B	170,000 ac-ft reservoir, 1,500 cfs pump capacity
Alternative 3C	170,000 ac-ft reservoir, 3,800 cfs pump capacity
Alternative 4A	220,000 ac-ft reservoir, 3,800 cfs pump capacity

FIGURE 2 depicts the parallel approaches to alternative analysis. Both approaches were initiated with flow data generated by the USACE approved South Florida Water Management Model (SFWMM 2X2). In the first approach MIKESHE was then used to model flows from S-77 to S-79. MIKESHE output at S-79 was fed into a salinity regression model that was used in combination with HSI models to generate habitat units (HUs). The second approach fed SFWMM 2X2 output at S-79 into the IMC Spreadsheet tool to produce modified flow estimates at S-79. This output was then fed into the same salinity regression model and HSI models to

generate HUs using the methodology from the first approach. The IMC Spreadsheet approach does not use the MIKESHE output at any point.

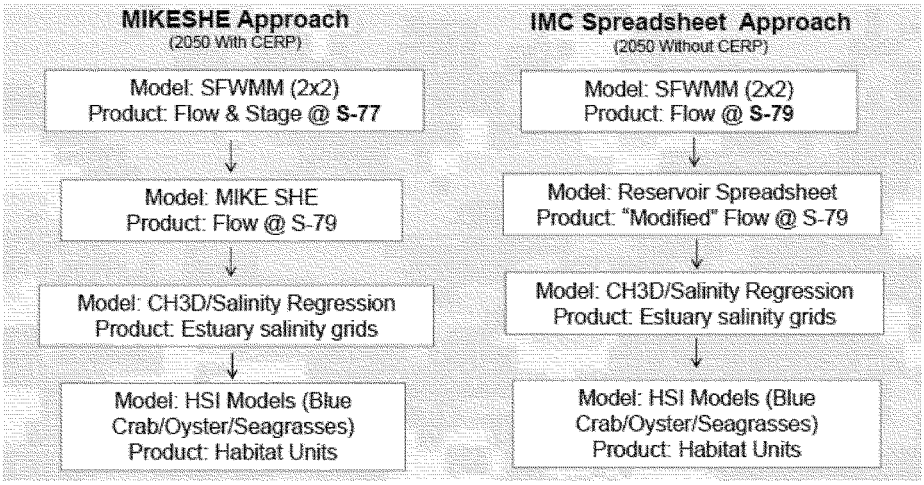

FIGURE 2: PARALLEL APPROACHES TO ALTERNATIVE ANALYSIS

TABLE 2 below presents the average annual lift (HUs) and average annual cost ($) comparison for the two approaches for each of the alternatives in the final array.

TABLE 2: SUMMARY OF NAI (SPREADSHEET) AND SYSTEM-WIDE (MIKESHE) AVERAGE ANNUAL HABITAT UNIT LIFT AND AVERAGE ANNUAL COST/AVERAGE ANNUAL HABITAT UNIT FOR EACH ALTERNATIVE IN THE FINAL ARRAY (OCTOBER 2006 PRICE LEVELS[1])

Alternative	AAHU lift (MIKESHE)	AAHU lift (Spreadsheet)	AA$/AAHU (MIKESHE)	AA$/AAHU (Spreadsheet)	Total Cost
2	10,628	13,624	$2,725	$2,126	$504,120,000
3B	12,809	15,297	$2,440	$2,043	$560,140,000
3C	16,397	17,694	$2,236	$2,072	$601,620,000
4A	15,907	18,410	$2,757	$2,382	$640,420,000

Note – The Costs presented in this analysis are planning level costs for comparison with original alternatives, as presented in Section 5 of the report. The costs have been revised based on additional engineering and design. The actual costs are presented in the updated MCACES analysis. NED costs do not include Recreation Cost for Plan Formulation.

Both the MIKESHE model approach and the IMC Spreadsheet analysis provided consistent results regarding the appropriate scale of the proposed reservoir (170,000 ac-ft storage, rather than 100,000 ac-ft or 220,000 ac-ft) as indicated in the highlighted cells in **TABLE 2**. Because the benefits per dollar achieved for alternatives 3C and 3B were close, the team selected the less

expensive alternative; Alternative 3B, which cost approximately $41 million less than alternative 3C in 2007 ($560 versus $601 million). The difference in cost is primarily associated with the smaller pump capacity in Alternative 3B.

Report Review and Approval Process

The parallel approaches to alternative analysis were presented to the USACE Vertical Team in a series of In Progress Reviews (IPRs) in early 2007 and endorsed by USACE Headquarters and the SFWMD in April of 2007. As a component of the South Florida Water Management District (SFWMD) Acceler8 program, this project had thorough engineering-level analyses included in the Final PIR. The design was completed to 90% plans and specs, which is far beyond what is typical for a standard USACE feasibility level report.

Interagency technical reviews (ITR) of the Caloosahatchee River (C-43) West Basin Storage Reservoir document were carried out through collaboration with the National Ecosystem Restoration Planning Center of Expertise (PCX) in compliance with guidance at the time of Final PIR completion (2007). Extensive external scientific peer review through the National Academy of Science (NAS) has been conducted at the Comprehensive Everglades Restoration Plan (CERP) programmatic level and will continue throughout the planning and implementation of the CERP program through the NAS biennial reports to Congress. In particular, the NAS promoted the use of traditional water storage technologies and the use of adaptive management principles within the formulation process. Both of these comments have been integrated into the formulation and design of the C-43 WBSR project. The Caloosahatchee River (C-43) West Basin Storage Reservoir Chief's Report states that no further IEPR was deemed necessary or recommended for the study. In addition, no further IEPR is needed in response to WRDA 2007, since C-43 studies had been initiated and alternatives identified more than two years prior to its enactment and the final report had been submitted for approval prior to its passage.

The MIKESHE hydrologic model used in alternative analysis and plan selection is a USACE certified engineering model approved by the USACE Science, Engineering, and Technology (SET) for use on CERP projects. The IMC Spreadsheet was a water budget analysis tool utilized for plan comparison and, unlike the MIKESHE, was not considered a hydrologic engineering model, which excluded it from the review requirements specified in the existing Engineering Model Certification guidance. The *IMC Spreadsheet Technical Memorandum for the Caloosahatchee River (C-43) West Basin Storage Reservoir Spreadsheet Model for Alternative Evaluation,* which presents the spreadsheet analysis output, is included in the Engineering Appendix of the Final PIR and underwent ITR in 2007 as part of Final PIR package. A list of significant meetings, reviews, and approval milestones are captured in the timeline below (**TABLE 3**).

TABLE 3: C-43 WBSR PROJECT TIMELINE 2006-2007

Action	Date
Evaluate Alternatives (MIKESHE)	**Summer 2006**
MIKESHE problems realized	**Oct-06**
ITR pre-AFB	**25-Oct-06**
AFB	**2-Nov-06**
QRB Guidance- abandon MIKESHE, develop spreadsheet model for plan formulation to achieve DPIR in July 2007	**1-Jan-07**
Management Guidance - use MIKESHE for plan selection, spreadsheet for assurances (IOR, NAI)	**1-Feb-07**
HQ review of PIR completion strategy	**20-Feb-07**
Spreadsheet Analysis (NAI/Alternative Analysis)	**Mar-07**
HQ/SAD **IPR**	**16-Mar-07**
2nd HQ/SAD **IPR**	**22-Mar-07**
ITR on Draft PIR	**28-Mar-07**
Management Guidance - release DPIR for public and agency review	**13-Apr-07**
DPIR **IPR**	**18-Jun-07**
ITR on Final PIR	**11-Jul-07**
CWRB	**23-Aug-07**
90% P&S Rcieved	**17-Sep-07**
Chief's Report	**11-Mar-10**

Conclusion:

In conclusion, the team feels that the Final PIR contains valid and complete feasibility level engineering analysis to support plan selection in accordance with plan formulation guidance. Both the Draft and Final PIRs met all review requirements in place at that time. The ASA is correct in stating that the underlying H&H model (MIKESHE) used in plan selection had unresolved errors. However, the team sought to address these errors by utilizing a second alternative analysis method to validate plan selection. These two approaches produced results justifying the selected alternative as a reasonable sized reservoir to benefit the Caloosahatchee Estuary. The Final PIR recognized the need for follow-on analyses and potentially additional storage to benefit the estuary, which is consistent with the principles of adaptive management and the incremental adaptive restoration approach espoused by the NAS.

CENTRAL AND SOUTHERN FLORIDA PROJECT
CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR
FINAL INTEGRATED
PROJECT IMPLEMENTATION REPORT
AND
ENVIRONMENTAL IMPACT STATEMENT

Responsible Agencies: The lead agency is the U.S. Army Corps of Engineers, Jacksonville District. The South Florida Water Management District is the non-Federal cost sharing partner for the project. Other participating agencies are the U.S. Fish and Wildlife Service, the U.S. Environmental Protection Agency, the National Park Service, the Florida Fish and Wildlife Conservation Commission, the U.S. Geological Survey, the Natural Resources Conservation Service, and the Florida Department of Environmental Protection. The U.S. Fish and Wildlife Service, Florida Department of Environmental Protection, Everglades National Park, U.S. Environmental Protection Agency and Florida Fish and Wildlife Conservation Commission were invited to be Cooperating Agencies. None of these agencies accepted this invitation; therefore there are no cooperating agencies for this environmental impact statement (EIS).

Abstract: This report documents studies for the Caloosahatchee River (C-43) West Basin Storage Reservoir project, in accordance with the requirements of Section 601(d) of the Water Resources Development Act of 2000 (WRDA 2000) and recommends authorization of this project. This Project addresses the need to restore the ecosystem function in the Caloosahatchee Estuary by reducing the number and severity of events where harmful amounts of freshwater from basin runoff and Lake Okeechobee releases are discharged into the estuary system. The project also helps to maintain a desirable minimum flow of fresh water to the estuary during dry periods. These two primary functions help to moderate unnatural changes in salinity which is extremely detrimental to estuarine communities.

The purpose of the Caloosahatchee River (C-43) West Basin Storage Reservoir project is to contribute to the restoration of the Caloosahatchee Estuary as part of a comprehensive plan for restoring the south Florida ecosystem. The project provides approximately 170,000 acre-feet (ac-ft) of above-ground storage volume in a two-cell reservoir with normal pool depths when the reservoir is full varying from 15 feet at the southeast corner to 25 feet at the northwest corner. Major features of the project include external and internal embankments, canals, two pump stations, internal control and outflow water control structures, and environmentally responsible design features. The project provides deepwater habitat within the impoundment cells, including refugia (created by embankment excavation) for fish and other aquatic animals during extremely dry periods. The perimeter canal may also include littoral areas which may be utilized as forage and nursery habitat by wading birds. The configuration and extent of these areas will be determined during detailed design work. Reservoir operations will also incidentally improve water quality in the Caloosahatchee Estuary, since some of the nutrient-laden runoff and lake water will be stored in the reservoir, allowing for the settling of nutrients and other pollutants within the reservoir cells prior to delivery to the estuary.

This Final Project Implementation Report and Environmental Impact Statement describes public and agency involvement in project development (including comments received and responses), explains the plan formulation and alternative evaluation and plan selection processes, and documents recommended plan features, including costs and environmental benefits.

THE OFFICIAL CLOSING DATE FOR THE RECEIPT OF COMMENT IS 30 DAYS FROM THE DATE ON WHICH THE NOTICE OF AVAILABILITY OF THIS EIS APPEARS IN THE FEDERAL REGISTER.

FOREWORD
A note to the reader of this Final PIR/EIS

The State of Florida has developed a program called "Acceler8" for the purpose of accelerating design and construction of a number of critical restoration projects consistent with the Comprehensive Everglades Restoration Plan (CERP) prior to one or more of the following: administration approval, Congressional committee resolution, Congressional authorization, or Federal construction funding. The State anticipates the Acceler8 program will provide immediate environmental, social, and economic benefits in the south Florida region. All Acceler8 projects must be specifically authorized by Congress before becoming a part of the Federal CERP. Anticipated Acceler8 crediting is based upon future legislation which specifically provides for it, since Acceler8 efforts are performed prior to a project cooperation agreement (PCA) execution and not creditable under existing authority. The South Florida Water Management District (SFWMD) is the state agency responsible for water resources management in south Florida and acts as the non-Federal sponsor for Federal water resources projects, including the CERP. The SFWMD is also the lead State agency responsible for implementing the Acceler8 program and will need to acquire Department of the Army permits under Section 404 of the Clean Water Act prior to construction.

Of the projects that make up SFWMD's Acceler8 program, the following projects were initially authorized CERP Projects under Water Resources Development Act of 2000 (WRDA 2000): C-44 Basin Storage Reservoir, Everglades Agricultural Area Storage Reservoir-Phase I, Site 1 Impoundment, Water Conservation Areas 3A and 3B Levee Seepage, C-11 Impoundment, C-9 Impoundment, and C-111 Spreader Canal. One Acceler8 project, Acme Basin B, potentially falls under the WRDA 2000 programmatic authority provisions. Three other Acceler8 projects require separate Federal authorization: Biscayne Bay Coastal Wetlands, Caloosahatchee River (C-43) West Basin Storage Reservoir, and the Picayune Strand Restoration Project (PSRP). While Federal authorization is required for crediting purposes, it is not required for construction performed by the State.

The U.S. Army Corps of Engineers (USACE) and SFWMD anticipate that the SFWMD will accelerate construction and attainment of ecosystem restoration benefits and other benefits of certain CERP projects by obtaining required permits and initiating construction upon completion of the Final Integrated Project Implementation Report (PIR) and Environmental Impact Statement (EIS) for the associated Federal CERP project.

The SFWMD proposes to initiate construction of the Caloosahatchee River (C-43) West Reservoir Acceler8 Project prior to implementation of the Federal Caloosahatchee River (C-43) West Basin Storage Reservoir project. The USACE

is proceeding with two separate and independent but related actions, the feasibility-level evaluation of the Federal project and the regulatory evaluation of the SFWMD's proposed Acceler8 project, both of which are described in this Final PIR/EIS. The SFWMD's Caloosahatchee River (C-43) West Reservoir Acceler8 project is the same as the National Environmental Policy Act (NEPA) preferred alternative or Federal Recommended Plan, described in this Final PIR/EIS. The purposes of the Federal Recommended Plan identified in this Final PIR and the SFWMD's Acceler8 project are consistent. Therefore, it is anticipated that this Final PIR/EIS will also serve as the basis for the Regulatory Division's NEPA evaluation of the SFWMD's proposed Acceler8 project.

This Final PIR/EIS is posted on the CERP website: (http://www.evergladesplan.org)

CENTRAL AND SOUTHERN FLORIDA PROJECT
CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR
INTEGRATED
PROJECT IMPLEMENTATION REPORT
AND
ENVIRONMENTAL IMPACT STATEMENT

EXECUTIVE SUMMARY

The U.S. Army Corps of Engineers (USACE), Jacksonville District, in cooperation with its cost-sharing partner, the South Florida Water Management District (SFWMD), has prepared an Integrated Project Implementation Report (PIR) and Environmental Impact Statement (EIS) for the Caloosahatchee River (C-43) West Basin Storage Reservoir project, located in Hendry County, Florida. This report describes the purpose and need for the project, location, alternatives considered, and the selected alternative plan (SAP), including plan implementation. The report also contains the evaluations conducted reaffirming that an above-ground storage reservoir in the Caloosahatchee River (C-43 Canal) basin is a cost-effective solution for achieving the benefits of the project and the goals and purposes of the Comprehensive Everglades Restoration Plan (CERP).

The purpose of the Caloosahatchee River (C-43) West Basin Storage Reservoir project is to contribute to the restoration of the Caloosahatchee Estuary as part of a comprehensive plan for restoring the south Florida ecosystem. The SAP provides approximately 170,000 acre-feet (ac-ft) of above-ground storage volume in a two-cell reservoir with normal pool depths when the reservoir is full that vary from 15 feet at the southeast corner to 25 feet at the northwest corner. Project features encompass approximately 10,700 acres acquired partially with funds provided by the Federal government via Department of Interior (DOI) funds for Everglades Restoration and partially with funds provided by the State of Florida. Major features of the SAP include external and internal embankments, canals, two pump stations, internal control and outflow water control structures, and environmentally responsible design features to provide fish and wildlife habitat such as littoral areas in the perimeter canal and deep water refugia within the reservoir.

In addition, the recent recommendations of the National Research Council (NRC) of the National Academies in the final selection of the SAP were considered. The NRC has reviewed the first five years of work on CERP. Starting in 2004, 12 science and engineering experts studied CERP's progress and, after two years of study, issued their findings: *Progress Toward Restoring the Everglades: The First Biennial Review, 2006.* Biennial evaluations will continue through the 30-year lifetime of CERP. The NRC recognizes that

Everglades' restoration is a complex undertaking with many scientific uncertainties, which can slow the rate of progress. The NRC concluded that if the construction of a restoration project is delayed until all scientific uncertainties are eliminated, there will be many negative consequences including: continued decline of the Everglades ecosystem, lagging public support, and increased project costs. The NRC identified an approach referred to as Incremental Adaptive Restoration where an incremental approach using steps that are large enough to provide some restoration benefits now, while addressing critical scientific uncertainties and taking actions to promote learning that can guide the remainder of the project design. Constructing projects using a phased approach will enable assessments of benefits and impacts to the environment as each phase is constructed. Remaining phases will then be adapted to optimize performance based on actual findings from the earlier phases.

To address changing conditions, concerns and issues which have arisen since the Restudy analysis of the Caloosahatchee River Watershed, it is recommend that project use an Incremental Adaptive Restoration approach of two PIRs, in which the first PIR, the Caloosahatchee River (C-43) West Basin Storage Reservoir will address the most immediate needs of the estuary, while ensuring that it is fully compatible and consistent with the CERP. The second PIR would be a more comprehensive study that could provide a complete solution to addressing the broader needs of the entire basin.

This report has been prepared in accordance with the requirements of Section 601(d) of the Water Resources Development Act of 2000 (WRDA 2000) and Programmatic Regulations for the CERP (33 Code of Federal Regulations [CFR] Part 385) and will be circulated for public and agency review and comment in accordance with the National Environmental Policy Act (NEPA). This PIR and EIS take into consideration public and agency comments, which will be the basis for the Chief of Engineer's Report to be submitted to the Assistant Secretary of the Army (Civil Works) for transmittal to Congress.

PURPOSE AND NEED FOR THE PROJECT

The Caloosahatchee River and Estuary is at the head of a vast estuarine and marine ecosystem that includes aquatic preserves (Matlacha Pass Aquatic Preserve, Estero Bay Aquatic Preserve, Pine Island Sound Aquatic Preserve, Charlotte Harbor National Estuary, and the Caloosahatchee, Matlacha Pass and Ding Darling National Wildlife Refuges), along with numerous other Federal, state, and local parks and recreation areas. Restoration of a healthy, productive aquatic ecosystem in the Caloosahatchee River is essential to maintaining the ecological integrity and associated economic activity in these publicly owned and managed areas.

The Caloosahatchee Estuary (which is generally considered to be that portion of the Caloosahatchee River west of the W. P. Franklin Lock and Dam, Structure S-79, including the Matlacha Pass, San Carlos Bay, and Estero Bay areas at the mouth of the Caloosahatchee River, ***Figure ES-1*** and ***Figure ES-2***) encompasses approximately 80 square miles of estuarine habitat on Florida's southwest coast in the vicinity of Fort Myers, Florida. The Fort Myers area, including Cape Coral, Fort Myers Beach, Sanibel and Captiva Islands, Bonita Springs and unincorporated areas is one of the fastest growing areas in the

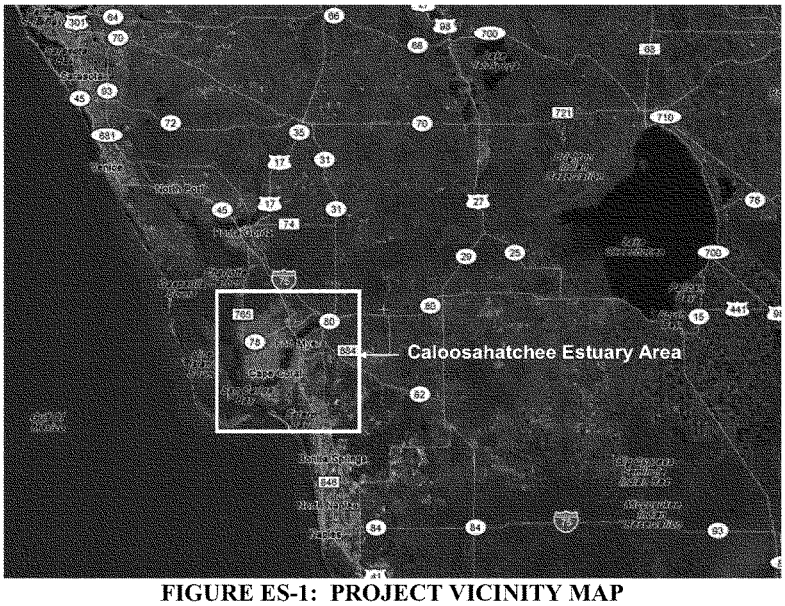

FIGURE ES-1: PROJECT VICINITY MAP

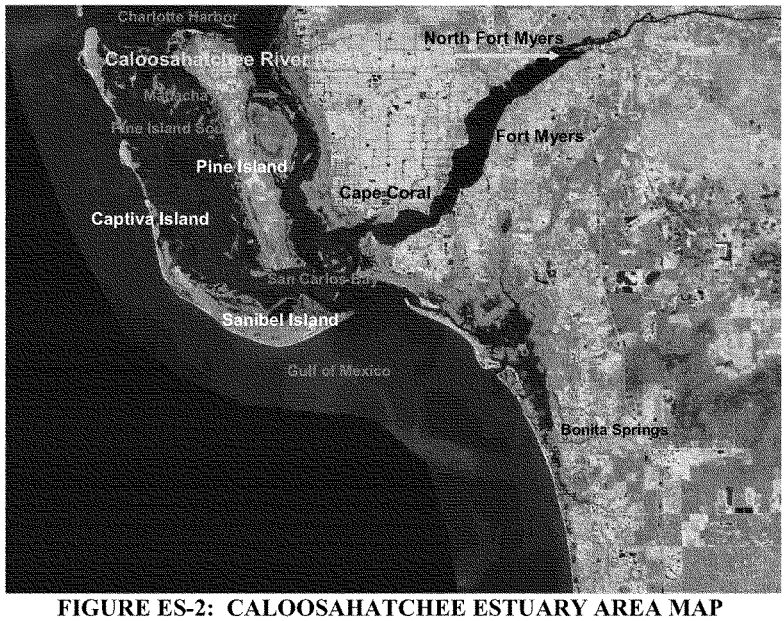

FIGURE ES-2: CALOOSAHATCHEE ESTUARY AREA MAP

Southeastern United States (2000 population approximately 440,000 according to United States [U.S.] census figures) and is an extremely popular tourist destination. The Caloosahatchee Estuary is connected to Lake Okeechobee by the Caloosahatchee River (C-43 Canal), a man-made connection to the lake originally created in the late 19th century. As part of the Central and Southern Florida (C&SF) Project for Flood Control and Other Purposes, the Caloosahatchee River has been widened and deepened to ensure that high water levels in Lake Okeechobee can be managed to prevent harmful high water levels in the lake and flooding in adjacent areas. The Caloosahatchee River is part of the federally maintained Okeechobee Waterway, and also serves to provide water supply deliveries from Lake Okeechobee to urban and agricultural areas in the basin while conveying basin runoff away from urban and agricultural areas.

Currently, there is not enough storage capacity in the regional water management system to minimize or prevent the possible harmful effects of periodic high volume discharges of freshwater to the Caloosahatchee Estuary. Conversely, during dry periods, there is sometimes not enough freshwater available in the regional system to maintain desirable salinity levels in the estuary. The combined result of too much and too little freshwater flowing to the Caloosahatchee Estuary is a degraded estuarine ecological community,

characterized by declines in the abundance and diversity of native finfish and shellfish populations and other marine and estuarine species, poor water quality, and reductions in the extent of submerged habitat suitable for sea grass and oysters (two primary indicators of healthy estuarine communities in south Florida) and other higher trophic level species, including threatened and endangered species (e.g., manatees, wood storks).

To restore ecological function and productivity in the Caloosahatchee Estuary, CERP, approved by Congress in the WRDA 2000, included an above-ground reservoir along the Caloosahatchee River to capture and store basin runoff and excess freshwater released from Lake Okeechobee. By capturing this excess water the reservoir can also serve as a source of environmental water supply to the estuary during dry periods. The need for additional storage to restore, protect, and preserve the Caloosahatchee Estuary, including Federal trust lands and other publicly owned and managed areas in and around the Caloosahatchee Estuary has also been validated by other planning efforts, including the Caloosahatchee Water Management Plan (2000) and Lower West Coast Water Supply Plan (2005-2006) prepared by the SFWMD. In accordance with Federal and state requirements for implementing CERP projects, this Final PIR was prepared to reaffirm that an above-ground storage reservoir in the Caloosahatchee River (C-43 Canal) Basin is a cost-effective solution for achieving CERP goals and Caloosahatchee River (C-43) West Basin Storage Reservoir project objectives and to present the results of evaluations required by Federal and state regulations.

WHAT WILL HAPPEN WITHOUT THE PROJECT?

Environmental conditions have declined sharply in the Caloosahatchee Estuary area due to flood control and water management actions in the study area. Additionally, since the greater Fort Myers area population has already increased considerably since the CERP was approved in 2000 and is projected to continue to increase, increasing demands for freshwater will be placed on the Caloosahatchee River and its tributaries to meet competing municipal, agricultural, and environmental water supply needs in the basin. The expected result is that undesirable high salinity levels will also continue to recur in the Caloosahatchee Estuary, and those events will likely be greater in severity and duration.

Economically, the decline in estuary functions has already had and will continue to create periodic significant adverse impacts on commercial, recreational and associated economic activities.

Without actions taken to reduce the effects of too much and too little freshwater entering the Caloosahatchee Estuary at the wrong times, the estuarine

ecosystem will continue to be degraded with the potential for some estuarine species to disappear entirely. If the recommended plan for the Caloosahatchee River (C-43) West Basin Storage Reservoir project is not constructed, ecologically damaging discharges of basin runoff and flood control releases from Lake Okeechobee will continue during wet periods, causing periodic unnatural low salinity levels in the Caloosahatchee Estuary and adjacent estuarine and marine areas, including adjacent parks, refuges, preserves and other publicly owned and managed areas.

The net ecological effect of continued degradation of the Caloosahatchee Estuary will be further loss and limited possibility for recovery of primary and secondary productivity, including forage and nursery areas in submerged habitats and adjacent wetlands. The reduction in the abundance and spatial distribution of primary organisms such as submerged vegetation, invertebrates, small fish, and other prey organisms normally part of a healthy estuarine community will continue to be adversely impacted and be magnified in higher-level organisms such as pelagic fish, marine mammals, birds, and other aquatic-dependent wildlife (including threatened and endangered species).

PLAN FORMULATION, EVALUATION, AND SELECTION

Previous ecosystem restoration and water supply planning efforts including the C&SF Comprehensive Review Study, Final Integrated Feasibility Report and Programmatic EIS (USACE and SFWMD, April 1999) have established the need for and the beneficial effects of an above-ground reservoir in the Caloosahatchee River (C-43 Canal) Basin as part of a comprehensive plan to achieve restoration objectives for the Caloosahatchee Estuary.

The Comprehensive Review Study included two primary structural components focused on improving environmental conditions in the Caloosahatchee River and Estuary: 1) an approximately 160,000 ac-ft reservoir with associated aquifer storage and recovery (ASR) wells and 2) basin runoff backpumping and stormwater treatment facilities. Due to technical uncertainty and implementation issues, the ASR features (Part 2) originally associated with a storage reservoir in the Caloosahatchee Basin will be evaluated and implemented separately. The availability and effectiveness of storing basin runoff, treating it and returning (back-pumping) it to Lake Okeechobee will also be further evaluated as part of a future study.

For this project, plan formulation efforts involved reaffirming that an above-ground storage reservoir, as originally described in the Comprehensive Review Study, is a cost-effective means for achieving the purposes of the project consistent with the goals and objectives of the CERP. After reaffirming that the benefits of the project could be achieved with an above-ground reservoir,

formulation efforts focused on optimizing reservoir size and features on lands already acquired using DOI funds for project implementation, combined with a consideration of planning and policy constraints such as the WRDA 2000 Savings Clause.

After consideration of an initial array of alternative plans involving storage volumes ranging from 100,000 to 220,000 ac-ft with various inflow pump sizes, a final array of four alternative plans were selected consisting of:

- Alternative 2: 100,000 ac-ft storage reservoir with 1,500 cubic feet per second (cfs) pump capacity
- Alternative 3B: 170,000 ac-ft storage reservoir with 1,500 cfs pump capacity
- Alternative 3C: 170,000 ac-ft storage reservoir with 3,800 cfs pump capacity
- Alternative 4A: 220,000 ac-ft storage reservoir with 3,800 cfs pump capacity

Based on performance measures and habitat suitability indices (HSI), a system formulation evaluation was performed comparing the performance of each of the alternative plans together with the remaining components of CERP to the No-Action Alternative (future without-project condition). The system formulation evaluation examines differences in the magnitude of the alternative plan outputs to illustrate which plan performs best in a system-wide context. One of the key assumptions for the system formulation model simulations was that water supply deliveries from Lake Okeechobee to the Caloosahatchee River would be constrained to the same volumes as provided in the Comprehensive Review Study. This assumption was included in the hydrologic simulation to maintain the benefits provided by the CERP in the Everglades and other south Florida basins due to projected increased demands for water supply in the Caloosahatchee Basin subsequent to the completion of the Comprehensive Review Study. The Tentatively Selected Plan (TSP) was identified from the system formulation evaluation.

After the TSP was identified, a next-added increment (NAI) analysis was performed to show how well the TSP would perform without the effects of other CERP projects (i.e., assuming no further investment of public funds after this project, is the TSP still a good investment?). In the NAI analysis, the planning constraint on water supply deliveries to the Caloosahatchee River was removed from the model simulation, to ensure that current levels of service for water supply in the Caloosahatchee Basin could still be met with implementation of the TSP.

Although it is clear based on the evaluations performed that plans with greater storage capacity and pump sizes would produce more benefits (Alternative 3C was identified as the NER plan) for the Caloosahatchee Estuary, the increase in benefits is associated with increasing cost (including additional real estate

interest) and increasing technical uncertainties regarding canal conveyance capacity, modifications to existing infrastructure and embankment design.

Alternative 3B is recommended for implementation, rather than Alternative 3C, which has been identified as the NER alternative plan. Alternative 3B meets the policy criteria established in Corps of Engineers guidance for planning in a collaboration environment[1]. This guidance provides that any alternative plan can be selected "if it has, on balance, net beneficial effects after considering all plan effects, beneficial and adverse..." Alternative 3B is clearly of less scope and cost than Alternative 3C, reduces uncertainty and financial risk to the government, and meets the Administration's policies for high priority outputs. Because Alternative 3B is an increment of Alternative 3C, this plan also supports adaptive implementation recommendations established by the NRC. The study considered various scales of reservoir storage and identified no alternative smaller than 3B which was more economical. For these reasons Alternative 3B is the recommended plan and no ASA(CW) waiver is required.

DESCRIPTION OF THE SELECTED ALTERNATIVE PLAN

The term "selected alternative plan" refers to the alternative that has been recommended for implementation. For the purposes of complying with the NEPA and in the spirit of NEPA, the plan that would be recommended for authorization is termed the "preferred alternative." For NEPA, a plan is not "selected" until it has been fully coordinated, is subject to alterations based on public involvement, and is then formally accepted by Congress or the Chief of Engineers, as appropriate, and authorized with the signing of a Record of Decision (ROD) or Finding of No Significant Impact (FONSI). Throughout this document, the analysis includes the NEPA evaluation and uses the term "selected alternative plan" or "selected plan" interchangeably as the preferred alternative. "Selected" throughout this document is meant to discern which alternative the team is recommending to Congress and the Chief of Engineers for further development and implementation

The selected plan ("preferred alternative") (***Figure ES-3***), Alternative 3B, consists of two cells and associated features totaling approximately 10,700 acres providing a normal maximum storage capacity of approximately 170,000 ac-ft surrounded by a perimeter embankment and canals. The SAP will require approximately 10,480 acres of fee and 20 acres of perpetual channel easement. Approximately 200 additional acres will be required on a temporary basis during project construction for staging areas. Major features of the SAP for the Caloosahatchee River (C-43) West Basin Storage Reservoir project include:

[1] EC 1105-2-409 "Planning in a Collaborative Environment"

- External (dam) embankments varying in height from 32-37 feet above existing grade;
- Soil-Bentonite slurry walls within and beneath the external embankments;
- An internal (dam) embankment separating the two reservoir cells with an approximate height of 31 feet above existing grade ;
- An inflow pump station consisting of diesel-powered pumps with a total pumping capacity of 1,500 cfs;
- A perimeter canal;
- A perimeter canal pump station consisting of electric-powered pumps with a total pumping capacity of 195 cfs;
- Numerous spillways, culverts, perimeter canal structures, an internal cell balancing structure, and outlet structures;

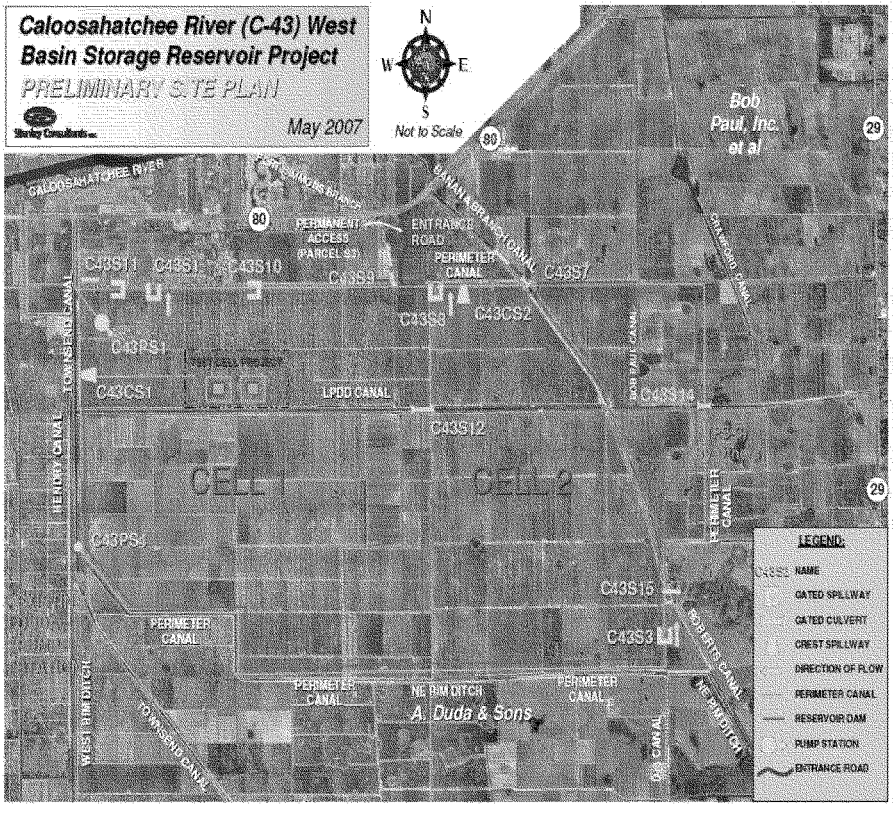

FIGURE ES-3: SELECTED ALTERNATIVE PLAN FEATURES

The external embankments include drainage features, and the top of the embankments and the upper portion of the outward side will be covered with soil-cement. The internal embankment does not include drainage structures, but will be covered on both sides with soil-cement. The reservoir is designed to withstand hurricane force winds of over 160 miles per hour (mph), as well as a combination of hurricane force winds with a rainfall event of over 54 inches in a 72-hour period.

The operation of the SAP is keyed to conditions at the W. P. Franklin Lock and Dam (structure S-79) on the Caloosahatchee River, as the flows over the dam are a good indicator of the resulting health of the estuary. The project will be operated to improve environmental conditions in the Caloosahatchee Estuary by reducing flows over S-79 during wet periods, and helping to maintain a minimum flow of 450 cfs at S-79 during dry periods. The S-79 structure is located approximately ten miles down-river (west) of the project site.

Project operations involve pumping inflows from the Caloosahatchee River (C-43) via an existing canal (Townsend Canal) into Cell 1. An internal cell balancing structure in the internal embankment will allow water in Cell 1 to enter Cell 2. Water may be released from both cells by outlet structures into the perimeter canal for delivery back to the Caloosahatchee River via the Townsend Canal and two other direct connections (Fort Simmons Branch and Banana Branch Canal) to the C-43 Canal. Other project structures help to maintain water levels in the perimeter canal and Townsend Canal, and provide water supply deliveries to adjacent lands affected by construction and operation of the reservoir.

BENEFITS OF THE SELECTED ALTERNATIVE PLAN

The SAP contributes toward the restoration of ecosystem function in the Caloosahatchee Estuary by reducing the number and severity of events where harmful amounts of freshwater from basin runoff and Lake Okeechobee releases are discharged into the estuary system. The SAP also helps to maintain a desirable minimum flow of fresh water to the estuary during dry periods. These two primary functions help to moderate unnatural changes in salinity that are detrimental to estuarine communities.

Based on a salinity model, the area within the Caloosahatchee Estuary system beneficially affected by the project conservatively encompasses at least 71,000 acres in the Caloosahatchee River, San Carlos Bay, and a portion of Pine Island Sound, although in all likelihood the area beneficially affected by project implementation will be much larger, including portions of Pine Island Sound, Estero Bay, and the Gulf of Mexico. These acres are within the navigable waters of the United States and within the navigation servitude of the United States.

The SAP also provides deepwater habitat within the impoundment cells, including refugia (created by embankment excavation) for fish and other aquatic animals during extremely dry periods. The perimeter canal may also include littoral areas which may be utilized as forage and nursery habitat by wading birds. The configuration and extent of these areas will be determined during detailed design work.

Though not designed specifically to provide water treatment benefits, the reservoir is expected to reduce downstream nutrient loads by retaining approximately 20 percent of the total phosphorus load that enters the reservoir. The reservoir's average hydraulic residence time of around 200 days is expected to result in substantial removal of pesticides and heavy metals through settling of suspended solids.

In accordance with the CERP Programmatic Regulations (33 CFR Part 385) and the Draft Programmatic Guidance Memoranda, the selection of plans for individual CERP projects is based on the performance of alternative plans when evaluated together with the rest of the CERP. This ensures that from a south Florida ecosystem-wide perspective, the SAP will contribute toward the achievement of system-wide restoration goals and objectives established for CERP, as well as the other water-related needs of the region. Plans must also be justified as the NAI (the next project to be added to a system of projects that includes only those that already have been approved and are likely to be implemented by the time the project being evaluated is completed). For this project, no other CERP projects were included in the NAI analysis, since other projects were not likely to be implemented by the time this project would be completed.

To evaluate the contribution of the SAP toward system-wide restoration goals and objectives, HSIs developed for the study area focused on the change in suitability of habitat in the Caloosahatchee Estuary. For analytical purposes, the area within the Caloosahatchee Estuary system beneficially affected by the project was assumed to encompass approximately 71,000 acres within the navigable waters of the United States and is within the navigation servitude of the United States. HSIs for the following key indicators of estuarine health were developed to evaluate project effects: oysters, sea grass, and *Vallisineria* ("tape grass" or "eel grass"; a submerged fresh water plant found in rivers and streams). Based on the HSIs, for the system formulation evaluation, the SAP will generate an average annual increase of approximately 12,809 habitat units within the affected area compared to without-project conditions (without any attempt to optimize system-formulation operations to further improve the Caloosahatchee Estuary). The average annual cost per average annual habitat unit for the system formulation evaluation is approximately $2,825. The cost

per acre of affected habitat (based on the total area of benefit) for this project is $8,035.

The NAI evaluation (using the same HSI and evaluation methodology as the system formulation evaluation) demonstrates that as a stand-alone project (i.e., without the benefit of other CERP water storage projects that would further reduce the harmful effects of excess fresh water on the Caloosahatchee Estuary), the SAP will generate an average annual increase of approximately 15,300 habitat units within the affected area compared to without-project conditions.

The area of benefit is recognized as significant at a local, regional, state and national level. The benefited area includes Matlacha Pass and Pine Island Sound state aquatic preserves. San Carlos Bay as well as the Caloosahatchee River are designated as a Federal Manatee Refuge. In addition, there are five national wildlife refuges in the benefits area including J.N. Ding Darling National Wildlife Refuge, Caloosahatchee National Wildlife Refuge, Matlacha Pass National Wildlife Refuge, Pine Island National Wildlife Refuge, and Island Bay National Wildlife Refuge. There has also been significant public recognition of the importance of this area through continued support of this project by the local public as well as governments.

Water for the Natural System and Other Water-Related Needs

WRDA 2000 requires that an analysis of water made available by CERP projects for the natural system be included in each PIR. This water must be reserved or allocated by the State of Florida prior to execution of a project operation agreement. PIRs must also include an analysis of water made available by the project to meet other water related needs (such as water supply and aquifer protection). An evaluation of water made available by the Caloosahatchee River (C-43) West Basin Storage Reservoir project was completed based on the requirements of draft Programmatic Guidance Memorandum 4 ("Identifying Water Made Available for the Natural System and Other Water-Related Needs").

The primary functions of the reservoir are two-fold: to capture excess basin runoff and discharges from Lake Okeechobee during periods of high volume flows, and to provide an additional source of water to maintain desirable salinity in the Caloosahatchee Estuary during periods of low flow. Since the estuarine system does not need additional fresh water during periods of excess flow, the analysis of water made available focused on the additional water delivered from the reservoir to the Caloosahatchee River and Estuary during periods when additional flows are needed to meet estuary flow targets. The additional water delivered from the reservoir to meet estuary flow targets (as measured by flows at the S-79 structure over the period of analysis) ranged from approximately

160,000 ac-ft at least ten percent of the time to approximately 27,600 ac-ft 90 percent of the time, with a median value of approximately 106,000 ac-ft per year. The State of Florida will reserve or allocate for the natural system the additional water made available by the project.

The conceptual intent of the project is that the reservoir will be operated to supply water to the Caloosahatchee River based on maintaining desirable salinity levels in the Caloosahatchee Estuary system. The project will not provide any additional water for water supply or other water-related needs in the Caloosahatchee River Basin. The Draft Project Operating Manual is consistent with the conceptual intent and this assumption. However, project operations include water supply deliveries to agricultural lands adjacent to the reservoir where water supply canals were interrupted due to the location of the reservoir and the severance of surface water connections to the Caloosahatchee River.

The Savings Clause

In addition to identifying water for the natural system and other water-related needs, Section 601(h)(5) ("Savings Clause") of WRDA 2000 also requires PIRs to include an analysis of project effects on existing legal sources of water for municipal and agricultural water supplies, the Seminole and Miccosukee Tribes, Everglades National Park (ENP), and fish and wildlife. The Savings Clause also requires an analysis of potential project impacts on the existing level of service for flood protection. These Savings Clause analyses were completed based on the requirements of draft Programmatic Guidance Memorandum 3 ("Savings Clause Requirements").

Consistent with the conceptual intent described above and the Draft Project Operating Manual, it was assumed that project operations will not reduce the quantity of water in the Caloosahatchee River Basin available for water supply, including sources for municipal and agricultural interests and fish and wildlife. Sources of water for the Seminole and Miccosukee Tribes and ENP are influenced by the regional water management system (C&SF Project, including Lake Okeechobee), and are not affected by this project.

An analysis of potential affects on water stages and elevations on lands adjacent to the reservoir was conducted with a local-scale hydrologic simulation model (MIKESHE). Differences in groundwater elevations and durations were calculated for various points in the vicinity of the reservoir site. These model results indicated that the project will not create harmful and adverse changes to water levels on adjacent lands.

ADVERSE EFFECTS OF THE SELECTED ALTERNATIVE PLAN

Several potential adverse effects of the SAP have been considered during this study. First, implementation of the SAP will impact approximately 125 acres of wetlands within the project footprint. The loss of this wetland habitat will be offset by the increase in ecosystem function and quality in the Caloosahatchee Estuary.

Second, the SAP will cause a shift in nutrient load from the wet season to the dry season; however, the SAP will decrease the frequency in which the monthly TN load exceeds the dry season, wet season, and annual targets established by F DEP (dry-season 190 tons/month, wet-season 350 tons/month, annual 3,000 tons/month).

While it is possible that nitrogen fixation within the reservoir will result in short-term increases in TN loading to S-79, the average annual TN load at S-79 will be reduced. Improvements will occur in the overall average water quality conditions at S-79 as well as downstream in the estuary. Given the uncertainty in the threshold chlorophyll-a concentration required for the restoration of the ecological function of the estuary, the degree to which the reservoir project will improve downstream water quality is unknown at this time. Based on the evidence presented here, it appears that the project will not cause or contribute to water quality degradation under future conditions. Prior to beginning operation, the State of Florida will require an application for a water quality permit to determine compliance with applicable water quality standards

Another concern raised during development of the draft report was the possibility that project operations would reduce the quantity of water available from existing sources for agricultural and urban water supply interests in the basin. Conceptually, the SAP is to be operated to capture excess basin runoff and releases from Lake Okeechobee that would be harmful if discharged to the Caloosahatchee Estuary. Storing such flows would not affect the quantities of water needed to meet water supply demands in those periods. The SAP also includes structures and operations to provide water supply to replace any existing legal source on adjacent lands that were affected by project implementation. The Project Operating Manual contains the operational intent and instructions to operators to ensure that water supply deliveries in the basin and adjacent to the reservoir are not adversely affected by project operations.

The USACE and USFWS have completed formal consultation under Section 7 of the Endangered Species Act (ESA) to identify and evaluate possible adverse impacts to the Florida panther, eastern indigo snake, and Audubon's crested caracara as a result of the Caloosahatchee River (C-43) West Basin Storage Reservoir. Potential adverse impacts to the Florida panther include the loss of

10,335 acres of panther habitat which will be compensated for through the protection and restoration of 102,129 acres off-site through implementation of Band 1/Acceler8 projects included in CERP. Potential adverse impacts to the eastern indigo snake include the direct loss of 10,264 acres of eastern indigo snake habitat resulting in the incidental take of up to 54 snakes during initial construction and operations. In addition to standard protection measures, initial and subsequent rehydrations of the reservoir will be monitored and reviewed to determine if snakes are re-populating the reservoir during drydown events. Potential adverse impacts to Audubon's crested caracara includes the incidental take of up to two adult pairs of caracara in the form of harassment, as well as up to two caracara nest sites for up to five consecutive breeding seasons. Monitoring and surveys of the birds will be conducted to minimize future impacts. The USACE has also completed informal consultation with the USFWS for the West Indian manatee. A manatee barrier will be placed at the confluence of the Townsend Canal and Caloosahatchee River to minimize potential impacts to the West Indian manatee. The USACE has concluded Section 7 Endangered Species Act (ESA) consultation with the USFWS.

In public outreach efforts to date, one potential environmental justice issue has been identified: the loss of jobs for low income and minority workers as a result of acquiring agricultural land for the construction of the reservoir. The expected loss in employment will occur to seasonal and/or temporary migrant workers. As can be noted in the future land use section, agricultural acreage in the surrounding study area and counties is expected to increase. The Caloosahatchee River (C-43) West Basin Storage Reservoir Project provides an opportunity to somewhat alleviate the potential loss of jobs for low income and minority workers by providing jobs during construction of the project, some of which could provide seasonal and temporary employment. In addition, it is anticipated that adjacent lands will continue to support agricultural operations.

A final potential adverse effect that was studied in detail is the hazard potential. The hazard potential for a dam is defined by the possible consequences that may result from the release of stored water due to dam failure or mis-operation of the dam or appurtenances during both normal and flood flow conditions. According to the joint USACE and SFWMD Design Criteria Memorandum, DCM-1, there are three classification levels of the hazard potential for a dam: Low Hazard Potential, Significant Hazard Potential and High Hazard Potential (SFWMD, 2005).

Based upon this classification system and its criteria, the proposed C-43 West Basin Storage Reservoir has been classified as a high hazard potential impoundment. A dam break analysis indicated that a dam failure would compromise the safety of existing residents living near the proposed reservoir possibly resulting in the loss of life. In addition, the proximity of a major

highway (SR80), the anticipated future development of areas near the facility, along with the size of the facility and volume of impounded water would all likely increase the potential for loss of life and high economic and infrastructure losses.

The High Hazard Potential classification of the C-43 West Basin Storage Reservoir means that the reservoir has been designed with the most stringent safety requirements and features designed to ensure that a weather extreme event or even a dam break would not compromise the safety of nearby residents. An extensive freeboard analysis and design process has been conducted to ensure the integrity and safety of the impoundment in cases of wind and wave run-up within the reservoir. This analysis is provided in the Engineering Appendix

PROJECT COST ESTIMATES AND COST APPORTIONMENT

The total initial estimated cost of the project, including all costs for construction, lands, easements, relocations, rights-of-way and disposals (LERRD), and pre-construction engineering and design (PED) and construction management costs is $570,480,000. Project construction costs will be shared equally between the Federal government and the non-Federal sponsor in accordance with Section 601 of the WRDA 2000 to maintain a 50/50 cost share as measured cumulatively for the entire CERP Program. Operations and maintenance (O&M) costs will be cost-shared 50/50 in accordance with the O&M cost-sharing provisions of Section 601 of WRDA 2000.

Section 601 of WRDA 2000 and USACE policy requires that the non-Federal sponsor must obtain and provide certification of LERRDs necessary for project implementation. ***Table ES-1*** provides additional details on initial costs for construction and non-construction items.

TABLE ES-1: CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR COSTS OCTOBER 2006 PRICE LEVELS (INITIAL COSTS ROUNDED TO THE NEAREST $10,000)

Ecosystem Restoration Elements	TOTALS
Construction	
Relocations	$1,180,000
Reservoir	$12,780,000
Reservoir (embankments, slurry wall, drains, soil cement, perimeter canal, spillways, structures, etc.)	$278,780,000
Channels and Canals	$5,180,000
Pumping Plants	$83,300,000
Recreation	$2,930,000
Floodway Control-Diversion Structures	$18,430,000
Sub-Total Construction Cost	**$402,580,000**
Non-Construction	
Lands and Damages	$84,650,000
Planning, Engineering, and Design	$51,880,000
Construction Management	$31,37000,000
Sub-Total Non-Construction Cost	**$167,900,000**
TOTAL INITIAL COST	**$570,480,000**

The estimated average annual cost for operations and maintenance is $3,100,000 (rounded to the nearest $10,000).

The costs shown above are updated, detailed costs and are not exactly equivalent to the costs that were utilized in the Economic Appendix cost/effectiveness and incremental costs analysis (CE/ICA). These updated costs were used, due to more detailed cost estimates becoming available, which warranted further justification of the original CE/ICA that was used for plan formulation and selection as can be noted in Appendix E.

SELECTED ALTERNATIVE PLAN IMPLEMENTATION

"ACCELER8"

The State of Florida has developed a program called "Acceler8" to accelerate design and construction of critical restoration projects prior to one or more of the following actions: administration approval, Congressional committee resolution,

Congressional authorization, and appropriation of Federal funds for CERP project construction and operation. Acceler8 projects are consistent with CERP projects, and are typically increments of a larger plan described in CERP PIRs. The "C-43 (Caloosahatchee River) West Reservoir" project is one of the projects included in the Acceler8 program (www.evergladesnow.org).

The State has determined that Acceler8 projects will provide immediate environmental, social, and economic benefits in the south Florida region, and has begun design and construction work in anticipation that future authority will provide for credit toward the fifty percent non-Federal cost-sharing requirements of WRDA 2000. The SFWMD is the lead agency for the State of Florida for implementing the Acceler8 program. The SFWMD proposes to initiate construction on the Caloosahatchee River (C-43) West Basin Storage Reservoir project prior to implementation of the Federal project, and has already constructed test cells at the project site to evaluate seepage and embankment design and water quality effects.

This report contains a recommendation that the non-Federal sponsor (SFWMD) receive credit toward the non-Federal cost-share for work completed prior to entering into a project cooperation agreement, provided that the work is integral to the CERP project and subject to certifications that: 1) the costs are reasonable, allowable, necessary, auditable, and allocable; and 2) that the activities were implemented in accordance with USACE design and construction standards and applicable laws.

Detailed design of the Caloosahatchee River (C-43) West Basin Storage Reservoir project will be accomplished by the SFWMD as part of the State of Florida's Acceler8 program. Design information and details will be coordinated and reviewed by the USACE pursuant to the Design Agreement between USACE and SFWMD dated May 12, 2000. Activities during the construction phase will be in accordance with the Acceler8 program and will be the responsibility of the SFWMD.

Real estate interests for LERRDs will be the responsibility of the SFWMD.

A draft Project Operating Manual is included with this report. An Interim Project Operating Manual will be completed during subsequent detailed design efforts to reflect design modifications. A Final Project Operating Manual will be prepared following completion of operational testing and monitoring which occurs at the end of the construction phase. The USACE and SFWMD will share in the responsibilities for conducting water management operations during operational testing and monitoring of the project.

In coordinating completion of the CERP PIR with Acceler8 activities, the USACE is proceeding with two separate and independent but related actions: the feasibility-level evaluation of the Federal project described in this final report and the regulatory evaluation of the SFWMD's proposed project as part of an application for a Department of the Army Section 404 (Clean Water Act) permit. The SFWMD's Acceler8 project is consistent with the SAP included in this final report. It is anticipated that the Final Integrated PIR and EIS to be prepared for this project will be considered as part of the regulatory permit application and provide the basis for the NEPA evaluation of the proposed Acceler8 project. A Section 404 permit decision will not be made until at least 30 days after the Notice of Availability of the Final Integrated PIR and EIS and execution of a Regulatory Record of Decision by the District Commander.

The scheduled construction start date for the Acceler8 project is initiation of clearing and grubbing, and embankment structure pre-loading in December 2007, and reservoir construction in February 2008, pending receipt of all required authorizations and approvals. It should be noted that the clearing and grubbing activities in uplands do not include any discharge of dredge or fill material into waters of the United States, thus there is no Department of Army permit associated with this work. Department of the Army authorization will be required prior to embankment structure pre-loading and reservoir construction.

STAKEHOLDER PERSPECTIVES

Initial public and agency comments received in response to a 2003 public notice of intent to prepare a Draft Integrated PIR and EIS focused on impacts to existing wildlife habitat in the vicinity of the reservoir site, the adequacy of habitat to be created within the reservoir, water quality impacts, recreation features to be included in the project, potential impacts to water supplies and reservoir operations, and potential impacts to a portion of State Road 80 adjacent to the reservoir.

Since 2003, several hurricanes passing over south Florida created exceptionally high volumes of fresh water entering the Caloosahatchee Estuary from local basin runoff and from Lake Okeechobee. In response to public concerns raised about impacts to both the Caloosahatchee and St. Lucie estuaries and the effect of high water levels in Lake Okeechobee on Herbert Hoover Dike, the USACE, Jacksonville District announced plans in early 2006 (during plan formulation efforts for this project) to prepare a supplemental EIS (separate from this PIR and EIS) to investigate modification of the Lake Okeechobee Regulation Schedule (LORS), or water control plan, to address these and related concerns.

Many stakeholders, local governments and representatives of non-governmental environmental organizations provided similar written comments and statements

at recent public meetings on the proposed changes to Lake Okeechobee's Regulation Schedule (LORS). The primary focus of their concern was the releases the lake would make to the Caloosahatchee River under the new regulation schedule and the effect those release would have on the health of the estuary. Some raised concerns about how the harmful effects of both excessive amounts of fresh water entering the estuary during the wet season and of insufficient fresh water to maintain desirable salinity levels in the estuary during dry periods affects the local economy. For example, in an October 2006 letter, the City of Sanibel commented:

> *"Sanibel Island's economy and its way of life depend upon the health of the Caloosahatchee River and Estuary. The Estuary provides essential habitat for fish populations that are central to the region's economy and recreational fishing economies. The City of Sanibel is particularly dependent on the health of the Caloosahatchee Estuary, as tourism generated by the diverse estuarine ecosystem in which it is located is central to the Island's economy."*

Similarly, the City of Fort Myers commented:

> *"The Caloosahatchee River and the estuary must be protected. The local economy is reliant on these waters through both the tourism industry and the fishing industry. We cannot afford to lose this most precious environmental and economic resource to the damaging effects of increased water releases from Lake Okeechobee."*

Since this Caloosahatchee River (C-43) West Basin Storage Reservoir Final PIR and EIS will be circulated for public and agency review and comment, and since it involves many of the same stakeholders and issues, it is expected that comments similar to those received on the LORS, Draft Supplemental EIS (USACE, Jacksonville District, August 2006) will be submitted for this project.

ENVIRONMENTAL OPERATING PRINCIPLES

The proposed project is consistent with the USACE "Environmental Operating Principles" (http://www.hq.usace.army.mil/cepa/envprinciples.htm), particularly with respect to the south Florida ecosystem-wide approach for plan formulation, evaluation, and selection, and a holistic consideration of water resources needs and solutions to water resources problems in the study area. The SAP incorporates monitoring, and CERP has an adaptive assessment and management program in place to ensure that projects, including the Caloosahatchee River (C-43) West Basin Storage Reservoir project, are achieving intended purposes. Project implementation, including plan formulation, involved collaborative interactions with the multiple agencies represented on the Project Delivery Team (PDT). Study area stakeholder groups and members of

the general public have had multiple opportunities to receive information on the project and to provide comments and recommendations via public meetings, internet postings, teleconferences, and interagency PDT meetings.

INDEPENDENT TECHNICAL REVIEW

An external independent technical review (ITR) was performed on both the Draft and Final PIR and EIS by a multi-disciplinary team consisting of technical staff from the USACE Wilmington, Savannah, Walla Walla, Rock Island and Mobile Districts, in accordance with recent Corps policy regarding coordination with the National Ecosystem Restoration Center of Expertise and the National Cost Engineering Directorate of Expertise. Significant comments addressed during ITR included:

- Environmental benefits quantification methodology and spatial extent;
- Use of a hydrodynamic modeling tool to evaluate salinity changes in the estuary;
- Project real estate requirements; and,
- Development of project cost estimates.

In general, the ITR Team found that the information presented in the report describing the plan formulation and evaluation supported plan selection. All concerns resulting from ITR of the Final PIR have been resolved.

UNRESOLVED ISSUES

There are no significant unresolved issues with respect to the design of features to be constructed, cost estimates, and expected project outputs.

The implementing agencies (USACE, SFWMD, and U.S. Department of Interior) agree that there are remaining water resources problems in the Caloosahatchee River Basin which were not fully addressed by the SAP, including providing additional pumping and storage capacity, the need for additional water storage and management features in the Eastern Caloosahatchee River (upper) basin, and improving basin water quality. These concerns were also clearly articulated by other Federal, state, and local agencies and stakeholder groups in the study area. To address these and other unmet needs, a subsequent PIR will be initiated upon completion of this PIR.

Related to the need to investigate additional water storage and management options in the Caloosahatchee River Basin, concerns have also been raised about the ASR features of the CERP associated with the C-43 Basin Storage Reservoir (Restudy). During the initial planning for CERP, ASR wells were formulated in association with several of the CERP reservoirs (including the C-43 Basin Storage Reservoir [Restudy]) to provide an additional source of water and to

improve the efficiency of the reservoir operations. However, at this time, a number of technical, regulatory, cost, and efficiency uncertainties remain unresolved for ASR as originally envisioned for CERP. To address these uncertainties, pilot projects have been initiated and a study is underway to more fully evaluate regional ASR performance and implementation issues. If these investigations indicate that ASR technology is a feasible and cost-effective means of achieving ecosystem restoration goals and objectives in the Caloosahatchee Basin, a third PIR (C-43 Basin ASR PIR) may be initiated to incorporate those features.

SECTION 1
INTRODUCTION

This page intentionally left blank

1.0 INTRODUCTION

The Comprehensive Everglades Restoration Plan (CERP or "the Plan") provides a framework for the restoration of ecological function for the diverse and significant habitats of the south Florida ecosystem, including the Everglades, which encompasses 18,000 square miles from Orlando to the Florida Reef Tract. Everglades National Park (ENP) (the largest national park east of the Mississippi River, comprising a significant portion of the greater Everglades ecosystem) is a World Heritage Site, an International Biosphere Preserve, and a Wetland of International Importance. The Everglades and the south Florida ecosystem are affected by competing demands for recreation, development, natural and commercial resources, and include 68 federally listed threatened and endangered plants and animals.

First authorized by Congress in 1948, the Central and Southern Florida (C&SF) Project expanded the existing network of canals, levees, water storage areas and water control structures in south Florida. Project objectives included flood damage reduction, regional water supply, prevention of saltwater intrusion, preservation of fish and wildlife, recreation and navigation. While fulfilling these objectives, the project has had unintended adverse effects on the natural environment that constitutes the Everglades and south Florida ecosystem by disrupting the pre-existing hydrologic regime. As a result, in 1996, the United States Army Corps of Engineers (USACE), in conjunction with the South Florida Water Management District (SFWMD), was directed to develop a comprehensive plan to restore, preserve, and protect the south Florida ecosystem while also providing for other water-related needs of the region such as water supply and flood protection. The resulting plan submitted to Congress on July 1, 1999, is called the CERP, and consists of proposed structural and operational modifications to the C&SF Project.

The CERP was approved as a framework for the restoration of the natural system in Section 601 of the Water Resources Development Act of 2000 (WRDA 2000). The Plan consists of 68 components to restore, preserve, and protect the south Florida ecosystem while providing for other water-related needs of the region. The Plan's components will be implemented over an approximately 40-year period. Together, these components will benefit the ecological functioning of more than 2.4 million acres of the south Florida ecosystem by improving and/or restoring the proper quantity, quality, timing and distribution of water made available for the natural system while also addressing urban and agricultural water supply concerns and maintaining existing levels of flood protection.

Significantly less water flows through the ecosystem today compared to the past. An average of 1.7 billion gallons of water per day that once flowed through the ecosystem is now discharged to the Atlantic Ocean or the Gulf of Mexico via

C&SF Project canals. The CERP will capture a significant amount of this water in above-ground, in-ground, and underground storage areas, retain this water and redistribute it as needed. Specifically, this water will be stored in 330 aquifer storage and recovery (ASR) wells, over 217,000 acres of new reservoirs, and wetland treatment areas. In addition, various means of seepage control along the remaining Everglades will retain more water in the Everglades ecosystem, thereby increasing the volume of water retained in the natural system. Finally, wastewater reuse facilities are included in the Plan to provide a source of additional water to meet restoration needs.

The natural alternating flooding and drying periods, termed hydroperiods, are vital to the Everglades ecosystem and have been severely altered by human activities. Restoring natural patterns of inundation and variability of water flows and levels is an integral part of the CERP. Specifically, the CERP modifies the timing of water held and released into the ecosystem so that it more closely matches historical natural patterns. Changes in water delivery schedules will be made in some areas to alleviate extreme fluctuations. Lake Okeechobee water levels will be modified to improve the health of the lake. In other areas, the rainfall-driven operational plan will improve the timing of water flows.

The final factor in the water equation is the real extent and movement of water through the system. The remaining Everglades ecosystem has been separated, or compartmentalized, by canals and levees. The CERP will remove over 240 miles of levees and canals to improve the connectivity of natural areas and restore sheetflow. In addition, excess phosphorus, mercury and other contaminants have diminished water quality in the south Florida ecosystem. The water quality of the Everglades Water Conservation Areas (WCAs), the coastal estuaries, Florida Bay and the Keys shows similar signs of degradation. The CERP will help improve the quality of water discharged to natural areas by directing flow through wetlands-based treatment areas totaling approximately 36,000 acres.

The CERP established the need for and the beneficial effects of an above-ground reservoir in the Caloosahatchee River (C-43 Canal) basin as part of a comprehensive plan for achieving restoration objectives for the Caloosahatchee Estuary. The Comprehensive Review Study included two primary structural components focused on improving environmental conditions in the Caloosahatchee River and Estuary: (1) an approximately 160,000 acre-foot reservoir with associated ASR wells and (2) basin runoff backpumping and stormwater treatment facilities. Due to technical uncertainty and implementation issues, the ASR features originally associated with a storage reservoir in the Caloosahatchee Basin will be evaluated and implemented separately (Part 2). The availability and effectiveness of storing basin runoff for

backpumping to the C-43 Canal and Lake Okeechobee will also be further evaluated as part of future CERP updates.

The Caloosahatchee River (C-43) West Basin Storage Reservoir project will contribute to the restoration of the Caloosahatchee Estuary as part of a comprehensive plan for restoring the south Florida ecosystem. This final report has been prepared in accordance with the requirements of Section 601(d) of the WRDA 2000 and Programmatic Regulations for the CERP (33 Code of Federal Regulations [CFR] Part 385). The Caloosahatchee River (C-43) West Basin Storage Reservoir project area is shown in ***Figure 1-1***.

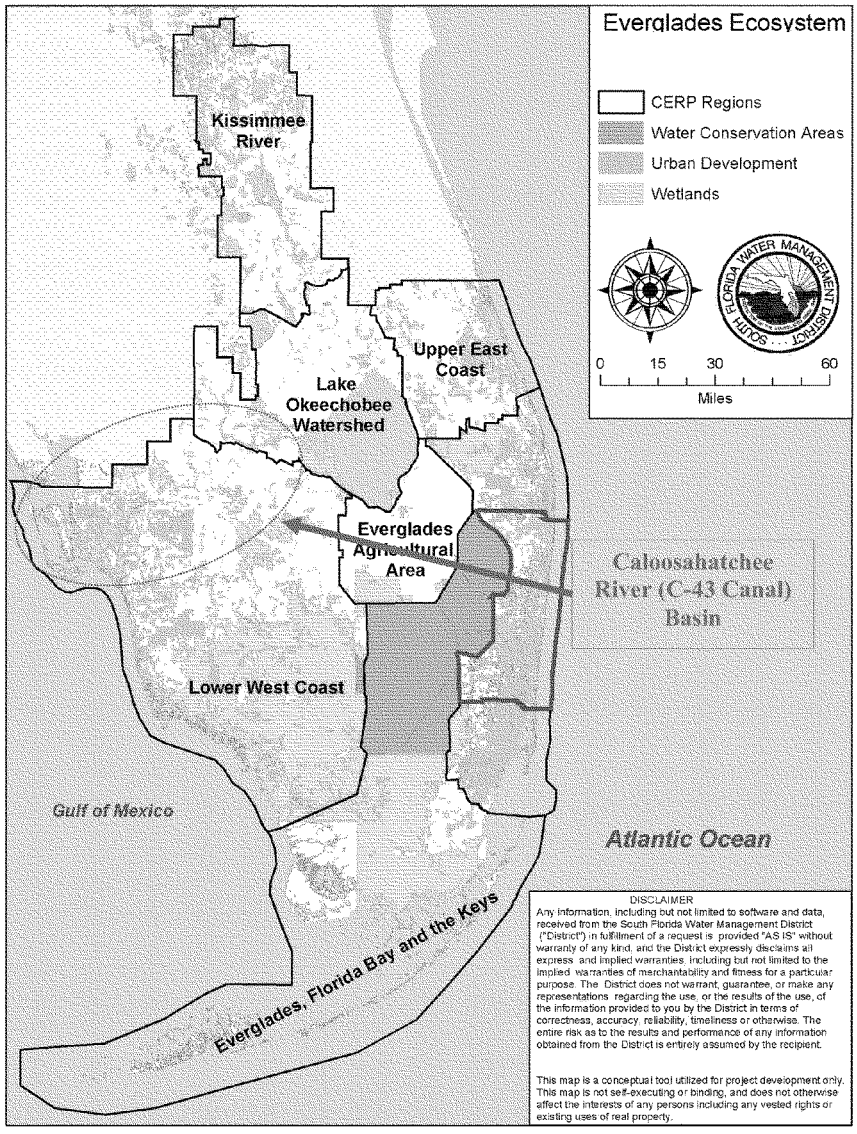

FIGURE 1-1: LOCATION OF THE CALOOSAHATCHEE RIVER & ESTUARY

1.1 REPORT AUTHORITY

The CERP was approved in Section 601 of WRDA 2000, which states, in part:

> *(b) Comprehensive Everglades Restoration Plan Approval –*
> *(1) APPROVAL*
> *(A) IN GENERAL. —Except as modified by this section, the Plan is approved as a framework for modifications and operational changes to the Central and Southern Florida Project that are needed to restore, preserve, and protect the South Florida ecosystem while providing for other water-related needs of the region, including water supply and flood protection. The Plan shall be implemented to ensure the protection of water quality in, the reduction of the loss of fresh water from, and the improvement of the environment of the South Florida ecosystem and to achieve and maintain the benefits to the natural system and human environment described in the Plan, and required pursuant to this section, for as long as the project is authorized.*

The authority for the preparation of the Caloosahatchee River (C-43) West Basin Storage Reservoir Project Implementation Report (PIR), one of a number of site-specific projects, is contained in Section 601(d) of WRDA 2000, which states:

> *(d) AUTHORIZATION OF FUTURE PROJECTS-*
> *(1) IN GENERAL- Except for a project authorized by subsection (b) or (c), any project included in the Plan shall require a specific authorization by Congress.*
> *(2) SUBMISSION OF REPORT- Before seeking congressional authorization for a project under paragraph (1), the Secretary shall submit to Congress--*
> *(A) a description of the project; and*
> *(B) a project implementation report for the project prepared in accordance with subsections (f) and (h).*

Section 601(h)(4) of WRDA 2000 further requires that a PIR document the following:

> *(4) PROJECT-SPECIFIC ASSURANCES-*
> *(A) PROJECT IMPLEMENTATION REPORTS-*
> *(i) IN GENERAL- The Secretary and the non-Federal sponsor shall develop project implementation reports in accordance with section 10.3.1 of the Plan.*
> *(ii) COORDINATION- In developing a project implementation report, the Secretary and the non-Federal sponsor shall coordinate with appropriate Federal, State, tribal, and local governments.*
> *(iii) REQUIREMENTS- A project implementation report shall--*

(I) be consistent with the Plan and the programmatic regulations promulgated under paragraph (3);
(II) describe how each of the requirements stated in paragraph (3)(B) is satisfied;
(III) comply with the National Environmental Policy Act of 1969 (42 U.S.C. 4321 et seq.);
(IV) identify the appropriate quantity, timing, and distribution of water dedicated and managed for the natural system;
(V) identify the amount of water to be reserved or allocated for the natural system necessary to implement, under State law, subclauses (IV) and (VI);
(VI) comply with applicable water quality standards and applicable water quality permitting requirements under subsection (b)(2)(A)(ii);
(VII) be based on the best available science; and
(VIII) include an analysis concerning the cost-effectiveness and engineering feasibility of the project.

1.2 PROJECT AREA

Located on Florida's lower southwest coast, the Caloosahatchee River (which is also commonly referred to as the C-43 Canal) region extends approximately 70 miles from Lake Okeechobee to the lower Charlotte Harbor Basin at San Carlos Bay. The Caloosahatchee River watershed constitutes the northern portion of the SFWMD Lower West Coast planning area. The Caloosahatchee River watershed covers an area of 1,125,000 acres in parts of Lee, Glades, Charlotte, and Hendry counties. The watershed can be further subdivided into seven drainage basins based on their hydrologic characteristics, hydrologic control features, and topography. Moving from east to west these basins are the C-21, East Caloosahatchee, West Caloosahatchee, Orange River, S-236, Telegraph Swamp, and the Tidal Caloosahatchee Basin (***Figure 1-2***). The population of the four counties that make up the Caloosahatchee River Basin was 630,000 in 2000 and is expected to nearly double to 1,220,000 by 2050. Major land uses in the area include agriculture (dominated by citrus, sugar cane, vegetables, sod, and cattle production), urban and municipal development, and natural areas.

The Caloosahatchee River watershed (or C-43 Basin) drains an area of about 1,758 square miles. Originally the Caloosahatchee River was a shallow meandering river. Prior to human disturbance, water moved slowly from the uplands and wetlands to the river and then downstream to the estuary. The lower Caloosahatchee River near its convergence with San Carlos Bay supported luxuriant seagrass beds with high light transmittance to the substrate and low nutrient and suspended solids concentrations. The interior basin was dominated by seasonally flooded cypress savannas and freshwater marshes with interspersed pine-dominated uplands, while the lower tidal portion consists of a coastal fringe of mangroves with extensive beaches and numerous estuaries (SFWMD 2000).

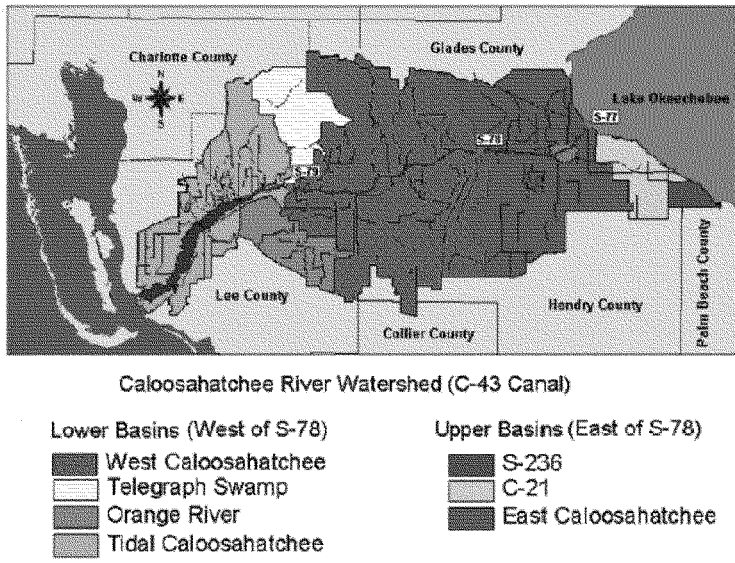

FIGURE 1-2: CALOOSAHATCHEE BASIN STUDY AREA

The Caloosahatchee River now serves as the western reach of the cross-state Okeechobee Waterway that connects Lake Okeechobee to the Gulf of Mexico at Fort Myers on the west coast. The Caloosahatchee River was hydrologically connected to Lake Okeechobee in 1881 by private interests, which resulted in the first lowering of the lake's water table. From 1910 to 1930, the canal's 65-mile course was channelized to improve navigation and flood control. Three lock-and-dam structures, (S-77, S-78, and S-79) were constructed to control flow and stage height in the lake and canal. From a hurricane gate located on the southwestern shore of Lake Okeechobee at Moore Haven (S-77), the Caloosahatchee River drains to the west for about five miles through very flat terrain into Lake Hicpochee. From Lake Hicpochee, the canal joins the upper reach of the Caloosahatchee River. The river is controlled by two navigation locks, one at Ortona (Ortona Lock and Dam or S-78), 15-miles downstream from Moore Haven and the other at Olga near Fort Myers (W.P. Franklin Lock and Dam or S-79). The S-78 aids in control of water levels on adjacent lands upstream and is the boundary that separates the Eastern Caloosahatchee Basin from the Western Caloosahatchee Basin. The S-79 is the most downstream structure and marks the beginning of the Caloosahatchee Estuary. The S-79 structure helps maintain specific water levels upstream, regulates freshwater discharges into

the estuary, and serves as an impediment to saltwater intrusion upstream of the lock.

1.3 PROJECT PURPOSE AND SCOPE

The Caloosahatchee River and Estuary is at the head of a vast estuarine and marine ecosystem that includes aquatic preserves (Matlacha Pass Aquatic Preserve, Estero Bay Aquatic Preserve, and Pine Island Sound Aquatic Preserve; the Charlotte Harbor National Estuary; and the Caloosahatchee, Matlacha Pass and Ding Darling National Wildlife Refuges), along with numerous other Federal, state, and local parks and recreation areas. Restoration of a healthy, productive aquatic ecosystem in the Caloosahatchee River is essential to maintaining the ecological integrity and associated economic activity in these publicly owned and managed areas.

The Caloosahatchee Estuary (***Figure 1-3***), which is generally considered to be that portion of the Caloosahatchee River west of the W. P. Franklin Lock and Dam, including the Matlacha Pass, San Carlos Bay, and Estero Bay areas at the mouth of the Caloosahatchee River, encompasses approximately 80 square miles of estuarine habitat on Florida's southwest coast in the vicinity of Fort Myers, Florida. The Fort Myers area, including Cape Coral, Fort Myers Beach, Sanibel and Captiva Islands, Bonita Springs and unincorporated areas is one of the fastest growing areas in the southeastern United States (2000 population approximately 440,000 according to U.S. Census figures) and is an extremely popular tourist destination.

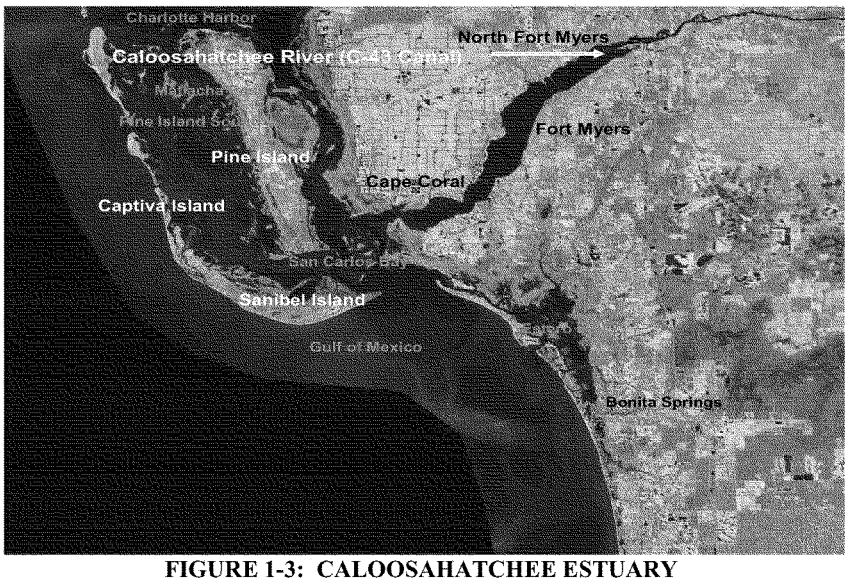

FIGURE 1-3: CALOOSAHATCHEE ESTUARY

Currently, there is not enough storage capacity in the regional water management system to minimize or prevent the harmful effects of periodic high-volume discharges of freshwater to the Caloosahatchee Estuary. Conversely, during dry periods, there is sometimes not enough freshwater available in the regional system to maintain desirable salinity levels in the estuary. The combined result of too much and too little freshwater flowing to the Caloosahatchee Estuary is a degraded estuarine ecological community, characterized by declines in the abundance and diversity of native finfish and shellfish populations and other marine and estuarine species, poor water quality, and reductions in the extent of submerged habitat suitable for sea grass and oysters (two primary indicators of healthy estuarine communities in South Florida) and other higher trophic level species, including threatened and endangered species (e.g., manatees, wood storks).

To restore ecological function and productivity in the Caloosahatchee Estuary, the CERP approved by Congress in WRDA 2000 included an above-ground reservoir along the C-43 Canal to capture and store basin runoff and excess freshwater released from Lake Okeechobee. By capturing this excess water the reservoir can also serve as a source of environmental water supply to the estuary during dry periods. The need for additional storage to restore, protect, and preserve the Caloosahatchee Estuary, including Federal trust lands and other publicly owned and managed areas in and around the Caloosahatchee Estuary has also been validated by other planning efforts, including the Caloosahatchee

Water Management Plan (CWMP) (2000) and Lower West Coast Water Supply Plan (2005-2006) prepared by the SFWMD. In accordance with Federal and state requirements for implementing CERP projects, this final PIR was prepared to reaffirm that an above-ground storage reservoir in the Caloosahatchee Basin is a cost-effective solution for achieving CERP goals and Caloosahatchee River (C-43) West Basin Storage Reservoir project objectives and to present the results of evaluations required by Federal and state regulations.

The primary restoration objective for the Caloosahatchee River (C-43) West Basin Storage Reservoir identified in the Restudy was:

> *"... to capture C-43 Basin runoff and releases from Lake Okeechobee. These facilities will be designed for water supply benefits, some flood attenuation, to provide environmental water supply deliveries to the Caloosahatchee Estuary, and water quality benefits to reduce salinity and nutrient impacts of runoff to the estuary..."*

Primary system benefits would include:

(1) Improvements in salinity and
(2) Improvements in water quality in the estuary.

Secondary system benefits would include:

(1) Improvements in flood attenuation within the basin; and
(2) A possible additional water supply source for agricultural and urban uses (via runoff capture and reuse methodology) once the needs of the estuary are met.

The Restudy recommended a plan that included restoration efforts in the Caloosahatchee River (C-43) region. The CERP project scope included the following description:

> *"This feature includes above-ground reservoir(s) with a total storage capacity of approximately 160,000 acre-feet and aquifer storage and recovery wells with a capacity of approximately 220 million gallons per day and associated pre- and post water quality treatment located in the C-43 Basin in Henry, Glades, or Lee Counties. The initial design of the reservoir(s) assumed 20,000 acres with water levels fluctuating up to 8 feet above grade. The final size, depth and configuration of this facility will be determined through more detailed planning and design. The initial design of the wells assumed 44 wells, each with the capacity of 5 million gallons per day with chlorination for pre-treatment and aeration for post-treatment. The level and extent of treatment and*

number of the aquifer storage and recovery wells may be modified based on findings from a proposed aquifer storage and recovery pilot project (U.S. Environmental Protection Agency, 1999)"

The plan formulated in the Restudy alternative for the Caloosahatchee Basin was to capture water in reservoir(s) to provide desirable flow volumes through the S-79 structure to achieve the appropriate salinity envelope in the Caloosahatchee estuary. Through screening and evaluation of plan components proposed in the Restudy it was determined that above ground water storage provided the most cost effective alternative for freshwater attenuation (CERP, Volume 1; Section 7.2).

As previously stated, during completion of the CERP Master Program Management Plan (MPMP) in August of 2000, the project was divided into two parts, Part I: The Caloosahatchee Basin Storage Reservoir Project, and Part II: The Caloosahatchee Basin ASR Project.

This PIR addresses formulation, evaluation, and justification of a separable reservoir project in the lower Caloosahatchee River basin by reaffirming that a reservoir in the lower basin will achieve the benefits of the Restudy Plan for the Caloosahatchee Basin in a cost-effective manner. It demonstrates that a reservoir has been optimized, and acknowledges that the project is part of a more comprehensive plan for the Caloosahatchee Basin.

Since this project located in the lower portion of the Caloosahatchee Basin is focused on estuary restoration, it has limited capability to provide additional water to meet water supply demands in the upper Caloosahatchee River basin. A subsequent study will address the water supply needs and water quality issues of the upper basin. This later study will also address any additional restoration needs and demands in the lower Caloosahatchee River basin not met by the Caloosahatchee River (C-43) West Basin Storage Reservoir project.

Storage of water within the C-43 Basin had been established as one of the primary management measures contributing to the goals and purposes of the Restudy. Based on these findings, the SFWMD originally acquired approximately 12,372 acres (including easements) using State funds and Federal funds. SFWMD is in the process of exchanging approximately 541 acres of this previously acquired land for approximately 600 acres adjacent to the property originally acquired. As the PIR development process was initiated, there was an effort to identify early opportunities to obtain system-wide benefits by utilizing readily available lands. One of these opportunities was the evaluation of a potential reservoir located in the western Caloosahatchee River Basin on lands acquired by SFWMD with both Department of Interior (DOI) and SFWMD funds (please see Real Estate Appendix D, section D1.10.2 for more information).

Draft Programmatic Regulations Guidance Memoranda #1 and #2 instruct project teams to affirm and optimize the component identified in the Restudy unless conditions or planning objectives have changed, or if the component no longer meets the purposes outlined in the Restudy, to formulate new alternatives. Additionally, for projects where the non-Federal sponsor has already acquired lands, formulation of alternative plans using other sites will be minimized if the intended project purposes can be achieved and no more cost-effective sites are identified during formulation. Additional management measures to address the new circumstances should be developed and screening should occur based on the project's evaluation criteria and performance measures. As stated in CERP Guidance Memorandum #2:

> **Reaffirmation:** If the project as described in the Plan is reaffirmed, then the Project Delivery Team's (PDT) efforts will focus on development of design alternatives and optimization of the project features, cost-effectiveness, satisfaction of programmatic regulations requirements for PIRs, Micro-Computer Aided Cost Engineering System (MCACES) cost estimates, and the integrated National Environmental Policy Act (NEPA) documentation to supplement the information contained in the Programmatic Environmental Impact Statement (PEIS) for the Plan, in accordance with the concept of tiering under NEPA.
>
> **Reformulation:** When the project described in the Plan no longer achieves the benefits of the project as described in the Plan, additional formulation will be required prior to initiating detailed design of the selected plan. However, the formulation completed and described in the Plan will provide the foundation for the PDT to formulate additional alternatives. The new or changed circumstances requiring additional formulation should be documented.

The plan formulation for this project focuses on reaffirming that an above-ground storage reservoir in the Caloosahatchee Basin continues to meet the goals, objectives, and purposes for the project as described in the Restudy. Accordingly, in reviewing the findings of the Restudy, the team has determined that based on the current conditions, the project as described in the Restudy still achieves the benefits of the project in a cost-effective manner. A summary of the events that led up to the decisions on how to approach the project is found in ***Figure 1-4*** located at the end of this section.

1.4 RELATIONSHIP TO OTHER USACE/NON-FEDERAL SPONSOR EFFORTS, STUDIES, DOCUMENTS, AND REPORTS

Listed within this section are brief descriptions of other key projects related to the Caloosahatchee River (C-43) West Basin Storage Reservoir project. Included in the description are the objectives and/or study area.

1.4.1 CERP Components

Each of the projects listed below is a CERP component as outlined in the Restudy.

1.4.1.1 C-43 Basin Aquifer Storage and Recovery Project, Part 2

The C-43 Basin ASR Project (Part 2) includes ASR wells with a capacity of approximately 220 million gallons per day and associated pre- and post- water quality treatment that is co-located with the reservoir. The initial design of the wells assumed 44 wells, each with a capacity of five million gallons per day with chlorination for pre-treatment and aeration for post-treatment. The level and extent of treatment and number of the ASR wells may be modified based on findings from the ASR pilot project. The ASR pilot project is being conducted in parallel with a regional study on ASR.

1.4.1.2 Caloosahatchee Backpumping with Stormwater Treatment

The purpose of this project is to capture excess Caloosahatchee River Basin runoff, which will be used to augment regional system water supply. This feature as described in the Restudy includes pump stations and stormwater treatment areas (STAs) with a total capacity of approximately 20,000 acre-feet located in the Caloosahatchee River Basin in Hendry and Glades counties. The initial design of the STAs assumed 5,000 acres with the water level fluctuating up to four feet above grade. The final size, depth, and configuration of these facilities will be determined through more detailed planning and design. This project will be further evaluated under a separate PIR in the future.

1.4.1.3 Southwest Florida Feasibility Study

The Southwest Florida Feasibility Study (SWFFS) covers approximately 4,300 square miles of Florida's southern peninsula. The study area encompasses all of Lee County, most of Collier and Hendry counties, and portions of Charlotte, Glades, and Monroe counties. In the SWFFS study area, the Caloosahatchee River serves as the western outlet for discharges of stormwater and flood releases from Lake Okeechobee to the Gulf of Mexico and is a major source of surface water supply for the basin. The SWFFS will provide a comprehensive review of the water issues that faces southwest Florida, and is not limited to those related to the C&SF Project. The SWFFS will develop and address alternatives that protect and restore early wet-season and overland sheet flow conditions that provide for restoration of amphibian, reptile, macro invertebrate, and forage fish populations. The SWFFS will consider the impacts of freshwater pulsing and/or depletion of freshwater flows to estuaries, improvement of shellfish and fisheries habitat, and protection and restoration of shoreline wetlands that are unique to southwest Florida such as mangroves. Wide-

ranging federal and state-listed threaten and endangered species, such as the Florida panther, wood stork and Florida black bear, as well as migratory birds and endemic species will be prioritized in the study's alternative development and analysis. The study will look at the protection and/or restoration of existing natural resources through land acquisition and conservation easement. The study will plan for proper infrastructure before or, as development occurs, not after. It will develop a water resources plan for the entire southwest Florida area and provide for ecosystem and marine/estuary restoration and protection, environmental quality, flood protection, water supply and other water-related purposes.

Recommendations for restoration of natural areas within the Caloosahatchee River Basin, which are not consistent with the Caloosahatchee River (C-43) West Basin Storage Reservoir project purpose, will be conveyed to the SWFFS for assessment and evaluation, since restoration of natural areas is consistent with the SWFFS purpose. Environmental benefits from Caloosahatchee River (C-43) West Basin Storage Reservoir project will be based on the improved estuary conditions resulting from modifying the salinity regime as a result of changes in the flows to the estuary, and any nutrient load reductions that result from the reservoir storage features. Additional environmental benefits may result from additional features implemented by the SWFFS. The SWFFS includes as one of its objectives the increase in the spatial extent of functional wetlands. The SWFFS will study/evaluate the potential for sites to be re-hydrated within the SWFFS project study area, which includes the Caloosahatchee River Basin. The SWFFS will formulate for environmental benefits in the estuary and in the upland areas, even in the C-43 watershed. The Caloosahatchee River (C-43) West Basin Storage Reservoir project will only have environmental benefits in the estuary, not in the upland areas, unless specifically adjacent to a reservoir. However, recommendations for restoration of natural areas within the Caloosahatchee River Basin not consistent with the Caloosahatchee River (C-43) West Basin Storage Reservoir project purpose will be conveyed to the SWFFS for assessment and evaluation

1.4.1.4 Lake Okeechobee Watershed Project

Lake Okeechobee (approximately 730 square miles) is located in portions of Palm Beach, Martin, Okeechobee, Glades, and Hendry Counties. Water flows into the Lake primarily from the Kissimmee River, Fisheating Creek, and Taylor Creek/Nubbin Slough. The Lake is the principal natural reservoir in south Florida and discharges water east through the St. Lucie Canal (C-44) into the St. Lucie Estuary, west through the Caloosahatchee River (C-43) into the Caloosahatchee Estuary, and south through four major canals in the Everglades Agricultural Area (EAA) into the Water Conservation Areas (WCA). Water levels in the Lake are currently regulated by a complex system of pump stations, spillways, and locks, in accordance with a regulation schedule developed by the

South Florida Water Management District (SFWMD) and the Army Corps of Engineers Jacksonville District (USACE).

The Comprehensive Everglades Restoration Plan contained in the Restudy includes five components that make up the Lake Okeechobee Watershed Study.

North of Lake Okeechobee Storage Reservoir–This feature includes an above-ground reservoir with total storage capacity of approximately 200,000 acre-feet and a 2,500-acre stormwater treatment area located in the Kissimmee River Region, north of Lake Okeechobee.

Taylor Creek/Nubbin Slough Storage and Treatment Area–This feature includes an above-ground reservoir with a total storage capacity of approximately 50,000 acre-feet and a stormwater treatment area with a capacity of approximately 20,000 acre-feet in the Taylor Creek/Nubbin Slough Basin.

Lake Okeechobee Watershed Water Quality Treatment Facilities–This feature will attenuate peak flows and reduce phosphorus loading into Lake Okeechobee by restoring the hydrology of selected isolated and riverine wetlands in the region by plugging drainage ditches that were established for agriculture water supply, and flood control.

Lake Okeechobee Tributary Sediment Dredging–This feature will remove phosphorus in canals located in areas with high phosphorus concentrations that discharge runoff in the Lake Okeechobee Watershed.

Lake Istokpoga Regulation Schedule–This component will examine Lake Istokpoga regulation schedule in order to develop a long-term comprehensive management plan while balancing water supply and flood control needs, while providing ecological benefits in the basin.

1.4.2 Non-CERP Components

The C&SF Project was authorized by the Flood Control Act of 1948 and modified by subsequent acts, as a plan of improvement for flood control, drainage, and other purposes covering an 18,000 square mile area of C&SF. Within the C-43 Basin Storage Reservoir Project area, C&SF canals include Canals 43, 20, and 21. A number of efforts are currently underway by the USACE to modify the C&SF Project for environmental improvements are listed below.

1.4.2.1 Manatee Protection

The West Indian manatee (*Trichechus manatus*) is listed as a Federally endangered species and is one of the most endangered species in Florida. As a response to recent manatee mortality trends associated with water control

structures, this project will provide operational changes and implement the installation of a manatee protection system at seven sector gates at navigational locks near Lake Okeechobee. The beneficial outcome of this project will be the reduction of risk, injury, and mortality of the manatee. The seven sector gates include S-193 at Okeechobee and S-310 at Clewiston on Lake Okeechobee; St. Lucie Lock, and Port Mayaca Lock on the St. Lucie canal; and Moore Haven Lock, Ortona Lock, and W.P. Franklin Lock on the Caloosahatchee River.

1.4.2.2 Caloosahatchee River Oxbow Restoration

The Caloosahatchee River oxbows that are currently being investigated under the authority of the USACE's Section 206 Continuing Authorities Program are located between S-79 and the boundary between Lee and Hendry Counties. The purpose of this project is to restore degraded oxbows, which support the only remaining natural riverine habitat in the altered Caloosahatchee River system. These areas provide important habitat for the critical ecosystem functions of feeding, nesting, refuge and nursery areas for aquatic dependent species, some of which are State and Federally listed species. These areas serve as a critical link in the life cycle of many organisms, from macroinvertebrate communities to fish, birds, reptiles, and mammals. The Caloosahatchee River oxbow restoration will impact future hydrologic conditions of the Caloosahatchee River by increasing river flow through the oxbows. This will result in improved water quality by removal of anaerobic sediments and increased productivity and ecological value by providing a diversity of functioning habitats. Restoring the historic river oxbows also slightly increases the natural storage capacity of the Caloosahatchee River and attenuates the river's hydrograph below the oxbows.

1.4.2.3 Lake Okeechobee Regulation Schedule

Lake Okeechobee is regulated to provide flood control, navigation, water supply, regional groundwater and salinity control, enhancement of fish and wildlife, and recreation. The current regulation schedule, Water Supply/Environmental (WSE), was approved in July 2000 for the regulation of Lake Okeechobee water levels. Per Restoration Coordination and Verification (RECOVER) system-wide determinations for all CERP projects, the current WSE schedule described in the existing conditions section is assumed to be the same regulation schedule in place for future without project conditions. WSE incorporates tributary hydrologic conditions and climate forecasts into the operational guidelines and is used in conjunction with the Operational Guidelines Decision Tree. The operational flexibility of the WSE schedule allows for adjustments to be made in the timing and magnitude of Lake Okeechobee regulatory discharges based on conditions in the Lake tributary basins and in the extended meteorological and climate outlooks. However, in the near future, the USACE plans to complete a detailed study of the Lake Okeechobee regulation schedule similar to the Final

Environmental Impact Statement (EIS) (FEIS, USACE 31 March 2000) that was completed for the Lake Okeechobee Regulation Schedule Study (LORSS).

1.4.2.4 State Initiatives

In addition to the Federal projects, there are multiple state projects that will also have an impact on future water quality both upstream and downstream of S-79. They are:

- SFWMD Lake Okeechobee Protection Plan;
- Florida Department of Environmental Protection (FDEP) Lake Okeechobee Total Maximum Daily Loads (TMDL);
- SFWMD Caloosahatchee Minimum Flows and Levels (MFL);
- SFWMD Caloosahatchee Water Management Plan (CWMP);
- FDEP Caloosahatchee Basin TMDL;
- Florida Department of Agriculture and Consumer Services (FDACS)/FDEP Agricultural Best Management Practices (BMP) Program for the Caloosahatchee Basin;
- SFWMD Urban Irrigation and Landscape BMP Implementation Projects;
- SFWMD Stormwater Management Regulations;
- Lee and Hendry Counties Stormwater Management Projects.
- Northern Everglades Initiative, Caloosahatchee River Watershed Protection Plan
  In June 2007, the Florida Legislature passed Senate Bill 392, The Northern Everglades and Estuaries Protection Program, which expands the Lake Okeechobee Protection Act to include protection and restoration of the Lake Okeechobee watershed and the Caloosahatchee and St. Lucie Rivers and estuaries, provides a dedicated State funding source for Northern Everglades restoration.

  The South Florida Water Management District (SFWMD) announced in July 2007 the allocation of $3.4 million to support 16 projects along Florida's lower west coast that will improve water quality in the Caloosahatchee River and estuary. The local projects, ranging from neighborhood sewer system improvements to treatment marshes and sediment removal, will be completed over the next six months to provide immediate pollution-control measures.

1.5 PROGRAMMATIC REGULATIONS GUIDANCE MEMORANDA

WRDA 2000 required the development of Programmatic Regulations to provide additional guidance for the implementation of CERP. Section 385.5 of the Programmatic Regulations specifically requires the development of six program-wide Guidance Memoranda (GM) that are consistent with the Programmatic Regulations and applicable law, and establish additional procedures to achieve

the goals and purposes of the Plan. The GM are fundamental to the integrated framework; provide direction for using the tools for planning, implementation, and evaluation; and provide assurances that the goals and purposes of the Plan will be achieved. The GM address numerous topics including common methods, general procedures, and guidance to implement the Plan. The six program-wide subjects for the GM as set forth in the Programmatic Regulations are:

- GM#1: Project Implementation Reports
- GM#2: Formulation and Evaluation of Alternatives for PIRs
- GM#3: Savings Clause Requirements
- GM#4: Identifying Water Made Available for the Natural System and for Other Water-related Needs
- GM#5: Operating Manuals
- GM#6: Assessment Activities for Adaptive Management

These GM are currently in draft form and were used to develop this PIR.

1.6 RELEVANT DOCUMENTS AND REPORTS

Reservoir storage was identified in the Restudy as the key component for the restoration of the Caloosahatchee River and estuary. The Restudy analysis identified a conceptual C-43 Basin Storage Reservoir Project of approximately 160,000 acre-feet of above ground storage for environmental restoration for the Caloosahatchee River and Estuary. This storage amount was established through various previously completed modeling efforts. In the Restudy analysis of the Caloosahatchee Basin, an acceptable salinity range for the estuarine ecosystem was established that translated to mean monthly freshwater inflows of 300 cubic feet per second (cfs) to 2800 cfs at S-79. This flow target included the need for low flow augmentation and minimizing high flow discharge events to improve estuarine water quality and to protect and restore estuarine habitat and biota. This flow target at S-79 helped produce modeling results indicating the most efficient size for determining the storage capacity of reservoirs to capture local basin and Lake Okeechobee inflows.

Since the Restudy, additional information has been developed (improved modeling, improved analysis of local hydrology and water budgets, and new estimates of land use and water demands) that refines the amount of storage identified as necessary to meet the needs of the Caloosahatchee Estuary and Basin. In 1998, the SFWMD undertook a water supply planning initiative to ensure prudent management of south Florida's water resources. As a result of this initiative, the SFWMD released the CWMP in the year 2000. The CWMP analysis determined that the projected surface water needs of the Caloosahatchee River and Estuary can be met during a one-in-ten drought condition with the development of water management and storage infrastructure that effectively captures and stores surface water flows in the basin. The CWMP determined that improved management for surface water through storage could

increase freshwater availability in the region and reduce potential impacts resulting from water use. The CWMP identified that at a conceptual level a storage reservoir with a capacity of 220,000 acre-feet (ac-ft) located in the lower West Caloosahatchee Basin would be adequate for environmental restoration of the Caloosahatchee Estuary.

Although the Restudy alternative provided information on the necessary storage volume, it did not provide project-specific details such as a location for the reservoir. Unlike the Restudy, the CWMP identified a suitable location for the storage reservoir in the Caloosahatchee Basin. Based on the findings of the CWMP, the West Basin Berry Groves site, together with adjacent and separately owned land south of the Caloosahatchee River, was identified as the ideal location for placement of a reservoir to meet the needs of the estuary.

Despite differences between the Restudy and the CWMP, both planning efforts arrived at the similar conclusion that above-ground water storage reservoirs were the most cost effective and appropriate method for the attenuation of freshwater runoff and capture of Lake Okeechobee inflows in the Caloosahatchee Basin.

1.7 CERP MASTER IMPLEMENTATION SEQUENCING PLAN

Included within Section 10 of the *Final Integrated Feasibility Report and Programmatic Environmental Impact Statement* dated April 1, 1999, was the original sequencing plan for the implementation of the CERP. Section 10 described the project implementation process and the schedules developed to implement the recommended Plan. Subsequent to the completion of the aforementioned environmental impact statement (EIS), the Implementation Plan was first updated in July 2001 and was known as the Master Implementation Schedule (MIS 1.0). MIS 1.0 updated the Implementation Plan and documented the status of CERP at that time.

The Master Implementation Sequencing Plan 1.0 (MISP 1.0), dated March 2005, built on these previous efforts and incorporated new information, implementation experience to date, and changes in legislation. The new information included the requirements in WRDA 2000 and the subsequent programmatic regulations, as well as the effects of the streamlining contained in the State of Florida's Acceler8 initiative (an accelerated implementation schedule for several CERP components). Acceler8 will hasten CERP implementation while maintaining the relationship of the MISP and the partnership between SFWMD and the USACE. The MISP 1.0 identified the Caloosahatchee River (C-43) West Basin Storage Reservoir project as a Band 1 project (completion in 2010) that would be constructed by the State of Florida under their Acceler8 program. The recommendations contained in this report for

additional investigations in the Caloosahatchee Basin may lead to an update of the next version of the MISP.

1.8 THE STATE OF FLORIDA'S ACCELER8 PLAN

The State of Florida has developed a plan called "Acceler8" for the purpose of accelerating design and construction of a number of critical restoration projects consistent with the CERP but prior to one or more of the following: Administration approval, Congressional committee resolution, Congressional authorization, or Federal construction funding. The State anticipates the Acceler8 program will provide immediate environmental, social, and economic benefits in the south Florida region. All Acceler8 projects must be specifically authorized by Congress before becoming a part of the Federal CERP. The SFWMD is the State agency responsible for water resources management in south Florida and acts as the non-Federal sponsor for Federal water resources projects, including CERP. The SFWMD is the lead agency for the State on implementing the Acceler8 plan and will need to acquire the Department of the Army permits under Section 404 of the Clean Water Act prior to construction.

The Acceler8 program consists of a number of projects, including "C-43 West Storage Reservoir Project." The Acceler8's C-43 Reservoir is referred to in this PIR as the Caloosahatchee River (C-43) West Basin Storage Reservoir project (see www.Acceler8Evergladesnow.org). The USACE and SFWMD anticipate that the SFWMD will accelerate construction and achievement of benefits of certain CERP projects by obtaining required permits and initiating construction upon completion of the Final EIS for the Federal CERP project.

The SFWMD proposes to construct the C-43 West Storage Reservoir Project, prior to implementation of the Federal Caloosahatchee River (C-43) West Basin Storage Reservoir project. The USACE is proceeding with two separate and independent but related actions: the planning evaluation of the Federal project and the regulatory evaluation of the SFWMD's proposed project, both of which are described in this Final PIR/EIS. The C-43 West Storage Reservoir Acceler8 project is the same as the selected alternative plan, described in this Final PIR/EIS. Therefore, it is anticipated that this Final PIR/EIS will also serve as the basis for the Regulatory Division's NEPA evaluation of the SFWMD's proposed Acceler8 project.

Concurrent with the Final PIR/EIS, the USACE Regulatory Division is circulating a Public Notice which describes the Acceler8 project and provides additional information applicable to the regulatory evaluation and is not included in this Final PIR/EIS. The Public Notice is available for public and agency review at the same time as this Final PIR/EIS for the proposed Federal project. For details of the SFWMD's proposed Acceler8 project or a copy of the

Public Notice, the reader is referred to the USACE's Jacksonville District web site at http://www.saj.usace.army.mil/pao/hotTopics/acceler8.htm.

1.9 LAND ACQUISITION ACTIVITIES

As described previously, storage of water within the Caloosahatchee Basin has been established as one of the primary management measures contributing to the goals and purposes of the Restudy. The SFWMD and others have been very proactive in acquiring lands needed for CERP implementation. Based on the findings of the Restudy and CWMP, which both call for a storage reservoir in the Caloosahatchee Basin, the SFWMD determined the best location to use both State and Federal funds to acquire property in the Caloosahatchee Basin. The Federal funds used for this project were appropriated to the DOI and a Grant Agreement entitled Everglades Watershed Restoration-Grant Number LWCF-1 was executed to acquire south Florida ecosystem restoration project lands in the C-43 Basin. The Florida Division of State Lands, in cooperation with the staff of the SFWMD, reached an agreement that allowed the SFWMD to acquire the Berry Groves and some adjacent property as a key component for Everglades restoration (February 2000). To date the State of Florida has purchased a total of 12,372 acres in the immediate area in anticipation of reservoir construction with Federal funding provided by the DOI at a total of approximately $32,800,000, a portion of which ($27,567,669) will be credited to the Federal government towards the acquisition of lands required for this project. SFWMD is the process of exchanging approximately 541 acres of this previously acquired land for approximately 600 acres adjacent to the property originally acquired. The revised total land would be approximately 12,430 acres. Of this approximately 12,430 acres, the Caloosahatchee River (C-43) West Basin Storage Reservoir project will require approximately 10,700 acres, of which approximately 10,480 acres will be required in fee, approximately 20 acres will be required in perpetual channel easement and approximately 200 acres will be required in temporary easements for staging areas.

The amount of the Federal credit may be increased or decreased based on more detailed analysis during the crediting review process after approval of the Project, execution of a Project Cooperation Agreement (PCA) and certification of land.

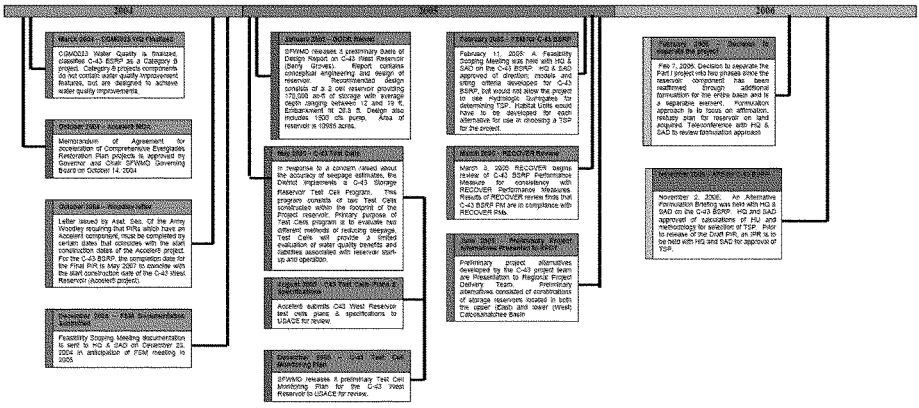

FIGURE 1-4: TIMELINE OF EVENTS AND MILESTONES FOR THE PROJECT (CONTINUED)

SECTION 2
EXISTING CONDITIONS/AFFECTED ENVIRONMENT

This page intentionally left blank

2.0 EXISTING CONDITIONS/AFFECTED ENVIRONMENT

2.1 GENERAL ENVIRONMENT

The Caloosahatchee River and Estuary extend about 70 miles from Lake Okeechobee to San Carlos Bay on Florida's southwest coast. The river basin drains an area of approximately 1,758 square miles. The Caloosahatchee River was originally a shallow, meandering river with headwaters in the proximity of Lake Hicpochee (Science Subgroup 1996). A canal was dredged to connect the Caloosahatchee to Lake Okeechobee in 1881, in order to lower the water table of Lake Okeechobee. It was first channelized to improve navigation and flood control from 1910 to 1930. Three lock-and-dam structures were added to control flow and stage height.

The most downstream structure (S-79) marks the beginning of the Caloosahatchee Estuary. Also referred to as the W.P. Franklin Lock and Dam, this structure maintains specific water levels upstream, regulates freshwater discharge into the estuary, and acts as a barrier to saltwater intrusion into the river. The Moore Haven Lock (S-77), located on the southwest shore of Lake Okeechobee, regulates lake waters. The Ortona Lock (S-78) aids in control of water levels on adjacent lands upstream and separates the Caloosahatchee River (C-43) into eastern and western basins.

Land use within the Caloosahatchee Watershed is dominated by pasture and agriculture, particularly in the upper part of the Caloosahatchee River basin. The West Coast has seen extremely high rates of urbanization in recent years. The major urban areas that occur along the Tidal Caloosahatchee watershed are Ft. Myers, on the south bank, and the large residential areas of Cape Coral and North Ft. Myers, on the north bank.

The Caloosahatchee River serves as an outlet from Lake Okeechobee to the Gulf of Mexico and is the major source of surface water supply for the lower west coast region. It provides agricultural and residential irrigation and public water supplies and is a source of drainage for private drainage systems and local drainage districts. The Caloosahatchee River makes up part of the Okeechobee Waterway, linking the Gulf of Mexico to the Atlantic Ocean through Lake Okeechobee and the St. Lucie Canal and River.

The project footprint covers approximately 10,700 acres, approximately 10,480 acres of land required in fee, approximately 20 acres of perpetual channel easement and approximately 200 acres of temporary easements for staging areas with all the land being located in Hendry County west of LaBelle. The site is a few miles south of State Road (SR) 80 and approximately two miles west of SR 29. The property is predominantly owned by the SFWMD and is under a leasing agreement with Jack M. Berry, Inc. for agricultural land use. Currently the

SFWMD is processing an exchange of 541.31 acres located north of the project boundary for the 600.1-acre Paul Property. This was necessitated by a requirement to locate the reservoir footprint away from existing power lines to the north and a need for additional lands to the east or west in order to maintain storage. The project site is currently a producing citrus grove. The site contains three major arterial canals that transport water for the purpose of irrigation and attenuation of Caloosahatchee Basin runoff waters. Two of the three canals, Roberts and Townsend, lie along the eastern and western perimeters of the footprint, respectively, The Header Canal, also called the LPDD Canal, transects the entire reservoir area and its use is primarily to cross feed water between the Roberts and Townsend Canals. These major canals are shown in ***Figure 2-1***.

Approximately 267 acres within the project site have been impacted through construction of the Caloosahatchee River (C-43) West Basin Storage Reservoir Test Cells Project. The SFWMD initiated construction of the test cells in January 2006, in order to evaluate seepage and water quality effects and improve embankment design. The test cells are also shown in ***Figure 2-1***.

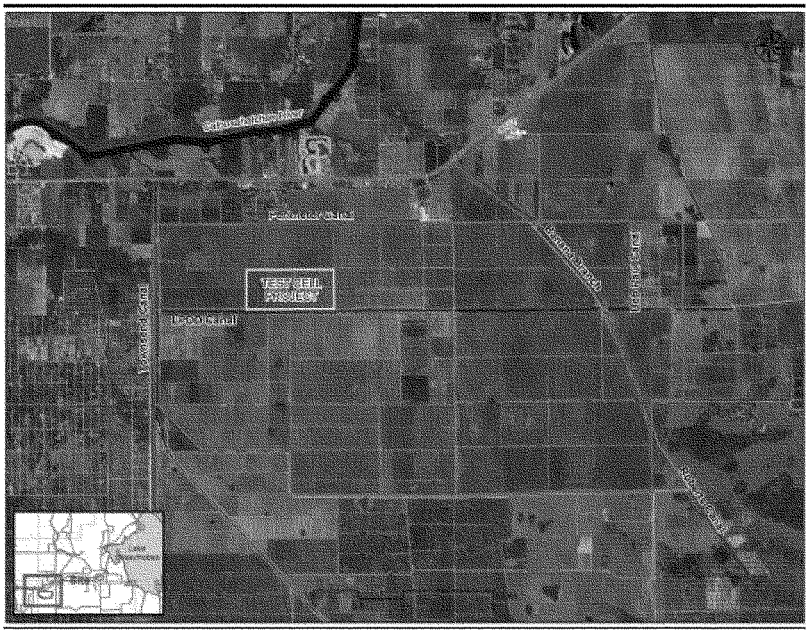

FIGURE 2-1: CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR SITE MAP

2.2 CLIMATE

The climate in southern Florida is subtropical and humid, with temperatures ranging from 60°F (16°C) in midwinter to around 80°F (27°C) in summer. The summer heat and humidity is tempered by frequent afternoon and evening thundershowers, which accounts for most of the region's rainfall. The winter months are dryer.

Average yearly rainfall is approximately 52 inches within the basin, with monthly averages ranging from two to ten inches. Two-thirds of the annual rainfall occurs in the wet season from May to October. There is also a high variability in rainfall at different locations in the basin. The inland portion of the basin receives more rain than the coast during the dry season. On average the wet season rainfall is greater along the coast. Although November is usually the driest month of the year, April is the month with the greatest water demand. During the spring months, cold fronts stall to the north of southwest Florida, causing drier weather and forcing water tables to their lowest levels of the year. This time of year is prone to frequent wild fires, sparked by the dry conditions.

Since climate will influence but not be influenced by the proposed project, it will not be further discussed in the evaluation of environmental effects later in this report.

2.2.1 Sea Level Rise

Sea level rise will have the most impact on coastal canals and communities, with loss of flood protection and increased saltwater intrusion being the primary impacts. Additionally, coastal ecosystems and estuaries may be adversely affected and would require additional deliveries of fresh water to maintain desirable salinity patterns and healthy ecosystems.

Sea-level rise is one of the more certain consequences of climate change, and because it affects the land/ocean interface, it has the potential for environmental impacts on coastal areas. Sea level rise will be discussed in Section 3.2 Future Without Project Condition, but will not be discussed in the evaluation of environmental effects later in this report since it will not be influenced by the proposed project.

2.3 PHYSICAL LANDSCAPE

2.3.1 Geology

A portion of the Caloosahatchee Drainage Basin, which encompasses both Collier and Hendry Counties, lies within the physiographic region denoted as the Sandy Flatlands or Gulf Coastal Lowlands, is characterized by terraced plains.

These terraced plains largely control the topography of the area that extends northward into Glades and Charlotte counties, westward to the Gulf of Mexico, and southward into Monroe County. The sands were deposited as three marine terraces: Talbot, Pamlico, and Silver Bluff, all of which were produced during the Pleistocene Epoch. The Talbot terrace ranges from 25 to 42 feet above sea level and is considered the highest in elevation within the subject area. The Pamlico terrace ranges from eight to 25 feet above sea level, and the Silver Bluff terrace, the lowest in elevation; is less than ten feet above sea level and gradates toward the western seaboard.

2.3.2 Soils

The soils of the Caloosahatchee River Basin are dominated by somewhat poorly drained sandy soils. These soils are considered recent deposits of limestone origin, underlain by marl and/or limestone.

A geotechnical engineering evaluation performed at the project site encountered a surficial layer of sands with isolated zones of silty sand material, one to fifteen feet thick. Below this sandy deposit, a layer of interbedded zones of silty sand, clayey sand, sandy clay, and sandy silt materials, 1 foot to 20 feet thick, was encountered. Below this sand/silt/clay mix deposit, limestone material was generally encountered with a thickness ranging from 2 feet to 12 feet, with isolated areas where the limestone deposit was thicker than 30 feet. Some of the borings performed did not encounter the limestone material. Below the limestone material and until boring termination depths, clayey deposits were encountered. These clayey deposits mainly consist of sandy silt, sandy clay, and clayey sand materials.

2.3.3 Aquifers

Three major aquifers, or producing zones, and three confining beds have been identified within the sequence of rocks for the study area. The upper surficial aquifer consists of sands, shells, and limestones, within the sediments of the Ft. Thompson and Tamiami Formations that are Holocene-Pliocene age, respectively. This aquifer and the lower Tamiami/Ochopee aquifer are separated by the Bonita Springs Marl confining unit. Below the lower Tamiami aquifer lies another confining unit of the Miocene age sediments, Upper Peace River confinement. The Sandstone aquifer is sandwiched between the Upper Peace River and Basal Peace River confining unit.

The lower Hawthorn/Tampa producing zone (which includes the basal part of the lower Hawthorn aquifer of Sproul et al., 1972) and the Suwannee aquifer are considered parts of the Floridan Aquifer System (FAS).

2.4 HYDROLOGY

Water for urban and agricultural uses in the Caloosahatchee River (C-43) Basin is supplied from both groundwater and surface water systems. Surface water is used primarily for agricultural irrigation, with groundwater being used in areas that do not have access to the river. In addition, the Caloosahatchee River is a potable water supply source in Lee County. Groundwater and surface water are dependent upon rainfall for recharge.

The Caloosahatchee River (C-43 Canal) receives water from Lake Okeechobee, runoff from the basin, and base flow from the Surficial Aquifer System (SAS). The river in turn supplies water for public supply, agriculture, and the environment. This source can be unreliable during the dry season or in periods of inadequate rainfall, when releases are required from Lake Okeechobee to meet demand. The USACE manages the Caloosahatchee River (C-43 Canal) via a regulation schedule, which presently accommodates navigation, flood protection, water supply, and environmental needs.

The Lake Okeechobee Demand Service Area (LOSA), defined as the area that is or could be supplied by surface water from the Caloosahatchee River, is the primary source for agricultural irrigation and surface potable water supply in the Caloosahatchee Basin. This area extends from the Franklin Lock (S-79) eastward to the Moore Haven Lock (S-77) and includes land in Lee, Glades, and Hendry counties.

Other surface water bodies in the Caloosahatchee Basin area include lakes, rivers, and canals. These areas provide storage and allow conveyance of surface water. Lake Hicpochee is the largest lake in the area and is bisected by the Caloosahatchee River (C-43) just west of Lake Okeechobee. Numerous canals and tributaries in the basin area drain into the Caloosahatchee River. The major tributaries are the Orange River and Telegraph Slough, which drain into the Caloosahatchee River (C-43) in the western portion of the basin near W. P. Franklin Lock and Dam (S-79). The majority of the canals in the basin were constructed as surface water drainage systems rather than for water supply purposes.

Surface water flows in the basin are derived from rainfall within the basin and discharge from Lake Okeechobee. Runoff from the West Caloosahatchee Basin is slightly higher than runoff from the East Caloosahatchee Basin indicating greater flow attenuation in the eastern basin due to the flatness and thick, sandy soils (Fan and Burgess, 1983). Inflow from Lake Okeechobee is the primary flow in the river during the dry season. Water is released from the lake to meet the supplemental agricultural water demand as well as supplying water for municipal consumptive use. Water is also released to reduce lake stages before the hurricane season. High volume water releases to lower Lake

Okeechobee during high rainfall seasons may result in very high flows to the estuary. There is little water storage in the basin. The intensive drainage on the south side of the river provides little storage. The north side of the river is largely undeveloped west of Lake Hicpochee, and although there is considerable wetland water storage, it is not managed water storage.

Groundwater is an important component of the agricultural water supply in the freshwater portion of the Caloosahatchee Basin. The groundwater resources in the area include the surface aquifer, the intermediate aquifer and the Floridan aquifer system (FAS). The yield and storage of the groundwater is highly variable throughout the basin. Where ever it is possible, surface water has been used for irrigation purposes. The surface aquifer system (SAS) is used for some irrigation in eastern Hendry and Glades counties.

The intermediate aquifers are used primarily for irrigation in the western portion of Hendry County. There is local recharge to both the surficial and intermediate aquifers. The Floridan aquifer which is located in the northwest corner of the Caloosahatchee Basis is used for irrigation in northern Glades County (groundwater is mixed with surface water for irrigation use). The water from the FAS is too highly mineralized elsewhere in the basin. This deep aquifer is recharged from outside the area.

There are three structures that provide for navigation and water control in the Caloosahatchee River (C-43 Canal). These structures serve to control the water stages in Caloosahatchee River (C-43) from Lake Okeechobee and the Moore Haven Lock (S-77) to W. P. Franklin Lock and Dam (S-79). Water levels upstream of the Ortona Lock (S-78) are maintained at approximately 11 feet National Geodetic Vertical Datum (NGVD), and three feet NGVD downstream. The W. P. Franklin Lock and Dam (S-79) serves as a saltwater barrier and maintains an upstream level of approximately three feet while the downstream NGVD elevation is generally near one foot. The operation schedule for these structures is dependent on rainfall conditions, agricultural practices, the need for regulatory releases from Lake Okeechobee, and the need to provide water quality control for the Public Water Supply (PWS) facilities. Detailed operation information for structures S-77, S-78, and S-79 can be obtained from the Water Control Plan for Lake Okeechobee and the Everglades Agricultural Area (EAA), Jacksonville District, USACE, July 2000.

The project site has numerous agricultural canals that provide water control. A large, deep, east/west canal (Header Canal) bisects the north central portion of the grove and drains into the Townsend Canal along the western and southern boundaries. Other smaller east/west canals drain into north/south canals that drain into the Header Canal. In most areas, north/south ditches are spaced every 250 feet and drain beds containing nine to ten rows of citrus trees. ***Figure***

2-2, Caloosahatchee River (C-43) West Basin Storage Reservoir Wetland and Surface Water Map, shows the extensive network of canals and ditches within the project site.

2.5 WATER MANAGEMENT

2.5.1 Water Supply

The Caloosahatchee River is the major source of surface water supply for the lower west coast region. It provides agriculture and lawn irrigation, potable water supply and also provides drainage for private drainage systems and local drainage districts.

The Caloosahatchee River Estuary is a large system where the waters of the Gulf of Mexico mix with the freshwater inflows from the river, sloughs, and overland sheetflow in the basin. The area is characterized by a shallow bay, widespread seagrass beds and sand flats. Extensive mangrove forests dominate undeveloped areas of the shoreline.

Lake Okeechobee is the largest freshwater lake in the southeastern United States, covering 730 square miles. It receives significant volumes of runoff from the Kissimmee River (beginning near Orlando), the Upper Chain of Lakes, Lake Istokpoga, and numerous small inflows along its the north shore. During the predevelopment period, Lake Okeechobee discharged to the south and west, into the Everglades and occasionally into the Caloosahatchee Basin during high water periods. The USACE and the SFWMD now control outflows from Lake Okeechobee and can direct flows via an intricate canal system southward into the EAA, to the southeastern coastal urban areas, to the Atlantic Ocean via the St. Lucie River, or to the Gulf of Mexico via the Caloosahatchee River. Inflows to Lake Okeechobee are now faster than they were during the pre-development period, due to channelization of the Upper Chain of Lakes and the Kissimmee River. Additionally, Lake Okeechobee is now confined within its banks by encircling levees (the Herbert Hoover Dike [HHD]) and the historic overflows to the south can no longer occur. During unusually wet years, Lake Okeechobee levels rise until water must be released to the west and east coasts through the Caloosahatchee (C-43) and St. Lucie (C-44). Thus, the Caloosahatchee River (C-43 Canal) now carries late wet season flows that are higher than occurred prior to its connection to Lake Okeechobee. During the end of the dry season or during unusually dry years, flows in the river are lower than historic flows, due to increased water supply demand in the basin.

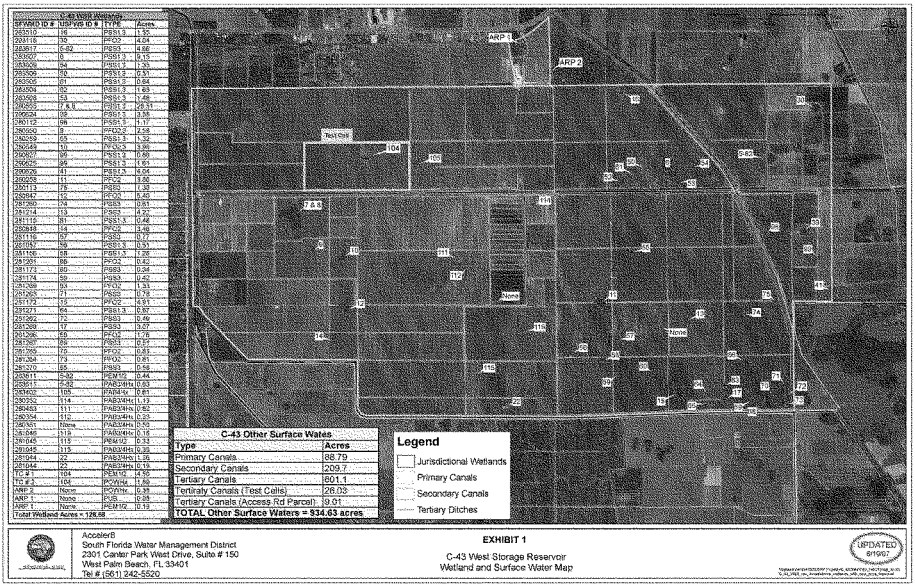

FIGURE 2-2: CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR WETLAND AND SURFACE WATER MAP

2.5.2 Water Demands

Non-environmental surface water demands within the basin are primarily agricultural with some potable water supply, commercial and industrial uses. The commercial and industrial demands vary greatly by type of business. In the project vicinity, commercial and industrial demands constitute about one percent of the overall water demand. Because the demand is relatively small and difficult to generalize, an average demand is not calculated for this use category. The emphasis is placed on estimation of agricultural and potable water uses.

A thorough investigation of water use for the Caloosahatchee River and surrounding basins was conducted by the SFWMD for the CWMP. Detailed information derived from this investigation can be found in the SFWMD CWMP Planning Document, April 2000. ***Table 2-1*** summarizes the water use allocation for major agricultural land use categories for the CWMP area based on the Integrated Surface Water/Ground Water Model.

TABLE 2-1: SUMMARY OF 1995 WATER USE DEMAND BASED ON THE INTEGRATED SURFACE WATER/GROUND WATER MODEL FOR MAJOR AGRICULTURAL LAND USE CATEGORIES

Crop	Water Use (acre-feet/year)
Citrus	143,000
Sugarcane	110,000
Vegetables	36,000
Total	290,000

Note: Based on 1995 land use, MIKESHE results indicate an additional 30,000 acre-ft/year of irrigation in addition to citrus, sugarcane and vegetables.

2.5.3 Water Usage

Every five years, the U.S. Geological Survey (USGS) estimates annual water withdrawals for Florida at the county-level. The most recent publication of findings was entitled "Water Withdrawals, Use, Discharge, and Trends in Florida, 1995" (USGS, 1995). Water use estimates for 2000 were not published at the time of this analysis. However, unpublished water use estimates for 2000 for the counties included in this water use analysis were obtained from the USGS. These uses are distributed as public-supply and self-supply domestic (residential), commercial, industrial, government, and recreational water use estimates, along with unaccounted-for water loss estimates. ***Table 2-2*** presents the USGS estimate of water use, excluding mining and power generation water use, for 2000 for the four county study area. Total public-supply water use for the region is estimated at 71.85 million gallons per day (MGD), and total

municipal and industrial (M&I) water use is estimated at 115.17 MGD. The addition of the 680.63 MGD of agricultural water use increases total water use for the region to 796.24 MGD. Agricultural water use accounts for 85 percent of the total use; public-supply water use accounts for nine percent and recreational self-supply accounts for about 3 percent.

On the county level, the largest total water user in the study area in 2000 was Hendry County, mainly because of agricultural water use. Hendry County used a total of 512.11 MGD, or 64 percent, of the total regional water use. Of this amount, 503.91 MGD (or 98 percent) was agricultural use and 4.72 MGD was public-supply M&I water use. Lee County's public-supply water use was about 52 MGD. Lee County's total water use was 144.95 MGD, the third highest in the region. Lee County had the highest self-supply domestic water use in the region at 8.86 MGD. Lee County also had high recreational water use of 22.66 MGD.

TABLE 2-2: USGS ESTIMATED TOTAL WATER USE, FOR SELECTED COUNTIES, 2000-EXCLUDING MINING AND POWER GENERATION (MGD)

	Municipal and Industrial							
		Self-Supply						
County	Public Supply	Domestic	Commercial	Industrial	Recreation	Sub Total	Agriculture	Grand Total
Charlotte	14.21	3.55	0.11	0	3.48	21.35	47.19	68.54
Glades	0.55	0.61	0.04	0	0.42	1.62	69.02	70.64
Hendry	4.72	1.67	0.21	0.51	1.09	8.2	503.91	512.11
Lee	52.37	8.86	0.46	0.09	22.66	84.4	60.51	144.95
Total	71.85	14.69	0.82	0.6	27.65	115.57	680.63	796.24

NOTE: Recreation self-supply water use includes golf course irrigation.

2.6 WATER QUALITY

The water quality conditions upstream and downstream of the S-79 structure were evaluated as part of recent Florida Department of Environmental Protection (FDEP) efforts within the Caloosahatchee River (C-43) Basin. The FDEP Verified List for the Caloosahatchee, (FDEP June, 2005) identifies impaired waters in the Caloosahatchee River (C-43) sub-basin as well as the Caloosahatchee Estuary sub-basins. The report was prepared in order to meet the requirements of the Federal Clean Water Act (CWA). Under Florida's implementation of the CWA, waters listed as impaired are then subject to the development of Total Maximum Daily Loads (TMDLs) intended to limit the future discharge of the offending pollutant by point and non-point contributors.

The FDEP has divided the Caloosahatchee Basin into five planning units. Two planning units, East Caloosahatchee and West Caloosahatchee, are the two sub-

basins that are upstream of the S-79 structure on the Caloosahatchee River (C-43 Canal). The three remaining planning units, Telegraph Swamp, Orange River, and Caloosahatchee Estuary, are downstream of the S-79 structure. To date, the EPA and DEP have developed several TMDLs within the Caloosahatchee Basin. For instance, for water body 3256 located in the East Caloosahatchee Planning Unit, TMDLs have been proposed for BOD, total nitrogen, and total phosphorus. In addition a TMDL has been developed for fecal coliform for 9-mile canal. As part of the subsequent Caloosahatchee Watershed PIR, the Corps and the SFWMD will coordinate with EPA and DEP in the ongoing development of additional TMDLs for the basin. In 2002, the FDEP performed a study to determine the relative loadings of total nitrogen and total phosphorus in the Caloosahatchee River (C-43) Basin (Janicki, 2002). This report ranks the sub-basins within the Caloosahatchee River (C-43) Basin in terms of their relative contribution of total nitrogen (TN) and total phosphorus (TP).

A third study, the Caloosahatchee Water Quality Data Collection Program" (ERD, 2002) sponsored by the SFWMD, quantifies pollutant concentrations and loads from the various sub-basins within the Caloosahatchee River (C-43) Basin. Summaries of water quality conditions for upstream and downstream of S-79 are presented below using the above referenced documents as well as other existing information.

2.6.1 Water Quality Conditions Upstream of S-79

2.6.1.1 Impaired Waters

The East Caloosahatchee and West Caloosahatchee planning units are the two sub-basins that lie upstream of the S-79 structure. While all of the East Caloosahatchee sub-basin is upstream of the planned reservoir, approximately 70 percent of the West Caloosahatchee sub-basin is upstream of the planned reservoir. The water quality conditions in these two sub-basins will have a significant impact on the reservoir water quality. The predominant land use in both of these planning units is agriculture. Water quality impairments in this sub-basin are primarily caused by non-point sources rather than point discharges from sewage treatment plants or other industrial activity. Within the East Caloosahatchee unit, six water body segments have been identified as impaired. Within the West Caloosahatchee planning unit, a total of three water body segments have been identified as impaired. The impairments are lead, coliforms, iron, dissolved oxygen, copper, and nutrients. In the West Caloosahatchee planning unit, there are three water bodies that have been identified as impaired; one is impaired for iron and lead, one is impaired for nutrients, and the third water body, the Townsend Canal (located immediately upstream of the planned reservoir intake) which has direct interest to this project, is impaired for copper and lead.

2.6.1.2 Pollutant Loading

Water quality pollutant loading upstream of the S-79 structure is composed of loading from runoff generated within the basin and from loading that results from Lake Okeechobee releases. Excluding the load from Lake Okeechobee releases, approximately 50 percent of the TN load resulting from runoff in the Caloosahatchee Basin comes from basin lands upstream of S-79. Similarly, excluding the phosphorus load from Lake Okeechobee releases, approximately 65 percent of the TP load resulting from runoff in the Caloosahatchee Basin comes from basin lands upstream of the S-79. When Lake Okeechobee flows and loads are included, more than 75 percent of TN and TP loads to the Caloosahatchee Estuary are a result of discharges at S-79 (ERD, 2002).

2.6.2 Water Quality Conditions Downstream of S-79

2.6.2.1 Impaired Waters

The three watershed planning units downstream of S-79 are Telegraph Swamp, Orange River, and Caloosahatchee Estuary. Within these three planning units, land use patterns transition from agricultural/natural areas in the east to residential in the west. In the FDEP Verified List, there are no impaired waters in Telegraph Swamp planning unit.

As the furthest downstream planning unit, the Caloosahatchee Estuary has to contend with its own pollution plus pollutants from the four upstream planning units. According to the June 2005 (FDEP) Verified List for the Caloosahatchee, the estuary-planning unit has 13 impaired water body segments, six of which are part of the main estuary and seven of which are tributary streams. All thirteen listed water body segments are impaired for coliforms (either total or fecal), seven are impaired for nutrients, six are impaired for dissolved oxygen, three are impaired for heavy metals (copper, lead), and one is impaired for specific conductivity. The FDEP Basin Status Report (FDEP 2002) states that the observed water quality violations are probably linked to urban land uses within the Caloosahatchee Estuary planning unit, poorly flushed residential tributary streams, and the effect of heavy pollutant loads discharged from upstream sub-basins.

2.6.2.2 Pollutant Loading

Within the Caloosahatchee Estuary planning unit there are a total of 31 permitted sewage treatment plants. The Caloosahatchee pollutant loading report (ERD 2002) includes pollutant-loading estimates for the four largest sewage treatment plants in the Caloosahatchee Estuary as well as for eight tributaries downstream of the S-79 structure. This report includes loading estimates for the following pollutants: ammonia, nitrate, nitrite, total kjeldahl

nitrogen, TN, orthophosphorus, TP, and total suspended solids. With the exception of ammonia, ten percent or less of the wet or dry season load of each of these pollutants to the Caloosahatchee Estuary comes from the portion of the watershed downstream of the S-79 structure. During the dry season, approximately five percent of the total ammonia load in the estuary comes from the portion of the watershed downstream of the S-79 structure; however, during the wet season, approximately 40 percent of the ammonia load to the estuary comes from downstream of the S-79 structure. A relatively large amount of the ammonia loading from downstream of the S-79 structure comes from the four large sewage treatment plants. The Caloosahatchee Estuary non-point sources of TN and TP contribute around 20 percent of the total loads delivered to the estuary.

2.6.3 Sediment Quality

Unlike the St. Lucie Estuary, a geographically extensive muck sediment layer is not present in the Caloosahatchee Estuary. This is evidenced by the presence of both freshwater and marine submerged aquatic vegetation (SAV) that usually do not coexist in areas where muck sediments are present. Scientists from the SFWMD and U.S. Fish and Wildlife Service (USFWS) have concluded that flocculent sediments are not a significant cause of water quality problems in the main channel of the Caloosahatchee Estuary.

In 1999 the USGS collected 58 sediment samples from downstream of the S-79 structure and two sediment samples from just upstream of the structure. The five sampling locations relative to the S-79 structure were downstream at mile 3.1, 9.3, 10.5, 12.2, and 23.8. Samples were tested for physical characteristics, organic content, pesticides, and heavy metals. Heavy metal results were compared with Florida Sediment Quality Assessment Guidelines (SQAG). Samples from five sites contained heavy metals (chromium, copper, lead, mercury, and zinc) at levels that exceed the Probable Effects Level (PEL) concentration published in the Florida SQAGs. Although a limited number of samples exceeded the PEL concentrations, bioaccumulation and bioconcentration studies would have to be done to quantify the impact of these sediments on in-situ biota. At present, there is no reason to believe that sediment contamination is a significant concern within the main stem of the estuary.

2.7 PLANT COMMUNITIES

The project footprint is currently an active citrus grove. Natural/biological features and land use within the Caloosahatchee River (C-43) West Basin Storage Reservoir project area were initially reviewed using the 2000 Florida Land Use, Cover and Forms Classification System (FLUCFCS) Geographic Information System (GIS) data. Citrus grove covers approximately 90 percent of the study site, more than any other land cover type. The citrus grove land use

classification includes acreage covered by citrus trees, grove maintenance roads, and small berms, brush piles, and other small features related to citrus grove operations. Open water comprises 8.9 percent of the site and includes extensive agricultural canals/ditches, classified as streams and waterways, and excavated ponds, classified as reservoirs less than 10 acres in size. Wetlands which are further discussed in Section 2.8 below comprise 1.1 percent of the site and include mixed wetland hardwoods, willow and elderberry, exotic wetland hardwoods, cypress, wetland shrub, and freshwater marsh.

Citrus groves, row crops and improved pasture with scattered cypress and mixed wetland hardwoods flank the project to the north, east, and south. The area to the north of the project site also contains some low-density residential areas. Forested uplands (parceled into low-density residential lots, various stages of development) such as pine flatwoods, longleaf pine-xeric oak, sand pine, and xeric oak are adjacent to the west of the project. At a landscape level, the Caloosahatchee River (C-43) West Basin Storage Reservoir project is surrounded by a matrix of agricultural, forested, and wetland land cover types, with pockets of urban land use. Urban areas are present to the southwest and northeast of the project area with small parcels along the Caloosahatchee River. Regions to the northwest and southeast of the project area are generally undeveloped.

2.7.1 Exotic Species

Because of its mild climate, international seaports, cultural diversity, and lenient importation laws, Florida has been the epicenter for more exotic species than almost any other region in the country. Some species have remained localized around the release sites, some have died off, and many have extended their ranges to other states. The most severe exotic species threats to the southwest Florida ecosystem come from plants, rather than animals. Therefore, the emphasis on exotics in Florida has been on flora, rather than fauna. The top seven exotic plant species include: Australian pine (*Casuarina* spp.), water hyacinth (*Eichornia crassipes*), hydrilla (*Hydrilla verticillata*), Old World climbing fern (*Lygodium microphyllum*), Melaleuca (*Melaleuca quinquenervia*), torpedo grass (*Panicum repens*) and Brazilian pepper (*Schinus terebinthefolius*) (Schmitz 1994).

Three of the exotic species found in the wetlands (Brazilian pepper, water lettuce, and water hyacinth) are classified by the Florida Exotic Pest Plant Council (EPPC) as Category I exotic species. Category I species are invasive exotics that are altering native plant communities by displacing native species, changing community structures or ecological functions, or hybridizing with natives. This definition does not rely on the economic severity or geographic range of the problem, but on the documented ecological damage caused.

2.8 WETLANDS

The 2000 FLUCCS GIS data set developed by the SFWMD for the Southwest Florida Feasibility Study (SWFFS) represents the most accurate wetland information available for the Caloosahatchee River Basin and was used for preliminary analyses of wetlands present in the Caloosahatchee River (C-43) West Basin Storage Reservoir Project site. Additional information on wetland location, acreage, type, and habitat function within the reservoir footprint was obtained during interagency field surveys conducted June 8 to 11, 2004, and February 21, 2007; during helicopter surveys conducted June 14 and 15, 2004; and from National Wetlands Inventory Maps and the SFWMD's November 2006 Department of the Army Permit application for the Acceler8 C-43 West Storage Reservoir Project.

In July 2004, the PDT used the Wetland Rapid Assessment Procedure (WRAP) (Miller and Gunsulas, August 1999) to assess existing wetland function within the Berry Grove property. The WRAP analysis and score sheets are further described in the Final CAR contained in ***Annex A***. IN 2007, the SFWMD, USACE, USFWS, and USEPA used the Uniform Mitigation Assessment Methodology (UMAM) Chapter 62-345 F.A.C., to reassess existing wetland function within the project area for SFWMD's Acceler8 regulatory action. The UMAM analysis was performed as a result of the State of Florida adopting UMAM as a rule in February 2004. Subsequently the USACE Regulatory Division agreed to use UMAM as the preferred functional assessment for evaluating impacts to aquatic resources for determining compensatory mitigation. See the Final CAR in ***Annex A*** for more detailed information on wetlands.

Wetlands are areas where water covers the soil, or is present either at or near the surface of the soil, for all or part of the year. Wetlands have characteristic soils, water saturation (hydrology), and plant species. The protracted inundation supports the development of distinctive wetland (hydric) soils. The hydrology largely determines the types of plant and animal communities living in and on the soil. Wetlands may support vegetation more commonly associated with water (aquatic species), land (terrestrial species), and/or facultative species that are adapted to both aquatic and terrestrial communities. Wetlands usually support the growth of plants that are particularly adapted to wet conditions (hydrophytes).

Based on the 2000 land use/cover data and maps, wetlands comprise approximately 135,277 acres (15.9%) of the land cover within the Caloosahatchee Basin. The wetland cover classes occurring in the Caloosahatchee River Basin include freshwater marsh and wet prairie, slough waters, wetland hardwood forest, wetland coniferous forest (cypress swamp and cypress/pine/cabbage palm) wetland mixed forest, mangrove swamp, and salt marsh. Other aquatic habitats

in the Caloosahatchee River Basin include streams and waterways, lakes, and reservoirs. Those habitats comprise approximately 21,682 acres (2.5%) of the land cover within the Caloosahatchee River Basin.

Based on 2000 land use/cover maps, field surveys, and additional information referenced above, 51 wetlands were identified within the reservoir footprint. Those 51 wetlands comprise approximately 112 acres (less than 1.1%) of the land cover within the reservoir footprint, and include several different land use cover classes (freshwater marsh, wet prairie mixed wetland hardwood, mixed wetland hardwood shrub, cypress, cypress/pine/cabbage palm, exotic wetland hardwood, and "reservoir less than 10 acres). Additional aquatic habitats identified include other surface waters such as agricultural ditches and canals which comprise approximately 914.5 acres (8.8%) of the land cover within the reservoir footprint. The remaining land cover within the footprint is predominantly citrus groves. These acreages were refined during a field visit by the USACE Regulatory Division on February 21, 2007, to verify the jurisdictional limits of the upland/wetland boundaries. As shown in ***Figure 2-2***, jurisdictional wetlands comprise 131.40 acres and other surface water comprises 925.62 acres of the total project area. Of these totals, 6.39 acres of wetlands and 26.03 acres of tertiary canals have already been impacted as a result of construction of the Caloosahatchee River West Basin Storage Reservoir Test Cells Project with 125 acres of wetlands and 899.59 acres of other surface waters remaining. This acreage also includes the entire limits of a wetland on the eastern perimeter of the project that is partially within the project footprint.

Development of the on-site citrus groves included perimeter ditching and regular placement of internal ditches to facilitate rapid removal of excess stormwater and control the depth of the water table. Surface water management regulations require that drainage/irrigation systems be engineered to reduce the potential for off-site flooding from increased runoff. Regulations also require that runoff from small storms be detained to prevent surface water quality degradation from fertilizers and pesticide use. Thus, efforts have been made to incorporate as many existing wetlands and flow ways into the local agricultural reservoir and wet detention system (i.e., impounded wetlands) to attenuate stormwater runoff and provide water quality treatment through sedimentation and nutrient uptake by wetland plants. Small outlying wetlands that could not be included in the reservoir system were not converted to citrus and were left in the landscape sometimes surrounded by ditches and/or dikes. Consequently, the water delivery to and the timing, depth, and duration of inundation of the on-site wetlands was altered resulting in changes to the vegetative community composition over time. For example, impounded wetlands may have become over-inundated while isolated wetlands generally have shortened hydroperiods when compared to hydrologic conditions prior to the citrus grove development.

Thus, wetlands in citrus groves are typically considered "impacted" wetlands or have been converted to reservoirs or wet detention areas.

2.9 FISH AND WILDLIFE RESOURCES

Life cycles, community structure and population densities of the fauna of south Florida are intricately linked to regional hydrology. The existing condition of fish and wildlife has been strongly influenced by the cumulative effects of drainage activities in the early 20th century, the C&SF Project, and the ensuing agricultural and urban development. A critical link in the aquatic food webs, and one that appears to have been adversely impacted by hydrologic alterations, is the intermediate trophic level of the small aquatic fauna. Small marsh fish, macro-invertebrates, and herpetofauna form the link between algal and detrital food web bases of the Everglades, and the larger fish, alligators, and wading birds that feed upon them. Aquatic fauna populations of south Florida are currently diminished due to a reduction in the spatial extent of Everglades wetlands (estimated loss of 50 percent) and changes in hydrology of the remaining wetlands.

As an active citrus grove, the proposed project site provides some limited wildlife habitat.

2.9.1 Estuarine and Riverine Invertebrates

The open bottom habitats in the estuarine and tidal Caloosahatchee are composed of mixtures of sand, mud, shell, and bedrock. Mollusks compose one the larger groups of macroinvertebrates within the Caloosahatchee ecosystems. The wedge clam (*Rangia cuneata)* and marsh clam (*Polymesoda carolineata)* are commonly found associated with mud and sandy bottoms in the Caloosahatchee Estuary. The common oyster (*Crassostrea virginica*) is the dominant species in the oyster reef community. Oyster bars serve as a food source and provide habitat for numerous estuarine species including other mollusks, polychaete worms, decapod crustaceans, and various boring sponges. The more common shrimp species include the pistol (*Alpheus* spp.), common (*Palaemonetes* spp.), grass (*Hippolyte* spp.) and broken-back (*Hippolyte pleuracantha*). The fisheries for the blue crab (*Callinectes sapidus*) are the largest, year-round fisheries in the upper and middle portion of the Caloosahatchee River. Other crab species occurring within the region are the spider (*Libinia emarginata*), fiddler (*Uca* spp.), horseshoe (*Limulus polyphemus*), stone (*Menippe mercenaria*) and hermit (*Pagurus* spp.). Sand dollar (*Echinarachnius* spp.) and starfish (*Solaster* spp., *Crossaster* spp. and *Ophioderma* spp.) are predatory invertebrates also found within the Caloosahatchee Estuary.

2.9.2 Amphibians and Reptiles

Many non-listed reptile and amphibian species are found in the Caloosahatchee Basin. These species provide recreational opportunities for residents as well as a forage base for many listed and non-listed wildlife species. Florida softshell and Florida red-belly turtles are common in the area. Southern black racers (*Coluber c. priapus*) and numerous water snakes are present throughout the waters of the basin. Other snake species likely to use these areas include the corn snake (*Elaphe guttata guttata*), yellow rat snake (*E. obsolete quadrivittata*), Everglades rat snake (*E. obsoleta rossalleni*), Florida kingsnake (*Lampropeltis getulus floridana*), Eastern coral snake (*Micrurus fulvius*), Florida cottonmouth (*Agkistrodon piscivorus conanti*), dusky pygmy rattlesnake (*Sistrurus miliarius barbouri*), Eastern diamondback rattlesnake (*Crotalus adamanteus*), coachwhip (*Masticophis flagellum flagellum*), rough green snake (*Opheodrys aestivus*), southern ringneck (*Diadophis punctatus punctatus*) and Eastern mud snake (*Farancia abacura abacura*). Alligators (*Alligator mississippiensis*) are numerous throughout southern Florida. Lizards found in the area include the six-lined racerunner (*Cnemidophorus sexlineatus*), southeastern five-lined skink (*Eumeces inexpectatus*), ground skink (*Scincella lateralis*) and green anole (*Anolis carolinensis*). Amphibians likely to be present include the southern toad (*Bufo terrestris*), spring peeper (*Hyla crucifer*), green treefrog (*H. cinerea*), Florida chorus frog (*Pseudacris nigrita verrucosa*), pig frog (*Rana grylio*) and southern leopard frog (*R. utricularia*).

2.9.3 Fish

The freshwater fishes of the Caloosahatchee River are a mix of northern freshwater species, marine species, and exotics. Among the principally marine species are the tarpon (*Megalops atlantica*), American eel (*Anguilla rostrata*), and mullet (*Mugil* spp.). These fish occasionally move far inland via canals and rivers. Freshwater fishes occupy at least nine different habitats common to the watershed. These include ponds, lakes, streams, marshes, prairies, river channels, and oxbows. These habitats may be broken down even further based on seasonal factors such as deep marsh and shallow marsh and seasonal or permanent ponds. Water quality, flora, and topographic distinctions of similar sites may also influence site suitability for certain species.

Aquatic habitats throughout the basin have been altered through channelization of river segments or are artificially created. Nevertheless, most areas support fishery resources of recreational and commercial importance. Recreational fishing is prevalent throughout the basin. Fishery resources are an economically important resource and have a large annual dollar value. Estuaries provide important habitat (i.e., nursery, escape cover, feeding grounds) for a variety of freshwater, marine, and estuarine-dependent fish and shellfish. Most economically important saltwater fishes and crustaceans spawn offshore and

then use estuarine areas for nursery habitat. Different species use the same location in different seasons, and different life stages of the same species use different locations. Some marine species have estuarine-dependent life stages, typically larval and juvenile stages, which use estuaries as nursery habitat. Larvae or juveniles immigrate on incoming tides and take advantage of the high productivity of the estuary.

Factors affecting the composition of the freshwater fish community in southwest Florida are fluctuating water levels, predation, geographic location, and habitat alteration. When water levels remain high for an extended time, larger predatory fish move into refuges previously safe from carnivores, and the smaller fish disperse into new shallows (Kushlan 1976a). The increased habitat space permits the expansion of the fish population. Continued decreases in water levels concentrate physical, chemical and biological materials and may eventually cause a fish kill or feeding frenzy. In addition to fluctuating water levels and predator-prey interactions, fish community composition differs geographically. Each aquatic habitat type exhibits a different set of physical/chemical characteristic and fish community.

Destruction of littoral zones, plant removal, channel dredging, contaminated run-off from agricultural lands and urban centers, and the drawdown of shallow aquifers are major examples of habitat alteration. Habitat alterations may also be caused by opening undisturbed water to invasion by exotic plants and fishes. Roadside ditches provide a convenient corridor for transporting species across former obstacles.

Six of the species of exotic fish currently established in southern Florida are members of the tropical secondary freshwater family Cichlidae, a highly diversified group considered to be in many ways the ecological counterpart of the centrarchids. Members of this family are generally well adapted to withstand drought. It is anticipated that the spread of cichlids will be at the expense of the native centrarchids. The future of both the exotic and native fish fauna should be a matter of concern.

2.9.4 Birds

The south Florida ecosystem is located along one of the primary migratory routes for bird species that breed in temperate North America and winter in the tropics of the Caribbean and South America. Because the south Florida ecosystem is located near Cuba and the West Indies, it draws Caribbean species that rarely appear elsewhere in North America. Fifteen species of herons, storks, and ibises nest in the south Florida ecosystem and are considered ecological indicators because of their wide foraging ranges, relatively narrow food requirements, and relatively specific habitat requirements. In addition, forested uplands and wetlands serve as important resting areas for migrating

passerine birds. Coastal Florida is often the last stop before these species cross the Gulf Stream or continue their migration south to Cuba. Development has eliminated many of the traditional forested stopover areas making remaining forested areas in south Florida more important to these species.

2.9.5 Mammals

Mammals found in the Caloosahatchee River Basin may include hispid cotton rat (*Sigmodon hispidis*), field mouse (*Peromyscus spp.*), raccoon (*Procyon lotor*), opossum (*Didelphis virginianus*), rabbit, mink, river otter, white-tailed deer (*Odocoileus virginianus*), bobcat, and black bear. Raccoon, opossum, rabbits and other small mammals provide prey items for larger mammals, including the endangered Florida panther. Deer and other fur-bearing animals provide recreational opportunities for residents through hunting, trapping, and wildlife viewing.

The bottlenose dolphin (*Tursiops truncatus*) and West Indian manatee (*Trichechus manatus*) are the only marine mammals that are likely to be found in the Caloosahatchee Estuary.

2.9.6 Protected Species

Nineteen federally listed species may potentially occur in the proposed project footprint or may be impacted by operations of the project. Although some of these species may be impacted by the loss of habitat within the project footprint, when implemented, the project has the potential to significantly contribute towards environmental restoration beyond the project footprint. For additional information on these species please refer to the Final Biological Assessment (BA) for the C-43 West Storage Reservoir Project found in ***Annex A***. The site information included in this report is based on surveys referenced in the BA. ***Table 2-3*** lists the threatened and endangered species within the Caloosahatchee River (C-43) West Basin Storage Reservoir study area. Please note that although beautiful paw-paw was originally provided by USFWS as a potential affected species for this project, once the project site was determined the beautiful paw-paw was removed from species needing consultation.

TABLE 2-3: FEDERALLY LISTED THREATENED (T) AND ENDANGERED (E) SPECIES IN THE CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR STUDY AREA

Scientific Name	Common Name	Status
Caretta Caretta	Loggerhead sea turtle	T
Chelonia mydas	Green sea turtle	E
Crocodylus acutus	American crocodile	E
Dermochelys coriacea	Leatherback sea turtle	E
Drymarchon corais couperi	Eastern indigo snake	T
Eretmochelys imbricata	Hawksbill sea turtle	E
Lepidochelys kempii	Kemp's (=Atlantic) ridley sea turtle	E
Ammodramus savannarum floridanus	Florida grasshopper sparrow	E
Aphelocoma coerulescens	Florida scrub jay	T
Charadrius melodus	Piping plover	T
Haliaeetus leucocephalus	Bald eagle	T
Mycteria americana	Wood stork	E
Picoides borealis	Red-cockaded woodpecker	E
Polyborus plancus audubonii	Audubon's crested caracara	T
Rostrhamus sociabilis plumbeus	Everglades snail kite	E
Felis concolor coryi	Florida panther	E
Trichechus manatus latirostris	West Indian manatee	E
Cucurbita okeechobeensis	Okeechobee gourd	E
Pristia pectinata	Smalltooth sawfish	E

2.9.6.1 Snail Kite

The snail kite (*Rostrhamus sociabilis plumbeus*) inhabits the watersheds of the Everglades, lakes Okeechobee and Kissimmee, the upper St. Johns River, and the Caloosahatchee Basin. Critical habitat for the snail kite is present immediately adjacent to the Caloosahatchee Basin inside of the Herbert Hoover Dike (HHD) in Lake Okeechobee. The snail kite could also be found foraging in a number of native wetlands and in canals and ditches adjacent to the project area. This medium-sized raptor has a highly specific diet composed almost entirely of Florida apple snails (*Pomacea paludosa*), which are found in palustrine emergent, long hydroperiod wetlands. As a result, the snail kite's survival is directly dependent on the hydrology and water quality of its habitat (Service 1999).

One snail kite was observed on a wire and eating a snail along SR 80 during a February 2006 survey. This location was approximately 0.75 miles west of the project footprint. In addition, during several field visits 2004-2006, populations of two species of apple snails, the Florida apple snail (*Pomacea paludosa*) and the exotic ramshorn apple snail (*Marisa cornuarietis*) were observed in large ditches of the project site. The network of large agricultural ditches provides

suitable foraging opportunities but evidence of foraging/feeding (shell discards) was not observed.

2.9.6.2 Wood Stork

The wood stork (*Myctria Americana*) is primarily associated with freshwater and estuarine habitats for nesting, roosting, and foraging. They have nested, at one time or another, in every county in south Florida. Typical foraging sites include freshwater marshes and stock ponds, shallow, seasonally flooded roadside or agricultural ditches, narrow tidal creeks or shallow tidal pools, managed impoundments, and depressions in cypress heads and swamp sloughs. Wood storks use a specialized feeding behavior called tactolocation, or grope feeding. A foraging wood stork wades through the water with its beak immersed and partially open (seven to eight centimeters [cm]). When it touches a prey item, a wood stork snaps its mandibles shut, raises its head, and swallows what it has caught (Kahl 1964). This unique feeding method of the wood stork gives it specialized habitat requirements; the habitats on which wood storks depend have been disrupted by changes in the distribution, timing, and quantity of water flows in south Florida. The loss or degradation of wetlands in central and south Florida is one of the principal threats to the wood stork.

The majority of the lands within the project footprint fall within the 18.6-mile core foraging area (CFA) of three wood stork colonies (see ***Annex A***). The BA only identified two colonies with a CFA that overlapped the project site but since that time a new colony has been identified. Individual wood storks have been observed foraging and loafing onsite, primarily in the tertiary and secondary canals. Within the project there are limited acres of wetlands that provide suitable wood stork foraging habitat. Wood stork foraging habitat available within the project site includes 6.72 acres of wetlands and 778.34 acres of ditches/canals as identified in ***Annex A***.

2.9.6.3 West Indian Manatee

The West Indian manatee is recognized as an endangered species by both the USFWS and Florida Fish and Wildlife Conservation Commission (FFWCC). Manatees are also protected under the provisions of the Marine Mammal Protection Act of 1972, and by Florida law. The manatee, or sea cow, is a large, plant-eating aquatic mammal that can be found in the shallow coastal water, rivers, and springs of Florida. Florida is essentially the northernmost extent of the West Indian manatee's range, though some manatees are occasionally spotted as far north as Virginia and the Carolinas (Florida Power & Light [FP&L], 1989). The endangered West Indian manatee is regularly found in the Caloosahatchee River and the Charlotte Harbor estuary. This large, aquatic mammal migrates along the Florida coast through fresh, brackish, and marine waters, with a seasonal distribution based on water temperatures. Water

depths of at least three to seven feet are preferred. Water temperatures below 20 degrees Celsius increase the manatee's susceptibility to cold-stress and cold-induced mortality. Distribution is also controlled by the availability of aquatic vegetation, proximity to channels of at least two meters in depth, and location of fresh water sources (Service 1999). During the summer months manatees range throughout water bodies of south Florida, usually in small groups. In the winter months they tend to congregate in warm water areas such as springs and electric generation facilities (FP&L, 1989).

Designated critical habitat for the manatee is located in the Caloosahatchee River Basin. Critical habitat extends downstream from the SR 31 Bridge and includes all United States territorial waters adjoining the coast and islands of Lee County.

Primary threats to manatees today consist of collisions with watercraft, degradation of seagrasses and accidents occurring at water control structures. Navigational locks along the Caloosahatchee River have a history of causing manatee mortality. Sixteen navigational lock/water control structure-caused manatee deaths have been recorded near Ortona Lock (S-78) between 1980 and 2001. Throughout those same years, six were discovered near S-77 at Moore Haven, and just one in 1999 at the Franklin Lock (S-79). Existing operational protocols for the structures and locks (unaffected by project planning for the Caloosahatchee River [C-43] West Basin Storage Reservoir) are important considerations in reducing these deaths.

Manatees have been known to utilize the Townsend Canal, which lies immediately adjacent to and west of the project footprint. During times of inflow from the Caloosahatchee River, manatees are capable of passing over the weir and traveling southward into the Townsend Canal. Individuals have been observed at the outfall area immediately west of the project boundary as well as at the mouth of the canal in the Caloosahatchee River. However, manatees cannot access the main distribution canal (i.e., Header Canal) for the grove property due to differences in elevation.

2.9.6.4 Southern Bald Eagle

The bald eagle is currently listed as a threatened species by both the USFWS and FFWCC. However, effective August 8, 2007, the bald eagle will be removed from the national list of threatened and endangered species. The bald eagle will continue to be protected by the Bald and Golden Eagle Protection Act and Migratory Bird Treaty Act. The southern bald eagle (*Haliaeetus leucocephalus*) is considered common and known to breed throughout the state. Nest sites are usually located near large rivers, lakes, or estuaries where they feed primarily on fish and water-dependent birds. Their distribution is influenced by the availability of suitable nest and perch sites near large, open waterbodies, typically with high amounts of water-to-land edge (Service 1999). The bald eagle is the only eagle unique to

North America. It ranges over most of the continent, from the northern reaches of Alaska and Canada down to northern Mexico. Current threats to the bald eagle include habitat loss and fragmentation, collisions with cars and powerlines, and shooting (USFWS 1998).

Data obtained from the Florida Fish and Wildlife Conservation Commission (FFWCC) 2004 Eagle Nest Database indicate that the closest documented bald eagle's nest, HE002, is located 3.4 miles east of the project and east of SR 29. This nest was documented to be last active during the 2003 nesting season. No other nests were observed in the project vicinity during field efforts in the summer of 2004 or spring of 2006.

2.9.6.5 Eastern Indigo Snake

The threatened eastern indigo snake (*Drymarchon corais couperi*) is present throughout the state, but its abundance is reduced to a point where it is uncommon. Its known habitat includes pine flatwoods, scrubby flatwoods, high pine, dry prairie, tropical hardwood hammocks, edges of freshwater marshes, agricultural fields, coastal dunes, and human altered habitats. This species was listed as a result of dramatic population declines caused by over-collecting for the domestic and international pet trade as well as mortalities caused by rattlesnake collectors who gassed gopher tortoise burrows to collect snakes. Since its listing, habitat loss and fragmentation by residential and commercial expansion have become much more significant threats to this species (USFWS 1999).

Specific information on the status of this species within the project area is not available; however, indigo snakes are known to occur in the Caloosahatchee River Basin in low densities and are known to occur along roads and the banks of larger ditches and canals in citrus groves, particularly if burrows (e.g., tortoise, armadillo, small mammal, and/or land crab), debris piles, or other shelter are in close proximity. Although the eastern indigo snake was not observed during field visits, suitable habitat exists on the project site; therefore, it could potentially occur. Additionally, the species is known to utilize a variety of habitat types including citrus groves.

2.9.6.6 Florida Scrub-Jay

The Florida scrub-jay (*Aphelocoma coerulescens*), a threatened species, is present in limited areas of scrub habitat in the study area. It is a relict species of fire-dominated oak scrub habitat that occurs on well-drained sandy soils in peninsular Florida. Scrub-jays are extremely habitat-specific, sedentary, and territorial. Florida scrub-jays form family groupings; fledglings remain with their parents in their natal territory as helpers. The Florida scrub-jay is listed as a threatened species because of loss, fragmentation, and degradation of scrub habitats throughout Florida, due primarily to urbanization, agriculture, and fire

suppression. During the last 10 to 23 years, the population has declined by an estimated 25 to 50 percent, and they have been extirpated from seven counties statewide.

No individuals, nests or appropriate habitat were detected in the project footprint during site visits. The nearest documented Florida scrub jay habitat and population occurs 1.1 miles west of the project area. This colony is beyond the foraging distance for the species to access the project area.

