HOUSE DOCUMENT NUMBER 112- 90

DEPARTMENT OF THE ARMY
OFFICE OF THE ASSISTANT SECRETARY
CIVIL WORKS
108 ARMY PENTAGON
WASHINGTON DC 20310-0108

FEB 14 2012

Honorable John Boehner
Speaker of the House
of Representatives
U.S. Capitol Building, Room H-232
Washington, D.C. 20515-0001

Dear Mr. Speaker:

In response to a resolution adopted by the Committee on Environment and Public Works of the U.S. Senate on June 5, 1997, the Secretary of the Army supports the authorization and construction of navigation improvements for the Sabine-Neches Waterway (SNWW) channel in Southeast Texas and Southwest Louisiana. The proposal is described in the report of the Chief of Engineers, dated July 22, 2011, which includes other pertinent reports and comments. The views of the States of Louisiana and Texas are set forth in the enclosed communications. The Secretary of the Army plans to implement the project at the appropriate time, considering National priorities and the availability of funds.

The recommended plan would contribute to the economic efficiency of commercial navigation in the SNWW. The recommended plan is the Locally Preferred Plan (LPP) and consists of the following features: 1) deepen the SNWW from 40 to 48 feet and deepen the offshore channel from 42 to 50 feet from offshore to the Port of Beaumont Turning Basin; 2) extend the 50 foot deep offshore channel by 13.2 miles to deep water in the Gulf, increasing the total length of channel from 64 to 77 miles; 3) taper and mark the Sabine Bank Channel from 800 feet wide to 700 feet wide; 4) deepen and widen Taylor Bayou channels and turning basins; 5) ease selected bends on the Sabine-Neches Canal and Neches River Channel; and 6) construct new and enlarge/deepen existing turning and anchorage basins on the Neches River Channel. The environmental benefits of the Neches River dredged material disposal plan would fully offset the environmental impacts within the State of Texas and on Federal lands, and some of the impacts in the State of Louisiana, by restoring degraded marsh habitat and nourishing three miles of Gulf shoreline in each state. A mitigation plan was developed specifically for Louisiana which compensates for unavoidable impacts to intertidal marsh habitat. The National Economic Development (NED) plan has similar features to the LPP, however, the SNWW would be deepened to 49 feet and the offshore channel would be deepened for a length of 16.5 miles.

The estimated Project First Cost is \$1,057,000,000 plus an additional first cost of \$7,830,000 that would be incurred over a 30-year period for mitigation construction efforts utilizing material from regular maintenance dredging of a separate Federal navigation project. Therefore, the estimated Total Project First

Cost is \$1,064,800,000. The estimated Total Project First Cost includes the cost of constructing the general navigation features and the value of lands, easements, rights-of-way and relocations estimated as follows: \$897,200,000 for channel modification and dredged material placement; \$87,400,000, for environmental mitigation; \$53,200,000 for bridge fender modifications; \$1,280,000 Federal cost for cultural resources mitigation; \$766,000 for Corps administrative costs; \$3,730,000 for the value of lands, easements, rights-of-way, and relocations (except utility relocations) provided by the non-Federal sponsor; and \$21,400,000 for one-half of the cost of utility relocations borne by the non-Federal sponsor pursuant to Section 101(a)(4) of WRDA 1986, as amended. The remaining one-half cost of deep draft utility relocations will be borne by the individual utility owners. The recommended navigation project is the LPP, not the NED plan. The recommended LPP is shallower and will be less costly than the NED plan which has an estimated first cost of \$1,147,837,000. The LPP qualifies as a Categorical Exemption to the NED plan because net benefits continue to increase as the non-Federal sponsor's budget constraints have been reached and no smaller plan maximizes net benefits.

The Sabine-Neches Navigation District is the non-Federal cost sharing sponsor and fully supports the LPP and is legally capable of fulfilling the requirements to be the non-Federal sponsor. Cost sharing is applied in accordance with the provisions of Section 101 of the Water Resources Development Act (WRDA) of 1986, as amended, as follows: 1) the costs for the deepening of the channel from 40 to 45 feet will be shared at the rate of 75 percent Federal and 25 percent by the non-Federal sponsor. Accordingly, the Federal and non-Federal shares of the estimated \$780,000,000 first cost in this zone are estimated to be \$585,000,000 and \$195,000,000, respectively, with the difference of \$1,280,000 being the Federal cost for cultural resources mitigation; 2) the costs for the deepening of the channel from 45 to 48 feet will be shared at the rate of 50 percent Federal and 50 percent by the non-Federal sponsor. Accordingly, the Federal and non-Federal shares of the estimated \$259,000,000 first cost in this zone are estimated to be approximately \$130,000,000 each. Total annual costs for operation, maintenance, repair, replacement, and rehabilitation (OMRR&R) are estimated to be \$32,900,000. In accordance with Section 101 of WRDA 1986, OMRR&R costs between 40 and 45 feet are allocated as 100 percent Federal and for depths greater than 45 feet costs are allocated as 50 percent Federal and 50 percent non-Federal. For the LPP, the annual OMRR&R costs are \$20,600,000 for up to the 45-foot depth of the project at 100 percent Federal expense and \$12,300,000 for project depths greater than 45 feet, at 50 percent Federal and 50 percent non-Federal expense or \$6,150,000 each.

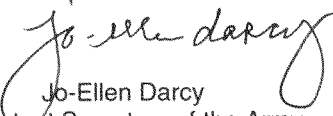

Based on October 2011 price levels, a discount rate of 4 percent, and a 50-year period of economic analysis, the average annual benefits for the recommended LPP are estimated at \$115,600,000 and average annual costs are estimated at \$89,700,000, including the annual cost of OMRR&R. The recommended plan has net benefits estimated at \$25,900,000 and a benefit-to-cost ratio of 1.3 to 1. In comparison, the NED plan has average annual benefits

estimated at \$123,400,000, average annual costs estimated at \$94,800,000, including OMRR&R, net benefits estimated at \$28,600,000 and a benefit-to-cost ratio of 1.3 to 1.

The recommended plan has been formulated to avoid, minimize and mitigate for potential environmental losses. One portion of the dredged material management plan would use the dredged material to build fish and wildlife habitat, and is also the least cost plan. An Independent External Peer Review (IEPR) was conducted before finalization of the feasibility report and the Corps satisfactorily addressed all critical issues raised by the IEPR panel.

The Office of Management and Budget (OMB) advises that there is no objection to the submission of the report to Congress. However, OMB also advises that should Congress decide to authorize this project for construction, to please be aware that the project will be required to compete for funds with other proposed investments considered in future budgets. I am providing a copy of this transmittal and OMB's letter dated January 26, 2012, to the House Committee on Appropriations' Subcommittee on Energy and Water Development, and the House Committee on Transportation and Infrastructure's Subcommittee on Water Resources and Environment. I am providing an identical letter to the President of the Senate.

Very truly yours,

Jo-Ellen Darcy
Assistant Secretary of the Army
(Civil Works)

RECORD OF DECISION

Sabine-Neches Waterway Channel Improvement Project Southeast Texas and Southwest Louisiana

The Final Feasibility Report (FR) and the Final Environmental Impact Statement (FEIS), dated March 2011, and the report of the Chief of Engineers, dated July 22, 2011, for the Sabine-Neches Waterway (SNWW) address navigation improvement opportunities along the Texas and Louisiana border. Based on these reports, the reviews of other Federal, State, and local agencies, input from the public, and the review by my staff, I find the plan recommended by the Chief of Engineers to be technically feasible, economically justified, environmentally acceptable, and in the public interest. Thus, I approve the SNWW Channel Improvement Project for construction.

The FR/FEIS documents the evaluation of both structural and non-structural alternatives to address the navigational improvement needs of the SNWW. The recommended plan is the Locally Preferred Plan (LPP) which consists of the following modifications to the existing SNWW:

- Deepening the SNWW from the Port of Beaumont Turning Basin through the Sabine Pass Jetty Channel from -40 to -48 feet and the offshore Outer Bar and Sabine Bank Channels from -42 to -50 feet;
- Extending the -50 foot deep offshore channel by 13.2 miles, increasing the total length of the channel from 64 to 77 miles;
- Decreasing the width of the Sabine Bank Channel from 800 to 700 feet;
- Tapering and marking the Sabine Bank Channel from 800 feet wide (Station 23+300) to 700 feet wide (Station 25+800);
- Deepening to -48 feet of Taylor Bayou channels and turning basins and associated various widenings of these same areas;
- Widening selected bends on the Sabine-Neches Canal and Neches River Channel;
- Constructing new turning and anchorage basins, and enlarging/deepening existing turning and anchorage basins on the Neches River Channel to -48 feet; and
- Constructing habitat features as part of the least cost disposal method for the SNWW Dredged Material Management Plan (DMMP):
 - The Neches River habitat features (Rose City East, Bessie Heights East, and Old River Cove) would restore approximately 2,853 acres of emergent marsh, improve 871 acres of open water habitat, and nourish 1,234 acres of existing marsh.
 - The Gulf Shore habitat feature would periodically nourish three miles of shoreline in Texas and three miles of shoreline in Louisiana.
- Compensatory mitigation consisting of:
 - Restoring 2,783 acres of emergent marsh, improving 957 acres of shallow water habitat, and stabilizing and nourishing 4,355 acres of existing marsh in the Willow and Black Bayou areas of Louisiana. These actions would provide 1,181 Average Annual Habitat Units (AAHUs) to compensate for a loss of 1,159 AAHUs.

- o Monitoring performance of habitat features and mitigation measures, with an adaptive management plan for corrective action, if needed.

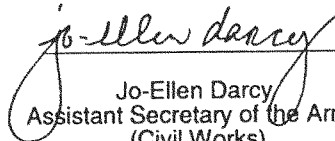

In addition to the no action plan, over 120 structural combinations of depths and widths and three non-structural alternatives for navigation improvements were evaluated as described in the FR/FEIS. Nonstructural alternatives considered were offshore oil terminals, a vessel traffic management system, and modification of pilot rules. The no action plan and six deepening alternatives (-45, -46, -47, -48, -49, and -50 feet) were advanced for final evaluation and are fully described and evaluated in the FR/FEIS, which is incorporated herein by reference. The -49 foot depth was identified as the national economic development plan. The recommended plan is the -48 foot plan, which is also the environmentally preferable alternative and the plan preferred by the local sponsor.

All practicable means to avoid or minimize adverse environmental effects have been incorporated into the recommended plan, and the compensatory mitigation plan would address all unavoidable impacts. Primary impacts would be a reduction in the biological productivity of intertidal marsh and the loss of marsh acreage in Louisiana due to increased salinities. All adverse impacts in Texas and some in Louisiana would be offset by the environmental benefits of the DMMP habitat features. The compensatory mitigation would address the remaining adverse impacts in Louisiana.

Technical and economic criteria used in the formulation of alternative plans were those specified in the Water Resource Council's Economic and Environmental Principles and Guidelines for Water and Related Land Resources Implementation Studies. All applicable laws, executive orders, regulations and guidelines were considered in the evaluation of alternatives and the selection of the recommended plan. The Louisiana Office of Coastal Management found the recommended plan to be conditionally consistent with Louisiana's Coastal Resource Program, per Section 307 of the Coastal Zone Management Act of 1972, as amended. The U.S. Army Corps of Engineers does not concur with the State of Louisiana's conditional consistency determination, and has determined that the recommended plan is fully consistent to the maximum extent practicable with the state's Coastal Resource Program. Water Quality Certifications under Section 401 of the Clean Water Act have been received from both the States of Louisiana and Texas. Based on review of these evaluations, I find that the public interest would best be served by implementing the recommended plan. This Record of Decision completes the National Environmental Policy Act process.

OMB

P.02

EXECUTIVE OFFICE OF THE PRESIDENT
OFFICE OF MANAGEMENT AND BUDGET
WASHINGTON, D.C. 20503

January 26, 2012

The Honorable Jo-Ellen Darcy
Assistant Secretary of the Army (Civil Works)
108 Army Pentagon
Washington, D.C. 20310-0108

Dear Ms. Darcy:

As required by Executive Order 12322, the Office of Management and Budget (OMB) has completed its review of the Army Corps of Engineers (Corps) feasibility study for the Sabine-Neches Waterway Channel Improvement Project, Southeast Texas and Southwest Louisiana.

In its economic analysis the Corps estimates that the project has a benefit-to-cost ratio of 1.3 at a discount rate of 4 1/8 percent. The report also notes that the estimated economic costs would exceed the benefits at a discount rate of 7 percent, which is the discount rate that the Administration uses to decide whether to include funds in the President's budget for project construction.

The Office of Management and Budget does not object to you submitting this report to Congress. However, when you do so, please advise the Congress that, should the Congress authorize this project for construction, the project would need to compete with other proposed investments for funding in future budgets.

Sincerely,

A handwritten signature in dark ink, appearing to read "Richard A. Mertens".

Richard A. Mertens
Deputy Associate Director
Energy, Science and Water Division

JUL 22 2011

CEMP-SWD (1105-2-10-a)

SUBJECT: Sabine-Neches Waterway Channel Improvement Project, Southeast Texas and Southwest Louisiana

THE SECRETARY OF THE ARMY

1. I submit for transmission to Congress my report on navigation improvements for the Sabine-Neches Waterway (SNWW) in Southeast Texas and Southwest Louisiana. It is accompanied by the report of the Galveston District Engineer and the Southwestern Division Engineer. These reports are in response to a Congressional resolution adopted on 5 June 1997 by the Senate Committee on Environment and Public Works. The committee requested a review of the reports on the SNWW and other pertinent reports to determine the feasibility of modifying the channels serving the ports of Beaumont, Port Arthur, and Orange, Texas in the interest of commercial navigation. Pre-construction engineering and design activities for this proposed project, if funded, would be continued under this authority. The existing SNWW 40-Foot Navigation Project was authorized by the River and Harbor Act of 1962 and construction of the 40-foot project was completed in 1968.

2. The report recommends a project that will contribute to the economic efficiency of commercial navigation. The SNWW is a system of navigation channels that have been superimposed upon the Sabine-Neches estuary in Texas and Louisiana. The study evaluated navigation and environmental problems and opportunities for the entire estuarine system, which is defined as the study area. The study area encompasses a 2,000-square-mile area, which contains the smaller project area that includes those areas that would be directly affected by construction of the project (i.e. the dredging footprint, existing and proposed placement areas, and mitigation areas). The study area includes the following water bodies and adjacent coastal wetlands: Sabine Lake and adjacent marshes in Texas and Louisiana, the Neches River channel up to the new Neches River Saltwater Barrier, the Sabine River channel to the Sabine Island Wildlife Management Area, the GIWW west to Star Bayou, the GIWW east to Gum Cove Ridge, the Gulf shoreline extending to 10 miles either side of Sabine Pass, and 35 miles offshore into the Gulf of Mexico.

3. The reporting officers recommend the Locally Preferred Plan (LPP) to modify the existing SNWW. The LPP consists of the following improvements:

a. Deepen the SNWW from 40 to 48 feet and the offshore channel from 42 to 50 feet in depth from offshore to the Port of Beaumont Turning Basin;

CEMP-SWD

SUBJECT: Sabine-Neches Waterway Channel Improvement Project, Southeast Texas and Southwest Louisiana

- b. Extend the 50-foot deep offshore channel by 13.2 miles to deep water in the Gulf, increasing the total length of channel from 64 to 77 miles;
- c. Taper and mark the Sabine Bank Channel from 800 feet wide to 700 feet wide;
- d. Deepen and widen Taylor Bayou channels and turning basins;
- e. Ease selected bends on the Sabine-Neches Canal and Neches River Channel;
- f. Construct new and enlarge/deepen existing turning and anchorage basins on the Neches River Channel.

Dredged material placement for this project would be provided in accordance with the Dredged Material Management Plan (DMMP) developed during the study. Deepening of the SNWW would generate approximately 98 million cubic yards of new work material and 650 million cubic yards of maintenance material over the 50-year period of economic evaluation. Material from the extension channel, Sabine Bank Channel, Sabine Pass Outer Bar Channel, and Sabine Pass Jetty Channel would be placed offshore, either in existing placement areas or newly designated sites. Material from the inland reaches would be placed in existing confined, upland placement sites adjacent to each reach. Expansion of some existing upland sites would also be required. Some dredged material from the inland reaches would be used beneficially to restore large degraded marsh areas on the Neches River and nourish the Gulf shoreline at Texas and Louisiana Points.

4. As discussed further in the report of the Galveston District Engineer and the Southwestern Division Engineer, the recommended plan includes preliminary conclusions that 41 pipelines located within the SNWW Channel must be relocated and are classified as utility relocations for which the non-Federal sponsor must perform or assure performance. In accordance with Section 101(a)(4) of the Water Resources Development Act (WRDA) of 1986, as amended, one-half of the cost of each such relocation will be borne by the owner of the facility being relocated and one-half of the cost of each such relocation will be borne by the non-Federal sponsor. All relocations, including utility relocations, are to be accomplished at no cost to the Federal Government. The recommended plan also includes preliminary conclusions that there are an additional 5 pipelines that must be removed but not replaced. The Government, in coordination with the non-Federal sponsor, will conduct further analysis and finalize its conclusions during the period of pre-construction engineering and design.

5. Environmental benefits of the Neches River beneficial use (BU) features would offset all environmental impacts in the state of Texas and on all Federal lands, by restoring 2,853 acres of emergent marsh, improving 871 acres of shallow water habitat, and nourishing 1,234 acres of existing marsh in Texas. After consideration of project impacts in Texas and on Federal lands in the project area, the Neches River BU features will provide a net increase of 316 Average

CEMP-SWD

SUBJECT: Sabine-Neches Waterway Channel Improvement Project, Southeast Texas and Southwest Louisiana

Annual Habitat Units (AAHUs). The Gulf Shore BU features would offset minor erosion impacts to Gulf shorelines in Texas and Louisiana by periodically nourishing three miles of shoreline in each state. Unavoidable environmental impacts on non-Federal lands in Louisiana would be fully compensated by restoring 2,783 acres of emergent marsh, improving 957 acres of shallow water habitat, and stabilizing and nourishing 4,355 acres of existing marsh. These actions will provide 1,181 AAHUs to compensate for a loss of 1,159 AAHUs in Louisiana. Post-construction monitoring and adaptive management plans for the BU features and mitigation areas will be required until such time that the following performance criteria are met, as determined by the Division Commander: (1) each mitigation site and the Neches River BU features have an aerial coverage of 60 to 80 percent native, typical, emergent marsh vegetation; and invasive noxious and/or exotic plant species comprise less than 4 percent of mitigation site marsh coverage; (2) Texas Point BU feature shows a decreased erosion rate averaging less than 44 ft/yr after two disposal events; and (3) Louisiana Point BU feature shows an accretion rate averaging more than 1.2 ft/yr after two disposal events.

6. The recommended navigation project is not the National Economic Development (NED) plan. The recommended SNWW improvement is shallower and will be less costly than the NED plan and is the LPP supported by the non-Federal sponsor. The Sabine-Neches Navigation District is the non-Federal cost sharing sponsor.

7. Project Cost Breakdown Based on October 2010 Prices.

a. Total First Cost of Constructing Project. The estimated total first cost of constructing the project is \$1,053,000,000 which includes the cost of constructing the general navigation features and the value of lands, easements, rights-of-way and relocations estimated as follows: \$894,500,000 for channel modification and dredged material placement; \$79,000,000 for environmental mitigation; \$52,800,000 for bridge fender modifications; \$1,270,000 Federal cost for cultural resources; \$774,000 for additional Corps administrative costs; \$3,690,000 for the value of lands, easements, rights-of-way, and relocations (except utility relocations) provided by the non-Federal sponsor; and \$21,300,000 for the one-half of the cost of utility relocations borne by the non-Federal sponsor pursuant to Section 101(a)(4) of WRDA 1986, as amended.

b. Estimated Federal and non-Federal Shares. The estimated Federal and non-Federal shares of the total first cost of constructing the project are \$707,000,000 and \$345,990,000, respectively, as apportioned in accordance with the cost sharing provisions of Section 101 of WRDA 1986, as amended, as follows:

(1) The costs for the deepening of the channel from 40 to 45 feet will be shared at the rate of 75 percent by the Government and 25 percent by the non-Federal sponsor. Accordingly, the Federal and non-Federal shares of the estimated \$772,000,000 cost in this zone will be approximately \$579,000,000 and \$193,000,000, respectively, with the difference of \$1,270,000 being the Federal cost for cultural resources.

CEMP-SWD

SUBJECT: Sabine-Neches Waterway Channel Improvement Project, Southeast Texas and Southwest Louisiana

(2) The costs for the deepening of the channel from 45 to 48 feet will be shared at the rate of 50 percent by the Government and 50 percent by the non-Federal sponsor. Accordingly, the Federal and non-Federal shares of the estimated \$256,000,000 cost in this zone will be approximately \$128,000,000 each.

(3) In addition to payment by the non-Federal sponsor of its share of costs as estimated and addressed in sub-paragraphs (1) and (2) above, the estimated non-Federal share of \$345,990,000 includes \$3,690,000 for the estimated value of lands, easements, rights-of-way, and relocations (except utility relocations) that it must provide pursuant to Section 101(a)(3) of WRDA 1986, as amended, and \$21,300,000 for one-half of the estimated costs of utility relocations borne by the non-Federal sponsor pursuant to Section 101(a)(4) of WRDA 1986, as amended.

c. Additional 10 Percent Payment. In addition to the non-Federal sponsor's estimated share of the total first cost of constructing the project in the amount of \$345,990,000, pursuant to Section 101(a)(2) of WRDA 1986, as amended, the non-Federal sponsor must pay an additional 10 percent of the cost of the general navigation features of the project in cash over a period not to exceed 30 years, with interest. The value of lands, easements, rights-of-way, and relocations provided by the non-Federal sponsor under Section 101(a)(3) of WRDA 1986, as amended, and the costs of utility relocations borne by the non-Federal sponsor under Section 101(a)(4) of WRDA 1986, as amended, will be credited toward this payment.

d. Operations and Maintenance Costs. The additional annual cost of operation and maintenance for this recommended plan is estimated at \$32,800,000. In accordance with Section 101(b) of WRDA 1986, the non-Federal sponsor will be responsible for an amount equal to 50 percent of the excess of the cost of the operation and maintenance of the project over the cost which would be incurred for operation and maintenance of the project if the project had a depth of 45 feet. The excess annual cost attributable to operation and maintenance for the depth in excess of 45 feet is \$12,300,000 with the non-Federal sponsor responsible for \$6,150,000.

e. Associated Costs. Estimated total project associated costs of \$43,500,000 include \$20,700,000 in non-Federal costs associated with dredging of berthing areas and development of other local service facilities; \$1,500,000 for navigation aids (a U.S. Coast Guard expense); and \$21,300,000 for the one-half of the cost of utility relocations to be borne by the facility owners in accordance with Section 101(a) (4) of WRDA of 1986, as amended.

f. Authorized Project Cost and Section 902 Calculation. The total estimated first cost of the project for the purposes of authorization and calculating the maximum cost of the project pursuant to Section 902 of WRDA 1986, as amended, should include the estimates for general navigation features (GNF) construction costs, the value of lands, easements, and rights-of-way,

CEMP-SWD

SUBJECT: Sabine-Neches Waterway Channel Improvement Project, Southeast Texas and Southwest Louisiana

the value of relocations provided under Section 101(a)(3) of WRDA 1986, as amended, and the one-half of the costs of utility relocations borne by the non-Federal sponsor for utility relocations under Section 101(a)(4) of WRDA 1986, as amended. Accordingly, as set forth in paragraph 7.a. above, based on October 2010 prices, the estimated total first cost of the project for these purposes is \$1,053,000,000 with a Federal share of \$707,000,000 and a non-Federal share of \$345,990,000.

8. Based on October 2010 price levels, a discount rate of 4 1/8 percent, and a 50-year period of economic analysis, the project average annual benefits and costs for the SNWW improvements are estimated at \$115,400,000 and \$90,600,000, respectively, with a resulting net benefit of \$24,800,000 and a benefit-to-cost ratio of 1.3 to 1.

9. In accordance with the Corps Engineering Circular on review of decision documents, all technical, engineering, and scientific work underwent an open, dynamic, and vigorous review process to ensure technical quality. This included an Agency Technical Review (ATR), an Independent External Peer Review (IEPR), and a Corps Headquarters policy and legal review. All concerns of the ATR have been addressed and incorporated into the final report. The IEPR was completed by Battelle Memorial Institute. A total of 18 comments were documented. The comments were related to plan formulation, vessel fleet analysis, benefits, dredging and sedimentation, risk and uncertainty, and impact of salinity changes. In response, sections in the main report and EIS were expanded to include additional information. The final IEPR Report was completed in June 2010 with all comments addressed sufficiently.

10. Washington level review indicates that the plan recommended by the reporting officers is technically sound, environmentally and socially acceptable, and on the basis of congressional directives, economically justified. The plan complies with all essential elements of the U.S. Water Resources Council's Economic and Environmental Principles and Guidelines for Water and Land Related Resources Implementation Studies, except for the measurement of the National Economic Benefits which was modified by Section 6009 of the ESAA of 2005. Further, the recommended plan complies with other administration and legislative policies and guidelines. The views of interested parties, including Federal, State and local agencies, have been considered.

11. I concur in the findings, conclusions, and recommendations of the reporting officers. Accordingly, I recommend that navigation improvements for the Sabine-Neches Waterway be authorized in accordance with the reporting officer's recommended plan at an estimated cost of \$1,053,000,000 with such modifications as in the discretion of the Chief of Engineers may be advisable. My recommendation is subject to cost sharing, financing, and other applicable requirements of Federal and State laws and policies, including Section 101 of WRDA 1986, as amended. This recommendation is subject to the non-Federal sponsor agreeing to comply with all applicable Federal laws and policies including that the non-Federal sponsor must agree with the following requirements prior to project implementation.

CEMP-SWD

SUBJECT: Sabine-Neches Waterway Channel Improvement Project, Southeast Texas and Southwest Louisiana

a. Provide 10 percent of the total cost of construction of the GNFs attributable to dredging to a depth not in excess of 20 feet; plus 25 percent of the total cost of construction of the GNFs attributable to dredging to a depth in excess of 20 feet but not in excess of 45 feet; plus 50 percent of the total cost of construction of the GNFs attributable to dredging to a depth in excess of 45 feet as further specified below:

(1) Provide 25 percent of design costs allocated by the Government to commercial navigation in accordance with the terms of a design agreement entered into prior to commencement of design work for the project;

(2) Provide, during the first year of construction, any additional funds necessary to pay the full non-Federal share of design costs allocated by the Government to commercial navigation;

(3) Provide, during construction, any additional funds necessary to make its total contribution for commercial navigation equal to 10 percent of the total cost of construction of the GNFs attributable to dredging to a depth not in excess of 20 feet; plus 25 percent of the total cost of construction of the GNFs attributable to dredging to a depth in excess of 20 feet but not in excess of 45 feet; plus 50 percent of the total cost of construction of the GNFs attributable to dredging to a depth in excess of 45 feet;

b. Provide all lands, easements, and rights-of-way (LER), including those necessary for the borrowing of material and the disposal of dredged or excavated material, and perform or assure the performance of all relocations, including utility relocations, all as determined by the Federal Government to be necessary for the construction or operation and maintenance of the GNFs;

c. Pay with interest, over a period not to exceed 30 years following completion of the period of construction of the GNFs, an additional amount equal to 10 percent of the total cost of construction of the GNFs less the amount of credit afforded by the Government for the value of the LER and relocations, including utility relocations, provided by the Sponsor for the GNFs. If the amount of credit afforded by the Government for the value of LER, and relocations, including utility relocations, provided by the Sponsor equals or exceeds 10 percent of the total cost of construction of the GNFs, the Sponsor shall not be required to make any contribution under this paragraph, nor shall it be entitled to any refund for the value of LER and relocations, including utility relocations, in excess of 10 percent of the total cost of construction of the GNFs;

d. Provide, operate, and maintain, at no cost to the Government, the local service facilities in a manner compatible with the project's authorized purposes and in accordance with applicable Federal and State laws and regulations and any specific directions prescribed by the Federal Government;

CEMP-SWD

SUBJECT: Sabine-Neches Waterway Channel Improvement Project, Southeast Texas and Southwest Louisiana

e. Provide 50 percent of the excess cost of operation and maintenance of the project over that cost which the Federal Government determines would be incurred for operation and maintenance if the project had a depth of 45 feet;

f. Give the Federal Government a right to enter, at reasonable times and in a reasonable manner, upon property that the Sponsor owns or controls for access to the project for the purpose of completing, inspecting, operating and maintaining the GNFs;

g. Hold and save the United States free from all damages arising from the construction or operation and maintenance of the project, any betterments, and the local service facilities, except for damages due to the fault or negligence of the United States or its contractors;

h. Keep, and maintain books, records, documents, and other evidence pertaining to costs and expenses incurred pursuant to the project, for a minimum of 3 years after completion of the accounting for which such books, records, documents, and other evidence are required, to the extent and in such detail as will properly reflect total cost of the project, and in accordance with the standards for financial management systems set forth in the Uniform Administrative Requirements for Grants and Cooperative Agreements to State and local governments at 32 CFR, Section 33.20;

i. Perform, or ensure performance of, any investigations for hazardous substances that are determined necessary to identify the existence and extent of any hazardous substances regulated under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), 42 USC 9601–9675, that may exist in, on, or under LER that the Federal Government determines to be necessary for the construction or operation and maintenance of the GNFs. However, for lands, easements, or rights-of-way that the Government determines to be subject to the navigation servitude, only the Government shall perform such investigations unless the Federal Government provides the Sponsor with prior specific written direction, in which case the Sponsor shall perform such investigations in accordance with such written direction;

j. Assume complete financial responsibility, as between the Federal Government and the Sponsor, for all necessary cleanup and response costs of any hazardous substances regulated under CERCLA that are located in, on, or under LER that the Federal Government determines to be necessary for the construction or operation and maintenance of the project;

k. To the maximum extent practicable, perform its obligations in a manner that will not cause liability to arise under CERCLA;

l. Comply with Section 221 of Public Law 91-611, Flood Control Act of 1970, as amended, (42 U.S.C. 1962d-5b) and Section 101(e) of the WRDA 86, Public Law 99-662, as amended,

CEMP-SWD

SUBJECT: Sabine-Neches Waterway Channel Improvement Project, Southeast Texas and Southwest Louisiana

(33 U.S.C. 2211(e)) which provide that the Secretary of the Army shall not commence the construction of any water resources project or separable element thereof, until the Sponsor has entered into a written agreement to furnish its required cooperation for the project or separable element;

m. Comply with the applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, as amended, (42 U.S.C. 4601-4655) and the Uniform Regulations contained in 49 CFR Part 24, in acquiring lands, easements, and rights-of-way necessary for construction, operation, and maintenance of the project including those necessary for relocations, the borrowing of material, or the disposal of dredged or excavated material; and inform all affected persons of applicable benefits, policies, and procedures in connection with said act;

n. Comply with all applicable Federal and State laws and regulations, including, but not limited to: Section 601 of the Civil Rights Act of 1964, Public Law 88-352 (42 U.S.C. 2000d), and Department of Defense Directive 5500.11 issued pursuant thereto; Army Regulation 600-7, entitled "Nondiscrimination on the Basis of Handicap in Programs and Activities Assisted or Conducted by the Department of the Army"; and all applicable Federal labor standards requirements including, but not limited to, 40 U.S.C. 3141-3148 and 40 U.S.C. 3701-3708 (revising, codifying and enacting without substantive change the provisions of the Davis-Bacon Act (formerly 40 U.S.C. 276a et seq.), the Contract Work Hours and Safety Standards Act (formerly 40 U.S.C. 327 et seq.), and the Copeland Anti-Kickback Act (formerly 40 U.S.C. 276c);

o. Provide the non-Federal share of that portion of the costs of mitigation and data recovery activities associated with historic preservation, that are in excess of 1 percent of the total amount authorized to be appropriated for the project; and

p. Not use funds from other Federal programs, including any non-Federal contribution required as a matching share therefor, to meet any of the Sponsor's obligations for the project unless the Federal agency providing the Federal portion of such funds verifies in writing that such funds are authorized to be used to carry out the project.

12. The recommendation contained herein reflects the information available at this time and current departmental policies governing formulation of individual projects. It does not reflect program and budgeting priorities inherent in the formulation of a national civil works construction program or the perspective of higher review levels within the executive branch. Consequently, the recommendation may be modified before it is transmitted to the Congress as a proposal for authorization and implementation funding. However, prior to transmittal to the

CEMP-SWD

SUBJECT: Sabine-Neches Waterway Channel Improvement Project, Southeast Texas and Southwest Louisiana

Congress, the States of Louisiana and Texas, the Sabine Neches Navigation District (the non-Federal sponsor), interested Federal agencies, and other parties will be advised of any significant modifications and will be afforded an opportunity to comment further.

MERDITH W.B. TEMPLE
Major General, USA
Acting Commander

United States Department of the Interior

OFFICE OF THE SECRETARY
WASHINGTON, D.C. 20240

APR 1 2011

ER 11/225

Mr. Theodore A. Brown, P.E.
Chief, Planning and Policy Division
Headquarters
U.S. Army Corps of Engineers
CECW-P (SA)
7701 Telegraph Road
Alexandria, VA 22315-3860

Dear Mr. Brown:

The U.S. Department of the Interior (Department) has reviewed the Chief's Report, Final Feasibility Report (FFR) and Final Environmental Impact Statement (FEIS) for the Sabine-Neches Waterway Channel Improvement Project, Southeast Texas, and Southwest Louisiana.

Our U.S. Fish and Wildlife Service (FWS) Lafayette, LA and Clear Lake, TX Field Offices were members of the Sabine Neches Interagency Coordination Team (ICT) and prepared the March 2010 Final Sabine-Neches Waterway Fish and Wildlife Coordination Act Report. We offer the following comments based upon further review and analysis by the FWS.

Sabine-Neches Waterway Chief's Report

The Chief's Report is consistent with the information found in the March 2011 Sabine-Neches FFR and FEIS. The project features, beneficial use and mitigation benefits are accurate as presented in those reports and the March 2010 Fish and Wildlife Coordination Act Report.

Section 7a (page 3) - Project Cost Breakdown based on October 2009 Prices. - The 2009 first cost is listed as \$1,029,000,000 in the Chief's Report, but listed as \$1,071,877,000 (\$1,100,935,000 in Budget year 2012 price levels), in the March 2011 Feasibility Report that reported at the October 2009 price level (page S-5). The current 2011 first and other costs should be considered for listing.

Sabine-Neches FEIS

Page 5-1, Mitigation Plan, Table 5.1-1 – The numbers in the table are incorrect. The table should be consistent with Table VIII-1 in the Feasibility Report (page VIII-2).

Page 5-5, Mitigation Plan, Table 5.1-2 – The numbers in the table are incorrect, but are correct in the paragraph preceding that table. The numbers should be consistent with Table VIII-2 (page VIII-5) of the Feasibility Report.

Page 5-22, Willow Bayou Mitigation, First Paragraph, Sentence 6 – 1,112 acres of existing marsh will be re-nourished, not the 1,966 acres stated.

Sabine-Neches FFR

Page VI-26, Table VI-14, Impact Analysis and Mitigation Need – The Texas net land loss should be – 247 acres and the project total land loss before DMMP BU should be -938 acres.

Page VIII-2, Table VIII-1, Net Project Impacts and Benefits – Recommended plan benefits for Texas intermediate and brackish marsh should be 305 and 363 AAHUs respectively.

Page VIII-13, Mitigation Plan, Table VIII-5 – The AAHUs for the LA 2-ADD B measure should be 214, not 21. Table VIII-5 should be consistent with EIS Table 5.5-1 (page 5-21 EIS).

Thank you for the opportunity to provide comments. If you have any questions regarding these comments, please contact Mr. Darryl Clark, FWS, Lafayette, LA, at 337-291-3111, or Darryl_Clark@fws.gov.

Sincerely,

RE: Sabine-Neches Waterway Channel Improvement Project, Southeast Texas and
Southwest Louisiana

Dear Mr. Brown:

Per your request, we have reviewed the soils information for the project location as it pertains to prime and unique farmlands. The only segment of the project which contains prime farmlands is from the Sabine River /GIWW east to Gum Cove Ridge. See enclosed farmland classification map and legend. The soils which are prime farmland are indicated in green and contain the following map units for Calcasieu parish; Cr--Crowley-Vidrine silt loams, Ju--Judice silty clay loam, Lt--Leton silt loam, Mn--Midland silty clay loam, Mr--Morey loam, Mt--Mowata-Vidrine silt loams, and Ju--Judice silty clay in Cameron parish. The prime farmland soils in this segment have a relative value of 95. The remaining segment from the Sabine Island Wildlife Management Area south and east along the Sabine River to the Gulf are in the marsh and the soils are not prime farmland. Please find the attached NRCS-CPA-106 Farmland Conversion Impact Rating for corridor type projects form with our agencies information completed.

Please contact me regarding all future requests at the address shown above.

Respectfully,

Baton Rouge, Louisiana 70804-4487

Dear Mr. DuCote:

Reference is made to your letter dated April 4, 2011, regarding the Sabine-Neches Waterway Channel Improvement Project (SNWW CIP) Final Environmental Impact Statement (FEIS). Your letter raises the same issues that were the subject of coordination between our agencies during the feasibility stage of the project. Each issue raised in your letter has been fully addressed by the Galveston District. Our position has not changed and the U.S. Army Corps of Engineers finds that each issue raised has been satisfactorily addressed.

Your letter will be made a part of the project record. We continue to offer to coordinate with Louisiana Department of Natural Resources every step of the way as this project moves forward. To that end, if you have questions or concerns please contact Mr. Tom Hughes, (202) 761-5534.

In Re: Sabine – Neches Waterway Channel Improvement Project FEIS and FFR

Dear Ms. Stokes:

We are in receipt of your notice to submit comments regarding the FEIS and FFR. We previously commented on our support for the Neches Waterway Channel Improvement Project. A copy of the Resolution previously passed by the Jefferson County Commissioners' Court supporting same is attached.

I would ask that you also extend our thanks and appreciation for all of the fine work the USCE has performed and we again wish to reiterate our support for this project. The proposed enhancement of this waterway will provide much needed improvements to help us maintain our national security and to enhance our competitiveness in the world market. It is our earnest desire that this project work proceed at the earliest date. With kindest regards, I remain,

Sincerely yours,

COMMISSIONERS' COURT

COUNTY OF JEFFERSON

§

OF JEFFERSON COUNTY, TEXAS

BE IT REMEMBERED at a meeting of Commissioners' Court of Jefferson County, Texas, held on the 8th day of February, 2010, on motion made by Everette D. Alfred, Commissioner of Precinct No. 4, and seconded by Mark L. Domingue, Commissioner of Precinct No. 2, the following Resolution was adopted:

Resolution Concerning the Sabine-Neches Waterway Channel Project

WHEREAS, the U.S. Army Corps of Engineers (USACE), in concert with Sabine-Neches Navigation District has proposed a project to widen and deepen the Sabine-Neches Waterway; and

WHEREAS, the USACE has prepared a study analyzing the feasibility and environmental impacts of proposed modifications to the portions of the Sabine-Neches Waterway that serves the ports of Beaumont and Port Arthur, Texas; and

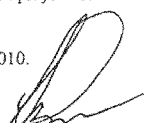

WHEREAS, the USACE study clearly demonstrates the necessity for these improvements to provide a safe waterway that will accommodate the current needs of our ports and industry; and

WHEREAS, the proposed improvements reasonably accommodate environmental concerns; and

WHEREAS, the proposed improvements are clearly cost effective and will provide a positive economic benefit and enable our ports to facilitate the handling of vital military cargo; and

NOW THEREFORE, be it resolved that the Commissioners' Court of Jefferson County, Texas Urges all elected officials and citizens to support this project and the adoption of the plan for these improvements as proposed.

SIGNED this 8th day of February, 2010.

SABINE-NECHES WATERWAY CHANNEL IMPROVEMENT PROJECT, SOUTHEAST TEXAS & SOUTHWEST LOUISIANA

ASA/OMB Briefing Slides
Galveston District
July 2011

US Army Corps of Engineers
BUILDING STRONG®

Study Authority

This feasibility study was conducted in response to the June 5, 1997 congressional resolution from the Committee on Environment and Public Works, House of Representatives.

The Resolution States:

“The Secretary of the Army shall review previous reports on the Sabine-Neches Waterway published as Senate Document No. 80, 83rd Congress, Second Session; House Document No. 553, 87th Congress, Second Session; and other pertinent reports to determine the feasibility of modifying the channels serving the ports of Beaumont, Port Arthur, and Orange, Texas in the interest of commercial navigation.”

Study Purpose

- Determine feasibility of providing navigational improvements to the SNWW
- Maintain coastal and estuarine natural resources

Non-Federal Sponsor

Vicinity/Project Location

Problems and Opportunities

- **Navigation and Commerce**
 - ▶ Existing SNWW designed for vessels with loaded drafts of 36 feet
 - ▶ Larger vessels use SNWW today
 - ▶ Tankers lighter before entering SNWW
 - ▶ Longest deep-draft waterway in Texas
 - ▶ Narrow channel reaches
 - ▶ Large amounts of dredged material

xxx

Problems and Opportunities

- **Environmental**
 - ▶ Very large study area with complex salinity and circulation patterns
 - ▶ Existing and potential increase in salinity intrusion and wetland impacts
 - ▶ Need for increase in beneficial use of dredged material
- **Economic**
 - ▶ Transportation efficiency

Alternatives Considered

- No Action Alternative
- Nonstructural Alternatives
 - ▶ Vessel Traffic Service
 - ▶ Relaxation of Pilots Rules
 - ▶ Alternative Mode of Commodity Transport

- Existing Louisiana Offshore Oil Port (LOOP)
- Inactive proposal for Bulk Oil Offshore Transfer System (BOOTS)

Alternatives Considered

- Structural Alternatives

- ▶ More than 120 combinations of different channel depths and widths
- ▶ Deepening to 43, 45, 46, 47, 48, 49, 50, 53, and 55-foot depths
- ▶ Widening from 500 to 700 feet for all depths

xxxiii

Recommended Plan Features

- Plan consists of:
 - ▶ Deepening to 48-foot channel
 - ▶ Dredged Material Management Plan
 - ▶ Beneficial Use Plan
 - ▶ Marsh Mitigation

XXXV

Navigation Features

- Deepening SNWW to Beaumont to 48 feet
- Extending the Entrance Channel 13.2 miles offshore
- Deepening and widening Taylor Bayou channels and turning basins
- Adding/enlarging turning and anchorage basins along Neches River Channel
- Bend easing on Sabine-Neches Canal and Neches River Channel

50-Yr Dredged Material Management Plan

- Offshore channels
 - ▶ 4 existing and 4 new Ocean Dredged Material Disposal Sites (ODMDS)
 - ▶ New sites to be established by EPA using ODMDS EIS prepared by USACE and approved by EPA
 - ▶ Material determined suitable for unconfined ocean disposal by EPA
 - ▶ All sites are dispersive and have unlimited future capacities
- Inshore channels
 - ▶ Regular levee lifts at 16 existing upland placement areas
 - ▶ 2 expanded upland placement areas (PA 18A and PA 24A)
 - ▶ 2 groups of least-cost Beneficial Use (BU) features
 - Neches River BU Feature
 - Gulf Shore BU Feature

Beneficial Use Map

Beneficial Use Features

Neches River BU Marsh Restoration	Acres
▶ Rose City East (modified)	345
▶ Bessie Heights East	1,869
▶ Old River Cove	<u>639</u>
Total	2,853

Gulf Shoreline BU Nourishment	
▶ Texas Point	3 mi
▶ Louisiana Point	3 mi
	

Mitigation Plan Measures

- BU features compensate for all Texas impacts
- Unavoidable impacts in Louisiana mitigated by restoration of 5 large degraded marshes
 - ▶ 2 in Willow Bayou watershed
 - ▶ 3 in Black Bayou watershed

Mitigation Measures

Emergent Marsh
Acres Restored

Willow Bayou

- LA 2-18B 251
- LA 2-ADD B 436

Black Bayou West

- LA 3-10R 792

Black Bayou East

- LA 3-15B 683
- LA 3-18B 621

Total Acres

2,783

LPP Selection

- NED Plan is 49-foot depth
- LPP is 48-foot depth (Less in scope than NED)
 - Net benefits continue to increase beyond the 48' LPP depth
 - Greater benefits than smaller scale plans
 - Non-Federal sponsor's financial constraints
 - Cost-Sharing is same as NED Plan

Economic Comparison LPP/NED

(Made at October 2009 price level; 4.375% interest rate; cost in \$1000's)

	48-foot	49-foot

BUILDING STRONG[®]

Environmental Compliance

- Draft Feasibility Report (DFR)/Draft EIS (DEIS) released in December 2009
- Received highest rating (lack of objections) from USEPA
- Section 7 Endangered Species Act consultation complete
- Section 401 Water Quality Certification received from TX and LA
- Historic Properties Programmatic Agreement executed with TX and LA SHPOs for Section 106 compliance

Environmental Compliance

- Coastal Zone Consistency
 - ▶ Concurrence from TX
 - ▶ Conditional Consistency proposed by LA but not accepted by USACE
 - Louisiana Department of Natural Resources notified in letter on April 26, 2010 and in letter on July 20, 2011.
 - ▶ Recommended Plan is fully consistent to the maximum extent practicable with the enforceable policies of both state programs; therefore we are proceeding with the project.
- Recommended Plan is compliant with all other applicable Federal and State regulations and pertinent Executive Orders

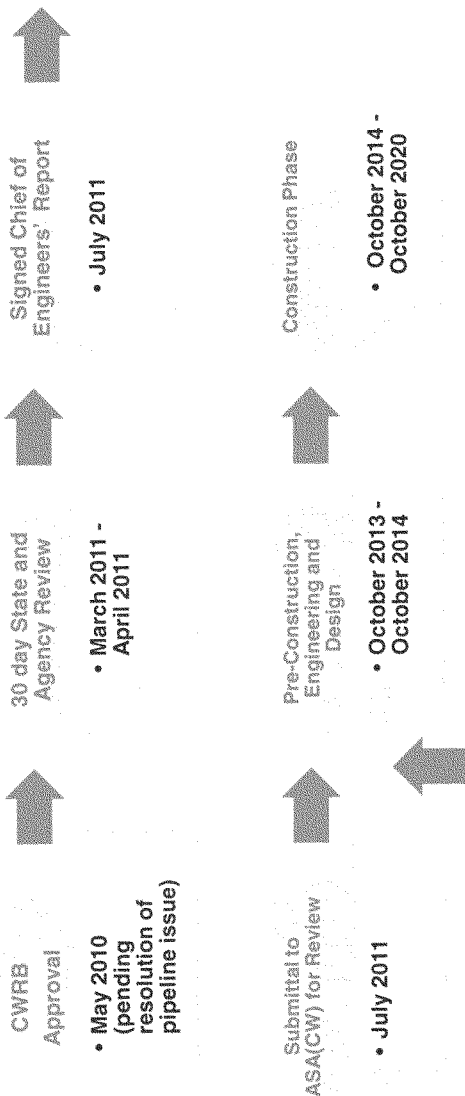

Public Involvement

- Three scoping meetings in TX and LA 2000 and 2003
- Series of workshops in TX and LA in 2002 to identify BU opportunities
- Public meetings (one TX, one LA) 2010 on draft reports
- All comments and responses incorporated into report
 - ▶ Nearly all resource agency comments were positive
 - ▶ Local Texas governments expressed support
 - ▶ Majority of 31 public comments related to pipeline removals

Future Timeline

Tentative WRDA 2012

CWRB

- 25 MAY 2010
- Approved subject to resolution of pipeline relocation issue and completion of IEPR back-check

L

CWRB Issue Resolution

- IEPR
 - Back-check was completed 16 June 2010
- Pipeline Relocation Issue
 - All pipelines within the channels that must be removed and replaced will be considered “utility relocations.”
 - In accordance with Sec 101(a) WRDA 1986, the non-Federal sponsor is responsible for performing all relocations, including utility relocations, with the cost of each utility relocation shared equally between the owner of the facility and the non-Federal Sponsor.

March 2011

Syllabus

INTRODUCTION

This Feasibility Report was prepared as a final response to the study authorization contained in the Senate Committee on Environment and Public Works Resolution adopted on June 5, 1997. The report presents the results of studies investigating the need to deepen and widen the Sabine-Neches Waterway (SNWW) along the border of Texas and Louisiana. In response to the study authority, the reconnaissance phase of the study was initiated in September 1998. The reconnaissance investigations resulted in a finding that there was an interest in continuing the study into the feasibility phase. The Jefferson County Navigation District, as the non-Federal sponsor (Sponsor), and the U.S. Army Corps of Engineers (USACE) initiated the feasibility phase of the study on March 6, 2000. The feasibility phase study cost was shared equally between the USACE and the Sponsor. In 2002, the Jefferson County Navigation District was renamed the Jefferson County Waterway and Navigation District (JCWND), and in 2007 the JCWND was renamed the Sabine Neches Navigation District (SNND); the latter designation is used throughout the remainder of this document.

This syllabus is intended to inform the reader of the major factors that were considered in the investigation and influenced the decisions documented in the Final Feasibility Report (FFR) and Final Environmental Impact Statement (FEIS).

MAJOR CONCLUSIONS AND FINDINGS

Planning Objectives

The water resources problems to be solved with this study are the navigational and safety issues that have developed on the SNWW because of the growth in the area. The investigation of the problems and opportunities in the study area led to the establishment of the following planning objectives:

- Improve the navigational efficiency along the SNWW waterway; and
- Maintain the ecological value of coastal and estuarine resources within the project area.

Alternatives

Over 120 alternatives at nine different depths (43, 45, 46, 47, 48, 49, 50, 53, and 55 feet) in combination with several different width scenarios were evaluated in order to address the planning objectives and the problems and opportunities identified by the Sponsor and the public.

Identification of the National Economic Development Plan

The Federal objective in water resources planning is to contribute to the National Economic Development (NED) consistent with protecting the nation's environment, pursuant to national environmental statutes, applicable executive orders, and other planning requirements. Through thorough investigation and analysis, deepening the SNWW to 49 feet (with selective widening) is the best plan to meet the NED objective. However, the Sponsor has indicated that the 48-foot plan is preferred because the cost of the NED and deeper plans would make the project unaffordable. The 48-foot plan is the Locally Preferred Plan (LPP) and is the Recommended Plan.

Recommended Plan and Locally Preferred Plan

The alternative plan selected for recommendation is the 48-foot plan that is also the LPP. The Recommended Plan calls for the following modifications to the existing SNWW:

- Deepening the SNWW from 40 to 48 feet and offshore channel from 42 to 50 feet in depth from offshore to the Port of Beaumont Turning Basin;
- Extending the 50-foot-deep offshore channel by 13.2 miles, increasing the total length of the channel from 64 to 77 miles;
- Decreasing the width of the Sabine Bank Channel from 800 to 700 feet;
- Tapering and marking the Sabine Bank Channel from 800 feet wide (Station 23+300) to 700 feet wide (Station 25+800 through the end of the channel);
- Deepening and widening of Taylor Bayou channels and turning basins;
- Easing selected bends on the Sabine-Neches Canal and Neches River Channel; and
- Constructing new and enlarging/deepening existing turning and anchorage basins on the Neches River Channel.

Features of the Recommended Plan

The Recommended Plan consists of navigation channel improvements (see following table), marsh mitigation, and a 50-year Dredged Material Management Plan (DMMP) with beneficial use (BU) areas, upland placement areas (PAs), and Ocean Dredged Material Disposal Sites (ODMDS).

Sixteen existing and two expanded upland PAs are proposed for use with the Recommended Plan. Offshore placement consists of four existing and four new ODMDSs. As part of the DMMP, dredged material would be used beneficially to restore degraded marsh areas on the Neches River and nourish the Gulf shoreline along the Texas and Louisiana coasts. Both BU features are least-cost plans and as such are considered General Navigation Features (GNF) of the Recommended Plan. The Neches River and Gulf Shore BU features would offset all direct and indirect marsh impacts in Texas by creating 2,853 acres of emergent marsh vegetation, improving 871 acres of open water habitat, and nourishing 1,234 acres of existing marsh in Texas. Benefits of the Neches River BU Feature more than offset the direct

impact of conversion of 86 acres of fresh marsh to a confined placement area (PA 24A) and the indirect impact of the increase in salinity over approximately 39,000 wetland acres in Texas. The Gulf Shore BU Feature offsets minor erosion impacts by periodically nourishing 6 miles of Texas and Louisiana Gulf shorelines.

Project Dimensions for Recommended Plan

Reach	Station	to	Station	Bottom Width (feet)	Project Depth (feet)
Extension Channel	165+443		95+734	700	50
Sabine Bank Channel	95+734		25+800	700	50
Sabine Bank Channel	25+800		23+300	700–800*	50
Sabine Pass Outer Bar Channel	23+300		0+000	800	50
Sabine Pass Jetty Channel	–214+88		0+00	800–500	48
Sabine Pass Channel	0+00		296+25	500	48
Port Arthur Canal	0+00		325+84	500	48
Sabine-Neches Canal	0+00		592+94	400	48
Neches River Channel	0+00		980+00	400	48
Taylor Bayou					
Entrance Channel	0+00		25+27	406–764	48
East Turning Basin	0+00		17+65	532–354	48
West Turning Basin	25+27		41+30	776	48
Connecting Channel	41+30		71+50	470–250	48
Taylor Bayou Turning Basin	71+50		106+25	1,000	48

*Sabine Pass Outer Bar Channel would be 800 feet wide to address maneuverability issues caused by current velocities around end of jetties

The primary impact of the Recommended Plan is an indirect impact associated with a small increase in salinity and an associated reduction in biological productivity over approximately 182,000 acres of intertidal marsh in Louisiana, and the potential loss of 691 acres of marsh in Louisiana as some marsh converts to open water. The mitigation plan compensates for all impacts by restoring 2,783 acres of emergent marsh, improving 957 acres of shallow-water habitat, and stabilizing and nourishing 4,355 acres of existing marsh in the Willow and Black Bayou areas, Louisiana.

Environmental Compliance

All project components were evaluated for environmental impacts, and an FEIS has been prepared in accordance with Council on Environmental Quality requirements. A mitigation plan was developed to compensate for all unavoidable environmental impacts. USACE has evaluated the proposed SNWW Channel Improvement Project (CIP) for consistency with the Texas and Louisiana coastal management programs, and concluded that the Recommended Plan is fully consistent to the maximum extent practicable with the enforceable policies of both state programs. The Texas Coastal Coordination Council has concurred with the USACE consistency determination. The Louisiana Department of Natural Resources, Office of Coastal Management (LDNR-OCM), found that the SNWW CIP is conditionally

consistent with their state program. Since conditional consistency as proposed by LDNR-OCM is not acceptable, LDNR-OCM has been notified that USACE will proceed with the project. Additional information on this matter is presented in FEIS Section 6.0. Clean Water Act §401 State Water Quality certification has been received from Texas and Louisiana for this action. Short-term increases in turbidity may be caused by the unconfined flow of dredged material during construction of BU features and mitigation measures. There would be temporary, minor impacts from ocean placement at the new ODMDSSs. Proposed channel improvements should increase safety, thus decreasing the probability of a spill. A Clean Water Act §404(b)(1) evaluation of the proposed action, provided in the FEIS (Appendix E), describes the effects of the proposed discharges. The Recommended Plan is the least environmentally damaging practicable alternative. Coordination with the U.S. Fish and Wildlife Service (USFWS) and the National Marine Fisheries Service (NMFS) regarding potential endangered species impacts has been concluded. Critical Habitat for wintering piping plovers is present in the Louisiana portion of the Gulf Shore BU Feature. The USFWS has concurred that the BU feature may affect, but is not likely to adversely affect, the species or its Critical Habitat because the Gulf Shore BU Feature would protect existing Critical Habitat. Hopper dredging of the Entrance Channel is likely to adversely affect but not jeopardize the continued existence of loggerhead, Kemp's ridley, and green sea turtles. In the Biological Opinion, the NMFS authorizes the incidental lethal take of four sea turtles and has identified reasonable and prudent measures to be adopted during construction. Based upon recent chemical analyses of water and sediment collected from within the channels, the potential for encountering hazardous material during dredging operations is considered minimal. Shoaled sediments and new work material that would be dredged from the SNWW during construction has been determined to be of sufficient quality to be used for beneficial uses. In compliance with requirements of the Clean Air Act and the State of Texas, the TCEQ has provided written concurrence that emissions from the Recommended Plan are conformant with the Texas State Implementation Plan for the Beaumont-Port Arthur area, and the USACE has prepared a Final General Conformity Determination. Potential impacts to historic properties will be addressed in accordance with the terms of the Historic Properties Programmatic Agreement with the SNND.

Benefits and Costs of the Recommended Plan

Project Benefits

The basic economic benefits from a navigation improvement project are the reduction in transportation costs for commodities and the increase in the value of output for goods and services. Specific transportation savings may result from the use of larger vessels, more-efficient use of large vessels, more-efficient use of existing vessels, reductions in transit time, and lower cargo handling and tug assistance costs. Based on the economic analyses performed during the study, total average annual project benefits are estimated at \$115,074,000. Transportation cost savings are expected to occur for the following:

- Crude Petroleum Imports
- Petroleum and Chemical Products
- Grain Exports

- Steel Slab and Iron Ore
- Limestone and Rock
- Liquefied Natural Gas (LNG) traffic (benefits stop at 43 feet)

Project Costs (October 2009 Price Levels)

The First Cost of all project components in current dollars totals \$1,071,877,000. Based on Budget Year 2012, the first cost would be \$1,100,935,000. The Fully Funded Cost for the project (e.g., First Costs and escalation in current dollars) totals \$1,161,372,000. The LPP investment cost of all components totals \$1,191,259,000 in current dollars, and includes \$119,382,000 in interest during construction (IDC). The total average annual LPP investment cost for the project is \$91,341,000. The LPP cost includes average annual incremental costs for operations and maintenance (O&M) (\$32,067,000) and deferred construction for fish and wildlife mitigation (\$215,000).

Benefit-Cost Ratio

Based on the annualized project benefits estimated at \$115,074,000 and annualized project costs estimated at \$91,341,000, the benefit-cost ratio for the Recommended Plan is 1.3.

Cost Sharing

General navigation features (GNF) costs for deepening from the existing authorized depth of 40 feet down to 45 feet are cost shared at 25 percent non-Federal and 75 percent Federal; costs for deepening below 45 feet (recommended authorized depth of 48 feet) are cost shared at 50 percent non-Federal and 50 percent Federal. Fish and wildlife mitigation to compensate for project impacts is considered a GNF and is cost shared in the same manner as other GNF costs. The Sponsor also must pay an additional 10 percent of the GNF costs in cash over a period not to exceed 30 years. This additional 10 percent cash contribution is offset by credit for Lands, Easements, and Rights of Way (LER) and relocations (including utility relocations) pursuant to Section 101(a)(2) of Water Resources Development Act of 1986, as amended. Owners of berth and dock facilities that would require modification are responsible for 100 percent of those associated costs. The U.S. Coast Guard (USCG) is responsible for 100 percent of the cost for new channel markers (aids to navigation).

PUBLIC COORDINATION

The USACE and SNND developed a public involvement plan as part of the study process to ensure responsiveness to the needs and concerns of stakeholders and to ensure public involvement through an open, interactive process. Extensive coordination with State and Federal resource agencies was conducted throughout the study process, primarily through an Interagency Coordination Team (ICT) and workgroup meetings. Over 30 workgroup meetings and 11 ICT meetings were held during the study process.

NON-FEDERAL SPONSOR SUPPORT

SNND fully supports the project and is willing to sponsor project construction in accordance with the items of local cooperation set forth in this report. The Sponsor has indicated financial capability to satisfy its obligations for the construction of the Recommended Plan. A self certification has been prepared by the Sponsor and provided to the USACE.

AREAS OF CONTROVERSY AND UNRESOLVED ISSUES

The USACE has evaluated the proposed SNWW CIP for consistency with the Louisiana coastal management program, and concluded that the Recommended Plan is fully consistent to the maximum extent practicable with the enforceable policies of the state's coastal management program. The Louisiana Department of Natural Resources, Office of Coastal Management, found that the SNWW CIP is conditionally consistent with their state program. Since conditional consistency as proposed by LDNR-OCM is not acceptable, LDNR-OCM has been notified that USACE will proceed with the project. See FEIS Section 6.0 for further details.

Coordination with the Louisiana Department of Wildlife and Fisheries (LDWF) has not been able to resolve issues related to the offset of project impacts to Federal lands using benefits from BU features in Texas, LDWF requirements that the Recommended Plan include additional BU features, and royalty, license, and further assessment requirements concerning areas in Sabine Lake that would be affected by the removal of fill material for use in marsh mitigation. The USACE has proposed that an assessment survey be completed, following the protocol established by the LDWF, during the Preconstruction Engineering and Design phase of the SNWW CIP.

In order for the four new ODMDSs to be approved for use, the Environmental Protection Agency (EPA) must publish a final rulemaking in the *Federal Register*. An FEIS for the proposed ODMDS and a Final Site Management and Monitoring Plan have been prepared and accepted by EPA for use in this rulemaking at a later date (FEIS, Appendix B).

Issues related to contaminated materials in PA 17 (a capped landfill and other waste disposal areas within the PA) must be resolved by the non-Federal sponsor before the PA can be used as part of the Recommended Plan. Alternative placement areas are available should this not be resolved in time for use.

Table of Contents

The Final Feasibility Report (FFR) and Final Environmental Impact Statement (FEIS) for the Sabine-Neches Waterway Channel Improvement Project are contained in four volumes. Volume 1 contains the FFR and FFR Appendices 1 through 4. Volume II contains the FEIS Main Report. Volume III contains FEIS Appendices A and B. Volume IV contains FEIS Appendices C through K.

I. STUDY INFORMATION

I.A OVERVIEW

This Feasibility Report was prepared to determine the feasibility of modifying the portion of the existing Sabine-Neches Waterway (SNWW) that serves the ports of Beaumont and Port Arthur, Texas. The Port of Orange was not interested in participating in the study; therefore, modifications to the Channel to Orange were not considered in this study. To allow for a more effective, safe, and efficient waterway, the study focused on eliminating the major problems contributing to the inefficiencies on the waterway. The study reviewed and analyzed alternatives to address the insufficient channel depth and width, as determined by fleet forecasts. The possibility of conducting two-way traffic in portions of the channel, and ways of maintaining a safe waterway for all commercial and public users were also investigated. Economic benefits and costs were identified for proposed channel modifications, and recommendations were made that would maximize project benefits.

I.B STUDY AUTHORITY

This Feasibility Report was conducted in response to the June 5, 1997, Senate resolution from the Committee on Environment and Public Works. The resolution states:

The Secretary of the Army shall review previous reports on the Sabine-Neches Waterway published as Senate Document No. 80, 83rd Congress, Second Session; House Document No. 553, 87th Congress, Second Session; and other pertinent reports to determine the feasibility of modifying the channels serving the ports of Beaumont, Port Arthur, and Orange, Texas, in the interest of commercial navigation.

I.C PURPOSE AND SCOPE

This report presents the findings of a feasibility investigation conducted to determine whether there is a Federal interest in providing channel improvements to the SNWW. This report analyzes the problems and opportunities, and expresses desired outcomes as planning objectives. Alternatives were then developed to address these objectives. These alternatives include a plan of no action and various combinations of structural and nonstructural measures. The economic and environmental impacts of the alternatives were then evaluated to identify the Recommended Plan. The report also presents details on U.S. Army Corps of Engineers (USACE) and Sponsor participation needed to implement the plan. The report concludes with a plan that is recommended for Congressional authorization (the Recommended Plan).

I.D PROJECT AREA DESCRIPTION

Physical Description of Study Area

The SNWW is an approximately 64-mile federally authorized and maintained waterway located in Jefferson and Orange counties in southeast Texas and Cameron Parish, Louisiana. The area surrounding

the waterway is generally referred to as the “Golden Triangle” and is delineated by the three major Texas seaports of Port Arthur, Beaumont, and Orange. Sabine Pass, Sabine Lake, and the Sabine River together form part of the boundary between the states of Texas and Louisiana (Figure I-1). Improvements to the 30-foot Sabine River Channel to Orange were not evaluated due to the expectation of continued low utilization of the existing project depth.

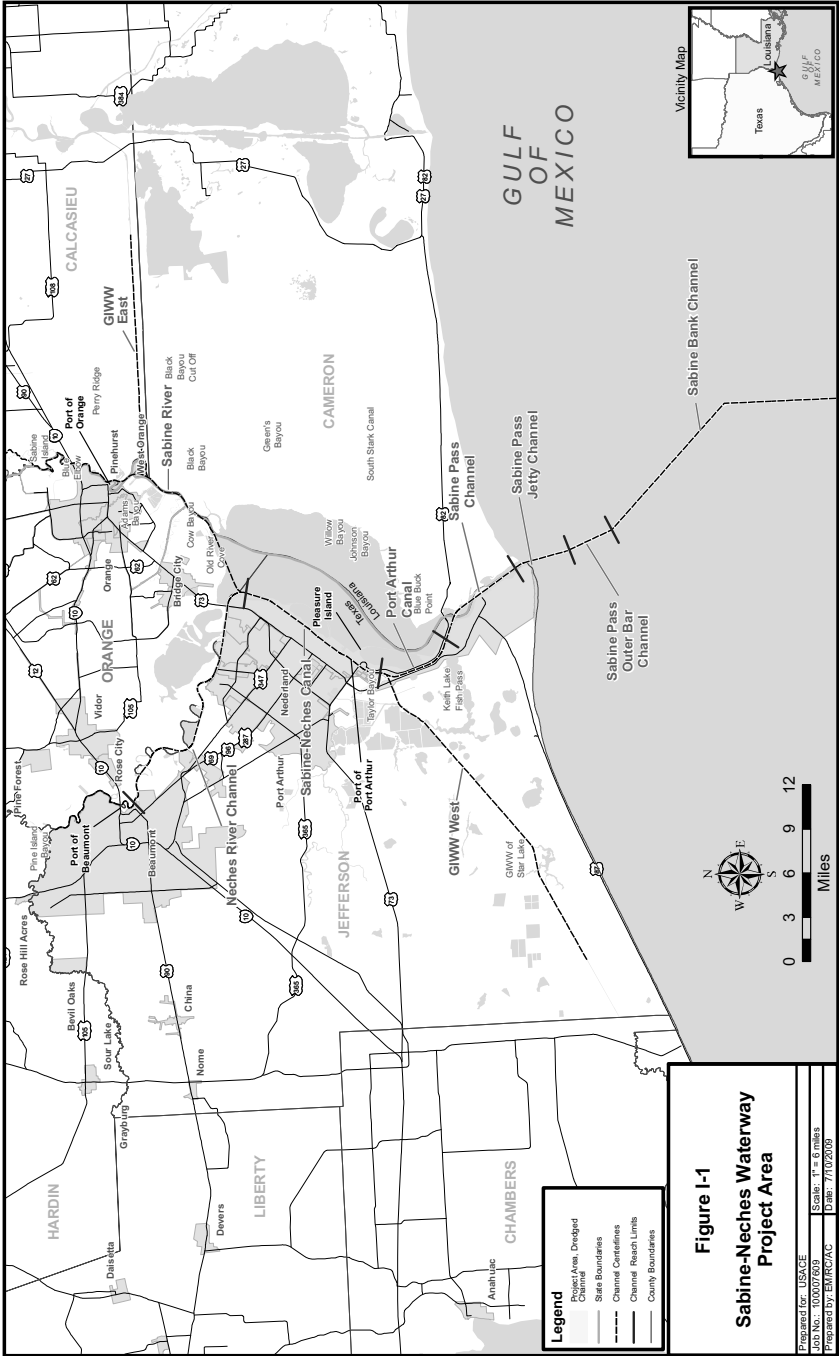

The SNWW is a system of navigation channels that has been superimposed upon the Sabine-Neches estuary in Texas and Louisiana. The estuary includes Sabine Lake, tidal portions of the Sabine and Neches rivers, and a number of tidally influenced bayous and shallow coastal lakes. The only connection with the Gulf of Mexico is a long narrow pass called Sabine Pass through which all tidal interchange occurs. Sabine Pass is stabilized by jetties that extend 4.1 miles into the Gulf of Mexico. The jetties were initially constructed for navigational purposes in the late 1880s.

The existing SNWW is made up of seven reaches as shown in Table I-1, beginning with the Sabine Bank Channel in the Gulf of Mexico and working upstream to the Neches River Channel.

Table I-1
Existing Sabine-Neches Waterway Channel Dimensions

Channel Reach	Authorized Depth (feet)	Bottom Width (feet)	Length (miles)
Sabine Bank Channel	42	800	14.7
Sabine Pass Outer Bar Channel	42	800	3.4
Sabine Pass Jetty Channel	40	800–500	4.0
Sabine Pass Channel	40	500–1,133	5.6
Port Arthur Canal (including Taylor Bayou)	40	500–1,788	6.2
Sabine-Neches Canal	40	400–1,060	11.3
Neches River Channel	40	400	18.6

The SNWW enters from deep water in the Gulf through the Entrance Channel, which is divided into the Sabine Bank Channel and the Sabine Pass Outer Bar Channel. It enters into Sabine Pass through the Sabine Pass Jetty and Sabine Pass channels, and follows the west bank of Sabine Lake to Port Arthur in the Port Arthur Canal. The project includes Taylor Bayou Channels and Turning Basins (TB) at the confluence of the Port Arthur Junction Area. On the west side of Sabine Lake, the Sabine-Neches Canal is separated from the lake by an artificially created band of land called Pleasure Island, that extends to the near the mouth of the Neches River. From the northwestern to the northeastern corner of Sabine Lake, another section of the Sabine-Neches Canal connects the mouths of two rivers, the Neches River (to Beaumont, Texas) and the Sabine River to the east (to Orange, Texas). The Neches River Channel ends at the Beaumont TB just south of the Interstate Highway (IH) 10 Bridge. The deep-draft portion of the authorized Federal project generally provides for a channel 42 feet deep and 800 feet wide at the entrance to the Gulf of Mexico, a channel 40 feet deep and 500 feet wide to Port Arthur, and a channel 40 feet deep

This page intentionally left blank.

and 400 feet wide to Beaumont by way of the Neches River. The existing SNWW channel has four open-water dredged material placement areas (PAs) and 24 upland confined PAs.

Shallow- and deep-draft vessels use the same channel where the routes of the Gulf Intracoastal Waterway (GIWW) and SNWW overlap. The GIWW coincides with parts of the SNWW, entering from the west just south of Port Arthur, extending through the confined channel reach at Pleasure Island, crossing the more exposed northern edge of Sabine Lake, and following the Sabine River Channel north to just south of the City of Orange, where the GIWW turns eastward and continues into Louisiana.

Study Area

The study area includes the area for which environmental effects of alternatives have been analyzed (Figure I-2) and encompasses a 2,000-square-mile area, which contains the smaller area referred to as the “project area.” The project area includes those areas that would be directly affected by construction of the Channel Improvement Project (CIP) (i.e., dredging footprint, existing and proposed PAs, and mitigation areas). The study area includes the following water bodies and adjacent coastal wetlands: Sabine Lake and adjacent marshes in Texas and Louisiana, the Neches River channel up to the new Neches River Saltwater Barrier, the Sabine River channel to the Sabine Island Wildlife Management Area (WMA), the GIWW west to Star Bayou, the GIWW east to Gum Cove Ridge, the Gulf shoreline extending to 10 miles either side of Sabine Pass, and 35 miles offshore into the Gulf of Mexico.

The major rivers within the study area are the Sabine and Neches rivers, and smaller streams such as Taylor, Adam, Cow, and Little Cypress bayous on the Texas side. Major bayous flowing into Sabine Lake from Louisiana include Lighthouse, Johnson’s, Madame Johnson’s, Willow, Three, and Black bayous. Approximately 80 percent of the freshwater drainage bypasses Sabine Lake, traveling down the SNWW and flowing into the Gulf of Mexico or southwestward into the GIWW (Gosselink et al., 1979).

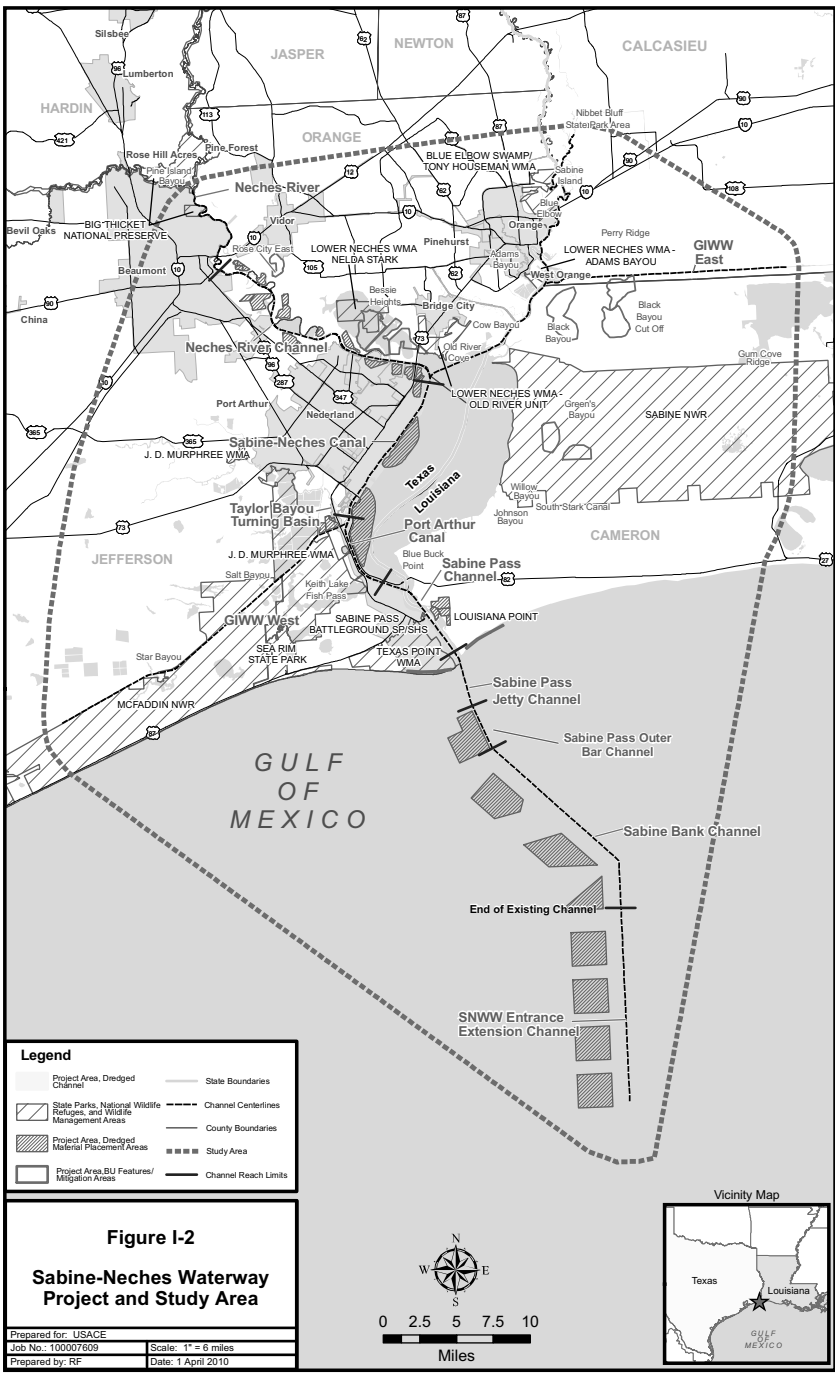

Environmental Setting

Terrain

The coastline of the study area differs from most of the Texas coast in that there are no barrier islands or lagoons. The study area is characterized by a diversity of features that are a result of the natural transition between marine and freshwater environments and anthropogenic impacts. The mainland portion of the study area can be classified as either coastal-marsh or coastal-prairie. These extensive wetland areas occur in areas less than 5 feet above mean sea level (msl) and extend inland 4 to 15 miles along the entire Gulf shoreline. Expansive marsh borders Sabine Lake on the southeast side, PAs on the west and north sides of the lake, and swamps and bottomland hardwoods extend up the lower reaches of the Neches and Sabine rivers.

This page intentionally left blank.

1-7

This page intentionally left blank.

The gentle sloping coastal prairie lies landward of the coastal marshes and is broken into smaller prairie segments by belts of pine and hardwood trees and by small meandering coastal streams with their associated wetlands. Farmers and ranchers are the principal users in the higher marsh areas. Cities and industries cover most of the higher elevations, and this is largely restricted to the west bank of Sabine Pass and Sabine Lake, and between the mouth of the Sabine and Neches rivers, northwest of Sabine Lake.

The timberlands in the flood-prone areas were commercially lumbered in the past but have experienced only small-scale lumbering in the twentieth century. Topography of the study area is essentially featureless, except for the surface expression of salt domes (Big Hill, Fannett, and Spindletop in Texas and Hackberry in Louisiana). These salt domes are still producing limited quantities of oil and gas.

Sabine Lake has a water surface area of approximately 100 square miles and a maximum natural depth of 9 feet. Due to the abundance of rainfall in this region, the rivers and bayous of this reach provide substantial freshwater inflow into Sabine Lake. However, instream flows to this reach have been altered from their natural hydrograph due to major impoundments in the middle and upper Sabine and Neches River basins. The combined discharges of the Sabine and Neches rivers into the northern part of Sabine Lake constitute the greatest freshwater input to any Texas bay. These rivers discharge large quantities of fine sediments into the lake but do not form deltas at their mouths because most of this material remains in suspension and is dispersed over the northern portion of the lake. During flood flows, these fine sediments are dispersed over the entire lake, and some are expelled through the Sabine Pass into the Gulf of Mexico.

The Gulf in the study area consists of open seas, coastline, and a dredged channel extending from the jettied Sabine Pass seaward. This area is heavily influenced by the Mississippi River Delta located to the east. When the Mississippi River occupied one of its western courses, sediment deposits were carried westward by littoral currents that built the Chenier Plain (Davis, 1996). The Chenier Plain is a unique salt marsh area on the extreme eastern edge of the Texas Gulf Coast, and is part of a much larger chenier plain in western Louisiana. A chenier plain is a series of sandy or shelly ridges or “cheniers,” many more than 10 feet high, separated by clayey or silty marsh deposits. The distance from chenier to chenier may be as much as 1 or 2 miles or more.

Chronic erosion is believed to be associated with the diversion of sand and other sediment resulting from channelization and regulation of the Mississippi and Atchafalaya rivers to the east, and the Sabine and Neches rivers in Texas. The Sabine Pass jetties intercept sediment moving westward in the littoral drift, creating a wide, muddy, tidal flat next to the east jetty (PBS&J, 2006; USACE, 2004). Texas Point is undergoing severe beach erosion, with shoreline retreat of up to 1,150 feet between 1974 and 2000 (King, 2007; Morang, 2006). This is the highest rate of shoreline loss on the upper Texas coast, and a Texas Coastal Erosion Planning and Response Program (CEPRA) has identified several parts of the study areas as “critical erosion areas” (Texas General Land Office [GLO], 2004, 2005). In Louisiana, persistent erosion along the shoreline between Ocean View and Holly Beach, on the order of –4.3 feet/year between 1985 and 1998, was recorded here prior to Hurricane Rita (USACE, 1971a, 2004). Nearer to Louisiana

Point, significant accretion over the last 100 years has slowed to +1.2 feet/year, and the behavior of this shoreline has become erratic, with some areas eroding and some accreting (USACE, 2004).

The study area lies in the easternmost portion of the humid climatological zone of Texas and usually has mild summers and winters. Winds generally are from the south or southeast except during the winter when polar fronts (northers) move across the state. Winds from these northers are important in lowering water levels and help to flush coastal estuaries. Temperatures are moderated by the influence of the winds from the Gulf, resulting in mild winters and relatively cool summer nights. The mean daily temperature ranges from the mid-50s (degrees Fahrenheit, °F) in December and January to the mid-80s in the summer months. The temperature rarely drops below 22°F or rises above 98°F. Relative humidity levels average approximately 78 percent throughout the year (USACE, 1975). Freezing temperatures occasionally occur during the winter but rarely last more than a few days. The historical temperature variance has been from a low of 11°F to a high of 107°F. The growing season, or the average period from the last frost in spring to the first frost in fall, is about 294 days.

The study area is also subject to dense fog throughout the year, but such conditions are most prevalent during the fall and winter months. Heavy fog occurring on an average of 29 days per year tends to hamper navigation by producing limited-visibility conditions along the waterway. Clear days during the year average about 117; partly cloudy days, 191; and cloudy days, 57.

Another effect of the nearness of the Gulf is abundant rainfall distributed throughout the year. The average annual rainfall is about 52 inches, with monthly precipitation averaging from 3.2 inches to about 6.6 inches. The area is occasionally subject to periods of intense rainfall, which may occur during any time of the year, but are usually associated with tropical storms, which typically occur from June through October.

Tides

The Sabine Lake area is a dynamic estuary only recently subject to the extensive mixing of fresh and seawater due to tidal currents. The tidal inlet at Sabine Pass differs from the other Texas tidal passes in that it is very long, 7 miles, and narrow, 0.4 mile, and is solidly entrenched in earlier geologic deposits. Normal tidal fluctuation in the area is relatively small with a diurnal range of 1 to 2 feet. A tidal range varying from 1.03 at Sabine Pass to 0.65 foot at Orange can be derived from the tide records. These ranges are typical of the Gulf coast area. Water levels in the SNWW are also influenced by the prevailing winds from the south-southeast direction. Water levels generally rise slightly with winds out of the south and south-southeast and fall, sometimes significantly, with winds from the north or northwest. Water surface elevations in the SNWW can vary greatly when driven by wind and storm activity. Water levels as low as -4 feet during strong northwesterly winds and as high as +16 to +18 feet during hurricane surges have been observed.

Salinity

The SNWW estuarine system exhibits very complicated circulation and salinity patterns (Brown and Stokes, 2009). Fresh water enters the system via several tributaries, including the Sabine River, the Neches River, and other smaller inflows. The Neches River flows directly into Sabine Lake and the Sabine-Neches Canal. The Sabine River flows into Sabine Lake, the Sabine National Wildlife Refuge (NWR) and into Calcasieu Lake via the GIWW. During times of low flow, the direction of this flow is reversed and higher salinity Calcasieu waters flow westward into the Sabine basin (Gammill et al., 2002).

The Sabine-Neches Canal connects the Neches River Channel to Sabine Pass, flowing through a narrow, confined channel between Pleasure Island on the east and the Port Arthur area on the west. This canal acts as a flow pathway for both fresh water from the inflowing rivers, and saline waters intruding via tidal propagation through Sabine Pass. This combination results in highly stratified conditions in the Sabine-Neches Canal. The stratification contributes to saltwater intrusion migrating up the Sabine-Neches Canal and into the northwest corner of Sabine Lake and the lower reaches of the Neches River. To combat these conditions, a saltwater barrier (Neches River Saltwater Barrier) has been installed approximately 30 stream-miles upstream of Rainbow Bridge to prevent saltwater intrusion north of the Port of Beaumont. As a result of the intrusion, the observed salinity in Sabine Lake is highest at both the southern end (where the lake connects to Sabine Pass) and at the northern end (where the lake connects to the Sabine-Neches Canal). The lowest salinities are observed in the central and eastern portions of Sabine Lake, which are farthest from the hydraulic connection to sources of saline water.

The estuary experiences wide swings in salinity levels that are associated with periods of drought and high freshwater inflows. During periods of drought, the flow in the Neches and Sabine rivers can drop drastically and a saltwater wedge can proceed farther upstream of both the Sabine and Neches rivers from the Gulf (Lower Neches Valley Authority, 2002; Sabine River Authority of Texas, 2002). The strength and intensity of winds and intensity of rainfall influences salinity levels in the SNWW, Sabine Lake, and Calcasieu Lake. The salinity of the waterway ranges from open Gulf levels of about 34 parts per thousand (ppt) to 0 ppt in the upper reaches of the Neches and Sabine River channels. Sabine Lake is predominantly a brackish-water estuary with salinity content ranging from 15 ppt at Sabine Pass to 0 ppt at times at the northern end of the lake. During periods of normal rainfall, high-salinity water transported by the SNWW is buffered by inflows from the Sabine and Neches rivers, direct rainfall, and coastal watershed inflows that have little effect on the salinity levels of Sabine Lake and the surrounding marshes. On the other hand, during periods of high flows, the SNWW and Sabine Lake can experience occasional freshwater conditions (very low salinity levels) due to large quantities of fresh water entering the system from the Sabine and Neches rivers (Coalition to Restore Coastal Louisiana, 2002).

Geology

The soils of Jefferson and Orange counties, Texas, and Cameron Parish, Louisiana, are separated mainly into Holocene and Pleistocene sediments with modern river sediments in the vicinity of the Neches and Sabine River channels. The coastal zone in the study area has evolved to its present condition by erosion,

deposition, compaction, and subsidence, all of which are still active. Gradual faulting continues as Pleistocene and older Gulf basin muds continue to compact.

The site geology is characterized by modern marine deposits overlaying recent Holocene deposits that in turn overlay Beaumont and Lissie formations of the Pleistocene Series (Bureau of Economic Geology, 1982). The modern deposits are generally normally consolidated clays, silts, and fine sands that were deposited through natural overwash and sedimentation processes or through man-made depositional processes. The recent deposits of the Holocene consist of silts, clays, silty sands, clayey sands, and clayey silts that exhibit the characteristics of normally to lightly overconsolidated materials. These deposits are generally encountered to depths of 30 to 40 feet. Beaumont Clay is the predominant Pleistocene formation whose eroded surface forms the upper limit of stiff to very stiff clay material. Lenses of fine-grained, poorly graded sand and silt, and a few calcareous nodules are sometimes encountered in this formation. The clay fraction is composed of montmorillonite, kaolinite, illite, and finely ground quartz, in that order of prevalence, and it has a high shrink-swell potential.

Sabine Lake was formed from the flooding of an ancient river valley (Kane, 1959) and was later separated from the Gulf by the advancement of the Gulf shoreline and deposition of the beach ridge/mudflat complex known as the Chenier Plain (Gould and McFarlan, 1959). Two types of landforms characterize the Chenier Plain: broad marshes containing organic clays and peat, and long narrow relict beach features called cheniers that appear as ridges parallel to the coast. The Chenier Plain fronts the entire study area on the Gulf shoreline in both Texas and Louisiana.

High-volume freshwater inflow into Sabine Lake helped maintain Sabine Pass as a narrow and relatively shallow link between the Gulf and Sabine Lake (Morton, 1996). Filling of Sabine Lake with sediment continues from the Sabine and Neches rivers and the Gulf of Mexico. Muddy river deposits slowly fill the upper parts of the estuarine systems and are responsible for much of the muddy sediment that fills the upper part of Sabine Lake. Only small amounts of bedload sand have been deposited in the estuarine system.

Fish and Wildlife Resources

The SNWW study area contains estuarine, wetland, and upland habitats that support a variety of fish and wildlife resources. Since the study area has tidal and freshwater habitats, wildlife species are diverse. The area also supports productive sport and commercial fishing. Due to the diversity of bird life, bird watching is an important recreational activity.

Aquatic Resources

The study area consists of both freshwater and marine ecosystems. The Sabine and Neches rivers and their tributaries were dominated by fresh water prior to the late 1800s, before Sabine Lake was opened for navigation. It is likely that Sabine Lake was almost entirely fresh, with the exception of saltwater intrusions that emanated from tidal surges during storms or during severe droughts. Thus, the biological communities have changed significantly within the past century due to the encroachment of saltwater.

The salinity extremes that often occur in Sabine Lake preclude lasting colonization of stenohaline species (tolerating narrow salinity ranges). Most of the tributaries adjacent to Sabine Lake are also influenced by salt water to some extent. A general overview of the freshwater and marine resources is described below. For a more detailed description of the biological resources within the study area, see Section 3.10 of the Final Environmental Impact Statement (FEIS).

Freshwater Resources

Freshwater fauna typically occur in the tributaries of Sabine Lake including the Sabine and Neches rivers, Taylor, Cow, Adams, and Little Cypress bayous in Texas, Black and Johnson's bayous in Louisiana, as well as numerous other smaller tributaries. In addition, freshwater fauna can be found in the multitude of wetlands, oxbows, ponds, canals, and ditches within the study area.

Due to the variety of habitats and the typical diversity of southeastern U.S. streams, the study area has an exceptionally diverse fish community consisting of approximately 56 freshwater and 25 estuarine species (Hubbs, 1982; USACE, 1975). The Louisiana Department of Wildlife and Fisheries (LDWF), Inland Fisheries Division, monitors fish populations and has identified a variety of freshwater species from this area including largemouth bass, spotted bass, bowfin, black crappie, spotted sucker, golden shiner, sunfish, blue catfish, channel catfish, spotted gar, shad, and striped mullet (LDWF, n.d.).

Both benthic macroinvertebrates and plankton support the food chain in the freshwater zones. Food chains in the larger, slow-moving rivers, bayous, and backwater areas are similar to that found in lakes. In these systems, the food chain consists primarily of plankton, including microscopic algae (phytoplankton) and crustaceans (zooplankton) that are suspended in the water column. Diverse communities of plankton occur throughout the freshwater system, but gradually shift to marine taxa as the water enters the estuarine areas.