2.9.6.7 Red-Cockaded Woodpecker

The red-cockaded woodpecker (*Picoides borealis*) was listed as threatened in 1970. The red-cockaded woodpecker is one of 22 species of woodpeckers native to North America. Its historic range encompasses the southeastern Unite States from eastern Texas to Oklahoma to New Jersey, and it was characterized as "abundant" in the 19th century literature. Throughout the 20th century, however, the species' distribution within its historic range has become fragmented, and its total population numbers have decreased dramatically due to the destruction of its habitat. Although south Florida is not a designated recovery population for the red-cockaded woodpecker, the area contains significant support populations for recovery of the species in the southeast. Additional population surveys and research on habitat requirements within the hydric pine flatwoods of south Florida are needed to assess the current status of the birds and to adapt conservation measures used elsewhere to the distinct conditions in this area. The nearest documented red-cockaded woodpecker population occurs approximately 14 miles northwest of the project area (FFWCC data).

2.9.6.8 Florida Panther

The Florida panther (*Puma concolor coryi*), a subspecies of mountain lion, is one of the most endangered large mammals in the world. The most recent population estimate for the Florida panther is a total of 87 individuals, not including denning kittens (McBride 2003). This small population in south Florida represents the only known remaining wild population of an animal that once ranged throughout most of the southeastern United States from Arkansas and Louisiana eastward across Mississippi, Alabama, Georgia, Florida, and parts of South Carolina and Tennessee. The panther presently inhabits a contiguous system of large private ranches and public conservation lands in Broward, Collier, Glades, Hendry, Lee, Miami-Dade, Monroe, and Palm Beach counties totaling more than 809,400 ha. Panthers have a strong affinity for hardwood forests and mixed swamps but also use freshwater marshes, prairie and shrub/scrub habitats, agricultural lands (i.e., wooded pasture, rangeland, citrus groves, row crops, etc.), and even urban areas. Geographic isolation, habitat loss, population decline, and associated inbreeding have resulted in a

significant loss of genetic variability and overall health of the Florida panther population. Natural gene exchange ceased when the panther became geographically isolated from other subspecies of *Puma concolor*. Population viability projects have concluded that under current demographic and genetic conditions, and without implementation of recovery actions, the panther will probably become extinct within two to four decades.

The Caloosahatchee Basin plays an important role in the recovery of the Florida panther. The USFWS has organized a multi-agency subgroup of the Multi-species/Ecosystem Recovery Implementation Team (MERIT) to produce a Florida panther landscape conservation strategy. That strategy included the identification and prioritization of habitat zones (dispersal, primary, and secondary zones) that are essential for effective Florida panther conservation. In addition to protection of habitat for adult home ranges, the strategy includes provision of corridors for dispersal of juveniles between larger areas of contiguous habitat. Dispersal across the Caloosahatchee River, between existing primary habitat south of the river and habitat that is presently only occasionally used by panthers north of the river, is considered essential for recovery of the species.

The proposed project is located within the USFWS Consultation Area and includes areas within the panther primary, secondary, and "other" zones, as identified by the Florida panther subteam of the MERIT and USFWS Consultation Area updates. The most recent available FFWCC telemetry data of radio collared Florida panthers, current through January 2004, depicts three (3) Florida panthers and one (1) Texas cougar (*Felis concolor*) within a five-mile radius of the project area. A more landscape level inspection (25-mile radius) identifies habitat utilization by several additional panthers, particularly within Okaloacoochee Slough State Forest and other conservation lands.

2.9.6.9 Audubon's Crested Caracara

Audubon's crested caracara (*Polyborus plancus audobonii*) is another federally listed species present in the Caloosahatchee Basin. It is a large, boldly patterned raptor, with a crest and unusually long legs. It is a resident, diurnal, and non-migratory species that occurs in Florida as well as the southeastern United States and Central America. In Florida, this species is found in the prairie area of the south-central region of the state. Historically, this species was a common resident in Florida from northern Brevard County, south to Ft. Pierce, Lake Okeechobee, and Hendry County. Today, the region of greatest abundance for this large raptor is a five-county area north and west of Lake Okeechobee. The preferred native habitat is dry or wet prairie with scattered cabbage palms (Service 1999). Improved and unimproved pastures are also highly utilized. Effect determinations for caracara are based mostly on potential impacts within the primary nest zone (i.e., within a radius of 985 feet from a

nest tree) or the secondary zone (a radius of 6,600 feet). Additionally, potential effects within juvenile congregation areas are also considered.

The project falls within the caracara USFWS Consultation Area. One caracara nest site was confirmed to the north of the project during spring 2006 surveys. This nest is located along the southern edge of the SR 80 right-of-way (ROW) and approximately 4,750 feet north of the project boundary. While individuals were not observed foraging in the project footprint, a portion of the project falls within 2000 meters (secondary zone) of this nest, as defined in the Standard Local Operating Procedures for Endangered Species (SLOPES). In addition, a possible nest was identified approximately 1,065 feet south of the project boundary, within a pasture of the A. Duda & Sons, Inc. property. Individuals from the possible nest site were seen flying into and out of the Caloosahatchee (C-43) West Basin Storage Reservoir project site. While the project area provides only sub-optimal foraging habitat for the species, and individuals were only observed utilizing the project area in the southeast portion of the footprint, it does fall within the home range of both the confirmed and possible nests.

2.9.6.10 Florida Grasshopper Sparrow

The Florida grasshopper sparrow (*Ammodramus savannarum floridanus*) is a subspecies of grasshopper sparrow that is endemic to the dry prairie of C&SF. This subspecies is extremely habitat-specific and relies on fire every two to three years to maintain its habitat. It is now known to occur only from Highlands, Okeechobee, Osceola, and Polk counties, but other populations may occur in Glades County, which may bring it into the study area considered in this PIR. The species is not known to occur in Hendry County but populations may occur in nearby Glades County (USFWS 4-11-02 Planning Aid Letter [PAL]). The nearest Florida grasshopper sparrow record in the 1999 Florida Natural Areas Inventory (FNAI) database is a 1984 observation located 17.3 miles north of the project. Mapping of potential Florida grasshopper sparrow habitat (Shriver and Vickery, 1999) shows marginal habitat zones to the northeast and southeast of the project, and the project area falls within the Florida grasshopper sparrow USFWS Consultation Area. However, the nearest marginal habitat zone is located approximately 2.5 miles to the southeast of the project footprint. No grasshopper sparrows were observed during field surveys and no suitable habitat exists in the project area.

2.9.6.11 Piping Plover

A wintering population of piping plovers (*Charadrius melodus*) uses the tidal area of the Caloosahatchee River. The piping plover was listed as threatened along the Atlantic coast in 1985. It is a small, migratory shorebird that breeds only in three geographic locations of North America: sandy beaches along the Atlantic Ocean: sand shorelines throughout the Great Lakes: and on riverine

systems and prairie wetlands of the Northern Great Plains. This species does not breed in Florida, but all three breeding populations winter here. Bunche Beach, at the mouth of the Caloosahatchee River, has a population of wintering piping plovers and is also designated critical habitat for this species. The USFWS established critical habitat areas for the species, which include several locations on barrier islands west of the Caloosahatchee Estuary. The nearest piping plover critical habitat zone to the project area includes Punta Rassa, a mainland location at the southwestern edge of the Caloosahatchee Estuary, and Bunch Beach.

2.9.6.12 Okeechobee Gourd

The Okeechobee gourd (*Cucurbita okeechobeensis*) is a vine that was locally common in the extensive pond apple forest that once grew south of Lake Okeechobee (Small 1922). It is a vine that is now restricted in the wild to two small distinct populations; one along the St. Johns River which separates Volusia, Seminole, and Lake Counties in North Florida, and a second around the shoreline of Lake Okeechobee in South Florida.

2.9.6.13 American Crocodile

The USFWS and the FFWCC list the American Crocodile (*Crocodylus acutus*) as endangered. This species occurs in extreme south Florida primarily in Biscayne and Florida Bays. Crocodiles have been observed as far north as the coasts of Lee and Collier counties, but these counties are not thought to support a significant resident population of crocodiles. The American crocodile has not been documented in Hendry County but is present in coastal counties of the Caloosahatchee River Basin, namely Lee and Collier counties. The nearest documented individual occurrence to the project is on Sanibel Island in Lee County. The American crocodile is known to inhabit mangrove and seagrass habitats in coastal areas of south Florida. In addition to the American Crocodile, the American alligator is listed for similarity of appearance to the American Crocodile. The American alligator is abundant throughout South Florida.

2.9.6.14 Sea Turtles

Sea turtles including the Atlantic loggerhead turtle (*Caretta caretta*), Atlantic green turtle (*Chelonia mydas*), leatherback turtle (*Dermochelys coriacea*), Kemp's ridley turtle (*Lepidochelys kempii*), and hawksbill turtle (*Eretmochelys imbricata*) are listed as endangered by the USFWS and FFWCC with the exception of the loggerhead turtle, which is listed as threatened. These are marine species with a presence in south Florida waters and are known to utilize bays and estuarine habitats, such as the Caloosahatchee Estuary, for feeding and resting. Sea turtles forage in the near shore waters, bays and sounds of Florida and come ashore at night to nest on the beaches above the high tide line.

Alterations in the timing and quantity of freshwater flowing through the estuary has an impact on natural biodiversity by affecting food availability, predation pressure, reproductive success, and most likely has caused chronic and acute stress to these species.

2.9.7 Essential Fish Habitat

The National Marine Fisheries Service (NMFS) website lists the Caloosahatchee estuary as essential fish habitat for juvenile Brown shrimp (*Penaeus aztecus*), juvenile Gray snapper (*Lutjanus griseus*), juvenile Pink shrimp (*Penaeus duorarum*), adult and juvenile Red drum, (*Sciaenops ocellatus*), adult and juvenile Spanish mackerel (*Scomberomorus maculatus*), and juvenile Stone crab (*Menippe mercenaria*).

Aquatic habitats within the Caloosahatchee Basin have been altered through the channelization of the river. Nevertheless, the basin continues to support fishery resources of some recreational or commercial importance. At least 70 percent of Florida's recreationally or commercially sought fishes depend on estuaries for at least part of their life histories (Harris *et al.* 1983; Estevez 1998; Lindall 1973). Seagrass communities within the Caloosahatchee Estuary provide critical refugia for juvenile fish such as red drum, grouper, snook, and spotted seatrout. The decline in juvenile abundance and distribution of these and other species, along with an overall decrease in species richness may be related to the loss of seagrass habitat and/or a result of alterations in the salinity regime and the timing of the freshwater discharges from the S-79 structure.

2.10 ESTUARINE RESOURCES

The Caloosahatchee Estuary is located on the southwest coast of Florida (***Figure*** 2-3**)**. The major source of freshwater is the Caloosahatchee River, which runs 65 kilometers (km) from Lake Okeechobee to the head of the estuary at the Franklin Lock and Dam (S-79). The estuary extends about 40 km downstream to Shell Point where it empties into San Carlos Bay (***Figure 2-4***). Major environmental concerns for the Caloosahatchee Estuary are altered freshwater inflows and extreme variation in salinity levels, eutrophication and habitat loss.

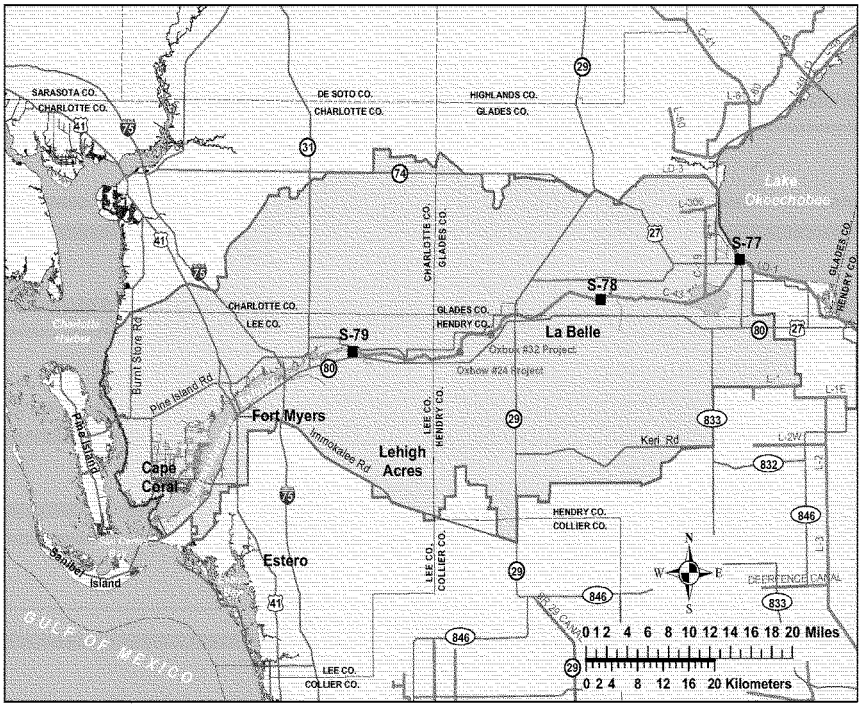

FIGURE 2-3: THE CALOOSAHATCHEE RIVER, ESTUARY, AND SOUTHERN CHARLOTTE HARBOR WATERSHED

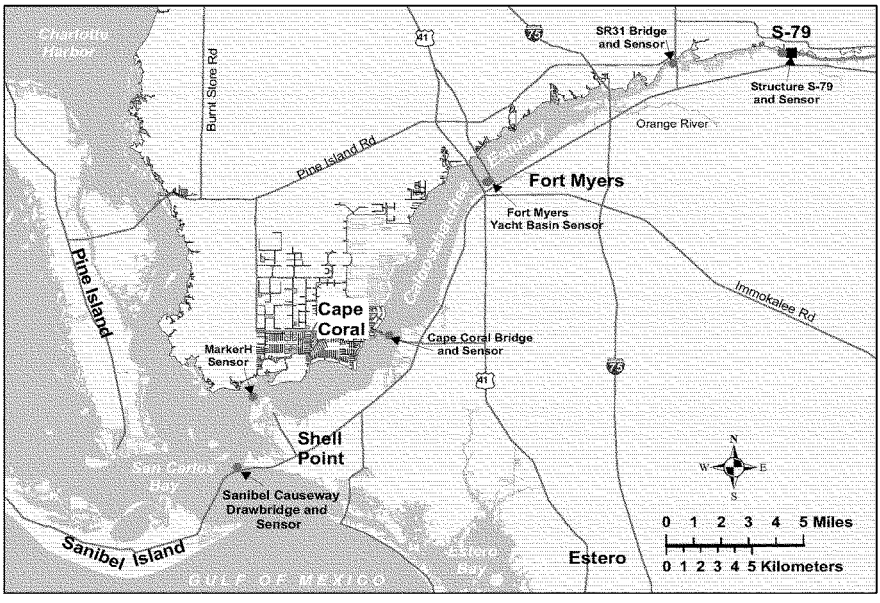
The Caloosahatchee River historically bisected its basin and probably only rarely received water from outside its watershed or from Lake Okeechobee except during extreme regional flooding events that sent water to the marshlands at the headwater of the river. Now the river functions as a primary canal (C-43) that conveys both basin runoff and regulatory releases from Lake Okeechobee. The canal has undergone a number of alterations to facilitate this increased freshwater discharge, including channelization, bank/levee stabilization, and the addition of the three locks and dams. The last structure before the canal flows into the estuary (S-79) maintains specific water levels upstream, discharges freshwater into the estuary, and acts as a barrier to salinity and tidal action, which historically extended far upstream. Therefore, when S-79 was completed, it truncated the estuary and now spatially limits the dry season oligohaline (freshwater and low salinity brackish water) zone of the estuary, as well as the free passage of organisms seeking refuge, nursery, and breeding areas characteristic of this zone.



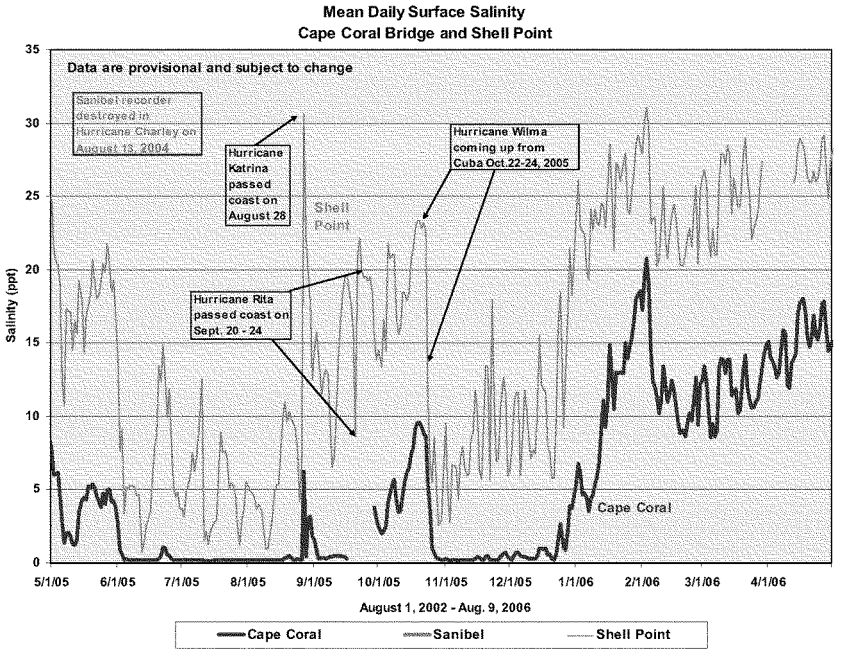


FIGURE 2-4: CALOOSAHATCHEE ESTUARY SALINITY SENSORS AND IMPORTANT LANDMARKS

The long-term mean monthly discharge measured at S-79 ranges between 300 and 3,000 cfs. However, daily and monthly flows often exceed this long term average, with prolonged flows commonly exceeding the 4,500 cfs monthly average that adversely affect the San Carlos Bay area. Flows above this threshold (occasionally exceeding 10,000 cfs) can push freshwater into Pine Island Sound and the Gulf of Mexico, thus impacting ecologically and commercially important high-salinity marine resources that historically were not directly affected by Caloosahatchee River discharges. During the dry season, the combination of limited rainfall, lack of water storage in the basin and withdrawals to meet human demands for irrigation and potable water often results in periods of no freshwater discharge to the estuary. Saline water can intrude all the way upstream to S-79 eliminating the oligohaline zone and threatening species that require low salinity to complete their life cycle (Chamberlain and Doering 1998a; 1998b, Doering et al. 2002; SFWMD 2002).

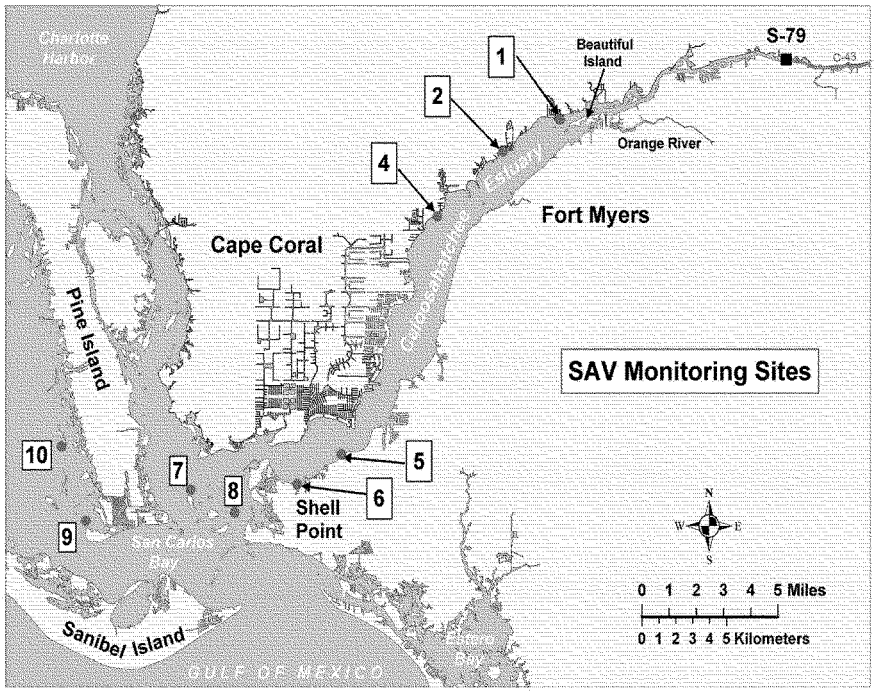
Excessive variation in discharge and salinity (***Figure 2-5***) occurs in the Caloosahatchee Estuary (Chamberlain and Doering 1998a), resulting in a constant flux of estuarine biota between those favoring higher salinity and those favoring lower salinity (Bulger et al. 1990). Optimal salinity conditions may not

last long enough for organisms to complete their life cycle and the estuary can become devoid of some populations, even keystone species that support major ecosystem components along the estuary's salinity gradient.

Environmental research by the SFWMD began in the Caloosahatchee Estuary during the mid-1980s and focused on the impacts associated with the extreme variability in freshwater inflow from S-79 (Chamberlain and Doering 1998a). The purpose of the research was to determine the proper timing and volume of freshwater inflows required to support valued ecosystem components (VECs) such as oysters and SAV, as well as the impacts of flows on general biotic indicators, such as plankton and benthic invertebrates (SFWMD 1998). This research has resulted in the development of optimum S-79 flow ranges and delivery patterns for the estuary (Chamberlain and Doering 1998b; Doering et al. 2002; Volety et al. 2003). This information forms the scientific basis for development of hydrologic performance measures for Comprehensive Everglades Restoration Plan (CERP), the SWFFS, and Lake Okeechobee, as well as meeting legislative mandates for the establishment of minimum flows and levels (MFL).

Note: The timing and influence of three hurricanes is depicted here.

FIGURE 2-5: DAILY AVERAGE SALINITY COLLECTED BY CONTINUOUS SENSORS AT TWO DOWNSTREAM LOCATIONS (CAPE CORAL BRIDGE AND SHELL POINT AT THE RIVER MOUTH) IN THE CALOOSAHATCHEE ESTUARY



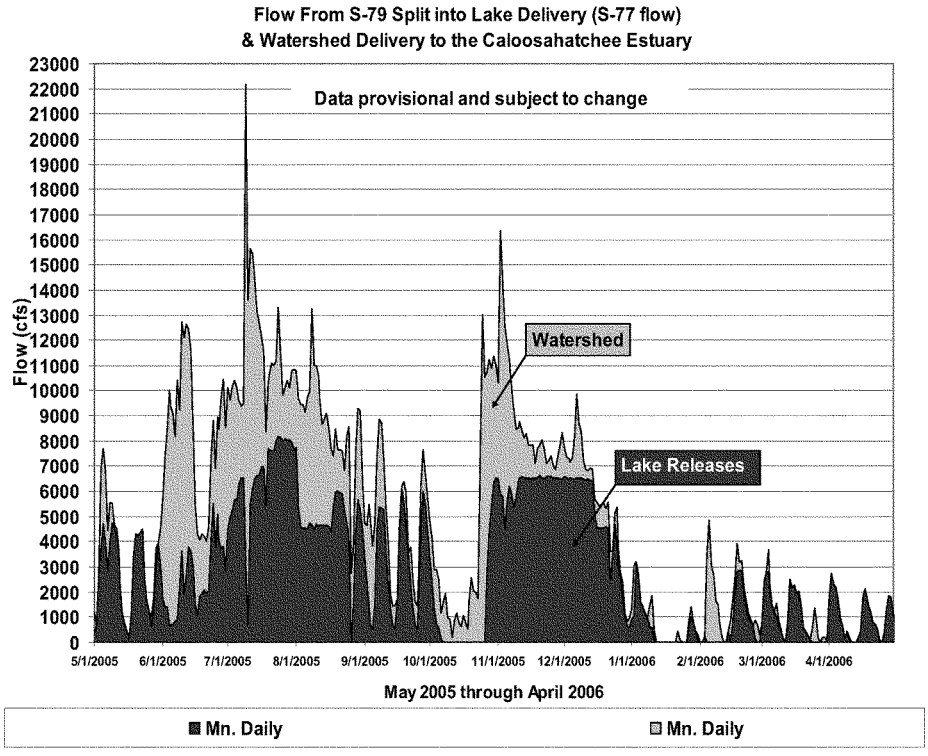
A distribution of monthly average inflows with the greatest frequency range from 300 to 1,500 cfs and a peak between 300-800 cfs was initially determined by SFWMD scientists to be the most beneficial for the species evaluated. This original frequency distribution was reported as provisional (Chamberlain and Doering 1995, 1998a, and 1998b), with the intent to update it as more information became available about the salinity requirements of key biota. This original flow recommendation was used to formulate the MFL and identified 300 cfs as the required average monthly inflow from S-79 for protecting the oligohaline zone of the estuary and the submerged plant, *Vallisneria americana*. The MFL was based on a flow-salinity relationship that was predicated on the delivery of S-79 discharges. However, salinity in the estuary is also influenced by additional inflows from creeks and groundwater downstream of S-79. On average, when flow at S-79 is 300 cfs, an additional 150-200 cfs comes from downstream sources for a total of approximately 450 cfs. However, during low

flow conditions the entire system is drier than normal and the downstream contribution is much lower than 150-200 cfs, so 300 cfs at S-79 is insufficient to achieve the MFL salinity criteria. The original basin flow optimization model used historic S-79 flow data from 1965 to 1990 to recommend a time series of basin flows (Labadie 1995: Otero et al 1995). More resent efforts use a 2000 Base and subsequent modeling related to the Restudy, the CWMP, and the Caloosahatchee River (C-43) West Basin Storage Reservoir CERP project have resulted in reconsideration of the original time series of flows to the estuary. The time series denoted as EST05 (see Section 4.3.1.1 of this report for a more detail explanation of the ESTO5 flow distribution) goes farther toward providing a higher level of protection in the upper estuary than previous time series by establishing a low flow limit of 450 cfs from S-79, which is consistent with meeting the total flow requirements associated with the MFL and its salinity criteria for protecting *Vallisneria.*

The discharge of water at S-79 also is a major determinant of macro-nutrient concentrations and other aspects of water quality in the Caloosahatchee Estuary. Influence of this discharge can be detected nearly 60 km downstream in Pine Island Sound (Doering and Chamberlain 1999). This control of water quality stems from the overwhelming dominance of the Caloosahatchee River at S-79 as a source of nutrients and other materials to the downstream estuary.

Loss of habitat has also been of concern. Hardening of the shoreline, increased freshwater discharge and oyster mining are thought to have singly or in combination reduced mangrove, seagrass and oyster bar habitats (e.g. Harris et al 1983).

Several prominent species are among those identified for long term monitoring and environmental assessment because they constitute important habitat in the Caloosahatchee, San Carlos Bay, Matlacha Pass and Pine Island Sound. In addition to tape grass (*Vallisneria americana*) that serves as an indicator of estuarine health in the upper estuary, oysters and marine seagrasses represent the more downstream, seaward portions of the system (***Figure 2-6***).



Note: *Vallisneria americana* is found at stations 1-2, *Halodule wrightii* at stations 5-10, *Thalassia testudinum* at stations 8-10. Oysters are located throughout the region downstream of station 5, but the core population is between stations 6 and 7.

FIGURE 2-6: CALOOSAHATCHEE ESTUARY SAV MONITORING STATIONS AND GENERAL OYSTER LOCATIONS

2.10.1 Recent Hurricane Impacts

In water year 2006 (WY2006) [May 2005-April 2006]), three hurricanes either directly or indirectly impacted the estuary. Hurricanes Katrina and Rita passed to the west in the Gulf of Mexico and the tidal surge associated with both caused spikes in water levels and salinity (***Figure 2-5***). During the fourth week in October 2005, Hurricane Wilma made landfill south of the region near Naples, which also caused similar spikes. Rainfall associated with Wilma brought tremendous rainfall to the basin and to Lake Okeechobee and its tributaries, which resulted in large releases from S-79 that extended to January 2006

(***Figure 2-7***). These releases drove down salinity at Shell Point (Marker H sensor) and San Carlos Bay. Salinity in the estuary upstream of Shell Point at Cape Coral was near zero parts per thousand (ppt) (freshwater) for almost two months because of the indirect impacts from Wilma.

Note: The portion of the discharge accounted for by Lake Okeechobee releases is shown in blue.

FIGURE 2-7: TOTAL DISCHARGE INTO THE CALOOSAHATCHEE ESTUARY (WATERSHED RELEASES) AT S-79

2.10.2 Estuarine Indicators

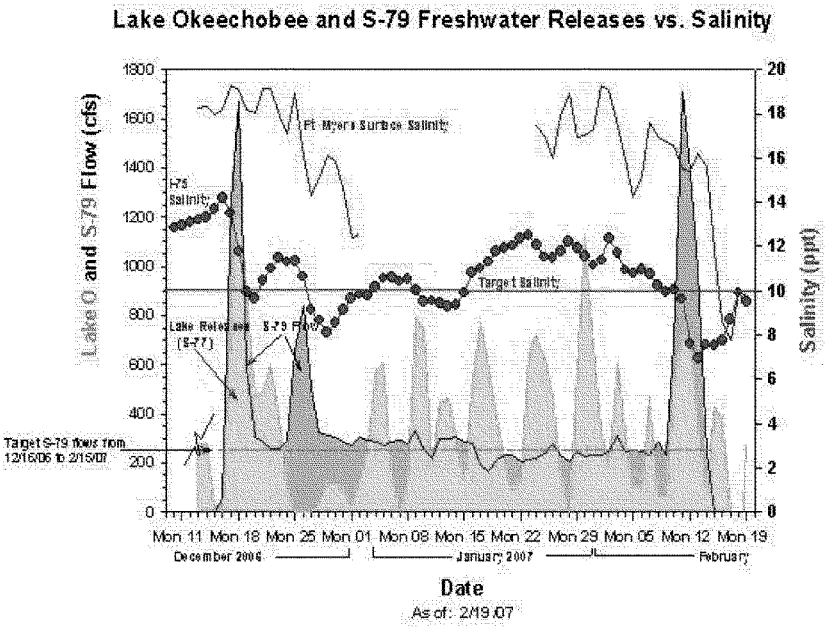
2.10.2.1 Freshwater Inflow at S-79 and Salinity at Ft. Myers

There were releases from Lake Okeechobee every month of WY2006. This was in part related to a high lake level remaining from WY2005 as a result of Hurricanes Frances and Jeanne. Therefore, Level II–III pulses were still being made to the Caloosahatchee through S-79 in October of 2005 (***Figure 2-7***). A very wet June 2005 throughout the upper district resulted in a dramatic increase in basin discharges, coupled with regulatory releases from Lake Okeechobee through August 2005. These discharges were followed by four Level III pulses, lasting into October 2005. As a result, salinity remained very low (0 ppt at Cape Coral Bridge) for four months (***Figure 2-5***). Salinities began to recover during mid-October until Hurricane Wilma (see description in the previous section). During January and the remainder of WY2006, salinities again began to recover as discharges at S-79 declined, with only Level I pulse releases being made at the end of WY2006 (April 2006). However, heavy basin rains during the 2006 wet season resulted in a single day's discharge of 21,000 cfs and average monthly discharge during September that exceeded 7,000 cfs (with no flow from Lake Okeechobee). This very wet season has been followed by a very dry season, that even with small environmental releases from the Lake Okeechobee, has resulted in violation of the MFL rule.

The long-term average discharge at S-79 is approximately 1.2 million ac-ft per year. In WY2006, discharge at S-79 was 3.6 million ac-ft, 2.2 million ac-ft of which were discharges coming from Lake Okeechobee. Most of the total annual discharge (3.3 million ac-ft or 92 %) entered the estuary through S-79 in the first eight months. WY2006 was the second consecutive year that annual discharge to the estuary was well above normal (WY2005 = 2.0 million ac-ft).

As discussed above, research and modeling conducted by the SFWMD has resulted in the identification of a preferred average monthly flow distribution between 450 and 2,800 cfs to protect and promote desirable estuarine biota and resources. In an ordinary year, flows less than 450 cfs occur for approximately 4.2 months and are greater than 2,800 cfs for 2.6 months. Thus, in an average year under current conditions, flows exceed the target about seven months per year. In WY2006, mean monthly flows were above the upper limit of the envelope, which occurred during the first eight months of WY2006 (May through December 2005). Flows exceeded 4,500 cfs during six of those eight months, which can have significant negative impacts on seagrass in San Carlos Bay. Half (4) of the flow exceedances were attributed to average monthly flows greater than 8,000 cfs, which can extend freshwater influence well into lower Pine Island Sound.

Surface salinity recorded at the Fort Myers sensor (***Figure 2-8***) during WY2006 did not exceed either of the two MFL criteria. Even though daily average salinity was greater than (>)10 ppt during three days near the beginning of February 2006 (maximum = 11.25 ppt), it did not exceed the one day limit of 20 ppt. In addition, the maximum 30 day average salinity at the same location was 6.0 ppt, well below the MFL target of 10 ppt. The period of record for salinity at Fort Myers extends back to 1992. During the 15 years of record, WY1995, WY2004, and now WY2006 are the only three years in which neither of the two criteria were exceeded (criteria: 1) moving 30-day average salinity of less than (<) 10 ppt at Fort Myers Yacht Bain; and 2) a daily average salinity of < 20 ppt). However, the dry season extending into 2007 has been extremely dry and has resulted in salinity that exceeds the monthly criteria (***Figure 2-8***).



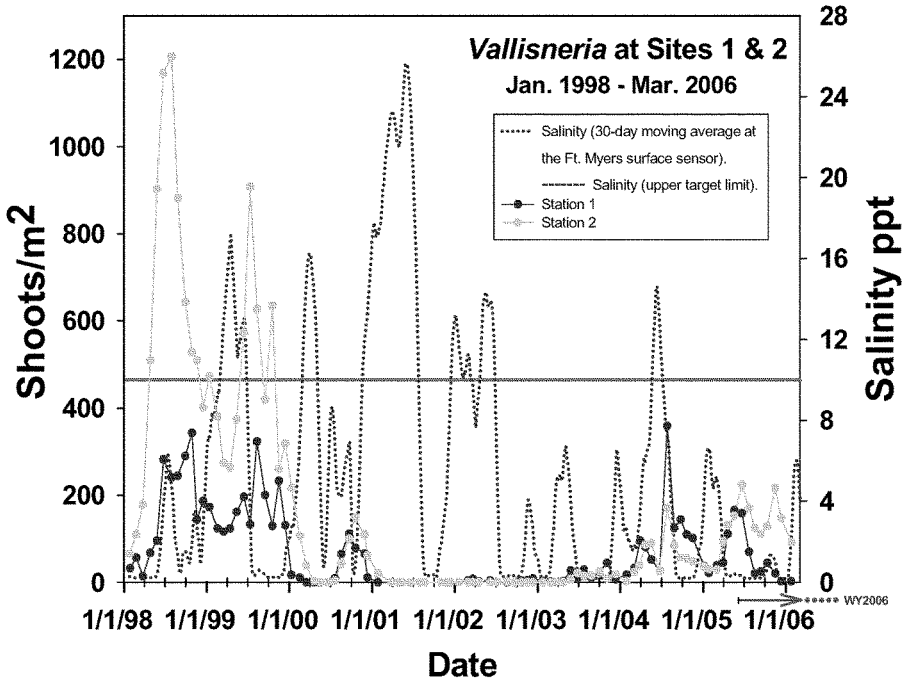


FIGURE 2-8: FRESHWATER FLOW THROUGH S-77 AND S-79 COMPARED TO SALINITY AT INTERSTATE-75 BRIDGE AND FT. MYERS

2.10.2.2 Tape Grass in the Upper Caloosahatchee

Due to high salinity experienced during the 2001 drought, tape grass beds in the upper Caloosahatchee Estuary essentially vanished, and have been in recovery since that period (***Figure 2-9***). There was an apparent slight trend toward

increasing plant density since the growing season of 2003. During WY2004, the beds began to recover in the spring-summer growing season, coinciding with favorable salinity conditions. Similar seasonal growth patterns were evident in the spring-summer growing season of 2005 (WY2006).

Before the 2001 drought, plant density was significantly greater at Station 2. WY2006 was the first time since the drought that this pattern was evident. During the high freshwater inflows in June, plant density decreased upstream at Station 1, possibly due to the associated drop in water clarity, while more plants persisted at Station 2 during November 2005 through March 2006 than in previous years since 2001. However, due to the unusually high salinity associated with the 2007 dry season (***Figure 2-9***), the plants have again almost disappeared.

(Note: Recent data are from stations monitored by the Sanibel-Captiva Conservation Foundation and Mote Marine Laboratory.)

FIGURE 2-9: TAPE GRASS (*VALLISNERIA AMERICANA*) SHOOT DENSITY IN THE UPPER CALOOSAHATCHEE ESTUARY

2.10.2.3 Oysters

Based on WY2004 aerial surveys, there are presently only 3.02 acres of Eastern oysters (*Crassostrea virginica*) in the lower Caloosahatchee Estuary and 15.04 acres in lower Charlotte Harbor. Most of these are located in the Shell Point region. This low number of oysters, especially to the east, is a result of the combination of: 1) high freshwater inflows into the estuary from the basin and Lake Okeechobee, 2) the lack of suitable substrate, and 3) shell mining in the twentieth century for construction material that decimated the live oyster population and their substrate in this region.

A preliminary target for the aerial extent of oyster reefs is 40 and 60 acres respectively in these two regions during the next 10 to 15 years. With the addition of hard substrate, this target can be increased to 200–300 acres upstream of Shell Point and 150-200 acres downstream. Eighty-seven volunteers from Florida Gulf Coast University, concerned citizens, SFWMD, and other state, Federal, and local agencies placed 200 shell-bags at two locations upstream of Shell Point (Iona Cove and Piney Point) during October and November 2005 to provide recruitment substrate for oyster reef development.

Monitoring of oysters' health and recruitment began in 2000. Results indicate that oysters in the Caloosahatchee Estuary spawn continuously from April–October, a period that coincides with freshwater releases into the estuary. High freshwater flows flush out oyster larvae and spat from upstream areas with suitable cultch and/or reduce salinities to levels that are unfavorable for spat settlement and survival. Recruitment during WY2005 was among the lowest observed (Volety; personal communication, 2005), which included the 2005 spring start-up. The high flows, which drastically increased during June 2006, resulted in another poor year for oyster survival and recruitment, especially upstream of Shell Point.

2.10.2.4 Marine Seagrass

Seagrasses have been sporadically surveyed in the Caloosahatchee by aerial photography since the 1940s. More recently, aerial surveys were conducted in 1999, 2002–2003, and 2004. No aerial surveys were conducted during 2005 or 2006. There appears to have been a dramatic increase in aerial extent of seagrass in the region between 1999 and 2002-2003 (***Table 2-4***). This increase may be due to the quality of the photography rather than a real change. Methodological and other differences between surveys preclude a reliable trend analysis (Corbett et al, 2006). However, with that said, this increase does follow the 2000-2001 drought when flows from S-79 were low and salinity in the seagrass areas were consistently in the preferred range.

Processing of the 2004 survey was completed during this WY2006 (***Figure 2-10***). The results of this survey indicate that there are approximately 38,494 acres in the combined Lower Caloosahatchee, Matlacha, San Carlos Bay and Pine Island Sound regions, with respective individual coverage of 62 acres, 7168, 3905, and 27359 acres.

TABLE 2-4 AERIAL EXTENT OF SEAGRASS

Year	Acres of Seagrass
Water Year 1999	38,197.16
Water Year 2002 and 2003	43,590.91
Water Year 2004	38,494

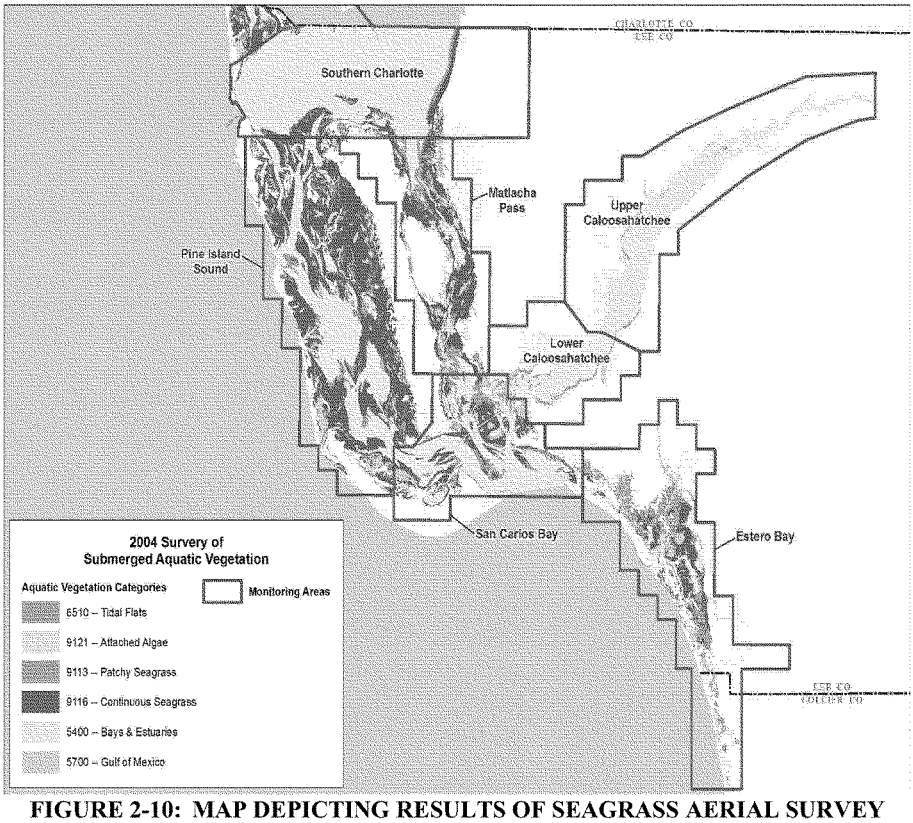

FIGURE 2-10: MAP DEPICTING RESULTS OF SEAGRASS AERIAL SURVEY CONDUCTED IN 2004 AND PROCESSED IN WY2006

Manual (in-water) seagrass monitoring by the Sanibel-Captiva Conservation Foundation Marine Laboratory indicates WY2006 was a very poor year for seagrass at all stations sampled, both upstream of Shell Point and in San Carlos Bay (***Figure 2-11***). This follows a poor WY2005 for *Halodule* upstream of Shell Point when shoot density remained below 200 m^{-2}. During WY2006, *Halodule* remained low upstream, while *Halodule* and especially *Thalassia* fell to a new seasonal low in San Carlos Bay following the large discharges that began in June 2005. These low densities persisted into the winter dry season and recent field trips indicate that *Thalassia's* percent of seagrass species composition has significantly declined.

FIGURE 2-11: DENSITY OF SEAGRASS: (FIGURE A.) *HALODULE WRIGHTII* (SHOAL GRASS); AND (FIGURE B) *THALASSIA TESTUDINUM* (TURTLE GRASS) IN THE CALOOSAHATCHEE ESTUARY AND SAN CARLOS BAY

2.11 AIR QUALITY

A few common air pollutants are found all over Florida. The existing air quality within south Florida is considered good, and the region attains all National Ambient Air Quality Standards. There are no non-attainment areas in the State of Florida. The current sources of air pollution are area-wide, resulting from autos in urban areas, land clearing, and partly from various licensed emitters (SWFRPC, 2002). Large industrial polluters are limited.

2.12 HAZARDOUS, TOXIC, AND RADIOACTIVE WASTE

The reservoir currently under consideration will be constructed on property formerly owned by J&H Grove Holdings, L.C. (Berry Groves), the Griffin Family Limited Partnership, the MG Enterprises, L.L.C. and the Bryan Paul Citrus. All these lands are currently owned in fee by the SFWMD except the Bryan Paul Citrus parcel that will be an exchange of 541.31 acres of SFWMD ownership in exchange for 600.17 acres of the Bryan Paul Citrus property. Prior to the 1960s these lands were primarily used as unimproved pasture. For the last 30 to 40 years these four parcels have been used to cultivate citrus. Over the operating life of these groves, fertilizers, herbicides and pesticides have been applied

routinely as part of normal agricultural operations. From the 1960s to 1980s, pesticide use would have included the application of persistent organic compounds such as DDT, chlordane, and toxaphene. Use of these and other persistent pesticides has since been severely restricted by the U.S. Environmental Protection Agency (USEPA). Normal farm operations would also typically result in point-source contamination associated with maintenance areas, pesticide mixing and loading sites, and fuel storage areas. The non-Federal sponsor shall be responsible for ensuring that the development and execution of Federal, State and/or locally required HTRW response actions are accomplished at 100 percent non-project cost. No cost sharing credit will be given for the cost of response actions.

Prior to and after the acquisition of each of these land parcels, a Phase I and Phase II Environmental Site Assessment (ESA) were performed to identify and characterize contaminated sites within the properties. In addition to identifying human health impacts, the site assessments also investigated the presence of widespread residual soil contamination in the cultivated areas to determine if the level of contamination might pose a threat to wildlife inhabiting the proposed reservoir. All site assessments were performed in general accordance with the American Society for Testing and Materials Standard Practice for Environmental Site Assessments (ASTMS Practice E 1527-00). These site assessments typically focus on identifying contamination that is a threat to human health. Analytical results were compared to FDEP SQAG and the Florida Administrative Code Soil Cleanup Target Levels (SCTL) and Groundwater Cleanup Target Levels (GCTL). In those cases where contaminant concentrations were at or above the relevant guidelines, an Environmental Risk Assessment (ERA) was performed to determine if the contamination would pose a risk to affected species. The risk assessments focused on the potential for bioaccumulation of residual contaminants by avian species that might feed on fish caught from the reservoir. In particular, the USFWS identified the listed snail kite as the species at greatest risk. Short summaries of the environmental audits for each property are provided below. A detailed discussion can be found in section 9.25 of this report.

2.12.1 Berry Groves Property

The 9,000 acre Berry Grove property, only a portion of which will be utilized in the Caloosahatchee River (C-43) West Basin Storage Reservoir Project, is owned by the SFWMD. Phase I and Phase II ESA studies as well as ERAs were performed on this parcel during the period from December 1999 through 2006. These investigations identified more than 40 potential point source contamination sites within the parcel boundaries. These point source sites typically consist of refueling sites, maintenance sheds, pesticide storage/mixing sites, and irrigation pump stations. Seventeen (17) of the 40 sites were designated as requiring no further action because further investigation

determined that contamination was not present at levels requiring remedial action. Fifteen (15) of the sites were identified as presenting a contingent hazardous, toxic, and radioactive waste (HTRW) risk because contamination has been identified and quantified but remediation has either not begun or been completed. An additional five sites were identified in March 2003 as requiring remediation. The 40 contaminated sites discussed above can be generally categorized as point source contamination sites in which the contamination is contained within an area of a few acres or less. Though most of these sites have been re-mediated as of February 2007, remediation of the remaining sites will be completed prior to transferring control of the land from the lessee to the SFWMD.

Of greater concern to the USACE and the USFWS is the widespread presence of elevated copper concentrations in the cultivated soils on the Berry Groves property. The presence of elevated copper in the soils is a result of the application of fungicides that have been applied to the citrus groves. To investigate the risk posed by copper, a Phase III ERA was conducted by the URS Corporation under contract with the SFWMD and in coordination with the USFWS. The purpose of the ERA was to determine the risk that elevated concentrations of copper in the soil posed to populations of invertebrates, fish, and birds (the listed snail kite, for instance) that would use the Caloosahatchee River (C-43) West Basin Storage Reservoir for habitat.

At the onset of this study, the 9,000 acre Berry Grove property was divided into 181 fifty-acre grids for purposes of sampling shallow soils for copper content. A total of 89 of these plots were randomly selected for sampling for residual copper in the surface soils. Copper concentrations in composite samples collected from these plots ranged from 13.1 (Grid 100) to 169 milligrams per kilogram (mg/kg) (Grid 125), resulting in a contractor calculated geometric mean of 51.9 mg/kg (95 percent upper confidence level of 56.6), which exceeds the threshold effects concentration (TEC) of 32 mg/kg for effects on benthic invertebrates. In fact, seventy-five of eighty-nine 50-acre grids exceeded the TEC. Since copper concentration in Grids 58, 124, 125, and 134 exceeded the probable effect concentration (PEC) of 108 mg/kg, discrete samples were collected in 2002 from those grids to look for potential contamination hot spots.

In 2003, the FDEP adopted a new PEC for copper (150 mg/kg) reducing the number of grids with copper concentrations exceeding the PEC to one (Grid 125). Additionally, a site-specific ecological risk assessment was performed in 2003 which concluded that impacts were likely for the benthic community. It also predicted potential risk for the Everglades snail kite if copper concentrations in soil exceed 85 mg/kg (interim screening concentration for risk to the snail kite). Contamination in Grids 56 and 145, in addition to grids 58, 124, 125, and 134, exceeded 85 mg/kg. Therefore, in 2005, discrete samples were collected from

Grids 56 and 145 to locate potential contamination hot spots. Lastly, in 2005, delineation sampling of copper contamination in the above-noted six grids was performed. The delineation sampling indicated copper exceeded 85 mg/kg in Grid 135 as well, but was less than 85 mg/kg in Grid 145. The consultant's final report recommended remediation of copper contamination in soils of Grids 56, 58, 124, 125, 134, 135, and 143.

2.12.2 MG Enterprises LLC Property

The 2,399 acre MG Enterprises LLC property is owned by the SFWMD. The entire property will be utilized in the reservoir project. The MG Enterprises LLC property is located south and west of the larger Berry Groves property. The MG Enterprises LLC property has been used to cultivate citrus for the last 30 or more years. Like the Berry Groves property, persistent pesticides such as DDT, toxaphene, and chlordane were probably widely used until the application of such chemicals was restricted by the USEPA in the 1980s. A Phase II ESA report was prepared in March 2003 by Environmental Consulting & Technology, Inc. (ECT) on behalf of the SFWMD. This report identified five areas of potential concern including the cultivated areas, canal sediments, two maintenance areas, and an exploratory oil/gas well. Grid based testing was performed in the cultivated areas such as was done on the Berry Groves property. The results of these sediment analyses indicated the presence of aldrin and aldicarb at levels exceeding the threshold concentrations. A preliminary ERA was done using a fugacity-based food chain model to determine the risk that elevated aldrin concentrations might pose to avian species. The results of this modeling indicated that at the highest detected concentration (29 ug/kg), the calculated hazard quotient ranged from 0.01 to 0.02 for birds exposed to the contamination. Two of the remaining four suspected areas, Maintenance Area A and Maintenance Area B, require corrective action. Soils samples collected in the vicinity of Maintenance Area A had high levels of endrin, copper, and zinc. No contamination of groundwater was detected at this site. Soil samples collected in the vicinity of Maintenance Area B had high levels of anthracene, flourene, and acenaphthalene. No groundwater contamination was detected at this site.

2.12.3 Griffin Property

The approximately 954 acre Griffin property is owned by the SFWMD, and all will be utilized in the Reservoir project. The Griffin property is located south and west of the larger Berry Groves property. The Griffin property (954 acres) has been used to cultivate citrus for the last 30 or more years. The Phase I and Phase II ESA report identified five areas of potential concern including the cultivated areas, canal sediments, maintenance area/chemical barn, fertilizer mix/load area, and burn area. Grid based testing in the cultivated areas was performed by dividing the property into 20 cells of 50 acres each. Discrete

samples were collected from 10 five-acre sub-grids on each larger grid and composited into one sample. The results of these sediment analyses indicated evidence of low level contamination of barium, copper, lead, mercury, zinc and paraquat. However, none of these analytes exhibited concentrations which exceeded the SQAG PEC. Aldicarb was detected in one sample grid at a concentration of 67 ug/kg which exceeds the site-specific SQAC of 1.75 uk/kg developed specifically for this site. Soils contaminated with polyaromatic hydrocarbons (PAHs) were found at the maintenance area/chemical barn. At the burn area, soils contaminated with copper were found. Seven sediment samples were collected from the drainage canal. One of these samples contained residual copper at a concentration exceeding the TEC of 32 mg/kg but not exceeding the interim screening concentration of 85 mg/kg. Another sample contained pentacholorophenol (PCP) at a concentration of 32 mg/kg which is well below the site-specific effect level of 617 ug/kg. Remediation was recommended for the maintenance area, and burn area.

2.12.4 Bryan Paul Citrus Property

The approximately 600-acre Bryan Paul Citrus property is located east of the Berry Groves property and has not been acquired by the SFWMD. It will be acquired in an exchange for approximately 541 acres of the Berry Grove property. In the 1960s the property was converted from a cattle ranch to row crops such as tomatoes, watermelons, and peppers. In 1972, the property was converted to citrus groves (see Appendix D "Real Estate Plan").

In 2004, the SFWMD conducted a Phase I and Phase II Environmental Assessment as part of a due diligence investigation prior to acquiring the lands. The Phase I assessment identified the following seven sites of environmental concern: 1) pump stations, 2) former nursery barn, 3) C-1 mixing site, 4) auxiliary tank area, 5) solid waste site, 6) burn area, and 7) grove area. To test the grove area for the presence of elevated pesticide and heavy metal residues in the soils, the 600 acres were divided into a grid composed of 119 five-acre squares. Soil samples from each of the 119 cells were collected and then composited into ten samples. The resulting 12 composite soil samples were submitted to the laboratory for analysis. The results of the analysis indicated that the soil in two grids (8 and 9) had elevated chlordane levels in excess of the recommended 100 ug/kg limit. Further testing indicated that approximately 13 acres in the vicinity of grids 8 and 9 had chlordane impacted soils.

At the solid waste area, soil samples were collected from below the buried waste. These samples indicated that the soils were not impacted though the presence of buried solid waste would have to be addressed. At the burn area, soil samples were collected to determine if concentrations of heavy metals exceed the standards. At the former pump stations, soil samples were collected and analyzed for petroleum and heavy metal contamination. The results indicate

that the visibly contaminated soils should be removed. At the burn site, the analysis of soils indicated that the surrounding soils were not impacted. However, the removal of ash was recommended by the environmental consultant. From the drainage canal, eight soil/sediment samples were collected for analysis. The results indicated that canal sediments were not contaminated; however, some canal bank soil directly adjacent to a burn area had high levels of barium, copper, and silver. The consultant's recommendation was to remove the canal bank soil that appears to be contaminated by the adjacent burn site.

2.13 CULTURAL RESOURCES

Cultural resource surveys (Florida State Department of Historic Preservation numbers 2004-8676 and 2006-07757) have been conducted for the Caloosahatchee River (C-43) West Basin Storage Reservoir site. Three isolated prehistoric artifacts, one isolated historic artifact, one prehistoric archeological site (8HN129), and four modified historic buildings were identified. All except the prehistoric archeological site were determined to lack integrity and determined not eligible for listing on the National Register of Historic Places. The prehistoric archeological site (8HB129) is located near the edge of the proposed project.

2.14 SOCIOECONOMICS

As a result of the flood protection and available supply of drinking water supplied by the C&SF project, the population of southwest Florida has grown to approximately 880,000 persons as of the year 2000. By the year 2050, the population of southwest Florida is expected to reach two million people. Lee County has one of the fastest growing populations in both south Florida and in the state. The coastal areas in these counties have become highly urbanized. As a result, this urbanization has caused development to move eastward into areas that were once agricultural or natural.

The Governor's Commission for a sustainable south Florida identified agriculture and tourism as "critical industries" for maintaining the economy in the southern part of the state. In Lee and Hendry County, agriculture is a major industry and citrus production predominates. A rapidly expanding human population demanding more developable lands and advancing agricultural development now threatens the relatively pristine natural areas. The tourism industry is also dependent upon the region's ability to sustain its economy and its quality of life through management of its resources. Agriculture and tourism depend on a system that can provide vital water supply needs and flood protection.

2.14.1 Population

Population for the four counties in the study area (Charlotte, Glades, Lee and Hendry County) increased at a high growth rate during the period from 1990 to 2000 (***Table 2-5***). Charlotte increased at 27.6 %, Lee at 31.6 %, Glades at 39.3 % and Hendry at 40.5 %. The population of Florida and the United States increased 23.5 % and 13.1 % respectively over the same period.

TABLE 2-5: CHARLOTTE, GLADES, LEE AND HENDRY COUNTY 2000 POPULATION

		Race							
	Population, 2000	**White**	**%**	**Black**	**%**	**Hispanic**	**%**	**Other**	**%**

Hendry County	36,210	23,935	66.1%	5,323	14.7%	14,339	39.6%	7,083	19.6%
Census Tract 1	6,567	4,973	75.7%	729	11.1%	2,655	40.4%	41	0.6%
Census Tract 2	7,506	3,750	50.0%	2,898	38.6%	2,007	26.7%	664	8.8%
Census Tract 3	6,926	4,222	61.0%	132	1.9%	4,256	61.4%	615	8.9%
Census Tract 4	11,066	8,503	76.8%	802	7.2%	3,738	33.8%	1,761	15.9%

Hendry County has a large percentage of people that claim Hispanic origin. Of the 36,210 residents in the county during the year 2000, almost 40% (14,339 persons) are of Hispanic origin. Glades, Charlotte and Lee counties all have lower proportions of persons of Hispanic origin than does the rest of the state. Florida's African-American population is 2,333,427, which is 14.6% of the State's total population. Hendry County has a total African-American population that is slightly higher than that of the state total. There are also three census tracts in the study area that have a higher African-American representation than that of the state.

The Native-American population of the study area represents less than one percent of the aggregate population of the study area.

2.14.2 Economy

Generally, a strong wholesale and retail trade, government and service sectors characterize Florida's economy. Florida's warm weather and extensive coastline attracts vacationers and other visitors and helps make the state a significant retirement destination for people all over the country. Agricultural production is also an important sector of the state's economy, and is especially significant to portions of the study area. Compared to the national economy, the manufacturing sector has played less of a role in Florida, but high technology manufacturing has begun to emerge as a significant sector in the state over the last decade.

The unemployment rate for Florida is 5.1 % (2003), which is greater than that of Lee (4.0%) and Charlotte (4.4%) counties. Hendry and Glades counties had unemployment rates that were much greater than the state total, with Glades' unemployment rate at 8.7% and Hendry County's unemployment rate at 11.7% (***Table 2-6***).

TABLE 2-6: INCOME AND EMPLOYMENT FOR COUNTIES AND CENSUS TRACTS

	Income					Employment	
	Median Household, 1999	**Personal Per Capita, 1999**	**Persons Below Poverty Level**	**% Below Poverty Level**	**Average Household Size**	**In Labor Force (+16 yrs old)**	**Unemployed**

Lee County	40,319	24,542	46,137	9.7%	2.31	186,417	7,234
Fort Myers MSA	40,139	24,542	42,316	9.6%	2.31	3,120	230
Hendry County	33,592	13,663	8,727	24.1%	3.09	14,579	1,235
Census Tract 1	37,210	15,460	1,197	18.2%	2.92	3,120	230
Census Tract 2	31,760	13,047	2,034	27.1%	3.15	3,318	420
Census Tract 3	34,250	12,315	1,894	27.3%	3.55	3,512	237
Census Tract 4	33,022	15,417	2,492	22.5%	2.87	4,425	280

Personal per capita income in Florida is $21,806 (1999), but is somewhat lower in Charlotte County at $21,557, and substantially lower in Glades County at $15,338 and Hendry at $13,663. Lee County experiences higher per capita income than that of the state average. Every rural census tract associated with the study area has lower than the state average per capita income.

In 1999 it was reported that 12.5% of Florida's population lived below the poverty level, while 24.1% of Hendry County's population lived below the poverty level, and 15.2% of Glades County lived below the poverty level. Charlotte County and the census tracts associated with it are both below the state poverty level figures. All Census tracts in Hendry County are above the poverty level than that of the state.

2.14.3 Commercial and Recreational Fishing

There exists some commercial fishing in the Caloosahatchee Estuary. The Florida Statistical Abstract (FSA) contains estimates for the direct employment in fishing in Lee County. According to the FSA, the fishing industry in Lee

County involves an estimated 40 businesses (FSA, 1997), with 180 employees, and an estimated annual payroll of $3.54 million. The use of cast nets in the estuary is reported to be common. In addition, there is reported to be substantial crabbing activity in the estuary. In Lee County, there are 638 saltwater products licenses and 267 permits for blue crab fishing.

The Caloosahatchee Estuary has important ecological connections with offshore commercial fish stocks. As described in Nelson (1992), many commercial finfish and invertebrate species use estuaries for critical stages of their development. ***Appendix G*** presents commercial landings, trips, and value data collected by the FDEP for the Pine Island Sound/San Carlos Bay area. As indicated in this appendix, in 1997 the value of the commercial landings from this area was approximately $1.7 million. The finfish and bait shrimp fisheries account for most of the landings and value. Although the shrimp landings are small, there is a significant offshore pink shrimp fishery that is based on Sanibel Island. This fishery is reflected in 1997 pink shrimp landings data for Lee County, which totaled 4,033,537 pounds. The Caloosahatchee Estuary and the area affected by freshwater releases from Lake Okeechobee comprise part of the nursery habitat for this fishery. The finfish and bait shrimp poundage, trips, and value data vary widely from year to year. This is due to changes in the fish population dynamics, fishing conditions, and fishing effort.

The Caloosahatchee Estuary also supports guided sport fishing and recreational fisheries. Nelson (1992) described the following recreational species as "highly abundant", "abundant", or "common" in the Caloosahatchee Estuary: tarpon, sea catfish, snook, crevalle jack, silver perch, pinfish, spotted seatrout, red drum, black drum, and stripped mullet.

2.15 EXISTING LAND USE

The Caloosahatchee River (C-43) West Basin Storage Reservoir is proposed for construction in north-western Hendry County. This reservoir is intended to reduce the fresh water pulses into Charlotte Harbor and the Caloosahatchee Estuary, and provide water storage for meeting environmental needs. Additional water, after environmental needs are met, could be used as supplemental water to help meet the needs of agriculture and urban communities in southwest Florida. The study area includes Lee, Hendry, Glades and parts of Charlotte County. Collier County is located in the general vicinity of the study area. ***Figure 2-12*** depicts the 2000 land use map for the southwest Florida region. This map was generated for the SWFFS and includes the Caloosahatchee River (C-43) West Basin Storage Reservoir study area.

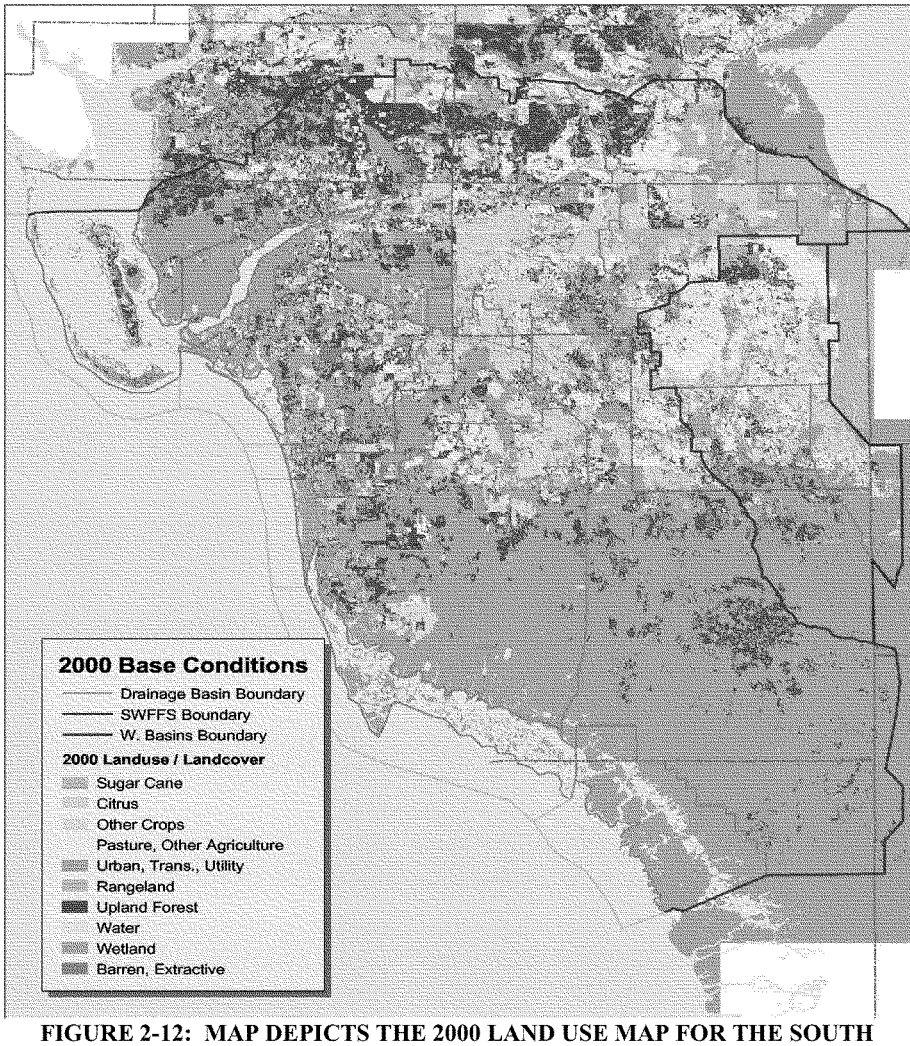

FIGURE 2-12: MAP DEPICTS THE 2000 LAND USE MAP FOR THE SOUTH WEST FLORIDA REGION

Much of the land use/cover change occurring in southwest Florida over the past several years can be categorized as either the creation of new developments in previously natural or agricultural areas, or the change in the types of agriculture practiced. Most of the new development appears to be in golf course/residential areas concentrated near Interstate 75 in Lee County. A majority of these residential areas and small reservoirs were associated with new golf course

communities. ***Table 2-7*** presents the number of acres associated with existing golf courses.

TABLE 2-7 GOLF COURSE ACREAGE

County	Year	Acreage
Lee	2000	8,962
Hendry	2000	120
Glades	2000	220
Charlotte	2000	460

The agricultural areas are inland from the urban areas and the Gulf Coast. They are being encroached upon by the urban areas and undergoing conversion within agricultural types. Much of Lee County is being converted from cattle farms to citrus, and there is a great deal of conversion year to year between pasture and row crops.

2.15.1 Agricultural Land Use

The Study Area continues to experience growth in irrigated agricultural acreage, especially citrus. The irrigated crops in this region are citrus, sugarcane, vegetables, sod, and greenhouse/nursery. Growth in citrus acreage is usually on land that was formerly pastureland. Descriptions of the agricultural acreage in each county are included ***Table 2-8.***

TABLE 2-8: TOTAL LAND AND FARM ACREAGE

Item	Florida	Charlotte	Glades	Hendry	Lee
Total Land Acreage	34,513,162	443,907	495,123	737,622	514,323
Farms	44,081	284	231	456	643
Farm Acreage	10,414,877	191,529	379,278	606,839	134,649

Source: USDA, NASS, 2002 Census of Agriculture

The following acreage by specific crop types was obtained from the Lower West Coast Water Supply Plan (LWCWSP) and pertains to acreage in 1995. The Caloosahatchee River (C-43) West Basin Storage Reservoir study area does not coincide exactly with the LWCWSP study area, but falls within the study area. Citrus is by far the dominant agricultural crop in the Lower West Coast (LWC) study area, and occupies approximately one-half of agricultural acreage in the region. Between 1968 and 1980 acreage remained at about the same level.

From about 1984 until about 1992, acreage grew rapidly, associated with the inter-regional movement of citrus acreage southward from Central Florida following several severe winter freezes in the mid-1980s. Since approximately 1992, citrus growth has slowed in the area. Tropical fruits (primarily avocados and mangos) and nuts are produced only in Lee County. In 1995, there were 1,930 acres of tropical fruits and nuts in Lee County. Vegetable crops grown in the study area include cucumbers, peppers, tomatoes, squash, eggplant, watermelons, Latin vegetables, snap beans, and potatoes. Different types of vegetables are often grown interchangeably, and in 1995 there were 44,231 acres of land used for vegetable production.

Hendry and Glades county areas are the only parts of the study area where sugarcane is produced. As a result of the cultivation practices used for sugarcane, 25 percent of the land used for sugarcane production is fallow in any given year. In 1995, a total of 35,443 acres of sugarcane were produced in the Hendry County Area. The seed corn production in southeastern Charlotte County varies from year to year, based primarily on the demand for seed corn, which in turn is dependent on seed corn production in other parts of the country. This variation in production is more a fluctuation than a trend. The estimate for seed corn production is 2,100 acres and 1,000 acres for soybeans. While fluctuations are anticipated, the magnitude of this acreage is typical. Rice in southern Glades County is grown during the summer months in rotation with sugarcane or winter vegetables, and takes place on land that would otherwise be fallow. Rice acreage in southern Glades County was assessed at 200 acres in 1995.

In 1995, there were a total of 650 acres of irrigated sod production in the LWC planning area. In 1995, there were 6,089 acres of greenhouse/nursery operations in the LWC planning area, and this is projected to increase to 10,627 acres by the year 2020.

2.16 NOISE

Within the major natural areas of south Florida, external sources of noise are limited and of low occurrence. Rural areas have typical noise levels in the range of 34-70 decibels, and urban areas may attain 90 decibels or greater. Noise generated on the project site is basically limited to agricultural machinery.

2.17 RECREATION AND AESTHETICS

Recreational opportunities in the basin include hiking, boating, fishing, and camping. Numerous recreation areas, such as Ortona Lock Recreation Area, Caloosahatchee Regional Park, and W.P. Franklin Lock Recreational Area, are extensively used by natives and visitors alike. Since the river is used for boat traffic between the east and west coasts of Florida, boat traffic is moderately

heavy and boating and fishing occurs in the area. The river banks are too steep to be useful for bank fishing. Several access points and three USACE lock structures are located along the river. Additionally, the FFWCC owns ramps at Wayside Park in Hendry County and at the intersection of SR 80 and Highland, east of Fort Myers, in Lee County. All the recreation sites along the river are well used, particularly on weekends.

Within the project footprint there are currently no recreation opportunities, as it is an active citrus grove. The visual aesthetics are characterized by limited viewsheds controlled by low topographic relief, typical of views of citrus groves, with a few remaining wetland areas scattered within the grove.

SECTION 3
FUTURE WITHOUT PROJECT CONDITIONS

This page intentionally left blank

3.0 FUTURE WITHOUT PROJECT CONDITIONS

The future "without project" condition describes the planning area's future if there is no federal action taken to solve the current problems. This condition is vitally important to the evaluation and comparison of alternative plans and to identify impacts (both beneficial and adverse) attributable to proposed federal actions. The without plan condition is the same as the "No Action" alternative that is required to be considered by the federal regulations implementing the National Environmental Policy Act (NEPA).

The assumption for this future without project analysis is that the project footprint would be in agricultural production as a citrus grove in 2050. Please see Section 3.15 Land Use for a more detailed description of future conditions of the project site and surrounding areas.

3.1 GENERAL ENVIRONMENTAL SETTING

The general environmental trends in the future without project condition are tied to the increase in population and decrease in quality and quantity of natural areas, as well as the continued high and low flows to the Caloosahatchee Estuary. The distribution of these high and low flows may change as increased demands on the water in Lake Okeechobee develop. Urban growth in Lee County has the potential to impact the region's environmental and water resources. Urban and industrial areas will increase, while range lands and upland forests will decrease. Wetland and aquatic habitat quality will continue to decline, as extreme flows from Lake Okeechobee will continue to cause huge variances in the salinity regime. The quantity and quality of fresh- and saltwater SAV will decline. This will generally leave less habitat for wildlife, resulting in a detriment to many threatened and endangered species as well as a decline in general ecological diversity of the region. The project site would most likely continue to be a producing citrus grove in the future without project condition.

Regulatory impacts were considered when compiling the future without project conditions. The MIKESHE model assumed no net loss of wetlands in the basin in the future without project (FWOP) scenario due to regulatory mitigation requirements. Under section 404 of the Federal Clean Water Act (CWA) permits are required for the discharge of dredge or fill material in waters of the United States including wetlands. In addition, unavoidable impacts to wetlands or other aquatic resources require compensatory mitigation. There are some exemptions under the CWA for agricultural activities. Digging ditches and farming uplands does not require a permit so this activity could occur in the basin without any USACE permit. Clearing and filling for development would likely require a permit. In that situation, mitigation may be done on site through enhancement and preservation of existing wetlands or offsite. In

addition, through the federal permit process the regulatory division of USACE evaluates compliance with other environmental laws such as Endangered Species Act (ESA).

3.2 CLIMATE

The National Oceanic Atmospheric Administration (NOAA) published historic rates of sea level rise at some NOAA stations in Florida (***Table 3-1***). The closest station to the Caloosahatchee River (C-43) West Basin Storage Reservoir Project area is Fort Myers; therefore, this station will be used to estimate sea level rise. The historic rate of sea level rise at Fort Myers is 2.29 millimeters per year (mm/yr) with a standard error of 0.452. Under current trends, it is estimated that sea level will rise 14 cm between 1990 and 2050 (2.29mm/yr x 60yr x 1/10cm/mm = 13.74 cm ≈ 14 cm).

TABLE 3-1: HISTORIC RATE OF SEA LEVEL RISE AT NOAA STATIONS IN FLORIDA

Atlantic Coast			Gulf Coast		
NOAA station name	Rate of sea level rise (mm/yr)	Standard error	NOAA station name	Rate of sea level rise (mm/yr)	Standard error
Fernandina Beach	2.04	0.12	Key West	2.27	0.09
Mayport	2.43	0.18	Naples	2.08	0.43
Miami Beach	2.39	0.22	**Ft. Myers**	**2.29**	**0.45**
-------	-------	-------	St. Petersburg	2.40	0.18
-------	-------	-------	Cedar Key	1.87	0.11

(Source: Sea Level Variations for the United States 1854-1999, NOAA, technical Report NOS CO-OPS 36, National Ocean Service, Silver Spring MD, Chris Zervas, 2001.)

Normalized sea level projections for 2025, 2050, and 2100, compared with 1990 level are shown in ***Table 3-2***. The normalized projection estimates represent the projected acceleration in sea level compared with historic trends due to the greenhouse contribution.

TABLE 3-2: NORMALIZED SEA LEVEL PROJECTIONS FOR 2025, 2050 AND 2100, COMPARED WITH 1990 LEVELS

Cumulative probability (%)	Exceedance frequency (%)	2025 (cm)	2050 (cm)	2075 (cm)	2100 (cm)
10	90	-1	-1	0	1
20	80	1	3	6	10
30	70	3	6	10	16
40	60	4	8	14	20
50	50	5	10	17	25
60	40	6	13	21	30
70	30	8	15	24	36
80	20	9	18	29	44
90	10	12	23	37	55
95	5	14	27	43	66
99	1	19	35	57	92
Mean		5	**11**	18	27
Standard deviation		6	10	15	23

To estimate sea level rise at a particular location, historic rate of sea level rise is added to the projected rise that would occur if current trends were to continue. For example, the historic rate of sea level rise at Fort Myers is 2.29 mm/yr with a standard error of 0.452 mm (***Table 3-3***). Under current trends, sea level will rise 14 cm between 1990 and 2050 (2.29mm/yr x 60yr x 1/10cm/mm = 13.74 cm ≈ 14 cm). Adding this 14 cm to the normalized values in ***Table 3-2***, the mean estimate for 2050 is 24 cm.

Since the historic rates of sea level rise in ***Table 3-1*** include the local vertical land motion, there is no need to adjust the estimated sea level rise to include historic vertical land motion unless there is strong evidence that the historical rate in vertical land motion has increased or decreased.

Table 3-3 shows the probabilities of various sea level rise amounts in the vicinity of Fort Myers for years 2025, 2050, 2075, and 2100.

TABLE 3-3: PROBABILITY DISTRIBUTION OF SEA LEVEL RISE FOR FORT MYERS FOR YEARS 2025, 2050, AND 2100

Cumulative probability (%)	Percent chance exceedance	2025		2050		2075		2100	
		cm	ft	cm	ft	cm	ft	cm	ft
10	90	7	0.2	13	0.4	19	0.6	26	0.9
20	80	9	0.3	17	.6	25	0.8	35	1.1
30	70	11	0.4	20	0.7	29	1.0	41	1.3
40	60	12	0.4	22	0.7	33	1.1	45	1.5
50	50	13	0.4	24	0.8	36	1.2	50	1.6
60	40	14	0.5	27	0.9	40	1.3	55	1.8
70	30	16	0.5	29	1.0	43	1.4	61	2.0
80	20	17	0.6	32	1.0	48	1.6	69	2.3
90	10	20	0.7	37	1.2	56	1.8	80	2.6
95	5	22	0.7	41	1.3	62	2.0	91	3.0
99	1	27	0.9	49	1.6	76	2.5	117	3.8
Mean		13	0.4	25	0.8	37	1.2	52	1.7

3.3 PHYSICAL LANDSCAPE

The lands within the project area would be developed consistent with surrounding land use patterns. The surrounding areas are predicted to still be in agricultural production in 2050. If the site remained a citrus grove, the geology and soils would not change significantly from the existing description.

3.4 HYDROLOGY

Changes to local hydrology are driven by changes in land use, water supply, water quality, and changes caused by other water resource projects in the watershed. Urban development and encroachment on previously undeveloped and low intensity agricultural lands in some areas of the Caloosahatchee Basin would be expected to increase the intensity and volume of runoff to local drainage systems and the Caloosahatchee River (C-43 Canal) during the wet season, thereby increasing flow rates and contributing to poor water quality. The increase in total area of impervious urban lands will also further decrease dry season base flows because less water infiltrates to the groundwater system, resulting in declining water table elevations.

As explained above, it is anticipated that a sea level rise of approximately 24 cm will occur over the period through the year 2050. This will impact control levels for canals within the Caloosahatchee River Basin to maintain a stable saltwater interface.

All of these factors would contribute to increasing ecological stress in the Caloosahatchee Estuary.

3.5 WATER MANAGEMENT

This section discusses the physical facilities and operational changes that are planned for the study area and are assumed to be in place for the future without plan condition.

3.5.1 Central and Southern Florida Project Modifications

The C&SF Project was authorized by the Flood Control Act of 1948, and modified by subsequent acts, as a plan of improvement for flood control, drainage, and other purposes covering an 18,000 square mile area of both central and southern Florida (C&SF). Within the Caloosahatchee River (C-43) West Basin Storage Reservoir Project area, C&SF canals include the C-43, C-20, and C-21. A number of efforts are currently underway by the USACE to modify the C&SF Project for environmental improvement. The following C&SF Project modifications are either in the planning, design, or construction phases and are included in the future without plan condition: 1) manatee protection, 2) other projects and structures, and 3) Lake Okeechobee Regulation Schedule (LORS).

3.5.1.1 Manatee Protection

The West Indian manatee (*Trichechus manatus*) is listed as a federally endangered species and is one of the most endangered species in Florida. As a response to recent manatee mortality trends associated with water control structures, the manatee protection C&SF modification project will provide operational changes and implement the installation of a manatee protection system at seven sector gates at navigational locks near Lake Okeechobee. The beneficial outcome of this modification project will be the reduction of risk, injury, and mortality of the manatee. The seven sector gates include S-193 at Okeechobee and S-310 at Clewiston on Lake Okeechobee; St. Lucie Lock and Port Mayaca Lock on the St. Lucie canal; and Moore Haven Lock, Ortona Lock, and W.P. Franklin Lock on the Caloosahatchee River. The future without plan condition for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project assumes that the automatic gate sensor devices are installed on these lock sector gates.

3.5.1.2 Other Projects and Structures

Existing projects and structures discussed in the existing conditions section of this report are assumed to remain in place and should be considered future without project conditions.

3.5.1.3 Lake Okeechobee Regulation Schedule

As part of the operation of the C&SF Project, the USACE establishes a water regulation schedule for Lake Okeechobee. A regulation schedule is a guideline for water managers to use in regulating the inflow and outflow of water through the various water control structures such as pumps, spillways and locks. Typically, a regulation schedule has water level thresholds which vary with the time of year and trigger discharges. The threshold values of regulation schedules define the release zones and are traditionally displayed graphically. Additionally, a corresponding table is typically used to identify the structure discharge rules for release zones.

Water levels are driven largely by climatic conditions across the entire watershed. One challenge of managing stage within Lake Okeechobee is that inflows to the lake frequently exceed total outflow capacity, causing the lake to rise very quickly. These sudden rises in stage may trigger discharges through the major outlets to the coastal estuaries in an effort to control excessive buildup of water in Lake Okeechobee. While the timing and magnitude of these releases is important for preserving the level of service for flood protection in the region, it also has significant impacts on the natural habitats of the downstream estuaries.

There is a need to manage Lake Okeechobee at a lower stage. Evidence of this has been clearly established for ecological reasons, such as the continued deterioration of Lake Okeechobee's littoral zone and both the Caloosahatchee and St. Lucie estuaries. The need to manage the lake lower also stems from integrity issues with the Herbert Hoover Dike (HHD) levee system that protects the surrounding communities from flood damage.

The goal of the new LORS is to implement a regulation schedule that would improve the health of Lake Okeechobee and the St. Lucie and Caloosahatchee estuaries, while continuing to ensure public health and safety, and with minimal or no impact to the competing project (lake) purposes. These goals are:

a. Ensure public health and safety
b. Manage Lake Okeechobee at optimal lake levels to allow recovery of the lake's environment and natural resources
c. Reduce high regulatory releases to the estuaries
d. Continue to meet Congressionally authorized project purposes including, flood control, water supply, navigation, fish and wildlife enhancement, and recreation

The 2007 LORS will result in water management operational guidance to be used on a daily basis in the management of Lake Okeechobee. Through the 2007LORS plan, the management of Lake Okeechobee water levels and

determination of Lake Okeechobee releases to the Water Conservation Areas (WCAs) and to tide (estuaries) is based on seasonally varying lake elevations divided into three bands. These bands include "High Lake Management," "Operational," and "Water Shortage Management." The High Lake Management Band is meant to address public health and safety, especially related to the structural integrity of HHD by providing the ability to make releases up to the maximum capacity that lake outlets will allow. The Operational Band is meant to facilitate authorized project purposes by providing the ability to make releases of various volumes, including no release; and Lake Okeechobee outlet canals should be maintained within their optimum water management elevations. The Water Shortage Management Band pertains to low lake levels which necessitate rationing water supplies. In this band, Lake Okeechobee outlet canals may be maintained below their optimum water management elevations. The water supply releases made within this band are made according to the SFWMD's draft Lake Okeechobee Water Shortage Management Plan (LOWSM).

The 2007 LORS provides the ability to make long-term, low-volume releases to the Caloosahatchee Estuary, St. Lucie Estuary, and WCAs. These releases include low-volume pulse releases and base flow releases to the Caloosahatchee and St. Lucie estuaries that allow Lake Okeechobee to be maintained at more desirable levels throughout the year. A pulse release attempts to simulate a natural rainstorm event within the basins. The receiving body would respond to the pulse release in a similar fashion as if a rainstorm had occurred in the upstream watershed. Although an average flow rate is targeted for the duration of the pulse release, daily releases vary. The pulse releases and base flow releases are intended to regulate lake levels and reduce the potential for future prolonged high-volume releases to the estuaries. The base flow releases also provide a benefit of maintaining desirable salinity levels in the estuaries. By regulating lake levels, these low-volume releases improve public health and safety performance by reducing risk to the HHD and provide improved benefits for the health of Lake Okeechobee and the estuaries.

3.6 WATER QUALITY

Future water quality conditions in the basin will be directly influenced by future land use, the operation schedule of Lake Okeechobee, and the implementation of Best Management Practices (BMPs) to control nutrient discharges. There are multiple state and Federal projects that will have an impact on future water quality loads within the freshwater Caloosahatchee Basin (upstream of S-79) as well as from the Caloosahatchee Estuary Basin (downstream of S-79). Two CERP projects, the Lake Okeechobee Nutrient Removal project and the Lake Okeechobee Sediment Removal project will result in reduced nutrient loading from discharges at S-79. Non-CERP programs that will impact water quality within the basin include:

1. USACE and SFWMD Revised LORS
2. SFWMD Lake Okeechobee Protection Plan
3. FDEP Lake Okeechobee Total Maximum Daily Loads (TMDL);
4. SFWMD Caloosahatchee Minimum Flows and Levels (MFL);
5. SFWMD Caloosahatchee River Water Management Plan (CWMP);
6. FDEP Caloosahatchee Basin TMDL
7. FDACS/FDEP Agricultural BMP Program for the Caloosahatchee Basin
8. SFWMD Urban Irrigation and Landscape BMP Implementation Projects
9. SFWMD Stormwater Management Regulations; and
10. Lee and Hendry Counties Stormwater Management Projects.

The Revised LORS is intended to decrease the frequency and severity of large volume discharges from the lake to the Caloosahatchee (C-43) and St. Lucie (C-44) rivers. The Lake Okeechobee Protection Plan and the Lake Okeechobee TMDL regulatory program will reduce nutrient loading into the lake through structural and non-structural measures. When implemented these programs should result in a reduction of nutrients contained in Lake Okeechobee discharges which in turn will reduce nutrient loading to the Caloosahatchee Estuary. The Caloosahatchee MFL program and CWMP are intended to ensure that urban, agricultural, and environmental water demands are met in the future. To the extent these projects alter the timing of river flows to the estuary, the shifting of nutrient loads from the wet to the dry season will result. The TMDL program for the Caloosahatchee will coincide with the development of numeric nutrient standards as well as the implementation of agricultural BMPs to meet those standards. Local government stormwater protection programs and projects within the basin will result in a reduction of pollutant loading from existing and future development. The net result of these programs should be a reduction of nutrient and other pollutant loads to the estuary in 2050.

Projections of future water quality in the Caloosahatchee River and Estuary are presented below. The estimates for Future Without Conditions have been developed under the assumption that non-CERP projects are successfully implemented by 2050 while CERP projects have not been implemented. In the absence of the CERP projects, the state will still be compelled by the TMDL regulations to achieve similar reductions in nutrient loads in order to meet requirements of the CWA.

3.6.1 Freshwater Caloosahatchee Sub-Basin (Upstream of S-79)

Flows at S-79 consist of runoff from the freshwater Caloosahatchee Basin as well as discharge from Lake Okeechobee. As this basin becomes more urban or more intensely cultivated, the quantity of runoff will increase which will likely result in higher nutrient loads. There are several commonly used methods to estimate the impact of land use changes on the quality of rainfall runoff. A quick and fairly standard method for calculating average annual pollutant loading is to

adapt the rational method used for estimating rainfall runoff. This load quantification methodology requires estimates for land use acreages, average annual rainfall, land use specific loading factors, and land use specific runoff factors. Loading estimates were prepared using land use specific runoff quality factors adapted from Harper (2003). The results of the analysis indicate that nitrogen and phosphorus loading from the freshwater Caloosahatchee Basin will increase by approximately eight percent. The increase in nitrogen and phosphorus loading expected under 2050 future without conditions is a reflection of the increase in the volume of runoff which will accompany urbanization of rural areas. If the implementation of BMPs to control runoff quantity and quality are moderately successful, it is likely that 2050 future without nutrient loads from this basin will be no higher than existing condition loads.

It is difficult to predict how much the average annual flow from Lake Okeechobee will change if CERP is not implemented. However, since there is a great desire to reduce the magnitude and frequency of extremely large discharge events at S-79, it is likely that 2050 without project average annual flow through S-77 will be reduced relative to the existing flow quantity. At the same time, efforts to reduce nutrient loading in Lake Okeechobee are likely to result in an improvement in the quality of water discharged from the lake. The net impact of reduced S-77 releases and improved lake water quality is a reduction in nutrient loads contributed by the lake to the estuary. Overall, nutrient loads delivered through S-79 to the estuary are expected to be no more than presently delivered to the estuary. If BMPs are implemented within the basin and are moderately effective, nutrient loads from upstream of S-79 in the future without condition should be less than the existing condition loads.

3.6.2 Caloosahatchee Estuary (Downstream of S-79)

Water quality conditions in the Caloosahatchee Estuary are influenced by nutrient loads at S-79, by runoff from the estuary sub-basin, and nutrient loads contributed by point source contributors such as wastewater treatment plants. Under the future without 2050 condition, the fraction of nutrient loads within the estuary that are contributed by flows from upstream of S-79 will continue to be between 65 percent and 75 percent as in the present condition.

Using present land use and future land use projections combined with typical runoff coefficients, it appears that the quantity of runoff from the estuary sub-basin may increase by up to 25 percent if no BMPs are implemented. The actual increase in runoff and nutrient load is likely to be significantly less than 25 percent since most of the shift in land use is to new urban development that will be required to have stormwater ponds. These ponds are effective in reducing offsite runoff as well as providing effective removal of non-nutrient pollutants such as hydrocarbons and heavy metals.

Since the 2050 population will be substantially greater than the year 2000 population, the quantity of treated wastewater effluent discharged to the estuary will increase. Regardless, with the expected implementation of TMDLs for the discharge of nutrients into the estuary, it is not unreasonable to expect that by 2050 most existing wastewater treatment plants and all future plants will incorporate tertiary treatment processes to remove nutrients. If the TMDL program is effective, the 2050 nutrient loads from wastewater effluent will be similar to or less than the present nutrient loads.

3.6.3 Summary

The overall change in nutrient loads delivered to the estuary under the future without condition will depend upon the success of the implementation of BMPs to control point and non-point discharge quality. Nutrient loads to the estuary will likely increase by ten percent or more if no BMPs or nutrient TMDLs are implemented in the Caloosahatchee Basin. If the implementation of BMPs substantially reduces non-point source nutrient loads and tertiary wastewater treatment is implemented basin wide, the 2050 future without nutrient loads may decrease by more than 25 percent as compared to the existing condition.

3.7 PLANT COMMUNITIES

The project site would most likely continue to be a producing citrus grove in the future without project condition. Consequently, the plant communities would be almost identical to those in the existing conditions.

3.7.1 Exotic Plants

Exotic plants have the potential for devastating effects to the entire south Florida ecosystem in the future. Species such as Melaleuca, Lygodium, Brazilian pepper, and Australian pine are all well established in south Florida and have the potential to drastically alter the entire ecosystem. The abundance and distribution of exotic/nuisance vegetation (e.g., Brazilian pepper) that provide little to no value for wildlife is expected to increase unless intensive control and removal efforts are successfully implemented. However, there are many efforts occurring to control exotic plants, including a CERP project entitled *Melaleuca Eradication Project and Other Exotic Plants-Implement Biological Controls*. If this occurs, the future without project would still include exotic plants but would likely include a different array of damaging plants, as controls are developed for established exotics and new exotics are introduced into the system. Because the project site is predominantly agriculture, it is not likely that exotics would be a predominant feature in the landscape. Within the project footprint, the exotic vegetation distribution along canals might change as biological controls become available for various exotics and/or new exotic plants invade the site.

It is difficult to forecast the future success of exotic control programs. Through a concerted effort across many agencies, there has been good success in controlling Melalecua in South Florida. It is still a major exotic pest, but it is now controlled rather than spreading. If similar resources are invested to control other major exotic pests in south Florida (such as those listed above), there is good reason to believe these programs would be a success. However, since there are a large number of exotic pest plants and limited resources to invest in this problem, it is hard to determine what will occur. If the programs are at least somewhat successful a more natural ecosystem will evolve due to other restoration efforts. If the ecosystem is overwhelmed with exotics and adequate exotic control programs are not implemented, exotic plants are expected to continue to spread and multiply at an alarming rate.

3.8 WETLANDS

This site would most likely continue to be a producing citrus grove in the future without project condition. Therefore the description of wetlands would be almost identical to that in existing conditions. It is likely that the quality of the wetlands may continue to decline as fluctuations in the hydrology continue and water quality declines as a result of agricultural run-off.

3.9 FISH AND WILDLIFE RESOURCES

Land use projections for 2050 predict that the acreage of natural habitats (e.g., upland forests and wetlands) and low intensity agricultural lands (e.g., unimproved and woodland pastures) in the area will decline. As these lands are developed or converted to more intensive uses, the quality of fish and wildlife habitat will likely decrease and become more fragmented. Wetland and aquatic habitat quality will continue to decline as extreme flows from Lake Okeechobee continue to cause huge variation in the salinity regime. The quantity and quality of fresh and saltwater SAV will also decline. Marshes will continue to deteriorate and convert to monocultural stands of emergent plants such as cattail, or convert to shrub/scrub habitats containing exotic or nuisance species. Both monocultures and exotic/nuisance shrub/scrub communities are low quality habitats.

Loss and degradation of habitat have generally resulted in the reduction of reptile and amphibian populations and that trend would likely continue. Populations of several furbearing animals that are dependent on higher quality habitats (e.g., muskrat, mink, and river otter) or that require large areas of contiguous habitat to survive (e.g., black bear) are also projected to decrease by 2050. Raccoons, opossums and other species that can survive in fragmented habitats with greater human presence will increase by 2050. In general seabird and shorebird populations show decreasing population trends and are projected to continue to decline into 2050. Waterfowl, wading birds, raptors, rails, coots,

and gallinules are also expected to decrease by the year 2050 as estuarine and freshwater habitat quality continues to decline under future without project conditions. The above predictions are based almost exclusively on the deterioration of wetland and forested habitats adjacent to the study area.

The project site in the future without project would not change significantly from the existing condition, although anticipated urbanization and fragmentation of surrounding natural areas will result in an overall decline in wildlife resources in the future.

Within the Caloosahatchee Estuary, salinity and proximity to SAV, mangroves, or marsh edge strongly determine the distribution of most fishes. For example, fish abundance declines dramatically with distance from marsh edge (Baltz et al. 1993). SAV, mangroves, and marsh habitats provide cover for juvenile fishes and adults of smaller species, as well as substrate for epiphytes and epifauna, which small fishes consume. Larger predatory fishes, such as spotted seatrout and red drum, forage along the edges of such intertidal habitats for small fishes, blue crab, and shrimp. Fishes that live in the open water of estuarine bays, such as bay anchovy and Gulf menhaden, gain refuge from sight-feeding predators in the turbid water. Those prey species are typically filter feeders, which eat zooplankton and phytoplankton. Demersal fishes, such as flounders, live in proximity to the bottom and are typically indistinguishable from the substrate. The deterioration of SAV and marsh habitats may temporarily benefit some estuarine-dependant fisheries, but an eventual decline in productivity will result as detrital input and SAV are significantly reduced due to extreme variations in salinity levels. The long-term loss of nursery habitat will result in population declines for many species of estuarine and marine fishes and macroinvertebrates, including those whose young of the year use fresher habitats.

3.9.1 Threatened and Endangered Species

As an active citrus grove, the proposed project site would continue to provide limited habitat value for threatened and endangered species. Direct loss of habitat, as well as fragmentation of habitat in surrounding areas, is likely to result in a continued decline in threatened, endangered, and state listed species. Section 9 of the Endangered Species Act (ESA) prohibits the unauthorized "take" of listed species on public and private lands, as a result of Federal and non-Federal actions. Future Federal actions unrelated to the proposed action but located in the study area, will require separate consultations pursuant to Section 7 of the ESA. In addition, future non-federal actions will be coordinated with USFWS through Section 10 of the ESA.

3.9.2 Essential Fish Habitat

Aquatic habitats within the Caloosahatchee Basin have been altered through the channelization of the river. Nevertheless, the basin continues to support fishery resources of some recreational and commercial importance. At least 70 percent of Florida's recreationally or commercially sought fishes depend on estuaries for at least part of their life histories (Harris et al. 1983, Estevez 1998, Lindall 1973). Seagrass communities within the Caloosahatchee Estuary provide critical refugia for juvenile fish such as redfish, grouper, snook, and spotted seatrout. The decline in juvenile abundance and distribution of these and other species, along with an overall decrease in species richness may be related to the loss of seagrass habitat and/or a result of alterations in the salinity regime and the timing of the freshwater discharges from the S-79 structure. The future without project condition would result in a loss of essential fish habitat by projected further disruptions in the distribution, timing and quantity of water flows into the Caloosahatchee Estuary.

3.10 ESTUARINE RESOURCES

Without the Caloosahatchee River (C-43) West Basin Storage Reservoir Project, conditions in the estuary will continue to worsen between the present state and 2050. Annual variability in flow and salinity will remain high and established MFLs for the region will not be met. This will lead to salinity extremes outside of the tolerance ranges of many estuarine organisms and result in decreased species diversity. Further, there will be declines in estuarine habitat (SAV and oysters) and as a result, additional declines in the species that utilize these habitats.

Without the reduction of extreme flow and high salinity events, oyster reefs will eventually loose a large percent of the adult population and the ability to produce enough spat to reestablish previously stressed reefs. Without continued settlement, reefs (substrate) will eventually breakdown and become buried in the soft organic sediments. SAV will continue to follow current trends of spatial reduction. There will be substantial losses of *Vallisneria* and its seed bank, possibly to the point of no recovery, in the low salinity areas as it tends to be more fragile than the higher salinity species. In addition, water clarity is expected to decrease resulting in additional stress on the SAV.

3.11 AIR QUALITY

Due to increased population and urbanization, air quality in the future is expected to be degraded, while still complying with air quality standards.

3.12 HAZARDOUS, TOXIC AND RADIOACTIVE WASTE

The four major land parcels acquired or being acquired for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project are the Berry Groves tract, Bryan Paul tract, the MG Enterprises, LLC property, and the Griffin property. Over the last six years, the SFWMD has performed multiple Environmental Site Assessments as well as worked to remediate most of the point source contamination sites (a description of the findings of these assessments and completed remediation efforts are found in the existing conditions portion of this report). At present, most of this land is leased to agricultural operators who continue to cultivate the thousands of acres of citrus groves located on the properties. If the reservoir project is not constructed, it is likely that the SFWMD will either continue to lease the land to citrus farmers or sell the land to willing buyers. With no reservoir on the site, the potential for bioaccumulation of copper or other toxic substances from contaminated site soils is much less since this usually occurs when the soils are submerged. If the properties continue to be used as working groves, the application of pesticides will continue. New point source contamination sites on the properties will likely occur, but these new sites may be contaminated to a lesser extent than in the past given modern best management practice (BMPs) for the application of fertilizers, pesticides, herbicides and fungicides. Overall, since the future without condition will not include a reservoir on the site, the properties will pose only a typical HTRW risk to the environment similar to other citrus operations.

3.13 CULTURAL RESOURCES

Without the proposed project, archeological site 8HN129 may be destroyed as a result of development or expansion of citrus production. Since the site is located in the uplands, even though it is adjacent to a large wetland, it is probable that the site would be destroyed without evaluation or mitigation.

3.14 SOCIO-ECONOMIC CONDITIONS

Competition for regional water resources has intensified with the increase in population and agriculture industry growth. This places a strain on existing resources, which will eventually surpass the readily available sources. When the needs of the natural system are then factored in, demands become greater and conflicts among competing water users will become even more severe.

While most people recognize the need for a healthy ecosystem to support the region's economy and jobs, many people are concerned that restoration projects will displace farms and other businesses, limit development, reduce available water supply and reduce job opportunities. By contrast, continued degradation of the southwest Florida ecosystem will adversely affect the tourism and recreational industry that are important to the regional economy. The economic

future of the area will depend on both continued agriculture presence and new residential and commercial prospects. There is local concern that the infrastructure and services demanded by a growing residential population will exceed the means of producing the infrastructure and services.

3.14.1 Population Projections

Population for the four counties in the immediate study area (Charlotte, Glades, Lee and Hendry counties) increased at a high rate during the period from 1990 to 2000 (***Table 3-4***). Charlotte increased 27.6 percent, Lee 31.6 percent, Glades 39.3 percent, and Hendry 40.5 percent. The population of Florida and the United States increased 23.5 percent and 13.1 percent respectively over the same period.

According to the population projection derived from the Florida Bureau of Economic and Business Resources (BEBR), population in Charlotte County is expected to increase over 83 percent from 2000 to 2050; in Glades County, to increase by 74 percent; Hendry County, to increase by 96 percent; and Lee County, to grow by 97 percent. Florida as a whole is projected to grow 86 percent by 2050. The projected growth of the entire south Florida nine-county area is anticipated to be 78 percent over the same 50-year period. These estimated population increases are reflected in future without project condition water demands and land use patterns.

TABLE 3-4: CHARLOTTE, GLADES, HENDRY & LEE COUNTIES, POPULATION ESTIMATES 2000-2050 (1,000S) (BEBR PROJECTIONS, US CENSUS (2000))

Area	2000	2010	2020	2030	2040	2050
Florida	15,982.4	18,866.7	21,792.6	24,528.6	27,118.7	29,714.5
Charlotte County	141.6	169.5	198.9	225.9	242.8	259.8
Glades County	10.6	12.4	14.2	16	17.2	18.4
Hendry County	36.2	44.4	53.3	61.8	66.4	71.1
Lee County	440.9	546.8	653.3	753.9	810.3	866.9

3.15 LAND USE

Future land use projections in the Caloosahatchee Basin were updated as part of the larger regional Southwest Florida Feasibility Study (SWFFS). These regional projections will serve as a starting point for describing the C-43 project

study area's land use. These projections have been reviewed by agricultural and governmental interests in the study area and will be used as the most likely future scenario. These land use figures have been incorporated into C-43 project modeling efforts and presented in this PIR. The projections resulting from the SWFFS update apply to 2025 and 2050 conditions. For the C-43 study area, the 2025 land uses have been extended to reflect expected 2050 conditions. It is not anticipated that the agricultural acreages will increase or decrease substantially between 2025 and 2050, but the total urban acreages will increase in area and increase in density to account for the increase in population.

Land use in the Caloosahatchee Basin is split between agricultural land use, urban/metropolitan land and conservation land. In the eastern portion of the Caloosahatchee Basin, Hendry, Charlotte, and Glades counties have been predominantly agriculture and rural in nature, while in the western portion of the basin, Lee County is more urban and supports industrial and commercial development. The land use, as described by the Southwest Florida Regional Planning Council (SWFRPC), details Hendry County as remaining largely agricultural, with urbanized areas in Clewiston to the east and La Belle to the west, and intermittent preserves and wetlands throughout. Additionally there are two main industrial concerns in Hendry County, one west of Clewiston and one near the Lee County border. Like Hendry County, Glades County remains largely agricultural in 2025, with some urbanized areas (La Belle's northern reaches and Moore Haven on Lake Okeechobee) and preserves and wetlands throughout. Within the study area, Charlotte County will remain vastly agricultural with some preserves and wetlands areas.

The predominant land use in the Caloosahatchee Basin is agricultural, and is expected to remain so in the future. The study area continues to experience growth in irrigated agricultural acreage. The irrigated crops in this region are citrus (the dominant irrigated crop), sugar cane, vegetables, sod, and greenhouse/nursery. Over the past two decades, southwest Florida has had the fastest growing citrus acreage in the state. Growth in citrus acreage is usually on land that was formerly pastureland. Sugar cane closely follows citrus in dominance in terms of crops grown in the Caloosahatchee Basin. It is produced in the Caloosahatchee Basin in close vicinity to Lake Okeechobee (in Hendry and Glades counties). Sugar cane acreage has continued to increase since 1995 and is expected to continue to increase in the future. Irrigation is typically applied from the surface water sources in the Caloosahatchee Basin and consequently, subsidence is not a significant problem due to the soils being generally sandy, rather than organic.

In terms of urban and industrial development, Lee County is the most populous part of the study area. The Fort Myers/Cape Coral Metropolitan Statistical Area (MSA), unincorporated areas of Lehigh Acres, Buckingham, North Fort Myers, South Fort Myers, and East Fort Myers constitute the bulk of the population in

the western portion of the Caloosahatchee Basin (see ***Table 2-4*** in ***Section 2*** on population estimates by county). Urban growth in Lee County has the potential to impact the region's environmental and water resources. Drainage of wetlands caused by urban expansion, loss of natural surface water storage areas, and contamination from urban land use are the major water related issues in the urban areas. Growth in this part of the basin generally follows the I-75 corridor, with the greatest portion of the population being located west of S-79. The majority of projected urban growth in this part of the basin is located to the east of I-75 toward the S-79 and contains a mixture of single family/multifamily dwellings, commercial and industrial facilities, some mining operations and preserves/wetlands. ***Figure 3-1*** presents a map of the 2050 future land use conditions in the C-43 study area. ***Figure 3-2*** presents a map showing changes between existing (2000) conditions and future without project conditions. ***Table*** 3-5 shows changes to land use for the 2025 and 2050 conditions.

There are a number of areas where urban development, agriculture, and/or proposed conservation areas compete for the same land. While these competing areas are not large compared to the entire area being modeled, they are significant. There were two most likely scenarios that were determined to be applicable to the C-43 study area. The first of these scenarios corresponds to land use in 2025, the second to land use in 2050. The first scenario has agriculture out-competing or "trumping" new low-density residential urban use, agriculture develops in areas proposed for conservation (not existing conservation lands, however), and marginal urban land has not developed yet. The second scenario, or 2050 conditions, also has agriculture trumping new low-density residential urban, agriculture is allowed to develop in areas proposed for conservation, but marginal urban land has now developed. ***Figure 3-1***, ***Figure*** 3-2, and ***Table 3-5*** show the projected difference between 2000 and 2050 land use. General characterizations of the study area can be determined and forecasts that in the future, urban lands and agriculture will increase in acreage, resulting in a decrease in natural areas. Within the C-43 study area, urban lands are expected to increase from 47,000 acres in 2000 to 114,000 acres in 2025 and 127,000 acres in 2050. Sugar cane is expected to increase to 116,000 acres in 2025 and decline slightly to 113,000 acres in 2050. Acreages for citrus are 118,000 in 2025 and 110,000 in 2050. Vegetable crops and sod production are expected to increase by 10,000 acres by 2025. Given the high probability that urbanization will meet or exceed the counties' current future-growth plans within the next 20 years, it may be difficult for the agricultural community to meet its 2025 goals.

3.16 MUNICIPAL AND INDUSTRIAL WATER SUPPLY

The Restudy recommended the development of a feasibility study to identify southwest Florida water resource conditions, and to develop potential solutions to any problems that may be identified. This municipal and industrial (M&I) water use forecast is part of the overall SWFFS, and includes Lee County, most of Collier and Hendry counties, and portions of Charlotte, Glades and Monroe counties, which encompass the Caloosahatchee River Basin and the C-43 study

area. The water demand projections for the SWFFS do not exactly coincide with the C-43 study area. Collier County is not included in the C-43 study area. The water use sectors for which forecasts were developed include public and self-supply domestic (residential), commercial, industrial, government, and unaccounted-for water loss. Water use in agriculture, mining, and power generation were not addressed as part of the M&I forecast, but are addressed under a separate agricultural water demands section. The purpose of the M&I water use forecast is to estimate existing water use and to develop water use projections for the SWFFS area.

An M&I forecast is required as input to modeling efforts which serve as the basis for planning and optimally designing the Caloosahatchee River (C-43) West Basin Storage Reservoir for both existing and future planning conditions. The planning horizon extends to the year 2050. Water use is estimated from the present to 2050 for natural area environmental purposes, agricultural irrigation purposes, M&I use, and other purposes.

The M&I water use forecasts were developed using the IWR-MAIN Water Demand Management Suite. The IWR-MAIN software allows water use forecasts to be developed based on existing water use patterns and existing or forecast socioeconomic parameters and then allows the impact of water conservation measures on those water uses to be evaluated. To maintain consistency with the water use forecasts developed for the Initial CERP Update (ICU), the water use models developed for the western portion of the study area in the ICU analysis will be used in this analysis. In the ICU, residential water use was forecast using a multiplicative forecast model and nonresidential water use was forecast using a constant use rate model.

Golf course irrigation requirements were based on a model developed by SFWMD and previously used in projecting water use in the Lower West Coast Water Supply Plan (LWC WSP). The SFWMD model consisted of using multiple regression analysis to project future golf course acreage as a function of projected population, and then applying irrigation requirements to those acreages based on the Agricultural Field Scale Irrigation Requirements Simulation (AFSIRS) model. Irrigation requirements from AFSIRS, based on a representative irrigation system/rainfall station/soil type combination for each county, were then applied to the projected golf course acreage to develop projected golf course irrigation requirements.

Consistent population projections are critical to the development of M&I water use because they are used to directly project housing and employment statistics, the main drivers of the IWR-MAIN water use models. The population projections from 2000 to 2050 were based on population projections produced by the University of Florida, BEBR. BEBR generates low, medium, and high sets of population projections for each county in Florida for 2005 through 2030. The

medium population projections are believed by BEBR to most likely provide an accurate forecast of future county populations. The high and low population projections were developed to address uncertainty based on past population forecast error.

Three population projection scenarios were developed for this analysis. The BEBR medium projections were the basis for the medium or most-likely scenario for all counties, and the BEBR high and low population projections were the basis for the high and low scenarios, respectively. In order to develop projections to 2050, the growth rate exhibited in the national population projections from 2030 to 2050 was applied to the projected 2030 BEBR population for each county.

The IWR-MAIN models were calibrated to local water use patterns using the most recent data available (2000), then used to estimate water use for 2000 and project water use, in five-year intervals, to 2050. Four sets of forecasts were developed. Three were based on differing population projection scenarios, and one was based on one-in-ten year drought conditions. Projection of future water use included the implementation of all reasonable conservation measures.

According to the USGS, in 2000 estimates of annual water withdrawals (***Table*** 3-6***)*** total public-supply water use for the region is estimated at 72 MGD and from the IWR-MAIN model (***Table 3-6***) the total M&I water use is estimated at 115 MGD. The addition of 681 MGD of agricultural water use increases total water demand for the region to approximately 796 MGD. Agricultural water use accounts for 86 percent of the total use; public-supply water use, nine percent; and recreational self-supply, about four percent.

TABLE 3-6: USGS ESTIMATED TOTAL WATER USE (MGD), FOR SELECTED COUNTIES, 2000, EXCLUDING MINING AND POWER GENERATION

	Municipal and Industrial							
		Self-Supply						
County	Public Supply	Domestic	Commercial	Industrial	Recreation	Sub Total	Agriculture	**Grand Total**
Charlotte	14.21	3.55	0.11	0	3.48	21.35	47.19	**68.54**
Glades	0.55	0.61	0.04	0	0.42	1.62	69.02	**70.64**
Hendry	4.72	1.67	0.21	0.51	1.09	8.2	503.91	**512.11**
Lee	52.37	8.86	0.46	0.09	22.66	84.4	60.51	**144.95**
Total	**71.85**	**14.69**	**0.82**	**0.6**	**27.65**	**115.57**	**680.63**	**796.24**

On the county-level, the largest total water user in the study area in 2000 was Hendry County, mainly because of agricultural water use. Hendry County used a total of 512 MGD, or 64 percent, of the total regional water use. Of this

amount, 504 MGD (or 98 percent) was agricultural use and 4.7 MGD was public-supply M&I water use. Lee County's total water use was 145 MGD, the second highest in the study area, with public-supply water use accounting for 52 MGD or 36 percent. Lee County had the highest self-supply domestic water use in the region at 8.9 MGD. Lee County also had high recreational water use, with 22.7 MGD.

Table 3-7 represents the conservation-adjusted, most likely population scenario, water use forecast and the percent of total water use associated with each county or county area in the study area, for 2000, 2025, and 2050. Lee County accounted for 90.7 percent of all M&I water use in the study area in 2000, and will account for 90.4 percent of all water use by 2050. The population of Lee County is projected to increase by 97 percent over the same time period. The Glades County Area generates the smallest use, at slightly more than two percent of the total regional water use over all time periods. Due to the small population in the Charlotte County portion of the study area, the water use totals for Charlotte County are incorporated into those of Glades County and therefore the USGS 2000 baseline totals do not exactly equal the IWR-MAIN 2000 totals.

TABLE 3-7: C-43 STUDY AREA, M&I CONSERVATION-ADJUSTED WATER USE AND DISTRIBUTION, BY COUNTY AREA MOST-LIKELY POPULATION SCENARIO, 2000, 2025, AND 2050

	2000		2025		2050	
Area	MGD	Percent of Total	MGD	Percent of Total	MGD	Percent of Total

3.16.1 Agricultural Water Demand

The SFWMD calculated agricultural water demands as part of the CWMP in April 2000. These water demand calculations are the most current demands available for the C-43 study area and are a sufficient base point for demonstrating future demands and trends for the planning horizon.

The Southwest Florida Regional Planning Council (SWFRPC) has estimated that total agricultural acreage will increase between three percent and seven percent between 1995 and 2020 while citrus acreage will increase between 54 and 81 percent and sugar cane between 62 and 190 percent. The increase in

citrus and sugar cane acreage is due in a large part to conversion of existing irrigated acreage that is in other crop types to citrus and sugar cane. Based upon representation from the agricultural industry and Citrus Administrative Committee (CAC) discussion and concurrence, 2020 citrus acreage of 112,500 and sugar cane acreage of 125,000 were modeled. This represented a reduction from the SWFRPC estimate but an increase from the SFWMD District-Wide Water Supply Assessment (DWSA) completed by the SFWMD in July 1998.

The acreage for citrus and sugar cane in the 1995 CWMP does not exactly coincide with the land use update presented in this section. Upon adoption of the new land use figures, the agriculture water demand figures will be updated. A scientific procedure that considered existing land use, ownership, suitability for crop use, and proximity to existing agricultural lands was used to adjust the 1995 land use map to the 2020 land use projections. An explanation summarizing the steps involved in development of the 2020 land use coverage is included in the Land Use section of the CWMP. Based on the 2020 land use map, the MIKESHE model was used to estimate future agricultural demands.

The MIKESHE model developed for the CWMP was used to estimate the future demands by incorporating the 2020 land use information and modifying irrigated areas within the model to match the new land use. The MIKESHE model used an eight-year period (1988-1995) to simulate demand. The selected period represents a combination of wet, dry, and average years representative of variations within the Caloosahatchee Basin. The resulting demands for the 2020 Base Case using the MIKESHE methodology therefore represents probable demands based on 2020 land use and hydrologic data corresponding to an eight-year period. The resulting demands for the entire planning area, including both the Lake Okeechobee Service Area (LOSA) and non-LOSA portions of the basin, were obtained.

Table 3-8 summarizes the simulated 2020 irrigation demand for major agricultural land use categories for the CWMP area based on the MIKESHE model

TABLE 3-8: SUMMARY OF 2020 WATER USE DEMAND BASED ON THE MIKESHE FOR MAJOR AGRICULTURAL LAND USE CATEGORIES.

Crop	Water Use (1,000 acre-feet/year)
Citrus	242
Sugar cane	181
Vegetables	27
Total	450

Irrigation demands are expected to increase approximately 55 percent in the Caloosahatchee Basin between 1995 and 2020, according to the CWMP. No projected increases in irrigated acreages between 2020 and 2050 are expected, and there may potentially be a slight decline. It is expected that 2050 demands will approximate 2020 demands of 450,000 acre feet annually. After completion of the 2025 and 2050 land use projections, these new acreage figures will be modeled and new estimates of agricultural water demand will be presented.

3.17 NOISE

Noise in south Florida is expected to increase due to increased populations and urbanization. Noise levels within the project site should not change significantly in the future without project condition.

3.18 RECREATION AND AESTHETIC RESOURCES

The Florida State Comprehensive Outdoor Recreation Plan (SCORP) is the best source of information on recreation demand and supply at the state and regional scales. It divides the state into 11 planning regions, each with clusters of counties. Region 9 is the planning region that encompasses the study area and includes the following counties: Charlotte, Collier, Glades, Hendry, Lee, and Sarasota.

Recreation demands were developed for the SCORP through surveys of residents and tourists. The State of Florida's Division of Recreation and Parks conducts periodic surveys of resident and tourist participation in recreation activities to estimate outdoor recreation in Florida. The recreation participation information was derived from the 2000 surveys conducted by the University of Florida, Department of Recreation, Parks, and Tourism. Participation in outdoor recreation activities is expressed in terms of user-occasions, which occur each time an individual participates in a single outdoor recreation activity. The number of user-occasions was calculated for each planning region as well as the entire state by type of activity. Demand was estimated for 1997, 2000, 2005 and 2010 by applying the per capita participation rates to population projections.

Table 3-9 presents 1997 and projected 2010 user-occasion demands for selected recreation activities. Activities selected were those that could potentially be affected by the hydrologic changes or ecological changes associated with the alternative restoration plans. The table includes user-occasions as well as facility/resource needs. The region is expected to have significant increases in demands for the selected recreation activities with a commensurate need to increase development of the regions' recreation resources and facilities.

TABLE 3-9: DEMAND AND FACILITY NEEDS (1997 AND 2010) FOR SELECTED RECREATION ACTIVITIES IN SOUTHWEST FLORIDA (SCORP REGION 9)

Activity	Units	Demand (user-occasions)		Resources / Facility Needs	
		1997	2010	1997	2010
Hunting	Acres	108,131	139,247	0	0
RV / Trailer Camping	Camp Sites	1,501,713	2,386127	0	0
Tent Camping	Camp Sites	155,069	204,538	0	0
Hiking	Miles	1,299,375	2,011,069	223	517
Freshwater Fishing	Feet	543,125	779,561	0	0
Nature Study	Miles	2,146,713	3,073,615	10.87	56.8
Bicycle Riding	Miles	11,761,917	16,675,164	771.33	1,177.08

Source: Florida Department of Environmental Protection, 2000.

In summary, the Southwest Region (Region 9) ecosystems support a significant amount of outdoor recreation. A large portion of the expenditures comes from tourists. As can be seen from ***Table 3-9***, recreation activities for which there is an existing and increasing supply shortage include hiking, bicycle riding and nature study. With continued development and growth in southwest Florida, recreational demands are anticipated to increase and the current level of recreational opportunities will be insufficient.

The aesthetics of the proposed project site will be unchanged in the future without project condition. Surrounding areas will reflect a mixture of unchanged agricultural views as well as an increase in urbanization and population growth in some areas.

3.18.1 Commercial and Recreational Fishing Resources

Altered freshwater releases to the Caloosahatchee Estuary from Lake Okeechobee and the Caloosahatchee watershed have stressed estuarine ecosystems due to excessive salinity fluctuations, critically low benthic oxygen levels, increased turbidity that blocks sunlight to seagrass communities, algae blooms and subsequent declines in dissolved oxygen. These detrimental environmental effects can lead to commercial and recreational fishing impacts. The challenge in estimating the economic effects on commercial and recreational fishing in the Caloosahatchee Estuary is complicated by the inability to quantify the decrease in fish numbers and accurately measure the decrease in fish yields. It is reasonable to assume that as fish populations decrease due to degraded conditions in the estuary, the supply of fish will decrease, restrictions will be placed on certain species of fish, and greater distances will have to be traveled for commercial fishing vessels who in turn will realize smaller catches, all

leading to a decrease in economic activity associated with commercial and recreational fishing.

SECTION 4
IDENTIFICATION OF PROBLEMS AND OPPORTUNITIES

This page intentionally left blank

4.0 IDENTIFICATION OF PROBLEMS AND OPPORTUNITIES

4.1 STATEMENT OF PROBLEMS AND OPPORTUNITIES

To focus on water resources problems and opportunities in the C-43 Canal (Caloosahatchee River) basin to be addressed with this project, the project delivery team (PDT) began with the project components and purposes for the C-43 Canal basin as described in the 1999 Central & Southern Florida Comprehensive Review Study. The CERP Programmatic Regulations Draft Guidance Memoranda (GM) #1 and #2 (USACE 2004) instruct PDTs to focus on specific issues and problems identified in the Comprehensive Plan related to a given project component, and to update project-specific concerns as needed based on more current or improved information. The PDT therefore began by examining the problems and opportunities identified in the Comprehensive Plan for the Caloosahatchee River and its estuary, but also undertook a more detailed analysis of problems and opportunities in the study area in response to more recent questions and concerns expressed by the resource agencies and the public. This section describes the problems and opportunities identified in the study area and the planning goals and objectives developed by the PDT for the project.

While this section outlines the problems and opportunities identified by the PDT for the entire basin, it should be noted that the project has been split into two separate PIRs. The first of these two PIRs (Caloosahatchee River (C-43) West Basin Storage Reservoir project) will focuses on reaffirming that project goals and objectives can be achieved by constructing and operating an above-ground reservoir on lands already acquired for this purpose (Berry Groves).

4.1.1 Public Concerns

An integral component of the identification of problems and opportunities is an understanding of the public's concerns (USACE 1999). Public workshops were conducted early in the planning process for this project in order to gather public input and to document public concerns related to the problems, needs, and opportunities within the Caloosahatchee River watershed. Numerous presentations to public groups were conducted, including Lee, Collier, Hendry and Glades counties; the cities of LaBelle, Moore Haven, and Clewiston; local agencies; agricultural organizations; civic groups; business groups; clubs and neighborhood organizations.

In February of 2001 and 2002, representatives from the USACE and the SFWMD conducted two workshops/public meetings with various groups and individuals to provide a brief overview of the process for development of a PIR for the Caloosahatchee River (C-43) West Basin Reservoir Project and to obtain an understanding of the public's concerns and issues. The public meetings were held in LaBelle, Florida at the Hendry County Extension Service Building on

February 26, 2001 and at the LaBelle Civic Center on February 28, 2002. Approximately 35 people attended the meeting in 2001 and approximately 35 people attended the meeting in 2002. Information collected at these meetings was used to help inform the plan formulation process.

In addition to the earlier meetings, a NEPA scoping letter was sent out in March 2003 requesting input from the public and federal, state, and local government agencies. A public scoping meeting was subsequently held in LaBelle on May 1, 2003. By this time the team had completed some initial plan formulation and screening. The public was updated on the progress and status of the project to that point. Meetings were also held in the spring of 2003 with various stakeholders including recreational interests, agricultural interests, and local policy makers.

Table 4-1 outlines the public concerns that were brought to the PDT's attention through written correspondence, phone calls, and public meetings.

TABLE 4-1: PUBLIC COMMENTS AND HOW THEY WERE ADDRESSED

Issue Category	Public Comment-Issue, Problem, or Opportunity	Response/Action taken
Ecological	Health of the estuary	Main purpose/objective of study
	Fish health and abundance for commercial and recreational uses	Performance measures will be used to evaluated the different plan alternatives ability to improve estuarine conditions for improving fish health
	Water quality	Water quality of reservoir(s) to be evaluated as to not cause or contribute to water quality problems; also addressed in later study
	Wildlife health and abundance	Ecological performance measures
	Dredging of oxbows	Being accomplished by several other projects
	Use of water stored in reservoir	Water reservations and effects on water supply studied as part of project assurances analyses; Draft operating manual will accompany PIR
	Water allocation concerns	Water reservation studies will be completed
Ecological	Water level on the river	Project objective to deliver a more consistent water flow to estuary, which would result in a more consistent water level
	Littoral zone around reservoir to promote fishing and fish habitat	Included around seepage canal

Issue Category	Public Comment-Issue, Problem, or Opportunity	Response/Action taken
	Lake Hicpochee for natural area restoration	Lake Hicpochee will be considered for natural area restoration under later study
	Exotic/invasive plant control	Other projects are addressing this issue; proper procedures will be used to minimize this problem during construction
	Recreation and restoration as opposing uses	Restoration is the main purpose of this study, so restoration will not be sacrificed for recreational opportunities. However, recreation will be considered wherever it is viable and applicable trade-offs displayed.
Economic	Economic impacts	Socioeconomic analysis
	Tourism	Healthier estuary will promote tourism
	Water supply	Effects on water supply studied as part of project assurances analyses
	Cost of project	Cost estimates in PIR; part of alternative screening; addressed through cost effectiveness and incremental cost analyses
	Loss of tax base in Hendry County	Project will analyze impacts resulting from a reduction of agriculture land and its effect on county tax base.
	Concern that cost will outweigh benefits	Cost effectiveness/ incremental cost analyses will be performed to justify costs
	Loss of Highway 80 property for development	The State has located the reservoir a significant distance from Highway 80 so that development will not be hindered.
Engineering	Flood control	Modeling of alternatives to ensure no harm
	Questions on ASR	Separate study–see ASR pilot project Draft PIR/EIS
	Drainage problems in basin	Not a project purpose–will recommend to the SWFFS
	Suggest deeper reservoir	Geotechnical studies were conducted to determine appropriate maximum depths
	Visual aesthetics – high levee is not conducive to visual enjoyment	Due to the soils, aquifers, and topography, high embankments cannot be avoided

Issue Category	Public Comment-Issue, Problem, or Opportunity	Response/Action taken
	Water loss due to evaporation	ASRs (part of a later study) are envisioned to complement the reservoir(s), and will decrease total loss to evaporation
Other	Hurricane evacuation: route/safety issues	A meeting was held to develop safety standards for all CERP projects; local evacuation planning is not included as part of this PIR, but evacuation plans/procedures are considered in the project operating manual.
Recreation	Recreational opportunities	CERP recreation plan: Project has considered recreational opportunities compatible with restoration objectives;
	Active recreation opportunities (baseball fields, playgrounds, etc.)	Recreation plan is attached; passive recreation is most appropriate for this site.
	"Watchable" wildlife areas	These were incorporated into the Recreation Plan for the selected alternative plan (SAP)

4.1.2 Ecological Problems and Opportunities

Natural resource specialists agree that the remaining ecosystems in south Florida no longer exhibit the functions and diversity that characterized the pre-drainage system, and that key measures of ecological health will continue to decline without preventative actions. Not only is it certain that these natural systems will not recover their defining attributes under current conditions, it is unlikely that even the current, unacceptable ecological conditions can be sustained into the future (USACE, 1999).

The Caloosahatchee watershed has some ecological problems that are unique to the basin, as well as environmental problems that can also be found elsewhere in south Florida. Agricultural industry growth, urban development and the associated water management practices that accompany these activities have created undesirable conditions in the river and estuary. These problems are predicted to be magnified in the future. Some of the identified problems affecting the Caloosahatchee Basin are:

- Extreme changes in salinity in the Caloosahatchee Estuary due to either excessive or insufficient freshwater discharges over the W.P. Franklin Lock and Dam (the S-79 structure), which demarcates the division between the freshwater and tidal portions of the Caloosahatchee River.

- Loss of freshwater and marine SAV, due to salinity imbalances in the estuary.
- Truncation of estuarine extent and function due to the physical constraint of S-79 (the structure effectively blocks tidal flows upstream of that point).
- Major changes in riverine, drainage, and seepage characteristics due to excavation of 25-foot deep navigational channel in C-43.
- Reduction of oysters and blue crab habitat areas due to low salinity conditions in the lower estuary.
- Water quality problems in the river and estuary that are the result of pollutant laden (particularly nutrients) runoff from within the basin.
- Other water quality problems, including low dissolved oxygen (DO), high metals, high coliform bacteria, and diminished biological integrity.
- Increased occurrences of phytoplankton algal blooms and fish with lesions in the Caloosahatchee Estuary (FDEP2003).
- Loss of spatial extent of wetlands and associated uplands in the Caloosahatchee Basin.
- Availability of and competition for water supply for environmental, agricultural, and urban needs during dry periods.

To understand the full extent of these problems and to formulate potential solutions, it is necessary to first understand the changes that have occurred in the river and estuary.

Since the turn of the twentieth century, land reclamation, flood damage reduction and water management projects (consisting of complex networks of canals, structures and levees) have drastically altered the wetland ecosystem and hydrologic regime that once existed in the Caloosahatchee watershed. The manmade connection between Lake Okeechobee and the Caloosahatchee River (originally created in the late 1800s) has disrupted the natural pattern (quantity and timing) of freshwater flow into the Caloosahatchee Estuary. Problems in the estuary have been compounded due to the addition of water control structures on the river, the network of channelized tributaries and drainage canals in the basin connecting to the river, and associated water demands and flood protection requirements of urban and agricultural users.

The W.P. Franklin Lock and Dam structure (S-79) is the beginning of the tidal Caloosahatchee Estuary, and maintains higher water levels upstream of the structure while acting as a barrier to salinity and tidal action, which historically extended upriver as far as Fort Denaud and LaBelle (Sackett 1988). Construction of S-79 together with C-43 improvements have allowed for better conveyance of basin storm water discharge along with regulatory releases from Lake Okeechobee downstream to the estuary. This has created unnatural hydrologic and salinity regimes, and periodically causes extremely adverse effects on estuarine health and productivity. This also adversely affects the local

economy, as a significant amount of economic activity in the study area is associated with tourism and recreational and commercial fishing and related services.

Benefits obtained from the construction of the S-79 structure include the prevention of salinity intrusion into drinking water supplies upstream during dry, low flow periods. It also allowed the construction of a potable water supply intake facility upstream of the structure (the Lee County drinking water facility). In the dry season (approximately November–May), releases through S-79 are occasionally initiated to support environmental needs downstream by maintaining minimum flows.

Although S-79 has been instrumental for supporting and protecting this water supply, it has been detrimental for many estuarine organisms that historically could proceed further upstream in the dry season to find the optimum salinity and habitat. During the dry season when discharges are not occurring due to restrictions in water availability, very low or no freshwater inflow to the estuary can occur, resulting in a salinity wedge moving upstream into the upper-most reaches of the estuary, threatening fresh-water dependent species such as *Vallisneria* (tape grass), and shifting the competitive advantage to larger predatory marine fish species and adult (as opposed to juvenile) life stages. This disruption at the base trophic levels threatens the future viability of the estuarine ecosystem. Primary ecological functions (such as forage and nursery habitat) disrupted by such extreme changes in salinity do not rebound readily when more desirable salinity levels are restored, and may take several uninterrupted annual cycles to fully recover.

The amount of water available for the estuarine organisms during the dry season is constrained by at least two factors. First, the Caloosahatchee Basin has a significant amount of agriculture that depends upon surface water (and some groundwater) for its water supply. Many of the canals that discharge to the Caloosahatchee River in the wet season are used for irrigation water supply in the dry season. Second, there are several public water supplies in the basin, one of which is the Lee County drinking water facility, that rely upon surface water from the Caloosahatchee River. The net effect of increasing demands for agricultural and municipal water supply is a reduction in the amount of fresh water available to be delivered to the estuary to maintain viable ecological conditions.

Water from Lake Okeechobee has historically been released to supply water for urban and agricultural uses in the basin. The current approved LORS WSE provides for the regulation of Lake Okeechobee's freshwater discharges as a multipurpose water resource affecting the timing and volume of water available to the estuary. With the WSE regulation schedule, some water is supplied to

maintain minimum flows to the estuary when lake levels are high enough to provide those minimum flows while not endangering water supply demands elsewhere in the C&SF system. However, the historical and most predominant type of releases from Lake Okeechobee continues to be for lowering the lake when levels are too high. These regulatory releases, which can be very large and often occur in addition to basin runoff, are extremely detrimental to estuarine health. During the wet season releases (approximately June–October), the estuary can receive freshwater flows in excess of 10,000 cfs measured at S-79, significantly exceeding the historically-occurring volumes of freshwater and essentially flushing the estuary of saltwater and water column organisms, such as plankton.

To improve the problems created by high water levels in Lake Okeechobee, the USACE has also initiated a separate study to prepare a revision to the LORS. However, it should be noted that a revision to the LORS cannot by itself significantly reduce the harmful affects of excessive lake discharges and basin runoff on the Caloosahatchee Estuary. Additional storage is needed to enable management of Lake Okeechobee to minimize the frequency and severity of such harmful events.

Estuarine manifestations of the combined effects of water quantity, quality, and timing problems include the reduction and/or losses in such valued ecosystem components as SAV, oysters, and blue crab, as well as periodic declines in plankton and soft bottom benthic invertebrates. Restoring the flows and achieving hydrologic targets to maintain desirable salinity levels remains the overwhelming and overriding environmental priority within the Caloosahatchee River Basin.

4.1.3 Water Quality Problems and Opportunities

The 1999 Central and Southern Florida Project Comprehensive Review Study Final Feasibility Report and Programmatic Environmental Impact Statement (the "Restudy") reported that 14 water body segments in the Caloosahatchee River Basin and downstream coastal waters were impaired or potentially impaired, according to the FDEP in 1998. Water quality parameters of concern included excessive nutrients, coliform bacteria, biochemical oxygen demand, and depressed levels of dissolved oxygen. The Restudy report estimated that water quality conditions in the upper (eastern) and central portions of the Caloosahatchee watershed would remain unchanged through 2050, while water quality in the downstream and coastal portions would decline as a result of increased population growth and agricultural development.

The Restudy report identified the purpose of the Caloosahatchee River (C-43) West Basin Storage Reservoir Project as capturing Caloosahatchee Basin runoff and releases from Lake Okeechobee. The project was formulated to provide

water supply benefits, some flood attenuation, environmental water supply deliveries to the Caloosahatchee Estuary, and water quality benefits to reduce salinity and nutrient impacts of runoff to the estuary. It was assumed that the project might also provide significant water quality improvements depending on the location of the project and pollutant loading conditions in the watershed. According to CERP guidance memorandum-GM 23.01 "Water Quality Considerations for the PIR Phase," the Caloosahatchee River (C-43) West Basin Storage Reservoir Project falls in Category B, which means the project should be designed to achieve water quality improvements.

Because of water quality problems within the basin that were identified during the Restudy, as well as the purposes the project was designed to meet, the C-43 project team collected additional, updated water quality information for this PIR. According to the FDEP's 2003 Caloosahatchee Basin Status Report, the same water quality parameters of concern were identified for the basin as were identified in the Restudy report. In addition to problems associated with extremes in salinity levels, excessive nutrients (expressed as high chlorophyll-a concentrations), depressed levels of DO, and elevated coliform bacteria levels have been identified as problematic within the estuary. The extent of and research associated with these problems, as well as the over-arching problem of excessive salinity variations in the estuary, are discussed in the following paragraphs.

Water quality within the Caloosahatchee watershed is influenced by fresh water inflows from Lake Okeechobee, non-point pollution in local basin runoff, as well as point sources such as wastewater treatment plant discharges. Due to the geology of the region, there is also a direct interaction between the surface water and groundwater, which can affect the dissolved oxygen and iron concentrations in the surface water column. The upper Caloosahatchee River watershed from the Moore Haven Lock and Dam (S-77) to the Lee/Hendry county line has been classified by the State of Florida as a Class III water body in accordance with 62-302 Florida Administrative Code. The Class III designation establishes specific water quality standards that are intended to protect and sustain the natural attributes necessary for these waters to meet their intended use (recreation, propagation and maintenance of a healthy, well-balanced population of fish and wildlife). The surface water directly upstream of S-79 east to the Lee/Hendry county line is designated as a Class I water body and must meet the standards required for use as a potable water supply (see ***Table 4-2*** for surface water classification status of Caloosahatchee River).

TABLE 4-2: SURFACE WATER CLASSIFICATION FOR CALOOSAHATCHEE RIVER

Water Class	Location
Class I Water: Caloosahatchee River	East Lee County line to SFWMD structure S-79 (Franklin Lock & Dam Spillway)
Class III Water: Caloosahatchee River	SFWMD structure S-77 (Moore Haven Lock & Spillway) at Lake Okeechobee to Lee/Hendry County line.

Several ecological functions of the Caloosahatchee Estuary are directly affected by water quality. The water quality problems negatively impacting ecological resources are primarily related to excessive variations in freshwater inflow and salinity as well as increased nutrient loads and color that result from excessive freshwater discharges in the wet season.

Water quality within this study area has been significantly altered due to the construction of the three locks and dams, excavation of the riverbed to 25 feet, increases in both urban and agricultural land use, and by the construction of an extensive network of canals and drainage ditches to accommodate this level of development. These hydrologic alterations have resulted in discharges of unnaturally large quantities of freshwater runoff into the river and eventually into the downstream receiving estuarine systems. Extensive documented research on the tidal portion of the Caloosahatchee River has shown that salinity changes in the estuary are the result of either low to no flows or too high flows of freshwater being discharged at the S-79 structure. Together, extreme flows and changes in salinity are by far the largest problem affecting the ecologic health of the estuary.

4.1.3.1 Salinity

It has long been established that freshwater inflow dynamics and salinity are major determinants of the distribution of estuarine species and those species' life stages, especially regarding their location and association with favorable habitat for rearing, protection and settlement (Gunter 1961; Pearcy and Richards 1962; Kinne 1966; Remane and Schlieper 1971; Bulger et al. 1993). Therefore, the ability of each estuary to function as a nursery differs according to its biological features, physical configuration, and inflow volume, magnitude and timing. Research by the SFWMD on the tidal Caloosahatchee began in the mid-1980s to determine the proper timing and volume of water required to support valued ecosystem components (i.e., such key estuarine species as oysters and SAV, such as *Vallisneria* spp.) and general biotic indicators (plankton and benthic invertebrates). Since the predominant source of freshwater to the tidal

Caloosahatchee (especially in the wet season) is water through the S-79 (70 percent of total flow), the research focused on issues of timing and volume of water through this structure; however, the latest models and methods do take into account the other major sources of freshwater discharged to the tidal Caloosahatchee from the "tidal" watershed. The SFWMD has focused on development of optimum S-79 flow ranges and delivery patterns for the estuary (Chamberlain and Doering, 1998b; Doering, 2002; Volety et al., 2003). As part of the state-mandated minimum flows and levels (MFLs) process, the SFWMD initially determined that a minimum dry season discharge at S-79 of 300 cfs (monthly average flow) is required to provide salinity conditions capable of supporting *Vallisneria*; however, the minimum flow target has been revised upwards to 450 cfs based on more recent scientific research by SFWMD staff. *Vallisneria* in the upper estuary is still recovering from the last drought and could suffer additional harm as the MFL requirements continue to be unmet (***Figure 4-1***).

Also as part of this research, maximum freshwater inflow limits (set at mean monthly values of 2,800 cfs and 4,500 cfs depending on frequency) and a frequency distribution of flows have been recommended that support valued ecosystem components and promote estuarine ecological benefits (Chamberlain et al. 1995, Chamberlain and Doering 1998b, Doering et al 2002, SFWMD 2003). It is these recommended flows that were used initially to determine CERP storage requirements and infrastructure changes in the Caloosahatchee Basin and Lake Okeechobee during the Restudy. These minimum and maximum flow targets have also been adopted for this PIR.

Based on the above biotic and water quality research, restoring the flows and achieving the hydrologic targets is an environmental priority within the Caloosahatchee River Basin. The estuary will remain at risk as long the quantity and timing of freshwater flows into the estuary remains unchanged. If water management practices are not changed, large releases will continue to have far reaching salinity and water quality impacts that may even influence Florida Bay (Rudnick et al. 1999).

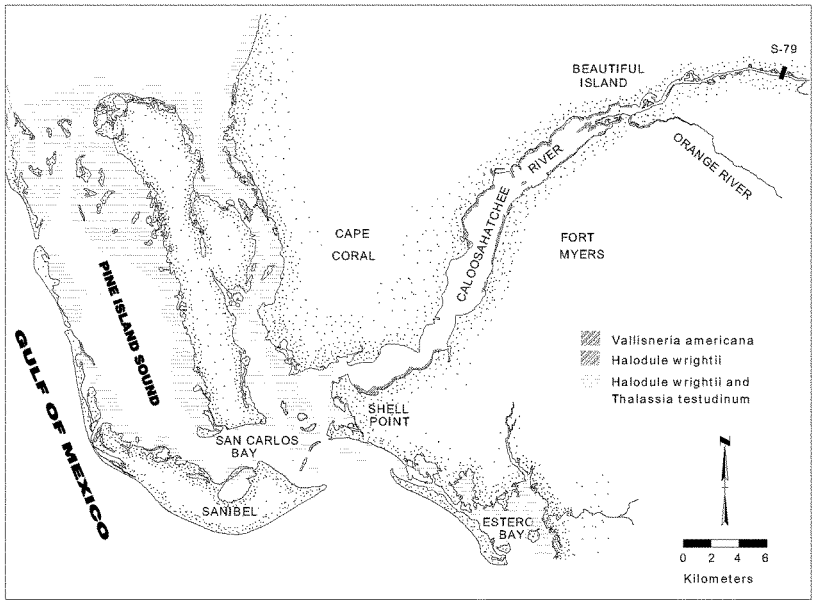

FIGURE 4-1: SUBMERGED AQUATIC VEGETATION IN THE CALOOSAHATCHEE ESTUARY

The excessive and unnatural variation in discharge and salinity that now occurs in the Caloosahatchee Estuary is due in large part to the man-made connection between Lake Okeechobee and the construction of C-43 Canal, the S-79 structure, and the network of secondary canals in the Caloosahatchee Basin (Chamberlain and Doering 1998a). Even before the S-79 was installed in 1965, a study was conducted by the University of Miami (under contract to the USACE) to determine the effects of the Lake Okeechobee releases on the St. Lucie and the Caloosahatchee estuaries (University of Miami, 1954). This study found significantly more sediment and salinity problems in the St. Lucie Canal than in the Caloosahatchee River, but the study did concluded that salinity was reduced as far downstream on the Caloosahatchee River as San Carlos Bay (downstream of Shell Point) when large releases from Lake Okeechobee occurred. According to the study, "These conditions are sufficiently severe during conditions at or near maximum release to cause temporary movements of marine life from the lower river, the southern part of Matlacha Pass, and sections of San Carlos Bay.

These conditions are also severe enough to cause the death of some forms unable to move from these areas (University of Miami, 1954)."

Subsequent biological field sampling of plants and fish by Phillips and Springer (1960), as well as Gunter and Hall (1962), before the S-79 structure was built also reported impacts on biota related to freshwater releases that extended into San Carlos Bay.

The Caloosahatchee River is the predominant source of freshwater discharges to the estuary. Bierman (1993) determined that over 90 percent of the variance in salinity in the estuary was related to discharges from S-79. The primary research on the tidal Caloosahatchee has focused on assessing the biological and water quality impacts from S-79 discharges, in order to determine optimum flow ranges, salinity, and water quality. Ideally, an estuary should provide a complete range in salinity from zero parts per thousands (ppt) (freshwater) to 35 ppt (ocean water). The long-term mean discharge through S-79 falls between approximately 300 cfs and 3,000 cfs. However, daily and monthly average inflows often exceed this long term average, with changes in salinity caused by either too little or too much freshwater being discharged over S-79. Studies conducted by the SFWMD on the Caloosahatchee Estuary indicate that discharges in excess of 2800 cfs from S-79 has caused most of the estuary above Shell Point to become oligohaline (low salinity between zero and five ppt) and inflows that commonly exceed 4,500 cfs adversely reduce salinity and water quality not only in the estuary, but also in the San Carlos Bay area and outer embayments (Chamberlain and Doering 1998a, Doering and Chamberlain 1998). During the dry season, lack of freshwater availability and subsequent low to no flow conditions can upset the salinity balance in the upper estuary and threaten the associated species, which depend on a minimum of freshwater inflow to maintain the low salinity zone that has been spatially reduced because the placement of the S-79 structure that truncated this zone (Doering et al. 2002, SFWMD 2002).

4.1.3.2 Nutrients

Although the salinity regime in the tidal Caloosahatchee has been the primary focus of much of the research, the SFWMD, FDEP, USGS and other agencies have also been examining other water quality issues in the basin and estuary. Work done by FDEP's Watershed Management Program has documented water quality impairments in the basin for several parameters and, in particular, for nutrients.

Urban and agricultural development within the drainage basin typically results in an increase in runoff and nutrient loads delivered to the downstream estuary. If excessive, the additional nutrients can cause a decrease in critical water quality when subsequent increases in phytoplankton (algae) production cause a

depletion of dissolved oxygen and a reduction in light penetration. Decreased light penetration can result in declines in SAV abundance since some of the estuary bottom that presents favorable conditions for SAV no longer obtains enough light to sustain these plants. The sediment in areas no longer supporting SAV can become mobile and increase water column turbidity which further impacts SAV viability. Excessive nutrients also trigger a thick growth of epiphytes, which can block the sunlight before it can reach the surface of the seagrass (Murray et al. 1999). In fact, in some estuaries, nutrient input has such an effect that relatively minor changes in water quality can lead to sharp reductions in the productivity of seagrasses which can lead to broad habitat changes (Livingston 1984).

Fortunately, within the Caloosahatchee Estuary, salinity swings rather than excessive nutrient loads have been identified as the primary limiting factor for SAV viability. McPherson et al. (1990) in their study of phytoplankton productivity in Charlotte Harbor determined there are three regions of productivity within an estuary that are characterized primarily by salinity and associated water quality parameters from freshwater. These regions are: (1) low salinity areas typical of the upper estuary or where high flows lowered salinity to less than approximately 10-15 ppt; (2) moderate to high salinity areas near the mouth of the major rivers or in Matlacha Pass; and (3) high salinity near the marine influence of passes to the Gulf of Mexico, well away from the influence of freshwater runoff (e.g., in Pine Island Sound). Increased phytoplankton productivity occurs when early spring temperature, light availability, and supportive water quality conditions co-occur. Typically, in Region 1, the highly-colored water from dissolved organic matter in freshwater runoff limits availability of light and is the determining factor controlling phytoplankton production and chlorophyll biomass, even when sufficient nutrients and temperature co-occur. A short residence time related to high flows also limits production. SAV (*Vallisneria* spp.) in this region of the estuary is inhibited during the wet season (high freshwater inflows) by colored water that reduces light availability. During the dry season (low freshwater inflows), low temperature and high salinity inhibit SAV.

In Region 2, nutrient-rich colored water is diluted by seawater so that the availability of light has increased and stimulates phytoplankton productivity. It is in this region of the Caloosahatchee Estuary (middle to lower estuary, western San Carlos Bay, and southern Matlacha Pass) that Chamberlain and Doering (2003) reported good statistical correlations between nutrient loading and chlorophyll concentrations. However, research by SFWMD indicates that SAV growth in shallower areas is predominately influenced by salinity, while SAV at deeper depths are impacted by a combination of salinity and light availability (Chamberlain and Doering 1997). In this region, the amount of influence on

water clarity from colored water versus chlorophyll biomass depends on the magnitude of flow and is currently being analyzed

In Region 3, even though water clarity is high, chlorophyll levels are typically low, primarily because nutrients are limited due to the distance from freshwater runoff and proximity to marine water. In this region of the estuary, SAV biomass and canopy height are high and typically extend to two meters depth.

4.1.3.3 Nutrients Impacts to the Caloosahatchee

Currently, nutrient standards for the State of Florida are narrative (non quantitative); therefore a surrogate standard for chlorophyll-a has been set at above 11 micrograms per liter (ug/l) (mg/m3) for estuaries and above 20 ug/l for freshwater. In the latest FDEP impaired water analysis for the Caloosahatchee, seven segments of the tidal Caloosahatchee River were found to be potentially impaired for nutrients. Chlorophyll-a is used as a measure of nutrient imbalance since Florida surface water quality standards do not include numerical criteria for nutrients such as nitrogen and phosphorus.

The watershed downstream of the S-79 structure that contributes directly to the tidal Caloosahatchee River is primarily urban (Cape Coral and Fort Myers). Although some of this urban area pre-dates the 1979 state rule regarding the prevention of the pollution of state waters from stormwater runoff (62-25 Florida Administrative Code), much of it was developed after this rule went into place. Although urban areas can be significant sources of nutrients and pollutants, the impact from this urban area appears to be relatively minor compared to the proportion of nutrient loads delivered to the Caloosahatchee Estuary through S-79 inflows. A study by ERD (2003) found that, discharge from S-79 contributes from 90 percent to 95 percent of the mean annual mass of total nitrogen (TN) and total phosphorus (TP) to the tidal Caloosahatchee River (for this report, the USACE has estimated that S-79 contributes more than 75 percent of the nutrient loads). The next largest contributor to the tidal Caloosahatchee River was the Orange River with 1.1 percent to 3.8 percent of the annual mass of TN and TP.

As stated above, approximately 75 to 90 percent of the nitrogen and phosphorus load sent to the Caloosahatchee Estuary comes from sources upstream of S-79. To address questions regarding the effect of reservoirs on water quality, specifically nutrients, FDEP contracted with Tetra Tech (and subcontractors Janicki Environmental and Soil and Water Engineering Technology, Inc.) to examine the potential nutrient impairment problem in the estuary. The study developed regression equations to describe two relationships: 1) between chlorophyll-a concentration and nitrogen loading and 2) between chlorophyll-a concentration and phosphorus loading. Due to the naturally occurring high levels of phosphorus in the watershed, the indication was that nitrogen was the

limiting nutrient, which is consistent with the other studies identified earlier. Thus, of the two regression equations, this study determined that the nitrogen/chlorophyll-a relationship was the best means of predicting nutrient impairment (or phytoplankton algal blooms) in the estuary. The report has identified three preliminary targets for TN loading to the estuary from releases at S-79 in order to achieve a chlorophyll-a concentration limit of 11 ug/l:

1. Maximum annual load less than 3,000 tons/year, where annual load ~ (wet season monthly load x 5) + (dry season monthly load x 7)
2. Dry season monthly load less than 190 tons/month, and
3. Wet season monthly load less than 350 tons/month.

The estimated annual TN load at S-79 is approximately 2600 tons/year at present. During the wet season an average of approximately 310 tons/month is discharged at S-79 while during the dry season an average of approximately 150 tons/month of TN is discharged at S-79. On an average basis, therefore, the nitrogen loads delivered through S-79 fall within the State's nutrient targets (i.e., TN loads associated with acceptable chlorophyll-a concentrations). The amount of nutrient loading to the estuary is mostly dependent on the magnitude of freshwater inflow (Chamberlain and Doering 2003).

During the 1996-2002 time period, the suggested annual TN target load has been exceeded three times. The exceedence years were 1998, 1999 and 2002. A dry season TN target exceedence occurred in 1998 when dry season flows from the C-43 basin along its eastern boundary with Lake Okeechobee were approximately three times higher in 1998 than the average for 1996 to 2002, probably reflecting a large controlled release from Lake Okeechobee. Wet season exceedences occurred in 1999 and 2002. These were the highest wet season flows observed at S-79 between 1996 and 2002. It should be noted that between 1996 and 2002, many of the years analyzed were wet years, resulting in high loads.

Additional documentation of the extent of the nitrogen problem in the estuary comes from research conducted as part of the Initial CERP Update (ICU). For the ICU, 22 years of TN concentrations collected just upstream of S-79 were used to calculate the average monthly concentrations at S-79 for each of 12 months. Then TN loading for each month of the 36-year period of record for CERP was calculated by multiplying each month's discharge by the average monthly TN concentration for that month. For each 36-year scenario, the number of years in which the annual TN load at S-79 exceeded 3000 tons (the load limit meeting the FDEP's estuarine standard) was calculated. Nitrogen loads were exceeded in ten of 36 years for the 2000 Base scenario (i.e., existing conditions), nine years for the 2050 Base scenario (future without project conditions), one year for the

CERP0 scenario (CERP as defined in the Restudy), and 1 year for CERP1 (updated CERP as defined in the ICU).

Similarly, ***Table 4-3*** below depicts analysis from the ICU showing results of seasonal, rather than annual TN loading. The number of months in which TN loading exceeded critical seasonal loads of 350 tons/month during the wet season and 190 tons/month during the dry season (wet season defined as June–October, dry season as November–May) are shown.

TABLE 4-3: NUMBER OF MONTHS OF TN SEASONAL LOAD EXCEEDANCES IN THE CALOOSAHATCHEE ESTUARY

Scenario	2000 Base	2050 Base	CERP0	CERP1
Wet Season	60	48	8	8
Dry Season	45	36	9	8

Under existing conditions (2000 Base) and future without conditions (2050 Base), critical seasonal loads were exceeded 28 percent (2000 Base) and 22 percent (2050 Base) during the wet season and exceeded 21 percent (2000 Base) and 17 percent (2050 Base) during the dry season. As will be discussed in greater depth under the evaluation of C-43 alternatives, TN loads under existing and future without project conditions exceed critical seasonal loads four to five times more frequently in the dry season and six to seven times more frequently in the wet season than infrastructure alternatives related to CERP0 and CERP1 (***Table 4-3***). This analysis conducted for the ICU thus demonstrates that nitrogen loadings exceeding the estuary's targets, while not a frequent problem, do occur, but are likely to be greatly improved by implementation of the Caloosahatchee River (C-43) West Basin Storage Reservoir project as described in CERP.

4.1.3.4 Nutrient Reduction Opportunities

Nutrient loads to the estuary can be reduced through treatment in stormwater treatment areas (STAs) or through the widespread adoption of best management programs (BMPs) by farmers, land developers, and urban residents. Lower nutrient loads will result in improved estuary habitat through increased light penetration and increased dissolved oxygen concentrations. The implementation of BMPs to control nutrient loads, while quite useful in the case of the Caloosahatchee Estuary, has not been considered as a central element of the Caloosahatchee River (C-43) West Basin Storage Reservoir Project strategy. Because achievement of water quality standards is a responsibility resting primarily upon individual states, the underlying assumption of the project team has been that the State of Florida will implement state and local water quality programs necessary to achieve appropriate load reductions through actions by

the FDEP, Florida Department of Agriculture and Consumer Services (FDACS), and SFWMD.

However, the Caloosahatchee River (C-43) West Basin Storage Reservoir itself can potentially reduce and alter the timing of nutrient loads through the construction and operation of storage reservoirs. The reservoir is expected to reduce nutrient loading (particularly nitrogen) through settling and nutrient uptake.

4.1.4 Economic and Social Well-Being Problems and Opportunities

As a result of the C&SF Project, by providing flood protection and an available supply of drinking water, the population of south Florida has grown from approximately 900,000 as reported in 1950 to a population of over 5.5 million in 1995. By the year 2050, the population of south Florida is projected to grow to 11.6 million. Lee County (including Fort Myers, Cape Coral, Sanibel and Captiva Islands, Bonita Springs, and surrounding areas) has one of the fastest growing populations in both south Florida and in the state. The increased growth in population in Lee County can be attributed to net in migration and not as a result of high birth rates for this area. The coastal areas in the study area have become highly urbanized. As a result, this urbanization has caused development to move eastward into areas that were once agricultural or undeveloped.

The Governor's Commission for a Sustainable South Florida identified agriculture and tourism as "critical industries" for maintaining the economy in the southern part of the state. In the project area, agriculture is a major industry. A rapidly increasing human population demanding more developable lands and advancing agricultural development now threaten the relatively pristine natural areas. The tourism industry is also dependent upon the region's ability to sustain its economy and its quality of life through management of its resources. Agriculture and tourism depend on a system that can provide vital water supply needs and flood protection without harming the natural system upon which tourism, recreational activities, and associated services depend.

In response to the proposed modification to the LORS, the City of Sanibel commented in an October 2006 letter to the USACE:

"Sanibel Island's economy and its way of life depend upon the health of the Caloosahatchee River and Estuary. The Estuary provides essential habitat for fish populations that are central to the region's economy and recreational fishing economies. The City of Sanibel is particularly dependent on the health of the Caloosahatchee Estuary, as tourism generated by the diverse estuarine ecosystem in which it is located is central to the Island's economy."

Similarly, the City of Fort Myers also commented in 2006:

"The Caloosahatchee River and the estuary must be protected. The local economy is reliant on these waters through both the tourism industry and the fishing industry. We cannot afford to lose this most precious environmental and economic resource to the damaging effects of increased water releases from Lake Okeechobee."

Competition for regional water resources has intensified with the increase in population and agriculture industry growth. This places a strain on existing resources, which will eventually surpass the readily available sources. When the needs of the natural system are then factored in, demands become greater and conflicts among competing water users will become even more severe. While most people recognize the need for a healthy ecosystem to support the region's economy and jobs, many people are concerned that restoration projects will displace farms and other businesses, limit development, reduce available water supply and reduce job opportunities. By contrast, continued degradation of the south Florida ecosystem will adversely affect the tourism and recreational industry that are important to the regional economy.

4.1.4.1 Water Supply

While providing additional water supply for urban and agricultural users represents a potential opportunity to be addressed by the Caloosahatchee River (C-43) West Basin Storage Reservoir, providing water supply to meet the environmental needs of the estuary during dry periods is one of the primary purposes of this project. Upon meeting flow targets at the S-79 structure necessary for ecosystem restoration in the Caloosahatchee Estuary, any additional water stored by the Caloosahatchee River (C-43) West Basin Storage Reservoir could be delivered to the C-43 Canal and would be available for other water related needs.

Water supply and flood control benefits of the Caloosahatchee River (C-43) West Basin Storage Reservoir implementation will be classified as incidental. Increases to flood damage reduction benefits and water supply benefits will not be further analyzed as part of this study; however, a later PIR will investigate opportunities to increase the quantity of water available for municipal, agricultural, and other environmental interests in the basin. Analysis of area water supply is being conducted by the SFWMD in a report entitled Lower West Coast Water Supply Plan (LWCWSP) Update.

4.1.4.2 Flood Damage Reduction

While flood damage reduction is not the primary intent of this project, the evaluation of alternatives will include an analysis of their effects on the current

level of flood protection. The project will not compromise that existing level of protection, and although it was not a specific goal of the study to increase the level of protection, some incidental benefits may be achieved.

4.2 PLANNING GOALS, OBJECTIVE AND CONSTRAINTS

4.2.1 Project Goals and Objectives

The Restudy assessed some but not all of the water resource problems and issues within the Caloosahatchee River Basin. The Restudy purpose of the Caloosahatchee River (C-43) West Basin Storage Reservoir is to capture Caloosahatchee Basin runoff and releases from Lake Okeechobee as a means to meet water demands (moderate extreme damaging high and low flows) for ecosystem restoration within the Caloosahatchee Estuary, with some benefits to municipal and agricultural water supply. However, since this project is focused on reaffirming a plan to construct and operate a reservoir with approximately 160,000 ac-ft of storage, the primary goal of this project is to produce a plan that, when implemented, will meet the ecosystem restoration objectives of the Caloosahatchee Estuary. Opportunities for providing additional water to meet municipal and agricultural needs for water supply will be investigated under a subsequent study.

Based on a consideration of the Restudy purpose for the project and problems and opportunities in the study area, specific planning objectives to meet the goal of enhancing ecological values are listed below:

Goal: Enhance ecological values by restoring ecosystem function in the Caloosahatchee River and Estuary

Objectives:

- Improve the quantity, timing, and distribution of freshwater flows to the Caloosahatchee Estuary.
- Improve water quality in the Caloosahatchee Estuary by reducing nutrient inflows from the Caloosahatchee Basin.
- Improve salinity balance in the Caloosahatchee Estuary for estuarine organisms. Reduce the spatial extent and duration of occurrences of extreme low and high salinities.
- Improve the spatial extent and functional quality of habitat for estuarine biota.
- Increase plant and animal diversity and abundance, particularly increasing the spatial extent of SAV. Increase seagrass and oyster production through improved salinity regime.
- Increase spatial extent and quality of wetlands in watershed.
- Increase suitable habitat for oysters and seagrasses in estuary.

Specific planning objectives to meet the goal of restoring economic values and social well-being are listed below:

Goal: Enhance economic values and social well being

Objectives:

- Conserve and protect water resources to ensure sustainability of economic and natural resources.
- Ensure availability of ground and surface water supplies for environmental resources while protecting existing legal sources of water for agricultural and urban uses.
- Maintain existing level of service for flood protection in the project area.
- Provide recreational, tourism, and environmental education opportunities.

Table 4-4 shows the CERP goals and project specific goals and objectives.

TABLE 4-4: CERP AND PROJECT GOALS AND OBJECTIVES

CERP Goals and Objectives	Project Goals and Objectives
Enhance Ecological Values	
Increase the total spatial extent of natural areas	• Improve the spatial extent and functional quality of habitat for estuarine biota. • Increase spatial extent and quality of wetlands in watershed
Improve habitat and functional quality	• Improve the quantity, timing, and distribution of freshwater flows to the Caloosahatchee Estuary by capturing runoff from the Caloosahatchee Basin and Lake Okeechobee releases. • Improve salinity balance in the Caloosahatchee Estuary for estuarine organisms. Reduce the spatial extent and duration of occurrences of extreme low and high salinities. • Improve water quality in the Caloosahatchee Estuary by reducing nutrient inflows from the Caloosahatchee Basin. Increase plant and animal diversity and abundance, particularly increasing the spatial extent of SAV. Increase seagrass and oyster production through improved salinity regime. • Increase suitable habitat for oysters and

CERP Goals and Objectives	Project Goals and Objectives
	seagrasses in estuary.
Improve native plant and animal species abundance and diversity	• Increase plant and animal diversity and abundance, particularly increasing the spatial extent of SAV.
Enhance Economic Values and Social Well Being	
Reduce Flood Damages (agricultural/urban)	
Provide recreational and navigation opportunities	• Increased recreational opportunities are directly related to improved habitat function and quality objectives.
Protect cultural and archaeological resources and values	

4.2.2 Constraints

The C&SF Project has supported agricultural and urban development in the Caloosahatchee Basin through a variety of benefits such as water supply, flood protection, drainage control, navigation, and recreation opportunities. This economic development has, however, adversely affected ecosystem functions and values in the study area, including reductions in the spatial extent and functional quality of wetland, riverine, estuarine, and marine habitats and decreases in native animals, fish, and plant populations. While alternative plans are formulated to achieve restoration of these functions and values, to be considered for implementation, plans must also avoid violating planning constraints. All CERP projects are constrained by WRDA 2000 provisions such as avoiding the elimination or transfer of existing legal sources of water unless a new source of comparable quantity and quality is available and maintaining existing levels of service for flood protection. In addition, all USACE projects are constrained by legal requirements that seek to minimize, for example, impacts to cultural resources or impacts to threatened and endangered species or their habitats.

Planning constraints specific to the Caloosahatchee River (C-43) West Basin Storage Reservoir project include:

- Avoid or minimize impacts to navigation.
- Avoid contributing to the degradation of water quality in the estuary or any of the contributing water bodies within the basin.
- Minimize impacts that will adversely affect the tourism or recreational industries which are critical to the regional economy.

4.3 PROJECT EVALUATION CRITERIA AND EVALUATION METHODS AND MODELS

Alternatives were evaluated based on their ability to meet specific evaluation criteria and performance targets, which relate directly to the goals and objectives identified in this report. A key criterion for the Caloosahatchee River (C-43) West Basin Storage Reservoir project is the need to capture and retain excess basin stormwater runoff and to capture excess flows discharged from Lake Okeechobee into the Caloosahatchee Estuary. The goal of the Caloosahatchee River (C-43) West Basin Storage Reservoir is to capture this excess water at times of peak or high flows and retain it for release at a later time when an increase in the freshwater flows are needed to maintain desirable salinity levels in the estuarine system. Reservoir operations were optimized to first address the environmental needs of the Caloosahatchee Estuary.