Marine Resources

Sabine Lake, when compared to the other estuarine ecosystems in Texas, covers the smallest surface area (43,978 acres/68.6 square miles) and volume; however, it has the largest surrounding marshland (over 185,000 acres/288.6 square miles) (Armstrong et al., 1987; Blackburn et al., 2001). Phytoplankton (microscopic algae) are the major plant life in the open-bay, taking up carbon through photosynthesis and nutrients for growth. Phytoplankton are fed upon by zooplankton (small crustaceans), fish, and benthic consumers. Zooplankton are most abundant when the salinities are higher. Sabine Lake supports a diverse nekton population including fish, shrimp, and crabs such as Atlantic croaker, white and brown shrimp, Gulf menhaden, bay anchovy, red drum, blue crab, and southern flounder. These species are present all along the Texas and Louisiana coast and are unaffected by changes in salinity. Sabine Lake sustains an important blue crab fishery in Texas and Louisiana. Eastern oyster reefs are located in the southern part of Sabine Lake near Blue Buck Point, in Sabine Pass, and in Keith Lake. Oysters are not commercially harvested from Sabine Lake. The Texas Department of Health (TDH) has prohibited the harvesting of molluscan shellfish from this system since the late 1970s (Heideman, 2002; TDH, 2002). Louisiana has

designated Sabine Lake as a “Public Oyster Area.” However, no harvesting is currently allowed due to water quality issues.

Coastal Wetland Resources

The SNWW study area contains a high concentration of significant coastal wetlands. Approximately 109,175 acres (171 square miles) in Texas and 197,530 acres (309 square miles) in Louisiana were identified as coastal marsh, bottomland hardwood, or cypress-tupelo swamp habitats. Coastal marshes occur in four distinct types within the study area: (1) salt marsh, (2) brackish marsh, (3) intermediate marsh, and (4) freshwater marsh. A summary of the habitat acreage by state is provided in Table I-2, and a distribution of these habitats is presented on Figure I-3.

Table I-2
Summary of Habitat Acreages by State, 2004

	Fresh	Inter- mediate	Brackish	Saline	Total Marsh	Bottomland Hardwood	Swamp	Total Wetlands
Texas								
Acreage	13,580	30,336	24,047	4,898	72,861	5,458	10,157	88,476
Water	2,117	9,240	8,254	810	20,421	0	0	20,421
Totals	15,697	39,576	32,301	5,708	93,282	5,458	10,157	108,897
Louisiana								
Acreage	20,336	101,405	23,112	3,551	148,404	3,206	6,641	158,251
Water	4,772	31,872	2,049	586	39,279	0	0	39,279
Totals	25,108	133,277	25,161	4,137	187,683	3,206	6,641	197,530
Total								
Acreage	33,916	131,741	47,159	8,449	221,265	8,664	16,798	246,727
Water	6,889	41,112	10,303	1,396	59,700	0	0	59,700
Totals	40,805	172,853	57,462	9,845	280,965	8,664	16,798	306,427

Salt marsh is located along the Gulf shoreline of Texas and Louisiana, and the shores of Sabine Pass. Subjected to regular tidal inundation, low saline marsh is dominated with smooth cordgrass/oystergrass, seashore saltgrass, and marshbay cordgrass/wiregrass. The dominant species in high salt marsh subject to less frequent tidal inundation is glasswort. Relative to other marsh types, salt marsh typically supports fewer terrestrial vertebrates although some shorebird species are common.

Brackish marsh in the study area is located inland from salt marsh along the Gulf shoreline and in the Sabine Pass area, lines the Salt Bayou/Keith Lake watershed south of the GIWW, and fringes the northern and eastern shores of Sabine Lake in Louisiana. The dominant species in high brackish marshes are saltmarsh bulrush, seashore saltgrass, and marshbay cordgrass. Brackish marshes are extremely important as nurseries for fish and shellfish.

Intermediate marshes are subjected to periodic pulses of salt water. In the SNWW study area, these areas grade inland from brackish marshes in the Salt Bayou/Keith Lake watershed, are the major marsh type along the lower Neches River, and dominate the interior marshes of Louisiana east of Sabine Lake.

This page intentionally left blank.

Freshwater marshes are heterogeneous, with local species composition governed by frequency and duration of flooding, topography, substrate, hydrology, and salinity. A large expanse of fresh marsh is located between the GIWW and the Neches River, and in the riparian zone of the Neches and Sabine rivers. Freshwater marsh is also present in most interior portions of the Louisiana marshes east of Sabine Lake. Species range from maidencane, giant cutgrass, and bulltongue in lower areas to squarestem spikerush and marshbay cordgrass in the higher areas.

Sensitive Areas

Sensitive habitat generally refers to the vulnerability of a habitat. Areal extent, uniqueness, endemic quality, or vulnerability to ongoing pressures or imminent changes may make a habitat environmentally sensitive (e.g., large historical losses as with the coastal prairie or fresh marsh losses due to saltwater intrusions). They may be unique to the region and/or historical losses have made them less common or rare. They may be particularly vulnerable to changes in the landscape. The following areas were identified as part of the vegetative mapping in the study area and are described in more detail in the Wetland Value Assessment (WVA) Ecological Modeling Report found in Appendix C of the FEIS.

In Texas, beginning at the coast and working inland, the following protected and sensitive habitat areas are present within the study area:

- Approximately 10,000 acres of fresh to salt marsh in the chenier plain west of Sabine Pass, the majority of which consists of the Texas Point NWR.
- 55,700 acres of fresh to salt marsh located west of the Sabine River between Texas Point and the mouth of the Neches River. Much of this area is protected by the J.D. Murphree WMA.
- 22,100 acres of fresh, intermediate, and brackish marshes and 2,850 acres of cypress-tupelo swamp and bottomland hardwoods on the Neches River from the mouth of the river where it empties into Sabine Lake to the City of Beaumont.
- 6,490 acres of Neches River cypress-tupelo swamp and bottomland hardwoods and 1,970 acres of fresh marsh between the City of Beaumont and the new Neches River Saltwater Barrier near Pine Island Bayou.
- 4,771 acres of cypress-tupelo swamps, bottomland hardwood, and fresh and intermediate marshes on Cow and Adams bayous.
- 689 acres of cypress-tupelo swamp west of the Sabine River and south of IH 10.
- 2,737 acres of cypress-tupelo swamp and bottomland hardwoods in the Blue Elbow Swamp.
- 2,277 acres of cypress-tupelo swamp and bottomland hardwoods west of the Sabine River, across from the Sabine Island WMA in Louisiana.
- 6,000 acres of cypress-tupelo swamp, bottomland hardwood forest, and freshwater marshes, acquired by the Big Thicket National Preserve in 2009, located upstream of I 10.

In Louisiana, beginning at the coast and working inland, the following protected and sensitive habitat areas are present within the study area (Louisiana Coastal Wetlands Conservation and Restoration/

Wetlands Conservation and Restoration Authority [LCWCR/WCRA], 1999; U.S. Geological Survey [USGS]-National Wetlands Resource Center, 2004).

- 71,470 acres of saline, brackish, and intermediate marshes in the Louisiana Chenier Plain habitat at Louisiana Point, Blue Buck Point, and Johnson Bayou areas.
- 44,325 acres of brackish, intermediate, and fresh coastal marsh in the western half of the Sabine NWR.
- 46,511 acres of brackish, intermediate, and fresh marsh in the area north of Willow Bayou and south of the GIWW.
- 25,721 acres of fresh and intermediate marsh and bottomland hardwood habitat in the Perry Ridge mapping unit, north of the GIWW and east of the Sabine River.
- 650 acres of cypress-tupelo swamp and bottomland hardwoods in the Blue Elbow Swamp, east of the Sabine River and north IH 10.
- 7,039 acres of cypress-tupelo swamp and bottomland hardwoods in the Sabine Island WMA, north of the Blue Elbow Swamp and east of the Sabine River.

Upland Resources

The study area supports a diverse population of wildlife species. According to Blair (1950), at least 47 species of mammals, 29 species of snakes, 10 lizards, 2 land turtles, 17 anurans, and 18 urodeles occur or have occurred there. Common mammals include, but are not limited to rabbits, rats, raccoons, coyotes, mice, bats, armadillos, and bobcats. Virtually all of the original Gulf Coastal Prairies community has been converted to agricultural, industrial, or other uses although some remnants still exist (Smeins et al., 1991). Agricultural areas typically have sparse ground cover and provide poor-quality habitat for wildlife.

Threatened and Endangered Species

Plants

There are no Federal or State-listed threatened, endangered, or candidate plant species potentially occurring in Jefferson and Orange counties of Texas, and Cameron and Calcasieu parishes of Louisiana (National Diversity Database, 2005; U.S. Fish and Wildlife Service [USFWS], 2005).

Wildlife

There are a total of 32 State and/or federally listed threatened and endangered fish and wildlife species, and 9 listed by the U.S. National Marine Fisheries Service (NMFS) as Species of Concern—species that may potentially occur in Orange and Jefferson counties, Texas, and Cameron and Calcasieu parishes, Louisiana. Some of the species listed as threatened and endangered include brown pelican, piping plover, interior least tern, West Indian manatee, black bear, Louisiana black bear, red wolf, hawksbill sea turtle, green sea turtle, leatherback sea turtle, Kemp’s ridley sea turtle, and loggerhead sea turtle. The West Indian manatee, black bear, Louisiana black bear, and red wolf formerly occurred along the Gulf Coast; however, it is unlikely that they would occur within the study area. Designated Critical Habitat for the

wintering populations of the piping plover is present in the study area on the Louisiana shoreline beginning at the east jetty and extending eastward into Louisiana beyond our study area.

Essential Fish Habitat (EFH) is present in the study area for adult and juvenile brown and white shrimp, red drum, red snapper, lane snapper, greater amberjack, king mackerel, Spanish mackerel, cobia, Gulf stone crab, gag grouper, scamp, and adult gray snapper. The EFH is defined as “those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity.” When referring to estuaries, it is further defined as “all waters and substrates (mud, sand, shell, rock, and associated biological communities) within these estuarine boundaries, including the sub-tidal vegetation (seagrasses and algae) and adjacent tidal vegetation (marshes and mangroves)” (Gulf of Mexico Fisheries Management Council [GMFMC], 2004).

Significant Habitats

The State of Louisiana also includes a ranking of natural areas it deems as imperiled or threatened due to one or more reasons. Cameron and Calcasieu parishes contain 10 such habitats. These significant habitats include bottomland hardwood forest, brackish marsh, coastal prairie, coastal dune grassland, coastal live oak-hackberry forest, freshwater marsh, migratory bird staging/stopover sites, waterbird nesting colony, western longleaf pine savannah, and western saline longleaf pine savannah. While none of these habitats are federally designated as threatened or endangered, some of them are significant due to their losses during the past century and their value as habitat to fish and wildlife.

Cultural Resources

Within the study area, the National Register of Historic Places (NRHP) for Texas and Louisiana identifies 6 NRHP-listed architectural properties for Orange County, 19 such properties for Jefferson County, and 1 property, the Sabine Pass Lighthouse, for Cameron Parish. Two of the National Register-listed sites are located adjacent to the proposed CIP: the Rainbow Bridge and the Sabine Pass Lighthouse. The Rainbow Bridge is the cantilever bridge crossing the Neches River just upstream from Sabine Lake. The Sabine Pass Lighthouse is located on the Louisiana side of Sabine Pass. The lighthouse was constructed in 1856 and began operation in 1857.

These National Register-listed properties represent civic, commercial, religious, and private residential properties that span the history of the study area from the mid-nineteenth century to the mid-twentieth century. In addition to these National Register-listed properties, there are many other eligible, recorded, and reported resources in the study area. Numerous potentially eligible historic sites and shipwrecks are present in the project area. These include the Sabine Pass Battleground Park, Fort Griffin, and shipwrecks associated with important battles during the U.S. Civil War.

Socioeconomic Considerations

The following counties and parishes were used as units of socioeconomic analysis: Hardin, Jefferson, and Oranges counties in Texas, and Cameron and Calcasieu parishes in Louisiana. The following cities were

reviewed: Beaumont, Port Arthur, Port Neches, Nederland, Vidor, Orange, and Bridge City in Texas and Lake Charles in Louisiana. The study area for the socioeconomic review included areas within a 1-mile-wide corridor of the areas proposed for channel improvement.

Population

From 1980 to 1990, population growth within the study area was negative largely due to high unemployment rates and economic problems within the region due to the 1980s “oil bust,” when manufacturing and construction industries within the study area suffered heavy economic losses and layoffs. From 1990 to 2000, population growth was slow to moderate (at 7.4 percent), with the greatest population growth in Bridge City and Nederland. Population growth from 2000 to 2050 is expected to be slow to moderate if the socioeconomic trends continue as they have over the past 30 years. The greatest population growth rates in the study area during this period are anticipated in Hardin County (average decade growth rate of 8.1 percent) and in Calcasieu Parish (average decade growth rate of 5.9 percent).

Employment and Income

Total employment in the port, manufacturing, and industrial industries is currently 30,000 with approximately 13.7 percent of the population in port-related jobs (estimated one member per family works in industries directly or indirectly linked to waterborne commerce). Since the “oil bust” in the 1980s, the area relies to a greater extent on industries such as service, Federal, State, and local government, retail and wholesale trade, medical services, education, and Federal and state jails for its livelihood. It is estimated that 25 percent of the study area population depends on these port-related industries.

The highest median family income within the study area is found in Hardin County (at \$37,612), while the lowest median family income is found in Cameron Parish (at \$34,232). All median family income figures for the study area counties and parishes are higher than that of Louisiana (at \$32,566), and lower than that of Texas (at \$39,927).

Commercial and Recreation Fishing

Commercial fishing within the Sabine Lake system and adjacent offshore waters of the Gulf of Mexico is a relatively small contributor to the study area economy. Commercial harvesting of oysters in Sabine Lake and Sabine Pass is prohibited due to public health concerns. A small offshore commercial shrimp fleet operates out of Sabine Pass.

The largest total value for all finfish and shellfish landings was \$6.0 million in 1992. Recreational fishing continues to be a major outdoor recreational activity with a large variety of fresh- and saltwater species in the area. Sabine Lake, numerous wetlands, and the Gulf of Mexico are sources of recreational fishing within the study area. Between 1991 and 2001, saltwater fishing increased by 22 percent, and freshwater fishing decreased by 6 percent (USFWS, 2002a). Recreational fishing in this area is a year-round activity. Largemouth bass in the inland waters and speckled trout in the Gulf of Mexico and Sabine Lake are

favorites among anglers in the area. Although most species are commercially exploited, recreational anglers contributed more than \$400 million to the local economy in 2005, with more than half a million people involved in this leisure-time activity (USFWS, 2003).

Outdoor Recreation

One of the benefits of outdoor recreation is the economic impact it has on a state and its region. In Louisiana, over \$3.0 billion was spent on wildlife-associated activities (hunting and fishing yielded over \$1.4 billion and associated activities yielded over \$1.6 billion), and in Texas, almost \$9.4 billion was spent on wildlife-related activities (hunting and fishing yielded over \$5.3 billion and wildlife-associated activities yielded almost \$4.1 billion) (USFWS, 2002a).

The economic impact of hunting in Texas resulted in \$1.5 billion spent in Texas in 2001. Hunting within the Louisiana portion of the study area is equally popular, with numerous seasonally occupied camps located primarily on private land, and leased to club members who often travel from metropolitan areas of Louisiana and Texas to hunt waterfowl and deer, among other game.

Wildlife-watching, particularly birding, is an extremely popular activity within the study area and in the nearby vicinity. The Great Coastal Birding Trail is a series of trails that links bird-watching sites and many communities along the entire Gulf Coast. Several sections are located in or nearby the project study area, in both Texas and Louisiana. Participation in the Texas portion of the trail has grown over 33 percent overall between 2001 and 2002 (Scroggs, 2002; USFWS, 2002a).

I.E NON-FEDERAL SPONSOR AND COORDINATION

The USACE District Engineer, Galveston District is responsible for the overall management of the study and the report preparation. The Sabine Neches Navigation District (SNND) is the Sponsor for the study. The Sponsor was previously known as the Jefferson County Navigation District or the Jefferson County Waterway and Navigation District. In 2007, the SNND name was adopted. An Interagency Coordination Team (ICT) comprised of the Federal and State resource agency representatives from Louisiana and Texas was established to:

- 1) Involve agencies in scoping and identifying environmental issues and concerns;
- 2) Evaluate the significance of fish and wildlife resources and select resources to be evaluated;
- 3) Recommend and review necessary environmental studies;
- 4) Evaluate anticipated impacts; and
- 5) Recommend and evaluate potential mitigation measures.

The ICT agencies are listed in Table I-3. Representatives from other local and State agencies or governments also participated in the ICT in an advisory capacity: Jefferson and Orange counties, Texas; Cameron and Calcasieu parishes, Louisiana. While the ICT was a true decision-making body for issues related specifically to the environmental impact review, the USACE did retain final decision-making

authority on issues related to compliance with USACE policy. The USACE ICT members ensured that decisions were made within the framework of the USACE planning process and in compliance with Federal Law and policy, including guidance such as Planning in a Collaborative Environment (Engineering Circular [EC] 1105-2-409) and the Environmental Principles (Engineering Regulations [ER] 200-1-5). Important decisions related to identifying and studying potential ecological impacts and identifying alternatives for compensatory mitigation measures were made by consensus within the ICT. The ICT meetings were open to the public, and public comments were taken either before or after some of the meetings. Technical work addressing specific environmental concerns or planning objectives was performed by several smaller workgroups (whose members were taken from the ICT). Each of the workgroups and their purpose are identified below:

- **Restoration and Beneficial Uses Workgroup** was created to develop ideas for ecosystem restoration and the Beneficial Use (BU) of dredged material in the study area.
- **Hydrodynamic and Salinity Modeling Workgroup (MW)** provided data to assist the hydrodynamic salinity modeling (HS model) and verification process, and reviewed modeling results as part of the impacts evaluation.
- **Contaminants Workgroup** evaluated water and sediment quality associated with the proposed CIP, including characterization of existing conditions in the project area and the results of physical and chemical analyses conducted.
- **Ocean Dredged Material Disposal Sites (ODMDSs) Workgroup** was created to provide advice in the preparation of the Site Designation FEIS for the proposed ODMDSs.
- **Habitat Evaluation Workgroup** reviewed and classified existing habitat, performed field evaluations to document existing conditions, and developed procedures for the prediction of without- and with-project conditions.

U.S. Natural Resource Conservation Service	Texas Water Development Board
National Marine Fisheries Service	Texas Commission on Environmental Quality
Louisiana Department of Natural Resources	Texas Department of Transportation
Louisiana Department of Environmental Quality	

I.F PRIOR STUDIES, REPORTS, AND EXISTING WATER PROJECTS

Federal involvement in navigation improvements along the SNWW began with the River and Harbor Act (RHA) of 1885. This authorization provided for improvements to the mouth of the Sabine River. On March 3, 1905, the RHA authorized the first major improvement to the waterway, the construction of a

channel 9 feet deep and 100 feet wide through Sabine Lake from the mouth of the Sabine and Neches rivers to the mouth of Taylor Bayou. Major channel improvements continued to occur along the SNWW. Table I-4 shows the congressional authorizations and the authorized channel improvements.

Table I-4
Congressional Authorizations for Sabine-Neches Waterway Channel Improvements

RHA 1885	Improvements to mouth of Sabine River.
RHA 1905	Construction of a channel 9 feet deep and 100 feet wide through Sabine Lake from the mouth of Sabine and Neches rivers to the mouth of Taylor Bayou.
RHA 1912	Construction of a channel 25 feet deep, repair of jetties, enlarge Port Arthur Canal to a depth of 26 feet and a width of 150 feet, and dredge Port Arthur Turning Basin 26 feet deep, 600 feet wide, and 1,700 feet long.
RHA 1927	Enlargement of Sabine Pass and jetty channels to 300-foot width, Port Arthur Canal to a width of 200 feet, and the Sabine-Neches Canal up to the mouth of the Neches River to a width of 150 feet, provide two passing places in the Sabine-Neches Canal.
RHA 1935	Enlargement of the project to depths of 35 feet on the outer bar, 35 to 32 in jetty channel, and 32 feet up to and including turning basins at Port Arthur and Beaumont. Widen to widths of 450 feet on the outer bar, 450 feet to 300 feet through the jetties, 250 feet up to Port Arthur, and 200 feet up to the mouth of the Neches River.
RHA 1946	Deepen Sabine Pass outer bar channel to 37 feet, Sabine Pass jetty channel to 36 feet at the inner end, deepen to 36 feet Sabine Pass Channel, Port Arthur Canal, Port Arthur East and West Turning Basins, and widen to 400 feet the Sabine-Neches Canal from Port Arthur Canal to the mouth of the Neches River, except through Port Arthur Bridge; deepen Neches River channel from mouth to Beaumont Turning Basin to 36 feet, widening to 350 feet from Smith's Bluff to Beaumont Turning Basin, widen Sabine-Neches Canal between Neches and Sabine rivers to 150 feet.
RHA 1962	Deepen Outer Bar Channel to 42 and 40 feet for all inland channels to Port Arthur and Beaumont; width of 500 feet in Port Arthur Canal and 400 feet in Neches River Channel to Beaumont with three turning points in Neches River; a channel, 12 by 125 feet, extending in Sabine River to Echo; Deauthorization of uncompleted portion of channel between Port Arthur West Turning Basin and Taylor Bayou Turning Basin and enlargement of entrance channel to Port Arthur Turning Basins.

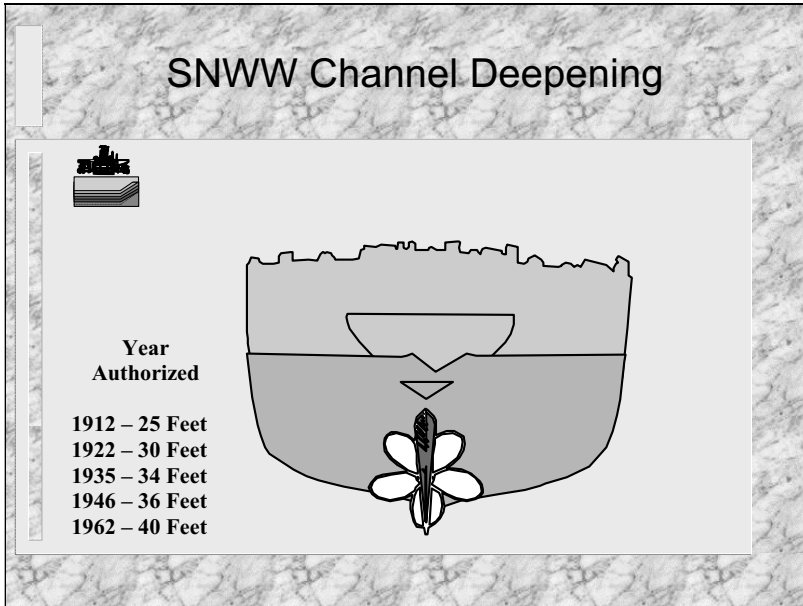

Major deepening efforts on the SNWW were authorized in 1912 resulting in a channel depth of 25 feet. Under the RHA of 1962, the waterway was authorized to be deepened to its current depth of 40 feet (Figure I-4).

On December 11, 1969, the Committee on Public Works House of Representatives adopted a resolution authorizing a review of the SNWW project. The resolution requested review of the report of the Chief of Engineers on the SNWW, published as House Document No. 553, 87th Congress, 2nd Session, and prior reports, with a view to determining whether the existing project should be modified in any way at this time, with particular reference to providing increased depths in the channel and basins.

As a result, a feasibility study was initiated and a Draft Feasibility Report was completed in April 1982. The report determined that it was feasible and advisable to deepen and widen the SNWW. The Recommended Plan recommended a channel depth of 52 feet at the Gulf of Mexico entrance channel and

a channel 50 feet deep for the Sabine Pass Channel, Port Arthur Canal, Sabine-Neches Canal, and the lower 12 miles of the Neches River Channel.

Figure I-4. History of Channel Deepening of Sabine-Neches Waterway

The plan also included widening of the Sabine-Neches Canal, located adjacent to Port Arthur, from 400 feet wide to 500 feet in width to reduce traffic congestion and delays in this reach of the waterway, which also serves as part of the GIWW. The Recommended Plan was not implemented because the Sponsor withdrew their support for the project.

I.G STUDY AND REPORT PROCESS

In September 1998, the USACE completed a Reconnaissance Report for the SNWW. The reconnaissance concluded that deepening and widening of the SNWW offers sufficient opportunity for navigation improvements with potential benefits outweighing the anticipated project costs. Without the increase of channel depths and widths to accommodate the anticipated increase in commodity transportation, more vessels would need to make lighter-drafting trips, increasing vessel delays and decreasing the efficiency of movement of bulk commodities along the waterway.

The USACE planning process involves a six-step, iterative process. This process provided for systematic preparation and evaluation of alternative plans to address problems and opportunities for the SNWW. The feasibility study process involved all of the six functional planning steps:

- 1) Specification of water and related land resources future without-project (FWOP) problems and opportunities;
- 2) Inventory, forecast, and analysis of water and related land resources conditions within the study area;
- 3) Formulation of alternative plans;
- 4) Evaluation of the effects of the alternative plans;
- 5) Comparison of the alternative plans; and
- 6) Selection of the Recommended Plan.

The Reconnaissance Report emphasized problem identification and formulation of alternatives. The emphasis of this Feasibility Report is on the evaluation of alternatives, assessment of impacts, and selection of a Recommended Plan. The goal of a feasibility study is to identify the plan that contributes to the National Economic Development (NED) consistent with protecting the Nation's environment.

II. PROBLEMS AND OPPORTUNITIES

II.A OVERVIEW

This chapter covers the first step of the planning process and identifies the problems with the existing SNWW and potential opportunities available if the existing SNWW channel is deepened and widened. The SNWW continues to play a significant role in the growth and economic development of the Golden Triangle area of Port Arthur, Beaumont, and Orange, Texas. As growth and economic development of the study area continues, the increasing use of the SNWW intensifies the need for more-efficient movement of commodities, particularly crude petroleum, by vessels traveling the waterway.

The amount of the vessel traffic along the waterway also increases concerns for the safety of the users and the local communities and businesses all along the waterway. With the current channel dimensions, the tonnage is not being moved as efficiently due to the size restrictions of the larger tankers utilizing the channel. These tankers are either limited by the current channel depth of 40 feet or by the physical and safety limitations of the channel.

The water resources problems to be solved with this project are the navigational and safety issues that have developed on the SNWW because of the growth in the area. Existing water resource problems and needs in the study area were identified through coordination with Federal, State, and local agencies; area residents; waterway users; and the USACE and SNND. Numerous concerns were raised during the public scoping meetings, letters received in response to those meetings, and a series of workshops with local public agencies and private organizations. The major issues and concerns identified through this process are discussed below. Summaries of the scoping meetings and copies of public comment letters are provided in Appendix A of the FEIS.

II.B NAVIGATION AND COMMERCE

General

The SNWW serves the ports of Port Arthur, Beaumont, and Orange. Channel improvements are needed to support the SNWW's critically important role in the Nation's economy. In 2007, the SNWW ranked first in the nation in crude oil imports, importing 56.2 million tons (Institute of Water Resources [IWR], 2007). In 2006, the SNWW (ports of Beaumont, Port Arthur and Orange) was ranked 4th in the nation for domestic and total tonnage with Beaumont (Figure II-1) ranked 5th and Port of Port Arthur (Figure II-2) ranked 28th in the nation (IWR, 2007).

The Port of Beaumont's public docks are located on the Neches River Channel, as well as several crude petroleum and product terminals. Port Arthur's general cargo facilities are located on the Sabine-Neches Canal, and its crude petroleum and product terminals are in the Taylor Bayou Basins. The Taylor Bayou Basins are located immediately south of Port Arthur at the junction of the Sabine-Neches Canal with the GIWW. In addition to its deep-draft traffic, the Sabine-Neches Canal serves as a through channel for

Figure II.1. Port of Beaumont

Figure II.2. Maritime and Petrochemical Use of Sabine-Neches Waterway
near Port Arthur, Texas

shallow-draft barge traffic on the GIWW. The locations of the facilities along the SNWW are identified on Figure II-3.

Commerce

Sixty percent of the SNWW tonnage total is deep-draft movements, and the remaining 40 percent is shallow-draft GIWW traffic. Crude petroleum imports and petrochemical product imports and exports comprised approximately 95 percent of Beaumont's and 85 percent of Port Arthur's oceangoing tonnage. Other significant commodities and breakbulk cargoes that are handled by the SNWW ports include petroleum coke, ammonia, sulphuric acid, metallic salts, liquid sulphur, grain, manufactured iron and steel products, limestone, sand, and gravel. Twenty percent of 2005–2007 U.S. metallic salts were exported from Port Arthur.

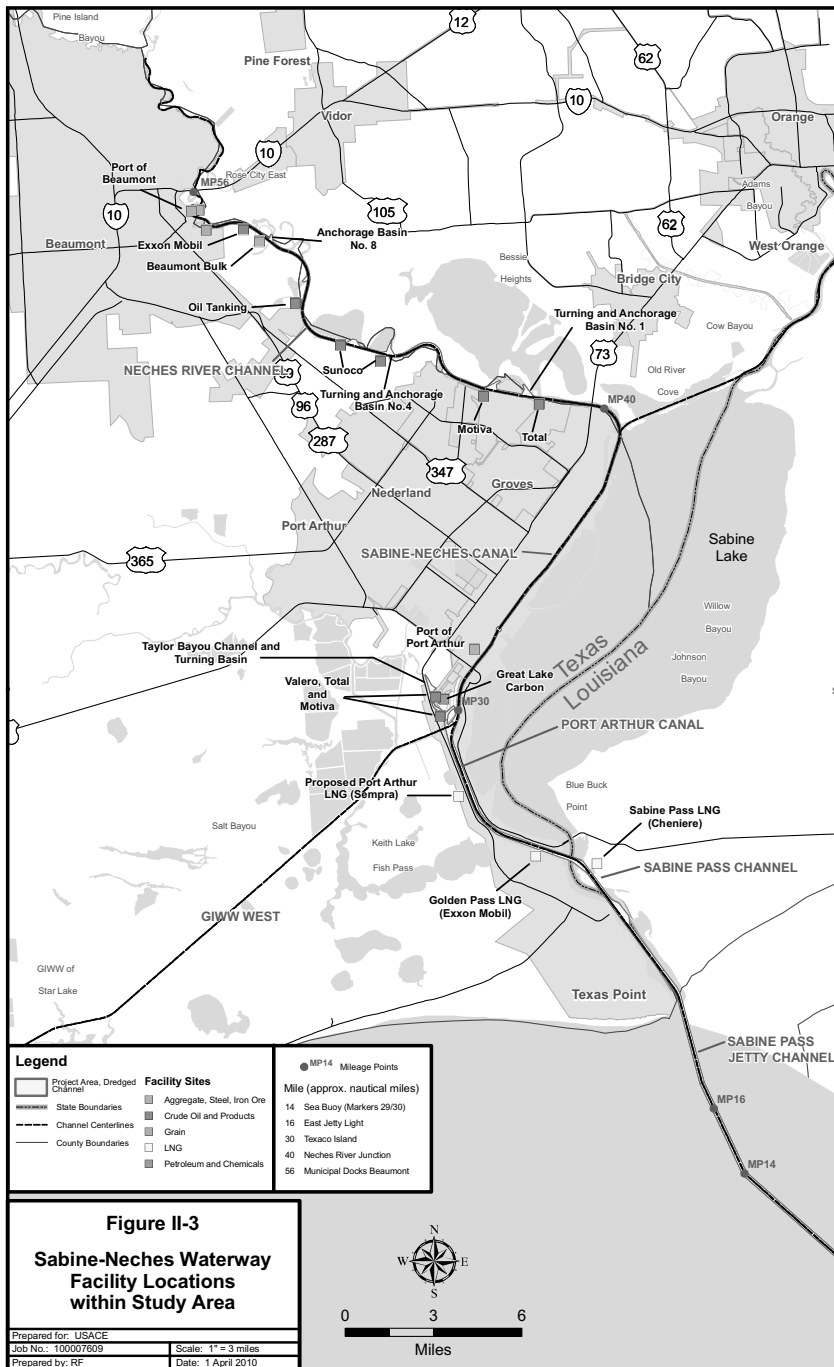

Domestic refineries on the Gulf Coast, the East Coast, and in the Midwest rely on the SNWW for 12–16 percent of waterborne crude oil deliveries (Martin Associates, 2006). The SNWW's four local refineries represent 6 percent of the U.S. total. SNWW refining capacity levels for 2007 are presently 9.4 percent higher than in 2004, and 29 percent higher than in 1994. In 2007, Motiva announced plans for a major refinery expansion in Port Arthur that would make it the largest refinery in the U.S. and one of the largest in the world. The ExxonMobil Beaumont refinery on the Neches River Channel is presently the third largest refinery in the world. As a result of these additions, SNWW's combined capacity would be the largest concentration in the State of Texas. Refined petroleum products are shipped from the SNWW via three major pipeline systems to 21 states east of the Rockies, including states as far away as Delaware, New York, and Pennsylvania (Martin Associates, 2006).

The existing SNWW navigation channel system is congested. The existing 40-foot project depth was designed to efficiently and safely accommodate much smaller vessels than are being used today. The current channel was completed in the late 1960s, and at that time, crude oil tankers averaging 40,000 deadweight tons (DWT) with loaded drafts of 36 feet were common. Vessels over 90,000 DWT are now used routinely for crude oil imports to both Beaumont and Port Arthur. In addition to larger vessels, the amount of vessel traffic on the SNWW has also increased. Both SNWW and U.S. crude oil imports have steadily risen since the 1970s, and this trend is projected to continue into the foreseeable future. The 2005–2007 crude oil import volume is nearly three times the average 1990–1992 levels. In the short term, it is expected that SNWW imports would grow at rates comparable to or higher than regional and national trends, and long-term expectations are for growth equal to regional and national trends. From 2005 to 2007, SNWW volumes of crude petroleum imports exceeded other Texas Gulf Coast ports by nearly 35 percent. Recent increases in SNWW refinery capacity indicate that the region would gain an increasing share of U.S. totals.

In addition to the large base of existing crude oil and petrochemical product facilities on the SNWW, three Liquefied Natural Gas (LNG) terminals have been proposed at Sabine Pass. LNG is expected to play an increasingly important role in the natural gas industry and global energy markets in the next several years and in the long-term future. Construction of the Sabine Pass Terminal is complete, and the

This page intentionally left blank.

II-5

This page intentionally left blank.

first vessels arrived in April 2008. Construction is ongoing at the Golden Pass Terminal; the Port Arthur Terminal has received regulatory approval. The SNWW LNG facilities are located in the Sabine Pass Channel and Port Arthur Canal; these reaches are presently 500 feet wide and would remain so under the without-project future. LNG vessels using the SNWW would be subject to strict U.S. Coast Guard (USCG) regulations and to local pilot rules, and all LNG vessel movements would be subject to one-way traffic.

With the current channel depth, there are draft restrictions on large vessels currently utilizing the channel. The majority of the tonnage carried on the SNWW is in deep-draft vessels, and the vast majority of the deep-draft traffic is comprised of crude oil and petrochemical products. However, LNG, grain, and aggregate products, such as iron ore, steel slab, limestone, sand, and gravel, are also carried in draft-constrained deep-draft vessels. For the period 2002–2007, 89 percent and 64 percent of crude petroleum imports to Beaumont and Port Arthur, respectively, were transported in vessels with design drafts over 40 feet.

Currently at the SNWW, Very Large Crude Carriers (VLCC) transfer tonnage at an offshore location onto one or more shuttle vessels in a process called lightering. These very large carriers cannot enter the SNWW because of their size and draft. In addition, other large crude tankers presently offload a partial load to a shuttle vessel or vessels and then enter the SNWW with the shuttle vessels as they are small enough to navigate the SNWW with a lighter load. This process is called lightening.

The SNWW experienced strong growth over the past decade, with total tonnage increasing from an average of 108 million short tons for 1995–1997 to 138 million for 2005–2007. As imports have increased, the number of lightered and lightened vessels and product carriers has also increased, adding to shipping delays and congestion. The total number of inbound vessels on the SNWW is projected to increase in the short-term at rates comparable to or higher than regional and national trends. Recent increases in SNWW refinery capacity indicate the region would regain an increasing share of U.S. totals.

Ships are not only requiring deeper drafts, but the sizes of the vessels are wider (Figure II-4). The vessel beams of both Port Arthur's and Beaumont's vessels cause them to be regularly impacted by the present 500-foot width of the Sabine Pass Jetty Channel and Port Arthur Canal. The most common crude oil tankers unloading at the Taylor Bayou Basins have design drafts of 45 feet and beams of approximately 124 feet. Tankers using the Taylor Bayou Basins are smaller than those offloading at terminals on the Neches River Channel because existing width at the mouth of Taylor Bayou and the configuration of the docks within Taylor Bayou limit the allowable vessel size. The maximum size vessels unloading at Port of Beaumont facilities on the Neches River Channel are approximately 900 feet long, with a beam width of 164 feet.

The Sabine Pilots Association (SPA, or Sabine Pilots) has adopted self-imposed transit rules for safety in the narrow channel; these rules result in navigation constraints. These rules are presented in Table V-54 later in this report. These constraints include daylight-only and one-way sailing restrictions in specific reaches. The main restrictions place limitations on the combined beam widths and drafts for vessel

meetings on the waterway. A major restriction is that vessels with combined beam widths in excess of 50 percent of the channel width cannot meet. The effects of these and other navigation restrictions cause significant delays along the waterway.

Figure II-4. Increasing Vessel Sizes

As a result of these rules, inbound vessels intending to use a specific dock must wait offshore until the outbound vessel at that dock sets sail, resulting in considerable delays because of the length of the inshore channel. In addition, vessels are now wider due to new double-hull requirements and to industry changes to wider but shorter vessels, which makes vessel-meetings more difficult. The probability of accidents and other safety problems may increase with increases in both inland barge and deep-draft vessel traffic along the waterway. Channel deepening and/or widening could alleviate some of these congestion and safety problems by enhancing the maneuverability and control of deep-draft vessels, and permitting two-way traffic in the widened SNWW reaches and providing additional TB and anchorage basins (AB) on the Neches River Channel.

The CIP would provide benefits by reducing the number of vessel trips needed for crude oil imports. Vessel trips would be reduced since the mother vessels could enter the waterway more-heavily loaded and fewer shuttle vessels would be used for lightening. In addition, shuttle vessels used in lightering the VLCC could be more-heavily loaded, which would reduce the number of shuttle vessels required. Some petroleum products and other commodities would also be able to take advantage of increased channel depths by loading additional tonnage; however, crude oil is expected to be the principal beneficiary of the deeper channel. Widening of the inshore channels below Taylor Bayou would allow more vessels to meet under existing rules, and increase efficient utilization of the channel. Additional TB and anchorages on

the Neches River Channel would allow some vessels to wait at nearby docks rather than waiting offshore, significantly reducing delays associated with one-way traffic restrictions.

Safety

Navigational safety on the SNWW is a concern given the SNWW's large existing traffic base, the number of crude oil and dangerous cargo transits, and the 2008 introduction of LNG vessels to the vessel mix. Vessels are now wider due to new double-hull requirements and to industry changes to wider but shorter vessels. Wider vessels make meetings more difficult and, therefore, more dangerous (Figure II-5). Historically, however, casualty incidents on the SNWW channel are very low, due in large part to existing pilot rules that minimize the probability of incidents involving deep-draft vessels. A list of the transit rules is provided in Section V.E (see Table V-54.) of this report. The pilot rules would continue to limit the vessel sizes that can meet in each portion of the channel. Recent installation of the Port Arthur Vessel Traffic Service (VTS) would allow the USCG to assist vessel operators in managing their transits in relation to other traffic on the waterway, reducing potential interactions between deep-draft vessels and tows or barges on the congested Sabine-Neches Canal. LNG vessels using the SNWW would be subject to strict USCG regulations and to local pilot rules and, therefore, would not have the opportunity to meet other vessels. Under current pilot rules, the wide beams of LNG tankers would make them subject to one-way traffic restrictions.

Figure II-5. Widening to Address Safety

Channel improvements would allow more deep-draft cargo to be carried with fewer vessel trips. Associated reductions in deep-draft vessel traffic would thereby serve to reduce the probability of casualties. However, since casualty occurrences in the SNWW are rare, the proposed improvements would not have a discernible effect on casualty rates.

National Security

Congestion is increased during times when the SNWW serves an important military function. One of the busiest ports for military cargo in the world is located on the SNWW. The Port of Beaumont is the Nation's busiest Strategic Port of Embarkation, and it is the second largest commercial military out-load port worldwide. For the war in Iraq, it has handled approximately one-third of all the military cargo deployed to and from the war, which is more military cargo than any other U.S. port (Military Surface Deployment and Distribution Command, 2004, 2006). The SNWW must accommodate the military's increased use of newer and larger transport ships, which are three times the size of transport ships used in 1990. Improved transportation efficiency on the SNWW is vital in maintaining the Port of Beaumont's ability to provide critical support to U.S. military operations. The SNWW contributes to national security in one other key aspect. Two terminals on the Neches River are connected by pipelines to underground storage facilities of the U.S. Department of Energy's Strategic Petroleum Reserve at Big Hill, Texas, and West Hackberry, Louisiana.

II.C ENVIRONMENTAL

The most significant trend adversely affecting the study area is the high rate of wetland loss that has occurred over the last century. In Louisiana, a net land loss of 21 percent between 1978 and 2000 has been reported in the Chenier Plain subregion of coastal Louisiana, which includes the Sabine estuary. In Texas, the most extensive losses of interior coastal wetlands in the state have occurred in the Neches River delta, an example of which is shown in Figure II-6. These losses total 12,632 acres between 1930 and 1978. In total, over 90 percent of the emergent marshes in the Lower Neches River delta have been converted to open water, which is more than half of the total wetland loss in the State of Texas.

While the future rate of relative sea level rise (RSLR) at the Sabine-Neches estuary is very uncertain, it must be considered in project planning. RSLR consists of two components: global (eustatic) sea level rise and local subsidence. The uncertainty in the rates of eustatic sea level rise is evident in the variability of the different modeled rates given for the National Research Council (NRC, 1987) projections and the 2007 Intergovernmental Panel on Climate Change (IPCC). A similar degree of uncertainty exists with the rate of local subsidence.

A detailed review of both eustatic and local subsidence rates was performed by the Engineer Research and Development Center (ERDC) in fulfillment of requirements of Circular No. 1165-2-211, Water Resources Policies and Authorities Incorporating Sea-level Change Considerations in Civil Works Programs (USACE, 2009a). This review found the eustatic rate estimates range from 1.8 millimeters per year (mm/year) to 6.45 mm/year for the next 50 years. This study employs an estimate for eustatic rise of

Figure II-6. Rose City Marsh (Historical Cypress Swamp to Open Water)

4.5 mm/year. This estimate is in the middle of the range projected by NRC (1987) and in the high middle range of that predicted by IPCC. In coastal Louisiana, estimates of the local subsidence component of RSLR were found to range from 0.4 to 0.6 mm/year based on basal peat measurements (Törnquist et al., 2006), to 2 to 5 mm/year as averaged from 48 years of tide gage data (Morton et al., 2005), and 10 to 15 mm/year measured from settling rates of established benchmarks (Shinkle and Dokka, 2004). The ERDC's review concluded that the lower rates (0.4 to 0.6 mm/year) were the most technically valid. These lower rates represent long-term trends in the subsidence rate, and seem to be the closest approximation of consensus concerning the local subsidence rate that is currently available.

Adding these to the NRC II projections for eustatic sea level rise yields a value for the RSLR in the SNWW study area over 50 years of 4.9 to 5.1 mm/year. The average of these, 5.0 mm/year, is used for modeling purposes.

Therefore, the “most likely” value of RSLR to be used for the SNWW deepening study's 50-year period of analysis is 0.82 foot. Adjusting this to account for the period of analysis beginning in 2019 and ending in 2069, the period of analysis for the SNWW reformulation, the “most likely” amount of RSLR by the year 2069 is 1.1 feet.

Potential for increased Gulf shoreline erosion is also a concern. In recent years, high shoreline erosion has caused substantial wetland losses on the Gulf of Mexico shoreline from Texas Point westward to the

vicinity of Sea Rim State Park. Inland shoreline erosion due partly from the passage of large vessels occurs along the waterway, especially in the narrow portions of the channel. Inland shoreline erosion results in thousands of dollars being spent every year to provide bank stabilization and maintain roads, some of which are critical for evacuation during hurricanes.

Since the devastating hurricane season in 2005, concerns have increased regarding the potential for channel-deepening projects such as the SNWW CIP to exacerbate the adverse effects of tropical storms like hurricanes Rita and Katrina on environment and infrastructure in the study area. These concerns are also related to recent forecasts of more intense tropical storms in the future due to global climate change.

There is an increasing potential for environmental harm as a result of an increase in the probability of shipping accidents due to predicted increases in vessel traffic. Environmentally sensitive areas that could be affected by spills resulting from shipping actions are located along both sides of Sabine Pass, west of the Port Arthur Canal, and along portions of the Neches River Channel. The need to protect environmental resources in the study area is related to the high concentration of significant coastal wetland habitats (see Figure I-3).

As part of the feasibility study process and as required by the National Environmental Policy Act (NEPA), the public and State and Federal resource agencies were coordinated with to obtain their comments and concerns regarding the proposed project. These comments are summarized in Section XII of this report. Detailed comments are located in Appendix A of the FEIS.

III. FORMULATION OBJECTIVES, CONSTRAINTS, AND CRITERIA

III.A OVERVIEW

This chapter addresses the remainder of step one in the planning process by identifying the Federal objectives for the study, identifying public concerns, planning objectives and potential constraints, and developing the criteria to be used for evaluating plan formulation alternatives.

III.B FEDERAL OBJECTIVES

The fundamental objective of Federal participation in water resource development projects is to assure that an optimum contribution is made to the welfare of all people. The Water Resources Council's Economic and Environmental Principles and Guidelines for Water and Related Land Resources Implementation Studies, dated March 1983 and the NEPA of 1969 provide the basis for Federal policy for planning Federal water resources projects. These authorities have established the procedures for formulation and evaluation of water resources projects. Additional policies and regulations, derived from executive and legislative authority, further define the criteria for assessment of plan impacts, risk analysis, review and coordination procedures, and project implementation.

Current Federal policy dictates that NED is the primary Federal objective in water resources planning. NED objectives stress increasing the value of the Nation's output of goods and services, and improving economic efficiency on a national level. The NED Plan is the plan that reasonably maximizes net NED benefits. The Federal objective of water and related land resources planning is to contribute to NED in a manner that is consistent with protecting the Nation's environment. Consequently, the resource's condition should be more desirable with the Recommended Plan than under the without-project condition.

III.C PUBLIC CONCERNS

A number of public concerns have been identified during the course of the study. Input was received through coordination with the Sponsor, coordination with Federal and State agencies, public review of draft and interim products, and public meetings. A discussion of public involvement is included in Section XII of this document. The majority of the concerns/comments from the public that are related to the establishment of planning objectives and planning constraints are:

- Potential saltwater intrusion impacts on the adjacent marshes in Texas and Louisiana;
- Potential increase in water levels, including tidal movements;
- Potential impacts to the eastern shore of Sabine Lake;
- Natural resources (e.g., ducks, freshwater marsh birds, alligators, etc.) that would likely be affected by the proposed project;
- Impact of doing nothing that would result in economic reductions, loss of jobs, and reduction of property values; and

- Utilize the dredged material beneficially to improve the coastal shoreline by increasing vegetative dune structure and replenishing eroding beaches.

III.D PLANNING OBJECTIVES

The Federal objectives are general statements and not specific enough for direct use in plan formulation. The water and related land resource problems and opportunities identified in this study are stated as specific planning objectives to provide focus for the formulation of alternatives. The primary objective of Federal navigation activities is to contribute to the Nation's economy while protecting the Nation's environmental resources in accordance with existing laws, regulations, and executive orders.

These planning objectives reflect the problems and opportunities expressed by the Sponsor and the public, and represent the desired positive changes to the existing project conditions. The following planning objectives were used in formulation and evaluation of alternative plans:

- Improve the navigational efficiency along the waterway; and
- Maintain the ecological values of coastal and estuarine resources within the project area.

III.E PLANNING CONSTRAINTS

Unlike planning objectives that represent desired positive changes, planning constraints represent restrictions that should not be violated. Plans must be formulated with regard to addressing the problems and needs of the area, taking into consideration FWOP conditions. The plans should identify tangible and intangible benefits and costs from economic, environmental, social, and regional perspectives. Institutional implementation constraints should also be identified.

The formulation framework requires the systematic preparation and evaluation of alternative solutions to the recognized water resource-related problems within the study area. The process requires that impacts of the proposed action be measured and results displayed or accounted for in terms of contributions to NED, environmental quality, regional economic development, and other social effects.

Interaction with other interests must be maintained throughout the planning process to avoid duplication of effort, minimize conflicts, obtain consistency, and assure completeness. The following constraints apply to this feasibility study:

- The study process and plans developed must comply with Federal and State laws and policies;
- Fish and wildlife habitat affected by a project plan should be minimized as much as possible and preserved, if possible; and
- Alternative plans that resolve problems in one area should not create or amplify problems in other areas.

Current guidance specifies that the Federal objective of planning is to contribute to NED consistent with protecting the Nation's environment. The following general criteria are applicable to all water resource studies and have generally guided the formulation of the study. Technical, economic, environmental, and social criteria have been established to guide the project development process. These criteria are discussed below.

III.F TECHNICAL CRITERIA

Technical criteria require the preservation of adequate project dimensions to provide safe passage of commercial navigation traffic through a reach of waterway while minimizing environmental impacts. These criteria require plans to be compatible with navigation needs and consistent with the requirements of the navigational equipment using a portion of the waterway and to provide a long-term plan for the placement of dredged material in order to continue maintenance of the waterway in the future.

The plans must be consistent with specific environmental conditions of the area including soil conditions, topography, and terrestrial and aquatic ecosystems. Formulation of alternative alignments and dredged material placement alternatives and their evaluation was accomplished by analysis of historical and projected shoaling rates, erosion causes and rates, and general structural and nonstructural alternatives applicable for conditions that are specific to this area.

Technical information (both historical data and specific information prepared for this project) and analyses used during the study included, but was not limited to:

- Hydrodynamic/salinity study
- Ship simulation study
- Gulf shoreline study
- Vessel effects study
- Sediment and water quality analyses
- Aerial photography
- Historical dredging records
- Previously published scientific reports related to the project area
- Stability analyses
- 50-year Dredged Material Management Plan (DMMP)
- Pipeline identification and relocation analysis
- Marine and estuarine resource investigations
- Threatened and endangered species assessment.

III.G VALUE MANAGEMENT

Following the guidance in ER 1110-2-1150 Paragraph 13.14 Value Engineering, "A value engineering study shall be performed on the earliest document available that satisfies the functional requirements of the project and includes a MII cost estimate. The Project Delivery Team (PDT) shall determine if the

initial value engineering study shall occur during the feasibility phase or be delayed until the Pre-Construction Engineering and Design (PED) phase.” Galveston District received approval for a delay of the Value Engineering Study until the PED phase is completed from Southwestern Division.

The inherent nature of a feasibility study process involves considerable value analysis and management efforts within all aspects of the study. This section summarizes the value management efforts that were utilized in this phase of the study. Various nonstructural alternatives were investigated throughout the feasibility phase as a means to solve the navigational problems. Some of these nonstructural measures included vessel traffic systems to alleviate transportation inefficiency and safety concerns, changes in pilot rules, and alternative modes of commodity transport. Structural alternatives were evaluated and included channel deepening and widening.

Standard dredging practice utilizes pipeline and hopper dredges, the only applicable method of construction for deepening the channel. Because the type of equipment to be used as part of the construction was limited, the value analysis efforts concentrated on the other construction aspects. These included construction of new placement areas, rehabilitation of existing placement areas, mitigation features, and BU sites. Identifying cost-saving alternatives that used resources more efficiently and decreased project costs, as well as operation and maintenance costs, played a major part in the feasibility study’s value management.

Beneficial use of the dredged material, new work, and maintenance material, was investigated to find the most economical and practical placement within the project constraints. The “life-cycle” of the waterway was considered with emphasis on practical placement of new work within the placement areas for use in future levee construction. Additionally maintenance material was used beneficially for marsh creation, which was an economical advantage over standard placement practices.

The public was afforded an opportunity to provide input regarding more-cost-effective alternatives that could be used to accomplish the project purpose. The plan was presented to the public at industry group meetings, public workshops, and public meetings.

During the PED phase, the construction contracts will undergo value management and value techniques following guidance found in the ER 11-1-321- Army Programs Value Engineering.

III.H ECONOMIC CRITERIA

The economic criteria require that tangible benefits attributable to projects exceed project costs. Project benefits and costs are presented as average annual equivalent values and related in a ratio of benefits to costs (Benefit-to-Cost Ratio or BCR). This ratio must exceed unity to meet the NED objective. Recommended plans, whether structural, nonstructural, or a combination of both, should maximize excess benefits over costs; however, unquantifiable features must be addressed subjectively. These criteria are used to develop plans that achieve the objective of NED and provide a base condition for consideration of economically unquantifiable factors, which may impact on project proposals. The USACE planning guidelines required that the alternative that most reasonably maximizes net economic benefits, consistent

with protecting the Nation's environment, be identified as the NED Plan. This NED Plan may be selected as the Recommended Plan. However, for a navigation project, if a plan with lesser benefits is preferred by the sponsor due to financial constraints, guidance allows for a categorical exemption to be granted and this lesser plan to be selected as the Recommended Plan. This process is addressed in more detail later in this report.

All structural and nonstructural measures for navigation projects should be evaluated using the appropriate period of analysis and the currently applicable interest rate. Total annual costs should include amounts for operation, maintenance, and major replacements, as well as amortization and interest on the investment.

III.I ENVIRONMENTAL CRITERIA

The general environmental standards for navigation projects are identified in Federal laws, executive orders, and the USACE planning guidance. It is Federal policy that conservation of fish and wildlife resources be given equal consideration with other study purposes in the formulation and evaluation of alternatives. Care must be taken to preserve and protect significant ecological, aesthetic, and cultural values and to conserve natural resources. These efforts should provide the means to maintain and restore, as applicable, the desirable quality of the human and natural environments.

Throughout the study process, the USACE Environmental Operating Principles (EOP) should be considered. The EOP principles ensure conservation, environmental preservation, and restoration are considered at the same level as economic issues. The seven EOP principles are (1) strive for environmental sustainability, (2) consider environmental consequences, (3) seek balance and synergy, (4) accept responsibility, (5) mitigate impacts, (6) understand the environment, and (7) respect other views.

Consistent with laws and policy, alternative plans formulated to improve navigation should avoid damaging the environment to the extent practicable and contain measures to minimize or mitigate unavoidable environmental impacts. The following criteria were used to address environmental impacts during the evaluation of alternatives:

- Protection, preservation, and improvement of the existing fish and wildlife resources along with the protection and preservation of estuarine and wetland habitats and water quality;
- Consideration in the project design of the least disruptive construction techniques and methods;
- Mitigation for project-related impacts by minimizing, rectifying, reducing, or eliminating impacts, or compensating for unavoidable impacts by replacing or substituting resources;
- Protection and preservation of endangered and/or threatened species, Critical Habitat, and EFH; and
- Preservation of significant historical and archeological resources through avoidance, if possible, or data recovery if destruction of the resource is necessary.

III.J SOCIAL CRITERIA

Plans proposed for implementation should have an overall favorable impact on the social well-being of affected interests (e.g., community impacts, health and safety, displacement, energy conservation, and others) and have an overall public acceptance. Structural and nonstructural alternatives must reflect close coordination with interested Federal and State agencies and the affected public. The effects of these measures on the environment must be carefully identified and compared with technical, economic, and social considerations and evaluated in light of public input.

III.K OTHER USACE INITIATIVES

USACE Campaign Plan

In August 2006, as a result of lessons learned from hurricanes Katrina and Rita, the USACE Chief of Engineers initiated the “Actions for Change” in an effort to transform the USACE planning, design, construction, and operation and maintenance principles and decision-making processes. This program has been further developed into the Campaign Plan. The USACE is moving forward with this Campaign Plan to transform the way business is done. The USACE Campaign Plan is available on the internet at: <http://www.usace.army.mil/about/campaignplan/Pages/Home.aspx> (USACE, 2009b).

The successful achievement of the goals and objectives contained in this Campaign Plan are dependent on actions implemented by the entire USACE team. The Campaign Plan included four goals for the USACE. These goals are:

Goal 1: Ready for all Contingencies – Deliver USACE support to combat, stability, and disaster operations through forward deployed and reachback capabilities.

Goal 2: Engineering Sustainable Water Resources - Deliver enduring and essential water resource solutions through collaboration with partners and stakeholders.

Goal 3: Delivering Effective, Resilient, Sustainable Solutions - Deliver innovative, resilient, sustainable solutions to the Armed Forces and the Nation.

Goal 4: Recruit and Retain Strong Teams – Build and cultivate a competent, disciplined, and resilient team equipped to deliver high quality solutions.

Goals 1 and 4 do not apply directly to the USACE planning process and are not discussed in detail. Goals 2 and 3 pertain to water resources planning and directly to the SNWW study. These goals are described in more detail below.

Goal 2: Engineering Sustainable Water Resources

With Goal 2 USACE focuses on comprehensive, sustainable, and integrated solutions to the Nation’s water resources challenges through collaboration with stakeholders. This goal refers to not only developing and delivering comprehensive and lasting solutions but also ensuring that these solutions are long lasting, integrated, and holistic to respond to today’s and future challenges.

Goal 3: Delivering Effective, Resilient, Sustainable Solutions

Goal 3 emphasizes that the USACE will provide innovative, resilient, and sustainable infrastructure solutions for the Nation today and in the future. The USACE is the Nation's premier public service engineering and construction organization and can provide infrastructure support to serve both the military and national civilian arenas. This effort will improve resilience and lifecycle investment in critical infrastructure, deliver reliable infrastructure using a risk-informed asset management strategy, and develop and apply innovative approaches to delivering quality infrastructure.

IV. FORMULATION AND EVALUATION OF ALTERNATIVES

IV.A OVERVIEW

Navigational and safety issues that have developed on the SNWW because of the growth in the area are the water resources problems to be solved with this project. The ultimate objective of a feasibility study is to arrive at a recommended plan after a full range of alternatives has been analyzed. This involves a comparison between each alternative and the FWOP condition consequences, considering economic, environmental, and social impacts.

This chapter provides a summary of the screening processes and evaluations conducted on the project alternatives. Structural and nonstructural alternatives were identified based on their ability to address the planning objectives, as well as the project problems, needs, concerns, and opportunities.

IV.B PLAN FORMULATION PROCESS

The planning framework requires a systematic preparation and evaluation of alternative ways of addressing the project problems, needs, concerns, and opportunities while considering environmental factors. The criteria and planning objectives previously identified form the basis for subsequent plan formulation, alternative screening, and ultimately identification of the Recommended Plan. Planning for Federal water resources projects constructed by the USACE, as well as other agencies, is based on the Principles and Guidelines (P&G) adopted by the Water Resources Council. Based on the Economic and Environmental Principles for Water and Related Land Resources Implementation Studies, there are four accounts that have been established to facilitate evaluation and display of the effects of alternative plans (ER 1105-2-100). The rationale for the Recommended Plan as it relates to these four accounts is presented later in this chapter.

The planning process for this feasibility study has been driven by the overall objective of developing a comprehensive plan that would allow for safe and efficient barge and ship traffic along the SNWW while protecting the Nation's environmental resources. Secondary objectives have been to address other related water resources problems within the study area.

The first phase of the study process was to determine the magnitude and extent of the problems along the SNWW, then to develop and evaluate an array of alternative solutions to meet the existing and long-range future needs of the Sponsor and the public. During the feasibility phase of the project, lines of communication were opened with Federal, State, and local agencies, private groups, and the affected public. Through scoping and other coordination meetings, public involvement occurred throughout the planning process.

The expected FWOP scenario was first developed for comparison with other alternatives. Nonstructural and structural plans were developed to address the planning objectives identified earlier in this report. For the structural plans, a variety of channel modifications and dredged material placement alternatives were developed, evaluated, and screened. The various channel modifications were investigated as to a possible

means to satisfy the objectives of constructing a safer, more-efficient waterway. Through a two-phased (preliminary and detailed) screening process, a recommended channel modification plan for the SNWW was selected. Figure IV-1 presents the process used to identify and evaluate project alternatives.

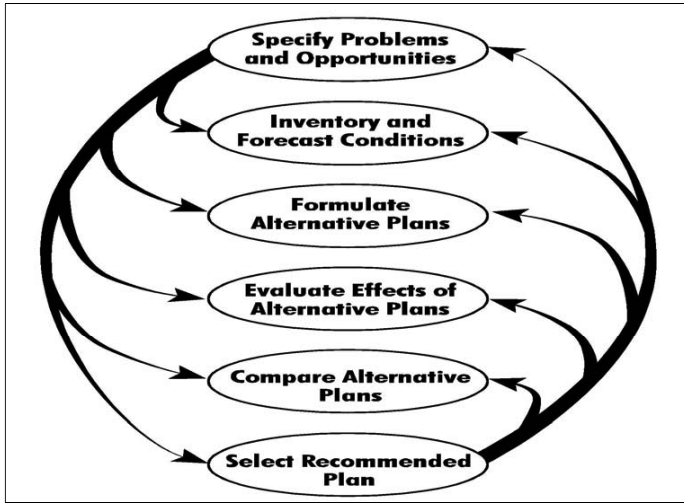

Figure IV-1. Planning Process

IV.C PRELIMINARY SCREENING OF ALTERNATIVES

During preliminary screening, the expected “No Action” Alternative was developed for comparison with other alternatives. Nonstructural and structural alternatives that could address planning objectives were also developed.

Future Without-Project Condition (No-Action Alternative)

The USACE is required to consider the option of “No Action” as one of the alternatives in order to comply with ER 1105-2-100 and the requirements of NEPA. With the No-Action Alternative, which is synonymous with the FWOP condition, it is assumed that no project would be implemented by the Federal Government or by local interests to achieve the planning objectives of improving the navigational efficiency and safety of the waterway. The No-Action Alternative forms the basis against which all other alternative plans are measured.

The No-Action Alternative would retain the existing 40-foot-deep SNWW navigation channel with its various widths along the waterway. The current dimensions would continue to limit the efficient

movement of commodities by vessels traveling the waterway and the safety limitations that result in one-way and daylight-only sailing restrictions. Under the FWOP condition, safety would continue to be a concern for the waterway users and the local communities adjacent to the waterway.

The waterway is often congested because of frequent movements of lightered vessels carrying petroleum products from the Gulf to refineries on the Neches River Channel, and because of barge through-traffic using the GIWW. Vessels are now wider, placing limitations on the combined beam widths and drafts for vessel meetings on the waterway. As vessels increase in draft and beam width, the restrictive depth and width in certain reaches of the waterway would prevent some vessels from entering with full loads or prevent larger vessels from even utilizing the waterway. The potential for accidents on the waterway and their effects on users and the local communities adjacent to the waterway would remain the same. The need to lighter products and/or light load vessels would increase, thereby increasing overall project costs and decreasing the efficiency of the vessels using the waterway.

Methods of shipping crude oil are direct, lightered, and lightened. Direct shipment, as the name implies, is the transfer of tonnage by vessel between two coastal ports. Lightering involves the transfer of tonnage at an offshore location from a larger vessel, called a VLCC, onto one or more shuttle vessels. U.S. Gulf Coast lightering occurs in the international waters of the Gulf of Mexico and is extremely cost effective for long-haul bulk freight. With lightering, the VLCC does not enter the coastal receiving port. A frequent alternative to either direct shipment or lightering is lightening. The term lightening describes the process where enough cargo is offloaded from a tanker to permit the light-loaded vessel to enter a confined channel system.

It is expected that imports of crude oil and petroleum products would continue to expand to keep pace with the predicted national need for these products and the projected continuing declines in U.S. production. Vessel trips would increase to accommodate the higher imports, and higher costs associated with the current lightering and vessel movement limitations would continue. In addition to increasing petroleum imports, continued growth of petroleum and chemical exports is expected. The need for dock reinforcement and stabilization necessary to realize project-deepening benefits was recognized in the plan formulation process. The costs associated with berth stabilization necessary due to channel deepening are included in the project construction cost calculations. Crude petroleum refinery expansion was initiated by Motiva in 2007 due to current refinery limitations and future throughput needs. Dock improvements on both the Neches River and Taylor Bayou were recently completed by industry to accommodate larger crude oil vessels. The results of the plan formulation analyses indicated that berth and terminal capacities were not a constraint to realizing benefits from using larger and more-fully loaded vessels.

Increased vessel trips associated with higher tonnage and increasing concentration of larger vessels would exacerbate the existing channel bank erosion caused by vessel wakes in the confined channel reaches of the SNWW. It is projected that the existing trend in wetland losses would continue due to the combined effect of sea level rise and subsidence, and altered hydrology and salinity levels caused by the existing SNWW navigation channels, the GIWW, and canals, levees, and water control structures associated with oil and gas exploration and production, logging, fishing, and hunting lands.

The No-Action Alternative would continue disposal activities for maintenance material from the 40-foot project in conformance with most, but not all, existing practices. In this Final Feasibility Report (FFR), the DMMP for the No-Action Alternative (the FWOP) is referred to as the Base Plan. The Base Plan forecasts disposal facility needs for all material that would be generated by maintenance dredging of the existing 40-foot project over a 50-year period of analysis. The 50-year analysis determined that additional capacity in upland PAs would be required, and it identified a least-cost BU feature that should be adopted as part of the Base Plan.

No differences from existing offshore placement activities were identified for the Base Plan. The offshore channels (Sabine Bank Channel, Sabine Pass Outer Bar, and Sabine Pass Jetty Channel) would be maintained with a hopper dredge, and approximately 162 million cubic yards (mcy) of material would be placed in the four existing ODMDs (sites 1–4). Bed sediments in the offshore channels vary from 4.3 percent sand and 95.7 percent silt plus clay in the Sabine Pass Outer Bar Channel to 24.3 percent sand and 75.7 percent silt plus clay in the Sabine Bank Channel (Parchure et al., 2005). These ODMDs have sufficient capacity for the 50-year period of analysis as they are located in a dispersive environment where dredged material does not accumulate.

For the inshore Sabine Pass Channel, a cost analysis of placement alternatives (presented in Chapter VII) resulted in a change from traditional upland placement practices involving PA 5. Rather than placing all of the maintenance material from this channel into upland PA 5, the BU of material from the channel section closest to the coast (Sabine Pass Channel, Section 5) was evaluated to determine whether it could be used to nourish the Gulf shoreline on both sides of Sabine Pass. Material from Sabine Pass Channel would continue to be placed into PA 5 because the longer pumping distance to the coast makes shore nourishment cost prohibitive. The cost analysis determined that the Gulf Shore BU Feature is more cost effective than placing the material in the upland PA 5, and therefore it was adopted as part of the Base Plan.

Under the Base Plan, all of the inshore channels of the existing project (Sabine Pass Channel, Port Arthur Canal, Sabine-Neches Canal, and the Neches River Channel) would continue to be maintained by hydraulic pipeline dredge. Material from non-Federal dredging of private mooring and dock facilities would also continue to be placed in upland PAs along with the material from the Federal project. Existing management practices that utilize 16 upland PAs located adjacent to the channel from Sabine Pass to the Beaumont TB would continue. To contain 231.6 mcy of material over the 50-year period of analysis, the heights of existing PAs would be raised on a regular, recurring schedule in accordance with existing SNWW management practices. One new PA in the middle reach of the Neches River Channel (an expansion cell at PA 24A) would be needed to provide sufficient capacity for the period of analysis. On average, bed sediments vary in the inland channels from 38.3 percent sand and 61.7 percent silt plus clay in the Neches River Channel, to 16.2 percent sand and 83.8 percent silt plus clay in the Port Arthur Canal (Parchure et al., 2005). BU features are not included in the Base Plan for the inland channels because the lack of suitable material makes construction and maintenance of containment levees more expensive than placing the material in existing PAs. However, BU of dredged material (Section 204) projects would be

considered on a project-by-project basis if non-Federal sponsors express an interest in paying the incremental cost for such projects.

Preliminary Screening of Alternatives

Based on the problems and opportunities identified by the Sponsor and the public comments received at the May 2000 public scoping meeting, a wide variety of management measures (alternatives) were identified to address one or more of the planning objectives. A preliminary (first) screening of the alternatives was conducted to eliminate any alternatives that did not meet the study objectives. This screening focused on whether deepening, and perhaps widening, would be cost effective, and whether any nonstructural alternatives to deepening and/or widening could be identified.

In order to evaluate the preliminary alternatives, screening criteria that would likely have the most influence in determining the viability of the alternatives were identified. The following criteria were used to evaluate and screen the alternatives:

- | | |
|------------------------------|--|
| – Dredging Quantities | – Environmental Considerations |
| – Cultural Resource Concerns | – Hazardous, Toxic, and Radioactive Waste Concerns |
| – Real Estate Issues | – Construction Costs |
| – Project Benefits | – Sponsor's Preferences |
| – Safety Issues | |

Each of the following alternatives was assessed and a determination made regarding whether it should be retained for the second screening of alternative plans. The following is a list of the preliminary alternatives considered:

Nonstructural Alternatives

- Alternate mode of commodity transport,
- Vessel traffic service, and
- Modification of existing pilot rules on the waterway.

Structural Alternatives

- Deepening only (43-, 45-, 48-, 50-, 53-, 55-foot depths)
- Widening only, along the entire channel (widths varying from 500 to 700 feet) from Sabine Pass to the Port of Beaumont
- Deepening and widening (combinations of six depths and various widths for entire channel length)
- Selective widening only (widening only certain reaches of the channel)
- Deepening with selective widening (combination of depths and widening options)

- Expansion of existing and construction of new TB and/or AB
- Construction of barge lanes (for passing)

Plans Eliminated During Preliminary Screening

All of the nonstructural plans were advanced into the second screening because it was determined that these alternatives could potentially meet one or more of the planning objectives, but a more in-depth analysis would be necessary for a full assessment. In addition, most of the structural alternatives were also advanced into the second screening. It was found that deepening and widening the existing 40-foot channel would allow for existing ships to more fully utilize the channel and potentially reduce traffic delays, without prohibitive costs.

Two of the preliminary structural alternatives considered were found to be infeasible due to technical, economic, and environmental constraints, and were therefore not advanced into the second screening:

- Widening the entire existing channel from Sabine Pass to the Port of Beaumont, at widths varying from 500 to 700 feet, was found to be infeasible based upon a number of criteria. The length of the widening would generate a tremendous quantity of dredged material, resulting in greatly increased costs for construction and placement facilities. A number of large commercial docks and berthing facilities are located along the channel, and these would be disrupted or displaced by widening activities. The Martin Luther King (MLK) Bridge that crosses the Port Arthur Canal would need to be relocated as the existing span is not wide enough to accommodate channel widening. The widening would affect a large amount of emergent land, especially along the narrow confined Port Arthur Canal and narrower sections of the Neches River. Landfills containing hazardous materials would be affected by the widening, as well as some wetland areas. And perhaps most pertinent, widening only would not provide the additional draft needed to increase navigation efficiency for the largest number of waterway users.
- Selective widening only (widening only certain reaches of the channel) would reduce or eliminate some of the environmental, real estate, and cost concerns discussed above. However, selective widening would provide even fewer navigation benefits than the widening for the entire channel and also would not increase navigation efficiency for the largest number of waterway users.

IV.D SECOND SCREENING

The alternatives remaining from the preliminary screening underwent more-detailed analyses. These analyses were conducted on three nonstructural plans and over 120 structural combinations of the alternative depths and widths (including seven TBs and anchorage features). Alternatives were evaluated for a 50-year period of analysis.

Technical Studies

To evaluate the depth alternatives with selective widening options, TBs, and barge lanes, several technical studies were conducted by the ERDC and IWR. The additional study efforts included:

- Hydrodynamic/Salinity Modeling Study (ERDC)
- Ship Simulation Study (ERDC)
- Sediment Study and Velocity Analysis (ERDC)
- Vessel Effects Study (ERDC)
- Gulf Shoreline Desktop Study (ERDC)
- Harbor Simulation Model (Widening Analysis) (IWR)

The reports from these studies are available upon request from the USACE. The following is a brief overview of each of the studies:

Hydrodynamic-Salinity Model. The HS model study was conducted to determine the hydrodynamics (water levels and current velocities) of the SNWW and the potential salinity impacts due to the proposed deepening and widening of the existing channel (Brown and Stokes, 2009). The model was originally developed by Resources Management Associates (King, 1993) and extensively modified by the ERDC staff. The model has been used extensively over the past decade on such projects including the Houston-Galveston Navigation Channels; New York Harbor; St. Johns River, Florida; and Atchafalaya Bay, Louisiana. The model was performed for the 48- and 50-foot channel depths. The 45-foot channel depth was not modeled since the salinity differences between 45-foot and 48-foot depths were expected to be similarly small (FEIS, Section 2.3.2)

Ship Simulation. The ship simulation was used to determine navigation and safety impacts due to anticipated changes in vessel sizes as a result of the proposed channel widening (Webb, 2003). The main objective of the study was to determine whether the “design” ship could safely operate within the width and depth of the proposed channel dimensions. The simulation was conducted on a channel depth of 50 feet with varying widths and proposed barge lanes, including simulation of Taylor Bayou. Additional ship simulation was conducted to determine the navigation and safety implications of reducing the offshore entrance channel from its existing 800-foot width to a 700-foot width.

Sediment Study and Velocity Analysis. To determine anticipated shoaling rates (sediment build-up) along the waterway and estimate any increases in channel erosion, a sediment study was conducted (Parchure et al., 2005). Erosion concerns along Pleasure Island and East Sabine Lake were also addressed by the analysis. An additional study effort was performed along the Pleasure Island reach and Sabine-Neches Canal to determine whether the channel velocities in these areas would result in increased channel erosion.

Vessel Effects Study. A vessel effects study was conducted to determine the potential erosional effects to Pleasure Island from vessel traffic in the Port Arthur and Sabine-Neches canals (Maynard, 2005). Project vessel traffic was modeled with HIVEL2D, a two-dimensional (2-D) finite element model designed specifically to simulate flow in typical high-velocity channels. The model has been used since the mid-1980s and is maintained by the ERDC-Coastal and Hydraulics Laboratory (CHL).

Gulf Shoreline Study. This ERDC-CHL study was conducted 10 miles on either side of the SNWW entrance channel to determine potential erosion impacts to the existing shoreline at the Gulf of Mexico, on the Texas and Louisiana sides of the channel (Gravens and King, 2003). The spectral nearshore wave transformation model, Steady State Spectral Wave (STWAVE), was applied to examine wave conditions within a bathymetry grid extending 20 miles along the shoreline. The STWAVE model has been used on studies at Willapa Bay and Grays Harbor, Washington, and Ponce de Leon, Florida.

Harbor Simulation Model. The HarborSym model was used to evaluate widening of the entrance channel. HarborSym is a planning-level model developed by the IWR to assist in economic analyses of channel-widening improvements. The model creates an event-driven simulation based on empirical data and includes data from user-specified transit rules that the model processes with each vessel call in order to calculate delays within the system. More-detailed information on the model results can be found in the Economic Appendix of this report.

Nonstructural Alternatives

The nonstructural alternatives were evaluated during the preliminary screening process to determine their ability to meet some or all of the planning objectives for the project. The nonstructural alternatives evaluated the use of a VTS to alleviate transportation inefficiency and safety concerns, the relaxation of existing pilot rules, and an alternative mode of commodity transport.

Vessel Traffic Service

The existing VTS along the SNWW was evaluated as a nonstructural alternative. Although this service is managed by the USCG and thus is not within the jurisdiction of the USACE, it was evaluated because it appeared to be a potential alternative to structural plans. The VTS was authorized by certain sections of the Ports and Waterways Safety Act of 1972; the Oil Pollution Act of 1990 made participation mandatory in areas serviced by existing and future VTS (USCG, 2008a). The purpose of VTS is to provide active monitoring and navigational advice for vessels in particularly confined and busy waterways. VTS is designed to expedite ship movements, increase transportation system efficiency, improve all-weather operating capability, and enhance vessel safety and marine environmental protection (USCG, 2007, 2008b).

The VTS Center in Port Arthur monitors every ship, vessel, or boat that attempts to enter or leave the SNWW and the GIWW in the Port Arthur service area. Infrared cameras, along with radar, radio-telephone reports from vessel operators, and satellite surveillance sensors on towers along the SNWW, allow VTS controllers to zoom-in on vessel activity at a moment's notice. The satellite-based Automatic Identification System (AIS), required by the Maritime Transportation Security Act of 2002, assists the VTS by determining exactly what a specific commercial vessel is carrying, along with its speed, dimensions, and destination. Most commercial vessels using the waterway were required to have AIS equipment installed by the end of 2004 (USCG, 2004). These include power-driven vessels 66 feet in length or longer, power-driven vessels of 100 gross tons or more carrying one or more passengers for hire, towing vessels 26 feet or longer while navigating, all dredges and floating plant likely to restrict or

affect the navigation of other vessels, and all vessels required to participate in the Vessel Movement Reporting System. However, not all vessels are required to carry AIS; in particular, pleasure crafts, fishing boats, and warships are exempt.

Currently, the VTS Port Arthur is a voluntary system operated in accordance with existing VTS regulations. Until rules regarding VTS Port Arthur are published, vessels are exempt from all VTS and vessel movement reporting system requirements, except the requirement for AIS continuous broadcasts. When VTS Port Arthur is included in the VTS regulation, participation will become mandatory. At that time, VTS Port Arthur would be authorized to designate temporary reporting points and procedures, impose vessel-operating requirements, or establish vessel traffic routing schemes. During conditions of vessel congestion, restricted visibility, adverse weather, or other hazardous circumstances, VTS may control or manage traffic by specifying times of entry, movement, or departure to, from, or within a VTS area.

While the VTS would help congestion and improve safety to some degree, the USCG's traffic management role is limited to specific circumstances when the SNWW is congested or experiencing hazardous conditions. The VTS assists vessel operators in making independent decisions regarding the safe navigation of their vessels, for which they retain complete responsibility. In this sense, VTS should be considered primarily a navigational aid, a tool for mariners to use along with numerous other tools to facilitate safe navigation (USCG, 2008b), and thus would not improve deep-draft navigation inefficiencies created by the need for lightering and associated vessel delays.

Relaxation of Existing Pilot Rules

The SNWW is currently subject to transit rules that are needed for the pilots to safely guide large tankers through the existing, narrow channel. Relaxation of these rules as an alternative to channel improvements was evaluated. These transit rules or restrictions are agreed upon by the shipping industry, supported by the USCG Captain of the Port Orders under the Ports and Waterways Safety Act of 1978, as amended, and administered by the Sabine Pilots (2007). The agreement, dated January 12, 1981, will remain in force until the Sabine shipping industries, SPA, and USCG agree to its revision or modification.

The existing 700-foot-wide reach of the SNWW channel does not have vessel-meeting restrictions; however, in the narrower channel reaches vessel-meeting restrictions are currently imposed. The specific rules posted by the Sabine Pilots are displayed in Table VI-54. A general overview of the transit rules are:

- Daylight-only sailing restrictions applied in specific reaches for vessels that exceed certain DWT, length, and breadth criteria.
- No meeting during nighttime sailing for vessels exceeding a given draft limitation.
- No meeting during either day or night, applied to vessels by DWT, length, breadth, and draft combinations.

Relaxation of the existing pilot rules for the waterway was considered as a nonstructural alternative. However, given concerns about vessel handling and associated safety issues and that vessels utilizing the

waterway are wider than those using the channel even 5 to 10 years ago, the Sabine Pilots would not consider relaxing the rules. The expectation for the with- and without-project future is that pilot rules would continue to limit the possibility of vessel meetings in the Sabine-Neches Canal reach and that both vessel and shallow-draft tow movements would be scheduled through both VTS and communication between vessel pilots. More discussion of the transit rules and coordination with the SPA can be found in Chapter V, Economic Evaluation of Alternatives.

Alternative Mode of Commodity Transport

Offshore oil terminals were evaluated as an alternative mode of commodity transport to determine whether it was economically more effective for the primary users of the waterway (crude oil tankers) to utilize this mode of transportation than it would be to construct a deeper and wider channel. Two offshore terminal alternatives were considered in the analysis, one existing and one proposed. The decision to use an offshore terminal instead of lightering or constructing a deeper channel is complicated but largely depends on the relative cost per ton, relative market volumes, and facility accessibility.

Louisiana Offshore Oil Port

Louisiana Offshore Oil Port (LOOP) is America's first and only deepwater (offshore) port and has been operating at capacity since 2005. The LOOP is located offshore of Grande Isle, Louisiana, in 110 feet of water. Grande Isle is 302 miles east of Port Arthur and Beaumont. The LOOP was organized in 1972 as a Delaware corporation and converted to a limited liability company in 1996. Marathon Ashland Pipe Line LLC, Murphy Oil Corporation, and Shell Oil Company are the LOOP's owners. The LOOP is the only port in the U.S. capable of offloading deep-draft tankers known as Ultra Large Crude Carriers and VLCC. Along with offloading crude from VLCC, the LOOP also offloads smaller tankers. The LOOP consists of three single-point mooring buoys used for the offloading of crude tankers and a marine terminal consisting of a two-level pumping platform and a three-level control platform.

Access to the LOOP for the SNWW market would require substantial investment as SNWW crude oil import volume nearly equals LOOP's capacity. The LOOP's design capacity of 1.4 to 1.8 million barrels per day is marginally higher than SNWW 2004–2006 crude petroleum import volume, which ranged from 1.2 to 1.4 million barrels per day (USACE, 2007a). The investment necessary for LOOP to process SNWW's entire crude petroleum throughput would require a doubling of capacity.

A 48-inch-diameter pipeline connects the LOOP Marine Terminal located 23 miles offshore in the Gulf of Mexico to the Clovelly, Louisiana, storage facilities. Clovelly is approximately 260 miles east of the SNWW Port Arthur and Beaumont facilities. Four pipelines connect the onshore storage facility to refineries in Louisiana and along the Gulf Coast. The Clovelly facility provides interim storage for crude oil before it is delivered via connecting pipelines to refineries on the Gulf Coast and in the Midwest. The oil is stored in eight underground caverns leached out of a naturally occurring salt dome. In 1996, one cavern was dedicated to the production streams coming in from the deepwater Gulf of Mexico.

The domestic offshore crude oil system uses the same distribution system used by the foreign barrels. The caverns are capable of storing approximately 50 million barrels of crude oil (a barrel of oil is equal to 42 U.S. gallons). In addition, LOOP has an aboveground tank farm consisting of six 600,000-barrel tanks. LOOP operates the 53-mile, 48-inch LOCAP pipeline that connects the LOOP to CAPLINE (Amoco Cushing-Chicago Pipeline Company) at St. James, Louisiana. CAPLINE is a 40-inch pipeline that transports crude oil to several Midwest refineries. St. James is 227 miles east of Port Arthur and Beaumont. LOOP is connected to over 50 percent of the U.S. refinery capacity and has offloaded over 7 billion barrels of foreign crude oil since its inception.

Present users of LOOP consist of Louisiana-based refineries and U.S. Gulf Coast state domestic offshore production interests. In addition to new customers brought on due to infrastructure damages associated with the 2005 hurricanes, recent increase in the LOOP is tied to utilization associated with domestic production in the U.S. Gulf. It was noted that LOOP's existing base of customers uses it as one of several options for delivering crude oil to their Gulf Coast refineries (personal communication with Kathleen Jackson, Exxon, 2007). While all of SNWW's crude oil could not currently transfer to LOOP, additional tonnage could potentially be diverted. SNWW users continue to consider LOOP along with other alternatives; however, continued practices suggest that LOOP is not a cost-effective alternative to the existing SNWW practice of its land-based ports. The large fixed cost of expansion, and associated financing costs, necessitates participation by a consortium of companies. SNWW industries have not found the option of investing in LOOP, and the necessary associated infrastructure expansions, to be a cost-effective alternative to existing practices of either direct shipment or offshore lightering. The lack of incentive has remained since the 1970s. An additional variable pertinent to the current evaluation is that LOOP would appear to be a less-attractive cost option when compared to lower shipping costs that the SNWW improvement project is expected to provide.

LOOP is designed to handle 1.4 million barrels per day, but depending on the sizes of ships being serviced, it can handle 1.8 million barrels per day. The variance relates to the pumping rates of the tankers using the facility. Larger tankers tend to have faster pumping rates with some capable of pumping 80,000 barrels per hour. Smaller tankers may only be able to pump 35,000 barrels per hour. When fully operational, LOOP is generally the largest point of entry for crude oil imports into the U.S. About 13 percent of all waterborne foreign imports pass through LOOP each day. Again, LOOP's design capacity of 1.4 to 1.8 million barrels per day is only marginally higher than SNWW 2004–2006 crude petroleum import volume, which ranged from 1.2 to 1.4 million barrels per day. Of SNWW's approximately 1.3 million barrels per day import volume, terminals on the SNWW transport approximately 400,000 barrels per day of waterborne crude oil via pipelines to inland refineries including refineries in Texas, Louisiana, Oklahoma, Ohio, Arkansas, and Kentucky (Martin Associates, 2006). In total, the SNWW delivers approximately 12 to 16 percent of the crude oil supplied to domestic refineries east of the Rockies. Refineries supplied via the SNWW provide transportation fuels and other products to consumers along the Gulf Coast, East Coast, and Midwest regions. The SNWW ports presently receive about 1 percent of their daily input through LOOP. Additional offshore and landside infrastructure would be necessary for an increase in volume to take place.

Although there are some competing markets, the SNWW and LOOP generally serve parallel markets with LOOP consistently processing very large volumes and SNWW serving relatively smaller parcels. The sizes of the VLCC using LOOP typically exceed 300,000 DWT, whereas the maximum sized vessels using the SNWW are 175,000 DWT. The maximum design draft of these vessels is 55 feet or less. The minimum sized crude oil tankers using SNWW are in the 70,000 to 80,000 DWT range and have design drafts between 40 and 48 feet. LOOP's foreign petroleum imports are from the Middle East, whereas SNWW's market consists of direct shipments from Mexico and Venezuela and lightened mother vessels and shuttles. It has been noted that the cost effectiveness of LOOP lessens for small vessel sizes. The SNWW has the ability to serve a more general market and range of users. In discussions with local port and oil industry personnel, it is noted that LOOP and similar proposals serve crude petroleum but do not serve a full range of petroleum and bulk cargoes that use the SNWW.

The most-immediate obstacle to increased use of LOOP or a new offshore facility is major limitations for direct connection from LOOP to SNWW. A marginal increase in SNWW use of LOOP from its present 1 percent share would require LOOP pipeline connection modifications involving multiple pipelines and multiple companies. Such an investment may generate the necessity for higher throughput charges, which in turn may make access less cost effective than in the past. An industry analyst noted that, to a large extent, the companies demand that each segment, including pipeline transportation, stand on its own economically (Rabinow, 2004). The long-term availability of LOOP since the 1970s and low participation by SNWW companies indicate that LOOP and new offshore terminal proposals have not provided the market utilization incentives for significant shares of SNWW crude oil to shift towards these alternatives. The long-term trend is for domestic refining capacity to become more concentrated in regional centers and for imports of petroleum products to grow. This trend is evident with SNWW with crude oil import tonnage exceeding that of any other U.S. port and being equal to LOOP. Imports of refined products and partial refined crude oil have grown significantly as have the use of draft-constrained vessels for transporting these cargoes.

Bulk Oil Offshore Transfer System

Consideration of a Texas offshore oil terminal was also recognized as an alternative. In 2001, construction of a new terminal (called the Bulk Oil Offshore Transfer System, or BOOTS) offshore of Sabine Pass, Texas, was proposed. The relatively long distance from LOOP to SNWW and the need for additional infrastructure suggest that a facility closer to SNWW would be an attractive alternative to LOOP for SNWW channel improvements. However, the BOOTS facility has not yet been constructed and the regulatory permit application is inactive. The USCG has had no update on the proposal and does not expect a submittal. At the present time, the potential user of the proposed project is the terminal proponent. They noted that their participation as sole supporter is not feasible financially. It was specifically noted that their feedstock needs were not sufficient to finance the expansions to LOOP.

The BOOTS project proponent was contacted, and it was found that a new location farther down the Texas Coast near Freeport is presently being considered. The Freeport, Texas, site is about 100 miles southwest of the previous BOOTS location. Access by the SNWW refineries to a Freeport site involves

longer distances than the previous BOOTS location but it has advantages over LOOP. There is an existing pipeline from Freeport to Texas City; however, its connection to Port Arthur would necessitate a new pipeline from Texas City to SNWW, a distance of approximately 95 miles. Construction of a Freeport offshore facility could help serve the Freeport, Houston, and Texas City markets. Freeport's annual crude oil import volumes for the most recent 3-year period equate to approximately 0.4 million barrels per day; Houston's imports equate to about 1.0 million barrels per day; and Texas City's imports equate to about 0.9 million barrels per day. Industry indications are that the use of an offshore Freeport terminal would not serve as the exclusive supplier, just as LOOP is not the exclusive supplier for the Louisiana markets. Foreign imports by vessels into Louisiana and Mississippi are presently about 0.8 million barrels per day.

In a general discussion with industry, a representative noted that offshore oil terminal projects surface periodically, but the cost of these alternatives keeps them from moving beyond the initial planning stage. It is noted that the attractiveness of offshore alternatives over existing use of the SNWW is diminished by its ability to only serve one commodity (i.e., crude petroleum). It was added that the various crude oil blends and grades of oil introduce a range of additional concerns that add to throughput costs. The pipelines and associated infrastructure requirements vary between potential users and mingling of products and grades of crude is complex and difficult to facilitate. The construction of an offshore terminal that can meet the needs of various users is a challenge with the costs to realize multiparty usage creating an impasse to these proposals moving beyond the initial planning stage. Recognition of the cost of multiple pipelines necessary to meet the needs of the large base of customers necessary to finance these project alternatives has resulted in a stalemate in the decision process.

Expansion of LOOP, construction of a new offshore facility such as BOOTS, or an unloading terminal along the Sabine Pass or Port Arthur Canal reaches would reduce the vessel traffic on the Neches River. The reduction in ship traffic resulting from LOOP or BOOTS would reduce the economic viability of the SNWW deepening and widening project. However, past and present trends in infrastructure and fleet investments indicate that industry intends to continue using the Neches River Channel. An increase in the number of specially designed SNWW vessels was recently completed by one company, and another has invested in Neches River dock modifications for the larger "Aframax" and "Suezmax" vessels. The focus of immediate private sector petroleum vessel investments is concentrated on SNWW improvements rather than offshore or on the Sabine Pass Channel or Port Arthur Canal.

SNWW industry evaluation of offshore alternatives remains a reality; however, specific investments and commitments have not been made during a period when industry has invested in construction of new crude petroleum docks on the Neches River and in Port Arthur. Ongoing consultation with industry continues to show that commitments to offshore terminal investment have not materialized. During the 30 years since LOOP has become operational, several Texas Gulf Coast channel improvement projects have been completed and the benefits have been accrued. Offshore terminals would not accommodate products other than crude oil, and a significant proportion of benefits for the SNWW project improvement are from refined petroleum products. The offshore terminal was not found to meet the efficiency objective for all waterway users as it addressed the needs of only one user and commodity (crude oil). For these reasons, this alternative was eliminated from further consideration.

Structural Alternatives

In order to reach the appropriate depths offshore, all deepening alternatives would involve an increase in the Entrance Channel ranging from 5 to 25 miles in length. Deepening and widening alternatives that were evaluated during this second screening analysis are listed in Table IV- 1.

Table IV-1
Structural Alternatives

Alternative	Depths (feet) Evaluated	Section/Reach to be Widened	Widths (feet) Evaluated
No Action	40	None	Existing – Sabine Bank Channel to Outer Bar Channel – 800 Jetty Channel to Port Arthur Canal – 500 Sabine-Neches Canal/Neches River Channel – 400
Deepen only	43, 45, 48, 50, 53, 55	None	Existing
Deepen and Widen	43, 45, 48, 50, 53, 55	Sabine-Neches Canal/Neches River Channel to Beaumont	Widen to match lower reach – 500
Deepen and Widen	43, 45, 48, 50, 53, 55	Sabine Pass Channel – Sta. 180+00 to Port Arthur Canal – Sta. 275+00	600 or 700
Deepen and Widen	43, 45, 48, 50, 53, 55	Sabine Pass Channel – Sta. 265+00 to Port Arthur Canal – Sta. 85+00	600 or 700
Deepen and Widen	43, 45, 48, 50, 53, 55	Sabine Pass Jetty Channel	600 or 700
Deepen and Widen	43, 45, 48, 50, 53, 55	Sabine-Neches Canal	500, 600, 700, selective widening, or barge lanes
Deepen and Widen	43, 45, 48, 50, 53, 55	Neches River Channel	600, 700 or Turning Basins/Anchorages
Deepen and Widen	45, 48, 50	Sabine Pass Jetty Channel to Port Arthur Canal, selective widening on Taylor Bayou	700

Additional engineering and environmental analyses were conducted to identify the specific channel modifications and environmental impacts for the various depths. Modifications to these alternatives were considered in an effort to decrease costs and identify an economically justified project. As part of the iterative plan formulation process, the following alternatives were added:

- Deepening the SNWW to Beaumont to 48 feet, widening to 700 feet width through the end of the Port Arthur Canal, and deepening and widening the Taylor Bayou Channel and TBs, but with a modification (narrowing) of the Outer Bank and Sabine Bank channels to 700 feet width through the end of the channel.
- Deepening the SNWW to Beaumont to 48 feet, widening to 700 feet width through the end of the Port Arthur Canal, deepening and widening the Taylor Bayou Channel and TBs, and tapering Sabine Bank Channel from 800 feet wide (Station 23+300) to 700 feet wide (Station 25+800 through end of the channel).

- Deepening the SNWW to Beaumont to 47 feet, widening to 700 feet width through the end of the Port Arthur Canal, deepening and widening the Taylor Bayou Channel and TBs, and narrowing of the Outer Bar and Sabine Bank channels to 700 feet width through the end of the channel. The 47-foot depth alternative was considered later in plan formulation phase in an attempt to reduce project costs and find an economically justified project. This alternative was later dropped since a modification to the original 48-foot depth alternative was found to be economically justified.

Evaluation of Alternatives

As a result of the second screening, detailed evaluations were conducted on channel depths of 45, 48, and 50 feet in order to identify the optimal depth. Analysis of additional depths of 46, 47, and 49 feet were conducted later in the study to further optimize the NED depth. Along with these above-mentioned studies, various analyses including benefit and cost analyses, were conducted on the three alternative depths including the selective widening and TB/anchorage area options.

Incremental analyses of separable elements were also performed to determine if each was economically justified on its own. These separable elements included deepening to Port Arthur, deepening to Beaumont, and deepening Taylor Bayou with selective widening to ease navigation problems.

Second screening costs for the three depths were revised to include additional estimates developed for dock modifications, dock dredging, bridge pier replacement, costs for TBs and AB, and operations and maintenance (O&M) (including extension of the channel into the Gulf of Mexico to reach the proposed depth alternatives). Mitigation costs were assumed to be the same for each alternative for the reasons described below. Throughout this detailed analysis, environmental coordination and evaluation efforts were being conducted with the State and Federal resource agencies to identify mitigation requirements and BU locations for the estimated new work and maintenance material for the 50-year period of analysis.

Ecological mitigation costs for the six depth alternatives were estimated using the HS model salinity projection for the 40-, 45-, and 48-foot channel depths. Salinity was chosen as the best factor on which to base interpolation of mitigation costs because it is the primary driver in the ecological modeling that was used to determine the compensatory mitigation plan. The cost interpolation assumed that there would be a linear relationship between predicted salinities for each channel depth at the end of the period of analysis and the cost of mitigation.

Direct ecological effects associated with the navigation channel improvements under all proposed alternatives and the placement of dredged material consist of:

- Impacts to benthic organisms and their Gulf, estuarine, and riverine water-bottom habitats would be similar for all alternatives. Benthic organisms are expected to quickly rebound from the short-term impacts of channel dredging, the use of offshore PAs, and the Sabine Lake borrow trench/access channel associated with compensatory mitigation in Louisiana.
- Dredging impacts to bottom-feeding and pelagic organisms such as sea turtles may occur with hopper dredging of offshore channel reaches for all alternatives; reasonable and prudent measures to avoid impacts would be instituted with an avoidance plan.

- Impacts to marsh would result from the enlargement of one PA under the No-Action Alternative, and two PAs under all other alternatives. The new PAs would be small and the incremental cost associated with one additional PA are too small to affect alternative selection. Most PAs would be enlarged by raising levee heights, which means that the footprint of the PA impacts would be similar for all alternatives.
- Impacts to shorebirds and their habitat would result from the regular placement of maintenance material on the Gulf shoreline under all alternatives, including the No-Action Alternative. Birds would be temporarily displaced to nearby habitat during each placement episode. These impacts would be minor and temporary, and the number and footprint of each placement episode would be the same for each alternative.

Indirect effects provide the primary ecological impacts of all structural alternatives. Although the SNWW channel is located primarily in Texas, large indirect impacts may occur in both Texas and Louisiana due to small increases in salinity levels causing an increase in wetland loss rates and a decrease in biological productivity in aquatic habitats of the study area. HS modeling indicates that none of the depth alternatives would result in significant impacts to swamp and fresh marsh habitats in the upper reaches of the Sabine and Neches rivers. Salinity impacts of the six depth alternatives to the vast saline through intermediate marshes would be similar, with an average difference between the 45- and 50-foot alternatives of less than 0.5 ppt.

Second Screening Costs

Second screening costs were prepared for the existing channel width (500 feet) at the six alternative depths. These costs are included in Table IV-2. These estimates included costs for relocations (including utility relocations), dredging, levee construction, engineering and design, and construction management. Costs for selective widening to 700-foot widths were determined for two channel reaches for all six alternative depths and the existing 40-foot depth. Costs for O&M for each of the structural alternatives were not included in this second screening evaluation of the alternatives, but would be considered later in the screening process. Costs for real estate lands and damages, mitigation, and BU features were not calculated for the 120 plus variations during this screening. Project benefits were based on reductions in transportation costs generated from more-efficient vessel loading and from reduction in vessel delays for the channels to Port Arthur and Beaumont. With the high number of alternatives to be screened, the results of the economic analysis, specifically the BCRs and the net excess benefits, were used as the main screening tool.

Ecological benefits and mitigation costs were not calculated for the nonstructural and 120-plus variations of structural alternatives for channel improvements during the screening process. However, all alternatives, including the No-Action Alternative, were informally reviewed for potential effects to the environment in a nonquantitative manner, and this information was evaluated along with cost data in determining which plans would advance into detailed evaluation.

Table IV-2
SNWW (including Taylor Bayou and Neches River Channels)
Alternative First Cost
(2002 Calculations)

Channel Depth (feet)	First Cost Deepening (\$)
43	134,295,000
45	191,843,000
48	297,787,000
50	373,275,000
53	496,691,000
55	575,436,000

Second Screening Economic Analysis

Project Benefits

An economic evaluation of various deepening and widening alternatives was conducted to identify alternatives that maximized NED benefits. This evaluation is presented in detail in Chapter V of this report. Benefits were calculated for Port Arthur and Beaumont depth alternatives of 43, 45, 48, 50, 53, and 55 feet, and for other separable elements of the proposed CIP. Based on the BCRs, the screening analyses indicated that the improvements through the Neches River Channel to Beaumont were economically justified. It was found that 65 percent of the project benefits were associated with the upstream Beaumont area and 35 percent with the Port Arthur area; therefore, continuing improvements up the Neches River to Beaumont was economically justified. Alternative depths of 45 feet and greater had higher net excess benefits than depths less than 45 feet. In addition, the non-Federal sponsor did not wish to pursue depths less than 45 feet; therefore, depth alternatives less than 45 feet were dropped from further analysis.

Preliminary benefit calculations prepared for the early screenings were limited to crude petroleum and refined petroleum products. These groups represent over 88 percent of 2000–2006 total deep-draft tonnage. Tables IV-3 to IV-5 display the transportation savings benefits calculated for the second screening. The benefits for the Neches River Channel to Beaumont deepening are shown in Table IV-3, and the benefits for the Taylor Bayou reach are shown in tables IV-4 and IV-5. The benefits presented in Table IV-4 assume deepening Taylor Bayou, widening at the mouth of the Bayou and the west TB bottleneck curve, and placement of a structural wall that would protect local railroad tracks. The widening associated with the Table IV-4 scenario would facilitate the existing fleet and reduce the level of maneuvering necessary. The second set of Taylor Bayou benefits (Table IV-5) assumes major reconfiguration of the Taylor Bayou channel so that larger Aframax and Suezmax vessels (i.e., 120,000 to 175,000 DWT) could access the facilities. Facilitating the full range of Aframax and Suezmax vessels would require moving the railroad tracks rather than just constructing a retaining wall. The maximum sized tankers presently using the Taylor Bayou channel are in the 80,000 to 115,000 DWT range.

Table IV-3
Average Annual Benefits (\$), Neches River Channel
(2002 Calculations at 6.375%, 50-Year Period)

Channel Depth (feet)	Crude Oil Imports	Petroleum Products		Total Benefits
		Imports	Exports	
43	11,192,741	2,673,782	1,034,112	14,900,635
45	13,905,184	3,429,983	1,327,696	18,662,863
48	21,048,641	5,396,346	2,090,369	28,535,356
50	23,182,977	6,448,183	2,497,512	32,128,672
53	26,816,688	7,580,793	2,929,141	37,326,622
55	29,047,523	8,067,929	3,114,431	40,229,883

Table IV-4
Average Annual Benefits (\$), Taylor Bayou Channel and Basin
Accommodates Limited Range of Aframax Vessels
(2002 Calculations at 6.375%, 50-Year Period)

Channel Depth (feet)	Crude Oil Imports	Petroleum Products		Total Benefits
		Imports	Exports	
43	5,415,881	653,569	855,527	6,924,977
45	6,715,426	836,923	1,096,613	8,648,962
48	10,147,206	1,314,065	1,723,108	13,184,379
50	10,918,029	1,567,326	2,035,245	14,520,600
53	11,216,492	1,567,326	2,035,245	14,819,063
55	11,216,492	1,567,326	2,035,245	14,819,063

Table IV-5
Average Annual Benefits (\$), Taylor Bayou Channel and Basin
Accommodates Limited Range of Aframax and Suezmax Vessels
(2002 Calculations at 6.375%, 50-Year Period)

Channel Depth (feet)	Crude Oil Imports	Petroleum Products		Total Benefits
		Imports	Exports	
43	6,546,410	789,997	1,034,112	8,370,519
45	9,130,533	1,013,283	1,327,696	10,471,512
48	12,309,970	1,594,143	2,090,369	15,994,482
50	13,526,683	1,904,115	2,497,512	17,928,310
53	15,641,626	2,255,707	2,929,141	20,826,474
55	18,999,767	2,398,070	3,114,431	24,512,268

Table IV-6 summarizes the results of the screening depth optimization. The Taylor Bayou construction cost contained in Table IV-6 assumes deepening of the existing channel framework and limited widening. The widening associated with the cost shown would facilitate the upper end of the existing fleet and reduce the level of maneuvering necessary but it would not accommodate the full range of Aframax and Suezmax tankers.

53	16,548,523	1,105,259	14,819,063	13,713,534	13.4
55	19,051,425	1,272,425	14,819,063	13,546,638	11.6

Second Screening Net Excess Benefits

As indicated in Table IV-6, the results of the initial formulation showed that the 48- to 50-foot channel depth produced the highest net excess benefits. While additional commodities, specifically aggregate, grain, chemicals, and LNG, were not included in the initial formulation, it was anticipated, based on analyses conducted for other studies, that inclusion of these additional groups would push the formulation closer to 48 feet rather than 50 feet. Consideration of LNG came later in the plan formulation process after the Federal Energy Regulatory Commission (FERC) approval and construction commencement. However, its inclusion also had the effect of pushing the depth optimization below 50 feet.

Consideration of relatively flat net excess benefits between the 48- and 50-foot depth, as well as the anticipated effects on the formulation from additional commodities as discussed above, and the Sponsor's interest in minimizing the construction costs suggested that the focus of the detailed formulation should be on depths between 45 and 50 feet. The NED plan is the plan that reasonably maximizes net NED benefits. This second screening analyses indicated that the 48-foot depth had the highest net excess benefits and would be the probable NED depth. More-detailed analysis was conducted to confirm the identification of the NED depth. Analysis of additional depths, such as 46, 47, and 49 feet, was conducted

later in the study in order to determine potential changes to NED depth optimization based on 1-foot depth increments.

Evaluation of Structural Alternatives

Deepening and Widening

Interest in the project was driven by two factors: (1) allow the existing fleet to carry additional cargo, and (2) reduce congestion and associated risk along the waterway. For a given volume of traffic, channel deepening results in fewer trips and reduces congestion. With this in mind, the optimization initially focused on depth and then looked for widening options. Determination of channel width alternatives was driven by pilot input and followed up with the ERDC vessel (ship) simulation modeling. During the screening, channel widening was evaluated for all of the channel reaches from Sabine Pass Channel, inland through the Neches River Channel. With the exception of the Entrance Channel reaches, widening alternatives were limited because of physical structures, including docks on the Neches River and Sabine-Neches Canal reaches and the Port Arthur Hurricane Protection Levee in the Sabine-Neches Canal reach. The widening alternatives were subsequently screened based on comparison of associated vessel delay costs and initial project construction cost estimates.

The ERDC model results, transportation cost outputs, project construction costs, and anticipated environmental effects helped in identifying the optimal choice of plans. The results of the ERDC ship simulation showed that a channel width of 700 feet through the Sabine Pass Channel and Port Arthur Canal would be necessary for the Suezmax and Aframax vessels to meet smaller vessels in these channel reaches. The project design vessel is 899 feet long and 164 feet wide. These dimensions correspond to a 158,000 DWT Suezmax crude petroleum tanker. A loaded and a ballast design vessel could not successfully meet in the ERDC test of the 600-foot channel, nor could the design vessel and a smaller 110,000 DWT tanker meet.

As noted, the ERDC ship simulation showed that a width of 700 feet was necessary for the largest combinations of vessels. While the results of the ERDC ship simulation modeling showed that a minimum width of 700 feet was necessary for inbound and outbound vessel meeting for many vessels in the existing and future fleet, economic analysis of alternative widths was also included as part of the HarborSym economic widening model. Preliminary estimates of the widening benefits were calculated during the preliminary screening; however, a width optimization analysis was not performed until the second screening.

Numerous widening scenarios were evaluated in the various alternatives in the second screening. Narrowing of the entrance channel from the existing 800-foot width to a 700-foot width was investigated in the phase for cost reduction purposes. The Ship Simulation studies verified that these channels could be narrowed from 800 to 700 feet, with the exception of the Sabine Pass Outer Bar Channel where the 800-foot width was necessary because of crosscurrents in that area. Based on the analysis, the Sabine Outer Bar Channel would maintain the existing 800-foot width. For the Sabine Bank Channel and Extension, the channel would taper down to a 700-foot width after the first ½ mile. The Sabine Pass Jetty Channel

would transition from 800-foot to 500-foot width going upstream through the jetties. No impacts to the existing jetties would occur as a result of the modifications. The Sabine Pass Channel and the Port Arthur Canal would remain 500 feet wide with the Sabine-Neches Canal remaining 400 feet wide. The Neches River Channel would maintain the 400-foot width with new and existing TBs/AB. Pilots expressed concern that widening the Neches River Channel would prove too costly and would raise numerous environmental issues that would prevent completion of the widening project. They preferred the use of TBs and AB to help traffic efficiency. Ship simulation confirmed that no widening was necessary and TBs and AB were acceptable navigation modifications to improve navigation efficiency.

Turning Basins and Anchorage Basins

As an additional structural alternative, modifications to existing TBs and AB or creation of new TBs and/or AB along the waterway were considered, coordinated with the SPA, and modeled by the ERDC. The proposed Neches River TB anchorages were identified as a less costly alternative to channel widening. The anchorages would be used to facilitate vessel passing. Preliminary estimates of the TB and AB benefits were not calculated during the preliminary screening but later in the study process.

Barge Lanes

Another structural alternative evaluated was the construction of a barge shelf in a portion of the Sabine-Neches Canal. Interest in the barge shelf was prompted by the large volume of tow-barges using the Sabine-Neches Canal reach, along with a high flow of deep-draft traffic. The mix of deep- and shallow-draft traffic in this reach raised safety concerns and prompted interest in evaluation of a barge shelf through the canal reach between the east and west junctions with the GIWW. Initial responses to the barge shelf alternative revealed large variances in expectations about potential effects, with some tow operators questioning the usefulness and safety of the proposed project feature. For these reasons, in 2005 the Gulf Intracoastal Canal Association (GICA) withdrew their support for the barge shelf. The GICA is an organization created to ensure that the GIWW is maintained, operated, and improved to provide the safest, most efficient, economical, and environmentally sound water transportation route in our Nation. Part of their mission is to identify existing physical hazards and other opportunities to improve the safety and efficiency of the GIWW (GICA, 2008).

The initial indication from some of the deep-draft and shallow-draft operators was that a barge shelf could provide an increased degree of safety; however, benefits from casualty reductions were not calculated because the without-project condition is “avoidance behavior” in the form of pilot rules, radio, VTS communication, and transit delays. The indication from some vessel operators was that if a barge shelf was available, vessel operators would only use it in an emergency but that avoidance of tow-vessel and tow-tow meetings in the Sabine-Neches Canal would continue as the most likely future.

Anticipated and continued success of the VTS, as a nonstructural alternative, contributed to the vessel operators’ decision to forgo the barge shelf. Overall, improved deep-draft and barge vessel communication was initiated by the USCG and user safety board that resulted in questions concerning the need for the barge shelf. Ongoing improvements to the VTS system are expected to result in accelerated

safety and communication improvements. The VTS nonstructural initiative made by the USCG, SPA, and GICA represent alternatives to the barge shelf proposal.

Plans Eliminated During Second Screening

For evaluation of the nonstructural alternatives, the alternative mode of commodity transport (LOOP and BOOTS) and the VTS alternatives would help with improving safety along the existing channel (by reducing vessel traffic or better managing the traffic). However, these alternatives do not address the navigational efficiency of the waterway and would not allow the vessels utilizing the channel to load more fully. The potential relaxation of the current transit rules by the pilots was evaluated but screened out as not implementable because the pilots do not support this course of action. Therefore, all nonstructural alternatives were eliminated from further consideration.

The widening alternatives included widening of the Sabine Pass Channel and Port Arthur Canal from 500 to 700 feet. Although the widening in combination with the deepening of the channel was economically justified, the widening alone resulted in a BCR of 0.4. The economic summary of this channel widening is included in Table IV-7. Therefore, the widening alternative for this reach was not an incrementally justified feature and was eliminated from further evaluation.

Table IV-7
Sabine Pass Channel and Port Arthur Canal
Widening Only (700 feet)
Economic Summary Data (2008 Dollars at 4.375%)

Item	Sabine Pass and Port Arthur Canal (\$)
First Cost	78,448,000
Mitigation Cost	48,484,500
Interest During Construction	36,282,311
Total First Cost	163,241,841
Average Annual Construction Cost	8,091,727
Incremental Average Annual O&M Cost	9,587,005
Total Average Annual Cost	17,678,732
Average Annual Benefits	6,379,579
BCR	0.4

As previous shown in Table IV-6, net excess benefits were relatively flat from depths of 48 to 50 feet. However, construction costs increased significantly between those depths. The results of this screening analysis indicated that NED depth was between 48 and 50 feet, with the highest net excess benefits being at the 48-foot depth. Due to cost-sharing requirements for deep-draft channels (depths greater than 45 feet) and the Sponsor's uncertainty of the preferred depth, the 45-foot depth alternative was also carried forward for further analysis. Continuous widening of the Sabine-Neches Canal and Neches River Channel to 500 feet throughout their lengths was eliminated when the ship simulation determined that a 700-foot width was necessary for safe two-way traffic.

In summary, since structural alternatives (e.g., deepening the channel) were the only alternatives that would fully address the project objective of navigational efficiency, only the No-Action Alternative and some structural alternatives for improvements to the SNWW navigation system were carried forward for detailed analysis. Among all of the structural alternatives, only six depths (45, 46, 47, 48, 49, and 50 feet) were carried forward into detailed evaluation.

IV.E FINAL SCREENING OF ALTERNATIVES

During detailed evaluation of screened alternatives, the identification of the Recommended Plan was based upon technical, economic, and environmental factors. Operation and maintenance costs for extending the entrance channel for the deeper depth alternatives were developed to better estimate project costs of each proposed depth.

Final Screened Alternatives

Based on additional information from the traffic analysis, the revised BCRs, net excess benefits, and the Sponsor's lack of support for depths greater than 50 feet, the deepening alternatives were screened to a 5-foot range from 45 to 50 feet, focusing on those depths with the highest net excess benefits. Selective widening and TBs were also carried forward for more-detailed analysis and formulation with the deepening alternatives.

This selective widening included sections in the Sabine-Neches Canal and the Neches River Channel. The Sabine-Neches Canal included realignment in the section adjacent to Port of Port Arthur to place the centerline directly in the center of the channel width. This change shifted the channel over approximately 10 feet while keeping the same bottom width. This allowed for additional berthing space in the area while avoiding impacts to the Hurricane Protection Levee and Pleasure Island properties. Additionally, bend easings were included to improve ship maneuverability and eliminate a wiggle in the alignment. The Neches River Channel was widened at the mouth of the Neches River prior to the State Highway (SH) 87 twin bridges. Additional TB/AB or enlargement of existing TB/AB on the Neches River Channel were also included in the final screening.

The structural alternatives evaluated during this final screening phase of the study are listed in Table IV-8.

Since the deepening alternatives would result in the existing project channel extending in the Gulf of Mexico (potentially an additional 17 miles), consideration of O&M costs, in addition to other detailed evaluations and analyses, was deemed necessary in conducting the further screening.

The identification of the Recommended Plan from the various alternatives was based upon economic and environmental factors. Costs were estimated for all of the alternatives and compared to the project benefits. Included in the costs were dredging, levee construction, relocations (including utility relocations), and O&M costs for the 50-year period of analysis. Costs for ecosystem mitigation were estimated using HS model salinity projections.

Table IV-8
Alternatives for Final Screening

Alternative	Depths (feet)	Sections	Width (feet)
Deepening	45, 46, 47, 48, 49, 50	Extension Channel	700
		Sabine Bank Channel	700 (tapers to 800)
		Sabine Pass Outer Bar Channel	800 (existing)
		Sabine Pass Jetty Channel	500 (existing)
		Sabine Pass Channel	500 (existing)
		Port Arthur Canal	500 (existing)
		Taylor Bayou	selective widening
		Sabine-Neches Canal	400 (existing)
Turning Basins/ Anchorage Basins (various combinations)	48	Neches River Channel	400 (existing)
		Neches River Channel	

Table IV-9 presents the economic summary of the final screening of alternatives and includes BCRs and net excess benefits for the 45- to 50-foot plans, including TBs and AB. From these data, the 49-foot depth produced the most net excess benefits compared to the cost of the proposed project modifications. Therefore, the 49-foot alternative was identified as the NED Plan. The sponsor has indicated a preference for the 48-foot project because of cost savings. Therefore, the 48-foot project is the locally preferred plan (LPP).

Table IV-9
SNWW Economic Summary Data
Cost and Benefits (\$1,000s) by Channel Alternative
(50-Year Period of Analysis at 4.375%)
(December 2008 Vessel Costs)

	45 feet	46 feet	47 feet	48 feet	49 feet	50 feet
First Cost of Construction (\$)	798,920	889,906	980,891	1,071,877	1,152,079	1,232,280
Total Annual Cost (\$)	70,217	77,258	84,299	91,341	96,626	101,911
Average Annual Benefits (\$)	83,844	95,856	104,303	115,074	122,875	127,696
Net Excess Benefits (\$)	13,627	18,598	20,004	23,733	26,249	25,785
BCR	1.2	1.2	1.2	1.3	1.3	1.3

Finally, the abbreviated array of alternatives was compared against the four primary evaluation criteria specified in the P&G: acceptability, completeness, efficiency, and effectiveness (Table IV-10). To meet the first criterion, plans should be acceptable to State and Federal resource agencies and local governments; they should also be able to show evidence of broad-based public support. To be considered complete, plans must provide and account for all investments necessary to implement the plan. For the third criteria, plans must be cost effective. For the final criterion, effectiveness, the plan must make a significant contribution to addressing the specific planning objectives addressed by the study.

Table IV-10
Comparison of P&G Evaluation Criteria

Item	No Action	45 feet	NED – 49 feet	LPP – 48 feet
Criteria	Maintain existing 40-foot-deep x 800-foot-wide x 22-mile-long Sabine Bank and Outer Bar channels, transitioning to 500 feet wide in the Sabine Pass Jetty Channel, and 400-foot x 40-foot-deep channel to Beaumont	45-foot-deep x 8.45-foot-deep x 8.3-mile-long x 800-foot-wide Extension, Sabine Bank, and Outer Bar channels, transitioning to 500-foot-wide channel to end of Port Arthur Canal, and 400-foot x 45-foot-deep channel to Beaumont; deepening and widening of Taylor Bayou Channels and Basins	4- foot-deep x 16.5-mile-long x 800-foot-wide Extension, Sabine Bank, and Outer Bar channels, transitioning to 500-foot-wide channel to end of Port Arthur Canal, and 400-foot x 49-foot-deep channel to Beaumont; deepening and widening of Taylor Bayou Channels and Basins	48-foot-deep x 13.2-mile-long x 700-foot-wide Extension and Sabine Bank channels, 800-foot-wide Outer Bar Channel, then 500-foot-wide channel to end of Port Arthur Canal, and 400-foot x 48-foot-deep channel to Beaumont; deepening and widening of Taylor Bayou Channels and Basins
Acceptability (meets all laws, regulations and guidance)	Acceptable	Acceptable	Acceptable	Acceptable
Completeness (provides and accounts for all necessary investments or other actions to ensure the realization of the planning objectives)	No Action is an incomplete solution to all planning objectives	Plan is an incomplete solution; it provides some improvement in navigation efficiency over No Action but does not maximize transportation benefits	Plan is a complete solution; it maximizes navigation efficiency over other plans; no impacts to bridges and Hurricane Flood Protection (HFP) Plan	Plan is more complete than others, but does not maximize transportation benefits, no impacts to bridges and HFP Plan
Efficiency (extent to which an alternative plan is the most cost effective means of achieving the objectives)	No Action does not address the planning objectives	Less costly than Recommended Plan but does not address objectives as effectively; net excess benefits are not maximized	More costly than Recommended Plan; achieves all objectives; net excess benefits are maximized	Cost-effective; achieves all objectives; net excess benefits are not maximized; Sponsor indicated this plan is LPP
Effectiveness (extent to which the alternative plans contribute to achieve the planning objectives)	Ineffective for improving navigational efficiencies	Not as effective as Recommended Plan for improving navigation efficiency or maintaining environmental quality	Most effective plan for improving navigation efficiency and maintaining environmental quality; Sponsor has indicated this plan is not affordable	Not as effective as NED Plan for improving navigation efficiency; Sponsor has indicated this plan is LPP

IV.F IDENTIFICATION OF THE RECOMMENDED PLAN

The detailed evaluation of screened alternatives concluded with the identification of a Recommended Plan. The identification of the Recommended Plan was based upon a comparison of economic, engineering, environmental, and socioeconomic factors, as well as the Sponsor's preference. The alternative described below has been identified as the Recommended Plan:

Deepening of the SNWW to Beaumont to 48 feet with an extension of the Entrance Channel 13.2 miles in length, deepening and widening of Taylor Bayou Channel and turning basins, and tapering the Sabine Bank Channel from 800 feet wide (Station 23+300) to 500 feet wide (Station 25+800 through the end of Sabine Bank Channel). Turning and anchorage basins would be added and/or enlarged along the Neches River Channel and bend easing performed on the Sabine-Neches Canal and Neches River Channel.

Detailed evaluations of alternatives for the management of dredged material and the mitigation of ecological impacts were then performed for the Recommended Plan. This evaluation concluded with the development of a DMMP and a mitigation plan. The DMMP includes measures in which dredged material is used to restore wetland habitat, offsetting impacts of the Recommended Plan. The evaluation of alternatives for the management of dredged material and the recommended placement plan are described in Chapter VII of this report and in Section 2.5 of the FEIS. The evaluation of mitigation alternatives that compensate for remaining unavoidable impacts to significant habitats and resources and the recommended mitigation plan are described in Chapter 5 of the FEIS. Least cost analyses of dredged material placement and an incremental cost analysis of mitigation alternatives were conducted to select recommended placement and mitigation measures. These analyses are presented in Chapter VIII of this report.

IV.G PRINCIPLES AND GUIDELINES EVALUATION ACCOUNTS

The four P&G evaluation accounts were used throughout the planning process to evaluate the effects of the project alternatives. Each of the four accounts is identified below as well as an explanation of how the Recommended Plan complies with these evaluation accounts.

National Economic Development

The NED account shows the changes in the economic value of the national output of goods and services. The main economic benefit from a navigation project is the reduction in the value of the resources required to transport the various commodities associated with the waterway. National benefits can result from any of the following: increased efficiency of moving commodities resulting in cost reductions in commodities, savings from using a more-cost-effective mode of transportation (alternate mode of transportation), a shift in origin and destination of commodities thereby reducing the costs of transport, new

movements of commodities, and/or commodities delivered either at less cost or additional commodities being transported due to lower transportation costs.

The Recommended Plan is the culmination of the various benefit analyses mentioned above. The 49-foot depth including TBs and AB was found to produce the most net excess benefits compared to the cost of the proposed project modifications. Therefore, the 49-foot alternative was identified as the NED Plan. However, the Sponsor has indicated that the 48-foot plan is preferred because the cost of the NED and deeper plans would make the project unaffordable. The 48-foot plan is the LPP, the plan preferred by the sponsor.

The USACE guidance requires that the NED plan be recommended unless there are believed to be overriding reasons favoring the selection of another alternative. Planning guidance (ER 1105-2-100) states that if the non-Federal sponsor identifies a financial constraint due to limited resources, and if net benefits are increasing as the constraint is reached, a categorical exemption may be granted and the constrained plan recommended. Categorical exemptions for plans that are lesser projects than the NED plan are cost shared on the same basis as the NED and become a federally supportable plan.

In this study's selection of the Recommended Plan, the sponsor has indicated a preference of the 48-foot LPP due to cost restraints. This plan is a justified plan that is less costly than the NED plan. This LPP still meets the policies for the high-priority outputs and has greater benefits than the smaller scale plans (see Table IV-9). Since the 48-foot plan is the Sponsor's preference due to financial constraints and fits all of the criteria regarding categorical exemptions for navigation projects, this plan has been identified as the Recommended Plan. This LPP is less costly than the NED plan; therefore, cost sharing will be the same as the NED plan.

Effects on Environmental Quality

The Environmental Quality account identifies the nonmonetary effects on significant natural and cultural resources (ER 1105-2-100). The primary impact of the Recommended Plan is an indirect impact associated with an increase in salinity intrusion and an associated reduction in biological productivity over 182,000 acres of intertidal marsh and swamps within the area of tidal influence in the Sabine-Neches study area. As quantified by the WVA model, the net decrease in productivity for the project as a whole is -843 average annualized habitat units, or AAHUs, after application of benefits from the Recommended Plan. Later in this report, Table VIII-2 summarizes the calculations made resulting in these -843 AAHUs. Minor impacts to cypress-tupelo swamp or bottomland hardwood productivity are projected. The ICT considered this to be acceptable since the loss in function is negligible. No adverse impacts to threatened or endangered species or Critical Habitat would result from the indirect effects of salinity increases or land losses.

Most of the direct effects of the Recommended Plan on ecological systems and resources are minor and temporary. These impacts are associated with navigation channel improvements and the placement of dredged material. They include (1) impacts to benthic organisms and their Gulf, estuarine, and riverine

water-bottom habitats resulting from dredging to construct the navigation improvements, offshore PAs, borrow areas for mitigation measures, and marsh restoration in shallow, open-water areas; (2) potential dredging impacts to bottom-feeding and pelagic organisms such as sea turtles; and (3) impacts to shoreline birds and their habitat from the placement of maintenance material on the Gulf shoreline.

The Recommended Plan would have no long-term adverse environmental effects, after benefits of the DMMP and compensatory mitigation are taken into account. The Recommended Plan is expected to produce beneficial effects that would contribute to the long-term sustainability of valuable habitat in the SNWW area as described below. A detailed discussion of the effects of the Recommended Plan and the mitigation plan are presented in the FEIS.

BU features of the DMMP (Neches River and Gulf Shore BU Features) would minimize and offset all direct and indirect marsh impacts in Texas by creating 2,853 acres of emergent marsh vegetation, improving 871 acres of open water habitat, and nourishing 1,234 acres of existing marsh in Texas. Benefits of the Neches River BU Feature also more than offset the direct impact of conversion of 86 acres of fresh marsh to a confined PA (PA 24A) and the indirect impact of the increase in salinity over 39,000 wetland acres in Texas. The Gulf Shore BU Feature offsets minor erosion impacts by periodically nourishing 6 miles of Texas and Louisiana Gulf shorelines.

Since the DMMP offsets all impacts of the Recommended Plan in Texas, no compensating mitigation would be required for Recommended Plan effects in this state. It is important to note that the impacts presented here do not include all impacts of the Preferred Alternative in Texas as future with project (FWP) impacts in Texas's Salt Bayou (TX 9) hydro-unit are not included. Jefferson County, Texas, and USACE, with support from the Texas Parks and Wildlife Department (TPWD), GLO, and Texas Water Development Board (TWDB), have been studying ways to reduce the amount of saltwater intrusion, decrease high-energy inflows, and minimize impacts to larval fish access in an on-going Section 1135 Continuing Authorities Project (CAP) study for the Salt Bayou hydrologic unit. When the Keith Lake Section 1135 CAP study was begun in 2003, it seemed likely that the CAP study and construction would be completed before the SNWW CIP could be authorized and constructed. The Keith Lake Section 1135 study was therefore considered separable from the SNWW CIP, and for planning purposes, it was assumed that a water control structure at the Fish Pass would be part of the future without-project condition for the SNWW CIP. Incremental impacts of the SNWW CIP will be calculated for the Salt Bayou unit of the SNWW study area when WVA modeling is completed for the Keith Lake Section 1135 study. It is possible that the excess DMMP benefits (316 AAHUs) of the SNWW CIP will cover all incremental project impacts. However, if it is determined that additional mitigation is needed, then USACE and the non-Federal sponsor of the SNWW CIP will initiate consultation with resource agencies, identify and incrementally justify additional compensatory mitigation for the Salt Bayou unit, and prepare a supplemental environmental impact statement (EIS).

Unavoidable losses to marshes in Louisiana, which remain after application of all DMMP benefits, are fully mitigated by marsh creation in the Willow Bayou and Black Bayou watersheds east of Sabine Lake.

Potential adverse effects to threatened and endangered sea turtles from the use of hopper dredges to construct the Entrance Channel in the Gulf of Mexico would be avoided by the adoption of reasonable and prudent measures recommended by the USFWS Biological Opinion. No long-term impacts to air quality or noise levels are expected, and temporary impacts to air quality during construction have been determined to be in general conformity with the Texas State Implementation Plan. No impacts to historic properties have been identified at this time. However, should adverse effects to historic properties be identified in the future, mitigation plans would be developed and implemented in accordance with the Historic Properties Programmatic Agreement for the Treatment of Historic Properties (FEIS, Appendix H).

DMMP BU features on the Neches River and compensatory mitigation east of Sabine Lake are expected to have long-term beneficial effects on water quality and terrestrial and aquatic habitats. Both entail the restoration of large-scale areas of degraded marsh. Restored marshes would filter runoff from surrounding uplands, and improved shallow-water habitat would encourage the growth of additional submerged aquatic vegetation. The restored marshes would increase available habitat for bird and wildlife species, and the improved shallow-water habitat would provide additional nursery areas and nutrients for aquatic organisms. Gulf shore nourishment is expected to have a long-term beneficial effect on piping plover Critical Habitat at Louisiana Point, by replacing shoreline habitat predicted to be lost as a result of plan implementation.

Regional Economic Development (RED)

The RED account identifies changes in the distribution of regional economic activity. Evaluations of regional effects are to be carried out using nationally consistent projections of income, employment, output, and population (ER 1105-2-100). With the value of the current 40-foot SNWW channel to the region, it is expected that the Recommended Plan of deepening the channel for navigational efficiency and safety would increase benefits to the region. Even with the implementation of the Recommended Plan, the study area would continue to have large industrial facilities and would not result in negative impacts to the local economy. During project construction, the study area may have a slight increase in construction employment and local purchases of construction materials but would be temporary, if any change at all. The primary economic bases of the study area include petrochemical processing, construction, mineral extraction, tourism, commercial fishing, and agriculture. As a result of the Recommended Plan, the positive economic effects to the study area would be moderate at the least and substantial at best. A detailed overview of RED is included in the Economic Appendix.

Other Social Effects

The other social effects account identifies the plan effects from perspectives that are relevant to the planning process, but are not reflected in the other three accounts (ER 1105-2-100). The Recommended Plan would likely not have an effect on population growth trends within the study area. As a result of the Recommended Plan, demand for community facilities, services, and housing would not increase in the study area. The population living within the study area is primarily composed of White persons (59.6 percent), followed by Black or African American persons (26.7 percent), and Hispanic or Latino

persons (9.6 percent). The proposed project would not be located within a minority area. The minority and low-income populations living within the study area would likely experience no adverse changes to the demographic, economic, or community cohesion characteristics within their respective neighborhoods as a result of the Recommended Plan.

The construction of the Recommended Plan would have minimal negative effects on recreation within the study area, and proposed BU of dredged material from the construction of the Recommended Plan are expected to have beneficial impacts to recreational activities by providing additional habitats important to current sportfishing, recreational fishing, wildlife watching, and hunting.

V. ECONOMIC EVALUATION OF ALTERNATIVES

V.A OVERVIEW

This chapter presents the economic analysis for proposed project modifications to the existing 40-foot SNWW channel. The project benefits were evaluated for deepening and widening the channels to Port Arthur and Beaumont and are based on reductions in transportation costs generated from more-efficient vessel loading and from reductions in vessel delays. Improvements to the 30-foot Sabine River Channel to Orange were not evaluated at this time due to the expectation of continued low utilization of the existing project depth.

V.B SCREENING PROCESS

Deepening benefits were calculated for SNWW depth alternatives of 45, 46, 47, 48, 49, and 50 feet. Determination of the depths evaluated was based on the cost-benefit results of the alternative screening and input from the Sponsor. Widening benefits for deep-draft traffic were also evaluated. Evaluation of widening alternatives was based on data obtained from vessel simulation modeling conducted by the ERDC. The alternatives were subsequently screened based on comparison of associated vessel delay costs and the initial project construction cost estimates. The ERDC model results, transportation cost outputs, project construction costs, and anticipated environmental effects identified the optimal choice of plans. Benefits were calculated for incremental widening and for holding area alternatives and are based on comparison of transit times between project alternatives. The calculations were made using the HarborSym economic traffic model.

Total Tonnage

The SNWW experienced strong growth over the past decade, with total tonnage increasing from an average of 108 million short tons for 1995–1997 to 138 million for 2005–2007. In 2007, the SNWW ranked 4th in the U.S. in terms of total tonnage. As individual ports, Beaumont ranked 5th with 81.4 million short tons. Port Arthur’s 2007 tonnage totaled 29.3 million short tons with a ranking of 28th. Channel to Orange tonnage totaled 682,000 in 2007. Table V-1 presents SNWW 1970–2007 total tonnage and principal deep-draft movements. Approximately 60 percent of the SNWW tonnage total consists of deep-draft movements. The remaining 40 percent consists of shallow-draft GIWW-related traffic. Table V-2 displays Sabine-Neches Canal 1970–2007 shallow-draft GIWW tonnage and the relative percentage of shallow-draft to total tonnage. For 2007, nearly 30 million short tons of the 59.7 million shallow-draft total (Table V-2) were transported through SNWW facilities. Beaumont’s shallow-draft barge tonnage totaled 21.2 million short tons with Port Arthur’s 8.3 million, Orange’s 0.7 million, and Sabine Pass 0.9 million. The remaining 30.3 million short tons of 2007 shallow-draft barge traffic consisted of “through movements” between the Lower Mississippi River and Houston and points westward. In reviewing trends for commodities presently or anticipated to be constrained, the initial focus was on the commodity groups displayed in Table V-1.

Table V-1
SNWW Total Tonnage and Major Commodity Tonnage

Crude Petroleum

SNWW's 2002–2006 crude petroleum waterborne imports comprised 12 percent of U.S. and 18 percent of Petroleum Administration Defense District (PADD III) imports. The SNWW is contained in the U.S. Gulf Coast (PADD III), which includes the states of Texas, Louisiana, Arkansas, Mississippi, Alabama, and New Mexico. The U.S. Gulf Coast leads the Nation in refinery capacity, with 41 percent of the Nation's crude oil distillation capacity, and one-half of the Gulf Coast refinery capacity is in Texas and the remainder is in Louisiana. The Gulf Coast is also the Nation's leading supplier of refined products. Table V-3 displays SNWW 1985–2007 crude petroleum imports and its share of the national and regional totals.

Source: USACE (2007a) and Energy Information Administration (EIA, 2008). The U.S., PADD III, and SNWW percentages were compiled from EIA 2008.

Although SNWW tonnage exhibits more variance than the region and the Nation, short-term expectations are that SNWW imports would grow at rates comparable to or higher than regional and national trends. Long-term expectations are that SNWW imports would grow at rates comparable to the regional and national trends. These expectations are based on analysis of long-term historical trends and the study area's established infrastructure of regional and national pipeline distribution links. While SNWW 2005–2007 import volumes are down, Figure V-1 shows that SNWW imports from 1992 through 2007 grew at higher rates than the region or the Nation. In comparison to other Texas Gulf Coast ports, SNWW 2000–2007 crude petroleum imports volumes exceeded other ports by nearly 35 percent. Additionally, recent increases in SNWW refinery capacity indicate the region would regain an increasing share of U.S. and PADD III totals.

Figure V-1
U.S. and Sabine-Neches Crude Oil Imports, 1980–2007

SNWW refinery capacity presently represents 6 percent of the U.S. total. Specific capacities are 572,000 barrels per calendar day for Port Arthur and 577,000 for Beaumont (Table V-4). SNWW capacity levels for 2009 are presently 12 percent higher than in 2004, and 31 percent higher than in 1994. In December 2007, Motiva announced plans for a 325,000-barrel-per-day refinery expansion in Port Arthur. The expansion would increase the refinery's crude oil throughput capacity to 600,000 barrels per day, making it the largest refinery in the U.S. and one of the largest in the world. The ExxonMobil Beaumont refinery is presently the third largest refinery in the world. As a result of these additions, SNWW's combined capacity would represent the largest concentration in the State of Texas

The SNWW terminals transport 400,000 barrels per day of waterborne crude oil via pipelines to inland refineries including refineries in Texas, Louisiana, Oklahoma, Ohio, Arkansas, and Kentucky (Martin Associates, 2006). Colonial Pipeline delivers over two million barrels per day of refined products via pipeline serving Louisiana, Alabama, Mississippi, Georgia, Tennessee, South Carolina, North Carolina, Virginia, Maryland, Delaware, and New Jersey. Explorer Pipeline delivers 650,000 barrels per day of refined products via pipeline serving Texas, Oklahoma, Missouri, Illinois, and Indiana. Products, such as gasoline, heating oil, diesel, and jet fuel, are transported from the Gulf Coast to the East Coast and the Midwest through existing pipeline networks. Product traffic also moves between U.S. ports by coastwise tankers and inland waterway barges. The SNWW refineries supply 15 percent of the product on Colonial's system and 13 percent of the product on Explorer's system.

Port Arthur and Beaumont Tonnage Bases

Distributions of Port Arthur's and Beaumont's 1999–2007 deep-draft tonnages are displayed in tables V-5 and V-6. Port specific data for years prior to 1999 are not included in these tables due to Navigation Data Center (NDC) reporting problems which resulted in a portion of Beaumont tonnage being attributed to Port Arthur. Crude petroleum imports and petroleum and chemical product imports and exports comprised 80 percent of Port Arthur's 2007 total oceangoing tonnage. The 1999–2007 average was 83 percent. The remaining percent of tonnage consisted of imports of crude material and manufactured goods and domestic coastwise shipment of gasoline and chemical shipments.

As shown in Table V-5, Port Arthur's highest growth rates were for product exports and domestic coastwise. Analysis of the commodity-specific data showed that 81 percent of Port Arthur's 2005–2007 petroleum product exports were comprised of petroleum coke. Port Arthur's petroleum coke exports make up 11 percent of the U.S. total.¹ Plans for a new 45,000 barrels-per-day "delayed coker" in Port Arthur were announced in February 2008, with construction anticipated to be complete by 2011 (*Port Arthur News*, 2008). Delayed cokers are used to convert residual oils into gasoline and diesel oil. Delayed coker feed originates from the crude oil, and the effect of new construction would be used to produce residual fuel and other products. Demand for petroleum coke has been noted to be increasing due to growing use of heavy crude oil.

¹ EIA website data shows Port Arthur's 2007 annual petroleum coke imports exceeding 250,000 short tons.

Source: USACE (2007a).

Analysis of Port Arthur tonnage also shows significant increases in chemical imports and exports. Import growth is associated with ammonia and sulphuric acid. Increases in exports are associated with metallic salts and hydrocarbons. Twenty percent of 2005–2007 U.S. metallic salts export tonnage was exported from Port Arthur. Metallic salts and organic compounds are used in the production of paints and solvents, paper and wood products, cleaning products, and various chemical products, and more recently in the production of nylon in Latin America and China. The increase in Port Arthur's metallic salt exports experienced since 2004 is associated with the completion of a 266,000-metric-ton-per-year cyclohexane facility in the Taylor Bayou section of Port Arthur in early 2004. Port Arthur's steady volume of coastwise tonnage shown in Table V-5 is associated with continuing shipments of gasoline, distillate fuel oil, and petroleum coke between Port Arthur and other deep-draft U.S. ports.

Port Arthur's crude petroleum imports remained relatively flat since 2001 but steady. In 2009, Port Arthur's refinery capacity was nearly 13 percent higher than in 2004. Additionally, Motiva announced plans for a 325,000 barrels-per-day refinery expansion in Port Arthur in December 2007. Port Arthur's other commodity movements include imports of crude materials and primary manufactured goods. In 2007, crude material imports consisted of 513,000 short tons of limestone, sand, and gravel. For the most recent 10-year period, crude material volumes averaged nearly 500,000 short tons annually. In 2007, imports of primary manufactured goods were down from 1999–2006 annual volumes that exceeded 500,000. Port Arthur's crude material and primary manufacturing facilities are located on the Sabine-Neches Canal near mile 32, and its crude petroleum and product terminals are in the Taylor Bayou basin.

Examination of Beaumont's tonnage showed that crude petroleum imports and imports and exports of petrochemical products comprised 89 percent of Beaumont's 2007 total oceangoing tonnage. For 2005–2007, 4 percent of U.S. nitrogenous, potassic, and fertilizer mixes were exported from Beaumont. For 2005–2007, the Beaumont share of fertilizer exports increased to 12.5 percent. Beaumont's other commodity movements include grain exports, gasoline and liquid sulphur coastwise shipments, and imports and exports of crude material and manufactured goods. Beaumont's crude material imports, which include limestone, sand, and gravel, comprised 1 percent of the 2005–2007 U.S. total. Beaumont's imports of manufactured goods for 2005–2007 consisted of 336,000 short tons of iron and steel products, representing 1 percent of the U.S. total. Coastwise shipments for 2005–2007 averaged 2.4 million short tons and included 1.3 million short tons of gasoline and 720,000 short tons of chemicals. Liquid sulphur comprised 85 percent of coastwise chemical shipments. For the period 1999–2007, sulphur shipments ranged from a low of 506,000 short tons in 2004 to a high of 679,000 in 2001. In 2007, Beaumont's sulphur shipments totaled 553,000 short tons.

While crude petroleum growth dominates SNWW total tonnage, significant increases in other commodities are notable. Figure V-2 displays comparison of SNWW 1990–1992 through 2005–2007 volumes by major commodity group.² Petroleum and chemical product imports and exports, breakbulk

² Data for the years prior to 1999 are not presented for the individual ports. The Bureau of Census data contained in the *Waterborne Commerce of the United States* does not reflect correct allocation of Port Arthur and Beaumont traffic between the ports. Some of Beaumont's traffic was recorded under Port Arthur due to a Bureau of Census error. Total tonnage values were found to be correct for the SNWW, but the individual counts for years prior to 1999 were found to be unreliable.

imports and exports, and bulk grain exports are shown. Tonnage increased for all groups except grain. In spite of declines, grain exports have increased marginally since the middle 1990s, and Beaumont's 2005–2007 wheat exports represent 5 percent of total U.S. wheat exports. The U.S. Department of Agriculture (USDA) forecast shows a constant export level of 1,075 million bushels for 2014–2015 through 2018–2019, with the forecast volume down by 17 percent from the 2007/2008 high of 1,264 million bushels.

1990–1992 to 2005–2007 Distribution

Expansion of the Deep-Draft Traffic Historical Base

In addition to its large existing base of crude petroleum, petroleum and chemical products, and dry bulk deep-draft cargoes, the without-project future condition includes operation of three LNG terminals. LNG is expected to play an increasingly important role in the natural gas industry and global energy markets in the next several years and in the long-term future. The combination of higher natural gas prices, lower LNG costs, rising gas import demand, and the desire of gas producers to monetize their gas reserves is setting the stage for increased global LNG trade. *The Global Liquefied Natural Gas Market: Status & Outlook*, which characterizes the global LNG market, recent trends, and future prospects in the LNG market, was evaluated in relationship to national trends and anticipated market shares.

Liquefied Natural Gas Traffic

LNG will play an increasingly important role in the natural gas industry and global energy markets in the next several years. In 2007, the U.S. imported an estimated 771 billion cubic feet (Bcf) or 21.2 million short tons of LNG. Shipments to existing U.S. facilities in 2006–2008 came from Trinidad (64 percent), North Africa (22 percent), Western Africa (11 percent), Norway (2 percent), and Middle East (1 percent).

During the early 2000s, LNG permits were approved for the Sabine Pass, Golden Pass, and Port Arthur terminals. The SNWW LNG facilities are located in the Sabine Pass Channel and Port Arthur Canal reaches; these reaches are presently 500 feet and would remain so under the without-project future. LNG vessels using the SNWW would be subject to strict USCG regulations and to local pilot rules and, therefore, would not have the opportunity to meet other vessels or barges. The USCG regulations require that a safety zone is in place 2 miles ahead of a loaded LNG vessel and 1 mile astern of the vessel while transiting. LNG vessels using the SNWW would be subject to this rule. Even in the absence of the safety concerns inherent to LNG, the beams of LNG tankers would result in vessel meeting restrictions; however, all LNG vessel movements would be subject to one-way traffic. Operation of the LNG terminals is part of the without-project future condition.

Phase I of the Sabine Pass terminal, which is operated by Cheniere, is complete and the first vessels arrived in April 2008. Phase 1 consists of 10.1 Bcf of LNG storage in three tanks, each with an LNG capacity of 160,000 cubic meters, and a maximum continuous regasification rate of 2.6 billion cubic feet per day (Bcf/d). Phase 2 will be built in stages. The first stage of Phase 2 includes the addition of a fourth and fifth storage tank, additional vaporizers that would bring the maximum continuous regasification rate up to 4.0 Bcf/d with a peak sendout capacity of 4.3 Bcf/d. In the future stages of Phase 2, a sixth storage tank may be added and related facilities would bring the total LNG storage volume to 20.2 Bcf.

Construction of the Golden Pass LNG terminal is currently in progress and is scheduled for completion by 2011. The Golden Pass facility, which is being constructed by ExxonMobil and Conoco Phillips, will consist of a dock and unloading facilities, five LNG storage tanks (≈ 17 Bcf), and vaporization capacity of 2.7 Bcf/d. The Port Arthur project consists of two ship berths, three to six storage tanks (160,000 cubic meters), and vaporization capacity of 1.5–3 Bcf/d. The LNG for the Golden Pass terminal is anticipated to be supplied primarily from the Ras Laffan 3 and the Qatargas 3 projects in Qatar, which will produce and process natural gas from Qatar's offshore North Field.

Construction of the Port Arthur terminal has not started but is anticipated after 2012. The Port Arthur LNG terminal, constructed and operated by Semptra Energy, would be capable of delivering between 1.5 and 3 Bcf/d of natural gas. The terminal will include two unloading docks for ships and three to six full containment storage tanks and associated equipment in order to transform the LNG back to its gaseous state. As noted, construction of this third facility is planned for after 2012. At full utilization, Sabine Pass and Golden Pass could handle 2.05 trillion cubic feet (Tcf) annually. The Port Arthur terminal annual capacity would increase regional capacity by 2.97 Tcf without pushing peak capacity. Table V-7 shows SNWW current and future capacity volumes.

Table V-7
 SNWW Economic Analysis, U.S. Liquefied Natural Gas
 Facility Expansions and New Construction
 (Given Current FERC Approval and Existing Facility Status)

Facility	Storage Capacity (Bcf)	Output Capacity (Bcf/d)	Completion Date
Sabine Pass			
Phase I	10.1	2.6	2008
Phase II	10.1	1.4	-
Total	20.2	4.0	
Golden Pass	17.0	2.7	2010
Port Arthur	20.0	3.0	2012
Total SNWW	57.2	9.7	

There are about 40 LNG terminals that are before the FERC being discussed by the LNG industry for North America. Six terminals are already operating on the East Coast, Puerto Rico, and Alaska. There are seven onshore LNG terminals in the continental U.S. These are located in Everett, Massachusetts; Lake Charles, Louisiana; Elba Island, Georgia; Cove Point, Maryland; Cameron, Louisiana; Sabine, Texas; and Freeport, Texas. The Cameron, Sabine, and Freeport terminals are new. In addition to these three terminals, the Northeast Gateway port offshore Massachusetts received its first supplies in 2008. With these four terminals now operational, U.S. capacity to receive LNG imports has increased from approximately 5.0 Bcf/d at the end of 2007 to 14.5 Bcf/d per day at the end of 2008. The Sabine Pass facility adds 2.6 Bcf and about 18 percent to U.S. Bcf capacity. Table V-8 displays 2007–2008 U.S. LNG capacity and shows 2003–2009 imports. The Energy Information Administration (EIA) reported total LNG import shipments of 771 Bcf in 2007 to these terminals, with each importing similar volumes – each between 20 and 30 percent of the total. Imports in 2008 only reached 351 Bcf.

Despite declines in 2008, the EIA expects U.S. LNG imports to increase to about 500 Bcf in 2009, up from 352 Bcf in 2008, and rise to about 740 Bcf in 2010. The 2008 fall in imported natural gas to the U.S. reflects the increased need for natural gas in other countries willing to compete for available global supplies. While U.S. imports increased in 2009 over 2008 levels, U.S. LNG import growth this year has been constrained because of increased LNG demand in Europe and delays and maintenance to new and existing LNG liquefaction capacity. With limited natural gas storage availability, recent data suggest that European inventory levels are now nearing capacity. The expectation is that LNG shipments may be redirected to U.S. ports in the coming months as prices in the European market become less attractive to LNG suppliers.

The *2009 Annual Energy Outlook* (AEO2009) forecast shows U.S. LNG imports reaching 2007 levels again in 2014 and peaking at 1,380 Bcf in 2020. Between 2020 and 2030, imports are forecasted to turn down once again. Figure V-3 shows the Department of Energy's 2006–2030 U.S. LNG import forecast. Identification of the region's future share of the LNG market is obviously subject to uncertainty. The SNWW facilities have the advantage of the FERC approval, relatively high levels of public and political

support, and locational advances in terms of access to the U.S. Gulf. For the analysis, 25 percent of U.S. waterborne LNG imports market was used for SNWW. The SNWW forecast is included in Table V-9.

V.C COMMODITY AND FLEET FORECASTS

Commodity and fleet forecasts were prepared for SNWW crude petroleum, petroleum and chemical products, grain, iron and steel products, limestone and building materials, and LNG. The crude petroleum, petroleum, and chemical products forecasts are presented first, followed by discussion of the new LNG market and its tonnage forecast. Finally the grain, iron, metal products, and aggregate are presented. The remaining oceangoing commodity groups, which were found either not to be transported in draft constrained vessels at the current time or were of limited volumes, were analyzed in the aggregate. Estimation of total traffic was needed for the widening analysis and also provided critical input for the shore erosion effects evaluation performed by the ERDC.

Source for U.S. Imports: U.S. Department of Energy (2009b).

National crude petroleum and petrochemical forecast data and general indicators were assessed in relationship to the study area's historical commodity-specific tonnage flows for the purpose of evaluating the relationship between historical U.S. tonnage volumes and study area tonnage. Assessment of the statistical variables associated with the U.S. and study area tonnage provides the analytical support needed to determine which forecasts furnish the best long-term estimation of future study area tonnage flows. The vessel fleet forecasts incorporate recent historical practices, which reflect continued and increased utilization of draft-constrained vessels, regardless of the proposed channel enlargement alternatives.

The outputs of the commodity and fleet projections were based on forecasts published in the EIA AEO2008 and AEO2009; Global Insight, *The U.S. Economy, The 30-Year Focus*, First Quarter 2008 and Second Quarter 2009; USDA *Agricultural Baseline Projection Tables, USDA Baseline Projections Report to 2019*, February 2009; and from indices developed from historical trend data. The forecasting methodologies, the distribution of tonnage by vessel class, and the determination of the number of vessel trips are discussed in the sections that follow.

Tables V-10 and V-11 summarize the forecasts for the major commodity groups evaluated for channel deepening. The Port Arthur forecast is shown in Table V-10 and Beaumont's forecast in Table V-11. Detailed discussions of the commodity forecasts are presented in the Economic Appendix. The following section presents SNWW vessel fleet data.

Vessel Utilization Trends

The existing 40-foot project depth was designed to efficiently and safely accommodate vessels of approximately 40,000 DWT with loaded drafts of 36 feet. Since the authorization of the existing project, the size and draft of vessels using the waterway increased to meet the competitive demand for more-efficient movements. Table V-1 displays SNWW 1970–2007 total tonnage and principal deep-draft movements by major commodity group. Examination of SNWW historic traffic data showed that if deeper depths were available, a significant share of the vessels used in the transport of crude petroleum and petroleum products could be loaded to drafts over 40 feet. In addition, but to a lesser extent, examination of the 1995–2007 vessel sizes, loaded drafts, design drafts, and parcel sizes revealed that some of the vessels used to transport grain, chemical products, and breakbulk cargo, such as iron ore, metal products, and limestone and other aggregate, warranted additional analysis.

Analysis of the vessel fleets and utilization, and existing and future constraints associated with crude petroleum; petrochemical products, including LNG; grain; and aggregate products, such as iron ore, steel slab, limestone, and sand and gravel, provided the basis for identifying the commodities expected to be transported in vessels loaded to channel depths over 40 feet and estimating specific percentage utilization for channel depths over 40 feet. Additional considerations were foreign port depths and constraints such as the Panama Canal. Completion of the Panama Canal expansion, from its present width restriction of 106 feet and approximate loaded draft limit of 39.6 feet, in the year 2014 would allow for more fully loaded vessel movements from deepwater ports in Western Mexico, South America, and the Far East. The

canal expansion would accommodate maximum loaded drafts of 48 feet. Port depth, trade route, and historical vessel utilization data were used to identify the percentage of tonnage anticipated to benefit from the proposed SNWW depth increases.

Discussion of the commodity-specific percentages is contained in the Economic Appendix (Appendix 2).

Crude Petroleum Fleet

Crude petroleum growth dominates total tonnage for both Beaumont and Port Arthur. In a comparison of the relative port statistics, a greater percentage of crude tonnage is loaded to drafts of 38 feet or more for Port Arthur than for Beaumont. This is due to Port Arthur receiving a higher share of direct shipments from Mexico than Beaumont does. Generally, vessels would be loaded to deeper drafts for longer distance direct routes. In comparison, Beaumont receives a higher share of lightened tonnage from both lightened mother vessels and shuttles. While there are obvious cost incentives to load to the maximum allowable depth, in looking at average loaded drafts, the lightened mother vessels and shuttles were lighter than vessels associated with direct shipments. Port Arthur's petroleum refineries are located inside the Taylor Bayou complex. The maximum size using the Taylor Bayou facilities are in the 110,000 to 116,000 DWT range. While Port Arthur vessels are loaded to deeper draft, the Port Arthur fleet is smaller than Beaumont's in terms of DWT because the existing width at the mouth of Taylor Bayou and the configuration of the docks within Taylor Bayou limit the allowable vessel size.

**Deepening benefits were calculated for a percentage of the tonnage presented in this table.

Discussion of the commodity-specific percentages is contained in the Economic Appendix (Appendix 2).

Widening of the mouth of the entrance to Taylor Bayou would occur under the with-project future condition and this would allow better vessel maneuverability. Widening of the mouth was recommended as a result of the ERDC vessel simulation modeling. Port Arthur's breakbulk docks and new LNG facilities are located outside of the Taylor Bayou complex and are not subject to similar vessel beam and length restrictions. The maximum sized vessels using the Channel to Beaumont are in the 150,000 to 175,000 DWT class. The maximum length for that group is approximately 900 feet, with a corresponding beam width of 164 feet. Five percent of Beaumont's 2006 crude petroleum imports are associated with this group. Table V-12 displays Port Arthur's and Beaumont's 2002–2006 port-specific distributions by loaded draft. Distributions of Port Arthur and Beaumont crude oil imports by vessel DWT range are shown in tables V-13 and V-14.

Petroleum Product Carriers

Examination of the vessel characteristics and geographic routings associated with SNWW products indicates that some vessels could be more fully loaded. Table V-15 presents a percentage distribution of SNWW petroleum product imports and exports by vessel DWT class. This table shows that 32 to 54 percent of 1998–2007 imports and 5 to 27 percent of exports were transported in vessels of 60,000 DWT or more.

Source: USACE (2007a).

The Lloyd's Register-Fairplay was used to obtain the vessel DWT and associated characteristics.

Table V-16 presents the percentage of Port Arthur and Beaumont tonnage for design drafts greater than and less than 40 feet and shows that in 2007, an average of 59 percent of Port Arthur and 46 percent of Beaumont petroleum product imports were transported in vessels with design drafts over 40 feet. For exports, the 38 percent of Port Arthur and 20 percent of Beaumont tonnage were transported in vessels with design drafts over 40 feet. Comparison of the 2002–2007 statistics shows that the percentage of Port

Arthur and Beaumont exports transported in vessels with design drafts over 40 feet experienced relatively large increases; however, the annual rates are subject to variability based on annual changes in trade routes and commodity mixes.

Tables V-17 and V-18 show product totals by commodity and the corresponding percentage of imports and exports shipped in vessels of 60,000 DWT or more. As shown, the annual percentages vary greatly and discernible patterns are not apparent. As also shown in Table V-17, higher percentages of imports are associated with vessels of 60,000 DWT than are exports.

Table V-16
SNWW Petroleum Products 2002–2007 Imports and Exports by Vessel Design Draft

Source: USACE (2007a). The Lloyd's Register-Fairplay was used to obtain the vessel DWT and associated characteristics.

While it is anticipated that this variance would continue to remain high, the use of draft-constrained vessels for several markets served by the SNWW is also anticipated to continue. While published forecasts of specific trade routes are not available, the SNWW presently serves markets that can accommodate more fully loaded product carriers, and it was assumed that some cargo movements would transition to more fully loaded vessels based on the economics of scale of loading to increased depths and availability of channel depths in excess of 40 feet at some trading ports. As shown in tables V-16 and V-17, larger product carriers are used for high volume commodities such as distillate and residual fuel imports and petroleum coke exports

The Lloyd's Register-Fairplay was used to obtain the vessel DWT and associated characteristic

Examination of the data in tables V-13 through V-17 shows that there are large annual variances in the percentage of annual tonnage associated with the draft and parcel criteria, and, therefore, depths at trading ports and comparable operations at similar ports were also evaluated. Examination of petroleum product imports and exports through other U.S. Gulf Coast ports with channel depths over 40 feet shows that 34 percent of distillate imports from Russia, North Africa, and Venezuela were shipped in vessels with loaded drafts of 42 feet or more.

The use of the Panama Canal for all of the Far East and over half of the South America destinations would limit the sizes of vessels used for that trade until the Panama Canal expansions are complete. Completion of the Panama Canal deepening and widening is expected to occur before 2014. In addition to foreign flag product carriers, a steady volume of domestic coastwise product tankers use Port Arthur and Beaumont. Domestic coastwise movements primarily consist of gasoline and distillate and residual fuel shipments. These products are refined at the SNWW ports and shipped to the U.S. East Coast, specifically eastern Florida. In 2006, coastwise shipments totaled 3.6 million short tons. Coastwise receipts totaled 978,000 short tons. Examination of vessel specifics showed that approximately 10 percent of outbound coastwise shipments were transported in draft-restricted tankers. These product carriers generally are between 60,000 and 70,000 DWT with design drafts in the 41- to 43-foot range.

Chemical Product Carriers

For the period 2002–2007, chemical imports represented approximately 3 percent of both SNWW and U.S. total foreign tonnage. Both U.S. and SNWW imports exhibited consistent upward growth from the mid-1990s through 2007, with SNWW overall rates increasing at nearly five times the U.S. rate but also exhibiting higher annual variances. As with imports, SNWW chemical exports exhibited significantly higher overall growth than the national rates, with overall rates increasing at nearly five times the U.S. rate. Chemical product growth can be attributed to diversification of the SNWW product base and the development of new markets. Table V-19 shows SNWW and U.S. total tonnage for 1990–2007, with recent tonnage representing record highs.

Evaluation of 1998–2007 chemical product exports showed that the percentage of tonnage associated with design drafts between 40 and 44 feet ranged from zero to 14 percent, averaging 4 percent annually. An average of 16 percent of 1998–2006 export tonnage was transported in loaded drafts between 36 and 40 feet. In 2007, 18 percent of SNWW chemical exports were transported in vessels with loaded drafts between 36 and 40 feet. Approximately two-thirds of 2002–2007 exports were shipped from Beaumont and the remainder from Port Arthur. Seventy-nine percent of 2002–2007 imports were shipped into Beaumont and the remainder to Port Arthur.

Review of the Lloyd's Register-Fairplay showed that 21.6 percent of the chemical tankers on order in 2009 have design drafts of 43 feet or more and 1.6 percent of chemical tankers on order have design drafts of 47 feet or more. Table V-20 presents the distribution of the world chemical carrier fleet as of January 2009.

Current vessel usage and general indicators, such as depths at trading ports, overall tonnage, and the design drafts for the current fleet of vessels, suggest that some future chemical movements would benefit from channel depths up to 48 feet. Of the vessels on order, 1.8 percent of vessels have design drafts of 48 feet. Review of existing cargo loads suggests that the draft-constrained tonnage would likely consist of metallic salt exports and acyclic hydrocarbon exports. Project benefits were calculated assuming that 5 to 10 percent of future chemical export tonnage would be transported in vessels with loaded drafts between 40 and 49 feet. Eight percent of 2019–2069 chemical export tonnage was assumed to be loaded to drafts over 40 feet. Deepening benefits were not calculated for chemical imports due to current limited utilization of larger vessels and loaded drafts over 36 feet and uncertainty about future trends towards the use of either larger or more fully loaded vessels.

Grain Carriers

Grain is exported from the Beaumont elevator located just below the Port of Beaumont main TB. While exports have exceeded 1 million short tons since 2003, recent volumes are less than one-half the 1993 peak volume of 3.5 million short tons. In 2007, Beaumont’s wheat exports totaled 1.6 million short tons. While relatively low in comparison to the Pacific Northwest and the Lower Mississippi, Beaumont has maintained a 1.4 to 1.7 percent share of the U.S. waterborne bulk grain export market. Table V-21 displays Beaumont’s 2001–2007 grain export tonnage by grain type and loaded draft. Wheat presently comprises 100 percent of Beaumont’s grain exports for the most recent 5-year period. Beaumont’s 2007 wheat exports composed 5 percent of the U.S. wheat export total. Figure V-4 provides a comparison of Beaumont and U.S. wheat exports. During earlier years, wheat represented 85 percent, sorghum 10 percent, and corn 5 percent.

The maximum DWT presently used for grain exports is in the 60,000 to 70,000 DWT range. These vessels have design drafts between 42 and 43 feet. The specific type of bulk carriers used for grain is “load-on/load off” or “LoLo” vessels. Table V-22 displays the existing fleet of “LoLo” vessels in the world fleet and LoLo vessels on order. The median year of construction for the range of vessels transporting grain from Beaumont is 1985, which is older than the median of 1998 associated with the world fleet. Review of the distribution of vessels on order and the port depths at receiving ports indicates that some transition in the average DWT range from the existing 60,000 to 70,000 DWT into the 80,000 to 94,000 DWT range is reasonable to expect.

The USDA’s February 2009 forecast shows modest growth in wheat exports between 2006 and 2018/2019. U.S. 2006–2018/2019 exports are forecasted to increase from approximately 990 million bushels in 2006 to 1,075 million bushels by 2014/2015 and remain constant at that level through the end of the forecast period in 2018/2019.

Steel Slab and Iron Ore Carriers

For the period, 2002–2006, an average of 2.5 percent of U.S. iron ore and steel slab imports were transported through the SNWW ports. For the period 2002–2007, imports ranged from a low of 240,000 short tons in 2007 and a high of 1,136,000 short tons in 2005. In 2006, SNWW imports totaled 859,000 short tons. The 2002–2006 average annual import volume of 783,000 short tons is over 100 percent higher than 1990–1993 average levels.

Steel slab is transported in LoLo bulkers in the 45,000 to 53,000 DWT range, with a maximum vessel size of 78,000 DWT. Review of the Lloyd's Register-Fairplay (2003) showed that 23 percent of bulk carriers constructed over the past decade are in the 66,000 to 78,000 DWT range. This is same vessel type used for grain; however, the specific vessels are different with each cargo having dedicated carriers.

Examination of the foreign ports of call for 1998–2007 SNWW tonnage showed that an average of 8 percent of tonnage was transported through world ports with channel depths of 44 to 47 feet. Current

vessel usage and general indicators, such as depths at trading ports and the design drafts for new vessel orders, suggests that, in the short term, a minimum of 10 percent of present iron ore movements would utilize channel depths over 40 feet. Expansion of the Panama Canal is expected to increase the percentage to 50 percent by the year 2014. Project benefits were calculated assuming that 10 percent of 2015–2020 tonnage and 50 percent of 2020–2069 would be transported in vessels with loaded drafts between 40 and 49 feet.

Limestone and Rock Carriers

SNWW aggregate tonnage primarily consists of imports of limestone, rock, and other raw building materials. For the period 2005–2007, 3 percent of U.S. limestone and rock imports were transported through the SNWW ports. Table V-23 displays SNWW aggregate tonnage. Presently, the most common carriers used on the SNWW are in the 46,000 to 77,000 DWT range. Table V-24 displays the fleet used for SNWW 2002–2007 aggregate imports. Presently, nearly all tonnage is transported in vessels with design drafts over 40 feet. Current vessel usage and general indicators, such as depths at trading ports and the design drafts for new vessel orders, suggests that some 50 percent of iron ore movements would utilize channel depths over 40 feet due to the expansion of the Panama Canal. The shipments of clay and refractory materials are associated with vessels with loaded drafts over 37 feet and design drafts over 40 feet.

Table V-23
SNWW Building Material Imports
(1,000s of short tons)

Wood Product Carriers

For the period 1998–2006, approximately 1 percent of U.S. wood product tonnage was transported through the SNWW ports. Wood products also represent 1 percent of the SNWW 1998–2006 foreign total. The largest wood product carriers used on the SNWW are in the 50,000 to 60,000 DWT range. The design drafts of these ships are right at 40 feet; and it was found that wood chip carriers, like container vessels, characteristically reach capacity in terms of volume before they reach their design drafts. Review of 2002–2006 data showed that the load patterns were the same as for 1998–2001. The nature of wood chip cargo suggests it is unlikely that the current fleet could be loaded to depths greater than 40 feet, and therefore, deepening benefits were not calculated for wood products. Discussion with industry representatives confirmed this.

Liquefied Natural Gas Fleet

Discussion with industry representatives and review of the vessels on order revealed that LNG vessels with design drafts of 40 feet or more are being constructed. Table V-25 displays the world LNG fleet, including vessels on order.

V.D CHANNEL DEEPENING BENEFITS

The transportation costs and the savings associated with the proposed project depth increase were calculated using commodity-specific vessel class and trade route distributions. Transportation costs were calculated based on the channel depth alternatives and variables associated with vessel design drafts, maximum feet of light-loading, underkeel clearance, mileage traveled, and the number of hours to load and unload. Maximum vessel cargo capacities for crude oil and petroleum products were estimated based on review of the range of load factors obtained based on review from IWR Report 91-R-13, *National Economic Development Procedures Manual Deep-draft Navigation* (1991) and consultation with SNWW industry and pilots association. The IWR (1991) cargo capacity factors published in the deep-draft manual

for dry bulk carriers and tankers are shown in Table V-26. Consultation with industry and the pilots revealed that these estimates are reasonable. Table V-27 presents representative round trip mileage for the trade routes or junction points used for the transportation savings computations.

Vessel Operating Costs

The vessel operating costs are shown in tables V-28 through V-30. Table V-28 displays the hourly operating costs for tankers. The hourly operating costs include fuel, labor, and maintenance. The costs used were obtained from deep-draft vessel operating cost Economic Guidance Memorandum (EGM) December 2008 update (USACE, 2008a). The tanker costs were used for the crude petroleum, petroleum product, and chemical product transportation cost calculations. The maximum sized vessels using the channel to Beaumont on a regular basis are in the 150,000 DWT class. The maximum size using the Taylor Bayou Port Arthur facilities are in the 110,000 to 116,000 DWT range. As previously noted, the Port Arthur fleet is smaller, in terms of DWT, because the existing width at the mouth of Taylor Bayou limits the allowable vessel size. The U.S. flag tanker costs contained in Table V-28 were used for U.S. coastwise product movements. Table V-29 displays the foreign flag bulk carrier operating costs that were used for the grain exports and imports of iron ore, metal products, limestone, and rock. Table V-30 displays the LNG vessel operating costs. The LNG costs were estimated in consultation with the IWR.

The LNG design vessel used by the ERDC for the ship simulations consisted of a 140,000 cubic meter spherical-tank-type vessel 920 feet long, 142 feet wide, and 37.4 feet in draft, and a proposed 250,000-cubic-meter membrane-type tanker 1,126 feet long, 177 feet wide, and 39.4 feet in draft. The LNG facilities are in the Sabine Pass Channel and Port Arthur reaches. The project design vessel for crude petroleum tankers using the Entrance Channel and going to Beaumont is 899 feet long and 164 feet wide. These dimensions correspond to a 158,000 DWT crude petroleum tanker.

125,000	40	265,000	372.4	2,423	2,039

For the transportation cost calculations, an average of 1 foot of underkeel clearance was used for petroleum vessels. Based on industry input, a 4- to 6-foot underkeel clearance was used for LNG vessel. The indication from pilot discussion was that an absolute minimum of 4 feet underkeel clearance would be required; and the preference was for 6 feet. The effects of varying underkeel clearance are addressed in detail in the sensitivity section of the Economic Appendix (Appendix 2).

Transportation Savings Benefits for Channel Deepening

Transportation savings benefits from reductions in the vessel operating costs were calculated based on the relative difference in transportation costs between the without-project and with-project conditions. Transportation costs and savings were calculated for vessels that minimize transportation costs given trade route constraints. As previously noted, long-term fleet selection would continue to reflect goals of minimizing vessel operating costs. The basic procedure used to calculate transportation costs using 110,000- and 150,000-DWT foreign flag tankers as an example is illustrated in Table V-31. Similar computations were made for appropriate distances and vessel sizes for each of the channel depth alternatives. The resulting costs-per-ton computations were calculated over the relevant range of vessels projected for each channel depth improvement, and the associated savings per ton were measured using the net differences in costs between the existing 40-foot channel and the depth alternative. Unless otherwise noted, the 2019–2069 tonnage forecasts used for the benefit calculations were summarized in tables V-10 and V-11.

Crude Petroleum Imports Transportation Savings Benefits

The transportation costs used to calculate the benefits for crude petroleum imports are presented in Table V-32. The per-ton transportation costs correspond to the least-cost method of shipment associated with the particular trade route. Review of the depths at trading ports and significant savings per ton indicates that a large share of crude petroleum tonnage from Mexico, Venezuela, and Trinidad would be loaded to vessel drafts over 40 feet. Expectations concerning the percentage of Middle East and Africa movements are subject to greater uncertainty. Nearly all Middle East tonnage is lightered and nearly all West Africa crude is lightened. The logistics associated with these offshore transfers introduces higher degrees of uncertainty than with direct shipment and, therefore, generates large cost variances.

Table V-31
Transportation Cost Calculation (South America to SNWW)

Channel Depth (feet)	40	45	50	40	45	50
Vessel Deadweight Tons	110,000	110,000	110,000	150,000	150,000	150,000

Total Loading, Unloading, and Port Costs (\$)	91,821	94,944	97,351	109,603	113,011	115,588
Total Cost Sum (\$)	538,948	542,072	544,478	623,124	626,532	629,109
Total Cost Per Ton (\$)	7.32	6.18	5.35	7.25	6.08	5.24

*Estimated short tons \cong (DWT * Maximum % Load) - (Immersion Factor * 12 inches per ton * number of feet light-loaded).

**Weighted mileage based on distance from Venezuela and Brazil. The weight factor of 0.7 was used for Venezuela, and a factor of 0.3 was used for Brazil. The weights were determined based on the expected percentage of tonnage by origin.

Additionally, and as Table V-32 illustrates, the cost savings for offshore transfer is lower than with direct shipment; however, distinct cost savings are apparent. The savings for lightering results from increases in shuttle loads due to greater channel depth in SNWW. For lightering, the effect of increasing channel depths at SNWW allows for the reduction in the number of shuttles necessary to totally lighter VLCC. The savings for lightened movements results from decreases in offshore unloading time from the mother vessel to shuttles. For lightening, the mother vessel is substituting offshore unloading time for dock-side unloading time. Additionally, the shuttle vessel reduces its overall loading and unloading time.

Savings/ton Port Arthur		0.29	0.35	0.36	0.37	0.38	0.42

Lightening generates comparatively lower savings than lightering because the latter produces the possibility of reducing the number of shuttles needed. Examination of the cost data also revealed that as channel depth increases the resulting savings may provide incentive to switch from lightening to direct shipment for movements from Africa and the North Sea. Table V-33 presents the lightening costs and Table V-34 presents the lightering costs. Historically, lightening was the most common choice for Africa and the North Sea movements; however, lightering has become more common for this route in recent years due to structural changes in oil production of the coast off West Africa. Lightering has always been

the method of choice for Middle East movements. The small percentage of North Sea using SNWW tends to be lightered, and an increasing portion of West Africa crude is lightered. Lightering was assumed to represent the without- and with-project future choice for West Africa crude due to its relative low cost and increasing popularity.

Tables V-35 and V-36 display Beaumont and Port Arthur's transportation cost savings based on the least-cost shipping methods displayed in Table V-32. For Port Arthur, the maximum vessel DWT used for the benefit calculations is less than 120,000 DWT. As previously noted, deepening of the channel leading to the Taylor Bayou terminal would enable the existing fleet to be more fully loaded but it would not result in transition to larger vessels. The transportation savings calculation costs shown in tables V-35 and V-36 reflect continuation of this limitation. As previously noted, the 2019–2069 tonnage forecasts used in the

benefit calculations are presented in tables V-10 and V-11. The specific tonnage volumes used for the benefit calculations are presented in the Economic Appendix.

Petroleum and Chemical Product Transportation Savings Benefits

Reductions in the vessel operating costs for SNWW foreign petroleum product import and exports and coastwise shipments were calculated based on the relative difference in transportation costs between the without-project and with-project conditions. As with crude petroleum, transportation costs and savings were calculated for vessels that minimize transportation costs given trade route constraints. Again, long-term fleet selection would continue to reflect goals of minimizing vessel-operating costs. Table V-37 displays the annual transportation costs for Beaumont's petroleum and chemical product imports and exports. Table V-38 summarizes the annual transportation savings benefits for Port Arthur's petroleum and chemical product imports and exports. Table V-39 summarizes the annual transportation savings benefits for Beaumont's and Port Arthur's petroleum and chemical product imports and exports.

Table V-40 summarizes the benefit calculations for coastwise product shipments. As noted, deepening of the channel leading to the Taylor Bayou terminal would enable the existing fleet to be more fully loaded, but it would not result in transition to larger vessels. The transportation savings shown in Table V-40 reflect continuation of this limitation. The maximum sized coastwise vessels do not exceed Taylor Bayou's limitation.

Grain Exports Transportation Savings Benefits

Beaumont wheat exports comprise 5 percent of the current U.S. total. Forecast of future exports were estimated based on analysis of USDA's February 2009 forecast. Per ton transportation costs were estimated based on exports shipped from Beaumont to Europe and the Mediterranean. The per ton transportation costs are presented in Table V-41. The transportation costs by channel depth alternative are presented in Table V-42.

Reductions in the vessel-operating costs for SNWW steel slab and iron ore imports were calculated based on the relative difference in transportation costs between the without- and with-project conditions. As with the previous presentations, transportation costs and savings were calculated for vessels that minimize transportation costs given trade route constraints. Again, long-term fleet selection would continue to reflect goals of minimizing vessel-operating costs. Port Arthur's breakbulk terminal is located outside the Taylor Bayou reach and the bulk carriers are not subject to the beam and length limitations. However, the maximum beam width for the bulk carrier fleet is 106 feet. The design drafts for these vessels are generally less than 45 feet. The DWT range of bulk carriers used for the benefit calculations is 60,000 to 99,999. Larger vessels could be used but are not anticipated over the next 20 years. The maximum size presently being used is 78,000 DWT. The transportation savings calculations were based on average costs for the anticipated 60,000 to 99,999 DWT range. As previously noted, the tonnage forecast and average annual growth rate for 2002–2004 to 2069 tonnage growth was displayed in tables V-10 and V-11.

2069		2,948	3,343	3,896	4,325	4,726	5,041	

Table V-43 presents the cost-per-ton transportation cost for steel slab and iron ore. The costs shown are for Beaumont tonnage. The costs for Port Arthur would be approximately 1 percent less. Based on existing port depths and vessel utilization, an estimated 15 percent of tonnage was projected to use channel depths over 40 feet for the years prior to 2014. By 2014, the expansion of the Panama Canal is expected to result in the existing base tonnage from the deepwater port of Lazaro Cardenas on the West Coast of Mexico to load to vessel drafts over 40 feet. At that time, an estimated 50 percent of tonnage is anticipated to be loaded to vessel drafts over 40 feet. As outlined in the Economic Appendix (Table 48) 99 percent of sand and gravel 1999–2007 imports, 70 percent of limestone 1999–2007 imports, and 15 percent of 2005–2007 dry sulphur exports were shipped in vessels with design drafts of 40 feet or more. Review of the Lloyd’s Register-Fairplay (2003) showed that 23 percent of bulk carriers constructed over the past decade are in the 66,000 to 78,000 DWT range. Table V-44 summarizes the annual transportation savings benefits for Beaumont’s steel slab and iron ore import tonnage. Table V-45 summarizes the annual transportation savings benefits for Port Arthur’s tonnage.

Table V-43
Beaumont Steel Slab and Iron Ore from South America, Mediterranean, and the Far East
(December 2008 Vessel Costs)

DWT	40	45	46	47	48	49	50
Transportation Cost (\$)/Ton to Port Arthur							
60,000	17.63	14.60	14.13	13.66	13.66	13.66	13.66
70,000	15.60	13.08	12.68	12.29	12.29	12.29	12.29
80,000	15.22	12.74	12.35	11.96	11.60	11.26	11.26
90,000	14.12	11.95	11.60	11.25	10.94	10.63	10.35
Transportation Cost (\$)/Ton to Beaumont							
60,000	18.35	15.22	14.73	14.23	14.23	14.23	14.23
70,000	16.23	13.63	13.22	12.80	12.80	12.80	12.80
80,000	15.84	13.29	12.89	12.49	12.12	11.77	11.77
90,000	14.70	12.47	12.12	11.77	11.44	11.14	10.84

The transportation cost calculations are based on a representative weighted mileage for the applicable South America, Mediterranean, and Far East routes. The weighted mileage is approximately 14,000 miles round trip. One of its greatest impacts would be felt in the breakbulk trade where expansion would enable larger vessels to transit the canal. Expansion of the canal project is expected to be completed in 2014. Completion of the Panama Canal expansion, from its present width restriction of 106 feet and approximate loaded draft limit of 39.6 feet, by the year 2014 would allow for more fully loaded vessel movements from deepwater ports in the Asia and the western coasts of Mexico and South America. The canal expansion would accommodate maximum loaded drafts of 15 meters or approximately 49 feet. Completion of the canal will coincide with port expansion projects in India and Chile. Steel is imported to SNWW from Dhamra. The Dhamra channel expansion will provide a channel depth of 18 meters, which can accommodate super cape-size vessels up to 180,000 DWT. Dhamra’s master plan provides for 13 berths, capable of handling more than 83 million metric tons per annum of dry bulk, liquid bulk, breakbulk, and containerized cargo.

Limestone and Rock Transportation Savings Benefits

As with steel slab and iron ore, the DWT range of bulk carriers used for the aggregate rock benefit calculations are in the 60,000 to 90,000 DWT range. Larger vessels could be used but are not anticipated over the next 20 years. The maximum size presently being used is 78,000 DWT. The transportation savings calculations were based on average costs for the anticipated 60,000 to 90,000 DWT range. As with the previous presentations, transportation costs and savings were calculated for vessels that minimize transportation costs given trade route constraints. The DWT range of bulk carriers used for the benefit calculations are in the 60,000 to 90,000 range.

The applicable tonnage forecast and average annual growth rate for 2002–2004 to 2069 was contained in tables V-10 and V-11. Based on existing port depths and vessel utilization, an estimated 50 percent of tonnage was projected to use channel depths over 40 feet. A representative weighted mileage for the applicable Mexico, South America, Mediterranean, and Far East routes was used. The weighted mileage is approximately 14,000 miles round trip. Table V-46 presents the cost-per-ton transportation costs. The costs shown are for Port Arthur tonnage. The costs for Beaumont would be approximately 1 percent higher. Table V-47 summarizes the annual transportation savings benefits for Beaumont's import and SNWW export tonnage. Table V-48 summarizes the annual transportation savings benefits for Port Arthur's import tonnage. Port Arthur's share of bulk material exports has historically been low in comparison to Beaumont's, with Beaumont's recent historical share representing approximately 90 percent of the SNWW total. Due to the recent historical distribution, the benefit calculations were estimated using the average mileage for Beaumont and Port Arthur. For presentation purposes, the benefit calculations for exports are presented in Table V-47.