4.3.1 Hydrologic Performance Measures

The hydrologic performance measure was derived from relationships between the distribution, abundance, growth and survival of estuarine organisms and changes in salinity or freshwater discharge. Salinity tolerances of submerged grasses were initially used to identify an optimum S-79 freshwater inflow range of 300-2800 cfs (Chamberlain et al. 1995; Chamberlain and Doering 1995; Doering et al. 1999, 2001, and 2002; Doering and Chamberlain 2000; and Kraemer et al. 1999). Flows greater than 2800 cfs depress salinity in the lower estuary and threaten the marine shoal grass (*Halodule wrightii*) typical of this region (Chamberlain and Doering 1998b; and Doering et al. 2002), while flows that approach 4500 cfs have similar adverse impacts downstream in San Carlos Bay (Chamberlain and Doering 1995). Research has shown that the optimum flows for SAV are beneficial to other organisms as well.

A steady-state salinity model (Scarlatos 1988; Bierman 1993) and a statistical model of salinity (SFWMD 2000) were used to estimate mean monthly flows from S-79 that would establish a desirable salinity range in the geographic (historical) locations of SAV, without adverse impacts to benthic invertebrates, ichthyoplankton, and zooplankton (Chamberlain et al. 1995, 1999, 2001; Chamberlain and Doering 1998b; Doering et al. 2002; and Volety et al. 2003). An upgraded, fully hydrodynamic model has been developed and is under refinement. An early version of this model was used to verify and improve estimates of inflow requirements based on model prediction of salinity distribution in the estuary. For the Caloosahatchee Estuary, a mean monthly inflow of at least 300 cfs is needed from S-79 to ensure that the 30-day moving average salinity at Fort Myers (Yacht Basin) is less than ten ppt (< 10 ppt) (target maximum salinity for healthy *Vallisneria americana*) and single day maximum salinity (daily average) does not exceed 20 ppt (Doering et al. 1999, 2001, and 2002, Kraemer et al. 1999).

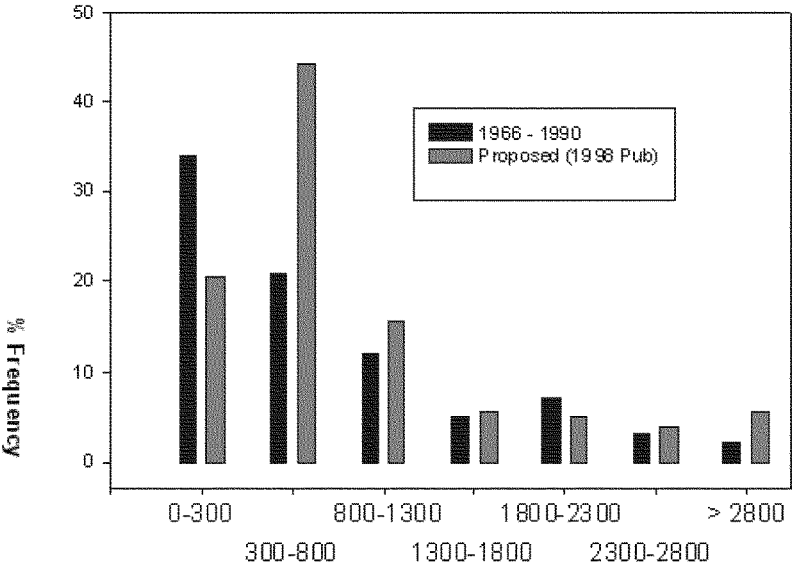
These MFL salinity criteria were initially designed to protect *Vallisneria americana* (tape grass) upstream of Fort Myers, but are also beneficial for other organisms that utilize this low salinity region of the estuary (Chamberlain and Doering 1998b; and SFWMD 2000 and 2002). For tape grass, this estimated MFL depends on about 200 cfs of additional flow from the tidal basin tributaries downstream of S-79. However, violations of the salinity criteria commonly occur during dryer than normal periods in the dry season when tidal tributary flows are less than 200 cfs (< 200 cfs). Additional field and laboratory research (Hunt and Doering 2005) indicates that tape grass is more sensitive to water quality conditions related to high salinity during low flows, as well as poor water clarity during excessive discharges. The last major drought constituted significant harm to the tape grass beds, which have still not fully recovered after four years. Therefore, a minimum flow of 300 from S-79 is not enough. A greater frequency of flows are needed from S-79 that are closer to a minimum of 450-500 cfs to achieve the required salinity goals associated with the MFL and prevent MFL salinity violations during these very dry conditions. Hydrologic performance measures for discharge at S-79 and MFL salinity criteria are summarized in the table below (***Table 4-5***).

TABLE 4-5: CERP PERFORMANCE MEASURES FOR FRESHWATER DISCHARGE AT S-79 AND MFL SALINITY CRITERIA AT FORT MYERS, FL

Freshwater Discharge At S-79	
Low Flow for Estuary (mean monthly)	Number of months < 450 cfs
High Flow for Estuary (mean monthly)	Number of months > 2800 cfs Number of months > 4500 cfs
Low Flow Duration	Frequency of consecutive months < 450 cfs
High Flow Duration	Frequency of consecutive months > 2800 cfs Frequency of consecutive months > 4500 cfs
Minimum Flow and Level (MFL) at Fort Myers, FL (Yacht Basin salinity sensor)	
Salinity Criteria (daily average)	Shall not exceed 20 ppt more than once in 2 years
Salinity Criteria (30-day moving average)	Shall not exceed 10 ppt more than once in 2 years

4.3.1.1 Flow Distribution Target for the Estuary

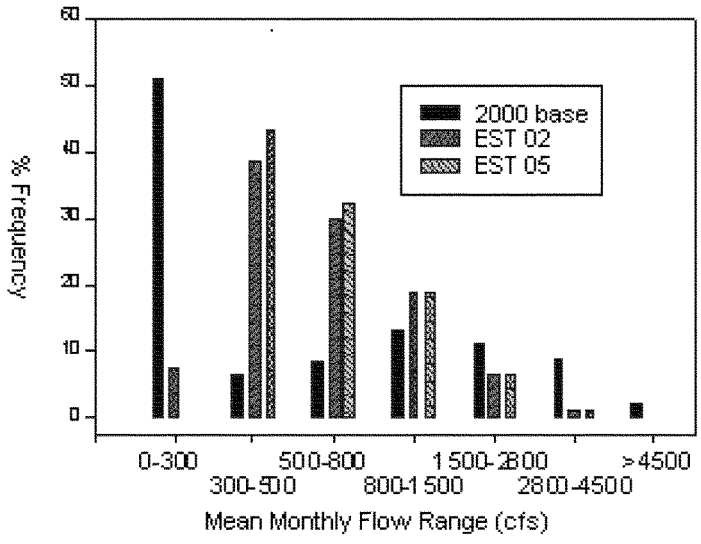
Environmental investigations done in the Caloosahatchee Estuary by the SFWMD in the 1980s and 1990s led to the initial establishment of freshwater inflow targets (average monthly flows through S-79), based on key biota, such as the freshwater-low salinity plant, *Vallisneria americana*, in the upstream portion of the estuary. As part of this analysis, the SFWMD made the initial attempts to define a preferred distribution of flows from S-79 that would best support the estuary's biotic resources. This effort began by evaluating the inflows that had occurred during the 25-year period 1966-1990 after installation of S-79. These flows were obviously skewed toward the very low end of the range (***Figure 4-2***), which routinely threatened the low salinity zone of the estuary where the submerged plant *Vallisneria* provides important habitat when allowed to flourish.



A distribution of inflows that has the greatest frequency range from 300 to 1,500 cfs, with a peak between 300-800 cfs was initially determined to be the most beneficial to the range of species evaluated. However, the SFWMD also recognized that a percentage of flows outside the preferred range (violations) may be an important component of the natural variability inherent in the estuary. An optimization program was employed as a first attempt to define the percent of acceptable violations (Labadie 1995: Otero et al 1995). The desired inflow ranges (limits for biota) were input variables to the model, along with the natural periodicity of violations of the upper and lower limits (estimated from the 1966-1990 historic data). For the Caloosahatchee, 20.5 percent violation of the low flow limit created inflows that emulated the natural variability established from the rainfall during 1966-1990. In addition to natural variation, this original frequency distribution generated by the model revealed that (1) the appropriate initial inflows limits were attained (300-2,800 cfs); and (2) the greatest frequency of inflows were within the range from 300-1,300 cfs, with a peak of inflows between 300-800 cfs. This original frequency distribution was reported and published as provisional (Chamberlain and Doering 1998), with the intent to update it as more information became available about the salinity requirements of key biota.

Instead of the original 1966-1990 base data set, more recent modeling efforts use a 2000 base condition (***Figure 4-3***), which have approximately 51 percent of the flows falling below 300 cfs (45% <150 cfs). Additional field and laboratory research since the Chamberlain and Doering (1998) publication indicates that *Vallisneria* is more sensitive to water quality conditions related to high salinity during low flows, as well as poor water clarity during excessive discharges. The last major drought constituted significant harm to the *Vallisneria* beds, which have still not fully recovered after four years.

Subsequent hydrologic modeling work (related to the Restudy, the Caloosahatchee Water Management Plan, and the development of MFL criteria) provided at least two new flow distributions that have fewer low flow violations than the original 20.5 percent and will better protect *Vallisneria*. The flow distribution known as EST02 was based on improving minimum flow deliveries at S-79. It allows fewer violations of flows below 300 cfs (seven percent) and is the best available estimate of pre-development freshwater deliveries to the estuary.



Both the earliest flow distribution estimates and EST02 assumed an average 200 cfs would be contributed by tidal basin inflows downstream of S-79, which would be adequate for meeting the *Vallisneria* salinity limits and MFL criteria. Most recently, estimates of tidal tributary inflows were added to the modeling effort to better assess total estuarine inflows related to salinity distribution targets. Assuming that 200 cfs will be contributed by the tidal basin will not achieve the MFL requirements. Also, permanent alterations have occurred in the estuary and watershed, such as the installation of S-79, which truncated the salinity gradient, preventing upstream migration of low salinity water during the dry season, thus eliminating the dry season oligohaline low salinity zone that historically existed. Therefore, a flow distribution that provides flows below 450 cfs at S-79 will not achieve the protection defined in the MFL (SFWMD 2000 and 2002) rule.

EST05 is similar to EST02, except that mean monthly inflows at S-79 are maintained above 450 cfs. Most of the EST05 flows from S-79 (75 percent) are in the ideal range of 450-800 cfs and almost all the remaining inflows are in the 800 to 2800 cfs range at S-79. Therefore, EST05 provides a slightly higher level of protection (against high salinity) in the upper estuary than other time series. This proposed frequency distribution has an estimated estuary delivery volume demand of ~524,000 ac-ft/yr and will maintain a full estuarine salinity gradient that is not unnaturally compressed.

Percent frequency of mean monthly flows from S-79 for: (a) 1966 – 1990, and (b) initially proposed during 1998 publication.

FIGURE 4-2: PERCENT FREQUENCY OF MEAN MONTHLY FLOWS FOR 1966 THROUGH 1990

Percent frequency of mean monthly flows from S-79 for:

(a) 2000 Base Condition
(b) EST 02
(c) EST 05

FIGURE 4-3: PERCENT FREQUENCY OF MEAN MONTHLY FLOWS (EST 02, EST 05 FLOW DISTRIBUTIONS)

In order to better achieve the CERP project and MFL restoration goals, scientists on the Caloosahatchee River (C-43 West Basin Storage Reservoir project team selected the EST05 flow distribution (***Table 4-6***) as the restoration target. It provides no allowances for monthly average discharges from S-79 less than 450 cfs. However, salinity violations are allowed under the MFL rule once every two years for the moving monthly average and daily salinity criteria. Therefore, the West Basin Storage Reservoir can still achieve estuarine protection and restoration success if the final selected alternative has flow occurrences beyond the distribution limits, including those below 450 cfs. The degree of achievement will be in part demonstrated by comparing performance

measure targets and habitat units (Hus) between base conditions and the alternative.

TABLE 4-6: FREQUENCY DISTRIBUTION OF FLOWS FROM S-79 ASSOCIATED WITH EST05 (WITHOUT TIDAL BASIN CONTRIBUTION)

Discharge Range (cfs) From S-79	Percent Distribution Of Flows From S-79
0 to 450	0%
450 to 500	42.8%
500 to 800	31.7%
800 to1500	19.2%
1500 to 2800	5.6%
2800 to 4500	0.7%
>4500	0%

4.3.2 Ecological Performance Measures

Estuarine ecosystem improvements will be measured as improvements to the salinity regime and water quality achieved in the river and estuary. These improvements will be measured by performance measures developed for six key indicator species:

- SAV (tape grass and seagrass)
- Oyster
- Blue crab
- Zooplankton
- Spotted seatrout

Performance measures have been established for the above biological resources in the Caloosahatchee Estuary (values are provisional and may be adjusted upon new evaluation of historic and current research efforts). These current ecological targets and supportive salinity requirements include the following:

1. SAV
   a) Tape grass–A permanent presence of tape grass beds (above the Fort Myers U.S. 41 Highway Bridges) that improve water quality and provide viable habitat for other organisms. Requires maintaining a 30-day moving average salinity < 10 ppt during the dry season at the Fort Myers continuous salinity sensor (near the surface at the Fort Myers Yacht Basin), such that tape grass in the Beautiful Island area does not decrease below 20 percent coverage and blade length is > 10 cm. Daily average salinity shall not exceed 20 ppt at Fort Myers more than

once every two years, and neither shall the 30-day moving average salinity of 10 ppt (MFL Rule: SFWMD 2000);

b) Seagrass–Return of viable seagrass that has been lost in the lower Caloosahatchee River (Iona Cove Region) and return of the 38 percent of seagrass lost in San Carlos Bay since 1982 (Harris et al. 1983). Limit the occurrence of average monthly salinity <15 ppt at the Cape Coral Bridge sensor, so salinity > 20 ppt is promoted in Iona Cove (Bierman 1993), which is supportive of minimum seagrass density (coverage > 30 percent at one meter water depth and average blade length > 10 cm). Maintain an average monthly salinity > 25 ppt, as measured at the Sanibel Causeway Bridge near-surface continuous sensor, so that historical seagrass density and coverage in the San Carlos Bay area (as determined from previous surveys, hydroacoustic monitoring, and aerial photography) is protected and restored to a previous condition (at least circa Harris et al. 1983), which includes reestablishment of continuous coverage at deeper depths in the San Carlos Bay area between Shell Point and the Sanibel Causeway.

2. Fauna

a) Oysters–A five fold increase in area coverage to approximately 100 acres and possibly 400 acres with placement of suitable substrate. Maintain daily salinity at Piney Point > 5 ppt to prevent high mortality. Consistently provide the preferred salinity of 14-28 ppt that supports the recruitment, survival, and growth of juvenile oysters upstream of Shell Point during March–October (juvenile oyster growth > 2.5 mm a month; recruitment > 3 spats per substrate shell a month; and mortality < 20 percent per month-values are based on information interpreted from Volety et al. 2003).

b)Plankton–Improve the nursery function of the estuary and better support each generation of fish recruited by improving food supply (zooplankton available). Zooplankton density spikes currently occur. Increase by 30-40 percent the occurrences of spikes that double or triple zooplankton density. Significantly reduce the occurrence (>10 percent) the frequency of total wash-out of fish eggs from the estuarine area upstream of Shell Point that result from high flows (Chamberlain and Doering 1998b; Chamberlain et al. 1999 and 2001, and SFWMD 2002)

c) Blue Crabs–Substantially (significantly) increase the blue crab population and commercial landing (catch per unit effort). Expect increase (return) of landings to 1-3 million pounds annually (assuming that fishing effort does not substantially increase or decrease).

d) Spotted seatrout-Substantially (significantly) increase the population and catch per unit effort.

Several prominent species have been identified for long-term monitoring and environmental assessment because they constitute important habitat in the Caloosahatchee, San Carlos Bay, Matlacha Pass and Pine Island Sound. In addition to tape grass that serves as an indicator of estuarine health in the upper estuary, these are oysters and marine seagrasses that represent the more downstream, seaward portions of the system. ***Table 4-7*** outlines each species chosen by the study team as a performance measure, the variables used in the habitat suitability index (HSI) for that species, and the preferred flow range identified by SFWMD research to be ideal for the Caloosahatchee estuary (Chamberlain and Doering 1998). The preferred flow ranges tend to fall in the same range as the target flow rates as outlined in EST05. Once the selected alternative plan (SAP) is identified, the ecological benefits to the Caloosahatchee estuary that accrue from achieving flow targets at S-79 will be quantified.

The ecological model which will be used to quantify benefits of the SAP relies on the HSIs to determine what conditions will make an area more suitable for each species. Each species identified as a performance measure is dependent on factors (such as flow, salinity, and temperature) that make up the variables of the HSI for that species. By plugging in each of these variables to the ecological model, a spatially explicit benefit output will be developed. Therefore, it is evident that improving the ecological conditions would be a direct result of modifying the flows. Flow will also affect other variables, most noticeably salinity. The ecological model, using the HSIs, will indicate those areas that will be most supportive of each species as a result of each alternative. The model will be able to quantify the benefits that will be provided under the chosen plan, and compare those to existing and future without project conditions.

TABLE 4-7: ECOLOGICAL PERFORMANCE MEASURES

Species	Variables in HSI	Preferred Flow Range (cfs)
SAV	Light, salinity, temperature, flow	Halodule <800 Halodule/Thalassia <2800
Oyster	Salinity, temperature, depth, substrate, flow	500-2000
Blue Crab	Substrate, salinity, temperature, flow	300-800
Zooplankton	Salinity, flow	150-600
Spotted Seatrout	Salinity, temperature, seagrass cover, proximity to seagrasses and drop offs, flow	300-1300 (general fish requirement)
Vallisneria	Previous condition, salinity, temperature, light availability	~800- 1500

4.3.3 Water Quality Evaluation Criteria

A secondary goal of the project is to improve water quality in the river and estuary. This can be accomplished by: (1) reducing high flows during the wet season, capturing, storing, and partially treating this water, then releasing it in a more environmentally sensitive manner that is beneficial to estuarine resources during the dry season; and (2) eliminating regulatory (non discretionary) discharges from Lake Okeechobee to the Caloosahatchee Estuary.

In addition, an evaluation of project-related water quality impacts is necessary to determine if the alternative plan under consideration would meet the FDEP's requirement that the project not contribute to the degradation of water quality and also to determine any benefits the project might create by improving water quality conditions both upstream and downstream of the S-79. The primary means of assessing the water quality benefits of the project will be to determine the net change in annual average nitrogen and phosphorus loads at S-79. An increase or decrease in nutrient loading will affect other water quality constituents such as dissolved oxygen, light penetration, and chlorophyll which are all critical to the quality of the estuary habitat that lies downstream of S-79.

Regional and sub-regional models will be used to simulate historical, current, and predicted flows to the estuary with and without the Caloosahatchee River (C-43) West Basin Storage Reservoir and CERP features for each alternative considered. Output (flows) from the above model runs in conjunction with water

quality analyses will be used to assess the extent of project effects on water quality.

SECTION 5
FORMULATION OF ALTERNATIVE PLANS

This page intentionally left blank

5.0 FORMULATION OF ALTERNATIVE PLANS

This section describes the plan formulation and evaluation process necessary to achieve the goals and purposes of the project and maximize the achievement of the system-wide benefits of the Plan. The Caloosahatchee River (C-43) West Basin Storage Reservoir project is an integral part of the Comprehensive Everglades Restoration Plan (CERP). The main purpose of the Caloosahatchee River (C-43) West Basin Storage Reservoir project is to provide for the retention and management of excess water within the natural system that is lost to tide (to the ocean), then release it back into the natural system when needed to help moderate extreme salinity changes in the estuary which are detrimental to estuarine communities. Captured excess water is made up of regulatory releases from Lake Okeechobee, basin runoff from storm events passing through the Caloosahatchee Watershed, and irrigation runoff from agricultural fields.

The Caloosahatchee River (C-43) West Basin Storage Reservoir project is needed primarily to perform two functions: (1) reduce high-volume flows to the Caloosahatchee Estuary during the wet season by capturing and storing excess surface water runoff and (2) supplement water for the natural system by increasing the availably of water to be delivered to the estuary during the dry season. Thus, a project in the lower Caloosahatchee River Watershed will increase the amount of water made available for the restoration of the Caloosahatchee Estuary.

5.1 PRIOR FORMULATION

The plan formulation and evaluation process employed during the Restudy utilized a base set of management measures identified during the reconnaissance phase of the study from which comprehensive plan alternatives were formulated in a "building block" fashion to achieve desired objectives. To address problems in the Caloosahatchee River Watershed, the Restudy recommended plan, Alternative D-13R, called for the use of above-ground reservoir(s) with a total storage capacity of approximately 160,000 ac-ft to capture excess water being lost to tide, then return this water back to the Caloosahatchee Estuary during low flow conditions Captured water in the reservoir(s) would then be released during dry periods to provide the desirable flow volumes through the S-79 structure to achieve the appropriate salinity envelope in the Caloosahatchee Estuary, thereby restoring the salinity balance to promote estuarine restoration (refer to Section 1 for more detail information on the evaluation of the project).

In 1997, significant amendments were made to the Florida Water Resources Act of 1972 (Chapter 373, Florida Statutes) regarding regional water supply planning. These changes required the SFWMD to prepare a District-wide Water Supply Assessment (DWSA) and to prepare water supply plans for regions that

were anticipated to have the potential of demand outstripping available supply by the year 2020. In 1998, the SFWMD began a water supply planning initiative to ensure prudent management of south Florida's water resources. As a result of this initiative, the SFWMD released in 2000 the Caloosahatchee Water Management Plan (CWMP) whose findings determined that the improved management of surface water through storage containment, could increase freshwater availability in the region and reduce potential impacts resulting from water use.

In building alternative plans, the Restudy PDT considered cost effective means to achieving the desired output. The conclusion drawn in the Restudy determined that above ground water storage provided the most cost effective alternative for freshwater attenuation (CERP, Volume 1; Section 7.2). Additionally, this same conclusion was also reached in the Caloosahatchee Water Management Plan (CWMP). Both the Restudy and the CWMP concluded that above ground water storage areas are the most cost affective and appropriate method for capturing and storing excess water in the Caloosahatchee River Basin project area resulting from regulatory releases from Lake Okeechobee and freshwater runoff.

5.2 PLAN FORMULATION RATIONALE

Draft Programmatic Regulations Guidance Memoranda (GM) #1 (Project Implementation Reports) and GM #2 (Formulation and Evaluation of Alternatives Developed for Project Implementation Reports) instruct project teams to affirm and optimize the component identified in the Restudy unless conditions or planning objectives have changed or if the component no longer meets the purposes outlined in the Restudy. Additionally, for projects where the non-Federal sponsor has already acquired lands, formulation of alternative plans using other sites will be minimized if the intended project purposes can be achieved and no more cost-effective sites are identified during formulation. Additional management measures to address the new circumstances should be developed and screening should occur based on the project's evaluation criteria and performance measures.

The plan formulation for this project focuses on first reaffirming that above-ground storage reservoirs in the Caloosahatchee River (C-43) Basin continue to meet the goals, objectives, and purposes for the project as described in the Restudy (Refer to Section 1 for more detail on Reaffirmation versus Reformulation). The project team then optimized the reservoir reviewing smaller and larger alternatives (including increased/decreased footprints, increased/decreased depths, varying infrastructural features such as numbers of pumps and pumps sizes and different cell configurations) in addition to the State's Acceler8 alternative referred to as the C-43 West Storage Reservoir. This

project implementation report (PIR) will also identify any additional unmet needs in the study and a process to address them.

Once a TSP is identified through system-wide formulation analysis, a next-added incremental (NAI) analysis evaluates the effects, or outputs, of the TSP as the next project added to the group of already approved CERP projects. This analysis helps illuminate the beneficial effects of the selected alternative plan (SAP) contributions without regard to future CERP projects as well as the importance of the project in the sequence of implementing CERP and dependence of other CERP projects on the project under evaluation. This analysis also helps to ascertain whether sufficient benefits attributable to the SAP can justify the cost, if no additional CERP projects (other than those already existing or authorized) are implemented.

Studies conducted for this report will confirm that the problems, opportunities, objectives, and constraints remain consistent with the Plan; the existing and future without project conditions identified in the Plan remain consistent; and the plan as described in the Restudy remains a viable alternative.

In addition the PDT considered the recent recommendations of the National Research Council (NRC) during the formulation of alternative plans and ultimately in the final selection of the TSP. The NRC has reviewed the first five years of work on CERP. Starting in 2004, 12 science and engineering experts studied CERP's progress and, after two years of study, issued their findings: *Progress Toward Restoring the Everglades: The First Biennial Review, 2006.* Biennial evaluations will continue through the 30-year lifetime of CERP. The NRC recognizes that Everglades' restoration is a complex undertaking with many scientific uncertainties, which can slow the rate of progress. They concluded that if the construction of a restoration project is delayed until all scientific uncertainties are eliminated, there will be many negative consequences including: continued decline of the Everglades ecosystem, lagging public support, and increased project costs. The NRC identified an approach referred to as Incremental Adaptive Restoration where an incremental approach using steps that are large enough to provide some restoration benefits now while addressing critical scientific uncertainties and to take actions that promote learning that can guide the remainder of the project design. Constructing projects using a phased approach will enable assessments of benefits and impacts to the environment as each phase is constructed. Remaining phases will then be adapted to optimize performance based on actual findings from the earlier phases.

The primary purpose of the Caloosahatchee River (C-43) West Basin Storage Reservoir project is to provide water supply to meet environmental needs, with surplus water being used as a potential opportunity to meet additional water

supply demands for urban and agricultural users in the area. Additionally, Stakeholders in the basin have expectations that the Caloosahatchee River (C 43) Basin project will address water quantity problems while providing water quality improvement features. The ability of the project to address these needs is affected by at least two factors:

- Agriculture in the area depends upon surface water and groundwater for water supply to meet irrigation needs, especially in the East Caloosahatchee River (upper) basin; and
- Several public water supplies sources in the basin rely on surface water withdrawals from the Caloosahatchee River (C-43 Canal) to meet urban water demands.

Taking into consideration all of the issues, constraints and expectations for this project, formulating and evaluating larger-scale alternatives that take into consideration all of the issues and problems in the basin while trying to meet the public's expectation for the project will be technically complex due to modeling requirements, requiring additional time to conduct the analysis of the watershed. Additionally, cost estimates for potential solutions will be costly and considerably over the Caloosahatchee River (C-43) Basin Storage Reservoir cost estimate from the Restudy. The basin-wide approach to restoration in the Caloosahatchee Basin remains consistent with the approach and issues identified in the Restudy, but require further investigation, will be more complex and time consuming, and will taking longer periods of time to complete and implement. The Caloosahatchee Estuary is in need of immediate help and cannot wait until a holistic approach is developed to address all of the issues of the entire basin.

In order to address these changing conditions and other issues and concerns that have arisen since the Restudy analysis of the project, it is recommended that the project use an Incremental Adaptive Restoration approach in which the basin study is divided in to two separate PIRs. This first PIR, the Caloosahatchee River (C-43) West Basin Storage Reservoir, will address the most immediate needs of the estuary, while ensuring that it is fully compatible and consistent with the CERP. A subsequent PIR will then provide a more comprehensive solution to the broader needs of the entire basin.

5.3 PLAN FORMULATION

The Restudy identified that above ground storage is the most cost effective means for capturing, storing and distributing excess water in the Caloosahatchee Watershed. The Restudy also realized that further in-depth analysis would result in project refinements, resulting in a more realistic and implementable design.

The refinement of the Restudy Plan for the Caloosahatchee River Watershed is known as the Caloosahatchee River (C-43) West Basin Storage Reservoir. The first major step of the plan formulation process for this project consists of reaffirming an above ground impoundment or storage reservoir with associated features such as a pumping station and seepage management system meets the goals and objectives as outlined in the Restudy. The refinement of the Restudy Plan is known as Alternative 3. To complete the plan formulation analysis, alternative plans with different storage volumes and pump sizes were then compared to determine cost-effectiveness and implementability of the selected plan.

5.3.1 Management Measures for Reaffirmation

Both structural and non-structural management measures were developed to ensure the achievement of an overall CERP goal that the proposed project would provide environmental restoration benefits as outlined in the Restudy.

In developing an initial set of management measures for the Caloosahatchee River (C-43) West Basin Storage Reservoir, the team looked at both structural and non-structural management measures. ***Table 5-1*** provides a description of management measures considered and how they could meet the planning objectives.

In order to develop and select a plan that will reasonably maximize ecosystem restoration benefits while addressing the water supply issues and opportunities in the basin, restoration of estuarine and riverine health were sought by improving hydrologic conditions. This could be done by evaluating two objectives: 1) providing additional water to augment low or no flows over S-79 during the dry season/dry periods, and 2) reducing damaging peak flows by providing adequate storage during high flow conditions.

Informal methods of analysis were used in the development of the screening process for initially selecting management measures. This consisted of an interactive process used to identify the significant differences between the management measures, to evaluate each measure utilizing best professional judgment, and to narrow down the number of measures to those that achieved the planning objectives and goals of the project (while taking into consideration constraints and environmental needs and requirements).

TABLE 5-1: DESCRIPTION OF MANAGEMENT MEASURES CONSIDERED FOR THE PROJECT

Management Measures Type	Management Measure Name	Description	Comments
Structural	Above Ground Reservoir Storage Areas	Large water storage areas surrounded by perimeter levees constructed from excavating soil from the interior of the reservoir adjacent to the levee locations. Would allow storage of water during extreme high runoff periods for release during low flow periods.	**Advantages:** Cost effective way of storing water, can be a secondary source of agricultural and urban water supply. **Disadvantages:** As the dry season's end approaches, water levels in the reservoir may drop to near the existing ground surface. **Water Quality**: Potential to improve water quality of water stored in the reservoirs somewhat through settling. Could also be combined with implementation of an STA to provide additional treatment. **Increased Habitat:** Improving habitat quality in the river and estuary by better meeting flow and associated salinity targets.
Structural	Restoration of Natural Areas	Natural areas that capture and provide natural storage & retention of stormwater runoff.	**Advantages:** Introduces an opportunity to re-hydrate and restore historic wetland and lacustrine areas and upland areas that have been altered due to urban and agricultural encroachments. **Disadvantages:** Few locations available to provide natural storage. Introductions of large amounts of water could be detrimental to the health of the existing wetlands by altering hydro-periods. **Water Quality:** Reduces the amount of stormwater reaching the canal systems, river, and estuary through the natural retention of stormwater runoff **Increased Habitat:** Improving habitat quality in the estuary, also increasing spatial extent of watershed wetlands and lake habitats.
Structural	Stormwater Treatment Areas (STAs)	Shallow water bodies created through the construction of small levees, generally ranging from one to three feet in depth. Divide vegetated cells (in which the water depth and rate flow can be controlled) are designed to uptake nutrients and remove suspended sediments from the water column.	**Advantages:** Designed and built to capture and treat stormwater runoff from the drainage basin, then release it back to the receiving water body **Disadvantages:** Due to the naturally occurring high levels of phosphorus in the watershed, nitrogen, rather than phosphorus, was the limiting nutrient, and high nitrogen loads were responsible for the elevated chlorophyll-a concentrations in the

Management Measures Type	Management Measure Name	Description	Comments
			Caloosahatchee Estuary. STAs recently constructed in South Florida have been designed to optimize phosphorus removal, but are not as effective at the removal of nitrogen. **Water Quality:** Vegetated STAs are designed to remove at least 80% of the incoming phosphorus load in water captured by the reservoirs **Increased Habitat:** Increased acreage for fish and wildlife. STAs often provide excellent areas for many migratory and threatened and endangered bird species.
Structural	Backpumping with Stormwater Treatment (STAs)	When a series of conditions are met, a series of pump stations could backpump excess water from reservoir(s) and from the Caloosahatchee River (C-43) Basin, to Lake Okeechobee after treatment through a STAs	**Advantages:** Unused water captured in reservoir(s) could be treated and returned to Lake Okeechobee. **Disadvantages:** Potentially insufficient water supply to meet all future environmental, agricultural, and urban demands in Caloosahatchee River (C-43) Basin. Series of conditions must be met before water can be sent to Lake Okeechobee. **Water Quality:** Stormwater treatment could address to small degree phosphorus loading in Lake Okeechobee **Increased Habitat:** Increased acreage for fish and wildlife. STAs often provide excellent areas for many migratory and threatened and endangered bird species.
Structural	Aquifer Storage and Recovery (ASR)	Water pumped from the storage reservoir into an ASR well for storage (at a specific capacity) in the aquifer.	**Advantages:** Provide additional water through subsurface storage to meet water needs in the Caloosahatchee River (C-43) Basin (44 ASRs) wells within the Caloosahatchee Basin, each having an injection or withdrawal capacity of five million gallons per day). It was assumed for the Restudy that the recovery efficiency would be 70% of water injected. **Disadvantages:** Water needed for ASR would be pumped from reservoir. Lack of information on the specific water quality characteristics of water to be injected, the specific water quality characteristics and the amount of water recovered from the aquifer, and the water quality

Management Measures Type	Management Measure Name	Description	Comments
			characteristics of water within the receiving aquifer. **Water Quality:** Chlorination for pre-treatment of water taken from reservoir prior to injection, and aeration for post-treatment of water recovered from ASR well prior to release. **Increased Habitat:** Improve habitat quality in the river and estuary by better meeting flow and associated salinity targets.
Structural	Oxbow Restoration	A crescent shape lake that forms in an abandoned meandering river channel, when the course of the river changes over a period of time, sedimentation builds up and closes the bend off from the river.	**Advantages:** 35 of these oxbows located along the Caloosahatchee River from the S-79 structure to the City of LaBelle. Could provide habitat within the river. **Disadvantages:** Water quality is poor in all of the oxbows; all have dissolved oxygen problems due to decaying vegetation and sediment buildup. Oxbows offer little storage value. **Water Quality:** Provides no water quality advantages. **Increased Habitat:** Increase wetland habitat. Could provide both riverine and wetland habitat improvements for many fish and wildlife species.
Nonstructural	Operation of Reservoirs	Focus on the capture and release of basin runoff through the timing of releases from the reservoir(s) that will alter the timing and quantity of nutrients delivered to the estuary through S-79 Structure.	**Advantages:** Depending upon the design and operation of the reservoir system, settling and some biological uptake will remove between 20% and 30% of the TN load captured by the reservoirs. **Disadvantages:** Will alter the timing and quantity of nutrients delivered as a result of changing discharge rates to the estuary. **Water Quality:** A nutrient loading analysis of reservoir operations conducted by FDEP determined that with an available storage of 228,000 acre-feet of storage, the project would capture approximately 500 tons/year of TN. **Increased Habitat:** Improving habitat quality in the river and estuary by better meeting flow and associated salinity targets.
Nonstructural	Best Management Practices (BMPs)**	The focus of the BMP effort is to reduce the pollutant load for a variety of water quality	**Advantages:** FDACS BMP program adopts BMPs developed by growers through workshops as the most

Management Measures Type	Management Measure Name	Description	Comments
		constituents contained in runoff from all major agricultural commodity groups (i.e., citrus, sugarcane, cattle, and row crops) and from urban land uses.	effective and practicable on-location means to improve water quality from agricultural discharges. Benefits of participation include a mechanism for "presumption of compliance" with state water quality standards and a waiver of liability. **Disadvantages:** Participation is self-implementing in that a grower chooses to participate. **Water Quality:** Reduction in nutrient and pollutant content of runoff from all major agricultural commodity groups through self imposed practices. SFWMD will expand its Urban BMP Program into the urban areas within the next year. The concept behind the BMP program is to identify and establish effective measures to prevent polluted stormwater from entering the receiving water bodies. **Increased Habitat:** Could benefit system by reducing algae blooms and other adverse affects of poor water quality.

**Note: The BMP programs described above are considered as part of the future without project conditions for the West Basin Storage Reservoir project and will not be considered as management measures in the formulation of alternative plans.

After a thorough review of the different structural and nonstructural management measures developed for the project, all but two were screened out based on the screening criteria described above. The results of the screening are shown in ***Table 5-2***. Above ground storage reservoirs (structural management measure) and operation of above ground storage reservoirs (non-structural management measures) were the selected features that the team determined were best able to meet the planning goals and objectives, opportunities, constraints, and environmental needs of the project.

TABLE 5-2: SCREENING OF POTENTIAL MEASURES FOR USE IN THIS PROJECT

Measure	Selection for First PIR	Reason
Above Ground Reservoir Storage Areas	Yes	Primary focus of Caloosahatchee River (C-43) West Basin Storage Reservoir project is to evaluate various reservoir storage areas.
Restoration of Natural Areas	No	This measure was deferred for further consideration in later study
STAs	No	This measure was deferred for further consideration in later study. STAs may not be needed. STAs most effectively treat phosphorus, and nitrogen loading is key issue in the basin.
Backpumping with Stormwater Treatment	No	This measure was deferred to later study. However, this option is less likely, since current modeling shows insufficient water supply to meet all future demands.
Aquifer Storage and Recovery	No	This measure was deferred to later study.
Oxbow Restoration	No	This measure is currently being evaluated as part of a Continuing Authorities Program - Section 206 study. Areas not addressed by the 206 study were deferred to a later study or separate SWFFS
Operation of Reservoirs	Yes	Primary focus of Caloosahatchee River (C-43) West Basin Storage Reservoir project is to evaluate various reservoir storage areas, and operational approaches
BMPs	No	Considered part of the future without project condition - will not be considered a measure in the formulation of alternative plans

5.3.2 Summary of Reaffirmation of Management Measures

The above analysis of management measures reaffirmed that above ground reservoir storage areas and operations of reservoirs meet the goals and objectives as outlined in the Restudy. These management measures will now be further optimized to meet those goals and objectives in a cost effective manner.

5.3.3 Project Siting Analysis

After screening of management measures concluded that above ground reservoir storage areas and operations of reservoirs meet the CERP-wide and project specific goals and objectives, an alternative site analysis was conducted to determine the most feasible and productive location. Previous studies such as the CWMP examined areas in existence that could be utilized for the proposed project.

Originally, an in-depth site analysis was performed for both the Eastern Caloosahatchee River (upper) basin and Western Caloosahatchee River (lower) basin to identify potential reservoir sites prior to the splitting of the project into two PIRs, see Plan Formulation Appendix for complete Siting Analysis. The siting criteria used to rank the potential reservoir sites included threatened and endangered species, wetlands, cultural resources, basin locations, effects to natural tributaries, potential seepage and flooding, and compatibility with enterprise zone. Sites with significant wetlands were eliminated from this level 1 screening.

For the West Caloosahatchee Basin, seven sites were further investigated as possible locations for placement of storage reservoirs. The seven sites included lands currently in agriculture i.e., citrus, pasture, etc. and were therefore similar with respect to type and quality of wetlands present. As a result of the in-depth screening analysis, six of the seven sites were eliminated either due to impacts to threatened or endangered species or due to geotechnical concerns with seepage rates of the soils on site. Based on this analysis a site referred to as the "Berry Groves" site was selected (***Figure 5-1***), since it represented the most promising site given the location, land use, geology, and soils (see Appendix F for more information on siting analysis).

Based on the findings of the Restudy and CWMP, which both require a storage reservoir in the Caloosahatchee River (C-43) Basin, the SFWMD determined the best location to use both State and Federal funds to acquire property in the Caloosahatchee River (C-43) Basin. The Federal funds used for this project were appropriated to the Department of Interior (DOI) and a Grant Agreement entitled Everglades Watershed Restoration-Grant Number LWCF-1 was executed to acquire south Florida ecosystem restoration project lands in the Caloosahatchee River (C-43) Basin. The Florida Division of State Lands in cooperation with the SFWMD staff reached an agreement that allowed the SFWMD to acquire the Berry Groves property as a key component for Everglades restoration (February 2000). To date the State of Florida has purchased a total of 12,372 acres in the immediate area in anticipation of reservoir construction with Federal funding provided by the DOI at a total of approximately $32,800,000, a portion of which will be credited to the Federal government towards the acquisition of lands for this project. It was determined

that the currently identified site was the most practicable location for the proposed project without incurring exorbitant costs of purchasing lands in the basin. Additionally, where the non-Federal sponsor has already acquired lands, formulation of plans using other sites will be minimized if the intended project purposes can be achieved and no more cost effective land sites are identified in plan formulation.

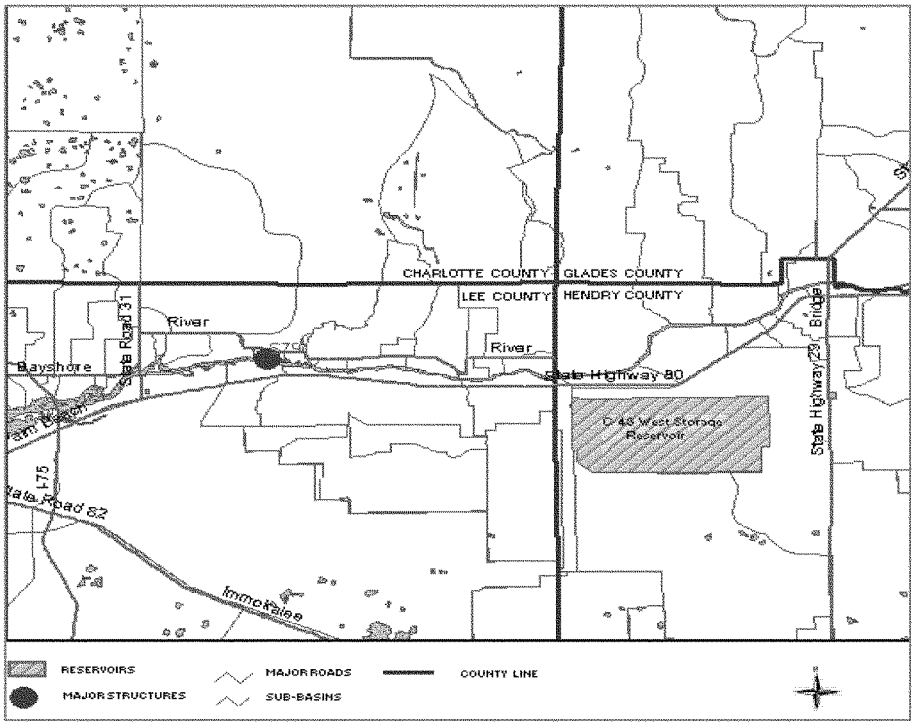


FIGURE 5-1: LOCATION OF THE BERRY GROVES SITE

5.3.4 Screening of Final Array of Alternatives

With the reaffirmation of the management measures (above ground reservoir storage areas and operations) identified in the Restudy and the selection of a cost effective site for its implementation, the PDT focused on the optimization of the management measures in identifying a cost effective and implementable alternative. The alternatives noted below were subjected to a screening process described in ***Section 5.3.1***. Also included within all these analyses was the "No Action" Alternative.

The alternative described in the Restudy used the Everglades Screening Model to identify approximately 160,000 acre-feet of storage volume as the targeted amount of storage necessary to capture wet season flows and to meet dry season minimum flows in order to provide desired salinity levels in the Caloosahatchee Estuary. The project team used the Restudy alternative (construction of above ground storage reservoirs totaling approximately 160,000 ac-ft) as a starting point for the basis of developing project alternatives.

5.3.4.1 Alternative 1

Alternative 1 is the No Action Plan, which is also the Future Without Project Condition described in ***Section 3*** of this report. This alternative was developed from the existing hydrology with modifications for anticipated changes in the watershed due to land use changes, water supply changes, water quality changes, and changes caused by other water resource projects in the watershed.

5.3.4.2 Alternative 2 (100,000 ac-ft Reservoir with 1,500 cfs Pumping Capacity)

Alternative 2 was developed as a smaller restoration alternative for the Western Caloosahatchee River (lower) Basin. This alternative is consistent with the CERP recommendation for a reservoir in this area, but it should be noted that this alternative's total storage volume of 100,000 ac-ft is significantly reduced from the 160,000 ac-ft of storage CERP estimated would be needed in this sub-region.

Alternative 2 is a two-cell reservoir with a "normal pool" storage capacity of 100,000 ac-ft (***Figure 5-2*** shows the configuration of this alternative and is applicable to the other alternatives). The design details of this alternative are outlined in ***existing on-site*** material and have a low permeability core. A graded filter is to be provided on the exterior side of the dam to direct seepage. Soil cement protection would be included on the interior side of all reservoir slope faces. A freeboard of 15 feet was used based on detailed analysis of wind and wave height run-up.

Table 5-3. The two-cell design was selected based on the fact that an internal embankment reduces wind set-up and wave-run up helping to reduce the embankment size and cost and it also allows for independent dewatering for unscheduled maintenance if necessary. The reservoir design includes a pump station (1,500 cfs capacity) to pump water from the C-43 Canal through the Townsend Canal to fill the reservoir. While a two pump station design was considered, the single pump station option was found to be most cost effective. Locating the pump station in the northwest corner minimizes improvements necessary for the Townsend Canal.

The water surface elevation of 35 ft North American Vertical Datum of 1988 (NAVD88) at "normal pool" is constant within the cells, with the depths ranging from 10-15 feet based on the elevation of the existing land surface. Dam heights for Alternative 2 will range from 29-34 feet. The maximum water depths and dam heights will occur in Cell 1, due to lower land surface elevations. The exterior and interior dams are to have a top width of 15 feet. The side slopes are 3 Horizontal: 1 Vertical (3H:1V). The exterior dams are to be constructed from

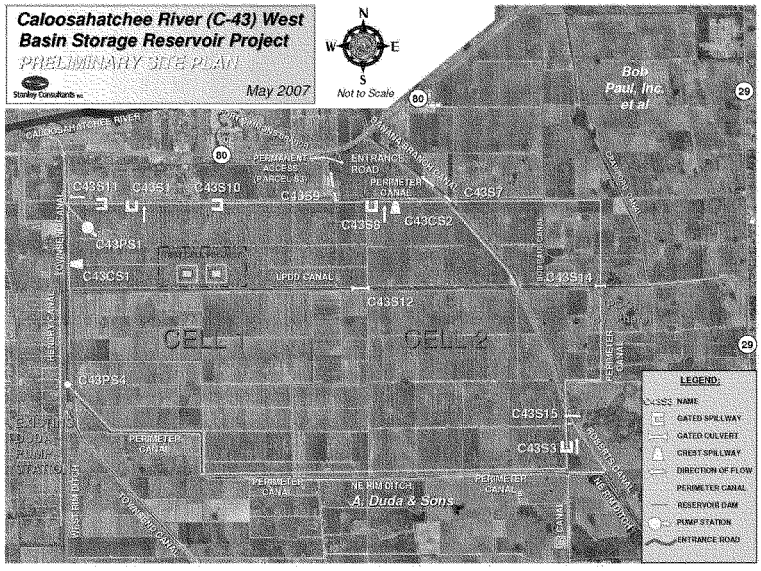

FIGURE 5-2: TYPICAL ALTERNATIVE SITE PLAN

existing on-site material and have a low permeability core. A graded filter is to be provided on the exterior side of the dam to direct seepage. Soil cement protection would be included on the interior side of all reservoir slope faces. A freeboard of 15 feet was used based on detailed analysis of wind and wave height run-up.

TABLE 5-3: ALTERNATIVE 2 DESIGN SUMMARY

Design Parameters	Parameter Values
Storage Volume (ac-ft)	100,000
Storage Area/Reservoir (acres)	9,220
Project Footprint-Staging, O&M, etc. (acres)	10,500
Normal Pool Elevation/ Average Pool Depth	35 ft NAVD88/ 10-15 ft
Dam Elevation/Dam Height	54 ft NAVD88/29-34 ft
Total Fill Rate–Pump Capacity (cfs)	1,500
Time to Fill (days)	33

A perimeter canal (seepage canal) is provided on the south, east, and north sides of the reservoir. The existing Townsend Canal will act as a seepage canal on the west side of the reservoir. In addition to seepage collection, the perimeter canal will also convey discharges from the reservoir; convey surface runoff from the south and east of the reservoir including improved drainage for SR 29; provide flows to the Crawford Canal, Banana Branch and Fort Simmons Branch; and maintain the surface water elevation in the expanded northeast rim ditch that provides irrigation for the A. Duda and Sons (Duda) citrus operations, located to the south of the reservoir. A 17-foot cutoff wall along the perimeter of the dam embankment has also been included.

Improvements to the Townsend Canal are based on the necessary capacity to meet maximum pumping requirements to fill the reservoir. Pre-storm and post-storm event flows have been simulated to evaluate flows in the Townsend Canal and other local canals and tributaries. Storm event flows in the Townsend Canal will be decreased over existing conditions with the construction and operation of the reservoir.

Each cell in the alternative is designed to discharge independently through separate discharge structures. Cell 1 discharges via S-1 into the Townsend Canal. Cell 2 discharges via S-8 into the perimeter canal. These structures will be designed for incremental operation allowing required flows to be released to the Caloosahatchee River (C-43 Canal) during periods of low flow. These structures could also serve as design storm control structures for releases prior to and during a storm event. The storm releases must be balanced with the targeted maximum flow allowed over S-79, which is 4,500 cfs. An emergency spillway with a crest elevation based on retaining the 25-year, 72-hour storm

event is to be provided within each cell's discharge structure. The 25-year, 72-hour storm captured in the reservoir would be a "control release" after the storm event in order to restore the water surface to the normal pool elevation while not exceeding the maximum flow of 4,500 cfs at S-79. The final design of the emergency spillway(s) will be in accordance with the requirements of Design Criteria Memorandum 3 (DCM-3).
Within the reservoir, structure S-12 hydraulically connects the reservoir cells and is designed to be gated so that either cell can be "isolated" for operational or maintenance purposes. A number of other culverts, weirs, and spillways are included to operate the reservoir and maintain appropriate water levels in existing canals and the perimeter canals.

5.3.4.3 Alternative 3 (A and B)–170,000 ac-ft Reservoir with 1,500 cfs Pumping Capacity

This alternative comes closest to approximating the Restudy-recommended volume of approximately 160,000 ac-ft for the West Basin storage reservoir and is the size evaluated and recommended in the Acceler8 planning process. Alternative 3 is a two-cell reservoir with a "normal pool" storage capacity of 170,000 acre-feet. The reservoir design includes a pump station with 1,500 cfs capacity to pump water from the Townsend Canal to fill the reservoir. The site layout would remain unchanged. This alternative was subdivided into a Alternatives 3A and 3B for evaluation purposes. The key distinction between Alternatives 3A and 3B is the operational methodology related to filling and draining the reservoir, rather than any structural differences. In general, Alternative 3A, the original plan identified by the State's Accler8 program attempts to maintain very specific flow rates at S-79 at all times while Alternative 3B attempts to meet the dynamic flow targets supplied by the ecological sub team (EST05).

Further in the formulation process these two alternatives were merged to fully meet the goals and purposes as identified in this report. For Alternatives 3A and 3B, the water surface elevation would be 42 feet at "normal pool" (NAVD88), with the average depth ranging from 17-19 feet. Dam heights for Alternatives 3A and 3B range from 32 -37 feet. The maximum water depths and dam heights will occur in Cell 1 due to lower land surface elevations in that cell. The exterior and interior dams are to have a top width of 14 feet. The side slopes are 3 Horizontal to 1 Vertical (3H:1V). The exterior dams are to be constructed from existing on-site material and have a low permeability core. A graded filter is to be provided on the exterior side of the dam to direct seepage. Soil cement protection would be included on the interior side of all reservoir slope faces. A freeboard of 15 feet was used based on detailed analysis of wind and wave height run-up. The design details of this alternative are outlined in ***Table 5-4***.

TABLE 5-4: ALTERNATIVE 3A AND 3B - DESIGN SUMMARY

Design Parameters	Parameter Values
Storage Volume (ac-ft)	170,000
Storage Area/Reservoir (acres)	9,220
Project Footprint Staging, O&M, etc. (acres)	10,500
Normal Pool Elevation/ Average Pool Depth	42 ft NAVD88/17-19 ft
Dam Elevation/Dam Height	57ft (NAVD88)/32-37 ft
Total Fill Rate–Pump Capacity (cfs)	1,500 cfs
Time to Fill (days)	57

The perimeter canal, improvements to the Townsend Canal, and construction of culverts, weirs, and spillways is essentially unchanged from Alternative 2. Because this alternative has a larger storage volume yet maintains the same pumping capacity, the amount of time required to fill the reservoir is approximately 24 days longer.

5.3.4.4 Alternative 3C–170,000 ac-ft Reservoir with 3,800 cfs Pumping Capacity

Alternative 3C is very similar to Alternatives 3A and 3B. The only difference is a larger pumping capacity and the associated modified reservoir operations to optimize storage performance with greater pumping flexibility. Alternative 3C is a two-cell reservoir with a "normal pool" storage capacity of 170,000 acre-feet. The reservoir design includes a pump station (3,800 cfs pumping capacity) to pump water from the Townsend Canal to fill the reservoir. The water surface elevation of 42 feet (NAVD88) at "normal pool" is the same for both cells, with depths ranging from 17-19 feet. Other structural elements would be the same as described in the previous Alternative 3B.

The inclusion of the larger pump allows for greater operational flexibility. In particular, the reservoir can be filled approximately 34 days faster than under Alternatives 3A and 3B and ten days faster than Alternative 2. This allows the reservoir to capture more water during the relatively short duration high flow events. Within this alternative there is uncertainty regarding the amount of retrofitting that may be required to the Townsend Canal and roadways. These uncertainties would not be known until additional engineering and design could be completed in the planning, engineering and design phase. For the purposes of this analysis it was assumed that no additional retrofitting would be required. The design details of this alternative are outlined in ***Table 5-5***.

TABLE 5-5: ALTERNATIVE 3C - DESIGN SUMMARY

Design Parameters	Parameter Values
Storage Volume (ac-ft)	170,000
Storage Area/Reservoir (acres)	9,220
Project Footprint-Staging, O&M, etc. (acres)	10,500
Normal Pool Elevation/ Average. Pool Depth	42 ft NAVD88/17-19 ft
Dam Elevation/Dam Height	57 ft NAVD88/32-37 ft
Total Fill Rate–Pump Capacity (cfs)	3,800 cfs
Time to Fill (days)	23

5.3.4.5 Alternative 4A–220,000 ac-ft Reservoir with 3,800 cfs Pump

Alternative 4A is a two-cell reservoir with a "normal pool" storage capacity of 220,000 ac-ft with dam heights of 41-46 feet and water depths of 22-27 feet at "normal pool." The pump station capacity is 3,800 cfs. The reservoir location and other associated features are the same as Alternative 3C.

The major difference is that by increasing the storage capacity and maintaining the same foot print normal pool elevations and levee elevations would be approximately five feet higher. In addition, by maintaining the same pump capacity as Alternative 3C approximately six additional days would be required to fill the reservoir. The design details of this alternative are outlined in ***Table*** 5-6. The selection of the upper bound 220,000 acre-feet reservoir matches findings of the SFWMD CWMP that recommended a storage reservoir with a capacity of 220,000 ac-ft located in the Western Caloosahatchee River (lower) basin at Berry Groves. The CWMP concluded that a 220,000 ac-ft reservoir would provide for environmental restoration of the Caloosahatchee Estuary.

TABLE 5-6: ALTERNATIVE 4A - DESIGN SUMMARY

Design Parameters	Parameter Values
Storage Volume (ac-ft)	220,000
Storage Area/Reservoir (acres)	9,220
Project Footprint-Staging, O&M, etc. (acres)	10,500
Normal Pool Elevation/Average Pool Depth	47 ft NAVD88/22-27 ft
Dam Elevation/Dam Height	66 ft NAVD88/ 41-46 ft
Total Fill Rate–Pump Capacity (cfs)	3,800
Time to Fill (days)	29

5.3.4.6 Alternative 4B–220,000 ac-ft Reservoir on Expanded Footprint with 3,800 cfs Pumping Capacity

Alternative 4B maintains the same storage volume as Alternative 4A; however, an approximately 5,610 acre larger footprint would be utilized allowing for an approximately eight foot lower dam height and pool elevation. Alternative 4B would also be a two-cell reservoir with 220,000 ac-ft of storage. Dam heights would range from 32-37 feet and water depths from 14-19 feet at "normal pool." The pump station location and capacity is the same as Alternative 3C and 4A. The exact locations of other culverts, weirs, and spillways would be similar to Alternative 4A. The general site plan and design details can be found in ***Figure*** 5-3 and ***Table 5-7*** respectively.

Although Alternative 4B was carried into the final array of alternatives, it was screened from further consideration at this point. Alternative 4B provides the same level of ecosystem output as Alternative 4A, however, the cost estimates indicated that while construction costs would be lower, total land costs would increase by approximately $150 million resulting in a roughly $80 million higher cost. The real estate costs for the additional land area associated with Alternative 4B were estimated to be considerably higher than previous purchases based on increasing development pressures in the area. In addition, the larger surface area of this alternative would result in greater evapotranspiration of water. Based on these findings, Alternative 4B was removed from further consideration.

FIGURE 5-3: ALTERNATIVE 4B SITE PLAN

TABLE 5-7: ALTERNATIVE 4B - DESIGN SUMMARY

Design Parameters	Parameter Values
Storage Volume (ac-ft)	220,000
Storage Area/Reservoir Footprint (acres)	15,140/16,610
Project Footprint-Staging, O&M, etc. (acres)	18,910
Normal Pool Elevation/ Average Pool Depth	39 ft NAVD88/14-19 ft
Dam Elevation/Dam Height	57 ft NAVD88/32-37 ft
Total Fill Rate–Pump Capacity (cfs)	3,800
Time to Fill (days)	29

5.3.5 Summary of Final Array of Alternative Plans

The final array of alternatives consists of seven alternative plans, including the No Action Alternative and variations on three reservoir capacities of 100,000, 170,000 and 220,000 ac-ft. Alternative 4B would require the purchase of approximately 5,610 additional acres to support an expanded footprint and lower dam heights. This array of alternatives would serve the needs of the Caloosahatchee River (C-43) Basin through the creation of a single reservoir in a location that would capture water from Lake Okeechobee and basin runoff from a majority of the Caloosahatchee River (C-43) Basin. The Berry Groves location also provides for efficient and flexible management of the stored water. The final array of alternatives is summarized in ***Table 5-8***.

TABLE 5-8: SUMMARY OF FINAL ARRAY OF ALTERNATIVES

Alternative 1	No Action (Future-Without Project)
Alternative 2	100,000 ac-ft reservoir, 29-34 feet dam, 10-15 feet average pool depth, and 1,500 cfs pump capacity
Alternative 3A	170,000 ac-ft reservoir, 32-37 feet dam, 17-19 feet average pool depth, and 1,500 cfs pump capacity • Restudy/Acceler8 design and operations
Alternative 3B	170,000 ac-ft reservoir, 32-37 feet dam, 17-19 feet average pool depth, and 1,500 cfs pump capacity • Restudy/Acceler8 design with alternate operations
Alternative 3C	170,000 ac-ft reservoir, 32-37 feet dam, 17-19 feet average pool depth, and 3,800 cfs pump capacity • Restudy design with larger pump
Alternative 4A	220,000 ac-ft reservoir, 41-46 feet dam, 22-27 feet average pool depth, and 3,800 cfs pump capacity
Alternative 4B	220,000 ac-ft reservoir, (expanded footprint) 32-37 feet dam, 14-19 feet average pool depth, and 3,800 cfs pump capacity

Note: Range in height is due to site elevations which vary by approximately 5 feet over the reservoir area.

5.3.6 Alternatives within the Jurisdiction of the Lead Agency

The Caloosahatchee River (C-43) West Basin Storage Reservoir project contains one component that is a part of the CERP, and is authorized in WRDA 2000. The measures considered in this study fall within the jurisdiction of the USACE and its sponsor the SFWMD. The implementation of this plan by the Federal government is being led by the USACE along with its non-Federal partner, the SFWMD. All alternatives being evaluated for the Caloosahatchee River (C-43)

West Basin Storage Reservoir project are consistent with CERP and within the USACE's jurisdiction. No measures considered were outside the jurisdiction of the USACE or its sponsor.

5.3.7 Evaluation of the Final Array of Alternatives

The next step was to evaluate the final array of alternatives using ecological output measured in habitat units (HUs) and costs. The following sections summarize the tools used for this evaluation and how they were used.

5.3.7.1 Analytical Tools Used to Evaluate the Final Array of Alternatives

In formulating and evaluating project alternatives, operational effects of proposed management measures on the existing ecosystem must be considered. To do this, computer simulation models and spreadsheets were used to evaluate the proposed operational criteria for each alternative in terms of its hydrologic influences on potentially affected natural areas.

A description and interpretation of all model results, including a review of the reliability and accuracy of the assumptions and data used in the model as well as risks and uncertainties associated with their use, is provided in ***Appendix A***.

5.3.7.1.1 South Florida Water Management Model

The most commonly used integrated model in South Florida is the South Florida Water Management Model (SFWMM). The model simulates the hydrology and the management of the water resources system from Lake Okeechobee in the north to Florida Bay in the south, covering an area of 7,600 square mile with a mesh of 3.2 km (2 miles) by 3.2 km (2 miles) cells. The SFWMM incorporates current or proposed water management protocols and operational rules and has the ability to simulate water management practices and policies that affect urban, agricultural, and environmental water uses in south Florida in one of its major strengths. Since the boundary of the SFWMM does not extend into the Caloosahatchee River (C-43) West Basin Storage Reservoir project area, the SFWMM model can only provide boundary conditions at the point where Lake Okeechobee discharges into the Caloosahatchee River (C-43 Canal), at Structure S-77. Therefore, a sub-regional model will be needed to simulate the hydraulics and hydrology of the project area.

5.3.7.1.2 MIKESHE Model

For this PIR, hydrologic indicators and hydraulic models were used to evaluate potential affects that could occur in the watershed for average wet season water levels (July 1 to October 1), average dry season water levels (April 1 to May 15), and hydroperiods. The MIKESHE modeling platform was used to develop sub-

regional models of the Caloosahatchee River (C-43) Basin to simulate the hydraulics and hydrology for purposes of showing hydrographs and stage duration curves, water level fluctuations and hydroperiods for selected indicator regions within natural areas associated with each of the alternative plans. These modeling results provide a comparison between Pre-Development, Existing (2000) conditions, 2050 Without Project conditions, and With Project conditions for each of the proposed alternatives for the system-wide analysis (with CERP) to identify the SAP.

5.3.7.1.3 Spreadsheet Analyses

The intent of this project is to help maintain desirable salinity levels in the Caloosahatchee Estuary System as measured by flows calculated for the S-79 structure. As an additional verification of modeling results used in selection of the SAP, a spreadsheet analysis will calculate flow data for the S-79 structure for use in a Next Added Increment (NAI) analysis of each alternative to verify environmental benefits achieved by each plan evaluated.

The source of Caloosahatchee River (C-43 Canal) flow data for the spreadsheet analyses for the Existing Conditions Baseline (2000) and Future Without Project Condition (2050 with no-CERP projects in place) is derived from South Florida Water Management Model (SFWMM) version 5.4.2 base model simulation 2000RD, for the Existing Conditions Baseline and 2050RD model simulation for the year 2050 with no CERP projects in place. Listed below are key assumptions utilized in these analyses, and which are consistent with this conceptual intent.

- The spreadsheet will take into consideration the evapotranspiration (ET) losses from the reservoir due to evaporation. The mass balance terms for the reservoir are reservoir inflow, reservoir releases, reservoir seepage (assumed to be zero based on results of the C-43 Test Cell Pilot Project– July 2006), ET losses (based on area volume relationship), and reservoir direct precipitation.
- No agricultural or urban water supply deliveries will be supplied by the reservoir. These demands continue to be supplied from Lake Okeechobee or existing groundwater sources.
- The eastern Caloosahatchee Basin (east of the S-78 structure) will not be affected by the project.
- With the exception of changing flows to the Caloosahatchee Estuary downstream of S-79, there will be no impacts on the Western Caloosahatchee Basin.

5.3.7.2 Hydrologic Modeling Evaluation of Alternatives

As previously discussed, the reservoir's design utilizes the selected site to its fullest capacity in order to capture the greatest volume of water needed to meet

the flow targets (EST05) just downstream of S-79 at the start of the Caloosahatchee Estuary. To determine the appropriate size and performance of the reservoir at the area known as the Berry Groves, hydrologic data was compiled and analyzed to determine if the reservoir was designed to meet the flow and salinity targets.

Average daily flows between January 1988 and June 1999 were approximately 500 cfs. Low flows of 0 cfs and flows as high as 17,283 cfs were recorded during the same period (CWMP, April 2000). Therefore, in order to mimic natural fluctuations in flows to the estuary, other flow ranges and their frequency of occurrence needed to be determined. To do this, the SFWMD evaluated average monthly flow data for a period of 36 years (1965 to 1999), and developed the following flow distributions (EST05) shown in ***Table 5-9***.

TABLE 5-9: TARGET FLOW DISTRIBUTION FOR EST05

S-79 Freshwater Discharge (Mean monthly flow range)	Frequency -Mean Monthly Flow (36 Year Period of Record)
Number of months < 450 cfs	0.0%
Number of months between 450 cfs and 1500 cfs	74.5%
Number of months between 1500 cfs and 2800 cfs	24.8%
Number of months > 2800 cfs	0.07%
Number of months > 4500 cfs	0.0%

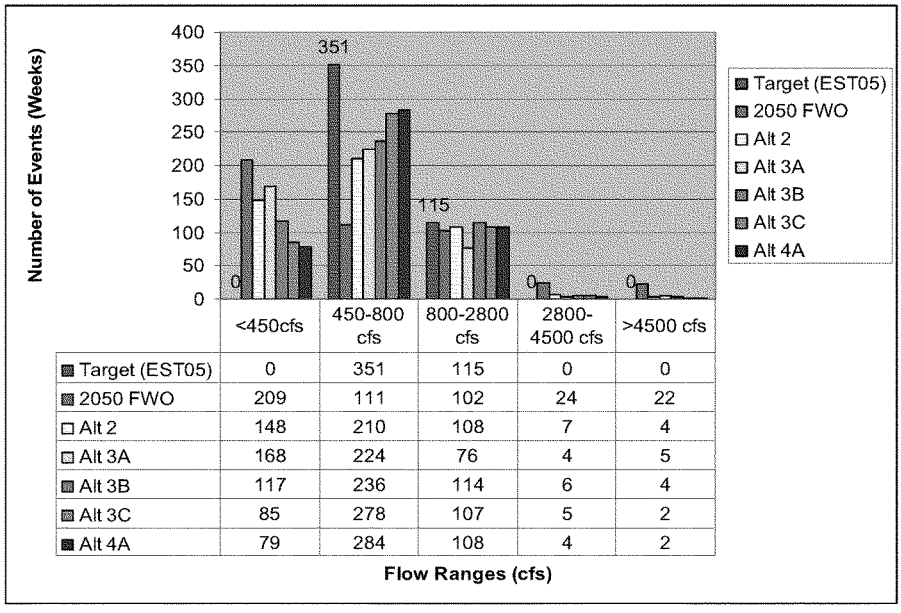
For each of the alternatives evaluated for this project, comparisons were made between the flow frequency distribution performance of the alternative and the target frequency distribution of the combined monthly and weekly average freshwater inflows through S-79 from the watershed and Lake Okeechobee for the nine year period of record (9 years out of the 36 year period of record containing three wet, three dry and three normal years on record).

The resulting flow frequency distributions from the analysis of Alternatives 1, 2, 3A, 3B, 3C and 4A were compared against the EST05 target distribution to determine the top performing plan. Based on this analysis, all alternatives show an increase in hydrologic performance. As the size of the project increases the performance also increases. Of the alternatives analyzed, Alternatives 3C and 4A came closest to matching the EST05 flow frequency distribution at S-79 (providing the desired number of months where the flows at S-79 were in the 450 cfs to 2800 cfs flow range) as they are the largest projects. These results are reflected in ***Table 5-10***.

The result of the analysis for each alternative was to show either an increase or decrease in the number of events where the mean monthly flows at S-79 were either above, below or within the flow envelope as compared to the future without project condition (***Table 5-10***).

TABLE 5-10: SUMMARY OF MEAN MONTHLY FLOW EVENTS AT S-79 WITHIN DIFFERENT FLOW RANGES

Alternative	Number of Months <450 cfs	Number of Months 450 – 800 cfs	Number of Months 800 – 2800 cfs	Number of Months 2800 – 4500 cfs	Number of Months >4500 cfs
Target (EST05)	0	79	29	0	0
2050FWO	43	27	28	7	3
Alternative 2 (2050)	33	46	27	2	0
Alternative 3A (2050)	33	56	17	2	0
Alternative 3B (2050)	30	26	49	3	0
Alternative 3C (2050)	19	60	29	0	0
Alternative 4A (2050)	19	60	29	0	0



It is anticipated that project benefits will see additional lifts in benefits over those currently predicted using available ecologic and hydrologic models.

5.3.7.3 Evaluating the Ecological Significance of Hydrologic Change

Because all of the species indicators are also somewhat dampened by the effect of averaging over months, seasons, and spatially, it was determined that it would be beneficial to have at least one benefit stream that depicts a more accurate picture of how well each alternative is matching the hydrologic target flow at S-79. EST05 is the hydrologic target used for a suite of estuarine organisms but, because it represents a time series/flow range necessary for an ecological balance within the estuary, it may not reflect the optimal hydrology for any one species.

As stated above, species indicators were dampened by the effect of averaging over months, seasons, and spatially. In reviewing the flow data for each

alternative, it was determined that by looking at the monthly values of flows over S-79 for each alternative, not all of the flow events that were greater than 2,800 cfs were being captured due that the averaging of data for monthly periods. Extreme short duration events that occurred over a few days rather than an entire month were not being accounted for in the habitat analysis. Additionally, weekly data were available which did capture these shorter duration extreme events so the results are not as diluted as the monthly averages. The alternatives were then evaluated based on mean weekly flows through the S-79 structure. Using this method, the relative ranking of alternative performance remained unchanged across alternatives. Alternative 3C and Alternative 4A again provide the best performance at 84 percent of the period of record respectively (***Table 5-11***). Percentages used for calculating HUs were then calculated based upon weekly averages as to how well each alternative came close to matching the EST05 frequency distribution at S-79. These analyses are summarized in ***Figure 5-4*** and ***Table 5-11***. What these evaluations continue to show is that as storage and pump size are increased, the resulting benefits also increase.

	<450cfs	450-800 cfs	800-2800 cfs	2800-4500 cfs	>4500 cfs
Target (EST05)	0	351	115	0	0
2050 FWO	209	111	102	24	22
Alt 2	148	210	108	7	4
Alt 3A	168	224	76	4	5
Alt 3B	117	236	114	6	4
Alt 3C	85	278	107	5	2
Alt 4A	79	284	108	4	2

FIGURE 5-4: MEAN WEEKLY DISTRIBUTION OF FLOWS FROM S-79

TABLE 5-11: PERCENT MATCH TO TARGET (EST05) AT S-79 FOR MEAN WEEKLY FLOWS

Alternative	450-800 cfs	800-2800 cfs	%POR in Desired Envelope
Target	75.0%	24.6%	99.6%
2050FWO	23.7%	21.8%	45.5%
Alt2	44.9%	23.1%	67.9%

Alt3B	50.4%	24.4%	74.8%
Alt3C	59.4%	22.9%	82.3%
Alt4A	60.7%	23.1%	83.8%

5.3.7.4 Ecological Benefits Evaluation of the Final Array of Alternatives–System-Wide Perspective

In practice, USACE's ecosystem restoration studies typically measure the ecosystem benefits of alternative plans in terms of physical dimensions (number of acres of wetlands, for example), or population counts (number of wading birds, for example), or various habitat-based scores ("habitat unit (HUs) based on the USFWS's Habitat Evaluation Procedures, or [HEP], for example). The next step was to evaluate the final array of alternatives using ecologic output measured in HUs and costs

The purpose of the Caloosahatchee River (C-43) West Basin Storage Reservoir project is to develop a plan that will help moderate flows: i.e., reduce flows during high flow periods and augment flows during low flow periods. Therefore, in order to present benefits of each plan, the impacts must be determined during those critical flow events. Once benefits are determined for each of the final alternatives, they will be compared to determine the differences between plans for basis of selection of the tentatively selected plan (TSP). Benefits of each plan are measured in terms of HUs. A HU is a measure of how a particular species responds to changes in its environment as a result of contributions of a particular plan. More detailed information on the calculation of HUs for this project can be found in ***Appendix C***. Species selected for evaluation (focal species) are ecologically, recreationally or economically important and have a well established linkage to stressors of management interest. They may also make good focal species because they engage the public in caring about the outcome of restoration projects. To measure the responses of these indicator species to the different alternatives, Habitat Suitability Indices (HSI) models were developed by choosing specific life stages of particular species with the most limited, restricted, or tightest range of suitable conditions, to capture the highest sensitivities of the organisms to the environmental changes associated with the planned restoration activities. The intent of the habitat suitability model is not to simulate the life-cycles of the species. Rather, it is to estimate the number of HUs to serve as a relative basis for comparing management

alternatives. HSI models were developed with each stressor variable portrayed spatially and temporally across the study area at scales appropriate to the organism or community being portrayed. The HSI models have been incorporated into a Geographic Information System (GIS) to portray responses spatially and temporally to facilitate policy decisions. That is, the model describes a response surface of habitat suitability values that vary spatially according to stressor levels throughout the estuary and temporally according to temporal patterns in stressor variables (see ***Appendix C***).

The project team originally decided to use seven species–eastern oysters, blue crabs, *Vallisneria,* seagrass (*Halodule and Thalassia)*, spotted seatrout, decapod larvae, and zooplankton. Once all models were run on all alternatives, the team decided to narrow the full analysis to three species–oysters, *Vallisneria* and seagrass. It was useful to run all of the species models, as they affirmed that all species showed an improvement over base conditions. However, it was determined that some species would be dropped for purposes of quantification for the final analysis because:

- they were less sensitive to changes between alternatives
- they were redundant and added little additional value
- the team decided to focus on habitats rather than individual species

The chosen species also cover a full range of both temporal and spatial attributes. Oysters are found in the middle estuary and are impacted by both wet and dry season flows. Seagrass are found in the lower Caloosahatchee River Estuary and are most impacted by the wet season flows. *Vallisneria* is found in the upper Caloosahatchee River Estuary and is most impacted by the dry season flows. Benefits were calculated using the appropriate period of record to reflect when species are most affected. Wet years analyzed include 1979, 1982, and 1983. Dry years include 1980, 1981 and 1985. The wet season was defined as July through November and the dry season was defined as December through May. June was not included, because for some years June is dry and for some years it is wet, therefore it causes inconsistency in the benefits calculations. However, in practice benefits will be realized in June based on the current recommended operations.

This project is expected to primarily benefit the Caloosahatchee Estuary. However, because CERP projects are required to be selected and justified based on their system-wide benefits, the following analysis conducted for the plan selection process is based on a system approach in which the Caloosahatchee River (C-43) West Basin Storage Reservoir project benefits would coincide with the rest of CERP being constructed. For system formulation analyses, the environmental evaluations were based on five attributes:

1) Average HSI for oyster–based on all seasons of dry years and all seasons of wet years
2) Average HSI for *Vallisneria*–based on dry seasons of dry years
3) Average HSI for seagrass–based on wet seasons of wet years
4) Extreme Events–Average HSI of oyster, *Vallisneria*, and seagrass during the three driest months and three wettest months in the period of record.
5) EST05–This attribute reflects the percentage of weeks each alternative matches our target flow (EST05). EST05 is a time series of flow developed to maximize beneficial conditions for a suite of organisms in the Caloosahatchee River Estuary. EST05 was adopted as the system-wide performance measure for the Caloosahatchee Estuary (NE-03) by the RECOVER team.

Upon review of the data, there is little value in averaging all habitat suitability index (HSIs) for all seasons of all years. The purpose of the Caloosahatchee River (C-43) West Basin Storage Reservoir project is to help moderate flows; reducing flows during high flow periods and augmenting flows during low flow periods. Therefore, in order to present benefits, the impact must be determined during those periods of time. Thus the benefits were calculated using the appropriate seasons to reflect when species are most impacted. Wet years analyzed include 1979, 1982, and 1983. Dry years include 1980, 1981, and 1985. The wet season was defined as June through November. The dry season was defined as December through May.

5.3.7.4.1 HSI Assumptions

The following is a list of assumptions for the HSI models:

- Linear relationship between the index and individual habitat parameter
- Positive relationship between the index and habitat carrying capacity
- Time scales are appropriate to capture change
- Spatial scale appropriate to capture change
- Variables strongly correlates with habitat quality and can be quantified by the model
- Habitat quality for selected species is a good indicator of habitat quality for other estuarine species
- Input data used to create HSI curves are reliable
- Where local data is lacking, data from other regions/estuaries are applied to models

5.3.7.4.2 HSI Background

The forecasting model used to evaluate alternatives for the Caloosahatchee River (C-43) West Basin Storage Reservoir project consisted of a set of stressor-response (habitat suitability) models for individual species. These Habitat

Suitability Indices (HSI) models were developed from scientific literature, expert knowledge, and available field data. The HSIs portray each stressor variable spatially and temporally across the study area at a scale appropriate to the organism or community being portrayed. HSI models were incorporated into a Geographic Information System (GIS) to describe responses spatially and temporally for the selection of restoration alternatives for each project.

Each HSI model describes a response surface of habitat suitability values between 0 (unsuitable) and 1 (most suitable) that varies spatially according to stressor levels throughout the estuary and temporally according to temporal patterns in stressor variables. Much of the temporal variation is a result of temporal cycling of important stressor inputs, such as salinity. The models calculate habitat suitability monthly as the weighted geometric mean of the environmental variables identified as important for each model. The geometric mean is derived from the product of the variables rather than the sum (as in the arithmetic mean), and has the appropriate property that if any of the individual variables are unsuitable for species success (i.e., the value of the variable is zero) then the entire index goes to zero. This HSI value was then multiplied by the area within each grid cell and the grid cell values added to calculate habitat units for each species. ***Figure 5-5*** represents how the various HSI's were combined to generate habitat unit scores and support the cost effectiveness/ incremental cost analysis (CE/ICA) effort.

Scoring each of the attributes above resulted in a quality index number (HSI or percent) for each alternative. Those quality index numbers were then combined using a Habitat Unit Combination Method (HUCM) in order to arrive at one total HU number for each alternative. ***Figure 5-5*** outlines the process for the environmental analysis.

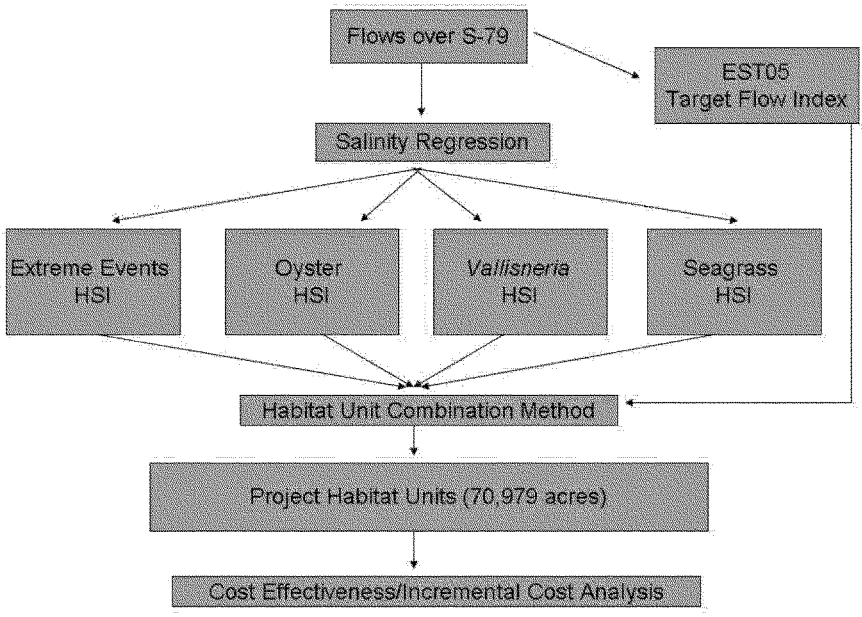

FIGURE 5-5: FLOW CHART FOR THE ENVIRONMENTAL ANALYSIS PROCESS

Table 5-12 summarizes the five attributes and quality index calculations for the 2000 base case, 2050 future without project, and each of the alternatives.

TABLE 5-12: TOTAL HABITAT UNIT CALCULATIONS FOR SYSTEM FORMULATION

Condition	Oyster	*Vallisneria*	Seagrass	Extreme Event	EST 05
2000 Base (Existing)	.48	.16	.51	.28	.38
2050 Future Without Project	.52	.20	.54	.30	.43
Alternative 2	.60	.31	.59	.42	.64
Alternative 3B	.60	.33	.59	.43	.70
Alternative 3C	.61	.35	.59	.45	.80
Alternative 4A	.61	.35	.59	.45	.79

5.3.7.5 Water Quality Analysis of Final Array of Alternatives

Under the conservative assumption that no water quality treatment occurs in the reservoir, the project alternatives in the system formulation condition (which include the rest of CERP) will reduce TP and TN loads at S-79 by approximately 28% to 34% in comparison to the future without condition. This reduction in nutrient loads at S-79 is largely the result of the reduction in discharges from Lake Okeechobee. All of the selected alternatives will cause a shift in nutrient load from the wet season to the dry season; however, all of the alternatives will decrease the frequency in which the monthly TN load exceeds the dry season, wet season, and annual targets established by DEP (dry-season 190 tons/month, wet-season 350 tons/month, annual 3,000 tons/month).

While it is possible that nitrogen fixation within the reservoir will result in short-term increases in TN loading to S-79, the average annual TN load at S-79 will be reduced. Each of the alternatives results in an improvement in overall average water quality conditions at S-79 as well as downstream in the estuary. Given the uncertainty in the threshold chlorophyll-a concentration required for the restoration of the ecological function of the estuary, the degree to which the reservoir project will improve downstream water quality is unknown at this time. Based on the evidence presented here, it appears that the project will not cause or contribute to water quality degradation under future conditions.

5.3.7.6 Planning Level Cost Estimates of Final Array of Alternatives

The cost estimate for the alternatives includes construction, lands, easements, right-of-ways, relocation, and disposal (LERRD), pre-construction, engineering and design (PED) costs, and construction management. Data for initial construction/implementation, land acquisition, monitoring, and periodically recurring costs for operation, maintenance, repair, replacement, and rehabilitation (O&MRR&R), have been developed through engineering design and cost estimation, and real estate appraisal efforts (See Appendix B: Cost Estimates for details of data development for cost estimates).

For purposes of this report and analysis, national economic development (NED) costs, as defined by USACE, are expressed in October 2006 price levels, and are based on costs estimated to be incurred over a 40 year period of analysis. Costs of a plan represent the value of goods and services required to implement and operate and maintain the selected plan. These costs are included in ***Table 5-13*** and were used in the cost effectiveness analysis of the alternatives. Based on additional engineering and design that would be performed in the planning, engineering and design phase, Alternative 3C may require modifications to the Townsend Canal and a major road downstream of the impoundments. For this purposes of this planning level cost estimate these costs were not included.

The costs in this section of the main report are updated, detailed costs and are not exactly equivalent to the costs that were utilized in the Economic Appendix cost/effectiveness and incremental costs analysis (CE/ICA). These updated costs were used, due to more detailed cost estimates becoming available, which warranted further justification of the original CE/ICA that was used for plan formulation and selection as can be noted in Appendix E. The result of this analysis verifies the conclusions of the original CE/ICA and the results seen in ***Table 5-18*** are consistent for both CE/ICA evaluations.

TABLE 5-13: COST OF FINAL ARRAY OF ALTERNATIVES (ROUNDED TO THE NEAREST 10,000)

	Alternative 2	Alternative 3B	Alternative 3C	Alternative 4A
Cost Component*				
Construction	$319,200,000	$355,170,000	$395,100,000	$425,500,000
S/A	$25,500,000	$27,000,000	$31,600,000	$34,000,000
PED	$31,900,000	$44,660,000	$39,500,000	$42,500,000
Lands	$80,420,000	$80,420,000	$80,420,000	$80,420,000
Initial Cost	$457,020,000	$507,240,000	$546,620,000	$582,420,000
Interest During Construction				
Construction	$33,600,000	$39,400,000	$42,000,000	$45,000,000
Lands	$13,500,000	$13,500,000	$13,000,000	$13,000,000
Total IDC	$47,100,000	$59,900,000	$55,000,000	$58,000,000
Total Project Investment	$504,120,000	$560,140,000	$601,620,000	$640,420,000
Average Annual Cost				
Interest & Amortization	$28,900,000	$32,100,000	$34,500,000	$36,700,000
Operation & Maintenance	$3,000,000	$3,000,000	$3,930,000	$3,930,000
Total Average Annual Cost	$31,900,000	$35,100,000	$38,430,000	$40,630,000

*Note – Final Costs of Selected Alternative Plan will be revised based on additional engineering and design
NED cost do not include Recreation Cost for Plan Formulation

5.3.7.7 Cost-Effectiveness/Incremental Cost Analyses for Final Array of Alternatives

Cost effectiveness analysis begins with a comparison of the costs and outputs of alternative plans to identify the least cost plan for every level of output considered. Alternative plans are compared to identify those that would produce greater levels of output at the same cost, or at a lesser cost, as other alternative plans. Alternative plans identified through this comparison are the cost effective alternative plans. Next, through incremental cost analysis, the cost effective alternative plans are compared to identify the most economically efficient alternative plans. Cost effective plans are compared by examining the

additional (incremental) costs for the additional (incremental) amounts of output produced by successively larger cost effective plans. The plans with the lowest incremental costs per unit of output for successively larger levels of output are the "Best Buy" plans. The results of these calculations and comparisons of costs and outputs between alternative plans provide a basis for addressing whether the additional outputs are worth the costs incurred to achieve them.

The final arrays of alternative plans for this project consisted of an aboveground reservoir (a single management measure) of varying storage volumes and pump sizes. All other management measures were screened from further consideration as a result of prior studies. Since all of the plans in the final array of alternative plans consisted of the same cost effective management measure, an incremental cost analysis was performed to determine the incremental costs of the benefits produced by the remaining four structural plans. Incremental cost analysis of the system-wide effects of the final array of plans was performed using IWR Plan software for the remaining alternative plans.

This analysis is based on and follows guidance from the USACE's Institute for Water Resources publication, Evaluation of Environmental Investment Procedures Manual, Interim: Cost Effectiveness and Incremental Analyses, May 1995, IWR Report #95-R-1. Costs are based initially on a rough order of magnitude (ROM) and include PED and construction costs, interest during construction, as well as O&M costs after construction.

5.3.7.8 Average Annual Benefits

The analysis of ecological response times for large, diverse ecosystems is extremely difficult to calculate. For example, when analyzing an estuarine system, certain attributes will have to be examined when predicting the response to changes in salinity. While some species will generally provide responses within a year of salinity change towards normal conditions, others will respond fairly quickly, but are difficult to measure due to changing conditions. To account for this, a linear approach to predict ecological response time was used and it resulted in:

- 80% of the benefits would be realized by three years from start of construction,
- 90% within five years after that,
- 100% of the lift would be realized within ten years of construction.

If nothing was done to improve the conditions in the estuary, the project team determined that eventually the ecosystem would stabilize in a severely degraded condition.

In ecosystem restoration projects, cost effectiveness and incremental cost analyses require a comparison of average annual costs and average annual benefits. In an ecosystem restoration project, the analyses compare the alternative plans' average annual costs against the appropriate average annual HU estimates. ***Table 5-14*** summarizes the four alternatives and their respective project HU lift totals. The average annual outputs were calculated as the difference between with-plan and without-plan conditions over the period of analysis (through year 2050). Costs used for CE/ICA and outputs used for CE/ICA are displayed in ***Table 5-15***.

TABLE 5-14: HABITAT UNIT LIFT, SYSTEM FORMULATION

Alternative	Average Annual Project Habitat Units
Alternative 2	10,628
Alternative 3B	12,809
Alternative 3C	16,397
Alternative 4A	15,907

Note that the output values shown reflect the differences between without project and with project on an average annual basis (i.e., ecological "lift" provided by each of the alternatives). For increases in oyster population under the future with project condition, recycled and fossil oyster shell and stabilizing mesh (where needed) could be used to establish suitable substrate for oyster recruitment (Oyster Reef Construction). Although this oyster reef restoration is not a part of the recommended plan, a description is included in this document as a recommendation for enhanced restoration of the estuary. A full description of the oyster reef restoration plan can be found in ***Appendix C*** (C.8 Oyster Reef Restoration Plan). ***Figure 5-6*** graphically represents a plot of the average annual benefits for the combined habitat streams for the future with and future with-out conditions. Any year on the graph can be picked to represent the HUs created in any particular period. The analysis used a 40 year period for benefit annualization, with the base year (first year benefits) beginning to accrue in 2010. Each alternative that took longer periods for benefits to begin accruing, had their costs annualized over 39 years and the 2010 present worth of the annualization calculated. In order to account for discrepancies in the annual benefit period of analysis, the benefits were annualized over 40 years (which is consistent with the cost annualization); with a year of zero lift being included in the average. The average annual HUs lift is then calculated as subtracting the future without project HUs from the future with project HUs for each year and averaging over the life of the project, which in this case is 40 years.

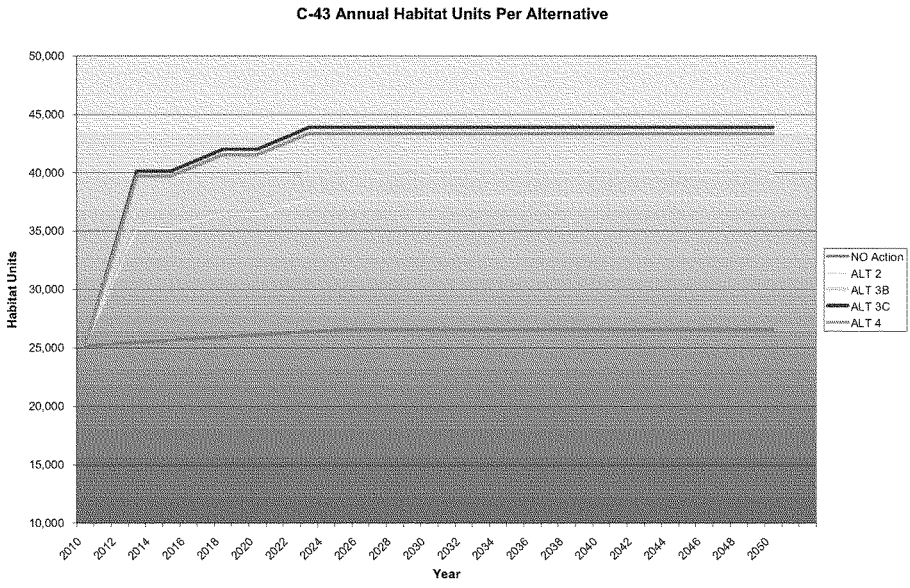

FIGURE 5-6: ANNUAL HABITAT UNIT LIFT

TABLE 5-15: COSTS AND OUTPUTS USED IN COST EFFECTIVENESS AND INCREMENTAL COST ANALYSES

	Alternative 2	Alternative 3B	Alternative 3C	Alternative 4A
Annual Cost	**$31,900,000**	**$35,100,000**	**$38,400,000**	**$40,600,000**
Average Annual Habitat Units	**10,628**	**12,809**	**16,397**	**15,907**

Note: Values assume system benefits (ecosystem outputs that would accrue to the Caloosahatchee River (C 43) West Basin Storage Reservoir study area if rest of CERP is constructed). Values for Alternatives are Differences Between "Without" Plan and "With" Plan (on an average annual basis)

5.3.7.9 Cost Effectiveness Analysis

Cost effectiveness and incremental cost analyses (CE/ICA) were conducted for each of the Caloosahatchee River (C-43) West Basin Storage Reservoir alternative plans. The analyses compared the alternative plans' average annual costs against the appropriate average annual HU estimates. The average annual outputs were calculated as the difference between with-plan and without-plan conditions over the period of analysis (through year 2050). CE/ICA

was performed using a combination of the following five metrics to represent various ecosystem outputs of the C--43 alternatives:

- *Vallisneria*
- Oyster
- Seagrass
- EST05
- Extreme Event

The total cost of CERP is not included in this CE/ICA. The cost of the balance of the CERP features, those not included in the West Basin Storage alternatives, is the same for all the alternatives. As such, including it in this analysis does not bring any additional insight or differentiation between alternatives. For this analysis, the difference between the alternatives can be shown through a display of the outputs and costs of each alternative without the cost of the "other CERP" features.

All of the environmental outputs were calculated on an average annual basis to account for the fact that several years may be required for full attainment of the functional capacities to be realized. This was performed for the expected future with and without project HUs, which were used to calculate the average annual benefits for each ecosystem output. A summary of the average annual lift calculations and average annual costs used in the CE/ICA analysis are provided in ***Table 5-16***, ***Table 5-17***, and ***Table 5-18*** show that for Alternatives 2, 3B and 3C; are all cost effective alternatives. Alternative 3C provides the greatest habitat lift of all the alternatives, and this alternative also has the lowest average cost per unit of output.

TABLE 5-16: RESULTS OF COST EFFECTIVENESS ANALYSIS

Alternatives	Average Annual Cost ($1,000)	Output	Average Cost Per Output	Cost Effective?
Without Plan	$0	0	N/A	
Alternative 2	$31,900	10,628	$3,002	YES
Alternative 3B	$35,100	12,809	$2,740	YES
Alternative 3C	$38,400	16,397	$2,344	YES
Alternative 4A	$40,600	15,907	$2,554	NO

Note: Freshwater Wetland Habitat Units (HU). All plans and cost effective plan arrayed by increasing output for each output category.

5.3.7.10 Incremental Cost Analysis

Typically, cost effective plans are arrayed by increasing outputs to clearly demonstrate changes in costs (i.e., increments of cost) and in outputs (i.e., increments of output). For comparison purposes, each cost effective alternative plan is compared to the without plan condition to determine which of the alternative plans has the lowest incremental costs per unit of output of all plans. This plan is then considered the National Ecosystem Restoration (NER) plan. After the NER plan is identified, all larger cost effective plans are compared to the NER plan in terms of increases in (increments of) cost and increases in (increments of) output. The alternative plan with the lowest incremental cost per unit of output (for all cost effective plans larger than the NER plan) is then considered the second best buy plan. ***Table 5-17*** presents the results of the ICA of the different alternative plans for the Caloosahatchee River (C-43) West Storage Reservoir project (for the respective ecological zones). The results of the analysis show that there is only one best buy plan for the Caloosahatchee River (C-43) West Basin Storage Reservoir project. From the analysis of incremental cost for all of the alternatives, Alternative 3C provides the greatest HU lift while having the lowest cost per unit of output and is considered the NER plan for the project.

TABLE 5-17: RESULTS OF INCREMENTAL COST ANALYSIS–COST EFFECTIVE AND BEST BUY PLANS ARRAYED BY INCREASING OUTPUT

	Average Annual Cost ($1000)	Output	Average Cost Per Output ($1,000)	Incremental Average Annual Cost ($1,000)	Incremental Output	Incremental Cost Per Output	Best Buy?
				(Habitat Units)			
Without Plan	$0	0	N/A	N/A	N/A	N/A	
Alt 3C	$38,400	16,397	$2,344	$38,400	16,397	$2,344	Best Buy

While the CE/ICA of the various alternatives in obtaining habitat outputs is the primary evaluation technique in the selection of the NER plan. Engineering Circular (EC) 1105-2-409 states that in regards to plan selection: Any alternative plan may be selected and recommended for implementation if it has, on balance, net beneficial effects after considering all plan effects, beneficial and adverse, in the four Principles and Guidelines (P&G) evaluation accounts: NED, Environmental Quality (EQ), Regional Economic Development (RED), and other social effects (OSE).

This section provides a full discussion and display of the beneficial and adverse effects of each plan, and a comparison of costs and effects among plans as well as cumulative effects.

5.3.7.11 National Economic Development (NED)

NED benefits are defined as increases in the economic value of the goods and services that result directly from a project. These are benefits that occur as a direct result of the project but are national in perspective.

The P&G states: "the alternative plan with the greatest net economic benefit consistent with protecting the Nation's environment (NED plan) is to be selected (paragraph 1.10.2)." There is no similar rule for plan selection where outputs are not measured in dollars, as in the case of ecosystem restoration analyses. While the CE/ICA does not provide a discrete decision rule for plan selection, it does provide the types of information to support an informed decision regarding ecosystem restoration (see ***Table 5-18***). Information about the acceptability, completeness, efficiency and effectiveness can also provide valuable support in making an informed decision in answering the question: "Is it worth it?"

TABLE 5-18: SUMMARY OF ALTERNATIVE PLANS

Alternative 2	Alternative 3B	Alternative 3C	Alternative 4A
Cost Effective	Cost Effective	Cost Effective and Best Buy	Not Cost Effective

Using the P&G evaluation criteria, the final array of alternatives were evaluated for:

- Acceptability: the workability and viability of the alternative plan with respect to acceptance by state and local entities and the public. The alternatives are evaluated for compatibility with existing laws, regulations, and public policies
- Completeness: the extent to which a given alternative plan provides and accounts for all necessary investments or other actions to ensure the realization of the planned effects.
- Efficiency: the extent to which an alternative plan is the most cost-effective means of alleviating the specified problems and realizing the specified opportunities, consistent with protecting the nation's environment

- Effectiveness: the extent to which an alternative plan alleviates the specified problems and achieves the specified opportunities

Each plan (except the No Action Alternative), was rated on a scale of 0 to 2 on the ability of each plan to meet the specified criteria (0 = does not meet; 1 = partially meets; 2 = fully meets) (***Table 5-19***).

TABLE 5-19: P&G EVALUATION CRITERIA

	Alternative 2	Alternative 3B	Alternative 3C	Alternative 4A
Acceptability	1	2	1	1
Completeness	1	1	1	1
Efficiency	1	1	2	0
Effectiveness	1	2	2	1

5.4 SELECTION OF THE FINAL PLAN

This section of the report began with a brief overview of the findings of the NRC that stated that they recognize that Everglades' restoration is a complex undertaking with many scientific uncertainties, which can slow the rate of progress. The NRC concluded that if the construction of a restoration project is delayed until all scientific uncertainties are eliminated, there will be many negative consequences including: continued decline of the Everglades ecosystem, lagging public support, and increased project costs. The NRC identified an approach referred to Incremental Adaptive Restoration where an incremental approach using steps that are large enough to provide some restoration benefits now while address critical scientific uncertainties and to take actions that promote learning that can guide the remainder of the project design. Constructing projects using the suggested NRC phased approach will enable assessments of benefits and impacts to the environment as each phase is constructed. Remaining phases will then be adapted to optimize performance based on actual findings from the earlier phases.

While utilizing a basin-wide approach to plan formulation remains consistent with the Restudy, formulation of comprehensive restoration plans for the entire Caloosahatchee River Watershed will necessitate further investigations of the basin, is more complex, and will require more time to complete the study and implement a recommended plan. The Caloosahatchee Estuary cannot wait on a larger study to address all basin wide issues; the estuary is in need of immediate action now if restoration efforts are to be successful.

To address the immediate issues of the estuary, an Incremental Adaptive Restoration approach (as suggested by the NRC) in which the basin study is

divided in to two separate PIRs is recommended. The first PIR (the Caloosahatchee River (C-43) West Basin Storage Reservoir project) will address the most immediate needs of the estuary, reaffirm the reservoir component in the Comprehensive Review Study, and ensure that it is fully compatible and consistent with the CERP. To address the overall needs and issues of the Caloosahatchee River Watershed, a subsequent PIR will address a more complete solution to the broader needs of the entire basin.

This first PIR focuses on the formulation and evaluation of a reservoir located in the lower West Caloosahatchee River basin to address the immediate restoration needs of the Caloosahatchee River Estuary. Through the formulation process, Alternative 3C is identified as the NER plan and is also identified as the Best Buy Plan in the CE/ICA analysis of project alternatives.. Although identified as the NER and Best Buy Plan, Alternative 3C does carry with it greater uncertainty, such as the potential to require more extensive modification to numerous structures downstream of the reservoir,, resulting in possible additional costs and time delays to the project. Delays in implementing the project will ultimately result in a loss of time for the estuary to realize potential ecological benefits. Alternative 3B is a variation of Alternative 3C, with the only difference between plans being the major pump station size (Alternative 3B uses a 1500 cfs pump while Alternative 3C uses a 3800 cfs pump). Alternative 3B is a cost effective plan, it is implementable, it achieves estuarine benefits, it does not carry as much uncertainty as Alternative 3C, and it received a high score based on the P&G selection criteria. While Alternative 3B is not a Best Buy Plan it ultimately may become one if Alternative 3C should require more extensive modifications to downstream features in order to meet project objectives.

Alternative 3B is recommended for implementation, rather than Alternative 3C (identified as the NER alternative plan). Alternative 3B meets the policy criteria established in Corps of Engineers guidance for planning in a collaboration environment[1]. This guidance provides that any alternative plan can be selected "if it has, on balance, net beneficial effects after considering all plan effects, beneficial and adverse..." Alternative 3B is clearly of less scope and cost than Alternative 3C, reduces uncertainty and financial risk to the government, and meets the Administration's policies for high priority outputs. Because Alternative 3B is an increment of Alternative 3C, this plan also supports adaptive implementation recommendations established by the National Academy of Science. The study considered various scales of reservoir storage and identified no alternative smaller than 3B which was more economical. For these reasons Alternative 3B is the recommended plan, and no ASA (CW) waiver is required.

[1] EC 1105-2-409 "Planning in a Collaborative Environment"

Therefore, the recommendation is to select Alternative 3B as the SAP (preferred plan) and adaptively monitor and manage implementation of the project.

As part of the second PIR for the Caloosahatchee River Watershed, the PDT will evaluate if additional pump capacity is required and the feasibility of making modifications to the 1500 cfs pump station. The design of the Caloosahatchee River (C-43) West Basin Storage Reservoir Project does take into consideration the potential future addition of pumps to provide additional pumping capacity if it is determined necessary in the second PIR analysis. Additional pumps can be added to the pumping station but would require additional construction (building on to the pump station) to accommodate the new additional pumps. A new operations plan would also be needed to account for the additional pumping capacity. The addition of pumps would allow the reservoir to capture additional flows from the Caloosahatchee River and to be filled in a shorter period of time, but it would not add any additional volume for water storage.

This decision will be based on real time data collection and engineering and ecological analysis and adaptive management while the SAP is functioning and benefits are being realized in and around the estuary.

5.4.1.1 Next Added Increment Plan Selection Verification

The intent of a system-wide analysis is to demonstrate how an alternative plan will function in conjunction with all CERP projects in place. However, potential benefits achievable by each alternative plan may not be realized due to differences in water budgets resulting from the implementation of additional CERP projects that have the Lake Okeechobee Regulation Schedule (LORS) shifting water away from the Caloosahatchee River (C-43) Basin in order to meet the demands of these projects under the system-wide analysis. To verify additional environmental benefits achievable by each plan, a NAI analysis was performed on all of the alternatives.

The NAI analysis does not include other CERP projects; therefore additional benefits achievable by each plan are more than likely resulting from the differences in additional water being released into the Caloosahatchee River (C-43) Basin under a water budget that is not influenced by CERP. A NAI analysis yields greater HUs and shows a larger lift in HUs calculated for each alternative over those calculated in the system-wide analysis. Additionally the NAI analysis can provide a better representation of the ranking of alternatives, thereby providing a validation of the plan rankings based on MIKESHE modeling results used in the selection of the SAP.

To validate the plan selection and address concerns with the MIKESHE modeling results, a spreadsheet analysis will calculate flow data for the S-79 structure for use in conducting a NAI analysis of each alternative (see

Engineering ***Appendix A*** for a detail discussion of the spreadsheet analysis used in the NAI analysis). The HSI models calculated HU for each alternative utilizing flow results from the spreadsheet analysis. ***Table 5-20*** and ***Table 5-21*** show the results of the HU benefit analysis of the different alternatives along with the system-wide analysis results providing a comparison of achievable HU lift from the NAI and system-wide analysis to validate selection of the SAP.

TABLE 5-20: TOTAL HABITAT UNIT CALCULATIONS FOR NAI FORMULATION

Metrics	2000	2050	ALT 2	ALT 3B	ALT 3C	ALT 4A
Vallisneria	0.03	0.08	0.58	0.60	0.59	0.59

Oysters	0.52	0.52	0.23	0.23	0.33	0.34
Extreme Events	0.22	0.24	0.24	0.24	0.26	0.27
EST05	0.20	0.21	0.65	0.71	0.76	0.78

TABLE 5-21: SUMMARY OF NAI AND SYSTEM-WIDE AVERAGE ANNUAL HABIT UNITS LIFT FOR EACH ALTERNATIVE EVALUATED

Alternative	System-wide AAHU lift (MIKESHE)	NAI AAHU lift (spreadsheet)
2	10,628	13,624
3B	12,809	15,297
3C	16,397	17,694
4A	15,907	18,410

As would be expected, under the NAI analysis, alternatives increase in benefit as the pump size and reservoir capacity increases.

Increased Benefits

The NAI analysis demonstrates that there are increased benefits for all of the alternatives, compared to system formulation. This is mainly due to the change in flows that the basin will be receiving from Lake Okeechobee in the system formulation condition compared to the NAI condition. In the system-wide formulation analysis, the basin will be receiving reduced flows, sometimes occurring during periods when the estuary demands increased freshwater flows. However, under the NAI analysis, there are fewer competing demands on Lake Okeechobee water, resulting in more lake water being made available to the Caloosahatchee Basin.

Alternative 3C versus Alternative 4A

In the system formulation, Alternative 3C provided more habitat units than Alternative 4A. This is counterintuitive to the assumption that a larger reservoir should provide more benefits. The NAI analysis using spreadsheet data does reflect Alternative 4A providing more benefits than Alternative 3C. In this case, issues with water budgets in the MIKESHE model may not realistically reflect the reservoir benefits. The NAI analysis is a better representation of the relative ranking of alternatives.

Alternative 3B versus Alternative 3C in the NAI Analysis

The relative difference in benefits between Alternatives 3B and 3C is less in the NAI analysis than in system formulation analysis. If there is more water in the Caloosahatchee Basin in the NAI, as stated above, all alternatives will perform better in the dry season. The dry season is where the reservoir feature provides most of its benefits, and these benefits during the dry season do not depend on pump size, since the pump is not used to release water to the estuary. Alternatives 3B and 3C are the same size reservoir, so they would provide roughly the same benefits during the dry season. In the wet season under NAI, the relative difference in benefits may be less than system formulation because there is so much more water available in NAI, that the larger pump of Alternative 3C still does not have much of a beneficial impact. There would be more flows that would be greatly over the target than in the system formulation scenario. So the added benefits of the larger pump in Alternative 3C would be less under NAI wet season than system formulation wet season. .

5.5 DISCUSSION OF MAJOR RISKS AND UNCERTAINTY

The primary focus areas for the risk and uncertainty evaluation are engineering and real estate considerations, modeling, and ecological response. This assessment includes evaluations of engineering and construction issues, such as project and construction scheduling, construction cost estimates, land availability, and technology. In addition, the reliability and accuracy of the assumptions and tools used to forecast with- and future without project conditions are evaluated. Finally, project performance and ecological response is discussed.

5.5.1 Engineering and Real Estate Risks and Uncertainty

The risk and uncertainty associated with the construction and operation of these features of the proposed project should be minimal. All features have been designed and constructed through established and applied technology. No experimental design was necessary for any component of the proposed impoundment. Additionally, both the USACE and the SFWMD have extensive

and reputable credibility in the design, construction and O&M of the proposed features from previous water resources planning efforts.

A cutoff wall along the perimeter of the dam embankment is being considered and will be further investigated as the project proceeds to design. For estimating purposes, a 17-foot cutoff wall was included. These features use standard technology and should pose minimal risk.

Soil cement protection was included for armoring. This will be further investigated as the team proceeds with the design. Armoring generally uses standard technology and should pose minimal risk.

A freeboard of approximately 15 feet was used in preparing the rough order of magnitude cost estimates. This value for freeboard was developed by Acceler8 and presented in their March 2006 Draft Technical Memorandum detailing their design assumptions and calculations for freeboard. Based on interagency review (USACE, SFWMD, USFWS, USEPA, USGS, FDEP, FFWCC, Hendry County, and Lee County) of the draft memorandum, it is expected that the final freeboard design will be somewhat less than the initial 13-foot assumption. The freeboard design will be further refined in accordance with applicable CERP DCM. These DCMs were developed to provide consistent working level guidance for impoundment design by the Acceler8 teams. The DCMs consolidate and incorporate design criteria from various agency regulations and guidelines including USACE, U.S. Bureau of Reclamation, Federal Energy Regulatory Commission, Florida Building Code, and the American Society of Civil Engineers. The DCMs do not supersede USACE's regulations. Freeboard designed in compliance with the DCMs, and thusly USACE regulations, should result in minimal risk of embankment failure due to overtopping (refer to DCM-2 for additional detail).

Through the Caloosahatchee Watershed plan, lands necessary for the construction and O&M of the West Basin Storage Reservoir have already been acquired by the SFWMD using funds appropriated to the DOI in Section 390 of the Federal Agricultural Improvement and Reform Act of 1996 together with State funds. As such, there is no uncertainty associated with land availability and acquisition.

A summary of project features and associated risks and uncertainties is provided in ***Table 5-22***.

TABLE 5-22: RISKS AND UNCERTAINTIES

Feature	Risk	Uncertainty
Reservoirs • Armoring • Cutoff Walls • Freeboard	Minimum	Minimum- established and applied technology
Pump Stations	Minimum	Minimum- established and applied technology
Spillways • Emergency Overflow • Vertical Lifts	Minimum	Minimum- established and applied technology

5.5.2 Modeling Risks and Uncertainty

5.5.2.1 Hydrologic Modeling

To formulate, evaluate, assess and adaptively manage the CERP and individual CERP projects, regional hydrologic simulation models, such as the SFWMM and the Natural Systems Model (NSM) are utilized by project teams and RECOVER. Both models use two-mile (2 mile by 2 mile) square grids with resolution based on available spatially distributed data. These models have been peer reviewed and represent the best available science. They are considered reliable for current decision-making processes (and have been used repeatedly to support decision-making). However, these models depict general hydrologic conditions that are assumed to be representative throughout the individual four-square mile area (2,560-acre) grid cells that comprise the model. Therefore, the models may not be fine enough in their resolution to simulate minor hydrologic changes that would result from variations in topography, soils, and vegetation within the grid cells, but which may be significant in terms of ecological response. The SFWMM was developed during the late 1970s and early 1980s and has served as the primary regional simulation model in south Florida for nearly two decades.

New initiatives such as the Everglades Restoration and Water Supply Planning have placed new demands for information on regional simulation models. This has led to the development of the next generation of the 2x2 model referred to as the Regional System Model (RSM). The RSM is the next generation SFWMM developed using recent advances in computer technology-in particular, GIS, databases, and object-oriented model development. The RSM makes use of the

more realistic, accurate, and efficient numerical algorithms to simulate hydrology and water management in south Florida. It uses a variable mesh structure capable of simulating the region at differing spatial resolutions. It is expected that the RSM will eventually replace the existing SFWMM, although years of development and testing will be needed before RSM becomes fully operational for the entire system.

While the hydrologic models can illustrate effects of alternative plans in relationship to hydrologic targets, it is often difficult to discern the ecological magnitude of the relative differences between alternatives (e.g., a small slope change in a stage duration curve). Furthermore, the simulation models are not sensitive to small changes in hydrology at the cell boundaries. As such, the effects of individual projects may be negligible or may not even be discernable using the regional modeling tool, particularly when their influence on the regional water management system is relatively small. This particular problem creates a lack of scientific certainty with respect to the spatial extent of a project's effects.

The uncertainties in using these models to predict reservoir function relate to the use of historical data, including:

1. Failure of the reservoir to be filled by the time of commissioning.
2. Mean flows in the watershed below what has been predicted/simulated.
3. Clustering of wet and dry years, especially the occurrence of a prolonged dry period.
4. Faster reservoir sedimentation than expected.

The risks due to this project are:

1. Risk to downstream settlement and environmental resources due to dam breach.
2. Higher than expected downstream damages during release of major floods due to infrastructure encroachment on flood plains.

The regional hydrologic simulation model is designed for regional, long-term applications. Although scalable, performance constraints may impose practical limits on the time and space scales. This regional model is not intended for local-scale decision-making support. Even if the hydrologic model shows differences in alternative plans in relationship to hydrologic targets, it is often difficult to discern the ecological magnitude of the relative differences between alternatives. Also, the relative size difference between the reservoir and the affected areas (Caloosahatchee Estuary) is such that even large changes in volume of water stored within the reservoir cannot be easily seen when water is spread over such a large area. To minimize these risks, the project team will use

a sub-regional model to determine seepage rates and the probability of spillover. The reservoir operations manual will include management measures such as:

1. Developing a reservoir regulation schedule
2. Creating flood storage prior to predicted storm
3. Design of outlet structures to handle release water after a major storm in preparation for a subsequent storm

5.5.2.2 Modeling of the Various Alternative Plans

The MIKESHE modeling platform was used to develop a subregional model to simulate the hydraulics and hydrology of the Caloosahatchee River (C-43) Basin in order to simulate the integral connection between groundwater and surface water interaction within the basin for existing and future conditions. For formulation purposes, the hydrologic outputs from the modeling analysis of the final array of alternatives are useful for determining and comparing the effects of alternative plans for plan selection.

The Caloosahatchee River (C-43) West Basin Storage Reservoir project was formulated to keep water in the regional system without adversely affecting existing legal uses of water. Excess water is captured and stored in the reservoir for later releases for meeting estuarine demands. The volume of water that could be retained by a reservoir for delivery to the estuary is likely limited to the volume of damaging Lake Okeechobee releases that can be captured and pumped to the reservoir and the volume of excess runoff captured by the reservoir from the Caloosahatchee River (C-43) Basin (largely agricultural and un-developed lands with some urban areas intermixed). To evaluate the performance of different reservoir sizes, modeling output data of the with project conditions (obtained from the MIKESHE/MIKE 11 analysis of the alternatives modeled) was compared to the CERP system-wide performance measure "NE-3" (Caloosahatchee salinity envelope (EST05)) to determine which alternative plan came closest to achieving the hydrologic performance targets set for the project.

In order to characterize the risk and uncertainty issues that are inherent in developing a model to simulate a natural and/or managed system, an assessment of the risk and uncertainty specific to the modeling of existing condition, future without condition and the final array of alternatives for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project must be considered. These assessments included a review of the reliability and accuracy of the assumptions and data used in the MIKESHE/MIKE 11 modeling platform to simulate existing conditions and for forecasting the future with and without project conditions. During a review of the sub-regional modeling results for all of the alternatives, several issues became apparent resulting in a level of uncertainty in calculating habitat units for the alternatives.

Analysis of the modeling results indicated a significant water budget discrepancy. It was determined that the source of this water budget error was in the MIKESHE irrigation routines. Within a given MIKESHE model, the irrigated areas are discretized into "irrigation command areas" which represent individual farms or groups of farms that draw from an individual source of water. These sources of water can be withdrawals from locations within a surface water canal, withdrawals from groundwater wells, or water introduced from an external source. This external source could represent water from sources outside or below the model domain (a deep aquifer), from a feature not modeled at all such as a water reclamation facility, or as in the case of this MIKESHE model application, it was used to represent irrigation demands that are unmet by the surface and groundwater systems. Within the irrigation module, this external source is treated as an infinite source of water. Each irrigation command area can also use multiple sources within each time step and a prioritized list is developed for each irrigated area based on currently permitted or projected irrigation operations. For example, a given command area can try to get its water from a canal source, then if the quantity of water available from that source is insufficient, then that command area will go to the next source which could be another surface water location or a groundwater source. If all preceding sources of water are insufficient, then the irrigation command area will receive the remaining unmet balance of its demand from the infinite external source.

In the development of the Freshwater Caloosahatchee MIKESHE model, it was decided to allow all the irrigated areas to use this infinite external source as a final source of water as a method of quantifying "demands not met" or the shortage in the amount of water that is required by an irrigation command area. It was anticipated that this quantity of water would be very small in relation to the remainder of the irrigation volumes and insignificant in relation to the total model water budget.

Upon analysis of the model outputs, specifically the irrigation outputs, it was discovered that this volume of water coming from external sources was significantly greater than anticipated. The quantity of water coming from external sources also varied significantly among the various model runs. The average-annual volume of water coming from external sources ranges from 125,100 ac-ft for the 2000 without-project run to 260,500 ac-ft for one of the with-project runs. For some model runs this equates to more than half of the total irrigation volume coming from an artificial external source of water. When compared to the volumes of the reservoirs being tested, this is a significant error in the water budget.

After consultation with the developer of the MIKESHE code, the Danish Hydraulic Institute, it was determined that there was a limitation in the

conceptualization of the irrigation routines. Essentially, the model grossly underestimated the available volume of water from existing sources of water such as canals and groundwater and prematurely resorted to the theoretically infinite external water source. At times when sufficient irrigation water was available in the canals, the model pulled in water from external water sources, producing this significant water budget error.

While this water budget error produces some level of risk and uncertainty, it is not anticipated that there will be a change to the ranking of environmental benefits for the alternatives. It is still reasonable to assume that alternatives with larger component features (pumps and reservoir sizes) will perform better than alternatives with smaller components. In the wet season, a larger pump will always be able to shave off more damaging flows than a smaller pump and a larger reservoir will always provide more storage volume than a smaller reservoir. That extra water that is stored in the wet season will always translate to a larger source of water carried over into the dry season.

This water budget error could also affect the various alternatives differently, changing the relative differences in project benefits between alternatives. As a result, it is possible that the final quantity of habitat units for each alternative will change (increase or decrease). This means that there could be changes in the number of habitat units achieved by each alternative as a result of the water budget error, but the ranking of the order of plans based on the number of habitat units achieved will remain the same.

Although there is a level of risk and uncertainty associated with the modeling results, for purposes of plan selection, the modeling data developed to date will be used in selecting the recommended plan for the project (SAP). Additionally, the CERP Programmatic Regulations require the evaluation of a tentatively selected plan (TSP) using a "next-added increment" (NAI) analysis to helps illuminate the amount of benefits the plan contributes without regard to future CERP projects prior to the selection of the SAP. The TSP must also demonstrate that it does not negatively impact existing levels of flood protection (saving clause) to meet the intent of the level of service analysis for flood protection contained in the WRDA 2000, the CERP Programmatic Regulations as well as Florida State law regarding the implementation of CERP. To minimize the risks and uncertainties resulting from the issues with the MIKESHE/MIKE11 modeling platform, the project team will use alternative methods for showing TSP compliance with CERP Programmatic Regulations, WRDA 2000 and Florida State law. A separate spread sheet analysis which utilizes modeling output from the SFWMM regional hydrologic simulation model will be used in the NAI analysis of the TSP. To demonstrate compliance with saving clause requirements concerning flood levels, a revised MIKESHE/MIKE11 model will

look at the localized areas around the reservoir to demonstrate that the project does not have an impact to flood levels on lands adjacent to the reservoir.

5.5.3 Ecological Response Risks and Uncertainty

5.5.3.1 Evaluating the Ecological Significance of Hydrologic Change

Hydrologic performance measures are useful for determining and comparing the effects of alternative plans. However, to determine a plan's outputs for purposes of depicting NER benefits, the assumption is made that the hydrologic performance measures fully characterize all of the attributes of ecosystem functions, since the analytical tool for system-wide effects is a hydrologic simulation model. This assumption results in some uncertainty with respect to the evaluation of system-wide ecological responses because not all ecological attributes can be simply reduced to hydrologic terms. However, to reduce some levels of uncertainty, the hydrologic performance measures have been related to certain ecological attributes by the ecological sub-team.

Additional uncertainty exists in the correlation between small hydrologic changes seen in the outputs of a regional model, and the ecological significance of those changes. The hydrologic change in a model grid cell, indicator region, or geographic sub-region that may result from individual projects is typically small in relative magnitude. Therefore, there is uncertainty in predicting the extent of system-wide change in ecological attributes due to relatively small differences in the hydrologic changes associated with incremental implementation of individual CERP projects.

Hydrologic performance measures illustrate the degree of attainment of specific hydrologic targets in specific areas (e.g., releases at the S-79 structure). However, the significance of change in a hydrologic performance measure with respect to the ecological attribute to which the performance measure applies is uncertain, especially when evaluating the effects of individual CERP projects. This is because the hydrologic change in a model grid cell, indicator region, or environmental sub-region that may result from individual projects is typically small in relative magnitude. Although target conditions are usually established for hydrologic performance measures, scientists on project teams usually have difficulty determining the meaningfulness of the relatively small differences between plans, including base conditions indicative of the degree of attainment of target condition. Typically, a more-or-less-is-better analysis is performed, and can be expressed as a percentage of the degree of attainment of the target. However, when the effects of all plans are relatively equal, it can be difficult to state the meaningfulness (in terms of the ecological response of the attributes affected by the performance measures) of relatively small differences between plans (e.g., 60, 61, and 63 percent attainment). Therefore, there is some uncertainty in predicting the extent of system-wide change in ecological

attributes due to relatively small differences in the hydrologic changes associated with incremental implementation of individual CERP projects.

5.5.3.2 Spatial Extent of System-Wide Effects of Alternative Plans

While the hydrologic models used for CERP project plan formulation and evaluation may effectively demonstrate meaningful changes between alternatives in hydrologic performance measures and where those changes occur (in terms of the model's four-square mile grid cells), describing ecological responses to those hydrologic changes over precise areas has proven to be difficult for many projects which are "invisible" to the hydrologic model. For example, a species may be sensitive to topographic, vegetation, and soil conditions, which would in turn affect habitat quality. Thus, determining the differences in the spatial extent of effects resulting from each alternative plan in an array of plans (for a given ecological attribute) has proven to be difficult to estimate with scientifically defensible certainty. This in turn makes the estimation of the spatial extent of the benefit units uncertain.

Determining the individual variable spatial response to hydrologic change of each attribute that is evaluated during plan formulation is also uncertain. Each of the Conceptual Ecologic Models (CEM) that are the basis for the system-wide hydrologic performance measures encompass multiple ecological attributes (for example, oysters, *Vallisneria*, and seagrass are all attributes of the Caloosahatchee CEM). Each attribute may vary independently in the spatial extent of response to differences in hydrology. These variations in area make the assignment of "spatial extent" affected by an alternative plan all the more difficult to determine. If "areas affected" for each attribute were simply summed, the issue of double-counting HUs could arise as multiple attributes could overlap in the same area affected by multiple projects, and thus the same benefit units could be counted more than once. Similarly, without fully understanding how each attribute responds independently to variations in hydrology (and without a sensitive enough hydrologic modeling tool to depict the spatial extent of the attribute response), it is equally likely that not enough benefit units (expressed as HUs) would be counted, thereby understating the beneficial effects of plans.

5.5.3.3 Ecological Response Time Risks and Uncertainty

There are no existing models that can be utilized to predict ecological response time. Although ecological response can be fairly well predicted for smaller restoration projects, it is difficult to address the effects of such a large restoration project as the Caloosahatchee River (C-43) West Basin Storage Reservoir project. Therefore, the natural system sub-team utilized current scientific knowledge and best professional judgment to predict responses within the natural system.

5.5.4 Adaptive Management

Adaptive management (AM) consists of an active strategy for dealing with the considerable uncertainties that characterize management of large natural ecosystems, which are complex and difficult to predict. The overall purpose of AM is to maximize the chance of success and includes methods, such as proactive approaches to dealing with uncertainties, the use of modern ecosystem science and scientific practices, active collaboration, and the use of open, inclusive, and integrative processes.

Five key principles help implement this approach to adaptive management (AM):

1. Anticipate future uncertainties and contingencies
2. Employ science-based approaches to build knowledge
3. Design robust projects that can be adapted to changing conditions
4. Build a shared understanding through collaboration and conflict resolution
5. Reconcile competing objectives to benefit both nature and society

The Caloosahatchee River (C-43) West Basin Storage Reservoir project is a component of the CERP, which consists of sixty-eight (68) major components. The uncertainty associated with a program of this magnitude was recognized during the Restudy, which led Congress to address the necessity of AM in the WRDA 2000.

As such, a fundamental implementation principle for CERP is to utilize adaptive assessment and management in order to continually refine and improve the performance of CERP projects so that planned benefits are attained. Incremental revisions of optimal project designs and project operations throughout the planning and implementation process will lead to improved performances. The use of the adaptive assessment policy minimizes the effects of uncertainty with respect to the effects of CERP projects on the natural system and other water-related needs of the region related to the design and implementation of the CERP.

The measurement of benefits attributable to CERP projects must consider individual outputs as well as system-wide interdependencies among projects. This evaluation methodology applies to hydrologically linked projects that operate optimally in a synergistic fashion. Therefore, until other CERP projects are implemented, some benefits may not be realized. Moreover, interim and long-term impacts will be largely determined by implementation of CERP components and operational strategies. Regional evaluations will be used to improve information necessary to predict and assess shortfalls attributable to sequencing issues versus shortfalls in performance.

The project team considered the uncertainty in the estimation of HU values for the various alternatives and how would ecological outputs respond over time, and how do continued high Lake Okeechobee inflows and runoff volumes affect outputs over time. Consideration of "if" and "when" other CERP components were constructed were also considered in the estimate of ecological outputs, demonstrating the sensitivity of Caloosahatchee Estuary outputs to the construction of other CERP components.

As part of the AM process, careful flow monitoring will occur to evaluate the ability of any implemented features to meet the performance measures. In addition, biological response data will be collected for use in further refining the performance measures, project operations, and system understanding. The NAI analysis showed that essentially all of the estuary outputs would still be produced by the Caloosahatchee River (C-43) West Basin Storage Reservoir project even if other CERP projects were never constructed. This same analysis also indicated that no other alternative performed more cost effectively than the recommended alternative (Alternative 3B) when other CERP project were not constructed. Furthermore, cost effectiveness analysis indicated that the various alternatives were sufficiently separate and distinct so that relatively large changes in either cost or output would be required before an alternative would appear to be the superior.

6.2 SUMMARY OF AFFECTED RESOURCES

Under the No Action Alternative, the Caloosahatchee Estuary would continue to be degraded due to excessive high and low flows. These episodes of abnormal flushing and hypersalinity would continue to adversely affect the overall health of the estuary. The project site would likely continue to operate as a citrus grove.

The project alternatives (Alternatives 2, 3B, 3C, and 4A) would all cause similar effects on resources within the project footprint and immediately adjacent to the project site since they utilize the same project footprint. ***Therefore some of the resources in this chapter are impacted by all four alternatives equally.*** The difference among alternatives, in the cases where they do differ, would be of magnitude rather than type of impact, as the alternatives represent a graduated series of reservoir storage, pump size, and embankment heights from smallest (Alternative 2) to largest (Alternative 4A) while the location and footprint size of all alternatives is nearly the same.

The most significant beneficial effects of the proposed project would be achieved in the Caloosahatchee Estuary. Generally, estuary benefits would increase directly as storage/pumpage volume increases. All alternatives provide a significant benefit to the estuary. All alternatives can store water during the wet season for release when needed during the low flow periods. Removal of the highest peak flows and supplementing the low flow periods to the estuary will improve the salinity regime and result in a healthier estuarine environment.

Flows in the lower Caloosahatchee River will be improved during dry periods, when water is available in the reservoir for release into the river. These releases can supplement releases from Lake Okeechobee and avoid conversion of the upper estuary to a fully saline environment, which is detrimental to the growth of *Vallisneria,* a plant species of brackish water SAV. The majority of benefits accrued by this project would be a result of this supplement during the dry season. The project will provide limited benefits attributable to catching and storing high flow events during unusually wet years, when the storage capacity of Lake Okeechobee may not be enough to avoid high volume discharges of fresh water to the estuary, causing blow-outs or flushing of brackish water loving species.

None of these alternatives are capable of completely resolving the problems of the Caloosahatchee Estuary and Caloosahatchee River (C-43) Basin. None of the alternatives provide enough storage or pumping capacity to truly alleviate all extreme events. However, they all move towards restoration of the estuary by lowering the number and severity of extreme events and they all provide significant improvement to the health of the estuary. Based on a salinity model, the area within the Caloosahatchee Estuary system beneficially affected by the

project conservatively encompasses 70,979 acres in the Caloosahatchee River, San Carlos Bay, and a portion of Pine Island Sound, although in all likelihood the area beneficially affected by project implementation will be much larger, including portions of Pine Island Sound, Estero Bay, and the Gulf of Mexico. These acres are within the navigable waters of the United States and within the navigational servitude of the United States.

6.3 PHYSICAL LANDSCAPE

6.3.1 No Action Alternative

The No Action Alternative would not change the proposed reservoir site's operation as a citrus grove, nor would it affect other aspects of the physical landscape.

6.3.2 Alternatives 2, 3B, 3C, and 4A

With the construction of the Caloosahatchee River (C-43) West Basin Storage Reservoir under all alternatives, topography within the proposed project area would change significantly due to construction of the embankment and excavation of the perimeter canal. Impacts are anticipated to be similar with all of the reservoir alternatives; however, since the alternatives share the same footprint, increasing the reservoir storage capacity also increases the dam height. This in turn necessitates additional excavation of materials to form the larger, higher embankment. These elevations are significantly different and represent a significant change to the existing landscape. The dam elevations are listed below:

- Alternative 2: 54 feet
- Alternative 3b: 57 feet
- Alternative 3c: 57 feet
- Alternative 4A: 66 feet

Groundwater modeling completed for project assurances has predicted there will be no impact to the surficial aquifer. All of the deeper aquifers are below a confining layer; therefore no impact is expected to the lower aquifers.

Surficial sands (approximately upper three feet) in the footprint of the perimeter canal and portions of the reservoir would be removed on site for use as construction material for embankments. Excavation of the perimeter canal would result in removal of surficial sands, sandy clay material, and limestone. Material unsuitable for use in the embankments would be spread over the interior of the reservoir. The underlying regional geology would not be affected.

After the citrus trees are removed from the site, the areas formerly covered by citrus trees would be disced (one pass using a disc with a diameter of at least twelve inches). Exterior areas (near the embankments) would be excavated for embankment materials. Internal areas that are not covered by citrus trees (such as wetlands, canals, ditches, roads) may be left unaltered.

The soils on the project site are classified as unique farmland by the NRCS. Coordination was completed with U.S. Department of Agriculture (USDA)/NRCS and a determination was made that 13,300 acres of unique farmland would irretrievably be lost through conversion of the project site to an open water reservoir. Further design refinements reduced the potentially affected area to about 10,500 acres, which was confirmed with NRCS. This is a little less than five percent of the unique farmland in the county to be converted. Refer to the Pertinent Correspondence Annex B, correspondence with NRCS for details.

The project site includes 267 acres impacted by construction of reservoir test cells. These test cells would be incorporated into the interior reservoir. Portions of the embankments of both test cells would be breached with mounds of embankments left in place.

6.4 HYDROLOGY

6.4.1 No Action Alternative

The No Action Alternative does not improve hydrologic conditions in the Caloosahatchee Estuary and may lead to further estuarine habitat degradation. Extreme events of high flow periods during the wet season and low flow periods during the dry season would continue to occur.

6.4.2 Alternatives 2, 3B, 3C, and 4A

All of the alternatives improve hydrologic conditions by varying degrees dependent upon project components in the Caloosahatchee Estuary. Alternative 2 provides the least benefit, with Alternative 3B providing more and Alternatives 3C and 4A providing the most benefit. In general, the larger the alternative (both pump size and reservoir storage capacity), the more benefit the alternative provides to the estuary. A larger pump allows more flexibility in operations and is able to capture more of the high volume flows, while a larger capacity reservoir stores more water to augment flows in the dry season and allows more of the large flows to be stored in the wet season. The difference in ability of each alternative to match the desired flow envelope is significant. All alternatives would reduce damaging Lake Okeechobee releases of large volume flows to the estuary through the S-79 by capturing some of these flows in the reservoir. This water would then be available to supplement flows during the dry season when minimal flows for estuarine health can often not be met. The

table below summarizes the percentage of time each alternative matches the desired envelope within the preferred flow target (EST05) (***Table 6-2***):

TABLE 6-2: PERCENTAGE OF TIME EACH ALTERNATIVE MATCHES THE DESIRED ENVELOPE WITHIN THE PREFERRED FLOW TARGET (EST05):

Alternative	% Flows in Desired Envelope
2050 FWO	45.5%
Alt 2	67.9%
Alt 3B	74.8%
Alt 3C	82.3%
Alt 4A	83.8%

Within and immediately surrounding the proposed project site there would be some minor impacts to hydrology. The Roberts Canal would be re-routed around the reservoir through the perimeter canal. This would result in the Banana Branch Canal (north of the reservoir) and Ft. Simmons Branch receiving its flows from the perimeter canal. When cell two of the reservoir is dry, pump station four will be used to pump out of cell one and around the perimeter canal in order to maintain levels in the Banana Branch Canal.

The Roberts Canal would serve as a water source for the perimeter canal. The local reservoir MIKESHE Modeling (for the SAP, Alternative 3B) groundwater level analysis included the Okaloacoochee Slough (***Annex C Figure 1***, Location 7). The model results show that with the project there would be no difference to existing conditions (***Annex C, Figure 2-G***). The project footprint, project operations, and project purpose would be the same with all of the reservoir alternatives; therefore, Alternatives 2, 3C, and 4 are not anticipated to adversely affect water levels in the Okaloacoochee Slough. However, under all of the alternatives, monitoring would be required to ensure that no impacts to existing groundwater levels occur.

Currently groundwater seeps from the project site north towards the river. All of the reservoir alternatives include a slurry wall within the embankment to effectively prevent this seepage. Due to a higher embankment under Alternative 4A, it may not be possible to construct a continuous slurry wall that could extend from the subsurface clay layer to the top of the embankment. Alternative seepage control would be necessary for Alternative 4A. Once constructed the perimeter canal will provide this groundwater flow to the areas north of the project. In order to minimize the disturbance to the natural groundwater flow, the perimeter canal will be kept at levels adequate to maintain existing levels of groundwater in the area.

Another potential hydrologic change may occur as a result of removing the siltation structure at the union of the Townsend Canal and Caloosahatchee River. This structure is being removed in order to increase flow velocities. However, the removal of this structure will allow free flow to occur between the Townsend and Caloosahatchee River and would result in the northern portion of the Townsend Canal being at the same stage as the river. This is not expected to cause any negative impacts but is noted since it will change hydrology in the immediate area.

6.5 WATER MANAGEMENT

6.5.1 No Action Alternative

Lake Okeechobee releases would continue as dictated by the current LORS. Without additional water storage in the Caloosahatchee River (C-43) Basin there will be insufficient capacity in Lake Okeechobee to retain storage during the wettest months or years without large volume releases to both Caloosahatchee River and St. Lucie estuaries, and it is likely that large pulse releases would continue to affect the estuary at least during extreme years. In addition, it is likely that harmful low flows in the dry season would also continue. Additional demands on Lake Okeechobee may decrease the magnitude of large pulses being released. However, increased watershed runoff due to an increase in urban areas would likely result in continued events which may effect the estuarine habitat.

6.5.2 Alternatives 2, 3B, 3C, and 4A

The proposed Caloosahatchee River (C43) West Basin Storage Reservoir in all alternatives would be designed as a storage area which could receive water from the following sources:

- Caloosahatchee River (C-43 Canal) water via Townsend Canal
- Drainage water from southwest of the reservoir via Townsend Canal
- Drainage water from southeast of the reservoir via Roberts Canal

Management measures included as part of all alternatives include canal improvements, culverts and culvert enlargements, pumping stations, inlet and outlet structures, levees, and seepage canal. These all serve to divert water to the reservoir in times of high flow and release water from the reservoir in times when the estuary would benefit from additional flows. Water can only go into and out of the reservoir via the perimeter canal

If there is more drainage coming from the Roberts Canal during the wet season than the Banana Branch, Fort Simmons Branch, and Townsend Canal can take, and the reservoir pump station is on at that time, these flows may be "indirectly"

picked up by the reservoir when the reservoir has capacity. The same holds true for the drainage from the Townsend Canal back to the Caloosahatchee River. If the reservoir pump station was on at the same time, this flow would be picked up along with the water pulled in from the Caloosahatchee River.
The storage capacities and pump sizes of the alternatives are outlined below:

- Alternative 2 100,000 ac/ft, 1500 cfs pump
- Alternative 3B 170,000 ac/ft, 1500 cfs pump
- Alternative 3C 170,000 ac/ft, 3800 cfs pump
- Alternative 4A 220,000 ac/ft, 3800 cfs pump

The reservoirs with the larger storage capacity would allow the water managers greater flexibility in operations, due to the ability to both capture and release more often. This is a significant improvement over the no action alternative. This flexibility is apparent in the reduction of weekly average flow events >4500 cfs over S-79 compared to the No Action Alternative:

- Alternative 2 82% reduction
- Alternative 3B 82% reduction
- Alternative 3C 91% reduction
- Alternative 4A 91% reduction

The S-79 gate would be operated to mimic EST05, which is a time series of flow derived from biological indicators in the Caloosahatchee Estuary (see Section C.6 in the Environmental Appendix.). Operations of this gate are currently and will continue to be discussed on a weekly basis between the SFWMD and USACE to discuss the state of the estuary and what flows would be most appropriate.

The existing water management system in the Caloosahatchee River (C-43) basin will be modified by the proposed reservoir to enhance water storage. The LORS may be adjusted to take advantage of additional off-lake water storage capacity as it is constructed and becomes operational.

It is possible that this reservoir may extend periods of full storage capacity as well as little to no storage capacity being used. The basic operational scenario is as follows (See ***Annex D***):

- Beginning of dry season– conservatively release water from reservoir
- End of dry season– aggressively release water from reservoir
- Beginning of wet season conservatively pump water into reservoir
- End of wet season aggressively pump water into reservoir

These operational constraints will be balanced with the needs of the estuary in order to best manage the water in the basin.

6.6 WATER SUPPLY

6.6.1 "No Action" Alternative

Lake Okeechobee releases would continue as dictated by the current LORS. Without additional water storage in the Caloosahatchee River (C-43) Basin there will be insufficient capacity in Lake Okeechobee to retain storage during the wettest months or years without large volume releases to both Caloosahatchee and St. Lucie estuaries, and it is likely that large volume releases would continue during wet years. In addition, it is likely that insufficient low flows in the dry season would also continue. Additional demands on Lake Okeechobee may decrease the magnitude of high volume releases. However, increased watershed runoff due to an increase in urban areas would likely result in continued events which may affect the estuary in some cases.

Existing water supply conditions would be maintained. Undesirable low flows and insufficient water for lower watershed operations will continue to occur during some very dry years.

6.6.2 Alternative 3B

The operations for this project focus on reducing high volume flows from S-79 and provide supplemental flows across S-79 to the Caloosahatchee Estuary to achieve restoration targets. Sources of water to meet agricultural and urban demand in the Caloosahatchee Basin will remain the same as before the project. Sources of water for the Seminole and Miccosukee Tribes and Everglades National Park (ENP) are influenced by the regional water management system (C&SF Project, including Lake Okeechobee), and will not be affected by this project. Therefore, there will be no elimination as a result of this project on existing legal sources of supply for:

- Agricultural or urban water supply
- Allocation or entitlement to the Seminole Indian Tribe of Florida under Section 7 of the Seminole Indian Land Claims Settlement Act of 1987 (25 U.S.C. 1772e)
- Water supply for Miccosukee Tribe of Florida
- Water supply for ENP
- Water supply for fish and wildlife

With the project in place, portions of the Roberts Canal and Header Canal will become part of the project footprint. To continue to provide an irrigation source to the Bob Paul property, which currently pumps irrigation water from the Header Canal and the Crawford Canal, pump station #3 was included in the reservoir perimeter canal to pump water to the east down the remaining Header canal assuring the same volume of water is available compared to existing

conditions. This will result in a partial transfer of water. The Crawford Canal will still be available to the Bob Paul property and is not affected by the project.

6.6.3 Alternatives 2, 3C, and 4A

The project footprint for Alternatives 2, 3C and 4 will remain the same with only embankment height and pump size changes as described in Section 5.4.1. While the updated system-wide spread sheet analysis and local reservoir level MIKESHE model was applied to the TSP and to date has not been applied to the alternatives, operations and project purpose remain the same as described in the TSP. Therefore, it is expected that sources of water to meet agricultural and urban demand in the Caloosahatchee Basin will remain the same as before the project. Sources of water for the Seminole and Miccosukee Tribes and ENP are influenced by the regional water management system (C&SF Project, including Lake Okeechobee), and will not be affected by this project. Therefore, there will be no elimination or transfer as a result of this project on existing legal sources of supply for:

- Agricultural or urban water supply
- Allocation or entitlement to the Seminole Indian Tribe of Florida under Section 7 of the Seminole Indian Land Claims Settlement Act of 1987 (25 U.S.C. 1772e)
- Water supply for Miccosukee Tribe of Florida
- Water supply for ENP
- Water supply for fish and wildlife

6.7 FLOOD PROTECTION

6.7.1 No Action Alternative

With the No Action Alternative existing water supply conditions would be maintained. Undesirable low flows and insufficient water for lower watershed operations will continue to occur during some very dry years.

Existing levels of flood protection would be maintained. There will be no significant impact on flood protection for any alternative.

6.7.2 Alternative 3B

The intent of the level of service analysis for flood protection, required by WRDA 2000 and the CERP Programmatic Regulations as well as Florida State law regarding the implementation of CERP, is to ensure that CERP components do not negatively impact existing levels of flood protection.

The operations of this project will not change the operations of the Caloosahatchee River (C-43) Canal based on the key assumptions outlined in the Federal Assurances and Savings Clause Analysis, Section 8.4. Therefore, there will be no system-wide effects on flood protection as a result of the project.

The MIKESHE model was used to evaluate flood protection by evaluating groundwater levels to determine if they were altered due to reservoir operations. A significant change in groundwater levels could signify a potential impact to flood protection. The results from the local reservoir-level MIKESHE modeling indicate a boundary slurry wall within the embankment will prevent seepage out of the reservoir and impacts to groundwater levels. In addition, optimization of the operating levels of the seepage canals and canal structures surrounding the reservoir will maintain existing groundwater levels adjacent to the project.

Of the eleven locations evaluated using the MIKESHE model, the only location where simulated groundwater elevations increased compared to the without-project conditions was north of the project. Simulated "with project" groundwater elevations increased slightly compared to the "without project" condition. The greatest difference was during the dry period (e.g., 1981) not the wet periods. This minor effect can be addressed through further optimization of perimeter canal control structure operations for the project. The remaining ten locations show practically no differences in groundwater elevations.

Therefore, there will be no adverse affects on existing levels of service for flood protection in the vicinity of the reservoir.

6.7.3 Alternative 2, 3C, and 4A

As described above, the project footprint for Alternatives 2, 3C and 4 will remain the same with only embankment height and pump size changes as described in Section 5.4.1. The cut-off slurry wall included in the SAP embankment to attenuate seepage will also be included in the alternative embankments for Alternative 2 and 3C. Due to construction equipment constraints and embankment height, a continuous slurry wall would not be practicable under Alternative 4A; however, alternate seepage control methodologies would be investigated. While the local reservoir level MIKESHE model groundwater analysis was applied to the SAP and to date has not been applied to the alternatives, operations and project purpose remain the same as described in the SAP.

Therefore, it is anticipated there will be no adverse affects on existing levels of service to flood protection in the vicinity of the reservoir.

6.8 WATER QUALITY

6.8.1 No Action Alternative

Future water quality conditions in the basin will be strongly influenced by future land use, the operation schedule of Lake Okeechobee, and the implementation of BMPs to control nutrient discharges. In the immediate vicinity of the project, the Townsend Canal will likely continue to be impaired for copper as long as citrus is cultivated on the project lands. Since the 2050 population will be substantially greater than the year 2000 population, the quantity of treated wastewater effluent discharged to the estuary will increase. However, with the expected implementation of TMDLs for the discharge of nutrients into the estuary, it is reasonable to expect that by 2050 most existing wastewater treatment plants and all future plants will incorporate tertiary treatment process to remove nutrients. If the TMDL program is effective, the 2050 nutrient loads from wastewater effluent will be similar to or less than the present nutrient loads.

Future water quality conditions will depend upon the overall change in nutrient loads delivered to the estuary from upstream of S-79 as well as below this structure. Nutrient loads to the estuary will likely increase by ten percent or more if no BMPs or nutrient TMDLs are implemented in the Caloosahatchee Basin. If the implementation of BMPs substantially reduces non-point source nutrient loads, discharges from Lake Okeechobee are significantly reduced, and tertiary wastewater treatment is implemented basin wide, the 2050 Future Without nutrient loads may decrease by more than 30 percent as compared to the existing condition. This scenario would result in fewer violations of water quality standards at least for nutrients and coliforms. The number of water bodies in the basin listed as impaired for other pollutants such as heavy metals is likely to increase as the basin becomes more developed.

6.8.2 Alternatives 2, 3B, 3C, and 4A

Under the conservative assumption that no water quality treatment occurs in the reservoir, the project alternatives would show the following reduction in TP and TN loads at S-79 in comparison to the future without condition (***Table 6-3***).

TABLE 6-3: REDUCTION IN TP AND TN LOADS AT S-79 IN COMPARISON TO THE FWO CONDITION

Alternative	TP% Reduction	TN% Reduction
FWO 2050	0	0
Alt. 2	30%	29%
Alt. 3B	29%	28%
Alt. 3C	32%	31%
Alt. 4A	34%	32%

The difference in load reduction between alternatives is not significant. Although the size of the reservoir and the pump have some influence on the S-79 pollutant load, the reduction in nutrient loads at S-79 is largely the result of the reduction in discharges from Lake Okeechobee. In other words, the majority of load reduction shown in ***Table 6-3*** will result from project elements of CERP other than the C-43 Basin Storage Reservoir project itself. All of the selected alternatives will cause a shift in nutrient load from the wet season to the dry season; however, all of the alternatives will decrease the frequency in which the monthly TN load exceeds the dry season, wet season, and annual targets established by the FDEP (dry-season 190 tons/month, wet-season 350 tons/month, annual 3,000 tons/month). While it is possible that nitrogen fixation within the reservoir will result in short-term increases in TN loading to S-79, the average annual TN load at S-79 will be reduced. Given the uncertainty in the threshold chlorophyll-a concentration required for the restoration of the ecological function of the estuary, the degree to which the reservoir project will improve downstream water quality is unknown at this time. However, each of the alternatives results in an improvement in overall average water quality conditions at S-79 as well as downstream in the estuary.

Section 303(d) of the CWA requires states to develop a list of waters not meeting water quality standards or not supporting their designated uses. Those waters not meeting water quality standards are designated as "impaired". TMDLs are required for the waters determined to be impaired. A summary of the current list of impaired water bodies in the Caloosahatchee Basin is included in the existing conditions section of this report. Using the current list as a baseline, the impact of the project on future compliance with state water quality standards can be estimated. Under the with project condition, the Townsend Canal will likely no longer be impaired for copper and lead since the much of the farmland in this sub-basin will be within the reservoir footprint. Several of the downstream estuary bodies that are presently impaired for nutrients will likely no longer be impaired since the project will significantly decrease nutrient loads to the estuary. Estuary water bodies that are currently impaired for heavy metals will likely continue to be impaired for these pollutants since this contamination is a result of the urbanization of the estuary sub-basin. Similarly, impairments of sub-basin water bodies not directly affected by S-79 discharges will not be influenced by the construction of the project. Based on the evidence presented here, it appears that the project will not cause or contribute to water quality degradation and will likely reduce the number of and intensity of violations of water quality standards.

6.9 SEDIMENT QUALITY

6.9.1 No Action Alternative

Under the No Action Alternative, the sediment quality in the estuary is expected to continue to slowly degrade. The conversion of farms and pastures to urban developments over the next 50 years will increase the concentrations of heavy metals and hydrocarbons in stormwater runoff. Many of these pollutants will become entrained in the estuary sediments despite the requirement to include stormwater treatment facilities in all new developments. Unless additional stormwater control such as retrofitting existing development is implemented, the rate at which the estuary sediments degrade may increase somewhat since the overall quantity of stormwater and sediment load to the estuary will increase.

6.9.2 Alternatives 2, 3B, 3C, and 4A

The with project total load of sediments transported to the estuary from the freshwater Caloosahatchee sub-basin will be reduced relative to future without conditions since some fraction of the available sediment load will be retained within the reservoir. Additionally, since construction of the reservoir will reduce the total area of farmed land by some 10,500 acres, sediment transport associated with farming this acreage will also no longer be transported to the estuary. The reduction in sediment load will be on the order of five percent to ten percent relative to existing without project conditions and approximately 30 percent relative to future without project conditions. The difference between alternatives would be minimal. This reduction in sediment delivered to the estuary should result in a slight improvement in sediment quality relative to without project conditions. However, since urbanization of the basin will continue over the next 50 years, non-project related anthropogenic impacts will likely result in the continued degradation of estuary sediment quality over time.

6.10 PLANT COMMUNITIES

The impacts described below are applicable to plant communities within the project site. Estuarine plant communities (such as SAV) are addressed in Section 6.12.4, Estuarine Resources. *Plant communities would be impacted by all four alternatives equally.*

6.10.1 No Action Alternative

The lands within the project area would be developed consistent with surrounding land use patterns. The surrounding areas are predicted to be in agricultural production, as at present, in 2050. If the site remained a citrus grove, there would be very little change to the plant communities under the No Action Alternative. There may be a slight change in the density and distribution

of exotic species along the perimeters and canals. The areas in production are controlled for noxious species. However, along the canals and perimeter there is a variety of exotic species. These may change due to biological control of existing noxious plants as well as the introduction of new exotic species into the south Florida ecosystem.

6.10.2 Alternatives 2, 3B, 3C, and 4A

Under all alternatives, an above ground reservoir with associated seepage canals and embankments would be constructed. Most existing plant cover within the project footprint would be removed. This is a significant impact to existing plant communities and would be equally significant among all alternatives.

Preparation for construction of the reservoir includes the removal and burning of all citrus trees within the project footprint. The total area of tree removal is approximately 7,970 acres. Only trees located in the cultivated citrus areas of the project will be removed. No other trees or vegetation within the project area will be removed. The remaining vegetation, including vegetation found in irrigation and drainage ditches, swales, canals, jurisdictional wetlands, and areas noted as contaminated soils within the project footprint will not be removed.

In general, construction will largely replace existing plant communities with aquatic habitat (water-covered reservoir areas) or maintained uplands (embankments, roads, berms). The construction of the reservoir and seepage canal may provide some deepwater refugia and/or littoral habitat for use by fish and amphibian species when the reservoir is drawn down. The operational plan for the reservoir, in order to meet the project objectives, constrains the ability of the project site (either reservoir or seepage canal) to be optimized for management as habitat for fish and wildlife. The reservoir would likely experience wide-ranging depth and duration fluctuations throughout the year ranging from complete dry down to full capacity i.e., 15-25 feet above soil surface, on an annual basis. This would potentially impact the survival of any wetland species and provide limited benefits to opportunistic plants that could adapt to such environmental dynamics.

The interior of the reservoir will lack much productive littoral zone because of the necessity to construct relatively steep sides to maximize water storage capacity. The design for the perimeter canals, however, includes littoral areas in the corners and along some of the banks.

Exotic plant species are not expected to be a problem under any of the alternatives, as appropriate construction and maintenance procedures would be established to deter and control exotic establishment at the project site.

6.11 WETLANDS

6.11.1 No Action Alternative

If the project site remained a citrus grove, the 125 acres of wetlands scattered throughout the project site would likely remain. (An additional 6.39 acres of wetlands present within the project site were previously impacted by discharge of fill material during construction of the C-43 Test Cell Project.) The function and value of the existing wetlands would continue to deteriorate due to infestation by exotic plant species and due to reduced hydroperiod from agricultural operations. Additionally, expansion of citrus operations could result in direct removal of some of these wetlands areas.

6.11.2 Alternatives 2, 3B, 3C, and 4A

Construction of the Caloosahatchee River (C-43) West Basin Storage Reservoir will result in the loss of 125 acres of wetlands through discharge of dredge or fill material, excavation, and/or flooding. This includes the total acreage of a wetland on the eastern portion of the project that will be bifurcated and partially impacted by construction activities. This acreage does not include wetlands previously impacted by the C-43 Test Cell Project. *This loss would be the same for all reservoir alternatives since the project footprint is nearly identical.* Operation of the reservoir to meet the project water storage and release objectives constrains its management for wetland function and habitat. Therefore, it is assumed that all wetlands within the project area will be eliminated. Currently, the design for the reservoir perimeter canals includes approximately 109 acres of littoral areas in the corners and along some of the banks.

E.O. 11990, Protection of Wetlands, was created to avoid to the extent possible the long and short term adverse impacts associated with the destruction or modification of wetlands and to avoid direct or indirect support of new construction in wetlands wherever there is a practicable alternative. The area proposed for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project is mostly farmland with a few disturbed wetlands. The reservoir design will include areas of littoral shelf along the seepage canal. This littoral shelf will create some new habitat which will help to minimize the impact of the loss of wetlands due to construction of the reservoir. There will be no mitigation for wetlands as a result of the federal project. Overall, CERP projects are expected to have a net positive lift of wetland function. The C&SF Project Comprehensive Review Study ("Yellow Book") states in Section 9.6 that "...construction features of the Comprehensive Plan will be designed to first avoid and then minimize unavoidable impacts to wetlands or other aquatic sites and natural upland habitats. Unavoidable impacts to these habitats are expected to be offset by the ecological improvement throughout the south Florida ecosystem that results

from the overall restoration achieved by the Comprehensive Plan. Accordingly, separate compensatory mitigation features are not included in the recommended Comprehensive Plan for these impacts." The state's Accler8 program may have separate wetland mitigation requirements for this project as a result of their permitting process. A wetland rapid assessment procedure (WRAP) was performed in 2004 to determine impacts of wetland function related to the proposed project. Additional information on wetlands can be found in the Final CAR in *Annex A*.

6.12 FISH AND WILDLIFE RESOURCES

This section will discuss the fish and wildlife impacts at the reservoir footprint, as well as all threatened and endangered species impacts. Impacts to the estuarine fish and wildlife resources are addressed in Section 6.12.4. *Impacts to fish and wildlife resources at the project site would be impacted by all four alternatives equally.* There will be significant, mostly beneficial, impacts to fish and wildlife resources.

6.12.1 No Action Alternative

The agricultural operation associated with the No Action Alternative would continue to provide some level of fish and wildlife resources, similar to existing conditions.

6.12.2 Alternatives 2, 3B, 3C, and 4A

Small areas of existing open water habitat would be lost under the construction footprint. Once the reservoir is filled aquatic (open water) habitat will substantially increase. The open water reservoir will likely harbor fish typical of nearby canals. Water would be conveyed to the reservoir by these canals which also act as conduits for the introduction of many aquatic organisms, including fish. Due to the operation of the pumps there will likely be some entrainment and impingement of fish and other aquatic organisms. The larger pumps (alternatives 3C and 4A) will likely increase the impingement and entrainment impacts. Species that will likely inhabit the reservoir include: largemouth bass, black crappie, red ear sunfish, shad, bluegill, and mosquitofish, among others. A high population of invertebrates is not expected, due largely to a lack of emergent vegetation. Shallow water fish bedding and rearing habitat will be limited to the margins of the reservoir. The design of the reservoir perimeter canal, however, includes littoral areas for fish and wildlife use.

Amphibians and aquatic reptiles including frogs, turtles, snakes, and alligators will likely inhabit the deepwater reservoir. Limited emergent vegetation in the reservoir will also affect these organisms by reducing available forage, cover, and reproductive habitat. The reservoir will likely create limited foraging habitat for

osprey, bald eagle, terns, cormorant, and other aquatic birds that feed on fish. Ducks may also use the reservoir, but low cover of submergent and emergent vegetation may limit the habitat value. Mammals in the reservoir will likely be limited to river otter.

Flooding a large area may create insect or rodent problems. If such problems occur, the SFWMD operations and maintenance staff will address these issues on an as-needed basis.

Additionally, the project site contains 899.59 acres of primary, secondary, and tertiary ditches. (Construction of the test cells has resulted in loss of 26.03 acres of tertiary ditches not included in this acreage). Ditches underlying the footprint of the open water portion of the reservoir will provide deepwater refugia to aquatic invertebrates, fish, and wading birds during periods when the rest of the reservoir is dry.

Prior to flooding of the reservoir, portions of the test cells embankments will be demolished in a few locations leaving some embankment mounds in place for wildlife when the reservoir is full.

Threatened and endangered species would be impacted by all four alternatives equally unless otherwise noted.

6.13 FEDERAL AND STATE LISTED SPECIES

6.13.1 No Action Alternative

Under the No Action Alternative, there would be no immediate impacts to threatened or endangered species. Use of the site by federal and state listed species would continue. Under the "No Action" Alternative including future without, continued degradation of marine seagrasses and *Vallisneria sp.* in the estuary would be harmful to the survival of the endangered West Indian Manatee.

6.13.2 Alternatives 2, 3B, 3C, and 4A

The USFWS has been an active member of the project team for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project and has provided guidance through informal consultation during plan formulation and evaluation. The USFWS provided a Biological Opinion on November 30, 2005, for construction of the Caloosahatchee River (C-43) West Basin Storage reservoir test cells, an area of approximately 267 acres. This area is not included in the ongoing Section 7 evaluation for the reservoir since consultation has been completed; therefore, the 267 acres associated with the test cells are not discussed in this section.

The USACE Regulatory Division's January 10, 2007, letters to the USFWS and NMFS transmitted the Final Biological Assessment for the Caloosahatchee River (C-43) West Basin Storage Reservoir (see Annex A). These documents describe the potential effects of the proposed Caloosahatchee River (C-43) West Basin Storage Reservoir project on federally listed threatened and endangered species. The USACE determined that the Caloosahatchee River (C-43) West Basin Storage Reservoir Project would not affect the bald eagle (de-listed effective August 8, 2007), Florida scrub jay, Florida grasshopper sparrow, red cockaded woodpecker, Okeechobee gourd, or the beautiful pawpaw because they do not occur within or adjacent to reservoir footprint, nor would there be direct or indirect impacts to those species. The USACE determined that the proposed project may affect, but is not likely to adversely affect the smalltooth sawfish, wood stork, West Indian manatee, Everglade snail kite, American crocodile, piping plover, or the green, hawksbill, leatherback, Kemp's ridley or loggerhead sea turtles. The American crocodile, piping plover, or the green, leatherback, Kemp's ridley and loggerhead sea turtles do not occur within or adjacent to the reservoir footprint and indirect effects resulting from operation of the reservoir are expected to be negligible, discountable or beneficial to those species. Additionally, wintering piping plover critical habitat will not be adversely modified by the proposed project. Additionally, the USACE determined the project may adversely affect the eastern indigo snake, Audubon's crested caracara, and the Florida panther and requested initiation of formal consultation for these species in the January 10, 2007 letter. Formal consultation for all species was completed per a Biological Opinion (BO) transmitted from the USFWS to the USACE dated July 20, 2007. A copy of the BO is located in *Annex A*.

The following is a summary of the effects on the remaining federally-listed species not already discussed in this section. These impacts are considered significant (although largely beneficial) but would be similar for all alternatives.

6.13.2.1 Wood Stork

The Caloosahatchee River (C-43) West Basin Storage Reservoir project area is within the CFA of three wood stork rookeries as discussed in Section 2.8.7.2. Construction of the reservoir will result in the loss of approximately 785 acres of potential wood stork foraging habitat within the reservoir footprint. This includes wetlands and secondary and tertiary drainage canals. The proposed project would improve salinity conditions during the dry season for 4,130 acres of *Vallisneria* beds in the upper Caloosahatchee estuary. Two of the wood stork rookeries are located on mangrove islands within the upper estuary and would directly benefit from the proposed project. Additionally, the proposed project is not expected to alter the hydroperiod of freshwater wetlands outside of the project footprint but within the wood stork CFAs as recommended in the USFWS' Habitat Management Guidelines for the Wood Stork in the Southeast

Region. The reservoir may intermittently provide foraging habitat for wood storks during the dry season if/when water releases for the estuary are great enough to create optimal shallow-water foraging areas with concentrated prey in the reservoir. Thus, the USACE has made the determination that construction of the Caloosahatchee River (C-43) West Basin Storage Reservoir may affect, but is not likely to adversely affect, the wood stork.

6.13.2.2 Everglade Snail Kite

No known snail kite nesting locations are documented within or adjacent to the reservoir site, and no designated critical habitat occurs within or adjacent to the project area. Snail kites have a specific diet comprised almost entirely of apple snails. Snail kite use of the site is low at present with apple snails having been documented only in the larger canals near the test cell project. Citrus operations in the project area and elsewhere have routinely applied heavy copper treatments as a fungicide for many years, resulting in extensive copper contamination in the soil. Potential copper risk to the endangered snail kite may occur due to copper accumulation in the kite's primary food item, the apple snail (URS 2003). Copper concentrations in the soils within the project area range from 13.1 to 169.0 mg/kg (URS Corporation 2003). Approximately nine percent of the sample concentrations within the project area exceed the interim effects level of 85 mg/kg agreed upon by the USFWS and SFWMD until a study to evaluate that value for the snail kite is completed. Those areas will be remediated before project construction. Construction of the reservoir would infrequently provide habitat for the snail kite as water levels would experience wide-ranging depth and duration fluctuations from complete dry down to 15 - 25 feet above soil surface, potentially impacting the survival of most wetland species. However, such widely fluctuating water levels are unlikely to provide suitable habitat for apple snails, and thus snail kite use is not expected. However, the perimeter canal may provide wetland vegetation for survival of apple snails in littoral areas created from uneven edges. The perimeter canal could potentially attract or increase usage of snail kites, providing foraging habitat but this use would be dependent on the presence of apple snails and appropriate perching sites. The USACE has therefore determined the project may affect, but is not likely to adversely effect, the Everglade snail kite and its' critical habitat.