Liquefied Natural Gas Transportation Savings Benefits

Table V-49 presents the trade route forecast used for the benefit calculations, Table V-50 presents the per-ton transportation cost, and Table V-51 presents the annual savings. The maximum loaded draft for LNG vessels is anticipated to be 40 to 42 feet. The majority of vessels would be loaded to 39 feet. The vessels will need from 3 to 6 feet of underkeel clearance. While the deepening benefits were believed to stop at an approximate channel depth of 43 feet, construction of LNG vessels with design drafts of 45 feet has taken place since 2007. The design drafts associated with 12 of the new vessels are identified to be in the 45-foot draft range (i.e., 13.6 meters).

Summary of Channel Deepening Benefits

Table V-52 presents the transportation cost savings by major commodity group for channel deepening. The majority of benefits are associated with imports of crude petroleum, LNG, and petroleum product and exports of petroleum products. Crude petroleum and petroleum products represent 84 percent of the benefits at the 45-foot depth and 89 percent at the 50-foot depth. The LNG composes 7 percent of benefits at the 45-foot depth and 4 percent at 50 feet. The LNG benefits are for facilities in the Sabine Pass Channel and Port Arthur Canal reaches. Distributions of the Taylor Bayou, Port Arthur, and Neches River deepening benefits are presented in Tables V-53.

V.E CHANNEL WIDENING BENEFITS

The SNWW is currently subject to transit rules that are needed for the pilots to safely guide large tankers through the narrow channel. The waterway's high volume of inland barge and deep-draft vessel traffic exacerbates congestion and results in increased delays and accident probabilities. To address these problems, a range of alternatives was evaluated, including channel widening and sidings. The effect of the project alternatives would be to reduce delay frequencies and durations. An additional expectation would be reductions in accident probabilities. Benefits were not quantified for reductions in accidents because, while accident probabilities are high, rates are low. Traffic increases and associated congestion recognizably increase the probability of accidents; however, "avoidance behavior," in the form of delays characterized by the existing conditions, keeps accident rates low. This behavior provides the basis for the monetary benefits associated with the proposed project alternatives as the proposed modifications would reduce the duration and frequency of delays.

Reduction in delay benefits were calculated for channel widening and for holding area alternatives. The benefit estimates are based on comparison of transit times between project alternatives. Transportation costs for existing conditions, the without-project condition, and the project alternatives were calculated using 2004 SNWW traffic base. Vessel characteristics and related details were obtained from the USACE NDC detailed records.

In terms of channel width, there are three main traffic rules presently affecting vessel traffic. The traffic rules, which affect movements in the 400- and 500-foot project reaches, are instituted by the SPA for the purpose of helping to ensure safe navigation. The general categorization of the transit rules are daylight-only sailing restrictions applied in specific reaches for vessels that exceed certain DWT, length, and breadth criteria. There is no meeting during nighttime sailing for vessels exceeding a given draft limitation. No meeting during either day or night applied to vessels by DWT, length, breadth, draft combinations. The specific rules posted by the Sabine Pilots are displayed in Table V-54. The results of these rules provide for a safe channel and a relatively low accident rate. The rules also affect a significant portion of traffic in the form of vessel delays.

The HarborSym model was used in evaluation of the entrance channel widening and the Neches River TB and anchorage features. HarborSym is a planning-level model developed by IWR to assist in economic analyses of channel widening improvements. HarborSym is an event-driven simulation model and includes data from user-specified transit rules that the model processes with each vessel call in order to calculate delays within the system. The model is presently in the model certification process. While not yet certified, the model is scheduled for review under the USACE certification system. The model is presently being used by several USACE district offices for channel widening studies, and the outputs of these studies have undergone Agency Technical Review (ATR) and USACE headquarters review.

HarborSym outputs were crucial for aggregation and understanding of base condition delays. Pilot interviews were used to identify a wide range of information, including delay times. Vessel class-specific

delay times were obtained from the model output, with these inputs having been defined using pilot logs and extensive pilot interviews. The key element in modeling the harbor system was replicating transit rules as listed in Table V-54.

Table V-54
SNWW Pilot's Rules

General: Vessels 85,000 DWT or over, or greater than 875 feet in length and 125 feet in beam width will move during daylight hours only above the Texas Island intersection with the GIWW West. In the event that meeting situations are applicable but circumstances will not permit the utilization of turning basins, the following criteria will prevail:	
1.	Vessels with combined beam widths that equal or exceed one-half of the channel width will not meet day or night.
2.	Vessels 48,000 metric DWT or more with a draft of 30 feet or more will not meet above Buoys 29 and 30.
3.	Vessels $\geq 85,000$ DWT will not meet vessels of either $\geq 30,000$ DWT or ≥ 30 -foot draft above Buoys 29 and 30.
4.	Vessels $\geq 85,000$ DWT will not meet vessels of either $\geq 30,000$ DWT or ≥ 25 -foot draft above the Texas Island intersection.
5.	Vessels with a combined draft of 70 feet or more will not meet between the Neches River intersection and Day Beacon #40 (Smith Bluff) at night. Vessels with a combined draft of 65 feet or more will not meet above Day Beacon #40 at night.

Source: SPA (2007).

Benefits from reductions in delays were calculated for widening the 500-foot entrance channel sections to a project width of 700 feet. A 700-foot project width up to the junction of the Sabine-Neches Canal with Taylor Bayou would provide a consistent series of reaches for vessels to meet. Specifically, it would allow two-way traffic for vessels that cannot presently meet in the 500-foot sections of the reaches. The 700-foot reach does not presently cause the pilots to impose vessel-meeting restrictions. The portions of the channel that are presently 500 feet do result in vessel meeting restrictions. The delays associated with the 500-foot width are a problem.

Two-way traffic is not allowed for LNG tankers under either the without- or with-project future. Construction of the Sabine Pass terminal is presently complete and the first vessels arrived in April 2008. Construction of the Golden Pass LNG terminal is scheduled for completion in September 2010. Construction of the third permitted facility, Port Arthur, is anticipated after 2012. All LNG tankers would be subject to one-way traffic rules in spite of channel widening. The LNG facilities are located in the Sabine Pass Channel and Port Arthur Canal reaches; these reaches are presently 500 feet. The ERDC modeling that was performed under the direction of the permit applicants showed that 500 feet is adequate for one-way transits of LNG vessels. The LNG traffic would be affected by USCG rules limiting the distance of other vessels traveling before and after the LNG tanker. Delays resulting from LNG traffic would occur under both the without- and with-project conditions. Channel deepening and widening would decrease the duration and frequency of delays for LNG and all vessels affected by either pilot or USCG rules. The beam widths for the smallest LNG (i.e., 76,000 DWT) are in the 142- to 158-foot range.

In addition to widening the entrance channel reaches, widening of the Neches River Channel to Beaumont was also evaluated and modeled by the ERDC. The results of the ERDC modeling showed increasing the Neches River channel width from 400 to 500 feet was not sufficient for safe negotiation of vessel meeting. Furthermore, both the 500-foot width and more optimal widths necessary for two-way traffic would necessitate extensive dock modifications and land acquisition, and this cost was anticipated to greatly exceed the reduction in delays that it would afford.

As a less costly and more practical alternative to the Neches River widening, the Sabine Pilots suggested the use of “sidings” or “channel pull-overs” to help facilitate vessel meeting. At the present time, suggested sites are commonly referred to and used as TB. The TBs are presently used as “holding” or “waiting areas”; however, the depth and width of these areas do not accommodate the full range of larger tankers common on the SNWW. Again, the “holding areas” serve the dual function of TB. In spite of their depth and width limitations, the TB are presently used to facilitate turning small vessels and are also used to “tuck small vessels away” while other vessels move along the channel.

Vessel Traffic

Over 70 percent of SNWW’s 1998–2007 crude petroleum tonnage was shipped in vessels of 90,000 DWT or larger, up by 30 percent since the early 1990s. The largest concentration of SNWW crude petroleum tonnage is in vessels between 90,000 and 119,999 DWT. Table V-55 displays SNWW’s 1990–2004 crude oil import by vessel class.

Table V-56 presents 1990–2007 vessel trips by loaded draft for vessels. Analysis of the data showed that trips increased at an annual rate of 3.7 percent, with the highest rates of growth for 36 feet and greater. Total trips for drafts over 35 feet greater at an average annual rate of 7.3 percent, while trips for loaded drafts of 35 feet or less grew at 3.7 percent. For the period 1990–2007, total deep-draft tonnage grew at an average annual rate of 5.2 percent.

SNWW’s vessel utilization patterns were also reviewed in terms of the average tonnage per trip for 1965–2007. Figure V-5 shows average tonnage per trip for oceangoing traffic. The graph shows trips increasing at a slightly decreasing rate and suggests an overall increase in average tonnage per trip. While the increases in the volume of tonnage per trip are primarily associated with crude petroleum and petrochemical products, larger vessels are being used for manufactured goods and crude materials. Since 1993, the volume of tonnage per vessel has increase as the variety of commodities using the waterway has diversified.

Examination of world trends showed that vessels are not only requiring deeper drafts but that there is an increased concentration of wider beams. Table V-57 displays SNWW 2000, 2001, and 2004 distributions of deep-draft vessels by vessel beam. The table helps illustrate the concentration of wide-beamed vessels. Vessel widths over 110 feet are generally associated with crude oil tankers. An effect of the growing concentration in wider-beam vessels using SNWW is more-difficult and subsequently more-dangerous vessel-meeting situations. The existing 500-foot channel is not wide enough for vessels with beams of 125 feet or more to meet comparable or larger-sized vessels. Project alternatives include channel widening and the construction of vessel holding areas. Widening to 700 feet would enable meetings between Panamax vessels, which have beams of 106 feet, and non-LNG tankers with beams of 144 feet or greater. The availability of several holding area improvements along the Neches River would allow loaded vessels to await berths and would save time that they originally would have spent in an inbound transit mode when the berth became clear. With the holding areas, vessels would only have to shift from the anchorage instead of waiting to sail from offshore.

Source: SPA (2005).

As input to the HarborSym model vessel trip estimate were prepared for the 2000–2004 period base and for 2030–2040 average trips. The vessel classes were established based on the HarborSym vessel structure. The coding sheet corresponding to the vessel class groupings is presented in Table V-58. The 2000–2004 period tonnage and the 2000–2004 fleet data used to define existing traffic patterns are presented in tables V-59 and V-60.

Tables V-61 through V-63 present the 2030–2040 period tonnage and trip data. Table V-61 presents the 2030–2040 period tonnage. Table V-62 presents 2030–2040 vessel trips based on no deepening. Table V-63 presents 2030–2040 vessel trips based on deepening. Comparison of the 2030–2040 tonnage and vessel transit data presented in tables V-62 and V-63 shows that the number of vessels for the “without-deepening scenario” is 12 percent higher than the number for the “with-deepening scenario.” The effect of modifications to the Sabine Pass Channel and Port Arthur Canal reaches would be a change in the vessel pilot rules. The pilot expectations are that the effect of deepening and widening would be likely to result in vessels with loaded drafts of less than 40 feet being able to meet; however, vessels with loaded drafts

over 40 feet would be much more restricted. While the vessel pilots indicated that the effect of deepening would mean a loss of some of the gains in terms of relaxing rules 3–4 (see Table V-54), the combined effect of deepening and widening would result in a reduction in the number of trips necessary to transport a given volume of tonnage and provide added savings to remaining traffic.

Entrance Channel Widening Benefits

The HarborSym model was run for existing conditions and each of the project alternatives. The widening alternatives included widening of the Sabine Pass Channel and Port Arthur Canal from 500 to 700 feet. Evaluation of widths less than 700 feet was also conducted. Widening of the Sabine Pass Channel and Port Arthur Canal reaches were evaluated with and without the Neches River TB and anchorage alternatives and the turning basin anchorage features were evaluated on an incremental basis. The transportation cost savings associated with widening of the Sabine Pass Channel and Port Arthur Canal reaches and Neches River TB and anchorage features were evaluated based on a 40-foot channel depth.

Examination of the output data shows that for the existing condition and pre-base year condition, which reflects the inclusion of LNG carriers, vessels are in the system for 78.2 hours. The output also shows that expansion of the Entrance Channel would reduce the time in system to 76.7 hours. In reviewing the changes in delay times, it was found that there are large variances in throughput times. The minimum time for the without-project condition was on average 11.9 hours and the minimum time for the with-project condition also averaged 11.9 hours. The larger crude oil tankers showed throughput savings for the with-project condition. For instance, Suezmax vessels took an average of 86.7 hours under the without-project condition and an average of 83.1 hours with the widened Entrance Channel. The addition of the LNG vessels would result in longer waiting times for several vessel classes. Without the LNG vessels, the average number of hours in the system was 66.4. The effect of introducing the LNG vessels increases total delay times but reduces average times because the LNG vessels represent a large increase in vessels that travel shorter distances than the existing tanker fleet going to the Neches River and, therefore would not be subject to delays.

Evaluation of widening of the Entrance Channel to 700 feet through the Sabine Pass Channel and Port Arthur Canal showed that, using 2000–2004 traffic levels, vessels would save an average of 1.5 hours per round-trip voyage, with an annual savings of \$3,487,322. Evaluation of Port Arthur by itself resulted in annual savings of approximately \$2,579,760.

The model was run using 2004-period traffic and 2035 projected traffic. The effect on the reduction in total vessel movements resulting from channel deepening is evaluated in the sensitivity section of the Economic Appendix. Table V-64 summarizes the average annual benefits for 2019–2069 for widening of the Sabine Pass Channel and the Port Arthur Canal. While the results show that widening the contingent reaches produces higher benefits than widening one reach without the other, widening the contingent reaches as a combined feature increases total benefits by less than the sum total. These results indicate that the added benefits decline when the second reach is added. Table V-65 displays the economic

summary data associated with the widening of Sabine Pass and the Port Arthur Canal. The results of the benefit-cost analysis indicated that widening was not an incremental justified feature.

Table V-64
Sabine Pass Channel and Port Arthur Canal

Neches River Holding Areas

Evaluation of the Neches River AB was conducted using the HarborSym Model. These proposed features would be used to facilitate vessel passing. The locations of the TBs are contained in Table V-66. As the titles indicate, some of the individual features would include a TB and an anchorage (No. 1, 2, and 4) and some just a TB (No. 3, 5, and 6) or an anchorage (No. 7 and 8). The Sabine Pilots noted that the Turning Basin Anchorages (TBA), such as 1, 2, 4, 7, and 8 would be designed to enable a 48-foot loaded Suezmax tanker to use the inner portion of the feature as an anchorage and also allow a 48-foot loaded Suezmax tanker to turn in the TB section. While some of the features described in Table V-66 would be developed from existing basins (1, 4, and 6) or are new basins (2, 3, 5, 7, and 8), the anchorage components of the

Table V-66

*Light vessels under emergency conditions.

**Under existing conditions, TB 5 is private and used by shallow-draft barges. A new turning basin is proposed immediately north of existing TB 5. This basin would be designed for loaded Suezmax tankers.

***For the "with-project future," anchorage basins 7 and 8 are designed for anchorage; however, the pilots intend to use anchorage basins 7 and 8 for both the anchorage and turning of Suezmax vessels.

features are essentially new, and the proposed dimensions represent new dredging. All but TB 6 are proposed to be dredged over the existing 40-foot project depth. HarborSym was not used to evaluate deepening of the existing TBs. Benefits would be based on related delays in waiting and traveling to another TB.

As an example of how the TBs would be used, an inbound convoy would arrive on the Neches River Channel with the vessels going to docks on the upper end of the Neches leading the convoy. Each vessel would proceed to their respective dock and head into the berth (for the SNWW vessels turn after finishing at the dock). The availability of several holding area improvements was emphasized as it allow loaded vessels to await berths and would save time that they originally would have spent in an inbound transit mode when the berth became clear. With the holding areas, vessels would only have to shift from the anchorage instead of awaiting the ship to sail and to start in according to the traffic rules. The pilots noted that the number of hours saved depends on the dock facility and that the benefits would be primarily for the crude oil tankers and some product carriers; however, all traffic would realize some savings. The availability of anchorages is expected to allow the inclusion of additional ships as part of inbound convoys. Under present conditions, the size of an inbound convoy is limited to berth space. When the berths are available, the vessels would switch from the holding area to a berth. It was noted that it is quicker to put a vessel in an anchorage (approximately 20 minutes) than to dock (approximately 1 hour). Similarly, it is quicker to depart from anchorage than to undock and turn. The net result is that the convoys would move faster and include additional vessels.

The with-project condition would provide for concurrent use of TBA1, TBA2, and TBA4 for both turning and anchorage of individual vessels. An additional item revealed at the meetings was that the maximum vessel size using the TBs was the same for the without- and with-project conditions. Additionally the model assumptions were based on “no change in Neches River transit rules” for the with-project condition. At the meeting, the pilots said that they would, in fact, trade vessels out between the Neches River “holding areas” and “docks” despite night rules and beam and depth restrictions. The vessel arrivals and departures from the Neches River Channel are planned and/or orchestrated rather than random. Under present conditions, a new Neches River inbound fleet cannot come in until the outbound Neches River fleet has traveled down the Neches River Channel and has cleared the Jetty Channel and is in the Outer Bar Channel. Under the without-project condition, the vessels wait offshore. Under the with-project condition, they would also wait offshore; however, the sidings would allow a vessel to move to the dock and start unloading when, under the without-project condition, it would be waiting for an outbound convoy to clear the Jetty Channel. The convoy behavior would not change between the without- and with-project conditions. It is recognized that it would take extra time to maneuver in and out of the sidings, and the effect of this behavior is accounted for in the benefit estimates.

Initial input concerning the number of TBs, TBA combinations, and ABs was made based on pilot interviews. The TBs and TBA combinations are used for both turning and for vessels to wait while others pass. In regard to incremental justification of review concerns, the pilots expressed considerable reluctance to agree to anything less than the six TBs; however, they conceded that if priorities had to be

placed on TBA construction, the priorities would be 1, 4, and 7. Next noted grouping was 1, 4, 5, and 7. It was emphasized that the priority was for all TB improvements.

The benefits of the TB features were evaluated based on pilot input and examination of the HarborSym output data associated with waiting times and other related variables. The initial focus of the discussions with the pilots was to understand present use of the TBs and obtain clarification on the DWT, loaded drafts, beam, length, and number of vessels associated with each of the TBs. Presently, the TBs are used for vessel turning and holding of light vessels (i.e., loaded drafts less than 29 feet). Some TBs are also used for holding light Aframax tankers, again with drafts loaded to less than 29 feet. It was noted that Aframax tankers can be pushed into a TB; however, lack of maintenance dredging makes this practice less frequent and more difficult but it would occur if a vessel, communication, or other breakdown situation requires. The vessel arrivals and departures from the Neches River Channel are planned and/or orchestrated rather than random. Under present conditions, a new Neches River inbound fleet cannot come in until the outbound Neches River fleet has traveled down the Neches, has cleared the Jetty Channel, and is in the Outer Bar Channel. Under the without-project condition, the vessels wait offshore. Under the with-project condition, they would also wait offshore; however, the sidings would allow a vessel to move to the dock and start unloading when, under the without-project condition, it would be waiting for an outbound convoy to clear the Jetty Channel. By building the Neches River sidings, an inbound convoy can save a significant portion of the inbound transit time by being in the sidings and ready to move to the docks as the outbound convoy leaves. The convoy behavior would not change between the without- and with-project conditions. Table V-67 presents the HarborSym output associated with the Neches River anchorages. Discussion with the pilots indicated uncertainty concerning shifting charges; therefore, the effect of their inclusion was evaluated. The benefits were calculated based on shifting costs being levied 50 percent of the time. Tables V-68 and V-69 summarize the average annual savings in comparison to the average construction cost. Table V-68 is similar to Table V-69 and presents the same combinations but differs in that the annual benefits reflect inclusion of “pilot shifting costs” for 100 percent of the time. The annual benefits presented in tables V-67 and V-68 do not reflect future growth and are based on 2004-period traffic levels. Analysis of the data presented in the tables shows that the combination of basins that include alternatives 1, 4, and 8 produce the highest net excess benefits among the alternatives evaluated.

Table V-70 summarizes the project cost and benefits associated with the combination of 1, 4, and 8. The annual benefits presented in Table V-70 are average annual numbers and reflect future growth based on 2019–2069 traffic levels.

Summary of Widening Benefits

Table V-71 displays a summary of the widening benefits. The benefits are for widening the Sabine Pass Channel and Port Arthur Canal to 700 feet and constructing the Neches River anchorage features. Table V-72 presents the economic summary data associated with the channel widening alternatives. The results of the widening analysis show that widening of the Sabine Pass Channel and Port Arthur Canal is not an incrementally justified feature. Widening was not carried forward as a project feature. The ABs are incrementally justified and were included as part of the recommended plan.

The benefit calculations shown in tables V-71 and V-72 are based on 2004-period historical and 2030–2040 projected traffic. The 2030–2040 traffic levels do not account for the effect of trip reductions due to channel deepening. The effect on the reduction in total vessel movements resulting from channel deepening is evaluated in the sensitivity section of the Economic Appendix. For the sensitivity, HarborSym widening model was run based on the reduction in vessel trips as a result of channel deepening. The purpose of the sensitivity was to determine changes in the annual delays in relationship to the widening alternative in combination with channel deepening. The change in vessel trips due to channel deepening was estimated based on the decrease in the number of trips necessary to transport future tonnage. The model results suggest that the reduction in the number of vessel trips, resulting from channel deepening, has a significant effect on the net difference in the duration of vessel delays between the without- and with-project conditions. Further analyses based on various ranges of fleet forecasts

indicate that the increase in benefits from scenarios that included either “deepening and widening” or “deepening and the TB” are primarily attributable to the reduction in trips due to channel deepening. These savings result from the reduction in trips based on vessels carrying additional cargo from the redistribution of vessel sizes based on the availability of a deeper channel and do not vary significantly from the “widening only” benefits shown in Table V-71. The effect of adding these savings to the project benefits is outlined in the sensitivity section of the Economic Appendix.

V.F NED BENEFIT SUMMARY

Table V-73 presents the transportation cost savings by major commodity group and channel reach. The majority of benefits are associated with imports of crude petroleum, LNG and petroleum products, and exports of petroleum products. Crude petroleum and petroleum products represent 84 percent of the benefits at the 45-foot depth and 89 percent at the 50-foot depth. LNG comprises 7 percent of benefits at the 45-foot depth and 4 percent at 50 feet. The LNG benefits are for facilities in the Sabine Pass Channel and Port Arthur Canal reaches.

Table V-74 summarizes the benefit cost analysis, including the first cost of construction, net excess benefits, and the BCR for the project alternatives. The results of the analysis indicate that the 49-foot channel depth represents the plan that most reasonably maximizes net excess benefits.

Incremental Analysis

The project benefits start in the Sabine Pass Channel reach where the Sabine Pass LNG terminal is located (see Figure II-3). The Port Arthur Canal reach follows the Sabine Pass Channel reach. The Golden Pass LNG terminal, which is nearing completion, is located in the Sabine Pass Channel reach. An additional LNG terminal, Port Arthur, is permitted for construction in the Port Arthur Canal reach; however, due to uncertainty, the LNG transportation savings benefits (see Table V-52) do not include the Port Arthur terminal. The Port Arthur Canal reach also provides access to the Taylor Bayou side channel and basin. The Port of Port Arthur facilities are located along the main portion of the Sabine-Neches Canal. The incremental analyses for channel improvements through Port Arthur excluding the Taylor Bayou side channel are shown in Table V-75.

Separable analysis of the Taylor Bayou is shown in Table V-76. The analysis presented in Table V-76 shows that the BCRs for the Taylor Bayou increment are well above unity. Table V-77 presents the Sabine-Neches and Taylor Bayou increments as a separable unit. Table V-77 indicates that the BCRs for the segment through the Sabine-Neches Canal and including Taylor Bayou are below unity due to the inclusion of the entrance channel costs and exclusion of the Neches River benefits. Incremental analysis of the Neches River reach in Table V-78 shows that the BCRs are well above unity. Table V-79 displays the Neches River analysis excluding Taylor Bayou. Table V-80 reflects exclusion of benefits from Taylor Bayou, LNG, and breakbulk. Table V-81 presents calculation of the benefits and costs without inclusion of LNG.

The results of the analyses presented in Tables V-75 through V-81 show that the downstream benefits are not needed to justify the upstream costs. The analysis shows that each of the major reaches provides significant incremental benefits.

Benefit-Cost Ratio at 7 Percent

Calculation of benefits and costs at 7 percent interest is required by EC 11-2-194, commonly referred to as the budget Engineering Circular (paragraph 11). The 7 percent calculations are used for budget ranking purposes. Table V-82 outlines the economic calculations at 7 percent.

Sensitivity Analysis for Additional Advanced Maintenance

During the development of the alternatives, several reaches of the channel were identified as requiring additional advanced maintenance beyond the standard practices of the Galveston District. These reaches included the Sabine Pass Outer Bar Channel, one section of the Sabine Pass Channel, the Port Arthur Junction, and portions of the Neches River Channel.

In these fast-shoaling areas, it was assumed that additional advance maintenance would be required to avoid frequent dredging and to ensure the reliability and least overall cost for operating and maintaining the project's authorized dimensions. This increase in advance maintenance (ranging from 1 to 5 feet) was proposed for some portions of some channel reaches to allow the proposed dredging frequency to remain the same as the existing O&M dredging frequency.

A sensitivity analysis was performed on the O&M costs to determine the impact to the BCR if the additional advance maintenance was not performed on these specific channel reaches. Table V-83 presents the summary of the economic data without this additional advanced maintenance in those limited channel reaches. In a comparison to Table V-74 which summarizes the costs and benefits for the study, the average annual O&M costs increases over the 50-year period of analysis without the additional

advance maintenance because, although less material would be dredged per dredging cycle, the frequency of O&M dredging would increase to maintain the project's authorized depth. This increase in average annual O&M costs results in a decrease in the net excess benefits and a decrease in the BCRs for each of the channel depths. The NED plan of 49-foot depth has a decrease in the BCR from 1.3 to 1.2.

V.G REGIONAL BENEFITS

The SNWW is America's largest military port and the second largest importer of crude oil based on tonnage. An estimated 20 to 30 percent of all military jet fuel is produced on the SNWW and an estimated 118 million tons of cargo are moved through the marine terminals. The waterway delivers 12 to 16 percent of the crude oil and refined products supplied east of the Rocky Mountains.

SNWW port activity contributes significantly to the local and regional economy by generating business revenue to local and national firms providing vessel and cargo-handling services at the marine terminals. These firms, in turn, provide employment and income to individuals. The SNWW marine terminals and refinery complexes generate revenue throughout the local, state, and national economies.

Terminals along the SNWW include the public marine terminals owned by the Port of Beaumont and Port of Port Arthur, as well as the petroleum refineries, chemical plants, and bulk/breakbulk terminals. These terminals use vessel and barge transportation to move crude oil, petroleum products, liquid and dry chemicals, steel, and dry bulk cargo.

Revenue generated by the waterway is generated by firms providing services to the commodity and vessel activity at the terminals, revenue from trucking firms, railroads, pipeline operations, terminal operators and associated refineries and chemical plants (from loading and discharging vessels), chandlers, agents, pilots, towing companies, shipyards, and maritime support firms. This revenue is used to purchase

employment (direct jobs) to provide the services, to pay stockholders and for retained earnings, and to purchase goods and services from local firms, as well as national and international firms (creating indirect jobs with these firms). Businesses also pay taxes from the business revenue.

For the communities within the study area, the SNWW is responsible for benefits to the local and regional economy. The Sponsor recently contracted for a study on the *Economic Impact of the Sabine-Neches Waterway* (Martin Associates, 2006). Regional benefits of the SNWW to the communities within the study area include (based on 2004 statistics):

- 83,692 jobs in Texas and Louisiana (private and public marine terminals along SNWW);
- 14,987 jobs directly related to activities along the waterway;
- 13,628 induced jobs from local purchases from SNWW workers;
- 55,077 indirect jobs;
- \$877.7 million of direct wages and salaries;
- \$2.2 billion in business revenue (excluding the cargo);
- \$426.5 million of State and local taxes (generated by activity at the marine terminals); and
- \$853 million of Federal taxes (generated by activity at the marine terminals).

The number of jobs that the waterway supports is impressive especially since the Southeast Texas labor force totaled 176,500 people in June 2006, with personal income and consumption attributable to the waterway at \$4.7 billion (*Beaumont Enterprise*, 2006).

With the value of the current 40-foot-deep SNWW channel to the region, it is expected that the proposed deepening and widening of the channel for navigational efficiency and safety would increase the benefits to the region or at a minimum maintain the existing benefits.

This page intentionally left blank.

VI. DESCRIPTION OF RECOMMENDED PLAN

VI.A OVERVIEW

In the previous chapter, the economic analysis identified the process and rationale used to identify the NED Plan, which is the 49-foot plan. However, the Recommended Plan identified in Chapter IV is the 48-foot deepening, which is also considered the LPP by the Sponsor. The Sponsor agrees that this plan best addresses the navigational efficiency and safety issues along the existing SNWW channel. This chapter describes the Recommended Plan in more detail. The Engineering Appendix, which includes design information, is available upon request.

VI.B DESCRIPTION OF RECOMMENDED PLAN

The Recommended Plan involves the following modifications to the existing channel:

- Deepening the SNWW to Beaumont to 48 feet, extending the Entrance Channel 13.2 miles,
- Deepening and selective widening of Taylor Bayou channels and TB,
- Decreasing the width of the Sabine Bank Channel to 700 feet with tapering from 800 feet (Station 23+300) to 700 feet wide (Station 25+800 through the end of Sabine Bank Channel),
- Adding or enlarging turning and AB along the Neches River Channel, and
- Bending easing on the Sabine-Neches Canal and Neches River Channel.

With the Recommended Plan, the existing channel depth would be increased by 8 feet, increasing the inland portion from 40 feet to 48 feet and increasing the existing offshore portions from 42 to 50 feet (plus overdepth or advance maintenance as needed). The channel deepening would result in the Entrance Channel being extended 13.2 miles farther south into the Gulf of Mexico. The Sabine Pass Jetty Channel, Sabine Pass Channel, Port Arthur and Sabine-Neches canals, and the Neches River Channel would be deepened from 40 to 48 feet. The existing offshore entrance channels (Sabine Pass Outer Bar Channel and Sabine Bank Channel) would be deepened from 42 to 50 feet, and the Sabine Bank Extension Channel would be dredged to 50 feet. This would increase the SNWW from 64 miles to approximately 77 miles in length. No modifications to the existing Sabine Pass jetties would be required as part of the CIP.

The Taylor Bayou TB and channels would also be widened at its entrance and the upstream bottleneck curve and deepened to 48 feet. Neither the Sabine-Neches Canal nor the Neches River Channel would be widened, but navigation efficiency would be improved with bend easings in both reaches, and the addition or enlargement of turning and ABs on the Neches River Channel.

The Recommended Plan would result in an estimated 98 mcy of new work and 650 mcy of maintenance material over the 50-period of analysis (Table VI-1). The annual maintenance dredging quantities in the SNWW would increase from an average of 8.1 mcy for the current 40-foot project to 13.0 mcy for the proposed 48-foot project. Dredged depths would actually be deeper than the authorized depth when allowances for overdepth and advance maintenance are included. Overdepth dredging and advance

maintenance would be 2 feet each; however, in critical and fast-shoaling areas, additional advance maintenance is required to avoid frequent dredging and to ensure the reliability and least overall cost for operating and maintaining the project's authorized dimensions. An increase in advance maintenance (ranging from 1 to 5 feet) was proposed for some portions of some channel reaches to allow the proposed dredging frequency to remain the same as the existing O&M dredging frequency. These channel depths were included in the mesh for the HS modeling.

Table VI-1
New Work and 50-Year Maintenance Quantities for the Recommended Plan

	Channel Reach	New Work Quantities	50-Year Maintenance Quantities
Offshore	Sabine Bank Extension	18,737,000	36,216,000
	Sabine Bank Channel	15,358,000	96,371,000
	Sabine Pass Outer Bar Channel	5,923,000	223,650,000
	Sabine Pass Jetty Channel	2,978,000	13,527,000
Inshore	Sabine Pass Channel	6,723,200	34,780,800
	Port Arthur Canal	11,697,200	82,857,600
	Sabine-Neches Canal	11,944,000	73,245,000
	Neches River Channel	25,014,000	89,724,800
	Total Quantities	98 mcy	650 mcy

The SNWW Recommended Plan is made up of eight channel reaches: three offshore and five inland. Each channel reach is divided into different sections for dredging contracts. These sections are shown on the Engineering Plates in Appendix 1 of this FFR. The specifics for each channel reach are discussed later in this section. Whenever economically and environmentally feasible, new work and maintenance material are used beneficially either for marsh restoration or shoreline nourishment. Sixteen existing and two new PAs would be used for upland placement.

General Navigation Features of the Recommended Plan

Proposed structural channel improvements are described individually for each reach below (figures VI-1 through VI-7). General navigation features (GNF) of the Recommended Plan consist of:

- 1) Deepening of navigation channels and basins;
- 2) 50-year DMMP for both new work and O&M (ODMDSs, upland PAs, and the Neches River and Gulf Shore BU features);
- 3) Marsh mitigation in Louisiana; and
- 4) Bridge reinforcements.

Non-General Navigation Features project elements (aids to navigation, Land, Easements, and Rights of Way [LER], and relocations [including utility relocations]) are described at the end of this chapter. The Sabine Bank Extension is discussed separately below, but it is actually part of the Sabine Bank Channel reach.

Sabine Bank Extension Channel

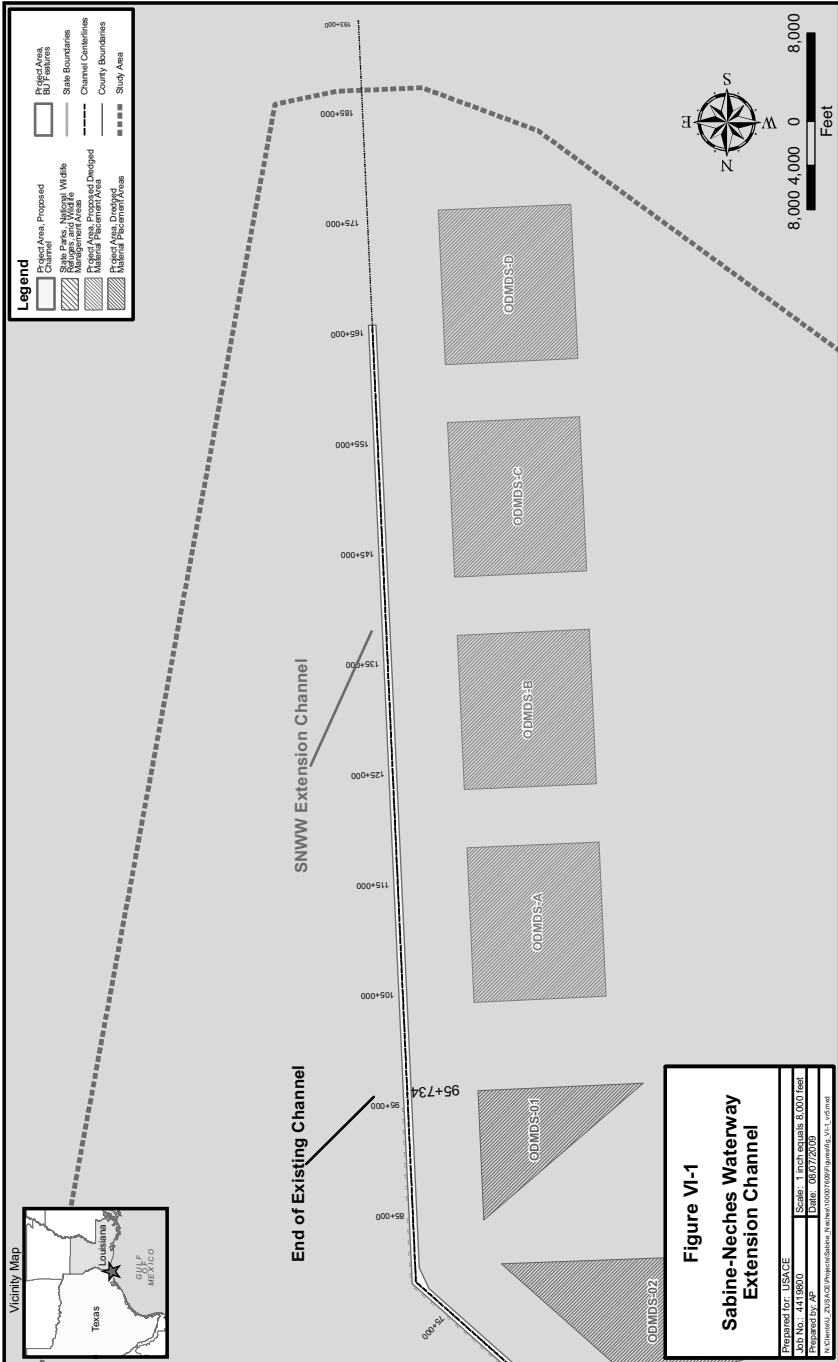

This channel lengthens the existing offshore Entrance Channel approximately 13.2 miles at a bottom width of 700 feet (Figure VI-1). The additional length is required to reach a water depth in the Gulf of Mexico equal to the proposed channel depth. The proposed offshore depth is 50 feet, but advance maintenance and allowable overdepth would add a total of 4 more feet, bringing the total dredged depth of the Extension Channel to 54 feet. It would be constructed by hopper dredge beginning at the end of the Sabine Bank Channel, and it would extend into the Gulf of Mexico at the same bearing as the Sabine Bank Channel. An overview of the project details for the Sabine Bank Extension is listed in Table VI-2.

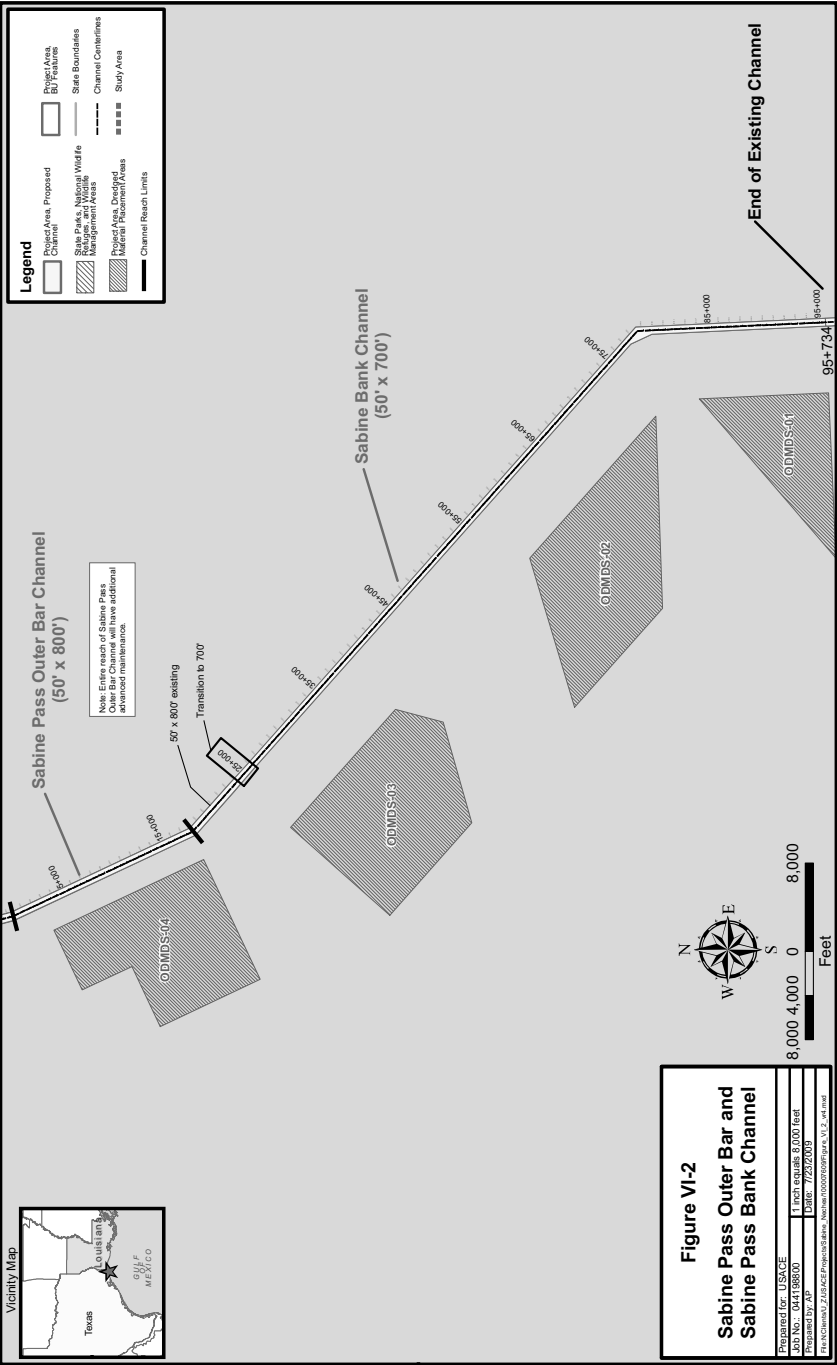

Table VI-2
Project Details of Sabine Bank Extension

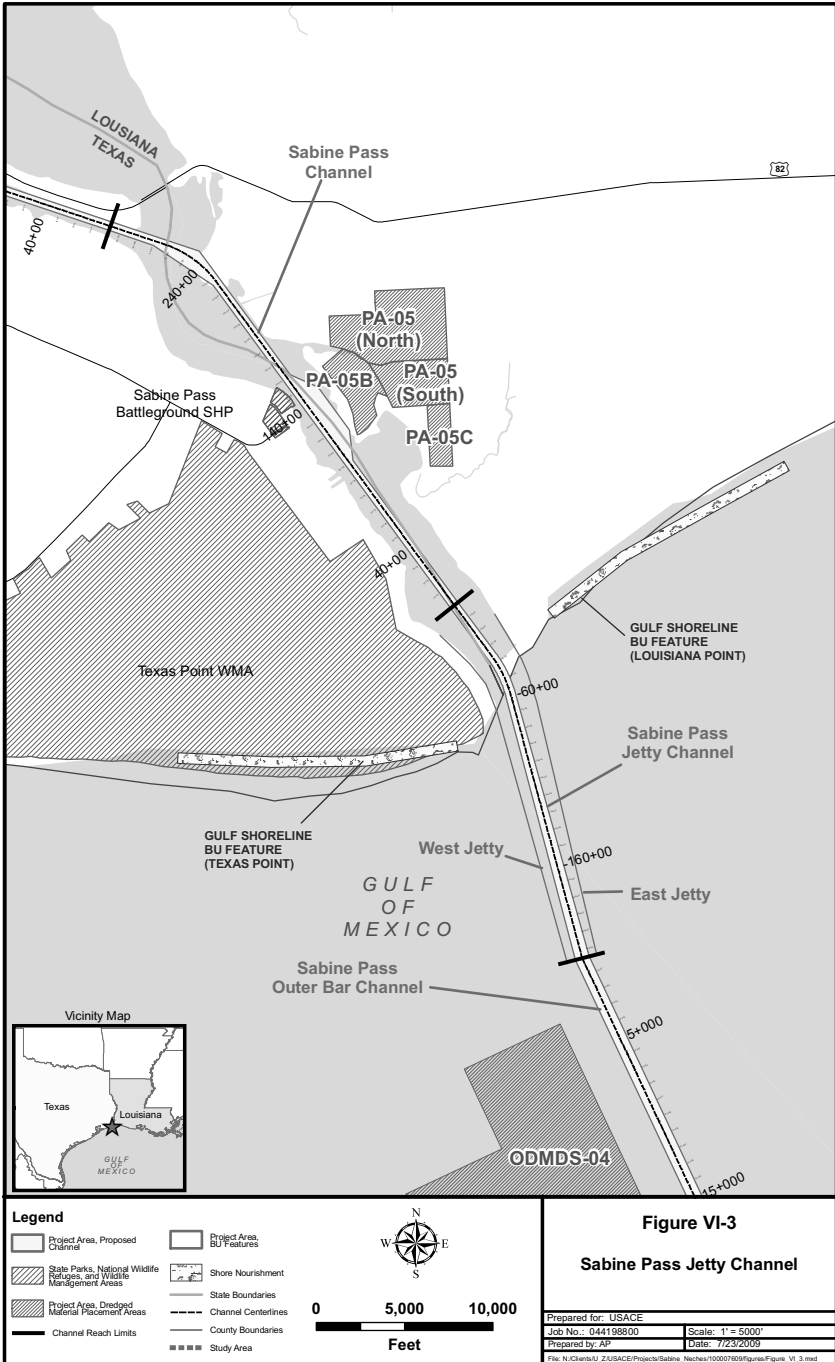

Length of Reach	13.2 miles (new)
Project Depth	50 feet
Bottom Width	700 feet
Advance Maintenance	2 feet
Allowable Overdepth	2 feet
New Work Material	18,737,000 cubic yards
Placement Areas	ODMDSs A, B, C, and D
Beneficial Use of Dredged Material	None
Maintenance Material (50-year quantity)	36,216,000 cubic yards
Increase in Maintenance Material	36,216,000 cubic yards
Placement Areas	ODMDSs A, B, C, and D
Beneficial Use of Dredged Material	None

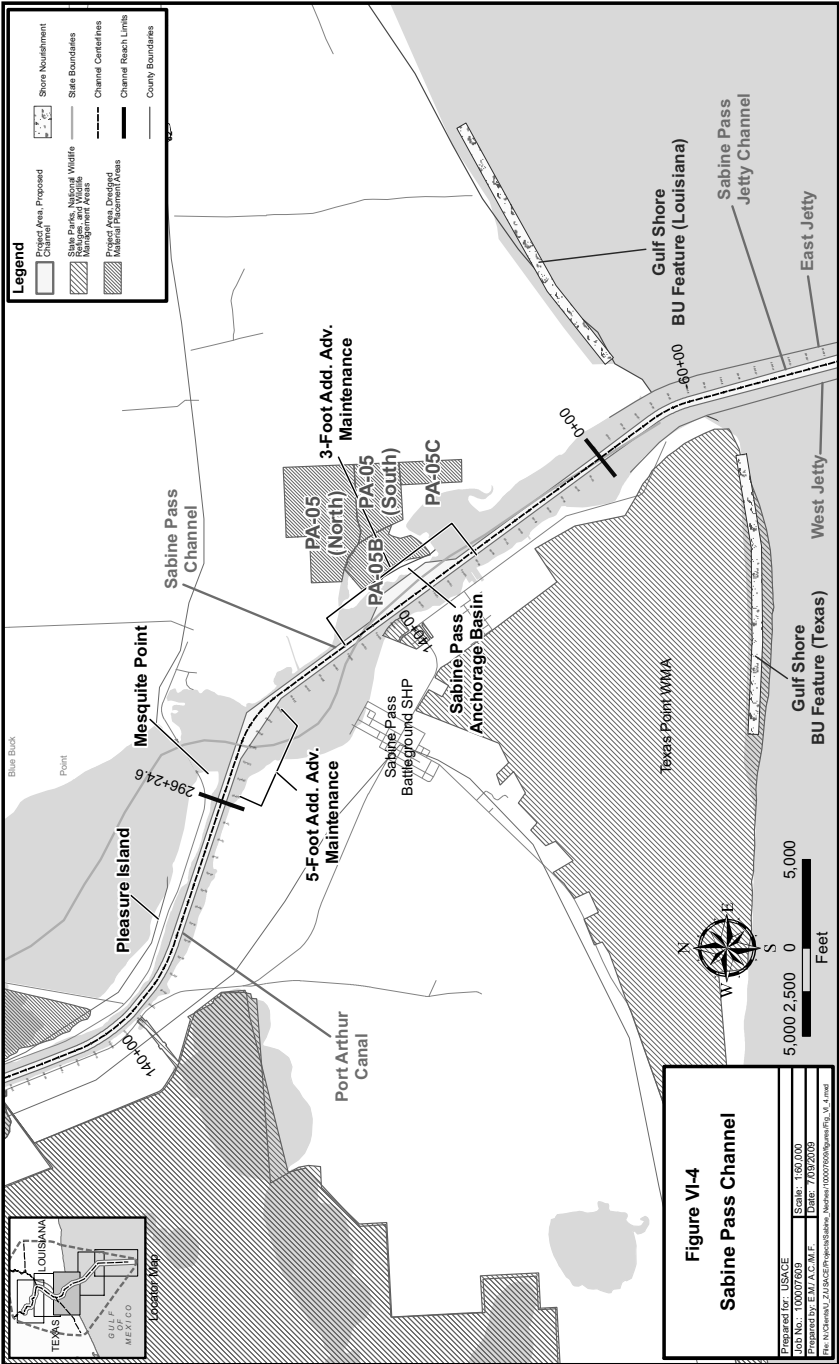

Sabine Bank Channel

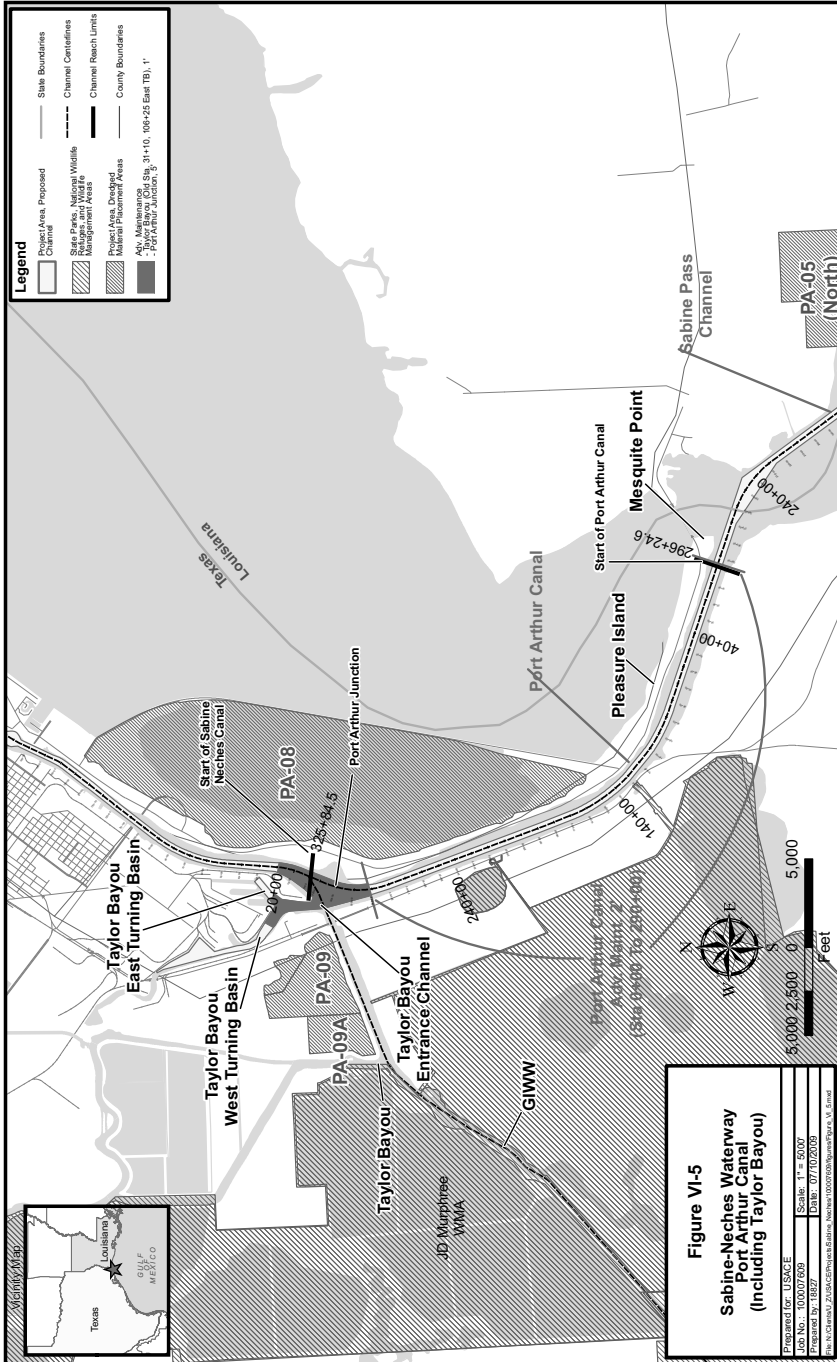

This 14.7-mile-long channel would be deepened from 42 to 50 feet using a hopper dredge (Figure VI-2). When advance maintenance and allowable overdepth are added to the proposed 50-foot depth, the Sabine Bank Channel would be dredged to 54 feet. The bottom width of the Sabine Bank Channel is currently 800 feet; it would remain 800 feet wide for the first mile past the end of the Outer Bar Channel, and then it would taper from 800 to 700 feet over the next one-half mile. The Sabine Bank Channel would continue the 700-foot bottom width for approximately 13.2 miles to its connection with the Extension Channel. Since the existing channel is 800 feet wide, new channel markers would be required to mark the tapered transition and the remainder of the narrowed Sabine Bank Channel. An overview of the project details for the Sabine Bank Channel reach is listed in Table VI-3.

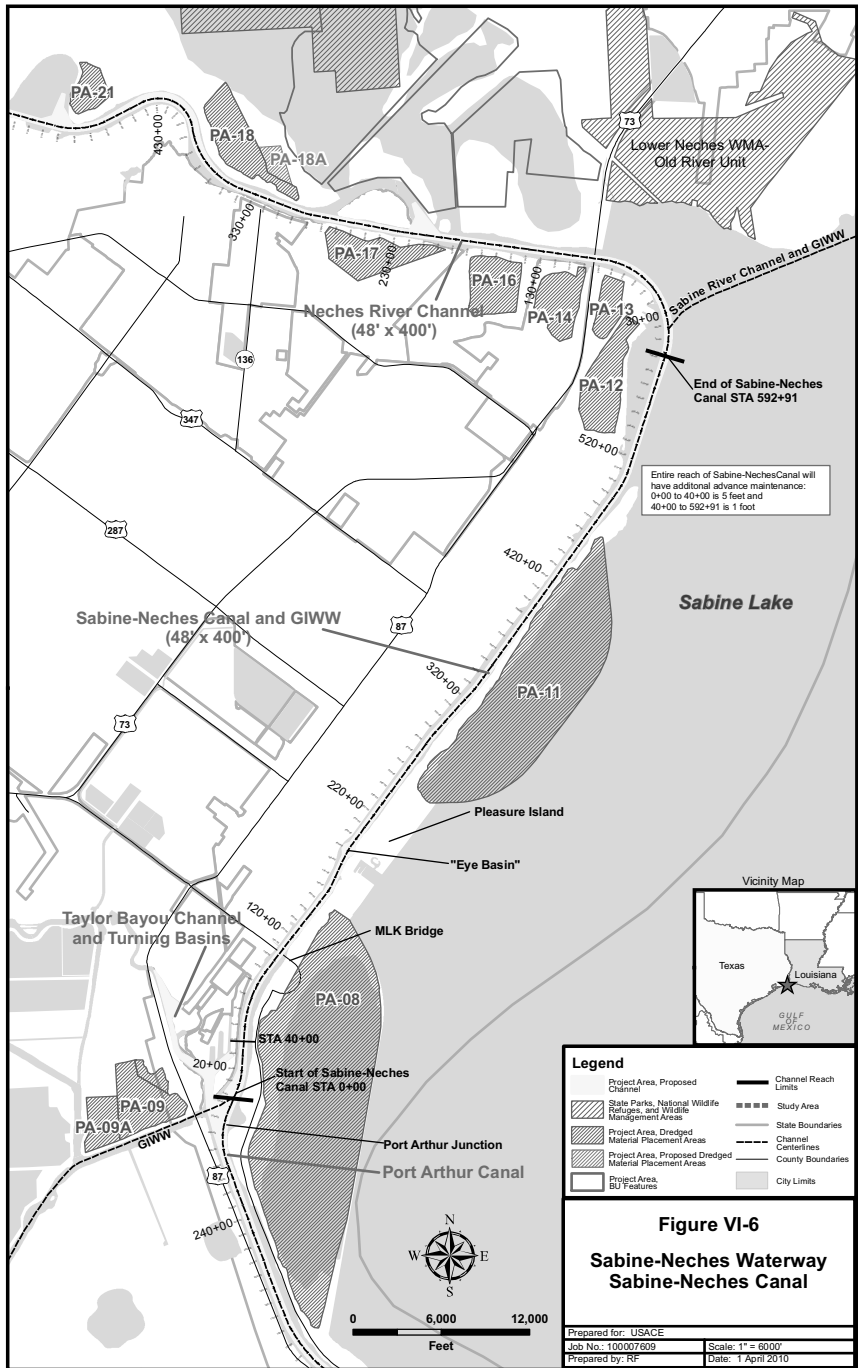

File: N:\Clients\J_Z\USACE\Projects\Sabine_Neches\100007609\figures\Figure_VI_6_v4.mxd

Table VI-3
Project Details for Sabine Bank Channel Reach

Length of Reach (Sections 1, 2)	14.7 miles (no change)
Project Depth	50 feet
Bottom Width	800 feet then narrow to 700 feet
Advance Maintenance	2 feet
Allowable Overdepth	2 feet
New Work Material	15,358,000 cubic yards
Placement Areas	ODMDS 1 and 2
Beneficial Use of Dredged Material	None
Maintenance Material (50-year quantity)	96,371,000 cubic yards
Increase in Maintenance Material	45,549,000 cubic yards
Placement Areas	ODMDS 1 and 2
Beneficial Use of Dredged Material	None

Sabine Pass Outer Bar Channel

This 3.4-mile-long channel would be deepened from 42 to 50 feet using a hopper dredge (Figure VI-2). This portion of the channel has higher velocity eddies moving around the end of the east jetty, which causes sediment to settle out as the currents cross the navigation channel, creating a higher shoaling rate. Due to the high shoaling rate, advance maintenance amounts are increased to maintain current maintenance dredging cycles. When advance maintenance and allowable overdepth are added, the Outer Bar Channel could be dredged to 58 feet. The Outer Bar Channel would remain at its current 800-foot bottom width due to strong crosscurrents just beyond the end of the jetties. An overview of the project details for the Sabine Pass Outer Bar Channel reach is listed in Table VI-4.

Table VI-4
Project Details for Sabine Pass Outer Bar Channel Reach

Length of Reach (Section 3)	3.4 miles (no change)
Project Depth	50 feet
Bottom Width	800 feet
Advance Maintenance	2 feet
Allowable Overdepth	2 feet
Additional Advance Maintenance	4 feet
New Work Material	5,923,000 cubic yards
Placement Areas	ODMDS 3
Beneficial Use of Dredged Material	None
Maintenance Material (50-year quantity)	223,650,000 cubic yards
Increase in Maintenance Material	123,965,000 cubic yards
Placement Areas	ODMDS 3
Beneficial Use of Dredged Material	None

Sabine Pass Jetty Channel

This 4.1-mile-long channel would be deepened to 48 feet using a hopper dredge (Figure VI-3). When advance maintenance and allowable overdepth are added, the Sabine Pass Jetty Channel could be dredged to 52 feet. The width of the channel would remain the same with the channel gradually tapering from the existing 800-foot width at the jetties mouth to 500 feet wide at the jetties head (Station 0+00). No impacts to the jetties have been identified that are associated with the proposed improvements. An overview of the project details for the Sabine Pass Jetty Channel reach is listed in Table VI-5.

Table VI-5
Project Details for Sabine Pass Jetty Channel Reach

Length of Reach (Section 4)	4.1 miles (no change)
Project Depth	48 feet
Bottom Width	800 to 500 feet
Advance Maintenance	2 feet
Allowable Overdepth	2 feet
New Work Material	2,978,000 cubic yards
Placement Areas	ODMDS 4
Beneficial Use of Dredged Material	None
Maintenance Material (50-year quantity)	13,527,000 cubic yards
Increase in Maintenance Material	2,142,000 cubic yards
Placement Areas	ODMDS 4
Beneficial Use of Dredged Material	None

Sabine Pass Channel

This 5.6-mile-long channel begins just north of the jetties and extends upstream to Mesquite Point on Pleasure Island (Figure VI-4). It would be deepened to 48 feet and constructed with a hydraulic pipeline dredge. Advance maintenance varies in different sections of the Sabine Pass Channel to account for differences in shoaling rates. The maximum dredging depth for two reaches of this channel (Station 0+00 to Station 100+00, and Station 180+00 to Station 230+00) would be 52 feet. Due to additional advance maintenance required to maintain existing O&M dredging cycles, the reaches from Station 100+00 to Station 180+00 and Station 230+00 to the end of the Sabine Pass Channel at 295+61 would be dredged to a depth of 55 feet. The bottom width of the Sabine Pass Channel would remain at 500 feet with a new centerline closely following the existing centerline. The Sabine Pass Anchorage is located in this reach and its footprint would be reduced in size because it has never been fully utilized. The width would be decreased from 1,500 to 855 feet, but the length would remain at 8,200 feet. The angle of approach would remain the same. An overview of the project details for the Sabine Pass Channel reach is listed in Table VI-6.

Table VI-6
Project Details for Sabine Pass Channel Reach

Length of Reach (Sections 5, 6)	5.6 miles (no change)
Project Depth	48 feet
Bottom Width	500 feet
Advance Maintenance	2 feet
Allowable Overdepth	2 feet
Additional Advance Maintenance	Station 100+00 to Station 180+00 is 3 feet Station 230+00 to Station 295+61 is 3 feet
New Work Material	6,723,000 cubic yards
Placement Areas	PA 5
Beneficial Use of Dredged Material	None
Maintenance Material (50-year quantity)	34,781,000 cubic yards
Increase in Maintenance Material	4,191,000 cubic yards
Placement Areas	PA 5
Beneficial Use of Dredged Material	Gulf Shore Beneficial Use Feature

Port Arthur Canal (including Taylor Bayou Channels and Turning Basins)

This 6.2-mile-long canal begins near Mesquite Point and ends at the Port Arthur Junction Area with the Taylor Bayou channels (Figure VI-5). The Junction Area serves as a TB and has an irregular shape where the Taylor Bayou channels and the GIWW merge with it. The Port Arthur Canal would be deepened to the proposed depth of 48 feet with a hydraulic pipeline dredge. Advance maintenance would vary in different sections of the Port Arthur Canal to account for differences in shoaling rates. The reach from Station 00+00 to Station 290+00 would be dredged to a maximum depth of 53 feet. The remaining part (Port Arthur Junction) between Stations 290+00 and 326+37 would be dredged to a maximum depth of 57 feet. The bottom width of the Port Arthur Canal would remain 500 feet. An overview of the project details for the Port Arthur Canal reach (including Taylor Bayou) is listed in Table VI-7.

Located at the confluence of the Port Arthur Junction Area, the GIWW, and the mouth of the original Taylor Bayou, the Taylor Bayou Channels and TB consist of several subreaches: Entrance Channel, East TB, West TB, Connecting Channel, and the Taylor Bayou TB. Several significant changes are proposed for this area. When advance maintenance and allowable overdepth are added to the proposed 48-foot depth, all of the Taylor Bayou channels and TB could be dredged to 53 feet. The Taylor Bayou portion of the Junction Area, between Taylor Bayou stations 0+00 and 31+10, would be dredged to 57 feet. The Taylor Bayou Entrance Channel and the West TB bottleneck curve would be widened, and a structural wall would protect local railroad tracks. Changes for each subreach are detailed below.

- Taylor Bayou Entrance Channel. The new bottom width widens on the west side of the channel. The channel would be widened to 444 feet at new Station 10+00. The new bottom width would taper back to the existing width by the end of the first curve at Station 28+38.

Table VI-7
Project Details for Port Arthur Canal Reach (including Taylor Bayou)

Length of Reach (Sections 7, 8)	6.2 miles (no change)
Project Depth	48 feet
Bottom Width	Varies (widest is 500 feet)
Advance Maintenance	2 feet
Allowable Overdepth	2 feet
Additional Advance Maintenance	(PA Canal) Station 0+00 to 290+00 is 1 foot (PA Canal) Station 290+00 to 326+37 is 5 feet (Taylor Bayou) Station 0+00 to 31+10 is 5 feet (Taylor Bayou) Station 31+10 to 106+25 is 1 foot
New Work Material	11,697,000 cubic yards
Placement Areas	PAs 8 and 9
Beneficial Use of Dredged Material	None
Maintenance Material (50-year quantity)	82,858,000 cubic yards
Decrease in Maintenance Material	5,391,000 cubic yards
Placement Areas	PA 8 and 9
Beneficial Use of Dredged Material	None

- East TB. The right side width would decrease 16 feet as the new depth extends down the existing side slope.
- West TB. The width of the existing bottleneck has been increased up to 120 feet on the west side, between new stations 33+00 and 55+00. The west bank of the basin would be protected by a structural wall, preventing impacts to the local railroad tracks present in this area.
- Connecting Channel. The West TB widening tapers back to the existing width in the Connecting Channel, between stations 55+00 and 67+00.
- Taylor Bayou TB. No changes would be made to the existing dimensions, but the basin would be deepened to the proposed 48-foot depth. Existing shore protection belonging to a local facility near Station 90+00 would be affected by penetration by the top-of-cut for the new depth.

Sabine-Neches Canal

The 11.2-mile-long canal begins at the Port Arthur Junction Area and ends just south of the mouth of the Neches River (Figure VI-6). The GIWW shares this canal with the deep-draft channel. It would be deepened to the proposed depth of 48 feet with a hydraulic pipeline dredge. When advance maintenance and allowable overdepth are added for the shoaling rate in the canal, stations 0+00 to 40+00 could be dredged to 57 feet, and remainder of the canal through Station 592+91 could be dredged to 53 feet.

The bottom width of this canal would be selectively widened in three separate sections. The bottom width of the most-downstream curve (stations 0+00 to 20+00) would be widened to 500 feet on the east side of the channel, and then promptly tapered to the existing 400-foot width prior to the MLK Bridge (SH 82). The canal would be widened to 450 feet adjacent to the Port of Port Arthur, with gradual tapering

upstream and downstream between stations 120+00 and 170+00. The third widening section begins to taper at Station 565+00, gradually widening to 500 feet and remaining that width to the end at Station 592+91.

Bend easing is planned for three areas in the Sabine-Neches Canal to improve ship maneuverability: stations 265+00 to 305+00, stations 350+00 to 395+00, and stations 500+00 to 520+00. The bend easing between Stations 350+00 to 395+00 eliminates a wiggle in the alignment, and shifts the footprint of the canal 10 feet east of the existing alignment up to Station 520+00.

Changes are also recommended for the canal bottom adjacent to the Port Arthur Dock and the “Eye Basin.” The canal toes adjacent to the Port of Port Arthur would be moved approximately 10 feet to the east while keeping the same bottom width of 450 feet. The diameter of the turning point (“Eye Basin”) at Station 190+00 would be decreased by 16 feet. An overview of the project details for the Sabine-Neches Canal reach is listed in Table VI-8.

Table VI-8
Project Details for Sabine-Neches Canal Reach

Length of Reach (Sections 9, 10)	11.2 miles (no change)
Project Depth	48 feet
Bottom Width	varies 400 to 500 feet
Advance Maintenance	2 feet
Allowable Overdepth	2 feet
Additional Advance Maintenance	Station 0+00 to 40+00 is 5 feet Station 40+00 to 592+91 is 1 foot
New Work Material	11,944,000 cubic yards
Placement Areas	PAs 8 and 11
Beneficial Use of Dredged Material	None
Maintenance Material (50-year quantity)	73,245,000 cubic yards
Increase in Maintenance Material	13,122,000 cubic yards
Placement Areas	PAs 8 and 11
Beneficial Use of Dredged Material	None

Neches River Channel

This 18.5-mile-long channel begins just south of the mouth of the Neches River (Figure VI-7). It would be deepened to the proposed depth of 48 feet to Station 980+00 with a hydraulic pipeline dredge. Advance maintenance would vary in different sections of the Neches River Channel to account for differences in shoaling rates. Between stations 0+00 and 440+00, the maximum dredged depth would be 52 feet; between stations 440+00 and 978+00, it would be 54 feet. While the overall bottom width of 400 feet does not change for the majority of the channel length, the first curve at the mouth of the Neches River (between stations 0+00 and 75+00) would be widened to 500 feet, and then tapered back to 400 feet prior to the SH 87 twin bridges. An overview of the project details for the Neches River Channel reach is listed in Table VI-9.

Table VI-9
Project Details for the Neches River Channel Reach

Length of Reach (Sections 11–18)	18.5 miles (no change)
Project Depth	48 feet
Bottom Width	400 feet (majority of channel)
	500 feet Station 0+00 to 75+00
Advance Maintenance	2 feet
Allowable Overdepth	2 feet
Additional Advance Maintenance	Station 440+00 to 978+00 is 2 feet
New Work Material	25,014,000 cubic yards
Placement Areas	PAs 12, 13, 14, 16, 18, 21, 23, 24, 25, 26, 27
Beneficial Use of Dredged Material	Neches River BU Feature
Maintenance Material (50-year quantity)	89,725,000 cubic yards
Increase in Maintenance Material	23,277,000 cubic yards
Placement Areas	PAs 12, 13, 14, 16, 17, 18, 21, 23, 24, 25, 26, 27
Beneficial Use of Dredged Material	Neches River BU Feature (Bessie Heights East, Rose City East)
Turning Basins/Anchorage Areas	1 new; 2 enlarged; 5 no change

Three basins would be added or enlarged on the Neches River Channel. All three would be dredged to the proposed depth of 48 feet, plus the advance maintenance and allowable overdepth associated with the specific channel reach in which they are located. One TB, Turning Basin No. 6, is an existing basin and would continue to be maintained at the existing 40-foot depth and existing advance maintenance and allowable overdepth.

- Turning and AB No. 1 is located in an old river oxbow at the east end of Texaco Island near Station 210+00. The TB enlarges the existing basin from 1,000 to 1,350 feet in diameter. A new AB, 250 by 1,100 feet in size, would be added.
- Turning and AB No. 4 enlarges an existing turning point at Station 510+00 from 1,000 to 1,350 feet in diameter. A new AB in the old river oxbow at Station 500+00 would be 250 by 1,100 feet in size.
- AB No. 8 is new and would be located at Station 850+00. The 250- by 1,100-foot basin is located in an old river oxbow.

Management of Dredged Material

Federal dredged material from construction and maintenance of the Recommended Plan would be managed in accordance with the DMMP as described in Section VIII of this document and Appendix D of the FEIS. The DMMP GNF includes an extensive BU plan that uses new work and maintenance material from the proposed 48-foot project to restore large marsh complexes on the Neches River, and nourish the Gulf shoreline in Texas and Louisiana.

Construction of the Recommended Plan would generate 98 mcy of new work material and 650 mcy of maintenance material for the 50-year period of analysis. Forty-four percent of the new work material would be placed in offshore disposal sites. Forty-seven percent of the new work material would be used to construct and rehabilitate PA containment levees; 8 percent would be used in DMMP marsh restoration; and 1 percent would be surplus and pumped to upland PAs. The material type expected to be dredged with construction of the Recommended Plan is predominantly clay (USACE, 1982), and is suitable material for the construction and rehabilitation of PA containment levees. However, one short stretch of the Neches River Channel near the upstream end of the project contains sandier sediments (clayey sands, sandy clays, silty sands, and poorly graded sands). Since specific dredging practices may influence the degree to which the material would stack, regular monitoring of the dredging activities would be necessary.

Shoaling is projected to increase with the Recommended Plan for several reasons (Parchure et al., 2005). The Entrance Channel is being extended an additional 13.2 miles into the Gulf of Mexico, and this would result in higher offshore maintenance dredging quantities. The larger channel cross section would lower velocities near the bottom of the navigation channel creating conditions favorable for sediment deposition; the deeper channel would have a greater surface area, making it function as a larger sediment trap; and higher salinities would increase flocculation and increase the deposition of suspended sediment.

Maintenance dredging material quantities for the proposed 48-foot project would therefore increase from 407 mcy to 650 mcy. Expressed as average annual equivalents, estimated dredging quantities increase from 8.1 mcy to 13.0 mcy per year over the 50-year period of analysis (Table VI-10). Fifty-seven percent of the maintenance quantities would originate from the offshore channels, and 43 percent from the inshore channels.

Table VI-10
Existing and Proposed Maintenance Dredging Quantities

Channel Reach	Existing 50-Year Maintenance Quantities	Proposed 50-Year Maintenance Quantities
Neches River Channel	66,447,680	89,724,800
Sabine-Neches Canal	60,122,600	73,245,000
Port Arthur Canal	88,248,750	82,857,600
Sabine Pass Channel	30,590,400	34,780,800
Sabine Pass Jetty Channel	11,385,000	13,527,000
Sabine Pass Outer Bar Channel	99,685,000	223,650,000
Sabine Bank Channel	50,822,400	96,371,000
Sabine Bank Extension		36,216,000
Total Quantities	407 mcy	650 mcy

Beneficial Use Features of the DMMP

Dredged material will be used beneficially to restore large degraded marsh areas on the Neches River (Rose City East, Bessie Heights East, and Old River Cove), and nourish the Gulf shoreline at Texas and

Louisiana Points. Shoreline nourishment at Texas Point is located within the boundaries of the Texas Point NWR. Detailed descriptions of these efforts can be found in Section VIII of this report and in Appendix C of the FEIS.

The DMMP BU features (Neches River and Gulf Shore BU features) are least-cost, environmentally acceptable placement alternatives and, as such, are considered GNF of the Recommended Plan. They will contribute significantly to a sustainable environment while providing placement capacity for the proposed project. The Neches River BU Feature would take advantage of new work material provided by the channel-deepening project to build hydraulic containment levees within degraded, former marsh areas at Rose City East, Bessie Heights East, and Old River Cove. Each of these areas is referred to as a component of the overall Neches River BU Feature. Marsh would be created in each component using only new work, or a combination of new work and maintenance material. At the Rose City East component, new work material would be used to construct containment levees and ridges, then the marsh would be completed with the placement of maintenance material during the first maintenance cycle following construction. In the Bessie Heights East component, maintenance material would be placed incrementally in seven maintenance cycles over 28 years. The Old River Cove component would be filled during initial construction with new work material, alone. The Gulf Shore BU Feature nourishes shorelines at Texas and Louisiana Points with the placement of maintenance material every 3 years over the 50-year period of analysis, with placement episodes alternating between each side of Sabine Pass.

BU features of the DMMP (Neches River and Gulf Shore features) will offset all project impacts in Texas by restoring 2,853 acres of emergent marsh, improving 871 acres of shallow-water habitat, and nourishing 1,234 acres of existing marsh. Benefits of the Neches River BU Feature also more than offset the direct impact of conversion of 86 acres of fresh marsh to a confined PA (PA 24A) and the indirect impact of the increase in salinity over 39,000 wetland acres in Texas. The Gulf Shore BU Feature offsets minor erosion impacts by periodically nourishing 6 miles of Texas and Louisiana Gulf shorelines. Benefits of the DMMP offset all impacts of the Recommend Plan in Texas and, therefore, no compensatory mitigation is proposed for Recommend Plan effects in Texas.

The Keith Lake Section 1135 CAP study was begun in 2003, well before impacts of the SNWW CIP had been determined or potential mitigation measures defined. Since at that time it seemed likely that the CAP study and project construction would be completed before the SNWW CIP could be authorized and constructed, the Keith Lake Section 1135 study was considered separable from the SNWW CIP. It was assumed that a water control structure at the Fish Pass would be part of the FWOP condition for the SNWW CIP.

Incremental impacts of the SNWW CIP will be calculated for the Salt Bayou unit of the SNWW study area when WVA modeling is completed for the Keith Lake Section 1135 study. It is possible that the excess DMMP benefits (316 AAHUs) of the SNWW CIP will cover all incremental project impacts. However, if it is determined that additional mitigation is needed, then the USACE and the non-Federal sponsor of the SNWW CIP will initiate consultation with resource agencies, identify and incrementally justify additional compensatory mitigation for the Salt Bayou unit, and prepare a supplement EIS.

Upland Placement Areas

Sixteen existing PAs and two expansion cells are proposed for use with the Recommended Plan. A list and description of proposed upland PAs can be found in Chapter VII of this report. For the inland channel reaches, existing upland PAs will be used to the greatest extent possible; however, expansion of some existing PAs will also be required. Forty-seven percent of the new work material will be used to construct and rehabilitate PA containment levees; 8 percent will be used in DMMP marsh restoration; and the remainder would be pumped to upland PAs. Upland PAs on the Port Arthur and Sabine-Neches canals and the Neches River Channel would also provide capacity for non-Federal dredging of private facilities. A capped landfill has been found in PA 17 that is unrelated to dredged material or dredging activities. Issues related to possibly hazardous materials in the landfill must be resolved by the Sponsor before the PA could be used. Alternate PAs are available should this issue not be resolved in time for use.

Ocean Dredged Material Disposal Sites

For the offshore channel reaches, the Recommended Plan provides for the use of four existing ODMDs (1–4) and four proposed ODMDs (A–D). These sites are in the Sabine Bank Channel and the Sabine Bank Extension (see figures VI-1 and VI-2). Site selection criteria for the four proposed Extension Channel ODMDs are discussed in the FEIS for ODMD designation (FEIS Appendix B) and in Chapter VII of this report. This document provides required NEPA review and public coordination to support Environmental Protection Agency (EPA) designation, per 40 CFR 228, of new ODMDs that provide environmentally acceptable, and economically and physically feasible, areas for the placement of the construction material and future maintenance material from the Extension Channel. All of the new sites, as well as the existing sites, are located west of the navigation channel to minimize channel-shoaling effects of the prevailing east to west littoral drift in this portion of the Gulf of Mexico.

Maintenance dredging volumes for the offshore channel would increase more than the inshore reaches (increase of 128 percent and 14 percent, respectively). Additional capacity for the offshore reaches would be obtained by designating new ODMDs. Material from four of the offshore channel reaches (Extension Channel, Sabine Bank Channel, Sabine Pass Outer Bar Channel, and Sabine Pass Jetty Channel) would be placed in the ODMDs as described in Appendix B of the FEIS. The types of material expected to be dredged with construction of the Recommended Plan were established with soil borings through the maximum dredging depth along the centerline of the existing channel and proposed channel extension (USACE, 1982). The cores are composed overwhelmingly of inorganic clays, with the exception of the channel segment adjacent to proposed ODMD C where sediments are approximately 70 percent silty or clayey sands and 30 percent clay.

Compensatory Mitigation

The USACE has developed a compensatory mitigation plan for project impacts that would remain after application of DMMP BU Feature benefits. Project impacts are fully described in the FEIS; DMMP BU benefits and compensatory mitigation are summarized in chapters VII and VIII of this document. No

mitigation would be necessary in Texas because benefits of the DMMP offset all impacts in Texas; therefore, all mitigation areas would be located in Louisiana.

The recommended Mitigation Plan would consist of restoring five degraded marsh areas east of Sabine Lake in Louisiana. Each of the mitigation measures is described in detail in Section 5.0 of the FEIS. The Mitigation Plan would compensate for the Recommended Plan's salinity increase and associated losses in biological function and productivity by marsh creation activities in the Willow and Black Bayou watersheds. A hydraulic pipeline dredge would pump a sediment slurry into a total influence area of 8,095 acres. The sediment would restore 2,783 acres of emergent marsh in existing open-water areas within the influence area; improve 957 acres of shallow-water habitat by creating shallower, smaller ponds and channels within the restored marsh; and stabilize and nourish 4,355 acres of existing marsh located in the influence area. The amount of recommended mitigation was determined by the WVA Model and is the amount of marsh that would need to be restored to compensate for the mitigation target of the 1,159 AAHUs. In total, these measures produce 1,181 AAHUs and provide full compensation for all impacts of the CIP. This plan is described more fully in Chapter VIII.

Aids to Navigation – USCG Channel Markers

Most of the existing USCG channel markers along the waterway would require removal and replacement. However, markers along the Neches River Channel upstream from the Beaumont Maneuvering Basin and in the vicinity of SH 87 would not require changes in the navigation aids. The Port Arthur Junction area would require relocation of the aids to navigation, and new aids would be required along the Extension Channel. The USCG would be responsible for replacing the structures when the channel modifications are constructed.

Bridge Reinforcements and Fenders

Deepening improvements to the SNWW navigation channels would affect existing fender systems of the Rainbow Bridge and Veteran's Memorial Bridge over the Neches River Channel on SH 87 and the MLK Bridge over the Sabine-Neches Canal on SH 82. Bridge fender systems on both sides of the channel would require removal and replacement. Additional stabilization of the bridge foundation would be needed at the MLK Bridge. None of the bridges would cause an unreasonable obstruction to navigation, and thus would not require modification or replacement pursuant to the Truman-Hobbs Act. Bridge piers with a hardened structure would be necessary to maintain the proposed 400-foot channel width.

Lands, Easements and Rights-of-Way

The project Sponsor is required to furnish the LER for the proposed cost-shared project. The real estate requirements must support construction as well as operation and maintenance of the project after completion. A summary of the real estate requirements for each channel reach is provided in Table VI-11. Specific details of the real estate requirements can be found in the Real Estate Plan, Appendix 4 of this document.

Table VI-11
Real Estate Requirements for Placement Areas

	Real Estate Requirement
Channel Reach	
Sabine Bank Extension	Navigational servitude
Sabine Bank Channel	Navigational servitude
Sabine Pass Outer Bar Channel	Navigational servitude
Sabine Pass Jetty Channel	Navigational servitude
Sabine Pass Channel	Acquire in Fee (PA 5)
Port Arthur Canal	Navigational servitude (PA 8) Acquire in Fee (PA 9)
Sabine-Neches Canal	Navigational servitude (PAs 8, 11)
Neches River Channel	Owned by Sponsor (no action) (PAs 12, 13, 14, 16, 18, 18A, 21, 23, 23A, 24, 24A, 25, 25A) Acquire in Fee (PAs 17, 26, 27A, 27C, 27D) Turning Basins – two would require the acquisition of land in perpetual channel improvement easement.
Louisiana Mitigation Areas	
Willow/Black Bayou Areas	Navigational Servitude

Relocations

The following assumptions were made to identify pipelines that could be affected by the Recommended Plan and to develop associated costs. The individual circumstances of each pipeline will be evaluated by USACE in consultation with the pipeline owner during the PED and Construction phases, and decisions regarding necessary actions will be made individually for each pipeline at that time. Feasibility engineering guidelines indicate that pipelines with a minimum of 8 feet of cover for trenched lines or 5 feet of cover for directionally drilled lines would not be adjusted. Pipelines that do not meet the minimum cover requirement would be required to be adjusted. The adjusted pipelines must be located 20 feet below the authorized 48-foot depth. The 20 feet includes any advance maintenance and allowable overdepth. The relocation of active pipelines is assumed to be installed with directional drilling, and bundled where possible.

A total of 104 pipelines have been identified crossing the SNWW navigation channels. Of the 104 pipelines, 46 require adjustment to meet the minimum required vertical and horizontal clearances for the CIP.

Pursuant to Section 101(a) of the Water Resources Development Act (WRDA) of 1986, as amended, the Sponsor is responsible for performing, or assuring performance, of all relocations, including utility relocations, which are necessary for the CIP. All relocations, including utility relocations, are to be accomplished at no cost to the Federal Government.

The Galveston District has concluded preliminarily that 41 of the 46 lines located within the channel must be relocated and are classified as utility relocations for which the Sponsor must perform or assure performance. In accordance with Section 101(a)(4) of WRDA 86, one-half of the cost of each such relocation will be borne by the owner of the facility being relocated and one-half of the cost of each such

relocation will be borne by the Sponsor. Such relocation costs will not include any cost for upgrading or improving such facilities, which is to be borne by the facility owner.

For more specific information regarding the utility relocations, and preliminary conclusions regarding the remaining five lines that must be removed but not replaced, see the Real Estate Plan, Appendix 4, of this document.

DMMP marsh restoration at Bessie Heights and mitigation marsh restoration measures east of Sabine Lake were assumed to require no relocations. However, since oil production is active in some of these areas, additional pipeline searches and coordination with pipeline owners would be required prior to construction to avoid impacts.

No relocations would be required for overhead power utilities, highway bridges, the Port Arthur HFP Levee, or its associated pump stations and closure structures.

Impact Analysis and Mitigation Needs Summary for the Recommended Plan

A summary of impacts before DMMP benefits and compensatory mitigation is provided in tables VI-12 and VI-13 for Louisiana and Texas, respectively. A full summary of the impact analysis and compensatory mitigation needs for the Recommended Plan is presented in Table VI-14 for each state. The calculation of impacts and benefits of the DMMP BU features and mitigation measures are described in Section 2.5 and throughout Section 4.0 of the FEIS.

Critical Assumptions

Critical planning and environmental assumptions were made in the evaluation of the benefits and impacts of the Recommended Plan. Table VI-15 provides a brief summary of the major assumptions, the scientific basis or rationale behind each assumption, and an indication of the consequences if the assumptions turns out not to be valid.

VI.C RECOMMENDED PLAN AND RECENT USACE INITIATIVES

As stated in Chapter III of this report, the USACE has implemented the EOP and the Actions for Change over the past few years. These initiatives were developed to ensure the USACE success in the future by improving the current practices and decision-making processes of the USACE organization. The application of those principles as they relate to the Recommended Plan for the SNWW CIP is described below:

USACE Environmental Operating Principles

- **Strive for environmental sustainability** – Construction of BU, restoration, and mitigation sites were developed for a 50-year period of analysis. Development and design of these areas were made to address potential changes over time (e.g., sea-level rise, shoreline erosion, etc.).

Table VI-15
Critical Assumptions

Assumption	Rationale for the Assumption	Consequences if Assumption Becomes Invalid
Future without-project (FWOP) Condition		
Louisiana Coastal Wetlands Planning, Protection, and Restoration Act (CWPPRA) Projects in operation at Willow Bayou, Black Bayou, and Perry Ridge for remainder of project life.	Ecological effects of CWPPRA projects (reductions in land loss rates and/or salinity) based upon changes projected in environmental assessments.	If ecological benefit of CWPPRA project is less than expected, then FWOP salinity and land loss impacts would be slightly higher than expected; conversely, if ecological benefits are higher, FWOP impacts would be slightly lower than expected.
Most likely rate of RSLR estimated to be 1.1 feet in the study area by year 2069. Full potential range of RSLR estimated to be from 0.3 to 2.8 feet over period of analysis.	Eustatic sea-level rise based upon mid- to high mid-range projected by NRC and IPCC, respectively. Local subsidence component based upon long-term trends obtained from basal peat analysis. Full potential range calculated as required by Circular No. 1165-2-211.	Little consequence if RSLR is lower than expected. High rate of RSLR could result in small increase in maintenance dredging and PA levee heights for existing project; increase in hurricane tidal surge elevation; an increase in land loss due to submergence of intertidal marshes and salinity increase. Functioning of navigation channel would not be affected; improvements at some dock facilities might be needed.
Future freshwater inflows assumed for HS modeling are slightly higher on Neches River than existing inflows; about the same as existing inflows on the Sabine River.	Future freshwater inflows were based upon demand projections and supply strategies approved by the 2007 Texas State Water Plan.	Little consequence if inflows are higher than projected. If inflows are lower than expected, FWOP ecological impacts would be higher than expected and more areas would be experiencing suboptimal salinities.
Changes in land loss rates are driven by the interaction of salinity and submergence, resulting in a reduction in plant productivity, leading to a decrease in plant growth, plant death, followed by peat collapse and wetland loss. Assumed linear relationship between change in salinity due to RSLR and change in FWOP land loss rate.	The salinity-vegetation productivity relationship is based upon algorithms developed for dominant wetland vegetation species in the study area. The algorithms were developed for the Louisiana Coastal Areas Ecosystem Restoration Study, using data from a large number of professional studies.	If the relationship between salinity and land loss is different from that projected, FWOP land loss would be higher or lower than current estimates.

Table VI-15 (Cont'd)

Assumption	Rationale for the Assumption	Consequences if Assumption Becomes Invalid
Future with-project (FWP) Condition (Recommended Plan)		
RSLR – same as FWOP because deepening project causes only negligible increase in water surface elevation.	FWP water surface elevation change determined by the ERDC HS modeling.	Little consequence if RSLR is lower than expected. No FWP effect on maintenance dredging, PA levee heights, or tidal surge penetration. At high rate, all areas suitable for marsh mitigation could be susceptible to submergence. DMMP BUs protected by containment structures.
Additional land loss would result primarily from the interaction of higher FWP salinities with FWOP RSLR. Assume direct linear relationship between salinity and land loss changes.	Associating land loss with salinity increases is based upon well-documented biological responses of inundated vegetation to salinity change. No data are currently available that relate specific salinity changes to specific land loss rate changes.	If the relationship between salinity and land loss is different from that projected, FWP impacts would be higher or lower than current estimates.
Cost Estimates		
Cost estimate of the Recommended Plan utilized appropriate probabilities of risk.	Cost risk analysis was performed using required forecasting and analysis tools. Cost contingencies developed by this analysis have been included in the total project cost estimate.	An increase in total project cost, exclusive of price level changes, of more than 20 percent of the total project cost stated in the authorizing legislation would require Congressional authorization.
It was assumed that up to 5 pipeline dredges would be available for use at one time for inshore channel dredging, and mitigation and BU marsh creation. Offshore dredging assumes use of only one hopper dredge at a time.	Assume offshore hopper dredge production averaging 7.9 mcy/yr; inshore pipeline dredge production of 7.2 mcy/yr; and no more than 550 acres/year of mitigation or BU marsh creation by any one dredge.	If the assumed production rate is too high, or if the assumed number of dredges is not available, then construction would take longer and the total cost of construction would increase.
Funding		
Sufficient funding streams would be available to construct the Recommended Plan over the assumed construction periods and to provide long-term operation and maintenance.	USACE planning policy states that plans should be developed without funding constraints. Federal funding priorities are difficult to predict.	Total project cost could be higher because of longer construction schedule. Inadequate O&M funding could cause an increase in navigation costs or adversely affect monitoring of mitigation and BU features.

mc/yr = million cubic yards per year.

- **Consider environmental consequences** – The direct and indirect effects of the project on the environment were quantified using ecological modeling. Compensatory mitigation is provided in the Recommended Plan for all project impacts.
- **Seek balance and synergy** – Opportunities to beneficially use the large quantities of dredged material that would be generated by this project were thoroughly explored. The needs of the project to find environmentally acceptable placement areas were satisfied with the development of BU features that would contribute to the long-term sustainability of interior wetlands and the coastal zone.
- **Accept responsibility** – All environmental impacts of the proposed project have been addressed and either offset by beneficially using dredged material or mitigating for impacts.
- **Mitigate impacts** – Project impacts were identified and the type and location of the compensation to be performed. No mitigation is required in Texas since the long-term management plan more than offsets the impacts to occur in that state. Mitigation has been identified to offset project impacts in Louisiana. The recommended mitigation plan results in an excess of overall environmental benefits vs. impacts.
- **Understand the environment** – Some of the most knowledgeable and experienced environmental professionals in Texas and Louisiana participated on an ICT. Their expertise ensured that the broad spectrum of environmental habitats of the study area were adequately understood, impacts accurately identified, and the appropriate amount and type of mitigation was developed.
- **Respect other views** – Collaboration among the USACE, Sponsor, and ICT members occurred throughout the study process. The interactions were professional and respectful, and always entertaining the opinions and expertise of others.

USACE Actions for Change as Reflected in the Campaign Plan

Engineering Sustainable Water Resource (integrated solutions, collaborative approaches, streamlined processes)

- SNWW study analyzed potential effects over a 2,000-square-mile area, incorporating the entire Sabine-Neches watershed.
- Dredged material placement plans were developed to beneficially use the material to the benefit of the entire system (inshore and offshore) to the greatest extent possible.
- Close collaboration with local sponsor throughout study.

Delivering Effective, Resilient, Sustainable Solutions (sustainable infrastructure, resilience, risk-formed strategy, innovative approaches)

- Developed plans over long-term, 50-year period of analysis.
- Utilized latest development in engineering, economic, and environmental modeling.
- Risk analyses conducted throughout the study are summarized in Chapter IX.
- Review and inspection of work will be conducted during design and construction.

- Project risks are communicated at public meetings and during the public review of the study findings. The public is allowed to comment and/or express concerns throughout the study process.
- Unlike flood risk management and hurricane protection projects, navigation projects involve minimal risk to the public.
- Independent review of the project documents and analyses was performed internally to the USACE and externally by professionals from academia and expert consultants. Comments from those reviews have been incorporated into the study documents, as appropriate.
- The expertise of State and Federal resource agency professionals familiar with the highly complex coastal ecosystems of Texas and Louisiana were integrally involved in the evaluation and development of plans to offset environmental impacts of the project.

VII. DREDGED MATERIAL MANAGEMENT PLAN (DMMP)

VII.A OVERVIEW

This chapter presents the process and analyses used to evaluate dredged material placement issues and opportunities for the proposed 48-foot project (the Recommended Plan). It begins with an introduction to Regional Sediment Management (RSM), an approach that uses understanding of the SNWW sediment system to provide a context for managing the dredged material that would result from construction and management of the project. The following section describes the sediment system, summarizes a sediment budget for the Sabine Pass littoral zone, and characterizes material types and shoaling for the existing project. The next section describes problems and opportunities related to sediment management that were identified for the SNWW study area, and presents the results of a preliminary screening that was designed to identify BU features to be carried forward into the detailed phase of analysis. These BU features are then combined with upland placement features to form two alternative DMMPs, and the costs of these plans are then compared to identify the DMMP for the Recommended Plan. The BU Alternative was identified as the most-cost-effective, environmentally acceptable placement plan for both the new work and maintenance material, and it becomes the 50-year DMMP for the Recommended Plan. The DMMP is then summarized, followed by a description of the ecological benefits of the DMMP. The Base Plan for without-project disposal practices for the existing SNWW 40-foot project is then compared to proposed O&M placement activities for the Recommended Plan in order to determine the incremental O&M cost of the Recommended Plan.

VII.B REGIONAL SEDIMENT MANAGEMENT OBJECTIVES AND SCOPE

The principles of RSM were applied in evaluating alternatives and developing the DMMP for the placement of dredged material from the proposed SNWW CIP. The RSM is an approach for managing projects involving sand and other sediments derived from dredging and other activities in riverine, estuarine, and coastal systems (USACE, 2006a). Its major objective is the retention of these sediments within natural aquatic systems, thereby supporting a more sustainable process and potentially reducing project costs (Martin, 2002). The RSM incorporates many of the principles of watershed planning, but applies them in the context of dredging and other activities that influence sediment resources. It broadens the problem-solving perspective from a project-specific scale to a larger spatial and longer-term perspective. This requires the integration of a broad range of disciplines and collaborative partnerships among stakeholders. The USACE authorities and policies that support implementation of the RSM are discussed in Technical Note No. 8 for the RSM Demonstration Program (USACE, 2003).

The geographic focus of an RSM analysis is a sediment system on a scale that is relevant to issues (e.g., dredged material management or processes like erosion or shoaling) that have been identified by stakeholders in the region. The RSM study area essentially coincides with the SNWW study area and contains riverine, estuarine, and coastal environments. It is large enough to facilitate understanding of sediment processes and behavior, and the inherent interconnectedness of all parts of a sediment system.

The RSM study area includes the existing 65-mile-long SNWW navigation channel that extends from 22 miles offshore in the Gulf of Mexico, through a jettied entrance at Sabine Pass, up artificial canals on the west side of Sabine Lake, and finally up the Neches River Channel to the City of Beaumont. The SNWW area of analysis incorporates all of the existing and proposed navigation and placement features, and significant inflows and structures that affect the system. The littoral portion of the study area extends from Holly Beach, Louisiana, to Sea Rim State Park in Texas, roughly a distance of 40 miles. It extends into the Gulf of Mexico along the existing Entrance Channel, proposed channel extension, and ODMDSs for a distance of roughly 40 miles; and it extends inland from the coastline approximately 40 miles to incorporate the tidally influenced reaches of the Sabine and Neches rivers watersheds and Sabine Lake.

The Texas Coastwide Erosion Response Plan has identified several parts of the study area as “critical erosion areas” because of impacts to habitats and traffic safety from ongoing erosion, and has called for an increase in the BU of dredged material from the SNWW project to help address these issues. The plan was developed as part of the CEPRA (GLO, 2004, 2005). The program has identified the Gulf shoreline between Texas Point and Sea Rim State Park as a critical erosion area. It attributes the erosion, in part, to a lack of sediment coming down the Sabine and Neches rivers, and the interruption of longshore sediment transport by the SNWW jetties.

The CEPRA Plan recommends that long-term RSM be utilized, along with highway realignment and beach dune restoration, to protect the important coastal evacuation route of SH 87 in Jefferson County. As described below, the Gulf Shore BU Feature would provide a long-term, RSM approach to restoring some sediment to the littoral zone in this area of high erosion. In Orange County, the CEPRA Plan calls for restoration of 9,400 acres of marsh in the Lower Neches River using dredged material to raise soil elevations in the former marsh areas that have become open water. These are the same marsh areas (i.e., Rose City, Bessie Heights, and Old River Cove) that have been combined into the Neches River BU Feature. The evaluation of these BU features is described more fully later in this chapter.

VII.C EXISTING SHOALING AND SEDIMENT TRANSPORT CONDITIONS

A detailed description of the existing SNWW sediment system is provided in Section 2.5 of the FEIS. The reader is referred to that document for descriptions of geomorphology, winds, tides, circulation, and longshore sediment transport patterns.

Shoreline Descriptions

Jefferson County and Cameron Parish coastlines in the study area are mainland beaches fronting the Chenier Plain (King, 2007; USACE, 2000a). The upland area adjacent to the coast is a relatively flat, gently sloping terrain with marsh elevations of 1 to 2 feet msl and ridge elevations of 5 to 6 feet msl. Saline marsh vegetation covers the upland area behind the eroding shoreface. In the Texas Point NWR, a fillet of muddy substrate that was created by rapid deposition over approximately the last 100 years lies seaward of the chenier ridges. For the period between 1883 and 1970, the net accretion was documented

at 2,225 feet (Morton, 1975). The fillet of recent deposits recedes rapidly and disappears approximately ½ mile from the west jetty, where the Chenier Plain again fronts the Gulf until it ends about 18 miles from Sabine Pass (Pacific International Engineering [PIE], 2003).

The shoreline in the Texas Point NWR (between Sabine Pass and Sea Rim State Park) is a muddy shoreface composed of consolidated mud (King, 2007; PIE, 2003). A thin veneer of sand thrown up onto the marsh edge by storms covers some areas of the mud substrate. Farther west, the Sea Rim State Park area is a sediment transport convergence zone, and the beach typically has a substantial veneer of sand. In Louisiana, the coastline for approximately 10 miles east of the jetty contains tidal sand/mudflats, sand bars, and sandy beaches with tidal flats (PBS&J, 2006). A narrow tidal sand/mudflat, ranging from 30 to 450 feet in width, extends for about 1.5 miles east of the jetty, and then transitions to a sandy beach. These beaches vary in width from 50 to 300 feet and end at an eroded, low mud bank shoreline.

Historical Shoreline Change in the Study Area

The northwest Gulf coast system is sand starved, and essentially no modern-day sand is being delivered to these beaches (Lee, 2003; Morton, 1977; Morang, 2006). The only coarse-grained sand reaching the Texas shores appears to originate from the erosion of underlying Pleistocene barrier-strand plain deposits, which contain lenses of fine-grained and poorly sorted sands in massive clay and silt deposits (Isphording et al., 1989). The lack of delivery of coarse-grained sand contributes significantly to shoreline erosion in the area. The very limited coarse-grained load of the Sabine and Neches rivers is deposited in bay-head deltas in Sabine Lake rather than on the coast (Mason, 1981; Morang, 2006; USACE, 1971b).

Chronic shoreline erosion is believed to be associated with the diversion of sand and other sediment resulting from channelization and regulation of the Mississippi and Atchafalaya rivers to the east, and the Sabine and Neches rivers in Texas. The Calcasieu and Mermentau also do not supply coarse-grained sediments, and the Cameron jetties deflect the little material that does exist away from the Holly Beach area, so that it accumulates to the west at Long Beach, Louisiana's westernmost sandy beach (Louisiana Department of Natural Resources [LDNR], 1997; USACE, 2000a). The Sabine Pass jetties also intercept sediment moving westward in the littoral drift, creating a wide, muddy, tidal flat next to the east jetty (PBS&J, 2006; USACE, 2000a). On the Texas side, a ½-mile-wide fillet of silt and mud immediately adjacent to the west jetty intercepts sediments moving from the west during periodic reversals near Sea Rim State Park in the dominant longshore movement (PIE, 2003).

Shoreline change has been extensive in this region. In the area between Ocean View Beach and the Sabine jetties, the shoreline prograded seaward at an average rate of +12.9 feet/year between 1883 and 1994. Recently, however, accretion has slowed to +1.2 feet/year, and the behavior of this shoreline has become erratic, with change rates varying between -13.2 and +14.7 feet/year (USACE, 2000a). On the Texas side of Sabine Pass, a ½-mile stretch of shoreline adjacent to the west jetty is aggrading at a rapid rate, but beyond this narrow zone, to the west, is an active erosion zone extending approximately 15 miles to the vicinity of Sea Rim State Park (Morang, 2006). This eroding stretch of the Jefferson County coastline is experiencing the largest erosion rate on the upper Texas coast, up to 40 to 50 feet/year (King,

2007). It has been identified as a “critical erosion area” by the Texas Coastwide Erosion Response Plan because of threats to traffic safety and wildlife habitat. Shoreline erosion has destroyed a portion of SH 87, an important hurricane evacuation route, and is eroding coastal wetland habitat at Texas Point and McFaddin NWRs (GLO, 2004, 2005).

Sabine Pass Sediment Budget

New littoral transport rates have recently been calculated for the Sabine Pass littoral zone. The Sabine Pass sediment budget (Morang, 2006) applied shoreline change statistics that were computed from changes in sediment volume for littoral cells, using cross-shore profiles that were projected with an ERDC modeling study (King, 2007). The sediment budget focused on characterizing sediment movement in the coastal segments of the navigation channel and nearby Texas shoreline. Accurate estimates of the percentage of total transport that is suspended sediment load from the inshore area were not available. Six of the 23 cells defined for this study are relevant to this discussion – 3 cells (the Sabine Pass Channel, the Sabine Jetty Channel, and the Sabine Outer Bar Channel) were used to analyze sediment movement in the navigation channels through Sabine Pass and past the jetties; 3 other cells (the Sabine Fillet, Texas Point NWR, and Sea Rim State Beach) were used to calculate sediment movement along the littoral zone westward of the Sabine Pass. A summary of the sediment budget results is presented in Table VII-1

Existing Project Shoaling and Sediment Transport Conditions

The following summary of shoaling and transport conditions for the existing SNWW includes all segments of the existing SNWW navigation system. The analysis of channel sections covered by the Sediment Budget (Table VII-1) is derived primarily from Morang (2006); dredging cycle lengths, velocity data, average percentages of sediment sizes, and dredging quantities (for channel reaches not covered by the Sediment Budget) were obtained from the SNWW Sediment Study (Parchure et al., 2005); other supporting analyses are identified as the data are presented. The discussion begins with the upstream end of the SNWW (the Neches River Channel), and moves downstream through the confined Sabine-Neches and Port Arthur canals, the Sabine Pass Channel, and then offshore into the Sabine Pass Jetty Channel, the Sabine Pass Outer Bar Channel, and the Sabine Bank Channel. Finally, the interaction of the channel and adjacent shoreline sections is described.

Neches River Channel

Dredging cycles on the Neches River Channel vary from 3 to 4 years along the eastern half of the channel near Sabine Lake to 6 years along the western segment near Beaumont. Approximately 3.1 mcy/cycle are dredged from eastern channel sections 11, 12, 13, 14, and 15 and placed into PAs 12, 13, 14, 16, 18, 21, 23, and 23A. Approximately 3.3 mcy/cycle are dredged from western channel sections 16, 17, and 18 and placed in PAs 24, 25, 25A, 26, 27A, 27C, and 27D near Beaumont. Peak ebb and flood velocities are low (0.8 foot/second and 0.3 foot/second, respectively). Bed sediments average 62 percent silt and clay and 38 percent sand.

Sabine-Neches and Port Arthur Canals

These canals traverse the confined channel segment between the City of Port Arthur and Pleasure Island. Sabine-Neches Canal sections 9 and 10 are dredged every 4 years. Approximately 3.7 mcy/cycle are placed in PAs 8 and 11. Bed sediments average 78 percent silt and clay and 22 percent sand. Port Arthur Canal Section 7 is dredged every 3 years and approximately 1.8 mcy/cycle are placed in PA 8. Section 8 and the Taylor Bayou Channels and Basins are dredged every 2 years; approximately 2.3 mcy/cycle are placed in PAs 8, 9, and 9A. Peak ebb and flood velocities are 2.6 and 2.2 feet/second, respectively. Bed sediments average 84 percent silt and clay and 16 percent sand. The junction of the Port Arthur Canal, Taylor Bayou Channel, and the Sabine Pass Channel is an existing dredging hot spot, often requiring dredging more frequently than the 2-year cycle. This is due, at least in part, to a rapid decrease in velocity as the flows move into the much wider junction. In addition, existing erosion along the channel side of Pleasure Island may be returning sediment to the system (Parchure et al., 2005).

Table VII-1
Annual Sediment Budget for Sabine Pass (adapted from Morang, 2006)

Cell	Sources and Quantity (1,000 cubic yards per year)	Sinks and Quantity (1,000 cubic yards per year)	PA/ODMDS and Quantity (1,000 cubic yards per year)
Sabine Pass Channel	866.7 (approximately 20% sand) from Port Arthur Canal and Sabine Lake	274.2 mud and sand into Jetty Channel	592.5 into PA 5
Sabine Pass Jetty Channel	274.2 (mud and minor sand) from Sabine Pass Channel	Unknown quantity of fine-grained material carried in suspension offshore	289.1 to ODMDS 4 (dispersed by shelf circulation, storm and tidal currents)
	14.9 (mud) offshore		
Sabine Outer Bar Channel	Unknown amount from Sabine Jetty Channel (possible mud input)		1,722.6 to ODMDS 3 (dispersed by shelf circulation, storm and tidal currents)
	1,722.6 from undetermined source (littoral sediments and/or ODMDS)		
Sabine Fillet	25.1 longshore transport from Texas Point NWR (west)	14.9 longshore transport (mud and minor sand) to Jetty Channel	
		10.2 shoreline growth at Sabine mud fillet	
Texas Point NWR	434.2 from beach erosion (90+ % mud)	152.0 overwash losses	
		173.7 mud lost offshore	
		25.1 longshore transport of mud to east	
		83.5 longshore transport to west (sand and shell)	
Sea Rim State Beach	83.5 longshore transport from Texas Point NWR (east)	117.7 beach growth at Sea Rim State Beach	
	34.3 longshore transport from McFadden NWR (west)		

*Sediment Budget quantities are based on 25 years of data from Galveston District's Dredging Database. SNWW CIP without-project shoaling quantities are based on data from 1967 to 2001. A cross check and conversion verified that the quantities are similar.

Sabine Pass Channel

Channel sections 5 and 6 are dredged every 3 years and approximately 1.9 mcy/cycle are placed in PA 5. Bed sediments average 70 percent silt and clay and 30 percent sand. There are no obvious sand sources because the banks of the channel are low mudflats. Little sand reaches the open coast from the Sabine and Neches rivers because Sabine Lake is an efficient sediment trap and most of its coarse material is deposited in the lake or trapped in the lower alluvial reaches of the rivers. Since the dredged material is removed from the system, some mechanism must be replenishing the sand. It may be delivered to this channel by unusually high runoff from Sabine Lake or the Port Arthur Canal. Although ebb and flood velocities are roughly equal through this section, lower velocities are present where Sabine Lake discharges into the channel; shoaling rates are higher than average around this discharge point. Peak ebb and flood velocities in the remainder of the channel are 4.0 and 3.2 feet/second, respectively. Negligible amounts of material come from the littoral system, entering the channel and moving upstream. Conversely, plumes of fine-grained material can be seen moving through the pass into the Gulf in satellite images. This material disperses over the continental shelf and does not contribute to the littoral budget.

Sabine Pass Jetty Channel

Section 4 is self-scouring and needs far-less-frequent maintenance dredging than the other coastal reaches. Ebb velocities are high, peaking at about 3.5 feet/second, and flood velocity reaches 3.0 feet/second. Despite this jetting action, on the average about 1.1 mcy/cycle of dredged material are placed in ODMDS 4 in a 5-year dredging cycle. Sediment delivered by the Sabine Pass Channel is predominantly silt and some sand, and about 5 percent of the total transport comes from the littoral system. A small boat cut in the east jetty may allow material carried by the longshore current moving west from Louisiana to enter the channel (PBS&J, 2004a). Bed samples average 89 percent clay and silt and 11 percent sand. Before- and after-dredging bathymetry surveys have demonstrated that the material placed offshore in the ODMDSs does not accumulate; it disperses quickly after placement in the offshore environment.

Sabine Pass Outer Bar Channel

Section 3 is the first 3.4 miles of navigation channel outside of the jetties. Ebb velocities fall rapidly as the channel discharges over the Outer Bar. Peak ebb velocities fall from about 3.5 feet/second within the jetties to 2.7 feet/second just beyond the jetties, to 1.3 feet/second near the intersection with the Sabine Bank Channel. Peak flood velocities of 3.0 feet/second within the jetties fall to 2.4 feet/second just beyond the jetties, and to 0.4 foot/second at the end of the channel reach. It appears that little material moves from the Sabine Pass Jetty Channel into the Sabine Outer Bar channel, based upon the balance of material entering versus what is removed by dredging. Yet, the shoaling rate in this section is very high. Approximately 1.9 mcy/cycle are removed yearly and placed in ODMDS 4. Bed samples average 96 percent silt and clay and 4 percent sand. The source of the sediment is undetermined. Existing and proposed ODMDSs are located west of the channel because the mean current flow in this area is westward most of the year. However, this flow reverses and moves eastward for a month or longer during the late spring (Rouse et al., 2004). During periods of reversal, sediment may drift back into the channel

from ODMDS 4. However, typical flow patterns move ebb flows to the south/south-southwest just beyond the jetties, and flood flows generally come from the east (Parchure et al., 2005). Furthermore, anecdotal accounts from Sabine Pilots report a strong east to west current crossing just outside the jetties in the vicinity of ODMDS 4 (Webb, 2003).

Sabine Bank Channel

Sections 1 and 2 (totaling 6.6 miles long) extend the navigation channel into the open Gulf. They are dredged every 4 years and approximately 4.2 mcy/cycle is placed in ODMDSs 1 and 2. Bed sediments average 76 percent silt and clay and 24 percent sand. Ebb and flood velocities are nearly equal (ranging between 0.25 and 0.70 foot/second), but the velocity pattern is erratic. Rapid shoaling is not a problem in this reach, and no other management concerns are known.

Adjacent Gulf Shorelines

At Louisiana Point, the littoral current has supplied sufficient sediment in the recent past to cause shoreline progradation between Ocean View Beach and the Sabine jetties (USACE, 2004), and create a wide tidal mudflat against the jetty (PBS&J, 2006). Some fine-grained sediment from this westward littoral current may be entering the Sabine Pass Jetty Channel through a small boat cut in the east jetty (PBS&J, 2004a).

All but the easternmost wedge of Texas Point (the Sabine Fillet) is undergoing severe beach erosion, with shoreline retreat of up to 1,150 feet between 1974 and 2000. Shoreface sediment losses are approximately 434,200 cubic yards/year. Longshore transport to the west carries 20 percent to Sea Rim State Beach (PIE, 2003), 35 percent is lost to overwash, and 40 percent is carried offshore. Approximately 6 percent moves eastward, carried by periodic reversals in the dominant longshore current (King, 2007; PIE, 2003). The west jetty intercepts about 40 percent of the total eastward transport, creating a ½-mile-wide fillet of silt and mud against the jetty; the remainder is carried into the Sabine Pass Jetty Channel.

In contrast to Texas Point, Sea Rim State Beach is located in a convergence zone and receives 117,700 cubic yards/year of littoral material from both the east and west. About 70 percent is carried by longshore transport from the east at Texas Point, and 30 percent comes from McFaddin NWR to the west. The accreting beach is comprised of sand (0.10 to 0.14 mm in size) and shell fragments, underlain by mud.

VII.D ANALYSIS OF SEDIMENT-RELATED PROBLEMS AND OPPORTUNITIES

The next section describes the RSM problems and opportunities that were identified by the SNWW study area, and presents the results of a preliminary screening that was designed to identify potential cost-effective BU for the dredged material that would be generated with the Recommended Plan.

The principles of the RSM were applied to ensure that the dredged material arising from the SNWW CIP would be viewed as a valuable resource, integral to economic viability and environmental sustainability

of the region. In developing the DMMP for the project, this study searched for opportunities to achieve savings by defining sediment-related problems, coordinating projects, and identifying opportunities for BU (Martin, 2002). The large quantities of dredged material that would be generated by the Recommended Plan created an ideal opportunity for the exploration of the BU of dredged material. A series of public workshops and extensive ICT consultation evaluated a wide array of opportunities to use dredged material beneficially (Gulf Engineers and Consultants, Inc. [GEC], 2002; Turner Collie & Braden, 2003).

A variety of private stakeholders, State and Federal resource agencies, and the USACE engineering and scientific experts identified the following existing and FWOP sediment-related problems in the region:

- Lack of sand in the littoral system
- Interruption to the littoral system caused by SNWW jetties
- Extensive shoreline erosion at Texas Point
- Erratic accretion and erosion at Louisiana Point
- Rapid shoaling in the Sabine Pass Outer Bar Channel
- Rapid shoaling in the Port Arthur Junction
- Erosion of west side of Pleasure Island
- Erosion of Sabine Lake eastern shore
- Lack of sediment recharge to, and continuing loss of, sediment from emergent marshes

The following future with-project (FWP) impacts that could potentially be addressed with the BU of dredged material or other project elements were also identified:

- Project impacts associated with the creation of new ODMDs for the Extension Channel
- Project impacts associated with the creation of new upland PAs to accommodate new work material, and increased quantities of maintenance material over the period of analysis
- Project impacts associated with a small increase in Gulf coast shore erosion within 3.5 miles of each jetty
- Project impacts to cypress-tupelo swamps and intertidal marshes from reductions in biological productivity due to project-induced salinity increases and marsh loss
- Additional advance maintenance due to a higher than average increase in shoaling in the Sabine Pass Outer Bar Channel, one section of the Sabine Pass Channel, the Port Arthur Junction, and portions of the Neches River Channel

Preliminary Screening – Features Eliminated from Consideration

Opportunities to use dredged material beneficially to address these sediment-related concerns were suggested by public workshop participants and the ICT, and/or developed by the USACE technical studies. These suggestions resulted in the evaluation of a wide array of BU features, which could reduce

or avoid salinity impacts, restore or replace degraded wetlands, create new terrestrial or marine habitat, and return sediment to the littoral zone. Table VII-2 lists all features that were considered and eliminated during preliminary screening, and the reason for dropping them from further consideration. The incremental cost estimates presented in the table were developed during preliminary screening; they are based upon 2005 cost levels and use \$2.05/gallon for marine diesel. Incremental costs are the additional costs that would be needed to use the material beneficially, over and above the normal costs of dredging and placement in designated PAs or ODMDs. It is likely that the actual costs would be much higher than estimated here.

The feasibility of using new work and/or maintenance material was considered for all features. In the analysis for the inshore reaches, PA containment levee construction was the first priority for the use of new work material, followed by BU opportunities. In the offshore reaches, opportunities for BU of new work material were evaluated and eliminated before material was committed to existing and proposed ODMDs. For maintenance material in both inshore and offshore reaches, priority was given to BU if it could be demonstrated to be the least-cost alternative.

Given the large amount of dredged material that would be generated with the proposed project, considerable effort was expended to identify areas that could benefit from its BU. All degraded marsh areas near the SNWW were investigated to determine whether least-cost BU features could be developed. No interior marsh areas in need of nourishment or restoration were identified adjacent to Sabine Pass in Louisiana. Areas in Louisiana that could benefit from BU of dredged material are all located in the marshes east of Sabine Lake. However, these were found to be too distant from the navigation channel to permit cost-effective use of dredged material from the SNWW navigation channels. Numerous degraded marshes in Texas with potential for BU were identified adjacent to the navigation channel. They are located in the Texas Point NWR adjacent to the Sabine Pass Channel, in the J.D. Murphree WMA adjacent to the Sabine-Neches Canal, and in areas of the Neches River WMA and private lands adjacent to the Neches River Channel. The Gulf shoreline at Texas and Louisiana Points is close enough to the navigation channel to allow cost-effective BU of dredged material. The shoreline on the Texas side of Sabine Pass was also identified as a high priority area for BU because of high ongoing erosion in this area.

Several hydrologic restoration features that were intended to prevent higher FWP salinities in portions of the study area were eliminated early in the screening process. They were modeled using the HS model and found to be either ineffective at reducing salinities or to have significant unintended impacts. For example, marsh islands constructed with new work material were proposed as a means of isolating the salinity wedge in the Sabine-Neches Canal from Sabine Lake. Modeling determined that the islands did block the flow into the lake, but forced a salinity wedge to travel up the Sabine River Channel, potentially affecting cypress-tupelo swamps in that watershed. Other proposed BU features that were unsuccessful in reducing salinities are described in Table VII-2.

Table VII-2
Preliminary Screening: Dredged Material Beneficial Use Features Eliminated from Consideration

Feature Description	Reason for Elimination
Hydrologic Restoration	
Marsh islands isolating Sabine-Neches Canal from Sabine Lake	Increased salinities in Black Bayou and up the Sabine River
Marshes constricting flow at mouth of Sabine Lake (north and south of SH 82 swing bridge)	Ineffective at reducing salinities Increases velocities through mouth of Sabine Lake
Marshes constricting flow along the side of the Port Arthur Canal	Ineffective at reducing salinities High cost relative to amount of marsh acres created
Construction of channel islands blocking flow from bayous emptying Neches River marshes at Rose City and Bessie Heights	Potential to cause backwater flooding Obstructed channel access for private landowners Navigation safety concerns
Filling canal at Texas Bayou using new work material from Sabine Pass Channel	Ineffective at reducing salinities because access still provided by Texas Bayou
Emergent Marsh Restoration	
Marsh restoration using new work material from Neches River Channel to restore marsh in Rose City West	Area is being developed as a mitigation bank; no longer available for restoration
Marsh restoration using new work material from Neches River Channel to restore marsh in Bessie Heights West	Would be feasible but cost exceeds Traditional Placement Plan. Preliminary estimate of incremental cost – \$581K. Sponsor has not been identified.
Marsh restoration using new work material along the east shore of PAs 8 and 11 at Pleasure Island	Unacceptable location – interferes with levee maintenance
Marsh restoration at Old River Cove, east of power plant inflow channel, using new work material from the Neches River Channel	Would be feasible but cost exceeds Traditional Placement Plan. Preliminary estimate of incremental cost – \$472K. Sponsor has not been identified.
Marsh restoration north of Keith Lake using maintenance material from Port Arthur Canal	Would be feasible but cost exceeds Base Plan. Preliminary estimate of incremental cost – \$300K. Sponsor has not been identified.
Marsh restoration in Texas Point NWR using new work material from Sabine Pass Channel to restore marsh behind subsided jetty section.	Would be feasible but cost exceeds Traditional Placement Plan. Preliminary estimate of incremental cost – \$445K. Sponsor has not been identified.
Wildlife Habitat Creation	
Bird island constructed in Sabine Lake using new work material from Sabine-Neches Canal	Would be feasible but cost exceeds Traditional Placement Plan. Preliminary estimate of incremental cost – \$1.9 million. Sponsor has not been identified.
Returning Sediment to Littoral Zone	
Texas or Louisiana Point shore nourishment using new work material from Section 5 of the Sabine Pass Channel	Would be feasible but cost exceeds Traditional Placement Plan. Preliminary estimate of incremental cost – \$6.6 million. Sponsor has not been identified.
Texas or Louisiana Point shore nourishment using new work material from sections 5 and 6 of the Sabine Pass Channel	Would be feasible but cost exceeds Traditional Placement Plan. Preliminary estimate of incremental cost – \$19.5 million. Sponsor has not been identified.
Stockpiling new work material from Extension channel for future beneficial use	Not feasible because material would disperse rapidly and not be available for use at a later date.
Transporting sediment from new work dredging of the Extension Channel to the Texas or Louisiana littoral zone	Would be feasible but cost exceeds Traditional Placement Plan. Preliminary estimate of incremental cost – \$86.3 million. Sponsor has not been identified.
Marine Habitat Restoration	
Construction of topographic high in littoral zone with new work material	Topographic elevation would be temporary. Incremental costs (\$268 million) make it economically infeasible.

A large number of conceptual designs for emergent marsh restoration throughout the study area were initially identified as possible compensatory mitigation measures. Because of their proximity to the navigation channel, several marsh restoration features in Texas were also evaluated to determine whether they would be less costly than traditional placement. Only the Neches River and Gulf Shore BU features were determined to be less costly than using upland PAs for new work (Traditional Placement Plan) or maintenance material (Base Plan). These features and the cost analysis are presented in detail later in this chapter. Marsh restoration features considered but eliminated included marsh restoration in Texas Point NWR using new work material from the Port Arthur Canal or the Sabine Pass Channel. Another feature used new work material for marsh restoration in the part of Old River Cove marsh that lies east of the intake canal. All were found to be feasible, but more costly than traditional upland placement. The preliminary incremental costs for these features were relatively low, ranging from \$300,000 to \$581,000. No sponsor has been identified to share the incremental cost of these features.

The creation of new wildlife habitat using new work material from the Sabine-Neches Canal was also explored. This feature would provide needed nesting habitat for colonial waterbird species such as cormorant, pelican, heron, egret, spoonbill, gull, tern, and skimmer. These birds regularly nest in large numbers along the Texas and Louisiana coasts, frequently on bay islands, both natural and man-made. Despite the presence of excellent waterbird habitat in the Sabine NWR, no colonies have been documented in Louisiana within the study area. The lack of isolated, predator-free islands is believed to be a primary cause for this lack of nesting habitat. It was proposed that an island be constructed in the middle of Sabine Lake with new work material from the Sabine-Neches Canal. This feature was eliminated when the cost was found to be approximately \$2 million higher than the use of traditional upland PAs and no sponsor was identified to share the incremental cost.

Several features were evaluated that would return sediment normally placed in upland PAs or ODMDSs to the littoral zone. Conceptual plans were developed for shore nourishment at Texas and Louisiana Points using new work material from Section 5 or sections 5 and 6 of the Sabine Pass Channel. The features were found to be feasible but cost \$6.6 and \$19.5 million, respectively, more than upland placement in PA 5. Stockpiling dredged material in ODMDS 4 for later use was also investigated. Like all other SNWW ODMDSs, material placed at this site disperses quickly after placement. Although it is closest to shore, the dispersed material in ODMDS 4 is not likely to migrate into the littoral zone because it is located beyond the depth of closure. It is expected that any material stockpiled within ODMDS 4 would be unavailable for use within 3 months of placement. Since stockpiling assumes that the beneficial use needs will not be immediate or short term, it was concluded that this feature is not a viable alternative.

Transporting and discharging coarser-grained sediments from the new work dredging of the Extension Channel (stations 117+000 to 146+000) into the littoral zone offshore of Texas or Louisiana Point was also evaluated. A hopper dredge with pump-out capability could be used to dredge the channel, move as close as possible to shore, and pump the material via a connecting pipeline to a discharge point within the 14-foot depth contour. Discharging the material at or inshore of the depth of closure should guarantee the reintroduction of sediments within the littoral zone, where natural processes will beneficially distribute

the sediments. It is estimated that the incremental cost of this action would be about \$86.3 million. While feasible, this BU feature is much more costly than placement in the proposed ODMDSs B and C. No sponsor has been identified to share the incremental cost of the feasible BU features discussed above.

The creation of new marine habitat in the form of a “topographic high” offshore of Louisiana Point was also investigated. This feature would involve the BU of new work material from the deepened Sabine Bank and Extension channels to create a new refuge or feeding locale for fish and shrimp. The material would be dredged as usual with a hopper dredge and then transported far enough upcurrent to prevent redeposition in the navigation channel. The material would be dropped in mounds forming a series of rows over a large area, roughly 2.0 x 2.5 miles. The actual ecological benefits of such a feature off the Texas coast have not been demonstrated. A similar feature was constructed outside of Galveston Bay, but no monitoring was conducted to determine whether any benefits accrued. In addition, the feature would be temporary because the dispersive processes acting on the ODMDSs would also be present here. It was eliminated from further consideration when it was estimated that the incremental cost of the temporary habitat would be approximately \$268 million.

Detailed Evaluation of Disposal Features

After the preliminary screening, BU features that appeared to be least-cost alternatives for the BU of dredged material in reducing with-project salinities, restoring marsh, or providing shoreline nourishment were advanced for detailed evaluation. Water and sediment sampling and bioaccumulation studies have established that dredged material from all SNWW navigation channels is suitable for BU (PBS&J, 1999, 2002, 2004b). The ecological benefits of the following BU features were evaluated and quantified using the WVA Model, and these benefits were used to offset project impacts as described below. A description of the WVA Model is provided in Section IX. In addition, numerous existing upland PAs were evaluated for use with the Recommended Plan. All BU alternatives to ODMDSs were eliminated during the preliminary screening. Existing and proposed ODMDS sites were therefore evaluated for the placement of all material from the offshore channel reaches.

Neches River Beneficial Use Feature

Four former marsh areas on the Neches River were combined into one large management feature, called the Neches River BU Feature, to provide flexibility in the use of new work and maintenance material from the several construction reaches of the Neches River Channel. The primary objective of this combination feature would be to beneficially utilize dredged material to restore emergent marsh in an area that has suffered dramatic, widespread loss of marsh. The BU feature would utilize new work and maintenance material that would otherwise be removed from the sediment system and stored in upland, confined PAs. Figure VII-1 shows the components of the Neches River BU Feature.

This page intentionally left blank.

The Neches River BU Feature would offset all indirect salinity impacts to Texas wetland habitats on the Neches and Sabine rivers (hydro-units TX 3 through TX 8, and TX 10 through TX 13) by restoring 2,853 acres of emergent marsh; improving 871 acres of shallow water by creating shallower ponds and interconnecting channels; and nourishing 1,234 acres of existing fringing marsh by winnowing fine-grained material from unconfined flows of dredged material effluent (Table VII-3). The BU feature thus provides benefits to a total of 4,958 acres of degraded marsh on the lower Neches River, or 53 percent of the restoration target set by the CEPRA 2004 plan update for the lower Neches River (GLO, 2004). The BU feature also offsets the direct impact of converting 86 acres of freshwater wetland to a confined placement area (PA 24A).

Table VII-3
Acreage Restored by Neches River BU Feature

Components of the Neches River BU Feature	Restored Emergent Marsh	Improved Shallow-water Habitat	Nourished Existing Marsh	Total Influence Area
Rose City East	345	72	151	568
Bessie Heights East	1,869	660	651	3,180
Old River Cove West	639	139	432	1,210
Total	2,853	871	1,234	4,958

Gulf Shore Beneficial Use Feature

The use of dredged material was also evaluated for Gulf shoreline nourishment at Texas and Louisiana Points (Figure VII-2). Over the 50-year period of analysis, approximately 24 mcy of maintenance material would be hydraulically pumped from Section 5 of the adjacent Sabine Pass Channel onto a total of 6 miles of shoreline on both sides of Sabine Pass. Some material is expected to flow over existing marsh while the remainder will flow into nearshore waters. Material placement during each 3-year Sabine Pass Channel dredging cycle would alternate between Texas and Louisiana, so that material would be placed on each state's shoreline every 6 years. This recurring action would nourish eroding marsh, restore sediment to the littoral zone, minimize projected FWP shoreline impacts, and, potentially, create new marsh with the recurring placement of approximately 1.5 mcy every 3 years.

Texas Point is undergoing severe beach erosion, with shoreline retreat of up to 1,150 feet between 1974 and 2000 (King, 2007; Morang, 2006). This is the highest rate of shoreline loss on the upper Texas coast and a CEPRA "critical erosion area" (GLO, 2005). In Louisiana, persistent erosion along the shoreline between Ocean View and Holly Beach, on the order of -4.3 feet/year between 1985 and 1998, was recorded here prior to Hurricane Rita (USACE, 1971a, 2004). Nearer to Louisiana Point, significant accretion over the last 100 years has slowed to +1.2 feet/year, and the behavior of this shoreline has become erratic, with some areas eroding and some aggrading (USACE, 2004).

Historic dredging records indicate that the maintenance material from Sabine Pass will average 51 percent silt, 31 percent clay, and 18 percent fine sand (USACE dredging database). This mix of materials does not contain typical beach-quality sand, but the material types and composition are similar to what is present

on the shorelines today. Narrow beachfronts of silt or clay lie seaward of eroding overwash marsh terraces (PBS&J, 2006). Given the unusual characteristics of this sand-starved system, returning the material to the littoral system is likely to have a net beneficial effect, regardless of material type. The longshore transport in this system contains primarily fine-grained sediments, but these sediments have been shown to accumulate in the near shore zone and result in shoreline accretion by as yet poorly understood processes (King, 2007; Morang, 2006).

The Gulf Shore BU Feature will provide a regular source of predominantly fine-grained sediment that should contribute to mudflat accretion and periodically move onshore to become shore-attached through a process described by PIE (2003). On the western Louisiana and east Texas coasts, sediments accumulate as mudflats and underwater mudshoals (or “fluid mud”) in the nearshore region. Nearshore, fluid mud can be trapped against the shoreline by prevailing south and southwesterly winds, and storms carry the trapped muddy ooze onto the chenier shoreline. The northwest Gulf is a microtidal, storm-dominated environment. In a typical year there are about 20 to 30 frontal passages generating waves, surges, and wind-driven currents, with most-frequent waves from the southeast about 3 to 4.5 feet in height (PIE, 2003).

Mudflat accretion on the western Louisiana coast appears to correlate with periods of high sediment influx from the Atchafalaya River and the passage of large storm systems. Up to 1,000 feet of shoreline accretion along 4.5 miles of shoreline in western Louisiana occurred over a few days during the passage of Hurricane Audrey (Morgan et al., 1958). Another study reports that accretion in western Louisiana occurs most frequently during storms and that it can be very rapid (Wells and Kemp, 1986). Huh et al. (1991) reports that surge deposits of gel-like mud become stranded on the upper shoreface during storms. These deposits can dry and crack, forming mud cobbles that help to armor the shoreline. Fluid mud and mudflat accretion at the shoreline has also been observed on the Jefferson County shoreline. At Sea Rim State Beach in June 2002 (PIE, 2003), shoreline features were observed that resembled the storm surge deposits of fluid mud and mud cobbles reported above.

The presence of additional fine-grained sediments in the littoral system that will be provided by the BU feature should reduce the current erosion rate and minimize the small increase in shore erosion predicted with the project (Gravens and King, 2003). In systems that have an abundant supply of fine-grained sediments, the nearshore seabed can be blanketed with fluid mud. The presence of additional muddy sediment in the nearshore environment may attenuate waves and lessen wave-induced erosion (Hsiao and Shemdin, 1980; Tubman and Suhayda, 1976; Wells and Kemp, 1986). There are also anecdotal reports of Gulf areas off Louisiana and Texas Points being safe havens for vessels during storms due to the near-total attenuation of waves (Block, 1984; King, 2007; Wells and Kemp, 1986).

The BU dredged material is expected to be composed largely of unconsolidated muds. The fine-grained sediments are expected to initially be highly mobile and some portion of the material will be rapidly lost from the vicinity of the shoreline. As demonstrated by another BU project at Texas Point (USACE, 2000a), a significant percentage will also flow onshore and nourish existing marsh along the eroding

beachfront. Because of the prevailing wave climate, the mobile material within the surf zone should generally migrate to the west at both Texas and Louisiana Points (Wamsley, 2008). Transport processes identified by the Sabine Pass Sediment Budget (Morang, 2006) indicate that the material would move toward the eroding shoreline at Texas Point. There, the additional fine-grained sediments could lower erosion rates through the mudflat accretion and wave attenuation processes described above. A small quantity of material may migrate to the east and contribute to the Sabine fillet at the west jetty (King, 2007; Morang, 2006).

In Louisiana, the sand bar formed by BU sediments from the Sabine Pass LNG project may shelter the shoreline from wave energy sufficiently to allow fine-grained sediments to form a mudflat behind the sandbar (Nairn and Willis, 2002). While a significant percentage of the sediment will be rapidly carried offshore, some is likely to move downcoast with the littoral current, enlarging the sand and mudflat already present at the east jetty. Potential impacts of elevated levels of total suspended solids are expected to be similar to those that resulted from the Sabine Pass LNG BU project (PBS&J, 2004a). A temporary increase in suspended silt/clay was expected during the first 8–9 months following placement. After the termination of placement activities, total suspended solids were expected to decrease for about 18 months when concentrations reached background levels. Modeling conducted for the Sabine Pass project indicated that it will take 9 years before the silt and clay component of Sabine Pass LNG BU material become totally suspended and are removed from the littoral zone. Since the Gulf Shore BU Feature proposes a placement episode every 6 years, all the fine-grained sediments would not have been removed before new material is added.

This should result in the retention of some portion of the fine-grained sediment, and thus facilitate mudflat accretion through the processes described above. During and after each placement episode, most of the resuspended silt and clay are expected to enter the Sabine Pass Jetty Channel through the shallow boat cut, but deposition in the channel is not expected. It should remain in suspension and be transported back into the Gulf.

Although the BU sediments will be largely fine grained, approximately 18 percent of maintenance material is expected to be sand. Sands that are deposited onshore will nourish and stabilize eroding marshes; sand deposited in the nearshore zone should stay in the nearshore environment, moving back and forth across the shoreface (Wamsley, 2008). Sand placed at Louisiana Point should remain on the shoreface where it was deposited; no significant amounts of sand are expected to enter the Jetty Channel. On erosive mud shorelines like those in the BU area, the sand percentage should increase, and it will form sandy lenses or a veneer over the mud shoreline substrate. As the sand lenses thicken, the sands help protect the underlying mud from further erosion (Nairn, 1992). However, in smaller quantities, sand can also accelerate erosion of a mud beach. If the consolidated mud is not covered by a sand veneer, any sand that is mobilized by wave action will act as a scouring agent (King, 2007).

It is acknowledged that the behavior of the BU sediments within this complex littoral system cannot be predicted with certainty over the period of analysis, especially given the potential for strong storms to affect the coastal environment. However, there is sufficient knowledge of general processes and baseline

conditions to support evaluation of potential impacts and benefits. Furthermore, the engineering feasibility and potential environmental benefits have been demonstrated by successful recent BU projects at Texas and Louisiana Points (PBS&J, 2004a; USACE, 2000a). All of this information was used to establish explicit assumptions about the expected behavior of the BU material in the quantification of project impacts and benefits using the WVA model, as described in Appendix C of the FEIS. The WVA analysis assumed that 60 percent of the pumped quantity will remain in the existing marsh and on the shallow nearshore slope in front of the existing shoreline immediately after material placement. Since the material is unconsolidated and prone to erosion, only 50 percent of that material was assumed to remain by the end of each 6-year cycle. It was further assumed that the regular addition of material every 6 years would slow the resuspension of fine sediments, and result in the accumulation of some new marsh by the end of the period of analysis. No attempt was made to account for the effect of large storm systems.

No long-term impacts to vegetation or benthic sediments should result from nourishment episodes. The NWR personnel reported that the marsh vegetation at Texas Point rebounded quickly and with renewed vigor after being covered with up to 1 foot of material by a previous Texas Point BU project (Walther, 2005). Potential impacts to Critical Habitat for the wintering piping plover are expected to be beneficial in the long term, with short-term displacement of some birds during disposal activities. Benthic invertebrate fauna residing in the intertidal and tidal impact zones will be smothered, but studies have shown the impact to be similar to that resulting from natural events such as storms and hurricanes (Saloman and Naughton, 1977; Simon and Dauer, 1977). Following the burial, the resident species should recover quickly because of their short life cycle, high reproductive potential, and the rapid recruitment of larvae and motile macrofauna from nearby unaffected areas (Nelson and Pullen, 1988).

Upland Placement Features

Existing Active PAs

Existing PAs were evaluated to determine whether they possessed sufficient capacity for new work and maintenance material over the 50-year period of analysis. All of the upland PAs were reviewed by the ICT, and no further environmental review was recommended for existing PAs that were in active use. Existing and proposed upland PAs are shown on figures VI-3 through VI-7.

Existing Inactive PAs

Field visits were made to existing PAs that had been inactive in recent years (PAs 23A, 25A, 26, 27C, and 27D). Inactive PAs were visited to determine whether habitat and connectivity had developed since their last use such that they were contributing to the function of adjacent wetlands. No field visits or further review of inactive PA 25A were needed; no impacts are expected because it is known to contain low-quality, upland habitat. PA 25A is included in the DMMP.

The remaining inactive PAs were evaluated for potential impacts. All of these areas have been modified extensively by past placement activities and associated levee systems, which have artificially altered the

hydrology. Surrounding containment levees hold water and isolate the areas from adjacent water bodies, preventing them from contributing to the function of the adjacent wetlands and riparian corridor. All contain degraded habitat with low habitat values, primarily roosting habitat for birds and some wildlife cover. Renewed use of PAs 23A, 26, 27C, and 27D would not constitute a significant adverse change to the existing environmental condition, and all are included in the DMMP.

Areas Considered for PA Expansion

The quantities of dredged material projected for the Recommended Plan necessitated additional PA capacity. Finding areas suitable for the development of new upland PAs along the inshore reaches was difficult. The majority of land adjacent to the SNWW is either covered by residential and industrial development, existing PAs, forested uplands, or wetlands. Areas adjacent to existing PAs 14, 16, 18, and 24 were evaluated to determine their suitability as PAs. Potential expansion areas were designated as PA 14A, PA 16A, PA 18A, and PA 24A.

PA 14A (82 acres) is located south of existing PA 14, on the south side of the Neches River near its mouth. It is a relatively undisturbed intermediate marsh containing numerous small ponds that are seasonally connected to the riparian corridor. It provides habitat for numerous native wildlife species. It was determined that use of this area would be a significant adverse change to existing conditions because of its value to native wildlife species and preserving water quality. Placement needs for the Neches River Channel were reevaluated and the area was dropped from further consideration for use as a PA.

PA 16A (202 acres) is located west of existing PA 16 on the south side of the Neches River near its mouth. It is covered by intermediate marsh, has excellent hydrologic connectivity to adjacent wetlands, and provides important habitat for native fish and wildlife. The EPA includes the 16A area in a preliminary area of concern for the Star Lake Canal Superfund Site (EPA, 2006); an EPA feasibility study to determine the nature and extent of contamination is underway. Due to contaminant concerns and the biological and water quality value of its wetlands, the area has been dropped from further consideration for use as a PA.

PA 18A (71 acres) is located north of existing PA 18. It is a disturbed upland area containing low-quality scrub habitat. The Habitat Workgroup reviewed an aerial photograph of the proposed expansion area and determined that no field visit would be required. PA 18A is included in the DMMP.

PA 24A (187 acres) is located north of the Maritime Administration's Reserve Fleet area. The area contains a central upland ridge with surrounding wetland components. Initially, a 331-acre tract was evaluated for use. To minimize impacts to wetlands, 144 acres of marsh-hay cordgrass in the northern section were excluded, reducing the proposed PA to 187 acres. The 187-acre area contains 85 acres of lower quality wetlands comprised primarily of California bulrush and common reed. Impacts associated with conversion to a confined PA were evaluated with the WVA model, and it was determined that the impact of -44 AAHUs is fully offset by benefits of the DMMP Neches River BU Feature. PA 24A is included in the DMMP.

ODMDS Features

Four ODMDSs (Nos. 1–4) are currently in use for the existing SNWW project. Features for the placement of new work and maintenance material resulting from the construction of a deeper and longer offshore channel have been evaluated in an ODMDS Site Designation FEIS, which is included as Appendix B of the FEIS. Appendix B evaluates alternatives for the selection of new ODMDSs, including the use of the existing ODMDSs for the proposed CIP and BU sites. Existing and proposed ODMDSs are shown on Figure VII-3.

The existing ODMDSs were evaluated to determine whether they could accommodate all new work and maintenance material from the Recommended Plan. Although it was determined that they were large enough to hold all the material, the 13.2-mile length of the channel extension would make the cost of hauling all new work and maintenance material to existing ODMDSs prohibitively expensive. Designation of four new ODMDSs will be necessary. The best locations for the new sites were determined using the “zone of siting feasibility” screening technique, which delineates economically feasible sites that are sufficiently removed from ecologically sensitive or incompatible use areas to eliminate or minimize adverse impacts.

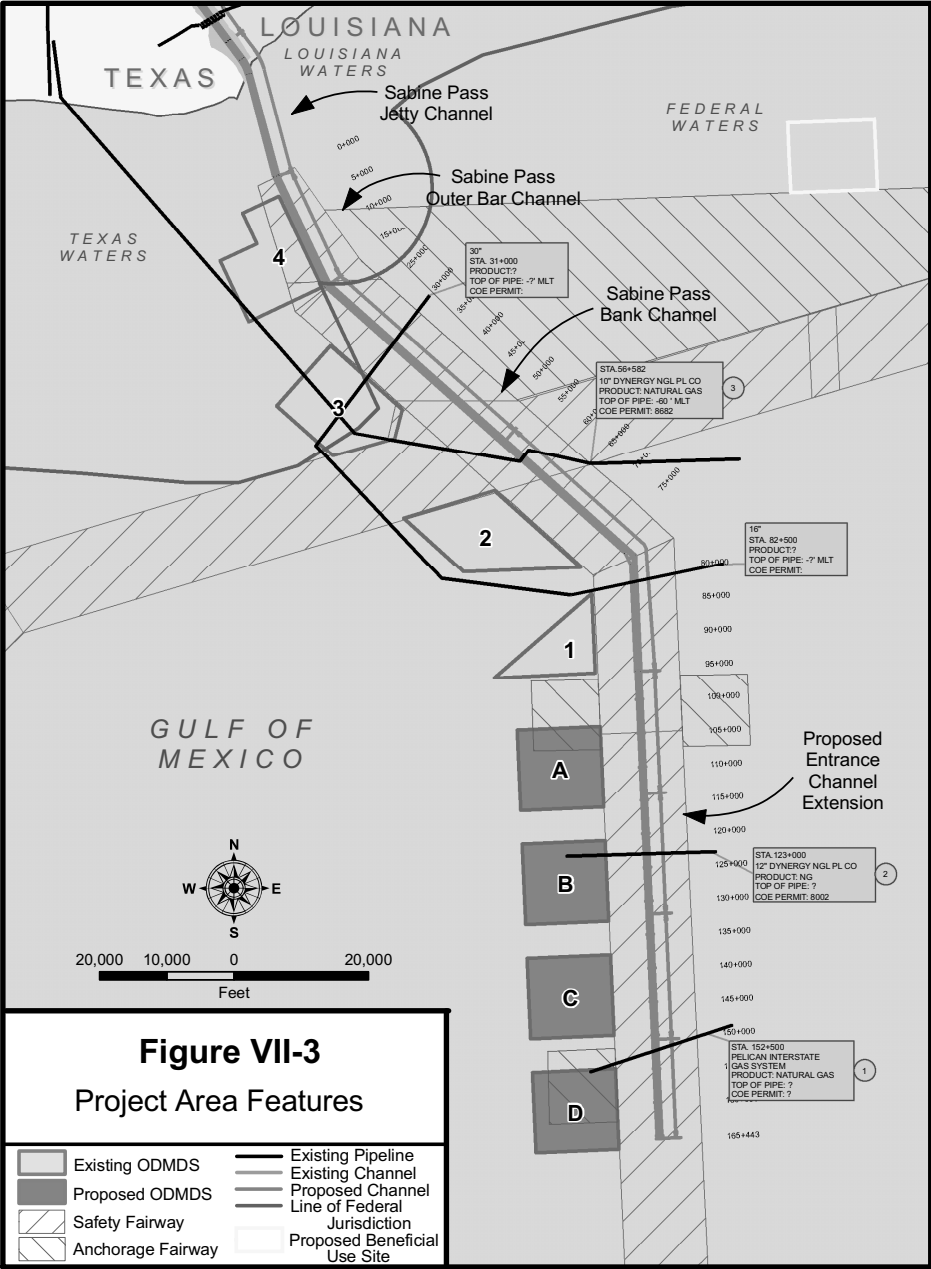

The ODMDS FEIS found no significant environmental impacts related to the use of existing and proposed ODMDS sites for the SNWW Recommended Plan. Analysis of northwestern Gulf of Mexico circulation patterns confirmed that the existing and proposed ODMDSs were properly located on the west side of the navigation channel. Before- and after-dredging bathymetry surveys have demonstrated that material placed offshore in the ODMDSs does not accumulate; it disperses quickly after placement in the offshore environment.

VII.E IDENTIFYING THE LEAST-COST PLACEMENT ALTERNATIVE

Description of Placement Alternatives

Placement features that survived the detailed evaluation were grouped into two comprehensive placement alternatives for further analysis. The Traditional Placement Alternative and the BU Alternative were compared to determine the least-cost, environmentally acceptable DMMP for both new work and maintenance material arising from the proposed 48-foot project.

In the Traditional Placement Alternative, it was assumed that management practices for the existing project would continue, adapting and expanding as needed to provide increased capacity for the proposed 48-foot project. Dredged material would be placed in the 4 existing and 4 proposed ODMDS features, the 16 existing upland PA features, and expansion cells in PAs 18A and 24A. Capacities of the existing upland PA features would be increased over the 50-year period of analysis by regular raising of containment levee heights. Without the additional capacity provided by the BU features described below, a final levee elevation of 36 feet would be required at PA 5 in Sabine Pass. On the Neches River Channel, final levee elevations at PAs 13–14, 16–18A, 21, and 23–27D would range from 17 to 47 feet. On the

N:441206/post_HU_projects/Projects/Original_Revised_Figure_Numbers/Figure_2_2_Vr2.mxd (A.P. 3/08/07)

Port Arthur and Sabine-Neches Canals (PAs 8, 9, 11, and 12), final elevations would be the same as the Recommended Plan. It is assumed that regular dewatering management practices (DAMP) would be required on the Neches River Channel PAs to provide the required 50-year capacity. PAs requiring DAMP include PAs 12, 13, 14, 16, 25A, 27A, and 27C. The Traditional Placement Alternative includes hopper and hydraulic dredging costs to place material at ODMDs and upland PAs, to construct and maintain higher containment levees over the 50-year period of analysis, and real estate costs to acquire property needed for proposed PAs 18A and 24A.

The BU Alternative assumed the use of the Neches River and Gulf Shore BU features, in addition to all of the upland PA and ODMDs features that are also included in the Traditional Placement Alternative. The final levee elevation at PA 5 at Sabine Pass would be 34 feet; on the Port Arthur and Sabine-Neches canals (PAs 8, 9, 11, and 12), final levee elevations would range from 23 to 42 feet; and on the Neches River Channel, final levee elevations at PAs 13–14, 16–18A, 21, and 23–27D would range from 14 to 39 feet. This alternative takes advantage of new work material provided by the channel-deepening project to build hydraulic containment levees within degraded, former areas at Rose City East and West, Bessie Heights East, and Old River Cove. Each of these areas is referred to as a component of the overall Neches River BU Feature. Marsh would be created in each component using only new work, or a combination of new work and maintenance material. Marsh would be created in Old River Cove using only new work material. The first phase of Rose City East would be constructed with new work material, and it would be completed with the first cycle of maintenance material. Bessie Heights East would be completed with maintenance material over seven cycles. In addition to costs associated with providing upland PA capacity, costs for this plan include additional pumping distances and pipe movements for the BU features and their containment structures, training levees and circulation channels; maintenance of containment structures over the multiyear marsh construction period; marsh plantings; and monitoring costs.

Cost Comparison of Placement Alternatives

The average annual cost of new work and 50-year O&M plans for both alternatives are compared in Table VII-4. These costs were developed during the detailed design phase, using a different cost (\$1.12/gallon fuel cost) and price level (October 2005). Costs have not been updated for this comparison because it is a screening phase cost comparison. Costs for both alternatives would change proportionately if they were updated with October 2009 price levels, and the difference in cost between the two plans would not be materially different. New work material is used beneficially only along the Neches River Channel. There are no differences between the new work costs for the first four channel reaches (Offshore Channels, Sabine Pass Channel, Port Arthur Canal, and Sabine-Neches Canal) because none of the new work material from these reaches would be used beneficially. New work material provided by the channel deepening is used at Rose City East, Bessie Heights East, and Old River Cove. Bessie Heights East and Rose City East would also use maintenance material from the Neches River to complete marsh restoration. These reaches exhibit differences in the O&M section of Table VII-4 because they are the only channel sections from which O&M material is proposed to be used beneficially. All of the costs have been annualized so that the time value of money is considered. Both the new work and O&M costs are

expressed as 50-year annualized costs to make them comparable. The annualizations were calculated on mid-year costs, using October 2005 price levels, and an interest rate of 4.875 percent.

Difference	–	–	–	–	(496,000)	(118,000)	(48,000)	(662,000)

The Gulf Shore BU Feature uses maintenance material to regularly renourish shorelines and Texas and Louisiana Points every 6 years over the period of analysis. This disposal method was found to be the least-cost method of disposal for all maintenance material from Section 5 of the Sabine Pass Channel, and is included in the base disposal plan. Therefore, displayed costs for this feature are equal for both the Revised BU Alternative and the Traditional Placement Alternative. All of the costs have been annualized so that the time value of money is considered. Both the new work and O&M costs are expressed as 50-year annualized costs to make them comparable. The annualizations were calculated on mid-year costs, using October 2005 price levels, and an interest rate of 4.875 percent.

Selection of the DMMP

The BU Alternative is recommended for adoption in the DMMP for the Recommended Plan because it is the least-cost, environmentally acceptable placement alternative. In addition to being a least-cost plan, it provides substantial ecological benefits that offset all project impacts in Texas, and some impacts in Louisiana.

VII.F DESCRIPTION OF THE DMMP FOR THE RECOMMENDED PLAN

The DMMP for the Recommended Plan provides for the placement of both new work and maintenance material for the 50-year period of analysis. The locations of channel reaches, waterway sections, PA and ODMDS features, and BU features are shown on Engineering Drawings C-01 through C-12 (Appendix 1). A comprehensive DMMP is needed because new work material would be used to construct containment levees for BU features that would be completed with maintenance material after channel construction is completed. The DMMP, therefore, differs from the discussion of the incremental O&M cost of the Recommended Plan in later sections of this chapter, as they focus solely on O&M costs and the placement plan for maintenance material only.

DMMP BU Features

All BU features proposed as part of the DMMP are described in Table VII-5. Details of plan implementation for each of the BU features were described above and are discussed further in the FEIS. The DMMP BU features are not being pursued as separable elements of an ecosystem restoration plan under Section 204 or 207 authorities. They are not ecosystem restoration measures, and as such, do not target a specific historical condition for the level of restoration. They are least-cost, environmentally acceptable placement features and are included as GNF of the DMMP.

Upland PA Features

Sixteen existing PA features, and two new cells (PAs 18A and 24A) that enlarge existing PAs, are proposed for use in the Recommended Plan (Table VII-6). Existing PAs will be used to the greatest extent possible; five currently inactive PAs or PA cells (PA 23A, 25A, 26, 27C, and 27D) will be rehabilitated

and restored to active use. Non-Federal dredging is projected to contribute 4.6 percent of material placed in upland PA features. Non-Federal facilities using these PAs are located along the Port Arthur and Sabine-Neches canals and the Neches River Channel; this material will be placed in the same PAs used for material from the adjacent navigation channels.

Table VII-5
DMMP BU Features

Beneficial Use Features	No.	Description	Size of Influence Area
Rose City East (component of Neches River BU Measure)	TX 3-1 East	Restoring 345 acres of fresh marsh, improving 72 acres of shallow-water habitat, and nourishing 151 acres of existing marsh in two construction events. New work material from Neches River Channel will be used to restore 225-acre marsh, and construct hydraulic containment levees and higher elevation features. Maintenance material from the first maintenance cycle will be used to restore an additional 120 acres of marsh.	Influence area – 568 acres
Bessie Heights East (component of Neches River BU Measure)	TX 5-2	Restores 679 acres of brackish and 1,190 acres of intermediate marsh, improves 660 acres of shallow-water habitat, and nourishes 651 acres of existing marsh. Marsh will be constructed with maintenance material from Neches River Channel for 28 years. New work material is used to build hydraulic containment levee.	Influence area – 3,180 acres
Old River Cove (component of Neches River BU Measure)	TX 6-1	Restores 639 acres of brackish marsh, improves 139 acres of shallow-water habitat, and nourishes 432 acres of existing marsh with new work material from Neches River Channel. New work material used to construct hydraulic containment levee.	Influence area – 1,210 acres
Gulf Shore BU Feature (Texas and Louisiana Points)	TX 8-11 LA 5-2/6-2	Nourish 3 miles of Gulf shoreline on both sides of Sabine Pass, from 0.5 to 3.5 miles from east and west jetties, using maintenance material from Sabine Pass Channel. Unconfined placement of maintenance material along shoreline every 3 years for 50-year period of analysis (8 placement episodes). Assume 50:50 split of material between Texas and Louisiana accomplished by alternating placement in Texas and Louisiana.	Affected shoreline 6.0 miles total

* New cells (PAs 18A and 24A), which enlarge existing PAs.

** Waterway sections are shown on FFR Engineering Plates C-01 through C-12 (Appendix 1).

Offshore Placement Features

The ODMDs for the Recommended Plan are four existing (sites 1–4) and four proposed ODMDs (sites A–D). All of the new ODMDs are located on the west side of the channel since the littoral drift (movement of offshore sediment) is most commonly from east to west. Sizes and associated channel reach, beginning with the farthest offshore reach, are provided in Table VII-7.

Table VII-7
Existing and New ODMDs

Placement Area	Size (acres)	Status	Associated Waterway Section
D	3,392	New	Extension Channel
C	3,392	New	Extension Channel
B	3,392	New	Extension Channel
A	3,392	New	Extension Channel
1	2,048	Active	Section 1
2	4,736	Active	Section 2
3	3,968	Active	Section 3
4	3,456	Active	Section 4

The USACE and EPA have cooperated in the preparation of an FEIS for the proposed ODMDs; this document is Appendix B of the FEIS. Public comment on the proposed ODMDs will be requested

concurrently with comments on the FEIS for the SNWW CIP. If the FFR and FEIS are approved by the USACE and the Recommended Plan is authorized by the U.S. Congress, the EPA will publish a rule-making in the *Federal Register* that establishes SNWW ODMDSSs A, B, C, and D for use in conjunction with construction and operation of the 48-foot project.

VII.G INCREMENTAL ENVIRONMENTAL IMPACTS AND BENEFITS OF THE DMMP

Incremental Environmental Impacts of the DMMP

Incremental DMMP impacts of the proposed 48-foot project are discussed in detail in the FEIS, but are summarized here. The incremental impact would consist of marsh lost with construction of one new upland placement cell, and four new ODMDSSs. No impacts are anticipated with improvements to existing upland PAs that are needed to provide additional capacity for the 50-year period of analysis, since improvements are limited to increasing containment levee heights. The DMMP BU features have net ecological benefits that are described below.

Incremental Ecological Benefits of the DMMP

Methods and Objectives

The DMMP BU features described above provide ecological benefits that would offset project impacts. The benefits were used to offset project impacts before remaining, unavoidable impacts were quantified and compensatory mitigation was developed. The WVA Model was used to quantify impacts to all affected habitat types in the study area and establish the appropriate amount of offsetting DMMP benefits by habitat type. An HS model was used to evaluate and quantify salinity impacts and benefits of the BU plan. The WVA model is summarized in Chapter VIII and described in detail in Appendix C of the FEIS. The HS model is also summarized in Chapter VIII, but it is described in detail in Brown and Stokes (2009). Evaluation of BU alternatives was conducted within the ICT and technical workgroups in meetings conducted from 2001 to 2006. The BU plan was revised by the USACE in 2009 to reflect changes necessitated by project reformulation and revised HS modeling.

The DMMP benefits contribute to multiagency regional plans (the TPWD regional management plan for J.D. Murphree WMA, Sea Rim State Park, Texas Point NWR, and McFaddin NWR [see Keith Lake: the Texas Coastwide Erosion Response Plan [GLO 2004, 2005]; the Louisiana Comprehensive Management Plan [Louisiana Coastal Protection and Restoration Authority [LACPRA], 2007; USACE, 2008b]; the LA Coast 2050 Plan [LCWCR/WCRA, 1998], and the North American Waterfowl Plan (NAWMP Committee, 2004)), by restoring and preserving scarce and vulnerable wetlands and wildlife habitat, nourishing eroding Gulf shorelines, restoring sediment to the littoral zone, and using dredged material beneficially to the greatest extent possible. The DMMP also complies with Coastal Zone Management Plans (CZMP) for each state by sharing dredged material from the Sabine Pass Channel to accomplish regular shoreline nourishment. The Gulf Shore BU Feature shares this resource equally between the states because it is dredged from a channel that straddles the state boundary.

Offsetting Ecological Impacts

BU features included in the DMMP provide benefits that offset all indirect and direct Texas impacts (–412 AAHUs) of the Recommended Plan (Table VII-8) and partially offset impacts in Louisiana (Table VII-9). In Texas, construction of the Neches River BU Feature and the Texas portion of the Gulf Shore BU Feature will produce benefits totaling 1,068 AAHUs. Therefore, there will be a net gain of 656 AAHUs, which more than offsets all negative impacts that occur in Texas. Impacts that are offset include the direct loss of 32 AAHUs for the conversion of fresh marsh to upland PA 24A. The majority of the offset Texas impacts are in the Neches River watershed, but approximately 16 percent are losses to cypress-tupelo swamp (–22 AAHUs) and fresh and intermediate marsh (–45 AAHUs) in the Sabine River watershed. In Louisiana, the Gulf Shore BU Feature provides benefits totaling 210 AAHUs. Given total Louisiana impacts of 1,709 AAHUs, there is a net loss of 1,499 AAHUs remaining in Louisiana after offsetting benefits of the Louisiana portion of the Gulf Shore BU Feature are applied.

It is important to note that the impacts presented here do not include all impacts of the Recommended Plan in Texas as FWP impacts in Texas’s Salt Bayou (TX 9) hydro-unit are not included. This is the result of an ICT decision made in response to a USACE policy determination on a related project. During an in-progress review of the Keith Lake Fish Pass Section 1135 study, it was determined that SNWW CIP impacts to this area were being evaluated concurrently for the same area. The USACE Headquarters concluded that impacts could not be evaluated under the CIP study if they were being addressed under the Section 1135 Keith Lake Fish Pass project. The non-Federal sponsor of the Section 1135 study elected to continue that study with the understanding that the ICT review of the Recommended Plan impacts to the Salt Bayou hydro-unit would be necessary if a Section 1135 project is not approved prior to authorization of the SNWW CIP. Excess in-kind benefits associated with Texas’s DMMP features (316 AAHUs) could be used to partially offset the predicted Salt Bayou AAHU loss of 658 AAHUs.

With adoption of the DMMP, all FWP impacts in Texas would be offset and no compensatory mitigation is proposed in conjunction with construction of the Recommended Plan. Impacts in Louisiana are minimized to the greatest extent possible by the DMMP, but unavoidable impacts of 1,499 AAHUs remain. When the impacts and DMMP benefits are not subdivided by state but are applied to the project as a whole, a loss of 843 AAHUs remains (Table VII-10). A mitigation plan, described in Chapter VIII, has been developed to compensate for unavoidable impacts of the Recommended Plan.

VII.H BASE PLAN FOR THE EXISTING 40-FOOT PROJECT

A Base Plan was developed that describes the without-project practices that would accomplish the disposal of dredged material from the existing 40-foot project in the least costly, environmentally acceptable manner. A summary description of existing and proposed PAs and BU features of the Base Plan are provided below. In the next section, the cost of the Base Plan is compared to the O&M cost of the Recommended Plan to determine the incremental O&M cost of the Recommended Plan (see Table VII-12).

The offshore channels (Sabine Bank Channel, Sabine Pass Outer Bar Channel, and Sabine Pass Jetty Channel) would be maintained with a hopper dredge, and approximately 162 mcy of material would be placed in four existing ODMDSs. Bed sediments in the offshore channels vary from 4.3 percent sand and 95.7 percent silt plus clay in the Sabine Pass Outer Bar Channel to 24.3 percent sand and 75.7 percent silt plus clay in the Sabine Bank Channel (Parchure et al., 2005). These sites have sufficient capacity for the 50-year period of analysis as they are located in a dispersive environment where dredged material does not accumulate.

For the inshore Sabine Pass Channel, the analysis of placement alternatives conducted for this study resulted in a change from traditional upland placement at PA 5. The Gulf Shore Feature was evaluated as a BU alternative for 13.8 mcy of maintenance material from Section 5 (total of 16 cycles, 3 years each), the channel section closest to the coast (see Engineering Plates C-09 and C-10, Appendix 1). Material from channel Section 6 would continue to be placed into PA 5 (16.8 mcy total; 16 cycles of 3 years each), because the longer pumping distance to the coast makes shore nourishment cost prohibitive. The 50-year stream of costs for BU and traditional upland placement alternatives was compared for both the Base and Recommended Plans, as shown in Table VII-11. These costs were developed during the detailed design phase, using a different cost (\$1.12/gallon fuel cost) and price level (October 2005). Costs have not been

updated because it is a screening phase cost comparison. No changes have been made to these alternatives since they were initially compared. Costs for both alternatives would change proportionately if they were updated with October 2009 price levels, and the difference in cost between the two plans would not be materially different. During the detailed evaluation of screened alternatives, the Gulf Shore Feature was compared to the Base Plan option. The Base Plan option entails placing all Section 5 material in upland confined PA 5, with regular raisings of the containment levee as required to contain the material. The cost analysis determined that the Gulf Shore Feature is the least-cost, environmentally acceptable alternative for the 40-foot Base Plan. It is, therefore, included in the Base Plan for the existing project. Since it is also the least-cost O&M alternative for the proposed 48-foot project, it is the preferred placement option for Sabine Pass Channel Section 5 in the Recommended Plan.

Table VII-11
Cost Comparison of Gulf Shore Beneficial Use Feature to Base Plan PA 5
(All costs in dollars)

Placement Alternatives for Section 5 Maintenance Material	Base Plan	Selected Plan
Gulf Shore BU Feature	2,006,000	3,225,000
Upland PA 5	2,200,000	4,366,000
Difference	(194,000)	(1,141,000)

Presented as average annual costs; October 2005 price levels, \$1.12 per gallon fuel cost;
4.875 percent interest rate

To contain 229.4 mcy of material from the inshore channels over the 50-year period of analysis for the project as a whole, the heights of existing PAs would be raised on a regular, recurring schedule in accordance with existing SNWW management practices. One new PA in the middle reach of the Neches River Channel (an expansion cell at PA 24A) would be needed to provide sufficient capacity for the 50-year period. On average, bed sediments vary in the inland channels from 38.3 percent sand and 61.7 percent silt plus clay in the Neches River Channel, to 16.2 percent sand and 83.8 percent silt plus clay in the Port Arthur Canal (Parchure et al., 2005). BU features are not included in the Base Plan for the inland channels because the lack of suitable material makes construction and maintenance of containment levees more expensive than placing the material in existing PAs. However, Section 204 projects will be considered on a project-by-project basis if non-Federal sponsors express an interest in paying the incremental cost for such projects.

Material from non-Federal dredging of private mooring and dock facilities would also continue to be placed in upland PAs along with the material from the Federal project. Non-Federal dredging quantities vary throughout the length of the waterway. The non-Federal dredging quantity is defined as a percentage of the channel shoaling by section and can be found within the Shoaling Parameters Table in the DMMP (FEIS, Appendix D). The quantity is based on the presence of local facilities, the square footage of the facility, and the shoaling rate of the adjacent channel. The non-Federal material is placed within the same PAs as the material from the adjacent waterway section.

The average annual cost of the 50-year Base Plan for the 40-foot project is \$40,938,000. Base Plan costs are presented as average annual equivalents of the stream of maintenance costs over the 50-year period of analysis. Prices used for the comparison were developed in October 2007, with an interest rate of 4.875 percent. Costs include cyclical maintenance dredging using a hopper dredge offshore and a hydraulic pipeline dredge for the inshore reaches, regular levee raisings to provide additional capacity at inland PAs, and the purchase and development of a new upland site at PA 24A. The cost to provide additional capacity for non-Federal dredging is included in the total cost per reach.

VII.I INCREMENTAL O&M COST OF THE PROPOSED 48-FOOT PROJECT

Description of O&M Activities for the Recommended Plan

The 50-year O&M plan for the placement of dredged material from the Recommended Plan is also summarized in Table VII-12. The O&M placement plan for the Recommended Plan must provide significantly more PA capacity than the SNWW 40-foot Base Plan. The Recommended Plan would generate 650 mcy of maintenance material over the 50-year period of analysis, which is 60 percent higher than the base plan quantities. Forty-three percent of the maintenance quantities projected for the Recommended Plan would originate from inshore channels, and 57 percent from offshore channels. It is projected that approximately 5.2 percent of the dredged material from inshore channels will be associated with non-Federal dredging. The quantity is based on the presence of local facilities, the square footage of the facility, and the shoaling rate of the adjacent channel. The non-Federal material is placed within the same PAs as the material from the adjacent waterway section.

O&M for the Recommended Plan consists of the continued use of 4 existing ODMDs; the creation of 4 new ODMDs; 16 existing upland PAs; the addition of 2 new cells at existing upland sites (PAs 18A and 24A), and BU components of the Neches River Feature (Bessie Heights East and Rose City East) and Gulf Shore Feature. The existing management practice of regular, recurring containment levee lifts would continue at all upland PAs, but no DAMP would be used.

The hydraulic construction of containment levees with new work material provides a cost-effective construction method that reduces the cost of providing capacity for the new work and maintenance material on the Neches River Channel by reducing final levee elevations at upland PAs.

Incremental O&M Cost of the Recommended Plan

The average annual cost of the 50-year O&M plan for the Recommended Plan is \$68,632,000. The total O&M incremental cost for the Recommended Plan is \$32,067,000. Of this total, \$61,000 is the cost of providing non-Federal disposal facility capacity. The O&M costs for the Recommended Plan presented in Table VII-12 do not include new work construction costs. The non-Federal disposal facility costs are summarized per channel for the Recommended Plan in Table VII-12 to facilitate proper distribution of Federal and non-Federal project costs. Costs are presented as average annual equivalents of the stream of

Average Annual Costs, October 2009 Price Levels, 4.375% interest

maintenance costs over the 50-year period of analysis. Prices used for the comparison were developed in October 2009, with an interest rate of 4.375 percent. O&M costs for the Recommended Plan include cyclical maintenance dredging using a hopper dredge in the offshore channels and a pipeline dredge for the inshore channels; offshore placement at four existing and four new ODMDS; real estate costs to obtain and construct two new upland sites at PA 18A and PA 24A; regular levee lifts and spillway rehabilitation for upland PAs; the placement of maintenance material at Bessie Heights East (7 cycles) and Rose City East (1 cycle) components of the Neches River BU Feature and the Gulf Shore Feature (15 cycles); maintenance of containment levees at the BU sites; and monitoring of the BU sites.

VIII. DEVELOPMENT OF THE MITIGATION PLAN

VIII.A OVERVIEW

This chapter discusses the evaluation of mitigation measures considered during formulation of the Recommended Plan, and presents the Ecological Mitigation Plan. The Ecological Mitigation Plan compensates for unavoidable impacts to nationally significant intertidal marsh habitat. Evaluation of measures was conducted within the ICT and technical workgroups. ICT and workgroup meetings were conducted from 2001 to 2006. In 2009, changes in the proposed project and HS modeling necessitated that the WVA modeling be revised. Due to schedule constraints, the USACE performed the modeling without the ICT involvement, basing it as closely as possible on methods and assumptions used by the ICT in the original modeling. The results of this remodeling were coordinated with the ICT. A quality check was also performed for the revised worksheets. The potential for cultural resource mitigation is described at the end of this section.

VIII.B ECOSYSTEM IMPACTS SUMMARY

The impacts of the Recommended Plan are related primarily to a decrease in the overall biological productivity of approximately 182,000 acres of marshes and forested wetlands over the 50-year period of analysis. Biological productivity of the wetlands in the affected area would decline as increases in salinity affect the productivity of marsh and cypress-tupelo swamp, and the fish and wildlife that depend upon this habitat. Indirect adverse effects could lead to the loss of marsh acreage as stressed emergent marsh converts to open water. The WVA Emergent Marsh Community Model (EMCM) predicts a loss of 691 acres of marsh in Louisiana over the period of analysis. Higher salinity would have a negligible effect on the productivity of cypress-tupelo swamp on the Sabine River near the GIWW by marginally slowing the rates of tree growth and reducing some herbaceous understory; no loss of cypress-tupelo swamp acreage would be expected. No impacts from the Recommended Plan were identified for bottomland hardwoods.

Direct effects of the Recommended Plan would be minor and temporary. These temporary, short-term impacts are associated with navigation channel improvements and the placement of dredged material. They include (1) impacts to water quality and benthic organisms and their Gulf, estuarine, and riverine water-bottom habitats resulting from dredging to construct the navigation improvements, the creation of new offshore ODMDs, the borrow area trench for Willow Bayou mitigation areas, and marsh restoration in shallow, open-water areas; (2) potential dredging impacts to bottom-feeding and pelagic organisms such as sea turtles; and (3) impacts to shoreline birds and their habitat from the placement of maintenance material on the Gulf shoreline.

Potential adverse effects to threatened and endangered sea turtles during hopper dredging to construct the Entrance Channel would be addressed by the adoption of reasonable and prudent measures to avoid impacts that are established in the Biological Opinion for the CIP. No other adverse effects to threatened and endangered species have been identified.

The Recommended Plan's effects on the SNWW's marsh and swamp systems were quantified using the WVA Model. In the table below, net changes in acres and AAHUs are presented for the Recommended Plan, including benefits of the DMMP BU features (Table VIII-1). The lost ecological value of all potential project impacts (prior to reduction by benefits of the BU features) is represented by -2,121 AAHUs. These impacts would be offset by adoption of the DMMP BU features that provide benefits of 1,278 AAHUs. When the impacts and DMMP benefits are applied to the project as a whole, unavoidable impacts of -843 AAHUs would remain.

Table VIII-1
Net Project Impacts and Benefits by Average Annual Habitat Units

	Bottomland Hardwood	Swamp	Fresh Marsh	Intrmd Marsh	Brackish Marsh	Saline Marsh	Totals
Recommended Plan Impacts (negative AAHUs)							
Texas	0	-22	-206	-48	-131	-5	-412
Louisiana	0	0	-78	-1,571	-23	-37	-1,709
Total Project Impacts	0	-22	-284	-1,619	-154	-42	-2,121
Recommended Plan Benefits (positive AAHUs)

Total Project Benefits	0	0	178	433	235	432	1,278
Net Project Benefits or Impacts (AAHUs)	0	-22	-106	-1,186	81	390	-843

VIII.C PROCEDURES FOR THE FORMULATION AND ASSESSMENT OF MITIGATION MEASURES

Compliance with Federal Requirements

Implementation guidance for Section 2036(a) of Water Resources Development Act (WRDA) 07 (Mitigation for Fish and Wildlife and Wetlands Losses), issued August 31, 2009, requires that the Recommended Plan contain a specific plan to mitigate fish and wildlife losses since it has been determined that the Recommended Plan would have unavoidable impacts after benefits of the DMMP BU features are applied. Adverse impacts to ecological resources that are caused by a proposed project must be avoided or minimized to the extent practicable, and remaining unavoidable impacts compensated to the extent justified. A Mitigation Plan has been developed for the CIP Recommended Plan, which minimizes impacts as described briefly below, and provides sufficient compensatory mitigation for significant resources such that only negligible adverse impacts remain.

Central to mitigation planning is the determination of significance, as mitigation is required only for impacts to significant resources. Significance must be based upon the contribution of the resource to the Nation's economy, and technical, institutional, and/or public recognition of the value the resource. Criteria for determining significance include, but are not limited to, scarcity or uniqueness of the resource

from a national, regional, state, or local perspective. The USFWS Habitat Stewardship Program has identified three nationally recognized “scarce and vulnerable” wetland habitats in the study area: estuarine intertidal emergent, palustrine emergent, and palustrine forested wetlands. These are the same sensitive wetland habitats (saline, brackish, intermediate and fresh marsh, cypress-tupelo swamps, and bottomland hardwoods) addressed by the CIP Mitigation Plan.

These same habitats are also considered significant and vulnerable by the Coastal Wetlands Planning, Protection and Restoration Act (CWPPRA), Public Law 101-646 (Title III) and the NAWMP (2004). The Texas Land and Water Resources Conservation Plan (TPWD, 2005) recognizes the Gulf coastal marshes in Tier One of high priority eco-regions, and considers these habitats to be the most threatened of the state’s two high diversity eco-regions. Significant marsh habitat on the Lower Neches River and along the Texas Point shoreline has been declared “critical erosion areas” by the Texas Coastwide Erosion Response Plan. Furthermore, coastal marshes in the Louisiana portion of the study area are recognized as threatened and vulnerable by the Louisiana Coast 2050 Plan (LCWCR/WCRA, 1998), the Louisiana Coastal Areas Ecosystem Restoration Study (USACE, 2004) and the Louisiana Comprehensive Management Plan (LACPRA, 2007; USACE 2008). High population growth and associated development along the coast have fragmented wildlife habitat, changed river flows, decreased water quality, and increased sediment loads and pollutants.

The most significant trend adversely affecting the study area is the high rate of wetland loss that has occurred in recent decades (Berman, 2005; Morton, 2003; Morton et al., 2005; Shinkle and Dokka, 2004; Titus and Narayanan, 1995). In Louisiana, a net land loss of 21 percent between 1978 and 2000 has been reported in the Chenier Plain subregion of coastal Louisiana, which includes the Sabine estuary (USACE, 2004). In Texas, the most extensive losses of interior coastal wetlands in the state (12,632 acres between 1930 and 1978) have occurred in the Neches River delta. In total, over 90 percent of the emergent marshes in the Lower Neches River delta have been converted to open water (Morton and Paine, 1990; White et al., 1987), which is more than half of the total wetland loss in the State of Texas (Sutherlin, 1996).

Mitigation may include avoiding and minimizing project impacts to ecological resources, rectifying impacts by restoring the affected environment, and reducing or eliminating impacts by preservation or maintenance operations during the period of analysis. The Recommended Plan includes large DMMP BU features on the Neches River and Gulf shoreline, which replace marsh and minimize shoreline erosion that would occur as a result of the Recommended Plan. These DMMP features are described and quantified in Chapter VII. In the Mitigation Plan, replacements of ecological resources are made “in-kind” to the greatest extent possible. The WVA Model quantifies impacts to all affected habitat types in the study area and provides a means to establish the appropriate amount of compensatory mitigation by habitat type. The WVA Model and its results are described in detail in Appendix C of the FEIS.

Recommended mitigation measures are justified by an incremental analysis that is presented in detail in the FEIS; results are summarized later in this chapter. This analysis identified the best-buy mitigation plan, e.g., that plan in which the value of the last increment of losses prevented, reduced, or replaced is at

least equal to the costs of the last added increment. The incremental analysis of mitigation measures was performed with the certified version of IWR-PLAN software.

The USACE regulations (USACE, 2000b) recognize wetland resources and bottomland hardwoods for special consideration in mitigation planning; these are the primary types of ecological resources affected by the Recommended Plan. Impacts to wetlands must be fully mitigated and projects must meet the goal of “no net loss” of wetlands. Mitigation for bottomland hardwoods should be made in-kind to the extent possible. Bottomland hardwood forests should be treated as an ecological system when devising mitigation, rather than mitigating specific species that use this habitat.

The Mitigation Plan described below fulfills the special requirements for wetlands and bottomland hardwoods. These plans also contribute to several multiagency regional plans, such as the Louisiana Comprehensive Management Plan (LACPR, 2007; USACE, 2008b), Louisiana Coast 2050 (LCWCR/WCRA, 1998), the Texas Land and Water Resources Conservation Plan (TPWD, 2005), and the NAWMP (NAWMP Plan Committee, 2004), by restoring and preserving scarce and vulnerable wetlands and wildlife habitat.

Mitigation Planning Objectives

The following objectives were established to evaluate mitigation measures considered for the SNWW CIP. The objectives were developed by the USACE in consultation with the ICT.

- Minimize salinity impacts to the SNWW affected area;
- Maximize the use of dredged material in mitigation measures;
- Meet the national goal of “no net loss” of wetlands;
- Replace lost habitat quality on a one-to-one basis as measured by AAHUs;
- Replace habitats in-kind to the extent practicable; and
- Mitigate losses in the state where they occur

These objectives reflected the most significant expected impacts of the CIP, widespread interest in potential BU of dredged material, the national policy objective to prevent wetland loss, and the USACE requirements to fully compensate for unavoidable project adverse effects. While the FEIS evaluates impacts on the SNWW coastal and estuarine system without regard to state boundaries, the mitigation plan should comply, to the greatest extent practicable, with the CZMP for each state. Under the Coastal Zone Management Act (CZMA), states with approved coastal management programs have jurisdiction within their coastal boundaries to ensure compliance with their programs. The CZMA and its implementing regulations require that Federal activities comply to the maximum extent practicable with these programs. In Louisiana, the Louisiana State and Local Coastal Resources Management Act functions as the state coastal management program for CZMA purposes. Compensatory mitigation is used to offset any net loss of wetland ecological value after efforts have been made to avoid or minimize impacts. Furthermore, the CWPRA requires that Federal agencies ensure that maintenance or

modification of navigation projects be consistent with the purposes of the restoration plan submitted under CWPPRA. Louisiana has adopted a Coastal Wetlands Conservation Plan under this authority with a goal of no net loss of wetlands in coastal areas of Louisiana as a result of development activities. In essence, this means that the SNWW mitigation plan for unavoidable project impacts in Louisiana would propose one-to-one compensation for all AAHU losses. There is, however, a significant exception to this requirement. Federal lands are excluded from coverage under the CZMA, and this means that compensatory mitigation for impacts to Federal lands may be developed without regard to state boundaries.

Since the CZMA does not apply to Federal lands, excess Texas BU benefits could be used to compensate for impacts to Federal lands in Louisiana. The only lands affected by this exclusion are located in the Sabine NWR. While the Texas Point and McFaddin NWRs in Texas would also be affected by salinity increases associated with the project, two DMMP BU features (the Neches River and the Gulf Shore BU features) provide benefits that offset all project impacts in Texas (including impacts to both NWRs) and provide excess benefits of 656 AAHUs. The DMMP BU features fulfill Texas's CZMP requirements to avoid and minimize impacts to the coastal zone, such that no compensatory mitigation for Texas state resources is needed.

Total SNWW project impacts to the Sabine NWR are -340 AAHUs. When these are removed from the total project impacts in Louisiana (-1,499 AAHUs), the mitigation target proposed for compliance with Louisiana's CZMP is -1,159 AAHUs. Table VIII-2 illustrates this calculation. Since all mitigation measures for the SNWW would be located in Louisiana, the new mitigation target would compensate for total project losses of -843 AAHUs by providing 1,159 AAHUs of compensatory mitigation.