6.13.2.3 West Indian Manatee

Manatees are known to use major inland freshwater waterways and canals, including the Caloosahatchee River from Lake Okeechobee to the Gulf of Mexico (i.e., Glades, Hendry, and Lee Counties). They are highly mobile and may be found in all waters accessible to them, including the Townsend Canal on the western side of the project footprint. When water levels are high in the Caloosahatchee River, manatees are capable of passing over the existing weir or

through a flap gate into the Townsend Canal and have been observed at the Berry Groves main pump station. However, manatees cannot access the main distribution canal (i.e., Header Canal) on the project site due to differences in elevation.

The Townsend Canal will serve as the intake canal for the reservoir. The weir will be removed, portions of the canal will be widened and armored, and two new pump stations will be constructed. In order to reduce the likelihood of thermal stress to manatees (due to warmer water from the reservoir being released into cooler canal and river water), the weir will be replaced with a structure that serves either as a permanent barrier or a seasonal barrier which restricts manatee access to the Townsend Canal only during the winter season (November 1 through March 31). A monitoring plan (described in the BO) will also be implemented when needed during the winter months. Thus, manatees in the river may continue to have seasonal access to the Townsend Canal where the two reservoir intake pump stations (i.e., C-43PS-1 and C-43PS-4) will be located. However, both intake pumps will include bar screens and trash rake systems that will prevent manatees from becoming trapped in the intake pipes as well as from entering the reservoir through C-43PS-1 or the perimeter canal through C-43PS-4, and reduce the likelihood of injury to manatees by the rake systems. The USFWS' manatee requirements for culverts, *Guidelines for Culverts Located in Manatee-Accessible CERP Projects* (USFWS 2006) and the *Standard Manatee Conditions for In-Water Work* (FWC 2005) will be followed. Manatee access to the pump intake will be blocked. Manatees feed on a variety of emergent, submergent, and floating vegetation. With implementation of the project, food sources for the manatee in the lower river and estuary will improve. Section 6.1.13.2 includes a discussion of estuarine resources that will improve as a result of the project. Therefore, the USACE has determined that the project "may affect but is not likely to adversely affect" the manatee.

6.13.2.4 Florida Panther

The proposed reservoir is within the current range of the Florida panther and will result in the conversion of approximately 10,335 acres of habitat suitable for use by the panther for foraging and dispersal to open water habitat. This acreage includes uplands i.e., agricultural lands, agricultural roads and embankments, as well as wetlands within the project area. (This acreage does not include suitable panther habitat within the test cells project area.) The project site is located within the Florida panther consultation area according to the USFWS' *Final Interim Standard Local Operating Procedures for Endangered Species for the Florida Panther* (USFWS 2000) and overlaps with the Florida panther "Primary", "Secondary", and "Other Habitat Zones" as defined in the report *How Much Is Enough? Landscape-scale Conservation for the Florida Panther* (Kautz et al. 2006) and in the *CERP Landscape Level Project Planning/Siting Map for Panther Conservation* (USFWS and FWC 2004:

Figure 15). A Biological Assessment (BA) including a panther cumulative impact analysis for a 25-mile radius action area around the project was prepared in December 2006, in order to evaluate the effects of the project on the Florida panther (See Annex A for a copy of the BA). Based on the BA, the USACE determined that the Caloosahatchee River (C-43) West Basin Storage Reservoir Project "may affect" the Florida panther and requested initiation of formal consultation with the USFWS on January 10, 2007.

In February 2007, the USACE and USFWS implemented a revised Panther Key and Panther Focus Area Map for use in determining effects to the Florida panther. In June 2007, the USACE and SFWMD provided the USFWS with an updated panther cumulative impact analysis based on the new information. On July 23, 2007, the USFWS terminated formal consultation for the Florida panther with a Biological Opinion (BO). The USFWS is using a system-wide approach for assessing impacts and benefits to panther habitat associated with the CERP Band 1/Acceler8 Projects. This includes maintaining a panther habitat mitigation ledger that shows individual projects that cause some habitat loss may be offset by habitat gains or improvements attributable to another project. The direct and indirect loss of 10,335 ac of panther habitat associated with this project as well as direct and indirect loss of panther habitat associated with other CERP Band 1/Acceler8 Projects will be offset through the preservation and restoration of approximately 102,129 ac of lands associated with implementation of the CERP Band 1/Acceler8 Projects (primarily Picayune Strand Restoration Project). This includes 63,099 ac, 5,290 ac, and 33,740 ac of habitat used by the panther within the Primary, Secondary, and Other Zones, respectively, to benefit the Florida panther and its prey. These lands, most of which have already been acquired for CERP, are located in the core area of occupied habitat. Acquisition of these lands for CERP has resulted in preservation of important lands that may otherwise be used for development. The majority of these lands are adjacent to other large tracts of natural and preserved lands (e.g., Picayune Strand State Forest), and are consistent with the USFWS' goal to locate, preserve, and restore sets of lands containing sufficient area and appropriate land cover types to ensure the long-term survival of the Florida panther south of the Caloosahatchee River.

The USFWS does not anticipate construction of this project will result in the direct mortality or injury of any Florida panthers. The USFWS does however, anticipate indirect take of the panther in the form of harm and harassment because of potential increases in interspecific aggression within the 25-mile radius action area. Based on their analysis, the USFWS believes this level of take is not likely to jeopardize the continued existence of the Florida panther. The complete habitat loss and other project effects including the panther mitigation ledger are addressed in the biological opinion (BO) prepared by the USFWS (*Annex A*).

6.13.2.5 Eastern Indigo Snake

Specific information on the status of the eastern indigo snake within the project area is not available. However, indigo snakes are known to occur in the Caloosahatchee River Basin in low densities and are known to occur along roads and the banks of larger ditches and canals in citrus groves, particularly if burrows (e.g., tortoise, armadillo, small mammal, and/or land crab), debris piles, or other shelter are in close proximity. The network of ditches and canals also provide prey items. Therefore, the USACE assumes that eastern indigo snakes occupy the site, and are more prevalent where habitat and prey items are more plentiful. Potential impacts to indigo snakes may occur due to project-related activities including citrus tree removal and burning, habitat destruction and degradation, earthmoving, construction of the reservoir and associated structures and canals, and operation and maintenance of the project. This action may cause individuals to leave the area, abandon den sites, and miss foraging and/or mating opportunities. Snakes fleeing the area could be more vulnerable to predation. Potential direct impacts to the eastern indigo or its habitat include direct injury or mortality and loss of available habitat for foraging, breeding, and dispersing.

The USFWS' *Standard Indigo Snake Protection Conditions* will be implemented during construction to minimize potential adverse effects to indigo snakes (USFWS 2002). Those measures include: 1) providing indigo snake educational materials to construction employees prior to project initiation; 2) if a live indigo snake is found, construction activities will cease until the snake has left the project area on its' own accord and the location of sightings will be reported to the USFWS; and, 3) if a dead indigo snake is found, the snake will be frozen as soon as possible and the USFWS will be contacted immediately for further instructions. With these conservation measures in place the USACE determined the proposed reservoir project "may adversely affect" the eastern indigo snake and by letter dated January 10, 2007, requested initiation of formal consultation with the USFWS. The USFWS terminated consultation with a BO on July 23, 2007. Terms and conditions of the consultation require a slow initial hydration rate for the reservoir in order to allow the snakes sufficient time to move to other habitats. Subsequent rehydration after the first extended drydown event will be monitored and the rate will be re-evaluated based on results of that monitoring. The USFWS anticipates that the direct permanent loss of approximately 10,264 ac of eastern indigo snake habitat will occur through conversion of citrus grove to reservoir and associated embankments, canals, and other infrastructure. The USFWS anticipates up to 54 eastern indigo snakes will be taken incidental to the initial project construction and operations. Complete details of the habitat loss and other project effects are addressed in the BO prepared by the USFWS (*Annex A*).

6.13.2.6 Audubon's Crested Caracara

The reservoir footprint occurs with the secondary (6,600-foot radius from the nest tree) protection zones of two known caracara nest sites. Caracara have been observed foraging in the southeast portion of the project footprint that overlaps with the secondary zone of one nest. However, no construction activities or habitat loss would occur within the primary zone (985-foot radius from the nest tree) of either nest. Since it is anticipated that construction within the secondary zone would occur all year round including during the nesting season, the USACE determined that the proposed project "may adversely affect" the crested caracara and requested initiation of formal consultation with the USFWS by letter dated January 10. 2007. The USFWS terminated consultation with a BO on July 23, 2007. Terms and conditions of the consultation require that the Caracara pairs proximate to the C-43 site will be monitored during land cover conversion and construction of reservoirs associated with this project. The USFWS anticipates that the proposed action will incidentally take the federally listed caracara, though the level of incidental take may be difficult to detect and quantify. The USFWS anticipates that up to two adult pairs of caracaras could be taken as a result of this proposed action. This incidental take for adult birds is expected to be in the form of harassment. No direct killing or injuring of adult caracaras is anticipated. The USFWS also anticipates that disturbance may cause the loss of productivity (eggs or young) associated with up to two caracara nest sites for up to five consecutive breeding seasons. The USFWS anticipates that up to six caracara eggs or young (a maximum of three per nest) could be incidentally taken per year during the construction of the project. This take would be in the form of mortality. The complete habitat loss and other project effects are addressed in the BO prepared by the USFWS (*Annex A*).

6.13.3 Essential Fish Habitat

6.13.3.1 No Action Alternative

Under the No Action Alternative, essential fish habitat (EFH) would continue to be adversely impacted by extreme high and low flows to the Caloosahatchee Estuary. Decline of marine and estuarine grasses would continue as a result of alterations in the salinity regime and the unsuitable timing of the freshwater discharges from the S-79 structure.

6.13.3.2 Alternatives 2, 3B, 3C, and 4A

The intent of the Caloosahatchee River (C-43) West Basin Storage Reservoir project is to improve the quantity and timing of flows to the Caloosahatchee Estuary by reducing high flows during the wet season and augmenting low flows during the dry season. This reservoir is expected to vastly improve the extent and health of EFH predicted for the "without project" condition. Reducing

salinity and nutrient fluctuations caused by large, pulsed freshwater flows would improve seagrass and mangrove habitat conditions in the downstream estuaries. With these improvements in water quality, the appropriate conditions for sensitive estuarine biota, such as species dependent on this habitat for egg, larval, and juvenile stages, are anticipated to benefit or rebound. These impacts are largely beneficial and are significant, and do vary in degree of improvement between alternatives.

The NMFS website (http://www.nmfs.noaa.gov/habitat/habitatprotection/efh/) lists the Caloosahatchee Estuary as EFH for juvenile Brown shrimp (*Penaeus aztecus*), juvenile Gray snapper (*Lutjanus griseus*), juvenile Pink shrimp (*Penaeus duorarum*), adult and juvenile Red drum, (*Sciaenops ocellatus*), adult and juvenile Spanish mackerel (*Scomberomorus maculatus*), and juvenile Stone crab (*Menippe mercenaria*).

All of the construction features of the alternatives are well upstream of EFH and any juvenile or adult habitat for the listed species. Standard BMPs to reduce erosion and downstream turbidity will be included in the construction specifications. Construction should have no impact on EFH in the Caloosahatchee Estuary. The USACE requested that NMFS review the draft EIS and concur with the determination stated as required by the Magnuson-Stevens Fisheries Conservation and Management Act. The USACE has determined that implementation of the project would not have an adverse impact on EFH or federally managed fisheries. The NMFS agreed with this determination per an email dated 30 May 2007.

6.13.4 Estuarine Resources

6.13.4.1 No Action Alternative

Under the No Action Alternative, the estuarine habitat would continue to be degraded as described in the existing conditions due to altered freshwater inflows and extreme variation in salinity levels, and eutrophication. Some areas of habitat may be so badly degraded that it would no longer serve as suitable habitat for important estuarine species.

6.13.4.2 Alternatives 2, 3B, 3C, and 4A

All alternatives would improve the estuarine environment. These impacts are largely beneficial and are significant, and do vary in degree of improvement between alternatives. As already described, the larger alternatives and pumps (Alternative 3C and 4A) provide the largest benefit to the estuary, as they are able to capture more of the high flows as well as hold more water in storage to augment the low flows. Specifically, salinity at Ft. Myers would be expected to fluctuate less than at present, and less than under the smaller alternatives.

Vallisneria sp. would be expected to increase in density and spatial extent. Most importantly, *Vallisneria*.cover would be more consistent year to year. Under existing conditions, the *Vallisneria* is in an almost constant state of recovery. This reservoir may stabilize conditions enough to allow the *Vallisneria* to establish and maintain consistent beds in the estuary. Oysters are currently limited in their recruitment due to high flow events. The reservoir would allow oysters to better maintain their populations and reduce the loss of live oysters and spat. This would also be expected to increase their spatial cover. Marine seagrasses would also be expected to increase in density and spatial extent. These gains would be seen both horizontally and vertically. The vertical improvement (grasses present at deeper depths) would be due to the increased clarity of the water. This improvement to seagrasses would be most beneficial in the San Carlos Bay area and upstream of Shell Point.

6.14 LAND USE

6.14.1 No Action Alternative

The SFWMD owns most of the lands within the 10,700 acre project site. (Currently the SFWMD is exchanging 541.31 acres north of the reservoir boundary for the 600.1 acres of Bryan Paul Property.) The project lands are commonly referred to as Berry Groves and were purchased in 1999 using DOI's Federal funds and State funds for Everglades restoration purposes. The DOI, USACE, FDEP, and the SFWMD are parties to a Framework Agreement under which all interim uses of lands acquired with these funds must be consistent with the ultimate use of the property in a Congressionally authorized federal project for Everglades restoration. Under the No Action Alternative the SFWMD could continue to lease the lands for citrus production, sell the lands, or consider another project; however, approval from DOI would be required.

6.14.2 Alternatives 2, 3B, 3C, and 4A

All alternatives include the construction of the Caloosahatchee River (C-43) West Basin Storage Reservoir within the same project footprint. As stated above, the lands were purchased for Everglades restoration. Implementation on any of the alternatives would be consistent with the Framework Agreement. This is a significant impact to land use and would be comparable across all alternatives.

6.15 AIR QUALITY

6.15.1 No Action Alternative

The air quality for this area is considered good and the region attains all National Ambient Air Quality Standards. In the future under the No Action Alternative, air quality is expected to be slightly degraded (due to regional

increased populations and urbanization) while still complying with air quality standards.

6.15.2 Alternatives 2, 3B, 3C, and 4A

Construction activities associated with implementing all alternatives would temporarily increase dust within the proposed project area. BMPs to control dust would be implemented during construction. All alternatives include the burning of citrus trees which may necessitate a local or state burning permit which the contractor would coordinate. Impacts to air quality are not expected to be significant and would not be significantly different across alternatives.

The operation of pumps and other equipment associated with the proposed action may have some impact upon local air quality, primarily in the form of elevated particulates, nitrogen oxides, and volatile organic compounds. Reservoir pumps and associated equipment would be powered by diesel engines or additional electric power with appropriate backup generators. The larger pumps associated with Alternatives 3C and 4 would result in a marginal increase in air quality impacts compared to the smaller pumps in Alternatives 2 and 3B.

Every Federally funded project must be consistent with state plans for implementing the provisions of the Clean Air Act Amendments (State Implementation Plans). This project is in conformance with the State Implementation Plan because it would not cause violations of the National Ambient Air Quality Standards.

6.16 NOISE

6.16.1 No Action Alternative

Within the major natural areas of south Florida, external sources of noise are limited and of low occurrence. With the No Action Alternative, noise is expected to be similar to the existing condition, which is mostly limited to agricultural machinery and a 300 cfs pump station that is exposed.

6.16.2 Alternatives 2, 3B, 3C, and 4A

Noise impacts associated with all alternatives would not increase over what presently exists within the project area. Noise impacts would not be significant and would be similar across all alternatives. Temporary increases in noise levels would be expected during construction of any of the alternatives; however, this would be limited to the immediate area of construction. This noise would mostly consist of typical construction equipment which generates an average of 80-88 dBA at 50 ft. This impact should be minimal as the area within and

surrounding the construction is mostly rural. The estimated construction timeline (during which construction noise impacts would occur) is 38 months. Although all of the reservoir alternatives include construction of two pump stations, PS-4 and PS-1, both pump stations would be housed to minimize noise. PS-4 is an electrical 195 cfs pump station that would be used only for filling the perimeter canal and therefore would not operate as frequently as PS-1. PS-4 is the same for all of the reservoir alternatives. PS-1 is a larger pump station with diesel pumps that would be used to fill and empty the reservoir. PS-1 would be of 1500 cfs capacity for Alternatives 2 and 3B and 3800 cfs capacity under Alternatives 3C and 4A. With a larger pump station under these latter alternatives, more pumps would be needed which could result in more noise; however, housing of the pump station will minimize noise effects.

6.17 HAZARDOUS, TOXIC AND RADIOACTIVE WASTE

6.17.1 No Action Alternative

The four major land parcels acquired for the project are the Berry Groves tract, Bryan Paul tract, the MG Enterpise, LLC (aka Winthrop) property, and the Griffin property. Over the last six years, the SFWMD has performed multiple Environmental Site Assessments as well as worked to remediate most of the point source contamination sites. (A description of the findings of the assessments and the remediation efforts completed to date are found in the existing conditions portion of this report.) At present, most of this land is leased to agricultural operators who continue to cultivate the thousands of acres of citrus groves located on the properties. If the reservoir project is not constructed, it is likely that the SFWMD will either continue to lease the land to citrus farmers or sell the land to willing buyers. With no reservoir on the site, the potential for bioaccumulation of copper or other toxic substances from contaminated site soils is much less since this usually occurs when the soils are submerged. If the properties continue to be to be used as working groves, the application of pesticides will continue into the future. New point source contamination sites on the properties will likely occur. However, these new sites may be contaminated to a lesser extent than in the past given modern environmental management practices. Overall, since the future without condition would not include a reservoir on the site, the properties will pose only a typical HTRW risk to the environment similar to other citrus operations.

6.17.2 Alternatives 2, 3B, 3C, and 4A

The HTRW impacts of all of the project alternatives are essentially identical since they all use the same real estate footprint. In general, all project related HTRW audits and remediation plans have been coordinated with state (FDEP) and federal (USFWS) agencies when necessary. The existing conditions portion of this document includes a summary of the Phase I/II Environmental Site

Assessment studies done on the four properties acquired for the reservoir project. In the course of these studies, over 50 point source sites with potential HTRW contamination were identified. At this time, most if not all of these potential contamination sites have been either remediated or further investigated to characterize the sites and prepare remediation plans. The project's non-Federal sponsor, SFWMD, has made a commitment to the USACE and USFWS that after it takes control of the properties from the present lessees and begins construction of the reservoir, all of the outstanding point source remediation efforts will be completed. In addition to the point source contamination sites, the SFWMD also identified distributed soil contamination in portions of the cultivated areas on all of the acquired properties. The remediation of the cultivated soil sites involves the placement of these soils into the core of the reservoir dam. This will isolate the contaminated soils from benthic organisms that serve as food for higher level organisms and thus reduce the potential for bioaccumulation of contaminants by fish and wildlife. In accordance with USACE policy, costs incurred by the non-Federal partner to characterize and remediate environmental contamination will not be cost-shared.

The USFWS has reviewed all of the SFWMD's remediation plans and indicated that they believe that the efforts will sufficiently reduce the risk of harm to fish and wildlife in those areas where the remediation will be performed. The USFWS has also stated that moderate levels of copper and other contamination of the cultivated areas are believed not to pose a direct threat to species of concern; however, they believe that an indirect effect may occur since widespread low-level soil contamination may reduce the population of benthic organisms upon which the species of concern normally feed.

Despite the diligent work performed by the SFWMD and USFWS to reduce the risk to environmental resources, it is possible that once the reservoir is built, bioaccumulation of soil contaminants does result in harm to one or more species of interest. If this does happen, additional remediation efforts, such as more extensive removal of the reservoir bottom sediments, could be done to further reduce the exposure of benthic organisms to near surface soil contamination at the end of a dry season. The cost of additional remediation, if necessary, would be the responsibility of the non-Federal sponsor. If such remediation is necessary, this remediation effort may be scheduled in one cell at a time, possibly during the late dry season, thereby keeping the reservoir somewhat operational.

6.18 CULTURAL RESOURCES

6.18.1 No Action Alternative

Under the No Action Alternative, the project site would continue to be an active citrus grove. Therefore, the existing cultural resource site that may be potentially eligible for listing in the National Register of Historic Places would likely be adversely affected by expansion of the existing citrus operations.

6.18.2 Alternatives 2, 3B, 3C, and 4A

Cultural resources would be impacted by all four alternatives equally. Cultural resources impacts are not considered significant for this project. Cultural resource surveys have been conducted for the Caloosahatchee River (C-43) West Basin Storage Reservoir. Three isolated prehistoric artifacts, one isolated historic artifact, one prehistoric archeological site (8HN129), and four modified historic buildings were identified. All except the prehistoric archeological site were determined to lack integrity and determined not eligible for listing on the National Register of Historic Places, the prehistoric archeological site (8HB129) is located near the edge of the proposed project and will be avoided by project design. The USACE has determined that the project will not affect historic properties eligible for listing on the National Register of Historic Places. The Florida State Historic Preservation Officer (SHPO) concurred with this determination (Florida State Department of Historic Preservation numbers 2004-8676 and 2006-07757). This determination and concurrence is the same for all alternatives since they utilize the same project footprint. The project has been reviewed by the SHPO and complies with the requirements of Section 106 of the National Historic Preservation Act.

6.19 SOCIOECONOMICS-REGIONAL ECONOMIC IMPACTS

The purpose of this section is to estimate the regional economic consequences of the project. The main impacts on the regional economy as a result of implementation of the project are expected to result from expenditures on construction and real estate.

6.19.1 No Action Alternative

In the event that the C-43 reservoir is not constructed, no regional impact will be realized from project expenditures. The local economy would continue to realize revenue stemming from the continued agricultural of the property.

6.19.2 Alternatives 2, 3B, 3C, and 4A

Although the expenditures for the various alternative plans are quite large, and are expected to result in fairly large, regional economic impacts, these impacts

are very small, relative to the regional economy in which they will take place (on the order of less than one percent).

Expenditures on project construction, non-construction and real estate, represent an influx of money into the local economy. Spending has a ripple, or multiplier, effect throughout the economy that can be estimated using multipliers that have been calculated using IMPLAN®. IMPLAN multipliers have been used to estimate the impacts on employment, earnings and output (sales) during the estimated three year construction period. The results of the expenditures resulting from construction of the SAP are presented in the table below. If the construction costs of the other alternatives are greater, the regional impacts will be greater, likewise it they are smaller, the impacts will be smaller.

At first glance the figures in ***Table 6-4*** look like enormous impacts resulting from the spending required to implement the project. However, these effects generally represent a very small percentage of the total economic activity in this region.

TABLE 6-4: OVERALL REGIONAL ECONOMIC IMPACTS

Alternative	Impacts			Project Costs
	Output	Earnings	Employment	
3B	$306,400,000	$79,990,000	2,258	$507,240,000

The construction of a reservoir of this size is not a one-year injection into the regional economy, but will be broken up over a number of years. The effects of the annual spending on the regional economy will prove even less significant than viewing the expenditures in total. Since the impacts are likely to occur in varying magnitude over time, the summary effects given in ***Table 6-4*** represent the upper limit if all these impacts were to occur simultaneously. In reality, the impacts of construction last only as long as those activities are carried out. The impacts represent the effects resulting from expenditures during project implementation that is expected to last three years beginning in 2008.

Table 6-5 contains the labor employment and earnings for Florida's South Region. The gross state product (GSP) for Florida is presented for a comparison to the output (sales) created by the construction projects.

When comparing the impacts of construction, as shown in ***Table 6-4*** to the actual total figures for the south region and state, it is important to recognize that the latest earnings data available were from 2000 census data. These figures have increased since 2000, but are considered sufficient for this analysis.

It can be seen that the impact on the region from the construction of the alternatives would be similar. There would be no major long-term impact and the short-term impacts would be insignificant compared to the economy of south Florida.

TABLE 6-5: REGIONAL AND STATE TOTALS

Region	Earnings (2003) ($millions)	Employment (2000)	Output (2003)*** ($millions)
Southwest Region	$320,000	9,391,709	**$910,000**
Florida	$ 10,000	357,914	**$30,000**

6.20 OTHER SOCIAL EFFECTS

The purpose of this section is to examine the social and community consequences of the project.

6.20.1 No Action Alternative

In the event that the reservoir is not constructed, the project footprint and immediate surrounding area is expected to remain a predominantly agricultural community, with earnings lower and unemployment slightly higher than that of the Florida in general. The overall outlook of the areas economic future is positive and an increase in population and residential development can be expected, while maintaining a rural community.

6.20.2 Alternatives 2, 3B, 3C, and 4A

The OSE account considers the effects of alternative plans in areas that are not already contained in the NED and RRED accounts. The categories of effects contained within the OSE account include:

- Urban and community impacts
- Life, health, and safety factors
- Displacement
- Long-term productivity
- Energy requirements and energy conservation

The alternative plans could result in both beneficial and adverse OSE within the study area. The alternative plans could have positive or adverse OSE impacts on the study area associated with (1) plan implementation, including land acquisition, project construction, and O&M activities, and (2) operation of the modified C&SF system. As in the case of the NED effects, the OSE account is

concerned with the net effects of the alternative plans (i.e., the differences between the with- and without-project future conditions).
Some of the potential OSE impacts would occur primarily at the regional scale, and others would have more localized effects. At both scales, there may be some individuals and communities that are positively affected by the alternative plans, some that are adversely affected, and many that are not affected at all. Relative to the size of the regional or local economies, the OSE effects may be minimal. However, if these effects occur predominantly within a limited geographic area, or affect a relatively small or vulnerable population, then the impacts can be disproportionately large. Therefore, the purposes of OSE analysis include not only determining the total magnitude of potential impacts, but also identifying the population (and its characteristics) that would be affected by any proposed action.

Some of the categories of effects typically included in the OSE account do not pertain to the alternative restoration plans. For example, the alternative plans are not expected to affect energy use or energy conservation in the study area.

An urban and community impact is the principal category of potential OSE impacts associated with the alternative restoration plans. This category of impacts includes effects on income distribution, employment distribution, population distribution and composition, and quality of community life. Regional income effects and fiscal impacts were discussed in the RED analysis. In addition, the impacts of agricultural water supply and M&I water supply were discussed in detail in earlier sections. The OSE assessment of urban and community impacts considers both the potential for exposure to the effects of the alternative restoration plans and the degree of vulnerability to potential impacts. Exposure refers to whether an individual or community is subject to the other social effects of the alternative plans. Vulnerability refers to the ability of that individual or community to respond or adjust to those effects.

Potential urban and community impacts of the alternative restoration plans could result from: (1) land acquisition and potential relocation of populations for reservoir and other project construction features, (2) reduced agricultural activity associated with taking the impoundment lands out of cultivation, and (3) construction activity associated with plan implementation. In general, construction activity is considered to have positive impacts. At the local scale, construction and O&M activities associated with the alternative restoration plans can have positive effects to local residents and communities by providing jobs, increasing local wages, increasing local sales, increasing tax revenues, increasing tourism and generally benefiting the local economy.

There are a variety of social and economic factors that are important determinants of an individual's or community's ability to cope with adversity.

One of the most important economic factors in the ability of individuals and groups to respond is the number of employment alternatives available locally. The ability to find another job depends on the education and training of the work force as well as the needs of local economic concerns, such as other farms, agricultural-related services, or some other local business. The socio-economic makeup of the community is also an important consideration of the ability of individuals and the community at large to cope with the adverse effects of large-scale agricultural land conversion. Some groups in society are recognized as having less opportunity to respond to adversity. These groups include ethnic and racial minorities, the elderly, and the poor.

The surrounding counties have a wide range of ethnic compositions, proportions of elderly population, unemployment rates, and per capita incomes. These socio-economic characteristics suggest that the rural counties of the study area – those that are expected to provide locations for new storage reservoirs – are areas that are least able to accommodate the associated economic and social effects on local communities. However, in these rural areas the affected populations should be relatively small.

6.21 AESTHETIC EFFECTS

6.21.1 No Action Alternative

The aesthetics of the project site would remain basically unchanged under the No Action Alternative.

6.21.2 Alternatives 2, 3B, 3C, and 4A

Aesthetic effects refer generally to impacts on the visual qualities of the environment. The area proposed for the Caloosahatchee River (C-43) Basin Storage Reservoir project is now overwhelmingly flat, rural and agricultural, with a mixture of pastures, citrus groves and other crops. The land slope is very gradual; thus long-distance viewsheds are hard to observe. The high walls of a large reservoir will present an abrupt landscape transition, which may initially be a visual shock. This will be a significant impact to aesthetics of the area and will be significantly different across alternatives due to the progressive dam elevations. The top of the enclosing levees, however, will provide wide panoramas of the Caloosahatchee River landscape, and should also offer good observation points for the surroundings. This man-made viewshed could be a good observation point for bird watching over the surrounding countryside. The main aesthetic difference between the alternatives will be in the dam elevations which are listed below:

- Alternative 2 54 feet
- Alternative 3B 57 feet

- Alternative 3C 57 feet
- Alternative 4A 66 feet

6.22 RECREATION

6.22.1 No Action Alternative

The No Action Alternative would not result in an improvement nor degradation of recreation resources. The continued operation of a citrus grove would not provide any additional recreational opportunities to the region.

6.22.2 Alternatives 2, 3B, 3C, and 4A

All of the alternatives would offer comparable recreational opportunities. These beneficial recreation impacts are considered significant. The recreation plan in ***Appendix G*** outlines wildlife viewing and hiking along the perimeter of the reservoir. Boating within the reservoir is also included in the plan. These recreational opportunities would help to fill the deficit in recreational facilities expected due to high population growth in south Florida. It is important to note, however, that recreation must be a secondary benefit of the reservoir. The reservoir must be operated to benefit the estuary in order to obtain the benefits outlined in this document. There will be times when the reservoir is predominantly dry. During those times boating may be limited or not possible within the reservoir. If the reservoir were to be operated to allow boating at all times, benefits being claimed by this project would be lost.

6.23 CUMULATIVE IMPACTS

Cumulative impact is the "impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions (40 CFR 1508.7)."

The Caloosahatchee River (C-43) West Basin Storage Reservoir will increase water storage in the Caloosahatchee River (C-43) Basin resulting in long-term benefits for the estuary. This storage function is essential to the overall restoration of the Caloosahatchee estuary. This project along with other CERP projects would cause some adverse consequences to agricultural land use, permanently removing thousands of acres from agricultural production. These impacts may be felt locally and/or regionally as the economic base derived from agriculture is incrementally reduced relative to other sectors of the economy.

There will be some loss of wetlands on the site. 125 acres of wetlands were identified on the proposed project site. (This acreage does not include a small wetland area within the project site that has already been impacted by

construction of the C-43 Test Cell Project.) Most of the existing wetlands have been impacted by surrounding agricultural activities, including reduced hydroperiod, ditching, and exotic plant species infestation. These relatively low-functioning wetlands would be converted to open water habitat. However, the overall benefit to the estuarine system which consists primarily of high value mangrove wetlands, coastal marshes, tidal flats, and aquatic and estuarine habitats such as streams, ponds, bays and SAV beds would be greater than the local wetland loss.

Other CERP projects which might directly affect this basin include the SWFFS and a subsequent Caloosahatchee River (C-43) Basin study. The SWFFS is currently in the PIR development stage and includes many alternatives in this watershed. The subsequent Caloosahatchee River (C-43) Basin study, at the time of this writing, is not yet in the PIR development stage but is planned to begin in late 2007. This subsequent study will evaluate building additional storage features in the eastern portion of the basin. These features might result in removal of additional lands from agricultural production. However, additional storage in the basin would also result in a greater ability to control flows to the estuary, potentially improving conditions in both the wet and the dry season. Indicator species such as oysters and SAV as well as species such as manatees which feed on the SAV and wading birds which forage on the estuarine fisheries would benefit. The cumulative effect of these projects in the Caloosahatchee River (C-43) Basin would be a great reduction in the large damaging flows during the wet season as well as augmentation of the low flows during the dry season.

Other state and local projects may have impacts on this basin. Immediately adjacent to and east of the reservoir, the SFWMD may work with Hendry County to provide some additional flood alleviation to SR 29, which captures drainage from a basin area east of SR 29. A series of culverts, located in the LaBelle Private Drainage District (LPDD) Canal to direct water away from the SR 29 west ditch towards the perimeter canal, may potentially be constructed. This initiative is not a part of the Caloosahatchee River (C-43) West Basin Storage Reservoir project, but may in the future be hydraulically linked to the C-43 reservoir project's perimeter canal. The impacts to the drainage area east of SR 29 would need to be determined and analyzed. The SR 29 west ditch flood alleviation project would be separately coordinated with the USACE and FDEP through permitting.

In early 2007 the Florida Legislature passed Senate Bill 392, The Northern Everglades and Estuaries Protection Program, which expands the Lake Okeechobee Protection Act to include protection and restoration of the Lake Okeechobee watershed and the Caloosahatchee and St. Lucie rivers and estuaries. This program includes development of a technical plan to identify the

storage and water quality treatment requirements for the Lake Okeechobee watershed by February 1, 2008. This plan is currently scheduled to include development of the Caloosahatchee and St. Lucie Rivers Watershed Protection Plans to identify watershed storage projects and water quality targets by January 1, 2009. The Caloosahatchee and St. Lucie River Watershed Protection Programs will include goals for salinity envelopes and freshwater inflow targets for each estuary. The goals of the program are to :

- Meet Lake Okeechobee Watershed Total Maximum Daily Loads
- Manage Lake Okeechobee levels within an ecologically desirable range
- Manage flows to meet desirable salinity ranges for the St. Lucie and Caloosahatchee Estuaries.
- Identify opportunities for alternative surface water supply sources in the watershed

This program has potential to benefit the watershed and would help to maximize the benefit of the reservoir by developing a comprehensive watershed plan for storage as well as water quality.

In addition to the above projects, many of the storage features of the CERP would affect the water levels in Lake Okeechobee, which will in turn affect how much water is released to the estuary. This could represent both positive and/or negative impacts. Reducing the water levels in Lake Okeechobee would be an improvement during the wet season by reducing the damaging high flows to the estuary. However, lower lake levels might also result in less water available to release during the dry season. Ideally the storage reservoirs would then have water available to release to the estuary.

The Caloosahatchee River (C-43) West Basin Storage Reservoir project is a proposed part of the CERP. Large areas north of Lake Okeechobee, within the EAA, around the lake, in the Caloosahatchee River (C-43) Basin, and on the Upper East Coast will be used to increase water storage for the overall gain and long-term benefit of the regional system. This will result in the conversion of lands to reservoirs. This will cause some adverse consequences to agricultural land uses permanently removing tens of thousands of acres from agricultural production. These impacts may be felt locally and/or regionally as the economic base derived from agriculture is incrementally reduced relative to other sectors of the economy. As these water storage features occur disparately across the landscape within different hydrologic basins, and as distinct units rather than multiple features within a single watershed, they will not likely result in a significantly detrimental cumulative effect. These project features will provide important storage functions and are essential to the overall restoration of the freshwater marshes and the estuaries of the area. The CERP contains 68 components that total approximately 217,000 acres of new reservoirs and

wetlands-based water treatment areas. This plan increases the supply of fresh water for the Everglades and south Florida ecosystem and improves the quantity, quality, timing, and delivery of water to the natural system.

A number of operational components have also been identified in the CERP and will, in most cases, occur in conjunction with related construction features. The operational features in the CERP include: a modified LORS; environmental water supply deliveries to the Caloosahatchee and St. Lucie estuaries; modifications to the regulation schedules for WCAs 2A, 2B, 3A, 3B, and the current rainfall delivery formula for ENP; modified Holey Land Wildlife Management Area Operations Plan; Modified Rotenberger Wildlife Management Area Operations Plan; a modification for coastal wellfield operations in the Lower East Coast ; Lower East Coast utility water conservation; and operational modifications to the southern portion of L-31N and C-111. These features will result in significant environmental benefits to the CERP project area.

6.24 IRREVERSIBLE AND IRRETRIEVABLE COMMITMENTS OF RESOURCES

Construction of the proposed project will include features considered permanent, which may be deemed irreversible. This would include construction of the reservoir, embankment, and perimeter canal. Resources committed would include state and Federal funding to purchase lands (project lands have already been acquired with state and Federal funds) and labor, energy and project materials to build, operate, and maintain the project. Limited fish and wildlife habitat on project lands will be converted to open water habitat.

6.25 UNAVOIDABLE ADVERSE ENVIRONMENTAL EFFECTS

6.25.1 Land Use

Existing citrus groves would be permanently altered to construct the reservoir and associated features.

6.25.2 Wetlands

Although the project site is a producing citrus grove, it contains 125 acres of remaining wetlands. These wetlands are of low to moderate quality with limited function and value due to their reduced hydroperiod, infestation by exotic plant species, and location in the landscape i.e., separation from other habitats and corridors). Implementation of the project would permanently alter wetlands within the footprint of the project features.

6.25.3 Water Quality

Temporary increases in turbidity of local waters within allowable limits are expected during construction. Precautions to limit turbidity will be employed.

6.25.4 Air Quality

Fugitive dust from vehicular traffic and earth moving during construction will be unavoidable but insignificant overall.

6.25.5 Soils

The disruption of soils is expected to result from construction activities. The conversion of prime farmland to an open water habitat is anticipated to be significant and irretrievable.

6.25.6 Wildlife

Localized short-term disturbance to fish and wildlife are expected from construction activities of the plan components.

6.25.7 Threatened and Endangered Species

Short-term disturbance to fish and wildlife are expected from construction activities of the plan components. Precaution measures and construction conditions to limit impacts to threatened and endangered species will be implemented.

6.26 RELATIONSHIP BETWEEN SHORT-TERM USE AND LONG-TERM PRODUCTIVITY

While regional conditions will improve, short-term or localized problems will undoubtedly occur. Although overall restoration of the Everglades ecosystem is expected to improve habitat for nesting wading birds regionally over time, the transition period might adversely affect regional wading bird populations. Proper sequencing of project features should mitigate impacts to existing wildlife resources expected to be impacted by restoration activities within their vicinity. Further assessment and monitoring will be critical to recovery of ecosystem attributes and maintaining a viable fish and wildlife population during the implementation of CERP.

6.27 COMPATIBILITY WITH FEDERAL, STATE, AND LOCAL OBJECTIVES

The proposed action is consistent with the overall goals and objectives of the CERP. It is expected that the proposed action will be consistent with Federal, State, and local plans and objectives.

6.28 SIGNIFICANCE OF HABITAT

The significance of the habitat for this project is clearly identified below using the categories and criteria defined in Section 3.4.3 of Principles and Guidelines and in paragraph 16.b of Engineering Pamphlet (EP) 1165-2-502. Significance of the benefited area (Caloosahatchee Estuary, San Carlos Bay, Pine Island Sound, and Matlacha Pass) is identified by the following:

- Plans and constitutions, laws, directives, resolutions, gubernatorial directives, and other policy statements of States with jurisdiction in the planning area.
  - Matlacha Pass and Pine Island Sound are designated as aquatic preserves by the Florida Department of Environmental Protection
  - Caloosahatchee Water Management Plan (April 2000)
  - Lower West Coast Water Supply Plan 2005-2006 Update
  - Minimum Flows for Caloosahatchee River (Chapter 40E-8, Florida Administrative Code)
- Endangered Species Act of 1973, as amended, Pub. L. 93-205; 16 U.S.C. 1531, et seq.
  - Threatened and endangered species found in the Caloosahatchee Estuary and other benefited areas include the West Indian manatee, smalltooth sawfish and five species of sea turtles
- Estuary Protection Act, Pub. L. 90-454; 16 U.S.C. 1221, et seq.
- Marine Mammal Protection Act of 1972, Pub. L. 92-522; 16 U.S.C. 1361, et seq
  - The West Indian Manatee could benefit immensely from increased aquatic vegetation which is its main source of food
  - Benefits area includes San Carlos Bay Federal Manatee refuge
- Migratory Bird Treaties and other international agreements listed in the Endangered Species Act of 1973, as amended, Section 2(a)(4).
  - The South Florida ecosystem is located along one of the primary migratory routes for bird species that breed in temperate North America and winter in the tropics of the Caribbean and South America.
- Significance based on public recognition means that some segment of the general public recognizes the importance of an EQ resource or attribute. Public recognition may take the form of controversy, support, conflict, or opposition and may be expressed formally (as in official letters) or informally.

  - This project has received intense public and local government support. There has been long-term and intense interest in the degraded state of the Caloosahatchee estuary and interest in improving its condition. Please see the inventory of public concerns and dPIR comment matrix in Annex B for further information.
  - American Rivers listed the Caloosahatchee River in the top 10 endangered rivers in US
- Effects on the resources in terms of differences between estimated future without- and with plan conditions
  - The selected alternative plan improves flows to the estuary during both the wet and dry season, but is especially good at meeting the dry season demands of the estuary. This results in a forecasted significant improvement of many ecosystem indicators such as oysters, crab, submerged aquatic vegetation, and fisheries.
- Other relevant information concerning duration, frequency, location, magnitude, and other characteristics, such as reversibility, retrievability, and the relationships to long-term productivity (P&G).
  - Please see Sections 6.23 – 6.28 for a discussion of these factors

In summation, the significance of the project is demonstrated by a combination of applicable policy, technical attributes and public interest as outlined above.

6.29 UNCERTAIN, UNIQUE OR UNKNOWN RISKS

The risk and uncertainty associated with the construction and operation of these features of the proposed project should be minimal. All features have been designed and constructed through established and applied technology. No experimental design was necessary for any component of the proposed impoundment. Additionally, both the USACE and the SFWMD have extensive and reputable credibility in the design, construction and O&M of the proposed features from previous water resources planning efforts.

A cutoff wall along the perimeter of the dam embankment is being considered and will be further investigated as the project proceeds to design. For estimating purposes, a 42-47 foot cutoff wall was included. These use standard technology and should pose minimal risk.

Soil cement protection was included for armoring. This will be further investigated as the team proceeds with the design. Armoring generally uses standard technology and should pose minimal risk.

A freeboard of approximately 17 feet was used in preparing the ROM cost estimates. The freeboard design will be further refined in accordance with applicable CERP DCM. These DCMs were developed to provide consistent working level guidance for impoundment design by the Acceler8 teams. The

DCMs consolidate and incorporate design criteria from various agency regulations and guidelines including USACE, U.S. Bureau of Reclamation, Federal Energy Regulatory Commission, Florida Building Code, and the American Society of Civil Engineers. The DCMs do not supersede USACE. Freeboard designed in compliance with the DCMs, and thusly USACE regulations, should result in minimal risk of embankment failure due to overtopping (refer to DCM-2 for additional detail).

AM consists of an active strategy for dealing with the considerable uncertainties that characterize management of large natural ecosystems, which are complex and difficult to predict. The overall purpose of AM is to maximize the chance of success and includes methods, such as proactive approaches to dealing with uncertainties, the use of modern ecosystem science and scientific practices, active collaboration, and the use of open, inclusive, and integrative processes.

Five key principles help implement this approach to AM:

1. Anticipate future uncertainties and contingencies
2. Employ science-based approaches to build knowledge
3. Design robust projects that can be adapted to changing conditions
4. Build a shared understanding through collaboration and conflict resolution
5. Reconcile competing objectives to benefit both nature and society

The C-43 project is a component of the CERP, which consists of sixty-eight (68) major components. The uncertainty associated with a program of this magnitude was recognized during the Restudy, which led Congress to address the necessity of AM in the WRDA 2000.

As such, a fundamental implementation principle for CERP is to utilize adaptive assessment and management in order to continually refine and improve the performance of CERP projects so that planned benefits are attained. Incremental revisions of optimal project designs and project operations throughout the planning and implementation process will lead to improved performances. The use of the adaptive assessment policy minimizes the effects of uncertainty with respect to the effects of CERP projects on the natural system and other water-related needs of the region related to the design and implementation of the CERP.

6.30 ENVIRONMENTAL JUSTICE

In accordance with E.O. 12898, USACE has made achieving environmental justice part of its mission. While the President's E.O. on Environmental Justice made this directive explicit, it is implicit in NEPA and in planning regulations that USACE and SFWMD planners must conduct an objective evaluation of all

project objectives in terms of their social and economic performance. This is accomplished by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations. In public outreach efforts to date, only one potential environmental justice issue has been identified: the loss of jobs for low income and minority workers as a result of acquiring agricultural land for the construction of the reservoir. The expected loss in employment will occur to seasonal and/or temporary migrant workers, and as can be noted in the future land use section agricultural acreage in the surrounding study area and counties is expected to increase. The Caloosahatchee River (C-43) West Basin Storage Reservoir Project PIR and EIS is an opportunity to somewhat alleviate this potential problem by providing jobs within and during construction of the project, some of which could provide seasonal and temporary employment. To address this issue the SFWMD is conducting training programs to allow local individuals to acquire the skills needed to construct the reservoirs. In addition, it is anticipated that adjacent lands will continue to support agricultural operations.

In order to keep all members of the public updated, the SFWMD will be providing regular updates to the County Commission which are open to the public. In addition, meetings with stakeholders will be held on an as needed basis.

SECTION 7
THE SELECTED ALTERNATIVE PLAN

This page intentionally left blank

7.0 THE SELECTED ALTERNATIVE PLAN (SAP)

The Caloosahatchee River (C-43) West Basin Storage Reservoir project is planned and designed primarily to restore the ecosystem function in the Caloosahatchee Estuary by reducing the number and severity of events where harmful amounts of freshwater from basin runoff and Lake Okeechobee releases are discharged into the estuary system. The project also helps to maintain a desirable minimum flow of fresh water to the estuary during dry periods. These two primary functions help to moderate unnatural changes in salinity which is extremely detrimental to estuarine communities.

Detailed design of the Caloosahatchee River (C-43) West Basin Storage Reservoir project will be accomplished by the SFWMD as part of the State of Florida's Acceler8 program. Design information and details will be coordinated and reviewed by the USACE pursuant to the Design Agreement between USACE and SFWMD dated May 12, 2000. Activities during the construction phase will be in accordance with the Acceler8 program and will be the responsibility of the SFWMD.

The State of Florida's "Acceler8" program was developed for the purpose of accelerating design and construction of a number of critical restoration projects consistent with the Comprehensive Everglades Restoration Plan (CERP) prior to one or more of the following: administration approval, Congressional committee resolution, Congressional authorization, or Federal construction funding. The SFWMD proposes to initiate construction of the C-43 West Reservoir/Acceler8 Project prior to implementation of the Federal Caloosahatchee River (C-43) West Basin Storage Reservoir project.

7.1 DESCRIPTION OF PLAN COMPONENTS

Through the formulation of alternative plans described in Section 5.0, Alternative 3B was identified as the Selected Alternative Plan (SAP) for the Caloosahatchee River (C-43) West Basin Storage Reservoir project. The SAP was further refined based on additional engineering and design and described in this section of the report. The SAP provides approximately 170,000 ac-ft of above-ground storage volume in a two-cell reservoir with normal pool depths when the reservoir is full varying from 15 feet at the southeast corner to 25 feet at the northwest corner. Major features of the project include external and internal embankments, canals, two pump stations, internal control and outflow water control structures, and environmentally responsible design features to provide fish and wildlife habitat such as littoral areas in the perimeter canal and deep water refugia within the reservoir.

Once the SAP was identified more detailed design (i.e. surveys and real estate) was completed. The final design details necessary for the plan to be authorized

are described in this section with additional detail provided in ***Appendix A***. The additional engineering and design analysis that was completed does not effect the plan formulation as the cost changes and project refinements would be applied proportionally to all projects. The total benefits derived by the plan does not change based on these additional refinements.

The following is a general description of the location and design of SAP features. For a detailed description of project features refer to ***Appendix A***.

7.1.1 General Plan Description

The SAP, as shown in ***Figure 7-1,*** consists of a two-cell reservoir with a "normal pool" storage capacity of 170,000 ac-ft. This SAP comes closest to approximating the Restudy Caloosahatchee River (C-43) West Basin Storage Reservoir recommended volume of approximately 160,000 ac-ft of storage and is the size evaluated and currently being designed by the SFWMD under their Acceler8 program. The project footprint for the SAP encompasses approximately 10,700 acres, of which approximately 10,480 acres are required in fee, approximately 20 acres will be perpetual easements, and approximately 200 acres will be used on a temporary basis for staging area. The project consists of major features and components to include a two-cell reservoir with armoring, cutoff walls, and embankments. Other features are pump stations, spillways with emergency overflow and vertical lifts, drawdown structures, culverts, canals, earthwork artificial habitat creation, and recreational features. The reservoir design includes a pump station with 1,500 cfs capacity to pump water from the Townsend Canal to fill the reservoir.

The existing Townsend Canal, located along the west perimeter of the reservoir, will serve as the west perimeter canal. The existing disposal mounds along the east side of the Townsend Canal will be removed as part of the project. A drainage culvert will be located on the east perimeter canal connecting the LPDD Canal (also known as the Header Canal), which will maintain historical drainage from the Paul property east of the project. Improvements to or the relocation of the existing weir structure located at the mouth of the Townsend Canal are included. Work to that structure will be done within an existing easement.

The Selected Alternative Plan has a water surface elevation of 42 feet at "normal pool" (NAVD88), with the average depth ranging from 17-19 feet. Dam (embankment) heights for the SAP range from 32-37 feet (top of dam is at elevation 57 ft (NAVD88)). The maximum water depths and dam heights will occur in Cell 1 due to lower land surface elevations in that cell. The exterior and interior dams are to have a crest width of 14 feet. The side slopes are 3 Horizontal to 1 Vertical (3H:1V). The exterior dams are to be constructed from existing on-site material and have a low permeability core. A graded filter is to

be provided on the exterior side of the dam to direct seepage. Soil cement protection would be included on the interior side of all reservoir slope faces. A freeboard of 15 feet was used based on detailed analysis of wind and wave height run-up.

A perimeter canal (seepage canal) is provided on the south, east, and north sides of the reservoir. The existing Townsend Canal will act as a seepage canal on the west side of the reservoir. In addition to seepage collection, the perimeter canal will also convey discharges from the reservoir; convey surface runoff from the south and east of the reservoir including drainage for SR29; provide flows to the Crawford Canal, Banana Branch and Fort Simmons Branch; and maintain the surface water elevation in the expanded northeast rim ditch that provides irrigation for the A. Duda and Sons (Duda) citrus operations, located to the south of the reservoir. A cutoff wall (approximate total height of 47 feet) along the perimeter of the dam embankment has also been included in the reservoir design.

Improvements to the Townsend Canal are based on the necessary capacity to meet maximum pumping requirements to fill the reservoir. Pre-storm and post-storm event flows have been simulated to evaluate flows in the Townsend Canal and other local canals and tributaries. Storm event flows in the Townsend Canal will be decreased over existing conditions with the construction and operation of the reservoir.

Each cell is designed to discharge independently through separate discharge structures. Cell 1 will discharge via the S-1 structure into the Townsend Canal. Cell 2 will discharge via S-8 structure into the perimeter canal. These structures will be designed for incremental operation allowing required flows to be released to the Caloosahatchee River (C-43 Canal) during periods of low flow. These structures could also serve as design storm control structures for releases prior to and during a storm event. The storm releases must be balanced with the targeted maximum flow allowed over S-79, which is 4,500 cfs. An emergency spillway with a crest elevation based on retaining the 25-year, 72-hour storm event is to be provided within each cell's discharge structure. The 25-year, 72-hour storm captured in the reservoir would be a "control release" after the storm event in order to restore the water surface to the normal pool elevation while not exceeding the maximum flow of 4,500 cfs at S-79. The final design of the emergency spillway(s) will be in accordance with the requirements of Design Criteria Memorandum 3 (DCM-3).

Within the reservoir, structure S-12 will hydraulically connect the two reservoir cells and is designed to be gated so that either cell can be "isolated" for operational or maintenance (O&M) purposes. A number of other culverts, weirs, and spillways are included to operate the reservoir and maintain appropriate water levels in existing canals and the perimeter canals.

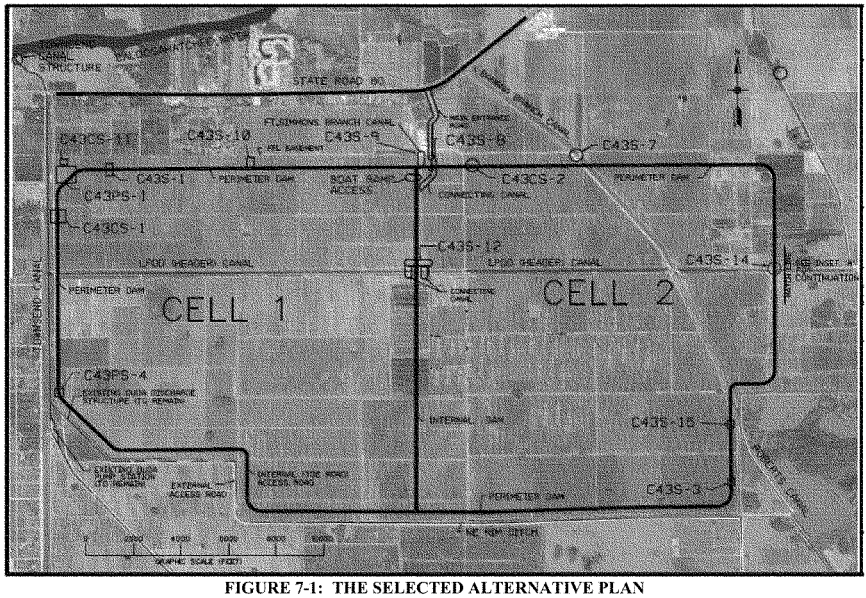

FIGURE 7-1: THE SELECTED ALTERNATIVE PLAN

7.1.2 Major Project Components

7.1.2.1 Reservoir

The reservoir is an earthen impoundment consisting of approximately 9,220 acres of interior storage that is to be constructed above the existing ground. It will consist of an approximate 170,000 ac-ft two-cell reservoir. Water will be pumped from the Caloosahatchee River (C-43 Canal) and into the reservoir by utilizing the existing Townsend Canal and a new pump station (C43PS-1) located in the northwest corner of the project.

Water will be discharged from the reservoir through gravity discharge structures in each cell that discharge into a perimeter canal. Both flows into and out of the reservoir will be controlled by monitoring flows at S-79.

7.1.2.2 Intake Canal

The existing Townsend Canal will serve as intake canal. The West Storage Reservoir (WSR) has been designed so that during storm events flows in the Townsend Canal will not exceed the "pre-existing" condition. Therefore, there will be no negative impacts to the Townsend Canal, SR 80 bridges, or the existing flap gate weir structure. However, two additional flap gates will be installed in the weir structure to provide capacity for pumping rates of 1500 cfs at C43PS-1.

The perimeter canal will serve as a seepage canal and as a means of conveying both surface storm water runoff and off site flows entering the project. The perimeter canal design includes littoral shelves along the exterior slope that are intended to promote wetland vegetation, fisheries, and recreation activities.

7.1.2.3 Embankments (Dams)

The perimeter embankment will have an external geometry that includes a 14-foot wide crest and 3 horizontal to 1 vertical sideslopes. Crest elevations have been established at +57 feet NAVD88 for both Cell 1 and Cell 2. The embankment will be constructed largely of random fill, but will also include a low permeability soil-bentonite wall, an internal drain, and upstream slope protection. The soil-bentonite wall will extend from an elevation that is five feet above the normal pool elevation to five feet below the top of a clay layer which underlies the project site at depths generally in the range of 20 to 25 feet below existing surface grades. A few structures pass through the perimeter embankment. At these locations, the above ground portion of the soil-bentonite wall will be replaced with select fill. A roughly 100-foot wide bench will be raised above the existing ground surface immediately downstream of the

perimeter embankment. A perimeter canal is to be located on the outside of the bench.

The separator dam between Cells 1 and 2 will be a homogenous embankment with a crest elevation of +50 feet NAVD88. It will not include any soil-bentonite wall or internal drain. The separator dam will be covered on both sides with soil-cement. The components of the embankments are described in more detail in the following sections.

7.1.2.4 Pumping Station C43PS-1

It will consist of a steel and reinforced concrete structure that will house the main pumps and pumping motors for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project. The structure will be located adjacent to the downstream side of the dam and will have plan dimensions of approximately 200 feet (parallel with the dam) by 100 feet (measured at the intake level). It will have a base slab elevation on the intake side of the structure of -16 feet with respect to the North American Vertical Datum of 1988 (NAVD88). The structure bottom will step up to elevation +10 feet NAVD88 for a distance of about 30 feet in the area between the intake bay and the toe of the dam. The existing surrounding grades at the site of the proposed construction are approximately +16 to +17 feet NAVD88.

7.1.2.5 Pumping Station C43PS-4

C43PS4 will provide water to the perimeter canal during dry periods when water cannot be released from Cell 2 of the reservoir due to low Reservoir water levels. C43P-S4 will maintain the water level in the perimeter canal, provide water to the Paul property, and supply water to the Banana Branch and Ft. Simmons Branch.

It will consist of a steel and reinforced concrete structure that will include a "can" type intake. The structure will be located adjacent to the top of bank of the Townsend Canal and will have plan dimensions of approximately 55 feet by 45 feet. It will have a separate intake bay that will have a top of slab elevation of -12 feet with respect to the NAVD88. The intake pipes will consist of three 48-inch diameter steel pipes that connect the intake bay with the vertical cans. Invert elevations for these pipes will be approximately elevation -10 feet NAVD88. The bottom of the can structures will be elevation -20.4 feet NAVD88. Surface water levels in the Townsend Canal are expected to range between +3 and -3 feet NAVD88. The pumping station floor level will be elevation +10 feet NAVD88, and will step up to elevation +19 feet NAVD88 in the discharge bay. The existing surrounding grades at the site of the proposed construction are approximately +22 to +23 feet NAVD88.

7.1.2.6 Culvert Structure C43S-7

This culvert structure will provide a hydraulic connection between the perimeter canal and the Banana Branch Canal. It will consist of a 222-foot long double barrel concrete box culvert that rests upon a combined footing with bottom width of approximately 26 feet. The culvert will have an invert elevation of +10 feet with respect to the NAVD88. The normal water level on the perimeter canal side of the structure will be +19 feet NAVD88. Finished grades above the culvert are expected to be about +22 to +23 feet NAVD88.

7.1.2.7 Culvert Structure C43S-9

This culvert structure will provide a hydraulic connection between the perimeter canal and the Fort Simmons Branch. It will consist of a 102-foot long double barrel concrete box culvert that rests upon a combined footing with bottom width of approximately 26 feet. The culvert will have an invert elevation of +14 feet with respect to the NAVD88. The normal water level on the perimeter canal side of the structure will be +19 feet NAVD88. Finished grades above the culvert are expected to be about +21 to +22 feet NAVD88.

7.1.2.8 Culvert Structure C43S-14

This culvert structure will provide a hydraulic connection between the perimeter canal and the Header Canal. It will consist of a 97-foot long single barrel concrete box culvert that rests upon a footing with bottom width of approximately 15 feet. The culvert will have an invert elevation of +15 feet with respect to the NAVD88. The normal water level on the perimeter canal side of the structure will be +19 feet NAVD88. Finished grades above the culvert are expected to be about +28 to +29 feet NAVD88.

7.1.2.9 Culvert Structure C43S-15

This culvert structure will provide a hydraulic connection between the perimeter canal and the Roberts Canal. It will consist of an 86-foot long double barrel concrete box culvert that rests upon a combined footing with bottom width of approximately 26 feet. The culvert will have an invert elevation of +14 feet with respect to the NAVD88. The normal water level on the perimeter canal side of the structure will be +19 feet NAVD88. Finished grades above the culvert are expected to be about +26 to +27 feet NAVD88.

7.1.2.10 Gated Culvert Structure C43S-3

This structure will consist of a gated dual culvert that will be situated in the perimeter canal and will control the water levels in the canal. It will have base dimensions of 65 feet (parallel with the canal) by 25 feet (across the canal). The

structure will bottom new elevation +11.5 feet with respect to the NAVD88. A concrete tremie seal will be placed between the structure bottom level and elevation +6.5 feet NAVD88. The ground surface elevation in the project vicinity is estimated to be +26 feet NAVD88. Surface water levels across the structure will be +23 and +19 feet NAVD88 on the upstream and downstream sides of the structure, respectively. Steel sheet piling will be used to construct wingwalls as needed. A seepage cutoff wall will be set below the upstream edge of the structure. The bottom of the cutoff wall is currently designed at elevation -1.5 feet NAVD88.

7.1.2.11 Gated Spillway Structure C43S-10

This structure will consist of a gated spillway that will be situated in the perimeter canal and will control the water levels in the canal. It will have a base slab that has plan dimensions of 64 feet (parallel with the canal) by 55 feet (across the canal). The structure will bottom near elevation +2 feet with respect to the NAVD88. A concrete tremie seal will be placed between the structure bottom level and elevation -3 feet NAVD88. The ground surface elevation in the project vicinity is estimated to be +20 feet NAVD88. Surface water levels across the structure will be +19 and +15 feet NAVD88 on the upstream and downstream sides of the structure, respectively. Steel sheet piling will be used to construct wingwalls and seepage cutoff walls. A seepage cutoff wall will be set below the upstream edge of the structure. The bottom of the cutoff wall is designed to be approximately elevation -8 feet NAVD88.

7.1.2.12 Gated Spillway Structure C43S-11

This structure will consist of a gated spillway that will be situated in the perimeter canal and will control the water levels in the canal. It will have a base slab that has plan dimensions of 75 feet (parallel with the canal) by 62 feet (across the canal). The structure will bottom near elevation -8 feet with respect to the NAVD88. A concrete tremie seal will be placed between the structure bottom level and elevation -13 feet NAVD88. The ground surface elevation in the project vicinity is estimated to be +17 feet NAVD88. Surface water levels across the structure will be +15 and +3 feet NAVD88 on the upstream and downstream sides of the structure, respectively. Steel sheet piling will be used to construct wingwalls and seepage cutoff walls. A seepage cutoff wall will be set below the upstream edge of the structure. The bottom of the cutoff wall is designed to be approximately elevation -18 feet NAVD88.

7.1.2.13 Cell 1 Main Outlet Structure C43S-1

Structure C43S-1 refers to the main operational outlet from Cell 1 to the perimeter canal. It will consist of twin concrete conduits, which will be constructed essentially at existing grade, and will be buried beneath the

perimeter dam and oriented perpendicular to the dam. The conduits will each be ten feet wide and six feet high. The outlet will include an intake structure located on the upstream side of the dam, consisting of a concrete box supported on a reinforced concrete mat foundation. The top of the box has been established at elevation +44 feet with respect to the NAVD88. The existing ground elevation in the vicinity of the intake box is estimated to be +17 feet NAVD88. The crest of the dam will have an elevation of +57 feet: NAVD88. Operational and emergency gates will be located within a control building near the center of the dam. The control works will also be supported on a reinforced concrete mat foundation. The outlet works will discharge to an impact stilling basin located on the downstream side of the dam. The stilling basin will be approximately 26 feet wide and have an invert elevation of +5 feet NAVD88. This portion of the facility will also be supported on a reinforced concrete mat foundation. The downstream water surface elevation at this structure is designed at +15 feet NAVD88.

7.1.2.14 Cell 2 Main Outlet Structure C43S-8

Structure C43S-8 refers to the main operational outlet from Cell 2 to the perimeter canal. It will consist of twin concrete conduits, which will be constructed essentially at existing grade, and will be buried beneath the perimeter dam and oriented perpendicular to the dam. The box culverts will each be ten feet wide and six feet high. The outlet will include an intake structure located on the upstream side of the dam, consisting of a concrete box supported on a reinforced concrete mat foundation. The top of the box has been established at elevation +29 feet with respect to the NAVD88. The existing ground elevation in the vicinity of the intake box is estimated to be +20 feet NAVD88. The crest of the dam will have an elevation of +57 feet NAVD88. Operational and emergency gates will be located within a control building near the center of the dam. The control works will also be supported on a reinforced concrete mat foundation. The outlet works will discharge to an impact stilling basin located on the downstream side of the dam. The stilling basin will be approximately 26 feet wide and have an invert elevation of +9 feet NAVD88. This portion of the facility will also be supported on a reinforced concrete mat foundation. The downstream water surface elevation at this structure is designed at +19 feet NAVD88.

7.1.2.15 Balancing Outlet Structure C43S-12

Structure C43S-12 refers to the operational hydraulic connection between Cells 1 and 2. It will consist of triple concrete conduits, which will be constructed essentially at existing grade, and will be buried beneath the internal dam and oriented perpendicular to the dam. The box culverts will each be ten feet wide and six feet high, and will be supported on a reinforced concrete mat foundation. The existing ground elevation in the vicinity of the spillway is estimated to be

+21 feet with respect to the NAVD88. The top of the internal dam is expected to have a crest elevation of +50 feet NAVD88.

7.1.2.16 Crest Spillway Structure C43CS-1

Crest Spillway Structure C43CS-l refers to the service spillway from Cell 1 to the Townsend Canal. It will consist of a concrete conduit, which will be constructed across the perimeter dam and oriented perpendicular to the dam. The conduit will be 12 feet wide. The invert elevation for the conduit will be set at elevation +38 feet with respect to the NAVD88. A concrete weir will be set at elevation +42 feet NAVD88. The existing ground elevation in the vicinity of the spillway is estimated to be +17 feet NAVD88. The crest of the dam will have an elevation of +57 feet NAVD88. The spillway will discharge down a concrete lined channel to a stilling basin located on the downstream side of the dam. The stilling basin will be approximately 12 feet wide and have an invert elevation of -feet NAVD88. This portion of the facility will also be supported on a reinforced concrete mat foundation. The downstream water surface elevation at this structure is designed at +3 feet NAVD88.

7.1.2.17 Crest Spillway Structure C43CS-2

Crest Spillway Structure C43CS-2 refers to the service spillway from Cell 2 to the perimeter canal. It wi11 consist of a concrete conduit, which will be constructed across the perimeter dam and oriented perpendicular to the dam. The conduit will be 12 feet wide. The invert elevation for the conduit will be set at elevation +38 feet with respect to the NAVD88. A concrete weir will be set at elevation +42 feet NAVD88. The existing ground elevation in the vicinity of the spillway is estimated to be +21 feet NAVD88. The crest of the dam will have an elevation of +57 feet NAVD88. The spillway will discharge down a concrete lined channel to a stilling basin located on the downstream side of the dam. The stilling basin will be approximately 12 feet wide and have an invert elevation of +7 feet NAVD88. This portion of the facility will also be supported on a reinforced concrete mat foundation. The downstream water surface elevation at this structure is designed at +19 feet NAVD88.

7.2 RECREATION FEATURES

The study area for the recreation benefit analysis for this project includes the counties of Lee, Collier, Hendry, Glades and portions of Charlotte county; approximately the same geographical extent as Region 9 of Florida Statewide Comprehensive Outdoor Recreation Plan (SCORP). The 2000 SCORP identifies the proposed project area as part of Region 9 comprised of Charlotte, Collier, Lee, Sarasota, Glades and Hendry counties. Recreation deficits identified by the SCORP for this region include; bicycle riding, tent camping, hiking, nature study and saltwater beach activities. Subsequent FWC and FDEP, letters included as

Addendums I and II in Recreation Appendix H demonstrate need for motor boat ramps. A statewide need assessment through 2010 identifies these deficits and the unit need for each (i.e. miles of trail and camp sites); is provided in SCORP 2000.

Some existing recreational facilities within the Caloosahatchee Basin provide opportunity to hike, boat, fish and camp. Existing recreation facilities near the project site include Ortona Lock Recreation Area, Caloosahatchee Regional Park, and WP Franklin Lock Recreational Area that are used by residents and tourists alike. The Caloosahatchee is used as a boating corridor between the east and west coasts of Florida. Boat traffic is moderately heavy with boating and fishing occurring on the river. The banks of the Caloosahatchee are too steep to be useful for bank fishing. Access for boat launch is provided at the three USACE lock structures located along the river. The FWC provides ramps at Wayside Park in Hendry County and at the intersection of SR 80 and Highland, east of Ft. Myers, in Lee County. All are well used.

The recreation activities proposed for the Caloosahatchee River (C-43) West Basin Storage Reservoir project include: nature study, multi-use trail atop the levee, equestrian use, boat and bank fishing, canoeing/kayaking, motor boating and hunting which will fit with the project purposes as managed by the SFWMD. A major recreation attraction of the Caloosahatchee River (C-43) West Basin Storage Reservoir project will be an approximately 12-mile multi-purpose trail loop atop the levee constructed as part of the project. Recreation facilities proposed include: parking and toilet facilities (clivas multrum waterless vault toilets), information kiosk, canoe/kayak launch facility, a shade structure, traffic-control fencing and a pedestrian footbridge bridge over the perimeter canal to provide public access to the reservoir.

Two handicapped accessible, double-lane public motor boat ramps would be provided; one into each of the two reservoir cells. Vehicle access will be provided via the single-lane bridge over S-10. The ramps are proposed within the reservoirs on the north levee. A paved two-lane public road will provide vehicular access to a one-lane bridge across the perimeter canal. A two-lane crushed shell road up the levee and to the ramps is proposed. Boat traffic control buoys would keep boaters clear of the reservoir structures. Signage would post warnings. The canoe/kayak launch facility would be on the perimeter canal.

Littoral areas are proposed at the corners of the seepage canal as part of the project and would provide ideal bank fishing locations outside the levee perimeter. The Florida Fish & Wildlife Conservation Commission (FWC) has endorsed the littoral shelf concept for habitat benefit and potential water quality benefits. Shades trees are proposed on the outside area of the north rim canal

adjacent to parking areas. Ample public parking will be developed outside of the north levee and perimeter canal in the general area of the construction staging location.

FIGURE 7-2: CONCEPTUAL RECREATION PLAN

7.2.1 Recreational Costs

The costs for proposed recreation features would be $2,519,000. An additional ten percent for PED, and an additional eight percent for construction supervision and administration bring the estimated total costs for recreation to $2,972,000.

The justification of incurring additional costs for recreation features is derived by utilizing a benefit to cost ratio. The tangible economic justification of the proposed project can be ascertained by comparing the equivalent average annual charges with the estimate of the equivalent average annual benefits, which would be realized over the period of analysis. These average annual recreation benefits and costs are summarized in (***Table 7-1***).

Engineering Regulation (ER) 1105-2-100 (The Planning Guidance Notebook) provides economic evaluation procedures to be used in all Federal water resources planning studies. The guidelines specified in the ER 1105-2-100 dated 22 April 2000 were observed in preparing this cost analysis. The Federally mandated project evaluation interest rate of 4 7/8 percent, an economic period of analysis of 40 years and current prices were used to evaluate economic feasibility.

TABLE 7-1: SUMMARY OF RECREATION COSTS AND BENEFITS (OCTOBER 2006 PRICE LEVEL)

Recreation Construction Costs	**$2,519,000**
PED & S/A (18%)	$453,000
Total Recreation Construction	**$2,972,000**
Construction Duration	12 months
Interest During Construction Costs	$72,000
Total Recreation Investment	**$3,044,000**
Period of Analysis	40 years
Annualized Cost	$174,000
OMRR&R	$25,000
Total Annual Costs	**$199,000**
Annual Benefits	
User Day Value	$6.79
Daily Use	145
Annual Use	52,925
Average Annual Benefit	**$359,000**

The benefit to cost ratio for the proposed recreation features is approximately 1.80, with net annual benefits equaling approximately $160,000. Therefore the Caloosahatchee River (C-43) West Basin Storage Reservoir project recreation sites are economically justified. ***Appendix H*** describes in greater detail the recreation plan and associated benefits and costs.

7.3 COST ESTIMATES

Table 7-2 includes a breakdown of the cost of the Caloosahatchee River (C-43) West Basin Storage Reservoir Project including construction, lands and damages, ecosystem restoration elements, Pre-Construction Engineering and Design (PED) costs, recreation and interest during construction. Costs are estimated at October 2006 price levels and rounded to the nearest $10,000.

TABLE 7-2: PROJECT COSTS FOR THE SELECTED ALTERNATIVE PLAN (OCTOBER 2006 PRICE LEVEL)

(Initial cost rounded to the nearest $10,000)

Ecosystem Restoration Elements	**TOTAL**
Construction	
Demolition	$70,000
Mobilization/Demobilization	$11,240,000
Relocations	$1,050,000
Site Work	$4,040,000
Reservoir (embankments, slurry wall, drains, soil cement, perimeter canal, spillways, structures, etc.)	$250,660,000
Pumping Plants	$72,820,000
Main Outlet Structures	$8,250,000
Townsend Canal Improvements	$2,000,000
Recreation	$2,520,000
Manatee Protection Structure	$2,520,000
Sub-Total Construction Cost	**$355,170,000**
Non-Construction	
Lands and Damages	$80,420,000
Planning, Engineering, and Design	$44,650,000
Construction Management	$27,000,000
Sub-Total Non-Construction Cost	**$152,070,000**
TOTAL INITIAL COST	**$507,240,000**

*The costs shown above are updated, detailed costs and are not exactly equivalent to the costs that were utilized in the Economic Appendix.

Table 7-3 includes a comparison of Yellow Book, project first cost and fully funded estimate in October 2006 price levels.

TABLE 7-3: COMPARISON OF YELLOW BOOK AND SELECTED ALTERNATIVE PLAN FIRST COST FOR CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR PROJECT (OCT 2006 PRICE LEVEL)

Component	Yellow Book	Project First Cost	Fully Funded Cost
Caloosahatchee River (C-43) West Basin Storage Reservoir	$400,000,000	$507,240,000	$565,700,000

Based on the engineering and design of the SAP for this study, the average annual cost for the SAP (Alternative 3B), is $35,100,000 that result in total average annual habitat units (HUs) of 12,809 and average annual net benefits for recreation of $160,000. The average annual cost per the combined average annual HUs generated by the project is $ 2,740.

7.4 DESIGN AND CONSTRUCTION CONSIDERATIONS

7.4.1 Engineering and Design

PED activities will be in accordance with USACE and SFWMD requirements. Preliminary design activities, which include survey and geotechnical investigations as well as cultural resources compliance, commenced in early 2004. Under the State's Acceler8 program, the SFWMD prepared a Basis of Design Report for the Caloosahatchee River (C-43) West Basin Storage Reservoir project (otherwise known in Acceler8 as the C-43 West Storage Reservoir). The Basis of Design Report includes all engineering assumptions and conceptual designs for each of the projects features. Upon reviewing the Basis of Design Report, the SFWMD will prepare initial, intermediate and final plans and specifications for construction contract award. All design work will be coordinated and reviewed with the USACE to meet USACE standards and regulations.

7.4.2 Construction and Implementation of the Plan

The non-Federal sponsor is exploring alternative project delivery methods to expedite implementation of the through the Acceler8 program. Such delivery methods may include the formation of a public-private partnership in which the non-Federal sponsor enters into an agreement or agreements with a private or not-for-profit entity for the provision of services that may include designing, building, operating or financing these components. It may also involve the non-Federal sponsor initiating construction activities prior to executing a Project Cooperation Agreement (PAC). Expedited implementation of the

Caloosahatchee River (C-43) West Basin Storage Reservoir project is in the best interest of the Federal government because it will provide early restoration benefits, potential cost savings, and reduced cash flow demands. Credit for such work is subject to the Secretary of the Army determining that the work performed was for a reasonable cost, necessary and integral to the authorized CERP project, and that the construction is consistent with applicable USACE construction standards and applicable Federal law. The non-Federal sponsor is aware that it will not receive credit for those costs unless the Congress approves the granting of the credit in law by the authorization of the Caloosahatchee River (C-43) West Basin Storage Reservoir project and the Secretary of the Army later determines the work is necessary and integral to the authorized Caloosahatchee River (C-43) West Basin Storage Reservoir project.

7.5 LANDS, EASEMENTS, RIGHTS-OF-WAY, RELOCATIONS, AND DISPOSALS (LERRD) CONSIDERATIONS

Section 601 of the WRDA of 2000 and USACE policy requires that the non-Federal sponsor will obtain and provide certification of all LERRDs necessary for project implementation.

7.5.1 Real Estate Requirements

The lands required for the recommended plan are based on an analysis of the lands needed for construction, and operation, maintenance, repair, replacement, and rehabilitation (OMRR&R) of the project. The real estate component of the recommended plan is tentative in nature for planning purposes only. Both the final real property acquisition lines and the real estate cost estimates provided herein and in ***Appendix D*** are subject to change. More detail on the real estate requirements for the recommended plan is discussed in ***Appendix D***.

7.5.2 Land Acquisition

Within the Caloosahatchee River (C-43) West Basin Storage Reservoir Project, comprised of approximately 10,700 acres, which consists of approximately 10,480 acres are required in fee, approximately 20 acres will be perpetual easements and approximately 200 acres will be used on a temporary basis for staging areas. Approximately 7,080 acres of the 10,700 acres within the project footprint were acquired under a Federal grant using a combination of State and Federal funds.

7.5.2.1 Department of Interior Grant Number LWCF-1, Addendum 3, Land and Water Conservation Act Funds

In June 1999, the DOI and SFWMD executed a grant agreement entitled Everglades Watershed Restoration-Grant Number LWCF-1, in which DOI provided $38,900,000 in Federal funds to the SFWMD for the acquisition of land

in the East Coast Buffer/Water Preserve Areas and Southern Corkscrew Regional Ecosystem Watershed Project. SFWMD matched the Federal share with a State share of $38,900,000, making the total expenditures on land acquisition at $77,800,000. This grant contained language to allow SFWMD to manage these acquired lands during an interim period defined as "...the period of time: 1) commencing a) with respect to Grant Lands, the date of purchase or date of possession under condemnation, as appropriate, and b) with respect to Match Lands, the effective date of the Grant Agreement as defined below, and 2) ending a) sixty (60) days prior to the issuance of a notice to proceed with construction phase of the District/Corps Caloosahatchee River (C-43) West Basin Storage Reservoir PIR project, at which time the Grant Land or Match Land is deemed to be 'Incorporated into a District/Corps project', or b) on the date of receipt by Interior of written notice from the Corps or the District that the particular Grant Land or Match Land is not to be included within a District/Corps project, or c) such other date agreed to by Interior and the District." .... "Upon incorporation of each Grant Land or Match Land into a District/Corps Project, such Grant Land or Match Land shall be managed in accordance with Corps approved water management and control plans and operation and maintenance manuals for the project so long as the project remains authorized."

This grant was amended in December 1999 to add an additional $13,900,000 from each of the parties bringing the total to $105,600,000. The grant was amended again in April 2000 to add an additional $18,900,000 from each of the parties bringing the total to $143,000,000. This additional $38,900,000 was to be used to purchase the Berry Groves property (C-43) West Basin Storage Reservoir Project). The DOI's additional $18,900,000 in funding came from Land and Water Conservation Funds provided to the DOI by Congress. The last amendment to this grant was executed in June 2001 with each party contributing an additional $5,974,000 bringing the total State and Federal funding under the grant to $155,348,000. Not all the lands covered in this grant agreement are within the footprint of the Caloosahatchee River (C-43) West Basin Storage Reservoir Project.

A total of $$27,567,669 in Federal funds was utilized to acquire approximately 7,080 acres, within the 10,700 acres within the project footprint, which will be credited to the Federal government.- These costs include both the land acquisition cost as well as the cost of any improvements and a major portion of SFWMD's administrative costs for the acquisition of the lands. This amount may be increased or decreased based on a more detailed analysis during the crediting review process after approval of the project, execution of a PCA and certification of the land.

A thorough discussion of this act, the Federal Grant, and its effects on this project are located in ***Appendix D***.

7.5.3 Hazardous, Toxic and Radioactive Waste

The existing conditions section of this document (**Section 2**) includes a summary of the Phase I/II Environmental Site Assessment (ESA) studies done on the five properties acquired (totaling approximately 12,372 acres) or being acquired (totaling approximately 600 acres) for the reservoir project. These are the Berry Groves tract composed of approximately 9,000 acres, the Bryan Paul Grove tract composed of approximately 600 acres, which has not been acquired, the MG Enterprises LLC property composed of approximately 2,399 acres, and the Griffin property, composed of approximately 954 acres. In the course of these studies, over 50 point source sites with potential HTRW contamination were identified. At this time, most if not all of these potential contamination sites have been either remediated or further investigated to characterize the sites and prepare remediation plans. The project sponsor, the SFWMD, has made a commitment to the USACE and USFWS that after it takes control of the properties from the present lessees and begins construction of the reservoir, all of the outstanding point source remediation efforts will be completed. In addition to the point source contamination sites, the SFWMD also identified distributed soil contamination in portions of the cultivated areas on all of the acquired properties. The remediation of the cultivated soil sites involves the placement of these soils into the core of the reservoir dam. This will isolate the contaminated soils from benthic organisms that serve as food for higher level organisms and thus reduce the potential for bioaccumulation of contaminants by fish and wildlife. In accordance with USACE policy, costs incurred by the non-Federal partner to characterize and remediate environmental contamination will not be cost-shared.

The USFWS has reviewed all of the SFWMD's remediation plans and indicated that they believe that the efforts will sufficiently reduce the risk of harm to fish and wildlife in those areas where the remediation will be performed. The USFWS has also stated that moderate levels of copper and other contamination of the cultivated areas are believed to not pose a direct threat to species of concern; however, they believe that an indirect effect may occur since widespread low-level soil contamination may reduce the population of benthic organisms upon which the species of concern normally feed.

Despite the diligent work performed by the SFWMD and USFWS to reduce the risk to environmental resources, it is possible that once the reservoir is built bioaccumulation of soil contaminants will result in harm to one or more species of interest. If this does happen, additional remediation efforts, such as more extensive removal of the reservoir bottom sediments could be performed to further reduce the exposure of benthic organisms to near surface soil

contamination. The cost of additional remediation, if necessary, would be the responsibility of the non-Federal sponsor. If such remediation is necessary, it may be schedule in one cell at a time, possibly during the late dry season, thereby keeping the reservoir somewhat operational. In accordance with Corps policy, costs incurred by the non-Federal sponsor to characterize and remediate environmental contamination will not be cost-shared.

A summary of the proposed SFWMD remediation efforts and USFWS opinions for each property are included below.

7.5.3.1 Berry Groves Property

The most environmentally significant soil contamination was found on the Berry Groves property which had elevated levels of copper contamination distributed over a large fraction of the approximately 9,000 acres. As part of an Environmental Risk Assessment (ERA) study, the SFWMD estimated an interim screening concentration for risk to the snail kite to be 85 mg/kg. After extensive grid based testing, the SFWMD identified approximately 300 acres of groves located within the footprint of the planned reservoir that exceed the interim screening concentration of 85 mg/kg. The copper contaminated grids cells (50 acres in size) are identified as the entirety of numbers 124, 125, 134, 135, 143, and the southern half of 56 and 58. In addition to these heavily copper contaminated grid cells, the geometric mean copper concentration in the Berry Groves property was calculated to be 51.9 mg/kg. This exceeds the threshold effects concentration (TEC) 32 mg/kg for benthic organisms.

To remediate the 300 acres of the Berry Groves property that exceed the interim screening criteria, the SFWMD proposed that one foot of topsoil be scraped and placed within the core of the reservoir levee as construction progresses. The intent is to isolate these soils from benthic organisms that typically live in sediments within one to two feet of the sediment/water interface. Since benthic organisms would not typically be present in the core of the levee, the potential for bioaccumulation of copper by these organisms and the later biomagnification of these contaminants by higher tropic levels will be much less than if the soils are left in place.

The USFWS reviewed the SFWMD's plan to place the contaminated soils from the 300 acres into the core of the levee and they agreed that this will reduce the copper concentrations in the affected grids to below the interim screening value for risk to the snail kite. However, the USFWS also believes that while remediating the 300 acres with the highest levels of copper concentration will likely protect the snail kite, the property-wide average copper concentration of 45 mg/kg will still exceed the TEC of 35 mg/kg for benthic organisms. The USFWS concludes that direct impacts to the snail kite are not likely, but indirect

impacts are likely since the food base for the snail kite will be reduced as a result of the elevated property-wide copper concentration.

7.5.3.2 Griffin Property

Five areas of potential concern including the cultivated areas, canal sediments, maintenance area/chemical barn, fertilizer mix/load area, and burn area were identified in the Phase I/II ESA studies. The investigation of the cultivated areas indicated that though there is evidence of residual pesticide contamination, the detected concentrations of persistent pesticides were not above the levels of concern. Aldicarb was detected at a concentration above the site-specific Florida Sediment Quality Assessment Guidelines (SQAG); however, this was not of great concern because discontinuing its use would likely result in much lower residual concentrations since this pesticide readily degrades.

The Phase II audit recommended that remediation be performed at the maintenance/chemical barn area and the burn area. The remediation plan for the maintenance area/chemical barn area requires the excavation and proper disposal of 140 tons of soil that is contaminated with petroleum products. Two groundwater monitoring wells will be installed at this site. Samples from the monitoring wells will be analyzed for petroleum products, organophosphorous pesticides, lead, arsenic, copper, and zinc. The remediation plan for the burn area requires the excavation and proper disposal of 50 tons of soil. One groundwater monitoring well will be installed at this site. Samples from this well will be analyzed for copper.

Based on a review of the Phase I/II ESAs and proposed remediation efforts, the USFWS indicated in a letter to the SFWMD (dated October 12, 2004) that incorporation of the Griffin property into the reservoir project would not pose a threat to listed species.

7.5.3.3 MG Enterprises LLC, also known as the Winthrop Property

Five areas of potential concern including the cultivated areas, canal sediments, two agricultural maintenance areas and the exploratory oil/gas well were identified in the Phase I/II ESA studies. The investigation of the cultivated areas indicated that though there is evidence of residual aldrin contamination in one sample, the risk to avian species was not significant. Aldicarb was also detected above levels of concern; however, the cessation of its use was considered by the SFWMD to be an adequate remediation method since this compound readily degrades.

Of the point source contamination sites, the two maintenance areas were identified as requiring remediation. The remediation plan for Maintenance Area A requires the excavation of approximately 300 tons of topsoil that is

contaminated with pesticide residue and petroleum products. Contaminated soils will be disposed of offsite. Clean fill will be placed and at least two monitoring wells will be installed to monitor for contamination of the surficial aquifer by petroleum products, pesticides, copper, lead, and zinc. The remediation plan for Maintenance Area B requires the excavation and proper disposal of 300 tons of contaminated soil. Clean fill will be placed and two monitoring wells will be installed to monitor for contamination of the surficial aquifer by petroleum products, and lead.

The USFWS, in a July 14, 2003 letter, indicated that the proposed remediation methods for the aldicarb and paraquat on the cultivated areas and the soil removal at the maintenance area should reduce the risk to benthic organisms from exposure to the detected contaminants. After review of the ESA studies the USFWS agreed (letter to Robert Kukleski, SFWMD, dated July 1, 2004) that the risk presented by aldrin contamination was not significant.

7.5.3.4 Bryan Paul Property

In a summary of the Phase I/II ESA studies, the SFWMD (internal memo dated August 24, 2004, from Robert Taylor to Ruth Clements) identified ten remediation actions that would have to occur to make the Bryan Paul property suitable for use in the reservoir project. The identified actions are cleanups at the nursery barn, C-1 mix station, graded area, auxiliary tank area, cultivated citrus area, burn area, and canal sediment sampling site. Tasks included removing the well/septic tank and the above ground storage tanks (ASTs). The total projected cost of these actions was $565,000. Of this amount approximately $90,000 could be attributed to actions required if the future land use of the property was agricultural or residential. The remaining expense is necessary only if the future land use would be water storage or natural use.

The most expensive remediation action required on this property is the removal and disposal of two feet of top soil from approximately 20 acres of cultivated land. This soil is contaminated with chlordane. The SFWMD has proposed that this soil be excavated and placed within the core of the reservoir's dam. In a letter to the SFWMD dated August 9, 2006, the USFWS states that it agrees with the SFWMD's proposed cleanup target level of 18 ug/kg. The USFWS also concurs that placing the contaminated soils within the reservoir dam is an appropriate remediation technique.

7.5.4 Relocation Assistance

In accordance with the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, as amended (Public Law [PL] 91-646), relocation assistance is required to be provided to affected residents and business. Information provided by SFWMD indicates that there is no relocation or

displaces. Upon certification of the LERRD, SFWMD will be required to demonstrate compliance with the requirements of PL 91-646 including that landowners have been properly advised of their rights under the program and that which evidence appropriate benefit determinations. To include:

- Number of persons, farms, and businesses displaced.
- Estimate of all PL 91-646, Title II costs and contingencies.
- Discuss/describe availability of replacement housing and any need for last resort housing benefits.

Based on current information, it appears that there were no relocation assistance payments made or required.

7.6 OPERATIONS AND MAINTENANCE CONSIDERATIONS

The SAP will be operated in a manner consistent with the original design intent for the Caloosahatchee River (C-43) West Basin Storage Reservoir project components included in the 1999 Comprehensive Review Study Report. In very brief summary, the Caloosahatchee River (C-43) West Basin Storage Reservoir project will be operated to capture regulatory releases from Lake Okeechobee (via pumping station) and to collect and store basin runoff from the lower southwestern Caloosahatchee River Basin currently discharged to the Caloosahatchee River (C-43 Canal) through existing canal systems and natural drainage ways. The reservoir will be operated to collect and store water during the wet season, then release the water when needed during the dry season to meet estuarine demands by helping to maintain a minimum flow of 450 cfs at S-79. Since the reservoir's perimeter canal serves as a means of conveying both surface storm water runoff and off site flows entering the project several canals discharge to and from the reservoir's perimeter. Additional details about project operations are included in ***Annex D*** (Draft Operating Manual).

7.6.1 Operations and Maintenance Costs

Annual operations and maintenance (O&M) costs were estimated for the construction features of the recommended plan for Caloosahatchee River (C-43) West Basin Storage Reservoir Project. The O&M costs were determined by extrapolation from operational costs histories supplied by the SFWMD using industry standard cost data and data from past and projected cost trends. O&M activities include such items as mowing, erosion control, pump maintenance, levee road maintenance, and building maintenance. The annual (OMRR&R) costs are estimated to be $3,000,000 (rounded to the nearest $10,000), which includes ecologic and water quality monitoring associated with the project level Adaptive Program described in ***Annex D***. Recreation OMRR&R costs have been estimated at approximately $25,000. The non-Federal sponsor is responsible for 100 percent of the OMRR&R recreation costs.

7.6.2 Monitoring and Adaptive Management Costs

The estimated cost for water quality during the initial year is $610,000, which would be construction funded. The estimated cost for water quality monitoring during operations of the project is $604,000 per year, which would be OMRR&R funded. The water quality monitoring plan is included in Annex D. The Ecological monitoring plan (also in Annex D) includes recommendations for salinity, oysters, SAV, fish, and estuarine water quality. This ecological monitoring plan is not recommended for funding by this project. It has been recommended to RECOVER for funding as part of the Monitoring and Assessment Plan (MAP). Most of the ecological monitoring recommended for the Caloosahatchee Estuary is already currently recommended by the MAP. A hydrologic monitoring plan is also included in Annex D which includes recommendations for monitoring of reservoir water level, flow, groundwater, weather, and structures. This cost is included in the OMRR&R estimate cited above in 7.6.1.

7.7 PLAN ACCOMPLISHMENTS

The SAP affirmed that an above-ground storage reservoir (including pump stations and water control structures) and associated conveyance can meet the needs of the Caloosahatchee Estuary at the right time, and is a cost-effective solution to achieving system-wide benefits in Caloosahatchee River, estuary and the south Florida ecosystem. In addition, the plan helps achieves the benefits of the project as previously developed for CERP.

The SAP includes a key component that was identified in the Restudy and helps to promote a salinity balance in the Caloosahatchee Estuary that will provide for vegetation, fish and wildlife habitat restoration functions that are critical to the continual health and development of the estuary. The additional water injected into the estuary's natural system areas are key aspects of restoration planning for the Caloosahatchee Estuary. The Caloosahatchee Estuary is part of south Florida's fragile ecosystem and has long been recommended as a management measure to achieve restoration objectives. Based on a salinity model, the area within the Caloosahatchee Estuary system beneficially affected by the project conservatively encompasses at least 71,000 acres in the Caloosahatchee River, San Carlos Bay, and a portion of Pine Island Sound, although in all likelihood the area beneficially affected by project implementation will be much larger, including portions of Pine Island Sound, Estero Bay, and the Gulf of Mexico. These acres are within the navigable waters of the United States and within the navigational servitude of the United States.

Two planning goals and seven planning objectives have been established for CERP projects through the Restudy. The two planning goals are: (1) enhance ecological values and (2) enhance economic values and social well-being. The

SAP for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project positively contributes to both of these goals and all seven of the objectives originally established for these two underlying planning goals.

7.7.1 Relationship of Other Projects in CERP to Caloosahatchee River (C-43) West Basin Storage Reservoir Project

The intent of Caloosahatchee River (C-43) West Basin Storage Reservoir Project is to meet the immediate needs of the Caloosahatchee Estuary and thereby show ecosystem restoration benefits in the estuary. Construction and implementation of the reservoir and the subsequent achievement of estuarine benefits are not dependent on CERP being in place. The implementation or non-implementation of CERP will not diminish benefits achieved by the Caloosahatchee River (C-43) West Basin Storage Reservoir. The need for additional storage to prevent harmful discharges to the natural system and improve the timing and quality of water delivered to the natural system is well-established as a basic premise of the CERP.

7.7.2 Project Justification: Next-Added Increment

7.7.2.1 Next–Added increment Analysis

Section 385.26 of the CERP Programmatic Regulations requires the development of a series of programmatic guidance memoranda (GM) that includes guidance for performing plan formulation and evaluation process and next-added incremental (NAI) justification. The CERP Programmatic Regulations requires a NAI evaluation of the Tentatively Selected Plan (TSP) as is defined in the CERP Programmatic regulations as "the next project to be added to a system of projects that includes only those projects that have been approved according to general provision of law or specific authorization of Congress and likely to be implemented by the time the project being evaluated is completed." The NAI analysis evaluates the effects, or outputs, of the TSP as the next project to be added to the group of already approved CERP projects. This analysis helps illuminate the amount of benefits the SAP contributes without regard to future CERP projects. It also helps to ascertain whether sufficient benefits would accrue to the SAP to justify the cost if no additional CERP projects (other than those already existing or authorized) were implemented. In the case of this analysis no other CERP projects are assumed to exist for the purposes of the NAI analysis.

The Caloosahatchee River (C-43) West Basin Storage Reservoir project aims to 1) reduce harmful discharges to the Caloosahatchee Estuary by capturing some high flow releases from Lake Okeechobee and basin runoff from the lower West Caloosahatchee River Basin during the wet season, 2) storing the water till needed in a reservoir and 3) provide incidental water deliveries to supplement

river flows over S-79 to Caloosahatchee Estuary during the dry season, thereby reducing stress on the natural system due to low flows which allowed increased salinity levels to occur in the estuary. The SAP affirmed that a reservoir and discharging to better meet the needs of the basins at the right time, together is a cost-effective solution to achieving system-wide benefits in the south Florida ecosystem. In addition, the plan achieves the benefits of the project as previously developed for the CERP.

Alternative 3C was identified as the NER plan that provides the maximum net environmental benefits on a system-wide basis. Alternative 3B, which is a variant of Alternative 3C, is a cost effective plan that will provide environmental benefits on a system-wide basis, has a lower project cost, is a part of an incremental adaptive restoration approach and is justifiable alternative. The project is justified by its beneficial effect on seagrass habitat, an important indicator of estuarine ecosystem function. The NAI condition produces more total benefits than seen in the system-wide analysis.

The system-wide formulation was conducted to determine the input for the CE/ICA and assist in the selection of the recommended plan. An additional analysis was also conducted to use in justifying and describing the benefits of the Caloosahatchee River (C-43) West Basin Storage Reservoir as a stand-alone project without the system-wide benefits attributed to other CERP projects, otherwise known as the NAI analysis. This analysis was completed for all the alternatives that were evaluated under the system formulation. This was done to demonstrate that all alternatives would have similar benefit outputs during the NAI as they do with the system-wide formulation analysis.

An identical method was used for the NAI as was used for the system formulation. As described in the system formulation analysis, five attributes were studied to determine system response. Oysters, *Vallisneria*, seagrasses, extreme events and EST05 were all measured and compared to 2050 in order to determine the benefit lift for the TSP (***Table 7-4***). This methodology is described in the environmental benefits evaluation section.

Although the NAI and system formulation analysis are listed below, this is not a valid comparison due to different sources of data for the two analyses. Therefore, even though the HSIs are similar, the total project average annual HUs are based on different 2050 model conditions, resulting in a larger lift for the NAI analysis. The NAI analysis reflects 28 percent more benefits than the system-wide formulation. There are several variables which could explain the higher benefits with the NAI approach. The first and most influential of these results from the rest of CERP's impact on the overall water budget provided to the Caloosahatchee River (C-43) basin. The system-wide analysis has a lower water budget than the NAI analysis, leading to diminished dry season

conditions. The other variances may stem from differing models being utilized for the benefit analysis. The system-wide analysis utilized the MIKESHE model and the NAI run utilized spreadsheet flow models, which utilized flows from the SFWMM and is further described in ***Section 8*** and ***Appendix A***.

TABLE 7-4: COMPARISON OF NAI AND SYTEM FORMULATION SCORES

Alternative	Oyster	*Vallisneria*	Seagrasses	Extreme Events	EST05	Total Project Average Annual Habitat Units
3B – System-wide	.60	.33	.59	.43	.70	12,809
3B – NAI	.23	.60	.52	.24	.71	15,297

7.7.2.2 Next–Added increment Analysis Conclusions

Both the system formulation and the NAI evaluations of Alternative 3B (SAP) demonstrate significant ecological benefits due to implementation of the Caloosahatchee River (C-43) West Basin Storage Reservoir Project.

It was determined through this analysis that there are benefits associated with the NAI analyses completed for the West Basin Storage Reservoir Project. Overall, the project design is consistent with attaining project goals and objectives. Operational flexibility will lead to increased benefits by further minimizing potential high flows to the estuary as well as by minimizing discharges (and associated sediment loads).

In comparing the NAI benefits with the system-wide analysis it can be noted that there is a perception of more benefits realized in the NAI analysis. There were approximately 12, 809 average annual HUs calculated for the system-wide analysis compared to the 15,300 average annual HUs in the NAI analysis. In reality the NAI and system-wide HSI scores are relatively close. ***Table 7-5*** presents a summary of the raw HSI scores for both the NAI and system-wide calculations.

TABLE 7-5: SUMMARY OF RAW HSI SCORES

	SYSTEM WIDE FORMULATION			NAI ANALYSIS		
	2000	2050	ALT 3B	2000	2050	ALT 3B
Vallisneria	0.16	0.20	0.33	0.03	0.08	0.60
Seagrasses	0.51	0.54	0.59	0.49	0.51	0.52
Oysters	0.48	0.52	0.60	0.52	0.52	0.23
Extreme Events	0.28	0.30	0.43	0.22	0.24	0.24
EST05	0.38	0.43	0.70	0.20	0.21	0.71

The Caloosahatchee River (C-43) West Basin Storage Reservoir project NAI analysis demonstrates that as a stand-alone project, all of the benefits achieved in the system-wide formulation process were met or exceeded. The NAI analysis yields a greater average annual HU lift than the system-wide analysis. The reason behind the additional benefits calculated during the NAI analysis is due to different water budgets afforded to the model for both the system-wide and NAI computations, stemming from demands on Lake Okeechobee. The variables in the water budget reflect additional demands from CERP features located outside the Caloosahatchee River (C-43) West Basin Storage Reservoir study area. This additional water being supplied to other CERP features in the system-wide analysis leads to a lower potential benefit to the study area. This does not imply that the West Basin Storage Reservoir is operating less efficiently as part of the CERP system, but instead illustrates difficulties in comparing model results when the boundary conditions are not consistent.

The system-wide analysis does not capture all of the benefits that are being provided to the other CERP features by limiting the water available to the Caloosahatchee River (C-43) West Basin Storage Reservoir study area, and mainly aims to capture the direct benefits to the study area. Due to the nature of the models and uncertainty in the independent CERP features included in the system-wide analysis it was not practicable to characterize all of the benefits. If all of the benefits to the other conceptual CERP features were characterized, it is fully expected that the cumulative system-wide benefit analysis would exceed the cumulative NAI benefits.

Total system-wide analysis includes each of the projects that are affected by the water budget changes reflected in the modeling. The NAI analysis does not include these other projects shifting water from the Caloosahatchee River (C-43) West Basin Storage Reservoir study area, so it is likely that the additional benefits calculated in the NAI analysis result from the difference in the water budget in the system-wide and NAI analysis, and are not directly related to the features in the NAI analysis.

The conclusion from this analysis is that as a stand-alone project the Caloosahatchee River (C-43) West Basin Storage Reservoir will be efficient and effective at meeting the goals and objectives of the project. The risk of being unable to obtain project benefits is expected to be minimal.

7.8 CONTRIBUTION TO ACHIEVEMENT OF INTERIM GOALS AND TARGETS

Section 601(h)(3)(C)(III) of the WRDA 2000 (PL 106-541) required the CERP Programmatic Regulations to include the "establishment of interim goals to provide a means by which the restoration success of the Plan may be evaluated

throughout the implementation process." Section 385.38 of the CERP Programmatic Regulations (33 CFR Part 385) further describes the intent and the underlying principles for establishing interim goals and a process for developing them. Section 385.39 of the CERP Programmatic Regulations also established the requirement to develop interim targets to measure progress toward meeting the other water-related needs of the south Florida region, and describes the intent, underlying principles, and the process for establishing interim targets.

Consistent with the processes for developing interim goals and targets required in the CERP Programmatic Regulations, RECOVER issued a final report containing recommendations for interim goals and targets on February 17, 2005. The RECOVER report was then utilized to develop the Interim Goals and Interim Targets Agreements and will be updated after the final PIR is completed and when the agreements are finalized.

For the purposes of this PIR the project delivery team (PDT) utilized the RECOVER report to evaluate the progress towards the interim goals and interim targets. Interim goals for evaluating progress toward the restoration of the south Florida ecosystem are recommended for the Northern Estuaries, Lake Okeechobee, the Everglades, and the Southern Estuaries. Interim targets for water supply and flood protection are also recommended.

7.8.1 Progress toward Interim Goals

Although the Caloosahatchee River (C-43) West Basin Storage Reservoir project will create minor hydrologic and ecosystem response effects throughout a large portion of the south Florida ecosystem due to the interconnectedness of the regional water management system, the magnitude of the project's contribution toward restoration objectives for the Northern Estuaries, Lake Okeechobee, and the Southern Estuaries is relatively insignificant when considered with other components which were specifically included in the Plan to beneficially affect those areas. However, the Caloosahatchee River (C-43) West Basin Storage Reservoir Project's effects on fish and wildlife habitat functions in the Northern Estuaries, specifically the Caloosahatchee Estuary, are quite significant. Accordingly, this applies to the project's effects on the twelve "Everglades Restoration Indicators" listed in RECOVER's Interim Goals and Interim Targets report, which in general are indicators of effects on hydrology, water quality, and biological response. The interim goal indicators for the Everglades included in RECOVER's February 17, 2005 report are listed in ***Table 7-6.***

TABLE 7-6: EVERGLADES INTERIM GOAL INDICATORS

No.	*Indicator*
1.1	American Oysters in Northern Estuaries
1.2	Submerged Aquatic Vegetation in Northern Estuaries
3.1	Water Volume
3.2	Sheet Flow in Natural Areas
3.3	Hydropattern
3.4	System-Wide Spatial Extent of Habitat

In general, the Caloosahatchee River (C-43) West Basin Storage Reservoir project will result in improvement in ecosystem function and will create a substantial incremental contribution toward the achievement of the interim goals for ecosystem restoration in the Northern Estuaries. The project's contributions toward the achievement of interim goals for the restoration of the south Florida ecosystem are assessed by evaluating the effects on the above-listed indicators. Although not all of the indicators were quantitatively assessed using hydrologic-based performance measures during plan formulation and evaluation work, a qualitative assessment was performed for all of the Everglades interim goals indicators. Due to the magnitude of hydrologic change necessary to meaningfully affect some of the indicators and the actual hydrologic effects predicted to result from implementation of the Caloosahatchee River (C-43) West Basin Storage Reservoir Project, it is not expected that the project will affect all of the indicators equally. Detailed information about the performance measures and methodologies used to evaluate and compare alternative plans can be found in ***Appendix C*** (Environmental Information). ***Table 7-7*** is a summary of the Caloosahatchee River (C-43) West Basin Storage Reservoir Project's effects on Northern Estuaries indicators.

TABLE 7-7: PROJECT EFFECTS ON EVERGLADES INTERIM GOALS AND INDICATORS

No.	*Indicator*	*Project Effects*
1.1	American Oysters In Northern Estuaries	The reduction in number and duration of high flow events reduces low salinities and creates favorable conditions for oyster recruitment that will lead to increased diversity and abundance of estuarine fauna. The reduction in low flow events reduces high salinities and will benefit oyster populations by killing predators, reducing disease and diminishing predation pressure on oyster spat allowing greater recruitment.
1.2	Submerged Aquatic Vegetation in Northern Estuaries	The reduction in the number and duration of high flow events reduces low salinities and creates favorable conditions for more extensive seagrass beds including shoal grass (*Halodule wrightii*), turtle grass (*Thalassia testudinum*) and manatee grass (*Syringodium filiforme*) that are an important habitat for a variety of estuarine invertebrate and vertebrate species, including some commercially and recreationally important fishes. The reduction in low flow events reduces high salinities and will lead to more extensive tape grass (*Vallisneria americana*) beds and greater ecological function.
3.1	Water Volume	170,000 ac-ft of storage capacity.
3.2	Sheet Flow in Natural Areas	No change; project does not include removal of barriers to sheet flow.
3.3	Hydropattern	The reduction in the number and duration of extreme high and low flow events will improve quantity, timing and distribution of freshwater flows to Caloosahatchee Estuary which will lead to increased diversity and abundance of estuarine flora and fauna.
3.4	System-Wide Spatial Extent of Habitat	The reduction in extreme high and low flow events will significantly benefit the valued ecosystem components such as tape grass (*Vallisneria americana*), shoal grass (*Halodule wrightii*), turtle grass (*Thalassia testudinum*) manatee grass (*Syringodium filiforme*) and the American oyster (*Crassostrea virginica*) which are crucial to maintaining the ecological structure and function of the estuary by providing food, living space and foraging sites for other naturally occurring estuarine species.

7.8.2 Progress toward Interim Targets

To evaluate project effects on progress toward meeting CERP objectives for other water-related needs of south Florida, eight interim target indicators were recommended by RECOVER in the February 17, 2005 report. The interim targets were developed using the Yellow Book version of the 2x2 model run which limited some of the information to certain geographic areas. The only performance measures available for flood control were for the southern Dade area so there is not an interim target to compare to in the Caloosahatchee River (C-43) West Basin Storage Reservoir project area. The severity and duration of water restrictions when drought levels exceed a one-in-ten condition need to be reviewed to determine the full extent of predicted water supply impacts in the

Caloosahatchee River (C-43) basin. To perform a review based on supply-side management, raw or post-processed data that will allow the determination of monthly demand volume, number of days per month with cutbacks (demands not met), and volume of cutbacks (demand not met) per each month is required. Since this data is not readily available from MIKESHE output, annual average volumes were evaluated. The average annual volumes will not allow for a determination of differences in alternative performance regarding water supply deliveries. However, of the eight indicators, the Caloosahatchee River (C-43) West Basin Storage Reservoir project is expected to improve surface water annual average volumes deliveries to agricultural users in the Caloosahatchee East and Caloosahatchee West basins. The project is expected to slightly increase groundwater average annual volumes agricultural demand over the 2050WO in the Caloosahatchee East Basin without significantly affecting performance. Detailed information about the project's effects on sources of water for supply, aquifer protection and flood damage reduction can be found in ***Annex C***. ***Table 7-8*** is a summary of the Caloosahatchee River (C-43) West Basin Storage Reservoir Project's effects on applicable interim targets indicators.

TABLE 7-8: PROJECT EFFECTS ON INTERIM TARGETS INDICATORS

No.	*Indicator*	*Project Effects*
5.1	Water Volume	Effects unknown due to absence of adequate evaluation tools.
5.2	Water Supply for Lower East Coast Service Area	Not applicable to this geographic area
5.3	Water Supply for Lake Okeechobee Service Area	Effects unknown due to absence of adequate evaluation tools.
5.4	Protect Biscayne Aquifer from Saltwater Intrusion	Not applicable to this geographic area.
5.5	Protect Southern Portion of Biscayne Aquifer from Saltwater Intrusion	Not applicable to this geographic area
5.6	Flood Control: Root Zone Groundwater Levels in South Miami-Dade Agricultural Area East of L-1N	Not applicable to this geographic area
5.7	Flood Control: Groundwater Stages for Miami-Dade, Broward, Palm Beach, and Seminole Tribe Surface Water Management Basins	Not applicable to this geographic area
5.8	Flood Control: Flood Water Removal Rate for Everglades Agricultural Area (EAA)	Not applicable to this geographic area

7.9 SUMMARY OF ECONOMIC, ENVIRONMENTAL, AND OTHER SOCIAL EFFECTS

7.9.1 Other Social Effects

The Caloosahatchee River (C-43) West Basin Storage Reservoir Project alternative restoration plans could result in beneficial and adverse Other Social Effects (OSE) within the study area. As is evident throughout this appendix, a variety of positive and adverse NED impacts on water supply, flood damage reduction and recreation are expected to result from the reservoir construction. Similarly, the alternative restoration plans could have positive or adverse OSE impacts on the study area associated with (1) plan implementation, including land acquisition, project construction, and O&M activities, and (2) operation of the modified C&SF system. As in the case of the NED effects, the OSE account is concerned with the net effects of the alternative plans (i.e., the differences between the with- and without-project future conditions).

Some of the potential OSE impacts would occur primarily at the regional scale, and others would have more localized effects. At both scales, there may be some individuals and communities that are positively affected by project implementation, some that are adversely affected, and many that are not affected at all. Relative to the size of the regional or local economies, the OSE effects may be minimal. However, if these effects occur predominantly within a limited geographic area, or affect a relatively small or vulnerable population, then the impacts can be disproportionately large. Therefore, the purposes of

OSE analysis include not only determining the total magnitude of potential impacts, but also identifying the population (and its characteristics) that would be affected by any proposed action.

Some of the categories of effects typically included in the OSE account do not pertain to the alternative restoration plans. For example, the alternative plans are not expected to affect energy use or energy conservation in the study area. As will be noted, other categories of potential OSE impacts have been addressed and can be found in ***Appendix G***.

7.9.2 Environmental Justice

Executive Order (E.O.) 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations, requires the Federal government to achieve environmental justice by identifying and addressing high, adverse and disproportionate effects of its activities on minority and low-income populations. E.O. 12898, Environmental Justice, states that the proposed action would not result in adverse human health or environmental effects. Any impacts of the action would not be disproportionate towards any minority or low-income population. The activity does not (a) exclude persons from participation in, (b) deny persons the benefits of, or (c) subject persons to discrimination because of their race, color, or national origin. The activity would not impact "subsistence consumption of fish and wildlife." It requires the analysis of information such as the race, national origin, and income level for areas expected to be impacted by environmental actions. It also requires Federal agencies to identify the need to ensure the protection of populations relying on subsistence consumption of fish and wildlife, through analysis of information on such consumption patterns, and the communication of associated risks to the public.

The Caloosahatchee River (C-43) West Basin Storage Reservoir project will provide benefits to quality of life by improving the natural environment in which we live. The project improves flows to the estuary. This is achieved through a reservoir which is located in a rural area so that negative impacts are minimized for all communities. The project is a Congressionally approved project funded with Federal and State dollars to make improvements to hydrology for people and the environment.

In public outreach efforts to date, only one potential environmental justice issue has been identified: the loss of jobs for low income and minority workers as a result of acquiring agricultural land for the construction of the reservoir. The expected loss in employment will occur to seasonal and/or temporary migrant workers, and as can be noted in the future land use section agricultural acreage in the surrounding study area and counties is expected to increase. The Caloosahatchee River (C-43) West Basin Storage Reservoir Project PIR and EIS is an opportunity to somewhat alleviate this potential problem by providing jobs

within and during construction of the project, some of which could provide seasonal and temporary employment. To address this issue the SFWMD is conducting training programs to allow local individuals to acquire the skills needed to construct the reservoirs. In addition, it is anticipated that adjacent lands will continue to support agricultural operations.

The reservoir does not present any environmental impacts that are high, adverse and disproportionate to low income, minority or Tribal populations. Through the public participation process of the outreach and NEPA scoping no high and adverse impacts became known. There was sufficient public input to feel confident that scoping was successful and that the breadth of the potential impacts were communicated and understood by the public. Thus this NEPA process has found no evidence of high, adverse and disproportionate impacts.

The reservoir site is located based upon hydrologic characteristics, land availability and interconnection to existing canals and structures to optimize operations. Furthermore, in the consideration of the project site, urban areas are avoided to eliminate the negative impacts typically associated with site location of large projects. Through "willing seller agreements" a variety of land rights have been or will be acquired that allow the use of land for the resulting improvements to the human quality of life and the intended environmental benefits intended by the impoundment.

These environmental benefits provide quality of life improvements to all people and primarily to people in the communities within the study area. By the nature of design, this operating procedure will maintain if not improve flood damage reduction. This will improve the quality of human life by providing increased wildlife activity; a special bonus for those who appreciate seeing increases in fish and bird populations. This logically translates to the increased benefits in enjoyment, aesthetics, and economics for recreational activities.

7.10 SIGNIFICANCE OF HABITAT

The Selected Alternative Plan is consistent with each of the USACE "Environmental Operating Principles" particularly with respect to the south Florida ecosystem-wide approach for plan formulation, evaluation, and selection, and a holistic consideration of water resources needs and solutions to water resources problems in the study area.

Principle One: **Strive to achieve environmental sustainability**. An environment maintained in a healthy, diverse condition is necessary to support life.

Natural resource specialists agree that the remaining ecosystems in south Florida no longer maintain the functions and richness that defined the pre-

drainage system. These measures of ecological health will continue to decline without preventative actions. Not only is it certain that these natural systems will not recover their defining attributes under current conditions, it is unlikely that the current, degraded ecological conditions can be sustained in the future.

The SAP contributes to the restoration of the Caloosahatchee Estuary by capturing high-volume flows released from Lake Okeechobee and basin run-off and storing this excess water to provide flows during the dry season to provide supplemental flows over S-79 to maintain correct salinity balance in the estuary.

Principle Two: **Recognize the interdependence of life and the physical environment.** Proactively consider environmental consequences of USACE programs and act accordingly in all appropriate circumstances.

Life within the Caloosahatchee Basin is dependent on the river as a source to meet drinking water and irrigation needs. The USACE currently manages Lake Okeechobee as well as the Caloosahatchee River (C-43). As a result of conditions within the lake and the lake infrastructure, large regulatory releases are required to maintain lake levels within acceptable safety parameters.

The Caloosahatchee River (C-43) West Basin Storage Reservoir will provide immediate benefits to the Caloosahatchee Estuary, a part of the South Florida Everglades Ecosystem. The damaging estuarine effects of basin run-off and water releases from Lake Okeechobee will be reduced. Untimely discharges of fresh water to the estuaries would be partially equalized, leading to more natural salinity levels and the recovery of the estuarine ecosystem in the project area. By maintaining salinity balance and preventing salinity intrusion, the SAP will reduce the need for desalinization technologies. Any additional water made available through this project could be used for incidental benefits for water supply.

The SAP footprint is located on an active orange grove which provides employment in the local community. This loss in jobs will be offset by the construction opportunities in relation to implementing the project as well as related recreation.

Principle Three: **Seek balance and synergy** among human development activities and natural systems by designing economic and environmental solutions that support and reinforce one another.

Caloosahatchee River (C-43) West Basin Storage Reservoir was designed to meet the needs of competing municipal, agricultural, and environmental water supply in the basin. Every effort was made to provide for a beneficial effect in the adjacent natural system and also to ensure that the proposed project would not

impact the current water supply needs. The proposed Reservoir would provide additional resources for the human environment through improved recreation within the Reservoir itself. The Caloosahatchee River (C-43) West Basin Storage Reservoir will have no negative effect on water resources for urban utilities, agricultural or flood damage reduction.

Principle Four: Continue to accept corporate responsibility and accountability under the law for activities and decisions under our control that impact human health and welfare and the continued viability of natural systems.

The Caloosahatchee River (C-43) West Basin Storage Reservoir PIR complies with all applicable laws such as the NEPA, Clean Water Act, Endangered Species Act, and all other applicable legislation. The proposed Reservoir will enhance both ecologic values and also economic values and social well-being.

Public safety concerns were raised in regards to possible flooding and damage to the SR 80 Bridge (main evacuation route for Lee County) and surrounding area homes and businesses. These concerns were addressed by designing the reservoir embankments to USACE dam safety standards.

Principle Five: Seek ways and means to assess and mitigate cumulative impacts to the environment; bring systems approaches to the full life cycle of our processes and work.

The Caloosahatchee River (C-43) West Basin Storage Reservoir is one of 68 different projects as part of the CERP. Congress approved the CERP as the "framework for modifications and operational changes to the C&SF Project that are needed to restore, preserve, and protect the south Florida ecosystem while providing for other water-related needs of the region, including water supply and flood protection (WRDA 2000). As such, the primary purpose of the CERP is the restoration of the Everglades ecosystem, including specific safeguards to ensure that the benefits to the natural system are achieved and maintained, while providing for other water-related needs of the south Florida region. By doing this, the USACE is able to avoid and minimize any potential project impacts that may occur as a result of the implementation of any project.

Potential impacts to the natural system have been assessed as part of the PIR process and considered in the plan selection. Specifically, NEPA consultation was performed for the Eastern Indigo Snake, Audubon's Crested Cara Cara and the East Indian Manatee. Guidelines for fill rates, operations and control structures have been established to minimize impacts to these species. In addition, a system wide monitoring plan of the natural environment will be in place to continue to assess all impacts, and used along with adaptive

management of the project and other CERP components, in order to maximize benefits to the system while identifying and limiting any negative effects.

Principle Six: Build and share an integrated scientific, economic, and social knowledge base that supports a greater understanding of the environment and impacts of our work.

As part of the Adaptive Management strategy for the CERP, three sub-teams from RECOVER meet monthly to discuss ways to improve the overall effects of the CERP program. The three RECOVER teams are the Planning, Evaluation, and Assessment teams. These three teams collectively are composed of many individuals with separate disciplines in order to integrate their specific knowledge of science, economics, and sociology. The teams evaluate the different environmental effects that are expected to occur as a result of CERP implementation, and also assess possible impacts to any areas that can be beneficially adjusted through Adaptive Management. RECOVER reviewed the proposed Caloosahatchee River (C-43) West Basin Storage Reservoir PIR as it was being developed and provided input as to how the project could best be implemented and operated.

Additionally, extensive modeling was performed to mimic the natural system in the project area, both hydrologically and ecologically, in order to better understand how the system will function with the SAP in place.

Principle Seven: Respect the views of individuals and groups interested in Corps activities, listen to them actively, and learn from their perspective in the search to find innovative win-win solutions to the nation's problems that also protect and enhance the environment.

The USACE fully addressed and considered all public comments concerning the proposed Caloosahatchee River (C-43) West Basin Storage Reservoir. Comments were received from state and federal agencies as well as non-governmental agencies, tribal interests, and the general public. As part of the NEPA process, the USACE sent out a scoping notice to provide information to the public and/or other agencies in order to encourage participation and receive comments about the proposed project. Further public input was encouraged through public meetings, stakeholder meetings, and Regional Project Delivery Team meetings. Changes to the report were made where applicable; as an example, changes were made to the final in response to comments provided by Lee County during the public review period for the draft PIR. These changes included adding information about the Northern Everglades and Estuary Protection Act to the final PIR, this information can be found on page 1-17 of this report.

The Selected Alternative Plan is consistent with the USACE's 12 Actions for Change. The "12 Actions for Change" can be grouped into three overarching themes: Effectively implement a comprehensive systems approach; communication; and reliable public service professionalism. Below is a summary of the grouped actions for change, and how the Caloosahatchee River (C-43) West Basin Storage Reservoir is consistent with those actions.

Effectively Implement a Comprehensive Systems Approach: Comprehensively design, construct, maintain and update engineered systems to be more robust, with full stakeholder participation.

1. Employ integrated, comprehensive and systems-based approach
2. Employ risk-based concepts in planning, design, construction, operations, and major maintenance
3. Continuously reassess and update policy for program development, planning guidance, design and construction standards
4. Employ dynamic independent review
5. Employ adaptive planning and engineering systems
6. Focus on sustainability
7. Review and inspect completed works
8. Assess and modify organizational behavior

In order to effectively implement a comprehensive systems approach the Selected Alternative Plan was formulated to optimize system-wide benefits to further CERP goals and objectives. The Selected Alternative Plan minimized risk in several ways. First, reservoir design complies with the Design Criteria Memoranda, developed jointly by USACE and the South Florida Water Management District, and USACE dam safety criteria. Test cells were constructed by the project's non-Federal sponsor at the project site in order to assess reservoir site characteristics, embankment design, reservoir cell operation, and overwash scenarios. The information gathered from test cell construction and operation has minimized risk of proposed construction methods, as well as reservoir operation. The project delivery team reviewed CERP program guidance and applied lessons learned from other projects to this project. Independent review was conducted at the programmatic level by the National Academy of Sciences/National Research Council. Lessons learned from those programmatic reviews were applied in the planning and design of the Selected Alternative Plan. In addition, external ITR was conducted at key milestone points throughout the planning and decision document preparation process. The SAP includes program-level adaptive assessment and ecological monitoring that will study the long-term system-wide contributions of the SAP. It also includes project-specific water quality monitoring, as well as operational monitoring to ensure the reservoir functions as planned and does not cause or contribute to water quality degradation.

Communication: Effective and transparent communication with the public, and within the USACE, about risk and reliability.

9. Effectively communicate risk
10. Establish public involvement risk reduction strategies

Information has been provided regularly via public notices PDT meeting and summaries, newsletters, internet, and other methods. Risk reduction strategies have been communicated through utilizing the above methods as well as by gathering the input of the public through public meetings and by public review of the draft PIR.

Risk and uncertainty analyses have been documented throughout the PIR. Risk and uncertainty were also discussed at public meetings as well as at PDT meetings.

Reliable Public Service Professionalism: Improve the state of the art and the USACE' dedication to a competent, capable workforce on a continuing basis. Make the commitment to being a "learning organization" a reality.

11. Manage and enhance technical expertise and professionalism
12. Invest in research

SAJ, SFWMD and SFWMD consultants have extensive expertise in dam and reservoir construction in South Florida, pump station construction and operation, and other technologies used in this project.

Project level investments were made in creating the habitat suitability index model which provided a new methodology for evaluating and ranking ecosystem benefits resulting from the different project alternatives. Additionally, the construction and operations of the test cells have provided important lessons learned which have been implemented in the reservoir design.

SECTION 8
PLAN IMPLEMENTATION

This page intentionally left blank

8.0 PLAN IMPLEMENTATION

8.1 DIVISION OF IMPLEMENTATION RESPONSIBILITIES

The SFWMD proposes to initiate construction on the Caloosahatchee River (C-43) West Basin Storage Reservoir project (also referred to as the "C-43 West Storage Reservoir" under Acceler8) project as part of the State's Acceler8 plan prior to implementation of the Federal project. The USACE is proceeding with two separate and independent but related actions: the planning evaluation of the Federal project and the regulatory evaluation of the SFWMD's application for a Section 404 (Clean Water Act) permit for the proposed project, both of which are described in this Final PIR/EIS. The Caloosahatchee River (C-43) West Reservoir (Acceler8 project) is consistent with the plan recommend in this document. The purposes of the Federal recommended plan identified in this Final PIR and the Acceler8 project are consistent. Therefore, it is anticipated that the Final PIR/EIS will also serve as the basis for the Regulatory Division's NEPA evaluation of the SFWMD's proposed Acceler8 project.

8.1.1 Schedule

Availability of a Final PIR/EIS is scheduled for July 2007. Once the public review period of the Final PIR/EIS is complete and comments are addressed the Record of Decision (ROD) will be signed in and a fully executed Project Cooperation Agreement (PCA) will follow (A separate ROD on the Section 404 permit application will be signed by the Jacksonville District Commander for SFWMD's proposed action.). SFWMD commenced engineering design in late 2003 under the Acceler8 program with survey and subsurface geotechnical investigations. It is anticipated that full scale construction on the Caloosahatchee River (C-43) West Storage Reservoir by the SFWMD will begin in 2008, pending issuance of all permits and authorizations. The Assistant Secretary of the Army for Civil Works (ASA[CW]) cannot consider awarding credit for the SFWMD design and construction work until the recommended project is authorized and funds are appropriated by Congress

8.1.2 Preconstruction Engineering and Design

Detailed design of the C-43 West Reservoir is currently being conducted by the SFWMD with coordination and review by the USACE under the Acceler8 program. All detailed design and construction will be coordinated with the USACE. Crediting for work performed by the SFWMD will be subject to project authorization and adherence to USACE design standards and regulations. Lands, Easements, Right-of-ways, Relocations and Disposal (LERRDs) will be the responsibility of the SFWMD.

8.1.3 Implementation of Project Operations

A Project Operating Manual has been prepared and is included in ***Annex D*** of this PIR. Modifications of the Project Operating Manual may occur as operational experience and knowledge is gained. An Interim Operating Manual will be completed during the Detailed Design phase of the project to allow for use during the construction phase. The Interim Operating Manual will incorporate any modifications to the Operating Manual resulting from the Detailed Design phase. The USACE and SFWMD will share in the responsibilities for conducting water management operations during the Operational Testing and Monitoring phase. Following completion of the Operational Testing and Monitoring phase, a Final Project Operating Manual will be prepared for the Operations and Maintenance (O&M) phase of the project.

8.2 COST SHARING

The total first cost of the project, including the value of LERRDs and pre-construction engineering and design costs will be shared equally between the Federal government and the non-Federal sponsor and is described in ***Table 8-1***. The non-Federal sponsor will provide cash or manage a portion of construction as necessary to meet its 50 percent share of the total first cost of the project to be balanced according to Section 601 of WRDA 2000 to maintain a 50/50 cost share as measured cumulatively for the entire CERP Program. Section 601 of the WRDA of 2000 and USACE policy requires that the non-Federal sponsor must obtain and provide certification of LERRDs necessary for project implementation.

TABLE 8-1: COST APPORTIONMENT TABLE FOR THE CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR (OCTOBER 2006 PRICE LEVEL ROUNDED TO THE NEAREST $10,000)

Item	Non-Federal Cost	Federal Cost	Total Cost
PED	$ 22,330,000	$ 22,330,000	$ 44,650,000
Lands & Damages*	$ 52,490,000	$ 27,930,000	$ 80,420,000
Construction Management**	$ 13,500,000	$ 13,500,000	$ 27,000,000
Construction Total	$165,300,000	$189,860,000	$355,170,000
Total	**$253,620,000**	**$ 253,620,000**	**$507,240,000**

Note: Total costs shown are consistent with costs shown through out the report. Due to rounding to the nearest $10,000, numbers may not total correctly.

*Federal costs include Federal funds provided via Grant Agreement entitled Everglades Watershed Restoration-Grant Number LWCF-1 and future estimated administrative expenses of the Federal Government associated with crediting and project implementation.

**Non-Federal Cost for construction total is less than Federal Cost since consideration is given for cost already provided by the Non-Federal Sponsor.

8.2.1 Cost Sharing of Construction and Land Costs for Restoration Features

Section 601 of the WRDA of 2000 and USACE policy requires that the non-Federal sponsor will provide LERRD.

The total first cost of the restoration features of the project, including the value of LERRD and pre-construction engineering and design costs, will be shared equally between the Federal government and the non-Federal sponsor. The non-Federal sponsor will provide cash or manage a portion of construction as necessary to meet its 50 percent share of the total first cost of the project to be balanced according to Section 601 of WRDA 2000.

8.2.2 Cost Sharing of Monitoring

A project monitoring plan, including water quality, hydrometeorological, and ecosystem monitoring has been prepared and is included in ***Annex D*** of this PIR. Water quality and hydrometeorological monitoring will be cost-shared during the construction and O&M phases of the project in accordance with Section 601(b)(2) of WRDA 2000 and USACE policy for cost-sharing of operational monitoring. Ecosystem monitoring will be performed as part of the CERP Adaptive Assessment and Management program implemented by RECOVER. Regional data collected as part of the monitoring program is critical to the refinement of the features and operation of the selected alternative plan by providing the basis for modifications to design and operational criteria as needed.

8.2.3 Cost Sharing of Operations and Maintenance

Section 601(e)(4) of the WRDA 2000 specifies that the O&M of authorized projects of the CERP would be cost shared equally by the Federal government and the non-Federal sponsor. Consistent with the provisions of section 601(e)(4) of the WRDA of 2000 and given the multi-objective nature of the features in this plan, it is appropriate for the Operation, Maintenance, Repair, Replacement, and Rehabilitation (OMRR&R) associated with this plan to be shared equally between the Federal government and the non-Federal local sponsor. OMRR&R costs associated with recreation features of the plan will be funded 100 percent by the non-Federal local sponsor. Note that the proposed one-lane bridge and boat ramps will be used by operations staff to access the reservoir and are necessary with or without recreation features.

8.3 PROJECT DESIGN

8.3.1 Application of the Design Criteria Memorandums for Hazard Potential Classifications of Impoundments

USACE Engineering Regulation typically provides rules and policies that engineers must follow to correlate their design parameters and decisions to for approval. USACE Engineering Manuals typically provide general guidance in formulations and procedures that can be followed to complete design efforts for typical projects. Therefore, these general based publications allow unique project factors to be considered to optimize designs on a case-by-case basis. The design of impoundments in south Florida is thought to be unique in that the impoundments are not classic cross-stream dams, but include 360° perimeter embankments where each foot of increase in embankment height adds significantly to the cost of the project, especially as normal pool depths for these impoundments are relatively deep (for C-43 West Basin Reservoir, between 17 and 19 feet). Another unique factor for south Florida reservoirs is the high design wind speed that is considered "reasonable" to be applied on the Probable Maximum Flood surcharged pool for High Hazard Potential Classification (HPC) impoundments. These factors led to a series of discussions between the USACE, Jacksonville District and the SFWMD that resulted in the Design Criteria Memorandums (DCMs) that provide selected and USACE approved design formulations and procedures for impoundments in south Florida that adhere to USACE and State of Florida engineering regulations. The following final DCMs were followed in the design of the Caloosahatchee (C-43) West Basin Storage Reservoir:

- DCM-1 Hazard Potential Classification
- DCM-2 Wind and Precipitation Design Criteria for Freeboard
- DCM-3 Spillway Capacity and Reservoir Drawdown Criteria
- DCM-4 Minimum Dimensions of Dams and Embankments

Other draft DCMs were used in the design of other features of the project, some associated with the impoundments, others not. Each DCM lists USACE, State of Florida, or literature references for all supporting data, procedures, and guidance that were used to complete the documentation(s).

DCM-2 produced as a non-binding guidance agreement for the project team's design use, four cases for completing a sensitivity analysis in selection of the embankment design. As a default for all reservoirs with a HPC, Case 1 (scenario that includes the Probable Maximum Flood (resulting from routing the Inflow Design Flood using the Probable Maximum Precipitation event) in combination with the 100-year return frequency wind speed) was the selected condition for design as it claims the more conservative design.

8.4 PROJECT OPERATIONS

8.4.1 Existing Operations

In the Caloosahatchee Drainage Basin, excess water in the eastern basin resulting from Lake Okeechobee releases (at S-77) and basin runoff drains to the west by way of the Caloosahatchee River (C-43 Canal). Releases from the eastern Caloosahatchee basin are then made at S-78 (which serves as the basin divide between the East and West Caloosahatchee River basins) where inflow along the river is passed into the West Caloosahatchee River Basin. Excess stormwater in the western basin also drains to the Caloosahatchee River (C-43 Canal) and along with the inflow from the East Caloosahatchee River (upper) basin is then discharged to the Caloosahatchee Estuary from S-79.

S-77, S-78, and S-79 are operated based on the Water Control Plan for Lake Okeechobee and Everglades Agricultural Area (EAA) (USACE, July 2000). Within the current approved Lake Okeechobee Regulation Schedule (WSE) is an "Operational Guidelines Decision Tree" used for deciding when and how much water can be discharged from Lake Okeechobee to the Caloosahatchee River. The range of water released to the Caloosahatchee River in the decision tree is from "up to maximum discharge" in the case where the lake is in Zone A of the regulation schedule, and "no discharge to tidewater" when the lake is in Zone D and the tributary conditions are dry. The operational flexibility of the WSE schedule allows for adjustments to be made in the timing and magnitude of Lake Okeechobee regulatory discharges based on conditions in the lake and in tributary basins, and on extended meteorological and climate outlooks.

8.4.2 Initial Operating Regime

The Initial Operating Regime is a depiction of the operational conditions that would exist when project operations would commence. For this PIR, initial operating regime baseline assumptions include a consideration of land use and water supply demands in the study area assumed for 2010, operations of the C&SF Project at the time that the selected alternative plan (SAP) is identified, the effect of non-CERP activities with approved operating manuals (if any), and authorized CERP projects with approved operating manuals (none at this point in time). The selected plan features and operations are incorporated into the initial operating regime baseline to prepare the Draft Project Operating Manual consistent with project objectives.

The conceptual intent of the project is that the excess runoff and discharges from Lake Okeechobee in the Caloosahatchee River (C-43 Canal) will be diverted to the reservoir. Water will be released from the reservoir back to the Caloosahatchee River (C-43 Canal) to maintain desirable salinity levels in the Caloosahatchee Estuary as measured by flow at the S-79 (W.P. Franklin Lock

and Dam) structure. Project operations will be dependent upon the stage in the Caloosahatchee River, Lake Okeechobee, the conditions at S-77, S-78, S-79, and the estuary. All of these locations are affected primarily by seasonal and short-term hydrologic and climatic conditions.

After the initial filling of the reservoir and operational testing and verification is complete, initial operating regime project operations will be a function of conditions of flows measured at the S-79 structure. When flows at the S-79 structure are less than 450 cfs, the C43S-1 structure (the main reservoir outflow structure located in Cell 1) will be opened to allow releases from the reservoir. When the flows at S-79 are greater than 450 cfs, releases from the reservoir will end. When excess flows are present in the basin and there is capacity in the reservoir, the C43PS-1 (1,500 cfs pump station) will begin pumping into the reservoir.

Annex D ("Draft Project Operating Manual and Monitoring Plan") contains additional detailed information on operations of all of the project structures.

8.4.3 Initial Operating Regime Local Water Supply Operations

The project is within the LaBelle Private Drainage District (LPDD) service area. The LPDD has historically served both the Berry Groves property (project site) and the Bob Paul property by pumping water from the Townsend Canal to the Header Canal. Irrigation water will continue to be supplied to the Bob Paul property. The existing Berry Groves No. 1 and No. 2 pump stations will remain in operation until project features including C43PS-4, a 150 cfs water supply pump station) and the perimeter canal are constructed and operational testing and verification is complete. The Crawford Canal will still be available to the Bob Paul property for drainage and is not affected by the project.

8.4.4 Future Operations

To depict conditions that are likely to exist in the future for analytical purposes and for purposes of describing future project operations, a next-added increment (NAI) baseline condition is prepared, including projected future (2050) land use and water supply demands and the effects of non-CERP activities. The selected plan features and operations are incorporated into the NAI baseline for inclusion in the Project Operating Manual to ensure that future operations will be consistent with the benefits that justify the project.

For project operations purposes, the conceptual intent of the project applies to both the initial operating regime and NAI operations. For this project, the only significant assumed difference between the initial operating regime and NAI conditions is water supply deliveries to the Caloosahatchee River (C-43 Canal) basin from Lake Okeechobee. As demand for water supply in the basin increases

in the future, additional water could be released from Lake Okeechobee (if available, and based on other C&SF project operations requirements) to meet those demands. However, such water supply releases from Lake Okeechobee would not effect reservoir operations, since filling of the reservoir is based on excess basin flows, and releases from the reservoir are based on maintaining desirable flows at the S-79 structure.

Similar to the initial operating regime, future project operations will be based on flow at the S-79 structure. When flows at S-79 are less than 450 cfs, the C43S-1 structure (the main reservoir outflow structure located in Cell 1) will be opened to allow releases from the reservoir. When the flows at S-79 are greater than 450 cfs, releases from the reservoir will end. When excess flows are present in the basin and there is capacity in the reservoir, the C43PS-1 (1,500 cfs pump station) will begin pumping into the reservoir.

8.4.5 Future Local Water Supply Operations

To maintain water supply to the Bob Paul properties, deliveries will be made via the C43PS-4 structure into the perimeter canal surrounding the reservoir.

8.5 PROJECT ASSURANCES

8.5.1 Level of Service for Flood Protection

Each PIR is required to include an analysis of the project's impacts on levels of service for flood protection that existed on the date of enactment of WRDA 2000, December 2000, and in accordance with applicable law. If a project is expected to result in an impact on the existing levels of service for flood protection, the PIR will modify operations or re-design the project, consider further acquisitions and or formulate other alternatives to address the potential impact. The analysis to determine if there was an impact on existing levels of service for flood protection was conducted on both the system-wide and project level scales.

8.5.1.1 System-wide

The operations of this project will not change the operations of the Caloosahatchee River (C-43 Canal) based on the key assumptions outlined in ***Annex C***. Therefore, there will be no system-wide effects on flood protection as a result of the project.

8.5.1.2 Project Level

Based on an analysis of effects on local groundwater using the local reservoir MIKESHE model as outlined in ***Annex C***, there will be no significant and adverse reduction to existing levels of service for flood protection in the vicinity

of the reservoir. In addition, results of the C-43 Test Cell Pilot Project described in ***Annex C*** support this conclusion. Furthermore, the canal stages and groundwater levels adjacent to the reservoir would be maintained by adjusting the operations of the perimeter canal water levels and its structures as explained in the project operating manual.

8.5.2 Effects on Existing Legal Sources for Water Supply

Each PIR is required to determine if existing legal sources of water are to be eliminated or transferred as a result of project implementation. If a project is expected to result in an elimination or transfer of an existing legal source of water, the PIR shall include an implementation plan that ensures a new source of water of comparable quantity and quality is available to replace the source that is being transferred or eliminated. The analysis to determine if there is an elimination or transfer of existing legal sources was conducted on both the system-wide and project level scales.

8.5.2.1 System-wide

The only system-wide basin affected by the project will be the Western Caloosahatchee Basin and Estuary. The operations of this project, as described in ***Annex C***, will result in no changes in the operations of the Caloosahatchee River (C-43 Canal) or to the source of water to meet agricultural and urban water supply. Therefore, there will be no system-wide effects that eliminate or transfer of existing legal sources of water as a result of this project.

8.5.2.2 Project Level

The project will transfer an existing legal source of water for agricultural water supply on lands adjacent to the project site from a portion of the existing Header Canal within the project's footprint to the perimeter canal surrounding the reservoir. However, the new source (water in the perimeter canal) will be comparable in volume of water available and water quality to the existing conditions. Upon completion of construction, operational testing and monitoring will occur to ensure that the reservoir and structures designed to deliver water from the reservoir to existing agricultural uses will function as intended. The Project Operating Manual includes project operations to ensure that agricultural water supply deliveries will be provided.

8.5.3 Identification of Water Made Available for the Natural System and Water for Other Water-Related Needs

Each project implementation report is required to identify the quantity, timing, and distribution of water to be dedicated and managed for the natural system, the amount of water to be reserved or allocated for the natural system by the

State of Florida, and water made available for other water-related needs of the region.

8.5.3.1 Identification of Water Made Available and Water for Other Water-Related Needs

The Caloosahatchee River (C-43) West Basin Storage Reservoir project was designed to store excess, high-volume flows in the basin (as measured by flows at the S-79 control structure) and to release water to supplement periods of low flows to improve salinity levels towards estuary restoration targets. To achieve the project purpose, all water made available by the project is for the natural system to attain the benefits of the project. Therefore, there will be no water made available for other water-related needs of the region by the project. Unmet municipal, agricultural and natural system needs for water supply will be further investigated in the second PIR to be initiated upon completion of this first PIR.

8.5.3.2 Identification of Water to be Reserved or Allocated for the Natural System

The volume of water to be reserved or allocated by the State of Florida is based on the Initial Operating Regime condition. As shown in ***Annex C***, section C.3.2.3, the 10th, 50th and 90th percentile average annual volumes of additional water for the natural system simulated in the initial operating regime condition were calculated to be approximately 159,485 ac-ft/year, 105,990 ac-ft/year and 27,619 ac-ft/year, respectively. These volumes will be reserved or allocated for the natural system to achieve the benefits of the project.

8.5.4 State and Federal Assurances

The overarching objective of the Comprehensive Everglades Restoration Plan ("Plan") is the restoration, preservation, and protection of the South Florida ecosystem while providing for other water-related needs of the region, including water supply and flood protection. The Federal Government and the State of Florida are committed to the protection of the appropriate quantity, quality, timing, and distribution of water to achieve and maintain the benefits to the natural system described in the Plan. As envisioned in WRDA 2000 and the Programmatic Regulations, each PIR will identify this appropriate quantity, quality, timing, and distribution of water for the natural system.

The following language sets forth these commitments:

> "The overarching objective of the Plan is the restoration, preservation, and protection of the South Florida ecosystem while providing for other water-related needs of the region, including water supply and flood protection. The Federal Government and the non-Federal sponsor are committed to the

protection of the appropriate quantity, quality, timing, and distribution of water to ensure the restoration, preservation, and protection of the natural system as defined in WRDA 2000, for so long as the project remains authorized. This quantity, quality, timing, and distribution of water shall meet applicable water quality standards and be consistent with the natural system restoration goals and purposes of CERP, as the Plan is defined in the programmatic regulations. The non-Federal sponsor will protect the water for the natural system by taking the following actions to achieve the overarching natural system objectives of the Plan:

1. Ensure, through appropriate and legally enforceable means under Federal law, that the quantity, quality, timing, and distribution of existing water that the Federal Government and the non-Federal sponsor have determined in this Project Implementation Report is available to the natural system, will be available at the time the Project Cooperation Agreement for the project is executed and will remain available for so long as the Project remains authorized.

2a. Prior to the execution of the Project Cooperation Agreement, reserve or allocate for the natural system the necessary amount of water that will be made available by the project that the Federal Government and the non-Federal sponsor have determined in this Project Implementation Report.

2b. After the Project Cooperation Agreement is signed and the project becomes operational, make such revisions under Florida law to this reservation or allocation of water that the Federal Government and the non-Federal sponsor determines, as a result of changed circumstances or new information, is beneficial for the natural system.

3. For so long as the Project remains authorized, notify and consult with the Secretary of the Army should any revision in the reservation of water or other legally enforceable means of protecting water be proposed by the non-Federal sponsor, so that the Federal Government can assure itself that the changed reservation or legally enforceable means of protecting water conform with the non-Federal sponsor's commitments under paragraphs 1 and 2. Any change to a reservation or allocation of water made available by the project shall require an amendment to the Project Cooperation Agreement.

8.6 PROJECT MONITORING PLAN

The SAP includes water quality, hydrologic, and environmental monitoring activities to ensure that the intended purposes of the project will be achieved through long-term operations.

Water quality and hydrologic monitoring activities are described in detail in ***Annex D*** ("Draft Project Operating Manual and Monitoring Plans"). Water quality monitoring involves sample collection and analysis for baseline, startup, and operational phases of the project. Water quality parameters to be monitored include physical parameters (i.e., temperature and dissolved oxygen concentration), turbidity, nutrients, and organochlorine compounds. Hydrologic monitoring includes measurements of stage and elevation (groundwater) and flow at water control structures. Project environmental monitoring includes monitoring of nuisance exotic vegetation within the reservoir and the perimeter canal around the reservoir.

A project-specific ecological monitoring plan was also prepared, focusing on estuarine performance measures. Ecological monitoring is recommended to be implemented as part of RECOVER's system-wide Monitoring and Assessment Plan (MAP) efforts and incorporated into the adaptive management (AM) strategy for south Florida ecosystem restoration.

8.7 COMPLIANCE WITH ENVIRONMENTAL LAWS, STATUTES, AND EXECUTIVE ORDERS

For more complete information on all coordination please see Section 9 Summary of Coordination.

TABLE 8-2: COMPLIANCE WITH ENVIRONMENTAL LAWS, STATUTES, AND EXECUTIVE ORDERS

Law, Regulation, or Policy	Status C, P, NC	Status	Compliance
Clean Air Act	C	PIR/EIS will be coordinated with USEPA. Air emissions permit may be required for large diesel pumps; normally applied for during PED phase	Compliance with Section 309 of the CAA will occur with the coordination and review of the PIR/EIS by EPA.
Clean Water Act	P	WQC will be required; NPDES permit will be required ; WQ evaluation completed and included in this PIR/EIS; 404b evaluation included in Annex F	Full compliance upon issuance of the WQC and NPDES permits by the state – before operation of reservoir; as well as review of the Final PIR by State agencies

Law, Regulation, or Policy	Status C, P, NC	Status	Compliance
Coastal Zone Management Act	C	Based on a review of the March 2003 scoping notice and comments provided by the state reviewing agencies, as well as the dPIR, the state has determined that, at this stage, the project is consistent with the Florida Coastal Management Program. CZM consistency review included in Annex F.	Additional consistency review by the state will occur during coordination of the final PIR/EIS.
National Environmental Policy Act (NEPA)	P	NOI published; scoping meetings held; draft PIR/EIS NOA in Federal Register April 27, 2007	Full compliance upon coordination of the final PIR/EIS, public outreach activities completed and signing of the ROD.
Fish and Wildlife Coordination Act	C	Funds transferred annually to FWS; PALs received; Draft CAR received in March 2007; Final CAR received July 2007 and included in Annex A. FWS active team participant; has provided info on fish and wildlife elements on project and been lead on field documentation.	Coordination complete.
Farmland Protection Policy Act	C	Form AD-1006 to NRCS in November 2006, returned to the USACE in January 2007 and re-submitted in March 2007.	Coordination complete.
Endangered Species Act	C	USACE submitted a BA and letter dated 10 January 2007 to USFWS requesting formal consultation on Eastern Indigo Snake, Florida panther, and Audubon's Crested Caracara. Formal consultation is complete. NMFS concurred with Corps' determination for sea turtles and smalltooth sawfish.	Coordination complete.
Magnuson-Stevens Fishery Conservation and Management Act	C	EFH present in Caloosahatchee River. NMFS concurred with Corps EFH evaluation.	Coordination complete.
National Historic Preservation Act	C	Coordination with SHPO has occurred and the Section 106 Process is complete. A determination of no historic properties affected has been made.	Coordination is complete.

Law, Regulation, or Policy	Status C, P, NC	Status	Compliance
RECRA, CERCLA, other HTRW laws	P	Caloosahatchee River (C-43) West Basin Storage Reservoir surveys completed – received recommendation letter from FWS Spring 2006.	Full compliance before construction. WMD responsible for ensuring present lessee provides final assurances.
Coastal Barrier Resources Act and Coastal Barrier Improvement Act	C	The Coastal Barrier Resources on Sanibel Island are being coordinated with USFWS. The project is expected to benefit these resources and is therefore consistent with the Act.	Coordination complete.
Marine Mammal Protection Act	C	The West Indian Manatee does occur in the Caloosahatchee River and associated canals. Incorporation of the safeguards used to protect T&E species during construction and operation would protect any marine mammals in the area. No take of Marine Mammals is expected.	The project is in compliance with the intent of this act.
Marine Protection, Research, and Sanctuaries Act	C	The Caloosahatchee River (C-43) West Basin Storage Reservoir does not involve any ocean dumping nor does it establish a marine sanctuary. The project is in compliance with this act.	The project is in compliance with the intent of this Act.
Estuary Protection Act of 1968	C	The main purpose of this project is to improve flows and salinity to the estuary. The project is in compliance with this act.	The project is in compliance with the intent of this Act.
Anadromous Fish Conservation Act	P	Anadromous fish species are not expected to be adversely affected by this project. The NMFS concurred with the Corps evaluation in the dPIR.	Coordination complete.

Law, Regulation, or Policy	Status C, P, NC	Status	Compliance
Migratory Bird Treaty Act and Migratory Bird Conservation Act	C	Few adverse impacts are expected to migratory birds. The restoration of the estuary should also increase available forage species such as amphibians, fish, and aquatic invertebrates for wading birds. Littoral zones created in the seepage canals may also benefit migratory birds.	Coordination complete.
Wild and Scenic River Act of 1968	C	No designated Wild and Scenic River reaches would be affected by project related activities	The project is in compliance with this Act.
Federal Water Project Recreation Act	C	The recreation plan for the project is included in Appendix H. The project is in compliance with this act.	The project is in compliance with the intent of this Act.
Submerged Lands Act of 1953	C	This project does not occur on submerged lands of the state of Florida.	The project is in compliance with the intent of this Act.
Rivers and Harbors Act of 1899	C	The proposed work would not obstruct navigable waters of the United States.	The project is in compliance with this Act.
E.O. 11988 Floodplain Management	C	The purpose of the EO is to discourage Federally induced development in floodplains. Commitment of lands to reservoirs will preclude such development. In addition, existing flood levels will not be significantly or adversely impacted.	The project is in compliance with this E.O.
EO 11990 Protection of Wetlands	C	The area proposed for the C-43 BSRP is mostly farmland with a few disturbed wetlands. The reservoir design will include areas of littoral shelf along the seepage canal. Construction of the Caloosahatchee River (C-43) West Storage Reservoir will result in the loss of 125 acres of wetlands through discharge of dredge or fill material, excavation, and/or flooding. However, CERP projects are expected to have a net positive lift of wetland function.	This project is in compliance with this EO.

Law, Regulation, or Policy	Status C, P, NC	Status	Compliance
EO 12898 Environmental Justice	C	This E.O. requires consideration of, and avoidance of disproportionately adverse effects on, minority and low-income populations. No such impacts were identified during project scoping. Minimal adverse impacts are expected.	This project is in compliance with this EO.
EO 13089 Coral Reef Protection	C	This project will not adversely impact coral reefs or coral reef resources.	This project is in compliance with this EO.
EO 13112 Invasive Species	C	The project will follow all feasible and prudent measures to minimize the risk of introducing new invasive species. An analysis of invasive species potential impacts is included in Sections 3 and 6.	This project is in compliance with this EO.

C= compliance; P=pending; NC=non compliance

8.8 COMPLIANCE WITH FLORIDA STATUTES

The State of Florida has enacted several laws pertaining to implementation of CERP projects. These include amendments to section 373.026 (8), F.S., which establishes a requirement for the SFWMD to submit a report for review and approval by the FDEP prior to formal submission of a request for authorization from Congress and prior to receiving an appropriation of state funds for construction and other implementation activities (except the purchase of lands from willing sellers); enactment of Section 373.1501, Florida Statue (F.S.), which establishes the intent of the Florida Legislature with respect to the CERP and the criteria for FDEP approval and the procedures to be followed by the SFWMD and FDEP for submitting and reviewing requests for approval; the enactment of Section 373.1502, which establishes permitting requirements and a process for the submittal, review, and issuance of certain regulatory permits for CERP projects; and the enactment of Sections 373.470, and 373.472 F.S. establishing the "Save Our Everglades Trust Fund," funding and reporting requirements, and procedures for distributions from the trust fund. The SFWMD's report addressing the criteria for approval listed in Section 373.1501, F.S. is included in ***Annex C***.

In addition to the above-described statutory requirements, other sections of Chapters 373 (Water Resources) and 403 (Environmental Control) of the F.S. include requirements that may apply to various aspects of CERP project

planning and implementation. In particular, Chapter 403 and the administrative laws adopted in accordance with Chapters 373 and 403 contain the requirements for facilities that involve the discharge or potential discharge of pollutants to surface and ground waters and the discharge of air pollutants, including facilities regulated under the Federal Clean Water and Safe Drinking Water Acts and the Federal Clean Air Act. Based on the information contained in the PIR, the selected plan complies with the applicable provisions of F.S. A detailed explanation of how the project complies with the applicable requirements for CERP projects contained in the F.S. can be found in ***Annex C***.

8.8.1 Permits, Entitlements and Certifications

In as much as construction activities on the Caloosahatchee River (C-43) West Reservoir are scheduled to begin in 2008 in accordance with the schedule for the State of Florida's Accler8 program, the SFWMD will be responsible for obtaining permits issued by the Regulatory Division of the USACE under the authority of Section 404 (discharge of dredged or fill material into waters) of the Clean Water Act (CWA) and any corresponding permits required by the State of Florida in accordance with Chapters 373 and 403 of the F.S.

SFWMD will also be responsible for obtaining the Section 401 (CWA) water quality certification or waiver of water quality certification, as appropriate, from the State of Florida. Typically, water quality certification is obtained through the State of Florida's regulatory program established under the authority of Chapter 373, F.S.

Section 402 National Pollutant Discharge Elimination System (NPDES) permits required under the CWA may be required for the construction (non-point source runoff) of project features. This program has been delegated by the U.S. Environmental Protection Agency (USEPA) for implementation to the State of Florida (FDEP). NPDES permits for construction of project features under the Acceler8 program prior to Federal approval and authorization of the Calooshatchee (C-43) West Basin Storage Reservoir project will be the responsibility of SFWMD. At this time, a NPDES permit will not be required for the operation of Caloosahatchee River (C-43) West Basin Storage Reservoir Project features, as the project does not involve treatment or the discharge of pollutant.

Depending upon the schedule for obtaining Federal review and approval of the project, the USACE will obtain the necessary permits to construct and perform initial operational testing and verification of remaining project features. The cost and schedule for obtaining the necessary permits are included in the project management plan.

8.8.2 Compliance with Applicable Water Quality Standards and Permitting Requirements

The Caloosahatchee River (C-43) West Basin Storage Reservoir project selected plan complies with water quality standards applicable to the project and adjacent waters. The selected plan's features are located in and adjacent to waters designated as Class III by the State of Florida. In accordance with Florida Administrative Code (F.A.C.) Rule 62-302 ("Surface Water Quality Standards"), the use classification of Class III waters is "Recreation, Propagation, and Maintenance of a Healthy, Well-Balanced Population of Fish and Wildlife." In addition to the minimum and general criteria for surface waters found in Section 62-302.500(1), there are numerous water quality criteria for specific parameters for Class III waters listed in Section 62-302.530, F.A.C. Although the selected plan for the Caloosahatchee River (C-43) West Basin Storage Reservoir project is not expected to affect most of the parameters listed in this rule, certain parameters (e.g., turbidity, certain metals, dissolved oxygen and nutrients) listed in the criteria may be affected by construction and operations activities.

In general, any short-term impacts to water quality associated with construction of the selected plan will be ameliorated by construction sequencing, best management practices (BMPs) for erosion and sedimentation control and monitoring during construction. Longer-term impacts to water quality associated with the operation of project features will be addressed through operational monitoring and AM actions, if potentially adverse affects are observed or predicted.

The selected plan is expected to significantly improve water quality in the study area, especially in the Townsend, Banana Branch and Ft. Simmons canals, by diverting nutrient-laden discharges from the existing canals and drainage basin and routing it through the reservoir. The diversion and storage of canal water in the reservoir and the sequestration and settling of pollutants associated with storage should also improve water quality in canals conveying source water from the reservoir. To the extent that releasing water out of the reservoir may result in the mobilization of water-borne pollutants or pollutants bound in impoundment sediments, operational protocols are included in the operations plan (see ***Annex D***, "Draft Operating Manual") to prevent the release of water not meeting Class III criteria to adjacent surface waters. Water quality in the reservoir is expected to meet Class III criteria, primarily as a result of the water quality improvement functions attributable to the reservoir; however, the Caloosahatchee River (C-43) West Basin Storage Reservoir project is not designed nor will it be operated specifically for the improvement of water quality. Upon completion of construction and initiation of operations, water quality and hydrology will be monitored to determine whether project design and operational objectives are being achieved.

8.9 ENVIRONMENTAL COMMITMENTS

The USACE, the non-Federal sponsor (SFWMD), and contractors commit to avoiding, minimizing, or mitigating for adverse effects during construction activities by taking the following actions:

1. Employ BMPs with regard to erosion and turbidity control. Prior to construction, the construction team should examine all areas of proposed erosion/turbidity control in the field, and make adjustments to the plan specified in the plan control device as warranted by actual field conditions at the time of construction.

2. The contract specifications will prohibit the contractor from dumping oil, fuel, or hazardous wastes in the work area and will require that the contractor adopt safe and sanitary measures for the disposal of solid wastes. The contractor will be required to prepare a spill prevention plan.

3. Demolition debris would be transported to a landfill or otherwise disposed of in accordance with Federal, State, and local requirements. Concrete or paving materials would be disposed of in accordance with Federal, State, and local requirements.

4. Inform contractor personnel of the potential presence of threatened and endangered species in the project area, the need for precautionary measures and the Endangered Species Act prohibition on taking listed species.

5. Any measures or restrictions resulting from Section 7 consultation shall be implemented.

6. The USACE and the SFWMD agree to maintain an open and cooperative informal consultation process with the USFWS and FWC throughout the design, construction, and operation of this restoration project.

7. To protect cultural resources, conditions stipulated by the State Historic Preservation Office (SHPO) will be followed. Language will be included in construction contract specifications outlining the steps to be taken in the event that undiscovered historical properties or unmarked human burials are encountered. An informational training session, developed by a professional archaeologist, will be conducted for the contractor's personnel to explain what kinds of archaeological/cultural materials might be encountered during construction of the impoundment, and the steps to be taken in the event these materials are encountered. A professional archaeologist will conduct periodic monitoring of the project area during ground disturbing activities to determine if activities are impacting unanticipated cultural resources.

8. As required under WRDA 2000, the PDT has identified water to be reserved for ecosystem restoration. This is addressed in ***Annex C*** of this report.

9. As likewise required under WRDA 2000, the SAP has been evaluated in the light of its potential effects on existing legal sources of water and the level of service for flood protection. This is addressed in ***Annex C*** of this report.

10. Compliance with the State of Florida's requirements for approval of CERP projects is also addressed in ***Annex C***.

8.10 VIEWS OF NON-FEDERAL SPONSOR

The non-Federal sponsor (SFWMD) supports the Caloosahatchee River (C-43) West Basin Storage Reservoir project, and has initiated design and construction efforts through the State of Florida's Acceler8 program.

This page intentionally left blank

SECTION 9
SUMMARY OF COOPERATING AGENCIES, COORDINATION, PUBLIC VIEWS, AND COMMENTS

This page intentionally left blank

9.0 PROJECT COORDINATION

9.1 COOPERATING AGENCIES

An official letter inviting USFWS, USEPA, ENP, FFWCC and FDEP to be cooperating agencies (as defined by NEPA) was sent in September 2006. These agencies were chosen because of their special expertise in the area. The selection of these agencies to be invited as cooperating agencies does not exclude any other agencies from full participation in the project.

None of these agencies agreed to be a cooperating agency. The USFWS sent a letter dated October 6, 2006 declining the offer. The reason given for declining the offer was "The Service must balance its role as a study team member with its statutory responsibilities to independently review this proposed action under the Fish and Wildlife Coordination Act and Endangered Species Act."

None of the other agencies replied.

9.2 SUMMARY OF COORDINATION, PUBLIC VIEWS, AND COMMENTS

This NEPA document is an integrated PIR and EIS (PIR/EIS). Early in project planning, a letter notifying interested parties, tribes, and Federal and state agencies was mailed to scope for potential issues or project suggestions. Comments received were evaluated and incorporated into the project planning as appropriate. Please see the NEPA ***Annex B*** for additional information on scoping and comments received. In addition, an interagency team was assembled to prepare and evaluate plans that could be implemented for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project. The interagency team includes local (Lee County, Hendry County), state (FFWCC, FDEP, SFWMD), and Federal (USACE, USFWS, USEPA, USGS) representatives.

9.3 SCOPING FOR THE CALOOSAHATCHEE RIVER (C-43) BASIN STORAGE RESERVOIR

In compliance with the NEPA, the Caloosahatchee River (C-43) West Basin Storage Reservoir project initiated a scoping process in early 2002. An initial scoping meeting was held in February/March of 2002, with a follow-up scoping meeting held on May 1, 2003. Following this meeting, a letter was sent to Federal, State, and local stakeholders requesting their assistance in identifying the extent of significant issues to be addressed in this study. A public meeting was held on February 28, 2002 to specifically identify critical fish and wildlife habitat and any threatened or endangered species that may be within the project area or affected by the activities of the project.

Once it was determined that an EIS would be necessary for this project, a Notice of Intent (NOI) to prepare a draft EIS was published in the Federal Register on 28 March 2003. A NEPA scoping letter was sent to Federal, State, and local stakeholders, including those who had earlier expressed an interest in this project. A public meeting, identified in the scoping letter, was held on May 1, 2003 to ensure continued public involvement. This meeting was recorded and all issues identified were noted and reviewed.

9.4 SCHEDULING COORDINATION WITH OTHER AGENCIES

Other agencies were integrally involved in scheduling efforts for both the PIR and PED stages. This is especially true of the SFWMD, through the Acceler8 program and continued scheduling coordination for that effort. USFWS has also been closely involved in order to ensure that all of their statutory requirements for review of the project can be completed. In addition, permitting agencies such as the Florida Department of Environmental Protection have been contacted to ensure that all permits can be coordinated in a timely and consistent manner. Other agencies and organizations were updated on schedules at periodic PDT meetings which were open to agencies and the public.

9.5 OTHER REQUIRED COORDINATION

Compliance with environmental laws is summarized below. The project is currently in compliance with all applicable laws. None of the coordination to date has indicated that the project will have compliance issues in implementing any of the proposed alternatives.