Table VIII-2
FWP Compensatory Mitigation Target for Louisiana

Units (AAHUs)	Texas	Louisiana	Project
Net FWP Benefits/Impacts			
Total Impacts (negative)	-412	-1,709	-2,121
Total BU Benefits (positive)	1,068	210	1,278
Net FWP Benefits (positive) or Impacts (negative)	656	-1,499	-843
Excess Texas Benefits Applied to Federal Lands			
Excess Texas Benefits	656		
Sabine National Wildlife Refuge Impacts	-340		
Net Excess Texas Benefits	316		
Compensatory Mitigation Target			
Net Impacts by State and Project		-1,499	-843
Federal Impacts Compensated with Texas Excess Benefits		340	
FWP Compensatory Mitigation Target		-1,159	-843

Models Used to Evaluate Environmental Effects and Mitigation Measures

Since the primary environmental concerns are the interrelated issues of saltwater intrusion, marsh loss, and destruction of wildlife habitat and fishery nursery areas, an engineering model was used to evaluate salinity changes and an ecological model was used to evaluate the ecological effects of the CIP. Both models played an integral role in the development of FWOP and FWP conditions and were used to compare the effectiveness of mitigation measures. The HS model used for this study is an established, three-dimensional (3-D) estuarine model adapted by the ERDC and applied to numerous deep-draft CIPs around the country over the last decade (Brown and Stokes, 2009). The WVA Model is a suite of ecological, habitat-based, community models known primarily from its use by a multiagency team of Federal and State agencies in Louisiana to evaluate proposals for coastal restoration projects (LDNR, 1993; USFWS, 2002b, 2002c, 2002d, 2002e). It has also been used for other USACE projects in Louisiana and on the upper Texas coast.

HS Modeling

Concerns that a deeper navigation channel would increase salinity in the Sabine Lake estuarine system were addressed with a 3-D HS model that predicts changes in salinity, circulation, and water elevation due to proposed channel improvements. The ERDC's CHL worked closely with the MW to calibrate and verify the base model for use in this system. Most of the agencies on the ICT were represented in the MW and several (TPWD, TWDB, and ERDC-CHL) provided individuals with experience and expertise in HS modeling. The MW reviewed the ERDC's model calibration and verification process, provided data and information on hydrologic connectivity, marsh elevation, and bathymetry, and reviewed modeling results as part of the impacts evaluation. Baseline conditions of the channel geometry included actual depths, not authorized depths, to ensure that environmental impacts associated with changes in salinity from the existing condition versus the proposed 48-foot deep channel were captured.

The ERDC-CHL applied an established 3-D estuarine model (the ERDC-modified TABS Multi-Dimensional Numerical Modeling System) to compute hydrodynamics and salinity transport for the proposed CIP. The model includes forcing due to tides, freshwater inflows, wind, Coriolis, and density gradients due to salinity variation, and accounts for precipitation and evaporation. The code uses a finite-element formulation, which gives it great flexibility in matching complex geometry. Over the last decade, the code has been extensively used for a variety of the USACE field projects, including the Houston-Galveston Navigation Channels project; New York Harbor; St. Johns River, Florida; and Atchafalaya Bay in Louisiana. Two of the special features of the code, wetting/drying and "marsh porosity," enable successful modeling of wetlands. A description of the model and its output is provided in a draft report by the ERDC-CHL (Brown and Stokes, 2009). A detailed description of assumptions and methods underlying use of HS model output in the ecological model is provided in Appendix C of the FEIS.

The estuarine model covers the entire study area from the Salt Bayou watershed on the west to near Gum Cove Ridge in Louisiana on the east, and inland to north of IH 10. Effects were predicted by comparing the model's simulation of existing conditions and FWOP with RSLR conditions to those resulting from a

48-foot channel. The design flows were based on inflows provided by the TWDB, utilizing future demand and supply strategies from the 2007 Texas State Water Plan (TWDB, 2006). Modeling indicated that RSLR would likely increase FWOP salinities up to 2.0 ppt in portions of the project area. FWP salinities would not increase on the upper Neches and Sabine rivers but an increase of about 1.8 ppt on the Neches River near Bessie Heights, 1.4 ppt near Keith Lake Fish Pass, and about 1.4 to 1.6 ppt on the eastern shore of Sabine Lake would be likely.

Ecological Modeling

Habitat-based ecological models were used to determine the impacts and benefits of proposed navigation channel improvements, BU features, and mitigation measures. The WVA Model employs a community approach that assumes that optimal conditions for all fish and wildlife within a specific type of coastal wetland habitat can be characterized by a group of significant variables, and that existing or future conditions can be compared to that optimum, providing an index of habitat quality similar to those developed under the well-established Habitat Evaluation Procedure (HEP). Variables utilized in the WVA Model were selected from existing, widely accepted HEP models of resident fish and wildlife species (USFWS, 1980). Appendix C of the FEIS maps and characterizes all significant habitats in the study area, explains how the WVA Model evaluates project impacts and benefits, describes the methods and assumptions used in the modeling process, assesses impacts of the Recommended Plan, and evaluates the effectiveness of DMMP BU and mitigation measures in AAHUs.

The WVA Model was chosen as the most appropriate ecological model for the SNWW project based on a number of factors. It is a quantitative, habitat-based assessment methodology developed to prioritize Louisiana coastal restoration projects submitted for funding under the CWPRA. The WVA model applies specifically to habitat types present along the Louisiana coast, and these same types of coastal habitat (Chenier Plain, emergent coastal marsh, bottomland hardwoods, and cypress-tupelo swamp) are present throughout the Sabine-Neches coastal watershed in both Texas and Louisiana, and in fact are a continuation of the same system (Daigle et al., 2006; Griffith et al., 2004). In addition, the areas contain the same fish and wildlife communities and similar soils and topography, and the Sabine-Calcasieu basins share an interconnected hydrology. Furthermore, the types of variables measured by the WVA Model are sensitive to the types of changes that have been identified as the highest concerns by resource agencies and the general public for the SNWW project. Specifically, these are potential changes in salinity, stress and death of marsh vegetation, and further loss or degradation of already stressed coastal marshes. The variables measured by the WVA Model are recognized scientifically and technically as important in characterizing overall habitat quality. The WVA Model has community-specific models (e.g., saline marsh or cypress-tupelo swamp) each with a unique set of variables. It combines the effects of changes in habitat productivity (quality) and changes in wetland acreage (quantity) into one AAHU value. Habitat productivity is measured by changes to both terrestrial and shallow-water habitat that affect its usefulness to fish and wildlife. Variables included in the models were selected based on their importance as fish and wildlife habitat and for their sensitivity to the types of changes that have been identified as the highest concerns for this study (e.g., salinity, stress, and death of marsh vegetation, further loss or degradation of already stressed coastal marshes).

The WVA Model has been assessed for use in conjunction with the SNWW project, as required by EC 1105-2-407. The WVA Model is not a USACE corporate model, and therefore certification is not required, but the model must be approved for use. This approval was provided by the Deep-Draft Center for Expertise based upon the results of a model assessment (Louis Berger Group and Toxicological and Environmental Associates [LBG/TEA], 2008). The assessment evaluated the application of all of the model components used to quantify impacts and benefits of SNWW CIP alternatives, including BU features and compensatory mitigation. The assessment determined that the model was theoretically appropriate and correctly applied, and it has been approved for use for the SNWW study by the Deep-Draft Navigation Center of Expertise (see FEIS Appendix C, Attachment 1).

Consideration of Environmental Mitigation Costs During Plan Formulation

During the preliminary plan formulation screening for the CIP project as a whole, ecological benefits and mitigation costs were not calculated for the nonstructural and 120-plus variations of structural plans for channel improvements. However, all plans, including the No-Action Alternative, were informally reviewed for potential effects to the environment in a nonquantitative manner, and this information was evaluated along with cost data in determining which plans would advance into detailed evaluation.

During detailed evaluation of screened CIP alternatives, the identification of the Recommended Plan was based upon technical, economic, and environmental factors. Costs were estimated for all of the alternatives and used to determine the benefit to cost ratio in the economic analysis. Included in the costs were dredging, levee construction, relocations (including utility relocations), and O&M costs for the 50-year period of analysis. Ecological mitigation costs for the six depth alternatives were estimated using HS model salinity projections for the 40-, 45- and 48-foot channel depths. Salinity was chosen as the best factor on which to base interpolations of mitigation costs because it is the primary driver in the ecological modeling that was used to determine the compensatory mitigation plan. The cost interpolation assumed that there would be a linear relationship between predicted salinities for each channel depth at the end of the period of analysis and the cost of mitigation.

VIII.D SELECTION OF THE BEST BUY MITIGATION PLAN

A detailed description of the preliminary and final screening of potential mitigation measures is provided in the FEIS. A large number of potential mitigation measures was evaluated; measures were generally of two types: measures to reduce or avoid salinity intrusion and measures to restore or protect habitat. The purchase of credits from mitigation banks established by others was considered as an option in providing compensatory mitigation for the Recommended Plan. Only two existing mitigation banks were identified in the lower Sabine and Neches watersheds. Neither was available for use as the credits from one were sold out and the other was developed for the exclusive use of a State agency.

The recommended mitigation plan was selected using the tools of cost-effectiveness analysis and incremental cost analysis (CE/ICA) and the certified version of IWR-PLAN. The result of the incremental analysis is shown on Figure VIII-1 and Table VIII-3. Ten best buy plans were identified, with incremental

costs ranging from \$2,716 to \$19,935 per AAHU. A detailed explanation of this table is provided in the FEIS, Chapter 5.

Figure VIII-1. Results of the CE/ICA Analysis

Table VIII-3
Best Buy Plans Identified by Incremental Cost Analysis (October 2005 Price Levels)

Counter	Plan Alternative	Output (AAHU)	Cost (\$1.00)	Average	Incremental Cost	Inc. Output (\$1.00)	Inc. Cost Per AAHU
				Cost			
(\$1.00 / AAHU)							
1	No Action Plan	0.00	0.00

10	A0B0C2D3E0F0G0H1I0J0K2L0M2	2,591.00	13,129,173.00	5,067.2223	370,062.0000	54.0000	6,853.0000
11	A0B0C2D3E0F0G0H1I0J0K2L0M3	2,627.00	13,846,826.00	5,270.9654	717,653.0000	36.0000	19,934.8056

Best Buy Plan 6 (Solutions D₂, H₁, and K₂ – shown in bold in Table VIII-4) appears to be an efficient mitigation plan since it reaches the mitigation target of 1,159 AAHUs by providing a total of 1,181 AAHUs. Best Buy Plan 6 consists of emergent marsh restoration in two Willow Bayou areas (totaling 687 acres) and three areas in the Black Bayou area (totaling 2,096 acres). Best Buy Plan 7 was also evaluated to determine whether its considerable additional benefits were worth the comparatively small incremental cost. Best Buy Plan 7 provides 420 additional AAHUs (719 more acres restored in Willow Bayou) by adding Solution D₃ for an additional average annual cost per unit of output of \$4,237 (total average annual cost of \$2,312,918). Since the estimated total first cost of this increment is \$39,275,000 (screening-level cost) and Best Buy Plan 6 meets the mitigation target, Best Buy Plan 7 was deemed not worth the additional investment.

Table VIII-4
Recommended Mitigation Plan

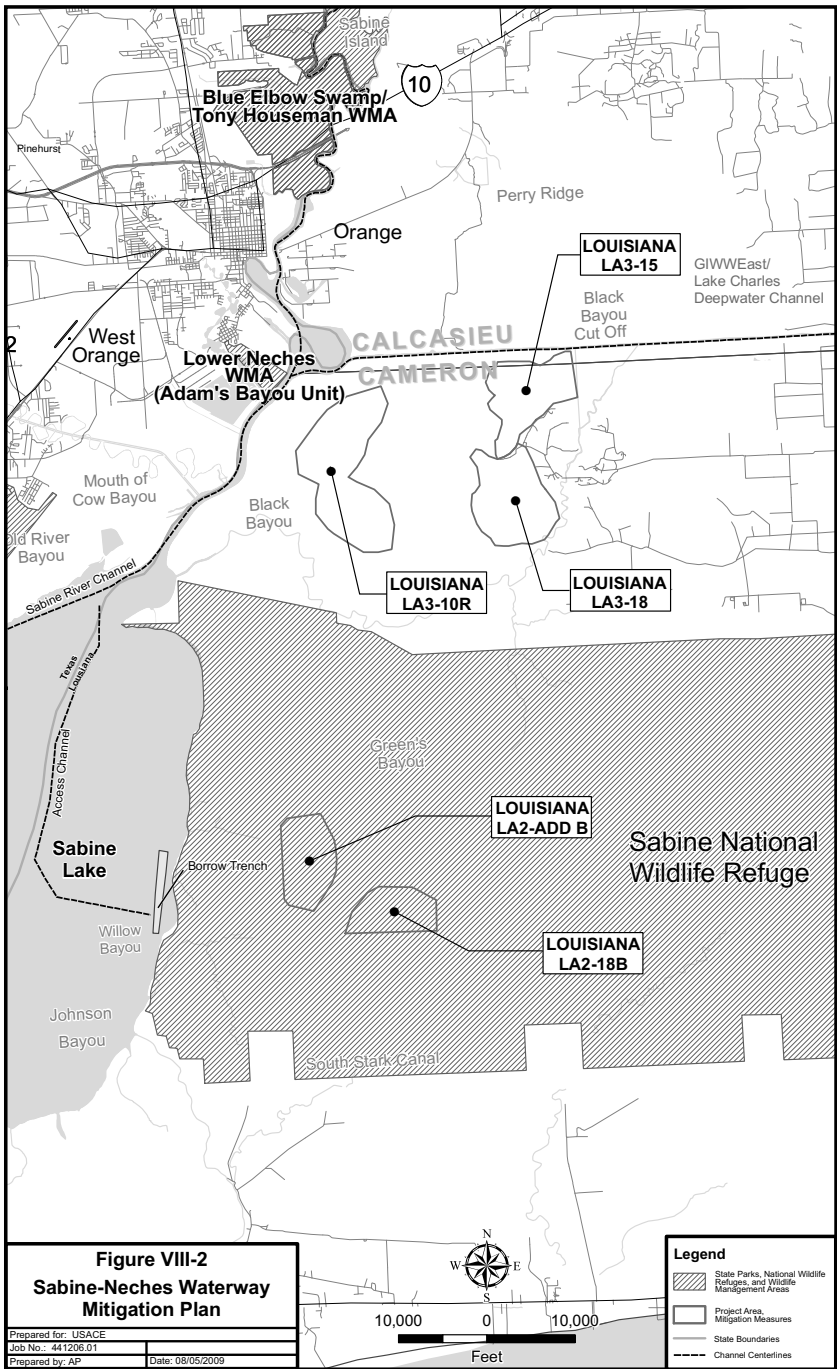

Recommended Mitigation Plan	Mitigation AAHUs
Willow Bayou	
LA 2-18 B Marsh Restoration (Sabine Lake dredging)	152
LA 2ADD B Marsh Restoration (Sabine Lake dredging)	214
Black Bayou West	
LA 3-10R Marsh Restoration (Sabine River Channel maintenance material)	198
Black Bayou East	
LA 3-15 B Marsh Restoration (GIWW dredging)	307
LA 3-18 B Marsh Restoration (GIWW dredging)	310
Total Compensation	1,181
FWP Mitigation Target	-1,159
Net Benefits After Compensation	22

VIII.E RECOMMENDED ECOLOGICAL MITIGATION PLAN

The CE/ICA selected Best Buy Plan 6 as the most efficient combination of mitigation measures to compensate for the indirect impacts of the Recommended Plan. It provides 1,181 AAHUs, which is 22 AAHUs more than the mitigation target. It is important to remember that additional compensatory mitigation would be provided in Louisiana beyond the total 843 AAHUs impacts of the Recommended Plan. The mitigation plan would result in a net gain of 338 AAHUs for the project as a whole.

Unavoidable impacts of the SNWW CIP remain only in Louisiana; all CIP impacts in Texas are minimized and offset by the DMMP BU and no mitigation is required. Therefore, all of the mitigation measures in Best Buy Plan 6 would be located in Louisiana. The mitigation plan consists of restoring five degraded marsh areas east of Sabine Lake near Willow and Black bayous, Louisiana (Figure VIII-2, Table VIII-5). The reader is referred to the FEIS for a detailed description of each mitigation measure.

11-111A

This page intentionally left blank.

Table VIII-5
Recommended Mitigation Plan – Acreage Analysis

Mitigation Measure	AAHUs	Total Influence Area (acres)	Nourished Existing Marsh (acres)	Restored Open Water (acres)	Restored Emergent Marsh (acres)
Willow Bayou					
LA 2-18B	152	681	367	63	251
LA 2-ADD B	21	1,285	745	104	436
Subtotal	173	1,966	1,112	167	687
Black Bayou West					
LA 3-10R	198	2,465	1,317	356	792
Black Bayou East					
LA 3-15B	307	1,788	878	227	683
LA 3-18B	310	1,876	1,048	207	621
Subtotal	617	3,664	1,926	434	1,304
Total Mitigation	1,181	8,095	4,355	957	2,783

The recommended Mitigation Plan compensates for the Recommended Plan's salinity increase and associated losses in marsh and productivity by marsh creation activities that would influence a total of 8,095 acres of Louisiana marshes in the Willow and Black Bayou watersheds. The plan would restore 2,783 acres of emergent marsh in existing open-water areas within the marsh, improve 957 acres of shallow-water habitat by creating shallower, smaller ponds and channels within the restored marsh, and stabilize and nourish 4,355 acres of existing marsh located in and around the marsh restoration zone.

Upon authorization of the CIP, the USACE would use its Navigation Servitude to access the mitigation areas for the purposes of planning, construction, and postconstruction monitoring. Landowners would be advised for access to their property. All restored areas would remain jurisdictional wetlands and continue to be subject to the navigational servitude; therefore, conservation easements would not be required.

Monitoring and Contingency Plans

Monitoring and contingency plans for the mitigation measures and DMMP BU features are presented in Appendix J of the FEIS. The monitoring and contingency plans for mitigation measures and BU features have been developed in accordance with recent implementing guidance for Sections 2036 (a) and 2039, respectively, of WRDA 07. The monitoring plans identify specific ecological success criteria to be used in determining if the mitigation and DMMP BU features have been successful. Appendix J presents a description of the key monitoring parameters, periodicity, costs, and responsible parties.

Periodic monitoring to determine the success of marsh mitigation measures and DMMP BU features would continue until the Division Commander determines that the ecological success criteria of the mitigation and DMMP BU features have been met. This determination would be based upon monitoring results and the ICT consultation reports provided by the District Engineer. The ICT would be consulted annually to determine progress in the planning, construction, and postconstruction evaluation of the ecological success of these features.

VIII.F FULFILLMENT OF MITIGATION PLANNING OBJECTIVES

Adoption of the ecological mitigation plan will fulfill the second planning objective to maintain the ecological values of estuarine resources within the project area. The mitigation plan (+1,181 AAHUs) fully compensates for AAHU losses to state resources in Louisiana, and results in a net gain of 338 AAHUs for the project as a whole. Impacts to East Sabine Lake marshes are replaced in-kind by the marsh mitigation plans in Willow and Black bayous. Minor productivity impacts to cypress-tupelo swamp on the Sabine River near the GIWW are not matched in-kind. The ICT considered this to be acceptable since the loss in function is negligible. Projected FWP salinity levels are within the tolerance levels of these swamps, and the CIP causes no loss of swamp acreage.

Sediment placed in former open-water areas of the marsh would increase marsh elevations and create a higher, more-stable landform for marsh growth and long-term survival. Restored marshes would filter runoff from surrounding uplands, and improved shallow-water habitat would encourage the growth of additional submerged aquatic vegetation. The restored marshes would increase available habitat for bird and wildlife species, and the improved shallow-water habitat would provide additional nursery areas and nutrients for aquatic organisms. The Coordination Action Report (CAR) for the SNWW CIP has been prepared by the USFWS and is included in FEIS Appendix A3. The CAR affirms the USACE impact assessment and approves the proposed BU and mitigation.

VIII.G CULTURAL RESOURCES MITIGATION

No specific cultural resource impacts requiring mitigation have been identified at this time. However, the Recommended Plan has the potential to affect significant cultural resources (e.g., historic properties) since numerous prehistoric and historic sites, structures, and shipwrecks are located adjacent to the project area. Investigations to identify historic properties that may be affected by the Recommended Plan were begun during the feasibility study, but will be completed during the PED phase in compliance with a Programmatic Agreement with the Texas and Louisiana State Historic Preservation Officers. Additional terrestrial archeological surveys and testing are anticipated for DMMP BU sites and marsh mitigation areas. Nautical archeological survey and dive assessments also must be completed for some project components. Funds for potential historic properties data recovery have also been included in the estimate and allocated in compliance with Section 7 of PL 93-291. Based upon historic properties identified to date, it is assumed that the highest potential for historic property data recovery is in the Sabine Pass Channel, the site of a significant Civil War naval battle.

IX. RISK AND UNCERTAINTY ANALYSIS

IX.A OVERVIEW

This chapter outlines the approach being taken for the SNWW CIP for evaluating risks, uncertainties, and consequences inherent in evaluation of alternatives and identification of the Recommended Plan. This approach involves a two-step process: (1) application of the USACE Risk and Uncertainty Analysis procedures assessing and incorporating uncertainty in the technical evaluation process; and (2) the evaluation and selection of a Recommended Plan that takes into account a wide array of economic, environmental, technical, and societal risk factors.

IX.B GUIDANCE AND CONCEPTS

Risk and uncertainty is an important part of the USACE planning process and feasibility analyses. The “Economic and Environmental Principles for Water and Related Land Resources Implementation Studies,” established pursuant to WRDA 65 (Pub. L. 89-80), as amended (42 USC 1962 a-2 and d-1), require that areas of risk and uncertainty be identified and clearly described so that public investment decisions can be informed by the degree of reliability of estimated costs, benefits, and effectiveness of alternative plans. This approach captures and quantifies the extent of risk and uncertainty in the various planning and design components of a project. The total effect of risk and uncertainty on the project’s design and viability can be examined and conscious decisions made reflecting an explicit trade-off between risks and costs.

Risk-informed decision making and asset management has been emphasized as part of Goal 3 of the USACE Campaign Plan (USACE, 2009b). This policy, developed from analyses done by the Interagency Performance Evaluation Task Force in the aftermath of Hurricane Katrina (Interagency Performance Evaluation Task Force, 2007), pointed to the need for organizational changes to transform the USACE priorities, processes, and planning in an effort to improve public safety and the USACE water resources infrastructure. The USACE has committed to developing and employing risk- and reliability-based approaches that evaluate the consequences of design, construction, and management decisions, especially as they affect risks to human health and safety.

Risk and uncertainty arise from measurement errors and the underlying variability of complex natural, social, and economic situations. Plans may be subject to measurement errors if the data are imperfect or the analytical tools are crude. Some future demographic, economic, hydrologic, and meteorological events are essentially unpredictable because they are subject to random influences. However, in some cases, the randomness can be approximated by developing a probability distribution using a historical database that is applicable to the future. If there is no such historical database, the probability distribution of random future events can be described subjectively, based upon the best available insight and judgment (ER 1105-2-100.E-4.a(3)). The latter case could also be applied to situations in which there is uncertainty as to whether historical conditions can be reliably applied to the future. Such is likely the case with environmental parameters affected by global warming, such as sea level rise. None of the historical

databases in use today can reliably be used to predict future conditions in which the rates of change are clearly diverging from historical precedents (IPCC, 2007).

The degrees of risk and uncertainty also will differ among various aspects of a project, and will vary by time. Obviously, high levels of risk associated with project elements that could adversely affect human health and safety are not acceptable; while it might be acceptable to trade lower economic costs for higher levels of risk for project elements that do not affect human health or safety. In relation to time, components that may be relatively certain at the beginning of a project may be relatively uncertain at the end of the period of analysis.

A variety of specific technical terms and concepts that are employed in risk and uncertainty analysis are described below:

- “Risk” is the probability that a hazardous outcome will occur as a consequence of uncertainty. It is “conventionally defined as those (situations) in which the potential outcome can be described in reasonably well known probability distributions” (ER 1105-2-100.E-4.a. (1)). These distributions are generally based upon well-established, empirical data (historical or experimental). The best-known examples of this concept are applied in flood damage reduction projects, i.e., it is known that a river will flood to a specific elevation on the average of once in 20 years. When applied to ecological modeling and impact analysis, risk should be viewed as an inevitable consequence of the uncertainties inherent in the current state of knowledge of ecological systems.
- “Uncertainty” is a measure of imprecision of knowledge of parameters and functions used to describe the hydraulic, hydrologic, geotechnical, ecological, and economic aspects of a project. “In situations of uncertainty, potential outcomes cannot be described in objectively known probability distributions. . . . Because there are no known probability distributions to describe uncertain outcomes, uncertainty is substantially more difficult to analyze than risk” (ER 1105-2-100.E-4.a. (2)).
- “Risk-based analysis” is defined as “an approach to evaluation and decision-making that explicitly . . . incorporates consideration of risk and uncertainty to compare plans in terms of likelihood and variability of physical performance, economic success and residual risk” (ER 1105-2-100.2-4.g). Analytical evaluation is sometimes restricted by a lack of data and understanding of biological and physical processes, effectively limiting risk considerations to more-subjective comparisons.
- “Sensitivity analysis” is a technique that varies assumptions of economic, demographic, environmental, and other factors and examines the effects of varying these assumptions on outcomes of benefits and costs (ER 1105-2-100.E-4.b.(1)(b)(6)).
- “Residual risk” This concept is best understood in relation to flood damage reduction studies, i.e., residual risk is the flood risk that remains after a proposed project is implemented; or, in other words, the residual damages and potential loss of life due to exceedence of design capacity. For navigation studies, one type of residual risk might be risk that benefits are foregone in those situations where LPPs are selected over the NED Plan.

IX.C UNCERTAINTY IN TECHNICAL EVALUATIONS

Forecasting Tools and Analyses

Forecasting future scenarios is an important part of the USACE planning process. In order to evaluate the risks and benefits of alternatives over the period of analysis, a forecast is created based on historical and existing information as well as quantitative and qualitative assumptions about what may happen within the study area in the future. One method is to identify the ‘most likely’ future, or the best guess about what may happen based on observed variables and assumptions of both natural and human behaviors. Another method is to conduct scenario planning, where multiple future scenarios are created in order to evaluate what would happen if observed variables or assumptions do not happen as projected. Scenario planning attempts to answer the “what if” questions that arise when making forecasting assumptions and predictions. For the SNWW CIP, the “most likely future” method was chosen due to the size, scope, and complexity of the overall analysis.

After the identification of the most likely FWOP scenario for the SNWW CIP, the next step was the evaluation of alternative depths (i.e., the 45-, 48-, and 50-foot channel depths and various widening scenarios advanced for detailed screening) using hydrodynamic, economic, and ecological models. Other variations of these alternatives (associated with placement features and mitigation measures) were also evaluated with selected models.

A suite of engineering models was employed to evaluate future without- and with-project conditions regarding the effect of proposed channel modifications on deep-draft ship maneuverability and safety (ship simulation model); estuarine hydrology, circulation, and salinity (HS model); shoaling rates (sediment model); channel bank erosion (vessel effects model); and coastal shoreline erosion (shoreline impacts model). All of the engineering models were developed by the USACE-ERDC and applied with the support of a team of the USACE and Federal and State resource agency representatives.

Planning models that were applied in this study include economic and ecological models. Economic models consist of desktop spreadsheet models and the HarborSym model. Ecological modeling was performed using the WVA model. Developed by an interagency working grouping of resource agencies in Louisiana, the WVA model was applied with the support of the ICT, comprised of representatives from the USACE, other Federal, and Texas and Louisiana state agency representatives.

While this section paints a broad picture of the application of techniques used to address risk and uncertainty, the FFR, Economic Appendix, and the FEIS and Appendix C go into greater detail on how each discipline addressed these issues.

Engineering Data and Models

Data

Hydrologic Data

Hydrologic data needed to calibrate and verify the HS model was collected by the ERDC-CHL in a 9-month field study (Fagerburg, 2003). Long-term and short-term data-collection sites were established to provide good coverage for determination of tidal velocity magnitudes and directions, ranges of water level elevations, and changes in salinity values. In coordination with USCG, existing Aids-to-Navigation structures were used whenever possible as more-permanent platforms for the deployment of the instruments. The pressure-sensing water level recorder was fully programmable with accuracy of the sensor of ± 0.01 foot. The fully programmable salinity recorders were calibrated properly at the start of monitoring. In order to assure quality data collection, the recorders were serviced regularly in 3-week intervals to download data and clean and recalibrate the instruments. Acoustic Doppler Velocity (ADV) meters had pressure sensors with an accuracy of ± 0.003 foot. Two of the water level recorders were destroyed and were not replaced due to the project economic constraints and lack of vital necessity of those data. Also, any of the field data that were obviously corrupted by bio-fouling of the salinity sensors were omitted in the hydrodynamic and other analyses.

It is believed that the selected gage sites provided an adequate coverage of the study area, and the programmable data recorders had a high degree of accuracy and minimal degree of human error involved. Further, more-conservative analyses were employed in the HS model and other models to provide more-reliable results. Thus, the degree of uncertainty in the collection and use of data is diminished appreciably. As such, considering project economics, it was deemed impractical to gather additional data for a logical, risk-based analysis since it would not essentially enhance the accuracy of the results.

New Work and Maintenance Material Data

New work material quantities were calculated using a digital terrain model generated by the InRoads software program. Each channel or canal had its own existing template and proposed template. A model was developed and volumes were calculated. The existing template included the current allowable overdepth and advance maintenance values. The proposed new template also included a standard advance maintenance depth of 2 feet and constant 2 feet of allowable overdepth per reach. Any potential uncertainties in these calculations are addressed by incorporation of the maximum amount of allowable overdepth and advance maintenance, and by the contingencies identified in the cost risk analysis discussed later in this section.

Maintenance material estimates for the proposed project were predicted by a desktop sediment model that incorporates information from historical dredging rates, the HS model (Brown and Stokes, 2009), and a subjective evaluation of contributive shoaling factors (Parchure et al., 2005; Brown and Stokes, 2009). An extensive amount of field data for the bed and suspended sediment, salinity, and velocities was collected and analyzed by the ERDC laboratory. An increase in shoaling quantities resulting from channel

deepening and widening is attributed to many different factors including increased bottom width, decreased flow velocity due to enlarged section, modified salinity regime from greater salt penetration, and other general factors such as increased erosion from higher vessel traffic, channel bank failure, and sediment brought down by rivers. The effect of RSLR was investigated by the ERDC, and it was found to have no significant effect on projected maintenance dredging quantities.

Because of the uncertainty involved in the assumptions and calculations of water levels, velocity data, and salinity data by the HS model, the calculated shoaling quantities for the project condition is subject to a certain degree of uncertainty. It is believed that the dredging data record is good reliable data and would not be essentially improved by more data. Moreover, the prediction of shoaling rates is influenced by assumed values of shoaling factors, which are subjectively selected as stated above. Hence, the future shoaling rates as calculated are not amenable to risk-based analysis. Further, a more-accurate shoaling analysis would require detailed numerical sediment modeling, which would entail a significant amount of additional data and analysis. Because of inherent assumptions involved in an analytical full-fledged sediment modeling procedure, albeit a significant amount of extra data, increased accuracy of results would still be questionable. Thus, no further additional work is recommended.

Models

For lack of extensive measurable data and reliable analytical methodologies, the 'Plans' and 'Conclusions' as developed by various modeling studies by the ERDC are subject to uncertainties. Moreover, some future economic, hydrologic, and meteorological factors are essentially unpredictable. Thus, no logical probability-based analysis can be developed. However, sensitivity or a subjective analysis can be performed describing the limiting values of various factors considered.

In general, the study analyzed the 50-foot depth alternative in addition to the recommended depth of 48 feet for the enlarged future channel, and there were minimal adverse effects for the with-project condition in terms of salinity, tidal current velocities, shoreline wave heights, sediment transport, potential bank-recession/erosion, and navigational safety. Thus, the uncertainty in assumed values or the reliability of analytical procedures is essentially covered by the conservative assumptions in the study.

Ship Simulation Model

Ship simulation modeling reproduced real-time vessel responses to various interacting forces including water currents, wind force, bank forces, tug and bow thruster forces, and ship-to-ship interaction (Webb, 2003). The visual database provided a feeling of realism for the site and its development included the ship being simulated and other vessels, shoreline, and other landmarks. The environmental database involved channel and bathymetric surveys, currents for the existing and proposed conditions, waves, and wind velocities. For the simulation validation, experienced pilots were used in real-time runs, and then various plans for existing and proposed conditions were tested. Final results for the optimized channel were based on comparison of simulation runs for existing and proposed conditions and analyses of vessel tracks, navigation parameter plots, and pilot evaluations.

Although there is a degree of uncertainty involved in the accuracy of visual and environmental data, the real-time simulation by ship pilots essentially validated the optimal channel widths required for safe navigation. So, the real-time runs are guided by the personal experience and knowledge of the pilots, and their testing is quite subjective. As such, the risk-based analysis is somewhat inappropriate for ship simulation.

HS Model

A 3-D numerical modeling study of circulation and salinity impacts resulting from proposed channel deepening was conducted (Brown and Stokes, 2009). The model was also validated for hydrodynamics and salinity using field data, evaluation of proposed plan conditions, and comparison and analysis of results.

The potential for the channel deepening to increase the effects of hurricane storm surges on water elevations and flooding was simulated using the HS model. The tidal signal was generated using tide gage records from Sabine Pass during Tropical Storm Frances (September 11, 1998). This storm was selected for the simulation because it produced very high tides for an extended period of time, and caused very significant damage to the upper Texas coast in the form of beach erosion and inland flooding. The tides rose above 4 feet above mean low lower water and reached maximum levels between about 5.5 and 7 feet for 36 to 48 consecutive hours. Maximum storm surge differences occurred at or near the peak storm surge, and varied between 0 and +0.4 foot. The modeling indicated that the largest effects would occur in the upper reaches of the Neches River near Beaumont. This result must be interpreted as exceedingly conservative. The predicted increase is calculated as if no flows were allowed to leave the channel and is therefore much higher than would occur under natural conditions when storm surge flows spread over the wide, flat coastal plain.

This model was previously run for the 50-foot channel depth, which marked the worst-case scenario for possible adverse impacts. Comparing the results of 48-foot (recommended) plan and the 50-foot plan, the difference in salinity impacts at various places remained within the range of standard deviation. Thus, the analysis essentially provided conservative results for the recommended 48-foot depth plan.

Storm Surge Model

A sensitivity analysis using the ADCIRC model was also performed to determine what effect the proposed SNWW CIP might have on surge levels in the study area (Wamsley et al., 2010). The ADCIRC model was run to estimate water levels for two worst-case hypothetical storms, both with and without proposed SNWW CIP project features in place. Project features evaluated by the modeling are the deeper navigation channel, proposed PAs with maximum levee heights, and 2 expanded PAs. The two simulated storms exhibited minimum central pressures of 900 millibars, offshore pressure radii between 14.9 and 18.4 nautical miles, and forward speeds of 11 knots. Each produced water levels near or higher than the estimated 500-year level, and both would be considered extreme events. One storm tracked in the northwesterly direction, producing maximum surges of 18 feet near the coast at Sabine Pass and surges of 13–14 feet in Sabine Lake near Port Arthur, Texas. The second storm tracked in a north-northeasterly

direction, producing maximum surges of over 20 feet near Sabine Pass and surges of 15 to 17 feet in Sabine Lake near Port Arthur.

The sensitivity analysis concluded that the greatest changes would occur north of Port Arthur along the Neches River. These changes are primarily due to the proposed increase in depth of the navigation channel. All changes are local, and there are no project-induced increases in surges away from the immediate vicinity of the navigation channel. Water levels in the marshes and open-water areas immediately north of the river would increase on the order of 4 to 8 inches or less. The modeling indicates some interior flooding would occur within the City of Port Arthur with both storms, both with and without the project. Changes in peak surge within the city for these two events, with the project in place, are caused by a slight increase in surge elevation and/or duration causing additional overtopping of the surrounding levee or internal topographic features. Peak surges for 100-year events are estimated to be approximately 9 feet in the Port Arthur area. Although simulations of less-intense events were not made as part of this study, in light of the 14- to 24-foot levees surrounding Port Arthur, significant interior flooding is not expected for the Base condition. Any changes in peak surge on the order of inches should not cause any significant change in interior flooding for the with-project condition.

The Recommended Plan for the SNWW CIP also includes ODMDSs and marsh restoration measures. All of the existing and proposed ODMDSs are located several miles from the Gulf shoreline in water too deep to affect wave setup on the shoreline. The influences of marsh restoration on hurricane surge have been documented by Wamsley et al. (2009a, 2009b). Surges tend to slightly increase over and just seaward of the marsh as the surge propagation is slowed, which may result in reductions in peak water levels landward of marsh features. The impact of the proposed SNWW CIP marsh restoration features are relatively small and expected to modify peak surge levels locally by a minimal amount (Wamsley et al., 2010). No significant reductions or increases in surge level would be expected from either the marsh restoration or the ODMDSs.

Sediment Model

The needed data for computed water levels, tidal velocities, and salinity values at various nodes was provided by the HS model for the Base and Plan conditions (Parchure et al., 2005). This report deals with two problems—the first is the effect of channel modifications on the future shoaling quantities, and the second is the impact of the channel modifications on the Pleasure Island shoreline erosion. As a first step, sediment modeling requires results from a satisfactorily validated hydrodynamic model. Since fine sediment dynamics is significantly influenced by salinity, a 3-D model including salinity simulation was used to provide results for this model. For some studies, a full-fledged numerical sediment model can be used to provide increased accuracy for sediment analysis. However, huge amount of additional data needed for a project extending over several miles would become very expensive and time consuming. Hence, a desktop modeling study was used as a good alternative to detailed sediment modeling. Because estimation of future shoaling involves an unavoidable subjective element and further, the detailed sediment modeling procedure has some inherent assumptions and limitations, the desktop study was considered adequate. Moreover, the computed changes in flow velocities, salinities, and erosion rates

between base and plan conditions are quite low in relation to their effects on shoaling and erosion. As such, no additional effort is needed, and no logical risk-based analysis is warranted.

Vessel Effects Study Model

This study was used to estimate erosion potential resulting from increased ship waves for the plan condition for the enlarged channel (Maynard, 2005). The analysis employed a numerical model (HIVEL2D) to simulate the ship-induced velocity at the bank, using information on vessels in the existing and future fleets and on vessel speeds under both the FWOP and FWP conditions. Overall, the effect of the Recommended Plan would be to reduce the rate of erosion on inland channels relative to the FWOP condition because of the larger channel and the fewer vessel trips that are predicted with the Recommended Plan. There is some uncertainty involved in the forecasting estimate of the future vessel fleet and the accuracy of predicted erosion rates. However, the modeling used the largest vessel that can efficiently use the waterway, and assumed that all erosion effects were due to vessel wakes. Therefore, the model provides a conservatively high estimate of ship effects on erosion, and further risk analysis would not add practical value.

Shoreline Impacts Model

Potential wave-induced impacts of the proposed deepening of the SNWW on the open coastal shorelines adjacent to the project area were modeled by the ERDC using the STWAVE and GENESIS models (Gravens and King, 2003). These models evaluate potential impacts due to changes in wave refraction patterns, and are well-known, widely used models that represent state of the practice in forecast modeling.

The STWAVE and GENESIS are deterministic models. As presently applied, results were not placed in a risk-based context and to do so would require a significant effort. However, such additional work is not warranted, would not add practical value, and would not be expected to change the specific STWAVE/GENESIS study conclusions. The models calculated insignificant changes in the waves and longshore sediment transport rates within the study area. It is important to note that the STWAVE/GENESIS analysis was extremely conservative in nature, and as performed the analysis overestimates any wave-induced impacts to the shoreline as a result of the channel deepening. The results are conservative since the wave dissipation due to the presence of mud and the sheltering effect of the jetties was purposely not included. Thus, the analysis as performed, without inclusion of jetties, maximized wave refraction and shoaling influence of the proposed channel deepening. Applying a risk-based type of analysis would only yield order of magnitude variability within these extremely conservative minor results, which would add no additional practical value and could not be expected to change the specific STWAVE/GENESIS study conclusions.

Other Analyses

Relative Sea Level Rise

In fulfillment of requirements of Circular No. 1165-2-211, Water Resources Policies and Authorities Incorporating Sea-level Change Considerations in Civil Works Programs (USACE, 2009a), the sensitivity of project alternatives to the full range of potential FWOP changes in sea level has been evaluated. There are a wide range of potential effects related to the full range of RSLR, but the sensitivity of project alternatives would be more limited. In particular, alternatives were evaluated to determine if the purpose and function of navigation features could be undermined, if environmental impacts might be exacerbated, and how economic benefits and costs might be affected by sea level change. Nonstructural alternatives were evaluated but eliminated in the second screening; they are therefore not addressed in this analysis.

RSLR rates that may be appropriate for the project area are discussed in detail in Section 3.3 of FEIS, Appendix C to the FEIS. The range of RSLR was determined using both tide gage and basal peat data for the local subsidence component of RSLR. Tide gage data reflect the effects of recent historical subsidence. The average rate of RSLR measured at the Sabine Pass tide gage was 0.2 inch/year for the 48-year period between 1958 and 2006 (U.S. Department of Commerce and National Oceanic and Atmospheric Administration, 2006, 2009). However, there is significant scientific debate concerning the validity of tidal records with respect to the projection of future subsidence rates in the northwest Gulf coastal plain. The relative influence of historic anthropogenic activities in this area (e.g., oil and gas withdrawal) is difficult to quantify. If these activities contributed significantly to recent observations of subsidence, then significant reductions in these activities may result in rapid deceleration of subsidence rates, returning them to long-term average rates best represented by the basal peat data. Deriving RSLR estimates using both basal peat and tide gage data, possible RSLR rates were estimated for the period from 2019 to 2069 to range from 0.3 to 2.8 feet. Possible low, intermediate, and high rates are as follows:

- 0.3 foot, Low (1.83 mm/year), based on basal peat subsidence rates
- 0.7 foot, Intermediate (4.27 mm/year), based on basal peat subsidence rates
- 1.1 feet, Intermediate (6.71 mm/year), based on tide gage subsidence rates. (This value was used in the HS modeling of the estuary for this project.)
- 1.5 feet, Intermediate (9.14 mm/year), based on tide gage subsidence rates
- 2.2 feet, High (13.44 mm/year), based on basal peat subsidence rates
- 2.8 feet, High (17.07 mm/year), based on tide gage subsidence rates

An intermediate rate of RSLR (1.1 feet by year 2069) was used as the “most likely” estimate of RSLR in the alternative analysis for this project, in accordance with the USACE planning guidance. The following discussion describes possible ways that high and low RSLR might affect the project alternatives and the recommended action. There are relatively little data and analyses currently available that would permit a detailed, quantitative, analysis of the impacts of each of the possible RSLR scenarios on the project

alternatives. Ways in which different RSLR rates might affect project design and impacts are presented in Table IX-1.

In general, the functioning of the navigation features associated with all alternatives (channel depths of 45 through 50 feet, TB/AB, PAs/ODMDSs, and the BU features) would not be significantly affected by the full range of potential sea level change. Construction dredging would occur within 10 years and would not be affected by future rates of RSLR. While shoaling rates toward the end of the period of analysis could increase due to an enlarged cross section and greater saltwater penetration, this small effect would probably be offset by increased overall water depths. PAs and BU features have been designed to accommodate sea level changes through the high RSLR range. PAs are located at sufficiently high elevations to withstand the potential rise, and appropriate erosion control measures are included. BU features are located well inland on the Neches River, and they have been designed with erosion control features that would survive the full range of RSLR. The addition of mineral soils and higher marsh elevations would provide stable landforms. Biomass accumulation and sediment from adjacent terrace margins should enable restored marsh vegetation to maintain itself even with the high RSLR rate.

The protection of human health and improvements in safety are not project objectives and therefore potential effects on calculated risk are not applicable. RSLR does not affect the functioning of the various depth alternatives or vessel safety. At the intermediate and high rates of RSLR, a significant increase in tidal surge penetration would be expected, but this would not affect project alternatives because tidal surge protection is not a project objective. Furthermore, HS modeling has determined that little or no increase in water surface elevation would be expected due to the deeper navigation channel.

The primary impact of RSLR on this project may be its potential impact on mitigation measures proposed for the Louisiana marshes along the east side of Sabine Lake. These mitigation measures are planned for marshes that could experience submergence and erosion at the high RSLR rate. In recent decades, marshes in the study area have been able to keep up with rates of 5.6 to 6.5 mm/year, suggesting that these marshes may be able to sustain themselves through rises in the intermediate range of RSLR (4.3 to 9.1 mm/year). The high rate of RSLR (17.1 mm/year) could threaten long-term survivability. Sustainability thresholds are determined by local physical, chemical, climatologic, and hydrologic conditions and cannot be extrapolated to other regions. However, as an example, studies in the mid-Atlantic region indicate that the tipping point for coastal ecosystems could range from a RSLR of as low as 2.0 mm/year to as high as 10 mm/year (U.S. Climate Change Science Program, 2009). There are relatively little data and analyses currently available that would permit a detailed, quantitative analysis of the impacts of the full range of potential RSLR on the SNWW ecosystem and project alternatives.

A monitoring and contingency/adaptive management plan has been developed to identify corrective actions (FEIS Appendix J). Corrective actions proposed in the contingency plan assume that the low to intermediate rates of RSLR will occur; the high rate is assumed to be unlikely. If monitoring determines that the extent of vegetation coverage does not meet ecological success criteria specified in the monitoring plan, manual planting would be employed to restore the requisite acres of emergent marsh. The ICT would determine if marsh planting is needed and if so, to what extent and in which areas.

Table IX-1
RSLR Sensitivity of Project Alternatives

Sensitivity of Design			Sensitivity of Impacts			
Navigation Channel Alternatives A-G	DMMP (PAs/ODMDSs)	DMMP (BU Features)	Mitigation Measures	Human Health/Safety	Environmental Impacts	Economic Costs/Benefits
Low Rate (0.3 foot over 50 years)						
No significant effect for any depth alternative. Low range of future RSLR is lower than recent historical rate.	No change to existing shoaling rate and maintenance dredging expected. All PAs designed for intermediate RSLR rate.	All BU features were designed to accommodate intermediate RSLR; low rate would have no effect.	All mitigation measures were designed to accommodate intermediate RSLR; low rate would have no effect.	RSLR does not affect the functioning of the various depth alternatives or vessel safety. Small increase in tidal surge penetration due to low RSLR rate would be expected; tidal surge protection is not a project objective. No increase in tidal surge impacts due to project.	Primary project impact is result of greater salinity intrusion. Salinity difference for low RSLR is within one standard deviation of the salinity difference between FWOP and FWP.	Benefits and costs of the deepened navigation channel would be the same as FWP forecast.
Intermediate Rate (0.7 to 1.5 feet over 50 years)						
No significant effect for any depth alternative. Rising water depth offset by increased shoaling. Potential impacts to Sabine Pass jetties addressed by separate O&M major rehabilitation project.	No significant increase in maintenance dredging for depths greater than 48 feet. Possible rise of water surface elevation is within range used for engineering design of all PAs. No effect to ODMDSs.	Possible RSLR rise is within range used for engineering design of all BU features.	Possible RSLR rise is within range used for engineering design of all mitigation measures.	RSLR does not affect the functioning of the various depth alternatives or vessel safety. Intermediate increase in tidal surge penetration due to RSLR rate; tidal surge protection is not a project objective. No increase in tidal surge impacts due to project.	Salinity impacts were based upon RSLR of 1.1 feet. Salinity difference for range of intermediate RSLR rates is within one standard deviation of the salinity difference between FWOP and FWP.	Benefits and costs of the deepened navigation channel for the full intermediate range would be the same as FWP forecast.

Table IX-1 (Cont'd)

Sensitivity of Design			Sensitivity of Impacts			
Navigation Channel Alternatives A–G	DMMP (PA's/ODMDSs)	DMMP (BU Features)	Mitigation Measures	Human Health/Safety	Environmental Impacts	Economic Costs/Benefits
High Rate (2.8 feet over 50 years)						
No significant effect for any depth alternative. Possible small increase in maintenance dredging for all depth alternatives resulting from enlarged cross section and greater saltwater penetration. Potential impacts to Sabine Pass jetties addressed by separate O&M major rehabilitation project.	Small increase in levee heights and/or armoring may be needed for some PAs. No significant effect to ODMDSs.	Addition of mineral soils and higher marsh elevations provides more-stable landforms. Biomass accumulation may enable restored marsh vegetation to remain stable relative to high RSLR rate. Erosion control features would survive the full range of RSLR.	Addition of mineral soils and higher marsh elevations provides more-stable landforms. High rate of RSLR could result in submergence and erosion of restored marsh. Monitoring and adaptive management plan recommended to guide decisions on changes that might be needed toward the end of the period of analysis.	RSLR does not affect the functioning of the various depth alternatives or vessel safety. High rate of RSLR would increase tidal surge penetration; tidal surge protection is not a project objective. No increase in tidal surge impacts due to project.	Potential salinity increase with high range of RSLR is still within one standard deviation of the salinity difference between FWOP and FWP. No significant increase in salinity impacts would be expected.	Benefits of the deepened navigation channel would be the same as FWP forecast. No facilities used by shipping industry would be rendered ineffective by the high range of RSLR. O&M costs could increase slightly toward the end of the period of analysis, but not enough to reduce BCR below parity.

Relocation of the mitigation areas to areas that would be protected from the potential effects of the full range of RSLR is not feasible. All intertidal marshes in the study area would be similarly affected by the sea level change because of the extremely low slope of the coastal plain. The option of purchasing credits in a mitigation bank was investigated; however, no mitigation banks exist for this area and resource type.

For the Coastal Shoreline Impacts Study (Gravens and King, 2003), the primary conclusion was that the proposed deepening project would have minimal impacts on adjacent shorelines. Actually, the project would result in a small beneficial reduction in erosion near the jetties. The changes resulting from the 2-foot increase in depth for the wave heights and wave angles would be minimal.

For the Sediment Study (Parchure et al., 2005), comparing the results of 2 feet increased depth, the overall changes in bottom velocities and bottom salinities would be insignificant. The estimated annual shoaling quantities would increase about 6 percent, but that is considered to be within uncertainty of assumptions of this estimate.

For the Vessel Effects study for Bank Recession (Maynard, 2005), based on the historical vessel traffic, vessel fleet (ship sizes and frequency of passage) was developed for the future years 2030 and 2060 for the existing and proposed waterway. The conclusion of this study was that for both sites in the Sabine-Neches Canal and Port Arthur Canal, bank recession for the FWP condition would be less than the FWOP condition because of fewer vessel trips. Impact on bank recession resulting from increased depth as a result of sea level rise is estimated to be minimal.

For the Ship Simulation Study (Webb, 2003), simulation by ship pilots essentially validates the optimal channel widths required for various reaches for safe navigation of vessels for the existing and proposed channels. So, navigable vessels are predicted to experience insignificant impacts of higher water elevation resulting from about 1.56-foot rise in sea level.

Stability Analyses (Bridges and Port Arthur Hurricane Protection Levee)

Limited stability evaluations were undertaken to identify potential impacts of the new channel to the HFP system, MLK Bridge, Rainbow Bridge, and Veterans Memorial Bridge and recommendations were made to accommodate a deeper channel while preserving the integrity of the above structures.

The evaluation of the HFP system, involved (1) reviewing original design documents and inspection reports of the adjacent levee system; (2) performing site reconnaissance; (3) reviewing subsurface data and soil strength parameters; (4) reviewing prior slope stability analyses methods and results; (5) evaluating cross section surveys at suspect areas; (6) performing additional slope stability analyses (using the Simplified Bishop and Simplified Janbu methods with the STABL6H computer program) of the slope configuration for new project; and (7) providing recommendations. This review indicated that the HFP levee between SNWW stations 165+00 and 240+00 would likely be impacted by the preliminary design layout of the deepened channel. Therefore, the channel was realigned and shifted away from the HFP levee. The design 2:1 slope angles for the deepened channel can be maintained if the channel is shifted far enough away from the HFP system to minimize adverse stability impacts. Acceptable factors of safety

were established for the recommendations from the slope stability analysis, and a suitable offset distance was determined and incorporated into the proposed alignment.

The evaluation of the MLK Bridge, consisted of (1) reviewing available soils data from Design Memorandum No. 2 (Sabine-Neches Waterway, Texas, 40-foot Project and Channel to Echo, Bridge Replacement at Port Arthur, dated May 1964), prepared by Modjeski and Masters, Inc.; (2) reviewing survey cross-section information taken in May 2005; (3) performing slope stability analysis using soil strength data from nearby HFP levee and empirical correlations (due to limited data provided in the DM No. 2.); and (4) providing recommendations. The analysis determined that the 48-foot channel slope would likely impact the embedment of the pile cap and the upper portions of the piles of the bridge's tower pier foundations. The degree to which this impact affects the bearing capacity of the piles or the integrity of the pile cap was beyond the scope of this study. Regardless, for this study, this anticipated impact is considered significant because the failure arc passes through the bridge foundation. Since it is necessary to maintain the 400-foot channel width beneath the bridge, the bridge piers must be protected with a hardened structure to minimize impact to the foundations. Designs and costs for construction of a bulkhead to protect the bridge foundations were developed by the Texas Department of Transportation, and the cost of this protection has been included in the project cost estimate.

The evaluation of the Rainbow Bridge involved reviewing a "Channel Stability Cut Analyses" report prepared by URS Group Inc. in the form of a memorandum with design drawings by the Texas Department of Transportation. Based on conclusions of the memorandum, no impact to the bridge foundations as a result of potential slope instability due to channel deepening is anticipated. However, URS recommended that the dolphins may need to be relocated. These design issues will be further addressed during the preconstruction engineering and design (PED) phase.

Cost Risk Analysis

In accordance with a July 2007 USACE memorandum (Application of Cost Risk Analysis Methods to Develop Contingencies for Civil Works Total Project Costs), a formal cost-risk analysis was performed for the SNWW CIP (FFR, Appendix 3). The cost risk analysis utilizes the MII cost estimate, along with specific project information, to develop contingencies to be used in the formulating the Total Project Cost for the project plan being recommended to Congress. The objective of using the cost risk analysis is to identify areas of high cost uncertainty and the probability that the estimated project cost will or will not be exceeded (USACE, 2007b).

Crystal Ball™, an accepted commercially available computer-based forecasting and analysis program, was used to run Monte Carlo simulations for developing the baseline contingency. The contingency simulation included estimates for all individual activities and risk variables. Since the 48-foot deepening alternative (including selective widening and TB and AB) has been identified as the Recommended Plan (and also the LPP), the Crystal Ball analysis was performed on the cost estimate for this alternative. The results of the cost risk analysis identified the contingency percentages (levels of uncertainty) in the cost estimates for specific project components (e.g., relocations, navigation ports and harbors, cultural

resources, etc.). The average contingencies determined from the cost risk analysis were 30–31 percent, which is higher than the original contingencies identified in the original project cost estimate.

The contingencies were used along with the updated estimate to revise the Total Project Cost Summary (TPCS). ATR of the TPCS for the Recommended Plan has been conducted by the USACE Center of Expertise for Cost Engineering for Civil Works. The ATR has verified that the Total Project Cost baseline, the project scope, report, cost estimate, schedule, escalation, and contingencies were developed in accordance with current cost engineering guidance.

Economic Data and Models

Data

The base data used to establish existing conditions and in preparation of the traffic forecasts were compiled from the sources listed in Table IX-2.

Risk and Uncertainty

The IWR is currently developing risk-based analysis procedures for the economic evaluation of deep-draft navigation studies. Unlike the current risk-based flood damage model, the navigation model will

integrate both benefit (related to fleet and commodity forecasts) and cost uncertainties (related to dredging and disposal costs). Districts are expected to use sensitivity analyses to evaluate risk and uncertainty until risk-based models for navigation studies are released to the field (ER 1105-2-100.E-10.a). The effects of uncertainty are addressed in terms of sensitivity analyses. An expanded sensitivity section is included in Section 8 of the Economic Appendix.

Models

Deepening Analysis. The USACE-SWG spreadsheet models were used for calculation of transportation costs and evaluation of deepening benefits associated with the without- and with-project futures.

Widening Analysis. The HarborSym model was used in evaluation of the entrance channel widening and the Neches River TB and anchorage features. The outputs from HarborSym were aggregated into Excel spreadsheets and are summarized in this section of the report. HarborSym is a planning-level model developed by the IWR to assist in economic analyses of channel widening improvements. HarborSym is an event-driven simulation model and includes data from user-specified transit rules that the model processes with each vessel call in order to calculate delays within the system. The model is presently in the model certification process. While not yet certified, the model is scheduled for review under the USACE's certification system. The model is presently being used by several USACE district offices for channel widening studies, and the outputs of these have undergone ATR and USACE headquarters review.

Environmental Data and Models

Uncertainty in environmental analyses is associated with the quality of data used to evaluate impacts. The quality of data used for assessments of environmental impacts in this study was assessed based on its origin as presented in Table IX-3.

WVA Model

An analysis of risk and uncertainty associated with the WVA model application to the SNWW CIP was performed. A summary of the sensitivity analysis is presented in FEIS Section 4.2, and the complete analysis is presented in FEIS Appendix C. Uncertainty is inherent in ecosystems, and therefore unavoidable when evaluating ecological processes and impacts. There is often a lack of extensive data sets for all parameters under study, and many of the physical and biological processes are not completely understood. Ecological analyses for the study utilized input from several engineering models referenced in the table above.

Risks to human health and safety associated with ecological impacts evaluated by the model are small. The predicted loss of marsh acreage is 691 acres (less than one-half of 1 percent of the affected marsh acreage) in the interior of the large estuarine marshes east of Sabine Lake. The loss of marsh elevation would make affected areas of these wetlands more vulnerable to the salinity pulses from large tropical storms and hurricanes, but it would not affect the overall effectiveness of these coastal wetlands in

buffering inland areas from storm surge effects. The proposed compensatory mitigation plan would contribute to the long-term sustainability of these areas by adding stabilizing mineral sediments in an amount well above the predicted loss, increasing marsh elevations, and decreasing the size of open-water areas within the interior marshes.

Table IX-3
Quality of Data Used in Ecological Analyses

Environmental Parameter	Data Origin	Data Quality
Hydrodynamic data on circulation, velocity, flows	Field sampling (ERDC-CHL; Brown and Stokes, 2009)	High
Water quality	Historical data and field sampling (ERDC-CHL; Fagerburg, 2003; PBS&J, 2004a, 2004b)	High
Salinity (for HS model verification)	Field sampling studies (ERDC-CHL; Fagerburg, 2003)	High
Salinity – FWP projections	HS Model (ERDC-CHL; Brown and Stokes, 2009)	Moderate
Sediment quality	Historical data, field sampling studies, and biological testing (PBS&J, 1999, 2004a, 2004b)	High
Gulf shoreline erosion	ERDC-CHL modeling (Gravens and King, 2003)	High
Inland channel erosion	ERDC-CHL modeling (Maynard, 2005; Parchure et al., 2005)	High
Vegetation/habitat type mapping	(TPWD, 1992, 2002, 2004; USFWS 2001a, 2001b, 2004, 2008; USFWS and GLO, 1992) and limited survey and field verification for this study	Moderate
Submerged aquatic vegetation	Limited field survey; best professional judgment	Low
Historic land loss rates	U.S. Geological Survey (USGS), TPWD and Bureau of Economic Geology GIS analyses (Britsch and Dunbar, 1992; Dunbar et al., 1992; Greco and Clark, 2005; TPWD, 2003; USGS-LDNR, 1993; White et al., 1996)	Moderate
Bottomland hardwoods growth rates	Professional literature (Brown and Montz, 1986; USDA, 1983, 1990)	Moderate
Endangered species habitat mapping	Field survey (PBS&J, 2006)	High
Fish and wildlife species	Professional literature (too lengthy to list; see FEIS)	Moderate
Oyster reef	Survey and field verification for possible channel widening (PBS&J, 2005)	High
Hazardous and toxic waste	Field sampling and biological testing (PBS&J) of specific areas near Superfund sites; literature and database review for entire area (PBS&J, 2002)	Moderate
Cultural resources-nautical	Marine remote sensing surveys (Hoyt et al., 1994; Hoyt and Schmidt, 1997; PBS&J, 2005)	Moderate
Cultural resources-terrestrial	Professional literature and state records searches (too lengthy to list; see FEIS)	Moderate
Marsh elevations in BU and mitigation areas	Field investigations in BU areas (TCB); best professional judgment in mitigation areas	Low

There are two types of uncertainty that have been identified for the predictive ecological modeling conducted in this study—uncertainty associated with model quality and performance, and uncertainty associated with model predictions. The first type of uncertainty was evaluated by an extensive technical review of the WVA model. Application of the WVA model for the SNWW study was evaluated by an independent technical review at the Deep Draft Center of Expertise, an External Peer Review (Battelle, 2010), and a formal model assessment in conformance with EC 1105-2-407. The WVA Model Assessment (LBG/TEA, 2008) determined that the theoretical approaches behind the WVA model's application to the SNWW project are valid, and approved its use for this study. The Planning Center of Expertise for Deep-Draft Navigation approved the model for use in conjunction with this project by memo dated June 30, 2009 (see FEIS Appendix C, Attachment 1).

For evaluating the second type of uncertainty, the WVA models do not include a direct way to calculate a probability distribution that provides a statistically significant confidence level for the model projections (LBG/TEA, 2008). However, a sensitivity analysis of the model results was conducted by substituting different values in the most important variables. This sensitivity analysis measures the degree of certainty associated with model predictions, and how different predictable outcomes could affect environmental impacts, benefits, and costs. In this case, a range of possible outcomes associated with variable V_1 (percent of emergent marsh) in the EMCM, and variables V_4 and V_5 (salinity) in the Swamp Community Model (SCM) and EMCM, respectively, were evaluated to determine how uncertainties related to variable assumptions and values could affect impact predictions and compensatory mitigation decisions.

Salinity Sensitivity Analysis

The salinity sensitivity analysis of the WVA model (variables V_4 and V_5 in the SCM and EMCM) demonstrated that there is a wide range of potential outcomes in AAHU losses attributable to uncertainties in salinity predictions. These outcomes range from a loss of -340 AAHUs to a loss of -3,146 AAHUs within the 95 percent confidence range of salinities used in the analysis. The total predicted FWP loss of -1,499 AAHUs for Louisiana hydro-units is based upon forecasts of the most likely salinity levels, and takes into account the potential effects of RSLR and future freshwater inflows. The recommended compensatory mitigation plan contains sufficient mitigation to ensure that the Recommended Plan will not have more than negligible impacts on the ecological resources of the study area. It is based upon scientifically based projections of changes in habitat resulting from the predicted salinity change, and the professional judgment and knowledge of the area by the large team of natural resource and engineering professionals who applied the HS and WVA models to the SNWW CIP.

Percent Emergent Marsh Sensitivity Analysis

The sensitivity analysis of the variable V_1 (percent of emergent marsh) in the EMCM explores the effects of an assumption that underlies the valuation of emergent marsh for this variable. In this application of the WVA model, optimal vegetative coverage is assumed to be 100 percent (Suitability Index [SI] = 1.0) for all marsh types. This assumption diverges from the general biological understanding that optimal cover falls in the 60–80 percent range, but it was adopted to reflect the significance of emergent marsh in the

study area. Existing and potentially accelerated marsh loss associated with channel deepening has been identified as one of the highest concerns by resource agencies and the general public. To evaluate the effect of this assumption on the SNWW application, the EMCM was rerun using a revised formula for the variable in which optimal vegetative coverage ($SI = 1.0$) is assumed for a marsh coverage of 60 to 80 percent (V_1 -Revised).

Overall, impacts using V_1 -Revised dropped 3 percent as expressed in AAHUs. However, this reduction would be more than offset by the increase in mitigation that would result from the use of V_1 -Revised to compute compensatory mitigation, because the amount of credit (in AAHUs) would decrease by about 30 percent. Using V_1 -Revised to compute required compensatory mitigation for the mitigation measures, as currently designed, would increase mitigation costs by 42 percent. If the same mitigation measures were redesigned so that marsh fill was a maximum of 80 percent, compensation measured with the V_1 -Revised formula would increase by about 10 percent. However, total cost of this revised mitigation plan would be about 3 percent greater than the recommended mitigation plan. More significantly, the modified plan would restore about 18 percent fewer acres and do less to ensure the long-term sustainability of the marsh.

The WVA Model Assessment (LBG/TEA, 2008) confirmed that the original model assumption applied for variable V_1 -Original (e.g., optimal vegetative coverage is assumed to be 100 percent) is appropriate for the SNWW application in computing both impacts and mitigation, as it reflects the importance of emergent vegetation as habitat for this study area. Given serious existing rates of marsh loss, the predicted increase in marsh loss in the FWP condition, and uncertainties related to salinity and land loss impacts due to the project, it is reasonable and appropriate to utilize the assumption that maximizes the value of emergent marsh to the sustainability of the marsh system. Without the structure provided by the emergent marsh, the majority of the ecological benefits provided by this system disappear.

Cultural Resources

There is uncertainty related to the potential cost of cultural resource mitigation because all areas that would be impacted by the CIP have not been assessed for their potential to contain properties eligible for NRHP listing. While no specific historic property impacts have been identified at this time, there is moderate potential to affect a significant historic shipwreck. The highest potential for historic property mitigation is associated with channel deepening through Sabine Pass, the site of a significant Civil War naval battle. To account for this uncertainty, the estimated cost for historic property data recovery has been included in the project cost estimate. More details can be found in Section 4.14 of the FEIS.

Real Estate Data

There are 16 PAs, of which 13 are already owned by the local Sponsor and 3 are to be acquired by the non-Federal sponsor. Contaminant materials have been found in PA 17 that are unrelated to dredged material or dredging activities. Issues related to these contaminated materials must be resolved by the non-Federal sponsor before PA 17 can be used. Alternate PAs are available. The other two PAs are

available and would be acquired by the non-Federal sponsor. There are three proposed TBs on the Neches River. Of those, two would require acquisition of 12.10 available acres. All of the remaining lands are subject to Navigation Servitude. The risks to increase project costs and lengthen the project schedule are low.

IX.D COMMUNICATION OF RISK

Extensive scoping effort allowed effective communication of public and agency perception of risks associated with potential channel deepening. The USACE and the SNND developed a public involvement plan to ensure that the USACE and SNND were responsive to the needs and concerns of all stakeholders and to ensure public involvement through an open, interactive process. The plan helped the USACE and SNND provide information to, and obtain information from, the stakeholders. A proactive outreach program ensured that the public, resource agencies, industry, local government, and other interested parties were informed about the project and that any concerns were identified and addressed. More discussion of the outreach program can be found in Chapter XII of this report and also in Appendix A of the FEIS.

Uncertainties associated with precision of data and model robustness were communicated to State and Federal resource agencies as they participated in the ICT review of data collection, model application, and model results. The risks of the various project alternatives and the Recommended Plan will be communicated to general public at public meetings held during public review of the FEIS. Public comments regarding perceptions of risk, uncertainties, and consequences will be included as part of the final feasibility report and FEIS. Potential risk and uncertainties with the CIP, and those expressed by the public will be provided to decision makers and during the Civil Works Review Board briefings.

X. RECOMMENDED PLAN

X.A OVERVIEW

Previous chapters described the analyses conducted during the planning study process to identify the NED Plan, the Recommended Plan, the DMMP, and Mitigation Plan with the ultimate goal of identifying the Recommended Plan. The purpose of this chapter is to describe the plan that will be recommended for implementation to the U.S. Congress.

The Recommended Plan described below addresses the problems and opportunities, identified at the beginning of the study, and satisfies the planning objectives of increasing navigational efficiency along the SNWW while maintaining the coastal and estuarine resources within the project area. The Recommended Plan is the LPP Plan, preferred by the Sponsor. Engineering Plates referenced in this section are in Appendix 1 of this document.

X.B GENERAL NAVIGATION FEATURES OF RECOMMENDED PLAN

The Recommended Plan calls for a 48-foot-deep channel from Sabine Pass Channel to the Port of Beaumont on the Neches River Channel with no additional widening, widening and deepening of Taylor Bayou TBs and channels to 48 feet, and several TBs and ABs on the Neches River Channel (Figure X-1). The Recommended Plan would increase the existing channel depth by 8 feet, increasing the inland portion from 40 to 48 feet and increasing the existing offshore portions from 42 to 50 feet (plus overdepth and advance maintenance as needed). Two feet of overdepth and 2 feet of advance maintenance are included for the entire channel length. In high shoaling areas, additional advance maintenance is required in order to maintain current maintenance dredging cycles along the waterway. The total length of the SNWW with the proposed channel modifications would be approximately 77 miles. No modifications to the existing Sabine Pass jetties are required by the proposed project.

The following description of the recommended channel improvements to the SNWW begins at the Gulf of Mexico (offshore) channel reach and moves inland to the Beaumont TB on the Neches River. A plan view of the Recommended Plan is provided on Engineering Plate G-02, and the project dimensions are identified in Table X-1.

Sabine Bank Extension Channel

This channel lengthens the existing offshore entrance channel approximately 13.2 miles at a bottom width of 700 feet (Engineering Plate No. C-12). The additional length is required to reach a water depth in the Gulf of Mexico equal to the proposed channel depth. The proposed offshore depth is 50 feet, but advance maintenance and allowable overdepth would add a total of 4 more feet, bringing the total dredged depth of the Extension Channel to 54 feet. It would be constructed by hopper dredge beginning at the end of the

Table X-1
Project Dimensions for Recommended Plan

Reach	Station	to	Station	Bottom Width (feet)	Project Depth (feet)	Side Slope
Extension Channel	165+443		95+734	700	50	1V/2H
Sabine Bank Channel	95+734		18+000	700–800	50	1V/2H
Sabine Pass Outer Bar Channel	18+000		0+000	800	50	1V/10H
Sabine Pass Jetty Channel	–214+88		0+00	800–500	48	1V/2H
Sabine Pass Channel	0+00		296+25	500	48	1V/2H
Port Arthur Canal	0+00		325+84	500	48	1V/2H
Sabine-Neches Canal	0+00		592+94	400	48	1V/2H
Neches River Channel	0+00		980+00	400	48	1V/2H
Taylor Bayou						
Entrance Channel	0+00		25+27	406–764	48	1V/2H
East Turning Basin	0+00		17+65	532–354	48	1V/2H
West Turning Basin	25+27		41+30	776	48	1V/2H
Connecting Channel	41+30		71+50	470–250	48	1V/2H
Taylor Bayou Turning Basin	71+50		106+25	1000	48	1V/2H

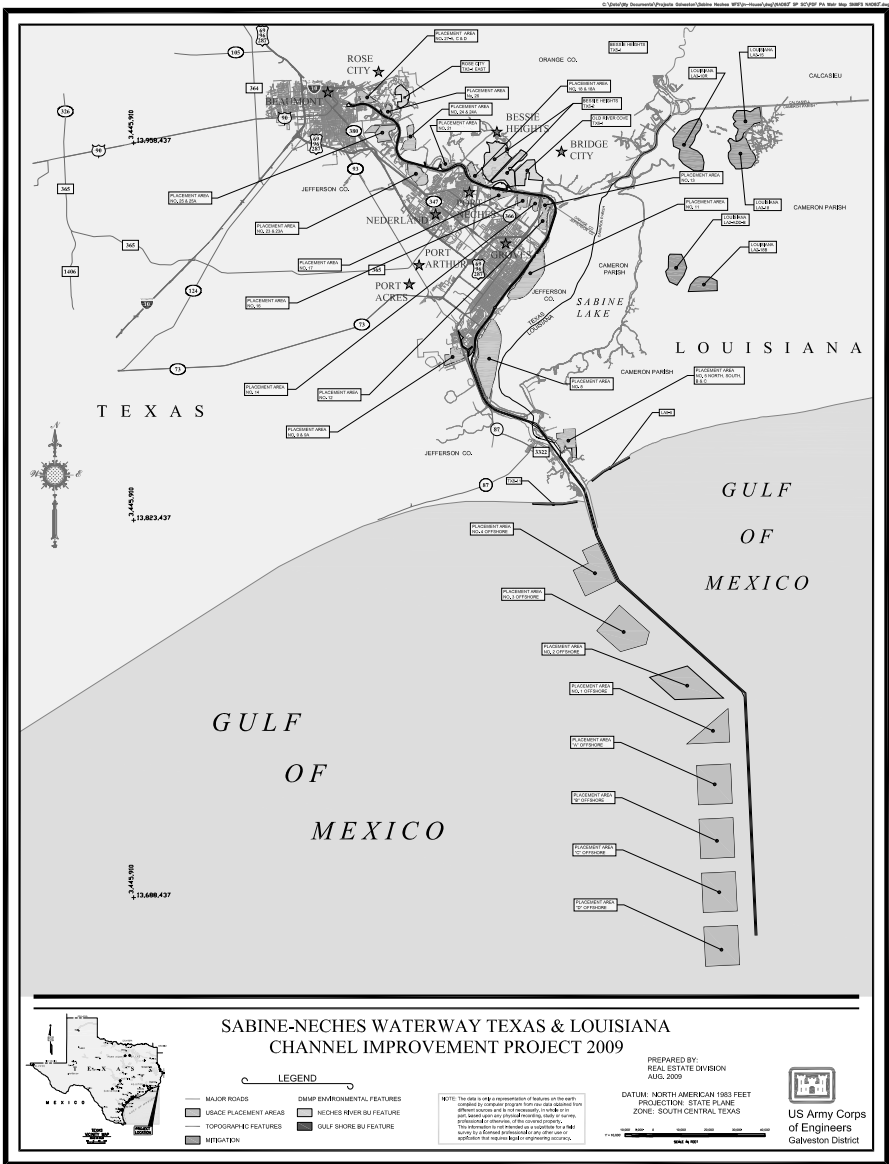

Sabine Bank Channel and it would extend into the Gulf of Mexico at the same bearing as the Sabine Bank Channel.

Sabine Bank Channel

This 14.7-mile-long channel would be deepened from 42 to 50 feet using a hopper dredge (Engineering Plate No. C-11). When advance maintenance and allowable overdepth are added to the proposed 50-foot depth, the Sabine Bank Channel would be dredged to 54 feet. The bottom width of the Sabine Bank Channel is currently 800 feet; it would remain 800 feet wide for the first mile past the end of the Outer Bar Channel, and then it would taper from 800 to 700 feet over the next ½ mile. The Sabine Bank Channel would continue the 700-foot bottom width for approximately 13.2 miles to its connection with the Extension Channel. Since the existing channel is 800 feet wide, new channel markers would be required to mark the tapered transition and the remainder of the narrowed Sabine Bank Channel.

Sabine Pass Outer Bar Channel

This 3.4-mile-long channel would be deepened from 42 to 50 feet using a hopper dredge. Due to high shoaling rates in this portion of the channel, advance maintenance depths would be increased to maintain current maintenance dredging cycles. Including allowable overdepth, advance maintenance, and additional advance maintenance, the Outer Bar Channel would be dredged to 58 feet. The Outer Bar Channel would remain at its current 800 feet bottom width due to strong crosscurrents just beyond the end of the SNWW jetties (Engineering Plate No. C-11).

Sabine Pass Jetty Channel

This 4.1-mile-long channel would be deepened to 48 feet using a hopper dredge. When advance maintenance and allowable overdepth are added, the Sabine Pass Jetty Channel would be dredged to 52 feet. The width of the channel would remain the same, the channel would gradually taper from the existing 800-foot width at the mouth of the jetties to 500 feet wide at the head of the jetties (Station 0+00). No impacts to the jetties have been identified that are associated with the proposed improvements.

Sabine Pass Channel

This 5.6-mile-long channel begins just north of the jetties and extends upstream to Mesquite Point on Pleasure Island (Engineering Plate Nos. C-10, C-11, and C-12). It would be deepened to 48 feet and constructed with a hydraulic pipeline dredge. Shoaling rates vary in different sections of the Sabine Pass Channel, and advance maintenance and allowable overdepth vary to meet these conditions. The total dredging depth for two reaches (Station 0+00 to Station 100+00, and Station 180+00 to Station 230+00) would be 52 feet. Due to higher shoaling rates, the reach from Station 100+00 to Station 180+00 would require additional advance maintenance and be dredged to a depth of 55 feet, while the reach from Station 230+00 to the end of the Sabine Pass Channel at Station 295+61 would be dredged to a depth of 57 feet. The bottom width of the Sabine Pass Channel would remain at 500 feet with a new centerline closely following the existing centerline. The Sabine Pass Anchorage is located in this reach, and its footprint would be reduced in size because it has never been fully utilized. The width would be decreased from 1,500 to 855 feet, and the length would remain at 8,200 feet. The angle of approach would remain the same.

Port Arthur Canal

This 6.2-mile-long canal begins near Mesquite Point and ends at the Port Arthur Junction Area with the Taylor Bayou channels (Engineering Plate Nos. C-08 and C-09). The Port Arthur Canal would be deepened to the proposed depth of 48 feet with a hydraulic pipeline dredge. The Port Arthur Junction Area serves as a TB and has a high shoaling rate due to the confluence of the GIWW and the Taylor Bayou TB with the SNWW. This confluence of water bodies decreases channel velocities resulting in increased shoaling. For these reasons, the reach from Station 0+00 to Station 290+00 would be dredged to a depth of 54 feet. The remaining part (Port Arthur Junction) between stations 290+00 and 326+37 would be dredged to a depth of 57 feet. Additional advance maintenance is required in these reaches to address high shoaling areas while keeping the current dredging frequency. The bottom width of the Port Arthur Canal would remain 500 feet.

Taylor Bayou Channels and Turning Basins

Located at the confluence of the Port Arthur Junction Area, the GIWW, and the mouth of the original Taylor Bayou, the Taylor Bayou Channels and TB consist of several subreaches: Entrance Channel, East TB, West TB, Connecting Channel, and the Taylor Bayou TB. Several significant changes are proposed for this area. When advance maintenance and allowable overdepth are added to the proposed 48-foot

depth, the Taylor Bayou channels and TB would be dredged to 54 feet. The Taylor Bayou portion of the Junction Area, between stations 0+00 and 31+10, would be dredged to 57 feet (see additional advance maintenance explanation provided for Port Arthur Canal). The Entrance Channel and the West TB bottleneck curve would be widened, and a structural wall would protect local railroad tracks. Changes for each subreach are detailed below.

- **Entrance Channel.** The new bottom width widens on the west side of the channel. The channel would be widened to 444 feet at new Station 10+00. The new bottom width would taper back to the existing width by the end of the first curve at Station 28+38.
- **East Turning Basin.** The right side width would decrease 16 feet as the new depth extends down the existing side slope.
- **West Turning Basin.** The width of the existing bottleneck has been increased up to 120 feet on the west side, between new stations 33+00 and 55+00. The west bank of the basin would be protected by a structural wall, preventing impacts to the local railroad tracks present in this area.
- **Connecting Channel.** The West TB widening tapers back to the existing width in the Connecting Channel, between stations 55+00 and 67+00.
- **Taylor Bayou Turning Basin.** No changes would be made to the existing dimensions, but the basin would be deepened to the proposed 48-foot depth. Existing shore protection belonging to a local facility near Station 90+00 would be affected by the top-of-cut for the new depth.

Sabine-Neches Canal

The 11.2-mile-long canal begins at the Port Arthur Junction Area and ends just south of the mouth of the Neches River (Engineering Plate Nos. C-04, C-05, C-06, and C-07). The GIWW shares this canal with the deep-draft channel. It would be deepened to the proposed depth of 48 feet with a hydraulic pipeline dredge. Additional advance maintenance (near the junction of the Port Arthur Canal and the Sabine-Neches Canal) is required since the area is a high-shoaling area, and additional advance maintenance dredging would allow current O&M dredging frequencies to be maintained. When allowable overdepth, advance maintenance, and additional advance maintenance are added, stations 0+00 to 40+00 would be dredged to 57 feet, and remainder of the canal through Station 592+91 would be dredged to 53 feet.

The bottom width of the canal would be selectively widened in three separate sections. The bottom width of the most-downstream curve (stations 0+00 to 20+00) would be widened to 500 feet on the east side of the channel, and then promptly tapered to the existing 400-foot width prior to the MLK Bridge (SH 82). The canal would be widened to 450 feet adjacent to the Port of Port Arthur, with gradual tapering upstream and downstream between stations 120+00 and 170+00. The third widening section begins to taper at Station 565+00, gradually widening to 500 feet and remaining that width to the end at Station 592+91.

Bend easing is planned for three areas in the Sabine-Neches Canal to improve ship maneuverability: stations 265+00 to 305+00, stations 350+00 to 395+00, and stations 500+00 to 520+00. The bend easing

between stations 350+00 and 395+00 eliminates a wiggle in the alignment, and shifts the footprint of the canal 10 feet east of the existing alignment up to Station 520+00.

Changes are also recommended for the canal bottom adjacent to the Port Arthur Dock and the “Eye Basin.” The canal toes adjacent to the Port of Port Arthur would be moved approximately 10 feet to the right while keeping the same bottom width of 450 feet. The diameter of the existing turning point (“Eye Basin”) at Station 190+00 would be decreased by 16 feet.

Neches River Channel

This 18.5-mile-long channel begins just south of the mouth of the Neches River (Engineering Plate Nos. C-01, C-02, C-03, and C-04). It would be deepened to the proposed depth of 48 feet to Station 980+00 with a hydraulic pipeline dredge. Shoaling rates vary in different sections of the Neches River Channel, and advance maintenance and allowable overdepth would vary to meet these conditions. Between stations 0+00 and 440+00, the total dredged depth would be 52 feet; between stations 440+00 and 978+00, it would be 54 feet (due to 2 feet of additional advance maintenance). While the overall bottom width of 400 feet does not change for the majority of the channel length, the first curve at the mouth of Neches River (between stations 0+00 and 75+00) would be widened to 500 feet, and then tapered back to 400 feet prior to the SH 87 twin bridges.

Three basins would be added or enlarged on the Neches River Channel. All three would be dredged to the proposed depth of 48 feet, plus the advance maintenance and allowable overdepth associated with the specific channel reach in which they are located. One TB, Turning Basin No. 6, is an existing basin and would continue to be maintained at the existing 40-foot depth and existing advance maintenance and allowable overdepth.

- **TB and AB No. 1** is located in an old river oxbow at the east end of Texaco Island near Station 210+00. The TB enlarges the existing basin from 1,000 to 1,350 feet in diameter. A new AB, 250 by 1,100 feet in size, would be added.
- **TB and AB No. 4** enlarges an existing turning point at Station 510+00 from 1,000 to 1,350 feet in diameter. A new AB in the old river oxbow at Station 500+00 would be 250 by 1,100 feet in size.
- **AB No. 8** is new and would be located at Station 850+00. The 250 by 1,000-foot basin is located in an old river oxbow.

DMMP

PAs would be able to accommodate material from both construction and maintenance dredging of the Federal channel over the 50-year period of analysis. They are also designed to accommodate non-Federal dredging (estimated at 5.2 percent of material to be placed in upland PAs) of private facilities on the Port Arthur and Sabine-Neches canals, and the Neches River Channel. PAs proposed as part of the Recommended Plan consist of upland PAs, ODMDS and GNF BU features (Neches River and Gulf Shore BU features) (tables X-2, X-3, and X-4). Sixteen existing and two expanded upland PAs are proposed for

use with the Recommended Plan. Offshore placement consists of four existing ODMDs (1–4) and four new ODMDs (A–D). More-detailed descriptions of the 50-year DMMP for the Recommended Plan can be found in Section VIII of this document and in Appendix D of the FEIS.

Table X-2
Upland Placement Areas for the Recommended Plan

Placement Area	Additional Cell(s)	Size (acres)	Associated Waterway Section
5	N&S, B, C	957	Sabine Pass Channel (sections 5 and 6)

Table X-4
GNF Beneficial Use Features in the Recommended Plan

Neches River BU Feature

- **Rose City East Marsh Restoration** (Engineering Plate No. C-01)
(TX 3-1 East) – Restoration of 345 acres of fresh marsh; improvement of 72 acres of shallow-water habitat; nourishment of 151 acres of existing marsh
- **Bessie Heights East Marsh Restoration** (Engineering Plate No. C-24)
(TX 5-2) – Restoration of 679 acres of brackish marsh and 1,190 acres of intermediate marsh; improvement of 660 acres of shallow-water habitat; nourishment of 651 acres of existing marsh
- **Old River Cove Marsh Restoration** (Engineering Plate No. C-25)
(TX 6-1) – Restoration of 639 acres of brackish marsh; improvement of 139 acres of shallow-water habitat; nourishment of 432 acres of existing marsh

Gulf Shore BU Feature

- **Texas Point Shoreline Nourishment** (Engineering Plate No. C-27)
(TX 8-11) – Nourishment of 3 miles of Texas shoreline with maintenance material every 6 years
 - **Louisiana Point Shoreline Nourishment** (Engineering Plate No. C-27)
(LA 5-6) – Nourishment of 3 miles of Louisiana shoreline with maintenance material every 6 years
-

Figure X-1 identifies the location of the major features of the Recommended Plan, specifically the DMMP BU features and the mitigation measures, existing and new PAs, and the existing and new ODMDs.

Ecological Mitigation for the Recommended Plan

Marsh Mitigation

Marsh mitigation for the Recommended Plan consists of restoring five degraded marsh areas east of Sabine Lake near Willow and Black bayous, Louisiana (Table X-5). The mitigation plan compensates for the Recommended Plan's salinity increase and associated losses in biological productivity by restoring 2,783 acres of emergent marsh in existing open-water areas within degraded marsh; improving 957 acres of shallow-water habitat by creating shallower, smaller ponds and channels within the restored marsh; and stabilizing and nourishing 4,355 acres of existing marsh located in and around the mitigation areas. Additional details are provided in the FEIS.

Table X-5
Mitigation for Recommended Plan

Recommended Mitigation Plan	Mitigation AAHUs
Willow Bayou	
LA 2-18 B Marsh Restoration (Sabine Lake dredging)	152
LA 2ADD B Marsh Restoration (Sabine Lake dredging)	214
Black Bayou	
LA 3-10R Marsh Restoration (Channel to Orange maintenance material)	198
LA 3-15 B Marsh Restoration (GIWW dredging)	307
LA 3-18 B Marsh Restoration (GIWW dredging)	310
Total Compensation	1,181
FWP Mitigation Target	-1,159
Net Benefits After Compensation	22

X.C LANDS, EASEMENTS, AND RIGHTS-OF-WAY

The project Sponsor is required to furnish the LER for the proposed cost-shared project. The real estate requirements must support construction as well as operation and maintenance of the project after completion. A summary of the real estate requirements for each channel reach is provided in Table VII-6. Specific details of the real estate requirements can be found in the Real Estate Plan, Appendix 4 of this document.

X.D RELOCATIONS

The following assumptions were made to identify pipelines that could be affected by the Recommended Plan and to develop associated costs. The individual circumstances of each pipeline will be evaluated by USACE in consultation with the pipeline owner during the PED and Construction phases, and decisions regarding necessary actions will be made individually for each pipeline at that time. Feasibility engineering guidelines indicate that pipelines with a minimum of 8 feet of cover for trenched lines or 5 feet of cover for directionally drilled lines would not be adjusted. Pipelines that do not meet the minimum cover requirement would be required to be adjusted. The adjusted pipelines must be located 20 feet below the authorized 48-foot depth. The 20 feet includes any advance maintenance and allowable overdepth. The relocation of active pipelines is assumed to be installed with directional drilling, and bundled where possible.

A total of 104 pipelines have been identified crossing the SNWW navigation channels. Of the 104 pipelines, 46 require adjustment to meet the minimum required vertical and horizontal clearances for the CIP.

Pursuant to Section 101(a) of the WRDA 86, as amended, the Sponsor is responsible for performing, or assuring performance, of all relocations, including utility relocations, which are necessary for the CIP. All relocations, including utility relocations, are to be accomplished at no cost to the Federal Government.

The Galveston District has concluded preliminarily that 41 of the 46 lines located within the channel must be relocated and are classified as utility relocations for which the Sponsor must perform or assure performance. In accordance with Section 101(a)(4) of WRDA 86, one-half of the cost of each such relocation will be borne by the owner of the facility being relocated and one-half of the cost of each such relocation will be borne by the Sponsor. Such relocation costs will not include any cost for upgrading or improving such facilities, which is to be borne by the facility owner.

For more-specific information regarding the utility relocations, and preliminary conclusions regarding the remaining five lines that must be removed but not replaced, see the Real Estate Plan, Appendix 4, of this document.

DMMP marsh restoration at Bessie Heights and mitigation marsh restoration measures east of Sabine Lake were assumed to require no relocations. However, since oil production is active in some of these areas, additional pipeline searches and coordination with pipeline owners would be required prior to construction to avoid impacts.

No relocations would be required for overhead power utilities, highway bridges, the Port Arthur HFP Levee, or its associated pump stations and closure structures.

X.E AIDS TO NAVIGATION

Channel Markers

Some of the existing channel markers along the waterway would require removal and replacement. No changes in channel markers are needed upstream of the Beaumont Maneuvering Basin and in the vicinity of SH 87 on the Neches River Channel. However, channel markers along the remainder of the waterway may need to be relocated, and new markers would be required along the Extension Channel.

X.F BRIDGE REINFORCEMENTS AND FENDERS

Channel modifications would require the removal and replacement of bridge fender systems that protect the Rainbow Bridge and the Veterans Memorial Bridge over the Neches River, and the MLK Bridge over the Sabine-Neches Canal. In addition, the existing support piers of the MLK Bridge would be hardened to prevent instability that may develop with construction of the proposed 400-foot channel width.