9.6 NATIONAL ENVIRONMENTAL POLICY ACT OF 1969

A NOI to prepare a draft EIS for the Caloosahatchee River (C-43) West Basin Storage Reservoir project was published in the Federal Register on March 28, 2003. A scoping letter describing the project objectives and array of alternatives was mailed on 18 March 2003, to Federal, State, and local agencies, Native American Tribes, private organizations, and other interested parties to solicit their views, comments, and information about resources, study objectives, alternatives, and important features within the study area. Comments received were reviewed and incorporated in project planning. This draft PIR/EIS served as the environmental coordination with many agencies. A Notice of Availability was published in the Federal Register on 27 April 2007 when this document was released for public and agency review. Comments received were addressed and are included in ***Annex B***.

9.7 ENDANGERED SPECIES ACT OF 1973

The USACE sent a letter to the USFWS dated January 10, 2007 requesting formal coordination for this project due to potentially adverse impacts to the Florida panther, Eastern indigo snake, and Audubon's crested caracara. A biological assessment (BA) was drafted by the SFWMD contractor, reviewed and edited by the USACE, and submitted by the USACE to the USFWS and NMFS. NMFS concurred with the USACE's determination of "may affect but is not likely to adversely affect" sea turtles or smalltooth sawfish by letter dated March 28, 2007. The USFWS concurred with the Corps' determinations in a biological opinion dated July 20, 2007 (***Annex A***). The USFWS has been an active participant throughout the planning process and continues to coordinate closely with the USACE. The following letters have been provided by the USFWS and are included in ***Annex A***:

- Planning Aid Letters dated August 13, 2003 and March 29, 2005
- Scoping comments dated June 10, 2003
- List of threatened and endangered species in the study area dated April 11, 2002

9.8 FISH AND WILDLIFE COORDINATION ACT OF 1958

The central objective of the Fish and Wildlife Coordination Act (FWCA) is to allow for equal consideration of wildlife resources. Transfer funds have been made available to the USFWS in order to participate in team meetings and workshops scheduled in conjunction with the USACE's planning, implementation, and evaluation process. Funding has also been provided for the USFWS to conduct surveys and investigations necessary to determine impacts of the C-43 project on wildlife resources and to make recommendations to the USACE on measures to prevent loss of or damage to wildlife resources. Recommendations for optimizing opportunities related to the conservation and enhancement of fish and wildlife resources have been provided through the submittal of PALs listed above. A final CAR has been prepared and is included in this PIR in ***Annex A***. Additionally, the FWC has been an active participant on this project and have provided a scoping letter dated June 10, 2003 and comments on the draft PIR dated June 8, 2007.

9.9 NATIONAL HISTORIC PRESERVATION ACT OF 1966 (INTER ALIA) (PL 89-665, THE ARCHEOLOGY AND HISTORIC PRESERVATION ACT (PL 93-291), AND EXECUTIVE ORDER 11593)

The USACE has reviewed information regarding historical properties that might be affected by the C-43 project, in compliance with Section 106 of the National Historic Preservation Act of 1966 (PL89-665), as amended in 2000; its implementing regulations (36 CFR Part 800) and the Archaeological and

Historic Preservation Act of 1974 (PL93-291), as amended. A Phase I survey has been completed on all sections of the C-43 West Reservoir site.

Coordination with the SHPO has occurred and the Section 106 process is complete. In consultation with the Florida SHPO (Florida SHPO numbers 2004-8676 and 2006-07757) a determination of no historic properties affected has been made. This project is in compliance with the National Historic Preservation Act.

9.10 CLEAN WATER ACT OF 1972

A Section 404(b)(1) evaluation is included in ***Annex F***. The Water Quality Certification (WQC) will be met by the Comprehensive Everglades Restoration Plan Regulation Act (CERPRA) permit. A NPDES permit will be required and water quality will be evaluated to ensure equal or improved discharge from the reservoir. Prior to constructing the project, the USACE or the local sponsor must obtain water quality certification from FDEP in order to comply with Section 401 of the CWA. The project must be shown to not cause or contribute to violations of state water quality standards. The assessment of water quality impacts prepared for this document indicates that the project will not cause or contribute to violations of state water quality standards. Presently, the local sponsor has applied for and will obtain a 404 permit and a Section 401 Water Quality Certificate from the FDEP to construct and operate the project. It is anticipated that these permits will be issued and the project will comply with these sections of the CWA.

9.11 CLEAN AIR ACT OF 1972

Section 176(c) of the Clean Air Act (CAA) requires that Federal agencies assure that their activities are in conformance with Federally-approved CAA state implementation plans for geographical areas designated as "non-attainment" and "maintenance" areas under the CAA. This project is not located within a "nonattainment" area since there are none of these within the State of Florida. If CAA permits are required for large diesel pumps, the required permits will be obtained during the PED phase. A NOI was issued March 28, 2003 and a scoping letter was sent March 18, 2003. This project will be coordinated with the USEPA for compliance with Section 309 of the Act and with local agencies as a matter of comity. The potential to adversely affect the air quality of nearby residences is expected to be low since the diesel engines that drive the intake pumps will meet the latest USEPA emissions requirements for non-road engines that burn ultra-low sulfur diesel. Additionally, the facility is located in a sparsely populated area of Hendry County where the closest private residence is slightly more than ½ mile from the pump station and where there are no more than 20 houses within 1 mile of the proposed pump station.

9.12 COASTAL ZONE MANAGEMENT ACT OF 1972

Based on a review of the March 18, 2003 scoping notice and comments provided by the state reviewing agencies, the State determined that the project was consistent with the Florida Coastal Management Program. The State later reviewed the draft PIR and stated in a letter dated June 11, 2007 that "the state has determined that, at this stage, the proposed activities are consistent with the Florida Coastal Management Program (FCMP)".

9.13 FARMLAND PROTECTION POLICY ACT OF 1981

USACE submitted form AD-1006 to the NRCS in accordance with the Act. The form was returned to USACE for evaluation and resubmitted by letter dated March 2, 2007. There will be an unavoidable loss of unique farmland which comprises approximately five percent of this type of farmland in Hendry County. Although this is a significant loss, there were several factors which contributed to the selection of this site. The SFWMD has previously purchased the land, making it cost-effective. More importantly, the team was not able to find a contiguous parcel of non-agricultural land in the appropriate location and condition for this reservoir. Therefore the alternatives were limited to agricultural areas. Consultation with NRCS is complete and the project is in compliance with the Farmland Protection Policy Act of 1981.

9.14 WILD AND SCENIC RIVER ACT OF 1968

No designated wild and scenic river reaches would be affected by project related activities.

9.15 MARINE MAMMAL PROTECTION ACT OF 1972

The West Indian manatee does occur in the Caloosahatchee River as well as the Townsend Canal. As a result of consultation between the USFWS, USACE, SFWMD, and FFWCC, a manatee barrier will be placed at the intersection of the Townsend Canal and Caloosahatchee River to protect manatees from any potential harm due to project operations. Incorporation of safeguards used to protect threatened and endangered species during construction and operation would protect the manatee and other marine mammals in the area. The MMPA prohibits, with certain exceptions, the take of marine mammals in United States waters and by United States citizens on the high seas, and the importation of marine mammals and marine mammal products into the United States. This project is not expected to result in the "take" of any West Indian manatees.

9.16 ESTUARY PROTECTION ACT OF 1968

The main purpose of this project is to improve flows and salinity to the estuary. The project is in compliance with this Act.

9.17 FEDERAL WATER PROJECT RECREATION ACT

The recreation plan for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project was developed in coordination with the CERP Master Recreation Plan. Details of this plan can be found in the Recreation Appendix. This project is in full compliance with this Act.

9.18 FISHERY CONSERVATION AND MANAGEMENT ACT OF 1976

The intent of this project is to improve estuarine conditions and will therefore improve fisheries. NMFS reviewed the draft EIS and stated in an email dated 30 May 2007 that "NOAA's National Marine Fisheries Service, Southeast Region, Habitat Conservation Division, has reviewed the Department of the Army permit application listed below. We anticipate that any adverse effects that might occur on marine and anadromous fishery resources would be minimal and, therefore, do not object to issuance of the permit." The permit application referred to used this draft EIS as the NEPA document, and therefore NMFS has found the project to be in compliance with this Act.

9.19 SUBMERGED LANDS ACT OF 1953

The project does not occur on submerged lands of the state of Florida. The project is in compliance with this Act.

9.20 COASTAL BARRIER RESOURCES ACT AND COASTAL BARRIER IMPROVEMENT ACT OF 1990

The coastal barrier resources on Sanibel Island are being coordinated with the USFWS. The project is expected to benefit these resources and is therefore consistent with the Act.

9.21 RIVERS AND HARBORS ACT OF 1899

The proposed work would not obstruct navigable waters of the United States. The project is in compliance with this Act.

9.22 ANADROMOUS FISH CONSERVATION ACT

Anadromous fish species are not expected to be adversely affected by this project. NMFS reviewed the draft EIS and stated in an email dated 30 May 2007 that "NOAA's National Marine Fisheries Service, Southeast Region, Habitat

Conservation Division, has reviewed the Department of the Army permit application listed below. We anticipate that any adverse effects that might occur on marine and anadromous fishery resources would be minimal and, therefore, do not object to issuance of the permit." The permit application referred to used this draft EIS as the NEPA document, and therefore NMFS has found the project to be in compliance with this Act.

9.23 MIGRATORY BIRD TREATY ACT AND MIGRATORY BIRD CONSERVATION ACT

The project site may be used by migratory birds that could be affected by project activities. Appropriate surveys will be conducted prior to construction. Construction will not take place during nesting seasons in the event migratory bird nest sites are discovered. Also, with the construction of the reservoir, habitat buffer, and littoral shelves, as well as its location adjacent to natural areas, it is anticipated that migratory birds, especially wading birds, would benefit from additional foraging areas provided by the project. The restoration of the estuary should also increase available forage species such as amphibians, fish and aquatic invertebrates for wading birds. The project is in compliance with these acts.

9.24 MARINE PROTECTION, RESEARCH, AND SANCTUARIES ACT

The Caloosahatchee River (C-43) West Basin Storage Reservoir project does not involve any ocean dumping nor does it establish a marine sanctuary. The project is in compliance with this act.

9.25 RESOURCE CONSERVATION AND RECOVERY ACT OF 1976

Phase I and II Environmental Site Assessment work was completed on the site in December of 1999. These investigations identified 40 potential contamination sites within the project boundaries (***Table 9-1***). Seventeen (17) of the 40 sites were designated as requiring no further action because further investigation determined that contamination was not present at levels requiring remedial action. Fifteen (15) of the sites have been identified as presenting a contingent HTRW risk because contamination has been identified and quantified but remediation has either not begun or been completed. An additional five sites have been identified as requiring remediation; however, these sites have not been completely characterized such that a remediation program has been initiated as of March 2006.

The 40 contaminated sites discussed above can be generally categorized as "point source" contamination sites in which the contamination is relatively contained within an area of a few acres or less. The SFWMD is currently working with the

present lessees to ensure that the remaining contaminated sites are remediated prior to the surrender of the lands to the SFWMD.

The HTRW investigations performed to date have identified a number of point source contaminated sites as well as elevated levels of copper in the cultivated soils. Most of the contamination at the point source sites has been delineated and much of it remediated. The remaining sites are expected to be remediated prior to certification of the lands and are not likely to cause a project delay. The copper contamination issue poses a greater risk to the success of the project. At this time, the SFWMD and the USFWS are working together to identify copper hotspots as well as studying potential remediation techniques. Preliminary studies indicate that it is likely that a combination of several remediation techniques will result in an acceptable level of environmental risk to benthic invertebrates, fish, and birds. Proof of the effectiveness of the proposed remediation techniques will have to be submitted to the USACE and the USFWS as part of the 404 permit application process. The FDEP and the USEPA will participate in the environmental risk assessment review through the 404 WQC, and State Environmental Resource Permitting processes.

Until the USFWS has reviewed the results of a revised Phase III audit/Environmental Risk Assessment and the USFWS is satisfied that environmental risk is acceptable, the USACE will not be able to certify the lands for the project purpose nor will the 404 permit for the accelerated project be issued. In other words, the non-Federal sponsor will not be able to build the facility until the USFWS determines that proposed remediation techniques are sufficient. Since the SFWMD has accelerated the construction of the reservoir and proposed remediation techniques appear to be affective, there is only a small risk that the resolution of the copper contamination issue will delay the certification of the project lands as part of the federal project.

TABLE 9-1: LIST OF ACTIVE AND INACTIVE HTRW SITES ON C-43 BASIN PROJECT LANDS

No.	Area of Concern	Environmental Concern	Corrective Action	Risk	Within Reservoir Footprint
TRACT NO. GX-100-001: JACK BERRY					
1	Pole Barns A&B	None identified	NFA	No	--
3	Landfill	None identified	NFA	No	--
4	Former Landfill	None identified	NFA	No	--
5	Former Airstrip	None identified	NFA	No	--
6	Shooting Range	None identified	NFA	No	--
7	Former Spray Field	None identified	NFA	No	--
8	Bone Yard	None identified	NFA	No	--
9	Irrigation Pump Stations	None identified	NFA	No	--
10	Building C, Machine Shop	None Identified, impacted soil	Excavation and off-site disposal	Yes	No
11	Former Nursery	None identified	NFA	No	--
12	Current Airstrip	None identified	NFA	No	--
13	Former UST	Petroleum	Enter in Abandoned Tank Program	Contingent, no impact once clean up is completed	No
14	Building G, Chemical Barn	None identified	NFA	No	-
15	Building E, Maintenance Shop/Fuel Island	Petroleum	Impacted Soil, excavation and off-site disposal	Yes	No
16	Building F vehicle repair	Haz-Solvent based impacted solid-excavation and offsite disposal	Yes		No
17	Equipment Washing Area	Haz-Solvent based	Impacted soil-excavate and off site disposal	Yes	No
18	Wastewater treatment ponds	Hazardous	Impacted soil-excavate and off-site disposal	NO. Clean up completed	--
TRACT NO. GX-100-001: GRIFFIN BROTHERS PROPERTY					
19	Agricultural lands	Metals and Pesticides	Paraquat cease immediately, aldicarb cease one year prior to flooding	Contingent-no impacts if paraquat and aldicarb cease	Yes
20	Canal sediments	Low levels Copper and Penata-chlorophenol	NFA	No	--
21	Maintenance area / chemical barn	Soil impacted-agrochemicals and petroleum	133 tons of impacted soil-excavation and off-site disposal	Contingent, no impact once cleanup is completed	Yes

No.	Area of Concern	Environmental Concern	Corrective Action	Risk	Within Reservoir Footprint
22	Burn area	Soil impacts-copper	121 tons of impacted soils-excavation and off-site disposal	Contingent, no impact once cleanup is completed	Yes
23	Fertilizer mix/load area	Soil impacts-zinc	38 tons of impacted soils-excavation and off-site disposal	Contingent, no impact once cleanup is completed	Yes
24	pump stations	None identified	NFA	No	--
25	Solid waste	None identified	Remove piles of solid waste	Mp	--
TRACT NO. GX-100-005: WINTHROP CITRUS GROVES					
26	Citrus Grove crop area	Metal and pesticides	Paraquat cease immediately, aldicarb cease one year prior to flooding	Contingent, no impact once cleanup is completed	Yes
27	Canal sediments	Low levels of copper	NFA	no	--
28	Agriculture maintenance area	Metals and pesticides	Paraquat cease immediately, aldicarb cease 1 year prior	Contingent, no impacts if paraquat and aldicarb cease	Yes
29	Exploratory oil and Gas well	None identified	NFA	No	--
30	solid waste	None identified	NFA	No	--
31	Maintenance Area A	Petroleum and pesticides	653 tons of impacted soil-excavate and off-site disposal	Contingent, no impacts once cleanup is complete	Yes
32	Maintenance Area B	Petroleum	694 tons of impacted soil, excavate and off-site disposal	Contingent, no impact once clean up is completed	Yes
TRACT NO. GX-100-009: BRYAN PAUL CITRUS INC.					
33	Pump Station	Visible presence of contamination	Soils excavation adjacent to the main pump station and former pump station	Contingent, no impact once clean up is completed	Probable
34	Former Nursery Barn	Arsenic, cadmium, chloropyrifos and malathion	Soil to be excavated and off-site disposal	Contingent, no impact once clean up is completed	Probable
35	Mix station	Metals and petroleum	Impacts to soils - excavate and dispose of soils near structure, groundwater contamination - perform groundwater treatment	Contingent - no impacts once soil excavation and groundwater treatment is completed and 1 year of GW monitoring is done	Probable

No.	Area of Concern	Environmental Concern	Corrective Action	Risk	Within Reservoir Footprint
36	Auxiliary tank area	Metals	Impacted soils-excavation and disposal	Contingent no impact once cleanup is complete	Probable
37	Graded area solid waste	None identified	Solid waste present, scrape and remove waste	no	Probable
38	Burn area	Metals	Removal ash material and excavate and dispose	Contingent no impact once cleanup is complete	Probable
39	Cultivated area	Chlordane	13 acres high level contamination Options: excavate, cover with clean fill, soil inversion	yes	Probable
40	Canal Sediments	Metals	Excavate ash from bank of canal and sediments within the canal adjacent to burn area	Contingent no impact once clean up is complete	Probable

NFA-No further Action
-- Designation not made as no further action required

9.26 TOXIC SUBSTANCES CONTROL ACT OF 1976

The most prevalent chemicals known to have been applied to project area soil are fertilizers, pesticides and herbicides. However, the Toxic Substances Control Act exempts pesticides from its regulations. Extensive HTRW efforts have been undertaken on the site to identify, delineate and remediate contaminated areas. However, until the USFWS has reviewed the results of a revised Phase III audit and ERA to be performed after remediation and the USFWS is satisfied that environmental risk is acceptable, the USACE will not be able to certify the lands for the project purpose.

9.27 MAGNUSON-STEVENS FISHERY CONSERVATION AND MANAGEMENT ACT

EFH is present in the Caloosahatchee Estuary. This habitat is discussed in this section under Existing Conditions as well as Effects of the Selected Plan. National Oceanic and Atmospheric Administration (NOAA) agreed to accept the Draft EIS as the EFH assessment. NMFS reviewed the draft EIS and stated in an email dated 30 May 2007 that "NOAA's National Marine Fisheries Service, Southeast Region, Habitat Conservation Division, has reviewed the Department of the Army permit application listed below. We anticipate that any adverse effects that might occur on marine and anadromous fishery resources would be minimal and, therefore, do not object to issuance of the permit." The permit

application referred to used this draft EIS as the NEPA document, therefore NMFS has found the project to be in compliance with this Act.

9.28 EO 11990, PROTECTION OF WETLANDS

The area proposed for the Caloosahatchee River (C-43) West Basin Storage Reservoir Project is mostly farmland with a few disturbed wetlands. The reservoir design will include areas of littoral shelf along the seepage canal. These littoral shelves will help to offset the loss of wetlands due to project construction. There will be no wetland mitigation for the federal project. Overall, CERP projects are expected to have a net positive lift of wetland function. However, the state Acceler8 program may have wetland mitigation requirements as a result of the permitting process. A WRAP was performed in 2004 to determine impacts of wetland function related to the proposed project. Details of the WRAP can be found in the final CAR in ***Annex A.*** This project is in compliance with this EO.

9.29 EO 13186 RESPONSIBILITIES OF FEDERAL AGENCIES TO PROTECT MIGRATORY BIRDS

The project has been coordinated with the USFWS concerning migratory birds. The project is expected to benefit migratory birds by improved habitat and increased availability of forage species (amphibians, fish, and aquatic invertebrates) for wading birds. The project is in compliance with this EO.

9.30 EO 11988, FLOOD PLAIN MANAGEMENT

The purpose of the EO is to discourage Federally induced development in floodplains. Commitment of lands to reservoirs will preclude such development. In addition, existing flood levels will not be significantly or adversely impacted. This project is in compliance with this EO.

9.31 EO 12898, ENVIRONMENTAL JUSTICE

This EO requires consideration and avoidance of disproportionately adverse effects on minority and low-income populations. No such area was identified during project scoping. In order to better communicate with minority populations in the area, a Spanish translator has been provided at public meetings. There will be no displacement of homes by this reservoir. Subsistence fishing is expected to improve due to an overall lift in habitat quality resulting in more abundant fisheries. In public outreach efforts to date, only one potential environmental justice issue has been identified. The loss of jobs for low income and minority workers as a result of acquiring agricultural land for the construction of the reservoir would be a potential issue. However, to offset this issue, the SFWMD is conducting training programs to allow local individuals to

acquire the skills needed to construct the reservoirs. Adverse impacts have been considered and minimized to the extent practicable. The project is in compliance with the EO.

9.32 EO 13089, CORAL REEF PROTECTION

This project will not adversely impact coral reefs or coral reef resources; therefore, the project is in compliance with this EO.

9.33 EO 13112, INVASIVE SPECIES

The existing and future problem of invasive species growing within the C-43 West Reservoir site has been considered during the planning process. An evaluation of exotic species was included in Existing Conditions, Future Without Project Conditions, and Effected Environment. All feasible and prudent measures to minimize risk of introducing new invasive species will be followed. The CERP also includes further studies of means and methods to reduce the influence of exotic invasive plant species. The project is in compliance with this EO.

9.34 STATUS OF COORDINATION AND COOPERATION WITH OTHER AGENCIES

This project has been developed with strong cooperation from the USFWS, USDA, NRCS, USEPA, NOAA, USGS, FFWCC and FDEP. The SFWMD is a cost-sharing partner in the study and had been a fully active participant in the formulation of this project and creation of the project report. USEPA, USFWS, and USGS have staffers located in the Planning sections of USACE, Jacksonville Division; these staffers aid in interagency coordination for CERP projects. There has also been local participation in the project from Lee and Hendry counties.

An official letter inviting USFWS, USEPA, ENP, FWC and FDEP to be cooperating agencies (as defined by NEPA) was sent in September 2006. These agencies were chosen because of their special expertise in the area. The selection of these agencies to be invited as cooperating agencies does not exclude any other agencies from full participation in the project. Although none of these agencies decided to become a participating agency, their input will continue to be valued and solicited for the project.

9.34.1 CERP Partnerships and Cooperating Agencies

For the purposes of the Caloosahatchee River (C-43) West Basin Storage Reservoir project and the preparation of this report, the lead agency is the USACE Jacksonville District, and the SFWMD is the non-Federal cost-sharing

partner. As part of the CERP partnership, the SFWMD has several roles as defined in the following Florida Statutes (F.S):

- F.S. 373.470 (3)(c) requires the completion of a PIR prior to the SFWMD entering into a PCA with the USACE;
- F.S. 373.026 (8)(b) requires the SFWMD to submit a PIR to the FDEP for approval prior to the allocation of funds for the construction of CERP projects; and
- F.S. 373.1501(5) requires the SFWMD to analyze and evaluate water supply, water quality, flood protection, threatened and endangered species, and other natural system and habitat needs and to determine that components of the Plan are feasible, efficient, cost-effective, and consistent with the purposes of the CERP.

USEPA, USFWS, and USGS have staffers located in the USACE, Jacksonville District; these staffers aid in interagency coordination for CERP projects. There has also been local participation in the project from Lee and Hendry counties.

9.35 REVIEW OF THE DRAFT CALOOSAHATCHEE RIVER (C-43) WEST BASIN STORAGE RESERVOIR PROJECT

A Notice of Availability of the Draft PIR/EIS was published in the Federal Register on April 27, 2007. The Draft PIR/EIS was sent to local, state, and Federal agencies, private interest groups, and interested public for review and comment in accordance with the Council on Environmental Quality's NEPA regulations and related USACE guidance. Public libraries in the project area were provided copies to maintain in the reference section of the libraries for public review. The Draft PIR/EIS was also posted on www.evergladesplan.org for web viewing. The comment period ended on June 11, 2007. Comments received during the review were considered in preparing the final study documents.

9.35.1 Comments Received and Responses

Many comments were received in response to the Draft PIR/EIS. A matrix of the comments and responses, as well as copies of the correspondence, is provided in ***Annex B***.

9.35.2 List of Agencies, Organizations and Persons to Whom Copies of the Draft PIR/EIS were Sent

The following agencies, groups, and individuals were sent copies of the Draft PIR/EIS:

Native American Tribes
Miccosukee Tribe of Indians of Florida
Seminole Tribe of Florida
Muscogee (Creek) Nation of Oklahoma
Seminole Nation of Oklahoma
Poarch Creek Indian Nation

Federal Agencies
Advisory Council on Historic Preservation
Federal Emergency Management Agency
Council on Environmental Quality
U.S. Environmental Protection Agency
U.S. Department of Agriculture
  Forestry Service
  Natural Resources Conservation Service
U.S. Department of Commerce
  National Oceanic and Atmospheric Administration
    Florida Keys National Marine Sanctuary
    National Marine Fisheries Service
U.S. Department of Energy
U.S. Department of Housing and Urban Development
U.S. Department of the Interior
  Bureau of Indian Affairs
  U.S. Fish and Wildlife Service
  U.S. Geological Survey
  National Park Service
  Office of Environmental Policy and Compliance
U.S. Department of Justice
U.S. Coast Guard
U.S. Department of Transportation
  Federal Highway Administration
U.S. Public Health Service

State Agencies
Office of the Governor
Florida House of Representatives, Environmental Protection Committee
Florida Coastal Management Program
Florida Department of Agriculture and Consumer Services
Florida Department of Community Affairs
Florida Department of Environmental Protection
Florida State Clearinghouse
Florida Fish and Wildlife Conservation Commission
Florida Department of Transportation
Florida Division of Forestry
Florida Division of Historical Resources–SHPO

Florida Division of State Lands

SECTION 10
RECOMMENDATIONS

This page intentionally left blank

10.0 DISTRICT ENGINEER'S RECOMMENDATION

The Caloosahatchee River (C-43) West Basin Storage Reservoir project will provide an above-ground storage reservoir (including pump stations and water control structures) and associated conveyance canals as a cost-effective solution to achieving estuarine restoration benefits in the Caloosahatchee Estuary, which is integral to achieving system-wide benefits in the south Florida ecosystem. The Project will help reduce wet season high volume flows from Lake Okeechobee and contributing basin runoff from the lower West Caloosahatchee River Basin by capturing and storing a portion of these flows in the reservoir. Then during the dry season when water levels are at their lowest, water will be released from the reservoir to the Caloosahatchee River (C-43 Canal) to promote a healthy salinity balance in the estuary, thereby reducing saltwater migration into the freshwater portion of the estuary. In addition, the plan achieves the benefits of the Project as previously developed for the CERP.

This Project is integral to achieving restoration in the Caloosahatchee Estuary and plays an important role in meeting the CERP system-wide ecosystem restoration goals and objectives and other water-related needs of the region. Fish and wildlife habitat benefits of the Caloosahatchee River (C-43) West Basin Storage Reservoir project includes improving the timing of water deliveries to the estuary thereby providing a salinity range suitable for a healthy ecosystem and reestablishment of natural hydropatterns within existing natural areas, improvement in seagrass beds in the estuary, and increase habitat for the eastern oyster, blue crab, and other fish and marine organisms. The Project is expected to produce a total of 12,809 average annual habitat units (HUs). Further, this Project is a critical building block upon which a subsequent study will be able to evaluate and achieve broader ecosystem restoration objectives in the Caloosahatchee River Watershed (includes the East Caloosahatchee River (upper) and West Caloosahatchee River (lower) fresh water river basin and the tidal basin).

I find that the Caloosahatchee River (C-43) West Basin Storage Reservoir project, located in western Hendry County, is an integral part of CERP. The Caloosahatchee River (C-43) West Basin Storage Reservoir project Recommended Plan features a reservoir with a storage capability of 170,000 ac-ft, a normal pool storage depth between 15 and 25 feet with a footprint of approximately 10,700 acres (of which approximately 10,480 acres are required in fee, approximately 20 acres will be perpetual easements, and approximately 200 acres will be used on a temporary basis for staging area).. The reservoir includes an individual inflow pump station of 1500 cfs capacity, discharge structures, emergency overflow spillways, and seepage control canals with associated structures. The reservoir may also provide opportunities to increase flood damage reduction capabilities through operational changes to the C&SF Project and local drainage systems. However, these opportunities are considered incidental and are not claimed as benefits. Additionally, the reservoir may provide some water quality improvements in the Townsend, Banana Branch and Ft. Simmons Branch canals and other areas. Again, these opportunities are considered incidental and are not claimed as benefits.

Therefore, I recommend that the Caloosahatchee River (C-43) West Basin Storage Reservoir project as described in the section of the report entitled "The Selected Plan", with such modifications that may be deemed advisable at the discretion of the Chief of Engineers, be

authorized for construction. The total estimated first cost for the Caloosahatchee River (C-43) West Basin Storage Reservoir project is $570,480,000 (October 2009 price level).The total first cost for the Caloosahatchee River (C-43) West Basin Storage Reservoir project includes recreation features totaling $2,930,000. The estimated total annual cost of OMRR&R of the ecosystem restoration elements is $3,100,000 with an estimated Federal annual OMRR&R cost of $1,550,000 and an estimated non-Federal OMRR&R cost of $1,550,000. The estimated cost for OMRR&R of the recreation elements is $25,000 which is 100 percent non-Federal.

The above recommendations are made with the provision that the non-Federal sponsor and the Secretary of the Army shall enter into a binding agreement defining the terms and conditions of cooperation for implementing the Project, and that the non-Federal sponsor agrees to perform the following items of local cooperation:

a. Provide 50 percent of total project costs consistent with the provisions of Section 601(e) of the Water Resources Development Act of 2000 as amended including authority to perform design and construction of project features consistent with Federal law and regulation.

b. Provide all lands, easements, and rights-of-way, including suitable borrow and dredged or excavated material disposal areas, and perform or assure the performance of all relocations that the Government and the Non-Federal Sponsor jointly determine to be necessary for the construction, operation, maintenance, repair, replacement and rehabilitation of the Project and valuation will be in accordance with the Master Agreement.

c. Shall not use the ecosystem restoration features or lands, easements, and rights-of-way required for such features as a wetlands bank or mitigation credit for any other projects.

d. Give the Government a right to enter, at reasonable times and in a reasonable manner, upon land that the non-Federal sponsor owns or controls for access to the Project for the purpose of inspection, and, if necessary, for the purpose of completing, operating, maintaining, repairing, replacing, or rehabilitating the Project;

e. Assume responsibility for operating, maintaining, repairing, replacing, and rehabilitating (OMRR&R) the Project or completed functional portions of the Project, including mitigation features, in a manner compatible with the Project's authorized purposes and in accordance with applicable Federal and State laws and specific directions prescribed in the OMRR&R manuals and any subsequent amendments thereto. Cost sharing for OMRR&R will be in accordance with Section 601 of WRDA 2000 as amended;

f. The non-Federal Sponsor shall operate, maintain, repair, replace and rehabilitate the recreation features of the Project with responsibility for 100 percent of the cost;

g. Keep the recreation features, and access roads, parking areas, and other associated public use facilities, open and available to all on equal terms;

h. Unless otherwise provided for in the statutory authorization for this Project, comply with Section 221 of Public Law 91-611, Flood Control Act of 1970, as amended, and Section 103 of the WRDA of 1986, Public Law 99-662, as amended, which provides that the Secretary of the Army shall not commence the construction of any water resources project or separable element thereof, until the non-Federal sponsor has entered into a written agreement to furnish its required cooperation for the Project or separable element;

i. Hold and save the Government free from all damages arising from construction, operation, maintenance, repair, replacement and rehabilitation of the Project and any project-related betterments, except for damages due to the fault or negligence of the Government or the Government's contractors;

j. Keep and maintain books, records, documents, and other evidence pertaining to costs and expenses incurred pursuant to the Project to the extent and in such detail as will properly reflect total project costs and comply with the provisions of the Master Agreement;

k. Perform, or cause to be performed, any investigations for hazardous substances that are determined necessary to identify the existence and extent of any hazardous substances regulated under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), 42 USC 9601-9675, that may exist in, on, or under lands, easements or rights-of-way necessary for the construction, operation, and maintenance of the Project; except that the non-Federal sponsor shall not perform such investigations on lands, easements, or rights-of-way that the Government determines to be subject to the navigation servitude without prior specific written direction by the Government;

l. Assume complete financial responsibility for all necessary cleanup and response costs of any CERCLA regulated materials located in, on, or under lands, easements, or rights-of-ways that the Government determines necessary for construction, operation, maintenance, repair, replacement and rehabilitation;

m. As between the Government and the non-Federal Sponsor, the non-Federal Sponsor shall be considered the operator of the Project for purposes of CERCLA liability. To the maximum extent practicable, the non-Federal Sponsor shall operate, maintain, repair, replace, and rehabilitate the Project in a manner that will not cause liability to arise under CERCLA;

n. Prevent obstructions or encroachments on the project (including prescribing and enforcing regulations to prevent such obstructions or encroachments) such as any new developments on project lands, easements, and rights-of-way or the addition of facilities which might reduce the outputs produced by the ecosystem restoration

features, hinder operation and maintenance of the project, or interfere with the project's proper function;

o. Comply with the applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public law 91-646, as amended by title IV of the Surface Transportation and Uniform Relocation Assistance Act of 1987 (Public Law 100-17), and the Uniform Regulations contained in 49 CFR part 24, in acquiring lands, easements, and rights-of-way, and performing relocations for construction, operation, and maintenance of the Project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said act;

p. Comply with all applicable Federal and State laws and regulations, including, but not limited to, Section 601 of the Civil Rights Act of 1964, Public Law 88-352 (42 U.S.C. 2000d) and Department of Defense Directive 5500.11 issued pursuant thereto; Army Regulation 600-7, entitled "Nondiscrimination on the Basis of Handicap in Programs and Activities Assisted or Conducted by the Department of the Army;" and all applicable Federal labor standards requirements including, but not limited to, 40 U.S.C. 3141-3148 and 40 U.S.C. 3701-3708[revising, codifying and enacting without substantive change the provisions of the Davis-Bacon Act (formerly 40 U.S.C. 276a et seq.), the Contract Work Hours and Safety Standards Act (formerly 40 U.S.C. 327 et seq.) and the Copeland Anti-Kickback Act (formerly 40 U.S.C. 276c)];

q. Comply with Section 106 of the National Historic Preservation Act in completion of all consultation with the Florida State Historic Preservation Officer, and as necessary, the Advisory Council on Historic Preservation, prior to construction as part of the preconstruction engineering and design phase of the project;

r. Provide 50 percent of that portion of total cultural resource preservation mitigation and data recovery costs attributable to the Project that are in excess of one percent of the total amount authorized to be appropriated for the Project;

s. Do not use Federal funds to meet the non-Federal sponsor's share of total project costs unless the Federal granting agency verifies in writing that the expenditure of such funds is expressly authorized and in accordance with Section 601 (e)(3) of the WRDA of 2000, as amended, and in accordance with the Master Agreement;

t. The Non-Federal Sponsor agrees to participate in and comply with applicable Federal floodplain management and flood insurance programs consistent with its statutory authority.

    1. Not less than once each year the Non-Federal Sponsor shall inform affected interests of the extent of protection afforded by the Project.

    2. The Non-Federal Sponsor shall publicize flood plain information in the area concerned and shall provide this information to zoning and other regulatory agencies for their use in preventing unwise future development in the flood

plain and in adopting such regulations as may be necessary to prevent unwise future development and to ensure compatibility with protection levels provided by the Project.

3. The Non-Federal Sponsor shall comply with Section 402 of WRDA 1986, as amended (33 U.S.C. 701b-12), which requires a non-Federal interest to have prepared, within one year after the date of signing a PPA for the Project, a floodplain management plan. The plan shall be designed to reduce the impacts of future flood events in the project area, including but not limited to, addressing those measures to be undertaken by non-Federal interests to preserve the level of flood protection provided by the Project. As required by Section 402, as amended, the non-Federal interest shall implement such plan not later than one year after completion of construction of the Project. The Non-Federal Sponsor shall provide an information copy of the plan to the Government upon its preparation.

4. The Non-Federal Sponsor shall prescribe and enforce regulations to prevent obstruction of or encroachment on the Project or on the lands, easements, and rights-of-way determined by the Government to be required for the construction, operation, maintenance, repair, replacement, and rehabilitation of the Project, that could reduce the level of protection the Project affords, hinder operation or maintenance of the Project, or interfere with the Project's proper function.

u. The overarching objective of the Plan is the restoration, preservation, and protection of the South Florida ecosystem while providing for other water-related needs of the region, including water supply and flood protection. The Federal Government and the non-Federal sponsor are committed to the protection of the appropriate quantity, quality, timing, and distribution of water to ensure the restoration, preservation, and protection of the natural system as defined in Section 601 of WRDA 2000, for so long as the project remains authorized. This quantity, quality, timing, and distribution of water shall meet applicable water quality standards and be consistent with the natural system restoration goals and objectives of the CERP, as the Plan is defined in the Programmatic Regulations. The non-Federal sponsor will protect the water for the natural system by taking the following actions to achieve the overarching natural system objectives of the Plan:

1. Ensure, through appropriate and legally enforceable means under Florida law, that the quantity, quality, timing, and distribution of existing water that the Federal Government and the non-Federal sponsor have determined in this Project Implementation Report is available and beneficial to the natural system, will be available at the time the Project Partnership Agreement for the project is executed and will remain available for so long as the Project remains authorized.

2. (a) Prior to the execution of the Project Partnership Agreement, reserve or allocate for the natural system the necessary amount of water that will be made available by the project that the Federal Government and the non-Federal sponsor have determined in this Project Implementation Report.

   (b) After the Project Partnership Agreement is signed and the project becomes operational, make such revisions under Florida law to this reservation or allocation of water that the non-Federal sponsor determines, as a result of changed circumstances or new information, is necessary for the natural system.

3. For so long as the Project remains authorized, notify and consult with the Secretary of the Army should any revision in the reservation of water or other legally enforceable means of protecting water be proposed by the non-Federal sponsor, so that the Federal Government can assure itself that the changed reservation or legally enforceable means of protecting water conform with the non-Federal sponsor's commitments under paragraphs 1 and 2. Any change to a reservation of water made available by the project shall require an amendment to the Project Partnership Agreement.

Section 601(e)(5)(B) of the WRDA 2000 authorizes the Secretary of the Army to provide credit to the non-Federal sponsor for work completed by it during the period of construction pursuant to a PCA and a determination by the Secretary that the work is integral to the CERP. As part of its initiative for early implementation of certain expedited CERP projects, formerly known as the "Acceler8 Program", the non-Federal sponsor has stated that it may construct portions of the Caloosahatchee River (C-43) West Basin Storage Reservoir project consistent with this report, in advance of Congressional authorization and the signing of a PCA. The non-Federal sponsor is exploring alternative project delivery methods to expedite implementation of the Project. Such delivery methods may include public-private partnerships in which the non-Federal sponsor contracts with a private or not-for-profit entity for services that may include designing, building, operating or financing these components. I believe that it would be in the public interest for this Project to be implemented expeditiously due to the early benefits to the surrounding habitat, as well as hydrologic benefits to Federal lands and estuaries in other portions of the south Florida ecosystem. Therefore, I recommend that should the non-Federal sponsor construct portions of the Caloosahatchee River (C-43) West Basin Storage Reservoir project prior to the execution of a PAC for this Project, the non-Federal sponsor be credited for such construction costs at the time the PAC for the Caloosahatchee River (C-43) West Basin Storage Reservoir project is executed. Such credit would be applied toward the non-Federal sponsor's share of the costs associated with the implementation of the CERP as authorized by Section 601(e)(5)(C) of WRDA 2000, shall not include cash reimbursements, and shall be subject to: a) the authorization of the Caloosahatchee River (C-43) West Basin Storage Reservoir project by law; b) a determination by the Secretary of the Army that the activities are integral to the CERP restoration project; c) a certification by the District Engineer that the costs are reasonable, allowable, necessary, auditable, and allocable; and d) a certification by the District Engineer

that the activities have been implemented in accordance with USACE design and construction standards and applicable Federal and State laws.

The recommendations contained herein reflect the information available at this time and current Departmental policies governing formulation of individual projects. They do not reflect program and budgeting priorities inherent in the formulation of a national Civil Works construction program nor the perspective of higher review levels within the Executive Branch. Consequently, the recommendations may be modified before they are transmitted to the Congress as proposals for authorization and implementation funding.

However, prior to transmittal to the Congress, the Sponsor, the State, interested Federal agencies, and other parties will be advised of any modifications and will be afforded an opportunity to comment further.

Alfred A. Pantano
Colonel, Corps of Engineers
District Engineer

13.0 GLOSSARY OF TERMS AND ACRONYMS

13.1 GLOSSARY OF TERMS

A

Acre — Area of land equal to 43,560 square feet. In S.I. metric system, one acre is equal to 4,046.9 square meters or 2.471 hectares.

Acre-foot — The quantity of water required to cover 1 acre to a depth of 1 foot. Equal to 43,560 cubic feet (1,233.5 cubic meters).

Activity – A specific project task that requires resources and time to complete.

Adaptive Assessment – A process for learning and incorporating new information into the planning and evaluation phases of the restoration program. This process ensures that the scientific information produced for this effort is converted into products that are continuously used in management decision-making.

Adverse Impact – The detrimental effect of an environmental change relative to desired or baseline conditions.

Affected Environment — Existing biological, physical, social, and economic conditions of an area subject to change, both directly and indirectly, as a result of a proposed human action.

Air Quality — Measure of the health-related and visual characteristics of the air, often derived from quantitative measurements of the concentrations of specific injurious or contaminating substances.

Aquatic – Consisting of, relating to or being in water; living or growing in, on or near the water; or taking place in or on the water.

Aquifer – An underground geologic formation, a bed or layer of earth, gravel or porous stone, that yields water or in which water can be stored.

Aquifer Storage and Recovery (ASR) – The practice of pumping freshwater, which has been treated to drinking water standards, approximately 1,000 feet underground where it is stored in a confined aquifer and can be recovered later. The pumped freshwater displaces, or pushes away, the brackish water of the Upper Floridan Aquifer, resulting in an underground reservoir of freshwater.

Authorization — An act by the Congress of the United States, which authorizes use of public funds to carry out a prescribed action.

B

Baseline – The initial approved plan for schedule, cost or performance management, plus or minus approved changes, to which deviations will be compared as the project proceeds.

Basin (or Caloosahatchee River Basin) - All the land drained by a river and its branches.

Best Management Practices (BMPs) – The best available land, industrial and waste management techniques or processes that reduce pollutant loading from land use or industry, or which optimize water use.

Bioaccumulation - If the input of a toxic substance to an organism is greater than the rate at which the substance is lost, the organism is said to be bioaccumulating that substance. Thus, the longer the biological half-life of the substance the greater the risk of chronic poisoning, even if environmental levels of the toxin are very low.

Bioconcentration - If the input of a toxic substance to an organism is greater than the rate at which the substance is lost, the organism is said to be bioaccumulating that substance. Thus, the longer the biological half-life of the substance the greater the risk of chronic poisoning, even if environmental levels of the toxin are very low.

Biota - The total collection of organisms of a geographic region or a time period, from local geographic scales and instantaneous temporal scales all the way up to whole-planet and whole-timescale spatiotemporal scales. The biota of the Earth lives in the biosphere.

Borrow Canal – Canal or ditches where material excavated is used for earthen construction nearby. Also, typically denotes a canal with no conveyance or water routing purpose.

C

Canal – A human-made waterway that is used for draining or irrigating land or for navigation by boat.

Central and Southern Florida Project (C&SF) – A multi-purpose project, first authorized by Congress in 1948, which provides flood control, water supply protection, water quality protection and natural resource protection.

Channel — Natural or artificial watercourse, with a definite bed and banks to confine and conduct continuously or periodically flowing water.

Comprehensive Everglades Restoration Plan (CERP) – The plan for the restoration of the greater Everglades and to meet water supply and flood protection needs in the urban and agricultural regions of south Florida.

Comprehensive Plan – See Comprehensive Everglades Restoration Plan.

Control Structure – A human-created structure that regulates the flow of waters or the level of waters.

Conveyance Capacity — The rate at which water can be transported by a canal, aqueduct, or ditch. In this document, conveyance capacity is generally measured in cubic feet per second (cfs).

Cost-Benefit Analysis – An analysis, often stated as a ratio, used to evaluate a proposed course of action.

Cost Effectiveness Analysis – An analysis, used in ecosystem restoration planning studies, in which comparison of the costs and non-monetary outputs of alternative plans to identify the least cost plan for every level of output considered. Alternative plans are compared to identify those that would produce greater levels of output at the same cost, or at a lesser cost, as other alternative plans.

Critical Habitat – A description, which may be contained in a Biological Opinion, of the specific areas with physical or biological features essential to the conservation of a listed species and which may require special management considerations or protection; these areas have been legally designated via Federal Register notices.

Cubic feet per second (cfs) — A measure of the volume rate of water movement. As a rate of streamflow, a cubic foot of water passing a reference section in 1 second of time. One cubic foot per second equals 0.0283 meter /second (7.48 gallons per minute). One cubic foot per second flowing for 24 hours produces approximately 2 acre-feet.

Culvert – A concrete, metal or plastic pipe that transports water.

D

Dam - A barrier across flowing water that obstructs, directs or slows down the flow, often creating a reservoir, lake or impoundment.

Discharge – The rate of water movement as volume per unit time, usually expressed as cubic feet per second.

Dissolved Oxygen (D.O.) – The concentration of oxygen dissolved in water, sometimes expressed as percent saturation, where saturation is the maximum amount of oxygen that theoretically can be dissolved in water at a given altitude and temperature.

Dry Season — Hydrologically, for south Florida, the months associated with a lower incident of rainfall, November through May.

Duration – The period of time over which a task occurs, in contrast to effort, which is the amount of labor hours a task requires; duration establishes the schedule for a project, and effort establishes the labor costs.

E

Ecology – The science of the relationships between organisms and their environments, also called bionomics; or the relationship between organisms and their environment.

Ecosystem — A functional group of animal and plant species that operate in a unique setting that is mostly self-contained.

Effectiveness – A measure of the quality of attainment in meeting objectives; this is distinguished from efficiency, which is measured by the volume of output achieved for the input used.

Effluent - An outflowing of water from a natural body of water, or from a man-made structure.

Embankment - An outflowing of water from a natural body of water, or from a man-made structure or to prevent or direct flooding by water.

Endangered Species — Any species or subspecies of bird, mammal, fish, amphibian, reptile, or plant which is in serious danger of becoming extinct throughout all, or a significant portion of its range. Federally endangered species are officially designated by the U.S. Fish and Wildlife Service or the National Marine Fisheries Service and published in the Federal Register.

Enhancement — Measures which develop or improve the quality or quantity of existing conditions or resources beyond a condition or level that would have occurred without an action; i.e., beyond compensation.

Environmental and Economic Equity (EEE) – A program-level activity, referred to in early phases of the program as Socioeconomic and Environmental Justice.

Environmental Consequences — The impacts to the Affected Environment that are expected from implementation of a given alternative.

Environmental Impact Statement (EIS) — An analysis required by the National Environmental Policy Act for all major federal actions, which evaluates the environmental risks of alternative actions.

Estuary – A semi-enclosed coastal body of water with one or more rivers or streams flowing into it, and with a free connection to the open sea. Estuaries are often associated with high rates of biological productivity.

Evaluate – To appraise or determine the value of information, options or resources being provided to a project.

Evapotranspiration (ET) - The sum of evaporation and plant transpiration. Evaporation accounts for the movement of water to the air from sources such as the soil, canopy interception, and waterbodies. Transpiration accounts for the movement of water within a plant and the subsequent loss of water as vapour through stomata in its leaves. Evapotranspiration is an important part of the water cycle.

Exotic species — Introduced species not native to the place where they are found.

F

Feasibility Study — The second phase of a project. The purpose is to describe and evaluate alternative plans and fully describe recommended project.

Federally Endangered Species — An endangered species which is officially designated by the U.S. Fish and Wildlife Service or the National Marine Fisheries Service and published in the Federal Register.

Flood Control Storage Capacity – Reservoir capacity reserved for the purpose of regulating flood inflows to reduce flood damage downstream (compare with reservoir storage capacity).

Flow — The volume of water passing a given point per unit of time.

- **Instream flow requirements** — Amount of water flowing through a stream course needed to sustain instream values.
- **Minimum flow** — Lowest flow in a specified period of time.
- **Peak flow**—Maximum instantaneous flow in a specified period of time.

G

Geospatial Data - Information, which includes, but is not limited to surveys, maps, aerial photography, aerial imagery, and biological, ecological and hydrological modeling coverages.

Goal – Something to be achieved. Goals can be established for outcomes (results) or outputs (efforts).

Groundwater — Water stored underground in pore spaces between rocks and in other alluvial materials and in fractures of hard rock occurring in the saturated zone.

Groundwater Level — Refers to the water level in a well, and is defined as a measure of the hydraulic head in the aquifer system.

Groundwater Pumping — Quantity of water extracted from groundwater storage.

Groundwater Seepage — Groundwater flow in response to a hydraulic gradient.

Groundwater Table — The upper surface of the zone of saturation, except where the surface is formed by an impermeable body.

H

Habitat — Area where a plant or animal lives.

Hectare – A unit of measure in the metric system equal to 10,000 square meters or 2.47 acres.

Hydraulic Gradient – Denotes slope of watercourse, above or below ground water level. Typically, defines energy loss or consumption in the conveyance process.

Hydraulic Head (Lift) – Denotes relative comparison of water stages for gravity flow. Pump stations generally provide lift or increase water level elevations.

Hydrologic Condition — The state of an area pertaining to the amount and form of water present. For example, saturated ground (water table at surface), lake stage and river flow rate.

Hydrologic Response — An observed decrease or increase of water in a particular area.

Hydrology – The scientific study of the properties, distribution and effects of water on the earth's surface, in the soil and underlying rocks, and in the atmosphere.

Hydropattern — Refers to depth as well as hydroperiod is hydropattern. Hydropatterns are best understood by a graphic depiction of water level (above as well as below the ground) through annual cycles.

Hydroperiod — For non-tidal wetlands, the average annual duration of flooding is called the hydroperiod, which is based only on the presence of surface water and not its depth.

I

Impoundment – An obstruction, such as a dam and reservoir,

Independent Technical Review Team – A group autonomous of the Project Team established to conduct reviews to ensure that design products are consistent with established criteria, guidance, procedures and policies.

Indicator Species — Organism, species, or community which indicates presence of certain environmental conditions.

In situ - A Latin phrase meaning in the original place. It is used in many different contexts

Invertebrate – A small animal that does not have a backbone, examples include crayfish, insects and mollusks, which can be indicators of ecosystem status.

L

Lag – The amount of time after one task is started or completed before the next task can be started or completed.

Lake Okeechobee Regulation Schedule (LORS)

- Manage Lake Okeechobee at optimal lake levels to allow recovery of the Lake's environment and natural resources.
- Reduce high regulatory releases to the Caloosahatchee and St. Lucie estuaries so that the health of the estuaries are not compromised.

- Continue to provide flood control, water supply, navigation and recreation water resource needs.
- Ensure public health and safety.

Land Classification — An economic classification of variations in land reflecting its ability to sustain long-term agricultural production.

Levee – A human-created embankment that controls or confines water.

Littoral Zone — The shore of land surrounding a water body that is characterized by periodic inundation or partial saturation by water level. Typically defined by species of vegetation found.

Local Sponsor – The South Florida Water Management District.

Lock and Dam - A lock is a particular type of device for raising or lowering boats between stretches of water at different levels. The distinguishing feature of a lock is a fixed chamber whose water level can be varied; whereas in a boat lift or canal inclined plane, it is the chamber itself which moves.

M

Macrophytes – Visible plants found in aquatic environments, including sawgrass, sedges and lilies.

Marl - Calcium carbonate or lime-rich muds or mudstones which contain variable amounts of clays and calcite or aragonite. The term is most often used to describe lacustrine (lake) sediments but may also be used for marine deposits.

Marsh — An area of low-lying wetland.

Master Program Management Plan (MPMP) – A document which describes the framework and processes to be used by the USACE and the SFWMD for managing and monitoring implementation of the Comprehensive Everglades Restoration Plan.

MIKESHE - An integrated surface water/ground water model, which includes a module for estimating supplemental irrigation requirements based upon land use, soil type, crop type, rainfall, and evapotranspiration.

Mitigation – To make less severe; to alleviate, diminish or lessen; one or all of the following may comprise mitigation: (1) avoiding an impact altogether by not taking a certain action or parts of an action; (2) minimizing impacts by limiting the degree or magnitude of an action and its implementation; (3) rectifying an

impact by repairing, rehabilitating or restoring the affected environment; (4) reducing or eliminating an impact over time by preservation and maintenance operations during the life of an action; and (5) compensating for an impact by replacing or providing substitute resources or environments.

Model — A tool used to mathematically represent a process which could be based upon empirical or mathematical functions. Models can be computer programs, spreadsheets, or statistical analyses.

Monitoring – The capture, analysis and reporting of project performance, usually as compared to plan.

N

National Environmental Policy Act (NEPA) - United States environmental law that was signed into law on January 1, 1970 by U.S. President Richard Nixon. (Although enacted on January 1, 1970, its "short title" is "National Environmental Policy Act of 1969.")

Nutrients - A chemical element or compound used in an organism's metabolism or physiology. Six nutrient groups exist and are broadly classified into those providing energy, and those used as components in the body or cellular structures.

O

Objective – A goal expressed in specific, directly measurable terms.

Off-peak – Less than peak design flow rate during storm runoff producing events.

Outreach - Proactive communication and productive involvement with the public to best meet the water resource needs of South Florida.
Oxbow - A bend in a river, similar to the shape of the wooden yoke of an ox.

Oxygen Demand — The biological or chemical demand of dissolved oxygen in water. Required by biological processes for respiration.

P

Performance Measure – A desired result stated in quantifiable terms to allow for an assessment of how well the desired result has been achieved.

Periphyton – The biological community of microscopic plants and animals attached to surfaces in aquatic environments, for example algae.

Phosphorus (P) — Element or nutrient required for energy production in living organisms. Distributed into the environment mostly as phosphates by agricultural runoff (fertilizer) and life cycles. Frequently the limiting factor for growth of microbes and plants.

Pollutants - Many of the compounds which are dangerous to the environment can also be harmful to humans in the long-term range and come from mineral and fossil sources or are produced by humans themselves.

Potable - Water of sufficient quality to serve as drinking water is termed potable water whether it is used as such or not.

Program – A group of related projects managed in a coordinated manner; programs usually include an element of on-going activity.

Program Management – A structure and set of strategies to be used during the implementation phase, which build upon the interagency partnership, implementation guidelines and successful strategies developed during the Restudy's feasibility planning phase.

Programmatic Environmental Impact Statement (PEIS) – An environmental impact statement prepared prior to a Federal agency's decision regarding a major program, plan or policy, which usually is broad in scope and followed by subsequently more narrowly focused National Environmental Policy Act compliance documents.

Programmatic Regulations – Section 601(h) of WRDA 2000 states that the overarching purpose of the Comprehensive Plan is the restoration, preservation and protection of the south Florida ecosystem while providing for the other water related needs of the region, including water supply and flood protection. The purpose of the regulations is to ensure that the goals and objectives of CERP are achieved. The regulations will contain: (1) processes for the development of Project Implementation Reports, Project Cooperation Agreements and operating manuals that ensure the goals and objectives of the plan are achieved; (2) processes that ensure new scientific, technical, or other information such as that developed through adaptive management is integrated into the implementation of the plan; and (3) processes to establish interim goals to provide a means by which the restoration success of the plan may be evaluated throughout the implementation process.

Project – A sequence of tasks with a beginning and an end that uses time and resources to produce specific results. Each project has a specific, desired outcome, a deadline or target completion date and a budget that limits the amount of resources that can be used to complete the project.

Project Area – The entire C-43 Basin.

Project Cooperation Agreement (PCA) – A document that describes the roles and responsibilities of the USACE and SFWMD for real estate acquisition, construction, construction management and operations and maintenance.

Project Team – An interdisciplinary group formed from the resources of the implementing agencies, which develops the products necessary to deliver the project.

Project Duration – The time it takes to complete an entire project from starting the first task to finishing the last task.

Project Implementation Report (PIR) – A decision document that will bridge the gap between the conceptual design contained in the Comprehensive Plan and the detailed design necessary to proceed to construction.

Project Management – A discipline of combining systems, techniques and people to complete a project within established goals of time, budget and quality.

Project Manager – A person who takes overall responsibility for coordinating a project to ensure the desired result comes in on time and within budget.

Project Phase – A collection of logically related project activities, usually culminating in the completion of a major deliverable.

Proposed Action — Plan that a Federal agency intends to implement or undertake and which is the subject of an environmental analysis. Usually, but not always, the proposed action is the agency's preferred alternative for a project. The proposed action and all reasonable alternatives are evaluated against the no action alternative.

Public Involvement — Process of obtaining citizen input into each stage of the development of planning documents. Required as a major input into any EIS.

Public Outreach – A program-level activity with the objectives of keeping the public informed of the status of the overall program and key issues associated with restoration implementation and providing effective mechanisms for public participation in the restoration plan development.

Pump Station – A human constructed structure that uses pumps to transfer water from one location to another.

Q

Quality Assurance (QA) – The process of evaluating overall project performance on a regular basis to provide confidence that the project will satisfy the relevant quality standards.

Quality Control (QC) – The process of monitoring specific project results to determine if they comply with relevant quality standards, and identifying means of eliminating causes of unsatisfactory performance.

R

Recharge — The processes of water filling the voids in an aquifer, which causes the piezometric head or water table to rise in elevation.

Reconnaissance Study — The first phase of a project. It has four phases (1) to define problem, (2) asses sponsor's level of interest and support, (3) decide to progress to feasibility phase based on Federal interest, (4) estimate time and money to complete feasibility study.

Record of Decision — Concise, public, legal document which identifies and publicly and officially discloses the responsible official's decision on the alternative selected for implementation. It is prepared following completion of an Environmental Impact Statement.

Refugia - Refers to locations of isolated or relict populations of once widespread animal or plant species.

Regional Water Supply Plan — Detailed water supply plan developed by the District under Ch. 373.0361, F.S.

Reservoir — Artificially impounded body of water.

Reservoir Storage Capacity — Reservoir capacity normally usable for storage and regulation of reservoir inflows to meet established reservoir operating requirements.

> **Flood control storage capacity** — Reservoir capacity reserved for the purpose of regulating flood inflows to reduce flood damage downstream.

Restoration – The recovery of a natural system's vitality and biological and hydrological integrity to the extent that the health and ecological functions are self-sustaining over time.

Restoration Coordination and Verification (RECOVER) – A program-level activity whose role is to organize and apply scientific and technical information in ways that are most effective in supporting the objectives of the Comprehensive Everglades Restoration Plan.

Restudy – The Central and South Florida Project Comprehensive Review Study, authorized by the Water Resources Development Act of 1992, which examined the Central and Southern Project to determine the feasibility of modifying the project to restore the south Florida ecosystem and provide for other water-related needs of the region, and which resulted in The Final Integrated Feasibility Report and Programmatic Environmental Impact Statement, which was transmitted to Congress on July 1, 1999.

Risk Analysis – An evaluation of the feasibility or probability that the outcome of a project or policy will be the desired one; usually conducted to compare alternative scenarios, action plans or policies.

Run off – Unfiltered water that reaches streams, lakes sounds, and oceans by means of flowing across impervious surfaces. These surfaces include roads, parking lots, driveways and roofs.

S

Salinity - The saltiness or dissolved salt content of a body of water

Scoping — The process of defining the scope of a study, primarily with respect to the issues, geographic area, and alternatives to be considered. The term is typically used in association with environmental documents prepared under the National Environmental Policy Act.

Scrub – A community dominated by pinewoods with a thick understory of oaks and saw palmetto, and which occupies well-drained, nutrient-poor sandy soils.

Seepage — Water that escapes control through levees, canals or other holding or conveyance systems.

Sheet Flow – Water movement as a broad front with shallow, uniform depth.

Slough – A depression associated with swamps and marshlands as part of a bayou, inlet or backwater; contains areas of slightly deeper water and a slow current; can be thought of as the broad, shallow rivers of the Everglades.

South Florida Ecosystem – An area consisting of the lands and waters within the boundary of the South Florida Water Management District, including the Everglades, the Florida Keys and the contiguous near-shore coastal waters of South Florida.

South Florida Water Management Model (SFWMM) - An integrated surface water groundwater model that simulates the hydrology and associated water management schemes in the majority of South Florida using climatic data from January 1, 1965, through December 31, 1995. The model simulates the major components of the hydrologic cycle and the current and numerous proposed water management control structures and associated operating rules. It also simulates current and proposed water shortage policies for the different subregions in the system.

Spatial Extent – Area that is continuous without non-integrating internal barriers or land usage.

Spillway — Overflow structure of a dam.

Stakeholders – People or organizations having a personal or enterprise interest in the results of a project, who may or may not be involved in completing the actual work on that project.

Stormwater – Surface water resulting from rainfall that does not percolate into the ground or evaporate.

Subspecies - The rank immediately subordinate to a species. It is equivalent to "race" in the biological (i.e. not social) sense

Substrate - The earthy material that exists in the bottom of a marine habitat, like dirt, rocks, sand, or gravel

Success Indicator – A subset of performance measures selected as a good representation of overall performance.

Surficial Aquifer – An aquifer that is closest to the surface and is unconfined; the water level of a surficial aquifer is typically associated with the groundwater table of an area.

Sustainability – The state of having met the needs of the present without endangering the ability of future generations to be able to meet their own needs.

Swamp – A generally wet, wooded area where standing water occurs for at least part of the year.

T

Threatened Species — Legal status afforded to plant or animals species that are likely to become endangered within the foreseeable future throughout all or a significant portion of their range, as determined by the U.S. Fish and Wildlife Service or the National Marine Fisheries Service.

Tiering — Procedure which allows an agency to avoid duplication of paperwork through incorporation by reference of the general discussions and relevant specific discussions from an environmental impact statement (EIS) of broader scope into a subsequent EIS of narrower scope.

Trade-Off – Allowing one aspect of a project to change, usually for the worse, in return for another aspect of the project getting better.

Tributary — A stream feeding into a larger stream, canal or waterbody.

W

Water Budget – An account of all water inflows, outflows and change in storage for a pre-specified period of time.

Water Column Turbidity – The measure of the cloudiness or opacity in the appearance of a water sample. Turbidity in natural waters is caused by the presence of suspended solids or colloidal particles. Turbidity measurement provides an indication of the clarity of water and water quality.

Water Conservation Areas (WCAs) – Marshland areas that were designed for use as storage to prevent flooding, to irrigate agriculture and recharge well fields and as input for agricultural and urban runoff; the Water Conservation Areas WCA-1, WCA-2A, WCA-2B, WCA-3A and WCA-3B comprise five surface water management basins in the Everglades; bounded by the Everglades Agricultural Area on the north and the Everglades National Park basin on the south, the WCAs are confined by levees and water control structures that regulate the inflows and outflows to each one of them.

Water Resource Development Act 2000 (WRDA 2000) – WRDA is legislation which provides for the conservation and development of water and related

resources and authorizes the Secretary of the Army to construct various projects for improvements to rivers and harbors of the United States, and for other purposes deemed appropriated by the U.S. Congress and the President of the United States.

Watershed – A region or area bounded peripherally by a water parting and draining ultimately to a particular watercourse or body of water.

Water Quality - The physical, chemical and biological characteristics of water. The primary bases for such characterization are parameters which relate to drinking water, safety of human contact and for health of ecosystems.

Wetlands – Areas that are inundated or saturated by surface water or groundwater at a frequency and duration sufficient to support a prevalence of vegetative or aquatic life that requires saturated or seasonally saturated soil conditions for growth and reproduction.

Wet Season – Hydrologically, for south Florida, the months associated with a higher than average incident of rainfall, June through October.

Wildlife Corridor – A relatively wide pathway used by animals to transverse from one habitat arena to another.

Wildlife Habitat – An area that provides a water supply and vegetative habitat for wildlife.

Attention: Deborah Wegman

Dear Mr. Barnett:

The Fish and Wildlife Service (Service) has prepared this Planning Aid Letter (PAL) in support of the C-43 Basin Storage Reservoir Project, Part 1 (C-43 Project). The C-43 Project is a component of the Comprehensive Everglades Restoration Plan (CERP), authorized under the Water Resources Development Act (WRDA) of 2000. This PAL is provided in accordance with the Fish and Wildlife Coordination Act of 1958, as amended (FWCA) (16 U.S.C. 661 *et seq.*), the Endangered Species Act of 1973, as amended (ESA) (87 Stat. 884; 16 U.S.C. 1531 *et seq.*), the Migratory Bird Treaty Act (MBTA) (40 Stat. 755, as amended; 16 U.S.C. 703 *et seq.*), and the Scope of Work agreed upon by the U.S. Army Corps of Engineers (Corps) and the Service for CERP planning studies in FY 2004.

This PAL does not constitute the report of the Secretary of Interior as required by section 2(b) of the FWCA, nor does it constitute a biological opinion under section 7 of the ESA. The purpose of this PAL is to provide guidance and recommendations on resource conservation issues related to the C-43 Project.

Introduction

The C-43 West Reservoir (previously identified as the Berry Groves Reservoir) is a component of the C-43 Project and will provide a significant portion of the overall water storage needed for restoration of the Caloosahatchee Estuary. Its funding, design, and construction have been expedited under the Acceler8 program and the design is currently under development by the South Florida Water Management District (District) and the Corps. The Service, as part of the C-43 Project Environmental Sub-team, is working with project managers to develop alternative plans that provide significant ecological benefits while supporting project goals and objectives.

Department of the Interior (DOI) funds were used to purchase lands within the C-43 West Reservoir for the purpose of ecological restoration. Fifty percent of the acquisition costs (i.e., $32,800,000) of the C-43 West Reservoir site were obtained through Federal grants, including $13,900,000 through Section 390 of the Farm Bill and $18,900,000 from the Land and Water

Conservation Fund. This letter provides Service recommendations for C-43 West Reservoir design and operation to optimize ecological benefits and minimize ecological impacts on lands purchased with DOI funding.

As per the Central and South Florida Project Comprehensive Review Study (Restudy), one of the goals and objectives of CERP projects is to enhance Everglades ecosystem ecological values by: (1) increasing the spatial extent of natural areas; (2) improving habitat and functional quality; and (3) improving native plant and animal species abundance and diversity (Corps 1999). Reservoir design and operation that achieves significant water quality improvements will help satisfy the three Restudy goals identified above.

Water Quality

Extreme variations in salinity levels and poor water quality have reduced the health and productivity of the Caloosahatchee Estuary and are linked to the volume and timing of freshwater flows at the Franklin Lock and Dam (S-79) that originate from the Caloosahatchee watershed and releases from Lake Okeechobee (McPherson and Miller 1990, Doering and Chamberlain 1998). Those releases deviate from the historical quantity, quality, and timing of freshwater flows into the river and estuary. According to the Restudy, the purpose of the C-43 Project is to capture Caloosahatchee River basin runoff and releases from Lake Okeechobee to improve water deliveries to the Caloosahatchee Estuary, and to provide some flood attenuation and water supply benefits. The Restudy included water quality benefits through the reduction of nutrient loadings to the estuary as a related consideration/assumption for the C-43 Project. Likewise, the CERP Master Program Management Plan and the C-43 Basin Storage Reservoir Project Management Plan state that the reservoir would be ". . . designed . . . to provide . . . water quality benefits to reduce salinity and nutrient impacts of runoff to the estuary" and both documents ". . . assumed that, depending upon the location of the reservoir and pollutant loading conditions in the watershed, the reservoir could be designed to achieve significant water quality improvements, consistent with appropriate pollution load reduction targets." However, the proposed design and operation of the C-43 West Reservoir primarily focuses on salinity control by improving the timing and volume of freshwater delivery to the estuary and does not address other water quality needs within the river basin and estuary, such as high nutrient loads.

The need for water quality improvements in the Caloosahatchee Estuary has been well documented. During the 1980's, the Florida Department of Environmental Regulation conducted waste load allocation studies and, based on elevated chlorophyll *a* levels and low dissolved oxygen (DO), concluded that the Cloosahatchee had reached its nutrient loading limits (Doering and Chamberlain 1998). Subsequent water quality studies have found that nitrogen is the most likely limiting nutrient to primary production in the Caloosahatchee Estuary and nitrogen levels exceed concentrations established as upper limits for the Caloosahatchee for chlorophyll *a* (20 milligrams/Liter (mg/L), total nitrogen (1.0 mg/L) and total phophorus (0.15 mg/L) (McPherson and Miller 1990, Doering and Chamberlain 1998, Doering and Chamberlain 1999, Doering and Chamberlain 2004). Those studies also found that the highest concentrations of water quality parameters (i.e., chlorophyll *a*, total nitrogen, total phosphorus,

color) tend to occur most frequently in the upper estuary, most likely as a function of discharges at S-79. Similarly, the occurrences of low DO levels (< 2 mg/L) were also observed at the head of the Caloosahatchee Estuary.

More recently, the Florida Department of Environmental Protection (DEP) has identified impaired water bodies in the Caloosahatchee Basin as part of their Total Maximum Daily Load Program (DEP 2004). DEP lists the tidally influenced Caloosahatchee River and estuary as impaired due to high levels of nutrients (chlorophyll *a*), metals (e.g., copper), and fecal coliform, and due to low levels of DO. High nutrients were identified as the causative pollutant for DO impairment.

High nutrient loads may adversely impact the natural resources within the Caloosahatchee river estuarine system, including the J.N. "Ding" Darling National Wildlife Refuge Complex and the fish and wildlife populations that depend on those resources during various stages of their life cycles. The estuarine system consists primarily of mangrove wetlands, coastal marshes, tidal flats, and aquatic and estuarine habitats (streams, ponds, bays and submerged aquatic vegetation (SAV) beds). Those habitats provide suitable escape, feeding, breeding/spawning, brood rearing/nursery, and wintering sites for a wide variety of aquatic, estuarine, and wetland-dependent organisms for which the Service has Federal-trust conservation responsibilities (e.g., migratory waterfowl, wading birds, shorebirds, seabirds, other water birds, neotropical migratory songbirds, threatened and endangered species, and interjurisdictional fisheries).

Increased nutrient levels (i.e., nitrogen and phosphorus) stimulate phytoplankton and/or algal blooms and thus, reduce light penetration which can lead to reduced fresh and salt water SAV abundance. The loss of feeding and nursery habitat can lead to population declines in commercial and sport fishes (i.e., anchovy, redfish, black drum, and spotted seatrout) and shellfishes (i.e., oysters, pink shrimp, and blue crab), and shifts in species composition.

Threatened and Endangered Species

Additionally, the endangered West Indian manatee (*Trichechus manatus*) and its designated critical habitat occur within the Caloosahatchee River basin and estuary. Critical habitat extends downstream from the State Highway 31 bridge and includes all U.S. territorial waters adjoining the coast and islands of Lee County. Manatees migrate along the Florida coast through fresh, brackish, and marine waters, with a seasonal distribution based on water temperatures. They feed primarily on freshwater and marine grassbeds. Changes in abundance and distribution of SAV in the estuary may impact manatees by increasing travel distance between warm water refugia and suitable food sources.

The endangered wood stork (*Mycteria americana*) and other colonial nesting waterbirds regularly use mangrove islands in the estuary for nesting, roosting, and foraging. Changes in the volume, timing, and quality of Caloosahatchee flows also impact habitat and food sources on which the wood stork and other wading birds depend.

Dennis Barnett Page 4

Recommendations

Based on the above information, the Service recommends that the Corps and the District design the C-43 West Reservoir to achieve water quality benefits by reducing nutrient loads in accordance with CERP Guidance Memorandum Number-Revision 023.01 (GM 023.01) (District and Corps 2004). The C-43 Project is described in the Restudy as a Category B project. Category B projects are not required to include specific water quality improvement features, but are to be designed to achieve water quality improvement. Evaluation criteria must be developed ". . . for alternative plan evaluation, comparison, and selection purposes, as well as for maximizing the the water quality improvement efficiency during design of the selected plan." The intent of GM 023.01 was to maximize nutrient and total suspended solid reductions of proposed alternatives without significant loss of water storage potential or the addition of water quality improvement features.

Reservoirs and natural storage areas have proven to be successful at removing nutrients and total suspended solids. Their efficiency can be evaluated based on hydrologic retention time and measured using hydrologic models. We, therefore, recommend that the Corps and District conduct further modeling to develop alternatives that maximize the reduction of nutrient loads and provide the following information for the final alternatives considered: (1) describe source of water to be captured by the reservoir and its' water quality; (2) predict the quality of water retained within the reservoir; (3) predict the quality of water released from the reservoir and the relationship with water quality of flows discharged at S-79; and (4) describe the effects of the quality and volume of water released at S-79 on the estuary, including changes in hydrologic residence time. The potential of alternative plans to cause additional or contribute to existing pollutant loads should also be evaluated.

At the In Progress Review meeting on the C-43 Project held December 1 and 2, 2003, the Corps and the District discussed expanding the scope of the Reservoir project to address additional water quality benefits beyond the project objectives of reducing freshwater pulses and restoring minimum flows to the Caloosahatchee Estuary. As originally envisioned and directed, the Service supported the approach that the more comprehensive Southwest Florida Feasibility Study (SWFFS) would address these broader watershed and estuarine issues. As described in our January 9, 2004, PAL for the SWFFS, we were concerned that an expansion of the C-43 Project objectives would result in significant project implementation delays which would have serious consequences to the health of the Caloosahatchee Estuary. However, inclusion of the C-43 West Reservoir in the Acceler8 program has resolved those concerns. Thus, if modeling results provide adequate justification, the Service recommends that the C-43 Project scope be modified to include water quality improvement objectives and water quality features be included in project design.

Closing Comments

Improvements in water quality will benefit estuarine habitats, improve their functional quality, and benefit fish and wildlife populations that utilize those habitats, including threatened and

Dennis Barnett Page 5

endangered species and colonial nesting waterbirds, at a local, regional, and system-wide scale. The Service appreciates this opportunity to provide recommendations to the Corps for the benefit of fish and wildlife resources. We look forward to our continued participation as a member of the C-43 Project team. If you have questions or comments, please feel free to contact Joyce Mazourek, Fish and Wildlife Biologist, at 239-472-1100, extension 231.

Sincerely yours,

James J. Slack
Field Supervisor

U.S. Army Corps of Engineers
Post Office Box 4970
Jacksonville, Florida 32232-0019

Dear Mr. Duck:

This Planning Aid Letter is submitted by the Fish and Wildlife Service (Service) in compliance with the Scope of Work for the C-43 Basin Storage Reservoir Project (C-43 Project). The purpose of this letter is to highlight potentially significant fish and wildlife issues or concerns, define fish and wildlife resource opportunities, identify information needs for plan formulation, and affirm our commitment and involvement to work on the C-43 Project in an expedited fashion. This letter is provided in accordance with the Fish and Wildlife Coordination Act (FWCA) of 1958, as amended (48 Stat. 401; 16 U.S.C. 661 *et seq.*) but does not constitute the final report of the Secretary of the Interior as required by section 2(b) of the FWCA. These comments are also provided under the provisions of section 7 of the Endangered Species Act of 1973, as amended (87 Stat. 884; 16 U.S.C. 1531 *et seq.*).

Introduction

The U.S. Army Corps of Engineers (Corps) is beginning to gather information on issues and concerns that will be addressed in their draft Environmental Impact Statement (EIS) for this C-43 Project. On March 28, 2003, the Corps announced the start of the public scoping process under National Environmental Protection Agency for the C-43 Project. On June 10, 2003, the Service submitted scoping comments pertaining to the Draft EIS. The discussion in this Planning Aid Letter (PAL) reiterates many of the concerns we initially expressed in our scoping comments. In addition, please refer to the Service's PAL, dated April 11, 2002, for additional information on fish and wildlife concerns.

Project Description

The C-43 Project is part of the Comprehensive Everglades Restoration Plan (CERP) authorized by the Water Resources Development Act of 2000. The purpose of the C-43 Project is to capture excess storm runoff and releases from Lake Okeechobee for later release into the Caloosahatchee

James C. Duck
August 13, 2003
Page 2

River during times of need (*e.g.*, prevent saltwater intrusion or provide water supply during droughts). This C-43 Project would entail above-ground reservoir(s) with a total storage capacity of about 160,000 acre-feet within the Caloosahatchee basin. The initial design of the reservoir(s) assumed a total surface area of 20,000 acres with water levels fluctuating up to 8 feet. Anticipated benefits of the proposed C-43 Project include the attenuation of flood flows; improvement of water quality and timing of releases to the Caloosahatchee River and Estuary; protection of the Caloosahatchee Estuary from excessive fresh water deliveries, and improvement of water supply benefits for environmental, urban, and agricultural users.

Project Area

The Caloosahatchee Basin is located in Hendry, Glades, Lee and a small portion of Charlotte, Collier, and Palm Beach counties (see Figure 1). The natural systems within the Caloosahatchee Basin consist of wetlands (freshwater swamps, sloughs, marshes, and estuaries) and upland (pine flatwoods, temperate oak/palmetto hammocks, tropical hammocks, dry prairie, and xeric scrub communities) habitats which are interdependent on each other. A number of these systems are located within relatively pristine areas which are recognized as having regional importance, such as the J.N. "Ding" Darling National Wildlife Refuge Complex and the Charlotte Harbor Aquatic Preserve. These areas serve as important habitat for a wide variety of wildlife, including over 20 Federal and State listed species.

The following is a list of federally listed threatened (T) or endangered (E) animals and their critical habitat (CH), or experimental population status (E/P), known or expected to occur within the Caloosahatchee Basin and Estuary. These protected species include: Florida panther (*Puma concolor coryi*) (E), West Indian manatee (*Trichechus manatus*) (E, CH), wood stork (*Mycteria americana*) (E), everglades snail kite (*Rostrhamus sociabilis plumbeus*) (E), red-cockaded woodpecker (*Picoides borealis*) (E), Florida grasshopper sparrow (*Ammodramus savannarum floridanus*) E, green sea turtle (*Chelonia mydas*) (E), American crocodile (*Crocodylus acutus*) (E), leatherback sea turtle (*Dermochelys coriacea*) (E), Kemp's ridley sea turtle (*Lepidochelys kempii*) (E), smalltooth sawfish (*Pristis pectinata*)(E), loggerhead sea turtle (*Caretta caretta*) (T), bald eagle (*Haliaeetus leucocephalus*)(T), Florida scrub jay (*Aphelocoma coerulescens*) (T), Audubon's crested caracara (*Caracara plancus*) (T), piping plover (*Charadrius melodus*) (T), whooping crane (*Grus americana*) T(E/P), and eastern indigo snake (*Drymarchon corais couperi*) (T). Federally listed plant species that occur or have the potential to occur in the study area include Florida bonamia (*Bonamia grandiflora*) (E), Okeechobee gourd (*Cucurbita okeechobeensis okeechobeensis* (E), and beautiful pawpaw (*Deeringothamnus pulchellus*) (E).

All of the above-mentioned species may be affected by the C-43 Project and should be considered during the planning process. As a clarification, the Service has consultation responsibilities for sea turtle nesting, and although sea turtles are known to nest on beaches in the region, the C-43

James C. Duck
August 13, 2003
Page 3

Project should have no effect on sea turtle nesting. However, the C-43 Project could have a direct effect on marine and estuarine habitats used by sea turtles, and the Corps should consult with the National Oceanic and Atmospheric Administration-National Marine Fisheries Service (NOAA-Fisheries) on these species. On April 1, 2003, the NOAA-Fisheries published a final rule listing the smalltooth sawfish (*Pristis pectinata*) as a distinct population segment. The Corps should consult with the NOAA-Fisheries regarding this species as well. In addition, the Corps should contact the Florida Fish and Wildlife Conservation Commission (FWC) to consult on the several species listed by the State of Florida.

The Berry Labelle-Congen Groves property is an intensive agricultural area that was considered capable of having high concentrations of various contaminants, including, metals, pesticides, and petroleum by-products. To address these concerns, a Phase I/II Environmental Site Assessment was conducted in the Berry Labelle-Congen Groves by the URS Corporation during 1999. In addition, URS Corporation conducted a follow-up Phase II Environmental Site Assessment, and a site-specific Ecological Risk Assessment in 2002. Results of these soil contaminant studies indicate that risks associated with detected copper concentrations appear to be isolated to the benthic macroinvertebrate community and do not appear to pose any pervasive risks to any other ecological resources. The URS Corporation concluded in this document that their findings should not preclude the conversion of Berry Labelle-Congen Groves property into a water retention area for the C-43 Project. However, a recent Phase II Environmental Site Assessment draft report for Berry LaBelle-Congen Grove indicates that copper desorption occurred in sediment samples after 3 days, and that toxicity tests showed adverse effects on growth and/or survival of flathead minnow, freshwater amphipod and midge larvae after 7 to 10-day exposures to sediment samples (URS Corporation 2003).

The Service is reviewing the results of these soil contaminant assessments at the Berry Labelle-Congen Groves properties in light of our concerns that the indicated copper concentration may have a deleterious effect on apple snails. If this is the case, then there could be an adverse impact on other species in the food web, such as the endangered snail kite and wading birds. We recommend that soil contaminant assessment data, potential impact evaluations, site remediation options, and other C-43 Project alternatives be reviewed by the Corps. We also recommend that contaminant evaluations using applicable Sediment Quality Assessment Guidelines for the protection of fish and wildlife be conducted on all proposed reservoir sites within historic or existing citrus groves in the CERP planning area.

Update of Work Completed

Since our April 11, 2002, letter, a subteam was established that developed site screening criteria for potential reservoir and restoration locations for the C-43 Project. After a series of meetings and conference calls throughout the fall and winter of 2002, the subteam and reached consensus on a screening matrix and the definitions for each criteria. The goal of this matrix is to allow the

subteam to objectively screen and rank each potential reservoir or restoration site during the alternative selection process. A preliminary site map was also generated containing potential reservoir and restoration site locations. In addition, the Service completed a series of species maps to screen T and E species, as well as other fish and wildlife trust resource concerns. These species maps were based on a 1995 land use map, digital orthophoto quads, species richness data from the FWC (Cox et al. 1994, Cox and Kautz 2000), and Florida Natural Areas elements of occurrence data. These coverages were used together with other maps provided by the Corps, South Florida Water Management District (SFWMD), FWC, and the Florida Department of Environmental Policy and applied to each criteria defined within the site selection matrix. This process refined our list of potential reservoir/restoration sites based on the occurrence of listed species habitat and cultural resources, and proximity to the river. The final draft of the matrix was accepted by the full Project Delivery Team (PDT) on March 20, 2003. We are now further refining the list of potential storage and restoration sites to develop alternatives for the Project Implementation Report.

Comments

It is important that the Corps conduct a water budget analysis for the entire Caloosahatchee Basin. This information is necessary to identify the amount of water required to restore and maintain the Estuary year around. As part of this analysis, we recommend evaluation studies to determine the quantity, quality, timing, and distribution of water necessary for riverine and estuarine recovery in the basin be conducted by the Corps, and evaluated by the Service and the subteam.

The primary C-43 Project purpose is to improve environmental conditions in the Caloosahatchee Basin. To support this purpose, the Corps, SFWMD, and Service should jointly identify specific ecological targets (*e.g.*, amounts and timing of water releases, and water quality controls) for the Caloosahatchee River and Estuary, as well as proposed changes in operational scenarios for the reservoir(s) and other adaptive management options in the event these targets are not met. Presently, minimum flows of 300 cubic feet per second (cfs) are authorized by the SFWMD. However, minimum discharges of this magnitude can cause harm to estuarine resources (SFWMD 2003). We recommend that minimum flow targets between 500 and 2000 cfs, which provide better conditions for oysters, be considered in determining minimum freshwater inflows for the Caloosahatchee Estuary. We also recommend that ecologically-meaningful measures, such as flow quantity, quality, duration and timing, be considered by the Corps for purposes of quantifying the water to be reserved for restoration of fish and wildlife habitats, pursuant to Section 601(h)(4)(A)(iii) of the Water Resources Development Act of 2000 (Published Law 106-541).

We suggest that the Corps address the construction of smaller reservoirs distributed along canals in the Caloosahatchee Basin as an alternative to one large reservoir for storing water to restore

James C. Duck
August 13, 2003
Page 5

estuarine values. Depending on their design, location and operation, these "distributed" reservoirs could provide significant onsite fish and wildlife values. Furthermore, if the Berry Labelle-Congen Groves location is chosen as the C-43 Project site (storage capacity of 64,000 acre-feet), then an additional 96,000 acre-feet of water would be required to reach the 160,000 acre-feet of water necessary to satisfy current C-43 Project objectives for the Estuary. We have discussed the restoration potentials in Lake Hicpochee and Telegraph Swamp in past meetings, and are interested in exploring additional areas with the Corps that may also be suitable for habitat restoration.

The impacts on fish and wildlife resources and habitats from the full-scale C-43 Project would include not only the direct effects within each project footprint, but also any potential impacts on fish and wildlife resources (including bioavailability of contaminants) up and downstream of the C-43 Project as a result of reservoir construction, operations, and water delivery. To be consistent with the C-43 Project objectives, the Corps should address potential project-related effects beyond the project footprint, including the restoration of the Caloosahatchee Estuary by modifying inflows to reflect a more natural hydrological regime. In addition, the Lake Okeechobee regulations and the schedule and operation protocols associated with the C-43 Canal should be included in the Corps' assessment of impacts. Currently, the Regulation Schedule and operating protocol for Lake Okeechobee calls for a minimum discharge of 300 cfs. The level of water storage in Lake Okeechobee at any given time would dictate how releases would be made, as well as how the C-43 Project would be operated. Therefore, the regulation schedule and operation protocol should be reevaluated in light of its effect on this and other CERP projects. We recommend that the Corps fully address these potential impacts in its Project Implementation Report and NEPA documents for the C-43 Project.

As discussed at the March 20, 2003, PDT meeting, we recommend that all potential reservoir locations be independently screened through the Site Selection subteam's storage and restoration criteria. This is important because no potential restoration location should be left out of the alternative selection process. In-basin restoration with storage, (*i.e.*, water storage facilities within the C-43 Project area that include habitat restoration benefits) will meet the goals of the C-43 Project, as well as benefit fish and wildlife resources within the basin by rehydrating wetlands and improving other habitats.

In the event infrastructure designs change during the planning process, the Service requests a complete description of these changes to evaluate the potential impacts to fish and wildlife resources and habitats, including listed species. An infrastructure change could include such actions as blocking a canal and rediverting water to a reservoir. The Service would need to know the quantity, design, and fate of diverted water to determine potential effects on fish and wildlife values.

James C. Duck
August 13, 2003
Page 6

This concludes our PAL which provides recommendations for planning activities related to the C-43 Project. The Service is committed to continued participation in future planning efforts with C-43 Project sponsors and other agency staff to evaluate the potential effects of the C-43 Project on fish and wildlife values. If you have any questions regarding these comments, please contact Stephanie Brady at 239-472-1100, extension 242.

Sincerely yours,

James J. Slack

Dear Mr. Duck:

The Fish and Wildlife Service (Service) has prepared the following scoping comments for consideration in the proposed development of a Draft Environmental Impact Statement (EIS) for the C-43 Basin Storage Reservoir Project. These comments are provided in accordance with the Fish and Wildlife Coordination Act (FWCA) of 1958, as amended (48 Stat. 401; 16 U.S.C. 661 *et seq.*) but do not constitute the final report of the Secretary of the Interior as required by section 2(b) of the FWCA. These comments are also provided under the provisions of section 7 of the Endangered Species Act (ESA) of 1973, as amended (87 Stat. 884; 16 U.S.C. 1531 *et seq.*) and are consistent with the National Environmental Policy Act of 1969, as amended (Pub. L. 91-190, 42 U.S.C. 4321-4347 *et seq.*). Please refer to the Service's Planning Aid Letter dated April 11, 2002, for additional information on fish and wildlife concerns.

Project Description

The C-43 Basin Storage Reservoir Project (Project) is part of the Comprehensive Everglades Restoration Plan (CERP) authorized by the Water Resources Development Act (WRDA) of 2000. The purpose of this project is to capture excess storm runoff and releases from Lake Okeechobee, and then release these stored waters into the Caloosahatchee River during times of need, such as saltwater intrusion or drought. This Project would entail above-ground reservoir(s) with a total storage capacity of about 160,000 acre-feet within the Caloosahatchee Basin. The initial design of the reservoir(s) assumed a total surface area of 20,000 acres with water levels fluctuating up to eight feet. Anticipated benefits of the proposed Project include the attenuation of flood flows, improvement of water quality and timing of releases to the Caloosahatchee River and estuary, protection of the Caloosahatchee estuary from excessive fresh water deliveries, and improvement of water supply benefits for environmental, urban, and agricultural users.

The Caloosahatchee Aquifer Storage and Recovery (ASR) pilot project is related to this Project and also authorized by WRDA 2000. The purpose of the ASR is to store partially-treated

James C. Duck
June 10, 2003
Page 2

available surface or groundwaters within the Floridan Aquifer System for subsequent recovery and use. Benefits of implementing the ASR technology within the Caloosahatchee River Basin would include minimizing high-volume stormwater releases to the Caloosahatchee estuary, maintaining minimum flows in the Caloosahatchee River, preventing salt water intrusion, and supplying future urban and agricultural demands. Another project associated with the C-43 Basin Storage Reservoir Project is the Southwest Florida Feasibility Study (SWFFS) which was recommended to Congress in July 1999 as part of the Central and Southern Florida Project (Restudy), now the CERP. The purpose of the SWFFS is to better define problems and opportunities to restore ecosystems in the southwest region of Florida.

Project Area

The Caloosahatchee Basin is located in Hendry, Glades, Lee, and a small portion of Charlotte, Collier, and Palm Beach counties (Figure 1). The natural systems within the Caloosahatchee Basin consist of wetlands (freshwater swamps, sloughs, marshes, and estuaries) and upland (pine flatwoods, temperate oak/palmetto hammocks, tropical hammocks, dry prairie, and xeric scrub communities) habitats which are interdependent on each other. A number of these systems are located within relatively pristine areas which are recognized as having regional importance, such as the J. N. "Ding" Darling National Wildlife Refuge complex and the Charlotte Harbor Aquatic Preserve. These areas serve as important habitat for a wide variety of wildlife, including over 20 Federal and State listed species.

The following is a list of federally listed threatened (T) or endangered (E) animals and their critical habitat (CH) or experimental population status (E/P), known or expected to occur within the Caloosahatchee Basin and estuary. These protected species include: the Florida panther (*Puma concolor coryi*) (E), West Indian manatee (*Trichechus manatus*) (E, CH), wood stork (*Mycteria americana*) (E), everglades snail kite (*Rostrhamus sociabilis plumbeus*) (E), red-cockaded woodpecker (*Picoides borealis*) (E), Florida grasshopper sparrow (*Ammodramus savannarum floridanus*) E, green sea turtle (*Chelonia mydas*) (E), American crocodile (*Crocodylus acutus*) (E), leatherback sea turtle (*Dermochelys coriacea*) (E), Kemp's ridley sea turtle (*Lepidochelys kempii*) (E), loggerhead sea turtle (*Caretta caretta*) (T), bald eagle (*Haliaeetus leucocephalus*)(T), Florida scrub jay (*Aphelocoma coerulescens*) (T), Audubon's crested caracara (*Caracara plancus*) (T), piping plover (*Charadrius melodus*) (T), whooping crane (*Grus americana*) T(E/P), and eastern indigo snake (*Drymarchon corais couperi*) (T). Federally listed plant species that occur or have the potential to occur in the study area include Florida bonamia (*Bonamia grandiflora*) (E), Okeechobee gourd (*Cucurbita okeechobeensis okeechobeensis* (E), and beautiful pawpaw (*Deeringothamnus pulchellus*) (E).

All of the above-mentioned species may be effected by the Project and should be considered during the planning process. As a clarification, the Service has consultation responsibilities for

James C. Duck
June 10, 2003
Page 3

sea turtle nesting, and although sea turtles are known to nest on beaches in the region, the Project should have no effect on sea turtle nesting. However, the Project could have a direct effect on marine and estuarine habitats used by sea turtles, and the U.S. Army Corps of Engineers (Corps) should consult with the National Marine Fisheries Service (NMFS) on these species. On April 1, 2003, the NMFS published a final rule listing the Smalltooth Sawfish (*Pristis pectinata*) as a distinct population segment. The Corps should consult with the NMFS regarding this species as well. In addition, there are several species listed by the State of Florida that should be addressed in this document.

The Berry Groves property is an intensive agricultural area that was considered capable of having high concentrations of various contaminants, including, metals, pesticides, and petroleum by-products. To address these concerns, a Phase I/II Environmental Site Assessment was conducted in the Berry Groves by the URS Corporation during 1999. In addition, URS Corporation conducted a follow-up Phase II Environmental Site Assessment and a site-specific Ecological Risk Assessment in 2002. Results of these soil contaminant studies indicate that risks associated with detected copper concentrations appear to be isolated to the benthic macroinvertebrate community and do not appear to pose any pervasive risks to any other ecological resources. Based on these data, URS Corporation concluded that their findings should not preclude the conversion of Berry Groves property into a water retention area for this Project.

The Service is reviewing the results of these soil contaminant assessments at the Berry Groves property in light of our concerns that the indicated copper concentration may have a deleterious effect on apple snails. If this is the case, then there could be an effect on other species in the food web, such as the endangered snail kite and wading birds. We recommend that soil contaminant assessment data, potential impact evaluations, site remediation options, and other Project alternatives be discussed in the Corps's National Environmental Policy Act (NEPA) document. We also recommend that contaminant evaluations using applicable Sediment Quality Assessment Guidelines for the protection of fish and wildlife be conducted on all proposed reservoir sites within historic or existing citrus groves in the CERP planning area.

Comments

It is important that the Draft EIS include analysis of a water budget for the entire Caloosahatchee Basin. This information is necessary to assess the amount of water that is required for restoration and maintenance of the estuary year-round. As part of this analysis, we recommend that evaluation studies determine the quantity, quality, timing and distribution of water necessary for riverine and estuarine recovery in the basin and be included in the Draft EIS.

The primary project purpose is to improve environmental conditions in the Caloosahatchee Basin. Consequently, the Draft EIS should identify specific ecological targets (*e.g.*, amounts and timing

James C. Duck
June 10, 2003
Page 4

of water releases, and water quality controls) for the Caloosahatchee River and Estuary, as well as proposed changes in operational scenarios for the reservoir(s) and ASR facilities and other adaptive management options in the event these targets are not met. Flow targets should be greater than the 300 cubic feet per second (cfs) minimum flows and levels that are currently authorized by the South Florida Water Management District because discharges of 300 cfs are too low and can cause harm to estuarine resources. Target flows from 500 to 2000 cfs, which provide better conditions for oysters, should be considered in determining minimum freshwater inflows for the Caloosahatchee estuary. We recommend that such ecologically-meaningful measures of flow, timing, and water quality be incorporated into the Draft EIS and Project Implementation Report for purposes of quantifying the water to be reserved for restoration, pursuant to Sec. 601(h)(4)(A)(iii) of the Water Resources Development Act of 2000 (Pub. Law 106-541).

We recommend that the Draft EIS address the option of smaller reservoirs distributed along canals in the Caloosahatchee Basin as an alternative to one large reservoir for storing water to restore estuarine values. Depending on their design, location and operation, these distributed reservoirs could provide significant fish and wildlife values. Furthermore, if the Berry Groves location is chosen as the Project site (storage capacity of 64,000 acre-feet), then an additional 96,000 acre-feet of water would be required because a total of 160,000 acre-feet of water would be necessary to satisfy estuary restoration objectives for this Project. For these reasons, we recommend that this option continue to be considered as a Project alternative.

We recommend that "in-basin restoration" at additional locations be identified in the Draft EIS as a possible alternative. We have discussed the restoration potentials in Lake Hicpochee and Telegraph Swamp in past meetings and are interested in exploring additional areas with the Corps that may also be suitable for habitat restoration.

It is important that the Draft EIS discuss the relationship of this Project to the Caloosahatchee ASR pilot project because all the ASR projects will be reservoir-dependent. It is also important that the Draft EIS discuss the relationship between this project and the SWFFS because if the C-43 Basin Storage Reservoir Project cannot meet the water needs of the estuary, then additional releases may be necessary from additional storage reservoirs that could be recommended through the SWFFS.

The Draft EIS should address any potential project effects outside the footprint of the C-43 Basin Storage Reservoir. These could include potential impacts on downstream receiving waters and associated aquatic communities including the beneficial effects of restoring the Caloosahatchee estuary by restoring more natural hydrological patterns. In addition, the Corps should include the Lake Okeechobee regulation schedule and operation protocols associated with the C-43 Canal. Currently, the regulation schedule and operating protocol for Lake Okeechobee calls for a minimum discharge of 300 cfs. Therefore, the level of water storage in Lake Okeechobee at any given time

James C. Duck
June 10, 2003
Page 5

would dictate how releases would be made, as well as how the C-43 would be operated. Therefore, the regulation schedule and operation protocol should be reevaluated in light of its effect on this and other CERP projects.

The NEPA defines Cumulative Impacts as those impacts on the environment which result from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such actions. For this Project, the potential impacts of the proposed ASR projects should be included in the Draft EIS among the reasonably foreseeable future actions that would affect the Caloosahatchee River and estuary.

The impacts on fish and wildlife resources and habitats from the full-scale C-43 Basin Storage Reservoir Project would include not only the direct effects within the Project footprint, but also any potential impacts on fish and wildlife resources (including bioavailability of contaminants) that could occur up and downstream of the Project as a result of reservoir operations and water deliveries to the ASR site. We recommend that the Draft EIS address the relationship between the ASR pilot and the C-43 Reservoir Project with regard to threatened and endangered species, as well as other fish and wildlife values.

The following comments are related to specific items that were discussed in various meetings associated with the C-43 Basin Storage Reservoir Project. As discussed at the March 20, 2003, Project Delivery Team meeting, we recommend all potential reservoir locations be independently screened through the sub-team's storage and restoration criteria in the Draft EIS. It is important that no potential restoration locations be left out of the alternative selection process. In-basin restoration with storage, (*i.e.*, water storage facilities within the project area that include habitat restoration benefits) will not only meet the goals of the Project, but it will also benefit fish and wildlife resources within the basin by rehydrating wetlands and improving other habitats. Future analysis may show that several smaller reservoirs throughout the basin could satisfy project goals while providing a greater gain in fish and wildlife values.

For each infrastructure change, we would need a complete project description to evaluate the potential impacts to fish and wildlife resources and habitats, including listed species. An infrastructure change could include such actions as blocking a canal and rediverting water to a reservoir. The Service would need to know how the water would be diverted to determine effects on fish and wildlife values. In addition, these changes may affect hydrological regimes that in turn may negatively impact fish and wildlife habitats and resources in the project area.

The Service appreciates this opportunity to offer input into the scoping of issues for the C-43 Basin Storage Reservoir Project Draft EIS. We are committed to our continuing participation in

James C. Duck

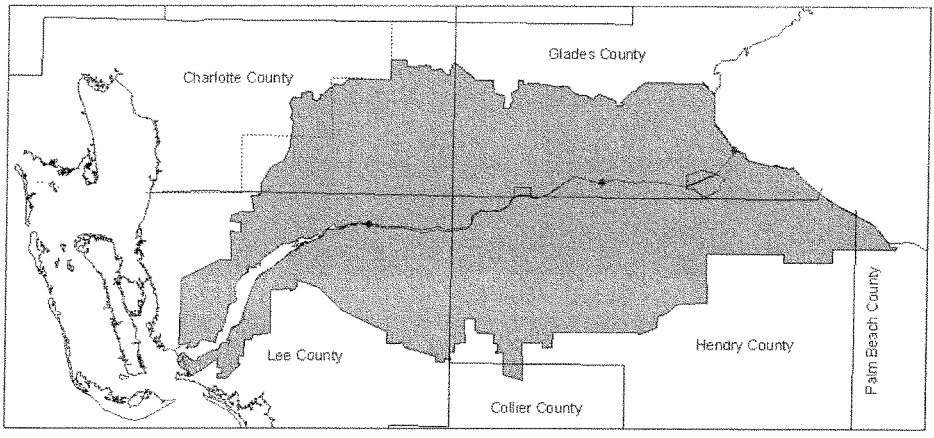
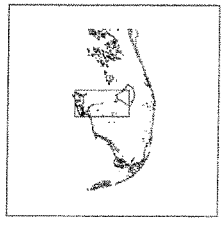
the NEPA process and development of a project consistent with the CERP goals. If you have any questions regarding these comments, please contact Stephanie Brady at 239-472-1100, extension 242.



Sincerely yours,



James J. Slack

RE: C-43 Basin Storage Reservoir

Dear Mr. Duck:

This is in response to your February 25, 2002, request for the U.S. Fish and Wildlife Service (Service) expertise in identifying any critical fish and wildlife habitat and any threatened or endangered species that may be within the project area or affected by the activities of the C-43 Basin Storage Reservoir. The Service has prepared this Planning Aid Letter (PAL) for the C-43 Basin Storage Reservoir Project, Hendry, Glades, and Lee counties. This PAL is provided in accordance with the Fish and Wildlife Coordination Act (FWCA) of 1958 (48 Stat. 401, as amended: 16 U.S.C. 661 *et seq.*) and section 7 of the Endangered Species Act (ESA) of 1973, as amended (16 U.S.C. 1531 *et seq.*).

This PAL does not constitute the report of the Secretary of Interior as required by section 2(b) of the FWCA, nor does it constitute a biological opinion under section 7 of the ESA. This PAL provides guidance and recommendations regarding several resource conservation issues to be considered in plan formulation and evaluation.

I. Introduction

The C-43 Basin Storage Reservoir is part of the Comprehensive Everglades Restoration Plan (CERP) authorized by the Water Resources Development Act of 2000. This project entails above-ground reservoir(s) with a total storage capacity of approximately 160,000 acre-feet within the Caloosahatchee basin. The initial design of the reservoir(s) assumed a total surface area of 20,000 acres with water levels fluctuating up to eight feet above grade. The purpose of this project is to capture excess storm runoff and releases from Lake Okeechobee. The captured water could then be released into the Caloosahatchee River during times of need or drought. Anticipated benefits of the proposed project include the use of water normally lost to tide, flood attenuation, improvements of water quality and timing of releases to the Caloosahatchee basin, river, and estuary, protection of Caloosahatchee estuary from excessive fresh water deliveries, and water supply benefits for environmental, urban, and agricultural users.

James C. Duck
April 11, 2002
Page 2

The 9,000-acre Berry Groves property, located in Hendry County, is available for an approximately 8,000-acre reservoir. Assuming an 8-foot maximum depth of storage, the Berry Groves reservoir could potentially hold 64,000 acre-feet of water. The property is currently in agricultural production with citrus as the primary crop. The locations for the remaining 96,000 acre-feet of storage are to be identified within the Caloosahatchee basin in Hendry, Glades, or Lee counties.

II. Project Area Setting

The Berry Groves reservoir site is located west of La Belle, in Hendry County (Figure 1). Currently, the land is an 9,000-acre citrus grove. There are two adjacent canals that adjoin the property, the Townsend Canal to the west and the Roberts Canal to the east. Staff from the Corps of Engineers (Corps), the South Florida Water Management District (SFWMD), and the Service conducted a site visit on February 28, 2002. The purpose of the site visit was to check the area for a monitoring well site for the C-43 Aquifer Storage and Recovery Pilot Project. However, the site visit also gave a Service biologist the opportunity to see a portion of the location for the reservoir project. The area is primarily citrus groves, with strips of shrubs along irrigation/drainage ditches in the grove. The primary vegetation in the ditches was Brazilian pepper (*Schinus terebinthifolius*), with some grasses and other herbaceous plants.

Currently, the Berry Groves operation obtains water from the Townsend Canal through a pump, located about half-way along the eastern-most boundary of the property. A system of many secondary ditches provides conveyance of water to, and drainage from, the citrus grove.

Other potential reservoir sites for the remaining 96,000 acre-feet of storage are yet to be determined. Based on a conversation at the Project Delivery Team meeting, the Service understands that the Corps is looking throughout the Caloosahatchee basin, and elevation contours are being used to make initial rough determinations of site suitability. This PAL provides additional rough screening of potential reservoir sites, based primarily on landuse coverages and species richness models.

IV. Fish and Wildlife Resources of the Project Area

A. Federally Listed Species

The focus of the Corps' February 25, 2002, letter requesting the Service's planning input was federally listed threatened and endangered species, and that is an emphasis of this PAL. As shown in Table 1, 19 federally listed species are known to occur in Lee, Collier, and Glades counties, and three of these species have a portion of their designated critical habitats within or adjacent to the study area.

Page 3

TABLE 1. FEDERALLY LISTED THREATENED AND ENDANGERED SPECIES IN LEE, HENDRY, AND GLADES COUNTIES

Scientific Name	Common Name	Status
Amphibians and Reptiles		
Caretta caretta	Loggerhead sea turtle	T
Chelonia mydas	Green sea turtle	E
Crocodylus acutus	American crocodile	E
Dermochelys coriacea	Leatherback sea turtle	E
Drymarchon corais couperi	Eastern indigo snake	T
Eretmochelys imbricata	Hawksbill sea turtle	E
Lepidochelys kempii	Kemp's (=Atlantic) ridley sea turtle	E
Birds		
Ammodramus savannarum floridanus	Florida grasshopper sparrow	E
Aphelocoma coerulescens	Florida scrub jay	T
Charadrius melodus	Piping plover	T*
Haliaeetus leucocephalus	Bald eagle	T
Mycteria americana	Wood stork	E
Picoides borealis	Red-cockaded woodpecker	E
Polyborus plancus audubonii	Audubon's crested caracara	T
Rostrhamus sociabilis plumbeus	Everglade snail kite	E*
Mammals		
Felis concolor coryi	Florida panther	E
Trichechus manatus latirostris	West Indian manatee	E*
Plants		
Cucurbita okeechobeensis	Okeechobee gourd	E
Deeringothamnus pulchellus	Beautiful pawpaw	E

*Critical Habitat present

James C. Duck
April 11, 2002
Page 4

The direct and indirect effects of the project as a whole would potentially benefit or adversely impact any of the species in Table 1. To our knowledge, no comprehensive surveys have been completed for fish and wildlife species within the Berry Groves property, but due to its highly altered habitat conditions, we expect that it has limited value for listed species. .

The snail kite (*Rostrhamus sociabilis plumbeus*) inhabits the watersheds of the Everglades, lakes Okeechobee and Kissimmee, the upper St. Johns River, and the Caloosahatchee basin. Critical habitat for the snail kite (see 50 CFR 17.95) is present immediately adjacent to the Caloosahatchee basin inside of the Herbert Hoover Dike in Lake Okeechobee. The snail kite could also be found foraging in a number of native wetlands and in canals and ditches adjacent to the project area. This medium-sized raptor has a highly specific diet composed almost entirely of Florida apple snails (*Pomacea paludosa*), which are found in palustrine emergent, long hydroperiod wetlands. As a result, the snail kite's survival is directly dependent on the hydrology and water quality of its habitat (Service 1999).

The wood stork is primarily associated with freshwater and estuarine habitats for nesting, roosting, and foraging. They have nested, at one time or another, in every county in south Florida. Typical foraging sites include freshwater marshes and stock ponds, shallow, seasonally flooded roadside or agricultural ditches, narrow tidal creeks or shallow tidal pools, managed impoundments, and depressions in cypress heads and swamp sloughs. Wood storks use a specialized feeding behavior called tactolocation, or grope feeding. A foraging wood stork wades through the water with its beak immersed and partially open (7 to 8 cm). When it touches a prey item, a wood stork snaps its mandibles shut, raises its head, and swallows what it has caught (Kahl 1964). This unique feeding method of the wood stork gives it specialized habitat requirements; the habitats on which wood storks depend have been disrupted by changes in the distribution, timing, and quantity of water flows in south Florida. The loss or degradation of wetlands in central and south Florida is one of the principal threats to the wood stork.

The endangered West Indian manatee (*Trichechus manatus*) is regularly found in the Caloosahatchee River and the Charlotte Harbor estuary. This large, aquatic mammal migrates along the Florida coast through fresh, brackish, and marine waters, with a seasonal distribution based on water temperatures. Waters colder than 20 degrees C increase the manatee's susceptibility to cold-stress and cold-induced mortality. Distribution is also controlled by aquatic vegetation availability, proximity to channels of at least 2 m in depth, and location of fresh water sources (Service 1999). In addition to the Service's concerns about boat-caused mortality throughout the species' range, navigational locks along the Caloosahatchee River have a history of causing manatee mortality. Sixteen navigational lock/water control structure-caused manatee deaths have been recorded near Ortona Lock (S-78) between 1980 and 2001. Throughout those same years, six were discovered near S-77 at Moore Haven, and just one in 1999 at the Franklin Lock (S-79). Existing operational protocols for the structures and locks (unaffected by project planning for the C-43 reservoirs) are important considerations in reducing these deaths. In

James C. Duck
April 11, 2002
Page 5

addition, however, the presently considered project should ensure that changes in water flows at these existing structures, and that construction, as part of this project, of any new structures in waters accessible to manatees do not increase the risks to the species.

The manatee may be affected by the water management plan to be developed in response to the increased storage of water in the reservoir(s). It is well documented that manatees require fresh water to survive. In addition to the fresh water needs, development of a draft water control plan as part of the Project Implementation Report should be based on modeling to estimate any changes in abundance and distribution of submerged aquatic vegetation (SAV) in the Caloosahatchee estuary. The distribution of these beds in proximity to warm water refugia for manatees is also an important factor. If SAV beds are eliminated close to their warm water refugia, manatees may be subject to more threats while traveling a greater distance to reach a suitable food source.

A proposed rule to de-list the threatened southern bald eagle (*Haliaeetus leucocephalus*) has been published. However, at this time, the species is still listed as threatened. The southern bald eagle is considered common and known to breed throughout the state. Nest sites are usually located near large rivers, lakes, or estuaries where they feed primarily on fish and water-dependent birds. Their distribution is influenced by the availability of suitable nest and perch sites near large, open waterbodies, typically with high amounts of water-to-land edge (Service 1999).

The threatened eastern indigo snake (*Drymarchon corais couperi*) is present throughout the state, but its abundance is reduced to a point where it is uncommon. Habitat includes pine flatwoods, scrubby flatwoods, high pine, dry prairie, tropical hardwood hammock, edges of freshwater marshes, agricultural fields, coastal dunes, and human altered habitats. Eastern indigo snakes could be encountered during construction, therefore implementation of the standard construction practices to avoid adverse effect on the species is expected.

The Florida scrub-jay (*Aphelocoma coerulescens*), a threatened species, is present in limited areas of scrub habitat in the study area. It is a relict species of fire-dominated oak scrub habitat that occurs on well-drained sand soils in peninsular Florida. Scrub-jays are extremely habitat-specific, sedentary, and territorial. Florida scrub-jays form family groups; fledglings remain with their parents in their natal territory as helpers. The Florida scrub-jay is listed as a threatened species because of loss, fragmentation, and degradation of scrub habitats throughout Florida, due primarily to urbanization, agriculture, and fire suppression. During the last 10 to 23 years, the population has declined by an estimated 25 to 50 percent, and they have been extirpated from seven counties statewide. Conservation measures for Florida scrub-jays will involve protection and long-term management of suitable scrub habitat. The Service's goal in planning assistance for the C-43 reservoirs is to ensure that the project does not affect any scrub habitats occupied by scrub-jays, and to minimize any impacts on other scrub habitats, due to their habitat value for a

James C. Duck
April 11, 2002
Page 6

number other wildlife species. Because scrub habitats occur at slightly higher elevations and have highly drained soils, these areas are typically poorly suited for siting water storage or treatment areas, so avoidance of these areas is not only ecologically sound, but is also justified by functional considerations. We would not advocate scraping down scrub areas to incorporate space for water storage or treatment.

The red-cockaded woodpecker (*Picoides borealis*) was listed as threatened in 1970. The red-cockaded woodpecker is one of 22 species of woodpeckers native to North America. Its historic range encompasses the southeastern U.S. from eastern Texas to Oklahoma to New Jersey, and it was characterized as "abundant" in the 19th century literature. Throughout the 20th century, however, the species' distribution within its historic range has become fragmented, and its total population numbers have decreased drastically due to the destruction of its habitat. The primary threat to the species continues to be destruction or degradation of its habitat as a result of timbering and other land-clearing activities. Although South Florida is not a designated recovery population for the red-cockaded woodpecker, the area contains significant support populations for recovery of the species in the southeast. Additional population surveys and research on habitat requirements within the hydric pine flatwoods of south Florida are needed to assess the current status of the birds and to adapt conservation measures used elsewhere to the distinct conditions in this area. The distribution of this species on private lands in the study area is poorly documented, and it is uncertain that the planning team members will obtain permission from private landowners to conduct surveys during plan formulation. The Service recommends minimizing the conversion of pine flatwood habitats to water storage or treatment areas.

The Florida panther (*Puma concolor coryi*), a subspecies of mountain lion, is one of the most endangered large mammals in the world. The most recent population estimate for the Florida panther is a total of 78 individuals, not including denning kittens (McBride 2001). This small population in south Florida represents the only known remaining wild population of an animal that once ranged throughout most of the southeastern United States from Arkansas and Louisiana eastward across Mississippi, Alabama, Georgia, Florida, and parts of South Carolina and Tennessee. The panther presently occupies one of the least developed areas in the eastern United States; a contiguous system of large private ranches and public conservation lands in Broward, Collier, Glades, Hendry, Lee, Miami-Dade, Monroe, and Palm Beach counties totaling more than 809,400 ha.

Geographic isolation, habitat loss, population decline, and associated inbreeding have resulted in a significant loss of genetic variability and overall health of the Florida panther population. Natural gene exchange ceased when the panther became geographically isolated from other subspecies of *Puma concolor*. Population viability projects have concluded that, under current demographic and genetic conditions, and without implementation of recovery actions, the panther would probably become extinct within two to four decades.

James C. Duck
April 11, 2002
Page 7

The Caloosahatchee basin plays an important role in the recovery of the Florida panther. The Service has organized a multi-agency subgroup of the Multi-species/Ecosystem Recovery Implementation Team (MERIT) to produce a Florida panther landscape conservation strategy. In addition to protection of habitat for adult home ranges, the strategy includes provision of corridors for dispersal of juveniles between larger areas of contiguous habitat. Dispersal across the Caloosahatchee River, between existing primary habitat south of the river and habitat that is presently only occasionally used by panthers north of the river, is considered essential for recovery of the species. The draft report of the Florida Panther Subteam is presently under technical review, but in recognition of the crucial need to coordinate the planning of the C-43 reservoir project with the MERIT efforts, we have include an illustration from their draft report as Figure 2 of this PAL. Figure 2 shows the apparent dispersal path of radio-collared Florida panther Number 84 across the Caloosahatchee River; and habitat characterized as primary, secondary, and dispersal. The dispersal habitat in Figure 2 coincides with the proposed land acquisition area in Figure 1 called the "Caloosahatchee Ecoscape." It is imperative to the continued survival of the Florida panther that facilities proposed as part of the C-43 reservoir project do not extend into the Caloosahatchee Ecoscape. The Service's planning team participant for the C-43 reservoir project will continue to coordinate with the Florida Panther Subteam of MERIT to ensure that project design is compatible with recovery efforts for the panther.

Audubon's crested caracara (*Polyborus plancus audubonii*) is another federally listed species present in the Caloosahatchee basin. It is a large, boldly patterned raptor, with a crest and unusually long legs. It is a resident, diurnal, and non-migratory species that occurs in Florida as well as the southwestern U.S. and Central America. In Florida, this species is found in the prairie area of the south-central region of the state. Because the Service anticipates that areas to be identified for reservoirs in addition to the Berry Groves property will include unimproved and improved pastures (land cover types which are preferred as habitat by the caracara and other species of wildlife), the C-43 reservoir project will likely have some impact on this species. We believe it would be impractical to set a planning goal to entirely avoid effects on this species, but rather, to direct siting of the additional reservoirs into areas with less intensive use by caracaras. Assuming that adverse effects cannot be entirely avoided, formal consultation under the ESA would be required, including provisions for incidental take for this species. In general, siting reservoirs in areas currently sustaining sugarcane or citrus, rather than unimproved and improved pastures, would reduce effects on the caracara, and other wildlife, such as the State-listed burrowing owl (*Speotyto cunicularia*) and Florida sandhill crane (*Grus canadensis pratensis*).

The Florida grasshopper sparrow (*Ammodramus savannarum floridanus*) is a subspecies of grasshopper sparrow that is endemic to the dry prairie of central and southern Florida. This subspecies is extremely habitat specific and relies on fire every two to three years to maintain its habitat. It is now known to occur only from Highlands, Okeechobee, Osceola, and Polk counties, but other populations may occur in Glades county, which may bring it into the study area considered here. Florida Natural Areas Inventory records include reports of the species from

James C. Duck
April 11, 2002
Page 8

northwestern Glades County, but little is known about the possible presence of the species on private lands in the southern part of the county, closer to the Caloosahatchee River. Similar to the red-cockaded woodpecker, the study team may be unable to gain access to conduct surveys on private lands in the plan formulation period, but unlike the red-cockaded woodpecker, the Florida grasshopper has a highly restricted range in Florida and is critically endangered. Therefore, the Service believes the planning goal for this species should be to avoid impacts not only on currently occupied habitat, but also on potential habitat that is determined to be critical to recovery of the species. As a starting point, an analysis of aerial photography by Shriver and Vickery (1999) identified potential habitat for the grasshopper sparrow, which includes some areas extending from northern Glades County south to the vicinity of the Caloosahatchee River (Figure 3). Avoidance of these areas in selecting sites for additional reservoirs is recommended, while we attempt to gather additional information from surveys of private lands in the area, if possible.

As stated above, a wintering population of piping plovers (*Charadrius melodus*) use the tidal area of the Caloosahatchee River. The piping plover was federally listed as threatened along the Atlantic coast in 1985. It is a small, migratory shorebird that breeds only in three geographic locations of North America: on sandy beaches along the Atlantic Ocean, on sand shorelines throughout the Great Lakes, and on riverine systems and prairie wetlands of the Northern Great Plains. This species does not breed in Florida, but there are three populations that winter here. Bunche Beach, at the mouth of the Caloosahatchee, has a population of wintering piping plovers and is also designated critical habitat for this species. This species will not be directly affected by the footprint of the reservoir, however, it may be indirectly affected by changes in water management.

Two endangered plants are found in or near the study area, the Okeechobee gourd (*Cucurbita okeechobeensis*) and the beautiful pawpaw (*Deeringothamnus pulchellus*). The Okeechobee gourd is a vine that is now restricted in the wild to two small disjunct populations -- one along the St. Johns River which separates Volusia, Seminole, and Lake counties in north Florida, and a second around the shoreline of Lake Okeechobee in south Florida. The beautiful pawpaw is a low shrub of the Annonaceae family that occurs in two disjunct locations in central and southwest Florida. It is found in xeric, mesic, and hydric pine flatwoods in western Charlotte and Lee counties and eastern Orange County. The Okeechobee gourd is not known to be present in the Caloosahatchee basin, but in the adjacent littoral zone of Lake Okeechobee. Therefore, the C-43 Reservoir project should be assessed only for any indirect impacts on water management in the lake, as opposed to any direct impacts of siting and construction of the reservoirs. The main documented sites for the beautiful pawpaw in Lee County are on Pine Island, which is at the periphery of the study area, and would not be a suitable location for the reservoirs. However, there is a slight chance that the species may be discovered in pine flatwoods communities north of the Caloosahatchee River. Similar to the red-cockaded woodpecker, the Service recommends that siting of reservoirs avoid pine flatwoods, and that any properties that contain pine flatwoods

James C. Duck
April 11, 2002
Page 9

which may be considered for acquisition as part of this project be thoroughly surveyed for the presence of the beautiful pawpaw prior to selection of a preferred alternative.

The Service has consultation responsibilities for sea turtle nesting, and although sea turtles are known to nest on beaches in the region, the project should have no effect on nesting. The project could have an indirect effect on marine and estuarine habitats used by sea turtles, and consultation for these potential impacts would be conducted with the National Marine Fisheries Service.

B. State-Listed Species

Our preliminary review indicates that several wildlife species are likely to occur in the study area that are listed as endangered, threatened, species of special concern, or are considered rare. Among reptiles, the American alligator (*Alligator mississippiensis*) is a species of special concern, and the gopher tortoise (*Gopherus polyphemus*) is threatened. Several wading bird colonies are present in the study area, and should be considered. Among the species known to nest in the area are the tricolored heron (*Egretta tricolor*), little blue heron (*Egretta caerula*), white ibis (*Eudocimus albus*), and the snowy egret (*Egretta thula*); these are all listed as species of special concern. The black skimmer (*Rynchops niger*), osprey (*Pandion haliaetus*), American oystercatcher (*Haematopus palliatus*), and the brown pelican (*Pelecanus occidentalis*) are all listed as species of special concern, and we expect these to be present in the Caloosahatchee estuary. The Florida sandhill crane (*Grus canadensis pratensis*) is State-listed as threatened and is widely distributed in the study area. The burrowing owl (*Speotyto cunicularia*) is a species of special concern. The Florida black bear (*Ursus americanus floridanus*) and the Big Cypress fox squirrel (*Sciurus niger avicennia*) are known to occur south of the Caloosahatchee River and are State-listed as threatened. We recommend that the Corps consult with the Florida Fish and Wildlife Conservation Commission as planning advances regarding potential impacts to State-listed wildlife.

C. Principal Habitats of the Study Area

While the Service has a statutory responsibility to ensure that Federal action agencies comply with section 7 of the ESA, we want to emphasize an ecosystem-level approach in project planning. Protection and restoration of the native habitats in the region will broadly benefit fish and wildlife, and will assist in recovery of federally listed species.

The ecological communities of south Florida represent a continuing succession beyond the primary stage (i.e. the initial development of a biological community not previously occupied), resulting in the development of a mosaic of pine forest, cypress strands, hardwood hammocks, coastal mangrove forests and salt marsh, sawgrass plains, and wet prairies (Carter *et al.* 1973). The natural systems within the Caloosahatchee basin consist of wetlands (freshwater swamps,

James C. Duck
April 11, 2002
Page 10

sloughs, marshes, and estuaries) and upland (pine flatwoods, temperate oak/palmetto hammocks, tropical hammocks, dry prairie, and xeric scrub communities) regions. Although classified as different habitats, these systems are interdependent on each other. A number of these systems are relatively pristine areas and are recognized as having regional importance. These areas serve as important habitat for a wide variety of wildlife and have numerous hydrological functions.

The major wetland system in the Caloosahatchee basin is Twelve-Mile Slough. It is located in Hendry County and is a tributary to the much larger and regionally significant Okaloacoochee Slough. The Twelve-Mile Slough covers 3,300 acres and contains a mosaic of freshwater wetlands, as well as pine flatwoods and oak/cabbage palm hammocks.

The upland communities with the Caloosahatchee basin include flatwoods and tropical hammocks. Flatwoods are the most dominant upland habitat and are divided into two types: dry and hydric. An open canopy of slash pine with an understory of saw palmetto characterizes dry flatwood communities. Hydric flatwood communities are vegetatively similar to dry flatwoods but are located in a slightly lower elevation and are seasonally inundated.

Tropical hammocks are diverse woody upland plant communities. They are scattered but not widespread throughout the Caloosahatchee basin. Tropical hammocks occur on elevated areas, often on Indian shell mounds along the coast or on marl or limestone outcroppings inland. These are among the most endangered ecological communities in south Florida.

Dry prairie is essentially treeless, a pyrogenic landscape with a ground cover diverse in regionally endemic plant taxa and dominated by wiregrass (*Aristida beyrichiana*), scattered, low, stunted saw palmetto(*Serenoa repens*), and low-growing runner oak(*Quercus minima*). The typical dry prairie has a mixture of upland and wetland plants. The portions of the study area that were historically dry prairie have been subject to drainage, conversion to pasture, and other human-caused alterations. Based upon DeSelm and Murdock (1993), Noss *et al.* (1995) considered ungrazed dry prairie of Florida as an endangered ecosystem (greater than 98 percent habitat loss and continued threat).

Upland plant communities serve as recharge areas, absorbing rainfall into soils where it is distributed into plant systems or stored underground within the aquifer. Ground water storage in upland areas reduces runoff during extreme rainfall events, while plant cover reduced erosion, and absorbs nutrient and other pollutants that might be generated during a storm event.

The Service recommends minimizing the impact of the C-43 reservoirs on native habitats as a first priority. Although grazed lands, particularly improved pastures, are not among the native habitats of Florida, they retain habitat value for a variety of fish and wildlife, most notably Audubon's crested caracara, Florida sandhill crane, Florida burrowing owl, gopher tortoise, Eastern indigo snake, short-tailed hawk (*Buteo brachyurus*), and gopher frog (*Rana capito*).

James C. Duck
April 11, 2002
Page 11

Therefore, as a second priority, we recommend that if siting of reservoirs allows a choice of lands with different agricultural land use histories, that areas supporting citrus and sugar cane be selected in preference to unimproved or improved pastures. However, we understand that given the abundance of pastures in the study area, that conversion of some pastures to reservoirs will most likely be part of the project design.

VI. Issues to Consider in Project Planning

First Issue - Establishing water reservations for the natural system

The Service is concerned about the use of the water retained in the reservoir(s) projects. During the Project Delivery Team meeting on February 28, 2002, it was stated that the water held back in these reservoirs will be used to enhance or restore the flows in the Caloosahatchee River, beyond those minimum flows and levels considered necessary to avoid ecological harm. A reservations document shall be prepared to ensure that the additional water stored in the reservoirs will enhance natural areas, primarily the Caloosahatchee estuary. The water in the reservoirs will be used for environmental needs first, before the water is allocated to urban or agricultural use. The Service will participate in efforts to establish specific ecological targets for the Caloosahatchee River and the estuary such that when these targets are not being met, the water from the reservoirs will be used to meet those needs. These goals will be developed for several components of the estuary and river, including, water quality parameters such as salinity; flow and stage data; and these will link to expected ecological benefits to important estuarine resources, such as submerged aquatic vegetation and oysters. One of the objectives of the Southwest Florida Feasibility Study (SWFFS) is to establish these targets for the estuary and Caloosahatchee basin. The C-43 Project Delivery Team should work closely with the SWFFS team to establish these goals and to ensure that the design and operation of the C-43 reservoirs are compatible with those targets.

Second Issue -Selection of other lands (in addition to Berry Groves) for reservoirs

The Service is concerned with the selection of additional lands for reservoirs. Using a variety of GIS data layers, we have performed a rough analysis of **potential** areas for siting reservoirs. We used 1995 land use, digital orthophoto quads, species richness data from the Florida Fish and Wildlife Conservation Commission (Cox *et al.* 1994, Cox and Kautz 2000), and Florida Natural Areas elements of occurrence data. We did not take into account suitability of soil type for use as a reservoir or topography, which, among other considerations, would most likely be used by engineers in siting these facilities. We have drawn several polygons labelled "additional areas to evaluate as potential reservoir sites" in Figures 2 and 3. As presented, these polygons total approximately 89,000 acres, and assuming 8,000 acres of Berry Groves will be used as a

James C. Duck
April 11, 2002
Page 12

reservoir, enough potential area appears to be available to further refine the boundaries for additional reservoirs totaling another 12,000 acres and to minimize impacts on native habitats . The Service will be involved in every step as it relates to choosing sites for additional reservoirs.

Third Issue - Contaminant assessments on the Berry Groves property and other potential reservoir sites

The Service and the SFWMD are collaborating under a draft protocol to assess contaminant risks to fish and wildlife for lands under consideration for acquisition as part of CERP components. This protocol establishes standards and procedures for Environmental Site Assessments and, when necessary, Environmental Risk Assessments. The Service's environmental contaminants section anticipates reviewing soon information for the Berry Groves site. We expect that the protocol, once finalized, will also be applied to all additional lands under consideration to obtain the necessary water storage capacity. As general guidance, the Service recommends avoidance of, as feasible, areas that are currently, or have a history of, cultivation of row crops, because these areas would have a higher probability for presence of contaminant levels that may impact fish and wildlife.

D. Fourth Issue -Federally listed species concerns

Please refer to the more specific guidance provided in Section IV.A. of this PAL regarding federally listed species. The intent of the Service with regard to the majority of these species is that through minimizing the selection of native vegetative communities for siting of reservoirs, any adverse effects on listed species would also be avoided or minimized. For the benefit of wetland-dependent listed species, such as the snail kite and the wood stork, selection of reservoir sites should also minimize impacts on wetlands, although we expect that some impacts to smaller wetlands, mainly within disturbed uplands, would likely be unavoidable.

We wish to summarize some additional special considerations. Siting and configuration of the reservoirs should be compatible with establishment and restoration of a dispersal corridor across the Caloosahatchee River for the Florida panther. Reservoir siting should also avoid or minimize effects on dry prairie and pasture lands considered to be suitable recovery habitats for the Florida grasshopper sparrow. We recognize that it may be impossible to entirely avoid placing reservoirs in areas serving as habitat for the Audubon's crested caracara, but the planning goal would be to see if it is feasible, using telemetry data, to locate facilities in areas of less intensive use by caracaras.

Thank you for this opportunity to provide recommendations for beneficial actions the Corps can take to restore, protect, or conserve fish and wildlife habitat and assist in the conservation and

recovery of Southwest Florida's threatened and endangered species. We would greatly appreciate attending any future meetings with Corps personnel as more refined plans are evaluated. Please feel free to contact Stephanie Brady at (941) 472-1100, extension 242, if you have any questions regarding this letter.

Sincerely,

for James J. Slack
Field Supervisor

Bob Taylor
Senior Environmental Engineer
South Florida Water Management District
3970 RCA Boulevard, Suite 7401
Palm Beach Gardens, Florida 33410

Dear Mr. Taylor:

The Fish and Wildlife Service (Service) has received and reviewed the document entitled, "Phase I/II Environmental Site Assessment for Griffin Brothers (GX-100-001)" prepared by Environmental Consulting and Technology, Incorporated (ECT). This document reports the results of extensive testing, laboratory analysis, and field investigation for this 954-acre parcel located south of State Road 80 in Hendry County. This property is planned for incorporation into the Caloosahatchee River/C-43 Basin project of the Comprehensive Everglades Restoration Plan. This parcel will be part of a 20,000-acre (160,000 acre-feet of storage) water retention reservoir designed to capture Lake Okeechobee releases for water supply, flood attenuation, and water delivery to the Caloosahatchee Estuary to reduce salinity and nutrient impacts.

This letter provides the Service's comments and recommendations regarding the assessment for this property, as identified and described in the subject report.

Generally, the document is well organized and thorough. All pertinent historical and existing land use, soil, geological, environmental, and regulatory information, in addition to future plans associated with Everglades restoration, are provided and evaluated in the Phase I report for this property. The Phase II report provides sampling rationale and laboratory data for soil and groundwater media. Florida Department of Environmental Protection, Sediment Quality Assessment Guideline (SQAG) values are presented and compared to the laboratory data collected from canal sediments, cultivated areas and point-source areas located on the property. Sampling from the cultivated areas of the property was performed from twenty two 50-acre grids. Discrete samples were taken from ten 5-acre sub-grids within each grid then composited. Canal sediments were sampled from seven locations and soils were sampled from a maintenance area/chemical barn, burn area, and fertilizer mix/load area. Groundwater was sampled from a total of five temporary monitoring wells; two from the cultivated area at Winthrop property and three from each point source. Upon review of the initial composite soil sample data, extended sampling was performed from the WBI sample grid within the cultivated area to better characterize selenium (Se) contamination.

Bob Taylor
May 19, 2003
Page 2

Specific editorial remarks include:

1. The table under section 7.2.2. ("Canal Sediment Sampling") on page 7-7. The "# Detections Above" column for pentachlorophenol (last row) indicates that one of seven samples exceeded the Threshold Effects Concentration (TEC). This is incorrect. One sample exceeded the Leachability-based Soil Cleanup Target Level (SCTL) (groundwater) criteria for this constituent. There is no TEC for pentachlorophenol.

2. The detection of 4,4'-DDT ("parent product") at WBXYZ, in the absence of associated analogues (4,4'-DDE and 4,4'-DDD) is unusual, even in low concentrations. The parent product is typically degraded into analogues within a relatively short period of time after application. Assuming the landowner has been using pesticides in compliance with Federal laws (the use of 4,4'-DDT has been banned for approximately three decades), it is unlikely that 4,4'-DDT was used at this location within the past 20 years. Detections of 4,4'-DDT without corresponding analogue detections should be scrutinized closely.

Cultivated Area

Generally, barium (Ba), copper (Cu), lead (Pb), mercury (Hg), zinc (Zn), and paraquat were detected throughout the cultivated area. However, none of these analytes exhibited concentrations which exceeded the SQAG Probable Effects Concentration (PEC) and only Cu at WAP (38 mg/kg) and 4,4'-DDT at WBXYZ (6.4 ug/kg) exceeded the TEC. The 95 percent Upper Confidence Level (UCL) of the mean for all analytes was below the TEC. Selenium, for which there is no SQAG, was detected in the composite sample taken from WBI (1.3 mg/kg). This grid was subsequently resampled (March 31, 2003) to better delineate the extent and intensity of Se contamination. An expanded sampling report was submitted by ECT on April 21, 2003, indicating that all discrete subsamples of the WBI grid exhibited Se concentrations less than 1.0 mg/kg (Range = below 0.56 mg/kg to 0.63 mg/kg).

Paraquat, a persistent herbicide (half-life in soil up to 1,000 days), was detected from all composite samples (range = 0.033 - 0.74 mg/kg). No soil samples demonstrated paraquat concentrations which exceeded the site-specific SQAG developed in the Environmental Risk Assessment (ERA) presented in Appendix I.

Aldicarb, a carbamate insecticide, was detected at only one sample grid (67 ug/kg), exceeding the site-specific SQAG (1.75 ug/kg) developed in the ERA in Appendix I. The 95 percent UCL of the mean for the entire parcel also exceeded the site-specific SQAG. Aldicarb degrades quickly and would likely represent little to no risk to fish and wildlife at this property, provided that its application is discontinued at least six months before inundation.

Bob Taylor
May 19, 2003
Page 3

Based upon the resampling of WBI (Se) and anticipated rapid degradation of aldicarb, the assessment recommended that no further sampling or corrective actions be taken in the cultivated area to reduce contamination. However, ECT did recommend that a restriction on any future use of aldicarb be incorporated into a Best Management Plan to be prepared for this property.

Canal Sediments

Canal sediments sampled from the property indicate that one sample exhibited a Cu concentration (60 mg/kg) which exceeded the TEC, but not the PEC. Another sediment sample exhibited a pentachlorophenol (an organochlorine pesticide) concentration of 32 ug/kg which exceeded the leachability SCTL based on groundwater criteria (30 ug/kg). This concentration of pentachlorophenol does not exceed the surface water SCTL (200 ug/kg) and there are no SQAG criteria for pentachlorophenol. However, this pesticide is often associated with highly toxic dioxin compounds, thereby creating a potentially hazardous environment upon inundation of the property.

Although arsenic (As) (seven of seven samples), Hg (six of seven samples), and paraquat (three of seven samples) were detected in canal sediments, none exceeded PEC criteria.

The assessment recommended that no remedial actions be taken to reduce contamination in canal sediments and that applications of paraquat be discontinued upon acquisition of the property. The Service agrees with the recommendation regarding future use of paraquat, but believes that additional delineation sampling will be necessary to adequately characterize pentachlorophenol contamination in the canal.

Point Sources

One soil sample taken from the burn area indicated detections of Ba, Cu, Pb, and Zn. Only Cu (150 mg/kg) exceeded SQAG criteria (PEC).

Soil samples taken from the maintenance area/chemical barn indicated the presence of As, Ba, Cu, Pb, Hg, Zn, and several Polynuclear Aromatic Hydrocarbons (PAHs). Only the PAH constituents exceeded SQAG criteria. Benzo(a)anthracene (0.25 mg/kg), chrysene (0.37 mg/kg), and fluoranthene (1.4 mg/kg) exceeded respective TEC values. Acenapthene (7.6 mg/kg), acenapthylene (0.97 mg/kg), anthracene (1.6 mg/kg), fluorene (9.2 mg/kg), naphthalene (5.9 mg/kg), phenanthrene (22 mg/kg), and pyrene (7.7 mg/kg) exceeded PEC values.

The fertilizer mix/load area demonstrated soils contaminated with As, Hg, and Zn. Only Zn (230 mg/kg) exceeded SQAG criteria (TEC).

The assessment recommended the removal of the top 12-inches of soil from all contaminated areas of the point source locations.

Bob Taylor
May 19, 2003
Page 4

Recommended corrective actions presented in ECT's report should alleviate potential risks to fish and wildlife and their resources from sediments contaminated with Cu, Zn, aldicarb, paraquat, and PAHs at the Griffin Brothers' property. However, the Service recommends that the South Florida Water Management District perform additional delineation sampling in the canal in the vicinity of the S5 sample site. Upon review of this additional data regarding pentachlorophenol in canal sediment, the Service will provide supplemental comments and recommendations.

Thank you for the opportunity to review and provide comments regarding this Environmental Site Assessment. If you have any questions or comments, please contact Dr. Robert Frakes at 772-562-3909, extension 242, or Jim Boggs at extension 223.

Sincerely yours,

Linda S. Ferrell

July 14, 2003

Bob Kukleski
Senior Environmental Engineer
South Florida Water Management District
3970 RCA Blvd, Suite 7401
Palm Beach Gardens, Florida 33410

Dear Mr. Kukleski:

The Fish & Wildlife Service (Service) has received and reviewed the document entitled "Phase I/II Environmental Site Assessment for Winthrop Citrus Investors (GX-100-005)," submitted by Environmental Consulting & Technology, Incorporated (ECT). The Service agrees with most of ECT's recommendations for site remediation.

However, the Service does not agree with ECT's conclusion with regards to the risk associated with aldrin contamination. Since the property-wide average aldrin concentration exceeds the provided low effect level (LEL), further assessment of aldrin contamination within the 50 acre grid is necessary. This should include re-sampling of 5-arcre discrete samples within the 50-acre grid, potentially followed by elutriate tests, bioassays, bioaccumulation studies, and then a risk assessment pending results of the re-sampling. The Winthrop property approximately 2,400 acres, is a large tract of land in Hendry County, Florida that is currently utilized for citrus, with some evidence that tomato row crop farming had occurred early in the property's history.

Following the Phase I Assessment, ECT concluded the site warranted further investigation due to the presence of extensive agriculture, maintenance areas, former exploratory petroleum wells, and drainage canals. The Phase II Assessment was performed according to Service protocols (47 composite samples from agricultural areas), in addition to soil and groundwater sampling near the maintenance areas and sediment sampling in the canals. A characterization of the potential risks was also provided by ECT given the presence of some contaminants at concentrations ECT considered to be of potential concern.

Site-wide contaminant levels (average for all composite values) in cultivated areas indicate some risk to benthic organisms may exist. The pesticides aldicarb and aldrin exceeded threshold concentrations developed in ECT's characterization and specified by the Ontario Ministry of the Environment, respectively. ECT recommended the best management practice of aldicarb application cessation at least 12 months prior to site inundation to ensure adequate natural pesticide attenuation. They also considered ecological risk from aldrin exposure insignificant since aldrin had been detected in a single composite sample, but no others. Extensive paraquat

Bob Kukleski
July 14, 2003
Page 2

contamination on the site, while being less than threshold effects concentrations, led ECT to recommend immediate cessation of paraquat applications due to its persistence in soils. In addition, paraquat use is not permitted on lands to be acquired by the Department of the Interior.

Point source contamination (maintenance areas, petroleum wells) also revealed potential ecological risk for sediment dwelling organisms. The soil concentrations for multiple contaminants (metals, petroleum hydrocarbons, pesticides) found in soil samples around the maintenance areas exceeded either threshold or probable effects levels. As a result, ECT recommended soil removal, up to the top 12 inches, to remediate these locations and reduce potential ecological risk.

The Service agrees that the preferred best management practice would be cessation of aldicarb and paraquat applications. Aldicarb concentrations in soils should decline with time, and paraquat contamination will not increase if applications are ceased. Soil removal may be the better remediation method for soils surrounding the maintenance areas, but the sites should be resampled following soil removal to ensure efficacy. Both of these remediation strategies should reduce the risk to benthic organisms from those contaminants if the property is inundated.

Aldrin contamination at the site is peculiar. A persistent chlorinated cyclodiene pesticide, aldrin registration was cancelled in 1987 because of the hazard it presents in the environment. While only a single *composite* sample contained aldrin, it is a composite of 10 samples collected from a 50-acre site. The contamination could be a single sub-sample with a very high aldrin concentration, a relatively homogenous distribution of aldrin contamination, or an analytical error. The actual situation is unknown without a further reassessment of the contamination. In addition, when averaged over the entire property, the upper 95 percent CI (2.53 ug/kg) exceeded a threshold effects level (LEL = 2 ug/kg, Ontario Ministry of Energy and Environment). This indicates potential risk to benthic invertebrates.

The Service is grateful for the opportunity to review this site assessment for the Winthrop property. If you have any questions regarding these comments, please contact Dr. Tim Bargar at 772-562-3909, extension 315.

Sincerely yours,

Linda S. Ferrell

July 1, 2004

Robert Kukleski
Senior Environmental Engineer
Center for Environmental Studies
3932 RCA Boulevard, Suite 3210
Palm Beach Gardens, Florida 33410

Dear Mr. Kukleski:

This letter has been prepared in reply to a response letter written by Environmental Consulting and Technology, Incorporated (ECT) received on September 26, 2003. That response letter was written to answer concerns expressed by the Fish and Wildlife Service (Service) about aldrin contamination on the Winthrop Citrus Investors property.

Aldrin was detected in one composite sample, out of 47 collected composites, at a concentration of 29 µg/kg. This concentration resulted in a property-wide jackknife mean of 1.52 µg/kg, and a 95 percent upper confidence level (UCL) of 2.53 µg/kg. Since no sediment quality assessment guideline (SQAG) value for aldrin was derived by MacDonald et al. (2003), equivalents of the threshold (LEL) and probable effects concentrations (SEL), from the Ontario Ministry of Energy, were utilized to determine potential ecological risk. The LEL was 2.0 µg/kg while the SEL equivalent was 80 µg/kg. The SEL was not exceeded in any soil sample, while the LEL was exceeded by the tract composite value and the property-wide 95 percent UCL.

Protocol agreed to by both the Service and the South Florida Water Management District (District) stipulates that either remediation of the contamination or further assessment be performed when the property-wide mean or 95 percent UCL equals or exceeds the threshold effects concentration (TEC). This was the basis for the Service's original recommendation of expanded sampling of the tract in which aldrin had been detected.

ECT stated in the phase I/II assessment that it did not believe aldrin presented a significant ecological risk and that further assessment was unnecessary because:

- Aldrin was detected in only one composite.
- The detection was less than the PEL.
- The 95 percent UCL (2.53 µg/kg) was only slightly above the LEL (2 µg/kg).
- Based on the District's fugacity-based food web model, no risk to piscivorous birds was predicted to result from aldrin concentrations detected in the soils.
- The property-wide average and 95 percent UCL was less than a wildlife-based SQAG of 6.39 µg/kg.
- Aldrin was not detected at any point source locations.

Robert Kukleski Page 2

Regardless of the number of detections and the degree of LEL exceedence by the 95 percent UCL, the Service maintains that further assessment of the contamination was warranted since the LEL was encompassed by 95 percent UCL. Further assessment can include a preliminary ecological risk assessment (ERA), i.e., an ERA not including site specific chemical availability information, utilizing the fugacity-based food chain model to give an approximation of risk to the Service's trust resources. A preliminary fugacity-based food chain model was done by ECT in the original phase I/II, which was not considered by the Service at the time of its original review. Results of that model indicated hazard quotients ranging from 0.01 to 0.02 for birds exposed to aldrin concentrations in soil of 29 µg/kg. These hazard quotients were independently confirmed by the Service. The hazard quotients are sufficiently less than one to indicate that aldrin concentrations on the Winthrop Citrus Investors property, likely to be encountered by piscivorous birds, will not present a significant risk. Therefore, the Service concurs that further assessment of aldrin contamination is not warranted.

If you have any questions regarding this letter, please contact Dr. Tim Bargar at 772-562-3909, extension 315.

Sincerely yours,

James J. Slack
Field Supervisor
South Florida Ecological Services Office

MEMORANDUM

TO: Ruth Clements, Deputy Department Director, Land Acquisition

FROM: Robert Taylor, Lead Engineer, Land Acquisition Support Division

DATE: August 24, 2004

SUBJECT: Phase I/Phase II Environmental Assessment
Bryan Paul Citrus, Inc (Tract No. GX 100-009)
Caloosahatchee Attenuation/C43 Project Area
Hendry County

Attached is a copy of the Phase I/Phase II Environmental Assessment (EA) of the Bryan Paul Citrus, Inc., property (Tract No. GX 100-009). Pursuant to the request of Thomas Hanaway, Tetra Tech FW, Inc. (TTFW) completed the attached report. The property is located south of State Road 80/Caloosahatchee River and west of State Road 29 Labelle, Hendry County. The property is a commercial citrus grove and consists of approximately 600 acres. This tract encompasses the eastern portion of Section 36, Township 43 South, Range 28 East, the western portion of Section 31, Township 43 South, Range 29 East, and the western portion of Section 1, Township 44 South, Range 29 East. The property can be accessed from State Road 29 through an unimproved road on the east entrance to the property. The subject parcels are proposed for acquisition as part of the Caloosahatchee Attenuation/C-43 Basin Project. The Project will enhance flood protection and stabilize water supply to the Caloosahatchee Estuary. The restoration efforts may include the filling of ditches, swales, canals and removal of site roads and pump stations. Additionally, a soil berm may be constructed on the perimeter of the site to store surface water. It is anticipated that the restoration activities will be preceded by interim land use. This interim land use will consist of continued cultivation of the citrus for a period of approximately one (1) year.

The purpose of the assessment activities was to confirm the presence or absence of soil/groundwater contamination or contaminated media associated with the previous and current activities conducted on the subject parcel. The Phase I EA was performed in general accordance with American Society for Testing and Materials Standard Practice for Environmental Site Assessments (ASTMS Practice E 1527-00). This method has been used as a guide to insure appropriate inquiry into the environmental characteristics and condition of the site consistent with good commercial and customary engineering and environmental practices.

Ruth Clements
August 24, 2004
Page 2

The results of the Phase I/II EA indicated that the property was historically used as a cattle ranch or open range land. The property was converted in the 1960s from range pasture to row crops (e.g., peppers, cucumbers, tomatoes, and watermelons). Beginning around 1972, the vegetable row crops were shifted to citrus trees. The property has been improved with a series of farm road drainage ditches, canals, and support structure.

A one-story concrete building, identified as the nursery building, is located on the western central section of the property. The nursery building is used to store agricultural pesticides. An aboveground storage tank (AST) and chemical mix area is located on the eastern central section of the property. This AST area is used to store diesel fuel, spray oil, and mix chemicals. The tanks are located within a concrete secondary containment area. Obvious stained soils were observed in this area. This area is identified as the C-1 mix station. The main support facility for this farm is located at the Bryan Paul main maintenance area, which is located on the adjacent property to the east. This area includes fuel tanks, chemical storage, and mixing as well as a maintenance repair area. This area was not investigated since it is not part of the proposed acquisition tract.

The main drainage canal for the property runs from west to east through the center of the property and is connected to the Roberts Canal which, in turn, connects to the Townsend Canal further to the west. Irrigation water for the property is provided by two large electric pumps. Water from the main canal is distributed by a series of other smaller pumps and structures to an underground irrigation piping system that runs throughout the grove. The citrus trees are individually irrigated by an in-ground drip irrigation system.

The results of the Phase I EA identified seven (7) areas as an environmental concern. These are as follows: (1) Pump Stations, (2) Former Nursery Barn, (3) C-1 Mix Station, (4) Auxiliary Tank Area, (5) Graded Area Solid Waste, (6) Burn Area, and (7) Cultivated Area.

Based on the presence of environmental concerns, a Phase II EA sampling plan was developed to evaluate each area. The scope of work for the Phase II sampling investigation was developed in conjunction with, and reviewed by, representatives of the United States Fish and Wildlife Service (FWS), Vero Beach office. A series of samples was collected at the potential point source locations. The potential regional areas of impact (citrus cultivation) were identified and plotted onto current aerial photographs. A total of 119 individual samples were collected on a 5-acre grid spacing throughout the entire 600-acre area. These 119 individual samples were mixed at the time of collection, stored in sealed jars, and then combined into groups of 10. This process resulted in a total of 12 samples that were submitted for laboratory analyses. In addition, a 500-milliliter aliquot from each of the 119 individual samples was shipped to the laboratory for archiving until the analytical results of the composite samples were

reviewed. Based on the initial sampling results, the archive samples collected from 2 grids (grids 8 and 9) were analyzed to further evaluate the grids for the presence of chlordane. This approach serves as an effective sampling methodology to evaluate relatively large areas of agricultural activities. This methodology has been embraced by the FWS as a suitable screening technique for expansive parcels and has been successfully utilized by the District on several previous projects.

Because of the projected land use, the sampling results were evaluated with respect to the recently revised Sediment Quality Assessment Guidelines (SQAGs) listed in Table 5-1 of the document prepared by McDonald Environmental Service, Ltd. in 2002. Florida Department of Environmental Protection (DEP) staff, as well as FWS staff, mandate the use of SQAGs to serve as initial screening criteria for future stormwater areas and reclaimed wetlands. The potential petroleum impacted area-sampling results and groundwater-sampling results were compared with the applicable criteria listed in Florida Administrative Code, Chapter 62-777. The cumulative sampling results were then subjected to a screening level ecological evaluation to determine whether the subject property exhibits a level of chemical contamination sufficient to warrant further evaluation of potential ecological risk. It should be noted that enhanced QA/QC protocols were implemented in the evaluation of sampling results. These QA/QC measures included the use of duplicate and split samples sent to separate laboratories.

The results of the Phase II ESA investigation confirmed that corrective action is required to render some portions of the property suitable for the District's intended land use. At your direction, the corrective action requirements/costs were bifurcated based upon two (2) acquisition scenarios. The first of these scenarios consists of a hypothetical pre-acquisition environmental assessment (and the resultant corrective action requirements/costs) based upon the continued current agricultural land use or a residential/industrial conversion. The second scenario consists of the corrective action requirements/costs triggered by the screening criteria associated with the District's projected use of the property. This exercise is solely intended to provide an additional decision making tool in the evaluation of attendant costs associated with this acquisition. This exercise is not intended to form the basis for a legal opinion as to the corrective action responsibilities of the property owner versus the District.

The following is an overview of the areas where the Phase II assessment activities were conducted and where corrective actions are required to assure the property is acceptable for the District's intended future use.

Nursery Barn

The analytical results of soil samples collected near the Nursery Barn identified the presence of arsenic, cadmium, chlorpyrifos and malathion at concentrations that would pose an unacceptable ecological risk, if left in place during the restoration. This contamination is limited to those surface soils above the water table. **Based on the assessment, the impacted soil should be excavated and disposed of off-site. Upon completion of the recommended corrective action, this portion of the property would be acceptable for the District's intended future use.**

C-1 Mix Station

The results of the Phase I/II investigation identified obvious stained soil, stressed vegetation, and strong odors in this area. The analytical results for soil/sediment and groundwater samples collected from the C-1 Mix Station identified the presence of copper, carbaryl, and petroleum constituents at concentrations that would pose an unacceptable ecological risk, if left in place during the restoration. Additionally, groundwater contamination was identified in the presence of floating petroleum product in one monitoring well. **The recommended corrective action includes the excavation and disposal of surface soil near the structure and sediment found in the catch basin. In conjunction, a system to perform groundwater treatment will be required to reduce contaminant concentration to an acceptable level. It is assumed that the groundwater treatment would be conducted during the soil excavation. Upon completion of the soil excavation and groundwater treatment, one (1) year of groundwater monitoring would be required. It is estimated that the site closure for this area will, therefore, take one (1) year from the implementation of the corrective actions. Upon completion of the recommended corrective action, this portion of the property would be acceptable for the District's intended future use.**

Auxiliary Tank Area

The results of the Phase I/II EA noted that the tank and structure in this area have been removed. Additionally, it appeared that soil in this area has been scraped and removed. According to the site operator, impacted soils were taken off-site for disposal/treatment. Analytical results of soil samples collected from the Auxiliary Tank Area indicated that a small area of surface soil near the structure has concentrations of copper that exceed the interim guidance concentration and zinc concentrations that exceed the PEC. The Phase I/II concluded that the impacted area is limited. It is recommended that, prior to any corrective action, additional soil samples be collected for these analytes to confirm the presence of impacts. **The recommended corrective actions**

include the excavation and disposal of impacted soil. Upon completion of the recommended corrective action, this portion of the property would be acceptable for the District's intended future use.

Burn Areas

The Phase I/II identified five burn areas on-site. The incineration of vegetative material and miscellaneous waste within the burn areas has the potential to cause the ash to contain elevated concentrations of metals. A soil sample was collected below the ash layer to evaluate undisturbed soils for the presence of metals contamination. The result of the soil sample analysis indicated that ash generated during the on-site burning has not impacted the underlying soils or the surrounding soils. **Therefore, it is recommended that only the ash material is excavated and disposed of offsite. Upon completion of the recommended corrective action, this portion of the property would be acceptable for the District's intended future use.**

Graded Area

Site observation conducted during the Phase I/II indicated this area was impacted with buried waste material. The analytical results of samples collected indicated that contaminants were not detected at a concentration that would pose an ecological risk. However, the obvious presence of solid waste was documented in this area. Site observations indicated that the solid waste/construction debris consisted of miscellaneous plastic, metal, wire glass and plastic items. **The recommended corrective action for this area includes the scraping and removal of solid waste. Upon completion of the recommended corrective action, this portion of the property would be acceptable for the District's intended future use.**

Existing and Former Surface Water Pump Stations

There are four (4) existing aboveground storage tanks (ASTs) and one former AST location on the property. As part of the Phase I/II, a site inspection was conducted at each location for the visible presence of contamination. Based on the site inspection, soil samples were collected adjacent to three (3) areas that exhibited visible evidence of contamination. Soil samples were collected from the south pump station, main canal pump, and a former pumping station on the main canal. **Based on the results of the Phase I/II investigation, soil excavation is recommend adjacent to the main pump station and the former pump station. Upon completion of the corrective actions, this portion of the property would be acceptable for the District's intended use.**

Canal Sediments

As part of the Phase II EA, eight (8) Sediment samples were collected from the surface water drainage canal on the property. The analytical results of the sediment samples indicated that only two of the sediment samples collected, adjacent to one of the larger burn areas on the property, exhibited concentrations of barium, copper, and silver above the SQAG TEC. Site observations indicated that ash and stained soil were present on the bank of the canal adjacent to the location of the sediment sample. The results of the assessment concluded that the impacted sediment was limited to the burn area and not representative of the typical canal sediments. **The recommended corrective action would include the excavation of ash from the bank of the canal and the sediments within the canal adjacent to the burn area. Upon completion of the recommended corrective action, this portion of the property would be acceptable for the District's intended future use.**

Cultivated Citrus Crop Areas

The analytical results of composite samples collected from areas located throughout the citrus groves on this property indicated that several areas contain high levels of chlordane, which warranted further investigation via a site-specific limited ecological risk assessment (SLERA). A SLERA was performed to evaluate the composite and individual soil samples collected from the cultivated citrus areas of the property. The results of the SLERA indicated that concentrations of chlordane above 100 ug/kg pose and ecological risk to endangered and or threatened aquatic birds. The Phase II EA determined that approximately 13 acre of the citrus grove was impacted with concentrations of chlordane above the 100 ug/kg limit. In order to ensure the protection of ecological receptors, including threatened and endangered species of wildlife, soils in this area will require corrective action. Additionally, assessment is also warranted to confirm the area of impacted soils estimated at 13 acres. Any increase or reduction of the impact area would require the corrective action cost to be revised accordingly.

Based on this risk, it is recommended that the District Project Manager and design team consider implementing a final design that would minimize the ecological risk associated with inundating/flooding this area. Design modifications that could minimize ecological risk may include shifting the boundary, site grading, and depth/time interval of flooding. This step should be conducted prior to developing/implementing a corrective action plan to address impacted soil. It is important to note that in the event the boundary is moved, an equivalent ecological risk may be realized on the adjacent property if they are allowed to passively flood as part of the restoration activities.

In the event that relocating the boundary to exclude the impacted area is not a reasonable alternative, corrective actions will be required to minimize the potential risks to ecological receptors. Prior to conducting any corrective actions, chlordane impacted soils will need to be further delineated. An additional 80 to 100 soil samples should be collected in the cultivated areas where elevated chlordane was detected. Soil samples should be collected from 0-6 inches, and a select number of samples collected from 6-inches to 2-feet to evaluate the vertical extent of impacts.

Corrective actions of soil impacts could consist of the following options: 1) excavating the chlordane impacted soils; 2) capping the impacted soils with clean fill; 3) soil inversion; 4) reuse of soil as berm material, and 5) formal consultation under Section 7 of the Endangered Species Act with the FWS.

Option #1: The cost to excavate and transport impacted soils (approximately 13 acres to a depth of one foot, or 21,519 cubic yards) off-site for disposal is approximately $1,410,202. Based on the cost to excavate and transport impact material offsite, this option was not considered feasible.

Option # 2: This option requires that the impacted area would be covered with 2 feet of clean fill. A management plan would be necessary to ensure that the impacted soil is not uncovered during the construction or operation of the restoration project. This alternative may be a less favorable option considering that impacted soils may be located in a sensitive ecological area during the site restoration. Additionally, long-term management of the area would be required to minimize any future risk associated with exposing the impacted soil to surface water. The estimated cost to cap the impacted soils with 2-feet of clean soil is the $645,177.

Option #3: Soil inversion is a relatively new concept that the District is considering. It was initially considered for citrus groves where untilled soils had been impacted with copper. It should be noted that since soils in these former vegetable cultivated areas would have been tilled as part of the agricultural process, it is likely that this technique would not be as effective as with soils that have not been tilled previously. The soil inversion could be conducted with a plow or standard excavating equipment. A pilot test would be necessary to evaluate the effectiveness of the soil inversion using either a plow or excavator. The approximate cost for soil inversion of 13 acres is $645,177.

Option #4: This option would require that the identified impacted soils (approximately 13 acres to a depth of one foot, or 21,519 cubic yards) would be excavated and used in an area where they would not pose an ecological risk. An example would be the access roads, building/pump station foundations, or the interior portions of an earthen berm or levee that will be constructed as part of the restoration. The utilization of the impacted soils in construction of the berm,

levees, roads, or foundations would reduce/eliminate the potential ecological risk in an efficient and effective manner. The estimated cost to relocate approximately 21,519 yards of impacted soil is $282,700.

Option #5: In the event that the District elects not to implement corrective actions or if corrective action is determined to be ineffective and/or infeasible, formal consultation under Section 7 of the Endangered Species Act with the FWS will be required to proceed with the construction of the reservoir. Formal consultation is required if District actions may affect a listed species (designated as threatened or endangered under the Endangered Species Act). Based on discussion with District staff, this option is consider problematic based on required timeframes, potential for legal challenge, and the availability of engineered controls for mitigation.

Well/Septic Tank Closure

The Phase I/II identified the presence of four (4) irrigation wells on-site. The irrigation wells are approximately 12-inches in diameter and 200 feet deep. Additionally, one septic tank is presumed to be present in the vicinity of the nursery barn. **The recommend corrective action would include the abandonment of the four (4) irrigation wells and the proper closure of the septic tanks.**

Best Management Plan

Based on the results of the Phase I/II EA and the proposed use of the property, development and implementation of a BMP for the site is recommended. The purpose of the BMP is to assure that the interim use activities will not degrade (further contaminate) soil /sediment conditions. It is recommended that an Agricultural Management Plan be developed for the continued interim use of the subject property. This plan should incorporate Best Management Practices for the storing, handling, mixing, and application of agrochemicals and petroleum products. It is suggested that a Mutual Land Stewardship Program Monitoring Plan also be developed and implemented. This Monitoring Plan would serve as an adjunct to an Agricultural Management Plan and would include an inspection/sampling component. The objective of these efforts would be to preclude environmental degradation during the interim use period, which would render the acquired land unsuitable for the intended project. The cost projection included in this report is based upon an anticipated one (1) year interim use period. With respect to the potential environmental impairment insurance associated with the interim land use, the exposure appears to be at the medium range of the matrix due to the document agricultural improvements. The continued operation of the pump stations,

storage tanks, mix area, and storage building warrants the $500,000 minimum coverage.

The following Table 1 provides a breakdown of the recommended additional assessment or corrective action activities that are necessary to prepare the property for its intended use.

Table 1
Corrective Action Cost by Area

Area of Concern	Estimated Cost
Nursery Barn	$ 35,600
C-1 Mix Station	$ 51,900
Graded Area	$ 5,200
Auxiliary Tank Area	$ 6,600
Former and Main Pump Stations	$ 2,400
Confirmation Sampling and Development of Corrective Action Plan	$135,200
Cultivated Citrus Crop Areas: Relocation of Impacted Soil To Acceptable Area *	$282,700*
Well/Septic Tank Closures	$13,100
Canal Sediment Removal	$10,900
Burn Area Ash Removal	$6,900
AST Closures	$10,100
BMP for Interim Use	$ 4,500
Total	**$565,100**

* Assumes that impacted soils could be relocated onsite in areas where they would not pose an ecological risk. In the event that this is not an acceptable alternative, additional corrective action cost would be incurred.

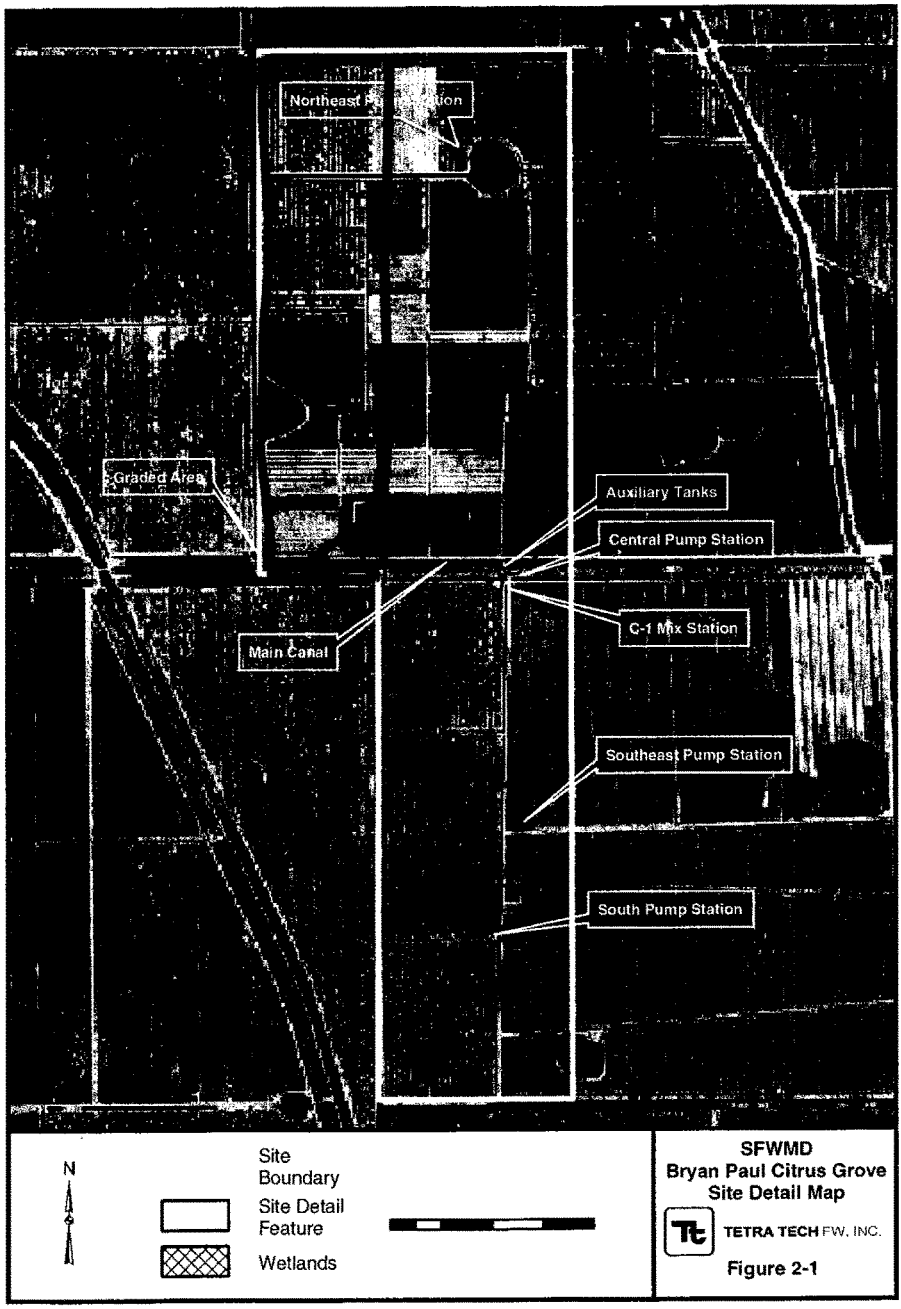
Detailed information concerning the costs for the proposed corrective actions is included in Section 9 of the EA report. The EA also includes several options and their associated costs to address the chlordane impacted soils in the cultivated area.

The following Table 2 bifurcates the corrective action requirements/costs based upon a hypothetical continued agricultural land use or conversion to a residential/industrial setting versus the District's projected use as a water attenuation reservoir, STA, or reclaimed wetlands. The triggering mechanism for the agricultural/residential/industrial land use is in exceedance of the Soil Cleanup Target Levels defined in FAC, Chapter 62-777. The previously described SQAGs trigger inclusion into the Water Attenuation Reservoir/STA/reclaimed wetlands column.

Table 2
Corrective Action Costs by Land Use

Recognized Environmental Condition	Approximate Remedial Cost	Agricultural and Residential Use	Water Storage and Natural Use
Nursery Barn	$35,600	X	
C-1 Mix Station	$51,900	X	
Graded Area	$5,200		X
Auxiliary Tank Area	$6,600		X
Pump Stations	$2,400	X	
Confirmation Sampling and Development of Corrective Action Plan	$135,200		X
Cultivated Citrus Crop Area	$282,700		X
Well/Septic Tank Closures	$13,100		X
Canal Sediment Removal	$10,900		X
Ash Removal	$6,900		X
AST Closures	$10,100		X
BMP for Interim Use	$4,500		X
Total	**$565,100**	**$89,900**	**$474,500**

In summary, it is important to note the Phase I/II identified point sources on the property that will require the implementation of corrective actions to render the property suitable for the projected use. The EA also identified the presence of approximately 13 acres of impacted soils which will require corrective actions prior to the conversion of the site to its intended use. The total environmental liability associated with conditions identified within the Phase I/Phase II EA is estimated to be $565,100. The FWS review and concurrence of the EA is pending. It is anticipated that their review will be completed in four weeks. In the event that FWS requests additional assessment/corrective actions, the projected cost may need to be revised.



Upon completion of the recommended corrective action, the property would be suitable for the District intended future use.

The Environmental Engineering Unit will await your direction as to the appropriate timeframe to implement the required corrective actions that are deemed the District's responsibility. Costs associated with the Phase I/Phase II Environmental Assessment described in this memo total $125,728. These expenditures were addressed in C-12452 Work Order No. 18.

Copies of this report have also been transmitted to Bob Frakes, FWS/Vero Beach office and Jeff Gould, DEP/Fort Myers. Should you have any questions or require additional information, please contact me at extension 2264.

Robert Kukleski, Senior Environmental Engineer
South Florida Water Management District
c/o Florida Center for Environmental Studies
3932 RCA Boulevard, Suite 3210
Palm Beach Gardens, Florida 33410

Dear Mr. Kukleski:

The Fish and Wildlife Service (Service) has received and reviewed the document entitled "Phase I and Phase II Environmental Site Assessment, Bryan Paul Citrus, Inc., 4930 State Road 29 South, Labelle, Hendry County, Florida," prepared by Tetra Tech FW, Incorporated (Tetra Tech). This document reports the results of the sampling investigation conducted on this 600-acre property proposed for incorporation into the Comprehensive Everglades Restoration Plan Caloosahatchee River/C-43 Canal Basin Project. Historically, the property has been used for cattle ranching, row cropping (1960's and 1970's), and citrus production.

The Phase I Environmental Site Assessment for the subject property identified eight areas of concern that required Phase II investigations. These areas include pump stations, a nursery barn, a mix station, an auxiliary tank area, a graded area, active citrus grove, burn areas, and irrigation canals. Discrete soil, sediment, and groundwater samples were collected to evaluate possible soil contamination in areas of concern. Analytical results were compared to Florida Department of Environmental Protection Sediment Quality Assessment Guidelines (SQAG), the Florida Administrative Code Soil Cleanup Target Levels (SCTL), and Groundwater Cleanup Target Levels.

Soil samples were collected from aboveground storage tanks at each of the three pump stations. The sample collected from the south pump station was not analyzed for copper; however, shortly after sampling the property owners removed this pump station, excavated, and disposed of the surrounding soils. Metals were found at concentrations below their probable effects concentrations (PEC) in samples from the main canal pump stations, but it was noted that in one of these samples selenium had a detection limit (1.9 mg/kg) above the Service's interim threshold toxicity screening level (1 mg/kg). Table 8-5, which presented results for the pump station samples, incorrectly reported the SCTL units for polynuclear aromatic hydrocarbons (PAH) (reported as µg/kg, instead of mg/kg). This error confounded the ability to properly evaluate PAH results from the pump stations. As a means of remediation, Tetra Tech proposed to excavate soil from contaminated areas around the pump stations.

Two samples were collected from the nursery barn, where chemicals were stored at the time of the assessment. Chlorpyrifos (2.1 mg/kg and 6,000 mg/kg), which currently has no SQAGs, and malathion (1 mg/kg), which has no PEC, were found at concentrations above the SCTL (0.001 mg/kg chlorpyrifos and 0.003 mg/kg malathion) and TEC (0.00067 mg/kg malathion). In addition, paraquat (0.366 mg/kg) was detected at concentrations below the SCTL (230 mg/kg). After review of the analytical results, it was noted that the detection limit used for malathion (0.015 mg/kg) in one of the samples was above the SCTL and threshold effects concentrations (TEC). Tetra Tech plans on excavating and removing contaminated soils from the nursery barn area.

The samples from the drain in the mix station detected concentrations of copper (590 mg/kg), toluene (20,000 mg/kg), and total petroleum hydrocarbon (100,000 mg/kg) above their respective screening values. In addition, paraquat was present at a concentration of 48.7 mg/kg. Some of the samples collected from the mix station were not analyzed for acenaphthene and carbaryl. Two of the samples analyzed for carbaryl were performed outside of the holding time and analyte was also detected in the method blank. The detection limits used for acenaphthene (110 µg/kg and 120 µg/kg) were above the PEC (89 µg/kg). Blank contamination was also a problem in analyses for arsenic, lead, and selenium. Despite these problems with laboratory analysis, Tetra Tech plans on removing contaminated soil and sediment from the mix station.

The auxiliary tank area, which contained two polyethylene chemical storage tanks, had a concentration of copper (110 mg/kg) in exceedance of the 85 mg/kg threshold value. The SCTL (based on surface water leachability) for toluene and paraquat were incorrectly reported in Table 8-4. The correct values are 5.6 mg/kg and 230 mg/kg, respectively. The Service agrees with Tetra Tech's suggestion to remove the copper contamination in the soil.

Partially buried metal debris and concrete were found in the graded area. Metals were detected at concentrations below their respective TECs, with the exception of selenium. The sample from this area was supposed to be analyzed for selenium and pesticides, specifically organochlorines; however, no results were presented. Tetra Tech proposed removal of the debris located in the graded area.

Using standard Service procedures for field sampling in agricultural areas, composite samples were collected from 12 50-acre grids in the citrus grove. Two of the composite samples contained concentrations of chlordane (100 µg/kg and 22.5 µg/kg) above the PEC (18 µg/kg). Archived aliquots from each of the discrete samples that compose the composites were analyzed to delineate the exact location of chlordane contamination. The analytical holding time for these analyses was exceeded; however, chlordane is unlikely to significantly degrade during the relatively short period of time (30 days) that the samples were held by the laboratory. To ensure that these samples were still comparable to the original analyses, one of the composites was extracted and reanalyzed with the discrete samples and the results were compared to the original composite values. While the chlordane concentration on this reanalysis was lower than the original (63 µg/kg vs. 100 µg/kg), it still exceeded the PEC. Analysis of these discrete samples showed that the area of chlordane contamination above the PEC was confined to just two

adjoining discrete samples (approximately 13 acres), with a mean concentration of 994 µg/kg. Tetra Tech suggested excavating this 13-acre area and disposing the soil on an area of the property that will not be inundated.

The burn area that was sampled contained no metals at concentrations in excess of the TEC; however, no results were presented for selenium, cadmium, or silver. Because of the historical practice of burning plastic chemical containers, Tetra Tech proposed to excavate and dispose of the ash at all five of the burn areas on the property.

Six samples were collected from the drainage canals throughout the property, none of which contained concentrations of contaminants above the PEC. The detection limit used for selenium (1.9 mg/kg) in one of the samples was above the Service's interim threshold toxicity screening level (1 mg/kg). Paraquat was detected in sediment samples at a maximum concentration of 1.76 mg/kg, near a possible burn area. Tetra Tech proposed to excavate sediments in the canal near this possible burn area.

In order to accurately evaluate soil sample data for the protection of ecological resources, the Service requests that non-detects (NDs) be reported as less than the practical quantitation limit (PQL) (<PQL), not less than the methods detection limit (MDL). While US Biosystems' lab reports NDs as <PQL, Millennium Laboratories, Incorporated is apparently still reporting NDs as <MDL.

After reviewing the analytical data, the Service agrees with Tetra Tech's recommendations for remediation at the pump stations, nursery barn, mix station, auxiliary tank area, graded area, burn areas, and canal sediments. The Service has reservations about the proposed plan to move the chlordane contaminated soil from the grove to an area that is not to be inundated. It is unclear from the report exactly where this non-inundated area is located, and with what assurance the area will not be exposed to water. If there is in fact an area where no inundation is guaranteed, the contaminated soils will, at the very least, need to be capped. We also suggest that post-remediation confirmatory sampling be performed to ensure that all contaminants of concern have been reduced to levels that do not present ecological threats to fish and wildlife resources. Assuming that all remediation is completed as proposed and the use of agricultural chemicals is in accordance with the Service's interim use pesticides, we believe that the Bryan Paul Citrus property is suitable for its intended use in the Caloosahatchee River/C-43 Canal Basin Project.

Thank you for the opportunity to provide comments regarding this assessment at Bryan Paul Citrus Grove. If you have any questions, please contact Emily Boughner at 772-562-3909, extension 335.

Sincerely yours,

James J. Slack
Field Supervisor
South Florida Ecological Services Office

October 13, 2004

Robert Taylor, Senior Environmental Engineer
c/o Florida Center for Environmental Studies
South Florida Water Management District
3932 RCA Boulevard, Suite 3210
Palm Beach Gardens, Florida 33410

Dear Mr. Taylor:

The Fish and Wildlife Service (Service) has received and reviewed the letter "United States Fish and Wildlife Service (USFWS) May 19, 2003 Review Letter Related to the Griffin Brothers Property," dated August 11, 2004. This letter supplements a previously submitted document entitled "Phase I/II Environmental Site Assessment for Griffin Brothers (GX-100-001)" (ESA) prepared by Environmental Consulting and Technology, Incorporated (ECT). The letter, also submitted by ECT, addresses Service concerns regarding residual pentachlorophenol (PCP) detected in canal sediments on the property. This property is planned for incorporation into the Caloosahatchee River/C-43 Basin project of the Comprehensive Everglades Restoration Plan (CERP). This parcel will be part of a 20,000-acre (160,000 acre-feet of storage) water retention reservoir designed to capture Lake Okeechobee releases for water supply, flood attenuation, and water delivery to the Caloosahatchee Estuary to reduce salinity and nutrient impacts. This letter provides our comments on the follow-up investigation regarding PCP at the Griffin Brothers property.

The Service agrees with ECT's contention regarding the likely source of this chemical and its low distribution across the property. Likewise, we also find ECT's calculation of a site-specific effect level (617 ug/kg in sediment) is derived appropriately and the result appears consistent with other toxicity reference literature regarding PCP levels which cause adverse effects to receptor species (Hazardous Substance Data Base, National Library of Medicine, National Institutes of Health). As such, the 32 ug/kg of PCP detected at the S5 sample site, as reported in the Phase I/II ESA, does not represent a level of contamination which could adversely affect benthic macroinvertebrates, fish, birds, or mammals which would use hydrologic features proposed for construction and operation at Griffin Brothers property.

It is not anticipated that the construction and/or operation of proposed hydrologic features at Griffin Brothers property will create an attractive nuisance to Service trust resources (including federally listed threatened and endangered species) from PCP contamination. Therefore, the Service agrees with South Florida Water Management District and ECT that this property is suitable for its intended use under CERP.

Robert Taylor, Senior Environmental Engineer Page 2

Thank you for the opportunity to review and provide comments regarding the letter and ESA. If you have any questions or comments, please contact Mr. Jim Boggs at 772-562-3909, extension 223.

Sincerely yours,

James J. Slack
Field Supervisor

Robert Taylor
Lead Environmental Engineer
South Florida Water Management District
3301 Gun Club Road
West Palm Beach, Florida 33406

Dear Mr. Taylor:

The Fish and Wildlife Service (Service) has received and reviewed the document entitled "Phase I/II Environmental Site Assessment for Bob Paul Citrus, Inc., 4930 State Road 29 South, Labelle, Hendry County, Florida (Tract No. GX100-015)," prepared by Tetra Tech FW, Incorporated (Tetra Tech). This document reports the results of the sampling investigation conducted on this 2,025-acre property that is proposed for incorporation as a component of the Comprehensive Everglades Restoration Plan Caloosahatchee River/C-43 Canal Basin Project. Historically, the property was used as cattle ranchland or open range land and, starting around 1972, the land was shifted towards citrus production.

The Phase I Environmental Site Assessment for the subject properties identified 13 areas of concern that required Phase II investigations. These areas include a maintenance area, chemical storage building, pole barn, shop, above ground storage tanks (ASTs), dispenser island, equipment staging area, storage area, irrigation pump stations, burn areas, former airstrip, irrigation canals, and cultivated area. Discrete soil, sediment, and groundwater samples were collected from point source locations to evaluate possible soil contamination in areas of concern. Using established procedures for field sampling in agricultural areas, composite samples were collected from 21 50-acre grids throughout the property. Within the grid that contained a 30-acre former row crop area, each discrete sample was analyzed for organochlorine pesticides and copper. Analytical results were compared to Florida Department of Environmental Protection Sediment Quality Assessment Guidelines (SQAG) and the Florida Administrative Code Soil Cleanup Target Levels (SCTL) and Groundwater Cleanup Target Levels (GCTL).

Out of the 21 composite samples that were collected from the agricultural area, 15 exceeded the threshold effects concentration (TEC) for copper (32 milligrams per kilograms [mg/kg]). Copper concentrations ranged from 19 mg/kg to 52 mg/kg, with a mean of 34.5 mg/kg. Each discrete soil sample that comprised the composite samples was also analyzed for copper. Six of these discrete samples had copper concentrations above the 85 mg/kg interim screening value for the protection of the endangered Everglade snail kite (*Rostrhamus sociabilis plumbeus*); however, none of the calculated means for the grids exceeded 85 mg/kg. Concentrations of the carbamate pesticides aldicarb (0.67 microgram per kilogram [µg/kg] to 27 µg/kg) and carbaryl (0.94 µg/kg to 2.4 µg/kg), which currently have no SQAG, were above their respective SCTLs (4 µg/kg and

0.7 µg/kg) in several of the composite samples. Concentrations of the organochlorine pesticides alpha- and gamma-chlordane (6.8 µg/kg and 5.3 µg/kg) exceeded their TECs (3.2 µg/kg) in one of the composite samples (#5036). It was noted that this sample, along with three others, was analyzed after the acceptable holding time. Another composite sample (#5007) also detected 4,4′-DDE (4.3 µg/kg) above its TEC (3.2 µg/kg) from the citrus grove. To determine the distribution of organochlorine contamination in grids #5036 and #5007, Tetra Tech decided to analyze the individual discrete samples with the understanding that these samples had exceeded their holding time. Out of these 20 discrete samples, 10 exceeded the TEC for 4,4′-DDE (3.2 µg/kg), 1 exceeded the probable effects concentration (PEC) (18 µg/kg), 3 were above the TEC (3.2 µg/kg) for alpha-chlordane, and 3 exceeded the TEC (3.2 µg/kg) for gamma-chlordane. A screening level ecological risk assessment (SLERA) determined that concentrations of chlordane, aldicarb, and carbaryl do not present unacceptable risk (hazard quotients (HQ) < 1) for any of the nine avian receptors of concern. In contrast, the maximum concentration of 4,4′-DDE did indicate risk for each of the receptors (HQs > 1). To determine the risk from individual grids, preliminary remediation goals (PRG) were calculated as the concentration of 4,4′-DDE in soil that corresponds to a HQ of 1. Results from this found that grid #5007 exceeded the no observed adverse effect level PRG and, therefore, suggest possible toxic exposures to avian species with small home ranges, such as the clapper rail (*Rallus longirostris*). Tetra Tech recommended further delineation of 4,4′-DDE contamination in grid #5007 and adjacent areas followed by soil inversion.

The one sample that was analyzed from the maintenance building had concentrations of copper (59 mg/kg) above the TEC (32 mg/kg) and total recoverable petroleum hydrocarbons (TRPH) (1n700 mg/kg) above the SCTL (340 mg/kg). Recommended corrective actions include soil removal and disposal to areas of the property that will not be inundated.

The sample from the chemical storage building detected concentrations of alpha- and gamma-chlordane (280 µg/kg and 300 µg/kg) and dieldrin (2,700 µg/kg) above their respective PECs (18 µg/kg, 18 µg/kg, and 62 µg/kg). Hepatochlor epoxide and endrin were found at levels above their TEC and aldrin (730 µg/kg), which currently has no SQAG, was detected at a concentration above the SCTL (10 µg/kg). In addition, copper was detected at a concentration of 15,000 mg/kg, a value three orders of magnitude above the screening level (85 mg/kg). Tetra Tech recommended removing soil and disposing it in an area not to be inundated.

The pole barn, shop/storage building, and three ASTs were all located adjacent to each other. The pole barn sample did not detect any contaminants at values above the SQAG, while the samples from the shop and ASTs had concentrations of 4,4′-DDE (20 µg/kg) above the TEC (3.2 µg/kg) and levels of TRPH (3,700 mg/kg) above the SCTL (340 mg/kg). One sediment sample collected from the drain near the pole barn contained concentrations of 4,4′-DDT, 4,4′-DDE, 4,4′-DDD, and alpha-chlordane above their respective TECs. Suggested remedial actions include soil removal and disposal in an area not to be inundated.

The diesel AST, gas/diesel AST, and dispenser island did not detect TRPH at levels above the SCTL. No further corrective actions are recommended for these ASTs. The samples collected from the spray oil AST detected concentrations of TRPH above the SCTL and GCTL. Recommended actions include soil removal and air sparging of groundwater.

The maintenance staging area had concentrations of 4,4'-DDE (97 µg/kg and 56 µg/kg) above its PEC (31 µg/kg) and gamma-chlordane (4.1 µg/kg) above its TEC (3.2 µg/kg). The sample from the fenced staging area detected alpha- and gamma-chlordane and copper at concentrations above their respective TECs. To remediate contamination in the staging areas, Tetra Tech recommended soil removal and disposal in an area not to be inundated.

Concentrations of 4,4'-DDE (3.8 µg/kg) and alpha- and gamma-chlordane (12 µg/kg and 13 µg/kg) were above their respective TECs and TRPH (12,000 mg/kg) was above the SCTL (340 mg/kg) in soil samples collected from the building in the grove. Limited soil excavation and disposal is recommended.

None of the 10 samples from the irrigation pump stations had concentrations of TRPH above the SCTL. No remedial actions are necessary for the pump stations.

Copper was detected at a concentration in exceedance of the TEC in one of the four burn areas. Tetra Tech recommended removing the ash from all of the burn areas.

Three of the 13 soil samples collected from the approximately 4,000 foot long former airstrip detected organochlorine pesticides at concentrations in excess of the SQAG. Concentrations of 4,4'-DDE (25 µg/kg, 8.4 µg/kg, and 90 µg/kg) were above the TEC (3.2 µg/kg) in three samples, one of which also exceeded the PEC (31 µg/kg). Alpha- and gamma-chlordane (48 µg/kg and 43 µg/kg) were in excess of the PEC (18 µg/kg) in one soil sample. All three of these samples were located in the eastern turn-around section of the airstrip. Tetra Tech recommends removal of the contaminated soil and disposal in an area not to be inundated.

Of the 11 sediment samples collected from the irrigation canals, 4 contained copper (mean of 26.6 mg/kg) at concentrations above the TEC (32 mg/kg). In two samples, 4,4'-DDE (mean of 15.0 µg/kg) was detected above the TEC and in excess of the PEC in one sample. In addition, TRPH (780 mg/kg) were detected above the SCTL (340 mg/kg) in one sediment sample. The samples containing organochlorine pesticide contamination were all located adjacent to the two turn-around areas of the airstrip. Corrective actions to remove organochlorine pesticide contamination include removal of sediments and disposal in an area not to be inundated.

Service Comments

After reviewing the analytical data, the Service agrees with Tetra Tech's recommendations for remediation at the spray oil AST, building in the grove, and burn area. However, the proposed actions to remediate the chemical storage area, ASTs, staging area, airstrip, and canals by way of soil removal and disposal in an area not to be inundated presents concerns. While burying

contaminated soil would limit its bioavailability to fish and wildlife resources, it would not remove the potential risk for groundwater contamination. Many of the contaminants that were proposed for onsite burial exceeded their SCTL for the protection of groundwater and, therefore, require special engineering controls that prevent lechate infiltration into groundwater. We suggest consultation with Florida Department of Environmental Protection (DEP) regarding the onsite burial of contaminated soil. The Service believes the low levels of copper contamination that were detected in the irrigation canals requires no further assessment or remediation, given that the mean (23 mg/kg) and 95 percent upper confidence limit (UCL) (33 mg/kg) for the site were below the interim screening value (85 mg/kg). According to established procedures, if the 95 percent UCL for a contaminant is below the TEC or interim screening value, then no further action is necessary.

Contamination in the grove area was limited to detections of aldicarb and carbaryl, which currently have no SQAG, and TEC exceedances for copper, 4,4'-DDE, and alpha- and gamma-chlordane; however, no discrete results were presented for the former row crop area. Because the mean concentrations in each of the 21 grids was below the TEC for 4,4'-DDE and alpha- and gamma-chlordane, and below the interim threshold value for copper (85 mg/kg), we believe these contaminants would not present an ecological risk to fish and wildlife resources after implementation into the canal basin project. A SLERA showed the concentrations of aldicarb and carbaryl in the grove do not present a risk to ecological resources. The Service feels no further assessment is necessary for the cultivated area.

Assuming all remediation is completed as proposed and DEP is consulted regarding onsite burial of contaminated soil, we believe the Bob Paul Citrus property is suitable for its intended use in the Caloosahatchee River/C-43 Canal Basin Project.

Thank you for the opportunity to provide comments regarding this assessment at Bob Paul Citrus. If you have any questions, please contact Emily Boughner at 772-562-3909, extension 335.

Sincerely yours,

Robert Drahn

August 9, 2006

Robert Kukleski
South Florida Water Management District
3301 Gun Club Road
Palm Beach Gardens, Florida 33406

Dear Mr. Kukleski:

The Fish and Wildlife Service (Service) has reviewed the document entitled "Additional Soil Assessment, Bryan Paul Citrus Grove, 4930 State Road 29 South, Labelle, Hendry County, Florida," prepared by URS Corporation (URS). This document reports the results of the additional sampling investigation conducted on this 600-acre property proposed for incorporation into the Comprehensive Everglades Restoration Plan Caloosahatchee River/C-43 Canal Basin Project. Historically, the property has been used for cattle ranching, row cropping (1960's and 1970's), and citrus production.

The 2004 Phase I/II Environmental Site Assessment (ESA) conducted by Tetra Tech FW, Incorporated, identified a 13-acre area in the citrus grove that contained chlordane contaminated soils. Initial composite samples from 2 of the 12, 50-acre grids contained concentrations of chlordane (100 µg/kg and 22.5 µg/kg) above the Florida Department of Environmental Protection Sediment Quality Assessment Guidelines (SQAG) probable effects concentration (PEC) (18 µg/kg). Analysis of the individual discrete samples that comprised the two composite samples found that the area of chlordane contamination above the PEC was confined to just two adjoining discrete samples (8B and 9A) at concentration of 1,770 µg/kg and 218 µg/kg.

The present assessment was conducted to further evaluate the lateral and vertical extent of chlordane concentrations surrounding the identified area of contamination. It was noted that when URS collected the additional soil samples, all of the citrus trees had been cleared and the land disked. Two subsurface (6 inches to 2 feet below ground surface) soil samples were collected from 8B and 9A and 11 surficial (0 to 6 inches below ground surface) soil samples were collected in the area surrounding these locations.

Results from this sampling investigation found concentrations of chlordane, 4,4`-DDE, and 4,4`-DDT above their respective SQAG threshold effects concentration (TEC), but below their corresponding PEC in samples surrounding the previously identified chlordane contaminated area. No chlordane was detected in the subsurface sample at 8B and a concentration (6.5 µg/kg) slightly above the TEC (3.2 µg/kg chlordane) was detected at 9A. URS estimated the chlordane impacted (concentrations above 18 µg/kg) soils to be within a 20-acre area. The proposed remedial action included removing the top two feet of soil in the contaminated area and relocating it in dams constructed for the creation of the C-43 water retention reservoir.

Robert Kukleski Page 2

After reviewing the analytical data, the Service concurs with the 18 µg/kg cleanup target level for chlordane. The 100 µg/kg chlordane cleanup target level, which has been used for other properties, is based on a total organic carbon (TOC) content of 1.6 percent. The TOC content at Bryan Paul Citrus is 0.5 percent. Since there is an inverse relationship between TOC and bioavailability, we feel that the 100 µg/kg chlordane cleanup target level would not adequately protect benthic invertebrates, fish, and wildlife resources. In addition, we concur with the recommended remedial action of using chlordane contaminated soils for the construction of dams on the property. We suggest capping contaminated soils and post-remediation confirmatory sampling to ensure that all contaminants of concern have been reduced to levels that do not present ecological threats to fish and wildlife resources.

Thank you for the opportunity to provide comments regarding this assessment at Bryan Paul Citrus Grove. If you have any questions, please contact Emily Boughner at 772-562-3909, extension 335.

Sincerely yours,

Robert Fraden

September 14, 2006

Robert Taylor
South Florida Water Management District
3301 Gun Club Road
West Palm Beach, Florida 33406

Dear Mr. Taylor:

The Fish and Wildlife Service (Service) has reviewed the document entitled, "Additional U.S. Fish and Wildlife Service Soil Investigations Berry Labelle – Congen Groves," submitted to the South Florida Water Management District (District) by URS Corporation (URS). This 8,682-acre property, located in Hendry County, Florida, is an active citrus grove of both oranges and grapefruit. It is slated to be included within the Caloosahatchee Attenuation Project as a deep water retention reservoir for regulating freshwater flow into the Caloosahatchee River Estuary.

Assessment of contamination on this property began in 1999 and has been ongoing for several years. The original phase II assessment involved the collection of 17 composite soil samples that were collected to a depth of 2 feet below ground surface. Subsequent development of a new site assessment protocol led to a recommendation to reassess contamination on the property in 2002. Because of both the magnitude and spatial extent of its presence on the property, only Cu was determined to be a contaminant of potential ecological concern. Copper concentrations in composite samples collected during the reassessment ranged from 13.1 (Grid 100) to 169 mg/kg (Grid 125), resulting in a contractor calculated geometric mean of 51.9 mg/kg (95 percent upper confidence level of 56.6), which exceeds the threshold effects concentration (TEC, 32 mg/kg) for effects on benthic invertebrates. In fact, 75 of 89 50-acre grids exceeded the TEC. Since Cu concentration in Grids 58, 124, 125, and 134 exceeded the probable effect concentration (PEC) of 108 mg/kg, discrete samples were collected in 2002 from those grids to look for potential contamination hot spots. In 2003, the Florida Department of Environmental Protection adopted a new PEC for Cu (150 mg/kg) reducing the number of grids with Cu concentrations exceeding the PEC to one (Grid 125). Also in 2003, URS performed an ecological risk assessment and concluded that impacts were likely for the benthic community. It also predicted potential risk for the Everglade snail kite (*Rostrhamus sociabilis*) if Cu concentrations in soil exceed 85 mg/kg (interim screening concentration for risk to the snail kite). Contamination in Grids 56 and 145, in addition to the above noted four grids, exceeded 85 mg/kg. Therefore, in 2005, discrete samples were collected from Grids 145 and 56 to locate potential contamination hot spots. Lastly, also in 2005, delineation sampling of Cu contamination in the above-noted six grids was performed. The delineation sampling indicated Cu exceeded 85 mg/kg in Grid 135 as well, but was less than 85 mg/kg in Grid 145. URS recommended remediation of Cu contamination in soils of Grids 56, 58, 124, 125, 134, and 135.

After review of the delineation performed in 2005, the Service recommended a second delineation. This delineation involved composite sampling in nine previously unsampled grids (59, 74, 77, 78, 115, 116, 126, 142, and 143) that were adjacent to Grids 56, 58, 124, 125, 134, and 135. Copper concentrations in the nine grids ranged from 22 (Grid 74) to 120 mg/kg (Grid 143). Grid 143 was the only one of the nine grids with Cu exceeding 85 mg/kg. Copper concentrations in the remaining eight grids were less than 63 mg/kg. URS subsequently recommended including Grid 143 with Grids 56, 58, 124, 125, 134, and 135 in the proposed remediation.

URS stated the District plans to excavate the top 1 foot of soil from the areas to be remediated and reutilize that soil within the levees around the future reservoir, burying the soils such that surface water will not contact the Cu contaminated soil.

Service Comments and Recommendations

- The Service concurs that Cu contamination in Grids 56, 58, 124, 125, 134, 135, and 143 is adequately delineated.

- The Service recommends remediation for the entirety of Grids 124, 125, 134, 135, and 143 (250 acres); and for the entirety of Grids 56 and 58 that will be within the future reservoir. The proposed remediation should adequately reduce Cu concentrations in the above noted grids to below the interim screening value for risk to the snail kite.

- Development of the future benthic community may be impacted by Cu contamination in the sediments. The property-wide average Cu concentration (45 mg/kg, Service calculated arithmetic mean) would still exceed the TEC for Cu after remediation. In addition, Cu concentrations in soils of 10 to 15 percent of the sampled grids exceed 64 mg/kg, the concentration at which adverse effects to benthic organisms were demonstrated in toxicity testing during the risk assessment. Copper contamination in the unsampled grids may equal or exceed 64 mg/kg. While risk to the snail kite may be reduced by the proposed remediation, impacts to the benthic community are not likely to be significantly reduced. Therefore, the food base for the Service's trust resources that utilize the future reservoir may be affected.

In summary, while direct impacts to the Service's trust resources are not likely, indirect impacts through a reduction in the food base for the trust resources may occur due to existing Cu contamination in soils. The Service assumes that continued Cu applications during the interim use period will add to the current contamination levels in soils and recommends that the proposed remediation not commence until the end of the interim use period. In addition, the Service recommends no further Cu application be permitted in Grids 38, 39, and 145 since Cu concentrations in soils from those grids were close to the interim screening value.

Robert Taylor Page 3

Thank you for the opportunity to review this additional sampling investigation report for the Berry Labelle-Congen Grove Property. If you have any questions regarding these comments, please contact Dr. Tim Bargar at 772-562-3909, extension 315.

Special Project/Enforcement Branch
SAJ-2005-5958(IP-TKW)

David Bernhart
Assistant Regional Administrator
Protected Resources
National Marine Fisheries Service
263 13th Avenue South
St. Petersburg, FL 33701

Dear Mr. Bernhart:

Pursuant to the Endangered Species Act (ESA), below is our determination of effects for potentially affected federally threatened and endangered species for the C-43 West Storage Reservoir Project located in Hendry County, Florida.

Scheda Ecological Associates, Inc. has prepared a Biological Assessment (BA) for the project on behalf of the South Florida Water Management District (SFWMD). The BA includes the information described in 50 CFR §402.12. This letter serves to transmit the BA and effects determination for the project. Also included with this letter is a copy of the permit application which further describes the project. The U.S. Army Corps of Engineers (Corps) has determined that the proposed project would cause the following effects on federally listed species:

No affect: The Corps has determined the proposed project will not affect threatened bald eagle (*Haliaeetus leucocephalus*), threatened Florida scrub jay (*Aphelocoma coerulescens*), endangered Florida grasshopper sparrow (*Ammodramus savannarum floridanus*), endangered red cockaded woodpecker (*Picoides borealis*), endangered Okeechobee gourd (*Cucurbita okeechobeensis*) or threatened Florida scrub-jay (*Aphelocoma coerulescens*).

May affect not likely to adversely affect: The Corps has determined the project may affect but is not likely to adversely affect the endangered smalltooth sawfish (*Pristia pectinata*), endangered American crocodile (*Crocodylus acutus*), endangered green sea turtle (*Chelonia mydas*), endangered leatherback sea turtle (*Dermochelys coriacea*), endangered Kemp's ridley sea turtle (*Lepiodchelys kempii*), endangered hawksbill turtle

(*Eretmochelys imbricata*), threatened loggerhead sea turtle (*Caretta caretta*), endangered Everglade snail kite (*Rostrhamus sociabilis*), threatened piping plover (*Charadrius melodus*), endangered wood stork (*Mycteria Americana)*, and endangered West Indian manatee (*Trichechus manatus latirostris*).

May adversely affect: The Corps has determined the project may adversely affect the endangered Florida panther (*Felis concolor coryi*), threatened Audubon's crested caracara (*Polyborus plancus audubonii*), and threatened eastern indigo snake (*Drymarchon corais couperi*).

It should be noted that the SFWMD has restricted the use of copper on the site and plans to conduct all required corrective actions as recommended by the U.S. Fish and Wildlife Service prior to commencement of construction. Therefore, the Corps' determination for the snail kite in this cover letter supersedes the determination for the snail kite as specified in the BA.

The Corps has requested the U.S. Fish and Wildlife Service initiate formal consultation for the Florida panther, Audubon's crested caracara, and eastern indigo snake. Additionally, we request your written concurrence with our "may affect not likely to adversely affect" determination for those species that are within the purview of the National Marine Fisheries Service. If you need additional information or have any questions, please Tori White at the letterhead address, at 561-472-8888 or by e-mail at tori.white@saj02.usace.army.mil.

Sincerely,

Tori K White

Mr. Paul Souza, Field Supervisor
South Florida Ecological Services Office
U.S. Fish and Wildlife Service
1339 20th Street
Vero Beach, Florida 32960

Dear Mr. Souza:

Pursuant to the Endangered Species Act (ESA), below is our determination of effects for potentially affected federally threatened and endangered species for the C-43 West Storage Reservoir Project located in Hendry County, Florida. A copy fo the Department of the Army permit application for the project was provided to Ms. Joyce Mazourek of your office on or about November 20, 2006.

Scheda Ecological Associates, Inc. has prepared a Biological Assessment (BA) for the project on behalf of the South Florida Water Management District (SFWMD). The BA includes the information described in 50 CFR §402.12. This letter serves to transmit the BA and effects determination for the project. The BA is also available in documentum at the following link: documentum\Docbases\CERPDoc_saj\Project Teams\RD-Acceler8\C-43 Basin Storage Reservoir\Transfer. The U.S. Army Corps of Engineers (Corps) has determined that the proposed project would cause the following effects on federally listed species:

No affect: The Corps has determined the proposed project will not affect the threatened bald eagle (*Haliaeetus leucocephalus*), threatened Florida scrub jay (*Aphelocoma coerulescens*), endangered Florida grasshopper sparrow (*Ammodramus savannarum floridanus*), endangered red cockaded woodpecker (*Picoides borealis*), endangered Okeechobee gourd (*Cucurbita okeechobeensis*) or threatened Florida scrub-jay (*Aphelocoma coerulescens*).

May affect not likely to adversely affect: The Corps has determined the project may affect but is not likely to adversely affect the endangered smalltooth sawfish (*Pristia pectinata*), endangered American crocodile (*Crocodylus acutus*), endangered

green sea turtle (Chelonia mydas), endangered leatherback sea turtle (*Dermochelys coriacea*), endangered Kemp's ridley sea turtle (*Lepiodchelys kempii*), endangered hawksbill turtle (*Eretmochelys imbricata*), threatened loggerhead sea turtle (*Caretta caretta*), endangered Everglade snail kite (*Rostrhamus sociabilis*), threatened piping plover (*Charadrius melodus*), endangered wood stork (*Mycteria Americana)*, and endangered West Indian manatee (*Trichechus manatus latirostris*).

May adversely affect: The Corps has determined the project may adversely affect the endangered Florida panther (*Felis concolor coryi*), threatened Audubon's crested caracara (*Polyborus plancus audubonii*), and threatened eastern indigo snake (*Drymarchon corais couperi*).

It should be noted that the SFWMD has restricted the use of copper on the site and plans to conduct all required corrective actions as recommended in your September 14, 2006, letter prior to commencement of construction. Therefore, the Corps' determination for the snail kite in this cover letter supersedes the determination for the snail kite as specified in the BA.

By action of this letter, we request initiation of formal consultation for the Florida panther, Audubon's crested caracara, and eastern indigo snake. Additionally, we request your written concurrence with our "may affect not likely to adversely affect" determination for those species that are within the purview of the U.S. Fish and Wildlife Service. If you need additional information or have any questions, please Tori White at the letterhead address, at 561-472-8888 or by e-mail at tori.white@saj02.usace.army.mil.

Sincerely,

for David S. Hobbie

EXECUTIVE SUMMARY

The C-43 West Storage Reservoir project comprises one of the management measures included in C-43 Basin Project Implementation Report (PIR) planning effort, and consists of approximately 10,360 acres located in Hendry County west of LaBelle. Design for the C-43 West Storage Reservoir site includes construction of a 170,000 acre-feet above ground storage reservoir and associated appurtenances. The purpose of the C-43 West Storage Reservoir project is to provide water storage for the Caloosahatchee Estuary. The South Florida Water Management District (SFWMD) has completed preliminary environmental investigations, impact analysis, 30 percent design, a Basis of Design Report (BODR), and a Preliminary Design Report (PDR).

During the review of the BODR, a public concern was raised on the actual amount of seepage to be expected. A test cell program, consisting of 2 cells within the footprint of the C-43 site and consisting of approximately 267 acres, was recommended to assess this concern. The test cell project was permitted in December 2005 by the United States Army Corps of Engineers (USACE) and Florida Department of Environmental Protection (FDEP) following a Biological Assessment, agency coordination, pre-construction surveys for specific listed species, and formal consultation with the United States Fish and Wildlife Service (USFWS). At the time of this report, the test cell project has been constructed and the 9-month seepage and water quality monitoring program is underway.

A listed species assessment is being conducted in four phases for the C-43 West Storage Reservoir project. The first phase consisted of initial data collection to develop a project overview, agency coordination, and determining if any species-specific surveys would be required. The second phase consisted of developing the appropriate methodology and conducting preliminary surveys for a Listed Species Report (November 2004). Following agency coordination, it was determined that a specific wildlife survey for the Audubon's crested caracara (*Polyborus plancus audubonii*) should be conducted (third phase). This survey was conducted in spring of 2006 as per USFWS guidelines to evaluate the presence of nests and utilization of the project area by the caracara. The fourth phase involved the update and compilation of data for this Biological Assessment.

The following is a list and brief description of state and federally listed species which may potentially occur within, or which may be affected by, the C-43 West Storage

Reservoir project. Species that are more likely to occur in or near the project are discussed in greater detail within this report.

PROTECTED SPECIES WITH BOTH FEDERAL AND STATE DESIGNATION

Fish

The **smalltooth sawfish** (*Pristia pectinata*) is listed by the USFWS as endangered; while it is protected by some fishing regulations in the state of Florida, it is not a state-listed species. The species is usually found in shallow waters very close to shore over muddy and sandy bottoms, in areas such as sheltered bays and in estuaries or river mouths, such as the Caloosahatchee River. The smalltooth sawfish may benefit from indirect project impacts which include salinity regime improvements to the downstream Caloosahatchee Estuary. The project may affect, but is not likely to adversely affect, and may actually benefit the smalltooth sawfish.

Reptiles and Amphibians

The project study area contains suitable habitat for the e**astern indigo snake** (*Drymarchon corais couperi*), listed by both the USFWS and the Florida Fish and Wildlife Conservation Commission (FWC) as a threatened species. Although the eastern indigo snake was not observed, habitat exists on the project site; therefore, it could potentially occur. The species is known to utilize a variety of habitat types including citrus grove. Construction precautions will be used to protect the Eastern indigo snake during construction. It is anticipated that the project may adversely affect the eastern indigo snake.

The **American alligator** (*Alligator mississippiensis*) is listed by the USFWS as threatened due to its similarity of appearance to the **American crocodile** (*Crocodylus acutus*) and by the FWC as a species of special concern. Since there is substantial additional foraging and nesting area in close proximity to the proposed impacts, and the wetland impacts will be appropriately addressed, it is anticipated that the project will have no effect on the American alligator.

The **American crocodile**, listed as endangered by the USFWS and FWC, has not been documented in Hendry County but is present in mangrove and seagrass habitats of coastal counties of the Caloosahatchee River basin. The American crocodile may benefit from indirect project impacts which include salinity regime improvements to the

downstream Caloosahatchee Estuary. The project may affect, not likely to adversely affect, and may actually benefit the American crocodile.

Sea turtles including the **Atlantic loggerhead turtle** (*Caretta caretta*), **Atlantic green turtle** (*Chelonia mydas*), **leatherback turtle** (*Dermochelys coriacea*), **Kemp's ridley turtle** (*Lepidochelys kempii*), and **hawksbill turtle** (*Eretmochelys imbricata*) are listed as endangered by the USFWS and FWC with the exception of the loggerhead turtle, which is listed as threatened. These are marine species with a presence in south Florida waters and are known to utilize bays and estuarine habitats, such as the Caloosahatchee Estuary, for feeding and resting. Sea turtles may benefit from indirect project impacts which include salinity regime improvements to the downstream Caloosahatchee Estuary. The project may affect, but is not likely to adversely affect, and may actually benefit sea turtles.

Avifauana

Audubon's crested caracara (*Polyborus plancus audubonii*) is listed as threatened by both the USFWS and the FWC. The project falls within the caracara USFWS Consultation Area (CA). One caracara nest site was confirmed to the north of the project during spring 2006 surveys. This nest is located along the southern edge of the SR 80 right-of-way (ROW) and approximately 4,750 feet north of the project boundary. While individuals were not observed foraging in the project footprint, a portion of the project falls within 2000 meters (secondary zone) of this nest, as defined in the Standard Local Operating Procedures for Endangered Species (SLOPES). In addition, a possible nest was identified approximately 1,065 feet south of the project boundary, within a pasture of the A. Duda & Sons, Inc. property. Individuals from the possible nest site were seen flying into and out of the C-43 project site. While the C-43 project area provides only sub-optimal foraging habitat for the species, and individuals were only observed utilizing the project area in the southeast portion of the footprint, it does fall within the home range of both the confirmed and possible nests. Given the above information, it is anticipated the project may affect Audubon's crested caracara.

The **bald eagle** (*Haliaeetus leucocephalus*) is currently listed as threatened by both the USFWS and the FWC. Data obtained from the FWC 2004 Eagle Nest Database indicate that the closest documented bald eagle's nest, HE002, is located 3.4 miles east of the project, eastward of SR 29. This nest is documented to be last active as of the 2003 nesting season (was not active in the 2004 nesting season). It is anticipated that the proposed project will have no effect on the bald eagle.

The **Florida scrub jay** (*Aphelocoma coerulescens*) is listed as threatened by both the USFWS and the FWC. No individuals, nests, or appropriate habitat were detected in the project footprint. The nearest documented Florida scrub jay habitat and population occurs 1.1 miles west of the project area. This colony is beyond the foraging distance for the species to access the project area and is well outside the SLOPES protection zone. While the project falls within the Florida scrub jay USFWS CA, based on the above information, the project is anticipated to have no effect on the Florida scrub jay.

Florida grasshopper sparrows (*Ammodramus savannarum floridanus*) are listed as endangered by both the USFWS and FWC, due to habitat degradation and loss. The species is not known to occur in Hendry County but populations may occur in nearby Glades County. Mapping of potential Florida grasshopper sparrow habitat (Shriver and Vickery, 1999) shows marginal habitat zones to the northeast and southeast of the project, and the project area falls within the Florida grasshopper sparrow USFWS CA. However, the nearest marginal habitat zone is located approximately 2.5 miles to the southeast of the project footprint. No grasshopper sparrows were observed during field surveys and no suitable habitat exists in the project area. Based on the above information, this project is anticipated to have no effect on the Florida grasshopper sparrow.

The **snail kite** (*Rostrhamus sociabilis*) is a medium-sized hawk listed as endangered by both the USFWS and FWC. One snail kite was observed on a wire and eating a snail along SR 80 during a February 2006 survey. This location was approximately 0.75 miles west of the project footprint. In addition, during several field visits 2004-2006, populations of two species of apple snails, the Florida apple snail (*Pomacea paludosa*) and the exotic ramshorn apple snail (*Marisa cornuarietis*) were observed in large ditches of the project site. The network of large agricultural ditches provides suitable foraging opportunities but evidence of foraging/feeding (shell discards) was not observed. There are substantial additional foraging areas in close proximity to the proposed impacts, and the wetland impacts will be appropriately addressed. However, some tested copper concentrations in the project area were noted to exceed the interim Effects Level; bioaccumulation of copper through snail kite prey is therefore possible. It is anticipated this project may adversely affect the snail kite.

The **red-cockaded woodpecker** (RCW) (*Picoides borealis*) is currently listed as endangered by the USFWS and as a species of special concern by the FWC. The nearest documented RCW population occurs approximately 14 miles northwest of the

project area (FWC data). Based on lack of suitable habitat within the project area, it is anticipated that the project will have no effect on the RCW.

The **piping plover** (*Charadrius melodus*) is listed as threatened by both the USFWS and the FWC. The USFWS established critical habitat areas for the species, which include several locations on barrier islands west of the Caloosahatchee Estuary. The nearest piping plover critical habitat zone to the project area includes Punta Rassa, a mainland location at the southwestern edge of the Caloosahatchee Estuary, and Bunch Beach. The species may benefit from indirect project impacts which include salinity regime improvements to the downstream Caloosahatchee Estuary. The project may affect, but is not likely to adversely affect, and may actually benefit the piping plover.

The **wood stork** (*Mycteria americana*) is listed as endangered by both the USFWS and the FWC. Portions of this project fall just inside the 18.6-mile core foraging areas (CFA) of two colonies. Individuals were observed foraging and loafing onsite. Since there are substantial additional foraging areas in close proximity to the proposed impacts, and the wetland impacts will be appropriately addressed, it is anticipated that this project may affect, but is not likely to adversely affect, the wood stork.

Colonial nesting birds protected under the Migratory Bird Treaty Act (MBTA) that may occur in the project area include wading birds, some of which are state listed as species of special concern. These species were commonly observed in the project area but no rookeries were identified during field surveys. The nearest, documented active wading bird rookery is located approximately 1 mile south of the project (#619317). In addition, nests of the state listed, threatened least tern (*Sterna antillarum*) are similarly protected under the MBTA. Because terns select open, sandy areas for nesting, construction sites have been known to cause temporal effects to the species by attracting terns to nest. Successful tactics have been used to deter least terns from nesting in construction sites. The project is not anticipated to have adverse effects on wading bird rookeries or least tern nests.

Mammals

The **West Indian manatee** (*Trichechus manatus latirostris*) is listed by both the USFWS and FWC as endangered. Manatees have been known to utilize the Townsend Canal, which lies immediately adjacent and to the west of the project footprint. During times of inflow from the Caloosahatchee River, manatees are capable of passing over the weir and traveling southward into the Townsend Canal. Individuals have been observed at the outfall area immediately west of the project boundary as well as at the mouth of the

canal in the Caloosahatchee River. However, manatees cannot access the main distribution canal (i.e., Header Canal) for the grove property due to differences in elevation.

The Townsend canal will be retained in the post-construction condition (reservoir) and will deliver more fresh water to the Caloosahatchee River than it does currently. Given this fact, it is anticipated that the proposed project may affect, but is not likely to adversely affect the manatee.

The **Florida panther** (*Felis concolor coryi*) is listed by both the USFWS and the FWC as endangered. The proposed project is located within the USFWS CA and the project proposes impacts to areas within the panther primary, secondary, and "other" zones, as identified by the Florida panther subteam of the Multi-Species/Ecosystem Recovery Implementation Team (MERIT) and USFWS CA updates. The most recent available FWC telemetry data of radio collared Florida panthers, current through 2006, depicts four (4) Florida panthers and one (1) Texas cougar (*Felis concolor*) within a five-mile radius of the project area. A more landscape-level inspection (25-mile radius) identifies habitat utilization by several additional panthers, particularly within Okaloacoochee Slough and other conservation lands.

The USACE has made a determination that the C-43 West Storage Reservoir (WSR) project may adversely affect the Florida panther under Section 7 of the Endangered Species Act. As one of the SFWMD CERP Projects on the Band 1 list of the Master Implementation Sequencing Plan (MISP), impacts to the Florida panther were estimated by the USFWS as 21,825 panther habitat units (PHU), as referenced in the November 30, 2005 Test Cell Biological Opinion. Since this estimate, the project footprint has been slightly modified and land cover types and exotic species coverage have been further refined. Using the panther habitat unit analysis example in the USACE July 28, 2006 Picayune Strand Road Removal concurrence letter, as well as the complete table of habitat suitability values provided in the USFWS November 30, 2005 Test Cell Biological Opinion, panther impacts are currently estimated at 20,719 PHUs.

The USFWS determined that SFWMD offsite acquisition and restoration of approximately 101,066 acres of habitat in primary and "other" zones for Band 1/Acceler8 projects will compensate for the loss of panther habitat in the C-43 project. The SFWMD land is located in the core area of panther-occupied habitat, the majority is adjacent to other larger tracts of natural and preserve lands, and will assist in the long-term protection of the species.

Plants

The **Okeechobee gourd** (*Curcurbita okeechobeensis* ssp. *okeechobeensis*) is a federal endangered species, as listed by the Federal Register, July 12, 1993 Clarification, Federal Register, April 1, 1994. It is also a state endangered species, as listed by the Florida Department of Agriculture and Consumer Services' Chapter 5B-40, Florida Administrative Code. No Okeechobee gourds or appropriate habitat were observed during field reconnaissance. Given the above information, the project will have no effect on the Okeechobee gourd.

The **beautiful pawpaw** (*Deeringothamnus pulchellus*) is a federal endangered species, as listed by the Federal Register, September 26, 1986 Clarification, Federal Register, May 18, 1999. It is also a state endangered species, as listed by the Florida Department of Agriculture and Consumer Services' Chapter 5B-40, Florida Administrative Code. No appropriate habitat or beautiful pawpaw plants were observed during field reviews. Given the above information, the project will have no effect on the beautiful pawpaw.

1.0 PROJECT DESCRIPTION

C-43 West Storage Reservoir

The C-43 West Storage Reservoir project comprises one of the management measures included in C-43 Basin Project Implementation Report (PIR) planning effort. The C-43 West Storage Reservoir site is comprised of approximately 10,360 acres located in Hendry County west of LaBelle. Design for the C-43 West Storage Reservoir site includes construction of a 170,000 acre-feet above ground storage reservoir and associated appurtenances. When completed, the C-43 West Storage Reservoir Project will comprise a significant amount of the overall basin storage requirements as established for the Comprehensive Everglades Restoration Plan (CERP).

Environmental considerations played a large role in the ultimate C-43 site selection (Figure 1). The project began a few years ago by assessing approximately 20 potential sites for the C-43 project. Potential sites were eliminated over time when environmental issues, such as impacts to wildlife and wetlands, were considered too significant. Once the current C-43 location was selected, the project boundary was further assessed and modified, again to reduce impacts to wildlife and natural wetland systems. Of note was a significant reduction of the footprint in the southeast corner, where habitat impacts to the Florida panther (*Felis concolor coryi*) and other wildlife would have been too great.

Test Cell Project

During the review of the Basis of Design Report (BODR) a public concern was raised on the actual amount of seepage to be expected. A test cell program, consisting of two cells within the footprint of the C-43 site and consisting of approximately 267 acres, was recommended to assess the concern. The test cells are designed to model the recommended embankment and seepage control system, provide real time baseline model calibration with some key design elements extrapolated, and to provide a platform to evaluate water quality components of the reservoir system.

The C-43 Test Cell Project was permitted in December 2005; site clearing and cell construction began shortly thereafter. As of the time of this report, the cells have been filled and the seepage and water quality monitoring has commenced. Monitoring of the test cells is scheduled to last nine months.

Listed Species Assessment

A listed species assessment was being conducted in four phases for the C-43 West Storage Reservoir project. The first phase consisted of initial data collection to develop a project overview, agency coordination, and determining if any species-specific surveys would be required. The second phase consisted of developing the appropriate methodology and conducting preliminary surveys for a Listed Species Report (November 2004). Following agency coordination, it was determined that a specific wildlife survey for the Audubon's crested caracara (*Polyborus plancus audubonii*) should be conducted (third phase). This survey was conducted in spring of 2006 as per United States Fish and Wildlife Service (USFWS) guidelines to evaluate the presence of nests and utilization of the project area by the caracara. The fourth phase involved the update and compilation of data for this Biological Assessment.

1.1 EXISTING ENVIRONMENTAL CHARACTERISTICS

Existing Land Use / Land Cover

Natural/biological features and land use within the C-43 West Basin Reservoir project area were initially reviewed using the 2000 Florida Land Use, Cover and Forms Classification System (FLUCCS) Geographic Information System (GIS) data layer available from the South Florida Water Management District (SFWMD) (Figures 2 and 3). Citrus grove (FLUCCS 2210) covers approximately 90 percent of the study site, more than any other land cover type. The citrus grove land use classification includes acreage covered by citrus trees, grove maintenance roads, and small berms, brush piles, and other small features related to citrus grove operations. Water (FLUCCS 500 series) comprises 8.9 percent of the site and includes extensive agricultural canals/ditches, classified as Streams and Waterways (FLUCCS 5100), and excavated ponds, classified as Reservoirs less than 10 acres in size (FLUCCS 5340). Wetland (FLUCCS 600 series) comprises 1.1 percent of the site and includes Mixed Wetland Hardwoods (FLUCCS 6170), Willow and Elderberry (FLUCCS 6180), Exotic Wetland Hardwoods (FLUCCS 6190), Cypress (FLUCCS 6210), Wetland Shrub (FLUCCS 6310), and Freshwater Marsh (FLUCCS 6410).

Citrus groves, row crops (FLUCCS 2140), and improved pasture (FLUCCS 2110), with scattered cypress and mixed wetland hardwoods flank the project to the north, east, and south. The northern portion of the study area also contains some low-density residential areas (FLUCCS 1100). Forested uplands (parceled into low-density residential lots, various stages of development) such as pine flatwoods (FLUCCS 4110),

longleaf pine-xeric oak (FLUCCS 4120), sand pine (FLUCCS 4130), and xeric oak (FLUCCS 4210) are adjacent to the west of the project. At a landscape level, the C-43 project is surrounded by a matrix of agricultural, forested, and wetland land covers with pockets of urban land use (Figure 3). Urban areas are present to the southwest and northeast of the project area with small parcels along the Caloosahatchee River. Regions to the northwest and southeast of the project area are generally undeveloped.

2.0 METHODOLOGY

2.1 PRELIMINARY DATA COLLECTION

Initially, a comprehensive literature search was conducted for the C-43 project to determine if protected species or critical habitat was present within the study area. The literature search included standard Florida references such as the Rare and Endangered Biota of Florida series, the Florida Atlas of Breeding Sites for Herons and their Allies (1991), the Florida Natural Areas Inventory (FNAI) (1999, 2003), SFWMD and Florida Geographic Data Library (FGDL) GIS databases, and the Florida Fish and Wildlife Conservation Commission (FWC) list of protected species. Detailed inspection of Land Boundary Information System (LABINS) 1999 aerial photography in conjunction with field surveys was then performed to confirm the various existing habitat types within the study area.

Following the literature search and preliminary field verification, a potentially occurring protected faunal and floral species list was developed for the C-43 project area and modified over the course of agency communications (Tables 1 and 2). Coordination with the FWC and USFWS was initiated and includes:

- Two Planning Aid Letters (PALs) received from USFWS;
- A Pre-application Conference held in accordance with Florida Statutes (F.S.) 373.1501(5)(c)(a), on May 20, 2004;
- A data collection meeting held on July 20, 2004 with FWC to gather additional information on protected species in the area;
- A C-43 listed species meeting was held on March 22, 2005 with USFWS and FWC to discuss listed species field findings to date and agency comments on the draft Listed Species Report;
- A C-43 listed species meeting (for the full project site and the test cell) was held on May 26, 2005 to discuss the Florida panther and habitat compensation assessment as well as the test cell project design and permit needs;
- A C-43 meeting was held on November 9, 2005 with USFWS and FWC to discuss the current status of littoral zone planning and their preliminary design; and

3.0 RESULTS

3.1 FEDERAL PROTECTED SPECIES

Based on survey data, 4 federally listed faunal and 0 federally listed floral species were either observed or reported within the C-43 project study area. Figures 4 and 5 show the approximate location of protected faunal species observations during field surveys and/or historically documented occurrences within an approximate 4-mile radius of the C-43 project area. The following is a discussion of federally protected species that may be affected by the project and/or received specific field survey efforts. Faunal species discussed include the smalltooth sawfish (*Pristia pectinata*), American alligator (*Alligator mississipiensis*), American crocodile (*Crocodylus acutus*), sea turtles including the Atlantic loggerhead turtle (*Caretta caretta*), Atlantic green turtle (*Chelonia mydas*), leatherback turtle (*Dermochelys coriacea*), Kemp's ridley turtle (*Lepidochelys kempii*), and hawksbill turtle (*Eretmochelys imbricata*), eastern indigo snake (*Drymarchon corais couperi*), bald eagle (*Haliaeetus leucocephalus*), Audubon's crested caracara, snail kite (*Rostrhamus sociabilis*), wood stork (*Mycteria americana*), Florida scrub jay (*Aphelocoma coerulescens*), Florida grasshopper sparrows (*Ammodramus savannarum floridanus*), red-cockaded woodpecker (RCW) (*Picoides borealis*), piping plover (*Charadrius melodus*), colonial nesters and other nesting birds, West Indian manatee (*Trichechus manatus latirostris*), and Florida panther. Floral species include the Okeechobee gourd (*Curcurbita okeechobeensis* ssp. *okeechobeensis*) and beautiful pawpaw (*Deeringothamnus pulchellus*).

For each species discussed, anticipated project-related effects are provided. For federally listed species, a "determination of effect" is made by the federal action agency (USACE) based on the proposed activities. In very general terms, project activities typically have no effect to species or various degrees of adverse effects, based on project and construction specifications as well as species and habitat factors. A determination of a beneficial effect is somewhat rare and occurs only if the project conditions provide greater habitat quantity or quality and outweigh any temporal impacts to species during the construction phase.

3.1.1 Fish

3.1.1.1 Smalltooth Sawfish

The smalltooth sawfish is listed by the USFWS as endangered; while it is protected by some fishing regulations in the state of Florida, it is not a state-listed species. Sawfish

are elasmobranches: modified rays with shark-like bodies, skeletons made of cartilage, and gill slits on the ventral side. They get their name from their "saws"—long, flat snouts edged with pairs of teeth which are used to locate, stun, and kill prey. Sawfish species inhabit shallow coastal waters of tropical seas and estuaries throughout the world. They are usually found in shallow waters very close to shore over muddy and sandy bottoms, in areas such as sheltered bays and in estuaries or river mouths, such as the Caloosahatchee River (Simpfendorfer, 2006). The smalltooth sawfish's current range is peninsular Florida and is relatively common only in the Everglades region at the southern tip of the state.

The smalltooth sawfish may benefit from indirect project impacts which include salinity regime improvements to the downstream Caloosahatchee Estuary. This potential beneficial effect is supported by findings in Simpfendorfer (2006); this study suggests that the species may travel upstream in the Caloosahatchee River in the spring when flow is limited. It is anticipated that the project may affect, but is not likely to adversely affect, and may actually benefit the smalltooth sawfish. The USACE will complete Essential Fish Habitat (EFH) consultation with the National Marine Fisheries Service (NMFS) on the species.

3.1.2 Reptiles and Amphibians

3.1.2.1 American Alligator

The American alligator is listed by the USFWS as threatened due to its similarity of appearance to the American crocodile and is listed by the FWC as a species of special concern. This species is known to inhabit most permanent bodies of water including swamps, lakes, marshes, and canals. The American alligator was observed many times throughout the course of field surveys in agricultural ditches and "rim ditches" of cypress swamps (Figure 4). Since there is substantial additional foraging and nesting areas in close proximity to the proposed impacts, and the wetland impacts will be appropriately addressed, the project will have no effect on the American alligator.

3.1.2.2 American Crocodile

The American crocodile is listed by the USFWS and FWC as an endangered species. The crocodile inhabits areas where fresh and salt waters mix, such as coastal wetlands and canals. They are also known to inhabit mangrove and seagrass habitats in coastal areas of south Florida. The crocodile has not been documented in Hendry County but is present in coastal counties of the Caloosahatchee River basin, namely Lee and

Collier Counties. The nearest documented individual occurrence to the project is on Sanibel Island in Lee County. The American crocodile may benefit from indirect project impacts which include salinity regime improvements to the downstream Caloosahatchee Estuary. The project may affect, not likely to adversely affect, and may actually benefit the American crocodile.

3.1.2.3 Sea Turtles

Sea turtles including the Atlantic loggerhead turtle, Atlantic green turtle, leatherback turtle, Kemp's ridley turtle, and hawksbill turtle are listed as endangered by the USFWS and FWC with the exception of the loggerhead turtle, which is listed as threatened. These are marine species with a presence in south Florida waters and are known to utilize bays and estuarine habitats, such as the Caloosahatchee Estuary, for feeding and resting. Sea turtles may benefit from indirect project impacts which include salinity regime improvements to the downstream Caloosahatchee Estuary. The project may affect, but is not likely to adversely affect, and may actually benefit sea turtles.

3.1.2.4 Eastern Indigo Snake

The eastern indigo snake is listed by the USFWS and the FWC as a threatened species. Eastern indigo snakes require a mosaic of habitats. A study in southern Georgia found that interspersion of tortoise-inhabited sandhills and wetlands improve habitat quality for the snake (Landers and Speake 1980). Eastern indigo snakes require sheltered retreats from winter cold and desiccating conditions, and often use burrows of the gopher tortoise when available (Speake et al. 1978, Layne and Steiner 1996). In habitats lacking gopher tortoises, snakes may take shelter in hollowed root channels, hollow logs, or the burrows of rodents, armadillos, or land crabs (Lawler 1977, Moler 1985b, Layne and Steiner 1996). In its Florida range, the eastern indigo snake frequents diverse habitats, including pine flatwoods, scrubby flatwoods, floodplain edges, sand ridges, dry glades, tropical hammocks, edges of freshwater marshes, muckland fields, coastal dunes, and xeric sandhill communities (Service 1999). Eastern indigos also use agricultural lands and various types of wetlands, with higher population concentrations occurring in the sandhill and pineland regions of northern and central Florida.

Because eastern indigo snakes are found throughout Florida and use a variety of habitat types, including citrus groves, its presence in the project area is likely. No individuals have been observed during project field surveys; while no gopher tortoise

burrows have been observed, armadillo burrows have been frequently observed along canal banks and may provide refuge for indigo snakes.

Snakes may be injured or killed during construction by heavy equipment. This activity may cause individuals to leave the area, abandon den sites, and possibly miss foraging and mating opportunities. Above ground refugia may be lost during project construction. Individual snakes fleeing the area may be more vulnerable to predation but some snakes may seek underground refugia, if available. To minimize adverse impacts to the species, the project team will commit to an initial flooding of the reservoir site at as slow a rate as possible. This slow filling process will provide an opportunity for the eastern indigo snake, as well as other ground-dwelling wildlife, to vacate the project area and find suitable habitat outside the reservoir footprint. In addition, the USFWS Standard Indigo Snake Protection Conditions will be implemented during construction to minimize potential adverse impacts to the species. Construction guidelines are provided in Appendix C.

Following construction, very minimal to no habitat for the eastern indigo snake will be available in the project area. The interior slopes of the reservoir cells will be lined with soil cement, thus making the majority of the reservoir site unsuitable for the species. In addition, the access road and other maintenance roads will mainly be all-weather roads consisting of a limerock base with gravel substrate surface. The entrance road and small portions of the perimeter access road and maintenance roads will be paved. The only portions of the C-43 West Storage Reservoir (WSR) that may provide limited habitat for the eastern indigo snake are the embankments that will be constructed between the crest of the dam and the project boundary except for the perimeter canal and the maintenance road. These embankments will consist of overburden from the project area and a maintained sod. Because these embankments will be regularly mowed, they will not provide highly desirable cover or habitat for the species. Based on the above information, the proposed project may adversely affect the eastern indigo snake.

3.1.3 Birds

3.1.3.1 Bald Eagle

The bald eagle is currently listed as threatened by both the USFWS and the FWC. A proposed rule to de-list the species may be considered but no change in status has yet occurred. The bald eagle prefers forested riparian habitats associated with lakes, rivers or coastal areas. One bald eagle was observed soaring over a pasture approximately

1.8 miles east of the project (near SR 29). Data obtained from the FWC Eagle Nest Database (most recent data from 2004) indicate that the closest documented bald eagle nest, HE002, is located 3.4 miles east of the project, east of SR 29. This nest location is depicted in Figure D-5 of the Florida Panther Cumulative Impact Analysis package (Appendix D). This nest is documented to be last active as of the 2003 nesting season (was not active in the 2004 nesting season). No other nests were observed in the project vicinity during summer 2004 or spring 2006 field efforts; USFWS construction monitoring procedures will therefore not be required. It is anticipated that the proposed project will have no effect on the bald eagle.

3.1.3.2 Audubon's Crested Caracara

The Audubon's crested caracara is listed as threatened by both the USFWS and the FWC. This large raptor opportunistically feeds on carrion, fish, small mammals, small turtles, turtle eggs, and invertebrates. In Florida, the caracara historically occupied native prairies, but fire suppression has caused widespread conversion of prairies to open brushland. Currently, the bulk of Florida's caracara population has been found on large cattle ranches with improved pastures and scattered cabbage palms. Dry prairies with wetter areas and scattered cabbage palm comprise typical habitat. Caracaras also occur in some improved pasturelands and even in lightly wooded areas with more limited stretches of open grassland. Within these habitats, caracaras exhibit a propensity for nesting in cabbage palms, followed by live oaks, during a nesting season that typically continues from September through June with a concentration during November to April (Rodgers et al., 1996; Morrison, 2001).

Caracaras forage within a variety of habitats including improved pastures, adjacent to dwellings and farm buildings; newly plowed or burned fields; agricultural lands, including sod and cane fields, citrus groves, and dairies; and wetland habitats (Morrison 1996). The caracara is a diet generalist and opportunistic feeder. They consume carrion, such as road-kill (raccoon, opossum, and armadillo), and a wide variety of live prey. Prey species include invertebrates such as crayfish, beetles, grasshoppers and small mammals, amphibians, reptiles, fish, and birds (Morrison 1998).

Caracaras are non-migratory and may be found in their home range year round. Home ranges average approximately 1,200 ha (approximately 3,000 acres), corresponding to a radius of 2 to 3 kilometers (1.2 to 1.9 miles) surrounding the nest site (Morrison and Humphrey 2001). Foraging typically occurs throughout the home range during nesting and non-nesting seasons.

The project falls within the caracara USFWS Consultation Area (CA). As per USFWS request, a specific survey for the caracara was conducted in spring of 2006. The final report is provided in Appendix E. The C-43 project site was not documented to support any Audubon's crested caracara nests, and provides little to no nesting habitat. Very few cabbage palms and other appropriate nest tree types are present within the property. Those that do exist flank cypress domes and other forested wetlands that remain in the citrus groves. These areas were examined for the species and associated nests but none were noted.

Caracaras have been documented to utilize the southeast portion of the site for foraging opportunities. The groves likely provide populations of small amphibians, reptiles, and mammals, that caracara can use as a food source. During field surveys, adults were observed on several occasions flying into and out of the southeast groves of the C-43 project site; one time, food was seen in an individual's beak as it flew from the site.

Two caracara nests were identified in the vicinity of the project. A confirmed nest is located approximately 4,750 feet north of the project boundary, along the southern edge of the SR 80 ROW (Figure 5). Individuals were not seen flying into the C-43 project boundary. Field surveys suggest that the caracara at this confirmed nest location utilize habitats within the primary zone (defined as 300 meters, or 985 feet radius of the nest tree as per Standard Local Operating Procedures for Endangered Species (SLOPES)), but do not commonly use habitats within the secondary zone (defined as 2000 meters, or 6,600 feet radius of the nest tree as per SLOPES) for foraging opportunities. No portion of the project area falls within the primary zone of this nest but 264 acres of the project area fall within the standard secondary protection zone.

While there is not enough survey information to rule out the possible utilization of the secondary zone of this confirmed nest, a reduction in the secondary zone radius is proposed. During the course of nine days of caracara surveys in the project area, adult and juvenile caracaras were observed flying to the north across SR 80 to a pasture, and to the south, east and west to citrus groves, to forage. Based on carcasses found under the nest tree, it is likely that the caracaras additionally forage within the SR 80 ROW for roadkill. However, at no time were individuals observed flying southward far enough to reach the project footprint. There is ample citrus grove immediately adjacent to the nest (approximately 2,012 acres of citrus grove fall within the secondary zone of the nest); the 264 acres of grove that fall within the secondary zone and project area is only 13 percent of this citrus grove acreage sum. Therefore, we do not believe that the caracara depend on or even utilize the habitat in the project area. A reduction of the

secondary zone for this nest from the standard 6,600 feet to 4,750 feet is therefore proposed. This modification is not anticipated to impact the nest since the nest tree will not be removed for the project, the primary zone will not be affected, and the majority of the secondary zone will not be affected.

A second nest is likely to occur within the A. Duda & Sons, Inc. pasture, approximately 1,065 feet south of the project boundary (Figure 5). Individuals from the possible nest site were seen flying into and out of the C-43 project site. If this is an accurate nest location, approximately 1,100 acres of the C-43 project area falls within the secondary protection zone of this nest. Based on field observations, the caracaras utilize some habitats within this secondary zone for foraging opportunities. However, this secondary zone impact is only an estimate based on a probable but unconfirmed nest location. Also, due to the uncertainty of the nest, a primary zone was not established. However, the project area is unlikely to fall within the primary zone of this possible nest site.

If this possible nest is re-examined during the nesting season and is confirmed, a reduction in the secondary zone will also be proposed based on field observations of caracara along the project footprint periphery only. Caracaras were not observed to venture far from the edge and the groves along the project edge likely provide adequate foraging opportunities for the species.

No caracara observations were made in regions west of the project site. Land use and habitat in this area consists primarily of forested upland communities, most of which contains street patterns with a recent boom of housing construction activity. No open pastures or other appropriate foraging areas exist for the caracara. Therefore, caracaras are very unlikely to utilize this region.

Lastly, no caracara observations were made in regions south of the project. The permissible survey region south of the project area was limited to 1,000 feet which may have contributed to the lack of observations. However, appropriate habitat in this southern region was somewhat limited as citrus groves, spotted with forested wetlands, is the typical landscape. In addition, no caracara were observed flying southward in this region. Surveys conducted from the permissible survey region were in good view range from which biologists could detect flying caracara up to 0.5 miles away. While the possibility of a caracara nest existing in the southern limits of the wildlife survey area cannot be eliminated completely, a nest is very unlikely to be located there.

In summary, very little suitable nesting habitat (i.e., a few cabbage palms adjacent to cypress domes and surrounded by citrus grove) occurs within the project. However,

suitable nesting habitat does exist outside of and adjacent to the southeast corner of the project footprint and two nests (one confirmed, one possible) were identified. Caracaras were documented to utilize foraging habitat within the C-43 project in the southeast corner of the footprint only. Based on observations of the confirmed nest at SR 80, a reduction in that nest's secondary zone is proposed (4,750-foot radius). If the possible nest is later confirmed, a reduction of its secondary zone will also be proposed. The project will not disturb nesting caracaras or remove nest trees, will not affect primary zones, and foraging habitat would not be significantly reduced since adjacent habitats provide ample foraging opportunities for the caracara. In addition, the following construction guidelines will be put into practice for known caracara nest sites during nesting season (November – April) (Based on Habitat Management Guidelines for the Audubon's Crested Caracara in Central and Southern Florida, USFWS, 2002).

1. Construction activities will not take place within the 300-m (985-foot) primary zone extending outward from the nest tree.

   Restrictions that will be put into effect in the **primary zone** consist of:

   - removal of pasture or natural or man-made wetlands within pastures
   - removal of nest trees, cabbage palms or oaks
   - removal of other vegetation in the general vicinity of the nest tree that would result in the loss of protective cover in the nesting area used by fledged chicks
   - construction of any buildings, roadways, power lines, or canals
   - changes in land management activities such as removal of cattle or reduction in burning or mowing
   - use of chemicals that are harmful to wildlife, including pesticide applications

2. Construction Best Management Practices (BMP) will be followed throughout the project area, including:

   - The construction team will be educated regarding nesting and foraging habits and nest trees and their potential inhabitants at a pre-construction conference and team meeting. Issues such as the minimization of tailgate slamming near the protection zone during nesting season will be addressed at the conference and subsequent team meetings. Updates throughout project construction will be made as appropriate to educate personnel regarding nest tree status, new nest sites, and construction BMPs.
   - The protection zone will be designated as a no-parking/staging/storage area on the construction plan sheets to reduce the potential for noise and

disturbance. Noise reduction in this zone will be a component of the monitoring program.

3. The construction team will need to comply with any permits issued by the state or federal government.
4. In the unlikely event that construction may encroach upon the protection zone during nesting season, the USFWS will be contacted for consultation and associated reports prepared according to the Audubon Crested Caracara SLOPES.

Given the above information, the proposed project may affect the Audubon's crested caracara.

3.1.3.3 Snail Kite

The snail kite is a medium-sized hawk listed as endangered by both the USFWS and FWC. The original species listing pursuant to the Endangered Species Conservation Act in 1967 referred to the snail kite as Everglade snail kite. Although the listing has remained unchanged, the official common name is now simply snail kite. The snail kite is known to occur in the Caloosahatchee basin and critical habitat has been identified adjacent to the Caloosahatchee basin in Lake Okeechobee. The species is dependent on appropriate hydrology and water quality of the wetland habitats it utilizes. The species inhabits relatively open, freshwater marshes that support adequate populations of apple snails. Favorable areas consist of extensive shallow open water such as sloughs and flats, vegetated by sawgrass (*Cladium jamaicense*) and spikerush (*Eleocharis* spp.). These areas are often interspersed with tree islands or small groups of scattered shrubs and trees that serve as perching and nesting sites. The water level must be sufficiently stable to prevent loss of the food supply through drying out of the surface. Although open freshwater marshes are absent from the project area, other water features (canals and stormwater ponds) may provide foraging habitat for the snail kite depending on their water regimes.

Although no snail kites were observed within the project footprint, one individual was observed on a wire and eating a snail along SR 80 during a February 2006 survey. This location was approximately 0.75 miles west of the project footprint (Figure 4). Populations of two species of apple snails, the Florida apple snail (*Pomacea paludosa*) and the exotic ramshorn apple snail (*Marisa cornuarietis*), were observed in several of the larger ditches throughout the C-43 project site. Ms. Joyce Mazourek (USFWS) also indicated observations of snails in one wetland in the northeastern portion of the C-43 project area. SEA did not detect apple snails in this location at the time of the field

surveys. Although suitable foraging opportunities exist within the C-43 network of larger ditches, evidence of foraging/feeding (shell discards) was not observed.

While the design of the C-43 reservoir cells is still underway, it is anticipated that water levels will vary greatly from month to month and year to year. An evaluation of reservoir stages for an 8-year period model finds that water levels in the cells will vary from approximately 20-42 feet in elevation with an average of 34.7 feet and the majority of water levels between 30-40 feet. Typically, 5-10 foot fluctuations occur every few months. Constant water levels are anticipated to be rare; in the eight-year period, a steady state was noted for approximately four months in Cell 2 but a similar constant was not noted in Cell 1. This hydrological regime will not be suitable for apple snails. There will however, be approximately 160 acres of habitat available in the perimeter canal, where water levels will not fluctuate as greatly. The Florida apple snail lays clusters of eggs on plant stems about 8 inches above the water's surface during March-May. A rise in water depth above the level of the eggs during the period of maturation (approximately 16-22 days) will drown the eggs, while a drydown to levels below 4 inches during this period will interrupt egg production and cause mortality of newly-hatched snails.

CERP projects, such as the C-43 West Storage Reservoir, involve the creation of reservoirs and stormwater treatment areas (STA) on land previously used for citrus cultivation. Citrus grove operations have routinely included the application of heavy concentrations of copper as a fungicide. Wetlands created in contaminated areas may release copper from the soil, which can bio-accumulate in the food chain. Preliminary studies indicate a positive relationship between copper concentrations in soil sediments and copper concentrations in apple snails (Bargar et al. 2005). Apple snails are a primary food source of the snail kite; therefore, there is concern that the snail kite may be impacted by copper levels through their prey.

Copper concentrations in sampling points within the project area range from 13.1 – 169.0 mg/kg (URS Corporation 2003). A map of the project area and copper sampling points (URS Corporation 2003) is provided in Appendix F. Approximately 9 percent of the sample concentrations within the project area exceed the interim Effects Level of 85 mg/kg agreed upon by the USFWS and SFWMD until a study to evaluate that value for the snail kite is completed. Therefore, some portions of the project area contain copper concentrations that are high enough to potentially bio-accumulate in apple snails.

At this time, the USFWS is still evaluating the bioaccumulation of copper in the food chain for snail kites. Therefore, based on the pending evaluation, the above information, and the presence of substantial additional foraging areas in close proximity to the project footprint, this project may adversely affect the snail kite.

3.1.3.4 Wood Stork

The wood stork is listed as endangered by both the USFWS and the FWC. This wading bird is opportunistic, utilizing various open hydric pine-cypress habitats and man-made wetlands (i.e., ditches, canals, stormwater ponds, and seasonally flooded roadside areas). The species feeds almost exclusively on small fish between 1 and 8 inches in length. Ideal feeding conditions are in shallow wetland areas where fish are concentrated in pockets. Sudden water level increases are detrimental to the species because it is difficult for them to capture their prey in deep water. Nesting seasons vary annually and geographically because they are dependent upon water levels. The nesting season in south Florida is typically from November to June, starting when water levels decline, and ending when water levels rise.

The closest documented wood stork nesting colony (619141) is present 16.6 miles to the south of the project. The wood stork SLOPES published by the USFWS identifies an 18.6-mile foraging range, or core foraging area (CFA), surrounding each wood stork nest colony. This radius is an average given that the species forages from 5 to 40 miles away from the nest colony during breeding/nesting season. Approximately 2,728 acres or 26 percent of the project footprint (27 percent excluding the previously-permitted test cell) falls within the CFA of this rookery. Figure D-6 of the Florida Panther Cumulative Impact Analysis package (Appendix D) depicts wood stork rookery and CFA locations in south Florida. An additional wood stork nesting colony (619041) to the project footprint is located in Lee County, approximately 17 miles west of the project. Approximately 2,412 acres or 23 percent of the C-43 project area falls inside the CFA of this rookery (Figure 4). This does not include the 267 acres of the previously permitted test cell project that also was contained within the CFA of colony 619041; therefore, 1 percent has already been permitted.

Potential foraging areas within the project area for the wood stork may include the citrus grove ditches and excavated waters, but these systems, due to typical agricultural water management practices, do not concentrate prey species necessary for the stork's tactile feeding behavior. Within the C-43 project, several wood storks were observed flying overhead, several were seen 'loafing' near a citrus grove maintenance road, and one individual was noted opportunistically feeding on small animals/fish trapped in piles of

common water hyacinth (*Eichhornia crassipes*) and water-lettuce (*Pistia stratiotes*) cast-aside during mechanical ditch maintenance (Figure 4). Wood storks are also highly mobile and the surrounding land use currently provides ample foraging opportunity.

A total of 499.9 acres of waters of the United States in the C-43 project area fall within wood stork CFAs; heavily vegetated shrub and forested wetlands, open-water borrow areas, and primary, secondary, and tertiary drainage ditches, would be impacted primarily by flooding activities. The majority of these waters do not provide reasonable foraging opportunity because the primary and secondary drainage ditches as well as excavated ponds are steep-sided, hold deep water, and are dominated by floating-leaved plants which interfere with the wood stork's ability to capture prey. The palustrine shrub and forested systems also provide poor feeding habitat as they contain dense ground and/or shrub vegetation, and only a small number of the systems have any emergent marsh component at all.

The tertiary drainage ditches have shallow slopes, reasonably shallow water (up to 3 feet) and contain emergent, submergent and floating-leaved vegetation. While the foraging quality of these ditches in actively maintained citrus grove is low (chemical run-off, altered hydrology), wood storks may forage on small fish, invertebrates, and amphibians that may occur in these ditches. Therefore, a total loss of 274.1 acres of wood stork foraging habitat would occur as a result of the project (tertiary ditches only). This does not include the loss of 17.2 acres of tertiary ditches that was previously permitted for the test cell project.

The loss of wood stork foraging habitat will be mitigated in kind by the proposed C-43 West Reservoir Project and by other Acceler8 projects. The shallow-sloped littoral zones along portion of the C-43 project will provide approximately half of the compensation for the loss of wood stork habitat. At this time, an estimated 40 acres of littoral zone will be created. Of these 40 acres, 9.5 acres is designated for compensation of the test cell project wood stork foraging habitat impacts (17.2 acres of tertiary ditches). During the permitting process for the test cell project, WRAP was utilized to assess the functional wetland loss from the tertiary ditches and the functional wetland credit from the littoral zones. The remaining 30.5 acres of littoral zone will be applied to offset impacts to wood stork foraging habitat resulting from the C-43 project.

Narrow, elongated littoral zones along the perimeter canal are intended to vary in water depth, ranging from 0 to 48 inches of water. These may become deeper or dry depending on the seasons and operational plan for the perimeter canal structures. The

design for littoral zones will anticipate a wide variety of changes in water depth so as to benefit fish and wildlife, including the wood stork. The wood stork forages most successfully in sites where water is 2-15 inches in depth, the water is relatively calm, and dense thickets of aquatic vegetation are absent. Therefore, the littoral zones of the C-43 WSR project will likely provide suitable foraging habitat for the wood stork.

In addition, it is anticipated that the C-43 WSR project will provide wood stork foraging habitat within the reservoir cells during times of drawdown. A dropping water level is beneficial to concentrate fish at suitable densities. In sites where water rises, especially quickly, fish disperse and the site is less suitable for the species. Fluctuations in water levels are anticipated to occur regularly in the reservoir cells; typical fluctuations of 5-10 feet will occur every few months according to modeling data. The largest noted fluctuations in the model are a 17-foot and 20-foot change in a period of 3 months for Cells 1 and 2, respectively. Constant water levels are anticipated to be rare; the 8-year water level model noted only one constant water level for approximately 4 months in one of the reservoir cells. During times of dry cells, deep water refugia within the cells will continue to provide foraging habitat for the wood stork.

Current USFWS Habitat Management Guidelines for the Wood Stork in the Southeast Region (1990) recommend restrictions to activities that would alter water elevations or wetland acreage within the colony location, primary zone (500 to 1,500-foot radius) or secondary zone (2,500-foot radius) in nesting and non-nesting season cycles. Because the project area is located far from wood stork colonies, the project or reservoir operations will not likely affect hydrology in the primary and secondary zones; modeling is still underway to assess hydrological affects. The proposed project will comply with USFWS standard guidelines for the wood stork which are provided in Appendix G. Since there is substantial additional foraging and nesting areas in close proximity to the proposed impacts, and the wetland impacts will be appropriately addressed, this project may affect, but is not likely to adversely affect the wood stork.

3.1.3.5 Florida Scrub Jay

The Florida scrub jay is listed as threatened by both the USFWS and the FWC due to loss of its preferred habitat. Optimal scrub jay habitat consists of low growing, scattered scrub canopy species with patches of bare sandy soil such as those found in sand pine scrub, xeric oak scrub, scrubby flatwoods, and scrubby coastal strand habitats. In areas where these types of habitats are unavailable, Florida scrub jays may be found in

less optimal habitats such as pine flatwoods with scattered oaks. Scrub jays live in family groups and defend territories that typically average 23 acres in size.

No individuals, nests, or appropriate habitat were detected in the project footprint. The nearest documented Florida scrub jay habitat and population occurs 1.1 miles west of the project area. This colony is beyond the foraging distance for the species to access the project area and is well outside the SLOPES protection zone. While the project falls within the Florida scrub jay USFWS CA, based on the above information, the project is anticipated to have no effect on the Florida scrub jay.

3.1.3.6 Florida Grasshopper Sparrow

The Florida grasshopper sparrow is a small, short-tailed bird listed as endangered by both the USFWS and FWC, due to habitat degradation and loss. The species is not known to occur in Hendry County but populations may occur in nearby Glades County (USFWS 4-11-02 PAL). The nearest Florida grasshopper sparrow record in the 1999 FNAI database is a 1984 observation located 17.3 miles north of the project. Mapping of potential Florida grasshopper sparrow habitat (Shriver and Vickery, 1999) shows marginal habitat zones to the northeast and southeast of the project, and the project area falls within the Florida grasshopper sparrow USFWS CA. However, the nearest marginal habitat zone is located approximately 2.5 miles to the southeast of the project footprint. No grasshopper sparrows were observed during field surveys and no suitable habitat exists in the project area. Based on the above information, this project is anticipated to have no effect on the Florida grasshopper sparrow.

3.1.3.7 Red-Cocaded Woodpecker

The RCW is currently listed as endangered by the USFWS and as a species of special concern by the FWC. The RCW is a small woodpecker that once was common throughout the southeast US, but is now more limited due to extensive logging and destruction of older pine forests. Preferred habitat for the RCW consists of open stands of older pine or pine-hardwood (50 percent or more pine) that are 30 years or older (Henry, 1989). RCW populations typically require a minimum of 5-10 acres of habitat for a tree cavity aggregate (cluster). No suitable RCW habitat exists on-site or near the project. The nearest documented RCW population occurs approximately 14 miles northwest of the project area (FWC data). Based on lack of suitable habitat within the project area, the project will have no effect on the RCW.

3.1.3.8 Piping Plover

The piping plover is listed as threatened by both the USFWS and the FWC. The USFWS established critical habitat areas for the species, which include several locations on barrier islands west of the Caloosahatchee Estuary. The nearest piping plover critical habitat zone to the project area includes Punta Rassa, a mainland location at the southwestern edge of the Caloosahatchee Estuary, and Bunch Beach. The species may benefit from indirect project impacts which include salinity regime improvements to the downstream Caloosahatchee Estuary. The project may affect, but is not likely to adversely affect, and may actually benefit the piping plover.

3.1.3.9 Colonial Nesters and Other Birds

The Migratory Bird Treaty Act (MBTA) governs the taking, killing, possession, transportation, and importation of migratory birds, their eggs, parts and nests. Nests and rookeries are protected during the nesting season from construction activities that would otherwise destroy them, but can be taken during non-nesting seasons when they are not utilized by the species.

Wading birds, some of which are state listed as species of special concern, were commonly observed in the project area but no rookeries were identified during field surveys. The nearest, documented active wading bird rookery is located approximately 1 mile south of the project (#619317). Observations at this rookery were last recorded in 1989 and included the little blue heron (*Egretta caerulea*), great egret (*Casmerodius albus*), and anhinga (*Anhinga anhinga*). The project is not anticipated to have adverse effects on wading bird rookeries.

Nests of the state listed, threatened least tern (*Sterna antillarum*) are similarly protected under the MBTA. No least terns were observed during field surveys and no data records exist for the species near the project. Because terns select open, sandy areas for nesting, construction sites have been known to cause temporal effects to the species by attracting terns to nest. Trained dogs have been successfully utilized in construction projects to prohibit birds from nesting in the open areas. This tactic can be further investigated if necessary. The project is not anticipated to have adverse effects on least tern nests.

The Florida sandhill crane is a large wading bird listed as threatened by the FWC, but remains unlisted by USFWS. The species typically constructs nests on a platform of vegetation surrounded by water within an herbaceous wetland. Extremely marginal

nesting and foraging habitat is present within the project. No documented Florida sandhill crane nests exist within the project study area and no individuals were observed in flight over or foraging within the project area. However, large-scale construction projects in Florida have been known to have temporal effects on sandhill cranes by attracting them to nest in work areas of the site. If sandhill cranes stay and build nests in standing water areas of construction sites, the following protection guidelines will be employed to avoid nest disturbance:

- Nest protection should include measures to prevent disturbance of incubating adults by providing spatial and/or visual separation between nests and construction activities. FWC biologists have recommended a 400-foot buffer around nests. If construction activities are required closer than 400 feet from a nest, monitoring should be provided to ensure the activity does not result in nest abandonment or disturbance of incubating adults;
- During incubation, adults may be expected to be continuously present at the nest. If adults are not present at an active nest for two consecutive 15-minute periods or are exhibiting agitated behavior or vocalization, surrounding activities should be evaluated to identify and correct the cause of incubation disruption;
- Artificial alteration of water levels in wetlands supporting active nests may contribute to nest failure and must be avoided. Dewatering of a nest wetland may increase the risk of the nest to predation. Adding water to a nest wetland may drown eggs. Any activity that would alter a nest wetland's hydrology should not be undertaken while an active nest is present and should be delayed as long after hatching as possible if the wetland is used for night roosting;
- Silt fences may be used to create barriers to prevent adults and chicks from entering work areas, haul roads, or drainage ditches. Where adults and chicks are present within work areas, openings in silt fences will allow dispersal to alternative foraging or roosting habitats; and
- Posting of sandhill crane warning signs within work areas and along haul routes near foraging or nesting habitats and education of construction staff will help to minimize risk to sandhill cranes.

Given the above information, and since there is substantial additional foraging and nesting areas in close proximity to the proposed impacts, and the wetland impacts will be off-set appropriately, the project is not anticipated to have adverse effects on Florida sandhill crane nests.

Field surveys did identify two red-shouldered hawk nests (*Buteo lineatus*) in the eastern portion of the project. This hawk is the most common hawk species in Florida and typically nests in large, mature trees. The species breeds from January through May or June, incubates eggs for approximately 33 days, and fledges at 40 to 45 days of age. Construction activity will not disrupt active nests during the nesting season (approximately January through July). The project is not anticipated to have adverse effects on the red-shouldered hawk nests observed in the project area.

3.1.4 Mammals

3.1.4.1 West Indian Manatee

The manatee is listed by both the USFWS and FWC as endangered. The species occurs in all south Florida coastal waters and is known to utilize the Caloosahatchee River as a winter aggregation area. Manatees have been known to utilize the Townsend Canal, which lies adjacent to the western side of the project footprint. During times of inflow from the Caloosahatchee River, manatees are currently capable of passing over the weir or through a flap gate and traveling southward into the Townsend Canal at the Berry Groves main pump station. Manatees have been observed in the Townsend Canal and at the outfall to the Caloosahatchee River.

The following provides specific information on structure designs as they relate to manatees.

Confluence of the Townsend Canal and the Caloosahatchee River

The existing weir structure located in this area has an elevation of 2.74. It provides 10 'windows' with flap gates on the upstream side, each 6' by 6', through which manatees can pass during inflow conditions, when the flaps open inward simply due to the inflow condition resulting from pumping. In the existing condition, it is then possible for manatees to become trapped in the Townsend Canal when pumping is ceased, the condition becomes an outflow condition, and the flaps close. In this area, the weir elevation is 2.74, normal water level (NWL) in the canal is approximately 3, and the canal bottom ranges from -6 to -10.

It is not known at this time if this weir structure will need to be replaced. If it does, provisions to prevent manatee entrapment will be examined. It the existing structure can be used in the future condition the system will be modeled to show the effects of removing one of the flaps permanently. At this time, this action would not have a negative affect on reservoir operations.

Intake Locations of Pump Stations - C43-PS-1 and C43-PS-4

At the main pump station, C43-PS-1, there will be an inlet channel with a separate vehicular bridge upstream and away from the pump station. This bridge supports the trash rake and the vehicles needed to clean trash collected along the rake. The trash rake system (screen) consists of vertical bars spaced approximately 6-8 inches apart; the system extends from above the water surface to the bottom. Due to the positioning of this trash rake, manatees will not be able to approach the intake pipes. Various trash collection systems have been designed to clean the trash rake, and a system will be selected to minimize the potential for harm to manatees (refer to plan sheet 83 for the location of the vehicular bridge and trash rake system). Note that there is potential for the separate vehicular bridge to be eliminated. If that happens, the trash rake system will be attached to the service bridge at the pump station. Regardless of the location of the trash rake system, the screen will be included.

At the smaller pump station, C43-PS-4, the suction end of the intake pipe(s) will be screened with a trash rake-type screen. This same screen will prevent manatees from entering the intake pipe (refer to plan sheet 86 and the pump station sections on sheets 169, 170, and 239).

Main outfall structure – C43-S-11

Due to the vertical difference between the NWL of 3 feet in the Townsend Canal and the NWL of 15 feet in the perimeter canal on the upstream side of C43-S-11, along with the lowest weir elevation at the bottom of the roller gate at 10.5, it will not be possible for manatees to enter the perimeter canal through the C43-S-11 structure (refer to plan sheets 85 and 191).

Structures C43-S-7 and C43-S-9 (Banana Branch and Fort Simmons Branch, respectively):

These structures are gated, double box culverts. Flows in one of the box culverts are controlled by a slide gate. Except under extreme high flow conditions, these slides gate will remain closed. The upstream NWL in the perimeter canal and the flows in the other box culvert will be controlled by a weir gate. Each weir gate is supported by a "knee wall" at the upstream end of the box culvert (refer to section M on sheet 209). The "knee wall" is 5-foot and 3-foot high in structures C43-S-7 and C43-S-9, respectively. In order for the manatees to reach the perimeter canal through these structures, they would need to overcome the 3 or 5-foot vertical walls.

Structures C43-S-14 and C43-S-15:

These structures take water from the Header Canal and Roberts Canal, respectively, into the perimeter canal for routing around the project (Plan Sheets 115 and 118). Since manatees are not known to occur in the Header or Roberts Canals, these structures should not be a concern.

The management of the reservoir will include regulated water releases into the Caloosahatchee River and ultimately, to the Caloosahatchee Estuary. The estuarine environment is sensitive to freshwater releases and disruptions of the volume, distribution and temporal patterns of freshwater discharge. In addition, increased nutrient levels, particularly nitrogen and phosphorus, reduce light penetration and restrict growth of submerged aquatic vegetation (SAV) such as seagrass (Barnes, 2003). Beneficial effects to the estuary water quality from the project are anticipated via salinity regime improvements; nutrient level improvements are possible, but not known. Freshwater, estuarine, marine, and coastal species that utilize the Caloosahatchee Estuary are therefore likely to experience improved habitats. One example of an anticipated estuary improvement is the re-establishment of a Valued Ecosystem Component (VEC) species, tape grass (*Vallisneria americana*). This species has been experiencing die-offs with the increased salinity and nutrient levels in the Caloosahatchee Estuary. Tape grass beds are utilized by a variety of freshwater and estuarine invertebrates and vertebrates including recreational fishes and the Florida manatee.

Protection measures for the manatee will be implemented during any construction in water and will follow the guidelines set forth in the USFWS 2005 Standard Manatee Conditions for In-Water Work. Conditions include education of construction personnel, posting of temporary notification signs, operation of vessels at "idle speed/no wake", use of siltation or turbidity barriers, and maintenance of a 50-foot barrier between construction activity and manatees. Secondly, project culverts will be designed in compliance with the Manatee Protocols for Existing and New Culverts Located in Manatee-Accessible CERP Projects. New culverts less than 36 inches in diameter will require grating to preclude manatee passage, and culverts are not advised to exceed 200 feet in diameter. Manatee guidelines are provided in Appendix H.

Based on the project design to preclude manatees from the reservoir, potential water improvements to the Caloosahatchee River and Estuary, and compliance with the standard manatee protection guidelines, the project may affect, but is not likely to adversely affect the manatee.

3.1.4.2 Florida Panther

The study area is located within the designated Florida panther USFWS CA per the USFWS SLOPES (USFWS, 2000) and as depicted in the USFWS' Draft CERP Landscape Level Project Planning/Siting Map for Panther Consultation dated February 18, 2004 (included in attachments; also see Figure D-7 of Appendix D). The CA boundary roughly extends from I-75 in Lee County east to US 27 in Palm Beach County, north to the southern boundaries of DeSoto and Highlands Counties, and south to the mangrove edge of the Everglades in Monroe and Dade Counties.

The Florida panther is listed by both the USFWS and the FWC as endangered. This species inhabits a variety of forested land cover types, including pine flatwoods, cabbage palm and live oak hammocks, and cypress wetlands. Although not preferred habitat types, the Florida panther will also utilize freshwater marshes and willow swamps as well as agricultural and disturbed lands.

The current verifiable Florida panther population, not including kittens, is estimated at 87 individuals in southern Florida (Land et al. 2003). In terms of population size and occupied range, the Florida panther population is at least stable and at best expanding as evidenced by natality rates exceeding mortality rates and by recent dispersals north of the Caloosahatchee River (Land et. al. 2000). From 1999 to 2000, the number of births in the radio-collared population has exceeded the number of deaths by a factor of three, and the primary cause of Florida panther mortality from 1979 to 2003 was intra-specific aggression (Land et al. 2003). There has been a misconception that vehicular trauma causes most Florida panther mortalities, but this is the result of sampling bias because un-collared panther mortalities are only found if caused by humans (Land et al. 2000).

Male and female panther home range size is inversely related to habitat quality; the greater the extent of agricultural land and wetland habitats the larger the home range, and the greater the extent of mixed hardwood forests and dry pine forests the smaller the home range. High-quality habitat produces abundant prey and promotes female panther reproductive success (Maehr 1992b, Maehr et al. 1989).

The following sections provide information on habitat utilization and impacts related to the C-43 project. Additional information is provided in graphical and tabular format in Appendix D (Florida Panther Cumulative Impact Analysis package).

Florida Panther Habitat Use in the Project Vicinity

The most recent available FWC telemetry data of radio collared Florida panthers current through 2006 depict 4 Florida panthers and 1 Texas cougar (*Felis concolor*) within a five-mile radius of the project area (refer to Figure 6 of this Biological Assessment and Figure D-8 and Table D-3 of Appendix D). These were Florida panther numbers 28, 65, and 74, 137, and Texas cougar TX101.

Telemetry data for these animals had been recorded over a period of 16 years with the oldest record from Florida panther No. 28 on May 8, 1989 and the most recent from Florida panther number 137 on March 7, 2005. The following is a brief history of each of the above listed panthers:

Florida panther number 28 was a juvenile male that was struck and injured by a vehicle on Daniels Road near the Southwest Florida International Airport on November 29, 1988. The animal was rehabilitated, instrumented with a radio-collar, and released in the Corkscrew Swamp Sanctuary on March 15, 1989 (Figure D-12 of Appendix D). He then moved north to the Caloosahatchee River, east along the river, and then southeast in a counterclockwise direction around the project area where he established a home range in the primary zone. Panther number 28 was later killed in a territorial dispute with another adult male on approximately September 24, 1992.

Florida panther number 65 is a juvenile male offspring of Texas cougar number 101. A large amount of telemetry data points exist for this individual. In 1999, Florida panther number 65 traveled north from the Big Cypress Seminole Indian Reservation, through the primary zone to the southeast of the project area to the Caloosahatchee River. It is unclear from telemetry data if the panther traveled through or around the project area to reach the river; telemetry points only exist at the edges of the project area. After spending approximately one month moving east and west along the south side of the Caloosahatchee River, he returned to the primary zone and dispersal zone to the southeast of the project area and moved northward across the Caloosahatchee River. The individual moved northward along US 27 in the area of Fisheating Creek, Palmdale, and beyond. The panther later traveled southward through the dispersal zone to the Big Cypress Seminole Indian Reservation where he established a territory.

Florida panther number 74 was a juvenile male that dispersed from the Big Cypress Seminole Indian Reservation. A good history of tracking data exists for this panther before its death in 1999. The following is a summary of Florida panther number 74's dispersal pattern as described in Land et al. (1999):

> "Male panther number 74, radio collared on 12 November 1998, began his dispersal event from the Big Cypress Seminole Indian Reservation in early February 1999. This young male moved northwest from the Big Cypress Seminole Indian Reservation and crossed the L-28 interceptor and feeder canals. He then moved north of CR 846 and traveled through Okaloacoochee Slough (Figure D-12 of Appendix D). In late February, he was south of SR 80 approximately 3 miles east of Goodno. During March, number 74 made multiple trips across SR 29 traveling between areas north of Okaloacoochee Slough to the Hickey Creek area southwest of Alva in Lee County. On the weekend of 8-9 May 1999, number 74 became the second radiocollared panther documented crossing the Caloosahatchee River near Goodno on 7 May 1999. On 10 May 1999, number 74 was found 11 miles north along Fisheating Creek west of Palmdale."

During this panther's travels, he moved through the primary zone to the southeast of the project area to the Caloosahatchee River. Similar to Florida panther #65, it is unclear from telemetry data if this panther traveled through or around the project area to reach the river; telemetry points only exist at the edges of the project area. He did not cross the Caloosahatchee River at this location. He instead backtracked southeast to the primary zone and utilized the dispersal zone to cross the river. Florida panther number 74 then died from vehicular trauma on US 27 north of Palmdale on September 8, 1999.

Florida panther number 137 has established a home range within the Okaloacoochee Slough State Forest and WMA, and the adjoining Spirit of the Wild WMA (Figure D-12 of Appendix D). This area is located southeast of the C-43 project area and is in Florida panther primary zone habitat. Telemetry data for this individual are recent, from 2005 to June 2006.

Texas cougar number 101 utilized the Big Cypress area and was documented as dead in March of 2000 from unknown causes (Land et al., 2000). Earlier 1995 telemetry data for this panther shows that he utilized habitat within the secondary, primary and dispersal zones to the east of the project area and south of the Caloosahatchee River.

In addition to the above described telemetry data near the project, Figure D-10 and Table D-4 of Appendix D present mortality and injury data for panthers within 25 miles of the C-43 project. Home ranges of panthers near the project area are depicted in Figure D-11 and described in Table D-5 of Appendix D. Note that home ranges are determined by statistical methods using telemetry data, but are not a direct reflection of telemetry data. Therefore, not all panthers with telemetry points near the C-43 project

are displayed as having a home range that includes the project site. For example, if a panther was noted to travel near the project site but did not have multiple data points in the vicinity, the home range for that individual would likely not include the project area. However, if a panther was not noted to occur very close to the project, but was observed to strongly utilize a region adjacent to the project, the home range for that individual would likely include the project area based on the potential for that animal to utilize habitats within a significant distance of its established home range.

Florida Panther Habitat Use at a Landscape Level

Examination of the project area at a landscape level depicts it at the northern periphery of the geographic range of the panther's breeding population in south Florida, as well as the northern limit of the majority of Florida panther Multi-Species/Ecosystem Recovery Implementation Team (MERIT) zones and telemetry data points (Figure 7 of this Biological Assessment and Figure D-9 and Table D-2 of Appendix D). A large area to the southeast of the project that falls within Florida panther primary and secondary habitat zones and within several preserve areas (Okaloacoochee Slough and Save Our Everglades CARL Project Macrosites, Big Cypress Indian Reservation) provides good habitat support for panthers (Figure D-12 and Table D-6 of Appendix D). Adjacent on the north side of this large expanse, and eastward of the project, lays a panther dispersal zone (Caloosahatchee Ecoscape CARL Project Macrosite). Telemetry data suggest that this zone may provide the most appropriate location for panthers to cross the Caloosahatchee River. Panthers utilizing the dispersal zone to cross the Caloosahatchee River include numbers 65 and 74, as previously detailed; and likely panther number 62, although telemetry points do not positively confirm this (Figure 6).

The project area does not appear to be in a high traffic zone for the panther. No panther-preferred habitat exists on-site. Radio telemetry data collected in 1998-1999 from collared Florida panthers indicate their occurrence near and on the edges of the project area. Panthers have not been documented directly in the project site, nor have they been documented with much frequency in the secondary habitat to the south. The project area therefore does not appear to play a role in panther movement along the south side of or across the Caloosahatchee River. It is unknown if panther utilization of the project area is limited simply because it lies outside the species desired travel route or because the project area is undesirable to the panther in terms of habitat (citrus grove) or accessibility (large canals surround the area).

Proposed Florida Panther Habitat Impacts

The USFWS has developed two plans, with maps, that identify important panther habitat areas in south Florida. The first is the Florida Panther Habitat Preservation Plan (FPHPP) (Logan et al., 1993), and the second is the Multi-Species Recovery Plan for South Florida (USFWS, 1999). The Multi-Species Recovery Plan was updated on September 6, 2001 by the Florida panther subteam of the MERIT. The FPHPP showed no Priority 1 or Priority 2 type habitats within the project area. Priority 1 type habitat is identified approximately 4.8 miles southeast of the project footprint. The more recent MERIT subteam map, however, identifies 1.4 percent (144.2 acres) of the C-43 project site as occurring within Florida panther primary habitat zone, 51.1 percent (5,290.6 acres) in secondary habitat zone, and 47.5 percent (4,925.2 acres) in "other" habitat zone (Figure 6). Of these impacts, 54 acres in the secondary zone and 213 acres in the "other" zone are part of the C-43 test cell project. Impacts associated with the test cell project totaled 388 PHUs (971 PHUs using the base multiplier of 2.5) as calculated by the USFWS and presented in their November 30, 2005 Biological Opinion for the C-43 Test Cell Project.

As one of the SFWMD CERP Projects on the Band 1 list of the Master Implementation Sequencing Plan (MISP), C-43 WSR impacts to the Florida panther were estimated by the USFWS as 21,825 PHUs, as referenced in the November 30, 2005 Test Cell Biological Opinion. Since this estimate, the project footprint has been slightly modified and land cover types and exotic species coverage have been further refined. Table 4 provides anticipated PHU impacts for the C-43 project. Using the panther habitat unit analysis example in the USACE July 28, 2006 Picayune Strand Road Removal concurrence letter, as well as the complete table of habitat suitability values provided in the USFWS November 30, 2005 Test Cell Biological Opinion, panther impacts are currently estimated at 20,719 PHUs. Like the USFWS 2005 estimate of panther habitat impacts, a base multiplier has not been applied to this estimate of 20,719 PHUs.

Prey Base

The ecological benefits currently provided by the proposed project may be related to availability of prey species, rather than habitat. Feral hog (*Sus scrofa*), white-tailed deer (*Odocoileus virginianus*), raccoon (*Procyon lotor*), nine-banded armadillo (*Dasypus novemcinctus*), and cottontail rabbit (*Sylvilagus floridanus*) are all common species in citrus groves and serve as a food source for the panther. In a study of panther diet, deer and hogs accounted for 85.7 percent of consumed biomass of panthers north of I-

75, with hogs dominating the diet in terms of estimated biomass and numbers (Maehr et al. 1990a). Deer and hog densities often exceed 1 animal per 20 hectares north of I-75. South of I-75, deer and hog densities rarely exceed 1 per 40 hectares. Panthers struggle when only deer are present and their density is below 1 per 40 hectares. As a result, panther density, average body weight, and reproduction success south of I-75 is lower than north of the interstate.

Interestingly, no recreational infrastructure currently exists in the project area. Recreational hunting is not allowed, which is perhaps unusual for a Florida citrus grove. Many groves throughout the state experience significant fruit and tree loss from deer and hogs and therefore encourage recreational hunting. It is therefore reasonable to conclude that if deer and hogs are not a significant problem on-site, populations of these species are relatively small as compared to other groves. However, field surveys in the C-43 project area have noted increasing numbers of observations of hogs from 2004 to 2006.

Field surveys for Florida panther prey items in the C-43 WSR project site as per SFWMD direction and USFWS requirements was conducted September-October 2006. The purpose of these surveys was to estimate the population size of white-tailed deer and feral hog in the project area, as these two species are primary prey items of the Florida panther. The following paragraphs summarize the survey findings and the complete report is provided in Appendix I.

Results from track counts indicated that the C-43 WSR site supports an early fall population of 3.9 deer or 9.6 deer depending on the statistical formula utilized. This corresponds to a density of 0.24 deer/mi^2 and 0.59 deer/mi^2, respectively. Similarly, the site supports an early fall population of 168.4 hog or 194.3 hog depending on the statistical formula utilized. This corresponds to a density of 10.4 hog//mi^2 and 12.0 hog//mi^2, respectively.

The estimates for a white-tailed deer population may seem low given the size of the C-43 WSR project, but considering the time of year of the survey and lack of preferred food sources in the grove, few sightings of deer by project biologists over the past two years of working on the site, and anecdotal evidence from the grove manager, it seems reasonable. In addition, a review of the scientific literature on white-tailed deer population densities in Florida identified many estimates, some of which approximated the population estimate on the C-43 WSR project.

It is important to keep in mind that our population density estimates for the white-tailed deer in the C-43 project are based on several assumptions. The first assumption is that deer do not utilize habitat equally throughout the year and seasonality affects their movement. The second assumption is that tracks are readily interpreted on transects, made possible by rain events prior to survey mornings that smooth the sand. Similarly, there are assumptions for the feral hog population density estimates that include hog daily average range, seasonality of population density, and rain prior to survey events.

The post-development condition will likely be attractive to aquatic and aquatic-dependent species, including invertebrates, fish, amphibians, and birds but may be less attractive to mammalian species, particularly during times of highwater storage. As a result, the typical prey base for the Florida panther, namely hogs and deer, may be less likely to utilize the project area in its post-construction condition (reservoir) than in its current condition (grove). These species typically prefer a mix of forested areas such as pine flatwoods and open, freshwater wetlands. There will be times in which water levels in the project area would be on the decline, or soils will only be saturated; during these times, hogs and deer would likely forage. Panthers and other predators, in turn, would be successful in locating prey. However, during times of high water storage, hogs and deer as well as other mammals may utilize other habitats for foraging, thereby decreasing the prey base available to panthers in the reservoir. It is difficult to assess how much, if any, prey base decline would result from the post-development condition, given the unknown habitat utilization of the post-condition. It is, however, anticipated that the prey base will fluctuate on a yearly basis with the rainy and dry seasons as well as on a larger time scale with wet and dry years.

Panther Accessibility

In the post-development condition, the project area may be more traversable by the panther. The high anthropogenic activity associated with grove operations will be eliminated including human presence, vehicle traffic and insecticide spraying. The absence of these disturbances to the Florida panther will provide a quieter and more attractive landscape for them to travel. Panthers would be able to cross the reservoir cells via embankments, dry wetland edges, and maintenance roads. Terrestrial access across the C-43 perimeter canal will be possible at 3 canal structure locations including S-10 and S-11 at the north and S-3 in the southeast corner.

The amount of construction traffic on adjacent roadways is not expected to create a dramatic increase from current volumes. A primary reason for this is the fact that fill-dirt

will not be hauled to the site. Onsite materials will be used to create the embankments for the reservoir cells and perimeter canal. Following construction, the reservoir pumps will be operated remotely. Occasional, scheduled maintenance work will be required but will not have any noticeable impact on traffic.

During construction, temporal effects to panther movement and foraging are possible. Approximately 200-300 construction personnel will be employed for approximately 3.5 years. Construction noise, ground vibrations, and truck and equipment presence may alter travel patterns of the species, particularly in area located to the southeast of the site, where panther habitat and activity is more prevalent. The project construction will have greater potential for disturbing wildlife than existing grove operations activity. However, there will be no long-term effects as construction disturbance will terminate with the completion of the reservoir and maintenance activities will be minimal.

Currently, no designated recreational areas or infrastructure are present within the project area as it is solely used as citrus grove operations. While the C-43 WSR is a civil works project, there is potential for incorporating recreational features into the project. Potential recreational opportunities include wildlife viewing, birding, hiking, biking, equestrian activities, fishing, and picnicking. Canoeing and other non-motorized boating is also under consideration. Recreational hunting of deer and hogs is not planned for the project area. Because grove operations activities have been in place for many years, none of these potential recreational features are anticipated to create a change in the anthropogenic effects of the project area.

Development Within 25 Miles of the Project

Pending development near the project is centered in Lee County, where Planned Unit Developments (PUD), Developments of Regional Impact (DRI), and Environmental Resource Permits (ERP) are most prevalent between SR 82 and SR 80, east of I-75. This region falls within the Florida panther CA. Development in Hendry, Glades, Charlotte, and northern Collier Counties is limited. Figure D-13 through D-18 and Tables D-7 through D-10 in Appendix D present development information. Future road projects are limited to southeastern Lee and northwestern Collier Counties (Figure D-19 of Appendix D).

Because of the nature of this project, additional land use changes are not anticipated. However, residential and commercial development may continue to spread eastward from Lee County into Hendry County. At this time, the total acreage of upland parcels

within a 25-mile radius of the project area is 866,093.80 acres (Figure D-13 of Appendix D). This quantity of land could be developed without USACE permit involvement.

Florida Panther Effect Determination

According to the Draft Florida Panther Effect Determination Key, dated July 1, 2003, the USACE initially determined that the C-43 WSR project may affect the Florida panther. With this determination, the USFWS was requested to initiate Section 7 Consultation. Following this consultation, the project may adversely affect the Florida panther.

The USFWS determined that SFWMD offsite acquisition and restoration of approximately 101,066 acres of habitat in primary and "other" zones for Band 1/Acceler8 projects will compensate for the loss of panther habitat in the C-43 project. The SFWMD land is located in the core area of panther-occupied habitat, the majority is adjacent to other larger tracts of natural and preserve lands, and will assist in the long-term protection of the species.

Due to the appropriate offsite land acquisition, paucity of suitable land cover types in the project area, small acreage of primary habitat zone in the project area, conversion of citrus to reservoir (not development, per se) and documented historical use by the panther on the project edges only, the project will not likely jeopardize the survival and recovery of the Florida panther. However, the USACE has made the determination that this project may adversely affect the Florida panther under Section 7 of the Endangered Species Act.

Additional panther-related information is located in Appendix D.

3.1.5 Plants

3.1.5.1 Florida Panther

The Okeechobee gourd is a federal endangered species, as listed by the Federal Register, July 12, 1993 Clarification, Federal Register, April 1, 1994. It is also a state endangered species, as listed by the Florida Department of Agriculture and Consumer Services' Chapter 5B-40, Florida Administrative Code. This species is a fibrous-rooted, high-climbing vine with tendrils. Historically, the Okeechobee gourd was associated with Tory muck soils and found in pond apple forests surrounding Lake Okeechobee. Presently, the Okeechobee gourd can be found in Palm Beach and Glades Counties inside the levee that encircles Lake Okeechobee, rarely along canal banks south of the lake, and on the St. John's River in Volusia County. The gourd is now linked with

natural or man-made disturbance and has been associated with alligator nests and thickets of elderberry and willow. No Okeechobee gourds or appropriate habitat were observed during field reconnaissance. Given the above information, the project will have no effect on the Okeechobee gourd.

3.1.5.2 Beautiful Pawpaw

The beautiful pawpaw is a federal endangered species, as listed by the Federal Register, September 26, 1986 Clarification, Federal Register, May 18, 1999. It is also a state endangered species, as listed by the Florida Department of Agriculture and Consumer Services' Chapter 5B-40, Florida Administrative Code. The species is a low-growing, diminutive shrub that occurs in the vicinity of Charlotte Harbor and the Caloosahatchee River from Punta Gorda to Fort Myers in southwestern Florida. The beautiful pawpaw is native to longleaf pine (*Pinus palustris*) and slash pine (*P. elliotii*) flatwoods consisting of grasses and low shrub species. No appropriate habitat or beautiful pawpaw plants were observed during field reviews. Given the above information, the project will have no effect on the beautiful pawpaw.

3.2 PROTECTED SPECIES WITH STATE DESIGNATION ONLY

The following is a summary of several state listed species with a potential to occur onsite. While the federal action agency (USACE) does not comment on these species, they were considered during field reviews, and, as in the case of the gopher tortoise, were identified as requiring particular surveys by the FWC. These species include the gopher tortoise (*Gopherus polyphemus*), gopher frog (Rana capito), Florida burrowing owl (*Speotyto cunicularia floridana*), sandhill crane (*Grus canadensis pratensis*), southeastern American kestrel (*Falco sparverius paulus*), peregrine falcon (*Falco perigrinus*), least tern, other wading birds such as the limpkin (*Aramus guarana*), white ibis (*Eudocimus albus*), little blue heron, snowy egret (*Egretta thula*), tricolored heron (*Egretta tricolor*), and the roseate spoonbill (*Platalea ajaja*), Florida black bear (*Ursus americanus floridanus*), Big Cypress fox squirrel (*Sciurus niger avicennia*), Sherman's fox squirrel (*Sciurus niger shermani*), Florida mastiff bat (*Eumops glaucinus floridanus*), and state-listed plants.

3.2.1 Reptiles and Amphibians

3.2.1.1 Gopher Tortoise

The gopher tortoise is not listed by the USFWS, but is listed by the FWC as a species of special concern. Declining numbers of gopher tortoises are due to a number of

variables including loss of habitat, low reproductive rates, predation, and disease. These tortoises are known to utilize a variety of habitats including pine flatwoods, but prefer well-drained soils that enable burrowing and support a high diversity of low-growing herbs. The gopher tortoise is known to be relatively rare in Hendy County as compared to other parts of Florida. Auffenberg and Franz (1982) described Hendry County as one of two counties in Florida lacking the species, but Diemer (1987) documented a few gopher tortoise burrows in northwest Hendry County. While some well-drained soils are present within the project boundary, these soils are present in highly maintained citrus grove. No natural habitats preferred by the gopher tortoise are present in the project footprint. Pre-construction surveys were conducted within the test cell project footprint as per FWC request in June 2005 for burrows and individuals; species presence was not detected. Similar surveys will be conducted within the C-43 project prior to construction. Given the above information, the project is not anticipated to have adverse effects on the gopher tortoise.

3.2.1.2 Gopher Frog

The Florida gopher frog is commensal with the gopher tortoise and is listed by the FWC as a species of special concern. Due to the absence of suitable habitat and gopher tortoise burrows within the project footprint, the project is not anticipated to have adverse effects on the Florida gopher frog.

3.2.2 Birds

3.2.2.1 Florida Burrowing Owl

The Florida burrowing owl is a small owl listed as a species of special concern by the FWC. The only areas within the project boundary that consisted of open, treeless, and sandy habitat were edges of grove maintenance roads and small parcels of open space at the end of some citrus rows used for grove maintenance operations. These areas were considered to be extremely marginal habitat for the species; they were examined for the presence of burrowing owls and no burrows or individuals were detected. Given the above information, the project is not anticipated to have adverse effects on the Florida burrowing owl.

3.2.2.2 Florida Sandhill Crane

The Florida sandhill crane is a large wading bird listed as threatened by the FWC, but remains unlisted by USFWS. Sandhill cranes forage in open habitats, e.g., improved

pastures and herbaceous marshes. The species typically constructs nests on a platform of vegetation surrounded by water within an herbaceous wetland. Extremely marginal nesting and foraging habitat is present within the project. No documented Florida sandhill crane nests exist within the project study area and no individuals were observed in flight over or foraging within the project area. However, large-scale construction projects in Florida have been known to have temporal effects on sandhill cranes by attracting them to nest in work areas of the site. If sandhill cranes stay and build nests in standing water areas of construction sites, the following protection guidelines will be employed to avoid nest disturbance:

- Nest protection should include measures to prevent disturbance of incubating adults by providing spatial and/or visual separation between nests and construction activities. FWC biologists have recommended a 400-foot buffer around nests. If construction activities are required closer than 400 feet from a nest, monitoring should be provided to ensure the activity does not result in nest abandonment or disturbance of incubating adults;
- During incubation, adults may be expected to be continuously present at the nest. If adults are not present at an active nest for two consecutive 15-minute periods or are exhibiting agitated behavior or vocalization, surrounding activities should be evaluated to identify and correct the cause of incubation disruption;
- Artificial alteration of water levels in wetlands supporting active nests may contribute to nest failure and must be avoided. Dewatering of a nest wetland may increase the risk of the nest to predation. Adding water to a nest wetland may drown eggs. Any activity that would alter a nest wetland's hydrology should not be undertaken while an active nest is present and should be delayed as long after hatching as possible if the wetland is used for night roosting;
- Silt fences may be used to create barriers to prevent adults and chicks from entering work areas, haul roads, or drainage ditches. Where adults and chicks are present within work areas, openings in silt fences will allow dispersal to alternative foraging or roosting habitats; and
- Posting of sandhill crane warning signs within work areas and along haul routes near foraging or nesting habitats and education of construction staff will help to minimize risk to sandhill cranes.

Given the above information, and since there is substantial additional foraging and nesting areas in close proximity to the proposed impacts, and the wetland impacts will

be off-set appropriately, the project is not anticipated to have adverse effects on the Florida sandhill crane.

3.2.2.3 Southeastern American Kestrel

The southeastern American kestrel is a small raptor currently listed as threatened by the FWC. Sub-optimal foraging habitat (citrus grove) for the southeastern American kestrel is present onsite. Field surveys did confirm the species in the project footprint. Although the possibility of species presence cannot be completely eliminated based on the existence of foraging habitat, the project is not anticipated to have adverse effects on the southeastern American kestrel.

3.2.2.4 Peregrine Falcon

The peregrine falcon is listed as endangered by the FWC. The species does not nest in Florida, but does pass through the state on its way from breeding habitats in the north to wintering habitats in Central and South America. Some peregrine falcons stay in Florida for the winter, including the coastal panhandle region and the Florida Keys (Boot and Pigeon Keys). The peregrine falcon was not observed during field surveys and no data records exist for the species near the project site. The project is not anticipated to have adverse effects on the peregrine falcon.

3.2.2.5 Least Tern

The least tern is listed as threatened by the FWC. No least terns were observed during field surveys and no data records exist for the species near the project. Because terns select open, sandy areas for nesting, construction sites have been known to cause temporal effects to the species by attracting terns to nest. Trained dogs have been successfully utilized in construction projects to prohibit birds from nesting in the open areas. This tactic can be further investigated if necessary. The project is not anticipated to have adverse effects on the least tern.

3.2.2.6 Other Wading Birds

Other wading birds such as the limpkin, white ibis, little blue heron, snowy egret (*Egretta thula*), tricolored heron, and the roseate spoonbill (*Platalea ajaja*) are not listed as protected by the USFWS, but are listed by the FWC as species of special concern. Avian field surveys noted that wading birds were detected within the C-43 project area more often during times of ditch maintenance (mechanical clean-out of water lettuce and water hyacinth), rainfall (structural point source discharges delivering numerous

prey items trapped in strong currents), or the operation of pumps (same results as rainfall). Concentrations of wading birds were therefore observed in several locations near desirable forage areas as described above. The nearest active wading bird rookery is located approximately 1 mile south of the project (#619317). Observations at this rookery were last recorded in 1989 and included both listed species (little blue heron) and unlisted species. Potential impacts to these species are anticipated to be temporal only. Due to the nature of this project and these species' high mobility, the project is not anticipated to result in any adverse effects to these species. Since there is substantial additional foraging and nesting areas in close proximity to the proposed impacts, and the wetland impacts will be appropriately addressed, the project is not anticipated to have adverse effects on wading bird species of special concern.

3.2.3 Mammals

3.2.3.1 Florida black bear

The Florida black bear is designated as a threatened species by the FWC, but is not federally listed. Information on the occurrence of Florida black bears in the project area between 1976 and 2002 (FWC telemetry data) indicates that activity occurs north of the project, north of the Caloosahatchee River. No black bear occurrence data exists within the project footprint or in its general vicinity south of the Caloosahatchee River. Field surveys conducted during this study did not detect signs of Florida black bear occurrence in the project area. However, marginal black bear habitat is present on-site as they have been known to utilize citrus groves to forage on the fruits. The project is not anticipated to have adverse effects on the Florida back bear.

3.2.3.2 Big Cypress Fox Squirrel and Sherman's Fox Squirrel

The Big Cypress fox squirrel is listed by the FWC as threatened. It is not currently listed by the USFWS. The Sherman's fox squirrel is distinctly larger than the Big Cypress fox squirrel, and is listed as a species of special concern by the FWC. It is not currently listed by the USFWS. No suitable habitat for either species is present in the project area and field surveys did not detect the species. Based on the above information, the project is not anticipated to have adverse effects on the Big Cypress or Sherman's fox squirrels.

3.2.3.3 Sherman's Short-tailed Shrew

The Sherman's short-tailed shrew is listed by the FWC as a species of special concern. Little is known about the species but it has been identified in southwest Florida. No Sherman's short-tailed shrews were observed during field surveys and no data records exist for the species near the project site. While species presence onsite is possible, it is very unlikely given the land use practices such as pesticide application, heavy equipment usage, etc. Based on the above information, the project is not anticipated to have adverse effects on the Sherman's short-tailed shrew.

3.2.3.4 Florida Mastiff Bat

The Florida mastiff bat is listed by the FWC as endangered. The species occurs in the southern quarter of the state and observations are very limited. A tree/building nester, it typically roosts and nests at high elevations in trees and tall buildings. No individuals or suitable habitat were identified during field surveys, and no data records exist for the species near the project site. Based on the above information, the project is not anticipated to have adverse effects on the Florida mastiff bat.

3.2.4 Plants

In addition to faunal surveys, the proposed project area was surveyed for protected flora. Small populations of wild pine (*Tillandsia fasciculata*), a state endangered species, and reflexed wild-pine (*T. balbisiana*), a state threatened species, as listed by the Florida Department of Agriculture and Consumer Services' Chapter 5B-40, Florida Administrative Code, were observed within a few of the forested wetlands. The listing of these species is due to the introduction of the Mexican bromeliad weevil (*Metamasius callizona*) also known as the 'evil weevil' that eats and destroys large *Tillandsia* species. A single individual of giant orchid (*Pteroglossaspis ecristata*), a state threatened species may have been observed (Wetland 281214). However, the plant was not in flower, which is necessary for accurate species identification since wild coco (*Eulophia alta*), an unprotected terrestrial orchid, is remarkably similar vegetatively. Four commercially exploited species were observed within the proposed project area: Florida butterfly orchid (*Encyclia tampensis*), cinnamon fern (*Osmunda cinnamomea*), royal fern (*O. regalis* var. *spectabilis*), and netted chain fern (*Woodwardia areolata*). The Florida butterfly orchid was limited to a single specimen (Wetland 280847), while the netted chain fern observation was limited to a population within one wetland (Wetland 280848). The cinnamon fern and the royal fern were more common in the project area, as they are throughout the state.

Due to the limited acreage of natural habitats, and lack of rare or endangered habitats, the number of individuals of threatened and endangered species is low and adverse affects to the listed plant species are not anticipated to result from the proposed project.

- A C-43 listed species meeting was held on February 6, 2006 with USFWS and FWC to discuss updates from the March 22, 2005 meeting and survey methodology for specific species.

Appendix A contains copies of pertinent letters and meeting minutes.

2.2 SURVEY METHODOLOGY

Project scientists conducted field reviews on June 30, July 1, 21, 22, 23, and August 9, 10, 11, 2004; June 27, 2005; February 27, 28, March 1, 14, 15, 16, 17, 28, 29, 30, and May 17, 18, 2006. Using meandering pedestrian and vehicular (including all-terrain vehicle (ATV)) transects as well as stationary observation points, all appropriate habitat in and, in some cases, adjacent to the C-43 study area, was visually scanned for evidence of listed species, their habitats and general wildlife. Various upland and wetland habitats within the project study area were also classified during this period using FLUCCS and NWI.

Wildlife surveys were generally conducted in the morning and late afternoon, while surveys for avifauna were conducted in the early morning to assess roosting areas and peak foraging times. Observation points were depicted on project aerial photography and all observations of wildlife were recorded. These observations included direct sighting of species or signs of their presence including tracks, burrows, dens, scat, nests, or calls (typically with avifauna).

The identification or potential presence for species of special concern, threatened species, or endangered species was given special attention. This included efforts to survey all appropriate habitat for the species listed in Tables 1 and 2. Following the general field survey efforts, a complete list of fauna observed or known to occur within the C-43 project study area was compiled (Appendix B).

4.0 IMPACT ASSESSMENT

4.1 ANALYSIS OF POTENTIAL PROTECTED SPECIES IMPACTS

4.1.1 Direct Effects Within the Project Footprint

Table 3 and Figure 2 detail the current land uses that will be impacted by the project.

Project impacts (90.04 percent; 9088.4 acres) will be to the existing citrus grove (FLUCCS 2210). Water (FLUCCS 500 series) comprises 8.87 percent (895.58 acres) of the site and includes extensive agricultural canals/ditches, classified as Streams and Waterways (FLUCCS 5100), and excavated ponds, classified as Reservoirs less than 10 acres in size (FLUCCS 5340). Wetland (FLUCCS 600 series) comprises 1.09 percent (109.67 acres) of the site and includes Mixed Wetland Hardwoods (FLUCCS 6170), Willow and Elderberry (FLUCCS 6180), Exotic Wetland Hardwoods (FLUCCS 6190), Cypress (FLUCCS 6210), Wetland Shrub (FLUCCS 6310), and Freshwater Marsh (FLUCCS 6410). Current land use types, totaling 10,093.66 acres, will be converted to aquatic habitat, wetlands, cell berms, maintenance access roads, and structures. The 267-acre test cell footprint is not included in this acreage summary as it was previously permitted.

Citrus groves provide poor habitat for wildlife in general. This principle may be more readily applied to protected species, which frequently demand stringent habitat criteria that are not met by land uses such as citrus grove. Additionally, the proposed wetland impacts are mostly to man-made surface waters (excavated ditches and ponds), all of which have been moderately to highly disturbed by citrus grove operations (hydrological alteration, infestation of nuisance/exotic species, nutrient loading, etc.).

The post-development condition will likely be attractive to aquatic and aquatic-dependent species, including invertebrates, fish, amphibians, and birds. Impacts to the large majority of listed species are expected to be temporal only during the project construction. These temporal impacts are expected to be offset by the long-term benefits to the listed wildlife species based upon multiple observations of other similar projects such as the SFWMD STAs.

The adjacent wetland and upland habitats should provide foraging, roosting, and/or nesting for many of the species that would be temporarily displaced by the proposed project. Further, the reduced anthropogenic activity within the project and the adjacent

areas should allow greater undisturbed wildlife utilization during the post-development condition.

No listed species nests or rookeries were observed or are known to occur in the C-43 project area. Two red-shouldered hawk nests were identified within the project footprint. While not a protected species per se, active nests are protected during the nesting season by the MBTA.

Listed wading birds were observed utilizing the canals and ditches within the citrus grove and the American alligator was observed in a few ditch/canal locations. A few wood storks were observed loafing in an open field but the closest rookery is approximately 17 miles away. One confirmed Audubon's crested caracara nest was identified to the north of the project along SR 80. A small portion of the project falls within the secondary protection zone of the nest but a reduction of this zone is proposed which would eliminate overlap with the project footprint. A second, possible nest was identified but not confirmed to the southeast of the project.

Review of FWC and FNAI species occurrence records for the project area and adjacent areas revealed the closest active wading bird (little blue heron) rookery approximately 1 mile to the south of the project area, the closest active bald eagle nest approximately 3.4 miles to the east of the project area, and no other listed avian nest sites within at least one mile of the C-43 project area.

4.1.2 Direct Effects Outside the Project Footprint

From a landscape perspective, the project is surrounded by a matrix of land uses including Urban and Built-Up (FLUCCS Series 100), Agricultural (200), Upland Forests (400), and Wetlands (600). Figure 3 depicts land use within a 25-mile buffer of the project. Currently, urban development is focused in coastal areas west of the project, and less so along the Caloosahatchee River. South of the river, where the project is situated, the predominant land uses are agricultural and wetlands. North of the river, the most common land uses include agriculture, wetlands, and upland forests. Because of the nature of the project, no additional land use changes will result.

Direct positive effects from the project may occur in the downstream Caloosahatchee Estuary as previously described in this report. The C-43 WSR will reduce high flows during the wet season by capturing and storing excess water. The water would then be released in a manner that is beneficial to the estuary during the dry season. Reducing the variability of freshwater releases to the estuary will support the restoration of salinity

ranges and habitat in the system. The effects may potentially benefit the Florida manatee, American crocodile, smalltooth sawfish, and sea turtles including the Atlantic loggerhead turtle, Atlantic green turtle, leatherback turtle, Kemp's ridley turtle, and hawksbill turtle.

Protected species including the bald eagle, snail kite, wood stork, Audubon's crested caracara, and Florida panther have large foraging ranges and subsequent large protection zones. As a result, they have a greater potential to be affected by development projects. This Biological Assessment has addressed these species and the potential project effects.

4.1.3 Indirect, Secondary, and Cumulative Impacts

Indirect and secondary impacts are adverse effects that may be reasonably expected to occur in or near the project subsequent to construction that are a result of the project. Cumulative impacts include all past, present, or future development adverse effects that can be reasonably attributed to occur in the project's area of influence.

Due to the limited habitat available with the existing land use types, the indirect, secondary, and cumulative impacts attributed to the project are estimated as negligible for most listed species that can reasonably be expected to utilize the project area.

Project area utilization by the Florida panther in its current condition is very low. Radio telemetry data obtained from FWC indicates that one known panther has been documented adjacent to and on the edge of the C-43 project boundary approximately 6 years ago. Panthers have not been documented within the project footprint. In addition, review of the land use clearly demonstrates that the project site currently provides poor quality habitat.

Small indirect, secondary, and/or cumulative impacts to the Florida panther may occur as a result of the proposed project due to possible reduction in a large mammal prey base. The feral hogs, deer and other mammals that inhabit the citrus grove and the remaining 'natural' areas within the grove serve as a prey source to these large carnivores. However, the project will not preclude these prey items from the reservoir site and the species may continue to utilize the area in the with-project condition.

5.0 CONCLUSIONS

The C-43 West Storage Reservoir project contains approximately 10,360 acres; 267 acres have been previously permitted for the test cell project. The majority of existing land use consists of citrus grove (90.04 percent of the remaining 10,093 acres). Little natural habitat remains on-site and consists only of remnant, isolated shrub and forested wetlands. Wetland and surface water impacts will occur to a total of approximately 895.58 acres of low quality ditches and excavated ponds, and 109.67 acres of wetlands. The existing land use types provide limited wildlife habitat value. Project construction should not adversely affect the floral or faunal species discussed in previous sections. The exception may be the Florida panther, a species that requires large individual territories. Project elements such as berms, sloped cell edges, maintenance roads and canal structures will facilitate panther movement across the reservoir.

Jacksonville, Florida 32207-8175

Service Federal Activity Code:	41420-2006-FA-0443
Service Consultation Code:	41420-2007-5-0589
Corps Application No.:	SAJ-2005-5958 (IP-TKW)
Date Received:	January 10, 2007
Formal Consultation Initiation Date:	March 26, 2007
Applicant:	South Florida Water Management District
Project:	Caloosahatchee River (C-43) West Basin Storage Reservoir Project
County:	Hendry

Dear Colonel Grosskruger:

This document transmits the Fish and Wildlife Service's (Service) Biological Opinion for the U.S. Army Corps of Engineers' (Corps) to issue a permit for the construction and operation of the Caloosahatchee River (C-43) West Basin Storage Reservoir project (C-43 West Reservoir project) and its effects on the endangered Florida panther (*Puma concolor coryi*), the threatened Audubon's crested caracara (*Polyborus plancus audubonii*), and the threatened eastern indigo snake (*Drymarchon corais couperi*) in accordance with section 7 of the Endangered Species Act of 1973, as amended (Act) (87 Stat. 884;16 U.S.C. 1531 *et seq.*).

The C-43 West Reservoir project is an Acceler8 component of the Comprehensive Everglades Restoration Plan (CERP), authorized under the Water Resources Development Act of 2000. The purpose of the C-43 West Reservoir project is to restore ecosystem function in the Caloosahatchee Estuary by reducing the number and severity of events where harmful amounts of freshwater from basin runoff and Lake Okeechobee regulatory releases are discharged into the estuarine system via the Caloosahatchee River and to maintain a desirable minimum flow of freshwater to the estuary during dry periods. The C-43 West Reservoir project was designed to capture high freshwater flows from the Caloosahatchee River during the wet season, and store water temporarily in a 10,492-acre (ac) reservoir before discharging it back into the river during the dry season to restore a healthy estuarine salinity balance in the Caloosahatchee River Estuary and Pine Island Sound. The proposed 10,492-ac reservoir footprint and adjacent 110-ac access road parcel are located in portions of Sections 31 through 36, Township 43 South, Range 28

East; Sections 6 and 31, Township 43 South, Range 29 East; and Sections 1 through 12, Township 44 South, Range 28 East, Hendry County, Florida (Figure 1).

Within the C-43 West Storage Reservoir project area, 267 ac were previously impacted during construction of the C-43 West Reservoir Test Cell project (Test Cell project) (Figure 1). The Test Cell project was constructed to evaluate the on-site seepage potential and effectiveness of seepage control measures, the suitability of on-site materials for embankment construction and slope protection, and the effects of water residence time and seepage on water quality. That project included two 500-foot by 500-foot test cells with offset seepage canals, a borrow area, settling ponds, and staging areas and was authorized under Department of Army (DA) Permit number 2005-6598 (IP-TKW) issued December 6, 2005. A total of 29 ac of jurisdictional wetlands and waters of the Unites States (US) were impacted during construction of the Test Cell project and included 1.9 ac of excavated open-water, 4.5 ac of wet prairie, and 26.0 ac of tertiary, agricultural drainage canals.

This Biological Opinion is based on information provided in the November 9, 2006, Department of Army (DA) permit application; the Corps' January 10, 2007, letter to the Service requesting initiation of formal consultation; the December 2006 Biological Assessment (BA) prepared by Scheda Ecological Associates, Inc. (SEA) for the South Florida Water Management District (District); the Corps' March 22, 2007, letter to the Service providing additional information; the Corps' April 2007 *CERP C-43 West Reservoir project, Draft Project Implementation Report* (DPIR); the Corps' April 30, 2007, Public Notice (PN); and maps, meetings, field investigations, telephone conversations, email correspondence, and other sources of information. A complete administrative record is on file at the Service's Ecological Service sub-office co-located at the J.N. "Ding" Darling National Wildlife Refuge in Sanibel, Florida.

The Corps' letters and the BA referenced above describe the potential effects of the proposed C-43 West Reservoir project on federally listed threatened and endangered species. The Corps determined that the C-43 West Reservoir project will have "no effect" on the bald eagle (*Haliaeetus leucocephalus*), Florida scrub jay (*Aphelocoma coerulescens*), Florida grasshopper sparrow (*Ammodramus savannarum floridanus*), red-cockaded woodpecker (*Picoides borealis*), Okeechobee gourd (*Cucurbita okeechobeensis*), and the beautiful pawpaw (*Deeringothamnus pulchellus*); and "may affect, but is not likely to adversely affect" the West Indian manatee (*Trichechus manatus*), Everglade snail kite (*Rostrhamus sociabilis plumbeus*), and the wood stork (*Mycteria americana*). The Corps also provided a "may affect and is likely to adversely affect" determination for the Audubon's crested caracara, eastern indigo snake, and Florida panther.

The following discussion pertains to the nine federally listed threatened or endangered species for which the Corps provided an effect determination of either "may affect, not likely to adversely affect" or "no effect." For these species, consultation was informal.

According to the BA, the Florida scrub jay, Florida grasshopper sparrow, red-cockaded woodpecker, Okeechobee gourd, and the beautiful pawpaw, or suitable habitat for those species, do not occur within or adjacent to the project area. Thus, the Corps has determined that the

proposed C-43 West Reservoir project will have no effect on those federally listed species. The Service concurs with the Corps' effect determinations for those species.

Bald Eagle

Likewise, the bald eagle is unlikely to be present within or adjacent to the project area. The closest documented nest is located 3.4 miles east of the project area and has not been active since 2003. No new nest locations were documented within 3,000 feet (ft) of the reservoir footprint during field surveys conducted during summer 2004 and spring 2006. Additionally, the Service has recently determined that the bald eagle has recovered and published the Final Rule to delist the bald eagle in the Federal Register on July 9, 2007. Removal of the bald eagle from the list of endangered and threatened wildlife will be effective August 8, 2007. Based on this information, the Corps has determined that that the proposed C-43 West Reservoir project will have no effect on the bald eagle. The Service concurs with the Corps' effect determination.

West Indian Manatee

The endangered manatee is known to occur in all coastal waters of south Florida including estuaries, bays, rivers, creeks, and canals (Service 2001). They have been documented within major inland freshwater waterways and canals, including the Caloosahatchee River from Lake Okeechobee to the Gulf of Mexico (*i.e.*, Glades, Hendry, and Lee Counties). Additionally, the Caloosahatchee River is a significant winter aggregation area for manatees. Manatees are highly mobile and may be found in all waters accessible to them. Access to some water bodies may be prevented by weirs, salinity control structures, and locks.

According to the BA and additional information provided, manatees are known to occur in the Townsend Canal which connects the C-43 West Reservoir project area to the Caloosahatchee River through the existing agricultural canal system. Manatees are capable of passing over the weir at the confluence of the Townsend Canal and the river during high water levels and of passing through existing flap gates in the weir into the Townsend Canal during periods of inflow. Manatees are currently prevented from accessing the remaining canals in the project area due to differences in canal elevations at the intersection of the Townsend and Header Canals. The Header Canal is adjacent to and provides water for the project area and is approximately 10 ft above the Townsend Canal at their intersection. The existing pump station located at that intersection takes water in from the Townsend Canal and releases it into the Header Canal at the higher elevation.

The proposed C-43 West Reservoir project includes removal of the weir at the confluence of the Townsend Canal and the Caloosahatchee River. That structure will be replaced with one that serves either as permanent barrier or seasonal barrier which restricts manatee access to the Townsend Canal only during the winter season (November 1 through March 31). Thus, manatees in the river will either have no access if a permanent barrier is erected, or continue to have seasonal access to the Townsend Canal where the two reservoir intake pump stations (*i.e.*, C-43PS-1 and C-43PS-4) will be located. However, both intake pumps will include bar screens and trash rake systems that will prevent manatees from becoming trapped in the intake pipes as

well as from entering the reservoir through C-43PS-1 or the perimeter canal through C-43PS-4, and reduce the likelihood of injury to manatees by the rake systems. The screens consist of vertical bars spaced 6 to 8 inches apart extending from above the water surface to the canal bottom. C43PS-1 includes a monorail picker rake system that extends across and along each intake bay. A Duperon (manatee friendly) trash rake system could not be used at C43PS-1 because Duperon does not manufacture a system that is as wide and deep as the C43PS-1 intake bays. However, through consultation with the Service, the following manatee-friendly components were incorporated into the picker rake system:

1. Slowing the descent speed of the picker rake;
2. Minimizing the width of the automated gripper to 24 inches (unless manually controlled); and,
3. Incorporating a bar across the picker teeth to prevent the tines from crossing.

C43PS-4 includes the Duperon system that extends across and along each intake bay. The Duperon system is considered manatee-friendly because there are no gripper or teeth. The system consists of a rotating cup attached to each bar screen that "scoops" the trash collected against the bar screen up to the trash rack on top of the screen to the trash conveyor.

Likewise, it is unlikely that manatees would be able to access the perimeter canal through any of the discharge structures or gated culverts. The main outfall structure, C-43S-11, is 10 to 12 ft higher in elevation than the Townsend Canal. The double box culverts at the Fort Simmons Branch and the Banana Branch Canals (*i.e.*, C43S-9 and C43S-7, respectively) are each controlled by a slide gate and a weir gate. The slide gates will remain closed except under extreme high flow conditions. The C43S-9 weir gate is supported by a 5-foot high "knee wall" and C43S-7 weir gate is supported by a 3-foot high "knee wall."

As referenced in the BA and discussed during the during the May 15, 2007, interagency meeting between the Corps, District, and Service, and subsequent teleconferences, manatee protection measures will be implemented as part of the proposed project. The Corps and District will follow the CERP Interagency Task Force's October 2006 *Guidelines for Manatee Conservation During Comprehensive Everglades Restoration Plan Implementation* (CERP Manatee Guidelines), particularly those summarized below:

1. Marine Species Observer Experience Requirements, including acceptable level of observer experience corresponding to the expected level of risk to manatees and location for a particular project. As described in the CERP Manatee Guidelines Appendix A-1, Manatee Observers must be approved by the Florida Fish and Wildlife Conservation Commission (FWC) by submitting a resume and a completed form titled Observer Experience and Education Documentation for Marine Species Watch Programs (June 2006). The C-43 West Reservoir project does not include the use of explosives (*i.e.*, blasting) and is not located in an Important Manatee Area. Therefore, observers qualified at Watch Level 2 or higher may fulfill permit requirements. All manatee observations for the C-43 West Reservoir project will be conducted by FWC approved Level 2 Manatee Observers through the Corps' existing volunteer manatee observer program for the Okeechobee Waterway.

2. Standard Manatee Construction Conditions (July 2005) should be followed, including education of construction personnel regarding manatee presence, speed zones, and that civil and criminal penalties exist for harming, harassing, or killing manatees under the Marine Mammal Protection Act, the Endangered Species Act, and the Florida Manatee Sanctuary Act; siltation and turbidity barriers shall not entangle or entrap manatees nor impede their movements; in-water operations and vessels must be shut down if a manatee(s) comes within 50 feet of the operation and will not resume until the manatee(s) has moved beyond the 50-foot radius of the project operation without being herded or harassed into leaving, or until 30 minutes elapses without the manatee(s) reappearing within 50 feet of the operation; any collision with or injury to manatees shall immediately be reported to the FWC Hotline at 1-888-404-FWCC and the Service's Vero Beach Office at 561-562-3909; and finally, temporary manatee signs that have already been approved by the FWC and described in the CERP Manatee Guidelines Appendix A-2 must be posted in prominently visible locations prior to and during all in-water project activities.

3. Minimization and Avoidance of Manatee Entrapment, including pre- and post-construction guidelines should be incorporated to avoid manatee entrapment during installation of the trash rakes on the intake pumps (*i.e.*, C43PS-1 and PS-4). As described in the CERP Manatee Guidelines Appendix A-3, the Corps or District should conduct ground surveys of the waterway prior to installation of the last section of any temporary or permanent barriers so that manatees are not trapped in the waterway between the pump stations and the bar screen and trash rake systems. Surveys should be conducted by qualified observers with conference with the Service and FWC. If no manatees are sighted within the exclusion area, the waterway should be closed off immediately. Otherwise, the manatees should be observed to see if they move beyond the proposed barrier on their own accord. Once the barrier is installed, the barrier and waterway should be monitored by land once daily for a period of one week to check for presence of manatees. The area should also be surveyed for manatee presence prior to initial operation of the pump stations. If manatees are sighted within the exclusion area, the FWC should be contacted at 888-404-FWCC.

4. Thermal Guidelines in Manatee Accessible Waters should be followed during the winter season, typically between November 1 to March 31, and include monitoring reservoir discharge water temperatures at both the reservoir discharge point (*i.e.*, C43S-11) and the receiving waters (*i.e.*, the confluence of the Townsend Canal and Caloosahatchee River) on a daily basis until the effect of the discharge has been determined. Intermittent reservoir discharges shall not increase the ambient temperature of receiving waters above 20° C and create an unreliable warm-water refugia that will not sustain manatees through cold periods (CERP Manatee Guidelines, Appendix A-5).

5. A report summarizing project construction and related manatee observations, including dates, names of qualified observers, and the duration and results of observation will be submitted to the Service annually, until construction is completed.

To achieve Guideline 4 above, the Corps and District agreed during the May 15, 2007, interagency meeting and subsequent teleconferences, to construct at least a seasonal barrier at the confluence of the Townsend Canal and Caloosahatchee River to prevent manatee access to the Townsend during the winter season (November 1 through March 31), and to implement the following monitoring plan during the winter season:

1. During reservoir releases conducted between November 1 to March 31 of each year, continuous recorders will be used to monitor water temperature daily at three locations: 1) the temperature of the reservoir discharge water will be monitored at the discharge point (*i.e.*, C43S-11); 2) ambient water temperature in the Caloosahatchee River will be monitored at the Ortona Lock (*i.e.*, S-78); and 3) the effect of reservoir discharge on the water temperature in the Caloosahatchee River will be monitored at the barrier that will be constructed at the confluence of the Townsend Canal and the Caloosahatchee River. Hourly data points should be downloaded and examined daily to determine the presence and downstream effect of the warm water plume.

2. If the reservoir discharges raise the ambient temperature of the water at the confluence of the Townsend Canal and the Caloosahatchee River greater than or equal to 20° C, or if less than 20° C but increases the water temperature at that location above the ambient water temperature, manatee observations will be conducted daily in the Caloosahatchee River at its confluence with the Townsend Canal to detect any shifts in manatee winter-use patterns and movements to the area. Observations should be conducted in four 10-minute intervals over a 2-hour period every morning. All manatee observations for the C-43 West Reservoir project will be conducted by FWC approved Level 2 Manatee Observers through the Corps' existing volunteer manatee observer program for the Okeechobee Waterway.

3. If manatees move to the area as result of the reservoir discharges and have been observed within the Caloosahatchee River at its confluence with the Townsend Canal during two consecutive observation days or during two of three consecutive observation days, then the Corps should notify the Service and the FWC immediately. The Corps shall continue the manatee observations and the FWC may monitor manatee health as appropriate. If reservoir releases are discontinued based on flows at S-79 during the cold season and the FWC determines that manatees exhibit signs of cold stress following cessation of reservoir discharges, then the Corps and District will reinitiate consultation with the Service.

4. Reports summarizing the water temperature monitoring and manatee observations conducted during the winter period will be submitted to the Service and the FWC, annually. Those reports should include: a) the water temperatures observed at the C-43S-11, S-78, and the barrier constructed at the Townsend and Caloosahatchee River from November 1 through March 31; b) the date, time, and duration of each observation, the name of the approved Level 2 observers, and the results of each observation; and c) if the Service and FWC were notified of manatee presence as outlined above, the date the agencies were contacted as well as the date and results of any additional monitoring of manatee health conducted by FWC.

5. After the reservoir has been in operation a minimum of 5 years, monitoring needs may be re-evaluated. At that time, the range of climatological and hydrological conditions (*i.e.*, occurrence of an extreme cold year, extreme drought year, etc.) under which the reservoir was operated will be considered in the re-evaluation of water temperature monitoring needs and manatee observations.

Based on the above information, the Corps has determined that the proposed C-43 West Reservoir project "may affect, but is not likely to adversely affect" the manatee. The Service concurs with the Corps' effect determination.

No designated manatee critical habitat occurs within the proposed project area. However, the C-43 West Reservoir project will benefit designated critical habitat downstream by improving salinity conditions in the Caloosahatchee Estuary, particularly during the dry season. Therefore, designated West Indian manatee critical habitat will not be adversely affected by the proposed C-43 West Reservoir project.

Everglade Snail Kite

Suitable habitat for the endangered snail kite consists of freshwater marshes, wet prairies, and the shallow vegetated edges of man-made or natural lakes where apple snails (*Pomacea paludosa*) can be found. The closest known nesting concentrations of snail kites and their designated critical habitat occur in the Lake Okeechobee watershed, east of the project area. Snail kites are occasionally known to occur in marshes west of Lake Okeechobee, along the Caloosahatchee River, and west of the project area in Lehigh Acres and borrow canals in Lee County. During February 2006 field surveys, SEA staff observed one snail kite eating a snail while perched on a power transmission line along State Road (SR) 80 approximately 0.75 miles west of the reservoir footprint. However, no snail kites and little suitable foraging habitat (*i.e.*, less than 10 ac) are known to occur within the C-43 West Reservoir project area, including the Test Cell project footprint.

No suitable snail kite habitat would be created within the 110-ac access road parcel. However, the construction and operation of the proposed reservoir may intermittently provide wetland habitats suitable for snail kite use within the 10,492 ac currently under citrus production when the reservoir is drawn down or within the 109 ac of littoral zones that will be constructed as part of the seepage canal. Citrus operations in the project area and elsewhere have routinely applied heavy copper (Cu) treatments as a fungicide for many years, resulting in extensive Cu contamination in the soil. Potential Cu risk to the endangered snail kite may occur due to Cu accumulation in the kite's primary food item, the apple snail (URS 2003). Snail kites have a specific diet comprised almost entirely of apple snails. Apple snails have been found in the larger agricultural canals and in 4.8 ac of retention marsh within the C-43 West Reservoir project area. Thus, wetlands created as a result of the project may occasionally attract foraging snail kites during drawdown conditions.

The Service is conducting an ongoing field study to develop a method to predict Cu concentrations in apple snails based on Cu concentrations in soils and to ultimately predict Cu

concentrations in apple snails in wetlands constructed on former Cu-contaminated citrus properties. Preliminary results of that study indicate a positive relationship between Cu concentrations in soil sediments and Cu concentrations in apple snails (Barger et al. 2005). An interim effects level of 85 milligrams per kilogram (mg/kg) of Cu concentrations in sediments was agreed upon by the Service and the District until that study is completed.

A total of seven grids (*i.e.*, grids 56, 58, 124, 125, 134, 135, and 143) in the Berry Labelle – Congen Groves portion of the project area will require remediation due to Cu contamination (Figure 2). The Service recommended remediation for the entirety of Grids 124, 125, 134, 135, and 143 (250 ac) and for the portions of Grids 56 and 58 that will be within the footprint of the proposed reservoir. The District's remediation plan includes excavation of approximately one foot of soil from those contaminated areas to be remediated and utilizing that soil within the reservoir embankments, burying the soils such that surface water will not contact the Cu-contaminated soil. The Service concurred in a letter dated September 14, 2006, that removing contamination from those seven grids would adequately reduce Cu concentrations in those grids to below the interim screening value for risk to the snail kite and would not likely have direct impacts on other trust resources for which the Service is responsible. However, the Service noted that the remaining Cu concentration in some areas of the property may be high enough to adversely impact benthic organisms. The Service also recommended that no further Cu applications be permitted in Grids 38, 39, and 145 since Cu concentrations in soils from those grids were close to the interim screening value, and that the proposed remediation not commence until project construction is initiated. According to information provided by the Corps in their March 22, 2007, letter, those recommendations have been followed and no additional Cu has been applied within the project area since soil sampling was conducted. Therefore, the Corps has determined that the proposed C-43 West Reservoir project "may affect, but is not likely to adversely affect" the Everglade snail kite. The Service concurs with the Corps' effect determination. No designated critical habitat occurs within or adjacent to the project area and therefore, none will be affected.

Wood Stork

Endangered wood storks utilize wetlands for foraging year-round. Regional declines in wood stork populations can be attributed to the loss and degradation of feeding habitat. Depending on local rainfall and habitat conditions, wood storks may forage in 50 to 200 wetlands within 5 to 40 miles of a rookery site. The Service has identified a Core Foraging Area (CFA) of 18.6 miles around known wood stork rookeries to minimize potential adverse effects to their foraging habitat. Although no wood storks are known to have nested within the project area, approximately 85 percent (*i.e.*, 8,995 ac) of the C-43 West Storage Reservoir project area including the access road parcel (i.e., 10,602 ac), is within 18.6 miles of three wood stork rookeries known to be active (Figure 3). Two rookeries are located to the west in the Caloosahatchee estuary in Lee County, and one rookery is located south of the project area in Collier County just south of Okaloacoochee Slough State Forest (OSSF) and Wildlife Management Area (WMA). Wood storks were observed during listed species surveys and other field inspections of the project area foraging within secondary agricultural canals, loafing along

access roads and borrow ditches, and feeding on prey trapped in vegetation cast aside during mechanical ditch maintenance.

Typical foraging sites for the wood stork include freshwater marshes, stock ponds, shallow and seasonally flooded roadside or agricultural ditches, narrow tidal creeks, shallow tidal pools, managed impoundments, and depressions in cypress heads, swamps, and sloughs. Because of their specialized feeding behavior, wood storks forage most effectively in shallow (*i.e.*, 2 to 15 inches) water areas with highly concentrated prey. Almost any shallow wetland depression where fish become concentrated, either through local reproduction or receding water levels, may be used as feeding habitat during some portion of the year.

The project will result in the loss of approximately 126.7 ac of wetlands and 934.6 ac of other jurisdictional surface waters on the site (Figure 4). The land will be converted primarily to an open-water, above-ground reservoir including associated structures and a seepage canal. However, suitable wood stork foraging habitat is limited within the project area and habitat quality for wood storks is generally poor. On-site freshwater wetlands are primarily impacted wetlands functioning as agricultural retention and detention areas. Secondary and tertiary agricultural canals and ditches may provide shallow-water foraging habitat and concentrate prey during low water periods and their hydrology is dependent on rainfall and irrigation. As a result, agricultural canals and ditches may often receive nutrient and chemical (*i.e.*, fertilizers, pesticides, and fungicides) laden runoff directly from the grove beds. Approximately 6.9 ac of emergent wetlands and depressions in cypress heads were determined to provide suitable wood stork foraging habitat within the C-43 West Reservoir project area and access road parcel during onsite field inspections and examination of aerial photography and photographs of onsite wetlands taken during helicopter surveys. Secondary (191.6 ac) and tertiary (558.5 ac) agricultural canals and ditches within the project area provide an additional 750.1 ac of potential foraging habitat within the CFA of three known rookeries (Figure 5) when hydrological conditions are suitable. The loss of approximately 17.2 ac of tertiary ditches that provide potential wood stork foraging habitat within the Test Cell project boundary was already compensated for under informal consultation for that project as described in our November 22, 2005, letter.

The Uniform Mitigation Assessment Method (UMAM) (Chapter 62-345, F.A.C. [effective date 02-04-2004]) was used to evaluate the current condition (*i.e.*, wetland value) of the existing wetlands (6.9 ac) and drainage canals and ditches (750.1 - 17.2 = 732.9 ac) within the project area that provide potential wood stork foraging habitat and the proposed compensation for the loss of that foraging habitat. During a May 15, 2007, interagency meeting, the Corps, District, Service, and Environmental Protection Agency (EPA) agreed to use the UMAM evaluations of onsite wetlands and agricultural canals and ditches conducted by an interagency team comprised of the Corps, District, and Service, during June and July of 2004. Thus, a total of 96.9 functional wetland units will be lost as a result of the C-43 West Storage Reservoir project (Table 1).

The purpose of the C-43 West Storage Reservoir project is to restore ecosystem function in the Caloosahatchee Estuary by reducing the number and severity of events where harmful amounts of freshwater from basin runoff and Lake Okeechobee releases are discharged into the estuarine

system and to maintain a desirable minimum flow of fresh water to the estuary during dry periods. Altered salinity in the estuary has resulted from hydrological modifications that have dramatically changed the natural quantity, quality, timing, and distribution of freshwater flows to the estuary, often without regard to the health of the estuarine community (Haunert et al. 2000). Salinity is a major ecological variable that controls important aspects of the estuarine community structure and food web (Myers and Ewel 1990). Flow alterations have impacted the natural biodiversity of the estuary by affecting food availability, predation pressure, and reproductive success, as well as directly causing chronic and acute stress on biota. Altered freshwater inflow can also influence primary productivity, zooplankton biomass, and nekton abundance by influencing nutrient concentrations and light attenuation.