XI. PLAN IMPLEMENTATION

XI.A OVERVIEW

This chapter identifies project cost sharing responsibilities for the Government and the Sponsor for the construction and O&M of the Recommended Plan.

XI.B DIVISION OF PLAN RESPONSIBILITIES AND COST SHARING REQUIREMENTS

The Recommended Plan would be accomplished at different cost sharing rates. Project cost sharing for the project would be as follows:

- **GNF down to 45-foot depth** – 75 percent Federal and 25 percent non-Federal
- **GNF deeper than 45-foot depth** – 50 percent Federal and 50 percent non-Federal
- **O&M down to 45-foot depth** – 100 percent Federal
- **O&M deeper than 45-foot depth** – 50 percent Federal and 50 percent non-Federal

XI.C DESIGN PHASE COSTS FOR ALTERNATIVES SCREENING

During the detailed design phase, a different cost (\$1.12/gallon fuel cost) and price level (October 2005) were used to identify the least-cost placement alternative (Section VII.E, Table VII-4). Costs have not been updated for this comparison because it was used to screen two placement plan alternatives (a Traditional Placement Alternative and the BU Alternative) during the detailed design phase. No changes have been made to the alternatives that were compared. Costs for both alternatives would change proportionately if they were updated with the most recent price levels. The difference in cost between the two plans would not be materially different, and thus the decision to adopt the BU Alternative as a GNF of the DMMP for the Recommended Plan would not be affected. An explanation of the \$1.12 fuel cost estimate is included below to explain the reasoning behind its use at that time.

Large fluctuations in fuel costs that occurred during the preparation of this report raised concerns that benefits and costs, based upon different cost assumptions as required by the USACE guidance, would lead to an unanticipated bias in the BCR. The USACE Headquarters provided interim guidance requiring a different method of cost determination, which was followed in the preparation of cost screenings for the SNWW CIP until deep-draft vessel operating costs were updated (EGM #08-04). In the interim guidance, the USACE Headquarters and the IWR developed a price adjustment applicable to existing estimates of inland vessel bunkerage costs, which approximated deep-draft or coastal dredge plant costs. The guidance recommended that an estimated value of \$1.12 per standard gallon be used for the economic analysis until the EGM could be updated. Subsequently, the revised EGM was issued in November 2007, and the project costs have been updated. The project cost tables presented in the sections below use the October 2009 price level and updated vessel-operating costs per EGM #08-04.

XI.D PROJECT COSTS

Three costs were developed for evaluation of the Recommended Plan. These costs include the Total First Cost, the Recommended Plan Investment Cost, and the Fully Funded Cost. The Total First Cost is at current levels, does not include interest during construction (IDC) or expected price escalation. The Investment Cost includes all first costs and IDC. The Fully Funded Cost includes all first costs and price escalation, but does not include the IDC. All three costs include associated costs such as LER, relocations (including utility relocations), berthing area and dock modifications, and aids to navigation. All costs in the project cost tables presented in the chapter were developed using October 2009 price levels; annualized costs use an interest rate of 4.375 percent. Deep-draft vessel operating costs for the economic analysis were developed based upon EGM #08-04.

Costs for the Recommended Plan**Total First Cost and Annualized O&M Costs**

The Total First Cost is the cost at current levels and does not include IDC, or expected price escalation. The Total First Cost for all project components (\$1,071,877,000; Table XI-1) includes implementation costs and associated costs. Implementation costs include postauthorization planning and design costs, construction costs, LER, relocations, mitigation costs, and O&M. Construction costs include costs for dredging, PA construction, aids to navigation (e.g., channel markers) and protection for MLK Bridge supports and bridge fender replacement. The USACE coordinated with the USCG to develop costs for aids to navigation, and with the Texas Department of Transportation to develop costs for bridge support protection and fender systems. Costs for compensatory fish and wildlife mitigation (including deferred construction costs for one mitigation measure) and cultural resource mitigation are also included. Associated Federal and non-Federal costs are the costs of resources directly required for project construction, but for which no project expenditure is made, such as USCG navigation aids, relocations (including utility relocations), and non-Federal berthing/dock modifications. A formal cost risk analysis was performed in accordance with Engineering and Construction Bulletin 2007-17 that developed project contingencies at the 80 percent confidence level. First costs and incremental O&M costs are expressed as total average annual costs in the bottom portion of Table XI-1. Construction funding would fund all project construction components.

Deferred Construction Costs

Deferred construction costs are related to one mitigation measure at West Black Bayou, Louisiana (LA 3-10R). This mitigation measure would be constructed using material from regular maintenance dredging of the Sabine River Channel to Orange over a 30-year period. The cost of the mitigation measure is the incremental cost of pumping the additional distance to Louisiana and marsh restoration activities. The first cycle of placement is included as a first cost of construction in the Recommended Plan cost estimates (Contract 14). Intermittent construction over 30 years (six additional 5-year maintenance cycles) is shown separately as an annualized deferred construction cost in tables XI-1 and XI-2. The Deferred construction would be cost shared with the non-Federal project sponsor for the SNWW CIP.

Table XI-1
Total First Cost and Annualized O&M for the Recommended Plan
(All costs in dollars)
(October 2009 price level; 4.375% interest rate)

First Cost of Construction	873,610,000
Fish and Wildlife Mitigation	77,491,000
Cultural Resources Mitigation	1,248,000
Lands	4,361,000
Relocations	41,627,000
Bridge Modifications	51,794,000
Navigation Aids	1,492,000
Berthing and Dock Modifications	20,254,000
Total Project Cost	1,071,877,000
Average Annual Costs	
First Cost Amortization	59,059,000
Deferred Construction (Fish and Wildlife Mitigation)	215,000
Incremental O&M	
Total Incremental	32,006,000
non-Federal Disposal Facility Costs	61,000
Average Annual Costs	91,341,000

Since the Sabine River Channel is a separate project with a different non-Federal sponsor, each Sabine River Channel maintenance cycle involving deferred construction would utilize three funding sources (Federal O&M funds from the Sabine River Channel, and Federal construction funds and Sponsor construction funds from the SNWW CIP). The Federal government and Sponsor must diligently budget for the deferred construction so that funds are available when needed to avoid any delays in channel maintenance and mitigation site construction.

Federal O&M Costs

The maintenance of project features would be funded through annual appropriations of the O&M program. The actual amounts would vary on a year-to-year basis because of variability in the volume of material removed during each dredging cycle and the variability of the cycles. O&M costs also vary between channel depths. In accordance with Section 101(b) of WRDA 86 (Policy Guidance Letter [PGL] 47), O&M dredging and placement costs for maintenance of the channel depths between 40 and 45 feet would be allocated as 100 percent Federal; this would be calculated as 62.5 percent of the total O&M cost, determined as described for the GNF features in the Fully Funded Cost section, below. Costs for maintenance of the channel depth below 45 feet (37.5 percent of the total O&M costs) would be allocated as 50 percent non-Federal and 50 percent Federal. Expected cost sharing for all project components is compliant with PGL 47, Dredged Material Disposal Facilities, and Dredged Material Disposal Facility Partnerships.

Table XI-2
Total Investment Cost for the Recommended Plan
(October 2009 price level; 4.375 percent interest rate)

Total First Cost	1,071,877,000
Months to Construct	96
Interest During Construction	119,382,000
NED Investment Costs	1,191,259,000
Average Annual Project Cost	59,059,000
Incremental O&M	32,067,00
Deferred Construction (F&W Mitigation)	215,000
Total Annual Cost	91,341,000
Annual Benefits	115,074,000
Net Excess Benefits	23,733,000
BCR	1.3

Additional PA capacity for the Recommended Plan would be constructed regularly over the 50-year period of analysis in conjunction with maintenance dredging cycles. Since established dredged material management practices for the SNWW 40-foot project include regularly recurring levee raisings and the enlargement or installation of new dewatering structures, the additional investment required to provide the increased PA capacity for the Recommended Plan and PA costs attributable to the 40-foot project Base Plan would be cost shared as O&M costs. Costs for disposal facility maintenance would be allocated as 100 percent Federal for maintenance of channel depths between 40 and 45 feet. Costs for disposal facility maintenance associated with channel deepening below 45 feet would be allocated as 50 percent non-Federal and 50 percent Federal.

Non-Federal O&M Costs

In the SNWW, non-Federal maintenance material has traditionally been placed into the same PAs as Federal material, at the request of the non-Federal sponsor. Additional capacity needed for the non-Federal maintenance material was therefore considered when determining improvements needed to provide capacity for the 50-year period of analysis. It is projected that approximately 5.2 percent of the 48-foot project 50-year maintenance dredging quantity to be placed in upland disposal facilities would originate from non-Federal dredging. Costs of providing the capacity needed to contain the non-Federal dredged material are a local responsibility and are shown separately from the incremental Federal O&M costs that would be cost-shared as described above.

National Economic Development Investment Cost

The Investment Cost is expressed in current dollars with IDC added (see Table XI-2). The Investment Cost includes all of the implementation costs and non-Federal and Federal associated costs included in the First Cost as described above. First costs, incremental O&M, and deferred construction for fish and wildlife mitigation are expressed as total average annual costs in the bottom portion of Table XI-2, and then net excess benefit totals and the BCR are calculated. Total average annual costs are compared to

projected annual benefits to determine net excess benefits and the BCR. The BCR for the Recommended Plan is 1.3.

Fully Funded Cost

Total First Costs and price escalation, calculated by estimating the midpoint of the proposed construction contracts, are combined to create the Fully Funded Cost. In order to allocate the share of construction and O&M costs between the Federal government and the Sponsor, the cost must first be allocated by depth in accordance with Section 101 of Public Law 99-662 (USACE, 2000b). Costs for the transportation and placement of material during construction of the 48-foot project are GNF costs. The GNF costs are assigned to the two depth ranges, in accordance with Section 101(a) of WRDA 86, by applying the proportion of the channel deepening that would occur within each depth range. The cost allocation by depth in first cost is shown in Table XI-3. Table XI-4 shows this cost allocation using the fully funded cost. The amount associated with deepening between 40 and 45 feet (cost shared at 25 percent non-Federal and 75 percent Federal) was calculated by using an estimate for the 45-foot project. This 45-foot cost estimate was developed to a level comparable to an MII cost estimate. The amount associated with deepening below 45 feet (cost shared at 50 percent non-Federal and 50 percent Federal) was calculated by taking the cost difference between the 48-foot alternative and the 45-foot plan. Costs for various categories such as advance maintenance and allowable overdepth dredging were included in both the 45-foot estimates and 48-foot estimates and are included in both depths in the same manner as other GNF costs. None of the existing berthing areas and docks is presently deeper than the 40-foot channel, and therefore these costs would also be allocated between the depths as are all other GNF costs. The Federal costs for lands, fish and wildlife mitigation, cultural resources, and aids to navigation are the same in both the 45-foot and 48-foot plans; therefore, there are no additional costs included in the analysis for deepening from 45 to 48 feet.

XI.E COST SHARING ALLOCATION

The GNF costs for deepening between 40 and 45 feet are cost shared at 25 percent non-Federal and 75 percent Federal; costs for deepening below 45 feet are cost shared at 50 percent non-Federal and 50 percent Federal. The costs are separated into expected Federal and non-Federal shares and detailed in tables XI-5 and XI-6. Table XI-5 used the projects first costs while Table XI-6 is in fully funded escalated costs. Fish and wildlife mitigation is considered a GNF and is cost shared in the same manner as other GNF costs. Costs for cultural resources data recovery would be handled in accordance with PL 93-291 (Section 7), e.g., data recovery costs would be 100 percent Federal up to 1 percent of the total amount appropriated for the project. Based upon information available at this time, data recovery costs are not expected to exceed the 1 percent limitation.

The Sponsor also must pay an additional 10 percent of the GNF costs in cash over a period not to exceed 30 years. This additional 10 percent cash contribution is offset by credit for LER and relocations (including utility relocations) pursuant to Section 101(a)(2) of WRDA 86, as amended. Owners of berth and dock facilities that would require modification in conjunction with the Recommended Plan would be

responsible for 100 percent of those associated costs. The USCG is responsible for 100 percent of the cost for aids to navigation.

Table XI-3
Recommended Plan First Costs Allocation by Depth

**XI.F ADDITIONAL NON-FEDERAL SPONSOR CASH
CONTRIBUTION**

For all navigation channel depths, the Sponsor must provide an additional cash contribution equal to 10 percent of fully funded GNF costs as shown below in Table XI-7 (USACE, 2000b). These costs may be paid over a period not exceeding 30 years. The Sponsor's costs for LER and relocations (including utility relocations) are credited against the additional cash contribution.

Table XI-7
Total General Navigation Features Costs and Credits
(October 2009 Price Level)
(All costs in dollars)

Cost-Shared GNF	1,088,745,000
10% of GNF	108,874,500
Creditable Land Costs	3,864,000
Relocation Costs	22,658,500
Total non-Federal Sponsor Creditable Costs	<u>26,522,500</u>
Creditable Difference	<u>(82,352,000)</u>

XI.G NON-FEDERAL SPONSOR VIEWS

The Sponsor for the existing project, SNND, has actively participated in the entire planning process. Their primary concern has been to provide the community with a channel design, preferably 48 feet deep, to increase navigation efficiency and prepare for future needs. The SNND fully supports the Recommended Plan and has indicated an interest in beginning construction as soon as possible.

XII. SUMMARY OF COORDINATION

XII.A OVERVIEW

This section identifies the coordination process used during the feasibility study to obtain comments and concerns from the general public, State and Federal resource agencies, and any other interested parties. A general summary of the comments is provided below. A more detailed description of the public involvement process and a complete list of all comments can be found in Appendix A of the FEIS.

XII.B COORDINATION

The USACE and SNND developed a public involvement plan to be used during the feasibility phase for the SNWW CIP. The goal of the public involvement plan was to ensure that the USACE and SNND were responsive to the needs and concerns of all stakeholders and to ensure public involvement through an open, interactive process. Stakeholders include all the various publics that could be affected or might be interested in the project. The plan helped the USACE and SNND provide information to, and obtain information from, the stakeholders.

Coordination with resource agencies was conducted primarily through the ICT and technical working group meetings. Resource agencies and the study team met regularly throughout the study process. Over 30 workgroup meetings and 11 ICT meetings were held.

A proactive outreach program was initiated to ensure that the public, resource agencies, industry, local government, and other interested parties were informed about the project and that any concerns were identified and addressed. Each of the activities listed here is described individually in Appendix A of the FEIS. The outreach program included:

- Scoping meetings;
- Public workshops to obtain ideas for BU of dredged material;
- Media trips by boat down the waterway;
- Presentations at the GMFMC's Texas Habitat Protection Advisory Panel;
- Presentations at regular meetings of Southeast Texas Waterway Advisory Council,
- Meetings with SPA;
- Presentation at the 2007 South East Texas Leaders meeting; and
- Meetings with SNWW industries.

XII.C PUBLIC/AGENCY COMMENTS

The following is an overview of the comments and concerns throughout the study process. These comments were received from the general public, State and Federal resource agencies, and other interested parties.

Saltwater Intrusion

The primary environmental concern is the potential for the proposed CIP to increase saltwater intrusion, and for higher salinity levels to further degrade marshes and cypress swamps in both Texas and Louisiana. The combined effects of subsidence and sea level rise are expected to increase marsh submergence and worsen this trend. The public and resource agencies identified severely stressed marsh areas at Texas Point and Salt Bayou in the Sabine Pass area, in the Neches River reach between Sabine Lake and IH 10, and in the extensive marshes east of Sabine Lake.

An associated issue is the deterioration of wildlife habitat and fishery nursery areas and the destruction of fish and wildlife resources that could occur as a result of increased wetland loss. All or portions of the following federally and State-protected lands are located in sensitive habitats, which may be affected by the proposed CIP: the Sabine NWR, the McFaddin NWR, the Texas Point NWR, the J.D. Murphree WMA, the Lower Neches WMA, the Tony Houseman WMA, and the Sabine Island WMA.

It was suggested that environmental impacts as a consequence of the proposed CIP should be avoided if possible. A lock at Sabine Pass, a sill or constriction at the mouth of Sabine Lake, and smaller water control structures in the marshes east of Sabine Lake were suggested as methods to minimize or avoid impacts. Other comments warned of the potential harmful effects of water control structures, which inhibit the movement of marine organisms into and out of intertidal marshes.

Threatened and Endangered Species

Potential impacts to threatened and endangered species are a concern, particularly dredging impacts to endangered sea turtles. The offshore channel deepening and extension would require the use of hopper dredges, which create particular hazards for sea turtles. Critical Habitat for the wintering piping plover is present in the study area.

Contaminated Sediments

The public also expressed concern that dredging for the proposed CIP and the placement of dredged material would spread contaminated sediments or affect water quality. It is feared that new work dredging would release contaminants from past industrial discharges into the water column, or that areas selected for the BU of dredged material could be polluted.

The BU of dredged material to restore degraded marshes was encouraged by the public and resource agencies. The following sites were specifically identified as areas that could benefit: Rose City marsh, Bessie Heights marsh, Keith Lake marsh, marshes in the McFaddin NWR, east Sabine Lake marshes, and the Gulf shoreline at Texas Point and Holly Beach. Construction of a bird island in Sabine Lake was also suggested. The BU of dredged material would reduce the need for new or expanded PAs and reduce potential wetland impacts.

Essential Fish Habitat

The proposed CIP, including the Gulf of Mexico ODMDSs, could impact EFH for red drum; brown, white, and pink shrimp; Spanish mackerel; and estuarine water column and mud/sand bottoms. Potential effects to nursery and foraging habitat for economically important marine fishery species such as spotted sea trout, flounder, Atlantic croaker, black drum, Gulf menhaden, striped mullet, and blue crab also need to be evaluated for adverse effects associated with proposed water control structures.

Storm Surge and Erosion

Concern has been expressed that the proposed CIP could increase tidal amplitude, and increase damage during storm surges by allowing the surge to inundate areas that have not been affected by previous storms. Concerns were also expressed about the potential increased erosion along the shoreline of the channel due to increased or larger vessel traffic.

Cultural Resources

Concern was expressed that the use of the existing PA 5 would adversely affect public access to the Sabine Lighthouse, a National Register-listed property. A road around the perimeter of the PA is currently the only access route to the Lighthouse. Changes or enlargements to this PA could limit or remove access to the historic property. Furthermore, proposed project improvements could affect the Sabine Pass Battleground Park, Fort Griffin, and associated shipwrecks along the waterway. These sites and the shipwrecks are associated with important battles during the U.S. Civil War.

Socioeconomic and Project Costs

Considerable concern was expressed by government agencies in Louisiana that the proposed CIP would have adverse effects on their State's environment while providing no economic benefits for Louisiana. Officials at the West Calcasieu Port, Harbor and Terminal District urged that navigation improvements be evaluated on a regionwide basis, because channel improvements in Texas could put their facilities and the Port of Lake Charles at a competitive disadvantage. Cameron Parish officials expressed support for economic development that would benefit their constituents. Cameron Parish officials were also concerned that lands suitable for commercial development at Sabine Pass were being considered for use as PAs. Developable lands are limited on the Louisiana side of the SNWW, and all are needed to promote economic development.

The high concentration of petrochemical refineries and terminals in the study area means that a large number of pipelines are also present. Local industries are concerned that these pipelines would be affected by the proposed channel deepening and that they would be responsible for the cost of relocating these pipelines below a deeper channel bottom.

Several members of the general public expressed concern that the cost of this project would be large, that benefits would not be sufficient to outweigh costs, and that costs would be passed on to taxpayers in the form of higher taxes.

Public Infrastructure

Jefferson County Drainage District #7 expressed concern that channel widening and deepening could affect the structural integrity of the Port Arthur Hurricane Protection Levee, pump stations, and closure structures. The Texas Department of Transportation expressed concern that increased erosion could adversely affect SH 82 and SH 87. Both are located immediately adjacent to the SNWW and are affected by present channel bank erosion. Additional erosion of SH 87 could destroy the only road access to the City of Sabine Pass.

XIII. RECOMMENDATIONS

Based on the analyses and information in this document and the FEIS, it is recommended that the existing SNWW, Texas, authorized by the RHA of 1962, be modified generally as described in this report as the Recommended Plan, with such modifications as in the discretion of the Chief of Engineers may consider advisable, and subject to cost-sharing and financing arrangements satisfactory to the President of the United States and Congress, to provide deep-draft channel and selective widening improvements and continued maintenance of the SNWW Channel.

A categorical exemption for navigation projects exists to deviate from selection of the NED plan in accordance with ER 1105-2-100, E-3.b(5) that states:

“Categorical Exemption for Flood Control and Navigation Projects. If the non-Federal sponsor identifies a constraint to maximum physical project size or a financial constraint due to limited resources, and if net benefits are increasing as the constraint is reached, the requirement to formulate larger scale plans in an effort to identify the NED plan is suspended. The constrained plan may be recommended. . . .”

The proposed project meets the requirements for a categorical exemption due to the sponsor’s financial constraint and is recommended as the recommended plan. This constrained LPP consists of deepening of the channel to 48 feet as described in Section X of this report.

XIII.A PROJECT COSTS (October 2009 Price Levels)

For the purpose of calculating the Section 902 limit, the total estimated first cost of the project is \$1,029,318,000, including an estimated Federal share of \$691,383,000 and an estimated non-Federal share of \$337,935,000. Total First Cost of all project components in current dollars, without escalation and IDC, totals \$1,071,877,000. The Fully Funded Cost for the project, which includes Total First Costs and expected escalation, is \$1,161,372,000. The Investment Cost of all components totals \$1,191,259,000, and includes \$119,382,000 in IDC. Total annual costs for the project are \$91,341,000 and total annual benefits are \$115,074,000, resulting in a project BCR of 1.3.

XIII.B REQUIREMENTS

These recommendations are made with the provision that, prior to implementation of the recommended improvements, the Sponsor shall enter into binding agreements with the Federal government to comply with the following requirements.

The SNND shall:

- a. Provide 10 percent of the total cost of construction of the general navigation features (GNFs) attributable to dredging to a depth not in excess of 20 feet; plus 25 percent of the total cost of construction of the GNFs attributable to dredging to a depth in excess of 20 feet but not in

excess of 45 feet; plus 50 percent of the total cost of construction of the GNFs attributable to dredging to a depth in excess of 45 feet as further specified below:

1. Provide 25 percent of design costs allocated by the Government to commercial navigation in accordance with the terms of a design agreement entered into prior to commencement of design work for the project;
2. Provide, during the first year of construction, any additional funds necessary to pay the full non-Federal share of design costs allocated by the Government to commercial navigation;
3. Provide, during construction, any additional funds necessary to make its total contribution for commercial navigation equal to 10 percent of the total cost of construction of the GNFs attributable to dredging to a depth not in excess of 20 feet; plus 25 percent of the total cost of construction of the GNFs attributable to dredging to a depth in excess of 20 feet but not in excess of 45 feet; plus 50 percent of the total cost of construction of the GNFs attributable to dredging to a depth in excess of 45 feet;
- b. Provide all lands, easements, and rights-of-way (LER), including those necessary for the borrowing of material and the disposal of dredged or excavated material, and perform or ensure the performance of all relocations, including utility relocations, all as determined by the Federal Government to be necessary for the construction or operation and maintenance, of the GNFs;
- c. Pay with interest, over a period not to exceed 30 years following completion of the period of construction of the GNFs, an additional amount equal to 10 percent of the total cost of construction of the GNFs less the amount of credit afforded by the Government for the value of the LER and relocations, including utility relocations, provided by the Sponsor for the GNF. If the amount of credit afforded by the Government for the value of the LER and relocations, including utility relocations, provided by the Sponsor equals or exceeds 10 percent of the total cost of construction of the GNFs, the Sponsor shall not be required to make any contribution under this paragraph, nor shall it be entitled to any refund for the value of LER and relocations, including utility relocations, in excess of 10 percent of the total cost of construction of the GNFs;
- d. Provide, operate, maintain, repair, replace, and rehabilitate, at its own expense, the local service facilities in a manner compatible with the project's authorized purposes and in accordance with applicable Federal and State laws and regulations and any specific directions prescribed by the Federal Government;
- e. Provide 50 percent of the excess cost of operation and maintenance of the project over that cost that the Federal Government determines would be incurred for operation and maintenance if the project had a depth of 45 feet;
- f. Give the Federal Government a right to enter, at reasonable times and in a reasonable manner, upon property that the Sponsor owns or controls for access to the project for the purpose of completing, inspecting, operating, and maintaining the GNFs;

-
- g. Hold and save the United States free from all damages arising from the construction or operation and maintenance of the project, any betterments, and the local service facilities, except for damages due to the fault or negligence of the United States or its contractors;
 - h. Keep, and maintain books, records, documents, and other evidence pertaining to costs and expenses incurred pursuant to the project, for a minimum of 3 years after completion of the accounting for which such books, records, documents, and other evidence is required, to the extent and in such detail as will properly reflect total cost of construction of the GNFs, and in accordance with the standards for financial management systems set forth in the Uniform Administrative Requirements for Grants and Cooperative Agreements to State and local governments at 32 CFR, Section 33.20;
 - i. Perform, or ensure performance of, any investigations for hazardous substances as are determined necessary to identify the existence and extent of any hazardous substances regulated under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), 42 USC 9601–9675, that may exist in, on, or under LER that the Federal Government determines to be necessary for the construction or operation and maintenance of the GNFs. However, for lands that the Government determines to be subject to the navigation servitude, only the Government shall perform such investigations unless the Federal Government provides the Sponsor with prior specific written direction, in which case the Sponsor shall perform such investigations in accordance with such written direction;
 - j. Assume complete financial responsibility, as between the Federal Government and the Sponsor, for all necessary cleanup and response costs of any hazardous materials regulated under CERCLA that are located in, on, or under LER that the Federal Government determines to be necessary for the construction or operation and maintenance of the project;
 - k. To the maximum extent practicable, perform its obligations in a manner that will not cause liability to arise under CERCLA;
 - l. Comply with Section 221 of Public Law 91-611, Flood Control Act of 1970, as amended (42 USC 1962d-5b), and Section 101 of the WRDA 86, Public Law 99-662, as amended, which provide that the Secretary of the Army shall not commence the construction of any water resources project or separable element thereof, until the Sponsor has entered into a written agreement to furnish its required cooperation for the project or separable element;
 - m. Comply with the applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, as amended (42 USC 4601–4655), and the Uniform Regulations contained in 49 CFR Part 24, in acquiring LER required for construction or operation and maintenance of the project; and inform all affected persons of applicable benefits, policies, and procedures in connection with said act;
 - n. Comply with all applicable Federal and State laws and regulations, including, but not limited to, Section 601 of the Civil Rights Act of 1964, Public Law 88-352 (42 USC § 2000d et seq.), and Department of Defense Directive 5500.11 issued pursuant thereto, as well as Army Regulation 600-7, entitled “Nondiscrimination on the Basis of Handicap in Programs and Activities Assisted or Conducted by the Department of the Army.” The Sponsor is also required to comply with all applicable Federal labor standards requirements including, but not
-

limited to, 40 USC 3144–3148 and 40 USC 3701–3708 (revising, codifying, and enacting without substantive change the provisions of the Davis-Bacon Act (formerly 40 USC 276a et seq.), the Contract Work Hours and Safety Standards Act (formerly 40 USC 327 et seq.), and the Copeland Anti-Kickback Act (formerly 40 USC 276c);

- o. Provide the non-Federal share of that portion of the costs of mitigation and data recovery activities associated with historic preservation, that are in excess of 1 percent of the total amount authorized to be appropriated for the project; and
- p. Not use funds from other Federal programs, including any non-Federal contribution required as a matching share therefor, to meet any of the Sponsor's obligations for the project unless the Federal agency providing the Federal portion of such funds verifies in writing that such funds are authorized to be used to carry out the project.

Construction of the recommended channel improvements is estimated to take 7 years to complete. During this period, the Government and the Sponsors shall diligently maintain the projects at their previously authorized dimensions according to the previous cooperation agreement. Maintenance materials that have accumulated in the channels at the time that "before dredging" profiles are taken for construction payment shall be considered as new work material and cost-shared according to the new cooperation agreement. Any dredging in a construction contract reach after the improvements have been completed and the construction contract closed would be considered to be maintenance material and cost-shared according to the new agreement.

XIII.C MAINTENANCE OF NEW CHANNEL AND EXISTING CHANNEL

The portions of the SNWW channel that are deepened and widened (including any newly created areas) shall be operated and maintained according to the terms and provision of the new agreements. All other portions of the existing SNWW channel shall continue to be operated and maintained according to the existing agreement applicable to that portion of the channel. With the cost of maintenance dredging continuing to rise every year, it is imperative to fully fund the maintenance portion of this project each year. Recent fiscal year funding of \$12–\$15 million is insufficient and does not allow the channel to be maintained at the current authorized depth of 40 feet. This report forecasts a shoaling rate nearly double the current rate. This increased rate, combined with more fully loaded ships traversing the waterway, stresses the importance of maximum and consistent funding of O&M costs for the new project depth.

XIII.D RECOMMENDATION

The recommendations of the Sabine-Neches CIP to deepen the waterway depth to 48 feet with selective widening, as described in Section X of this document, reflects the information available at this time and current Departmental policies governing formulation of individual projects. They do not reflect program and budgeting priorities inherent in the formulation of a national Civil Works construction program nor the perspective of higher review levels with the Executive Branch. Consequently, the recommendations may be modified before they are transmitted to the Congress as proposals for authorizations and

implementation funding. However, prior to transmittal to the Congress, the Sponsor, the State, interested Federal agencies, and other parties will be advised of any modifications and will be afforded an opportunity to comment further.

Economic Appendix

APPENDIX 2
ECONOMIC APPENDIX
SABINE-NECHES WATERWAY
CHANNEL IMPROVEMENT PROJECT
SOUTHEAST TEXAS AND SOUTHWEST LOUISIANA

PREPARED BY:

U.S. ARMY CORPS OF ENGINEERS
GALVESTON DISTRICT
SOUTHWESTERN DIVISION

June 2010

Table of Contents

	Page
1.0 GENERAL	1
1.1 COMMODITY OVERVIEW	8
2.0 DETAILED COMMODITY ANALYSIS	19
2.1 CRUDE PETROLEUM	19
2.2 PETROLEUM PRODUCT IMPORTS	26
2.3 PETROLEUM PRODUCT EXPORTS	30
2.4 CHEMICAL PRODUCT IMPORTS	34
2.5 CHEMICAL PRODUCT EXPORTS	38
2.6 GRAIN EXPORTS	42
2.7 EXPANSION OF THE DEEP-DRAFT TRAFFIC BASE	43
3.0 VESSEL FLEET ANALYSIS.....	46
3.1 SNWW VESSEL CASUALTIES.....	46
3.2 OFFSHORE ALTERNATIVES	52
3.3 VESSEL UTILIZATION AND OPERATING PRACTICES	56
3.4 CRUDE PETROLEUM FLEET	67
3.5 PORT ARTHUR AND BEAUMONT VESSEL FLEETS	69
3.5.1 Methods of Shipment for Crude Petroleum	72
3.6 PETROLEUM PRODUCT CARRIERS	82
3.7 CHEMICAL PRODUCT CARRIERS	86
3.8 GRAIN EXPORTS	88
3.9 STEEL SLAB AND IRON ORE CARRIERS	91
3.10 LIMESTONE AND ROCK CARRIERS.....	92
3.11 WOOD PRODUCT CARRIERS.....	93
3.12 LIQUEFIED NATURAL GAS (LNG) FLEET.....	94
4.0 COMMODITY AND FLEET FORECASTS	95
4.1 REVIEW OF PETROLEUM FORECASTS	95
4.2 SNWW CRUDE PETROLEUM FORECAST APPLICATION	98
4.3 PETROLEUM PRODUCT IMPORTS.....	106
4.4 FUEL OIL IMPORTS	107
4.5 GASOLINE IMPORTS	116
4.6 PETROLEUM PRODUCT EXPORT FORECAST	118
4.7 PETROLEUM COKE EXPORTS.....	118
4.8 GASOLINE EXPORTS.....	123
4.9 DISTILLATE EXPORTS	126
4.10 COASTWISE PETROLEUM PRODUCTS	128
4.11 REMAINING PETROLEUM PRODUCT EXPORTS	130
4.12 CHEMICAL IMPORTS	131

	Page
4.13 CHEMICAL EXPORTS.....	133
4.14 LIQUEFIED NATURAL GAS.....	136
4.15 U.S. LNG IMPORT FORECAST.....	137
4.16 GRAIN EXPORT FORECAST.....	138
4.17 BREAKBULK IMPORT FORECAST.....	147
5.0 FORECAST OF TOTAL OCEANGOING TONNAGE.....	148
6.0 TRANSPORTATION SAVINGS BENEFITS	150
6.1 VESSEL OPERATING COSTS.....	150
6.2 UNDERKEEL CLEARANCE	151
6.3 CHANNEL WIDENING BENEFITS	152
6.3.1 HarborSym Model	158
6.3.1.1 Model Input Overview.....	159
6.3.1.2 Vessel Traffic Input	160
6.3.1.3 Evaluation of Project Alternatives.....	166
6.3.1.4 Entrance Channel Widening Benefits.....	167
6.3.1.5 Neches River Holding Areas	183
6.4 CHANNEL DEEPENING BENEFITS	191
6.4.1 Transportation Savings Benefits for Channel Deepening.....	192
6.4.1.1 Crude Petroleum Imports.....	195
6.4.1.2 Petroleum and Chemical Product Transportation Savings Benefits	203
6.4.1.3 Grain Exports Transportation Savings Benefits.....	209
6.4.1.4 Crude Materials Transportation Savings.....	212
6.4.1.5 Crude Materials Transportation Savings Benefits	216
6.4.1.6 Liquefied Natural Gas Transportation Savings.....	220
7.0 NED BENEFIT SUMMARY	222
7.1 INCREMENTAL ANALYSIS	224
7.2 BENEFIT-COST RATIO AT 7 PERCENT	227
8.0 SENSITIVITY ANALYSIS.....	229
8.1 UNDERKEEL CLEARANCE SENSITIVITY	229
8.2 OFFSHORE TERMINAL	231
8.3 OFFSHORE TRANSFER TIME SENSITIVITY.....	232
8.4 VESSEL TRIP REDUCTION DUE TO CHANNEL DEEPENING	233
8.5 GRAIN EXPORT SENSITIVITY	235
8.6 DEPTH OPTIMIZATION SENSITIVITY REVIEW	235
8.7 SUMMARY OF MAJOR SENSITIVITY EFFECTS	236
9.0 REGIONAL ECONOMICS	238
9.1 OTHER INDICATORS	241
9.2 SUMMARY AND CONCLUSIONS	241

List of Figures

	Page
1 Project Location	2
2 SNWW Foreign Imports and Exports by Major Commodity Group	15
3 SNWW Breakbulk Imports and Exports 1989/1991 to 2004/20006 Distribution	15
4 SNWW Coastwise Shipments and Receipts.....	16
5 SNWW Coastwise Shipments and Receipts by Major Commodity Group.....	17
6 Port Arthur and Beaumont Outbound Coastwise Gasoline Shipments	18
7 Port Arthur and Beaumont Outbound Chemical Shipments.....	18
8 U.S. Petroleum Administration Defense District	22
9 U.S. Strategic Petroleum Reserves Gulf Coast Sites.....	22
10 Major U.S. Crude Petroleum and Product Pipelines	24
11 U.S. and Sabine-Neches Crude Oil Imports, 1985–2007	26
12 SNWW and U.S. Total Petroleum Product Imports 1990–2007	28
13 Comparison of Refinery Yields by Crude Type.....	29
14 U.S. and SNWW Total Petroleum Product Exports 1990–2007	32
15 U.S. and SNWW Total Petroleum Coke Exports, 1990–2007	32
16 U.S. and SNWW Metallic Salt Exports	41
17 SNWW Total and Port Arthur Metallic Salt Exports.....	41
18 U.S. and SNWW Bulk Grain Statistics, 1990–2007	44
19 U.S. LNG Imports 2006–2030	44
20 SNWW Casualty Incidents (2006) by Vessel Type	48
21 SNWW Casualty Incidents (2006) by Casualty Type	48
22 Sabine-Neches Waterway Average Tonnage Per Trip for Oceangoing Vessels	59
23 2001 Comparison of WCSC and Piloted Inbound Trips	65
24 2005 Comparison of WCSC and Piloted Inbound Trips	65
25 U.S. Gulf Coast Crude Petroleum Lightering Zones.....	74
26 U.S. Refinery Processing Gains, 1994–2006 Data.....	98
27 SNWW and Other Texas Ports Crude Petroleum Imports	100
28 SNWW and U.S. Crude Petroleum Imports, 1990–2004.....	102
29 SNWW Crude Petroleum Imports Projected and Actual Volumes	102
30 SNWW and U.S. Crude Petroleum Import Forecast Comparisons	104
31 U.S. Imports of Distillate Fuel, Waterborne and Land Routes, 1990–2007.....	109
32 U.S. and SNWW Distillate Fuel Imports, 1990–2007 (Waterborne Routes Only)	109
33 U.S. Imports of Residual Fuel, Waterborne and Land Routes 1990–2007	110
34 U.S. and SNWW Residual Fuel Imports 1990–2007 (Waterborne Routes Only).....	110
35 SNWW Distillate Imports 2000–2030 (1,000s of Short Tons) Comparison of AEO 2008 U.S. Forecast and SNWW Applications.....	115
36 U.S. and SNWW Waterborne Gasoline Imports and SNWW Gasoline Imports	117
37 U.S. Crude Petroleum Imports by API Gravity Classification.....	119
38 SNWW and U.S. Petroleum Coke Exports and % of U.S. Crude Petroleum Imports by API Gravity Classification.....	120
39 SNWW Petroleum Coke Exports 1990–2007 Point Averages.....	121
40 SNWW Petroleum Coke Export Forecast Scenarios.....	122
41 SNWW Gasoline Exports.....	123
42 U.S. and PADD III Gasoline Exports, 1982–2007.....	124

43	U.S. and PADD III Gasoline Exports, 1990–2030.....	125
44	U.S. and PADD III Distillate Fuel Exports, 1990–2007 Waterborne and Land Routes.....	126
45	U.S. and SNWW Distillate Fuel Exports, 1990–2006 Waterborne.....	127
46	SNWW Coastwise Shipments 1995–2007 Waterborne	129
47	U.S. Alcohol and Ammonia Waterborne Imports, 1990–2007	131
48	SNWW Alcohol and Ammonia Waterborne Imports, 1990–2007.....	132
49	SNWW Alcohol and Ammonia Imports 1995–2065 Waterborne.....	133
50	U.S. Metallic Salts and Organic Compound Exports, Waterborne	134
51	SNWW Metallic Salts and Organic Compound Exports.....	135
52	SNWW Metallic Salts and Organic Compound Exports, 1995–2069 Waterborne	135
53	U.S. Wheat Exports by Region	140
54	Beaumont Wheat Exports.....	140
55	U.S. and Beaumont Wheat Exports and U.S. Wheat Production	141
56	Wheat Exports by State and Beaumont Exports, 1997–2006.....	143
57	SNWW HarborSym Network.....	159
58	SNWW Depth Optimization Review	236
59	Flows of Economic Impacts through the Economy.....	238

List of Tables

	Page
1 SNWW Port Tonnage	3
2 Existing SNWW Channel Dimensions.....	4
3 SNWW Pilot Rules	5
4 SNWW Total Tonnage and Major Commodity Tonnage	9
5 SNWW Shallow-Draft Port and GIWW Through Tonnage, Deep-Draft Total Tonnage, and Shallow-Draft Percentage of Total Tonnage	10
6 Port Arthur Total Tonnage and Major Commodity Tonnage.....	11
7 Beaumont Total Tonnage and Major Commodity Tonnage.....	12
8 Comparison of SNWW and Regional and National Totals Crude Petroleum Imports.....	20
9 Beaumont and Port Arthur Crude Petroleum Imports	21
10 SNWW Atmospheric Crude Oil Distillation Capacity	23
11 SNWW and U.S. Petroleum Product Imports by Commodity Classification	27
12 Petroleum Product Imports by Port and Commodity Classification	29
13 SNWW and U.S. Total Petroleum Product Exports by Commodity Classification	31
14 Petroleum Product Exports by Port and Commodity Classification	33
15 SNWW and U.S. Chemical Imports by Commodity Classification	35
16 Chemical Imports by Port and Commodity Classification	36
17 SNWW and U.S. Chemical Exports by Commodity Classification	39
18 Chemical Product Exports by Port and Commodity Classification.....	40
19 Beaumont Bulk Grain Export Distribution of Tonnage by Grain Type	43
20 SNWW Casualty Incident Rates, 2006	47
21 Safety Risk Factors	50
22 Port Arthur's Safety Risk Factors	50
23 SNWW Trips by Loaded Draft	58
24 Total Imports and Exports by Year and Loaded Draft	60
25 Crude Petroleum Imports by Loaded Draft and Year.....	61
26 Petroleum Product Imports and Exports by Loaded Draft	62
27 Chemical Product Imports and Exports by Loaded Draft	63
28 Total Tonnage Excluding Petroleum and Chemicals by Loaded Draft	64
29 SNWW Crude Petroleum Imports, Percentage of Imports by Vessel DWT and Design Draft and Year Built	68
30 1981 and 2003 World Tanker Fleet Comparison of Vessel Beam by DWT and Design Draft	69
31 Port Arthur Crude Petroleum Imports, Percentage of Imports by Vessel DWT	70
32 Channel to Beaumont Crude Petroleum Imports, Percentage of Imports by Vessel DWT	70
33 Crude Petroleum Vessel Characteristics Representative of the Existing Fleet through 2006, Vessel Length, Beam, and Design Draft and Year Built	71
34 SNWW Crude Petroleum 2002–2007 Imports by Loaded Draft.....	71
35 SNWW Percentage of Crude Petroleum Imports by Trade Route	79
36 PADD III Percentage of Crude Petroleum Imports by Trade Route	80
37 SNWW Percentage of Crude Petroleum Imports by Trade Route, 2002–2007	80
38 EIA Production Forecast Conventional Crude Production and Sources of U.S. Crude Oil Imports and SNWW Application	81
39 SNWW Petroleum Product Import Tonnage by Vessel DWT	82

40	Imports and Exports Shipped in Vessels of 60,000 DWT or Larger, SNWW Petroleum Product Imports, 1998–2007 (select years)	84
41	SNWW Petroleum Product Exports, 1998–2007 (select years)	84
42	World Petroleum Product Fleet	85
43	U.S. Petroleum Coke Exports by Major Destination	86
44	World Chemical Product Fleet, Vessels Built between 1985 and 2004	87
45	Chemical Product Fleet	88
46	Beaumont Bulk Grain Export, Distribution of Tonnage by Grain Type and Loaded Vessel Draft	88
47	LoLo Bulk Dry Cargo Carriers (World Fleet)	90
48	Percentage of SNWW Iron and Steel Product Imports by Country of Origin	92
49	SNWW Building Material Imports and Exports	93
50	SNWW Aggregate Tonnage Fleet, 2002–2006	93
51	World Liquefied Natural Gas Fleet	94
52	U.S. Crude Oil Imports Comparative Projections	96
53	U.S. and SNWW Distribution of Crude Oil and Petroleum Imports Relative Percentage of Crude Petroleum Imports Versus Refined Products	96
54	1990–2007 Regression Equation Data for SNWW Crude Oil Imports	99
55	1990–2004 Regression Equation Data for SNWW Crude Oil Imports	101
56	SNWW Trendline Equation Output, SNWW 1980–2007 and 1990–2007 Crude Oil Imports as a Function of Time	103
57	SNWW Crude Oil Imports, 2002/2004 to 2069	105
58	U.S. and SNWW Petroleum Product Imports, 1994/1996 and 2004/2006 Averages	106
59	Comparison of AEO2008 and Global Insight Forecasts, U.S. Net Petroleum Product Imports	107
61	U.S. Residual Fuel Imports, 2002–2007	112
62	U.S. Distillate Fuel Imports, 2002–2007	113
63	SNWW 2004/2006 to 2069 Distillate Fuel Oil Imports	114
64	SNWW 2004/2006 to 2069 Residual Fuel Oil Import Forecast	116
65	Global Insight U.S. Residual and Distillate Fuel Oil Import Demand Forecasts	116
66	SNWW Gasoline Import Forecast	118
67	SNWW Petroleum Coke Exports, Forecast Scenarios	122
68	SNWW Gasoline Export Forecast Scenarios	125
69	SNWW Distillate Export Forecast Scenarios	128
70	SNWW Coastwise Movement Forecast Scenarios	130
71	Distribution of Liquefied Natural Gas Operational Capacity	136
72	U.S. and SNWW Liquefied Natural Gas Imports, 2005–2030	138
73	SNWW Liquefied Natural Gas Trade Route Forecast, 2019–2069	138
74	Beaumont Bulk Grain Exports and Percentage by Grain Type	139
75	Beaumont Wheat Exports by Destination, 1998–2006	142
76	Beaumont Wheat Export Forecast, 2004–2069	144
77	Beaumont Bulk Grain Exports to Ports with Channel Depths over 40 Feet	145
78	Importers of Wheat (USDA Forecast), 2004/2005 to 2015/2016	146
79	SNWW Bulk Commodities Forecast, 2019–2069, 2001–2007 Historical Data	147
80	Port Arthur Tonnage Evaluated for Channel Deepening	148
81	Beaumont Tonnage for Major Commodity Groups	149
82	Tanker Characteristics and Hourly Operating Cost, Double-Hull Tankers, December 2008 IWR Release	150

83	Dry Bulk Carrier Characteristics and Hourly Operating Cost, Foreign Flag Dry Bulk Carriers, December 2008 IWR Release	151
84	Liquefied Natural Gas Carriers Characteristics and Hourly Operating Cost.....	151
85	SNWW Mileage Points.....	154
86	Neches River Turning Basin and Anchorage Features.....	155
87	Neches River Inbound Vessels by Destination, Existing Base.....	157
88	SNWW HarborSym Model Vessel Classes.....	161
89	SNWW HarborSym Model Framework.....	162
90	HarborSym Vessel Classes.....	163
91	SNWW 2000/2004 Tonnage	164
92	Sabine-Neches Waterway 2000/2004 Trips.....	164
93	SNWW 2030/2040 Tonnage	165
94	SNWW 2030/2040 Vessel Trips Without Deepening.....	165
95	SNWW 2030/2040 Vessel Trips With Deepening.....	166
96	SNWW HarborSym Output Annual Savings by Vessel Class, Widening Only	168
97	Sabine Pass Channel and Port Arthur Canal Widening Only Average Annual Benefits	182
98	Sabine Pass Channel and Port Arthur Canal Widening Only Economic Summary Data.....	182
99	Neches River Proposed Turning Basin Anchorages.....	184
100	Neches River Anchorage Basins.....	187
101	Average Annual Cost, Transportation Savings Benefits, Net Excess Benefits, and Benefit to Cost Ratios (No Shifting Charges).....	188
102	Average Annual Cost, Transportation Savings Benefits, Net Excess Benefits, and Benefit to Cost Ratios (Shifting Charges 100% of the Time).....	189
103	SNWW Neches River Anchorage Analysis Basins 1, 4, and 8, Economic Summary Data.....	191
104	Adjustments for Estimating Actual Vessel Capacity	192
105	Representative Round-Trip Mileage to SNWW.....	192
106	Transportation Cost Calculation (South America to SNWW)	193
107	SNWW Facilities Associated with Draft-Constrained Vessels by Channel Reach, Mileage Point, Facility Name, Major Commodity, and Cross Section Reference	194
108	SNWW Crude Petroleum Imports by Port and Trade Route, 2019–2069.....	195
109	SNWW Foreign Flag Tanker Vessel Application Maximum Cargo by Vessel Size and Channel Depth.....	197
110	Number of Shuttle Vessels Needed by Channel Depth Alternative	198
111	SNWW Crude Petroleum Imports Transportation Cost and Savings Most Likely Transportation Mode Trade Route and Channel Depth.....	199
112	SNWW Crude Petroleum Imports, Lightening Cost Per Ton by Channel Depth and Trade Route	200
113	SNWW Crude Petroleum Imports Lightered Cost per Ton by Channel Depth and Trade Route	200
114	Beaumont Crude Petroleum Imports Annual Transportation Savings by Trade Route and Decade, 2019–2069.....	201
115	Port Arthur Crude Petroleum Imports, Annual Transportation Savings by Trade Route and Decade, 2019–2069.....	202
116	SNWW Petroleum Product Imports, 2019–2069	203
117	SNWW Petroleum Product Exports, 2019–2069	204
118	SNWW Chemical Product Imports, 2019–2069	205
119	SNWW Chemical Product Exports, 2019–2069	205
120	Beaumont Petroleum and Chemical Product Imports and Exports Annual Transportation Cost by Trade Route and Decade, 2019–2069	206

121	Port Arthur Petroleum and Chemical Product Imports and Exports Annual Transportation Cost by Trade Route and Decade, 2019–2069	207
122	SNWW Petroleum and Chemical Products Annual Savings by Channel Depth Alternative, 2019–2069	208
123	SNWW Petroleum Product Coastwise Shipments and Receipts Vessel Data, Base Tonnage, and Transportation Savings Benefit Summary	209
124	Beaumont Wheat Exports, Shipments to Europe, Mediterranean, and Far East Total Cost Per Ton by Channel Depth	210
125	Beaumont Wheat Exports and Annual Transportation Costs	211
126	Beaumont Wheat Annual Transportation Savings, 2019–2069	211
127	SNWW Steel Slab and Iron Ore from South America and Far East and the Mediterranean Cost Per Ton by Channel Depth	212
128	Port Arthur Steel Slab and Iron Ore from South America, Mediterranean, and the Far East Historical Tonnage and Annual Transportation Cost by Ton	213
129	Port Arthur Steel Slab and Iron Ore from South America, Mediterranean, and Far East Tonnage Forecast and Transportation Savings	214
130	Beaumont Steel Slab and Iron Ore from South America, Mediterranean, and Far East Tonnage Historical Tonnage and Transportation	215
131	Beaumont Steel Slab and Iron Ore from South America and Far East and the Mediterranean Tonnage Forecast and Annual Transportation Savings	216
132	Port Arthur and Beaumont Crude Materials Imports and Exports Summary of Recent Historical and Tonnage Forecast	217
133	SNWW Crude Material Imports and Exports Via South America and Far East and the Mediterranean Cost Per Ton	218
134	Port Arthur Limestone and Rock Imports from South America, Mediterranean, and Far East	219
135	Beaumont Limestone and Rock Imports from South America, Mediterranean, and Far East	219
136	SNWW Sulphur and Refractory Material Exports to South America, Mediterranean, and Far East	220
137	SNWW Liquefied Natural Gas Trade Route Forecast, Short Tons	220
138	Liquefied Natural Gas Transportation Cost per Ton by Channel Depth, Vessel Dead Weight Tons, and Shipment Origin	221
139	Total Average Annual Deepening Benefits by Project Depth Alternative	222
140	Total Average Annual Deepening Benefits by Channel Reach and Alternative	223
141	SNWW Economic Summary Data Cost and Benefits by Channel Alternative	223
142	Sabine Pass Channel, Port Arthur Canal, and Sabine-Neches Canal Incremental Analysis Cost and Benefits by Channel Alternative	224
143	Taylor Bayou Incremental Analysis Cost and Benefits by Channel Alternative	225
144	Project Improvements Through Port Arthur (including Taylor Bayou) Cost and Benefits by Channel Alternative	225
145	Neches River Incremental Economic Analysis Cost and Benefits by Channel Alternative	226
146	SNWW Improvements (Excludes Taylor Bayou) Cost and Benefits by Channel Alternative	226
147	Neches River Project Improvements (Excludes Transportation Benefits for All Other Reaches Except the Neches River), Cost and Benefits by Channel Alternative	227

APPENDIX 2

ECONOMIC APPENDIX

1.0 GENERAL

This appendix presents the economic analysis for proposed modifications to the Sabine-Neches Waterway (SNWW). The SNWW project area and the general boundaries of its channel reaches are shown on Figure 1. The existing project is defined by a 40-foot project depth from the Gulf of Mexico offshore entrance channel to Port Arthur and Beaumont and a 30-foot project depth to the Port of Orange. Project alternatives were evaluated based on reductions in transportation costs generated from more-efficient vessel loading and from reductions in vessel delays due to channel deepening and widening. The benefits were calculated for a 2019–2069 period of analysis using Fiscal Year (FY) 2009 Federal Discount rate of 4.375 percent and the deep-draft vessel operating costs contained in the unpublished update to Economic Guidance Memorandum (EGM 08-04). The deepening benefits were calculated using a Microsoft Excel spreadsheet model. The widening benefits were calculated using the HarborSym model. The analyses and computations presented in this appendix are based on data and statistics obtained from personal interviews with industry officials and from analyses of historical data and published trends.

The appendix contains of nine sections. This first section presents general information on channel use and the results of the initial screening, and an overview of the historical traffic base. Section 2 presents evaluation of the major commodity groups. Section 3 presents existing vessel utilization trend data and a casualty assessment. Section 4 presents the commodity and fleet forecasts. Section 5 summarizes total tonnage. Section 6 presents the transportation savings benefit analysis. Section 7 presents a summary of the project benefits and the incremental analysis. Section 8 presents the sensitivity analyses. Section 9 presents an overview of regional economics.

The SNWW terminals include the public marine facilities owned by the ports of Beaumont, Port Arthur, and Orange, as well as the petroleum refineries, chemical plants, and general cargo terminals. Vessels and barges are used to transport crude oil, petroleum products, liquid and dry chemicals, and steel and dry bulk cargo. Deep-draft cargoes are transported from offshore through the Sabine Pass Channel. The Port of Port Arthur's general cargo facilities are located on the Sabine-Neches Canal near mile 32, and its crude petroleum and product terminals are in the Taylor Bayou basin. The Port of Beaumont's public and private docks are located on the Neches River Channel. The Channel to Orange intersects with the Gulf Intracoastal Waterway (GIWW) at the east end of the SNWW. Improvements to the Channel to Orange were not evaluated due to the expectation of low utilization of the existing project depth. In addition to its large volume of deep-draft traffic, the Sabine-Neches Canal serves as a through channel for the GIWW. The GIWW extends from Apalachee Bay, Florida, to Brownsville, Texas, and connects with the SNWW at approximately 3 miles below Orange and then follows the Sabine River and Sabine-Neches Canal to the head of the Port Arthur Canal where it exits the SNWW and continues westward to Galveston Bay. Distributions of SNWW's port-specific deep-draft and shallow-draft tonnage are displayed in Table 1.

a/ Includes intraport movements.

An initial array of project alternatives was identified during the screening analysis. The screening results were presented at the May 2001 Feasibility Scoping Meeting. For the screening, channel-deepening benefits were calculated for 43, 45, 47, 48, 50, 52, and 55 feet. The results showed that the 50-foot channel depth produced the highest net excess benefits. The results also showed that the net excess benefits for 50 feet were only slightly higher than for 48 feet. Incorporation of later traffic data and improved cost estimates continued to indicate that the maximum net excess benefits were in the 48- to 50-foot range. Channel deepening was proposed by industry as a means to allow the existing fleet to be loaded more fully, reduce per ton transportation costs for vessels using the waterway, and allow for reductions in the number of annual vessel trips.

Identification of the channel-widening alternatives was driven by physical structures along the Neches River and Sabine-Neches Canal and the Port Arthur Hurricane Protection Levee in the Sabine-Neches Canal reach. Delays prompted by transit restrictions are a major concern under existing conditions and will continue to be a concern under the without-project future. As part of plan formulation, the Neches River anchorage basins were introduced as an alternative to widening of the Neches River Channel. The anchorages would be used to facilitate vessel passing. During the initial screening, extensive and intermittent widening was evaluated for the channel reaches from Sabine Pass Channel inland through the Neches River Channel. Widening of the Neches River was eliminated from consideration based on comparison of anticipated reductions in vessel delay costs and initial project construction cost estimates, and from the outputs of the Engineer Research and Development Center (ERDC) ship simulation modeling. Widening of the Neches River reach was found not to be a cost-effective alternative due to the costs associated with dock relocations and extensive dredging. Additionally, intermittent widening of the Neches River Channel did not perform well during ERDC ship simulation modeling. In comparison, the Neches River anchorages and Sabine Pass Channel and Port Arthur Canal widening features performed

favorably. The results of the ERDC modeling showed that a minimum width of 700 feet through the Sabine Pass Channel and Port Arthur Canal would be necessary for the Suezmax and Aframax vessels presently using the waterway to meet smaller vessels in the Sabine Pass Channel and Port Arthur Canal. Aframax tankers characteristically range from 90,000 to 120,000 dead weight tons (DWT), and Suezmax tankers characteristically range from 135,000 to 175,000 DWT. The project design vessel is an 899-foot-long, 164-foot-wide 158,000 DWT Suezmax crude petroleum tanker. ERDC testing of a 600-foot channel width alternative showed that neither a loaded or ballast design vessel was successful in meeting a comparably sized vessel, nor could the design vessel and a smaller 110,000 DWT Aframax tanker meet. In 2007, there were over 2,000 piloted vessels. The largest sized vessels using the channel to Port Arthur are Aframax tankers. The largest sized vessels using the Neches River Channel to Beaumont are Suezmax tankers. Sixty percent of piloted vessels shipped or received cargo from docks on the Neches River. Of the remaining 40 percent, 39 percent were associated with Port Arthur and the remaining 1 percent with the Channel to Orange.

Table 2 shows the existing channel dimensions. Channel width inside of the Sabine Pass Jetty Channel ranges from 400 to 500 feet except for reaches containing turning basins. The without-project future will continue to be defined by the channel dimensions shown in Table 2.

Table 2
Existing SNWW Channel Dimensions

Channel Reach	Authorized Depth (feet)	Bottom Width (feet)	Length (miles)
Sabine Bank Channel	42	800	14.7
Sabine Pass Outer Bar Channel	42	800	3.4
Sabine Pass Jetty Channel	40	800–500	4.0
Sabine Pass Channel	40	500–1,133*	5.6
Port Arthur Canal	40	500–1,788*	6.2
Sabine-Neches Canal	40	400–1,060*	11.3
Neches River Channel	40	400	18.6
Channel to Orange	30	200	14.1

* This reach contains an existing turning basin.

The SNWW is currently subject to navigation constraints, including one-way and daylight-only sailing rules. The pilot rules are summarized in Table 3. The transit rules and associated restrictions are agreed upon by the shipping industry, supported by the U.S. Coast Guard (USCG) Captain of the Port Orders under the Ports and Waterways Safety Act of 1978, as amended, and administered by the Sabine Pilots Association (SPA). These voluntary rules were agreed upon by the Sabine shipping industries and the SPA, and supported by USCG Captain of the Port Orders under the Ports and Waterways Safety Act of 1978, as amended. The agreement, dated January 12, 1981, will remain in force until the Sabine shipping industries, SPA, and USCG agree to its revision or modification. Liquefied natural gas (LNG) vessels are subject to additional rules. LNG vessels using the SNWW would be subject to strict USCG regulations and to local pilot rules and, therefore, will not have the opportunity to meet other vessels or barges. The USCG regulations require that a safety zone is in place 2 miles ahead of a loaded LNG vessel and 1 mile astern of the vessel while transiting. LNG vessels using the SNWW would be subject to this rule. Even in the absence of the safety concerns inherent to LNG, the beams of LNG tankers would result in vessel-meeting restrictions; however, all LNG vessel movements will be subject to one-way traffic. Operation of the LNG terminals is part of the without-project future.

Table 3
SNWW Pilots Rules

General: Vessels 85,000 DWT or over, or greater than 875 feet in length and 125 feet in beam width will move during daylight hours only above the Texas Island intersection with the GIWW West. In the event that meeting situations are applicable but circumstances will not permit the utilization of turning basins, the following criteria will prevail:

1. Vessels with combined beam widths that equal or exceed one-half of the channel width will not meet day or night.
2. Vessels $\geq 85,000$ DWT will not meet vessels of either $\geq 30,000$ DWT or ≥ 2 -foot draft above the Texas Island intersection.
3. Vessels $\geq 85,000$ DWT will not meet vessels of either $\geq 30,000$ DWT or ≥ 30 -foot draft above buoys 29 and 30.
4. Vessels 48,000 metric DWT or more with a draft of 30 feet or more will not meet above buoys 29 and 30.
5. Vessels with a combined draft of 70 feet or more will not meet between the Neches River intersection and Day Beacon #40 (Smith Bluff) at night. Vessels with a combined draft of 65 feet or more will not meet above Day Beacon #40 at night.

Source: SPA (2008) <http://www.sabinepilots.com/guidelines.htm>.

Non-LNG vessels utilizing the waterway are wider than those using the channel even 5–10 years ago. Due to wider beams and the difficulty associated with handling an increasing number of larger vessels, the Sabine Pilots would not consider relaxing the transit rules without structural modifications of the channel. Widening the channel up to the Taylor Bayou junction will result in a relaxation of the pilot rules as vessels will have an additional 200 feet of channel (i.e., the existing channel width is 500 feet and the with-project width for the Sabine Pass Channel and Port Arthur Canal, which leads up to Taylor Bayou, will be 700 feet). The expectation for the with- and without-project future is that pilot rules will continue to limit the possibility of vessel-to-vessel and vessel-to-tow meetings in the Sabine-Neches Canal reach and that both vessel and shallow-draft tow movements will be scheduled through both vessel traffic service (VTS) and communication between vessel pilots.

An anticipated effect of the alternative that includes widening the Sabine Pass Channel and Port Arthur Canal to 700 feet would be to allow a higher percentage of vessels presently affected by the 50 percent combined beam rule in the 500-foot reach to meet in the proposed 700-foot reach. The pilots are uncertain as to the effect that widening will have on the other rules and are reluctant to speculate on how these rules might be relaxed if the channel was deepened and widened. For a “widening only alternative,” rules 2 and 3 would be relaxed (see Table 3). For purposes of analysis, the only rule that would change if the channel were deepened and widened is the combined beam rule. The effect of relaxing the remaining two rules is expected if the channel was widened but not deepened. An increase in channel width to 700 feet would allow a higher percentage of vessels to meet in the proposed 700-foot reach. The effect of channel widening on Rule 1 would be that a larger number of wider beam vessels would be able to meet in the Sabine Pass Channel and Port Arthur Canal reaches. Rule 2 would not change meeting and passing restrictions in the Sabine-Neches Canal. The Sabine-Neches Canal is common to the GIWW. Safety concerns associated with the Sabine-Neches Canal reach provided the impetus for Port Arthur’s selection as one of 28 ports selected for participation in the 1999 Vessel Traffic Management (VTM) workshops and the subsequent implementation of the VTM service in the early 2000s.

The screening analysis included assessment of nonstructural alternatives. Nonstructural alternatives include the existing Louisiana Offshore Oil Port (LOOP); reactivation of the Beaumont Offshore Oil Terminal (BOOT) permit; and participation in the August 2008 Texas Offshore Oil Port System (TOPS) initiative. The SNWW ports presently receive approximately 1 percent of daily refinery input through LOOP. Extensive pipeline expansions to LOOP would be necessary to accommodate a higher percentage of SNWW’s crude petroleum throughput requirements, as SNWW’s capacity is close to LOOP’s capacity. Expansion is not under consideration by the LOOP stakeholders. While LOOP expansion was not considered for the SNWW without-project future base, the effect of a without-project future that includes utilization of offshore terminals was evaluated in the sensitivity section of this appendix (Section 8). The BOOTS project, which would be offshore from Beaumont, was announced in 2002. The BOOTS regulatory permit application is presently inactive, and the USCG has not received an update to the proposal since 2002. The TOPS initiative was announced in 2008. TOPS would be located offshore from Freeport (Texas) and would serve Port Arthur, Texas City, and Houston. Freeport is located on the Texas Coast southwest of the SNWW. As with BOOTS, TOPS would require construction of a pipeline from

offshore. The existing Seaway pipeline from Freeport to Texas City would be used as part of TOPS. The connection to Port Arthur from Texas City would necessitate a new pipeline extending approximately 95 miles. A March 2009 press release revealed that the Port Arthur participant, Motiva, put its participation on hold based on uncertainty associated with future crude petroleum import volumes and trade routes. The large fixed cost of offshore terminal construction requires high volumes of very large crude carriers (VLCCs) utilization in order to achieve a return on the investment. If constructed, industry indications are that TOPS and BOOTS would not serve as the exclusive supplies, just as LOOP is not the exclusive supplier for the Louisiana markets. The SNWW without-project future is based on the assumption that offshore port alternatives are not constructed. Current expectations are that regional crude oil imports will increase at lower rates in comparison to those experienced through the 1990s and into the early 2000s. The effect of a without-project future that includes utilization of offshore terminals is evaluated in the sensitivity section of this appendix.

An additional alternative is construction of a crude oil terminal in Port Arthur below Texas Island on the Sabine-Neches Canal, northeast of its junction with the GIWW. Port Arthur's existing petroleum terminals are located in the Taylor Bayou basin. The Taylor Bayou basin is immediately northwest of Texas Island. Construction of a new terminal in Port Arthur would divert crude petroleum import tonnage from the Neches River Channel to Beaumont. A new landside terminal on the Port Arthur Canal and the offshore alternatives remain uncertain; therefore, the effects of these alternatives on the 2019–2069 tonnage forecast was evaluated in the sensitivity section of this appendix.

The large volume of tow-barges using the Sabine-Neches Canal reach, along with a high flow of deep-draft traffic, compound congestion and prompted interest early in the study process of evaluation of a barge shelf through the canal reach between the east and west junction with the GIWW. Initial responses to the barge shelf alternative revealed large variance in expectations about its potential effects, with some tow operators questioning the usefulness of the proposed project feature. In 2005, the Gulf Intracoastal Canal Association (GICA) withdrew support for the barge shelf. While mixed concerns about the functionality of the proposed feature contributed to GICA's decision, the decision was primarily based on anticipated and continued success of the VTM as a nonstructural alternative. Additionally, and as part of the VTM initiatives, improved deep-draft and barge vessel communication initiated by the USCG and user safety board activities were noted by the USCG to have resulted in improved safety. Ongoing improvements to the VTM system are expected to result in accelerated safety and communication improvements. These nonstructural initiatives made by the USCG, Sabine Pilots Association, and GICA represent nonstructural alternatives to the barge shelf. The expectation for the with- and without-project future is that pilot rules will continue to limit the possibility of vessel-to-vessel and vessel-to-tow meetings in the Sabine-Neches Canal reach and that both vessel and shallow-draft tow movements in this reach will be scheduled through both VTM and communication between vessel pilots.

1.1 COMMODITY OVERVIEW

The SNWW tonnage experienced strong overall growth from the middle 1990s through 2007, with total tonnage increasing from an average of 108 million short tons for 1995–1997 to 138 million for 2005–2007. In 2007, tonnage totaled nearly 141 million short tons, and the waterway ranked 4th in the U.S. in terms of total tonnage and first in the Nation in crude oil imports. As individual ports, Beaumont ranked 5th in the nation with 81.4 million short tons. Port Arthur’s 2007 tonnage totaled 29.3 million short tons with a national ranking of 28th. Channel to Orange tonnage totaled 682 thousand short tons in 2007. Tonnage for the three ports totaled approximately 111 million short tons. The remaining 30 million short tons of the 141-million-short-ton total consist of shallow-draft barge cargo. Table 4 presents SNWW 1970–2007 total tonnage and principal deep-draft movements. Approximately 60 percent of the SNWW tonnage consists of deep-draft movements. The remaining 40 percent consists of shallow-draft GIWW-related traffic. Table 5 displays Sabine-Neches Canal 1970–2007 shallow-draft GIWW tonnage section and the relative percentage of shallow-draft to total tonnage. In 2007, nearly 30 million short tons of the 59.7 million short tons of shallow-draft barge tonnage using the waterway were transported through SNWW port facilities. Beaumont’s shallow-draft barge tonnage totaled 21.2 million short tons, Port Arthur’s 8.3 million short tons, Orange’s 0.7 million short tons, and Sabine Pass 0.9 million short tons. The remaining 30.3 million short tons of 2007 shallow-draft barge traffic consisted of “through movements” between ports such as those on the Lower Mississippi River, Houston, and the GIWW west of Houston. In reviewing trends for commodities presently or anticipated to be constrained, the initial focus was on the commodity groups displayed in Table 4.

Distributions of Port Arthur and Beaumont’s 1999–2007 tonnages are displayed in tables 6 and 7. Port specific data for years prior to 1999 are not included in these tables due to U.S. Army Corps of Engineers (USACE) Navigation Data Center (NDC) reporting problems which resulted in a portion of Beaumont’s tonnage being attributed to Port Arthur. Crude petroleum imports and petroleum and chemical product imports and exports comprised 80 percent of Port Arthur’s 2007 total oceangoing tonnage. The 1999–2007 average was 83 percent. Port Arthur crude petroleum imports remained relatively flat since 2001 but steady. Port Arthur refinery capacity in 2009 is nearly 13 percent higher than in 2004, with additional expansions scheduled. Motiva announced plans for a 325,000 barrel-per-day (BPD) refinery expansion in Port Arthur in December 2007. Construction on the refinery expansion is presently taking place.

As shown in Table 6, Port Arthur’s highest and most significant growth rates were for petroleum product exports and domestic coastwise, with overall tonnage growing at relatively steady rates. Analysis of the commodity-specific data showed that 81 percent of Port Arthur’s 2005–2007 petroleum product exports were comprised of petroleum coke. Port Arthur’s petroleum coke exports constitute 11 percent of the U.S. total, up from 3 percent for the early 1990s. Port Arthur’s 2005–2007 chemical exports also experienced significant increases. Port Arthur’s chemical export growth is attributable to significant gains in metallic salts and hydrocarbons exports. Twenty percent of U.S. 2005–2007 metallic salts exports were shipped from Port Arthur. Metallic salts and organic compounds are used in the production of paints and solvents, paper and wood products, cleaning products, and various chemical products, and more recently in the

production of nylon in Latin America and China. Increases in Port Arthur's metallic salt exports since 2004 are associated with the completion of a 266,000 metric-ton-per-year cyclohexane facility in the Taylor Bayou section of Port Arthur in early 2004.

a/ Includes intra-port movements.

As shown in Table 6, Port Arthur's commodity movements other than petroleum and chemicals include crude materials, which consist of 513,000 short tons of limestone, sand, and gravel. For 1999–2007, crude material volumes averaged nearly 500,000 short tons annually. Port Arthur's crude material facilities are located on the Sabine-Neches Canal near mile 32, and its crude petroleum and product terminals are in the Taylor Bayou basin.

Port Arthur's steady volume of coastwise tonnage shown in Table 6 is associated with continuing shipments of gasoline, distillate fuel oil, and petroleum coke between Port Arthur and other deep-draft U.S. ports. Approximately 39 percent of tonnage is shipped to Florida's Atlantic Coast, 34 percent to Florida's Gulf Coast, 9 percent to Baton Rouge, 6 percent to Houston, 3 percent to Lake Charles, and 2 percent to Corpus Christi. The remaining 7 percent of destinations include Puerto Rico, the U.S. West Coast, and the Northeast.

Examination of Beaumont's tonnage (see Table 7) showed that crude petroleum imports and petrochemical imports and exports composed 89 percent of Beaumont's 2007 total oceangoing tonnage. Four percent of 2005–2007 U.S. fertilizer and fertilizer mixes were exported from Beaumont. For 2005–2007, the Beaumont share of potassic fertilizer exports increased to 12.5 percent of the U.S. fertilizer export total, up from 1 percent prior to 2001. Beaumont's other commodity movements include grain exports, coastwise shipments of gasoline and liquid sulphur, and imports and exports of crude materials and manufactured goods. The latter groups comprise approximately 7 percent of Beaumont's deep-draft tonnage. Beaumont's crude material imports, which include limestone, sand, and gravel, comprised 1 percent of the 2005–2007 average U.S. total. Beaumont's imports of manufactured goods for 2005–2007 consisted of 336,000 short tons of iron and steel products, representing 1 percent of the U.S. total. Coastwise shipments for 2005–2007 averaged 2.4 million short tons and included 1.3 million short tons of gasoline and 720,000 short tons of chemicals. Liquid sulphur composed 85 percent of coastwise chemical shipments. For the period 1998–2007, sulphur shipments ranged from a low of 506,000 short tons in 2004 to a high of 679,000 in 2001. In 2007, Beaumont's sulphur shipments totaled 553,000 short tons.

While the initial screening focused on crude petroleum imports, interest in channel deepening alternatives was found to include aggregate, bulk grain, chemicals, and LNG. During the early 2000s, LNG permits were approved for the Cheniere Sabine Pass, Golden Pass (Exxon Mobil), and Semptra terminals. Cheniere opened its terminal in April 2008. Receipt of "commissioning cargo," which is used to chill the tanks and keep the natural gas in its liquefied state, occurred in 2008. Since opening, throughput has been low due to increased demand in other parts of the world. The effect of competing demand drove up LNG prices on the world market, with other countries willing to pay more than we are for LNG, little is being shipped to the U.S.¹ Japan imported much higher than anticipated volumes of LNG to fuel peaking plants after the summer of 2008 earthquake shut down most of the country's nuclear power generation. Tentatively there are short-term plans to export LNG from the Sabine Pass LNG import terminal in Louisiana. In a July 2009 press release, the U.S. Energy Information Administration (EIA) noted that expectations in 2010–2012 are for prices to stabilize and shipments to the U.S. to increase. Cheniere presently has three storage tanks built and another two under construction. Construction of the Exxon Golden Pass LNG terminal is scheduled for completion in 2011. Its schedule was delayed due to ongoing Hurricane Ike cleanup activities along with the unexpected surge in Japanese demand for LNG. Construction of the third permitted facility, Semptra, is anticipated after 2012. The three LNG sites are located in the Sabine Pass Channel and Port Arthur Canal reaches; these reaches are presently 500 feet wide and will remain so under the without-project future

As indicated, the EIA raised its projections for liquefied natural gas imports in July 2009, citing falling long-term demand elsewhere as new global production comes online. The EIA noted that U.S. LNG imports are expected to increase from 350 billion cubic feet (Bcf) in 2008 to about 480 Bcf in 2009 and 650 Bcf in 2010.² It was also noted that the U.S. tends to be the LNG market of last resort as producers send LNG to the higher-paying Asian and European markets first, adding that global LNG demand and prices have begun to decline 2009, potentially leaving more LNG for the U.S. whose extensive storage

¹ *Beaumont Enterprise*, "Sabine LNG Filing Tanks Up," June 28, 2009.

² USDOE, Short-Term Energy Outlook, EIA, June 9, 2009.

and pipeline network means it can absorb LNG even at times of low demand. Added effects expected to result in increases in U.S. LNG imports are new production projects coming online in Russia and Qatar late in 2009. Expectations through 2011 are for completion of projects in Yemen and Indonesia. The LNG projection is subject to considerable uncertainty, while noting that initial production from new liquefaction capacity has been slowed or delayed for extended periods.

The remainder of this section presents additional detail on breakbulk foreign imports and exports and coastwise commodities. SNWW's breakbulk commodities of wood products, iron ore, limestone, and rock fall within the classification of manufactured goods. Figure 2 displays SNWW's established base of import and export tonnage by major commodity group.³ Petroleum and chemical product imports and exports, breakbulk imports and exports, and bulk grain exports are shown. Tonnage increased for all groups except grain. In spite of declines, grain exports have increased marginally since the middle 1990s, and Beaumont's 2005–2007 wheat exports represent 5 percent of total U.S. wheat exports. The U.S. Department of Agriculture (USDA) shows 909 million bushels of wheat exports for the 2006–2007 crop-year, and 1,150 million bushels for 2007–2008. The USDA forecasted a constant export level of 950 million bushels for 2008–2009 through 2017–2018.⁴

Figure 3 provides a detailed display of SNWW's major breakbulk tonnage. With the exception of wood and related product exports, which decreased at an average annual rate 9.5 percent, overall breakbulk volumes increased from 1990 to 1992 through 2005 to 2007. Iron and steel imports grew at an average annual rate of 8.8 percent. Limestone and rock imports increased at a rate of 6.3 percent. Wood product imports increased at an annual rate of 31.7 percent.⁵ While 2005–2007 breakbulk volumes are up from the early nineties, 2007 tonnage was down. Approximately 60 percent of 2005–2007 combined imports and exports of breakbulk are transported through Port Arthur, and the remainder through Beaumont. Imports of iron and steel products and limestone and rock materials compose the majority of current breakbulk tonnage.

³ Data for the years prior to 1999 are not presented for the individual ports. The Bureau of Census data contained in the *Waterborne Commerce of the United States* does not reflect correct allocation of Port Arthur and Beaumont traffic between the ports. Some of Beaumont's traffic was recorded under Port Arthur due to a Bureau of Census error. Total tonnage values were found to be correct for the SNWW, but the individual counts for years prior to 1999 were found to be unreliable.

⁴ USDA, *USDA Agricultural Projections to 2017*, Long-term Projections Report OCE-2008-1, February 2008, p. 40.

⁵ The average annual growth rates for period such as 1990/1992 to 2005/2007 was calculated based on 15 years. The 1990/1992 to 2005/2007 averages were used as inputs.

Figure 2
SNWW Foreign Imports and Exports by Major Commodity Group
(Excluding Crude Petroleum)

Figure 3
SNWW Breakbulk Imports and Exports
1989/1991 to 2004/2006 Distribution

Source: USACE, *Waterborne Commerce of the U.S., Part 2, 1990–2007*.

Iron ore and rock materials increased dramatically from the early 1990s. Approximately 55 percent of 1999–2007 limestone and rock imports were shipped to Beaumont and the remainder to Port Arthur. SNWW aggregate tonnage primarily consists of imports of limestone, rock, and other raw building materials. For the period 2002–2007, 3.2 percent of U.S. limestone and rock imports were transported through the SNWW ports.

Approximately 62 percent of 1999–2007 iron and steel product imports were transported through Port Arthur and the remainder to Beaumont. While down in 2007, an average of 2.5 percent of 2002–2006 U.S. iron ore and steel slab imports were transported through the SNWW ports. For the period 2002–2007, imports ranged from a low of 240,000 short tons in 2007 and a high of 1.1 million short tons in 2005. SNWW wood and product imports primarily consist of pulp and waste paper, with the waterway importing 14 percent of 2005–2007 U.S. pulp and waste paper products.

Coastwise tonnage consists almost exclusively of petroleum and chemical commodities. Figure 4 shows SNWW's 1980–2007 coastwise tonnage. The dramatic declines in coastwise product shipments experienced in the 1980s resulted from the transition from domestic production of crude petroleum to imports.

Figure 4
SNWW Coastwise Shipments and Receipts

Since the mid-1990s coastwise tonnage has been relatively steady, with some modest increases in recent years. Petroleum product shipments represented 67 percent of 2005–2007 tonnage, petroleum product receipts 22 percent, and the remaining 11 percent represented chemical shipments. Figure 5 displays SNWW's 1990–2007 coastwise petroleum product shipment averages by major commodity classification.

Figure 5
SNWW Coastwise Shipments and Receipts
by Major Commodity Group

Shipments consist of gasoline, distillate fuel oil, residual fuel oil, lube oil, and petroleum coke. Gasoline and products are shipped to the U.S. East Coast, specifically eastern Florida. Figure 6 displays Beaumont's and Port Arthur's petroleum product port shares for 1999–2007. As noted, 11 percent of SNWW coastwise tonnage consists of chemical shipments. Analysis of total chemical shipments showed that Beaumont shipped 95 percent of 1999–2007 chemical coastwise tonnage and Port Arthur the remaining 5 percent. Liquid sulphur constituted 75 percent of outbound shipments and contributed to a 95 percent increase in SNWW chemical shipments since the early 1990s. All of SNWW sulphur is shipped from Beaumont, with nearly all movements going to Florida. Figure 7 displays Beaumont's and Port Arthur's port shares for 1999–2007 chemical products.

Figure 6
Port Arthur and Beaumont
Outbound Coastwise Gasoline Shipments

Outbound Chemical Shipments

2.0 DETAILED COMMODITY ANALYSIS

This section presents detailed analyses of the major commodity groups currently or anticipated to be transported in larger vessels. Data obtained from vessel operators and ongoing analyses of SNWW trends and commodity-specific world and regional fleet data indicated that a portion of these commodities are limited by the constraints of the existing and the without-project future channel dimensions. The analyses address crude petroleum, petroleum products, chemical products, grain, aggregate, and LNG, with crude petroleum representing the most significant group.

2.1 CRUDE PETROLEUM

There are 20 waterfront facilities in Port Arthur and 27 in Beaumont that receive and/or ship crude petroleum or petroleum products. The SNWW refineries supply crude oil to the U.S. Department of Energy's (USDOE) "Big Hill Site" in Texas and the "Hackberry Site" in Louisiana Strategic Petroleum Reserve (SPR). The SNWW is the primary means of delivery for crude oil to four refineries in Beaumont and Port Arthur. Beaumont and Port Arthur each have two oil refineries, and the four refineries serve four terminals on the Neches River. Two of the Neches River terminals are connected by pipelines to the USDOE Strategic Petroleum Reserve underground storage units. The Motiva and Valero refineries are in Port Arthur in the Taylor Bayou basin. Motiva has a vessel terminal in the Taylor Bayou basin and another terminal on the Neches River. The Total Petrochemicals and ExxonMobil refineries are on the Neches River. Additional crude oil terminals located on the Neches River include BASF-Fina, Sun Oil, and Chevron-Phillips. The Neches River crude petroleum tankers accommodate Suezmax tankers.

The SNWW is contained in the U.S. Gulf Coast Petroleum Administration Defense District (PADD III). PADD III includes the states of Texas, Louisiana, Arkansas, Mississippi, Alabama, and New Mexico. SNWW's 2002–2006 crude petroleum waterborne imports composed 12 percent of U.S. and 18 percent of PADD III imports. Table 8 displays SNWW crude petroleum imports and the waterway's share of the national and regional totals for 1990–2007, and Table 9 displays the port-specific shares for 1998–2007.⁶ Figure 8 shows the U.S. PADD boundaries. SNWW's crude petroleum imports represent 4 percent of the U.S. total and 7 percent of the U.S. Gulf Coast PADD III region. Figure 9 shows the regional SPR sites served by the SNWW terminals.

⁶ Data for the years prior to 1998 are not presented for the individual ports. The Bureau of Census data contained in the *Waterborne Commerce of the United States* does not reflect correct allocation of Port Arthur and Beaumont traffic between the ports. Some of Beaumont's traffic was recorded under Port Arthur due to a Bureau of Census error. Total tonnage values were found to be correct for the SNWW, but the individual counts for years prior to 1999 were found to be unreliable.

SNWW's capacity represents six percent of the U.S. total. Specific capacity is 572,000 BPD for Port Arthur and 577,000 BPD for Beaumont. SNWW capacity levels for 2009 are presently 12 percent higher than in 2004 and 31 percent higher than in 1994. The Motiva expansion is presently under construction and will increase the refinery's crude oil throughput capacity to approximately 600,000 BPD, making it the largest refinery in the U.S. and one of the largest in the world. The ExxonMobil Beaumont refinery is presently the third largest refinery in the world. As a result of these additions, SNWW's combined capacity will represent the largest concentration in the State of Texas.

Figure 8
U.S. Petroleum Administration Defense Districts

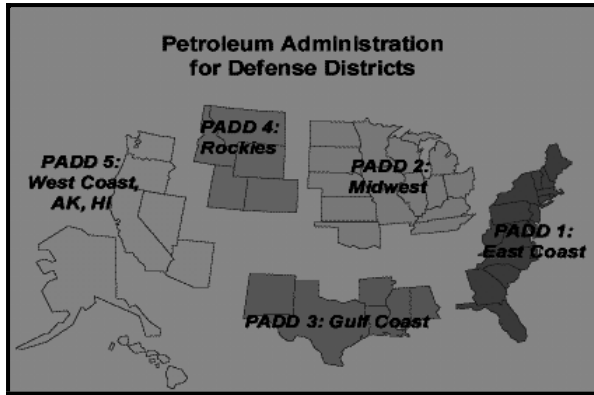

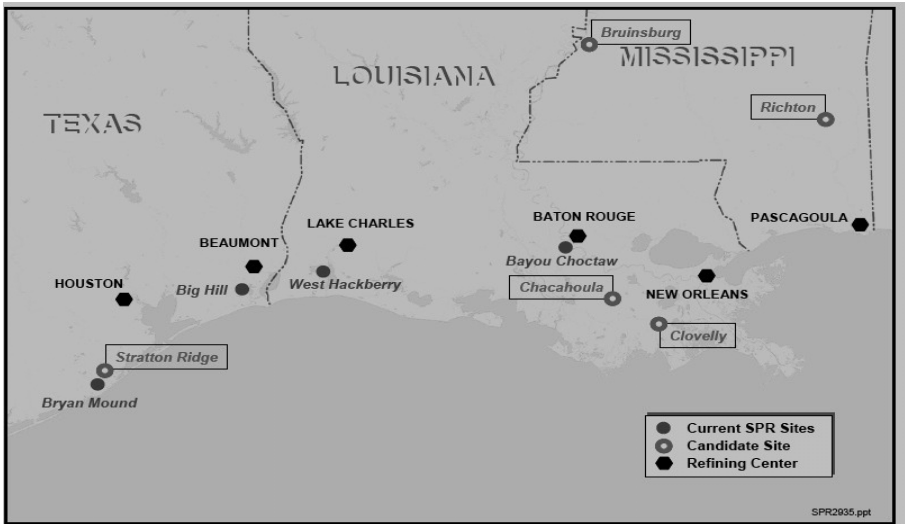

Figure 9
U.S. Strategic Petroleum Reserves Gulf Coast Sites

The amount of crude petroleum imported into the SNWW is largely dependent upon the area's capacity to refine crude and/or deliver pipeline by to other refining complexes. Table 10 displays regional crude petroleum refinery capacity data. In addition to supplying oil to two the USDOE SPR sites, the SNWW system delivers crude to refineries in Texas, Louisiana, Oklahoma, Ohio, Arkansas, and Kentucky. Examination of the refinery capacity data presented in Table 10 shows that the SNWW's 2002–2007 crude petroleum import volumes do not exceed crude petroleum refining capacity. Recent refinery expansions and anticipated new refinery construction prior to 2020 indicates that added capacity will be sufficient to meet anticipate crude petroleum import volumes.

Table 10
SNWW Atmospheric Crude Oil Distillation Capacity
(1,000s of Barrels Per Calendar Day)

Period	Beaumont	Port Arthur	Percent of Texas	Percent of U.S.	U.S. Total

* Variations occur in annual volumes due to temporary shutdowns and routine maintenance.

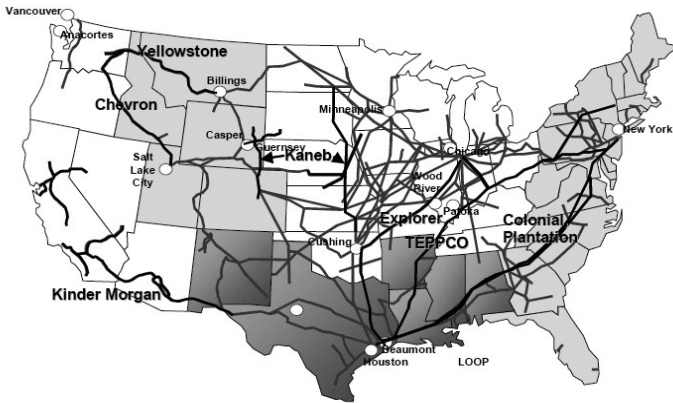

The Port Arthur and Beaumont terminals transport 400,000 barrels per day of waterborne crude oil via pipelines to inland refineries including refineries in Texas, Louisiana, Oklahoma, Ohio, Arkansas, and Kentucky.⁷ Colonial Product Pipeline delivers over 2 million BPD of refined products via pipeline serving Louisiana, Alabama, Mississippi, Georgia, Tennessee, South Carolina, North Carolina, Virginia, Maryland, Delaware, and New Jersey. Explorer Product Pipeline delivers 650,000 BPD of refined products via pipeline serving Texas, Oklahoma, Missouri, Illinois, and Indiana. Products, such as gasoline, heating oil, diesel, and jet fuel, are transported from the Gulf Coast to the East Coast and the Midwest through existing pipeline networks. Product traffic also moves between U.S. ports by coastwise tankers and inland waterway barges. The SNWW refineries supply 15 percent of the product on Colonial's system and 13 percent of the product on Explorer's system. The pipeline maps shown on Figure 10 illustrate the distribution that includes the SNWW ports.

Figure 10
Major U.S. Crude Petroleum and Product Pipelines

Major Refined Product Pipelines

Since the 1970s, overall SNWW and U.S. crude petroleum import volumes rose as U.S. crude production fell and was replaced by foreign imports of crude. The U.S. Gulf Coast leads the Nation in refinery capacity, with 41 percent of the Nation's crude oil distillation capacity, and one-half of the Gulf Coast refinery capacity is in Texas and the remainder is in Louisiana. The Gulf Coast is also the Nation's leading supplier in refined products. Figure 11 displays SNWW's 1985–2007 crude petroleum imports and SNWW's share of the national and regional totals. Although SNWW tonnage exhibits more variance than the region and the Nation, long-term expectations are that SNWW imports will grow at rates comparable to or higher than regional and national trends. These expectations are based on analysis of long-term historical trends and the study area's established infrastructure of regional and national pipeline distribution links. Declines in 2005–2007 imports are largely attributable to supply disruptions associated with Hurricane Rita, which devastated the SNWW region in September 2005.⁸ The hurricane surge resulting from Rita resulted in sand bars at the offshore Entrance Channel and silting of the Neches River Channel to Beaumont. Silting of the Neches River Channel severely limited transit of the upper reaches for several months and resulted in tonnage diversions to other ports due to loaded-draft limitations. Aside from pipeline movements and events such as hurricanes, analysis of SNWW's crude petroleum and product tonnages and discussions with industry revealed that the effect of planned maintenance contributes to annual variances. U.S. imports declined marginally in 2006–2007.