The excessive variation in discharge and salinity in the Caloosahatchee Estuary (Figure 6) maintains estuarine biota in a constant flux between those favoring higher salinity and those favoring lower salinity (Chamberlain and Doering 1998a; Bulger et al. 1990). Optimal salinity conditions may not last long enough for organisms to complete their life cycle and the estuary can become devoid of some populations, even keystone species that support major ecosystem components along the estuary's salinity gradient such as oysters or submerged aquatic vegetation. The tapegrass (*Valisneria* sp.) beds in the upper estuary provide important breeding, feeding, and escape cover for a variety of estuarine-dependent species, including foraging habitat for two of the rookeries impacted by construction of the reservoir. During the dry season, the combination of limited rainfall, lack of water storage in the basin and withdrawals to meet human demands for irrigation and potable water often results in periods of no freshwater discharge to the estuary. Saltwater can intrude upstream to the Franklin Lock and Dam (S-79), threatening the survival of the tapegrass beds and other species that require low salinity to complete their life cycle (Chamberlain and Doering 1998a; 1998b, Doering et al. 2002; District 2002). For example, tapegrass beds had essentially vanished from the upper estuary as a result of extremely high salinity levels during the 2001 drought. Tapegrass density remained low and started a slight increasing trend during the growing season of 2003. The beds began to recover while salinity conditions were favorable during the spring and summer growing seasons of Water Year (WY) 2004 and WY 2006. However, due to the unusually high salinity associated with the 2007 dry season the tapegrass beds have again almost disappeared.

The optimum S-79 flow ranges and delivery patterns for the estuary were initially designed to protect tapegrass upstream of Fort Myers and formed the basis for development of hydrologic performance measures for CERP, including the C-43 West Storage Reservoir project; the Southwest Florida Feasibility Study; and the Lake Okeechobee Regulation Schedule; as well as meeting legislative mandates for the establishment of the Caloosahatchee River and Estuary Minimum Flow and Level (MFL) (District 2000, 2003). The MFL was based on a flow-salinity relationship that was based on flows at S-79 and downstream salinity levels (Chamberlain and Doering 1998b; Doering et al. 2002).

Although wood storks may be impacted by the loss of foraging habitat within the project footprint, when implemented, the C-43 West Storage Reservoir project has the potential to significantly contribute towards restoration of tapegrass in the upper Caloosahatchee estuary. The C-43 West Reservoir project will improve estuarine health particularly by reducing the

number of damaging low flow events at S-79. Negative project effects to wood stork foraging habitat within the C-43 West Reservoir project area will be offset by the enhancement of about 4,130 ac of submerged tapegrass beds in the upper Caloosahatchee estuary (Figure 3) which will directly benefit two of the three wood stork rookeries in the project vicinity. Restoration and enhancement of the tapegrass beds in the upper estuary will provide approximately 446 wetland mitigation credits and is consistent with the Service's wood stork goal to acquire, enhance, preserve, and recover natural hydropatterns within foraging habitat of the wood stork. We anticipate that the hydrologic improvements would result in significant increases in the cover and density of tapegrass beds in the upper estuary and therefore, result in increases in the spatial extent and productivity of available wood stork foraging habitat. Based on the model results described in the DPIR, the proposed design and operation of the C-43 West Reservoir are effective at augmenting flows below 450 cubic feet per second (cfs) at S-79 to meet MFL criteria than at reducing the extreme high flows (Corps 2007). The MFL salinity criteria are also beneficial for other organisms that utilize this low salinity region of the estuary, including wood stork prey species. The Service, Corps, and EPA used UMAM to evaluate the future condition of the tapegrass beds based on the model results and project benefits analyses described in the DPIR. Restoration and enhancement of the tapegrass beds in the upper estuary will provide approximately 446 wetland mitigation credits and is consistent with the Service's wood stork goal to acquire, enhance, preserve, and recover natural hydropatterns within foraging habitat of the wood stork.

The District has also proposed to construct 109.3 ac of shallow-sloped littoral zones along portions of the C-43 West Storage Reservoir seepage canal. Although this habitat will not be considered as compensation for the loss of wood stork foraging habitat or as mitigation for functional wetland units lost as a result of the proposed project, the littoral zones may provide additional wood stork foraging habitat.

Accordingly, the restoration and enhancement of 4,130 ac of tapegrass beds in the upper Caloosahatchee estuary will compensate for the loss of approximately 749.8 ac primarily consisting of impacted wetlands and agricultural canals and ditches that provide wood stork foraging habitat within the reservoir footprint. Additional wetland habitat will be provided by the construction of 109 ac of littoral zones along C-43 West Storage Reservoir seepage canal. Based on this information, the Corps has determined that the proposed C-43 West Storage Reservoir project "may affect, but is not likely to adversely affect" the wood stork. The Service concurs with the Corps' determination.

This concludes the informal consultation for this project on the species presented above, and these species will not be addressed further in this Biological Opinion.

Audubon's Crested Caracara

Suitable nesting habitat for the threatened Audubon's crested caracara includes wet and dry prairies with scattered saw palmetto, scrub oak, or cypress, and improved or semi-improved pastures and range lands. Two documented caracara nest locations were identified in the project vicinity during species specific surveys conducted February through May of 2006, although none

occur within the proposed reservoir footprint. Project-related activities and resultant land cover changes would occur within the primary (985-foot radius from the nest tree) or secondary (6,600-foot radius from the nest tree) protection zones of one or both caracara nest sites. Therefore, the Corps has determined that the proposed project "may adversely affect" the crested caracara. The Service concurs with the Corps' determination.

Eastern Indigo Snake

The eastern indigo snake is listed by the Service and the FWC as a threatened species. Eastern indigo snakes require a mosaic of habitats. Because eastern indigo snakes are found throughout Florida and use a variety of habitat types, including citrus groves, its presence in the project area is likely. No individuals have been observed during project field surveys, although the Service observed a black snake on the site on February 21, 2007, that may have been an eastern indigo snake. While no gopher tortoise burrows have been observed on the project site, armadillo burrows are frequently observed along canal banks and may provide refuge for indigo snakes.

Following construction, very minimal habitat for the eastern indigo snake will be available in the project area. The interior slopes of the reservoir cells and the interior cell dam embankment will be lined with soil cement, thus making the majority of the reservoir site unsuitable habitat. A perimeter canal will make access to the reservoir difficult. In addition, the access road and other maintenance roads will mainly be all-weather roads consisting of a limerock base with gravel substrate surface. The entrance road and small portions of the perimeter access road and maintenance roads will be paved. The only portions of the C-43 West Reservoir project that may provide limited habitat for the eastern indigo snake are the embankments that will be constructed between the crest of the dam and the project boundary. These embankments will consist of overburden from the project area and maintained sod. Because these embankments will be regularly mowed, they will not provide highly desirable cover or habitat for the species. Therefore, the Corps has determined that the proposed project "may adversely affect" the eastern indigo snake due to the loss of 10,602 ac of potentially suitable habitat. The Service concurs with the Corps' determination.

Florida Panther

The proposed C-43 West Storage Reservoir project is within the Service's Panther Focus Area for the Florida panther (Figure 7) and provides habitat suitable for use for foraging and dispersal. The total construction footprint, including both wetlands and uplands, will be approximately 10,602 ac of which 10,492 ac are within the reservoir and 110 ac are within the access road parcel. In a January 10, 2007, letter, the Corps determined that the C-43 West Storage Reservoir project "may affect" the Florida panther and requested initiation of formal consultation. On January 24, 2007 and March 8, 2007, the Service requested the Corps to provide additional information on manatees, wood storks, snail kites, and panthers. The District provided that information in their March 22, 2007, letter received by the Service on March 26, 2007.

The overall purpose of the CERP is to restore the Everglades ecosystem and species assemblages. Implementation of CERP is expected to provide large-scale, long-term benefits to

the ecosystem and listed species, though individual actions may result in smaller-scale or short-term adverse effects to one or more listed species. Because CERP is a regional ecosystem restoration program with one project sponsor (*i.e.* the District), the Corps and the Service have agreed to evaluate the effects of the complex, long-term, inter-dependent nature of CERP on listed species using a programmatic or regional approach. Thus, the resultant positive (*e.g.*, habitat acquisition and restoration) and negative (*e.g.*, construction-related habitat loss) effects to the panther in south Florida will be evaluated by bands of projects identified in the Master Implementation Sequencing Plan (MISP). Band 1 consists of projects that will be constructed by 2010 including the state-expedited Acceler8 Projects of which the C-43 West Reservoir project is a component. Figure 8 shows the location of these Band 1 projects in relation to the various panther zones in south Florida. In addition to evaluating the effects of the proposed C-43 West Reservoir project in the Biological Opinion, the Service also aggregated the Band1/Acceler8 projects and evaluated them as a group using the method described in Analyses for the Effects of the Action to assess the overall effects of this phase of CERP implementation on Florida panthers and habitat used by the Florida panther. The Service will also assess other Band 1/Acceler8 projects individually in subsequent Biological Opinions as the Corps and District finalize plans for implementation and request consultation on those projects.

The proposed C-43 West Storage Reservoir project is one of several Band1/Acceler8 projects that fall within the Florida Panther Focus Area (Figure 8). The reservoir project will result in the direct loss of 10,602 ac of habitat the panther may use, of which 267 ac were already compensated for under formal consultation for the Test Cell project (DA Permit 2005-6598 [IP-TKW]). The remaining habitat loss (*i.e.*, 10,335 ac) provides approximately 19,438 panther habitat units (PHUs) (see definition in the Effects of the Action) with a recommended compensation of 46,933 PHUs. The Band 1/Acceler8 projects located within the core panther conservation area collectively provide compensation for the loss of 10,602 ac of panther foraging and dispersal habitat on the C-43 West Storage Reservoir project site through the off-site acquisition and restoration of approximately 100,492 ac of habitat used by the panther (Figure 8) (Analyses for Effects of the Action). CERP's ecosystem approach to habitat restoration and preservation will provide long-term net benefits to the Florida panther.

The Use of Best Scientific and Commercial Information by the Service

The Service uses the most current and up-to-date scientific and commercial information available. The nature of the scientific process dictates that information is constantly changing and improving as new studies are completed. The scientific method is an iterative process that builds on previous information. As the Service becomes aware of new information, we will ensure it is fully considered in our decisions, evaluations, reviews, and analyses as it relates to the base of scientific knowledge and any publications cited in our documents.

Specifically, there is one such document cited in this Biological Opinion the Service acknowledges has been affected in its cited form by new scientific information. The Service has taken these new sources of information into account when using this document to help guide our analysis and decisions. This document is the South Florida Multi-Species Recovery Plan (MSRP) of 1999 (Service 1999). In addition, the Service has examined Kautz et al. (2006) for its

scientific validity, specifically with regards to comments and recommendations by other reviewers.

South Florida Multi-Species Recovery Plan

The MSRP was designed to be a living document and it was designed to be flexible to accommodate the change identified through ongoing and planned research and would be compatible with adaptive management strategies. These principals are set forth in both the transmittal letter from the Secretary of the Interior and in the document itself. As predicted, this is what indeed occurred in the intervening years since the MSRP was published. The Service uses the MSRP in the context it still presents useful information when taken in conjunction with all the new scientific information developed subsequent to its publication.

Kautz et al. (2006)

The Florida Panther Subteam was charged with developing a landscape-level strategy for the conservation of the Florida panther population in south Florida. The Subteam produced the draft Landscape Conservation Strategy for the Florida Panther in South Florida in December 2002 and provided it to the Service. Upon receipt, the Service began to use the information in the draft Landscape Conservation Strategy in its decision making processes and documents since it was part of the best scientific information available to the Service at the time. Since then some portions of the science and findings in the draft Landscape Conservation Strategy have been challenged. Many, but not all, of the Subteam members have refined the methodology, further analyzed the data, and better defined the results of the Landscape Conservation Strategy into the publication, referred to here as Kautz et al. (2006). Therefore, Kautz et al. (2006) and the analyses contained therein, along with all other best scientific and commercial data available, is referred to in this document and will be used in our decision making process until or unless new information suggests revisions are necessary.

Consultation History

The Service received a Phase I and II environmental Assessment Report for the Berry Labelle-Congen Grove dated December 6, 1999.

In response to the Corps' February 25, 2002, request, the Service provided information on fish and wildlife resources included federally-listed species that may be within the proposed reservoir locations or affected by the activities of the C-43Basin Storage Reservoir in our April 11, 2002, Planning Aid Letter (PAL). The site-selection sub-team used this information guide the site selection process by focusing on suitable reservoir locations that would minimize impacts to fish and wildlife resources.

On March 20, 2003, site selection sub-team led by the Service, presented new updated preliminary site locations for potential reservoirs in the Caloosahatchee Basin overlayed on various GIS cover type maps.

On March 31, 2003, the Service met with Jim Beever (FWC) and Sandy Scheda (SEA) to review the new reservoir location maps and to apply the matrix to the revised map. Two sites dropped out due to conflicts with panther habitat, specifically, the Caloosahatchee escoscape.

The Service assisted the Corps by providing listed species maps within Caloosahatchee Basin for use in the reservoir siting process and explained these maps at an Environmental Stakeholders meeting on April 30, 2003 and public meeting on May 1, 2003.

In a letter dated May 19, 2003, the Service provided comments on the March 3, 2003, Phase I and II Environmental Site Assessment for the Griffin Brothers property. In that letter, the Service recommended further delineation of pentachlorophenol (PCP) in the canal in the vicinity of the S5 sample location.

The Service provided scoping comments under the National Environmental Policy Act (NEPA) for development of the Draft Environmental Impact Statement for the C-43 Basin Storage Reservoir Project, including information on federally-listed species that may be affected by the proposed project.

The Service provided information on listed species distributions to Alternative Selection sub-team on June 13 and June 26 to refine the list of potential reservoir locations in the Caloosahatchee Basin.

On July 14, 2003, the Service provided comments on the March 25, 2003, Phase I and II Environmental Site Assessment for the Winthrop Citrus Investors property (Winthrop property). In that letter, the Service recommended delineation of aldrin contamination.

The Service provided additional information on direct and indirect impacts to significant fish and wildlife resources in the project area in an August 13, 2003, PAL. That letter addressed wetland and upland habitats of significant importance, federally-listed species, and potential contaminant issues.

On March 31, 2004, the Service received a proposal for the Phase I and II Environmental Site Assessment for the Brian Paul Citrus Grove. The Service requested that zinc be added to list of metals analyzed via an April 8, 2004, email.

Service, Corps, and District staff conducted wetland assessments (Wetland Rapid Assessment Procedure and Uniform Mitigation Assessment Method) of Berry Groves and other potential reservoir sites in the Caloosahatchee River Basin. Ground surveys were conducted on June 8, 9, and 10, 2004, followed by aerial surveys on June 14 and 15, 2004.

Service, Corps, and District staff completed ground and aerial wetland assessment (Wetland Rapid Assessment Procedure and Uniform Mitigation Assessment Method) at Berry Groves July 13, 14, and 15, 2004.

The Service reviewed additional information provided by Environmental Consulting and Technology, Incorporated, (ECT) regarding aldrin contamination on the Winthrop property and agreed in a July 1, 2004, letter, that no further aldrin delineation was necessary.

Service staff met with SFWMD, FWC, and Scheda Ecological Associates on July 20, 2004, to discuss the boundary change for the Berry Groves reservoir. Due to the change in the project boundary, additional consultation on potential project impacts to federally-listed species, including the Florida panther, Audubon's crested caracara, Everglades snail kite, wood stork, and Florida grasshopper sparrow, will be necessary. The southern boundary was expanded to include Duda property in the southwest and southeast corners. The southeast corner contains pine flatwoods, cypress slough, saw palmetto, and lightly wooded pasture that was previously farmed. That area has also been identified as Primary and Secondary Zones for the panther.

Additional information on PCP contamination on the Griffin Brothers property was provided by the District via an August 11, 2004, letter, prepared by ECT. Based on that information, the Service agreed no further delineation of PCP was needed in an October 13, 2004, letter.

On August 17, 2004, the Service received the Phase I and II Environmental Site Assessment report for the Bryan Paul Citrus Grove. In our September 20, 2004, letter, the Service requested further evaluation and remediation for Chlordane. Additional information regarding our letter was provided by Tetra Tech on December 22, 2004.

On December 1, 2004, ECT recommended further delineation of chlordane on the Bryan Paul Citrus Grove in their Screening Level Ecological Risk Assessment for that site.

The Service reviewed and provided comments via a January 25, 2005, email on the November 17, 2004, proposal for the Phase I and II Environmental Site Assessment for the Bob Paul Citrus Grove. The Service requested complete sampling in the former row crop area.

On February 3, 2005, Service staff met with FWC staff to discuss fish and wildlife resource concerns associated with the C-43 West Reservoir location and the remaining potential alternatives.

On March 22, 2005, the Service held an interagency meeting at the District office in Fort Myers to discuss potential project impacts on federally and State-listed species. Representatives from the District, Corps, FWC, and the Service's Vero Beach office were in attendance. The discussion focused primarily on the accelerated C-43 West Reservoir component but also applies to the selected alternative plan that will be addressed in the Corps' Project Implementation Report.

On March 29, 2005, Service staff provided a PAL recommending that the Corps and the District design the C-43 West Reservoir to provide water quality benefits by reducing nutrient loads in accordance with CERP Guidance Memorandum Number-Revision 023.01. That letter also included information regarding federally-listed species in the Caloosahatchee estuary.

On May 5, 2005, the Service received the April 29, 2005, draft scope of work for the C-43 West Storage Reservoir Temporary Test (Embankment) Cells from the District.

On May 26, 2005, Service staff met with the Corps, District, SCI, FWC, and SEA to discuss potential adverse effects to threatened and endangered species that may occur as a result of the C-43 West Reservoir Project or the Test Cell Project. The meeting focused on: 1) the latest method for assessing habitat compensation recommended when adverse project effects to habitat used by the Florida panther cannot be avoided or when adverse effects have been minimized but loss will still occur; and 2) the Test Cell Project design, 404 permit needs, and listed species consultation.

On June 27, 2005, the Corps conducted an interagency site visit to delineate wetland boundaries and assess current conditions within the Test Cell Project footprint. Service, District, SCI, and SEA staff participated in the site visit.

On July 1, 2005, the Service provided comments on the May 27, 2005, Phase I and II Environmental Site Assessment for the Bob Paul Citrus Grove. In that letter, the Service recommended that the District consult with DEP regarding on-site burial of contaminated soil.

On July 25, 2005, the Corps issued a Public Notice for permit application SAJ-2005-5958 (IP-TKW) indicating the District applied for a permit to construct two temporary test cells within the proposed 11,000-acre footprint of the C-43 West Storage Reservoir. The proposed Test Cell Project would dredge, fill, or flood 4.5 acres of jurisdictional wetlands and 24.5 acres of "other surface waters." To mitigate for wetland impacts, the applicant has proposed to include wetland features in the C-43 West Reservoir design and/or other Acceler8 projects. They also requested the Corps to considered downstream environmental benefits that will result from construction and operation of the C-43 West Storage Reservoir during their project evaluation.

On July 28, 2005, Service staff met with the District, Corps, EPA, FDACS, and SEA staff to review and finalize WRAP scores for the wetlands occurring within the Test Cell Project footprint.

On July 29, 2005, the Service received the draft Biological Assessment prepared by SEA for the Test Cell Project via email.

On August 5, 2005, the Service emailed informal comments on the draft Biological Assessment to the District.

On August 19, 2005, the Corps submitted the final Biological Assessment for the Test Cell Project to the Service with a letter of the same date. In the that letter, the Corps determined that the Test Cell Project will have "no effect" on the West Indian manatee, and "may affect, but is not likely to adversely affect" the bald eagle, Audubon's crested caracara, Everglade snail kite, eastern indigo snake, and wood stork. The Corps also provided a "may adversely affect" determination for the endangered Florida panther and requested the Service initiate formal consultation.

On August 29, 2005, the Service telephoned and emailed the Corps requesting additional information necessary to evaluate project effects to the Florida panther.

Service attended a November 9, 2005, interagency meeting to discuss preliminary designs to incorporate littoral zones for fish and wildlife habitat adjacent to the seepage canal bordering the C-43 West Reservoir. Designs will be further developed by SEA and distributed to the group for review. The extent of wetland acreage is much smaller than originally discussed (*i.e.*, total is less than 30 acres) and will be spaced every 500 feet between areas reserved for potential ASR wells. The littoral zones will be used as compensation for the loss of wood stork foraging habitat as result of the Test Cell project.

On November 9, 2005, the District provided the additional information necessary to evaluate project effects to the panther to the Service, including information on living radio-collared panthers with home ranges overlapping the project area, locations of known panther vehicle collisions within the project area, and surrounding land use and permitted projects in the Test Cell Project area.

On November 18, 2005, the Service requested the District to provide information on state and local land acquisitions in the Test Cell project action area from 1999 to present via email.

The District provided the information on state and local land acquisitions in the project area on November 18, 2005, via email.

On November 30, 2005, the Service completed formal and informal consultation on the Test Cell project via a letter and accompanying Biological Opinion addressing project effects on the Florida panther.

The Service received a December 28, 2005, Closure Assessment Report on contaminants for the Griffin Brothers property.

On January 3, 2006, the Service email to Corps and District regarding follow up on the Test Cell project 404 permit and T&E educational materials; caracara and indigo snake surveys for the full reservoir footprint; and the design, location, and acres of littoral zones and other fish and wildlife features.

The Service met with the SFWMD and the Corps on the February 6, 2006, to review the March 28, 2005, draft Fish and Wildlife Recommendations for Comprehensive Everglades Restoration Plan (CERP) Stormwater Treatment Area and Reservoir Operation and Design developed by the Service and the Fish and Wildlife Commission and discuss incorporating those recommendations in the design of the 10,000-acre C-43 West Reservoir. The District will not incorporate any of those recommendations in the reservoir design that might encourage birds to nest in the vicinity. Additionally, the interior slopes of the reservoir levees will be lined with a concrete soil mixture to prevent erosion, reduce seepage, and increase levee stability. The current reservoir design does include construction of 9 to 28 acres of shallow wetland habitat adjacent to the seepage canal that

will be constructed 80 to 100 feet from the outside perimeter of the reservoir. Any existing canals and new borrow pits/canals dredged during levee construction will not be filled to provide deep water habitat for fish during periods of drought or when the reservoir is drawn down.

The Service received an informal summary of the first caracara surveys conducted by SEA in compliance with our survey protocol on March 6, 2006, via email and a formal Memorandum summarizing that first survey on March 22, 2006.

The Service received a formal Memorandum summarizing the second caracara surveys conducted by SEA in compliance with our survey protocol via email on March 24, 2006.

On March 30, 2006, Service staff participated in the third caracara surveys conducted by SEA and received a Memorandum summarizing those surveys via email on April 10, 2006.

The Service received the March 31, 2006, Work Plan for Additional soil Investigations to delineate chlordane contamination on the Bryan Paul Citrus Grove. The Service concurred with the work plan via an April 4, 2006, email.

By letter dated April 18, 2006, the Service provided comments on the October 13, 2003, Ecological Risk Assessment for the Berry Labelle-Congen Grove. In that letter, the Service recommended remediation of areas known to be contaminated with copper and that additional soil sampling for copper be conducted.

On April 24 and 25, 2006, the Service attended the C-43 West Reservoir Critical Criteria Meeting in Labelle, Florida. On April 25, 2006, a breakout session was held to review information needs for upcoming permit applications, including information on federally-listed species. Reservoir fill rates protective of indigo snakes recommended for other CERP projects (*i.e.*, C-44) were discussed. The District indicated that those rates were acceptable and that they probably couldn't fill the reservoir faster anyway.

On April 26, 2006 and May 15, 2005, the Service provided information to the Corps and District via email, on the need for and appropriate methodology to conduct panther prey surveys to adequately address project impacts and associated habitat loss to the Florida panther.

The Service held and internal meeting on May 24, 2006, in Vero Beach, Florida, on Eastern Indigo Snake section 7 consultation issues.

Service staff reviewed and provided comments on Acceler8's preliminary design for the C-43 West Reservoir Design. Comments and recommendations included: development of 3 sets of operating criteria for the reservoir based on current conditions and predicted long-term climatological conditions such as drought, normal, and above average rainfall years; ensure manatee protection measures will be incorporated in design of all water control structures where necessary; ensure inclusion of Indigo snake protection measures in construction contracts; potential decreased surface water elevations in wetlands southwest of the project area in primary panther habitat indicated by preliminary model results need to be evaluated in more detail; and to

ensure that current proposed recreation plans for the project area do not conflict with project goals.

The Service reviewed the July 21, 2006, Additional Soil Assessment Report for the Bryan Paul Citrus Grove. Chlordane contamination was identified to be within a 20-acre area. The Service concurred with the 18ug/kg target clean-up level for chlordane in our August 9, 2006, letter.

The Service provided comments on the Additional Soil Investigations, Berry Labelle-Congen Groves report submitted to the District by URS Corporation by letter dated July 26, 2006. In that letter, the Service recommended that further sampling be conducted to accurately delineate the spatial extent of copper contamination and that soil remediation be considered for grids 56 and 145.

On August 14, 2006, Service staff participated in an interagency (Corps, District, Service, and EPA) helicopter survey of the Caloosahatchee River basin and estuary to assess basin-wide project benefits for the Corps' mitigation ledger.

The Service provided comments on the July 20, 2006, document titled "Additional U.S. Fish and Wildlife Service Soil Investigations, Berry Labelle-Congen Groves" in a September 14, 2006, letter. In that letter, the Service concurred that copper contamination was adequately delineated and that grids 56, 58, 124, 125, 134, 135, and 143 require remediation.

On October 30, 2006, the Service responded to the Response to Corps' October 27, 2006 email regarding section 7 consultation process and keeping the Corps' C-43 West Reservoir Project Implementation Report and the District's Acceler8 C-43 West Storage Reservoir project on the same timeline with one consultation. The Service reiterated that formal consultation would be needed for three species, the caracara, indigo snake, and panther, and requested advanced review of the Biological Assessment before the Corps requested formal consultation.

The Service reviewed and provided comments to the Corps on the Draft Biological Assessment for the C-43 West Storage Reservoir Project, Hendry County, Florida on November 9, 2006.

On November 10, 2006, the Corps submitted the Service's and the Corps' comments submitted to the District.

The Service received combined Department of Army and state of Florida Environmental Resource Permit Application for C-43 project on November 20, 2006.

On December 1 and 7, 2006, the Corps and Service discussed the timing of the initial tree clearing on the project site via email. The District has proposed to clear existing citrus trees onsite after completion of section 7 consultation but prior to 404 permit issuance. They have proposed to avoid wetlands during the initial clearing. We also discussed project effects on snail kites as a result of copper contamination. If no additional copper has been applied to the project area and copper remediation occurs on the grids identified in our September 14, 2006, letter, then the project is probably not likely to adversely affect snail kites.

Via January 10, 2007, email correspondence, the Service reviewed the Corps' preliminary C-43 project effects determinations for listed species and identified information needed to complete consultation on manatees, including effects of reservoir operations.

The Service received a letter and a Biological Assessment from the Corps of Engineers on January 12, 2007, requesting initiation of formal consultation on the C-43 West Reservoir Project.

Service staff reviewed the information provided and requested additional information pertaining to consultation for wood storks and snail kites during a January 24, 2007, telephone conversation and by email on January 30, 2007.

The Service met with the Corps of Engineers and South Florida Water Management District on February 7, 2007, to discuss outstanding threatened and endangered species issues and additional information needed for consultation on wood storks, snail kites, caracara, and manatees; and information regarding potential project impacts to upstream wetlands in the vicinity of the Spirit-or-the-Wild Wildlife Management Area and the Okaloachoochee Slough State Forest and Wildlife Management Area.

Service staff conducted two site visits, February 7 and 8, 2007, to determine if the caracara territory and nest site off State Road 80 is active this year. A pair of caracaras were observed perched near the nest tree used last year. Although the territory is occupied, no nesting activity was observed.

The Service participated in the February 21, 2007, interagency site visit to evaluate wetlands and potential wood stork foraging habitat within the C-43 West Reservoir footprint.

On February 23, 2003, the Corps inquired through email correspondence if changes in the Service's Florida panther consultation area would change consultation needs for the C-43 West Reservoir project. The Service confirmed that compensation for project effects to panther habitat would still be needed.

Information presented during a March 6, 2007, C-43 West Reservoir Project Delivery Team meeting in LaBelle, Florida, included an access road parcel that was not included in the Biological Assessment or consultation initiation package. Through email correspondence on March 8, 2007, the Service requested that more information on that parcel be provided including size, preliminary site plan, and potential habitat alterations. The Service also requested more information on the pump stations and manatee excluders.

The Service received additional information requested from the Corps in a March 26, 2007, letter. The information provided included information on wood stork foraging habitat, copper applications and remediation in the project footprint, wetland impacts, manatees, and additional impacts to panther and caracara habitat associated with the access road parcel. Upon receipt of this information, the Service initiated formal consultation under section 7 of the Act.

Service staff met internally with our caracara species lead on April 14, 2007, to discuss C-43 West Storage Reservoir impacts to caracara habitat, estimating take, potential compensation for habitat loss and monitoring needs.

The Service met with the Corps and District on May 15, 2007, to discuss outstanding threatened and endangered species issues in order to complete informal and formal consultation on the effects of the C-43 project. Outstanding issues included incorporation of CERP Thermal Guidelines in Manatee-Accessible Waters in the project monitoring plan, compensation for impacts to wood stork foraging habitat, and compensation for impacts to crested caracara habitat. The Service attended the May 17, 2007, public meeting in LaBelle, Florida, on the C-43 West Storage reservoir project. The public asked questions regarding the status of endangered species consultation for the project.

The Service received and email on May 18, 2007, from the Corps committing to a monitoring and research project as compensation for impacts to caracara resulting from the proposed reservoir, and committing to using the Corps existing volunteer manatee observer program for the Okeechobee Waterway for manatee observations for the C-43 reservoir project as discussed during the May 15, 2007, meeting.

On May 22, 2007, the Service met with the Superintendent of Duda Farms and their consultant to confirm the location of the caracara nest on Duda property southeast of the reservoir.

In response to an information request made by telephone, the Service received additional information on the trash rake systems that serve as manatee excluders at the pump stations via a May 23, 2007, email. In response to that request, the Service also received information on the elevations of the Townsend Canal and the reservoir intake canal via an email dated May 24, 2007.

The Service sent the draft manatee section of the concurrence letter for the proposed project to the Corps, District, FWC, and other Service staff to review on May 24, 2007.

The Service received information on the construction schedule for the proposed project from the District via email on May 24, 2007.

On May 30, 2007, the Service received comments on the draft manatee section of the concurrence letter for the proposed project from the Corps and District via separate emails. The District did not agree with some of the project modifications to prevent harm to the manatee associated with the CERP Thermal Guidelines in Manatee-Accessible Waters.

The Service provided a map of the confirmed caracara nest location on private property southeast of the project area to the District via email on June 1, 2007.

On June 4, 2007, the Service requested updated habitat acres by Florida Land Use, Cover and Forms Classification System (FLUCCS) within the C-43 reservoir footprint. The Public Notice

identified a total of 10,492 acres within the reservoir footprint and the BA identified 10,361 acres within the reservoir footprint.

The Service held a conference call with the Corps and District on June 5, 2007, to discuss the outstanding issue regarding incorporation of CERP Thermal Guidelines in Manatee-Accessible Waters in the project design and monitoring plan. Both operational and structural modifications to the reservoir project were discussed.

The Service received the Intermediate Design Report (*i.e*, 60 percent design) via overnight mail on June 7, 2007, and the associated design plans on June 8, 2007.

On June 7, 2007, another interagency conference call was held to discus the thermal guidelines for manatees. The District obtained temperature data for the Townsend Canal and the Caloosahatchee River in the vicinity of the Townsend Canal from the Florida Department of Environmental Protection and provided that data as well as temperature data from the Test Cell project to the participants on the conference call.

On June 7, 2007, the Service and FWC further developed monitoring protocol to define what constitutes a shift in manatee distribution as a result of warm-water discharges into the Townsend Canal.

Through email correspondence on June 7, 2007, the Corps and the Service agreed to further discuss ways to prevent potential cold stress to manatees as a result of reservoir releases during the winter including replacing the weir at the Townsend and Caloosahatchee River. Two conference calls were held on June 13 and 14, 2007, to discuss what the potential impacts to manatees are related to thermal stress and potential barriers or other solutions that could prevent the situation from occurring.

On June 8, 2007, the Service received additional temperature data from the District for Test Cell 2 which was not included in the data provided on June 7, 2007, and the raw data provided to the District from DEP. DEP provided shapefiles of the water quality station locations via email.

On June 11, 2007, the Service received updated habitat acreages by FLUCCS code within the reservoir footprint and data on state acquisitions with 25 miles of the project footprint.

On June 11, 2007, the Service received temperature data for the Townsend Canal and Caloosahatchee River from the DEP. They searched the STORET database and the IWR database. The two datasets were essentially the same.

The Corps, EPA and the Service participated in a teleconference on June 12, 2007, to finalize the Uniform Mitigation Assessment Method Scores for the Caloosahatchee River and estuary and the tapegrass beds in the upper Caloosahatchee estuary that will be used for mitigation for on-site wetland impacts and compensation for the loss of on-site wood stork foraging habitat.

The Service provided bar graphs of temperature data and monthly flow comparison data developed by the District, and a spread sheet of temperature data provided by DEP and a map of the station locations to the Corps and FWC for review for the June 13 and 14, 2007, teleconferences referenced above.

The Service confirmed the reservoir fill rate that would reduce take of indigo snakes and reduce negative impacts to other wildlife species via email on June 14 and 15, 2007.

On June 15, 2007, Service contaminants staff reiterated that the copper remediation of all impacted grids in the reservoir footprint to less than 85 ppm will be protective of snail kites and other species, including the indigo snake, via email.

On June 20, 2007, the Service, Corps and District held a conference call to discuss a timeline for resolving the outstanding manatee issues. The Corps and District are researching appropriate weirs or gates that would serve as a barrier to prevent manatee access to the Townsend Canal while still achieving desired flow rates through the canal. The Corps requested more time to research barriers and develop cost estimates for construction and operation and maintenance of a structure. They requested we reach a resolution by August 1, 2007.

On June 20, 2007, the Service requested that the District provide updated habitat acreages by FLUCCS code within the reservoir footprint that was consistent with the jurisdictional wetland data and 10,492-acre reservoir footprint referenced in the Corps' Public Notice. That data was provided via email on June 20, 2007.

On June 21, 2007, the Service requested that the District provide information on cumulative panther habitat impacts (*i.e.,* Developments of Regional Impact, Planned Unit Developments, and South Florida Water Management District Environmental Resource Permits) in a concise manner that could easily be interpreted and used for the analyses in the Biological Opinion and that is consistent with our standard request for additional information for panther consultations.

On June 22, 2007, the Service provided a draft Biological Opinion to the Corps and the District for review.

The district provided information on a potential manatee barrier for the Townsend Canal and the associated cost to the Service and the Corps on June 25, 2007.

On July 3, 2007, the Service received comments from the District on the June 22, 2007, draft Biological Opinion. The District identified concerns regarding the manatee thermal guidelines; the recommended reservoir filling rates for the initial fill and subsequent rehydration events to protect indigo snakes; and the timing, duration, and site access for the caracara research and monitoring plan.

On July 10, 2007, the Service participated in an interagency conference call to discuss construction of a manatee barrier at the confluence of the Townsend canal and the Caloosahatchee River and temperature and manatee monitoring needs.

On July 10, 2007, the Service received information from the District on proposed volumetric reservoir filling rates instead of manually monitoring the depth as the reservoir is filled.

On July 11, 2007, the Service held an internal conference on manatee monitoring needs and the Service and the Corps agreed to a manatee monitoring plan to address the CERP manatee thermal guidelines.

On July 12, 2007, the Service received the revised data for the cumulative effects analyses for the Florida panther.

On July 13, 2007, the Service held an interagency conference call to discuss the District's concerns: the District and Corps agreed to install a barrier to prevent manatee access to the Townsend canal during the winter period; modifications to the temperature monitoring and manatee observation plan were discussed; the volumetric curves and reservoir fill rates were discussed, including the length of time to fill the reservoir at the ½ inch per day rate for the first 6 inches; and the site access, timing, and duration of caracara research and monitoring plan were discussed.

On July 16, 2007, the Service held an internal conference on indigo snakes and the volumetric fill data provided by the District on July 10, 2007.

On July 17, 2007, the Service requested additional information on filling the reservoir at 3 inches and 6 inches per day including the incremental fill times and plots of areas flooded at each interval.

On July 19, 2007, the District provided the incremental fill times and plots of the area flooded at each interval for a fill rate of 1 foot per day. The 1 foot per day was used due to the time needed to generate the plots at the slower pumping rates. Based on this information, the Service recommended an initial fill rate of 6 inches per day and a rehydration rate of 1 foot per day. The Service also recommended inclusion of an indigo snake monitoring plan to determine the effect of rehydration on snakes and the extent of their use of the reservoir during drawdown events.

On July 20, 2007, the service participated in an interagency teleconference to confirm acceptance of the fill rates and monitoring recommendations for indigo snakes.

The Service has reviewed all information received pertinent to the Florida panther, the crested caracara, and the indigo snake for the C-43 West Storage Reservoir project and concurs with the Corps' determination that this proposed project "may affect and is likely to adversely affect" the Florida panther, the crested caracara, and the indigo snake. As of March 26, 2007, the Service received all information necessary for initiation of formal consultation on the Florida panther, the crested caracara, and the indigo snake for this project as required in the regulations governing interagency consultations (50 CFR § 402.14). The Service is providing this Biological Opinion in conclusion of formal consultation.

BIOLOGICAL OPINION

DESCRIPTION OF PROPOSED ACTION

Proposed Action

The C-43 West Storage Reservoir project is a component of CERP and is included in the Band 1/Acceler8 Projects. The overall purpose of the CERP is to restore the Everglades ecosystem and species assemblages. Together, implementation of the CERP and Acceler8 is expected to provide large-scale, long-term benefits to the ecosystem and listed species, though individual actions may result in smaller-scale or short-term adverse effects to one or more listed species. The C-43 West Storage Reservoir project is located in portions of Sections 31 through 36, Township 43 South, Range 28 East; Sections 6 and 31, Township 43 South, Range 29 East; and Sections 1 through 12, Township 44 South, Range 28 East, Hendry County, Florida (Figure 1).

According to the DPIR/EIS and PN, the Corps and District propose to construct an approximately 10,492-ac above-ground reservoir surrounded by a perimeter embankment and canal. Reservoir access and recreational facilities will be located within an adjacent 110-ac access road parcel (Figure 1). The proposed project is designed to pump water from the Caloosahatchee River into the proposed reservoir via the Townsend Canal and capture basin runoff from the Townsend Canal, store water in the reservoir to reduce damaging high freshwater flows to the Caloosahatchee Estuary, and discharge water back to the Caloosahatchee River via the Townsend Canal to augment low flow events during the dry season and maintain a minimum flow of 450 cfs at S-79. The reservoir will consist of two cells capable of storing a total of 170,000 acre-feet of water at an approximate depth of 20 ft. Major features of the proposed project are described in Section 7 and Appendix A of the DPIR and include (Figure 9):

- 16.3 miles of external (dam) embankments varying in height between 27 and 38 ft above the existing grade;
- Soil-Bentonite slurry walls within and beneath the external embankments;
- 2.8 miles of internal (dam) embankment separating the two cells with an approximate height of 31 ft above existing grade;
- An inflow pump station (C43PS-1) consisting of four diesel-powered pumps with a total pumping capacity of 1,500 cfs (i.e., two 500 cfs pumps and two 250 cfs pumps);
- 14.7 miles of perimeter canal;
- A perimeter canal pump station consisting of electric-powered pumps with a total pumping capacity of 195 cfs (i.e., three pumps of 65 cfs);
- Numerous spillways, culverts, and perimeter canal structures; an internal cell balancing structure; and outlet structures; and
- Two discharge structures (C43S-1 and C43S-8) each with a discharge capacity of 500 cfs.

Water control structures C43S-16, C43S-17, C43S-18, and C43S-19 were included in the DPIR but have since been removed from the C-43 West Storage Reservoir project and are not included in the District's Corps permit application.

The C-43 West Storage Reservoir project site contains a total of 10,602 ac, including the reservoir footprint and access road parcel, currently under active citrus production. Land use and cover consists primarily of agricultural land and associated roads and other urban lands (9,540.7 ac). Jurisdictional wetlands and waters of the United States (US) cover 1,061.3 ac of the project site and include 934.6 ac of man-made agricultural ditches and canals used for irrigation and drainage conveyances for the citrus operations and 126.7 ac of jurisdictional wetlands (Figure 4).

Approximately 267 ac within the C-43 West Storage Reservoir project area were previously impacted during construction of the C-43 West Reservoir Test Cell project (Test Cell project), including 29 ac of jurisdictional wetlands and waters of the US (Figure 4). The Test Cell project was constructed to evaluate the on-site seepage potential and effectiveness of seepage control measures, the suitability of on-site materials for embankment construction and slope protection, and the effects of water residence time and seepage on water quality. That project included two 500-foot by 500-foot test cells with offset seepage canals, a borrow area, settling ponds, and staging areas and was authorized under DA Permit number 2005-6598 (IP-TKW) issued December 6, 2005. Impacted jurisdictional areas included 1.9 ac of excavated open-water, 4.5 ac of wet prairie, and 26.0 ac of tertiary, agricultural drainage canals.

The Service understands that the Corps will account for the unavoidable adverse impacts to wetlands and other aquatic resources resulting from both he C-43 West Storage Reservoir project and Test Cell project in an Acceler8 system-wide mitigation ledger. As described in the Corps' PN, that ledger includes accounting for system-wide interdependencies and watershed benefits of the District's Acceler8 projects (*i.e.*, Band 1 projects) in satisfying the regulatory mitigation requirements for wetland and other aquatic resource impacts resulting from construction of individual Acceler8 projects. The Corps is using the UMAM to assess the function and value of aquatic resources adversely impacted by construction of the C-43 West Storage Reservoir and Test Cell projects and to assess the anticipated environmental lift to the Caloosahatchee estuary as a result of implementation of the proposed project and remaining Acceler8 projects.

Although not considered as compensatory mitigation, the proposed C-43 West Storage Reservoir project incorporates features that will enhance fish and wildlife habitat. The existing agricultural canals and interior borrow areas excavated for fill material will provide deep-water refugia for fish and other aquatic organisms within the reservoir during drawdown conditions. The exterior face of the external embankments will be planted and maintained as grass. However, the interior face of the external embankments will be covered in concrete to reduce erosion potential and will not possess a vegetated littoral area. The perimeter canal will include approximately 109 ac of littoral zones to provide foraging and nursery habitat for aquatic fauna (*e.g.*, wading birds, fish, herpetofauna, etc.). Also, portions of the test cell embankments will be left in places to provide roosting habitat for birds, turtles, and other fauna when the reservoir is full.

The C-43 West Storage Reservoir will result in the direct loss of 10,602 ac of habitat suitable for foraging and dispersal by the Florida panther (see discussion under Wildlife Assessment), of which 267 ac were already compensated for under formal consultation for the Test Cell project (DA Permit 2005-6598 [IP-TKW]). The remaining habitat loss (*i.e.*, 10,335 ac) represents

19,438 PHUs with a recommended compensation of 46,933 PHUs (see discussion under Habitat Assessment Methodology). The project overlaps with the Service's Panther Focus Area (Figure 7) for the Florida panther and contains both Florida panther Primary and Secondary habitat (Kautz et al. 2006) (Figure 10).

The District will provide compensation for loss of the remaining 10,335 ac of low quality habitat used by the panther through the acquisition and restoration of approximately 59,294 ac of habitat used by the panther in the Primary Zone and approximately 41,198 ac in the Other Zone through the implementation of Acceler8 Projects under CERP. This gain equates to over 548,000 functional units of habitat used by the panther (see definition in the Effects of the Action). The Acceler8 Projects proposed for compensation will consist of bottomland hardwoods, freshwater marshes, hardwood swamps, cypress swamps, and other wetland habitats. The majority of compensation areas are also surrounded by other Primary Zone habitat used by the panther and protected conservation lands that are used by the Florida panther (Figure 8).

Action Area

The CERP implementation area in South Florida overlaps the Service's Panther Focus Area for the Florida panther (Figure 8). The Panther Focus Area includes lands in Charlotte, Glades, Hendry, Lee, Collier, Palm Beach, Broward, Miami-Dade, and Monroe Counties, as well as the southern portion of Highlands County (Figure 8). Developed urban coastal areas in eastern Palm Beach, Broward, and Miami-Dade Counties, and in western Charlotte, Lee, and Collier Counties were excluded because they contain little or no panther habitat and it is unlikely that panthers would use such areas.

Movements of Florida panthers are much larger than the project site and, therefore, the Service's action area is larger than the proposed action area identified by the Corps' public notice. The action area, which is a subset of the current panther range, includes those lands where the Service believes panthers may experience direct and indirect effects from the proposed development. Maehr et al. (1990a) monitored five solitary panthers continuously for 130-hour periods seasonally from 1986 to 1989, rarely observing measurable shifts in location during the day, but nocturnal shifts in location exceeding 20.0 kilometers (km) (12.4 miles) were not unusual. Maehr et al. (2002a) in a later report documented a "mean maximum dispersal distance" of 68.1 km (42.3 miles) for subadult males and 20.3 km (12.6 miles) for subadult females. In the same report Maehr et al. (2002a) documented a "mean dispersal distance" of 37.3 km (23.1 miles) for subadult males. Comiskey et al. (2002) documented a "mean dispersal distance" for subadult male panthers as an average distance of 40.1 km (24.9 miles) from their natal range, which is similar to the dispersal distance referenced by Maehr et al. (2002a).

Therefore, for both direct and indirect effects, the Service defined the action area (Figure 11) as all lands within a 25-mile radius of the C-43 West Storage Reservoir project, which is slightly greater than the mean dispersal distance for subadult males. This action area does not include urban lands or lands west of I-75. This action area includes areas anticipated to sustain direct and indirect effects, such as roadways experiencing increased traffic, areas with increased human

disturbance (project area and periphery of project), and areas in which habitat fragmentation and intraspecific aggression may be felt.

The CERP planning area overlaps the action area defined above for this consultation, as well as the Service's Panther Focus Area for the Florida panther (Figure 8) and the area currently used by the panther, and therefore, the CERP implementation will affect the Florida panther and habitat used by the panther. Though the overall purpose of the CERP is to restore the Everglades ecosystem and species assemblages, not all projects will benefit Florida panthers or all federally listed species. Implementation of the suite of Band1/Acceler8 projects is, however, likely to provide direct and indirect beneficial effects to the natural ecosystems and native species communities in the Everglades landscape within the area currently used by the Florida panther resulting in a net positive balance for Florida panthers.

STATUS OF THE SPECIES AND CRITICAL HABITAT RANGEWIDE - Florida Panther

Status - Panther Biology and Ecology

The Florida panther is the last subspecies of *Puma* (also known as mountain lion, cougar, painter, or catamount) still surviving in the eastern United States. Historically occurring throughout the southeastern U.S. (Young and Goldman 1946), today the panther is restricted to less than 5 percent of its historic range in one breeding population of less than 100 animals located in south Florida.

When Europeans first came to this country, pumas roamed most all of North, Central, and South America. Early settlers attempted to eradicate pumas by every means possible. By 1899, it was believed that Florida panthers had been restricted to peninsular Florida (Bangs 1899). By the late 1920s to mid 1930s it was thought by many that the Florida panther had been completely eliminated (Tinsley 1970). In 1935, Dave Newell, a Florida sportsman, hired Vince and Ernest Lee, Arizona houndsmen, to hunt for panthers in Florida. They killed eight in the Big Cypress Swamp (Newell 1935). Every survey conducted since then has confirmed that a panther population occurs in southern Florida south of the Caloosahatchee River, and no survey since then has been able to confirm a panther population outside of southern Florida.

Attempts to eradicate panthers and a decline in panther prey, primarily white-tailed deer (*Odocoileus virginianus*), resulted in a panther population threatened with extinction. Prior to 1949, panthers could be killed in Florida at any time of the year. In 1950, the Florida Game and Freshwater Fish Commission (now the Florida Fish and Wildlife Conservation Commission [FWC]) declared the panther a regulated game species due to concerns over declining numbers. The FWC removed panthers from the game animal list in 1958 and gave them complete legal protection. On March 11, 1967, the Service listed the panther as endangered (32 FR 4001) throughout its historic range, and these animals received Federal protection under the passage of the Act in 1973. In addition, the Florida Panther Act (State Statute 372.671), a 1978 Florida State law, made killing a panther a felony. The Florida panther is listed as endangered by the States of Florida, Georgia, Louisiana, and Mississippi.

Since the panther was designated as an endangered species prior to enactment of the Act, there was no formal listing package identifying threats to the species as currently required by section 4(a)(1) of the Act. However, the technical and agency draft of the Florida Panther Recovery Plan, third revision, addressed the five factor threats analysis (Service 2006). No critical habitat has been designated for the panther.

Taxonomy

The Florida panther was first described by Charles B. Cory in 1896 as *Felis concolor floridana* (Cory 1896). The type specimen was collected in Sebastian, Florida. Bangs (1899), however, believed the Florida panther was restricted to peninsular Florida and could not intergrade with other *Felis* spp. Therefore, he assigned it full specific status and named it *Felis coryi* since *Felis floridana* had been used previously for a bobcat (*Lynx rufus*).

The taxonomic classification of the *Felis concolor* group was revised and described by Nelson and Goldman (1929) and Young and Goldman (1946). These authors differentiated 30 subspecies using geographic and morphometric (measurement of forms) criteria and reassigned the Florida panther to subspecific status as *Felis concolor coryi.* This designation also incorporated *F. arundivaga* which had been classified by Hollister (1911) from specimens collected in Louisiana into *F. c. coryi.* Nowell and Jackson (1996) reviewed the genus *Felis* and placed mountain lions, including the Florida panther, in the genus *Puma.*

Culver et al. (2000) examined genetic diversity within and among the described subspecies of *Puma concolor* using three groups of genetic markers and proposed a revision of the genus to include only six subspecies, one of which encompassed all puma in North America including the Florida panther. However, Culver et al. (2000) determined that the Florida panther was one of several smaller populations that had unique features, the number of polymorphic microsatellite loci and amount of variation were lower, and it was highly inbred (eight fixed loci). The degree to which the scientific community has accepted the results of Culver et al. (2000) and the proposed change in taxonomy is not resolved at this time. The Florida panther remains listed as a subspecies and continues to receive protection pursuant to the Act.

Species Description

An adult Florida panther is unspotted and typically rusty reddish-brown on the back, tawny on the sides, and pale gray underneath. There has never been a melanistic (black) puma documented in North America (Tinsley 1970, 1987). Adult males can reach a length of 7 ft (ft) (2.1 meters [m]) from their nose to the tip of their tail and may exceed 161 pounds (lbs) (73 kilograms [kg]) in weight; but, typically adult males average around 116 lbs (52.6 kg) and stand about 24-28 inches (in) (60-70 centimeters [cm]) at the shoulder (Roelke 1990). Female panthers are smaller with an average weight of 75 lbs (34 kg) and length of 6 ft (1.8 m) (Roelke 1990). The skull of the Florida panther is unique in that it has a broad, flat, frontal region, and broad, high-arched or upward-expanded nasal bones (Young and Goldman 1946).

Florida panther kittens are gray with dark brown or blackish spots and five bands around the tail. The spots gradually fade as the kittens grow older and are almost unnoticeable by the time they are 6 months old. At this age, their bright blue eyes slowly turn to the light-brown straw color of the adult (Belden 1988).

Three external characters—a right angle crook at the terminal end of the tail, a whorl of hair or cowlick in the middle of the back, and irregular, white flecking on the head, nape, and shoulders—not found in combination in other subspecies of *Puma* (Belden 1986), were commonly observed in Florida panthers through the mid-1990s. The kinked tail and cowlicks were considered manifestations of inbreeding (Seal 1994); whereas the white flecking was thought to be a result of scarring from tick bites (Maehr 1992, Wilkins et al. 1997). Four other abnormalities prevalent in the panther population prior to the mid-1990s included cryptorchidism (one or two undescended testicles), low sperm quality, atrial septal defects (the opening between two atria in the heart fails to close normally during fetal development), and immune deficiencies and were also suspected to be the result of low genetic variability (Roelke et al. 1993a). A plan for genetic restoration and management of the Florida panther was developed in September 1994 (Seal 1994) and eight non-pregnant adult female Texas panthers (*Puma concolor stanleyana*) were released in five areas of south Florida from March to July 1995. Since this introgression, rates of genetic defects, including crooked tails and cowlicks, have dramatically decreased (Land et al. 2004). In addition, to date neither atrial septal defects nor cryptorchidism have been found in introgressed panthers (M. Cunningham, FWC, pers. comm. 2005). As of January 27, 2003, none of the eight female Texas panthers introduced in 1995 remain in the wild.

Population Trends and Distribution

The Florida panther once ranged throughout the southeastern U.S. from Arkansas and Louisiana eastward across Mississippi, Alabama, Georgia, Florida, and parts of South Carolina and Tennessee (Young and Goldman 1946). Historically, the panther intergraded to the north with *P. c. cougar*, to the west with *P. c. stanleyana*, and to the northwest with *P. c. hippolestes* (Young and Goldman 1946).

Although generally considered unreliable, sightings of panthers regularly occur throughout the southeast. However, no reproducing populations of panthers have been found outside of south Florida for at least 30 years despite intensive searches to document them (Belden et al. 1991, McBride et al. 1993, Clark et al. 2002). Survey reports and more than 70,000 locations of radio-collared panthers recorded between 1981 and 2004 clearly define the panther's current breeding range. Reproduction is known only in the Big Cypress Swamp and Everglades physiographic region in Collier, Lee, Hendry, Miami-Dade, and Monroe Counties south of the Caloosahatchee River (Belden et al. 1991). Although confirmed panther sign, male radiocollared panthers, and uncollared males killed by vehicles have been recorded outside of south Florida in recent years, no female panthers have been documented north of the Caloosahatchee River since 1973 (Nowak and McBride 1974, Belden et al. 1991, Land and Taylor 1998, Land et al. 1999, Shindle et al. 2000, McBride 2002, Belden and McBride 2005).

Puma are wide ranging, secretive, and occur at low densities. However, their tracks, urine markers, and scats are readily found by trained observers, and resident populations are easily located. Van Dyke (1986a) determined that all resident puma, 78 percent of transient puma, and 57 percent of kittens could be detected by track searches in Utah. In south Florida, the Florida panther's limited range and low densities may make the population count derived from track searches more accurate than in Utah. During two month-long investigations – one late in 1972 and early 1973 and another in 1974 – funded by the World Wildlife Fund to determine if panthers still existed in Florida, McBride searched for signs of panthers in portions of south Florida. In 1972, McBride authenticated a road-killed male panther in Glades County and a female captured and released from a bobcat trap in Collier County (R. McBride, Livestock Protection Company, pers. comm. 2005). In 1973, McBride captured one female in Glades County (Nowak and McBride 1974). Based on this preliminary evidence, Nowak and McBride (1974) estimated the "population from the Lake Okeechobee area southward to be about 20 or 30 individuals." In 1974, McBride found evidence of only two additional panthers in the Fakahatchee Strand and suggested that "there could be not more than ten individual panthers in the area around Lake Okeechobee and southward in the state" (Nowak and McBride 1975). This initial survey, while brief in nature, proved that panthers still existed in Florida and delineated areas where a more exhaustive search was warranted. After this initial investigation, more comprehensive surveys on both public and private lands were completed (Reeves 1978; Belden and McBride 1983a, b; Belden et al. 1991). Thirty individual panthers were identified during a wide-ranging survey in 1985 in south Florida (McBride 1985).

Maehr et al. (1991) provides the only published population estimate based on a substantial body of field data (Beier et al. 2003). Maehr et al. (1991) estimated a density of 1 panther per 27,520 ac911,137 hectares [ha]) based on 17 concurrently radiocollared and four uncollared panthers. They extrapolated this density to the area occupied (1,245,435 ac [504,012 ha]) by radio-collared panthers during the period 1985-1990 to achieve a population estimate of 46 adult panthers for southwest Florida (excluding Everglades National Park [ENP], eastern Big Cypress National Preserve [BCNP], and Glades and Highlands Counties). Beier et al. (2003), however, argued that this estimate of density, although "reasonably rigorous," could not be extrapolated to other areas because it was not known whether densities were comparable in those areas.

More recently, McBride (2000, 2001, 2002, 2003) obtained minimum population counts (*i.e.*, number known alive) based on panthers treed with hounds, physical evidence (*e.g.*, tracks where radio-collared panthers were not known to occur), documentation by trail-camera photos, and sightings of uncollared panthers by a biologist or pilot from a monitoring plane or via ground telemetry. He counted adults and subadult panthers but not kittens at the den). The population estimate in 2000 was 62 panthers (McBride 2000), with estimates of 78 in 2001 (McBride 2001), 80 in 2002 (FWC 2002), 87 in 2003 (FWC 2003), 78 in 2004 (R. McBride, Personal Communication, 2006), 82 in 2005 (R. McBride, Personal Communication, 2006), and 96 in 2006 (R. McBride, Personal Communication, 2006).

McBride (2002) documented an increase in the number of uncollared panthers captured each year between 2000 and 2002 relative to 1981 through 1999, while Shindle et al. (2001) reported data showing an apparent increase in the number of panthers killed by vehicles since 1999. In

neither case, however, was supporting evidence provided that would be necessary to conclude that these increases reflected population trends.

Although the breeding segment of the panther population occurs only in south Florida, panthers have been documented north of the Caloosahatchee River over 125 times since February 1972. This has been confirmed through field sign (*e.g.,* tracks, scrapes, scats), camera-trap photographs, seven highway mortalities, four radio-collared animals, two captured animals (one of which was radiocollared), and one skeleton. From 1972 through 2004, panthers have been confirmed in 11 counties (Flagler, Glades, Highlands, Hillsborough, Indian River, Okeechobee, Orange, Osceola, Polk, Sarasota, Volusia) north of the Caloosahatchee River (Belden et al. 1991; Belden and McBride 2005). However, no evidence of a female or reproduction has been documented north of the Caloosahatchee River in over 30 years (Belden and McBride 2005).

Life History

Reproduction: Male Florida panthers are polygynous, maintaining large, overlapping home ranges containing several adult females and their dependent offspring. The first sexual encounters for males normally occur at about three years based on 26 radio-collared panthers of both sexes (Maehr et al. 1991). Based on genetics work, some males may become breeders as early as 17 months (W. Johnson, National Cancer Institute, pers. comm. 2005). Breeding activity peaks from December to March (Shindle et al. 2003). Litters (n = 82) are produced throughout the year, with 56-60 percent of births occurring between March and June (Jansen et al. 2005, Lotz et al. 2005). The greatest number of births occurs in May and June (Jansen et al. 2005, Lotz et al. 2005). Female panthers have bred as young as 18 months (Maehr et al. 1989) and successful reproduction has occurred up to 11 years old. Mean age of denning females is 4.6 ± 2.1 (standard deviation [sd]) years (Lotz et al. 2005). Age at first reproduction for 19 known-aged female panthers averaged 2.2 ± 0.246 (sd) years and ranged from 1.8-3.2 years. Average litter size is 2.4 ± 0.91 (sd) kittens. Seventy percent of litters are comprised of either two or three kittens. Mean birth intervals (elapsed time between successive litters) are 19.8 ± 9.0 (sd) months for female panthers (n = 56) (range 4.1-36.5 months) (Lotz et al. 2005). Females that lose their litters generally produce another more quickly; five of seven females whose kittens were brought into captivity successfully produced another litter an average of 10.4 months after the removal of the initial litter (Land 1994).

Den sites are usually located in dense, understory vegetation, typically saw palmetto (*Serenoa repens*) (Maehr 1990; Shindle et al. 2003). Den sites are used for up to two months by female panthers and their litters from birth to weaning. Independence and dispersal of young typically occurs at 18 months, but may occur as early as one year (Maehr 1992).

Survivorship and Causes of Mortality: Mortality records for uncollared panthers have been kept since February 13, 1972, and for radio-collared panthers since February 10, 1981. One-hundred eighty-nine mortalities have been documented through October 30, 2006, with 86 (46 percent) of known deaths occurring in the past 5 years (FWC 2006a, FWC unpublished data). Overall, documented mortality averaged 3.6 per year through June 2001, and 16.0 per year from July 2001 through June 2006. Of the 189 total mortalities, 100 were radio-collared

panthers that have died since 1981 (FWC 2006a, FWC unpublished data). From 1990-2004, mean annual survivorship of radio-collared adult panthers was greater for females (0.894 ± 0.099 sd) than males (0.779 ± 0.125 sd) (Lotz et al. 2005). Except for intraspecific aggression, the causes of mortality were found to be independent of gender (Lotz et al. 2005).

Intraspecific aggression was the leading cause of death for radio-collared panthers, accounting for 42 percent (Jansen et al. 2005, Lotz et al. 2005). Most intraspecific aggression occurs between male panthers; but, aggressive encounters between males and females, resulting in the death of the female, have occurred. Defense of kittens and\or a kill is suspected in half (5 of 10) of the known instances through 2003 (Shindle et al. 2003).

Unknown causes and collisions with vehicles accounted for 24 and 19 percent of radio-collared panther mortalities, respectively. From February 13, 1972, through June 30, 2006, Florida panther vehicular trauma (n=96), averaged 2.8 per year for radio-collared and uncollared panthers (FWC 2006a). Ten of the collisions were not fatal. Three additional panthers were killed by vehicles from July 1, 2006, through November 30, 2006 (FWC, unpublished data), bringing the total to 99 panthers killed or injured by vehicles.

Female panthers are considered adult residents if they are older than 18 months, have established home ranges and bred (Maehr et al. 1991). Land et al. (2004) reported that 23 of 24 female panthers first captured as kittens survived to become residents and 18 (78.3 percent) produced litters; one female was too young to determine residency. Male panthers are considered adult residents if they are older than three years and have established a home range that overlaps with females. Thirty-one male panthers were captured as kittens and 12 (38.7 percent) of these cats survived to become residents (Jansen et al. 2005, Lotz et al. 2005). "Successful male recruitment appears to depend on the death or home-range shift of a resident adult male" (Maehr et al. 1991). Turnover in the breeding population is low with documented mortality in radio-collared panthers being greatest in subadults and non-resident males (Maehr et al. 1991, Shindle et al. 2003).

Den sites of female panthers have been visited since 1992 and the number of kittens that survived to 6 months for 38 of these litters has been documented. Florida and introgressed panther kitten survival to six months were estimated to be 52 and 72 percent, respectively, but were not significantly different (P = 0.2776) (Lotz et al. 2005). Survival of kittens greater than six months old was determined by following the fates of 55 radio-collared dependent-aged kittens, including 17 introgressed panthers from 1985 - 2004. Only 1 of these 55 kittens died before reaching independence, resulting in a 98.2 percent survival rate (Lotz et al. 2005). The FWC and NPS are continuing to compile and analyze existing reproductive and kitten data.

Dispersal: Panther dispersal begins after a juvenile becomes independent from its mother and continues until it establishes a home range. Dispersal distances are greater for males (n = 18) than females (n = 9) (42.5 mi [68.4 km] vs. 12.6 mi [20.3 km], respectively) and the maximum dispersal distance recorded for a young male was 139.2 mi (224.1 km) over a seven-month period followed by a secondary dispersal of 145 mi (233 km) (Maehr et al. 2002a). Males disperse an average distance of 25 mi (40 km); females typically remain in or disperse short distances from their natal ranges (Comiskey et al. 2002). Female dispersers are considered

philopatric because they usually establish home ranges less than one average home range width from their natal range (Maehr et al. 2002a). Maehr et al. (2002a) reported that all female dispersers (n = 9) were successful at establishing a home range whereas only 63 percent of males (n = 18) were successful. Young panthers become independent at 14 months on average for both sexes, but male dispersals are longer in duration than for females (9.6 months and 7.0 months, respectively) (Maehr et al. 2002a). Dispersing males usually go through a period as transient (non-resident) subadults, moving through the fringes of the resident population and often occupying suboptimal habitat until an established range becomes vacant (Maehr 1997).

Most panther dispersal occurs south of the Caloosahatchee River with only four radio-collared panthers crossing the river and continuing north since 1981 (Land and Taylor 1998, Land et al. 1999, Shindle et al. 2000, Maehr et al. 2002a, Belden and McBride 2005). Western subspecies of *Puma* have been documented crossing wide, swift-flowing rivers up to a mile in width (Seidensticker et al. 1973, Anderson 1983). The Caloosahatchee River, a narrow (295-328 ft [90-100 m]), channelized river, probably is not a significant barrier to panther movements, but the combination of the river, State Route (SR) 80, and land uses along the river seems to have restricted panther dispersal northward (Maehr et al. 2002a). Documented physical evidence of at least 15 other uncollared male panthers have been confirmed north of the river since 1972, but no female panthers nor reproduction have been documented in this area since 1973 (Belden and McBride 2005).

Home Range Dynamics and Movements: Panthers require large areas to meet their needs. Numerous factors influence panther home range size including habitat quality, prey density, and landscape configuration (Belden 1988, Comiskey et al. 2002). Home range sizes of 26 radio-collared panthers monitored between 1985 and 1990 averaged 128,000 ac (51,800 ha) for resident adult males and 48,000 ac (19,425 ha) for resident adult females; transient males had a home range of 153,599 ac (62,160 ha) (Maehr et al. 1991). Comiskey et al. (2002) examined the home range size for 50 adult panthers (residents greater than 1.5 years old) monitored in south Florida from 1981-2000 and found resident males had a mean home range of 160,639 ac (65,009 ha) and females had a mean home range of 97,920 ac (39,627 ha). Beier et al. (2003) found home range size estimates for panthers reported by Maehr et al. (1991) and Comiskey et al. (2002) to be reliable. Annual minimum convex polygon home range sizes of 52 adult radio-collared panthers monitored between 1998 and 2002 ranged from 15,360 – 293,759 ac (6,216 – 118,880 ha), averaging 89,600 ac (36,260 ha) for 20 resident adult males and 44,160 ac (17,871 ha) for 32 resident adult females (Land et al. 1999, Shindle et al. 2000, Shindle et al. 2001, Land et al. 2002). The most current estimate of home-range sizes (minimum convex polygon method) for established, non-dispersing, adult, radio-collared panthers averaged 29,056 ac (11,759 ha) for females (n = 11) and 62,528 ac (25,304 ha) for males (n = 11) (Lotz et al. 2005). The average home range was 35,089 ac (14,200 ha) for resident females (n = 6) and 137,143 ac (55,500 ha) (n = 5) for males located at BCNP (Jansen et al. 2005). Home ranges of resident adults tend to be stable unless influenced by the death of other residents; however, several males have shown significant home range shifts that may be related to aging (D. Jansen, National Park Service [NPS], pers. comm. 2005). Home-range overlap is extensive among resident females and limited among resident males (Maehr et al. 1991).

Activity levels for Florida panthers are greatest at night with peaks around sunrise and after sunset (Maehr et al. 1990a). The lowest activity levels occur during the middle of the day. Female panthers at natal dens follow a similar pattern with less difference between high and low activity periods.

Telemetry data indicate panthers typically do not return to the same resting site day after day, with the exception of females with dens or panthers remaining near kill sites for several days. The presence of physical evidence such as tracks, scats, and urine markers confirm that panthers move extensively within home ranges, visiting all parts of the range regularly in the course of hunting, breeding, and other activities (Maehr 1997, Comiskey et al. 2002). Males travel widely throughout their home ranges to maintain exclusive breeding rights to females. Females without kittens also move extensively within their ranges (Maehr 1997). Panthers are capable of moving large distances in short periods of time. Nightly panther movements of 12 mi (20 km) are not uncommon (Maehr et al. 1990a).

Intraspecific Interactions: Interactions between panthers occur indirectly through urine markers or directly through contact. Urine markers are made by piling ground litter using a backwards-pushing motion with the hind ft. This pile is then scent-marked with urine and occasionally feces. Both sexes make urine markers. Apparently males use them as a way to mark their territory and announce presence while females advertise their reproductive condition.

Adult females and their kittens interact more frequently than any other group of panthers. Interactions between adult male and female panthers last from one to seven days and usually result in pregnancy (Maehr et al. 1991). Aggressive interactions between males often result in serious injury or death. Independent subadult males have been known to associate with each other for several days and these interactions do not appear to be aggressive in nature. Aggression between males is the most common cause of male mortality and an important determinant of male spatial and recruitment patterns based on radio-collared panthers (Maehr et al. 1991, Shindle et al. 2003). Aggressive encounters between radio-collared males and females also have been documented (Shindle et al. 2003, Jansen et al. 2005).

Food Habits: Primary panther preys are white-tailed deer (*Odocoileus virginianus*) and feral hog (*Sus scrofa*) (Maehr et al. 1990b, Dalrymple and Bass 1996). Generally, feral hogs constitute the greatest biomass consumed by panthers north of the Alligator Alley section of I-75, while white-tailed deer are the greatest biomass consumed to the south (Maehr et al. 1990b). Secondary prey includes raccoons (*Procyon lotor*), nine-banded armadillos (*Dasypus novemcinctus*), marsh rabbits (*Sylvilagus palustris*) (Maehr et al. 1990b) and alligators (*Alligator mississippiensis*) (Dalrymple and Bass 1996). No seasonal variation in diet has been detected. A resident adult male puma generally consumes one deer-sized prey every 8-11 days; this frequency would be 14-17 days for a resident female; and 3.3 days for a female with three 13-month-old kittens (Ackerman et al. 1986). Maehr et al. (1990b) documented domestic livestock infrequently in scats or kills, although cattle were readily available on their study area.

Infectious Diseases, Parasites, and Environmental Contaminants: *Viral Diseases*--Feline leukemia virus (FeLV) is common in domestic cats (*Felis catus*), but is quite rare in non-

domestic felids. Routine testing for FeLV antigen (indicating active infection) in captured and necropsied panthers has been negative since testing began in 1978 to the fall of 2002. Between November 2002 and February 2003, however, two panthers tested FeLV antigen positive (Cunningham 2005). The following year, three more cases were diagnosed. All infected panthers had overlapping home ranges in the Okaloacoochee Slough ecosystem. Three panthers died due to suspected FeLV-related diseases (opportunistic bacterial infections and anemia) and the two others died from intraspecific aggression. Testing of serum samples collected from 1990-2005 for antibodies (indicating exposure) to FeLV indicated increasing exposure to FeLV beginning in the late 1990s and concentrated north of I-75. There was apparently minimal exposure to FeLV during this period south of I-75. Positive antibody titers in different areas at different times may indicate that multiple introductions of the virus into the panther population may have occurred. These smaller epizootics were apparently self-limiting and did not result in any known mortalities. Positive antibody titers, in the absence of an active infection (antigen positive), indicate panthers can be exposed and overcome the infection (Cunningham 2005). Management of the disease includes vaccination as well as removal of infected panthers to captivity for quarantine and supportive care. As of June 1, 2005, about one-third of the population had received at least one vaccination against FeLV (FWC and NPS, unpublished data). No new positive cases have been diagnosed since July 2004.

Pseudorabies virus (PRV) (Aujeszky's disease) causes respiratory and reproductive disorders in adult hogs and mortality in neonates, but is a rapidly fatal neurologic disease in carnivores. At least one panther died from PRV infection presumably through consumption of an infected feral hog (Glass et al. 1994). At least one panther has also died of rabies (Taylor et al. 2002). This panther was radiocollared but not vaccinated against the disease.

Feline immunodeficiency virus (FIV) is a retrovirus of felids that is endemic in the panther population. About 28 percent of Florida panthers were positive for antibodies to the puma lentivirus strain of FIV (Olmstead et al. 1992); however, the prevalence may be increasing. Between November 2004 and April 2005, 13 of 17 (76 percent) were positive (M. Cunningham, FWC, unpublished data). The cause of this increase is unknown but warrants continued monitoring and investigation. There is also evidence of exposure to Feline panleukopenia virus (PLV) in adult panthers (Roelke et al. 1993b) although no PLV-related mortalities are known to have occurred.

Serological evidence of other viral diseases in the panther population includes feline calicivirus, feline herpes virus, and West Nile virus (WNV). However these diseases are not believed to cause significant morbidity or mortality in the population. All panthers found dead due to unknown causes are tested for alphaviruses, flaviviruses (including WNV), and canine distemper virus. These viruses have not been detected in panthers by viral culture or polymerase chain reaction (FWC, unpublished data).

Other Infectious Diseases--Bacteria have played a role in free-ranging panther morbidity and mortality as opportunistic pathogens, taking advantage of pre-existing trauma or FeLV infections (FWC, unpublished data). Dermatophytosis (ringworm infection) has been diagnosed in several panthers and resulted in severe generalized infection in at least one (Rotstein et al. 1999). Severe

infections may reflect an underlying immunocompromise, possibly resulting from inbreeding depression or immunosuppressive viral infections.

Parasites--The hookworm, *Ancylostoma pluridentatum,* is found in a high prevalence in the panther population. Other parasites identified from live-captured or necropsied panthers include eight arthropod species, eight nematode species, three cestode species, two trematode species, and three protozoa species (Forrester et al. 1985, Forrester 1992, Wehinger et al. 1995, Rotstein et al. 1999, Land et al. 2002). Of these only an arthropod, *Notoedres felis*, caused significant morbidity in at least one panther (Maehr et al. 1995).

Environmental Contaminants--Overall, mercury in south Florida biota has decreased over the last several years (Frederick et al. 2002). However, high mercury concentrations are still found in some panthers. At least one panther is thought to have died of mercury toxicosis and mercury has been implicated in the death of two other panthers in ENP (Roelke 1991). One individual panther had concentrations of 150 parts per million (ppm) mercury in its hair (Land et al. 2004). Other environmental contaminants found in panthers include polychlorinated biphenyls (Arochlor 1260) and organochlorines (p, p'–DDE) (Dunbar 1995, Land et al. 2004). Elevated levels of p, p'– DDE were also detected in fat from that panther. The role of mercury and p, p'–DDE in this panther's death is unknown and no cause of death was determined despite extensive diagnostic testing. Elevated mercury concentrations have also been found in panthers from Florida Panther National Wildlife Refuge (FPNWR). Two sibling neonatal kittens from this area had hair mercury concentrations of 35 and 40 ppm. Although other factors were believed to have been responsible, these kittens did not survive to leave their natal den. Consistently high hair mercury values in ENP and FPNWR and the finding of elevated values in some portions of BCNP warrant continued monitoring (Land et al. 2004).

Habitat Characteristics and Ecosystem

Landscape Composition: Noss and Cooperrider (1994) considered the landscape implications of maintaining viable panther populations. Assuming a male home range size of 137,599 ac (55,685 ha) (Maehr 1990), an adult sex ratio of 50:50 (Anderson 1983), and some margin of safety, they determined that a reserve network as large as 15,625–23,438 mi^2 (40,469-60,703 km^2) would be needed to support an effective population size of 50 individuals (equating to an actual adult population of 100-200 panthers [Ballou et al. 1989]). However, to provide for long-term persistence based on an effective population size of 500 individuals (equating to 1,000 - 2,000 adult panthers [Ballou et al. 1989]), could require as much as 156,251-234,376 mi^2 (404,687-607,031 km^2). This latter acreage corresponds to roughly 60-70 percent of the Florida panther's historical range. Although it is uncertain whether this much land is needed for panther recovery, it does provide some qualitative insight into the importance of habitat conservation across large landscapes for achieving a viable panther population (Noss and Cooperrider 1994).

Between 1981 and 2003, more than 55,000 locations on more than 100 radio-collared panthers were collected. Belden et al. (1988), Maehr et al. (1991), Maehr (1997), Kerkoff et al. (2000), and Comiskey et al. (2002) provide information on habitat use based on various subsets of these data. Since almost all data from radio-collars have been collected during daytime hours (generally

0700-1100), and because panthers are most active at night (Maehr et al. 1990a), daytime radio locations are insufficient to describe the full range of panther habitat use (Beyer and Haufler 1994, Comiskey et al. 2002, Beier et al. 2003, Dickson et al. 2005, Beier et al. 2006).

The Service created the Multi-species/Ecosystem Recovery Implementation Team (MERIT) to assist with implementation of the MSRP after it was signed in 1999. The Florida Panther Subteam of MERIT developed a landscape-level strategy for the conservation of the panther population in south Florida which was not finalized. Many of the Panther Subteam members refined the methodology, further analyzed the data, and better defined the results of this landscape-level strategy into a spatial model (Kautz et al. 2006). In developing the model, data from radio-collared panthers collected from 1981 through 2000 were used to evaluate the relative importance of various land cover types as panther habitat, thus identifying landscape components important for panther habitat conservation. Those components were then combined with a least cost path analysis to delineate three panther habitat conservation zones for south Florida: (1) Primary Zone – lands essential to the long-term viability and persistence of the panther in the wild; (2) Secondary Zone - lands which few panthers use contiguous with the Primary Zone, but given sufficient habitat restoration could accommodate expansion of the panther population south of the Caloosahatchee River; and (3) Dispersal Zone - the area which may facilitate future panther expansion north of the Caloosahatchee River (Kautz et al. 2006) (Figure 10). The Primary Zone is currently occupied and supports the breeding population of panthers. Although panthers move through the Secondary and Dispersal Zones, they are not permanently occupied. The Secondary Zone could support panthers with sufficient restoration.

These zones vary in size, ownership, and land cover composition. The Primary Zone is 2,270,711 ac (918,928 ha) in size, 73 percent of which is publicly owned (R. Kautz, Dennis, Breedlove, and Associates, pers. comm. 2005), and includes portions of the BCNP, ENP, Fakahatchee Strand Preserve State Park (FSPSP), FPNWR, Okaloacoochee Slough State Forest (OSSF) and Wildlife Management Area (WMA), and Picayune Strand State Forest. This zone's composition is 45 percent forest, 41 percent freshwater marsh, 7.6 percent agriculture lands, 2.6 percent prairie and shrub lands, and 0.52 percent urban lands (Kautz et al. 2006). The Secondary Zone is 812,157 ac (328,670 ha) in size, 38 percent of which is public land (R. Kautz, pers. comm. 2005). This zone's composition is 43 percent freshwater marsh, 36 percent agriculture, 11 percent forest, 6.1 percent prairie and shrub lands, and 2.3 percent low-density residential areas and open urban lands (Kautz et al. 2006). The Dispersal Zone is 28,160 ac (11,396 ha) in size, 12 percent of which is either publicly owned or in conservation easement. This zone's composition is 49 percent agriculture (primarily improved pasture and citrus groves), 29 percent forest (wetland and upland), 8.8 percent prairie and shrub land, 7.5 percent freshwater marsh, and 5.1 percent barren and urban lands (Kautz et al. 2006).

As part of their evaluation of occupied panther habitat, in addition to the average density estimate of one panther per 27,181 ac (11,000 ha) developed by Maehr et al. (1991), Kautz et al. (2006) estimated the present average density during the timeframe of the study, based on telemetry and other occurrence data, to average 1 panther per 31,923 ac (12,919 ha). In the following discussions of the number of panthers that a particular zone may support, the lower

number is based on the 31,923 ac (12,919 ha) value (Kautz et al. 2006) and the higher number is based on the 27,181 ac (11,000 ha) value (Maehr et al. 1991).

Based on these average densities, the Primary Zone could support 71 to 84 panthers; the Secondary Zone 8 to 10 panthers without habitat restoration and 25 to 30 panthers with habitat restoration (existing high quality panther habitat currently present in the Secondary Zone is estimated at 32 percent of the available Secondary Zone lands); and the Dispersal Zone, 0 panthers. Taken together, the three zones in their current condition apparently have the capacity to support about 79 to 94 Florida panthers.

Kautz et al.'s (2006) assessment of available habitat south of the Caloosahatchee River determined non-urban lands in the Primary, Secondary, and Dispersal Zones were not sufficient to sustain a population of 240 individuals south of the Caloosahatchee River. However, Kautz et al. (2006) determined sufficient lands were available south of the Caloosahatchee River to support a population of 79 to 94 individuals (although not all lands are managed and protected).

Even though some suitable panther habitat remains in south-central Florida, it is widely scattered and fragmented (Belden and McBride 2005). Thatcher et al. (2006) used a statistical model in combination with a geographic information system to develop a multivariate landscape-scale habitat model based on the Mahalanobis distance statistic (D^2) to evaluate habitats in south central Florida for potential expansion of the Florida panther population. They identified 4 potential habitat patches: the Avon Park Bombing Range area, Fisheating Creek/Babcock-Webb Wildlife Management Area, eastern Fisheating Creek, and the Duette Park/Manatee County area. These habitat patches are smaller and more isolated compared with the current Florida panther range, and the landscape matrix where these habitat patches exist provides relatively poor habitat connectivity among the patches (Thatcher et al. 2006). Major highways and urban or agricultural development isolate these habitat patches, and they are rapidly being lost to the same development that threatens southern Florida (Belden and McBride 2005).

Diurnal Habitat Use: Diurnal panther locations appear to be within or closer to forested cover types, particularly cypress swamp, pinelands, hardwood swamp, and upland hardwood forests (Belden 1986, Belden et al. 1988, Maehr 1990, Maehr et al. 1991, Maehr 1992, Smith and Bass 1994, Kerkhoff et al. 2000, Comiskey et al. 2002). Dense understory vegetation comprised of saw palmetto provides some of the most important resting and denning cover for panthers (Maehr 1990). Shindle et al. (2003) show that 73 percent of panther dens were in palmetto thickets.

Radio-collar data and ground tracking indicate panthers use the mosaic of habitats available to them as resting and denning sites, hunting grounds, and travel routes. These habitats include cypress swamps, hardwood hammocks, pine flatwoods, seasonally flooded prairies, freshwater marshes, and some agricultural lands. Although radio-collar monitoring indicates forest is a preferred cover type, panthers also utilize non-forest cover types (Belden et al. 1988; Maehr et al. 1991; Comiskey et al. 2002). Compositional analyses by Kautz et al. (2006) confirmed previous findings that forest patches comprise an important component of panther habitat in south Florida, but other natural and disturbed cover types are also present in the large landscapes that support panthers (Belden et al. 1988; Maehr et al. 1991; Comiskey et al. 2002). Kautz et al. (2006)

found the smallest class of forest patches (*i.e.*, 9-26 ac [3.6-10.4 ha]) were the highest ranked forest patch sizes within panther home ranges; this indicates that forest patches of all sizes appear to be important components of the landscapes inhabited by panthers, not just the larger forest patches.

Nocturnal Habitat Use: Maehr et al. (1990a) provide the only descriptions of panther nocturnal activities and represent the available radiocollar data collected during night time hours. However, this paper does not provide analyses of nocturnal habitat use. Dickson et al. (2005) examined the movements of 10 female and 7 male puma at 15-minute intervals during 44 nocturnal periods of hunting or traveling in southern California. They found that traveling puma monitored over nocturnal periods used a broader range of habitats than what they appeared to use based on diurnal locations alone. The use of Global Positioning System (GPS) radiocollars is now being investigated to determine if this technology will be suitable to answer questions regarding Florida panther nocturnal habitat use.

Prey Habitat Use: Panther habitat selection is related to prey availability (Janis and Clark 1999, Dees et al. 2001) and, consequently, prey habitat use. Adequate cover and the size, distribution, and abundance of available prey species are critical factors to the persistence of panthers in south Florida and often determine the extent of panther use of an area. Duever et al. (1986) calculated a deer population of 1,760 in BCNP, based on Harlow (1959) deer density estimates of 1/210 ac (85 ha) in pine forest, 1/299 ac (121 ha) in swamps, 1/1,280 ac (518 ha) in prairie, 1/250 ac (101 ha) in marshes, and 1/111 ac (45 ha) in hammocks. Schortemeyer et al. (1991) estimated deer densities at 1/49-247 ac (20-100 ha) in three management units of BCNP based on track counts and aerial surveys. Labisky et al. (1995) reported 1/49 ac (20 ha) in southeastern BCNP. Using track counts alone, McCown (1994) estimated 1/183-225 ac (74-91 ha) on the FPNWR and 1/133-200 ac (54-81 ha) in the FSPSP.

Hardwood hammocks and other forest cover types are important habitat for white-tailed deer and other panther prey (Harlow and Jones 1965, Belden et al. 1988, Maehr 1990, Maehr et al. 1991, Maehr 1992, Comiskey et al. 1994, Dees et al. 2001). Periodic understory brushfires (Dees et al. 2001) as well as increased amounts of edge (Miller 1993) may enhance deer use of hardwood hammocks, pine, and other forest cover types. However, wetland and other vegetation types can support high deer densities. In the Everglades, for example, deer appear to be adapted to a mosaic of intergrading patches comprised of wet prairie, hardwood tree islands, and peripheral wetland habitat (Fleming et al. 1994, Labisky et al. 2003). High-nutrient deer forage, especially preferred by females, includes hydrophytic marsh plants, white waterlily (*Nymphaea odorata*), and swamp lily (*Crinum americana*) (Loveless 1959, Labisky et al. 2003). Wetland willow (*Salix spp.*) thickets provide nutritious browse for deer (Loveless 1959, Labisky et al. 2003).

Marshes, rangeland, and low-intensity agricultural areas support prey populations of deer and hogs. The importance of these habitat types to panthers cannot be dismissed based solely on use or lack of use when daytime telemetry are the only data available (Comiskey et al. 2002, Beier et al. 2003, Comiskey et al. 2004, Beier et al. 2006).

Travel and Dispersal Corridors: In the absence of direct field observations and measurements, Harrison (1992) suggested that landscape corridors for wide-ranging predators should be half the width of an average home range size. Following Harrison's (1992) suggestion, corridor widths for Florida panthers would range 6.1-10.9 mi (9.8-17.6 km) depending on whether the target animal was an adult female or a transient male. Beier (1995) suggested corridor widths for transient male puma in California could be as small as 30 percent of the average home range size of an adult. For Florida panthers, this would translate to a corridor width of 5.5 mi (8.8 km). Without supporting empirical evidence, Noss (1992) suggests regional corridors connecting larger hubs of habitat should be at least 1.0 mi (1.6 km) wide. Beier (1995) makes specific recommendations for very narrow corridor widths based on short corridor lengths in a California setting of wild lands completely surrounded by urban areas; he recommended corridors with a length less than 0.5 mi (0.8 km) should be more than 328 ft (100 m) wide, and corridors extending 0.6-4 mi (1-7 km) should be more than 1,312 ft (400 m) wide. The Dispersal Zone encompasses 44 mi^2 (113 km^2) with a mean width of 3.4 mi (5.4 km). Although it is not adequate to support even one panther, the Dispersal Zone is strategically located and expected to function as a critical landscape linkage to south-central Florida (Kautz et al. 2006). Transient male panthers currently utilize this Zone as they disperse northward into south-central Florida.

Panther Recovery Objectives

The recovery objectives identified in the draft third revision of the Florida Panther Recovery Plan (Service 2006) are to (1) maintain, restore, and expand the Florida panther population and its habitat in south Florida and, if feasible, expand the known occurrence of Florida panthers north of the Caloosahatchee River to maximize the probability of the long-term persistence of this metapopulation; (2) identify, secure, maintain, and restore habitat in potential reintroduction areas within the panther's historic range, and to establish viable populations of the panther outside south and south-central Florida; and (3) facilitate panther conservation and recovery through public awareness and education.

Panther Management and Conservation

Habitat Conservation and Protection

Panthers, because of their wide-ranging movements and extensive spatial requirements, are particularly sensitive to habitat fragmentation (Harris 1984). Mac et al. (1998) defines habitat fragmentation as: "The breaking up of a habitat into unconnected patches interspersed with other habitat which may not be inhabitable by species occupying the habitat that was broken up. The breaking up is usually by human action, as, for example, the clearing of forest or grassland for agriculture, residential development, or overland electrical lines." The reference to "unconnected patches" is a central underpinning of the definition. For panther conservation, this definition underscores the need to maintain contiguous habitat and protected habitat corridors in key locations in south Florida and throughout the panther's historic range. Habitat fragmentation can result from road construction, urban development, and agricultural land conversions.

Habitat protection has been identified as being one of the most important elements to achieving panther recovery. While efforts have been made to secure habitat (Figure 12 and Table 2), continued action is needed to obtain additions to and inholdings for public lands, assure linkages are maintained, restore degraded and fragmented habitat, and obtain the support of private landowners for maintaining property in a manner that is compatible with panther use. Conservation lands used by panthers are held and managed by a variety of entities including FWS, NPS, Seminole Tribes of Florida, Miccosukee Tribe of Indians of Florida, FWC, Florida Department of Environmental Protection (FDEP), Florida Division of Forestry (FDOF), Water Management Districts (WMD), non-governmental organizations (NGO), counties, and private landowners.

Public Lands: Public lands in south Florida that benefit the panther are listed below and shown in Figure 12:

1. In 1947, ENP was established with 1,507,834 ac (610,201 ha) and in 1989 was expanded with the addition of 104,320 ac (42,217 ha).

2. In 1974, Congress approved the purchase and formation of BCNP, protecting 570,238 ac (230,768 ha), later 145,919 ac (59052 ha) were added.

3. In 1974, the State of Florida began acquiring land for the FSPSP, which encompasses over 80,000 ac (32,375 ha). Efforts are underway to acquire about 16,640 ac (6,734 ha).

4. In 1985, acquisition of Picayune Strand State Forest and Wildlife Management Area (WMA) began with the complex Golden Gate Estates subdivision buyouts and now comprises over 76,160 ac (30,821 ha). The Southern Golden Gate Estates buyout through State and Federal funds is complete. The South Belle Meade portion of Picayune Strand is about 90 percent purchased and although the State is no longer purchasing in South Belle Meade, Collier County's Transfer of Development Rights program is helping to secure the inholdings.

5. In 1989, FPNWR was established and now protects 26,240 ac (10,619 ha).

6. In 1989, the Corkscrew Regional Ecosystem Watershed Land and Water Trust, a public and private partnership, was established and to date has coordinated the purchase of 42 26,880 ac (10,878 ha).

7. In 1996, the South Florida WMD, purchased the 32,000 ac (12,950 ha) OSSF.

8. In 2002 Spirit of the Wild WMA, consisting of over 7,040 ac (2,849 ha), was taken into public ownership by the State of Florida and is managed by FDOF.

9. In 2003, Dinner Island Ranch WMA consisting of 21,760 ac (8,806 ha) in southern Hendry County was taken into public ownership by the State of Florida and is managed by FDOF.

Tribal Lands: Lands of the Seminole Tribes of Florida and Miccosukee Tribe of Indians of Florida encompass over 350,079 ac (141,673 ha) in south Florida. Of these, 115,840 ac (46,879 ha) are used by panthers, and comprise 5 percent of the Primary Zone (R. Kautz, pers. comm. 2005). These lands are not specifically managed for the panther and are largely in cultivation.

Private Lands: A variety of Federal, State, and private incentives programs are available to assist private landowners and other individuals to protect and manage wildlife habitat. Voluntary agreements, estate planning, conservation easements, land exchanges, and mitigation banks are methods that hold untapped potential for conserving private lands. In 1954, the National Audubon Society established the nearly 10,880 ac (4,403 ha) Corkscrew Swamp Sanctuary. However, little additional private land has been protected south of the Caloosahatchee River for panther conservation. A number of properties identified by the State Acquisition and Restoration Council (ARC) for purchase by the Florida Forever Program are used by panthers (*e.g.*, Devil's Garden, Half Circle F Ranch, Pal Mal, Panther Glades). North of the Caloosahatchee River, Fisheating Creek Conservation Easement, 41,600 ac (16,835 ha) in Glades County is a private holding used by dispersing male panthers. Also, 73,235 ac of the 90,845 ac Babcock Ranch were purchased in 2006 by the State of Florida and Lee County for conservation and agriculture. An additional 2,000 ac of this ranch were put into a conservation easement.

Habitat and Prey Management

Land management agencies in south Florida are implementing fire programs that mimic a natural fire regime through the suppression of human-caused wildfires and the application of prescribed natural fires. No studies have been conducted to determine the effects of invasive plant management on panthers. However invasive vegetation may reduce the panther's prey base by disrupting natural processes such as water flow and fire and by significantly reducing available forage for prey (Fleming et al. 1994). All public lands in south Florida have active invasive plant treatment programs. Management for panther prey consists of a variety of approaches such as habitat management and regulation of hunting and off-road vehicle (ORV) use.

Response to Management Activities

Few studies have examined the response of panthers to various land and habitat management activities. Dees et al. (2001) investigated panther habitat use in response to prescribed fire and found that panther use of pine habitats was greatest for the first year after the area had been burned and declined thereafter. Prescribed burning is believed to be important to panthers because prey species (*e.g.*, deer and hogs) are attracted to burned habitats to take advantage of changes in vegetation structure and composition, including exploiting hard mast that is exposed and increased quality or quantity of forage (Dees et al. 2001). Responses of puma to logging activities (Van Dyke et al. 1986b) indicate that they generally avoid areas within their home range with intensification of disturbance.

There is the potential for disturbance to panthers from recreational uses on public lands. Maehr (1990) reported that indirect human disturbance of panthers may include activities associated with hunting and that panther use of Bear Island (part of BCNP) is significantly less during the

hunting season. Schortemeyer et al. (1991) examined the effects of deer hunting on panthers at BCNP between 1983 and 1990. They concluded that, based on telemetry data, panthers may be altering their use patterns as a result of hunting.

Janis and Clark (2002) compared the behavior of panthers before, during, and after the recreational deer and hog hunting season (October through December) on areas open (BCNP) and closed (FPNWR, FSPSP) to hunting. Variables examined were: (1) activity rates, (2) movement rates, (3) predation success, (4) home range size, (5) home range shifts, (6) proximity to ORV trails, (7) use of areas with concentrated human activity, and (8) habitat selection. Responses to hunting for variables most directly related to panther energy intake or expenditure (*i.e.*, activity rates, movement rates, predation success of females) were not detected (Janis and Clark 2002). However, panthers reduced their use of Bear Island, an area of concentrated human activity, and were found farther from ORV trails during the hunting season, indicative of a reaction to human disturbance (Janis and Clark 2002). Whereas the reaction to trails was probably minor and could be related to prey behavior, decreased use of Bear Island most likely reflects a direct reaction to human activity and resulted in increased use of adjacent private lands (Janis and Clark 2002).

Transportation Planning and Improvements

Construction of highways in wildlife habitat typically results in loss and fragmentation of habitat, traffic related mortality, and avoidance of associated human development. Roads can also result in habitat fragmentation, especially for females who are less likely to cross them (Maehr 1990).

There are presently 28 wildlife underpasses with associated fencing suitable for panther use along I-75 (Figure 13). There are four underpasses suitable for panther use currently existing, and two additional underpasses presently proposed by the Florida Department of Transportation (FDOT) along State Road 29 (SR 29) (Department of the Army Public Notice SAJ-2004-778) (Figure 13). Several additional panther and wildlife crossings are proposed along roadways in rural Lee and Collier Counties (Shindle et al. 2001). In addition, Collier County, in cooperation with the National Wildlife Federation and the Florida Wildlife Federation, is coordinating a study of the segment of CR 846 east of Immokalee and the section of Oil Well Road where the road crosses Camp Kies Strand by Dr. Reed Noss and Dr. Daniel Smith to determine the optimum location for wildlife crossing construction (WilsonMiller 2005). An additional crossing of Camp Kies Strand on CR 846 west of Immokalee is also being evaluated. However, vehicular trauma still occurs on outlying rural roads and the FWC is conducting a study to determine the impacts of vehicular collisions to panthers and studying ways to minimize panther vehicle collisions (Swanson et al. 2006).

No panther-vehicle collisions have been recorded in the immediate vicinity of wildlife crossings, with the exception of one collision in December 2005 on SR 29. There have been no collisions on east-west I-75 in the vicinity of crossings since installation in 1991. Prior to 1991, there were five recorded deaths from collisions. FDOT has also identified the location of and constructed wildlife crossings on SR 29. Proposed crossings A and B (Figure 13) will be in an area of 10 documented collisions from 1980 to 2004. Crossings C and D, north of I-75, were installed

in 1995. There were two recorded collisions in the vicinity of crossing D from 1979 to 1990, but none at either C or D since crossing installation. Crossing E was installed in 1997. There has been one collision about 1 mile to the north in 2002. Crossing F was installed in 1999. There was one documented collision in the immediate vicinity in 1981, two collisions about 1.5 miles to the north since crossing installation, and one collision about 0.5 mile to the south in December 2005.

Agriculture, Development, and Mining

The Service developed a draft Panther Habitat Assessment methodology and refugia design in 2003 to help guide the agency in evaluating permit applications for projects that could affect panther habitat (see discussion below). This draft methodology was a way to assess the level of impacts to panthers expected from a given project, and to evaluate the effect of any proposed compensation offered by the project applicant. Prior to development of the methodology, the Service from March 1984 through July 2003 concluded consultation on 42 projects involving the panther and habitat preservation (Table 3). The minimum expected result of these projects is impacts to 76,919 ac and the preservation of 15,479 ac of panther habitat. Of the 76,919 ac of impacts, 38,932 ac are due to agricultural conversion and 37,982 ac to development and mining. Portions (10,370 ac) of the largest agricultural conversion project, the 28,700 ac by U.S. Sugar Corporation, were re-acquired by the Federal Government as a component of the Talisman Land Acquisition (Section 390 of the Federal Agricultural Improvement and Reform Act of 1996 [Public Law 104-127] Farm Bill Cooperative Agreement, FB4) for use in the CERP. The non-agriculture impacts are permanent land losses, whereas the agricultural conversions may continue to provide some habitat functional value to panthers, depending on the type of conversion.

From August 2003 to February, 2007, the Service concluded consultations on 58 projects affecting 17,169 ac with preservation of 18,334 ac (Table 3). Following our refugia design assessment approach, the projects affected 7,287 ac in the Primary Zone, 5,911 ac in the Secondary Zone, and 3,965 ac in the Other Zone. Compensation provided included 15,118 ac in the Primary Zone, 652 ac in the Dispersal Zone, 2 ac in the Secondary Zone, and 1,410 ac in the Other Zone. The project affected lands were primarily agricultural fields consisting of row crops and citrus groves and natural lands with varying degrees of exotic vegetation. Functional habitat value of these lands to the Florida panther, following our Panther Habitat Assessment methodology provided a PHU loss from development of 74,505 PHUs, with a corresponding PHU preservation and enhancement complement of 143,133 PHUs. The preservation lands were generally native habitat lands or disturbed lands that included restoration components. Restoration components included exotic species removal, fire management, wetland hydrology improvement, improved forest management practices, and full habitat restoration from agriculture uses to native habitats.

Similar to residential, commercial, and industrial development projects, individual CERP projects may have an adverse direct effect on the Florida panther through: (1) the permanent loss and fragmentation of habitat used by the panther; (2) the permanent loss and fragmentation of habitat that supports panther prey; (3) the loss of available habitat for foraging, breeding, and dispersing

panthers; and (4) a reduction in the geographic distribution of habitat for the species. Indirect effects may include: (1) an increased risk of roadway mortality to panthers traversing the area due to the increase in vehicular traffic; (2) increased disturbance to panthers in the project vicinity due to human activities; (3) the reduction in panther prey; (4) the reduction in value of habitat used by the panther adjacent to the project due to habitat fragmentation; and (5) a potential increase in intraspecific aggression between panthers (and an increase in mortality of subadult male panthers) due to reduction of the geographic distribution of habitat for the panther.

Panther Habitat Evaluation and Compensation

Population Viability Analysis

Population Viability Analysis (PVA) has emerged as a key component of endangered species conservation. This process is designed to incorporate demographic information into models that predict if a population is likely to persist in the future. PVAs incorporate deterministic and stochastic events including demographic and environmental variation, and natural catastrophes. PVAs have also been criticized as being overly optimistic about future population levels (Brook et al. 1997) and should be viewed with caution; however, they are and have been shown to be surprisingly accurate for managing endangered taxa and evaluating different management practices (Brook 2000). They are also useful in conducting sensitivity analyses to determine where more precise information is needed (Hamilton and Moller 1995, Beissinger and Westphal 1998, Reed et al. 1998, Fieberg and Ellner 2000).

As originally defined by Shaffer (1981), "a minimum viable population for any given species in any given habitat is the smallest isolated population having a 99 percent chance of remaining extant for 1,000 years despite the foreseeable effects of demographic, environmental and genetic stochasticity, and natural catastrophes." However, the goal of 95 percent probability of persistence for 100 years is the standard recommended by population biologists and is used in management strategies and conservation planning, particularly for situations where it is difficult to accurately predict long-term effects (Shaffer 1978, 1981, 1987, Sarkar 2004).

Since 1981, 139 Florida panthers have been radio-collared and monitored on public and private lands throughout south Florida (Lotz et al. 2005). These data were used by researchers to estimate survival rates and fecundity and were incorporated into PVA models previously developed for the Florida panther (Seal et al. 1989, 1992, Cox et al. 1994, Kautz and Cox 2001, Maehr et al. 2002b). These models incorporated a range of different model parameters such as general sex ratios, kitten survival rates, age distributions, and various levels of habitat losses, density dependence, and intermittent catastrophes or epidemics. The outputs of these models predicted a variety of survival scenarios for the Florida panther and predicted population levels needed to ensure the survival of the species.

Root (2004) developed an updated set of PVA models for the Florida panther based on RAMAS GIS software (Akçakaya 2002). These models were used to perform a set of spatially explicit PVAs. Three general single-sex (i.e., females only) models were constructed using demographic variables from Maehr et al. (2002b) and other sources. A conservative model was based on Seal

and Lacy (1989), a moderate model was based on Seal and Lacy (1992), and an optimistic model was based on the 1999 consensus model of Maehr et al. (2002b). In each model, first-year kitten survival was set at 62 percent based on recent information from routine panther population monitoring (Shindle et al. 2001). All models assumed a 1:1 sex ratio, a stable age distribution, 50 percent of females breeding in any year, and an initial population of 41 females (82 individuals including males), the approximate population size in 2001-2002 (McBride 2001, 2002).

Basic Versions: The basic versions of each model incorporated no catastrophes or epidemics, no change in habitat quality or amount, and a ceiling type of density dependence. The basic versions of the models incorporated a carrying capacity of 53 females (106 panthers - 50/50 sex ratio). Variants of the models were run with differing values for density dependence, various levels of habitat loss, and intermittent catastrophes or epidemics. Each simulation was run with 10,000 replications for a 100-year period. The minimum number of panthers needed to ensure a 95 percent probability of persistence for 100 years was estimated in a series of simulations in which initial abundance was increased until probability of extinction at 100 years was no greater than 5 percent. More detailed information concerning the PVA model parameters appears in Root (2004).

The results of these model runs predicted a probability of extinction for the conservative model of 78.5 percent in 100 years with a mean final total abundance of 3.5 females. Also, the probability of a large decline in abundance (50 percent) was 94.1 percent. The moderate model resulted in a 5 percent probability of extinction and mean final abundance of 42.3 females in 100 years. The probability of panther abundance declining by half the initial amount was 20 percent in 100 years under the moderate model. The optimistic model resulted in a 2 percent probability of extinction and mean final abundance of 51.2 females in 100 years. The probability of panther abundance declining by half the initial amount was only 9 percent in 100 years under the optimistic model. These models also provide a probability of persistence (100 percent minus probability of extinction) over a 100-year period of 95 percent for the moderate model and 98 percent for the optimistic model.

One Percent Habitat Loss: Model results were also provided by Root (2004) for probability of extinctions for 1 percent loss of habitat, within the first 25 years of the model run. The 1 percent loss of habitat equates to essentially all remaining non-urban privately owned lands in the Primary Zone and corresponds to the estimated rate of habitat loss (Root 2004) from 1986 to 1996 for the five southwest counties based on land use changes. For the moderate model, the model runs predict a probability of extinction increase of about one percent, from a probability of extinction of about 5 percent with no loss of habitat to 6 percent with 1.0 percent habitat loss per year, for the first 25 years. For the optimistic model, probability of extinction increased from about 2 percent with no loss of habitat to 3 percent with 1.0 percent habitat loss per year, for the first 25 years. These models also predicted the mean final abundance of females would decrease from 41 to 31 females, a 24.3 percent reduction for the moderate model and from 41 to 38 females, a 7.3 percent reduction for the optimistic model.

The model runs also predict a probability of persistence (100 percent minus the probability of extinction) over a 100-year period of about 94 percent for the moderate model and 97 percent

for the optimistic model. The model runs, predict a mean final abundance of 62 individuals (31 females and 31 males) for the moderate model and 76 individuals (38 females and 38 males) for the optimistic model.

Population Guidelines: Kautz et al. (2006), following review of the output of Root's PVA models and those of other previous PVAs for the Florida panther, suggested a set of population guidelines for use in management and recovery of the Florida panther. These guidelines are: (1) populations of less than 50 individuals are likely to become extinct in less than 100 years; (2) populations of 60 to 70 are barely viable and expected to decline by 25 percent over 100 years; (3) populations of 80 to 100 are likely stable but would still be subject to genetic problems (*i.e.,* heterozygosity would slowly decline); and (4) populations greater than 240 have a high probability of persistence for 100 years and are demographically stable and large enough to retain 90 percent of original genetic diversity.

Population guidelines for populations of panthers between 50 and 60 individuals and between 70 and 80 individuals were not specifically provided in Kautz et al. (2006). However, the Service views the guidelines in Kautz et al. (2006) as a continuum. Therefore, we consider populations of 50 to 60 individuals to be less than barely viable or not viable with declines in population and heterozygosity. Similarly, we consider populations of 70 to 80 to be more than barely viable or somewhat viable with some declines in population and heterozygosity. Like other population guidelines presented in Kautz et al. (2006), these assume no habitat loss or catastrophes.

PVA Summaries and Population Guidelines: Root's (2004) moderate model runs, which have a carrying capacity 53 females (106 individuals), show final populations of 42.3 females (84 total) and 31.2 females (62 total) with extinction rates of 5 percent and 6 percent, respectively, for the basic and 1 percent habitat loss scenarios. The predicted final populations in Root (2004) are 84 and 62 panthers for no loss of habitat and 1 percent loss of habitat, respectively, over a 100-year period.

Kautz et al.'s (2006) population guidelines applied to the Root (2004) moderate models for a population of 62 to 84 panthers, with or without habitat loss, respectively, describe the "with habitat loss" population as barely viable and expected to decline by 25 percent over a 100-year period. The "without habitat loss" is likely stable but would still be subject to genetic problems.

In conclusion, the Service believes the model runs show lands in the Primary Zone are important to the survival and recovery of the Florida panther and sufficient lands need to be managed and protected in south Florida to provide for a population of 80 to 100 panthers, the range defined as likely stable over 100 years, but subject to genetic problems. As discussed in the following section, the Service has developed a south Florida panther conservation goal that, through regulatory reviews and coordinated conservation efforts with land owners and resource management partners, provides a mechanism to achieve this goal.

Model Violations: The actual likelihood of population declines and extinctions may be different than the guidelines and models suggest, depending upon the number of and severity of assumptions violated. The Service realizes that habitat loss is occurring at an estimated

0.8 percent loss of habitat per year (R. Kautz, FWC, personal communication, 2003). The Service has accounted for some habitat loss and changes in habitat quality within its regulatory program, and specifically through its habitat assessment methodology (discussed below). For example, we have increased the base ratio used within this methodology to account for unexpected increases in habitat loss. Similarly, we consider changes in habitat quality and encourage habitat restoration wherever possible.

With regard to the assumption of no catastrophes, the Service has considered the recent outbreak of feline leukemia in the panther population at Okaloacoochee Slough as a potential catastrophe. The FWC is carefully monitoring the situation and it appears to be under control at this time due to a successful vaccination program. However, if the outbreak spreads into the population, the Service will consider this as a catastrophe and factor this into our decisions.

We acknowledge uncertainties exist, assumptions can be violated, and catastrophes can occur. The Service and the FWC, along with our partners, will continue to monitor the panther population and the south Florida landscape and incorporate any new information and changes into our decision-making process.

South Florida Panther Population Goal

The Service's goal for Florida panther conservation in south Florida is to locate, preserve, and restore sets of lands containing sufficient area and appropriate land cover types to ensure the long-term survival of a population of 80 to 100 individuals (adults and subadults) south of the Caloosahatchee River. The Service proposes to achieve this goal through land management partnerships with private landowners, through coordination with private landowners during review of development proposals, and through land management and acquisition programs with Federal, State, local, private, and Tribal partners. The acreages of lands necessary to achieve this goal, based on Kautz et al. (2006) average density of 31,923 ac (12,919 ha) per panther is 2,551,851 ac (1,032,720 ha) for 80 panthers or 3,189,813 ac (1,290,900 ha) for 100 panthers.

The principle regulatory mechanism that allows the Service to work directly with private land owners during review of development and land alteration projects is section 10 of the Act. The Service coordinates with Federal agencies pursuant to section 7 of the Act. In August 2000, the Service, to assist the Corps in assessing project effects to the Florida panther, developed the Florida panther final interim Standard Local Operating Procedures for Endangered Species (SLOPES) (Service 2000). The Florida panther SLOPES provide guidance to the Corps for assessing project effects to the Florida panther and recommends actions to minimize these effects. The Florida panther SLOPES also included a consultation area map that identified an action area where the Service believed land alteration projects may affect the Florida panther.

In the original SLOPES the consultation area map (MAP) was generated by the Service by overlaying existing and historical panther telemetry data on a profile of Florida and providing a connecting boundary surrounding most of these points. Since the development of the MAP, we have received more accurate and up-to-date information on Florida panther habitat usage. Specifically we have received two documents the Service believes reflects the most likely

panther habitat usage profiles although documentation clearly shows panther use of areas outside these locations. These documents are the publications by Kautz et al. (2006) and Thatcher et al. (2006). Based on the information in these documents, we have clarified the boundaries of the MAP to better reflect areas where Florida panthers predominate (Figure 7) and refer to these areas cumulatively as the Panther Focus Area.

The Panther Focus Area was determined from the results of recent panther habitat models south of the Caloosahatchee River (Kautz et al. 2006) and north of the Caloosahatchee River (Thatcher et al. 2006). Kautz et al. (2006) model of landscape components important to Florida panther habitat conservation was based on an analysis of panther habitat use and forest patch size. This model was used in combination with radio-telemetry records, home range overlaps, land use and land cover data, and satellite imagery to delineate primary and secondary areas that would be most important and comprise a landscape mosaic of cover types important to help support of the current panther breeding population south of the Caloosahatchee River.

Thatcher et al. (2006) developed a habitat model using Florida panther home ranges in south Florida to identified landscape conditions (land-cover types, habitat patch size and configuration, road density and other human development activities, and other similar metrics) north of the Caloosahatchee River that were similar to those associated with the current panther breeding population.

The Panther Focus Area MAP, south of the Caloosahatchee River is divided into Primary, Secondary, and Dispersal Zones; and north of the Caloosahatchee River into the Primary Dispersal and Expansion Area.

Primary Zone is currently occupied and supports the only known breeding population of Florida panthers in the world. These lands are important to the long-term viability and persistence of the panther in the wild.

Secondary Zone lands are contiguous with the Primary Zone and although these lands are used to a lesser extent by panthers, they are important to the long-term viability and persistence of the panther in the wild. Panthers use these lands in a much lower density than in the Primary Zone.

Dispersal Zone is a known corridor between the Panther Focus Area south of the Caloosahatchee River to the Panther Focus Area north of the Caloosahatchee River. This Zone is necessary to facilitate the dispersal of panthers and future panther population expansion to areas north of the Caloosahatchee River. Marked panthers have been known to use this zone.

Primary Dispersal/Expansion Area is the Fisheating Creek/Babcock-Webb Wildlife Management Area region. These are lands identified by Thatcher et al. (2006) as potential panther habitat with the shortest habitat connection to the Panther Focus Area in south Florida. Several collared and uncollared male panthers have been documented in this area since 1973, and the last female documented north of the Caloosahatchee River was found in this area.

Landscape Preservation Need and Compensation Recommendations

Land Preservation Needs: To further refine the land preservation needs of the Florida panther and to specifically develop a landscape-level program for the conservation of the Florida panther population in south Florida, the Service as previously discussed, in February 2000, appointed a Florida Panther Subteam. The Subteam in addition to the assignments discussed previously, was also charged with developing a landscape-level strategy for the conservation of the Florida panther population in south Florida. The results of this collaborative effort are partially presented in Kautz et al. (2006). One of the primary goals of this effort was to identify a strategically located set of lands containing sufficient area and appropriate land cover types to ensure the long-term survival of the south population of the Florida panther. Kautz et al. (2006) focused their efforts on the area south of the Caloosahatchee River, where the reproducing panther population currently exists.

Kautz et al. (2006) created an updated Florida panther potential habitat model based on the following criteria: (1) forest patches greater than 4.95 ac (2 ha); (2) non-urban cover types within 656 ft (200 m) of forest patches; and (3) exclusion of lands within 984 ft (300 m) of urban areas. The potential habitat map was reviewed in relation to telemetry data, recent satellite imagery (where available), and panther home range polygons. Boundaries were drawn around lands defined as the Primary Zone (Figure 10), defined as the most important area needed to support a self-sustaining panther population. Kautz et al. (2006) referred to these lands as essential; however, as observed in the two previous plans (Logan et al. 1993; Cox et al. 1994), lands within the boundaries of the Primary Zone included some urban areas and other lands not considered to be truly panther habitat (*i.e.*, active rock and sand mines). The landscape context of areas surrounding the Primary Zone was modeled and results were used to draw boundaries of the Secondary Zone (Figure 10), defined as the area capable of supporting the panther population in the Primary Zone, but where habitat restoration may be needed (Kautz et al. 2006).

Kautz et al. (2006) also identified, through a least cost path model, the route most likely to be used by panthers dispersing out of south Florida, crossing the Caloosahatchee River, and dispersing into south-central Florida. Kautz et al. (2006) used ArcView GIS© version 3.3 and ArcView Spatial Analyst© version 2 (Environmental Systems Research, Incorporated, Redlands, California) to construct the least-cost path models and identify optimum panther dispersal corridor(s). The least-cost path models operated on a cost surface that ranked suitability of the landscape for use by dispersing panthers with lower scores indicating higher likelihood of use by dispersing panthers. The lands within the boundaries of the least cost model prediction were defined as the Dispersal Zone (Figure 10). The preservation of lands within this zone is important for the survival and recovery of the Florida panther, as these lands are the dispersal pathways for expansion of the south Florida panther population. The Primary Zone covers 2,270,590 ac (918,895 ha); the Secondary Zone covers 812,104 ac (328,654 ha); and the Dispersal Zone covers 27,883 ac (11,284 ha); providing a total of 3,110,578 ac (1,258,833 ha) (Kautz et al. 2006).

As part of their evaluation of occupied panther habitat, in addition to the average density estimate of one panther per 27,181 ac (11,000 ha) developed by Maehr et al. (1991), Kautz

et al. (2006) estimated the present average density during the timeframe of the study, based on telemetry and other occurrence data, to average 1 panther per 31,923 ac (12,919 ha). In the following discussions of the number of panthers that a particular zone may support, the lower number is based on the 31,923 ac (12,919 ha) value (Kautz et al. 2006) and the higher number is based on the 27,181 ac (11,000 ha) value (Maehr et al. 1991).

Based on these average densities, the Primary Zone could support 71 to 84 panthers; the Secondary Zone 8 to 10 panthers without habitat restoration and 25 to 30 panthers with habitat restoration (existing high quality panther habitat currently present in the Secondary Zone is estimated at 32 percent of the available Secondary Zone lands); and the Dispersal Zone, 0 panthers. Taken together, the three zones in their current condition apparently have the capacity to support approximately 79 to 94 Florida panthers.

Kautz et al.'s (2006) assessment of available habitat south of the Caloosahatchee River determined that non-urban lands in the Primary, Secondary, and Dispersal Zones were not sufficient to sustain a population of 240 individuals south of the Caloosahatchee River. However, Kautz et al. (2006) determined sufficient lands were available south of the Caloosahatchee River to support a population of 79 to 94 individuals (although not all lands are managed and protected).

Compensation Recommendations: To achieve our goal to locate, preserve, and restore sets of lands containing sufficient area and appropriate land cover types to ensure the long-term survival of a population of Florida panthers south of the Caloosahatchee River, the Service chose the mid point (90 panthers) in Kautz et al.'s (2006) population guidelines that a population of 80 to 100 panthers is likely to be stable, although subject to genetic problems, through 100 years. In addition, a population of 90 individuals is eight individuals greater than a population of 82 individuals, which according to the best available PVA (Root 2004) is 95 percent likely to persist over 100 years (assuming a 50:50 male to female ratio). These eight individuals provide a buffer for some of the assumptions in Root's (2004) PVA. Our process to determine compensation recommendations for project affects that cannot be avoided in both our section 7 and section 10 consultations is based on the amount and quality of habitat we believe is necessary to support a population of 90 panthers in south Florida.

The Service, based on Kautz et al.'s (2006) average panther population density of 31,923 ac per panther determined 2,873,070 ac of Primary Zone "equivalent" lands need to be protected and managed. This equivalency factor is needed, since Secondary Zone lands are of less value than Primary Zone lands to the panther, to assure that additional acreage (special consideration) is required in the Secondary Zone to compensate for its lower quality panther habitat. In other words, more than 31,923 ac per panther would be needed, hypothetically, if this acreage were all in the Secondary Zone (see discussion of Primary Zone equivalent lands in the following section). The combined acreage of lands within the Primary, Dispersal, and Secondary Zones is 3,110,577 ac (1,258,833 ha) (Kautz et al. 2006). Currently, 2,073,865 ac of Primary Zone equivalent lands are preserved (Table 4), so 799,205 additional ac need to be preserved to support a population of 90 panthers in south Florida (2,873,070 minus 2,073,865 equals 799,205).

The Service also consults on lands outside of the Primary, Secondary, and Dispersal zones that may effect panthers such as agricultural lands that are adjacent to the Panther Focus Area and proposals in urbanized areas that could generate traffic in or adjacent to the Panther Focus Area or have other identifiable impacts.

Primary Zone Equivalent Lands: Kautz et al. (2006), through their habitat evaluation of lands important to the Florida panther, identified three sets of lands, *i.e.,* Primary Zone, Secondary Zone, and Dispersal Zone, and documented the relative importance of these lands to the Florida panther. These lands generally referred to as the panther core lands (Figure 10), include the majority of the home ranges of the current population of the Florida panther. The Service, in our evaluation of habitat needs for the Florida panther expanded the boundaries of the Kautz et al. (2006) lands to include those lands south of the Caloosahatchee River where additional telemetry points historically were recorded. These additional lands (about 819,995 ac), referred to as the "Other" Zone, are added to the lands in Kautz et al.'s (2006) panther core lands (Figure 10) and represent the lands within the Service's 2000 consultation area boundary south of the Caloosahatchee River as shown in Figure 7. These lands (core lands and other zone lands) together are referred to by the Service as the core area. The "Other" Zone lands, as well as the lands within the Secondary Zone, provide less landscape benefit to the Florida panther than the Primary and Dispersal Zones, but are important as a component of our goal to preserve sufficient lands to support a population of 90 panthers in South Florida.

To account for the lower landscape importance of these lands in our preservation goals and in our habitat assessment methodology, we assigned lands in the Other Zone a value of 0.33 and lands in the Secondary Zone a value of 0.69 to convert these lands to Primary Zone value, *i.e.,* Primary Zone equivalents (Table 5). Kautz et al. (2006) identifies the need for restoration in the Secondary Zone to achieve maximum benefits. To estimate the Primary Zone equivalent of Secondary Zone lands, we derived a relative habitat value (average PHU value) for each by comparing the habitat ranks estimated in Kautz et al. (2006 – Table 1) for each habitat type per zone. The average PHU value for the Primary Zone is 6.94 and for the Secondary Zone 4.79. Based on this analysis, the habitat value of the Secondary Zone is roughly 69 percent of the Primary Zone, and restoration is needed to achieve landscape function (4.79/6.94=0.69). Dispersal Zone lands are considered equivalent to Primary Zones lands with a 1/1 value. At-risk lands in the Other Zone total 819,995 ac. Actions on some of the Other Zone lands such as some actions in areas that have already been urbanized will not have an impact on panthers or their habitat, and these case-specific determinations will be made based on a review of the specific proposals. We estimate 80 percent of these actions will have an impact on achieving the panther population goal, and will monitor this carefully as we review proposed actions (819,995 times 0.8 equals 655,996 ac). Multiply this acreage (655,996 ac) by 0.33 to determine the ac of Primary Zone equivalent lands the Other Zone can provide (655,996 times 0.33 equals 216,479 ac of Primary Zone equivalent lands) (Table 5). Using this assessment, the 503,481 ac of Secondary Zone lands equate to 347,402 ac of Primary Zone equivalent lands. These equivalent values, 0.33 and 0.69, for Other and Secondary Zones, respectively, and 1/1 for Dispersal Zone, are important components in our assessment of compensation needs for a project

in the panther consultation area and are components of our habitat assessment methodology as discussed below.

Habitat Assessment Methodology

To evaluate project effects to the Florida panther, the Service considers the contributions the project lands provide to the Florida panther, recognizing not all habitats provide the same functional value. Kautz et al. (2006) also recognized not all habitats provide the same habitat value to the Florida panther and developed cost surface values for various habitat types, based on use by and presence in home ranges of panthers. The FWC (2006b), using a similar concept, assigned likely use values of habitats to dispersing panthers. The FWC's habitats were assigned habitat suitability rank between 0 and 10, with higher values indicating higher likely use by dispersing panthers.

The Service chose to evaluate project effects to the Florida panther through a similar process. We incorporated many of the same habitat types referenced in Kautz et al. (2006) and FWC (2006b) with several adjustments to the assigned habitat use values reflecting consolidation of similar types of habitats and the inclusion of Everglades Restoration water treatment and retention areas. We used these values as the basis for habitat evaluations and the recommended compensation values to minimize project effects to the Florida panther (Table 6), as discussed below.

Base Ratio: To develop a base ratio that will provide for the protection of sufficient acreage of Primary Zone equivalent lands for a population of 90 panthers from the acreage of Primary Zone equivalent non-urban lands at risk, we developed the following approach.

The available Primary Zone equivalent lands are estimated at 3,276,563 ac (actual acreage is 4,376,444 ac [the "actual acreage" value includes acres of lands in each category in the Secondary and Other Zones as well as the lands in the Primary Zone]) (see Table 5). Currently 2,073,865 ac of Primary Zone equivalent lands (actual acreage is 2,578,152 ac) of non-urban lands are preserved. The remaining non-urban at-risk private lands are estimated at 1,202,698 ac of Primary Zone equivalent lands (actual acreage is 1,798,295 ac). To meet the protected and managed lands goal for a population of 90 panthers, an additional 799,205 ac of Primary Zone equivalent lands are needed. The base ratio is determined by dividing the primary equivalents of at-risk habitat to be secured (799,205 ac) by the result of the acres of at-risk habitat in the Primary Zone (610,935 ac) times the value of the Primary Zone (1); plus the at-risk acres in the Dispersal Zone (27,883 ac) times the value of the Dispersal Zone (1); plus the at-risk acres in the Secondary Zone (503,481 ac) times the value of the Secondary Zone (0.69); plus the at-risk acres in the Other Zone (655,996 ac) times the value of the Other Zone (0.33); minus the at-risk acres of habitat to be protected (799,205 ac). The results of this formula provide a base value of 1.98.

$$799{,}205 / ((610{,}935 \times 1.0) + (27{,}883 \times 1) + (503{,}481 \times 0.69) + (655{,}996 \times 0.33)) - 799{,}205 = 1.98$$

In evaluating habitat losses in the consultation area, we used an estimate of 0.8 percent loss of habitat per year (R. Kautz , FWC, personal communication, 2004) to predict the amount of

habitat loss anticipated in south Florida during the next 5 years (*i.e.,* 6,000 ha per year; 14,820 ac per year). We conservatively assumed that we would be aware of half of these projects. We assumed that half of the projects would occur in the Primary Zone and half would occur in the Secondary Zone. We estimated that over a 5-year period that about 37,000 ac would be developed without Federal review. We adjusted the base value from 1.98 to 2.23.

We also realize that collectively habitat losses from individual single-family residential developments will compromise the Service's goal to secure sufficient lands for a population of 90 panthers. We believe, on an individual basis, single-family residential developments by individual lot owners on lots no larger than 2.0 ha (5.0 ac) will not result in take of panthers on a lot-by-lot basis; however, collectively these losses may impact the panther. Panthers are a wide ranging species, and individually, a 2.0 ha (5.0 acre) habitat change will not have a measurable impact. Compensation for such small-scale losses on a lot-by-lot basis is unlikely to result in meaningful conservation benefits for the panther versus the more holistic landscape level conservation strategy used in our habitat assessment methodology. To account for these losses, we estimated about another 12,950 ac over a 5-year period (2,590 ac per year) would be developed through this avenue. We adjusted the base value from 2.23 to 2.48.

We also realize there is a need for road crossings in strategic locations and we believe there are projects that may not have habitat loss factors but will have traffic generation factors. The Service considers increases in traffic as an indirect effect from a project and can contribute to panther mortality. Therefore, we have added another 0.02 to the base ratio to address traffic impacts, which could provide an incentive to implement crossings in key locations. Following the same approached shown above, we adjusted the base ratio from 2.48 to the 2.5. The Service intends to re-evaluate this base ratio periodically and adjust as needed to make sure all adverse effects are adequately ameliorated and offset as required under section 7 of the Act and to achieve the Service's conservation goal for the Florida panther.

Landscape Multiplier: As discussed previously in the above section on Primary Zone Equivalent Lands, the location of a project in the landscape of the core area of the Florida panther is important. As we have previously discussed, lands in the Primary and Dispersal Zones are of the most importance in a landscape context to the Florida panther, with lands in the Secondary Zone of less importance, and lands in the Other Zone of lower importance. These zones affect the level of compensation the Service believes is necessary to minimize a project's effects to Florida panther habitat. Table 7 provides the landscape compensation multipliers for various compensation scenarios. As an example, if a project is in the Other Zone and compensation is proposed in the Primary Zone, a Primary Zone equivalent multiplier of 0.33 is applied to the PHUs (see discussion below) developed for the project. If the project is in the Secondary Zone and compensation is in the Primary Zone, then a Primary Zone equivalent multiplier of 0.69 is applied to the PHUs developed for the project.

Panther Habitat Units – Habitat Functional Value: Prior to applying the base ratio and landscape multipliers discussed above, we evaluate the project site and assign functional values to the habitats present. This is done by assigning each habitat type on-site a habitat suitability value from the habitats shown in Table 6. The habitat suitability value for each habitat type is

then multiplied by the acreage of that habitat type resulting in a number representing PHUs. These PHUs are summed for a site total, which is used as a measurement of the functional value the habitat provides to the Florida panthers. This process is also followed for the compensation-sites.

Exotic Species Assessment: Since many habitat types in south Florida are infested with exotic plant species, which affects the functional value a habitat type provides to foraging wildlife species (*i.e.,* primarily deer and hog), we believe the presence of these species and the value these species provide to foraging wildlife needs to be considered in the habitat assessment methodology. As shown in Table 6, we have a habitat type and functional value shown for exotic species. This category includes not only the total acres of pure exotic species habitats present but also the percent-value acreages of the exotic species present in other habitat types.

For example, a site with 100 ac of pine flatwoods with 10 percent exotics would be treated in our habitat assessment methodology as 90 ac of pine flatwoods and 10 ac of exotics. Adding another 100 ac of cypress swamp with 10 percent exotics would change our site from 90 ac of pine flatwoods and 10 ac of exotics to 90 ac of pine flatwoods, 90 ac of cypress swamp, and 20 ac of exotics.

Habitat Assessment Methodology Application – Example: To illustrate the use of our habitat assessment methodology, we provide the following example. A 100-acre project site is proposed for a residential development. Plans call for the entire site to be cleared. The project site contains 90 ac of pine flatwoods and 10 ac of exotic vegetation, and is located in the "Secondary Zone." The applicant has offered habitat compensation in the "Primary Zone" to minimize the impacts of the project to the Florida panther. To calculate the PHUs provided by the site, we multiply the habitat acreage by the "habitat suitability value" for each habitat type and add those values to obtain a value of 840 PHUs ((90 ac of pine flatwoods x 9 [the habitat suitability value for pine flatwoods] = 810 PHUs) + (10 ac of exotic vegetation x 3 [the habitat suitability value for exotics] = 30 PHUs) = 840 PHUs). The value of 840 PHUs is then multiplied by the 2.5 (the base ratio) and 0.69 (the landscape multiplier) resulting in a value of 1,149 PHUs for the project site. In this example, the acquisition of lands in the Primary Zone containing at least 1,149 PHUs are recommended to compensate for the loss of habitat to the Florida panther resulting from this project.

Analysis of the species likely to be affected

The Florida panther is an endangered animal restricted to two to three million acres of land (6 to 9 percent of the total land area of Florida) in south Florida. The panther is a wide-ranging species that requires a biotically diverse landscape to survive. Dispersing subadult males wander widely through unforested and disturbed habitat. Human population in south Florida has dramatically increased, from one million in 1950 to six million in 1990, resulting in secondary disturbances such as increased human presence and noise, light, air, and water pollution. Increasing human population has resulted in increasing impacts on native habitat and flora and fauna. Resulting threats to panthers include road mortality, habitat loss, habitat fragmentation, and human disturbance.

STATUS OF THE SPECIES AND CRITICAL HABITAT RANGEWIDE - Audubon's Crested Caracara

The caracara is a member of the Class Aves, Order Falconiformes, Family Falconidae. It was originally described by John James Audubon (1834), who discovered the caracara on November 21, 1831, and published an account under the name *Polyborus vulgaris*. John Cassin renamed it in 1865 to *Polyborus audubonii*. In 1999, Dove and Banks definitively renamed the species *Caracara cheriway* and eliminated all subspecies classifications. Dove and Banks (1999) conducted a taxonomic analysis of museum specimens of caracaras based on plumage and morphological characteristics and concluded that there are three caracara species with no subspecific groupings. They refer to the North American caracara as *Caracara cheriway*, and this name was subsequently accepted by the American Ornithologists' Union. The list of threatened and endangered animals (50 CFR 17.11) continues to refer to the old scientific name *Polyborus plancus audubonii*, but this species is referred to in the remainder of this document as the caracara. It is a resident, diurnal, and non-migratory species that occurs in Florida as well as the southwestern United States and Central America. Florida's population of the caracara is found in the prairie area of the south-central region of the State. Only the Florida population, which is isolated from other populations of the species in the southwestern United States and Central America, is listed under the Act.

Species Description

The caracara is a large raptor with a crest, naked face, heavy bill, elongated neck, and unusually long legs. It is about 50 to 64 centimeters (cm) long and has a wingspan of 120 cm. The adult is dark brownish black on the crown, wings, back, and lower abdomen. The lower part of the head, throat, upper abdomen, and under tail coverts are white, the breast and upper back are whitish, heavily barred with black. The tail is white with narrow, dark crossbars and a broad, dark terminal band. Prominent white patches are visible near the tips of the wings in flight. The large, white patches in the primaries and the white tail, broadly tipped with black, are both very conspicuous in flight and can be recognized at a long distance (Bent 1961).

Juveniles have a similar color pattern but are brownish and buffy, with the breast and upper back streaked instead of barred. Subadults resemble adults but are more brownish in color. Adults have yellow-orange facial skin and yellow legs. Facial skin of juveniles is pinkish in color, and the legs are gray (Layne 1978). Full adult plumage is obtained sometime after 3 years of age (Morrison 1997). There is no evidence of sexual dimorphism, the sexes being similar in color and size; however, gender can be determined surgically or through genetic analysis (Morrison and Maltbie 1999).

A caracara's feet and flight behavior are also notable. Their feet are clearly those of a raptor; however, their talons are flatter, enabling caracaras to run and walk more easily than other raptors. Caracaras are terrestrial and often forage by walking for extended periods on the ground (Morrison and Humphrey 2001). Bent (1938) noted the caracara's flight pattern resembles that of a northern harrier (*Circus cyaneus*), but caracaras fly faster and more gracefully. Caracaras

are strong fliers and may reach speeds of 40 mph. They have also been observed soaring in large circles at great heights (Howell 1932).

Critical Habitat Description

Critical Habitat has not been designated for this species.

Life History

Caracaras are resident, diurnal, and non-migratory. Adult caracaras may be found in their home range year-round. Home ranges average approximately 3,000 ac (approximately 1,200 ha), corresponding to a radius of 1.2 to 1.5 miles (2 to 2.5 kilometers) surrounding the nest site (Morrison and Humphrey 2001). Foraging typically occurs throughout the home range during nesting and non-nesting seasons.

The Florida caracara population historically inhabited native dry or wet prairie areas containing scattered cabbage palms, their preferred nesting tree. Scattered saw palmetto, and low-growing oaks (*Quercus minima, Q. pumila*), and cypress also occur within these native communities. Over the last century, many of the native prairie vegetation communities in central and south Florida have been converted to agricultural land uses, and frequently replaced by improved and unimproved pasture dominated by short-stature, non-native, sod-forming grasses. Morrison and Humphrey (2001) hypothesize that the vegetation structure of open grasslands (short-stature vegetation, scattered shrub cover, and nest trees) may be preferred by the caracara, due to its tendency to walk on the ground during foraging activities. The short vegetation stature and relatively simple vegetation structure may directly facilitate foraging by caracaras and provide less cover for predators. Consequently, caracaras appear to benefit from management actions such as prescribed burning that maintain habitat in a low stature and structurally simple condition. These activities reduce vegetation cover and may facilitate the observation and capture of prey. Within agricultural lands, regular mowing, burning, and high-density grazing may maintain low vegetative structure, an important habitat characteristic of the caracara's nest stand area (Morrison and Humphrey 2001). Regular prescribed burning maintains habitat in a favorable condition in native dry prairies. These field observations are consistent with the home range compositional analyses that indicate non-random selection of improved and semi-improved pasture land use.

Morrison and Humphrey (2001) characterized caracara distribution, reproductive activity, and land use patterns within a 21,000 km^2 area in south-central Florida. Comparisons of caracara home ranges to randomly selected areas and available habitat within the study area revealed caracara home ranges contained higher proportions of improved pasture and lower proportions of forest, woodland, oak scrub, and marsh. Home range size was inversely related to the proportion of improved pasture within the home range. In addition, breeding-area occupancy rate, breeding rates, and nesting success were consistently higher on private ranch lands during the study. Although it is unclear exactly which management activities best promote habitat utilization by caracaras, the mowing, burning, and grazing activities associated with improved pastures serve to maintain the short vegetation structure they appear to favor. The scattered cabbage palms that

are often present within improved pastures to serve as shade for cattle provide nesting substrate for caracaras.

Additional investigations into habitat suitability for caracara (Morrison *et al.* 2006) indicate that maintaining heterogeneity which includes specific land cover types as well as small (less than 1 hectare or 2.47 ac) of freshwater wetlands, is critical in maintaining suitable habitat for the crested caracara in Florida. The proportion of six vegetation and land cover types (*i.e.*, cabbage palm-live oak hammock, grassland, improved pasture, unimproved pasture, hardwood hammocks and forest, and cypress/pine/cabbage palm) and 2 types of water (*i.e.*, lentic and lotic) were determined to be the most important criteria for predicting habitat suitability for caracara. Most known nest locations (72.9 percent) in the study were present on improved pasture although that habitat type only comprised 12.5 percent of the entire study area. Caracara appear to be exploiting pastures, ditches, and impounded wetlands that have replaced the historic land cover as shown by the high occurrence of improved and unimproved pastures and lotic waters in caracara home ranges (Morrison *et al.* 2006).

Caracaras are highly opportunistic in their feeding habits, eating carrion and capturing live prey. Their diets include insects and other invertebrates, fish, snakes, turtles, birds, and mammals (Layne 1978). Live prey also include rabbits, young opossums (*Didelphis marsupialis*), rats (*Rattus* spp.), mice, squirrels, frogs, lizards, young alligators, crabs, crayfish, fish, young birds, cattle egrets (*Bubulcus ibis*), beetles, grasshoppers, maggots, and worms (Bent 1961; Layne et al. 1977; Morrison 2001). Scavenging at urban dumps has also been observed (Morrison 2001). More recent information from Morrison (2005) indicates that wetland-dependent prey items comprise about 64 percent of the total diet. Mammals make up about 31 percent of the diet, with the majority of this being carrion.

The birds also closely follow mowers in pastures and tractors plowing fields, in order to capitalize on prey that may be exposed. Agricultural drainage ditches, cattle ponds, roadside ditches and other shallow water features also provide good foraging conditions for caracaras (Morrison 2001). Within native habitats, caracaras regularly scavenge in recently burned areas, and forage along the margins of wetlands within dry prairie communities.

These raptors hunt on the wing, from perches, and on the ground (Service 1989). They will also regularly patrol sections of highway in search of carrion (Palmer 1988). They may be seen feeding on road kills with vultures. However, caracaras are dominant over vultures and may occasionally chase the larger vultures from the road kill (Howell 1932).

Although adult caracaras are generally territorial and primarily occupy home ranges, large groups of individual caracaras are occasionally encountered (Layne 1978). Oberholser (1974) attributes this to the birds' carrion-feeding habit, although Morrison (2005) has noted that juvenile caracaras are nomadic. Caracaras are capable of moving long distances. Between the time when young birds leave the natal territory, and when subadults establish a territory, each individual may traverse a large portion of the species' range in Florida. Adults will also occasionally leave their territory and travel great distances, primarily outside of the breeding season. The caracara's movement capability and nomadic character during subadult years may

be the cause of occasional observations of caracaras far outside their breeding range. Caracaras have been observed in the Florida Keys and into the panhandle of Florida (Bay County), as well as in other states, though some of these may have been escaped individuals (Layne 1996). There appears to be no migration or genetic exchange between the Florida population and other populations of the northern caracara.

Routine observation and radio-telemetry monitoring suggest there are several "gathering areas" in south-central Florida that may be important to caracaras during the first 3 years after leaving their natal territory, before first breeding (Morrison 2001). Relatively large numbers of caracaras (up to 50) have been observed along the Kissimmee River north of SR 98; south of Old Eagle Island Road in northern Okeechobee County; south of SR 70, west of Fort Pierce; and south of SR 70 in Highlands County, and on the Buck Island Ranch, for example. These gathering areas are regularly but not continually used by subadult and non-breeding caracaras and generally consist of large expanses of improved pasture; however, the particular habitat values of these areas have not yet been evaluated.

Morrison (1999) reported that breeding pairs of caracaras seem to be monogamous, highly territorial, and exhibit fidelity to both their mate and the site. The age at first breeding has been documented as 3 years (Nemeth and Morrison 2002).

Details of breeding behavior in the caracara have been documented by Morrison (1998, 1999). The initiation of breeding is marked by several behavioral changes, including the pair perching together near the nesting site, preening and allopreening, and sharing food. Caracaras are one of the first of Florida's raptors to begin nesting. Although breeding activity can occur from September through June, the primary breeding season is considered to be November through April. Nest initiation and egg-laying peak from December through February.

Caracaras construct new nests each nesting season, often in the same tree as the previous year. Both males and females participate in nest building. Nests are well concealed and most often found in the tops of cabbage palms (Morrison and Humphrey 2001) although nests have been found in live oaks (*Q. virginiana*), cypress (first record, Morrison et al. 1997), Australian pine (*Casuarina* spp.), saw palmetto, and black gum (*Nyssa sylvatica*). Caracaras usually construct their nests 4 to 18 m above the ground; their nests primarily consist of haphazardly woven vines trampled to form a depression (Bent 1938, Sprunt 1954, Humphrey and Morrison 1996). Caracaras vigorously defend their nesting territory during the breeding season (Morrison 2001).

Clutch size is two or three eggs, but most often two. Incubation lasts for about 31 to 33 days (Morrison 1999) and is shared by both sexes. Ordinarily only one brood is raised in a season, but around 10 percent of the population (annually) may raise a second brood. The young fledge at about 7 to 8 weeks of age, and post-fledgling dependency lasts approximately 8 weeks.

Population Dynamics

The great majority of caracara breeding territories occur on private lands in Florida, primarily within the ranchlands of central Florida. This fact makes monitoring the population and

determining territory occupancy and nesting effort or success very difficult. Consequently, estimates of the caracara population in Florida have been based on counts of caracaras along roadsides (Heinzman 1970; Layne 1995). These roadside counts also have the potential be strongly affected by the presence of non-territorial juvenile and sub-adult birds during the period when they are nomadic. Because the occurrence and density of caracaras is not evenly distributed within the region they occupy (due to congregation and nomadic individuals), these roadside surveys are probably unreliable for estimating the overall population.

Status and Distribution

The caracara's perceived decline, as described in historic literature, is attributed primarily to habitat loss (Layne 1996). This perceived decline and the geographic isolation of the Florida population eventually resulted in the caracara's listing as threatened in 1987 (52 FR 25232). In particular, the caracara was listed as threatened because its primary habitat, dry prairie, had been greatly eliminated or modified for agriculture and residential development. It was also listed because existing regulatory mechanisms did not adequately prevent the destruction or modification of the caracara's habitat, which is mainly located on private land.

Morrison and Humphrey (2001) stated that no data are available on historic abundance, habitat use, or nest distribution by caracaras in Florida. The size of Florida's caracara population remains in question. Accurate counts become difficult because of limited access to areas of suitable habitat and because of the bird's behavior and limited detectability (Humphrey and Morrison 1997). Heinzman (1970) published the results of a 4-year road survey (1967-1970), which suggested fewer than 100 individual caracaras at 58 localities remained in Florida. Stevenson (1976) concurred with this estimate in 1974. Layne (1995) monitored caracara distribution and population status in Florida from 1972 to 1989. Based on roadside surveys, he estimated that the adult portion of the population was stable with a minimum of about 300 birds in 150 territories. The immature portion of the population was estimated to be between 100 and 200 individuals, bringing the total statewide population to between 400 and 500 birds. However, given continued landscape change in areas where caracaras have been known to occur, and the fact that not all the probable breeding range has been adequately surveyed for breeding pairs, estimating this population's size remains difficult.

In addition to presumed population declines related to habitat loss, direct human-caused mortality may also be a factor to be considered in the recovery of the species. In the past, large numbers of caracaras were killed in vulture traps (Service 1989). Individuals may also be caught in leg-hold traps used to control mammalian predators (Morrison 1996). Road mortalities are a significant cause of caracara decline. Morrison (2003) identifies highway mortalities as a major cause of juvenile mortalities with young birds especially vulnerable within the first 6 months after fledging.

The Florida population of caracaras is isolated and habitat-specific. Therefore, it may be susceptible to environmental catastrophes and potentially reduced reproductive rates because of demographic accidents such as skewed sex ratios or disproportionate age-related mortality. Low numbers may also reduce the genetic viability through loss of heterozygosity, thereby increasing

vulnerability to environmental stresses. The location of many of the occupied territories on private land, and the inaccessibility of these territories to surveyors, makes it difficult to census the caracara and detect changes in its population size and distribution. This difficulty increases the possibility of not detecting a population decline that could result in extinction.

The major threat to this population remains habitat loss. Large areas of native prairie and pasture lands in south-central Florida have been converted to citrus operations, tree farms, other forms of agriculture, and real estate development and this loss has accelerated in the past few decades (Morrison and Humphrey 2001). However, historical conversion of forested habitats to pasture has not been adequately documented as partially offsetting losses to caracara habitat, so a full accounting of historic habitat changes is lacking. The current threat of habitat loss persists as changes in land use continue. Florida's burgeoning human population has also increased the number of motor vehicles and the need for roads. The increase in traffic as well as the caracara's predisposition for feeding on road-killed animals has probably increased the number of caracaras killed or injured as a result of vehicle strikes.

Cattle ranching and extensive pastures appear to be compatible with caracara survival. Inadequate information is available to assess current caracara use of native wet and dry prairie communities, but these communities are likely the primary communities that caracaras occupied in the historic Florida landscape. The number of territories occurring in improved or unimproved pasture can be expected to increase if sufficiently large overgrown pastures are reclaimed and new pastures or restored native prairies are created from other agricultural land uses. The conversion of pasture to citrus (Cox et al. 1994), sugarcane, and residential development is also cause for concern. Recognizing the conservation value of cattle ranches and enlisting landowner cooperation in the preservation and management of these lands are critical elements in recovery of the caracara.

Lack of habitat management is also a potential threat to caracaras in some areas, and can result in habitat degradation to the point where it is no longer suitable for occupancy. In particular, encroachment of woody shrubs and trees into open dry prairies, pastures and similar habitats will result in some reduction in habitat suitability. Complete clearing of large areas that includes removal of cabbage palms and other trees may also reduce the suitability of habitat, but generally only when very large areas are completely cleared.

While there is inadequate evidence available to conclude that the caracara population in Florida has declined significantly, loss of habitat is threatening remaining caracara territories at an increasing rate. The limited distribution of caracaras and a lack of opportunities for expansion of the distribution make this species vulnerable to reductions in habitat quality and other increasing threats within its range.

STATUS OF THE SPECIES AND CRITICAL HABITAT RANGEWIDE – Eastern Indigo Snake

Species description

The eastern indigo snake is the largest non-venomous snake in North America, obtaining lengths of up to 8.5 ft (2.6 meters) (Moler 1992). Its color is uniformly lustrous-black, dorsally and ventrally, except for a red or cream-colored suffusion of the chin, throat, and sometimes the cheeks. Its scales are large and smooth (the central 3 to 5 scale rows are lightly keeled in adult males) in 17 scale rows at mid-body. Its anal plate is undivided. In the Keys, adult eastern indigo snakes seem to have less red on their faces or throats compared to most mainland specimens (Lazell 1989). Several researchers have informally suggested that Lower Keys eastern indigo snakes may differ from mainland snakes in ways other than color.

Critical habitat description

Critical habitat has not been designated for this species.

Life history

In northern Florida, eastern indigo snakes breed between November and April, with females depositing 4 to 12 eggs during May or June (Moler 1992). Young hatch in approximately 3 months and there is no evidence of parental care. Limited information on the reproductive cycle in south-central Florida suggests that the breeding and egg-laying season may be extended. In this region, breeding extends from June to January; laying occurs from April to July; and hatching occurs during mid-summer to early fall (Layne and Steiner 1996). Eastern indigo snakes in captivity take 3 to 4 years to reach sexual maturity (Speake et al. 1987). Female eastern indigo snakes can store sperm and delay fertilization of eggs. There is a single record of a captive eastern indigo snake laying five eggs (at least one of which was fertile) after being isolated for more than 4 years (Carson 1945). However, there have been several recent reports of parthogenetic reproduction by virginal snakes. Hence, sperm storage may not have been involved in Carson's (1945) example (Moler 1998). There is no information on the eastern indigo snake lifespan in the wild, although one captive individual lived 25 years, 11 months (Shaw 1959).

Eastern indigo snakes are active and spend a great deal of time foraging for food and mates. They are one of the few truly diurnal snake species, meaning that they are active during the day and rest at night. The eastern indigo snake is a generalized predator and will eat any vertebrate small enough to be overpowered. They do not kill their prey by constriction, but swallow their prey alive. Food items include fish, frogs, toads, snakes (venomous, as well as non-venomous), lizards, turtles, turtle eggs, small alligators, birds, and small mammals (Keegan 1944; Babis 1949; Kochman 1978; Steiner et al. 1983).

Population dynamics

Eastern indigo snakes require a mosaic of habitats. A study in southern Georgia found that interspersion of tortoise-inhabited sandhills and wetlands improve habitat quality for the eastern indigo snake (Landers and Speake 1980). Eastern indigo snakes require sheltered retreats from winter cold and desiccating conditions, and often use burrows of the gopher tortoise (*Gopherus polyphemus*) when available (Speake et al. 1978; Layne and Steiner 1996). In habitats lacking gopher tortoises, eastern indigo snakes may take shelter in hollowed root channels, hollow logs, or the burrows of rodents, armadillos, or land crabs (Lawler 1977; Moler 1985a; Layne and Steiner 1996). In the milder climates of central and southern Florida, eastern indigo snakes exist in a more stable thermal environment, where availability of thermal refugia may not be as critical to snake survival. Over most of its range in Florida, the eastern indigo snake frequents diverse habitats such as pine flatwoods, scrubby flatwoods, floodplain edges, sand ridges, dry glades, tropical hammocks, edges of freshwater marshes, muckland fields, coastal dunes, and xeric sandhill communities (Service 1999). Eastern indigos also use agricultural lands and various types of wetlands, with higher population concentrations occurring in the sandhill and pineland regions of northern and central Florida. Observations over the last 50 years made by maintenance workers in citrus groves in east-central Florida indicate that eastern indigo snakes are occasionally observed on the ground in the tree rows and more frequently near the canals, roads, and wet ditches (Zeigler 2006). In extreme south Florida (*i.e.,* the Everglades and Florida Keys), eastern indigo snakes are found in tropical hardwood hammocks, pine rocklands, freshwater marshes, abandoned agricultural land, coastal prairie, mangrove swamps, and human-altered habitats (Steiner et al. 1983). It is thought that they prefer hammocks and pine forests since most observations occur there and use of these areas is disproportionate compared to the relatively small total area of these habitats (Steiner et al. 1983).

Eastern indigo snakes range over large areas and into various habitats throughout the year, with most activity occurring in the summer and fall (Smith 1987; Moler 1985a). In Georgia, the average range of the eastern indigo snake is 12 ac during the winter (December through April), 106 ac during late spring through early summer (May through July), and 241 ac during late summer and fall (August through November) (Speake et al. 1978). Adult males have larger home ranges than adult females and juveniles; their ranges average 554 ac, reducing to 390 ac in the summer (Moler 1985b). In contrast, a gravid female may use from 3.5 to 106 ac (Smith 1987). In Florida, home ranges for females and males range from 5 to 371 ac and 4 to 805 ac, respectively (Smith 2003). At the Archbold Biological Station (ABS), average home range size for females was determined to be 47 ac and overlapping male home ranges to be 185 ac (Layne and Steiner 1996).

Status and distribution

The eastern indigo snake was listed as threatened on January 31, 1978 (43 FR 4028), due to population declines caused by habitat loss, over-collecting for the domestic and international pet trade, and mortality caused by rattlesnake collectors who gas gopher tortoise burrows to collect snakes.

The eastern indigo snake ranges from the southeastern United States to northern Argentina (Conant and Collins 1998). This species has eight recognized subspecies, two of which occur in the United States: the eastern indigo and the Texas indigo (*D. c. erebennus*). In the United States, the eastern indigo snake historically occurred throughout Florida and in the coastal plain of Georgia and has been recorded in Alabama and Mississippi (Diemer and Speake 1983; Moler 1985b). It may have occurred in southern South Carolina, but its occurrence there cannot be confirmed. Georgia and Florida currently support the remaining endemic populations of the eastern indigo snake (Lawler 1977). The eastern indigo occurs throughout most of Florida and is absent only from the Dry Tortugas and Marquesas, Keys and regions of north Florida where cold temperatures and deeper clay soils exist (Cox and Kautz 2000).

Effective law enforcement has reduced pressure on the species from the pet trade. However, because of its relatively large home range, the eastern indigo snake is especially vulnerable to habitat loss, degradation, and fragmentation (Lawler 1977; Moler 1985a). The primary threat to the eastern indigo snake is habitat loss due to development and fragmentation. In the interface areas between urban and native habitats, residential housing is also a threat because it increases the likelihood of snakes being killed by property owners and domestic pets. Extensive tracts of undeveloped land are important for maintaining eastern indigo snakes. In citrus groves, eastern indigo snake mortality occurs from vehicular traffic and management techniques such as pesticide usage, lawn mowers, and heavy equipment usage (Zeigler 2006). Within the last 5 years, since the spread of citrus canker, Zeigler (2006) reported seeing at least 12 dead eastern indigo snakes that were killed by heavy equipment operators in the act of clearing infected trees.

Seven confirmed observations of eastern indigo snakes occurred on the A-1 Reservoir in Palm Beach County, an Acceler8 component of the EAA Storage Reservoir Project (EAA Project) under the CERP. The seven observations included a snake accidentally killed during reservoir construction on October 10, 2006.

Tasks identified in the recovery plan for this species include: habitat management through controlled burning, testing experimental miniature radio transmitters for tracking juveniles, maintenance of a captive breeding colony at Auburn University, recapture of formerly released eastern indigo snakes to confirm survival in the wild, educational lectures and field trips, and efforts to obtain landowner cooperation in conservation efforts (Service 1999).

To protect and manage this species for recovery, large expanses of land must be protected. Management of these lands must be directed towards maintaining and enhancing the diversity of plant and animal assemblages within these properties. Where these goals are achieved, eastern indigo snakes will directly benefit because of improved habitat conditions. Land managers are encouraged to utilize fire as a tool to maintain biodiversity in fire-dependent ecosystems.

ENVIRONMENTAL BASELINE – Florida Panther

The environmental baseline includes the past and present impacts of all Federal, state, or private actions and other human activities in the action area, the anticipated impacts of all proposed Federal projects in the action area that have already undergone formal or early section 7

consultation, and the impact of state or private actions, which occur simultaneously with the consultation in progress.

Status of the Species within the Action Area

As stated previously, for the purposes of this consultation, the action area includes the Corps' project area and surrounding lands frequently visited by panthers (Figure 11). The action area is a subset of the current geographic range of the panther and includes those lands that the Service believes may experience direct and indirect effects from the proposed development. Therefore, for both direct and indirect effects, the action area is defined as all lands within a 25-mile radius of the project. This action area does not include urban lands and lands west of I-75. The proposed action may have direct and indirect effects on the ability of panthers to breed, feed, and find shelter, and to disperse within the population.

The Service used current and historical radio-telemetry data, information on habitat quality, prey base, and evidence of uncollared panthers to evaluate panther use in the action area. Panther telemetry data are collected 3 days per-week from fixed-wing aircraft, usually in early to midmorning. However, researchers have shown panthers are most active between dusk and dawn (Maehr et al. 1990a, Beier 1995) and are typically at rest in dense ground cover during daytime monitoring flights (Land 1994). Therefore, telemetry locations may present an incomplete picture of panther activity patterns and habitat use (Comiskey et al. 2002). In addition, telemetry data alone may be misleading since less than half of the panther population is currently collared.

Although telemetry data may not provide a complete picture of panther activity patterns, telemetry locations are a good indicator, due to the extensive data set, of the approximate boundaries of home ranges, panther travel corridors, and the range of Florida panthers south of the Caloosahatchee River. The FWC also uses observational data collected during telemetry flights to assess the yearly breeding activity of radio-collared panthers. Female panthers accompanied by kittens or male panthers within close proximity of an adult female were assumed to have engaged in breeding activity during that year. Documentation by McBride (Shindle et al. 2003) shows that between July 2002 and June 2003, 3-collared panthers, 2-uncollared females, and 2-uncollared males had home ranges in or home ranges that overlapped or were immediately adjacent to the same survey unit as the C-43 West Storage Reservoir project. In addition, 8 other panthers that used this same survey unit previously died during this time period (FWC 2003). This unit, designated as Unit 7, includes the OSSF and WMA and adjacent private lands.

Within the 25-mile radius action area, based on telemetry data as of June 2006, at least 13 living radio-collared panthers have overlapping home ranges. These panthers are FP 48 (female), FP 62 (male), FP 65 (male), FP 66 (female), FP 75 (female), FP 81 (male), FP 83 (female), FP 84 (male), FP 110 (female), FP 131 (male), FP 137 (male), FP 139 (male), and FP 143 (male). In addition, McBride (2003) notes previous use of the action area by other panthers prior to their mortality. The nearest telemetry point to the site of a panther still alive as of this document was FP 65 (male), recorded about 0.04 miles to the north of the access road

parcel. During 1999, FP 74 (male) was documented twice within the reservoir footprint along the Townsend Canal and four times within 0.5 miles of the project footprint on adjacent private property to the southeast (Figure 14); however, he died of a vehicle collision in September of that same year. FP 28 (male) was documented along the perimeter of the reservoir footprint in the southeast corner and died in September 1992 due to intraspecific aggression.

Historically, there have been a total of five radio-collared male and female panthers (FP 28, FP 65, FP 74, FP 137, and TX 101) recorded within 5 miles of the project site on 28 occasions based on telemetry data from May 1989 through June 2006 (Figure 15). This translates to an average of 1.65 occurrences per year or one occurrence every 7 to 8 months. Panther 28 was documented 1 time in 1989 and died in 1992 from intraspecific aggression. Panther 65 was documented 14 times in 1998 and is alive with a home range on private property in Hendry County north of BCNP. Panther 74 was documented 9 times in 1999 and died in September 1999 from a vehicle collision. Panther 137 was documented 1 times in 2005 and is alive with a home range in OWMA. Texas puma 101 was documented 3 times in 1995 and died of unknown causes in 2000. No other radio-collared panthers have been documented within 5 miles of the project site since March 2005, and no radio-collared panthers have been recorded within the project site. The status and activities of uncollared Florida panthers within the action area are unknown. However, the Service believes the project site may occasionally be used by other non-collared panthers because it contains habitat types used by panthers and their prey, and the project vicinity has been used historically by panthers as indicated by telemetry locations.

Past and ongoing Federal and State actions affecting panther habitat in the action area include the issuance of Corps permits and State of Florida Environmental Resource Permits authorizing the filling of wetlands for development projects and other purposes. Since 1982, the Corps and the State have had a joint wetland permit application process, where all permit applications submitted to the State are copied to the Corps and vice versa. Within the 25-mile action area, the Service, since January 14, 1992, has formally consulted on 33 projects and informally consulted on 1 project regarding the panther that were a result of Federal actions (database entries for formal consultations prior to 1992 are incomplete for projects in the action area). These projects have impacted or are expected to impact about 33,062 ac of panther habitat. These projects have also incorporated a total of 22,967 ac of preservation and restoration of panther habitat. The impacted lands generally are: (1) on the western fringe of occupied panther habitat; (2) vegetated with dense stands of exotic species, which may adversely affect the density of the panther prey base; and (3) support agricultural enterprises, *i.e.*, row crops, citrus, etc., which provide a lower quality habitat value to the Florida panther. The preserved lands, which are generally proximate to larger tracts of Federal, State, and other preserves, provide a higher quality habitat value for the Florida panther. The Service determined in the Biological Opinions issued for the 33 Federal actions requiring formal consultation, that individually and cumulatively these projects do not jeopardize the survival and recovery of the Florida panther.

From July 2000 through September 2006, the Service also engaged in informal consultation for projects under 5 ac with the Corps for about 757 projects affecting about 764.1 ac in Collier County (primarily Northern Golden Gate Estates) and about 202.8 ac in Lee County (primarily Lehigh Acres) (database entries for informal consultations prior to 2000 are incomplete for

projects in the consultation area). Almost all of these projects involved the construction of single-family residences in partially developed areas, each in most cases involving less than an acre of direct impact. Although panthers have been known to cross these areas to other parts of their range, prey base and denning utilization of these areas have been affected by the level of development and the additions of these residences is not expected to significantly further impact these habitat functions. For these actions, the Service concurred with the Corps' determination of "may affect, but is not likely to adversely affect" for these individual projects. These projects have been incorporated into the Service's environmental baseline for the Florida panther.

We have received information that within the action area, the Corps has, between March 16, 2004, and August 8, 2005, issued non-jurisdictional wetland determinations (isolated wetlands) for 10 projects totaling 3,779 ac in Collier County and for 10 projects totaling 276 ac in Lee County. These determinations were issued per jurisdictional guidance provided recently in the Supreme Court decision, *Solid Waste Agency of Northern Cook County vs. U.S. Army Corps of Engineers,* 531 U.S. 159 (2001) and, therefore, they will not require a Federal Clean Water Act 404 wetland permit. These projects have been incorporated in the Service's environmental baseline for the Florida panther in this Biological Opinion and the Service has determined, based on the location of these projects (generally in the western fringe of the panther's geographic range), the quality of the habitat present on these project sites, and the overall status of the Florida panther, these projects individually and cumulatively do not jeopardize the survival and recovery of the Florida panther. However, since loss of panther foraging habitat may occur from construction of these projects and no Corps wetland permit is required, the Service is requesting the applicants pursue Habitat Conservation Plans in cooperation with the Service.

There have been 42 documented panther-vehicle collisions within the 25-mile action area (see Table 8 and Figure 16). The panther-vehicle collision closest to the project site (K 128 [male]) occurred in 2004, on CR 832, about 10.6 miles southeast of the site. Three other panthers, UCFP 29 (male), UCFP 90 (female), and UCFP 91 (male) were killed about 0.7, 0.1, and 1.3 miles from the K 128 mortality, respectively, on the same road. UCFP 29 was an adult killed during 1996 and UCFP 90 and UCFP 91 were both kittens (4 to 6 months old) killed during 2007. Two additional panther-vehicle collisions have already occurred in the action area in 2007. One occurred 23.5 miles southwest of the project on Interstate-75 0.5 miles north of Corkscrew Road; and one occurred 19.5 miles southwest of the project on Corkscrew Road near, Alico Road.

Activities within the action area have also benefited panthers. The issuance of Corps and State of Florida Environmental Resource Permits has preserved 22,967 ac of high quality panther habitat for permitted impacts to 33,062 ac of poor quality panther habitat (1992 to present). Installation of wildlife crossings under SR 29 and I-75 within the action area has also benefited the panther by protecting habitat connectivity and eliminating panther-vehicle collision mortalities. Additional benefits have resulted from the acquisition of high quality habitat through acquisition programs by other Federal, State, and County resource agencies. Table 9 provides a summary of State acquisitions within the last 8 years.

Moreover, the management of public lands, including prescribed fire and eradication of exotic vegetation in the Picayune Strand State Forest, Fakahatchee Strand State Preserve, Florida

Panther NWR, ENP, and other conservation areas, is intended to improve habitat for panther prey species, which benefits panthers within these areas.

Factors Affecting Species Environment within the Action Area

Factors that affect the species environment (positively and negatively) within the action area include, but are not limited to, the presence and construction of highways and urban development, agriculture, resource extraction, public lands management (prescribed fire, public use, exotic eradication, etc.), hydrological restoration projects, public and private land protection efforts, effects of genetic inbreeding, and genetic restoration.

Development activities may result in avoidance or limited use of remaining suitable habitat by panthers as well as habitat loss, habitat fragmentation, habitat degradation, and also an increase in risk of vehicular collision (*e.g.*, injury or death).

Public and private land management practices can have a positive, neutral, or negative effect, depending on the management goals. Land protection efforts will help to stabilize the extant population. Hunting of the panther is no longer sanctioned, although there still may be instances of intentional or unintentional shooting of individuals for various reasons.

Wildlife Value and Habitat Quality: As discussed previously in the status of the species, the Service believes the existing habitat conditions present on a site and the foraging value that a site provides to the Florida panther and panther prey species are an important parameter in assessing the importance of the project site to the Florida panther and other wildlife species. In order to assess this importance, the Service requires wildlife surveys and plant species compositions as part of the applicant's biological assessment prepared for the project.

***Wildlife Value*:** A protected species survey of the entire C-43 West Storage Reservoir project was initially conducted by SEA from June 2004 to August 2004 utilizing meandering pedestrian and vehicular (including all-terrain vehicles) transects and stationary observation points. Pre-construction surveys of the Test Cell project site were conducted June 27, 2005, and species specific surveys were conducted for nesting caracara February through May, 2006. Surveys for white-tailed deer and feral hog (*Sus scrofa*) tracks were conducted on seven occasions during September and October 2006 (Table 10). Based on five of the seven the track surveys conducted, SEA calculated a deer density of one deer per 1,093 ac to one deer per 2,623 ac, and a feral hog density of one hog per 54 ac to one hog per 62 ac. If all seven survey events are used, deer density estimates increase to one deer per 165 ac to one deer per 70 ac, and a feral hog density of one hog per 50 ac to one hog per 58 ac. However, two of the surveys conducted in September yielded unusually high deer track counts when compared to the other surveys, possibly due to increased human activity in the groves such as pesticide applicationa, irrigation maintenance, etc. Thus, the latter density estimates may not be realistic. According to the BA, Bobby Murray, the long-term operations manager for one of the onsite citrus operations, *i.e.*, Berry Groves, estimated the deer population to be no more than one deer per 525 ac. Evidence of armadillo, eastern cottontail (*Sylvilagus floridanus*), bobcat and raccoon was observed during the surveys. Other small mammals also constituting panther prey may utilize the site.

Based on the track surveys (Tyson 1952), deer densities on exotic-infested private lands in Lee County have averaged one deer per 591 ac (Turrell 2001) to one deer per 534 ac (Passarella Associates, Incorporated 2004). In comparison, deer densities on wildlife management areas average one deer per 165 ac to one deer per 250 ac (Steelman et al. 1999). Density estimates from deer tracks, however, should be viewed with caution. Track estimates are most appropriately used as long-term indicators (McCown 1991) and several factors can influence counts including weather, food abundance, population density, season, and availability of water (O'Connell et al. 1999).

Deer are known to forage in citrus groves on both the fruit trees and the associated vegetation communities. Citrus groves and other agricultural areas often produce quality bucks. In Hendry, Glades and Collier counties, a relatively high number of fish and wildlife species (*i.e.*, 203 species) were documented utilizing citrus groves and their associated cover types (*i.e.*, grove beds, agricultural reservoirs, impacted wetlands, canals, and ditches) (Mazzotti et al. 1992 and 1993). The majority of those species, however, were observed in natural wetlands now functioning as agricultural reservoirs or wet detention areas (Mazzotti et al. 1992 and 1993). Wildlife use of grove beds as habitat was similar to other disturbed habitats in south Florida in that most species commonly found in grove beds were habitat generalists and able to thrive in human-altered habitats (Mazzotti et al. 1992 and 1993). Nonetheless, mammals that commonly utilized citrus groves included deer, feral hog, raccoon, armadillo, Virginia opossum (*Didelphis virginiana*), marsh rabbit (*Sylvilagus palustris*), eastern cottontail, gray fox (*Urocyon cinereoargenteus*), bobcat, Florida black bear (*Ursus americanus floridanus*), several rodents, and other small mammals (Mazzotti et al. 1992 and 1993).

The Service believes the habitats on the property provide marginal quality foraging for prey species, which directly affects value of the habitat to panthers, and specifically, the frequency and duration of use of the property by panthers. As discussed previously, white-tailed deer densities and other prey species are influenced by the quality of the foraging habitat present in an area. Monotypic stands of poor quality foraging plant species and the invasion of a site by exotic plants provide lower habitat foraging values and affect the utilization by and density of foraging species. The C-43 West Storage Reservoir project area is dominated by citrus trees with an understory of mixed grasses, sedges and forbs. Less than two percent of the site consists of wetland vegetation communities, many of which were dominated by or contained minimal invasive exotic or nuisance vegetation such as Brazilian pepper and primrose willow.

Deer are ruminants with small stomach capacities and are selective for high quality forage to meet their nutritional needs. To meet these high quality forage needs, deer selectively move through the mosaic of habitat types taking advantage of the seasonal forage that provide the most benefit to the deer. The historical vegetation community within the project area was characterized as a mosaic of mesic and wetland habitats that provided seasonal patterns of plant growth. The past conversion of native habitats to citrus groves has resulted in an overall reduction of palatable plant species that provide high quality foraging needs for resident deer populations, hog, and other prey species. Although deer densities at the proposed compensation areas (*i.e.*, Band 1/Acceler8 Project areas) were not determined, they contain diverse habitats

with a variety of plant species that yield quality forage to panther prey species, especially resident deer populations, and many include exotic control, removal, or partial removal as a project feature.

Habitat Quality/Habitat Assessment Methodology Application: The application of the habitat assessment methodology including the base ratio, landscape multiplier, PHU determinations, and compensation recommendations are presented below for the 10,602-acre C-43 West Storage Reservoir project site (minus the 267-acre Test Cell project) and the compensation provided by the Band 1/Acceler8 Projects as a group.

Table 11 illustrates the PHU calculations for the C-43 West Storage Reservoir project with impacts to 144 ac of land in the Primary Zone, 5,236 ac of land in the Secondary Zone, and 4,955 ac in the Other Zone with compensation provided through implementation of the Band 1/Acceler8 Projects combined, including the purchase and restoration of approximately 59,294 ac in the Primary Zone and 41,772 ac in the Other Zone (Figure 17). Table 11 shows the 10,335-acre impact area to presently support 19,438 PHUs with a net loss of 18,773 PHUs. The net loss (*i.e.,* 18,773 PHUs) is multiplied by 2.5 to provide the base ratio compensation need, which is 46,933 PHUs.

Since the overall purpose of the CERP is to restore the Everglades ecosystem and species assemblages, the CERP and Acceler8 implementation is expected to provide large-scale, long-term benefits to the ecosystem and listed species, though individual actions may result in smaller-scale or short-term adverse effects to one or more listed species. Band1/Acceler8 projects which fall within the core panther area (Figure 8) were treated collectively as if they were a single project and the methodology described above was used to assess the effects of these collective District projects on Florida panthers (Table 12 and 13). Calculations for Band1/Acceler8 Projects habitat impacts are estimates based on current project information and will be updated as individual Band 1/Acceler8 Projects plans are further developed. Appendix A includes individual project habitat impacts.

The compensation provided by Band 1/Acceler8 Projects collectively exceeds 548,000 PHUs. Consequently, the Service believes the habitat values lost by the proposed C-43 West Storage Reservoir project will be offset by the resultant preservation and compensation actions from implementation of the Band 1/Acceler8 Projects combined. The lands proposed for development are in the northern fringe of the panther's range and panther habitat value has been diminished by previous conversion to citrus groves. Lands proposed for preservation will be in the core area currently used by the panther, the majority will be within the Primary Zone and adjacent to other natural lands, and will be consistent with the Service's panther goal to strategically locate, preserve, and restore sets of lands containing sufficient area and appropriate land cover types to ensure the long-term survival of the Florida panther population south of the Caloosahatchee River.

Conservation Measures:

Though the C-43 West Storage Reservoir project will result in a net loss in number of acres of habitat available to the panther, the combined beneficial effects of the Band 1/Acceler8 Projects on the habitat quality provided to the Florida panther through restoration and preservation will be superior to that of the areas to be impacted, and the habitat will be protected in perpetuity. The Band 1/Acceler8 Projects will result in a net gain in the number of acres of habitat used by the panther that will be superior in quality to that of the area to be impacted by the C-43 West Storage Reservoir project. The compensation provided by the Band 1/Acceler8 Projects is primarily (*i.e.*, 59 percent) located in the Primary Zone and contains habitat valuable for breeding, foraging, and dispersal by the Florida panther. The restoration and preservation of the habitats as a result of implementation of the combined Band 1/Acceler8 project will increase the overall quality of the habitats to panthers and should result in increased use by panthers.

ENVIRONMENTAL BASELINE – Audubon's Crested Caracara

Status of the Species within the Action Area

As discussed previously, caracaras are nonmigratory with a home range averaging 3,000 ac (1,200 hectare) in size and represented by an area with a radius of approximately 1.2 miles or 2 kms (Morrison 1997a). Adult caracaras typically forage throughout their home range during both the nesting and non-nesting seasons, and have different levels of tolerance and foraging needs that vary considerably throughout the year. Nesting caracaras are susceptible to disturbances that alter the existing levels or patterns of activity present around the nest tree. Observations of nesting caracaras by Morrison (2001) note that the birds will generally flush from the nest during incubation or early nestling stages if the source of the disturbance is within 300 meters (985 ft) from the nest tree.

For purposes of assessing levels of adverse project effects to nesting caracaras, two zones are recognized by the Service as being critical for conservation and recovery of the species. These are the primary zone and the secondary zone. The primary zone radius is the 300 meter (985 ft) flushing distance from the nest. The secondary zone radius is the 2,000-meter foraging territory in which the nest is located. Restrictions in the secondary zone are necessary to minimize disturbances that might compromise the integrity of the primary zone as well as to protect key areas outside of the primary zone. The Service acknowledges that caracara home ranges are not necessarily spherical; however, it demonstrates for the reader the spatial relationship of a typical caracara territory to the project's size and location.

Caracara surveys were conducted in accordance with Service guidelines (Service 2002) during February through May of 2006 by SEA. Suitable caracara habitat within 300 meters and 2,000 meters of the project boundary were identified using 2004 aerial imagery and 2000 Florida Land Use, Cover and Forms Classification System (FLUCCS) Geographic Information System (GIS) data. However, permission to access the private property south and southeast of the C-43 West Reservoir project was not granted until the last survey event and was limited to approximately 1,000 ft of the property line.

Two caracara nest locations (1 confirmed and 1 potential) were identified in the project vicinity during species specific surveys conducted February through May of 2006. One confirmed nest was located in a group of cabbage palms along the southern edge of SR 80, approximately 4,750 ft north of the project boundary (Figure 18). No portion of the C-43 West Reservoir project area falls within the primary protection zone (*i.e.*, 300-meter radius) of that nest tree. However, the 110-acre access road parcel and 264 ac of the reservoir footprint fall within the secondary protection zone (*i.e.* 2,000-meter radius of the nest tree), resulting in a loss of 374 ac of habitat available to those caracaras for foraging.

A potential second nest location was identified during the 2006 surveys in a privately-owned, unimproved pasture property approximately 1,065 ft southeast of the project boundary. Two adults and two juvenile caracaras were observed along the project boundary and within the adjacent property. Activities observed included caracaras flying to and from the project area and adjacent property, and caracaras perching, preening, and foraging along the perimeter of the project and within the adjacent property. One adult was observed carrying prey and feeding juveniles on the ground. SEA was not permitted beyond 1,000 ft of the project boundary to confirm the nest location.

Nestlings fledge the nest at about 7 to 8 weeks although they are incapable of sustained flight and remain dependent on the adults for food. They remain close to the nest site perched in low-lying vegetation or lying on the ground within about 1,600 ft (500 meters) and the adults continue to feed the young for up to 8 weeks or more. Young typically do not venture far away from the nest until about 3 months after fledgling. Therefore, SEA tentatively identified a live oak tree as the potential nest tree based on this information and repeated observations of the adults and young in or near that tree. During a May 15, 2007, site visit, Service staff and the Superintendent for the private property owner and their environmental consultant positively identified the location of the nest tree approximately 80 ft from the potential nest tree identified by SEA. Approximately 1.3 ac of the C-43 West Reservoir project area falls within the primary protection zone and 1,100 ac of the project site falls within the secondary protection zone of this second confirmed nest (Figure 18).

Additionally, District staff observed six caracaras scavenging in the Test Cell Project area during and initial site preparation (*i.e.*, clearing and grubbing) and construction activities. Such activities may provide good foraging conditions for caracaras as they can take advantage of exposed and injured prey.

Factors Affecting Species Environment within the Action Area

Caracara were historically associated with grassland and wetland habitats in Florida. The draining of wetlands and the conversion of prairie habitat to residential and agricultural land uses have negatively impacted the caracara throughout its range. In contrast, the conversion of forested areas to pastureland has seemed to benefit caracaras. According to predevelopment vegetation maps of developed for the Southwest Florida Feasibility Study (Corps 2005), the C-43 West Reservoir project site was historically comprised primarily of mesic and hydric flatwoods,

with lesser amounts of wet prairie and freshwater marsh. While pine flatwoods are valuable ecological communities and are becoming increasingly rare in South Florida, they generally are not suitable for caracaras. Although wet prairie and freshwater marsh may provide a substantial amount of wetland-based forage for caracaras, those habitat types were not historically abundant on the project site. The conversion of the project site to a citrus operation containing citrus groves and impacted wetlands that function as agricultural reservoirs or wet detention areas, may have enhanced the habitat for caracaras. Habitat suitability models developed by Morrison et al. (2006) ranked 13 vegetation cover classes for importance to crested caracaras in south-central Florida, including the C-43 West Reservoir project area, using compositional analysis of 28 caracara home ranges compared to the overall study area. Citrus was ranked 7 on a scale of 0 to 10 and was deemed of medium preference to caracara (Table 14). Only 4 other cover classes ranked higher (*i.e.*, improved pasture, freshwater marsh, grassland, and mixed upland hardwoods). Pinelands or flatwoods were ranked as a 2 and were deemed of low preference to caracara.

This is not to say that the current condition for this species as a whole is better today than it was historically. As a result of ongoing, land use changes, caracaras appear to be exploiting pastures, ditches, and impounded wetlands that have replaced the historic land cover. The level of agricultural development throughout the caracara's range has dramatically impaired or eliminated their native habitat and has substituted it with pastureland that is not self-sustaining. Southwest Florida has had the fastest growing citrus acreage in the state and growth in citrus acreage is usually on land that was formerly converted to pastureland (Corps 2005). Future land use projections for Hendry and Glades counties indicate continued conversion of pasturelands in the project vicinity to citrus operations and an increase in urban and rural development. The recent escalation in residential real estate prices in Florida has resulted in the sale and subdivision of large parcels of pastureland and citrus farms. This is a concern both within the action area and on private lands throughout the species range.

Continued residential development may further impact caracara territories by displacement of caracaras or their prey, or changes in habitat use patterns. Construction of single-family homes on 10 or 20 ac of ranchlands is an increasing threat to caracaras, and many of these will not require a Federal permit. The result is fragmentation of large tracts of pastures that caracaras have occupied. Quantifying the combined effects of these small, incremental reductions in caracara habitat suitability, and the potential effects of these small projects on caracara nesting is difficult, but some impacts have occurred and should be expected in the future. For example, habitat suitability modeling results indicate that some caracaras may nest in less suitable areas that contain suitable nesting trees (*i.e.*, small clumps of or scattered cabbage palms) and that have suitable foraging habitat nearby (Morrison et al. 2006). The two nest locations in the project vicinity may be evidence of this as both nests are located in cabbage palms within or adjacent to small tracts of pasture. The pasture directly north of SR 80 contains 61.7 ac (25.0 hectares) and the fallow agricultural field south of the nest tree contains 83.4 ac (33.7 hectares) and both are completely surrounded by citrus groves or rural development. The nest tree in the southeast corner is located within 67.1 ac (27.3 hectares) of pasture surrounded by citrus, cypress swamp, and pine flatwoods.

Past and ongoing Federal actions affecting the caracara within the action area that may cause additional impacts to the species include the 267-acre Test Cell project previously described and SR80 improvement and widening projects. The Service informally consulted on the Test Cell project in a letter dated November 30, 2005. No crested caracara nests or suitable nesting habitat occurred within the proposed test cell project area, and no construction activities or habitat loss would occur within the primary or secondary protection zones of known caracara nest sites or unknown nest sites in available nesting habitat that had not been surveyed. Based on this information, the Service concurred with the Corps determination that the Test Cell Project "may affect, but is not likely to adversely affect" the crested caracara. During initial site preparation and construction activities, District staff observed six caracaras scavenging in the Test Cell Project area. Such activities may provide good foraging conditions for caracaras as they can take advantage of exposed and injured prey. No birds were injured or killed as a result of project activities.

As noted earlier, one nest is located in the southern right-of-way of SR 80. SR80 is a 132-mile (211 km) route linking United States Highway (US) 1 in West Palm Beach and US 41 in Fort Myers and is an important east-west travel route. Due to high traffic volume, the Florida Department of Transportation has begun construction on a limited-access highway from Interstate 95 to US 441 in Palm Beach County, and a controlled-access highway from US 441 to Interstate 75 east of Fort Myers. Most of the main stretch of controlled-access highway has been completed from Loxahatchee to the northbound US 27 split-off west of Clewiston, as well as the stretch that crosses the action area extending from Interstate 75 to Labelle. Work is currently underway to make drainage improvements to the edge of the roadway from east of the Lee and Hendry County line to west of Grandma's Grove RV Park on SR 80. The Service has already consulted on the effects of those projects on listed species through the DA permitting process.

ENVIRONMENTAL BASELINE – Eastern Indigo Snake

Status of the species within the action area

Although the eastern indigo snake is documented throughout the project area, we have little information on the distribution and abundance of the eastern indigo snake in the action area. Indigo snakes are known to occur in the Caloosahatchee River basin in low densities and are known to occur along the banks of larger ditches and canals in citrus groves, particularly if burrows (*e.g.*, tortoise, armadillo, small mammal, and land crab), debris piles, or other shelter are in close proximity. The most intensive study of wildlife use of citrus groves in the action area was conducted by Mazzotti et al. (1993). That study area included 600,000 ha (1,482,632 ac) in southwest Florida; encompassing the region known as the Immokalee Rise which includes the C-43 West Storage Reservoir project area. Citrus groves, including grove beds, canals, impacted wetlands, and reservoirs, had a relatively high species richness (203 species) however the majority of species (159) were observed in agricultural reservoirs. One hundred six species were observed in grove beds of various ages. Following a scheme developed by Duever et al. (1986), habitat importance values for 380 taxa were assigned to different land cover types in the Immokalee Rise Citrus Development Study. Citrus grove habitat utilization for the indigo snake was assigned an index of 2 (commonly used). Roads and ditches are the most likely places to

observe eastern indigo snakes, but most sitings in natural habitat occur in pine flatwoods, hammocks, and edges of ecotones where prey is abundant. Animal burrows (especially armadillo) in the canal and ditch banks present in this project likely provide refugia for the eastern indigo snake. The Corps and the Service have assumed that eastern indigo snakes occupy the site, and are more prevalent where habitat and prey items are more plentiful.

Past and ongoing Federal actions affecting the eastern indigo snake within the action area include the construction, operation, and monitoring of a 267-acre Test Cell project to evaluate the on-site seepage potential and effectiveness of seepage control measures, the suitability of on-site materials for embankment construction and slope protection, and the effects of water residence time and seepage on water quality. That project included two 500-foot by 500-foot test cells with offset seepage canals, a borrow area, settling ponds, and staging areas and was authorized under DA Permit number 2005-6598 (IP-TKW) issued December 6, 2005. Impacted jurisdictional areas included 1.9 ac of excavated open-water, 2.6 ac of wet prairie, and 24.5 ac of tertiary, agricultural drainage canals. Fifteen armadillo burrows were identified within the 267-acre project area that may provide shelter for indigo snakes. Project-related construction activities were determined to have potential to destroy shelter and refugia sites and cause individuals to leave the area, abandon den sites, and miss foraging and mating opportunities. According to the site plan, the Test Cell Project would primarily impact the smaller, tertiary canals with little or no impact to the larger, secondary and primary canal banks that indigo snakes prefer, so it was deemed unlikely that eastern indigo snakes would occur within the Test Cell project footprint.

The Service informally consulted on the Test Cell project in a letter dated November 30, 2005. The Service's Standard Indigo Snake Protection Conditions were implemented during construction to minimize potential adverse effects to indigo snakes (Service 2002). Those measures include: 1) providing indigo snake educational materials to construction employees prior to project initiation; 2) if a live indigo snake is found, construction activities will cease until the snake has left the project area on its' own accord and the location of sightings will be reported to the Service; and, 3) if a dead indigo snake is found, the snake will be frozen as soon as possible and the Service will be contacted immediately for further instructions. Based on this information, the Service concurred with the Corps determination that the Test Cell Project "may affect, but is not likely to adversely affect" the eastern indigo snake.

Factors affecting species environment within the action area

The project action area is within one of the fastest growing areas in the country (http://www.census.gov/Press-Release/www/releases/archives/population/009865.html; Zwick and Carr 2006). Development includes both residential and agricultural demands that initially targeted coastal and upland areas that include pinelands and coastal hammocks. More recent development has impacted vast areas of wetlands, particularly short-hydroperiod wetlands such as wet prairie, hydric flatwoods, or isolated ponds (Corps 1997, Corps 2005, Service 2000). Degradation and fragmentation of habitat has reduced availability of both refugia and prey for this species. At a landscape level, the C-43 project is surrounded by a matrix of agricultural, forested, and wetland land covers with pockets of urban land use. Citrus groves, row crops and

improved pasture with scattered cypress and mixed wetland hardwoods flank the project to the north, east, and south. The area to the north of the project site also contains some low-density residential areas. Forested uplands (parceled into low-density residential lots in various stages of development) include pine flatwoods, longleaf pine-xeric oak, sand pine, and xeric oak are adjacent and west of the project. Urban areas are present to the southwest and northeast of the project area with small parcels along the Caloosahatchee River. Regions to the northwest and southeast of the project area are generally undeveloped. Intensive agriculture in the study area occurs mainly as citrus, with some row crops, sod farms, plant nurseries, and sugar cane. These non-native areas are generally less desirable habitats for fish and wildlife. They exhibit habitat uniformity and are subject to disturbance from humans, machinery, and pesticide usage. Still, some wildlife is usually present in these areas as either residents or transients from native habitats.

The project footprint is currently an active citrus grove. Natural and biological features and land use within the C-43 West Reservoir project area were initially reviewed using the 2000 FLUCCS GIS data. Citrus grove covers approximately 90 percent of the project site. The citrus grove land use classification includes acreage covered by citrus trees, grove maintenance roads, and small berms, brush piles, and other small features related to citrus grove operations. Water comprises 8.9 percent of the site and includes extensive agricultural canals and ditches, classified as streams and waterways, and excavated ponds, classified as reservoirs less than 10 ac in size. Wetland comprises 1.1 percent of the site and includes mixed wetland hardwoods, willow and elderberry, exotic wetland hardwoods, cypress, wetland shrub, and freshwater marsh.

The 10,602-acre site includes 1,061.3 ac of jurisdictional wetlands and waters of the United States, including 934.6 ac of man-made agricultural ditches and canals used for irrigation and drainage conveyance and 126.7 ac of natural wetlands. Natural wetlands in agricultural areas typically suffer from altered hydrology, typically exhibiting shorter hydroperiods, although some intermittent flooding may occur in areas of low relief. These conditions lead to the loss of habitat for breeding amphibians (Moler and Franz 1987). Agricultural ditches may be permanently flooded, providing habitat for non-native fish. The effect of the availability of non-native prey species, particularly fish and small mammals, is unknown (Mazzotti 1993).

With the exception of the area previously cleared for the Test Cell project, the citrus grove is actively managed. The current irrigation practice in the grove is accomplished through micro irrigation supported by adjacent seepage ditches. Pesticide usage is typical for this type of crop and includes a copper-based fungicidal spray twice a year. However, no copper has been applied to the project area for approximately 3 years. Canal banks and tree rows are regularly mowed. Maintenance vehicles regularly travel on the roads in the grove, providing opportunities for vehicle mortality.

EFFECTS OF THE ACTION – Florida Panther

This section analyzes the direct and indirect effects of the project on the Florida panther and Florida panther habitat.

Factors to be Considered

Residential, commercial, and industrial development projects may have a number of direct and indirect effects on the Florida panther and panther habitat. Direct impacts, which are primarily habitat based, may include: (1) the permanent loss and fragmentation of panther habitat; (2) the permanent loss and fragmentation of habitat that supports panther prey; (3) roadway improvements; (4) the loss of available habitat for foraging, breeding, and dispersing panthers; (5) a reduction in the geographic distribution of habitat for the species; (6) harassment by construction activities; and (7) habitat compensation. Indirect effects may include: (1) an increased risk of roadway mortality to panthers traversing the area due to the increase in vehicular traffic; (2) increased disturbance to panthers and panther prey in the project vicinity due to human activities (human and panther interactions); (3) the reduction in value of panther habitat adjacent to the project due to habitat fragmentation; and (4) a potential increase of intraspecific aggression between panthers due to reduction of the geographic distribution of habitat of the panther. These indirect effects are habitat based, with the exception of vehicular mortality. Intraspecific aggression, though habitat based, could also result in mortality.

This project site contains marginal quality panther habitat (see discussion under Wildlife Assessment) and is located within the northern periphery of the geographic range of the Florida panther's breeding population in south Florida. The timing of construction for this project, relative to sensitive periods of the panther's lifecycle, is unknown. Panthers have the potential to be found on and adjacent to the proposed construction footprint year-round. The project will be constructed in three disruptive events, and result in permanent loss and alteration of the existing ground cover on the project site. Project construction will be undertaken in phases over several years. The initial land clearing will commence July 2007 and proceed through March 2008, the first phase of construction will commence October 2007 and proceed through April 2008, and the final construction phase will commence February 2008 and proceed through December 2011. The disturbance associated with the project will be permanent and result in a loss of habitat currently available to the panther.

Analyses for Effects of the Action

The 10,602-acre C-43 West Storage Reservoir project site is on the extreme northern edge of the Florida panther Primary and Secondary Zones as designated by Kautz et al. (2006), and is located inside the Panther Focus Area as defined by the Service. The site currently provides habitat of mostly low quality for the Florida panther (see discussion under Wildlife Assessment). The project site is located on the northern fringe of occupied habitat, is encompassed by primarily by agricultural development (*i.e.*, citrus groves), and is located near but not within known dispersal corridors (FWC 2006b) between larger publicly owned managed lands. The project will result in the conversion of 10,335 ac of marginal quality panther habitat on-site primarily into open-water reservoir.

Compensation for the loss of 10,335 ac of panther habitat will be through the protection and restoration of 100,492 ac off-site through implementation of Band 1/Acceler8 Projects included in CERP. Fifty-nine percent of the lands preserved are in the Primary Zone (Kautz et al. 2006)

of the panther core lands (Figure 7) and the remaining ac are located in the Other Zone. These "core area" lands include the majority of home ranges of the current population of the Florida panther (see definition of core panther area in Effects of the Action - Primary Equivalent Lands). The total compensation will provide over 548,000 PHUs, primarily in areas with a relatively higher level of documented panther usage (telemetry data) to minimize the impact of the net loss of 18,773 PHUs in an area bordered by agricultural development (*i.e.*, citrus groves) and exhibiting limited documented panther usage (telemetry data).

Direct Effects

Direct effects are those effects that are caused by the proposed action, at the time of construction, are primarily habitat based, are reasonably certain to occur and include: (1) the permanent loss and fragmentation of panther habitat; (2) the permanent loss and fragmentation of habitat that supports panther prey; (3) roadway improvements; (4) the loss of available habitat for foraging, breeding, and dispersing panthers; (5) a reduction in the geographic distribution of habitat for the species; (6) harassment by construction activities; and (7) habitat compensation. The direct effects this project will have on the Florida panther within the action area are discussed below.

Permanent Loss and Fragmentation of Panther Habitat: The project will result in the loss of about 10,335 ac of habitat suitable for foraging and dispersal by the Florida panther. The project lands are located inside and along northern edge of the Florida panther Primary and Secondary Zones. The site offers a limited prey base and is surrounded by existing agricultural development (*i.e.*, citrus groves), or proposed residential development and agricultural activities. The land will be converted to an open-water reservoir. Though the habitat value of the project site to the panther is marginal, the habitat loss may adversely affect the panther by decreasing the spatial extent of lands available to the panther.

Panthers, because of their wide-ranging movements and extensive spatial requirements, are also particularly sensitive to habitat fragmentation (Harris 1984). Mac et al. (1998) defines habitat fragmentation as: "The breaking up of a habitat into unconnected patches interspersed with other habitat, which may not be inhabitable by species occupying the habitat that was broken up. The breaking up is usually by human action, as, for example, the clearing of forest or grassland for agriculture, residential development, or overland electrical lines." The reference to "unconnected patches" is a central underpinning of the definition. For panther conservation, this definition underscores the need to maintain contiguous habitat and protected habitat corridors in key locations in south Florida. Habitat fragmentation can result from road construction, urban development, and agricultural land conversions within migratory habitat use patterns of panther prey species and affect the ability of panthers to move freely throughout their home ranges. Construction of highways in wildlife habitat typically results in loss and fragmentation of habitat, traffic related mortality, and avoidance of associated human development. Roads can also result in habitat fragmentation, especially for females who are less likely to cross them (Maehr 1990).

As described above, the project site is adjacent to existing agricultural and rural development and roadways and is at the extreme north edge of occupied habitat south of the Caloosahatchee River. The property is not located within known dispersal or connection corridors (FWC 2006b) to

larger publicly owned managed lands. As a result of our analysis, we believe that fragmentation of panther habitat is not expected to be appreciable as a result of project implementation.

Permanent Loss and Fragmentation of Habitat that Supports Panther Prey: Prey surveys documented use of the C-43 West Storage Reservoir project site by two primary panther prey species, white-tailed deer and feral hogs. However, the site consists primarily of citrus groves and disturbed wetlands with minimal invasion by exotics, which provide poor foraging value to these and other prey species. The project will result in the loss of about 10,335 ac of habitat available for use by panther prey species. The project site is bounded by SR 80 and existing agricultural and rural development to the north, agricultural activity to the south, the Townsend Canal to the west, and existing agricultural and rural development and SR 29 to the east. Although the native habitats have been degraded through conversion to agriculture and associated hydrological alterations, the loss of habitat may adversely affect the panther by decreasing the spatial extent of lands available for use by panther prey. As described above however, the project site is in an area adjacent to existing agricultural and rural development and roadways and is at the northern edge of the core area of occupied habitat south of the Caloosahatchee River. The property is not located within known dispersal or connection corridors (FWC 2006b) to larger publicly owned managed lands. Therefore, as a result of our analysis, fragmentation of panther prey habitat is not expected to be appreciable.

Road Way Improvements: No expansion of surrounding roads will occur as part of the C-43 West Storage Reservoir project. Some improvements may be necessary to enhance the existing agricultural access roads to meet public health and safety standards for ingress and egress of vehicles to the project site for construction, maintenance, and future recreational access. Therefore, road improvements are not expected to impact the Florida panther.

Loss of Available Habitat for Foraging, Breeding, and Dispersing Panthers: The site is bounded by existing or proposed residential development to the west and south, agricultural activity to the north, and provides limited use potential for the panther due to the conversion to agriculture and the distance from the more commonly used core lands of the panther.
The project site is bounded by SR 80 and existing agricultural and rural development to the north, agricultural activity to the south, the Townsend Canal to the west, and existing agricultural and rural development and SR 29 to the east. Three deceased collared panthers (FP 28, FP 74, and TX 101) have been documented within 5 miles of the project area. One deceased collared male (FP 74) was tracked within the project area along the Townsend canal and four times within 0.5 miles of the southeastern project boundary during 1999. Two living panthers, FP 65 (male) and FP 137 (male) have been documented within 5 miles of the project on numerous occasions in 1998 and 2005, respectively. Since the habitat quality of the site is generally poor, as it is primarily citrus groves with impacted wetlands with limited foraging value for prey species, we believe panther usage of the site is limited; however, habitat loss may adversely affect the panther by decreasing the spatial extent of lands available to the panther for foraging, breeding, and dispersing.

Reduction in the Geographic Distribution of Habitat for the Species: The project will result in the loss of about 10,335 ac of agricultural land along the northern edge of the Panther Focus

Area south of the Caloosahatchee River. This loss represents only 0.53 percent of the 1,962,294 ac of available non-urban private lands in south Florida in the core area of the Florida panther (Table 5). The Service believes the habitat values lost by the project will be minimized by the preservation and restoration actions of the Band 1/Acceler8 projects combined. The project lands proposed are primarily citrus groves and disturbed wetlands with minimal invasion by exotics on the northern fringe of the occupied range of the Florida panther and are encompassed by agriculture, rural development, and existing roads. The lands proposed for compensation through implementation of the Band 1/Acceler8 projects are consistent with the Service's panther conservation strategy to locate, preserve, and restore sets of lands containing sufficient area, access, and appropriate cover types to ensure the long-term survival of the Florida panther south of the Caloosahatchee River.

Harassment by Construction Activities: The timing of construction for this project, relative to sensitive periods of the panther's lifecycle, is unknown. However, it is likely that all land clearing and construction associated with the project will commence during July 2007, and will be completed by December 2011. There are no known den sites within the project boundaries and the quality and quantity of the habitat foraging base for prey species is low. Therefore, we believe panther usage of the property is limited and we do not believe project construction will result in direct panther mortality, but may result in temporary disturbance to resident or dispersing panthers.

Compensation: The impact of the habitat lost as a result of the development will be minimized by the preservation and restoration actions of the Band 1/Acceler8 projects combined. The applicant's proposed preservation acreage is estimated at 100,492 ac. The lands proposed for development are primarily citrus groves and disturbed wetlands at least partially invaded by exotic vegetation, are on the fringe of the currently occupied range of the Florida panther, are adjacent to agricultural and rural development, and are adjacent to SR 80. The lands proposed for preservation are consistent with the Service's panther goal to locate and preserve sets of lands containing sufficient area and appropriate cover types to ensure the long-term survival of the Florida panther south of the Caloosahatchee River.

Interrelated and Interdependent Actions

An interrelated activity is an activity that is part of the proposed action and depends on the proposed action for its justification. An interdependent activity is an activity that has no independent utility apart from the action under consultation. All access and staging areas are to be located within the project footprint. Future maintenance and monitoring activities are expected to result in minimal impact to the surrounding environment. Therefore, only negligible impacts are expected to result from interrelated or interdependent actions as a result of the project.

Indirect Effects

Indirect effects are those effects that are caused by or will result from the proposed action and are later in time, but are still reasonably certain to occur. The indirect effects this project will

have on the Florida panther within the action area are discussed below and in the assessment of functional habitat values previously discussed. They include: (1) an increased risk of roadway mortality to panthers traversing the area due to the increase in vehicular traffic; (2) increased disturbance to panthers and panther prey in the project vicinity due to human activities (human and panther interactions); (3) the reduction in value of panther habitat adjacent to the project due to habitat fragmentation; and (4) a potential increase of intraspecific aggression between panthers due to reduction of the geographic distribution of habitat for the panther.

Increased Risk of Roadway Mortality: In evaluating a project's potential to increase roadway mortality to the Florida panther, we consider the location of the project in relation to surrounding native habitats, preserved lands, and wildlife corridors that are frequently used by the Florida panther. We also consider the current configuration and traffic patterns of surrounding roadways and the projected increase and traffic patterns expected to result from the proposed action. We evaluate the habitats present on-site, their importance in providing foraging needs for the Florida panther and panther prey species, and if the site development would further restrict access to surrounding lands important to the Florida panther and panther prey species.

The project will result in increased vehicular traffic in the project vicinity during construction and operation. Vehicular mortality and injury data (Table 8, Figure 16) provided by the FWC indicate collisions with motor vehicles have been increasing since 2000 in the 25-mile radius project action area. In 2003 and 2006, there were six documented panther-vehicle collisions per year within the project action area (Table 8). These 2 years represent the most panthers killed by vehicles in single years in the action area. However, this number may be surpassed this year (2007), as 4 panthers have already been killed by vehicle collisions during the first 5 months. Four panthers were killed per year in 2000 and 2002. All of the 42 documented collisions within the action area have occurred more than 10 miles away from the project site, and 37 (88 percent) occurred more than 15 miles from the project site.

Major travel routes in the vicinity of the project site (Figure 1) include SR80 to the north, and SR29 to the east. SR80 is a four-lane divided highway and is already a heavily traveled east-west transportation route. SR29 is a two-lane rural highway. Construction traffic will come from SR80 and then use the existing agricultural roads in the 110-acre access road parcel to travel to and from the project area. Construction is proposed to take place in phases through December 2011. Once construction is completed, additional vehicular traffic will operate in the area as a result of project monitoring, operations, and maintenance. Projected impacts to future traffic are related to maintenance vehicles and possible recreational access to the reservoir site. Considering this information and distances from the project site to documented collisions, it is unlikely the traffic generated by this project will significantly increase the risk of roadway mortality to panthers.

Panther and Prey Disturbance (Panther/Human Interactions): Potential increases in disturbance to the Florida panther and panther prey were evaluated. As discussed previously in our assessment of fragmentation, we considered habitat quality related factors and occurrence data for the Florida panther and panther prey species. This information is also the basis of our evaluation of disturbance to the Florida panther and to panther prey species. As discussed

previously, the habitat on the project site consists primarily of citrus groves and disturbed wetlands with minimal invasion by exotics, which provide low quality habitat to the Florida panther and panther prey species. Though panthers and panther prey may occasionally use the habitats within the project area, we believe panther usage of the property is infrequent and we do not believe project construction will result in a significant increase in panther and human interactions and prey disturbance.

Habitat Fragmentation: Considering our discussion of fragmentation under Direct Effects, the project site is located on the northern fringe of occupied habitat, is adjacent to existing agricultural and rural development, and is not located within known dispersal corridors to larger publicly owned managed lands important to the panther; therefore, fragmentation of panther habitat is not expected to result from project implementation. The project site is located on the northern fringe of the Panther Focus Area south of the Caloosahatchee River. Therefore, fragmentation of panther prey species habitat is not expected.

Intraspecific Aggression: Potential increases in intraspecific aggression and disturbance to the Florida panther were evaluated. As discussed previously in our assessment of fragmentation and habitat for panther and panther prey, we considered habitat quality related factors and occurrence data for the Florida panther and panther prey species as factors affecting intraspecific aggression. As previously discussed, the habitats on the property provide for low quality foraging for prey, which directly affects the frequency and duration of use of the property by panthers. Therefore, we do not believe that panther prey species or Florida panthers utilize the property on a frequent basis. However, the reduction in the geographic range of habitat for dispersal or escape cover may contribute to a potential increased risk of death or injury of panthers in the action area due to intraspecific aggression.

Species Response to the Proposed Action

The proposed action will result in increased human activity and noise in the project area during construction of the project. However, since panthers are not commonly known to use lands within and adjacent to the project site, activities associated with construction of the C-43 West Storage Reservoir project are not anticipated to significantly increase risk of disturbance to panthers, though some temporary disturbance may occur.

The project will result in the loss of 10,335 ac of potential panther habitat according to the most current home range estimates of the Florida panther (Lotz et al. 2005). This represents 35.6 percent of a female panther's average home range (29,059 ac) and 16.5 percent of a male panther's average home range (62,542 ac). The project area provides mostly poor quality panther habitat and panthers are not known to commonly use the project area; however, the loss of habitat may contribute to increases in intraspecific aggression decreasing the spatial extent of lands available to the panther for foraging, breeding, and dispersing. We anticipate any resident panthers with home ranges overlapping or in the vicinity of the project area will adjust the size and location of their ranges to account for this loss and that adjustment is anticipated to occur in concert with project construction.

Panthers are sensitive to habitat fragmentation. However, the project site is located on the northern fringe of occupied habitat, is adjacent to agricultural and rural development, and is not located within known dispersal corridors (FWC 2006b) between larger publicly owned managed lands. Therefore, appreciable fragmentation of panther habitat is not expected to result from project implementation.

EFFECTS OF THE ACTION – Audubon's Crested Caracara

This section includes an analysis of the direct and indirect effects of the proposed action on the caracara, including beneficial effects, interrelated and interdependent actions, and species response to the proposed action. To determine whether the proposed action would likely jeopardize the continued existence of this species, we focused on the expected consequences of the proposed action on the potential for future caracara nesting and habitat use.

Factors to be Considered

Caracaras have been documented to nest immediately adjacent to the C-43 West Reservoir project area and are known to forage within and adjacent to the project area. Thus, the action will take place when this species is likely to be present and nesting in the area. Construction will be conducted in phases commencing during July 2007 and extending through April 2011. The operation and maintenance of the project is anticipated to last at least 40 years. Potential direct and indirect impacts to caracaras may occur as a result of the initial destruction and degradation of existing habitat; dredging, earthmoving, and other activities associated with construction of the reservoir (including associated pump stations and water control structures), seepage canal, access roads, and recreational facilities; modifications to existing canals; and operation and maintenance of the project. Project-related activities may cause caracaras to leave the immediate vicinity, abandon nest sites, abandon territories, abandon active nests during the egg laying or brood-rearing stages, and possibly miss foraging, mating, and brood-rearing opportunities. Displaced adults may incur a higher risk of mortality because of either intraspecific aggression by caracaras defending territories into which displaced caracaras attempt to move, predation, or other sources of mortality such as vehicle collisions or other trauma associated with scouting unfamiliar areas. Potential direct impacts to the caracara or its habitat include direct injury or mortality from (1) all construction-related activities, (2) vehicular traffic, and (3) loss of available habitat for foraging, breeding and dispersing birds. Potential indirect impacts include injury or mortality from future operation and maintenance associated with the reservoir, including (1) vehicular traffic, mowing, and pesticide usage; (2) fluctuations in prey density in the reservoir and associated infrastructure as water levels fluctuate and potentially become dry; and (3) impacts from copper contamination of benthic fauna in the reservoir.

Analyses for Effects of the Action

Direct Effects

Direct effects are those effects that are caused by the proposed action. The direct effects evaluated by the Service include direct injury or mortality and loss or degradation of available

habitat for foraging and breeding. The direct effects that this project may have on caracaras within the action area are discussed below.

Injury and Mortality: Our data indicate that caracaras utilize the area in and around the C-43 West Storage Reservoir project for nesting and foraging. It is difficult to determine the number of caracaras that would be directly injured, disturbed, or killed by the project as it depends on the proximity of project-related activities to the nest trees and the timing of those activities in relation to the occurrence of caracara nesting and fledging. Accidental adult injury or mortality as a direct result of project-related activities would be unlikely since older birds are more wary and likely more experienced than juveniles. However, during winter months when caracara nesting is more prevalent, eggs and small chicks may perish from overexposure if adults are frequently flushed from nest trees or avoid the nest for extended periods (Morrison 1998). Additionally, fledgling and juvenile caracaras spend more time on the ground and do not venture far from the nest tree. Therefore, they are at risk of injury or death from heavy equipment operations, vehicular traffic, and mowers, particularly if such activities occur within the primary and secondary zones during the nesting season. Morrison (2005) identified vehicular traffic as a specific cause of mortality to juvenile caracaras feeding on carrion.

The best way to minimize the risk of this type of injury is to avoid the primary and secondary zones surrounding the nest tree during the nesting season. None of the proposed project activities would occur within the primary zone of the northern nest, and only one acre of the primary zone surrounding the southeastern nest overlaps the project footprint. That one acre is separated from the rest of the primary zone by agricultural roads and a canal that demarcate the boundary between the proposed project and the adjacent private property. Therefore, it is unlikely that recently fledged young incapable of sustained flight would utilize that acre. Juveniles, however, may venture farther from the nest and be present in the project area during construction, particularly in the secondary zones, and therefore may be at risk of direct injury or mortality. Proposed project activities in that area include initial clearing, grubbing and stripping, and construction of a portion of Dam Segment O including the adjacent portion of the seepage canal and associated littoral zones.

Avoidance of the secondary zone surrounding each nest is not entirely possible due to the scale of the proposed project and the methodology required for construction of the reservoir embankments. All or portions of Dam Segments E, F, G, M, N, O, and P, including the adjacent portions of the seepage canal and associated water control structures, will be constructed within the secondary zones of one of the two nests. The full embankment will be best constructed as the project progresses to allow for placement of the upstream soil-cement and establishment of grass on the downstream slope of the embankment. This also includes constructing the internal drain system, borrow, and fill placement as the embankment is built. The embankment construction is a critical element of the project and the quality of this work is key to the District's dam safety program.

Large equipment, such as bulldozers with rakes and pans, will be utilized for embankment construction. This equipment works in a linear fashion around the site borrowing soil and then placing the borrow material on the embankment in six inch lifts. The techniques and sequencing

used are important to insure the necessary quality of the work. The available 6 month work periods outside of the caracara nesting season (*i.e.*, May though October) in the secondary zone represent 1 month of the dry season and 5 months of the rainy season. Thus the majority of the reservoir embankment within the secondary zone can only be constructed during the rainy season which increases the uncertainties of the work. Not only will the construction of the earthen portion of the embankment be impacted by the enforcement of the secondary zone during the Caracara nesting season, the placement of the soil cement, of which the production rate and quality is greatly effected by rainy conditions, will have to also be scheduled for the rainy season. The periods for the construction of all Project elements within the secondary zone is insufficient to meet the requirements of the Project and will require modifying the construction sequence and techniques with an approach that is more difficult and possible raising questions of embankment integrity.

Accordingly, the Service anticipates that disturbance would occur through project activities in the primary or secondary zone that force caracaras to leave foraging or perching sites in the immediate vicinity, to nest in new locations either within or outside the existing territories, abandon active nests during the egg laying or brood-rearing stages, or possibly miss foraging, mating, and brood-rearing opportunities each year over the five-year construction schedule. If breeding or nesting opportunities are missed or abandoned, this could represent a loss of recruitment to the population from two nesting pairs for 5 years. Additionally, displaced adults may incur a higher risk of mortality because of intraspecific aggression by caracaras defending territories into which displaced caracaras attempt to move, predation, or other sources of mortality such as vehicle collisions or other trauma associated with scouting unfamiliar areas.

Loss of Habitat:
Although, no known nest trees or other cabbage palms suitable for nesting will be removed as part of the C-43 West Reservoir project, a total 1,474 ac of potential foraging habitat consisting primarily of citrus groves and impacted wetlands in the secondary zones of two known nest locations, will be converted to reservoir, embankment, or seepage canal. Thus, if we assume a worst-case scenario, the entire 1,474 ac will be habitat lost as a result of the proposed project. This loss of habitat may result in territory shift, intraspecific aggression, or territory abandonment.

It is possible that caracaras may forage in the interior of the reservoir when it is dry, along the exterior reservoir embankments, and along the seepage canal after construction. Caracaras are not expected to forage on the interior of the reservoir embankments as they will be lined with concrete and no vegetation that may support prey is expected to become established. In this scenario, slightly less than 1,474 ac of habitat would be lost. However, we are uncertain how caracaras will react to a change in land use over a substantial percentage of their territory. Morrison (2005) stated that natural wetlands larger than 25 ac (10 hectares) are not as likely to be included in caracara territories as wetlands less than 25 ac. Morrison et al. (2006) found that that 90 percent of 28 caracara home ranges contained 50 to 150 hectares of freshwater marsh (excluding sawgrass- and cattail-dominated marshes). However, 90 percent of those freshwater marshes were less than 1 hectare in size with approximately 50 percent less than or equal to

0.1 hectares in size. Thus, we do not expect caracaras to forage substantially in the reservoir when one or both cells are completely drawn down.

Indirect Effects

Indirect effects are those that are caused by or result from the proposed action, are later in time, and are reasonably certain to occur. The indirect impacts evaluated by the Service include: (1) post-construction maintenance of the roads, embankments, seepage canal, boat ramps, pump stations, and other water control structures; (2) future recreational activities such as picnicking, boating, fishing, hiking, or horseback riding; and (3) chemical contamination. The indirect effects that the proposed action may have on caracaras within the action area are discussed below.

Operation and Maintenance: Routine operation and maintenance may result in temporary and insignificant disturbance to the crested caracara. Once construction is completed, additional vehicular traffic will access and operate in the area as a result of project monitoring, operations, and maintenance which may include mowing of embankments or heavy equipment operation. Adult caracaras nesting in the project vicinity are already acclimated to human presence, and vehicular traffic and heavy equipment operations associated with routine agricultural activities.

Caracara may forage on prey items that could become established on the embankments and littoral zones of the seepage canals. The Service anticipates that vehicular activity or heavy equipment operation associated with maintenance may disturb, injure, or kill individual caracara fledglings or juveniles that may be foraging onsite, since they do not venture far from nest the tree following fledging and are inexperienced.

Recreation: Recreational activities may result in temporary and insignificant disturbance to caracaras. Detailed information on future recreational activities in the project area is not available at this time. However, recreational activities could reasonably include picnicking, boating, fishing, and hiking or horseback riding on the service road along the crown of the reservoir embankments. Future recreational access and facilities (*i.e.*, picnic tables, restrooms, etc.) will most likely be located in the 110-acre access road parcel which occurs within the secondary zone of the nest on SR80. Those adults are already acclimated to routine vehicular traffic along SR80 as well as vehicles traveling to and from the project area as a result of agricultural activities. Additionally, the proposed access route for the reservoir is currently the access route to and from and the location of the existing facilities for the citrus operation (*i.e.*, Berry Groves-LaBelle Congen). The adult caracaras nesting on SR80 are already acclimated to human presence, vehicular traffic, and heavy equipment use associated with routine agricultural activities, including fruit harvesting and ditch maintenance. Likewise, the caracaras nesting to the southeast of the project area are also acclimated to limited human presence, and vehicular traffic and heavy equipment operations associated with routine agricultural activities.

Contaminants:

An environmental site assessment for chemical contamination was performed by the District in 1999 for the entire C-43 West Reservoir project area.

Copper: Soil sampling has identified seven grids (*i.e.*, grids 56, 58, 124, 125, 134, 135, and 143) in the Berry Labelle – Congen Groves (Tracts GX-100-017 & GX-100-018) portion of the site that will require remediation due to copper contamination. The Service recommended remediation for the entirety of Grids 124, 125, 134, 135, and 143 (250 ac) and for the portions of Grids 56 and 58 that will be within the footprint of the proposed reservoir. The Service concurred in a letter dated September 14, 2006, that removing contamination from the seven grids would remove the risk of direct impacts to Service trust resources. Approximately one foot of soil will be excavated from areas to be remediated and the soil will be utilized within the reservoir embankments, burying the soils such that surface water will not contact the copper-contaminated soil. However, the Service noted that the remaining copper concentration in some areas of the property may be high enough to adversely impact benthic organisms.

We anticipate that remediated soils placed in the embankments will not adversely affect caracaras or their prey. The adverse effect of crested caracara consumption of contaminated prey associated with benthic organisms is not known, but is considered to be low given the periodicity and duration of expected draw down events.

Other contaminants: The 600-ac Bryan Paul Citrus Grove (Tract GX-100-009) will be remediated for chlordane contamination by removal of the top two feet of soil in the 20-acre area and utilizing that soil within the reservoir embankments. The 2,025-acre Bob Paul Citrus Grove (Tract GX-100-015) may be remediated for organochlorine pesticides in two 50-acre grids upon further investigation to delineate contamination. The 2,399-acre Winthrop Property (Tract GX-100-005) will be remediated for metals, petroleum hydrocarbons, and pesticides detected around maintenance areas by removal of contaminated soils. The 954-acre Griffin Property (Tract GX-100-001) will be remediated for metals and polycyclic aromatic hydrocarbons in burn areas, chemical barns, and fertilizer mix and load areas by removal of contaminated soils. Given proper remediation, the anticipated risk to crested caracara from other contaminants is considered low.

Beneficial Effects

The loss of caracara foraging habitat when the project is built may be offset, in part, by potential foraging along the external embankments and the seepage canal. The project would have approximately 16.3 miles of external embankments, 2.8 miles of internal embankment, 14.7 miles of perimeter canal, and 109 ac of littoral zones. Interior portions of the reservoir and the interior dam embankments are anticipated to be a harder material (soil cement or concrete) and therefore, would not provide the necessary herbaceous plant cover needed by caracara prey. The width of the side slopes of the external embankments would be 114 ft. The width of the toe between the bottom of the external embankment and the perimeter canal is 90 ft. For the perimeter reservoir embankments and toe, a total of 403.05 ac (204 ft of the perimeter

embankment x 86,064 ft [16.3 miles]) of potential caracara foraging habitat would be created. The top of the embankment was also considered caracara foraging habitat and provides 27.66 ac (14-foot crest of the perimeter embankment x 86,064 ft [16.3 mi]). The total potential caracara habitat created by this project was estimated to be 430.71 ac (403.05 + 27.66) of foraging habitat. The number of birds that may forage on this habitat depends on the number of intersecting territories. Two known territories intersect the C-43 West Reservoir project area. Thus, up to 4 adults and 4 juveniles (two per nest) might forage in the project area. However, these estimates are speculative given that large wetlands (greater than 1 hectare) or large areas of open water are generally not included in caracara territories and large reservoirs have not yet been operated within known territories of the caracara in south Florida. Therefore, we recommend monitoring to determine caracara usage at this site following construction.

Additionally, the proposed project may benefit caracara during the initial stages of construction by exposing prey for foraging birds. However, this benefit may be offset by the increased risk of injury and mortality to young, inexperienced caracara.

Interrelated and Interdependent Actions

An interrelated activity is an activity that is part of the proposed action and depends on the proposed action for its justification. An interdependent activity is an activity that has no independent utility apart from the action under consultation. All access and staging areas are to be located within the project footprint. Future maintenance and monitoring activities are expected to result in minimal impact to the surrounding environment. Therefore, only negligible impacts are expected to result from interrelated or interdependent actions as a result of the project.

Species' Response to the Proposed Action

Construction, operation, and maintenance of the project can result in actions that may kill or injure individual caracaras, and destroy or degrade occupied and potential nesting and foraging habitat. Due to their large territories (about 3,000 ac) and generally wary reaction to human activity, the risk of direct mortality of adult caracaras is not anticipated. Sub-adult caracaras, especially fledglings, are more at risk since they spend more time on the ground. As a result, the likelihood of mortality or injury increases through predation and vehicular collisions. Any clearing, burning, earthmoving, construction, operation, and maintenance activities may also adversely affect caracaras by disrupting parental care of the nest and chicks, and causing them to leave the area and possibly abandon territories, and miss foraging opportunities. The consequences of disrupting parental care of the nest (*e.g.*, reduced egg incubation or chick protection and feeding) may lead to egg or nestling mortality in a variety of forms, such as exposure, starvation, falling from the nest, or predation. Individual caracaras that leave the area may be more vulnerable to predation and intraspecific aggression.

The Service anticipates that 1,474 ac of caracara foraging habitat consisting primarily of citrus groves and impacted wetlands, would be directly impacted by the proposed project and converted to an above-ground reservoir with an average depth of 20 ft. This habitat conversion

may lead to indirect effects on an unknown amount of additional acreage outside of the project area via caracara territory shifts, shrinkage, or abandonment.

To determine the species' response to the action, we first assumed that the two known nesting pairs would continue to nest either in the same nest tree or one located nearby and may shift their foraging territory as a result of the proposed project and related activities. The pair nesting along SR 80 will likely continue to nest in the same location. The availability of cabbage palms is limited to the highway right-of-way near the current nest tree. The 61.7 ac pasture adjacent to west-bound lane (north) of SR 80 does not contain any cabbage palms which may explain why the pair chose to nest along the south side of the highway. However, if a typical territory is 3,000 ac and is assumed to be circular, the loss of 374 ac (or 12.4 percent of their territory) in the secondary zone consisting primarily of citrus groves and impacted wetlands would not force the pair to abandon their nest tree or territory. They may slightly shift their territory to avoid the project area during and post-construction.

We also do not believe that the pair nesting on private property southeast of the project area will abandon their territory unless the habitat converted to reservoir has critical resources (*e.g.,* better forage) and the remainder of the territory is marginal or sub-marginal habitat. That pair may be able to find another suitable nest tree slightly further away from the reservoir footprint. The current nest tree is located within 67.1 ac of pasture that will not be impacted by the proposed project and that contains several cabbage palms. However, if a typical territory is 3,000 ac and is assumed to be circular, that pair will lose approximately 37 percent (1,101 ac) of its territory. Although this is a significant loss of habitat, aerial photography indicates that additional suitable foraging habitat (i.e., pasture, fallow farm fields, and active citrus groves) is currently available within and adjacent to the remaining portion of their territory (1,899 ac) on privately owned land and the birds would be forced to shift their foraging territory. This prediction is based on limited caracara data and the assumption that this area is not already occupied by other caracaras.

Each nesting pair of caracaras may produce two to three offspring per year. The Service anticipates that the proposed construction activities may cause adults to abandon nest attempts or otherwise disrupt parental care of a nest or chicks, resulting in the loss of two to six juvenile caracaras per year. We also anticipate that the likelihood of reduced reproductive success is greater for the pair nesting on private property southeast of the project area due to greater loss of habitat within their potential territory and the close proximity of construction activities. Increased human presence and noise disturbance from associated equipment operation would occur on the periphery of the primary zone established to protect the nest site from disturbance during the nesting season

If both nesting pairs are successful, there could be up to 10 caracaras (4 adults and 2 to 6 offspring) using the C-43 West Reservoir footprint for at least part of the year. We believe that some caracaras may use the reservoir embankments and the seepage canal following construction if there are sufficient prey items. These individual caracaras may be temporarily displaced while foraging by on-going maintenance, operational, and recreational activities. However, the impact may be beneficial (e.g., mowing may expose prey) or negligible.

EFFECTS OF THE ACTION - Eastern Indigo Snake

Factors to be Considered

Eastern indigo snakes have been documented in the project action area. Because eastern indigo snakes use a variety of habitats, and have very large home ranges, they may occur throughout the project site and adjacent citrus groves and natural areas. This action will take place when this species is likely to be present in the area. The duration of the tree clearing and construction will be from July 12, 2007 to March 30, 2008. Pre-loading of embankments will occur from October 11, 2007 to April 30, 2008. Reservoir and pump station construction will occur from February 14, 2008 to December of 2011. The operation and maintenance of the project is anticipated to last approximately 50 years. Potential impacts to eastern indigo snakes may occur due to citrus tree removal and burning, habitat destruction and degradation, earthmoving, construction of the reservoir and operation and maintenance of the project. The action may also cause eastern indigo snakes to leave the area, abandon den sites, and possibly miss foraging and mating opportunities. Individual eastern indigo snakes fleeing the area may be more vulnerable to road mortality, predation or intraspecific aggression. Potential direct impacts to the eastern indigo snake or its habitat include mortality from (1) all construction activities including tree removal, burning, and contaminant remediation, (2) vehicular traffic, and (3) initial rehydration; and injury or disruption of normal behaviors from the loss of available habitat for foraging, breeding, and dispersing. Potential indirect impacts include mortality from future operation and maintenance associated with the C-43 West Reservoir project that may result in mortality or injury from (1) vehicular traffic, mowing, and pesticide usage; and injury from (2) fluctuations in prey density in the reservoir and associated infrastructure as water levels fluctuate and potentially become dry.

The eastern indigo snake is difficult to detect and quantify for the following reasons: (1) it has a wide-ranging distribution; (2) it has a patchy distribution within suitable habitat; (3) it has limited detectability due to use of burrows or holes for shelter, (4) there is likely unoccupied suitable habitat; (5) juveniles have limited detectability due to their affinity for thick vegetation, and (6) they may use cryptic sheltering areas that may be temporarily established during construction (e.g., brush piles, equipment stockpiles, and dirt mounds). The lack of practical methods to survey, in conjunction with wide-ranging activity and use of a variety of habitat types makes it difficult to determine the exact number of eastern indigo snakes that will be affected.

Analyses for effects of the action

Direct effects

Direct effects are those effects that are caused by the proposed action. The direct impacts evaluated by the Service include direct injury and mortality from construction (including initial hydration) and roadkill, loss of habitat for foraging, breeding, and dispersing, and disturbance related to the initial hydration of the reservoir. The direct effects that this project may have on eastern indigo snakes within the action area are discussed below. For purposes of this analysis,

the 267-acre Test Cell project site has been subtracted from the project effects analysis, and the total impact is estimated to be 10,264 ac.

Injury and mortality: It is difficult to determine the percentage of eastern indigo snakes that would be directly injured or killed by the project. However, due to the nature of the proposed construction (*i.e.*, complete disturbance of the site by tree removal, debris piling and burning, canal plugging or dredging, embankment construction, soil transport for contaminant remediation, and initial hydration), and the known death of an indigo snake on a similar reservoir construction project the Service estimates that the majority of the eastern indigo snakes present at the time of the action could be adversely affected by the project.

On October 10, 2006, an eastern indigo snake was killed while excavation of a sediment mound was occurring in the A-1 Reservoir footprint. The site of mortality was a sediment mound approximately 10-15 ft high and 20-25 ft in diameter along the far side of a canal levee road, adjacent to fallow sugarcane fields. The sediment had been excavated from a canal and deposited along the far side of the levee road approximately one to two weeks earlier, was now dry, and was subsequently being moved to an adjacent area. The equipment operator had been trained to identify eastern indigo snakes and to stop activity if any were observed. The operator did not see the snake on the mound. As the sediment was being deposited, the operator observed an eastern indigo snake falling from the sediment. Similar deaths of snakes have occurred in development of urban sites in Lee (Florida Gulf Coast University) and Collier counties, including the action area. Snakes typically seek refuge in burn or debris pile sites during construction (Dryden personal communication 2007).

It is not easy to estimate the density of eastern indigo snakes at the C-43 West Reservoir using existing data. However, a 26-year study conducted by Layne and Steiner (1996) at Archbold Biological Station (ABS) estimated a population density of 2.6 eastern indigo snakes (1.9 males, 0.7 females) per 247 ac (100 ha). ABS is approximately 30 miles northeast of the project area and contains better snake habitat (*i.e.*, the study area was comprised of 60 percent xeric pine and oak uplands, and 40 percent pine flatwoods, bayheads, swale, and seasonal ponds). Eastern indigo snakes have been observed at ABS in all natural and man-altered habitats with no obvious habitat preferences (Layne and Steiner 1996). The ratio of adult males to adult females at ABS was estimated to be approximately 4:1. The juvenile sex ratio was closer to 1:1. These estimates were consistent with other studies of captive eastern indigo snakes and museum specimens (Moulis 1976, Smith 1941, Duellman and Schwartz 1958).

The C-43 West Reservoir project site likely contains or intersects many eastern indigo snake home ranges. Based on population density estimates at ABS, one could estimate that as many as 108 adult eastern indigo snakes may be present within the C-43 West Reservoir project site (10,264 ac/247 ac x 2.6 snakes = 108 snakes). However, due to the differences in habitat between ABS and the project site, we anticipate that the density of eastern indigo snakes at the C-43 West Reservoir project site would be lower than that at ABS. Regular mowing, vehicular traffic, and pesticide usage on the project site are also likely to have decreased the suitability of the habitat for eastern indigo snakes and their prey. We have made an estimate that the quality

of the eastern indigo snake habitat at the project site is half that of ABS. In that case, then there could be up to 54 adult eastern indigo snakes within the C-43 West Reservoir project site.

Major travel routes in the vicinity of the project site (Figure 1) include SR80 to the north and SR29 to the east. SR80 is a four-lane divided highway and is already a heavily traveled east-west transportation route. SR29 is a two-lane rural highway. Construction traffic will come from SR80 and then use the existing agricultural roads in the 110-acre access road parcel to travel to and from the project area. Construction is proposed to take place in phases through December 2011, exposing eastern indigo snakes to changes or additions in vehicle traffic on the site over a period of approximately four and one-half years.

Loss of habitat: In general, citrus groves are not optimal eastern indigo snake habitat (Bolt 2006, Mazzotti et al. 1993). Some citrus growers maintain a higher herbaceous vegetative structure along canals, roads, and wet ditches as well as in between the rows of trees. Islands of more natural areas (hydric hammocks, cypress, and other wetlands) may also be present, either in or at the periphery of the groves. Groves interspersed or adjacent to natural habitat would have more prey items for eastern indigo snakes and also provide more cover than a grove that is more intensively managed (Zeigler 2006). Factors which influence species richness in citrus groves in the Immokalee Rise region in addition to grove age were size, interspersion of other important habitats, sampling effort, proximity to large natural areas, visibility of wildlife in groves of different ages and effects of workers on wildlife (especially snakes) (Mazzotti et al. 1993). In the Immokalee Rise Citrus Study, grove beds, agricultural reservoirs, impacted wetlands, canals and ditches in citrus groves provided habitat for prey species such as small mammals, birds, toads, frogs, fish, lizards, turtles, alligators, other snakes, and non-native speces such as house mice (*Mus musculus*), black rats (*Rattus rattus*), and Norway rats (*Rattus norvegicus*). For this project, we are assuming that the entire remaining 10,264-acre grove is potential habitat for the eastern indigo snake even though the areas around the wet ditches and canals are likely to have better snake habitat and prey than the interior portions. Therefore, the Service considers the entire 10,264 ac to be habitat lost as a result of construction.

Initial Hydration: The initial flooding of the reservoir has the potential to inundate indigo snakes and their burrows. Indigo snakes may seek temporary refuge in air pockets in burrows. Slow initial flooding may allow some indigo snakes to vacate the reservoir, although some snakes may drown if trapped in air pockets and eggs may be destroyed by water.

Indirect effects

Indirect effects are those that are caused by or result from the proposed action, are later in time, and are reasonably certain to occur. The indirect impacts evaluated by the Service include injury and mortality associated with: 1) post-construction traffic increases from vehicles accessing the area for project monitoring, operations, maintenance or possible recreational access; (2) post-construction maintenance of the roads, levees, pump stations, and reservoir (including vegetation management methods such as mowing, herbicide application, and physical removal; reduced foraging opportunities associated with fluctuations in the prey populations from reservoir, canal or ditch drawdown or flooding; and 3) possible drowning or loss of individuals or nests

associated with rehydration; and harassment associated with rehydration of the reservoir. The indirect effects that the proposed action may have on eastern indigo snakes within the action area are discussed below.

Injury and Mortality: Once construction is completed, additional vehicular traffic will access and operate in the area as a result of project monitoring, operations, maintenance, and recreation. Some portion of the crown of the embankments will also be accessible for recreation access. Considering this information, it is likely that a small amount of mortality will occur as a result of additional vehicles accessing the site.

The Service anticipates that a small number of eastern indigo snakes may occupy the project area during operation and maintenance for the life of the project. Given the elevation of the project site levees and the number of prey items that could become established in and around the reservoir during drydown; these snakes may be at risk from the operation of maintenance vehicles and equipment, although the precise impacts are difficult to measure.

Mowing of embankments, vehicular activity, or heavy equipment operation associated with maintenance has the potential to crush or injure individual eastern indigo snakes and eggs, and destroy or degrade potential habitat. In general, the District uses the following guidelines for mowing levees:

1. Mowing occurs approximately 4 times per year.
2. Mowing occurs when vegetative height reaches 8 to 10 inches.
3. Mowers are set at 6 inches height.
4. Mowing occurs slightly beyond the toe of the slope if water levels allow.
5. No wildlife is to be harmed in the mowing of any levees.

Loss of Prey: Following the establishment of vegetation on the reservoir embankments (within six months after completion), prey items may colonize the reservoir embankments. Additionally, depending on the operation of the project and available water, the reservoir may occasionally dry out in low-precipitation years. It is not clear whether an eastern indigo snake prey base could become established within the reservoir. The interior slopes will be lined with a soil-cement mixture but the floor would remain as a natural substrate. Exposed substrate could attract, expose, or trap prey for the eastern indigo snake. Rehydration of the reservoir could result in loss of prey items. However, due to the large volume of water stored in the reservoir, complete drydown is anticipated to occur infrequently and this potential effect should be re-evaluated as more data becomes available regarding inundation frequency. Pesticide application may occur as part of project maintenance or accommodation of recreational activities. Prey (insects and some amphibians and reptiles) may be vulnerable to pesticide application and may be lost as a result of these activities.

Rehydration of the reservoir: Because the interior of the perimeter emabankment and the sides of the interior dam will be concrete, snake access to a drying reservoir may be limited. If access to the reservoir floor occurs in the event that portions of the reservoir become dry, and in the event a prey base becomes established, eastern indigo snakes may be attracted to the reservoir

floor and cold potentially be vulnerable to inundation upon rehydration. Eastern indigo snakes may drown or have to move off the site to find a suitable substitute. Due to the volume of water stored in the reservoir, complete drydown is anticipated to occur infrequently. However, this effect should be re-evaluated as more data becomes available regarding inundation frequency.

Contaminants:

Copper: Soil sampling has identified seven grids (*i.e.*, grids 56, 58, 124, 125, 134, 135, and 143) in the Berry Labelle – Congen Groves (Tracts GX-100-017 & GX-100-018) portion of the site that will require remediation due to copper contamination. The Service recommended remediation for the entirety of Grids 124, 125, 134, 135, and 143 (250 ac) and for the portions of Grids 56 and 58 that will be within the footprint of the proposed reservoir. The Service concurred in a letter dated September 14, 2006, that removing contamination from the seven grids would remove the risk of direct impacts to Service trust resources. Approximately one foot of soil will be excavated from areas to be remediated and the soil will be utilized within the reservoir embankments, burying the soils such that surface water will not contact the copper-contaminated soil. However, the Service noted that the remaining copper concentration in some areas of the property may be high enough to adversely impact benthic organisms.

We anticipate that remediated soils placed in the embankments will not adversely affect eastern indigo snakes. Copper does not significantly biomagnify in the food chain beyond benthic invertebrates. Since the majority of the potential prey of the indigo snake associated with periodic drawdown of the reservoir is not composed of benthic invertebrates, the Service does not anticipate any effect to the indigo snake (Frakes, personal communication 2007)

Other contaminants: The 600-acre Bryan Paul Citrus Grove (Tract GX-100-009) will be remediated for chlordane contamination by removal of the top two ft of soil in the 20-acre area and utilizing that soil within the reservoir embankments. The 2,025-acre Bob Paul Citrus Grove (Tract GX-100-015) may be remediated for organochlorine pesticides in two 50-acre grids upon further investigation to delineate contamination. The 2,399-acre Winthrop Property (Tract GX-100-005) will be remediated for metals, petroleum hydrocarbons, and pesticides detected around maintenance areas by removal of contaminated soils. The 954-acre Griffin Property (Tract GX-100-001) will be remediated for metals and polycyclic aromatic hydrocarbons in burn areas, chemical barns, and fertilizer mix and load areas by removal of contaminated soils. Given proper remediation, the anticipated risk from other contaminants is probably low.

Beneficial Effects

The management of the C-43 West Reservoir project site may result in minor potential benefits to the eastern indigo snake. The loss of eastern indigo snake habitat when the citrus grove is cleared may be minimally offset after vegetation on the external reservoir embankment has stabilized and prey items for the eastern indigo snake become available at sufficient densities (two to five years following construction). At that time, there should be habitat suitable for the eastern indigo snake on the external portion of the reservoir embankment. Interior portions of the reservoir and the interior dam embankments are anticipated to be a harder material (soil

cement or concrete) and therefore, would not provide the necessary herbaceous plant cover needed by eastern indigo snakes and their prey. The width of the side slopes of the external embankments would be 114 ft. The width of the toe between the bottom of the external embankment and the perimeter canal is 90 ft. For the perimeter reservoir embankments and toe, a total of 403.05 ac (204 ft of the perimeter embankment x 86,064 ft [16.3 mi]) of potential indigo snake habitat would be created. The top of the embankment was not considered eastern indigo snake habitat, even though snakes may be found there, due to the offsetting consequence of potential road mortality and lack of prey. The total potential eastern indigo snake habitat created by this project was estimated to be 403.05. Using the density data for ABS, if this acreage was in one block instead of linear it would support 4.24 eastern indigo snakes. However, since this habitat covers the perimeter of the site, eastern indigo snakes from outside the project area may occasionally use this habitat, assuming prey and cover are suitable and that the perimeter canal can occasionally be crossed. Therefore, it is difficult to estimate how many eastern indigo snakes will actually use the site following construction. Similarly, the extent to which prey items may become available as a result of reservoir drawdown is unknown.

Interrelated and interdependent actions

An interrelated activity is an activity that is part of the proposed action and depends on the proposed action for its justification. An interdependent activity is an activity that has no independent utility apart from the action under consultation. The management of the C-43 West Reservoir project site is an interdependent action.

Species' response to the proposed action

Construction, operation, and maintenance of the project can result in actions that may kill or injure individual eastern indigo snakes and destroy nests, and destroy or degrade occupied and potential habitat and foraging areas. Due to their large home ranges and relative low density, risk of direct mortality would not normally be considered substantial. However, due to the large size of the project area, the likelihood of mortality or injury increases. Any clearing, burning, earthmoving, construction, operation, and maintenance activities may also adversely affect eastern indigo snakes by causing them to leave the area, and possibly miss foraging and mating opportunities. Individual eastern indigo snakes fleeing the area may be more vulnerable to predation and intraspecific aggression. The Service anticipates that the eastern indigo snake population at the C-43 West Reservoir project will not fully recover from the effects of the proposed action.

It is anticipated that all 10,264 ac of potential eastern indigo snake habitat within the citrus grove portion of the action area would be impacted by the proposed action. The number of individuals present at the time of the action is not known. The Service estimates that as many as 41 adult male and 13 adult female eastern indigo snakes may be present within the site. These estimates are based on population density estimates at ABS (Layne and Steiner 1996) and reduced based on inferior habitat quality in the groves. It is not known how many juvenile eastern indigo snakes may be present at the time of the action. Juvenile indigo snakes are more vulnerable

because they typically do not use underground refugia as adults do, preferring thick vegetation for cover (Speake et al. 1987).

We believe that some eastern indigo snakes may move to the reservoir embankments, interior dam embankments, and toe slopes between the reservoir embankments and the perimeter canal following construction and stabilization of the vegetation and establishment of prey items. Eastern indigo snakes may also access the reservoir if extended periods of drydown occur and prey items establish in the reservoir. Access to these prey items will likely be controlled by the ability of the snake to negotiate the concrete interior surface of the external embankment, water depth, and the extent of available forage habitat in ecotones between dry and wet areas. We cannot estimate the number or age of eastern indigo snakes that may move into either area. Individual eastern indigo snakes may also be affected by on-going maintenance and management activities.

CUMULATIVE EFFECTS – Florida Panther

Cumulative effects include the effects of future State, Tribal, local, or private actions reasonably certain to occur in the action area considered in this Biological Opinion. Future Federal actions unrelated to the proposed action but located in the action area that would affect panthers are not considered in this section because they would require separate consultations pursuant to section 7 of the Act. To identify future private actions that would affect panthers and that may reasonably be certain to occur in the action area, the Service first identified the types of land alteration actions that could occur in the action area, then developed a mechanism to distinguish between those that will require future Federal review and those that are not likely to be a future Federal action, and thus meet the cumulative effects definition. To estimate future non-Federal actions, the Service chose to identify and tabulate recent past non-Federal actions and project this level of development as representative of future non-Federal actions.

Within the action area, past and ongoing state and county actions affecting panther habitat include: (1) State of Florida Developments of Regional Impact (DRI) Orders (2001 to 2006); (2) Collier and Lee County Planned Unit Developments (PUDs) (2001 to 2006); and (5) South Florida Water Management District's Environmental Resource Permits (2001 to 2006) (Figure 19). To evaluate these effects, the Service incorporated the FLUCCS mapping to determine properties that may be exempt from Federal Clean Water Act section 404 wetland regulatory reviews by the Corps. To determine which of these projects would likely be exempt from Federal Clean Water Act section 404 wetland regulatory reviews by the Corps, we identified the percentage of the project site that was classified as wetland habitat, based on the FLUCCS mapping units. The mapping units relied on by the Service included the 600 series (wetland classifications) and the 411 and 419 pine flatwood classifications (hydric pine systems). For listing purposes, properties with less than 5 percent wetlands were considered by the Service to be generally exempt from regulatory review as these quantities of wetlands could be avoided by project design.

Within the action area, based on FLUCCS mapping, about 19,438 acres could be expected to be subject to development without Federal permit involvement through the Clean Water Act section

404 (Table 15). This level of development represents 66.9 percent of a female panther's average home range (29,059 ac) and 31 percent of a male panther's average home range (62,542 ac).

State and county land alteration permits in southwest Florida not part of those actions listed above, generally included single-family residential developments within Northern Golden Gate Estates and Lehigh Acres. Vacant lands within the area of Northern Golden Gate Estates (north of I-75), also within the action area, totaled about 34,028 ac as of September 2004 (Figure 20). To evaluate these effects, the Service overlaid the plat boundaries on 2004 aerials, queried the parcel data from Collier County's Property Appraisers Office, noted lots with developments, compared those to 2003 aerials, and noted the changes. Vacant lands within the area of Northern Golden Gate Estates (north of I-75) totaled about 35,768 ac as of August 2003. The breakdown of acres for August 2003 is: (1) wetlands, about 17,572 ac; (2) uplands, about 17,990 ac; and (3) water, about 210 ac. These changes were overlain on the National Wetlands Inventory (NWI) maps for presence of wetlands. This evaluation was used to estimate the acreage of properties that may be exempt from Federal Clean Water Act section 404 wetland regulatory reviews by the Corps. A comparison of the 2003 and 2004 data for Northern Golden Gate Estates indicates about 1,740 ac of land were converted from vacant to developed with the breakdown as: (1) wetlands, about 696 ac; and (2) uplands, about 1,740 ac.

The evaluation process provided an estimate of 417 lots totaling 1,740 ac for Northern Golden Gate Estates. Therefore, using NWI mapping for the Northern Golden Gate Estates, a total of about 1,740 ac could be expected to be subject to development in a year in these areas without Federal permit involvement. Based on historical records for wetland permits issued by the Corps for these areas, most of these projects will involve the construction of single-family residences in partially developed areas and will involve less than an acre of impact. This level of development represents 3.59 percent of a female panther's average home range (29,059 ac) and 1.67 percent of a male panther's average home range (62,542 ac).

Vacant lands within the area of Lehigh Acres, also within the action area, totaled about 34,852 ac as of April 2003 (Figure 21). The breakdown of acres is: (1) wetlands, about 1,057 ac; (2) uplands, about 33,592 ac; and (3) water, about 202 ac. A review of aerial photography and Lee County building permit data for Lehigh Acres from the 1-year period prior to April 2003 indicates about 441 ac of land was converted from vacant to occupied, during the 1-year period. The breakdown of converted acres is estimated as: (1) wetlands, 66 ac; (2) uplands, 375 ac; and (3) water, 0 ac. Therefore, using NWI mapping, about 375 ac could be expected to be subject to development in a year in this area without Federal permit involvement.

In conclusion, the Service's cumulative effects analysis has identified about 21,553 ac within the action area that could be developed without Federal wetland permit involvement. This level of development, which the Service believes is representative of future non-Federal actions, is reasonably certain to occur and, therefore, meets the definition of cumulative effect. This level of projected future development represents 74.2 percent of a female panther's average home range (29,059 ac) and 34.5 percent of a male panther's average home range (62,542 ac), though the impacts will be scattered and generally located on the fringes of occupied panther habitat, supported primarily with disturbed vegetative communities, in row crops, or in

partially developed areas. These lands represent 1.10 percent of the non-urban private lands at risk in the core area (1,962,294 ac) (Table 5). Based on the above analysis, we believe the loss of the habitat associated with these lands, though insignificant in the short-term, may adversely impact the panther as development continues to occur in the future in the action area. The Service has accounted for some habitat loss and changes in habitat quality through its habitat assessment methodology and is encouraging state and county environmental staff to pursue section 10 (HCP) process to account for and compensate for adverse effects to the Florida panther.

CUMULATIVE EFFECTS – Audubon's Crested Caracara

Cumulative effects include the effects of future State, Tribal, local, or private actions that are reasonably certain to occur in the action area considered in this Biological Opinion. Future Federal actions that are unrelated to the proposed action are not considered in this section because they require separate consultation pursuant to section 7 of the Act.

Conversion of land from pasture to more intensive agricultural or residential uses could be a cumulative effect on the species if no wetlands were impacted (or no Federal permit was required). The most significant threat to the caracara is habitat loss resulting from this type of land use conversion (Layne 1996, Humphrey and Morrison 1997). Our assumed post-construction shifts in caracara territories may ultimately result in nest or territory abandonment if these large tracts of privately owned pastures or other agricultural activities adjacent to the project site are converted to residential or other non-pasture or non-prairie land uses. Based on the information in Table 15, the likelihood of more intensive land use conversions on adjacent land without Federal permit involvement through the Clean Water Act section 404 is high.

As caracara are known to feed on road kills, road improvement and widening projects may benefit caracara by increasing traffic and consequently increasing the number of road kills. However, caracaras are often killed while feeding on carrion within and along roadways. Thus, increased traffic and increased road kills likely lead to increased mortality of caracaras, particularly juveniles.

CUMULATIVE EFFECTS – Eastern Indigo Snake

Cumulative effects include the effects of future State, Tribal, local, or private actions that are reasonably certain to occur in the action area considered in this biological opinion. Future Federal actions that are unrelated to the proposed action are not considered in this section because they require separate consultation pursuant to section 7 of the Act.

Conversion of large tracts of natural and rural habitats to more intensive agricultural or residential uses could be a cumulative effect on the species if no wetlands were impacted (or no federal permit was required). The primary threat to the eastern indigo snake is habitat loss and fragmentation due to development (Lawler 1977; Moler 1985a). Additional habitat may be lost by non-federally reviewed actions such as single-family residential developments. Residential developments also increase risk of harm to indigo snakes in the interface areas between urban and native habitats because it increases the likelihood of snakes being killed by property

owners and domestic pets. Increased traffic associated with development may also lead to increased snake mortality.

SUMMARY OF EFFECTS – Florida Panther

Panther Usage: The timing of construction for this project, relative to sensitive periods of the panther's lifecycle, is unknown. However, all land clearing associated with the development will be completed in phases over several years. There are no known den sites within the project boundaries and the quality and quantity of the foraging prey base is low. Though panthers likely use the habitats within the project's action area, we believe panther usage of the project site is infrequent and we do not believe project construction will result in direct panther mortality, but may result in temporary disturbance to resident or dispersing panthers.

Traffic: There will be traffic increases with project development. As discussed above and in previous sections, the lands on the project site provide limited value to the Florida panther and panther prey species, the site is encompassed by agricultural (*i.e.*, citrus groves) and rural development, and the proposed action will further restrict suitability of the site for use by either resident or dispersing panthers. Panthers, however, are known to use the lands within the action area and collisions with motor vehicles have been increasing since 2000 in the project action area. Although the risk to the panther from collisions with vehicles as a result of the C-43 West Reservoir project is difficult to quantify, the Service believes that the increase in traffic generated by the project is not likely to increase the risk of roadway mortality or injury to panthers in the 25-mile radius action area.

Habitat Loss: The Service, based on the habitat evaluations discussed previously, believes the project will result in the direct and indirect loss of about 10,335 ac of mostly low quality panther habitat within the Primary, Secondary, and Other Zones (see discussion under Wildlife Assessment). Habitat types are primarily citrus groves and disturbed wetlands. Wildlife utilization of the property shows limited foraging values to panther prey species. We believe panther usage of the site is limited; however, the permanent loss is anticipated to adversely affect the panthers in the action area by decreasing the spatial extent of lands available for foraging, breeding, and dispersing. This loss of about 10,335 ac of panther habitat represents 0.53 percent of the 1,962,294 ac of available non-urban private lands in the core area. This small loss (0.53 percent) of non-urban private lands on the northern edge of the panther's occupied range will not negatively impact the Service's land conservation and preservation goals.

Compensation: The Band1/Acceler8 Projects will collectively provide for the preservation and restoration of approximately 100,492 ac in the panther core area, including 59,294 ac in the Primary Zone and 41,198 ac in the Other Zone. Preservation of 41,198 ac in the Other Zone is equivalent to preservation of 13,733 ac (*i.e.*, 41,198 ac times 1/3) in the Primary Zone. Thus, the combined Band1/Acceler8 project lands in the panther core area preserves 73,027 ac (*i.e.*, 59,294 + 13,733) of Primary Zone equivalent lands, which represents 9.4 percent of the 778,082 ac of Primary Zone equivalent lands in private ownership still needed for the panther population goal of 90 individuals. The functional value of the habitats to the panther will be maintained long-term through hydrological restoration and the removal of exotic vegetation.

Therefore, we believe the preservation and restoration of approximately 100,492 actual ac of habitat used by the panther in the panther core area will minimize the impact of the loss of this lower quality habitat and will further the Service's panther conservation goal.

Compensation provided by the combined Band1/Acceler8 projects benefit the survival and recovery of the Florida panther as referenced in the draft Panther Recovery Plan (Service 2006) goal 1.1.1.2.3. This goal recommends that habitat preservation and restoration within the Primary Zone be provided in situations where land use intensification can not be avoided. The applicant has proposed equivalent habitat protection and restoration, to compensate for both the quantity and functional value of the lost habitat.

Fragmentation: The project site is also located on the northern edge of occupied habitat, is encompassed by agricultural (*i.e.*, citrus groves) and rural development, and is not located within known dispersal corridors to larger publicly owned managed lands important to the panther. Therefore, appreciable fragmentation of habitat used by the panther is not expected to result from project implementation.

Intraspecific Aggression: Potential increases in intraspecific aggression and disturbance to the Florida panther were evaluated. The Service believes, as previously discussed, the habitat on the property provides low quality foraging for prey species, which directly affects the frequency and duration of use of the property by panthers. However, the reduction in the geographic range of habitat for dispersal and escape cover may contribute to a potential increased risk of death of injury of panthers in the action area due to intraspecific aggression.

Cumulative Effects Analysis: In the cumulative effects analysis, the Service identified the potential loss of about 4,046 ac within the action area that could be developed without Federal wetland permit involvement and we believe this level of development represents future non-Federal actions expected to occur in the action area. This level of development represents a small percentage (0.22 percent of the 1,962,294 ac) of available non-urban private lands in the core area. In general, these lands are primarily within previously impacted areas or are in the western more urbanized portion of the Florida panther's consultation area. Although this small percentage of lands may be lost from the core area of private lands available for panther conservation, the Service believes the loss of these lands will not negatively impact the Service's land conservation and preservation goals.

Conservation Land Acquisitions: The State and County land acquisition programs acquired about 17,092 ac of lands within the action area from 2000 to 2004 (Table 9), which represents 2.1 percent of the 799,205 ac of private lands still needed for the population of 90 individuals. These lands are generally located within the core lands of the Florida panther and are intended to be actively managed for the benefit of many wildlife species including the Florida panther. The preservation of these lands in the panther core lands will have a beneficial effect on the panther and further the Service's goal in panther conservation.

SUMMARY OF EFFECTS – Audubon's Crested Caracara

The Service anticipates approximately 1,474 ac of caracara habitat will be lost through conversion of citrus groves to an above-ground reservoir. The Service anticipates disturbance of adults would occur that could also result in potential injury or mortality to eggs, chicks, and fledglings over a minimum of 5 years.

The Service anticipates a potential beneficial effect of the project for caracaras. We anticipate that up to 430.71 ac of levee-based foraging habitat could be generated by the project within the existing two caracara territories. Additionally, initial site preparation and construction activities may provide good foraging conditions by exposing prey.

SUMMARY OF EFFECTS – Eastern Indigo Snake

The C-43 West Storage Reservoir project will affect the eastern indigo snake by the loss of habitat associated with conversion of 10,264 ac of primarily upland citrus grove to deep water reservoir, embankments, canals, ditches and roadways. Direct injury or mortality could occur from construction activity and vehicle operation, destruction of temporary refugia (vegetation and debris piles) and the initial hydration. Indigo snakes will lose most of the project prey base to the initial rehydration and will have to move off of the site, risking exposure to predation and intraspecific aggression. Post-construction management and maintenance activities will include mowing, pesticide application, equipment maintenance, and possible recreation opportunities for the public which may result in injury or mortality. Rehydration after drydown may result in mortality, loss of habitat and loss of prey. The potential habitat replacement associated with embankments within 2 to 5 years after construction is estimated to be only 403 ac of habitat.

CONCLUSION

Florida Panther

In conclusion, the Service has determined there will be no direct mortality or injury of the Florida panther resulting from this project. Indirect effects are difficult to quantify due to the wide-ranging habit of the species and the challenge of linking the death or injury of a single panther to increases in panther interactions (intraspecific aggression) or traffic generated as a result of the C-43 West Reservoir project. The adverse affects of project-generated traffic and intraspecific aggression potential, however, is not anticipated to appreciably diminish or preclude the survival and recovery of the panther. The loss of habitat from implementing the project, taking into consideration the status of the species, remaining habitat, and other factors considered by this Biological Opinion, such as the overall recovery objectives and other cumulative effects from actions in the action area, will be minimized by the conservation of other, more functionally valuable habitat. Taking all of the above into consideration, the Service believes the proposed construction and operation of the C-43 West Reservoir project is not likely to jeopardize the continued existence of the Florida panther. Critical habitat has not been designated for this species; therefore, none will be affected.

Audubon's Crested Caracara

After reviewing the current status of the caracara, the environmental baseline for the action area, the effects of the proposed action and the cumulative effects, it is the Service's biological opinion that the C-43 West Reservoir project, as proposed, is not likely to jeopardize the continued existence of the caracara. The Service reached this conclusion based on the determination that there will be no direct mortality or injury to adult caracara from the proposed project. However, the project-related changes in land cover and use primarily in the secondary zones of active nests as well as the increase in human presence and construction activities may contribute to indirect effects on the nest success of caracaras in the project vicinity. The Florida population of caracara is considered stable (Morrison 1996) and the potential short-term loss of reproductive success of two nesting pairs as a result of the project is not expected to appreciably affect the overall population of caracaras over time as caracaras are long-lived, maintain pair bonds for life, and exhibit strong nest site fidelity.

No critical habitat has been designated for the caracara; therefore, none will be affected.

Eastern Indigo Snake

After reviewing the current status of the eastern indigo snake, the environmental baseline for the action area, the effects of the proposed action and cumulative effects, it is the Service's biological opinion that the C-43 West Storage Reservoir project, as proposed, is not likely to jeopardize the continued existence of the eastern indigo snake. Although we anticipate incidental take of eastern indigo snakes, the Service has determined that the loss of a large area of primarily upland citrus grove under active agricultural production will not reduce the distribution of indigo snakes in the action area or in southern Florida. The indigo snake has a broad distribution in a mosaic of habitats and is a generalist that forages on a variety of available prey. The eastern indigo snake has some ability to move away from situations which may result in direct injury and mortality (construction and hydration) and can access adjacent habitat if escape opportunities are made available. For this project, the presence of on-site observers, pre- and post education, speed restrictions, order of construction, and rate of reservoir fill should reduce the incidence of injury, mortality, and disturbance.

No critical habitat has been designated for the eastern indigo snake; therefore, none will be affected.

INCIDENTAL TAKE STATEMENT

Section 9 of the Act and Federal regulation pursuant to section 4(d) of the Act prohibit the take of endangered and threatened species, respectively, without special exemption. "Take" is defined as "harass, harm, pursue, hunt, shoot, wound, kill, trap, capture or collect, or to attempt to engage in any such conduct." "Harm" is further defined by the Service to include significant habitat modification or degradation that results in death or injury to listed species by significantly impairing essential behavioral patterns, including breeding, feeding, or sheltering. Harass is defined by the Service as intentional or negligent actions that create the likelihood of injury to

listed species to such an extent as to significantly disrupt normal behavior patterns which include, but are not limited to, breeding, feeding, or sheltering. Incidental take is defined as take that is incidental to, and not the purpose of, the carrying out of an otherwise lawful activity. Under the terms of section 7(b)(4) and section 7(o)(2), taking, that is incidental to and not intended as part of the agency action, is not considered to be prohibited taking under the Act provided that such taking is in compliance with the terms and conditions of this Incidental Take Statement.

The terms and conditions described below are nondiscretionary and must be undertaken by the Corps so they become binding conditions of any grant or permit issued to the District, as appropriate, for the exemption in section 7(o)(2) to apply. The Corps has a continuing duty to regulate the activity covered by this incidental take statement. If the Corps (1) fails to assume and implement the terms and conditions or (2) fails to require the District to adhere to the terms and conditions of the incidental take statement through enforceable terms that are added to the permit or grant document, the protection coverage of section 7(o)(2) may lapse. In order to monitor the impact of incidental take, the Corps or the District, must report the progress of the action and its impact on the species to the Service as specified in the incidental take statement [50 CFR § 402.14(i)(3)].

AMOUNT OR EXTENT OF TAKE

Florida Panther

The Service anticipates that incidental take of the Florida panther will be difficult to detect for the following reasons: (1) the Florida panther is wide-ranging; (2) the lands on the project site provide limited value to the Florida panther and panther prey species; and (3) lands adjacent to the project site consist of existing agricultural and rural developments that reduce their suitability for use by either resident or dispersing panthers. However, the Service does not anticipate construction of the project will result in the direct mortality or injury of any Florida panthers. The Service does however, anticipate indirect take of the panther in the form of harm and harassment because of potential increases in interspecific aggression within the 25-mile radius action area. This level of incidental take may is associated with the loss of 10,335 ac of panther habitat within the Primary, Secondary, and Other Zones (*i.e.*, 144, 5,236, and 4,955 ac, respectively).

Audubon's Crested Caracara

The Service anticipates that the proposed action will incidentally take the federally listed caracara, though the level of incidental take may be difficult to detect and quantify for the following reasons: (1) it has a wide-ranging distribution; (2) it has a protracted breeding season; (3) it would be difficult to find or identify dead or impaired individuals; and (4) there is a possibility for double brooding in a season, which may or may not occur in the same nest tree. The incidental take is expected to be in the form of harassment although take may also occur in the form of harm due to tree clearing, burning, construction, and operation and maintenance of the project. Caracaras will be permanently displaced from the project site in the open-water

portion of the reservoir cells. It is possible that these caracaras could utilize the reservoir embankments or seepage canal after construction.

The Service anticipates that up to two adult pairs of caracaras could be taken as a result of this proposed action. This incidental take for adult birds is expected to be in the form of harassment. No direct killing or injuring of adult caracaras is anticipated. Harassment of adults is limited to the flushing of adults off the nest, modification of their foraging and nesting behavior, and the possible displacement from their home territory to adjacent suitable lands due to a net loss of habitat quality for this species as a result of the action. The consequences of disrupted parental care of the nest (*e.g.,* reduced egg incubation, chick protection and feeding, or care of fledglings) may lead to egg, nestling, or fledgling mortality in a variety of forms, such as exposure, starvation, falling from the nest, or predation.

Therefore, the Service also anticipates that disturbance may cause the loss of productivity (eggs or young) associated with up to two caracara nest sites for up to five consecutive breeding seasons. The Service anticipates that up to six caracara eggs or young (a maximum of three per nest) could be incidentally taken per year during the construction of the project. This take would be in the form of harm.

The Service will not refer the incidental take of any migratory bird for prosecution under the Migratory Bird Treaty Act of 1918, as amended (16 U.S.C. 703-712), if such take is in compliance with the terms and conditions (including amount or number) specified herein.

Eastern Indigo Snake

Incidental take of the eastern indigo snake is difficult to detect and quantify for the following reasons: (1) it has a wide-ranging distribution; (2) it has a patchy distribution within suitable habitat; (3) it has limited detectability due to use of burrows or holes for shelter, (4) there is likely unoccupied suitable habitat; (5) juveniles have limited detectability due to their affinity for thick vegetation, and (6) they may use cryptic sheltering areas that may be temporarily established during construction (e.g., brush piles, equipment stockpiles, and dirt mounds). The lack of practical methods to survey, in conjunction with wide-ranging activity and use of a variety of habitat types makes it difficult to determine the exact number of eastern indigo snakes that will be incidentally taken.

The Service anticipates that the direct permanent loss of approximately 10,264 ac of eastern indigo snake habitat will occur through conversion of citrus grove to reservoir and associated embankments, canals, and other infrastructure. Based on the reported density of eastern indigo snakes at ABS, and reducing that density by half based on the inferior habitat characteristics of the existing citrus grove, the Service anticipates up to 54 eastern indigo snakes will be taken incidental to the initial project construction and operations. The Service estimates that up to 25 percent of the eastern indigo snakes potentially impacted by the C-43 West Reservoir project site may be killed or injured by the initial construction activities. Above-ground refugia (burn, sediment, or debris piles) may be lost during clearing and construction. Additionally, individual eastern indigo snakes fleeing the area may be more vulnerable to roadkill, predation and

intraspecific aggression. The remaining 75 percent of the snakes would not be directly killed or injured but would be be affected by the loss of habitat. These individuals could leave the area, abandon den sites, miss foraging and mating opportunities and experience lower productivity. The incidental take associated with construction activities and loss of the majority of the habitat on the site is in the form of harm and harassment.

Initial hydration and rehydration may drown indigo snakes or destroy nests. This incidental take is expected to be in the form of harm.

It is not expected that this species will be permanently extirpated from the project site; however, it is not know how many snakes may return to the site, reproduce on the site, or survive from juvenile or adult on the site. Reservoir embankments may provide limited habitat. Maintenance, operations, and recreational activities (including mowing, and vehicle and equipment operation) may kill or injure indigo snakes. This incidental take is primarily in the form of harm. Human disturbance, loss of prey from pesticide application, loss of prey from initial hydration or rehydration, and movement away from habitat as a result of rehydration may be the result of long-term project operation and management. This incidental take, which is difficult to quantify, is expected to be in the form of harassment.

The Service anticipates a potential beneficial but minor indirect effect of the project to be interrelated to the management of the reservoir. We anticipate that up to 403.05 ac of embankment-based eastern indigo snake habitat could be generated by the project within 2-5 years of project completion. Because this potential habitat is linear in shape, we estimated it as if it were all in one evenly-shaped block, providing potential benefits to four eastern indigo snakes.

EFFECT OF THE TAKE

In the accompanying Biological Opinion, the Service determined this level of anticipated take is not likely to result in jeopardy to listed species or adverse modification of their designated critical habitat. No critical habitat has been designated for the Florida panther, Audubon's crested caracara, or the eastern indigo snake; therefore, none will be affected.

REASONABLE AND PRUDENT MEASURES

Florida Panther

The Service believes the Corps and the District have developed a project that has conservation measures necessary and appropriate to minimize the effect of incidental take of the Florida panther. In summary, to compensate for impacts to 10,335 ac of habitat, the Corps and the District propose to enhance and preserve approximately 59,294 ac and 41,772 ac of habitat used by the panther within the Primary and Other Zones, respectively, to benefit the Florida panther and its prey.

Audubon's Crested Caracara

The Service believes the following reasonable and prudent measures are necessary and appropriate to minimize impacts of incidental take of the caracara. Disturbance and injury to caracaras should be minimized during construction activities. Education of personnel on the site will facilitate minimization of impacts and conservation of the species. The District staff will coordinate and report on their activities to the greatest extent practical to minimize potential adverse effects on natural resource compliance, management, and monitoring requirements; and post speed limit of 35 mph or slower.

Eastern Indigo Snake

The Service believes the following reasonable and prudent measures are necessary and appropriate to minimize impacts of incidental take of the eastern indigo snake. Disturbance and injury to eastern indigo snakes should be minimized during construction activities. Education of personnel on the site will facilitate minimization of impacts and conservation of the species. Initial and rehydration fill rates can be adjusted to minimize mortality of indigo snakes and reduce the loss of prey. The District staff will coordinate and report on their initial construction activities; initial reservoir fill and reservoir rehydration; and long-term maintenance, management, and recreational activities to minimize potential adverse effects on the eastern indigo snake.

TERMS AND CONDITIONS

In order to be exempt from the prohibitions of section 9 of the Act, the Corps must comply with the following terms and conditions, which implement the reasonable and prudent measures, described above and outline reporting and monitoring requirements. The terms and conditions described below are non-discretionary, and must be undertaken by the Corps so they become binding conditions of any grant or permit issued to the District, as appropriate, for the exemption in section 7(o)(2) to apply.

The Corps has a continuing duty to regulate the activity covered by this Incidental Take Statement. If the Corps (1) fails to assume and implement the terms and conditions or (2) fails to require the District to adhere to the terms and conditions of the Incidental Take Statement through enforceable terms that are added to the permit or grant document, the protection coverage of section 7(o)(2) may lapse. In order to monitor the impact of incidental take, the Corps or the District, must report the progress of the action and its impact on the species to the Service as specified in the Incidental Take Statement (50 CFR § 402.14(i)(3)).

Florida Panther

Although we have not identified any specific Reasonable and Prudent Measures not incorporated in the project for Florida panthers, we are providing the following for clarification:

1. The Corps will include, as special conditions to the permit instrument, the conservation measures listed below and in the description of the proposed action that commits the applicant to purchase, preserve, and manage high quality habitat used by the panther, which is necessary and appropriate to minimize incidental take of panthers by the proposed action. Specifically, to compensate for the loss of 10,335 ac of habitat used by the panther, the District proposes to preserve and enhance 59,294 ac and 41,772 ac of Florida panther habitat in the Primary and Other Zones, respectively;

2. The preservation-sites will be managed in perpetuity for the control of invasive exotic vegetation as defined by the Florida Exotic Pest Plant Council's Pest Plant List Committee's 2001 List of Invasive Species (Category 1)(2005);

3. The Corps will provide a copy of the final permit to the Service upon issuance. The Corps will monitor the permit conditions regarding conservation measures to minimize incidental take of panthers by providing the Service a report on implementation and compliance with the conservation measure within 1 year of the issuance date of the permit;

4. **Annual Report:** An annual report will be presented to the Corps and to the Service in order to comply with 50 CFR part 402.14(i)(3), which states "In order to monitor the impacts of incidental take, the Federal agency or any applicant must report the progress of the action and its impact on the species to the Service as specified in the incidental take statement." The report will contain the following information:

    a. The current status of the construction of the project as well as any construction phases or milestones that have been completed;

5. The Corps will provide a copy of the final as-builts to the Service within 1 year of construction completion. These as-builts will also include habitat types and acreages of all land cover types within the project footprint;

6. The Corps will provide documentation to the Service for completion of any proposed restoration and verification of the execution and terms of the conservation easement or deed, if applicable;

7. Upon locating a dead, injured, or sick threatened or endangered species, initial notification must be made to the nearest Service Law Enforcement Office; Fish and Wildlife Service; 9549 Koger Boulevard, Suite 111; St. Petersburg, Florida 33702; 727-570-5398. Secondary notification should be made to the FWC; South Region; 3900 Drane Field Road; Lakeland, FL; 33811-1299; 1-800-282-8002; and

8. Care should be taken in handling sick or injured specimens to ensure effective treatment and care or in the handling of dead specimens to preserve biological material in the best possible state for later analysis as to the cause of death. In conjunction with the care of sick or injured panthers or preservation of biological materials from a dead animal, the finder has

the responsibility to carry out instructions provided by Law Enforcement to ensure that evidence intrinsic to the specimen is not unnecessarily disturbed.

Audubon's Crested Caracara

In order to be exempt from the prohibitions of section 9 of the Act, the Corps shall ensure that the District complies with the following terms and conditions which implement the reasonable and prudent measures described above and outline reporting and monitoring requirements. These terms and conditions are non-discretionary.

Caracara pairs proximate to the C-43 site will be monitored during land cover conversion and construction of reservoirs associated with this project. The goal of monitoring is to obtain detailed information on how a caracara breeding pair is affected by project-related disturbance and the changes in habitat availability within their territory. This will include the ability to evaluate changes in area use by caracaras, changes in location of nesting, nest success, fledging success, and adult and juvenile survival. The monitoring will be conducted starting as soon as possible before any clearing or grubbing occurs within the primary or secondary zones of a caracara nest and will continue until 1 year post-construction. The approved monitoring plan should include the following specific objectives:

1. Conduct additional annual surveys for caracara nests and territories in the proposed project area and within 1.5 miles of the project area boundary to evaluate effectiveness of surveys and to increase knowledge of caracara nest sites and densities within these areas. This will also provide information to allow evaluation of how any observed changes in habitat use may affect any other caracara territories in the vicinity in conjunction with data collected on radio-tagged birds. Surveys of suitable habitat within 1.5 miles of the project area may be conducted from roads or other public access points.

2. Capture and radio tag caracaras at the nest located on private property southeast of the proposed project footprint. Use satellite or standard VHF telemetry to monitor the adult caracaras' movements, habitat use, and survival over multiple years, both pre- and post-conversion. Monitoring of radio-tagged birds must be sufficient to document movements away from the territory if they occur.

3. Compare documented habitat use before and after project activities using the recently available habitat model and map (Morrison et al. 2006).

4. Monitor reproductive effort, nest success, fledging success, and adult and juvenile survival of all caracara nests within 3,000 meters of the proposed project.

The monitoring must be sufficiently rigorous to determine which of the following hypotheses about caracara responses to habitat conversion are exhibited by each caracara pair whose territory overlaps the project area:

- Caracara pairs may move to the nearest suitable habitat and establish a new nest site and territory. This suitable habitat may already be occupied by other caracaras, but if the habitat is suitable and sufficient in size, territory boundaries may shift and all pairs may be able to coexist and reproduce successfully.
- Caracara pairs may leave the project area and travel some distance to find another area of suitable habitat where they can establish a new nest site and territory. If they can find such new areas, they may be able to survive and reproduce successfully.
- Caracara pairs may attempt to establish new nest sites and territories either near or far from the development area but may be unsuccessful either because of territorial aggressiveness from resident pairs or because no other suitable habitat exists.
- In the absence of being able to establish a new territory and nesting site, the caracaras may become nomadic, traveling around south-central Florida, perhaps joining sub-adult flocks, or if not, simply surviving but being unable to establish anywhere and breed. In this case, these pairs' reproductive contribution to the overall population's persistence is lost.
- Displaced caracaras could die prematurely. As nomads, displaced adults may incur higher risk of mortality because of either a) being killed by caracaras defending territories into which displaced caracaras attempt to move, or b) through collision with vehicles our other trauma associated with scouting unfamiliar areas.
- The effects of the project do not result in any changes to the territory location and habitat use, and do not affect survival or productivity of the caracara pair at the site.

A monitoring proposal that details the methods which address the objectives described above should be submitted to the Service for review and approval at least 30 days prior to initiating caracara monitoring. The agency personnel or contractor who will be conducting the monitoring will also be responsible for obtaining a section 10(a)(1)(A) recovery permit that authorizes affects to caracaras that result from caracara trapping, transmitter attachment, nest monitoring and other associated activities.

Annual reports on the caracara monitoring project which include results form the monitoring to date, preliminary results of analyses, and complete data sets that result from the monitoring efforts shall be submitted to the Service. A final report shall also be prepared that provides results and final analyses after completion of all data collection and analyses.

Eastern Indigo Snake

In order to be exempt from the prohibitions of section 9 of the Act, the Corps shall ensure that the District complies with the following terms and conditions, which implement the reasonable and prudent measures described above and outline reporting and monitoring requirements. These terms and conditions are non-discretionary.

1. Minimize road and construction-related mortality:

a. Precautions for the eastern indigo snake will be required to avoid injury to any individual animal. The Draft Standard Protection Measures for the Eastern Indigo Snake (Service 2002) will be incorporated into special conditions of the permit.

b. The District shall provide at least one qualified observer during ground clearing activities. The observer's qualifications will be provided to and approved by the Service's C-43 Project biologist (Fish and Wildlife Service, South Florida Ecological Services Office; J.N. "Ding" Darling National Wildlife Refuge, 1 Wildlife Drive, Sanibel, Florida 33957, (941) 472-1100 (ext. 231), 2 weeks prior to initiation of construction. The observer's sole function would be to visually evaluate the area to be cleared immediately prior to, and following vegetation removal, stockpiling, and burning and to record any eastern indigo snake activity. Only individuals who have been either authorized by a section 10(a)(1)(A) permit issued by the Service, or by the State of Florida through the FWC for such activities, are permitted to come in contact with an eastern indigo snake.

c. During initial removal of the citrus trees the canal banks will not be altered. The trees will be up-rooted, allowed to dry, and subsequently pushed into piles and burned. Brush piles would be located as far away from the ditches (snake habitat) as possible in order to keep snakes from recolonizing brush piles before they are burned. Removal of trees would proceed at a relatively slow pace, thus allowing eastern indigo snakes the opportunity to move away.

d. During tree clearing, the equipment operators will start work at the farthest point from ditches, canals, or other potential temporary refugia and work towards the ditches or canals so that the eastern indigo snake, if encountered, would be encouraged to move away from the disturbance and towards temporary refugia.

e. The District shall conduct a pre-construction wildlife education meeting with all workers and contractors that will be present on the site, including those conducting the initial remediation activities, using the standard Acceler8 preconstruction package, as well as conditions under which the Service should be notified with regard to eastern indigo snake concerns.

f. For avoidance and safety reasons, a speed limit of 35 mph will be posted for all vehicular traffic. Pre-construction education materials shall specify speed restrictions.

2. Minimize harm (habitat loss, mortality due to drowning) and harassment (disturbance, loss of prey) by:

a. Initial hydration of the reservoir will be at a maximum rate of 6 inches per day until the water depth is 6 inches above the highest surface elevation excluding existing embankments. The highest surface elevation is approximately 26.0 feet; thus the reservoir would be filled at a maximum rate of 6 inches per day until the water elevation

reaches 26.5 feet. Once the 26.5 foot depth is reached, the reservoir fill rate will not be restricted.

b. The subsequent first rehydration of the reservoir after an extended drydown event will be at a rate of 1 foot per day until the water is 1 foot above the highest surface elevation excluding embankments or other man-made structures such as boat ramps. The highest surface elevation is approximately 26.0 feet; thus the reservoir would be filled at a maximum rate of 1 foot per day until the water elevation reaches 27 feet. Once the 27 foot depth is reached, the reservoir fill rate will not be restricted. An extended drydown event will be defined and included as a 404 permit condition.

c. The Corps shall monitor indigo snake response during initial fill to determine the effect of hydration on indigo snakes. If necessary, snakes will be captured and released outside the reservoir. The Corps shall monitor indigo snakes during rehydration following the first extended drydown event to determine reservoir accessibility and use by indigo snakes and their prey during drydown events and the effect of rehydration on snakes if present. An extended drydown event will be defined prior to the 404 permit issuance and a detailed monitoring plan shall be submitted to the Service for review and approval at least 30 days prior to initial filling of the reservoir. The agency personnel or contractor who will be conducting the monitoring will also be responsible for obtaining a section 10(a)(1)(A) recovery permit that authorizes affects to indigo snakes as a result of trapping, transporting, and releasing them. If snake monitoring indicates that snakes are capable of escaping the reservoir without harm or that snakes do not use the reservoir bottom during extended drydown events, then restrictions on rehydration rates will be re-evaluated.

d. The Corps shall conduct a pre-construction wildlife education meeting with all workers and contractors that will be present on the site, including those conducting the initial remediation activities, using the standard Acceler8 preconstruction package; as well as conditions under which the Service should be notified with regard to eastern indigo snake concerns.

e. All vehicle and equipment operators will be notified for the life of the project, including all management and maintenance personnel, to avoid all snakes and burrows if at all possible. All on-site personnel will be educated to recognize the eastern indigo snake for the life of the project. If any snake is encountered, it will be avoided and allowed to leave the area on its own before vehicle or equipment use is resumed.

f. Educational information on the eastern indigo snake will be posted at the educational kiosks on the site.

3. Monitoring and reporting requirements:

a. Results of all observations associated with ground clearing activities (as required in Terms and Conditions 1.a.) shall be provided to the Service's C-43 Project biologist (Fish and Wildlife Service, South Florida Ecological Services Office; J.N. "Ding" Darling National Wildlife Refuge, 1 Wildlife Drive, Sanibel, Florida 33957, (941) 472-1100 (ext. 231), within 30 days following the activity.

b. Initial hydration shall be monitored to assure consistency with the Term and Condition 2 (a) and 2 (c). Results of observations associated with initial hydration including stage gauge levels, observations of indigo snakes or their prey, additional information identified in the monitoring plan, and recommendations to reduce effects to indigo snakes during rehydration shall be provided to the Service's C-43 Project biologist (Fish and Wildlife Service, South Florida Ecological Services Office; J.N. "Ding" Darling National Wildlife Refuge, 1 Wildlife Drive, Sanibel, Florida 33957, (941) 472-1100 (ext. 231) within 10 days following the activity.

c. Levee mower operators will scan the areas where vegetation has been cut immediately afterwards mowing and count and record the number of all species of dead or injured snakes observed with particular attention to identifying and counting any potential eastern indigo snakes.

d. The Corps shall provide the Service C-43 Project biologist (Fish and Wildlife Service, South Florida Ecological Services Office; J.N. Ding Darling National Wildlife Refuge, 1 Wildlife Drive, Sanibel, Florida 33957, (941) 472-1100 (ext. 231), a one-week advance notice on the schedule for ground clearing of citrus trees or other construction phases (pre-loading of embankments, perimeter canal construction, pump and infrastructure construction, and initial hydration) so that we may participate in on-site observational activities.

e. The Corps shall provide the Service C-43 Project biologist (Fish and Wildlife Service, South Florida Ecological Services Office; J.N. Ding Darling National Wildlife Refuge, 1 Wildlife Drive, Sanibel, Florida 33957, (941) 472-1100 (ext. 231), a two-day advance notice on the schedule to rehydrate the reservoir by pumping or weir operation after the first drydown event. This term and condition will be discontinued if rehydration events are determined to have no adverse effect on eastern indigo snakes as determined by monitoring and agreed to by the Service.

4. Disposition of dead or injured animals (salvage):

a. Annually, a report of all snakes killed or injured by operation or maintenance of the C-43 West Reservoir project (as indicated in Terms and Conditions 1.h.) must be submitted to the Service's C-43 project biologist (Fish and Wildlife Service, J.N. "Ding" Darling National Wildlife Refuge, 1 Wildlife Drive, Sanibel, FL 33957, (941) 472-1100. This report should contain the location, dates, and times for any sightings of eastern indigo snakes and the disposition of all eastern indigo snakes found. A site map with

observation locations should also be included in this report. If no snakes are encountered, a report should be submitted indicating that fact.

b. Upon locating a dead, injured, or sick federally listed species, initial notification must be made to referenced project biologist and the nearest Service Law Enforcement Office (Fish and Wildlife Service; Ed Lewis, Fort Myers, Florida (239) 561-8148. Secondary notification should be made to the FWC, South Region; 8535 Northlake Boulevard; West Palm Beach, Florida; 33412-3303; (561) 625-5122; 1-888-404-3922. If not specifically instructed by Service law enforcement to submit dead specimens, all dead specimens and snake sheds should be offered to the Florida Museum of Natural History, Gainesville, FL 32960. The museum should be contacted with regard to details for preservation and transport.

Care should be taken in handling sick or injured specimens to ensure effective treatment and care or in the handling of dead specimens to preserve biological material in the best possible state for later analysis as to the cause of death. Dead eastern indigo snakes should be placed on ice and frozen as soon as possible. In conjunction with the care of sick or injured specimens or preservation of biological materials from a dead animal, the finder has the responsibility to carry out instructions provided by Law Enforcement to ensure that evidence intrinsic to the specimen is not unnecessarily disturbed.

CONSERVATION RECOMMENDATIONS

Section 7(a)(1) of the Act directs Federal agencies to utilize their authorities to further the purposes of the Act by carrying out conservation programs for the benefit of endangered and threatened species. Conservation recommendations are discretionary agency activities to minimize or avoid adverse effects of a proposed action on listed species or critical habitat, to help implement recovery plans, or to develop information. We recommend the following:

Audubon's Crested Caracara

1. Support scientific studies to determine the response of breeding caracaras to habitat restoration efforts (*e.g.*, flooding of pasture, general construction activities) within their established territories. This information would be useful in predicting the effects of other restoration efforts in the CERP that are planned within the caracara's existing range, as well as in developing measures to reduce potentially adverse project effects on the caracara and assist in the recovery of this species.

2. Implement the procedures in *Recommended Management Practices and Survey Protocols for Audubon's Crested Caracara in Florida* (Morrison 2001) during project planning and construction, as appropriate. The implementation of these guidelines by land managers and Federal action agencies would help in the recovery of this species.

3. Monitor the long-term responses of caracaras to altered habitat conditions over broad areas. This would provide useful information in determining the potential effects of large-scale

projects, such as the CERP, agricultural conversion, and residential development on this species.

4. The Corps should continue to work with the Corps, Service, public land managers, and private landowners to identify other habitats that have the potential to be improved for caracaras. When potential habitat improvement sites are identified, the agencies will cooperate and jointly coordinate with the respective land management entities and landowners to improve these caracara habitats. Habitat improvement measures may include land management actions such as removal of exotic or nuisance species of vegetation, prescribed burning, and planting of native vegetation. The short-term goal of these habitat restoration measures would be to offset or compensate for any potential losses in caracara breeding pairs resulting from this and anticipated projects. A long-term goal of these measures would address the potential loss of caracara reproduction resulting from implementation of future phases of the CERP.

5. Following construction, maintain an on-site educational kiosk for the public on the listed species and other wildlife that may be observed in the project area.

Eastern Indigo Snake

1. Following construction, maintain an educational kiosk for the public on the listed species and other wildlife that may be observed in the C-43 West Reservoir project.

2. If large snake skins are found, they should be collected, dried, and sent to the Service's C-43 Project biologist (Fish and Wildlife Service, J.N. "Ding" Darling National Wildlife Refuge, 1 Wildlife Drive, Sanibel, Florida 33957, (941) 472-1100 for positive identification and genetic studies. Information on the collection date and location should be included.

3. Cooperate with research-based efforts to provide for long-term ecological monitoring on eastern indigo snake prey densities and habitats in the project area.

REINITIATION NOTICE

This concludes formal consultation on the C-43 West Reservoir project. As provided in 50 CFR § 402.16, reinitiation of formal consultation is required where discretionary Federal agency involvement or control over the action has been retained (or is authorized by law) and if: (1) the amount or extent of incidental take is exceeded; (2) the agency action is subsequently modified in a manner that causes an effect to the listed species or critical habitat not considered in this opinion; (3) new information reveals effects of the agency action that may affect listed species or critical habitat in a manner or to an extent not considered in this opinion; or (4) a new species is listed or critical habitat designated that may be affected by the action. In instances where the amount or extent of incidental take is exceeded, any operations causing such take must cease pending reinitiation.

Thank you for your cooperation and effort in protecting fish and wildlife resources. If you have any questions regarding this project, please contact Joyce Mazourek at 239-472-1100, extension 231.

Sincerely yours,

Paul Souza
Field Supervisor

Table 1. Wood Stork Foraging Habitat Assessment.

		Uniform Mitigation Assessment Method		
Cover Type	**Acres**	**Existing**	**With Project**	**Functional Value (+ or -)**
Freshwater Marsh	6.9	0.5	0.27	(-) 1.6
Secondary	191.6	0.4	0.27	(-) 24.9
Tertiary	541.3	0.4	0.27	(-) 70.4
Tapegrass	4,130	0.33	0.60	(+) 446

Table 2. *Targeted and Acquired Acreage Totals of Conservation Lands in South Florida Directly Affecting the Panther within the Consultation Area.

Name	Targeted[1] Acreage	Acquired Acreage	Indian Reservation
Federal Conservation Lands			
Everglades National Park	1,508,537	1,508,537	--
Big Cypress National Preserve	720,000	720,000	--
Florida Panther National Wildlife Refuge	26,400	26,400	--
Subtotal	**2,254,937**	**2,254,937**	--
State of Florida: Florida Forever Program			
Belle Meade	28,505	19,107	--
Corkscrew Regional Ecosystem Watershed	69,500	24,028	--
Twelvemile Slough	15,653	7,530	--
Panther Glades	57,604	22,536	--
Devil's Garden	82,508	0	--
Caloosahatchee Ecoscape	18,497	2,994	--
Babcock Ranch	91,361	0	--
Fisheating Creek	176,760	59,910	--
Subtotal	**540,388**	**136,105**	--
State of Florida: Other State Acquisitions			
Water Conservation Area Number 3	491,506	491,506	--
Holey Land Wildlife Management Area	33,350	33,350	--
Rotenberger Wildlife Management Area	25,019	20,659	--
Fakahatchee Strand State Preserve	74,374	58,373	--
Picayune Strand State Forest	55,200	55,200	--
Okaloacoochee Slough State Forest and WMA	34,962	34,962	--
Babcock-Webb Wildlife Management Area	79,013	79,013	--
Subtotal	**793,424**	**773,063**	--
Indian Reservations[2]			
Miccosukee Indian Reservation	--	--	81,874
Big Cypress Seminole Indian Reservation	--	--	68,205
Brighton Seminole Indian Reservation	--	--	37,447
Subtotal	**--**	**--**	**187,526**
GRAND TOTALS	**3,588,749**	**3,164,105**	**187,526**

[1] Targeted acres not available for all lands. In Such cases, targeted equals acquired acreage.
[2] Indian lands are included due to their mention in the MSRP. Acreages taken from GIS data.
* Table 2 was excerpted from the Brief of Amicus (2003). However, the lands shown as acquired in this table may include some private in-holdings and may include lands currently under sales negotiations or condemnation actions.

Table 3. Habitat preservation efforts resulting from formal and informal consultations with the Service for projects affecting Florida panther habitat from March 1984 to May 2007.

Table 10. Results of Panther Prey Abundance Surveys Conducted Within the C-43 West Reservoir Project Area. Table excerpted from Appendix I, Final Biological Assessment for the C-43 West Storage Reservoir Project, Hendry County, Florida.

Table 1. Number of tracks per survey date for white-tailed deer and feral hog.

		Number of Tracks per Survey Date							
Transect	Species	9/15/2006	9/26/2006*	9/27/2006*	9/28/2006	9/29/2006	10/12/2006	10/13/2006	Total (for the 5 analyzed days)
1	White-tailed Deer	1	1	5	0	0	1	0	2
	Feral Hog	7	10	1	7	9	0	4	27
2	White-tailed Deer	0	0	2	0	0	0	1	1
	Feral Hog	26	0	14	4	7	2	23	62
3	White-tailed Deer	0	0	0	0	0	0	0	0
	Feral Hog	15	0	23	4	1	0	2	22
4	White-tailed Deer	0	7	7	0	0	0	0	0
	Feral Hog	0	2	0	5	1	1	0	7
5	White-tailed Deer	0	1	0	0	0	0	0	0
	Feral Hog	5	2	6	0	4	1	2	12
Total	White-tailed Deer	1	25	35	0	0	1	1	3
	Feral Hog	53	14	44	20	22	4	31	130
t_i (average # of tracks/mile)	White-tailed Deer	0.4	10.4	14	0	0	0.4	0.4	0.24
	Feral Hog	21.2	5.6	17.6	8	8.8	1.6	12.4	10.4

Notes:

1. Data from these two days were considered outliers and were not used in the population density estimate.
2. All transects are 0.5 miles in length, and consist of grove access/maintenance roads (dirt surface).
3. t_i is derived from Tyson (1952) formula for population estimates $X_1 = 11 / D$ where X_1 is the population density per square mile, t_i is the number of tracks per mile, and D is the average daily range of deer.
4. sample calculation for deer using D=1 mile (as per Tyson, 1952): $X_1 = 0.24$ tracks per mile / 1 mile = 0.24 deer/mi^2. Then 0.24 deer per mi2 x 16.19 mi2 = 3.9 deer in the project site.

Table 14*. Thirteen vegetation cover classes ranked for importance to crested caracaras in south-central Florida. Ranks were obtained using compositional analysis of 28 caracara home ranges compared to the overall study area. Cover classes were derived from the original 43 classes in the Florida Vegetation and Land Cover layer (FWC 2003). General preference ranks were assigned subjectively, based on field observations of caracaras in the region.

Vegetation cover class	More detailed preference rank[1]	General Preference Rank
Improved pasture	10	High
Freshwater marsh	9	High
Grassland	9	High
Mixed upland hardwoods	8	High
Citrus	7	Medium
Agriculture	6	Medium
Shrub swamp	5	Medium
Bare soil	3	Low
Shrub and brushland	3	Low
Pinelands	2	Low
Urban	1	Low
Scrub	1	Low
Wetland forest	0	Not used
All other habitats	0	Not used

United States Department of the Interior

FISH AND WILDLIFE SERVICE
South Florida Ecological Services Office
1339 20th Street
Vero Beach, Florida 32960

July 17, 2007

Colonel Paul L. Grosskruger
District Commander
U.S. Army Corps of Engineers
701 San Marco Boulevard, Room 372
Jacksonville, Florida 32207-8175

Service Federal Activity Code: 41420-2006-FA-0443
Project: C-43 Basin Storage Reservoir

Dear Colonel Grosskruger:

The enclosed document is the final Fish and Wildlife Coordination Act (FWCA) report for the Caloosahatchee River (C-43) West Basin Storage Reservoir (C-43 West Storage Reservoir) Project for your review. This report is provided by the Fish and Wildlife Service (Service) in accordance with the FWCA of 1958, as amended (48 Stat. 401; 16 U.S.C. 661 *et seq.*) and the Endangered Species Act of 1973, as amended (Act) (87 Stat. 884; 16 U.S.C. 1531 *et seq.*).

The Service and the U.S. Army Corps of Engineers (Corps) have been actively engaged over several years to plan this project. The Service supports the Corps' preferred alternative identified in the draft Integrated Project Implementation Report (PIR) and Environmental Impact Statement (EIS) (Corps and South Florida Water Management District 2007).

This report does not constitute a biological opinion as described under section 7 of the Act. The Service is currently in the process of preparing a biological opinion for this project, which will address the project impacts on the Florida panther (*Puma concolor coryi*), Audubon's crested caracara (*Polyborus plancus audobonii*), eastern indigo snake (*Drymarchon corais couperi*), and other listed species. After consultation is concluded, if modifications are made to the selected plan or if additional information involving potential impacts to listed species becomes available, reinitiation of consultation may be necessary.

On June 27, 2007, the Florida Fish and Wildlife Conservation Commission concurred with the findings and recommendations contained within the draft FWCA report. A copy of those comments are included as an appendix to this report. This final FWCA report constitutes the Secretary of the Interior's recommendations for the C-43 West Storage Reservoir project, in accordance with section 2(b) of the FWCA, and will be incorporated into the Corps' final PIR and EIS for public review and comment in accordance with the provisions of the National Environmental Policy Act.

Colonel Paul L. Grosskruger Page 2

If you or your staff has any questions regarding the findings and recommendations contained in this final FWCA report, please contact Joyce Mazourek at 239-472-1100, extension 231. The cooperation of your staff and the staff of the South Florida Water Management District is greatly appreciated.

Sincerely yours,

Paul Souza
Field Supervisor
South Florida Ecological Services Office

EXECUTIVE SUMMARY

The Central and Southern Florida Comprehensive Review Study, Final Integrated Feasibility Report and Programmatic Environmental Impact Statement (Restudy) established the need for and the beneficial effects of an above-ground reservoir in the Caloosahatchee River (*i.e.,* Canal-43 or C-43) basin as part of a comprehensive plan to achieve restoration objectives for the Caloosahatchee Estuary. The Restudy included two primary structural components focused on improving environmental conditions in the Caloosahatchee River and Estuary: 1) a 160,000 acre-foot reservoir with associated aquifer storage and recovery (ASR) wells; and 2) basin runoff backpumping and stormwater treatment. Due to technical uncertainty and implementation issues, the ASR features originally associated with a storage reservoir in the Caloosahatchee Basin will be evaluated and implemented separately. The availability and effectiveness of storing basin runoff for backpumping to the C-43 Canal and Lake Okeechobee has been called into question since completion of the Restudy and will be re-evaluated as part of future Comprehensive Everglades Restoration Plan (CERP) updates. As such, this document discusses only the Caloosahatchee River West Basin Storage Reservoir (C-43 West Storage Reservoir) project, one of 68 components identified for Everglades restoration located in the Caloosahatchee River Basin in the Lower West Coast Region of Florida.

The purpose and scope of the C-43 West Storage Reservoir project is to restore the ecosystem function in the Caloosahatchee Estuary by reducing the number and severity of events where harmful amounts of freshwater from basin runoff and Lake Okeechobee releases are discharged into the estuary system and to maintain a desirable minimum flow of fresh water to the estuary during dry periods. The project may also achieve water supply benefits, some flood attenuation, and water quality benefits to reduce salinity and nutrient impacts of runoff to the estuary. The proposed reservoir footprint is located in Hendry County west of LaBelle, Florida, on approximately 10,492 acres south of State Road 80 and approximately two miles west of State Road 29. The majority of the property is owned by the South Florida Water Management District (District) and is under a lease agreement with Jack M. Berry, Inc. for continued citrus grove operations.

The Caloosahatchee River and Estuary is at the head of a vast estuarine and marine ecosystem that includes aquatic preserves (AP) managed by the State of Florida (*e.g.,* Matlacha Pass AP, Estero Bay AP, Pine Island Sound AP), as well as the federally designated Charlotte Harbor National Estuary Program, the J.N. "Ding" Darling National Wildlife Refuge Complex, and numerous other state and local parks and recreation areas. In 2006 the American Rivers organization listed the Caloosahatchee River as one of the top ten endangered rivers in the United States. Restoration of healthy, productive aquatic ecosystems in the Caloosahatchee River and estuary is essential to maintaining the ecological integrity and associated economic activity in these publicly owned and managed areas. The major environmental concerns for the estuary and adjacent waters are altered freshwater inflows and extreme variation in salinity levels, eutrophication, and habitat loss. Altered salinity in the estuary has resulted from hydrological modifications that have dramatically changed the natural quantity, quality, timing, and distribution of freshwater flows to the estuary. Salinity is a major ecological variable that controls important aspects of the estuarine community structure and food web. Flow alterations

impact the natural biodiversity of the estuary by affecting food availability, predation pressure, and reproductive success, as well as directly causing chronic and acute stress on biota.

Seventeen federally listed threatened or endangered animal species, two listed plant species, and one endangered fish species are present or potentially present in the study area or proposed project footprint, and may be impacted by the construction and operations of the project. Although some of these species may be impacted by the loss of habitat within the project footprint, when implemented, the project has the potential to significantly contribute towards environmental restoration beyond the project footprint.

The Service notes differences in methods and models used for plan formulation, alternative selection, and alternative analyses which add complexity to comparisons. Plan formulation and selection for the C-43 project was based on MIKE SHE hydrologic model output containing a significant error in the water budget. A separate spreadsheet analysis, based on output from the South Florida Water Management Model was used to evaluate the next added increment analysis for the preferred alternative (3B). Compliance with Saving Clause requirements were modeled using a spreadsheet analysis for system-wide effects and a localized reservoir model for project level impacts. Model assumptions, boundary conditions, and level of risk and uncertainty varied among modeling efforts.

The Service recognizes the importance of this project as an initial step to improve the timing and quantity of freshwater flows to the Caloosahatchee Estuary and adjacent waters and to enhance or conserve aquatic and estuarine habitats. In support of those objectives, we provide the following recommendations:

1. The Corps and District should consult with natural resource agencies in developing a detailed project operating manual for the reservoir to ensure restoration objectives are met. The operational plan should include the regulation schedules, operating criteria, and additional provisions as may be required to collect, analyze, and disseminate basic data. Detailed operating instructions to ensure that the project meets the restoration goals and targets should also be included in the form of a draft, interim, preliminary, and final operational plan. The water resource allocation for the natural system as described in the Project Implementation Report (PIR) should be utilized and described in both documents as the project progresses. An adaptive assessment team should meet when operations begin, during interim construction operations, and after construction to review the operational plan in concert with the information obtained from the Water Quality and Ecological Monitoring Plans to assure that restoration benefits are being met and that operations are optimized for restoration (Annex D in the Draft PIR).

2. The Service recommends that the hydrologic monitoring plan in Section D.2 of Annex D in the PIR be expanded beyond the immediate footprint of the reservoir to include both existing canals and adjacent and upstream wetlands to ensure operation of the reservoir will not result in adverse impacts to the Spirit-of-the Wild (SOW) Wildlife Management Area (WMA) and the Okaloacoochee Slough State Forest (OSSF) WMA, and that the Corps formulate and incorporate related ecological hypotheses to be tested in the adaptive management protocol in

Section D.4 of Annex D in the PIR. Emphasis should be placed on acquiring pre-project baseline data for existing canals (*i.e.,* Roberts Canal) that can either provide direct or indirect drainage of areas of concern such as the SOW and the OSSF WMAs.

3. The Corps should evaluate results of the Test Cell Water Quality Monitoring Plan and incorporate that information in the reservoir design and water management operation and maintenance plan to maximize the reduction of nutrient loads from C-43 West Reservoir outflows.

4. The Service recommends that the Corps use the results from the Test Cell Water Quality Monitoring Plan to further evaluate: the quality of water while it is retained within the reservoir; the quality of water released from the reservoir and its potential effects on water quality of flows discharged at S-79; and, the effects of the quality and volume of water released at S-79 on the estuary.

5. The Service recommends that the Corps monitor the water quality effects of the project consistent with the Water Quality portion of the Draft Project Operating Manual and Monitoring Plan (Annex D in the Draft PIR).

6. The Service recommends that the Corps monitor the surface water and groundwater effects of the project consistent with the Water Quality portion of the Draft Project Operating Manual and Monitoring Plan (Annex D in the Draft PIR) and recommendation number 2 above.

7. The Service recommends that the Corps monitor effects of the project on estuarine resources consistent with the estuarine portion of the Draft Project Operating Manual and Monitoring Plan (Annex D in the Draft PIR).

8. The Service recommends that the Corps implement the adaptive management protocols consistent with the Draft Project Operating Manual and Monitoring Plan.

9. If ASR wells are not constructed around the reservoir perimeter, the Service recommends that the Corps and the District expand the littoral zones created along the seepage canals.

10. The Service recommends that compatible public recreational opportunities which do not conflict with the primary function of the reservoir be provided in accordance with State Rule 40E-7.

11. The Service recommends that the Corps or District pursuit funding for oyster reef restoration by placement of hard substrate in the estuary through other programs to increase the likelihood of oyster reef expansion to 30 acres over a 10- to 15-year period and 100 acres over the project life. Although the proposed project will improve salinity conditions for oysters and associated flora and fauna in the middle estuary, oyster expansion is directly tied to the availability of hard substrate for colonization.

The Service has participated in the development and review of alternatives for the C-43 West Storage Reservoir project since it was initiated. Throughout the evaluation process we have provided recommendations involving the location, refinement, and selection of project alternatives based on ecological considerations onsite and within the Caloosahatchee Estuary. The Service believes that the selected plan could provide meaningful hydrologic, economic, and ecological improvements to the Caloosahatchee Estuary. Project operations will benefit the upper Caloosahatchee Estuary by augmenting low flows during dry periods and reduce the number of times the estuary suffers from high salinity, and to a lesser extent, will benefit the lower estuary by reducing the number of high flow events during the wet season.

ACKNOWLEDGEMENTS

The Service acknowledges Emily Boughner, Kim Dryden, John Galvez, Steve Glass, Todd Hopkins, LeeAnn Kelso, Freddie James, Anne Philip, Brad Rieck, Pamela Repp, and Art Roybal for their assistance in writing, reviewing, and preparing the Draft and Final Fish and Wildlife Coordination Act Reports.

The Service appreciates the cooperation of the C-43 West Basin Storage Reservoir project team for responding to our recommendations throughout the planning process, and we remain committed to assist in addressing our remaining recommendations to further enhance fish and wildlife resources as detailed project plans are reviewed and the project is constructed.

I. PURPOSE, SCOPE, AND AUTHORITY

A. Introduction

The Comprehensive Everglades Restoration Plan (CERP) was approved as a framework for the restoration of the natural system under Section 601 of the Water Resources Development Act of 2000 (WRDA 2000). The CERP consists of 68 components to restore, preserve, and protect the South Florida Ecosystem while providing for other water-related needs of the region. CERP's components will be implemented over an approximately 40-year period. Together, these components will benefit the ecological functioning of more than 2.4 million acres of the south Florida ecosystem by improving and restoring the proper quantity, quality, timing and distribution of water made available for the natural system while also addressing urban and agricultural water supply concerns and maintaining existing levels of flood protection.

Previous ecosystem restoration and water supply planning efforts, including the Central and Southern Florida Comprehensive Review Study, Final Integrated Feasibility Report and Programmatic Environmental Impact Statement (Restudy) (U.S. Army Corps of Engineers [Corps] and South Florida Water Management District [District] 1999) have established the need for and the beneficial effects of an above-ground reservoir in the Caloosahatchee River (*i.e.*, Canal-43 or C-43) basin as part of a comprehensive plan to achieve restoration objectives for the Caloosahatchee Estuary. The Restudy included two primary structural components focused on improving environmental conditions in the Caloosahatchee River and Estuary: (1) a 160,000 acre-foot (ac-ft) reservoir with associated aquifer storage and recovery (ASR) wells; and (2) basin runoff backpumping and stormwater treatment. Due to technical uncertainty and implementation issues, the ASR features originally associated with a storage reservoir in the Caloosahatchee Basin will be evaluated and implemented separately. The availability and effectiveness of storing basin runoff for backpumping to the C-43 Canal and Lake Okeechobee has been called into question since completion of the Restudy and will be re-evaluated as part of future CERP updates. The C-43 Basin Storage Reservoir (BSR) Project is one of 68 components identified for Everglades restoration and is located in the Caloosahatchee River Basin in the Lower West Coast Region of Florida. The C-43 West Storage Reservoir project is one of several projects authorized for implementation in Section 601(b)(2)(C)(ii) of WRDA 2000, and has been identified as the C-43 West Storage Reservoir "Acceler8" project.

The State of Florida has developed a plan called "Acceler8" for the purpose of accelerating design and construction of a number of critical restoration projects consistent with the CERP prior to one or more of the following: administration approval, congressional committee resolution, congressional authorization, or Federal construction funding. The State anticipates the Acceler8 program will provide immediate environmental, social, and economic benefits in the south Florida region. All Acceler8 projects must be specifically authorized by Congress before becoming a part of the Federal CERP. The District is the state agency responsible for water resources management in south Florida and acts as the non-federal sponsor for Federal water resources projects, including the CERP and is responsible for implementing the Acceler8 plan.

The District proposes to initiate construction of the C-43 West Reservoir Acceler8 project prior to implementation of the Federal C-43 Basin Storage Reservoir Project, Part 1. The Corps is proceeding with two separate and independent but related actions, the feasibility-level evaluation of the Federal project and the regulatory evaluation of the District's proposed Acceler8 project, both of which are described in the Draft Integrated Project Implementation Report (PIR) and Environmental Impact Statement (EIS). The District's C-43 West Reservoir Acceler8 project is the same as the National Environmental Policy Act (NEPA) preferred alternative or Federal Recommended Plan, described in the Draft PIR and EIS (Corps and District 2006). The purposes of the Federal Recommended Plan identified in this Draft PIR and the District's Acceler8 project are consistent. Therefore, it is anticipated that this Draft PIR and EIS will also serve as the basis for the Regulatory Division's NEPA evaluation of the District's proposed Acceler8 project.

The information provided in this Fish and Wildlife Service (Service) Fish and Wildlife Coordination Act (FWCA) report for the C-43 West Storage Reservoir project is based on information contained in the PIR and EIS, and other communication with the Corps and District. This report discusses the ecological effects of the project for all alternatives and the preferred alternative (PA). The PA is referred to as the selected alternative plan (SAP) in the Draft PIR and EIS.

B. Purpose and Scope of Project

The purpose and scope of the C-43 BSR and ASR Project as defined by CERP is to capture C-43 Basin runoff and releases from Lake Okeechobee to provide environmental water supply deliveries to the Caloosahatchee Estuary and water quality benefits to reduce salinity and nutrient impacts of runoff to the estuary. Facilities could be designed to provide water supply benefits and some flood attenuation.

The Restudy project features included:

- An above-ground reservoir with total storage capacity of approximately 160,000 acre-feet, and
- Aquifer storage and recovery wells with a capacity of approximately 220 million gallons per day and associated pre and post-water quality treatment.

The storage amount for the above-ground reservoir was established through various previously completed modeling efforts. In the Restudy analysis of the C-43 Basin, an acceptable salinity range for the estuarine ecosystem was established which translated into monthly freshwater inflows of 300 cubic feet per second (cfs) to 2,800 cfs at the W.P. Franklin Lock and Dam (S-79) which is the most downstream structure and marks the upstream extent of the Caloosahatchee Estuary. This flow target included the need for low flow augmentation and minimizing high flow discharge events to improve estuarine water quality and to protect and restore estuarine habitat and biota. This flow target at S-79 helped produce modeling results indicating the most efficient size for determining the storage capacity of reservoirs to capture local basin and Lake Okeechobee inflows.

In order to address these changing conditions and other issues and concerns that have arisen since the Restudy analysis of the project, it was decided that the Part I C-43 Basin Storage Reservoir project would be separated into two phases:

- Phase I – will address the most immediate needs of the estuary
- Phase II – will provide a comprehensive solution for the needs of the entire basin

Part I, Phase I of the C-43 West Storage Reservoir project will focus on restoration of the western Caloosahatchee River Basin and Estuary through hydrologic modification. Phase I seeks to reduce excessive high flows to the estuary during the wet season, while increasing availability of water for the estuarine system during the dry season. This improved hydrologic regime would establish a downstream salinity range suitable for a healthy estuarine ecosystem thereby promoting increased fish and wildlife abundance, and increased biological richness. Phase I is a separable element from Phase II and therefore will be evaluated and justified as an independent project.

The focus of the PIR/EIS was to optimize the C-43 West Reservoir as part of the first phase of the C-43 West Storage Reservoir project. The PIR/EIS for Phase I of the C-43 West Storage Reservoir project provides a solution for the immediate needs of the estuary, while anticipating that there will be unmet demands and needs (potentially both environmental and water supply needs) to be met in a future phase. Water quality features, if necessary to achieve the restoration objectives for the basin and to meet regulatory requirements, will also be addressed in a future phase.

The Part I, Phase II PIR will have two points of focus: (1) addressing those additional needs not met in the Western C-43 Basin that are identified in this PIR, and (2) identifying and addressing the need of the Eastern C-43 Basin which may include agricultural and urban water supply demands and needs. Water quality features, if necessary to achieve the restoration objectives for the basin and to meet regulatory requirements, will be addressed in the Part I, Phase II PIR. Cost-sharing will be in accordance with Federal cost-sharing policy requirements. Although this phased approach defers solving the problems of the upper basin to another PIR, it provides a mechanism for addressing the immediate problems and needs of the Caloosahatchee Estuary.

C. Authority

This Final FWCA report constitutes the report of the Secretary of the Interior as required by section 2(b) of the FWCA of 1958, as amended (48 Stat. 401; 16 U.S.C. 661 *et seq.*), which establishes fish and wildlife conservation as a co-equal purpose or objective of federally funded or permitted water resource development projects. The FWCA allows for reports and recommendations from the Service and the State agency exercising administration over wildlife resources (in this case, the Florida Fish and Wildlife Conservation Commission [FWC]) to be integrated into Corps reports seeking authorization for the Federal action. The FWCA also grants authority to the Corps to include fish and wildlife conservation measures within these projects. Other authorities relevant to Service participation in the planning process for this

project include the Endangered Species Act of 1973, as amended (Act) (87 Stat. 884; 16 U.S.C. 1531 *et seq.*), the National Environmental Policy Act (NEPA) of 1969, as amended (42 U.S.C. 4321 *et seq.*), the Bald and Golden Eagle Protection Act (16 U.S.C. §668 *et seq.*), and the Migratory Bird Treaty Act (16 U.S.C. § 703 *et seq.*).

The WRDA 2000 provides authority for the CERP and section 601(b)(2)(C)(ii) of the WRDA 2000 provides specific authority for implementing the C-43 Basin Storage Reservoir and ASR Project. The Corps and the District have executed a Design Agreement for the Design of Elements of the Comprehensive Plan for the Everglades and South Florida Ecosystem Restoration Project (Design Agreement) May 2000. The direction and guidance for the development of this project are contained within the CERP Master Program Management Plan (MPMP) developed and approved by the Corps and the District for the purposes of describing the framework and processes to be used by the Corps and District for managing and monitoring implementation of CERP. During completion of the MPMP in August of 2000, (Corps and District 2000) the project was divided into two parts, Part 1: The C-43 Basin Storage Reservoir Project (C-43 BSR)(D-Part 1), and Part 2: The C-43 Basin ASR Project (D-Part 2). The projects were separated to accommodate the inclusion of the findings of the Caloosahatchee ASR Pilot Project without delaying the implementation of the reservoir aspect of the project.

II. PREVIOUS SERVICE INVOLVEMENT IN THE C-43 WEST STORAGE RESERVOIR PROJECT

The Service participated in all project-related public workshops and NEPA hearings, PDT meetings and working subgroup meetings, field site inspections, and conference calls from 2002 to present. The following chronology includes most of the major milestones since. Additional meetings, conference calls, and correspondence are not included in this list.

The Service received a Phase I and II environmental Assessment Report for the Berry Labelle-Congen Grove dated December 6, 1999.

In response to the Corps' February 25, 2002, request, the Service provided information on fish and wildlife resources included federally-listed species that may be within the proposed reservoir locations or affected by the activities of the C-43 Basin Storage Reservoir in our April 11, 2002, Planning Aid Letter (PAL). The site-selection sub-team used this information guide the site selection process by focusing on suitable reservoir locations that would minimize impacts to fish and wildlife resources.

On March 18, 2003, the Service provided the C-43 Corps project planning leader with a boat tour of the J.N. "Ding" Darling refuge, as well as the Caloosahatchee Estuary.

On March 20, 2003, site selection sub-team led by the Service, presented new updated preliminary site locations for potential reservoirs in the Caloosahatchee Basin overlayed on various GIS cover type maps.

On March 31, 2003, the Service met with Jim Beever (FWC) and Sandy Scheda (SEA) to review the new reservoir location maps and to apply the matrix to the revised map. Two sites dropped out due to conflicts with panther habitat, specifically, the Caloosahatchee ecoscape.

On April 30, and May 1, 2003, the Service assisted the Corps by providing listed species maps within Caloosahatchee Basin for use in the reservoir siting process and explained these maps at an Environmental Stakeholders meeting (April 30) and public meeting on (May 1).

In a letter dated May 19, 2003, the Service provided comments on the March 3, 2003, Phase I and II Environmental Site Assessment for the Griffin Brothers property. In that letter, the Service recommended further delineation of pentachlorophenol (PCP) in the canal in the vicinity of the S5 sample location.

On June 10, 2003, the Service provided scoping comments under the National Environmental Policy Act for development of the Draft Environmental Impact Statement for the C-43 Basin Storage Reservoir Project, including information on federally-listed species that may be affected by the proposed project.

The Service provided information on listed species distributions to Alternative Selection sub-team on June 13 and June 26 to refine the list of potential reservoir locations in the Caloosahatchee Basin.

On June 25, 2003 Service biologists met to begin developing an ecological model for the C-43 project to assist the C-43 Basin Storage Reservoir Project Delivery Team (PDT) in determining appropriate locations for reservoirs within the Caloosahatchee Basin.

On July 14, 2003, the Service provided comments on the March 25, 2003, Phase I and II Environmental Site Assessment for the Winthrop Citrus Investors property (Winthrop property). In that letter, the Service recommended delineation of aldrin contamination.

The Service provided additional information on direct and indirect impacts to significant fish and wildlife resources in the project area in an August 13, 2003, PAL. That letter addressed wetland and upland habitats of significant importance, federally-listed species, and potential contaminant issues.

Service staff participated in the October 23, 2003, PDT meeting, where the Corps officially announced that the District was pursuing the Berry Groves Reservoir as an "Early Start" project on their own and the Corps' PIR process would continue concurrently.

On October 30, 2003, Service and District staff met to discuss the development and application of a completed ecological model of the Caloosahatchee Basin to assist in reservoir site selection within the Basin.

From December 1 to December 5, 2003, the Service participated in a video teleconference In-Progress Review, which included the C-43 project, and was held in Fort Myers. A major point

of discussion revolved around whether or not to expand the water quality objectives such as nutrient levels of the C-43 project within the context of the Southwest Florida Feasibility Study (SWFFS).

On March 31, 2004, the PDT met at the District's Lower West Coast Regional Service Center.

On March 31, 2004, the Service received a proposal for the Phase I and II Environmental Site Assessment for the Brian Paul Citrus Grove. The Service requested that zinc be added to list of metals analyzed via an April 8, 2004, email.

On April 19 and 20, 2004, the environmental sub-team discussed a plan to conduct a Wetland Rapid Assessment Procedure (WRAP) to assess wetland values and functions at the Berry Grove and Lake Hicpochee proposed reservoir sites.

On May 14, 2004 the Service met with the Corps and District in Clewiston to prepare and coordinate logistics for the WRAP of Berry Groves and other potential sites for the C-43.

Service, Corps, and District staff conducted wetland assessments using WRAP and the Uniform Mitigation Assessment Method (UMAM) of Berry Groves. Ground surveys were conducted on June 8, 9, and 10, 2004, followed by aerial surveys on June 14 and 15, 2004.

Service, Corps, and District staff completed ground and aerial wetland assessments using WRAP and UMAM at Berry Groves on July 13, 14, and 15, 2004.

The Service reviewed additional information provided by Environmental Consulting and Technology, Incorporated, (ECT) regarding aldrin contamination on the Winthrop property and agreed in a July 1, 2004, letter, that no further aldrin delineation was necessary.

On July 20, 2004, Service staff met with the District, FWC, and Scheda Ecological Associates, to discuss the boundary change for the Berry Groves reservoir. Due to the change in the project boundary, additional consultation on potential project impacts to federally listed species, including the Florida panther, Audubon's crested caracara, Everglades snail kite, wood stork, and Florida grasshopper sparrow, will be necessary. The southern boundary was expanded to include the Duda property in the southwest and southeast corners. The southeast corner contains pine flatwoods, cypress slough, saw palmetto, and lightly wooded pasture that was previously farmed. The latter area has also been identified as Primary and Secondary Zones for the panther.

Additional information on PCP contamination on the Griffin Brothers property was provided by the District via an August 11, 2004, letter, prepared by ECT. Based on that information, the Service agreed no further delineation of PCP was needed in an October 13, 2004, letter.

On August 17, 2004, the Service received the Phase I and II Environmental Site Assessment report for the Bryan Paul Citrus Grove. In our September 20, 2004, letter, the Service requested further evaluation and remediation for Chlordane. Additional information regarding our letter was provided by Tetra Tech on December 22, 2004.

During August 2004, Service staff reviewed and provided informal comments on the draft Existing Conditions chapter prepared by the Corps for the C-43 BSR EIS.

On August 24, 2004, Service staff attended the Regional PDT meeting. The agenda included a review of the C-43 BSR project status.

In September 2004, Service staff reviewed and provided informal comments on the draft Problems and Opportunities chapter prepared by the Corps for the C-43 BSR Environmental Impact Statement (EIS).

In our October 6, 2004, letter, Service staff provided comments to FDEP on the Draft Verified List of Impaired Waters for the Caloosahatchee Basin and the Total Maximum Daily Load program and the potential benefits or impacts to the J.N. "Ding" Darling NWR.

In October and November, 2004, Service staff assisted the Corps in preparing the draft Future Without Conditions chapter for the C-43 BSR EIS.

On December 1, 2004, Service staff participated in a telephone conference with the Corps and the District regarding C-43 Plan Formulation and Evaluation. Topics discussed included two strategies for performance measures and evaluation of alternatives and needs for the Feasibility Scoping Meeting (FSM) and the FWCA Report.

On December 1, 2004, ECT recommended further delineation of chlordane on the Bryan Paul Citrus Grove in their Screening Level Ecological Risk Assessment for that site.

On December 15, 2004 Service biologists and hydrologist met to review preliminary documentation regarding the hydrologic model to be used for evaluation of the C-43 alternatives and to discuss pros and cons of use of that model.

On December 20, 2004, Service staff provided comments to the Corps on the FSM materials for this project.

The Service reviewed and provided comments via a January 25, 2005, email on the November 17, 2004, proposal for the Phase I and II Environmental Site Assessment for the Bob Paul Citrus Grove. The Service requested complete sampling in the former row crop area.

In early January 2005 Service staff prepared for and conducted wetland assessments using both the WRAP and the UMAM, on five potential secondary reservoir sites in the Lake Hicpochee area, including the lake itself. Data were collected by helicopter on January 10 and 11, 2005, in cooperation with the District and Corps.

On January 12, 2005, Service biologists and hydrologist met with the District, Corps, and Joint Venture staff to review the preliminary design, hydrologic models, and fish and wildlife resource issues for the C-43 project.

On January 11, 2005, staff reviewed and provided comments on the Executive Summary for the FSM document.

On January 18, 2005, Service staff participated in a teleconference with the Corps and the District regarding their Internal Technical Review of the draft FSM document.

On January 20, 2005, staff met with the Corps and the District in Ft. Myers to prepare for the FSM presentation. Talking points, slides, and visual aids were determined and prepared.

On January 21, 2005, the Service attended the C-43 working group meeting in Fort Myers.

On January 28, 2005, Service staff reviewed and provided informal comments on the draft FSM Document.

January 31, 2005, and February 11, 2005, Service staff conducted helicopter surveys to classify wetland habitats within potential reservoir sites in the Lake Hicpochee vicinity. Land ownership and accessibility for ground surveys was also determined.

On February 3, 2005, Service staff met with FWC staff to discuss fish and wildlife resource concerns associated with the C-43 reservoir and the remaining potential alternatives.

On February 4, 2005, staff participated in an interagency teleconference to discuss nitrogen loading in the Caloosahatchee river and estuary. Most of the nitrogen entering the Caloosahatchee is organic, and at this time, it is unknown if the C-43 West reservoir would reduce nitrogen input to the estuary.

On February 4, 2005, Service staff reviewed and prepared slides for the FSM presentation. Staff also prepared poster-sized site screening maps for display during the FSM. The maps showed potential reservoir sites considered in relation to known threatened and endangered species distributions and habitats.

On February 10, 2005, Service staff traveled to Jacksonville to meet with the Corps and District staff to prepare for the FSM.

On February 11, 2005, staff participated in the presentation of the C-43 FSM package to the Corps vertical team. A description of the problems and opportunities in the Caloosahatchee Basin, project planning objectives and constraints, existing conditions in the basin, future without project conditions, preliminary plan formulation and evaluation, and unresolved issues were presented.

On February 18, 2005, Service staff attended the C-43 West Reservoir Stakeholders Meeting in Fort Myers.

On February 23, 2005, staff participated in a teleconference to discuss nitrogen loading in the Caloosahatchee river and estuary. The water quality objectives of the C-43 West reservoir, the reservoir's potential impacts on nitrogen as currently designed, and the potential need for a stormwater treatment area were also discussed.

On February 25, 2005, Service staff reviewed and provided comments on the Basis of Design Report for the C-43 BSR project.

On March 2, 2005, Service staff participated in the Restoration Verification and Coordination (RECOVER) review of the C-43 performance measures via teleconference.

On March 3, 2005, Service staff participated in a teleconference to discuss the C-43 West reservoir Acceler8 schedule and modeling needs.

On March 7, 2005, Service staff attended the Water Resources Advisory Committee (WRAC) Issues Workshop on the C-43 West Reservoir Project in LaBelle.

On March 10, 2005, Service staff participated in the first weekly interagency teleconference to discuss project status and issues, including opportunities to formulate for water quality improvements.

On March 15, 2005, Service staff participated in a teleconference to discuss the current status of the C-43 performance measures (PMs). The project team decided to request that RECOVER postpone their review until the PMs are updated. Specific issues that are currently unresolved are: 1) How do we estimate historic variability and apply to flows under current conditions? 2) Are we looking at the appropriate time scale?

On March 17 and 24, and April 7, 2005, Service staff participated in weekly interagency teleconferences to discuss project status and needs.

On March 21, March 23, and April 4, 2005, Service staff provided comments and guidance on potential methods to rank proposed project alternatives based on degree of match to preferred flow distributions at S-79.

On March 22, 2005, the Service held and interagency meeting at the District office in Fort Myers to discuss potential project impacts on federally and state listed species. Representatives from the District, Corps, FWC, and the Service were in attendance. The discussion focused primarily on the accelerated C-43 West Reservoir component but also applies to the selected alternative plan that will be addressed in the Corps' PIR.

On March 29, 2005, Service staff provided a PAL recommending that the Corps and the District design the C-43 West Reservoir to provide water quality benefits to the estuary by reducing nutrient loads in accordance with CERP Guidance Memorandum Number-Revision 023.01. We also recommended that the Corps and the District conduct further modeling to quantify those benefits.

On March, 30, 2005, Service staff participated in a meeting at the District office in Fort Myers to develop potential alternatives for water storage and restoration of Lake Hicpochee and to estimate hydrologic and biotic quality values for the natural system, existing, and future without project conditions similar to the South Florida Assessment Method. The team evaluated aerial photos taken by Service staff during a January 31, 2005, helicopter flight and a habitat type cover map developed during that flight.

On April 5, 2005, Service staff attended the Lee County Board of County Commissioners meeting in Fort Myers. The District presented the current design of the C-43 West Reservoir to the Board of Commissioners. Water quality issues were discussed, including the need for quantifying reservoir impacts on water quality and the potential need for a test cell. The test cell project would also address seepage concerns raised by local landowners during the March 7, 2005, WRAC public meeting in LaBelle.

On April 28 and May 5, 2005, Service staff participated in weekly interagency teleconferences to discuss project status and needs, specifically use of an existing WAM-View model to provide nutrient concentrations that would then be fed into Ecolab and MIKE SHE models. The nutrient loads could then be used as an evaluation criteria for screening potential alternatives. The existing WAM-View is poorly calibrated and was not created using the 2000 land use or updated rainfall data that the Ecolab and MIKE SHE models are based on. The Service recommended updating and recalibrating the WAM-View using existing and available data for improved confidence in model results.

On May 5, 2005, the Service received the April 29, 2005, draft scope of work for the C-43 West Storage Reservoir Temporary Test (Embankment) Cells from the District.

On May 26, 2005, Service staff met with the Corps, District, SCI, FWC, and SEA to discuss potential adverse effects to threatened and endangered species that may occur as a result of the C-43 West Reservoir Project or the Test Cell Project. The meeting focused on: 1) the latest method for assessing habitat compensation recommended when adverse project effects to habitat used by the Florida panther cannot be avoided or when adverse effects have been minimized but loss will still occur; and 2) the Test Cell Project design, 404 permit needs, and listed species consultation.

During June 2005, the District proposed a land swap with the Department of Interior (DOI) to swap land purchased within the reservoir footprint for land purchased with DOI funds north of the reservoir footprint but adjacent to and south of Highway 80.

On July 11, 2005, Service staff participated in a Natural Systems Group meeting to develop a restoration alternative for Lake Hicpochee. Service staff presented slides of field work conducted in June 2005 to persuade the group that the existing wetlands (short-hydroperiod to permanently flooded) are far more valuable to fish and wildlife than converting the area to an open-water and cattail marsh. The alternative agreed upon will focus on habitat improvements of existing wetlands, including exotic removal, muck removal, reintroduction of fire, etc.

On June 27, 2005, the Corps conducted an interagency site visit to delineate wetland boundaries and assess current conditions within the Test Cell Project footprint. Service, District, SCI, and SEA staff participated in the site visit.

On July 1, 2005, the Service provided comments on the May 27, 2005, Phase I and II Environmental Site Assessment for the Bob Paul Citrus Grove. In that letter, the Service recommended that the District consult with DEP regarding on-site burial of contaminated soil.

On July 18, 2005, Service staff completed the last helicopter surveys of wetlands within the proposed secondary reservoir locations in Glades and Hendry Counties.

On July 19, 2005, Service staff participated in an interagency teleconference on the status of the 404 permit for the C-43 pilot test cells. Service staff informed the Corps and District that no tree clearing or any other ground disturbing activities should be conducted in the test cell site until formal consultation on federally listed species has been completed.

On July 28, 2005, Service staff met with the District, Corps, EPA, FDACS, and SEA staff to review and finalize WRAP scores for the wetlands occurring within the Test Cell Project footprint.

On August 5, 2005, Service staff reviewed and provided comments on the draft Biological Assessment, C-43 West Storage Reservoir Test Cell Pilot Project, Hendry County, Florida to the District's Acceler8 permitting and NEPA staff.

On August 11, 2005, Service staff participated in the re-instated, weekly interagency teleconference to discuss project status and needs.

On August 18 and 25, 2005, Service staff participated in the weekly interagency teleconference to discuss project status and needs. Current issues discussed include hydrologic model status and timelines and savings clause issues.

On August 24, 2005, Service staff participated in a C-43 Natural Systems Group teleconference on the proposed alternative for Lake Hicpochee restoration. Water storage at Lake Hicpochee would only be possible with impoundments that would not achieve restoration goals and would compromise existing wetland values and functions. Lake Hicpochee is very unique and provides a mosaic of wetlands habitats in close proximity, including a range of short-hydroperiod wetlands. Short-hydroperiod wetlands are being lost across the state, and the country, to development which increases the importance and inherent value of wetlands at Lake Hicpochee. Due to Service staff recommendations, an alternative focusing on habitat improvement was developed for this site that includes exotic removal, muck removal, reintroduction of fire, etc. However, this alternative may be dropped from the C-43 project due to the minimal storage capacity and little to no benefits provided to the estuary and will be included in the SWFFS instead.

On September 8, 2005, Service staff participated in a C-43 Natural Systems Group meeting to develop a method to estimate benefits for the Lake Hicpochee restoration alternative and quantify costs.

On September 15, 2005, Service staff participated in an interagency teleconference to discuss project status and needs. Current issues discussed include hydrologic model status and current changes in the project timeline to reach the Alternatives Formulation Briefing (AFB).