While SNWW's 2005–2007 import volumes are down, Figure 11 shows that SNWW imports from 1992 through 2004 grew at higher rates than the region or the Nation. In comparison to other Texas Gulf Coast ports, SNWW 2000–2004 crude petroleum imports volumes exceeded other ports by nearly 35 percent. Additionally, recent increases in SNWW refinery capacity indicate the region will regain an increasing share of U.S. and PADD III totals. As noted, the Motiva expansion is presently under construction and will increase the refinery's crude oil throughput capacity to approximately 600,000 BPD, making it the largest refinery in the U.S. and one of the largest in the world, and the ExxonMobil Beaumont refinery is presently the third largest refinery in the world. The effect of Motiva expansion will result in SNWW's capacity representing the largest concentration in the State of Texas.

⁸ Personal communication, ExxonMobil, Beaumont Office.

Figure 11
U.S. and Sabine-Neches Crude Oil Imports, 1985–2007

2.2 PETROLEUM PRODUCT IMPORTS

Table 11 presents SNWW and the U.S. 1990–2007 petroleum product imports. SNWW imports consist primarily of gasoline, distillate fuel oil, residual fuel oil, and naphtha. Figure 12 displays a comparison of the SNWW and U.S. trendlines. Comparison of the SNWW and U.S. totals indicates a strong level of correlation between the study area and the Nation; however, product types show significant variability. Variability in product volumes is noted to be a function of the demand and the supply of the relative types of crude oil supplied. The EIA notes that the average sulfur content of U.S. crude oil imports increased from 0.9 percent in 1985 to 1.4 percent in 2005. Future expectations are for increasing volumes of high-sulfur crude. Import of a range of crude oil types and spot-market sales result in dynamic market conditions and annual fluctuation in the product imports. For SNWW, high variability is noted for SNWW naphtha and distillate fuel oil. Naphtha is produced as an intermediate product from the distillation of crude oil and is primarily used as feedstock for producing high-octane gasoline. It is also used by the chemical industry for producing olefins in steam crackers. Distillate fuel oil is also a by-product of the refining process, but like naphtha, it is also imported. Variability is also reflected in the distribution of the U.S. products types, which is also characterized by annual fluctuations prompted by conditions where outputs fall short or are preempted by other market drivers.

Figure 13 displays the product yield for six typical types of crude oil. The figure shows both light and heavy crudes as well as sweet and sour crude oils and the associated American Petroleum Institute (API) gravity. The chart provides a comparison of the different output when each crude type is processed in a simple distillation refinery. The chart includes five main product groups: gasoline; propane and butane (C3/C4); Cat feed (a partially processed material that requires further refining to make usable products); distillate (which includes diesel oil and furnace oil); and residual fuel (the heaviest and lowest-valued part of the product output, used to make heavy fuel oil and asphalt).

Table 12 displays Port Arthur and Beaumont petroleum products by major commodity group. Distillate fuel oil represents 50 percent of Port Arthur's 2005–2007 imports, up by approximately 250 percent from the early 2000s. Residual fuel presently represents 23 percent of Port Arthur's product total, with overall imports increasing but to a smaller degree than distillate. The remainder of 2005–2007 imports consists of naphtha (4 percent), gasoline (7 percent), and petroleum coke (10 percent). Port Arthur's product imports dropped in 2006 and again in 2007. These downturns are partially attributable to hurricane-induced channel damages and refinery expansion.

Beaumont's product imports are dominated by gasoline. Gasoline represents 43 percent of Beaumont's 2005–2007 total product import total. Imports totaled nearly 1.1 million short tons in 2007, up from zero in the late 1990s. Beaumont's remaining imports consisted primarily of distillate fuel oil and naphtha. Beaumont's other imports consist of lube oil, residual, and naphtha, with annual volumes exhibiting relatively high degrees of variation.

2.3 PETROLEUM PRODUCT EXPORTS

Table 13 displays SNWW 1990–2007 petroleum product exports. SNWW petroleum product exports primarily consist of petroleum coke, gasoline, and distillate fuel oil. Overall exports increased since the 1990s at a generally steady rate, with exports exceeding 6 million short tons since 2003. Petroleum coke exports dominate total exports and represented 63 percent of 2005–2007 and 14.1 percent of U.S. total petroleum coke exports. Gasoline represented 11 percent of the SNWW total and 16.7 percent of U.S. gasoline exports. Distillate fuel oil represented 5 percent of SNWW total exports and 1.6 percent of U.S. distillate exports. The remaining 21 percent of SNWW exports consisted of lube oil, naphtha, residual fuel oil, and general products. Analysis of the SNWW and national totals indicated a strong level of correlation between the study area and the Nation, with regional growth generally exhibiting higher annual growth rates. Figure 14 provides a comparison of the SNWW and U.S. trendlines, and Figure 15 provides a comparison of regional and national petroleum coke exports.

Table 14 presents Port Arthur and Beaumont product exports by major commodity group. Port Arthur's product imports averaged 4.1 million short tons in 2005–2007. Petroleum coke represented 81 percent of Port Arthur's 2005–2007 exports, with its 2007 share nearly 90 percent. Gasoline represented 11 percent of Port Arthur's 2005–2007 product exports, and distillate 7 percent. The remaining 9 percent consisted of relatively small amounts of lube oil, naphtha, residual fuel oil, and general products. Port Arthur's relative shares of gasoline and distillate fuel oil exports increased over the last 8 years. Port Arthur's 2005–2007 petroleum coke export volumes represented 11 percent of the U.S. petroleum coke total. Overall demand for petroleum coke has been noted to be increasing due to growing use of heavy crude oil. It was noted that the cumulative effect of increasing product demand, tightening crude oil supplies, heavier and coarser crude oil, and constrained refinery capacity has contributed to the need for additional coking capacity.⁹

Large volumes of excess petroleum coke, specifically calcined coke, have historically been exported from Port Arthur existing facilities. Calcined coke is used in production of plastics, as feedstock for continuous particle thermal desulfurization, and for special low-sulfur carbon raiser in steel production.¹⁰ Seven countries received more than 59 percent of U.S. coke exports in 2002. The major importer is Japan, which imports nearly 100 percent green coke and a trace of premium coke. The seven top importing countries use the green fuel-grade coke in their processing industries and as boiler fuel.¹¹ As indicated, world light sweet crude oil supplies are declining, and the refining of heavy oils is becoming a necessity. The refining of these heavy oils dramatically increases the amounts of petroleum waste product that are produced

The Port Arthur coker is used to convert heavy oil at the refinery directly to light products, in a process more typical of the refining process for conventional oils. Chief among methods of conversion is thermal coking, in which heavy oil from a vacuum distillation unit is fed to a heating unit (coker) that splits off lighter hydrocarbon chains and routes them to the traditional refinery units. The almost pure carbon remaining is a coal-like substance known as petroleum coke. The accumulated coke can be removed from

¹⁰ Ellis, Paul J. and Christopher A. Paul, "Tutorial: Delayed Coking Fundamentals," Great Lakes Carbon Corporation, Port Arthur, Texas, March 8, 1998.

¹¹ *Petroleum Coke*, Pacific Mountain Energy Center I-1, September 12, 2006.

the coking vessels during an off cycle and either sold, primarily as a fuel for electricity generation, or used in gasification units to provide power, steam, and/or hydrogen for the refinery. Plans for a new 45,000 BPD “delayed coker” in Port Arthur were announced in February 2008, with construction anticipated to be complete by 2011.¹² Delayed cokers are used to convert residual oils into gasoline and diesel oil. Delayed coker feed originates from the crude oil, and the effect of new construction will be used to produce residual fuel and other products.

Beaumont product exports consist primarily of gasoline and also petroleum coke, with Beaumont gasoline exports representing 13 percent of U.S. total gasoline exports. Beaumont petroleum coke exports represented 3 percent of the U.S. total petroleum coke exports. Beaumont product exports remained relatively steady from 1998 through 2007, with growth exhibited for both gasoline and petroleum coke. Gasoline represented over 55 percent of 2005–2007 Beaumont product exports and petroleum coke approximately 34 percent. The remaining 11 percent of product exports consisted of distillate fuel oil, lube oil, residual fuel oil, and general products.

2.4 CHEMICAL PRODUCT IMPORTS

Table 15 displays 1990–2007 commodity-specific import totals for the SNWW. Distribution of Port Arthur’s and Beaumont’s 1999–2006 chemical imports by major commodity group is shown in Table 16. Examination of Port Arthur’s and Beaumont’s 1999–2006 chemical product shares showed that while Port Arthur’s imports increased, overall tonnage remains relatively low in comparison to Beaumont’s. Beaumont’s 2005–2007 chemical imports averaged nearly 1 million. Increase in Beaumont’s tonnage is primarily attributable to alcohols (methanol or methyl alcohol) and ammonia. For 2005–2007, imports of these two groups averaged 822,000 short tons and represented 83 percent of Beaumont chemical imports. Beaumont imported 16 percent of U.S. alcohol and 6 percent of U.S. ammonia.

The USDA noted that the volatile and upward trend in U.S. natural gas prices from 2000 to 2006 has led to a 17 percent decline in the Nation's annual aggregate supply of ammonia. During the period, U.S. ammonia production declined 44 percent, while U.S. ammonia imports increased 115 percent. Also, the share of U.S.-produced ammonia in the U.S. aggregate supply of ammonia dropped from 80 to 55 percent, while the share from imports increased from 15 percent to 42 percent. Meanwhile, ammonia prices paid by farmers increased from \$227 per ton in 2000 to \$521 per ton in 2006, an increase of 130 percent. Natural gas is the main input used to produce ammonia. Additional increases in U.S. natural gas prices could lead to a further decline in domestic ammonia production and an even greater rise in ammonia imports.

Increases in SNWW methyl alcohol imports are also attributable to global market shifts. Methyl alcohol is used in the industrial production of many synthetic organic compounds and is a constituent of many commercially available solvents; it is noted that, when used as a gasoline additive, it lowers the carbon monoxide emissions but increases hydrocarbon emissions. Information published by SDI Consulting notes that a major shift in regional methanol capacity and production has occurred over the last two

decades.¹³ Countries with large reserves of natural gas and limited domestic consumption have built world-scale methanol facilities to monetize their low-cost natural gas. The largest producing region in 2006 was Central and South America, whereas in 2011, China (northeast Asia) and the Middle East will be the largest producing regions in terms of both capacity and expected production. Overall, world demand for methanol is projected to grow at an average annual rate of just over 5.6 percent from 2006 to 2011, with lower growth expected in the industrialized areas of the world where the markets are mature. As expected, the largest consuming region for methanol in 2011 will be northeast Asia (Japan, China, Republic of Korea, and Taiwan), with 44 percent of world methanol consumption. China will consume 76 percent of northeast Asia's share. As a reflection of its growth potential, it is interesting to note that in spite of its projected methanol capacity in 2011, China will still remain a net importer.

Worldwide, formaldehyde production is the largest consumer of methanol, with 34 percent of world methanol demand in 2007. This demand is driven by the construction industry since formaldehyde is used primarily to produce adhesives for the manufacture of various construction board products. Historically, the major end product has been plywood, but in developed countries, demand is also driven by the expanding use of engineering board products such as OSB (oriented strandboard).

It was noted that the second-largest market for methanol worldwide is methyl tertiary-butyl ether (MTBE). In the U.S., consumption of MTBE increased substantially when the Clean Air Act Amendments of 1990 mandated that oxygenated compounds be added to gasoline as one aspect of a program to alleviate air pollution. In recent years, MTBE use has decreased due to groundwater contamination issues. SDI noted that California, formerly the leading consumer of MTBE, banned the use of MTBE at the end of 2003, and several states followed suit. Methanol use in U.S. MTBE production is cited to have declined since 1999 and according to the EIA will likely decline further to a steady level, supported only by export-driven demand.

Eighty-nine percent of SNWW methyl alcohol imports come from Trinidad, 8 percent come from Chile, and the remaining 3 percent from Venezuela. The Trinidad plant represents the world's largest methanol production plant and is capable of producing 5,000 tons per day. The plant located in Punta Arenas, Chile, plans to triple its methanol production capacity by the end of 2008. Additionally, new plants are planned in West Africa and the Middle East, with those locations presently serving markets other than the SNWW.

Ammonia is the main input source for all nitrogen fertilizers. Increases in ammonia imports are attributable to rising price of natural gas.¹⁴ From 2000 to 2006, the increase in natural gas prices decreased the producers' gross return margins (the difference between the cost of natural gas to produce 1 ton of ammonia and the ammonia price [in the Gulf region] received by ammonia producers). The low average gross return margins in 2000–2003 suggest that, on average, ammonia production in these 3 years was less profitable than in 1992–1998, a period of high average gross return margins. Low profitability is

¹³ SDI Consulting, Guillermo A. Saade, Abstract, July 2007.

¹⁴ USDA, Impact of Rising Natural Gas Prices on U.S. Ammonia Supply, A Report from the Economic Research Service by Wen-yuan Huang, WRS-07-02, August 2007.

cited to have resulted in a significant number of ammonia producers ceasing production or merging with other producers. The USDA noted that U.S. net imports of ammonia maintained a relatively constant level from 1991 to 2000. Since 2001, however, with the decline of domestic ammonia production, imported ammonia has become increasingly important to the U.S. ammonia supply. From 2000 to 2006, annual U.S. imports of ammonia increased from 3.9 to 8.4 million tons, an increase of 115 percent, while ammonia exports remained constant. During that period, most SNWW ammonia imports came from Trinidad and Tobago, Canada, Russia, and Ukraine. In 2006, Trinidad and Tobago accounted for 57 percent of U.S. ammonia imports. North Dakota and Montana were the main entry ports for ammonia imports from Canada, while the Gulf States were the main entry ports for ammonia shipped from Trinidad and Tobago, Russia, and Ukraine. SNWW's points of origin for ammonia are Trinidad and Tobago, Russia, and Ukraine.

2.5 CHEMICAL PRODUCT EXPORTS

Table 17 shows SNWW and U.S. totals by commodity for 1990–2007. Table 18 presents Port Arthur's and Beaumont's 1998–2007 chemical exports by major commodity group. Port Arthur and Beaumont exports increased dramatically. Comparison of 1998–2000 with 2005–2007 data shows a 279 percent increase in Port Arthur's tonnage and a 107 percent increase in Beaumont's. Port Arthur's chemical exports consist primarily of metallic salts, which composed 73 percent of 2005–2007 tonnage and 91 percent of 2007 tonnage. The remainder of Port Arthur recent tonnage consists of hydrocarbons and organic compounds. For 2005–2007, 20 percent of U.S. metallic salts were exported from Port Arthur. Figure 16 shows the 1990–2007 U.S. and SNWW metallic salts trendline, and Figure 17 shows the distribution of these exports between Port Arthur and Beaumont. Approximately 60 percent of 2005–2007 metallic salt exports are shipped to the countries of Brazil, Argentina, Venezuela, Colombia, and Ecuador. The remaining 40 percent are shipped to Europe and South Africa. Metallic salts are included in the SIC classification of cyclohexane. The increase in Port Arthur's metallic salt exports experienced since 2004 is associated with the completion of a 266,000 metric-ton-per-year cyclohexane facility in Port Arthur. While most cyclohexane goes into the production of intermediates for nylon, it is also used as a solvent in chemical and industrial processes and recently has been substituted for benzene in many applications. The more general category of metallic salts and organic compounds is associated with the production of paints and solvents, paper and wood products, cleaning products, and various chemical products. It was noted in the September 2006 *Chemical Industry Newsletter* that by 2010, global demand for cyclohexane is anticipated to increase to 6 million metric tons, representing an average annual growth rate of 3 percent during 2005–2010.¹⁵ Two percent of the 2005–2010 growth is attributed to China, with the associated demand driven mainly by nylon. As previously noted, nearly 60 percent of Port Arthur's 2005–2007 exports is shipped to South America. Of the six producers noted to account for 50 percent of world capacity for cyclohexane, five have operations on the SNWW. The six producers include ExxonMobil, Chevron Phillips, Huntsman, Deutsche BP Aktiengesellschaft, ConocoPhillips, and Idemitsu Kosan.

Beaumont's 2004–2006 chemical exports primarily consist of potassic fertilizers and mixes (33 percent), organic compounds (32 percent), and hydrocarbons (23 percent). These three groups represented 88 percent of 2004–2006 exports, up from 66 percent for 1999–2001. For 2004–2006, 10 percent of U.S. nitrogenous, potassic, and fertilizer mixes was exported from Beaumont. In 2006, the Beaumont share increased to 14.8 percent. Nearly 80 percent of 2004–2006 exports was shipped to Mexico and Central and South America. The remaining 20 percent was shipped to Japan.

Figure 16
U.S. and SNWW Metallic Salt Exports

Figure 17
SNWW Total and Port Arthur Metallic Salt Exports

The Food and Agriculture Organization (FAO) of the United Nations (U.N.) notes that world fertilizer consumption is expected to increase at an annual rate of about 1.7 percent from 2007/2008 to 2011/2012, equivalent to an increment of about 15 million tons.¹⁶ Approximately 70 percent of growth is anticipated to take place in Asia and 19 percent in America, primarily Latin America. Total fertilizer consumption in Latin America is forecast to increase at an annual rate of 2.7 percent from 2007/2008 levels. Increased demand is expected to be concentrated mainly in Brazil and Argentina where there has been a rapid response to increased crop prices partly resulting from increased sugar cane plantings for ethanol production. Future production increases are expected to come from a combination of a larger cultivated area and higher yields, which will help Latin America further increase its share of global agricultural markets.

North American consumption of nitrogen, phosphate, and potash fertilizer is forecasted to grow by 0.3 percent, 0.5 percent, and 0.7 percent, respectively. It is noted that significant gains in nitrogen use efficiency over the past 2 decades, combined with greater recycling of organic nutrient sources, are likely to mitigate increased fertilizer demand resulting from expanding bioethanol production. Asian demand is forecasted to increase by 2.1 percent annually from 2007/2008 levels through 2011/2012. The respective growth rates by fertilizer types are 1.6 percent for nitrogen, 2.4 percent for phosphate, and 3.5 percent for potash. The U.N. expects that Asia will move from a small deficit to a considerable surplus of nitrogen and will reduce its dependency on imported phosphate, but will increase the volume of its potash imports.

World demand forecast for potash fertilizers is to increase at an annual average rate of about 2.4 percent, equivalent to an increment of 3.6 million. About 68 percent of this growth will occur in Asia and 21 percent in Latin America, 5 percent in North America, 6 percent in Eastern and Central Europe, and the remainder in Western Europe. World demand for nitrogen fertilizers is expect to increase at an annual rate of 1.4 percent, with about 69 percent of growth taking place in Asia, 10 percent in Latin America, 3 percent in North America, and 7 percent in Africa, and the remainder in Eastern and Central Europe. The expected annual growth rate in world demand for phosphate fertilizers is about 2.0 percent. According to the report, about 71 percent of this growth will take place in Asia and 18 percent in America, 3 percent in North America, and the remaining 7 percent in Eastern and Central Europe.

Review of SNWW 1990–2007 (see Table 17) shows that regional potassic fertilizer exports represent 12.5 percent of U.S. total exports. SNWW fertilizer exports are nearly all associated with Beaumont (see Table 18). In general, Beaumont’s chemical exports consist of a wide range of products, with fertilizer exports exhibiting notable overall increases since 2000.

2.6 GRAIN EXPORTS

Grain is exported from the Beaumont elevator located just below the Port of Beaumont main turning basin. Wheat presently represents 100 percent of Beaumont’s grain exports for the most recent 4-year

¹⁶ Food and Agriculture Organization of the United Nations, “Current World Fertilizer Trends and Outlook to 2011/12,” FAO, Rome, 2008.

period. During earlier years, wheat represented 85 percent, sorghum 10 percent, and corn 5 percent. Table 19 displays Beaumont's 2001–2007 grain export tonnage by grain type.

Table 19
Beaumont Bulk Grain Export
Distribution of Tonnage by Grain Type

	2001	2002	2003	2004	2005	2006	2007
Bulk Grain Export Totals by Year (Short Tons)							
Beaumont Exports	831,000	835,000	1,125,000	1,329,000	1,080,639	1,214,010	1,632,000

In 2007, Beaumont's wheat exports totaled 1.6 million short tons. While exports have exceeded 1 million short tons since 2003, recent volumes are less than one-half the 1993 peak volume of 3.5 million short tons. Beaumont exports are very low in comparison to the Pacific Northwest and the Lower Mississippi, but the port has maintained a 1.4 to 1.7 percent share of the U.S. waterborne bulk grain export market. Beaumont's 2006 wheat exports composed 5 percent of the U.S. wheat export total. Figure 18 displays comparison of Beaumont exports and U.S. exports and production levels for 1990–2007.

2.7 EXPANSION OF THE DEEP-DRAFT TRAFFIC BASE

In addition to its large existing base of crude petroleum, petroleum and chemical products, and dry bulk deep-draft cargoes, the without-project future includes operation of up to three LNG terminals. As noted, the Cheniere terminal is presently operational. Construction on the Golden Pass terminal will be complete by 2011. The LNG terminals are located below Texas Island in the portion of the waterway below the western GIWW intersection with the SNWW near Taylor Bayou.

LNG is expected to play an increasingly important role in the natural gas industry and global energy markets in the next several years and in the long-term future due to the combination of higher natural gas prices, lower LNG costs, and rising gas import demand. Figure 19 shows the USDOE's 2006–2030 U.S. LNG import forecast.

The SNWW LNG facilities are located in the Sabine Pass Channel and Port Arthur Canal reaches; these reaches presently have an authorized channel width of 500 feet. LNG vessels using the SNWW will be subject to strict USCG regulations and to local pilot rules and, therefore, will not have the opportunity to meet other vessels or barges. The USCG regulations require that a safety zone is in place 2 miles ahead of a loaded LNG vessel and 1 mile astern of the vessel while transiting. LNG vessels using the SNWW would be subject to this rule. Even in absence of the safety concerns inherent to LNG, the beams of LNG tankers would result in vessel-meeting restrictions; however, all LNG vessel movements will be subject to one-way traffic. Operation of the LNG terminals is part of the without-project future.

3.0 VESSEL FLEET ANALYSIS

This section presents vessel fleet data, examines vessel utilization, outlines existing and future constraints associated with the commodity groups discussed in the previous sections, and also includes discussion of vessel casualty records and nonstructural project alternatives initiated by the USCG and industry. The outputs of the commodity and fleet analyses provided the basis for helping to identify the commodities expected to utilize vessels loaded to channel depths over 40 feet. The commodity-specific discussions include the existing commodity groups such as petroleum, chemicals, grain, and breakbulk, and the introduction of LNG. The introduction of LNG and the SNWW's already large concentration of deep-draft tankers and barge traffic highlights safety concerns. The first part of this section presents discussion of vessel safety and accident records.

3.1 SNWW VESSEL CASUALTIES

The large volume of deep- and shallow-draft vessels using the SNWW provided the initial basis for evaluation of waterway improvements. While the implementation of the VTM system significantly improved safety, an evaluation of safety and casualties was reevaluated in 2008 due to the opening of the Cheniere LNG Terminal and general interest in an updated assessment of navigation safety since implementation of the VTM system. As part of this evaluation, SNWW historical casualty records were updated and the circumstances associated with marine casualties were discussed with the USCG's Port Arthur Marine Safety Office (MSO), the SPA, and the GICA in 2008.

Vessel casualties are classified by three general types including vessel grounding, vessel collisions with stationary objects (called allisions), and collision of two or more moving vessels. The Port Arthur MSO noted that marine casualties are caused by a variety of reasons including strong winds, fog, pilot error, bank forecast, traffic mix, and a variety of other circumstances. Distribution of SNWW 2006 casualty rates by vessel type is shown in Table 20.

The USCG and the SPA were asked for input on the effects of the SNWW project alternatives on casualty rates. In response to this inquiry, the MSO representatives noted that factors such as reductions in deep-draft vessel traffic and channel widening would serve to reduce the probability of casualties. While recognizing that widening would reduce the probability of casualties, the MSO emphasized that casualty occurrences in the Sabine Pass Channel and Port Arthur Canal are rare and that the proposal to widening those reaches would not have a discernible effect on the net change in casualty rates.

Table 20
SNWW Casualty Incident Rates, 2006

Transit Type a/	Transits	Incidents	Ratio of Incidents Per Transit
Tanker Transits	3,139	4	0.1%
Freighter Transits	913	4	0.4%
Tow Transits	41,793	42	0.1%
Other	1,460	15	1.0%
Certain Dangerous Cargo Transits	1,570	0	0.0%
Tanker Transits	48,874	65	0.1%

a/ Includes inbound and outbound transits.

As noted, the Sabine Pass Channel and Port Arthur Canal reaches are used by oceangoing deep-draft vessels either coming in from or going out to the Gulf of Mexico. In discussing casualties with the Sabine Pilots, the pilots emphasized that the main effect of widening these reaches would be to reduce delays associated with one-way traffic restrictions.

Figure 20 contains distribution of 2006 SNWW casualties by vessel type, and Figure 21 displays the distribution of casualty incidents by nature of incident. The data indicate that 60 percent of casualties involve tows or tugs, 11 percent involve tankers and freighter, and the remaining 30 percent involve other vessel types as presented.

The MSO noted that nearly all casualties occur in the Sabine-Neches Canal reach, which, in addition to being used by all deep-draft vessels going to Port Arthur and Beaumont, serves as a through channel for the GIWW. Potential interaction between the diverse mix of vessels in this reach is presently scheduled, and scheduling will continue under the without- and with-project future conditions. As previously discussed, the large volume of tow-barges using the Sabine-Neches Canal, along with a high flow of deep-draft traffic, has the potential of compounding congestion that would increase casualty rates and probabilities and, therefore, prompted interest early in the study process for evaluation of a barge shelf through the canal reach between the east and west junctions with the GIWW. The USACE evaluation of the barge shelf coincided with the USCG efforts to evaluate the need for and plan future VTM projects, including installation and upgrades to VTS. The VTS was authorized by certain sections of the Port and Waterways Safety Act of 1972; the Oil Pollution Act of 1990 made participation mandatory in areas serviced by existing and future VTS.¹⁷ The purpose of VTS is to provide active monitoring and navigational advice for vessels in particularly confined and busy waterways.

The Port of Port Arthur and safety concerns associated with the Sabine-Neches Canal reach provided the impetus for Port Arthur's selection as one of 28 ports selected for participation in the 1999 VTM workshops. As part of the VTM study initiative, the USCG conducted a series of in-depth, user-focused workshops using their Port Risk Model to frame participant discussions and develop computer algorithms to translate expert opinions into quantified data.

For purposes of the Port Risk Model, risk is defined as a function of the probability of a casualty and its consequences. As part of the selection process, the input data used for port section included accident/incident history, the numbers and types of vessels using the port, weather conditions, waterway characteristics (e.g., configuration and complexity), and cargo types and volume. Each of those data elements was thought to bear some relationship to one or more of the risk factors included in the Port Risk Model. The model includes variables associated with both the causes and the effects of vessel casualties. The USCG classified 20 port safety risk factors that are grouped into one of six categories (Table 21).

As noted in USCG report documentation, the participants calibrated a risk measurement scale for each risk factor by assigning numbers to qualify risk levels. It is noted that the most important segment of the workshop consisted of discussions of port-specific problems relating to each Port Risk Model factor. The participants used the risk-measuring scales to numerically evaluate the risk levels in their port. The categories were ranked on a scale between 1 (low risk) and 9 (high risk). Discussion of existing risk mitigation strategies and appropriate ways to further reduce risk occurred next. The participants were asked to evaluate the efficacy and appropriateness of selection of VTM measures for addressing unmitigated risk, i.e., risk that was not well balanced by mitigation strategies already in place. Port Arthur's ratings are shown in Table 22.

Currently, VTS Port Arthur is a voluntary system operated in accordance with existing VTS regulations. VTS is designed to expedite ship movements, increase transportation system efficiency, improve all-weather operating capability, and enhance vessel safety and marine environmental protection.^{18, 19} The VTS Center in Port Arthur monitors every ship, vessel, or boat that attempts to enter or leave the SNWW and the GIWW in the Port Arthur service area. Infrared cameras, along with radar, radio-telephone reports from vessel operators, and satellite surveillance sensors on towers along the SNWW allow VTS controllers to zoom-in on vessel activity at a moment's notice. The satellite-based Automatic Identification System (AIS), required by the Maritime Transportation Security Act of 2002, assists the VTS by determining exactly what a specific commercial vessel is carrying, along with its speed, dimensions, and destination.

Most commercial vessels using the waterway were required to have AIS equipment installed by the end of 2004.²⁰ These include power-driven vessels 20 meters in length or longer; power-driven vessels of 100

²⁰ U.S. Coast Guard (USCG). 2004. Automatic Identification System Carriage Requirements. Available on the internet at http://www.navcen.uscg.gov/enav/ais/AIS_carriage_reqmts.htm.

gross tons or more carrying one or more passengers for hire; towing vessels 26 feet or longer while navigating, all dredges and floating plant likely to restrict or affect the navigation of other vessels; and all vessels required to participate in the Vessel Movement Reporting System. However, not all vessels are required to carry AIS; in particular, pleasure crafts, fishing boats, and warships are exempt. Until rules regarding VTS Port Arthur are published, vessels are exempt from all VTS and Vessel Movement Reporting System requirements, except the requirement for AIS continuous broadcasts. When VTS Port Arthur is included in the VTS regulation, participation will become mandatory. At that time, VTS Port Arthur will be authorized to designate temporary reporting points and procedures, impose vessel operating requirements or establish vessel traffic-routing schemes. During conditions of vessel congestion, restricted visibility, adverse weather or other hazardous circumstances, VTS may control or manage traffic by specifying times of entry, movement, or departure to, from, or within a VTS area. The existing VTS along the SNWW was evaluated as a nonstructural alternative. Although this service is managed by the USCG and thus is not within the jurisdiction of the USACE, it was evaluated because it appeared to be a potential alternative to structural plans and it was found to be a better alternative than the barge shelf proposal. While the VTS would help congestion and improve safety to some degree, the USCG's traffic management role is limited to specific circumstances when the SNWW is congested or experiencing hazardous conditions. The VTS assists vessel operators in making independent decisions regarding the safe navigation of their vessels, for which they retain complete responsibility. In this sense, VTS should be considered primarily a navigational aid, a tool for mariners to use along with numerous other tools to facilitate safe navigation,²¹ and thus would not improve deep-draft navigation inefficiencies created by the need for lightering and associated vessel delays.

The effect of the channel indication from discussions with the industry is that channel widening and the Neches River anchorage basins will reduce the likelihood of accidents; however, the number of accidents remains small. The indication from discussion with the industry is increases in channel width, anchorages, and the VTS will all contribute to an overall reduction in accident probabilities. Most vessel accidents involve tows, and most of these occur in the Sabine-Neches Canal reach, with the majority being "intentional groundings."

There is not a historical record of vessel-tow accidents as the existing condition is avoidance. The USCG noted that while communication has always been good, improved deep-draft and barge vessel communication brought about through the USCG Southeast Texas Waterways Advisory Council (SETWAC) and the VTS activities have resulted in improved safety. The pilot rules place limitation on what vessels can meet where and when. For the without- and with-project future, the pilot rules will continue to limit the sizes of the vessels that can meet in each portion of the channel. Widening the channel up to the Taylor Bayou junction will result in a relaxation of the pilot rules as vessels will have an additional 200 feet of channel (i.e., the existing channel width is 500 feet and the with-project width for the Sabine Pass Channel and Port Arthur Canal, which leads up to Taylor Bayou, would be 700 feet. The expectation for the with- and without-project future is that pilot rules would continue to limit the possibility of vessel-to-

²¹ USCG. 2008b. VTS Port Arthur Operating Procedures Guide. http://www.uscg.mil/d8/VTSPortArthur/Documents/VTS%20Port%20Arthur_Operating-Guide.pdf (accessed March 9, 2008).

vessel and vessel-to-tow meetings in the Sabine-Neches Canal reach and that both vessel and shallow-draft tow movements would be scheduled through both VTS and communication between vessel pilots.

The relative impacts to tow-barge traffic are anticipated to generally be the same between the without- and with-project future. One difference is that for the with-project condition of channel deepening, there would be fewer oceangoing vessel trips and, therefore, an overall reduction in traffic density. The decision to forgo the barge shelf was made by the tow industry due to reconsideration of how vessels and barges would interact. The concern that was raised, and this was not physically modeled, was that the tow-barges could get pulled under or out into the channel as it either meet a deep-draft vessel or “held-up or idled” in the barge shelf. The tow operators originally thought that they wanted to shelf in case radio and/or other communication failed and a tow-barge could not clear the channel as a deep-draft vessel began its transit through the reach; however, the recent impact of the VTS has improved communication among vessel operators, and accident probabilities were not calculated for the without-project condition and benefits for reductions in casualties were not taken. The effect of the without-project condition is “avoidance behavior” in the form of “pilot rules.”

3.2 OFFSHORE ALTERNATIVES

Offshore oil terminals were assessed as an alternative mode to landside port delivery of crude petroleum. Two offshore terminal alternatives were considered in the analysis, one existing and one proposed. The decision to use an offshore terminal instead of lightering or constructing a deeper channel is complicated but largely depends on the relative cost per ton, relative market volumes, and facility accessibility. While a detailed quantitative analysis of a LOOP alternative is beyond the scope of USACE’s planning study, the overall infrastructure requirements were examined to the extent possible. Pipeline capacities and necessary expansions were identified, and the reasons for current and past choices were evaluated as were expectations about future interest.

The existing offshore terminal, the LOOP, is America’s first and only deepwater port. LOOP is presently operating at capacity and has been since 2005. In addition to new customers brought on due to infrastructure damages associated with the 2005 hurricanes, recent increase in the LOOP is tied to utilization associated with domestic production in the U.S. Gulf. Access to LOOP for the SNWW market is periodically reviewed; however, actualization would require substantial investment as SNWW crude oil import volume nearly equals LOOP’s capacity. LOOP’s design capacity of 1.4 to 1.8 million barrels per day is only marginally higher than SNWW’s 2003–2007 crude petroleum import volume which ranged from approximately 1.1 to 1.3 million barrels per day.²²

While all of SNWW’s crude oil could not currently transfer to LOOP, some tonnage could be diverted. The volume diverted depends upon various ranges of expansion of LOOP or construction of a new facility. The large fixed cost of expansion, and associated financing costs, necessitates participation by a

²² The *Waterborne Commerce of the U.S.*, Part 2, Waterways and Harbors, Gulf Coast, Mississippi River System and Antilles shows crude petroleum imports of 60 million short tons in 2005 and 70 million in 2003 of crude oil imports for the SNWW. The standard conversion factor to put short tons per year to barrels per day is 0.0182. The link for the public website for waterborne commerce publications is shown below. Detailed vessel records are not contained in a public domain but can be provided upon request. <http://www.iwr.usace.army.mil/ndc/wesc/wesc.htm>.

consortium of companies. While LOOP is presently at capacity, the SNWW industries have not found the option of investing in LOOP, and the necessary associated infrastructure expansions, to be a cost-effective alternative to existing practices of either direct shipment or offshore lightering. The lack of incentive has remained since the 1970s. The SNWW users continue to consider LOOP along with other alternatives; however, continued practices suggest that LOOP is not a cost-effective alternative to the existing SNWW practice of its land-based ports. An additional variable pertinent to the current evaluation is that LOOP would appear to be a less attractive cost option when compared to lower shipping costs that the SNWW improvement project is expected to provide.

LOOP is located offshore of Grande Isle, Louisiana, in 110 feet of water. Grande Isle is 302 miles east of Port Arthur and Beaumont. LOOP was organized in 1972 as a Delaware corporation and converted to a limited liability company in 1996. Marathon Ashland Pipe Line LLC, Murphy Oil Corporation, and Shell Oil Company are LOOP's owners. LOOP is the only port in the U.S. capable of offloading deep-draft tankers known as Ultra Large Crude Carriers (ULCC) and VLCC. Along with offloading crude from VLCCs, LOOP also offloads smaller tankers. LOOP consists of three single-point mooring buoys used for the offloading of crude tankers and a marine terminal consisting of a two-level pumping platform and a three-level control platform.

A 48-inch-diameter pipeline connects the LOOP Marine Terminal located 23 miles offshore in the Gulf of Mexico to the Clovelly, Louisiana, storage facilities. Clovelly is approximately 260 miles east of the SNWW Port Arthur and Beaumont facilities. Four pipelines connect the onshore storage facility to refineries in Louisiana and along the Gulf Coast. The Clovelly facility provides interim storage for crude oil before it is delivered via connecting pipelines to refineries on the Gulf Coast and in the Midwest. The oil is stored in eight underground caverns leached out of a naturally occurring salt dome. In 1996, one cavern was dedicated to the production streams coming in from the deepwater Gulf of Mexico.

The domestic offshore crude oil system uses the same distribution system used by the foreign barrels. The caverns are capable of storing approximately 50 million barrels of crude oil (a barrel of oil is equal to 42 U.S. gallons). In addition, LOOP has an aboveground tank farm consisting of six 600,000-barrel tanks. LOOP operates the 53-mile, 48-inch LOCAP pipeline that connects LOOP to CAPLINE (Amoco Cushing-Chicago Pipeline Company) at St. James, Louisiana. CAPLINE is a 40-inch pipeline that transports crude oil to several Midwest refineries. St. James is 227 miles east of Port Arthur and Beaumont. LOOP is connected to over 50 percent of the U.S. refinery capacity and has offloaded over 7 billion barrels of foreign crude oil since its inception.

LOOP is designed to handle 1.4 million BPD, but depending on the sizes of ships being serviced, it can handle 1.8 million BPD. The variance relates to the pumping rates of the tankers using the facility. Larger tankers tend to have faster pumping rates with some capable of pumping 80,000 barrels per hour. Smaller tankers may only be able to pump 35,000 barrels per hour. When fully operational, LOOP is generally the largest point of entry for crude oil imports into the U.S. About 13 percent of all waterborne foreign imports pass through LOOP each day. Again, LOOP's design capacity of 1.4 to 1.8 million BPD is only marginally higher than SNWW 2003–2007 crude petroleum import volume. Of SNWW's over 1 million BPD import volume, terminals on the SNWW transport approximately 400,000 BPD of waterborne crude oil via pipelines to inland refineries including refineries in Texas, Louisiana, Oklahoma, Ohio, Arkansas,

and Kentucky.²³ In total, the SNWW delivers approximately 12–16 percent of the crude oil supplied to domestic refineries east of the Rockies. Refineries supplied via the Sabine-Neches provide transportation fuels and other products to consumers along the Gulf Coast, East Coast, and Midwest regions. The SNWW ports presently receive about 1 percent of their daily input through LOOP. Additional offshore and landside infrastructure would be necessary for an increase in volume to take place. Expansion of the infrastructure was discussed with industry and they periodically evaluate new proposals. It was noted two proposals were due in December 2007 and acceptance of the proposals depended on participation by a consortium of users. As of June 2010, there has not been any action on these proposals.

Although there are some competing markets, the SNWW and LOOP generally serve parallel markets, with LOOP consistently processing very large volumes and SNWW serving relatively smaller parcels. The sizes of the VLCCs using LOOP typically exceed 300,000 DWT, whereas the maximum-sized vessels using the SNWW are 175,000 DWT. The maximum design draft of these vessels is 55 feet or less. The minimum-sized crude oil tankers using SNWW are in the 70,000 to 80,000 DWT range and have design drafts between 40 and 48 feet. LOOP's foreign petroleum imports are from the Middle East, whereas SNWW's market consists of direct shipments from Mexico and Venezuela and lightened mother vessels and shuttles. It has been noted that the cost effectiveness of LOOP lessens for small vessel sizes. The SNWW has the ability to serve a more general market and range of users.

The most immediate obstacle to increased use of LOOP or a new offshore facility is lack of or major limitations for direct connection from LOOP to SNWW. A marginal increase in SNWW use of LOOP from its present 1 percent share would require LOOP pipeline connection modifications involving multiple pipelines and multiple companies. Such an investment may generate the necessity for higher throughput charges, which in turn may make access less cost effective than in the past. An industry analyst noted that to a large extent the companies demand that each segment, including pipeline transportation, stand on its own economically.²⁴ In discussions with local port and oil industry personnel, it is noted that LOOP and similar proposals serve crude petroleum but do not serve a full range of petroleum and bulk cargoes that use the SNWW. The long-term availability of LOOP since the 1970s and participation by SNWW companies indicate that LOOP and new offshore terminal proposal have not provided the market utilization incentives for significant shares of SNWW crude oil to shift towards these alternatives. The long-term trend is for domestic refining capacity to become more concentrated in regional centers and for imports of petroleum products to grow. This trend is evident with SNWW with crude oil import tonnage exceeding that of any other U.S. port and being equal to LOOP. Imports of refined products and partial refined crude oil have grown significantly as have the use of draft-constrained vessels for transporting these cargoes.

In 2001, construction of a new terminal (called the Bulk Oil Offshore Transfer System, or BOOTS) offshore of Sabine Pass, Texas, was proposed. The relatively long distance from LOOP to SNWW and the need for additional infrastructure suggest that a facility closer to SNWW would be an attractive alternative to LOOP for SNWW channel improvements. However, the BOOTS facility has not yet been constructed and the regulatory permit application is inactive. The USCG has had no update on the

²⁴ Rabinow, Richard A., The Liquid Pipeline Industry in the United States, "Where It's Been, Where It's Going, a report for the Association of Oil Pie Lines, April 2004, p.14.

proposal and does not expect a submittal. At the present time, the potential user of the proposed project is the terminal proponent. They noted that their participation as sole supporter is not feasible financially. It was specifically noted that their feedstock needs were not sufficient to finance the expansions to LOOP.

The BOOTS project manager was contacted periodically, and it was found that a new location farther down the Texas Coast near Freeport is presently being considered. The Freeport, Texas, site is about 100 miles southwest of the BOOTS location. Access by the SNWW refineries to a Freeport site involves longer distances than the previous BOOTS location but it has advantages over LOOP. The Texas offshore terminal was reorganized as TOPS and announced plans for construction in August 2008. TOPS is a proposed offshore terminal project that would provide feedstock to Texas City, Houston, and Port Arthur. The Port Arthur Motiva refinery, which has terminals at Taylor Bayou and on the Neches River, was a major participant in TOPS. TOPS would connect from offshore Freeport to an existing landside pipeline from Freeport operated by Seaway Pipeline Company to Texas City. Connection to Port Arthur would necessitate a new pipeline from Texas City to Port Arthur, a distance of approximately 95 miles. TOPS was noted to serve as an addition and complement to existing methods of importing crude petroleum rather than a substitute for existing modes of shipment. A March 2009 press release revealed that the Port Arthur participant, Motiva, has put its participation on hold based on uncertainty associated with future crude petroleum import volumes and trade routes. Due to uncertainty, the use of an offshore alternative was evaluated as sensitivity (Section 8.2).

While recognizing potential diversion to the existing LOOP or to a new offshore terminal, an increase in the number of specially designed SNWW vessels was recently completed by one company and another has invested in Neches River dock modifications for the larger "Aframax" and "Suezmax" vessels. The focus of immediate private sector petroleum vessel investments is concentrated on SNWW improvements rather than offshore or on the Sabine Pass Channel or Port Arthur Canal. Ongoing consultation with industry continues to show that commitments to offshore terminal investment have not materialized. During the 30 years since LOOP has become operational, several Texas Gulf Coast channel-improvement projects have been completed and the benefits have been accrued. Offshore terminals would not accommodate products other than crude oil, and a significant proportion of benefits for the SNWW project improvement are from refined petroleum products. The offshore terminal was found not to meet the efficiency objective for all waterway users as it addressed the needs of only one user and commodity (crude oil). For these reasons, this alternative was eliminated from further consideration. While crude petroleum represents a significant share of SNWW tonnage, use of draft-constrained vessels for dry bulk commodities such as iron ore, building stone, and chemicals prompted interest by the navigation district and port authorities in the channel deepening and widening alternatives.

In a general discussion with industry, a representative noted that offshore oil terminal projects surface periodically, but the cost of these alternatives keeps them from moving beyond the initial planning stage. It is noted that the attractiveness of offshore alternatives over existing use of the SNWW is diminished by its ability to only serve one commodity (i.e., crude petroleum). It was added that the various crude oil blends and grades of oil introduce a range of additional concerns that add to throughput costs.

As noted, a constraining or complicating issue is that the pipelines and associated infrastructure requirements vary between potential users, and mingling of products and grades of crude is complex and difficult to facilitate. The construction of an offshore terminal that can meet the needs of various users is a challenge with the costs to realize multiparty usage creating an impasse to these proposals moving beyond the initial planning stage. Recognition of the cost of multiple pipelines necessary to meet the needs of the large base of customers necessary to finance these project alternatives has resulted in a stalemate in the decision process. As noted, LOOP is an existing offshore alternative. Current use of LOOP by SNWW users is very limited, and future use would require extensive pipeline investment. The major users of LOOP consist of a few major companies with high throughput volumes. In addition to serving crude oil tankers delivering imports, LOOP is used to transport domestic crude produced in the Gulf of Mexico. When asked about LOOP, potential users on the SNWW noted that LOOP's availability is sometimes limited and SNWW imports are within 1 percent of LOOP's annual throughput. The investment necessary for LOOP to process SNWW's entire crude petroleum throughput would require a doubling of capacity. A new facility such as BOOTS requires substantial investment on the part of several oil companies. Present use of LOOP consists of Louisiana-based refineries and U.S. Gulf Coast state domestic offshore production interests. LOOP's existing base of customers uses it as one of several options for delivering crude oil to their Gulf Coast refineries.

3.3 VESSEL UTILIZATION AND OPERATING PRACTICES

Analysis of the vessel fleets and utilization, and existing and future constraints associated with crude petroleum, petrochemical products including LNG, grain, and aggregate products, such as iron ore, steel slab, limestone, and sand and gravel provided the basis for identifying the commodities expected to be transported in vessels loaded to channel depths over 40 feet and estimating specific percentage utilization for channel depths over 40 feet. Additional considerations were foreign port depths and constraints such as the Panama Canal. Completion of the Panama Canal expansion, from its present width restriction of 106 feet and approximate loaded draft limit of 39.6 feet, in the year 2014 will allow for more fully loaded vessel movements from deepwater ports in Western Mexico, South America, and the Far East. The canal expansion will accommodate maximum loaded drafts of 48 feet. Port depth, trade route, and historical vessel utilization data were used to identify the percentage of tonnage anticipated to benefit from the proposed SNWW depth increases.

Examination of the vessel sizes associated with the historic traffic base suggested that, if deeper depths were available, vessels used in the transport of crude petroleum and petroleum products could be loaded to drafts over 40 feet. In addition, but to a lesser extent, examination of the 1995–2007 vessels sizes, loaded drafts, design drafts, and parcel sizes indicated that some of the vessels used to transport grain, chemical products, and breakbulk cargo, such as iron ore, metal products, and limestone and other aggregate, warranted additional analysis. The existing 40-foot SNWW project depth was designed to efficiently and safely accommodate vessels of approximately 40,000 DWT with loaded drafts of 36 feet. Since the authorization of the existing project, the size and draft of vessels using the waterway increased to meet the competitive demand for more-efficient movements. Evaluation of SNWW's vessel utilization

patterns was initially made based on examination of historical trends. The historical trend analysis was followed-up with user interviews and trade route analyses.

Table 23 presents 1990–2007 vessel trips by loaded draft for deep-draft vessels. Analysis of the data showed that trips increased at an annual rate of 3.7 percent, with the highest rates of growth for 36 feet and greater. Total trips for drafts over 35 feet increased at an average annual rate of 7.3 percent, while trips for loaded drafts of 35 feet or less grew at 3.7 percent. For the period 1990–2007, total deep-draft tonnage grew at an average annual rate of 5.2 percent. SNWW’s vessel utilization patterns were also reviewed in terms of the average tonnage per trip for 1965–2007. Figure 22 shows average tonnage per trip for oceangoing traffic. The graph shows trips increasing at a slightly decreasing rate and suggests an overall increase in average tonnage per trip. While the increases in the volume of tonnage per trip are primarily associated with crude petroleum and petrochemical products, larger vessels are being used for manufactured goods and crude materials. Since 1993, the volume of tonnage per vessel has increased as the variety of commodities using the waterway has diversified.

The largest vessels presently using the SNWW are crude petroleum tankers. Crude petroleum represents over 70 percent of 2007 deep-draft tonnage and 2005–2007 average deep-draft total. Trade routes, vessel sizes, and loaded drafts are of particular importance in calculating transportation costs. For the period 2005–2007, approximately 45 percent of SNWW crude petroleum imports were shipped from Mexico, Venezuela, Colombia, and Trinidad. Of the remaining 55 percent, 54.3 percent was shipped from the Middle East and Africa and 0.3 percent was shipped from Canada. In comparison to the Nation, the SNWW has a relatively higher share of imports from Mexico, the Caribbean, and South America, while also receiving relatively higher Middle East imports. The U.S. 2005–2007 distribution comprised 34 percent from Mexico, the Caribbean, and South America; 50 percent from the Middle East, Africa, and the North Sea; and 16 percent from Canada. In its Annual Energy Outlook, the EIA shows a 2030 U.S. distribution of 33 percent from Mexico, the Caribbean, and South America; 47 percent from the Middle East, Africa, and the North Sea; and 20 percent from Canada. Canadian imports include both ship and pipeline movements.

The following tables outline the distribution of tonnage by loaded vessel draft. Table 24 shows total import and export tonnage by loaded draft for select years. Table 25 shows the 1990–2007 distribution of SNWW’s crude petroleum imports by loaded draft, respectively. Tables 26 and 27 present petroleum and chemical product imports and exports by loaded draft. Table 28 shows tonnage by loaded draft for groups other than petroleum and chemicals. Every effort was made to compile data for as many years as practical; however, the schedule of data releases results in some gaps. The purpose of the analyses associated with these presentations was to identify the existence of patterns and provide inputs for establishing base conditions. Based on this consideration, all relevant years are displayed.

The presentations show that a significant portion of crude petroleum imports and petroleum product imports and exports were transported in vessels with loaded drafts of 36 feet or more (see tables 25 and 26). The chemical import and export data presented in Table 27 show a more limited utilization of loaded drafts over 36 feet. Table 28 displays the distributions associated with “all other imports and exports.” This group is largely comprised of bulk commodities.

The data shown in tables 29–32 were compiled from the USACE foreign freight databases. A subsequent comparison of the loaded draft records from the USACE NDC databases with those in the pilots’ records was made to identify differences in loaded drafts between the data sets. Comparisons of the data sets are displayed on figures 23 and 24.

Figure 23

Figure 24

The primary use of the pilot data was to obtain specific information on trips by dock. Dock-specific information for foreign imports and exports is not available from the USACE databases. Dock-specific routings are available for SNWW domestic coastwise vessels; however, those routings were generally limited as domestic coastwise represented 5 percent of total trips in 2001 and 3.5 percent of 2005 total trips.

The trip comparisons displayed on figures 23 and 24 correspond to loaded drafts between 31 and 40 feet. While examination of the pilot data and the NDC foreign freight traffic data showed that the maximum loaded draft for inbound vessels was 40 feet, one U.S. outbound domestic coastwise vessel showed a loaded draft of 43 feet. Additionally, a few U.S. domestic coastwise 1996–2004 records show loaded drafts up to 43 feet. In comparison to the USACE records, the pilot records for 2001 and 2005 showed no vessels with sailing drafts over 40 feet. A sample of pilot data for April–May of 2002 did not contain any loaded drafts over 40 feet. Review of the 2004 and 2006 pilot data also showed no loaded drafts over 40 feet. Pilot data for years later than 2006 were not obtained.

For purposes of analysis, the pilot guidelines and the associated documentation of trips by draft are believed to be more accurate and consistent, if for no other reason than being collected by one entity using the same metrics. The expectation that the pilots' records are more accurate than the Waterborne Commerce Statistics Center (WCSC) records also relates to the risk associated with misreading a loaded draft, particularly during low tide or late in the dredging cycle. The pilots stated that they normally will not move any vessel if the loaded draft exceeds 40 feet fresh water. The restrictions are rigid due to insurance liability. It was noted that allowance of 40 feet fresh water assumes optimal weather and a well-maintained channel. One of the subject matter experts recognize that the USACE and pilot data are collected at different locations and in different metrics. For piloted vessels, a mandatory and consistent check of loaded drafts is made prior to departure from either the dock or the offshore pilot loading station. These recordings are in feet. The USACE WCSC records of imports and exports are not based on pilot logs but census data. The USACE detail contains counts of export trips by loaded draft. The U.S. Customs' manifest document is the most common source for inbound vessels but these records do not include a trip field. The domestic coastwise database includes a trip field. Loaded draft of inbound domestic vessels may be called in from the last port of call. For imports, the last port of call is generally outside of the U.S., and therefore draft information may be relayed in meters. It is interesting to note that comparison of the 1996–2007 inbound with the outbound records shown in Table 28 reveal that there are more outbound vessels with loaded drafts over 40 feet than inbound vessels. A reason cited for this difference is that the outbound vessels have the additional weight of bunker fuel. The indication is that vessels traveling from distant locations will burn bunker fuel in transit. The inclusion of bunker fuel will add approximately 1 foot of draft.²⁵ The result being that the arrival drafts may be different than the draft recorded in the manifest or other documentation.

The pilots noted that they are only aware of a few incidents when a draft over 40 feet was allowed and wondered if they were due to recording errors. It was also noted that a 3-foot minimum underkeel

²⁵ Personal communication with Institute of Water Resources (IWR) navigation analyst.

clearance requirement was issued by the USCG in the early 2000s. Exceptions to the 3-foot rule may only be made by a pilot master conference to discuss the specifics.

For the USACE's NED analysis, loaded draft is critical to the calculation of SNWW channel deepening benefits. Loaded draft is also a crucial analytical consideration for the widening analysis due to the fact that there are specific pilot rules restricting loaded drafts above a given threshold from meeting vessels of comparable loaded drafts, gross tonnage, beam width, or other specifications. The calculation of widening benefits is based on discrete loaded draft classes.

While the waterborne commerce records show a few vessels sailing at loaded drafts over 39 feet, discussion with the pilots and Galveston District's Operation Branch suggest that the dredging practice of 2 feet advance maintenance and 2 feet overdepth provides nearly all vessels at least 3 feet of underkeel clearance. Analysis of the pilots' policy application and examination of the number of trips with loaded drafts over 37 feet implies the availability of advance maintenance and overdepth. Comparison of the USACE data with the pilot records shows differences between recorded drafts, which are problematic. Review of the USACE data revealed that the USACE data come from several sources and are, therefore, more likely to reflect the introduction of recording discrepancies than the pilot data. Additionally, allowance of less than 3 feet underkeel clearance introduces insurance liability issues. Analysis of the data and pilot records showing recorded drafts over 37 feet implies the availability of at least 41 feet of still water. Water displacement due to vessel squat and trim implies the availability of additional depth in the Entrance Channel, where the existing authorized channel depth is 42 feet mean low tide. It has been noted in the past that the SNWW, like other Gulf Coast channels, has a relatively soft bottom. It has also been noted that the SNWW heavy traffic flows may work to help maintain the channel or slow the silting processes; however, discussions with the SPA and previous project studies also point towards an increasing concern about safety and a reduction in risk-taking behavior. In general, liability and personal responsibility concerns associated with potential casualties and actual vessel damages has become increasingly apparent due to incidents such as the *Exxon Valdez* oil spill off the coast of Alaska. On a much smaller scale, general reviews of USCG records for GIWW traffic has shown that casualties and oil spills occur on a less frequent basis than 10 to 20 years ago. The latter suggests a reduction in risk-taking behavior.

3.4 CRUDE PETROLEUM FLEET

This section contains discussion of SNWW's crude petroleum fleet and methods of shipment. Data through 2007 show an average of 80 percent of import tonnage shipped in vessels with loaded drafts of 30 feet or more, and over 40 percent of import tonnage was shipped in vessels with loaded drafts of 36 feet or more. The analysis also showed that over 75 percent of SNWW crude petroleum tonnage was shipped in 90,000 to 119,999 DWT tankers, up from 30 percent in 1990. The largest concentration of SNWW crude petroleum tonnage is in vessels between 100,000 and 119,999 DWT. Table 29 presents SNWW distributions of crude petroleum imports by vessel size for 1993, 1998, and 2002–2007. The DWT range from 90,000 to 119,000 represents the dominant class for all years shown. Comparison of the data for the

early 1990s with that for 2002–2007 shows a general decrease in the vessels less than 75,000 DWT and resurgence in the 75,000 to 85,000 DWT range.

Review of the annual vessel statistics and follow-up meetings with the ship pilots and terminal operators revealed that petroleum tankers beams have increased significantly in recent years, and that the vessel beam increase is compounding the effect of delays. Double-hulled tanker legislation was initiated under 46 USC§3703a after the *Exxon Valdez* oil spill. The U.S. Congress passed the Oil Pollution Act of 1990 requiring double-hull tankers now, but allowing the transportation companies until 2015 to replace existing tankers. Table 30 provides comparison of the beam widths associated with the 1981 and 2003 world tanker fleets. The table illustrates the transition in tanker sizes to wider beam vessels and also illustrates an increase in cargo-carrying capacity at less draft.

3.5 PORT ARTHUR AND BEAUMONT VESSEL FLEETS

Port Arthur's and Beaumont's specific distributions are shown in tables 31 and 32. Port Arthur's two petroleum refineries are located inside the Taylor Bayou complex. The existing width at the mouth of Taylor Bayou and the configuration of the docks within Taylor Bayou limit the allowable vessel size. Widening of the mouth of the bayou and the west turning basin bottleneck curve was evaluated as part of the current study. The result of widening the mouth would facilitate increased use of larger vessels that are presently restricted from using this portion of the channel. The most common crude oil tankers unloading at the Taylor Bayou terminals are 85,000 DWT, have design drafts of 45 feet, and beams of approximately 124 feet. It was found that the design drafts associated with the current fleet of 75,000 to 85,000 DWT vessels are slightly greater than in the earlier period. Several new tankers in this group were constructed in the early 2000s and are presently using the Port Arthur portion of the channel. The maximum size using the Taylor Bayou facilities is generally in the 110,000 to 116,000 DWT class. Widening of the mouth of the entrance to Taylor Bayou will occur under the with-project future and this will allow better vessel maneuverability. Widening of the mouth was recommended as a result of the ERDC vessel simulation modeling. The Taylor Bayou current fleet is specially designed for that project reach, and the vessels are characteristically wider and shorter than other tankers in the 80,000 to 90,000 DWT class. The Taylor Bayou configuration currently makes it difficult to maneuver longer vessels, and therefore, the design of the Taylor Bayou fleet reflects wider beams. Based on application of the pilot rules (see Table 3), inbound 124-foot beam Taylor Bayou vessels cannot meet common-beam-range outbound Neches River tankers of 135 to 145 feet. Present beam restrictions for the 500-foot-wide Sabine

Pass Channel and Port Arthur Canal reaches stipulate that the combined beam width of meeting vessels cannot exceed 50 percent of the channel width. The proposed increase to a project width of 700 feet would enable Taylor Bayou tankers to meet the relatively wider Neches River tankers in the channel reaches up to the Taylor Bayou junction.

The maximum sized vessels using the Channel to Beaumont are in the 150,000 to 170,000 DWT range. The maximum length for that group is approximately 900 feet, with a corresponding beam width of 164 feet. One percent of Beaumont's crude petroleum imports are associated with this group. Table 33 presents fleet-specific data corresponding to Beaumont and Port Arthur. Table 34 displays Beaumont's and Port Arthur's distributions by loaded draft. The annual distributions of tonnage by loaded draft exhibit large variance and also show distinct differences between the two ports.

In comparison of Port Arthur and Beaumont relative port statistics, it was noted that for some years a greater percentage of crude tonnage is loaded to drafts of 38 feet or more for Port Arthur than for Beaumont. This is due to Port Arthur receiving a higher share of direct shipments from Mexico than Beaumont does. Generally, vessels will be loaded to deeper drafts for longer-distance direct routes. In comparison, Beaumont receives a higher share of lightered tonnage from both lightened mother vessels and shuttles. While there are cost incentives for loading to the maximum allowable depth, it was found that the average loaded drafts for the lightened mother vessels and shuttles were lighter than vessels associated with direct shipments. Deepening the Taylor Bayou reach would allow the present fleet of crude carriers to load to drafts over 40 feet; however, the transition to a larger DWT class is unlikely due to turning-area constraints. The turning-area constraints are unlikely to change even with channel deepening; however, industry representatives noted that a deeper channel will facilitate loading additional cargo on the existing range of vessels. While maximum vessel size ranges from 110,000 to 116,000 DWT, with design drafts of 49 feet, the most common crude oil tankers unloading at the Taylor Bayou terminals are 85,000 DWT and have design drafts of 43 feet. This common size is related to the entrance to Taylor Bayou for which widening was evaluated. A large portion of the vessels in the 85,000 and 110,000 to 116,000 DWT classes using Taylor Bayou were constructed in 2002–2003, which suggests that they will be utilized for another 20 years. The maximum beam width routinely allowed is 124 feet. Examination of vessel transits shows that the median and average beam for Taylor Bayou crude tankers is 124 feet and the maximum beam is 149 feet, with 92 percent of tonnage being transported in vessels with beam of 124 feet. The 124-foot beam corresponds to 85,000 DWT tankers, and the 149-foot beam corresponds to 116,000 DWT tankers. The maximum vessel length for Taylor Bayou vessels is approximately 758 feet. Vessels longer than 758 feet cannot easily be turned given Taylor Bayou boundaries and dimensions. For the Channel to Beaumont, 92 percent of tonnage is associated with beam widths over 130 feet. The vessel beams of both Port Arthur's and Beaumont's vessels causes them to be regularly impacted by the present 500-foot width of the Sabine Pass Jetty Channel and Port Arthur Canal.

3.5.1 Methods of Shipment for Crude Petroleum

The methods of shipping crude include direct, lightered, lightened, and transshipped. Direct shipment, as the name implies, is the transfer of tonnage by vessel between two coastal ports. Lightering is defined as the process involving ship-to-ship transfer of oil cargo, and it is extremely cost effective for long hauls. U.S. Gulf Coast lightering occurs in the international waters of the Gulf of Mexico and involves the transfer of tonnage from a larger vessel, called a VLCC, onto one or more shuttle vessels.

Figure 25 shows the U.S. Gulf offshore lightering zones. With lightering, the VLCC does not enter the coastal receiving port. A frequent alternative to either direct shipment or lightering is lightening. The term lightening describes the process where enough cargo is offloaded from a tanker to permit the light-loaded vessel to enter a confined channel system. The tanker sizes associated with lightening on the Texas Coast generally range from 120,000 to 175,000 DWT. Tankers larger than 175,000 DWT are normally lightered; however, there is a gap in the world tanker fleet between 175,000 and 250,000 DWT. The reason for the gap is that is not cost effective to use tankers significantly larger than 175,000 DWT for direct shipment even for channel depths of less than 55 feet. Analyses of the cost per ton transportation

costs also show that it is not cost effective to use vessels smaller than 250,000 DWT for lightering. An increase in channel depth to the SNWW would provide opportunity for these shuttles to be more fully loaded.

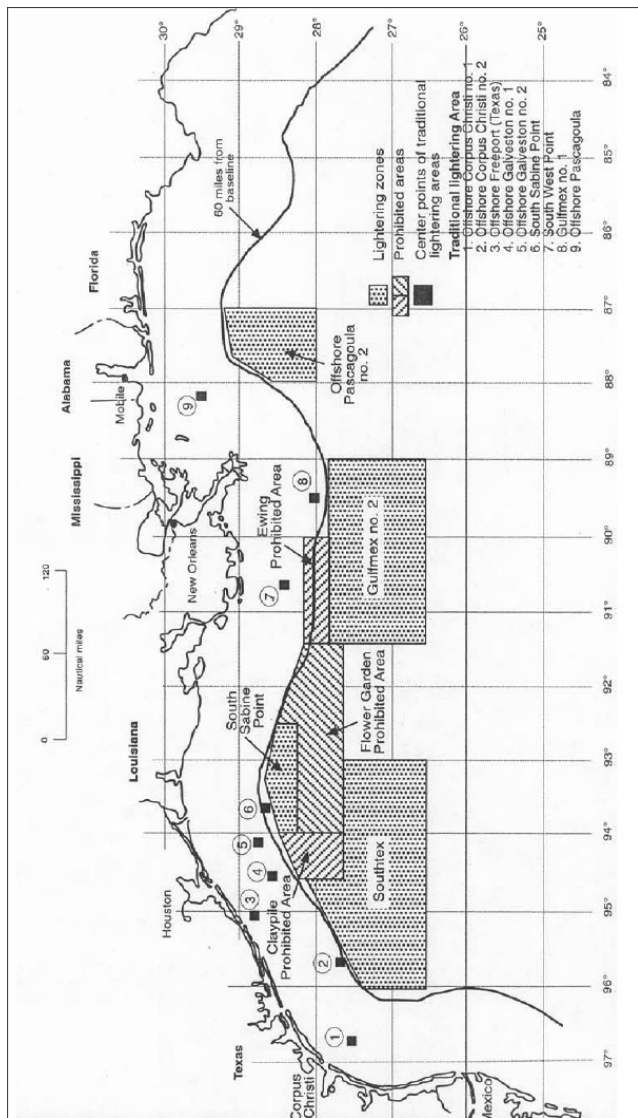

Africa, Mediterranean, and Europe movements are either lightened or shipped direct. The tanker sizes associated with lightening on the Texas Coast generally range from 120,000 to 175,000 DWT.²⁶ Tankers larger than 175,000 DWT are normally totally lightered offshore onto shuttles. Shipments from Africa, the Mediterranean, and Europe are usually transported in tankers between 90,000 and 175,000 DWT, with direct shipments generally using tankers between 90,000 and 120,000 DWT.

Transshipping is the fourth method of shipment. Crude oil is also transshipped through deepwater ports in the Caribbean. Crude is transported on VLCCs to the transshipped sites and later transferred to 90,000 to 114,000 DWT range shuttle tankers for shipment to the SNWW.

The primary sized vessel used on the Mexico/Eastern South America route for direct shipments into the SNWW is presently 90,000 to 114,000 DWT. Review of the 2007 *Fairplay Tanker Register* showed that the design drafts associated with tankers of 90,000 to 114,000 DWT generally range from 40 to 51 feet, with the average being 48 feet. An increase in channel depth to Port Arthur and Beaumont would provide opportunity for these shuttles to be more fully loaded. The size of the largest tankers using the SNWW in 2005–2007 on a regular basis is 169,146 DWT. The length, beam, and design draft for this vessel is 935x148x61 feet. In addition to transportation cost incentives, vessel selection is also related to the way crude petroleum is currently sold and how crude oil is shipped. Presently, parcels are generally sold in 500,000 to 650,000 barrels. A 500,000- to 650,000-barrel parcel converts to approximately 75,000 to 95,000 short tons. Many vessels arrive in the international waters of the Gulf of Mexico with double parcels. Cost analyses show that the most economical sized vessel for single parcels is between 75,000 and 100,000 DWT given the existing channel depth of 45 feet. For double parcels, the most efficient size is between 150,000 and 175,000 DWT.

Figure 25
U.S. Gulf Coast Crude Petroleum Lightering Zones

Source: Ellis, John, "Commonality of GoM [Gulf of Mexico] Lightering, Experience with GoM Shuttling", Floating Production, Storage and Offloading Global Workshop, September 25, 2002, <http://iovlive.org/pdf/John-Ellis.pdf>.

Gulf Coast industry personnel indicated that parcel size and associated ship size are primarily a function of the existing channel dimensions. The indication suggests that an increase in channel dimensions would likely result in a shift to larger parcel sizes and larger vessels. Comparison of the parcel sizes associated from the early 1990s with 2007 crude oil imports revealed that the distribution of tonnage by parcel size increased for Texas ports where the channel operating depths increased from 40 to 45 feet. Comparison of crude oil import records from the early 1990s with 2007 records illustrates that larger parcels are being shipped today and suggests that the channel deepening from 40 to 45 feet facilitated this transition.

Lightening is a common alternative to either direct shipment or lightering for some routings, and it describes the process where enough cargo is offloaded from a tanker to permit the light-loaded mother vessel to enter a confined channel system. Africa, Mediterranean, and Europe movements are either lightened or shipped direct. The tanker sizes associated with lightening on the Texas Coast generally range from 120,000 to 175,000 DWT. Tankers larger than 175,000 DWT normally are totally lightered offshore onto shuttles. Shipments from Africa, the Mediterranean, and Europe are usually transported in tankers between 90,000 and 175,000 DWT, with direct shipments generally using tankers between 90,000 and 120,000 DWT.

Shipments from the Europe/North Sea/Africa trade route are usually transported in tankers between 90,000 and 175,000 DWT, with direct shipments generally using tankers between 90,000 and 120,000 DWT. Tankers larger than 175,000 DWT are normally lightered. The primary sized vessel used on the Mexico/Eastern South America route for shipments into the SNWW and other U.S. Gulf Coast ports is 90,000 to 114,000 DWT; however, vessels up to 120,000 DWT are not uncommon.²⁷ Review of the 2007 *Fairplay Tanker Register* showed that the design drafts associated with tankers of 90,000 to 114,000 DWT generally range from 40 to 51 feet, with the average being 48 feet. The limited volumes of direct shipments from the Middle East are usually shipped in vessels between 90,000 and 120,000 DWT; however, direct shipment of crude originating in the Middle East is not a cost-effective choice.

The logistics associated with offshore transfers introduce higher degrees of uncertainty than direct shipment and, therefore, generate large cost variances. Industry indicated that lower cost differences between direct versus offshore transfer costs may increase the likelihood of direct shipment. Industry personnel indicated that the number of days to completely lighter a VLCC normally ranges from 4 to 10 and that the average number of days to completely lighter 200,000 to 300,000 DWT vessels is 5.5; however, it was noted that 2 weeks is not uncommon. Five and one-half days equate to 1.5 times the in-port unloading rate. Utilization of the upper limit of 2 weeks appears to relate to a less than optimal number of shuttles and shuttle turnaround rate.

Identification of the number of days used for the SNWW analysis was based on inputs from industry including data outlined in the Skaugen PetroTrans' publication "Introduction to Lightering."²⁸ The mother vessels used for Gulf Coast lightering are generally in the 300,000 to 350,000 DWT range. The SNWW

²⁷ USACE, unpublished data.

²⁸ Skaugen Petro Trans Inc., Introduction to Lightering, October 25, 2006. <http://www.teekay.com/PDFs/Lightering101.pdf>.

cost calculations were based on a VLCC of 320,000 DWT, which is the largest tanker presented in the USACE's EGM. The Skaugen publication includes a graphic with three shuttle vessels taking 3 days to totally offload a VLCC. While not noted in that publication, the use of three shuttles implies a channel depth of 45 feet or more, as each shuttle would need to accommodate 100,000 tons of cargo in order to offload a 300,000 DWT mother vessel. The maximum cargo load that can be transported on tankers between 100,000 and 150,000 DWT, given a 40-foot channel depth, ranges from approximately 70,000 to 86,000 short tons (see Table 109). Given a channel depth of 40 feet, four shuttles are needed to totally offload a 300,000 DWT vessel. Identification of the number of shuttle vessels needed by channel depth is outlined later in this document (see Table 110).

Discussion with industry personnel, including Skaugen, revealed that unloading rates for crude oil would generally range from 4,038 to 5,250 short tons per hour. It was also noted that the rate of 4,038 would be representative for offshore operations; therefore, this rate was used for the SNWW offshore vessel calculations. Given an unloading rate of 4,038 short tons per hour, a 300,000 DWT vessel carrying a full load of 291,000 short tons would take 3 days, or 72 hours, to completely unload based on optimal logistics. Using the same unloading rate, a 350,000 DWT vessel carrying a full load of 339,500 short tons would take 84 hours, or 3.5 days, to completely unload. The SNWW lightering cost calculations are based on the mother vessel being offshore for 24 hours for each shuttle vessel used. Based on 24 hours, the mother vessel would be offshore for a total of 96 hours given four shuttles and 72 hours given three shuttles.

An increase in channel depth would reduce the number of shuttles. For instance, a three-shuttle operation would take 72 hours, down from 84 hours for a four-shuttle operation. The affect of using greater and lesser offshore times on channel depth optimization is evaluated in the sensitivity section (Section 8.6).

The mother vessels associated with lightening are generally in the 150,000 to 175,000 DWT range. Given an unloading rate of 4,038 short tons per hour, a 175,000 DWT vessel carrying a full load of 160,050 short tons would take 19.8 hours, or 0.8 day, to discharge one-half of its cargo. The lightening cost calculations are based on one day or 24 hours. The 24 hours includes a combination of unloading at sea and waiting at sea. Travel time to port was calculated as a separate line item as was unloading time in port. The effect of using greater and lesser times on channel depth optimization is evaluated in the sensitivity section (Section 8.3).

Comparison of direct shipment costs with those for lightering or lightening for the Africa, Mediterranean, and Europe route revealed that while the average cost for lightering or lightening is less than the average cost for shipping direct, the percentage difference between direct shipment costs and the offshore alternatives is considerably less than for either Mexico/South America or Middle East and Far East origins. The relative closeness in the costs between shipping methods for Africa, Mediterranean, and Europe tonnage and, in particular, the variance associated with the number of days necessary to complete the offshore transfer process contributes to a higher percentage of direct shipment for this route than optimal or than least-cost computations would suggest. A risk of delays, in association with the closeness in costs between shipping methods, contributes to a proportion of direct shipments that is higher than

what might occur if the variance associated with the cost of lightering did not overlap with the cost of shipping direct. Examination of the cost data suggests that an increase in channel dimensions would probably result in an increase in direct shipment movements for Africa, Mediterranean, and Europe shipments.

Comparison of the method of shipment costs for Eastern South America and the Persian Gulf did not show that channel depth increases over 50 feet provided cost incentives to switch from one method of shipment to another, given channel depth constraints between 43 and 48 feet. In general, lightening is not cost effective for tonnage on the Persian Gulf trade route because the economies of scale associated with existing practices result in a lower cost for lightering than what would be attained through lightening. The reason lightering is cheaper than lightening for Persian Gulf/Indian Subcontinent shipments is because the magnitude of the mileage component of the per ton cost is large enough to offset the relatively large fixed cost attributable to having the mother vessel remain offshore for 5.5 days. For similar reasons, the relatively short distance and high fixed costs associated with either lightening or lightering eliminates any incentive for Mexico/Eastern South America shipments to shift to lightening. Despite the clear lack of economic rationale for lightering Mexico/Eastern South America tonnage or shipping Persian Gulf/Indian Subcontinent tonnage direct, relatively inefficient shipping methods are used for some shipments on these trade routes. The decision to lighter Mexico/Eastern South America tonnage or ship Persian Gulf/Indian Subcontinent tonnage direct results from less than perfect world market conditions. For purposes of analysis, the least-cost practical alternative was assumed given existing technology and anticipated future innovations. Specifically, the cost calculations were made using direct shipment for the Americas; lightering for the Middle East and Far East; and lightening for Africa, Europe, and the Mediterranean for the 40-foot channel with a transition to direct shipment for increased channel depth alternatives based on transportation cost efficiencies.

Regardless of trade route, the vessel size utilized is sometimes related to the way crude petroleum is sold. Currently, crude petroleum is traditionally sold in parcels of 500,000 barrels. A 500,000-barrel parcel converts to approximately 75,000 short tons. The most economical size vessel for a 75,000-ton parcel is between 75,000 and 100,000 DWT. For 150,000-ton parcels, the most efficient size is between 150,000 and 175,000 DWT. Ninety-four percent of the 100,000 to 140,000 DWT vessels in the world fleet have design drafts in excess of 45 feet, and 32 percent of the vessels between 75,000 and 100,000 DWT have design drafts over 45 feet. The SNWW channel deepening alternatives were formulated assuming that the maximum ship size for both direct shipments and lightered vessels would be 175,000 DWT. Vessels over 100,000 DWT would continue to be light-loaded under the with-project condition; however, there would be a reduction in the number of feet light-loaded. U.S. Gulf Coast industry personnel indicated that parcel size and associated ship size is primarily a function of the existing channel dimensions and that an increase in channel dimensions would likely result in a shift to larger parcel sizes and larger vessels.

Evaluation of the percentage of SNWW tonnage transported in vessels anticipated to utilize depths over 40 feet was primarily based on the relative change in per ton transportation cost between the existing 40-foot channel depth and increased channel depths. Cost analysis suggested that nearly all vessels used to transport crude petroleum from Mexico, Venezuela, and Central and South America would be loaded to

depths over 45 feet. Expectations concerning the percentage of Middle East and Africa movements are subject to greater uncertainty. Nearly all Middle East tonnage is presently lightered. Lightering is also the least-cost alternative for Far East tonnage.

Table 35 presents Port Arthur and Beaumont crude petroleum imports by trade route. The format of the USACE's WCSC's shipping records obtained by the USACE through the Bureau of Census do not provide sufficient information to distinguish lightened tonnage from direct or lightered tonnage. Industry discussions revealed that lightened tonnage is primarily limited to shipments from Western Africa, and transportation cost analysis conducted by the USACE for SNWW confirmed this. While the port loading facilities in Western Africa do presently accommodate the VLCCs associated with lightering, this situation could change over the 50-year period of analysis, and the affect of changing this variable is evaluated in the sensitivity analysis.

The data presented in Table 35 include a "trade route classification" titled "lightered." The tonnage included under this classification includes shuttle vessels associated with lightering and lightening; however, it does not completely reflect the total volume of tonnage associated with the lightering or "offshore transfer" process. In particular, a large part of the tonnage included under West Africa, North Europe, and the Mediterranean, and, to some degree, the Middle East and Far East is partially offloaded onto shuttle vessels. The port classification noted in the Census data for these lightening mother vessels is the country of origin. The port of origin shown for all shuttle vessels is the "international waters of the Gulf of Mexico." Using the data provided, it is not possible to reconstruct the specific routing. For this reason, the costs associated with lightering and lightening need to be reconstructed to determine what the most efficient method of shipment is. While it is cost effective to lighten crude shipped from West Africa and it is cost effective to lighter VLCCs from the Middle East, some tonnage from these routes is presently shipped direct. Additionally, some tonnage from Mexico is lightered. While the method of shipment for all cargo may not represent the most cost effective means, the transportation cost calculations were prepared assuming that the most cost effective method of shipment would be chosen under the without- and with-project future.

The LRS was used to obtain the vessel DWT and associated characteristics.

Table 36 presents comparative trade route data for PADD III. Table 37 presents SNWW's trade route distribution. The SNWW data were compiled were from USACE NDC, and the PADD III data were compiled from the EIA data records.²⁹ The first part of the top shows PADD III imports. Comparison of PADD III data with SNWW indicates the SNWW receives a higher percentage of its crude oil imports from Mexico and a lower percentage from Venezuela than PADD III. Additionally, based on the combined total of Middle East and "lightered tonnage," the SNWW receives a much higher percentage of Middle Eastern crude than PADD III; however, SNWW's "lightered tonnage" also includes shuttle vessels associated with lightening of tankers from West Africa.

Under the current and future without- and with-project conditions, the “mother vessels” offload partial cargoes to shuttle vessels and both vessels come into port. The lightened mother vessels were modeled in the ERDC ship simulation. These “lightened mother vessels” are the “design vessels.” The analysis for the offshore transfer process was based exclusively on operating costs. The duration of the transfer, number of shuttle tankers, supply boats, and equipment was estimated in terms of a “range of time,” and

the costs for vessels and equipment were determined. The shuttle vessel costs and additional pilot and tug charges were identified.

For a with-project condition that includes deepening, the mother vessels would discharge less cargo offshore. Based on the mother vessel discharging less cargo offshore, the with-project condition would affect the number and sizes of the shuttle vessels. For direct shipments, a with-project condition where the channel is deepened would allow for fewer vessel trips as the existing range of vessels would be able to carry more cargo. The specific differences in the without- and with-project conditions are outlined in the transportation cost analysis section (Section 6).

The trade route forecast for SNWW's crude petroleum imports was prepared based on analysis of U.S. import and world production forecasts and application of recent historical SNWW and U.S. Gulf Coast routings. The U.S. and Gulf Coast 2006 period base distribution and the EIA 2010–2030 trade route forecast are presented in Table 38. The EIA is forecasting significant decrease in imports from Mexico. The SNWW ports have historically received over 30 percent of its crude petroleum imports from Mexico; however, in 2007 imports from Mexico only represented 11 percent. The EIA forecasts indicate that the majority of U.S. crude oil imports will come from the Middle East, Europe, and Africa. The principal sources for Middle East and European shipments are included under the following origins: Persian Gulf, Russia, Asia, Eurasia, and China.

The trade route forecast presented in Table 38 was then applied to the crude petroleum tonnage projections. Mileages were weighted based on existing and anticipated percentage of tonnage by trade region. Trade regions were grouped based on general regions and similar vessel utilization patterns and port constraints.

3.6 PETROLEUM PRODUCT CARRIERS

Examination of the vessel characteristics and geographic routings associated with SNWW petroleum products suggests that some product carriers could be more fully loaded. Distribution of SNWW petroleum product imports and exports by vessel DWT class is displayed in Table 39. Analysis of product imports showed that from 32 to 54 percent of 1998–2007 imports and 5 to 27 percent of exports were transported in vessels of 60,000 DWT or more. In 2007, 42 percent of product imports and 14 percent of exports were transported in vessels of 60,000 DWT or more. As noted in Section 2.2, product import variability is also reflected in the distribution of the U.S. products types. This distribution is characterized by annual fluctuations prompted by conditions where outputs fall short or are preempted by other market drivers.

Table 39
SNWW Petroleum Product Import Tonnage by Vessel DWT

The Fairplay/Lloyds Register of Ships (LRS) was used to obtain the vessel DWT and associated characteristics. Vessel DWT, design drafts over 40 feet, and parcel size were among the variables examined to help evaluate the potential transition to deeper vessel loads. Tables 40 and 41 present product imports and exports by major commodity type and shows the annual percent of each grouping transported in vessels of 60,000 DWT or more.

Examination of the data in tables 40 and 41 shows that there are large annual variances in the percentage of annual tonnage associated with the draft and parcel size. Based on this variance and planning guidance, depths at trading ports and comparable operations at similar ports were also evaluated. Discussions with local shippers also indicated that product carriers for some trade routes and customers would be loaded to depths over 40 feet if the channel was deepened. Examination of petroleum product import and exports transported through other U.S. Gulf Coast ports with channel depths over 40 feet showed that 34 percent of distillate imports were loaded to drafts of 42 feet or greater and 24 percent of petroleum coke exports were loaded to drafts of 42 feet or more. Many of these shipments were associated with ports in Russia, North Africa, Venezuela, and Brazil. Other routings include the Far East. The use of the Panama Canal for all of the Far East and over half of the South America destinations will limit the sizes of vessels used for that trade until the Panama Canal expansions are completed after 2014.

Table 42 shows the world petroleum product fleet data as compiled from the LRS. The table includes the percentage of vessels on order as of January 2009. Table 42 shows that 45 percent of the petroleum product tankers on order in 2009 have design drafts of 47 to 49 feet or more and 12 percent have design drafts of 50 feet or more.

* Excludes crude oil and chemical tankers.

While it is anticipated that annual variance will continue, the use of draft-constrained vessels for several markets served by the SNWW is also anticipated to continue and likely increase due to increases in maximum beam width and loaded draft for Panama Canal transits that will open trade opportunities to additional markets. SNWW petroleum coke exports are expected to remain steady due to the construction of an additional coker and increased refinement of high-sulfur crude oil. Table 43 displays the major destinations for U.S. petroleum coke exports. Of the destinations shown in Table 43, the U.S. Gulf Coast primarily serves the North and South American and European markets; however, expansion of the U.S. Gulf Coast share to include Pacific markets may increase after 2014 as a result of the Panama Canal expansion. While published forecasts of specific trade routes are not available, the SNWW presently serves markets that can accommodate more fully loaded product carriers, and it was assumed that some cargo movements would transition to more fully loaded vessels based on the economics of scale of loading to increased depths and availability of channel depths in excess of 40 feet at some trading ports. As shown in tables 40 and 41, relatively large carriers are used for high-volume commodities such as distillate and residual fuel imports and petroleum coke exports.

For petroleum product imports and exports, a steady volume of domestic coastwise product tankers use Port Arthur and Beaumont. Domestic coastwise movements primarily consist of gasoline, distillate, and residual fuel shipments. These products are refined at the SNWW ports and then shipped to the U.S. East Coast, specifically eastern Florida. In 2006, coastwise shipments totaled 3.6 million short tons. Coastwise receipts were 978,000 short tons. Examination of vessel specifics showed that approximately 10 percent of outbound coastwise shipments were transported in draft-restricted tankers. These product carriers generally are between 60,000 and 70,000 DWT with design drafts in the 41- to 43-foot range. The vessels used are all U.S. flag vessels, Jones' Act vessels. The median age of the current fleet exceeds 10 years, with most vessels built in the 1980s. The combination of U.S. tanker availability, depths at trading ports, parcel size demand, the cost effectiveness of loading to greater drafts, and industry discussion suggest that the percentage of tonnage that would utilize channel depths over 40 feet would be closer to 10 percent in the short term increasing to 20 percent over the period of analysis

3.7 CHEMICAL PRODUCT CARRIERS

For the period 2002–2007, chemical imports and exports represented approximately 3 percent of both SNWW and U.S. total foreign tonnage. Evaluation of 1998–2007 chemical exports showed that the percentage of tonnage associated with design drafts between 40 and 44 feet ranged from zero to 14 percent, averaging 4 percent annually. An average of 16 percent of 1998–2006 export tonnage was transported in loaded drafts between 36 and 40 feet. In 2007, 18 percent of SNWW chemical products were transported in vessels with loaded drafts between 36 and 40 feet. Export tonnage represented 75 percent of SNWW 2002–2006 import-export total. Approximately two-thirds of 2002–2007 exports were shipped from Beaumont and the remainder from Port Arthur. Seventy-nine percent of 2002–2007 imports were shipped into Beaumont and the remainder to Port Arthur.

Review of the chemical carrier fleet showed the youngest fleet sector includes a large number of vessels between 30,000 and 49,999 DWT. This portion of the fleet represents over 50 percent of the total fleet. Tables 44 and 45 present data associated with the existing chemical fleet and with vessels on order. Table 44 shows the chemical fleet through 2004, and Table 45 provides comparison of the percentage of total deadweight tonnage for representative classes for 1985–2004 and 2009. Table 45 shows that 21.8 percent

of the chemical tankers on order in 2009 have design drafts of 43 feet or more, and 1.6 percent of chemical tankers on order have design drafts of 47 feet or more.

Consideration of “vessel-on-order” records, world port development trends, and the Panama Canal expansion represent indicators used for projecting future vessel use. Integral to estimating changes in vessel selections is the operational goal of minimizing vessel transportation cost. Minimization of transportation cost, given trade route constraints and commodity parcel needs, recognizably drives long-term vessel choices. Of the vessels on order, 1.6 percent of vessels have design drafts of 48 feet. Review of existing cargo loads suggests that the draft-constrained tonnage will likely consist of metallic salt exports, ammonia imports and acyclic hydrocarbon exports. Project benefits were calculated assuming that approximately 10 percent of future chemical imports and 15 percent of future chemical export tonnage would be transported in vessels with loaded drafts between 40 and 49 feet.

3.8 GRAIN EXPORTS

Grain is exported from the Beaumont elevator located just below the Port of Beaumont main turning basin. Wheat presently composes 100 percent of Beaumont's grain exports for the most recent 5-year period and represented 5 percent of U.S. 2007 wheat exports. During earlier years, wheat represented 85 percent, sorghum 10 percent and corn 5 percent. Table 46 displays Beaumont's 2001–2007 grain export tonnage by grain type and loaded draft.

Source: USACE, Waterborne Commerce Database, 2001–2007.

Thirty percent of 2002–2007 grain export tonnage was shipped in vessels with design drafts over 40 feet. The maximum DWT presently used for grain exports is in the 60,000 to 75,000 DWT range, with 68 percent of 2006 exports. These vessels have design drafts between 42 and 43 feet. The large increase in the concentration of larger vessels since 2006 was due to exports to Iraq. For 2003–2007, the destination for the larger vessels primarily consisted of Egypt, Jordan, and Lebanon. Until the early 1990s, grain carriers in excess of 100,000 DWT used the SNWW. These larger vessels were associated with Eastern Europe grain shipments. The deeper-loaded vessels are nearly all associated with wheat shipments. Review of grain exports for other U.S. Gulf Coast ports with channel depths of 45 feet showed that bulk carriers transporting wheat exports are loaded to 45 feet.³⁰ The specific type of bulk carriers used for grain is “load-on/load off” or “LoLo” vessels. LoLo vessels are also used for SNWW steel slab, limestone, and wood product tonnage. The median year of construction for the range of vessels transporting grain from Beaumont is 1985, which is older than the median of 1998 associated with the world fleet. Review of the distribution of vessels on order and the port depths at receiving ports indicates that some transition in the average DWT range from the existing 60,000 to 75,000 DWT into the 80,000 to 94,000 DWT range is reasonable to expect. Table 47 displays the existing fleet of LoLo vessels in the world fleet; the table also displays LoLo vessels on order.

3.9 STEEL SLAB AND IRON ORE CARRIERS

For the period, 2002–2006, an average of 2.5 percent of U.S. iron ore and steel slab imports were transported through the SNWW ports. For the period 2002–2007, imports ranged from a low of 240 thousand short tons in 2007 and a high of 1,136 thousand short tons in 2005. The 2002–2006 average annual import volume of 783 thousand short tons is over 100 percent higher than 1990–1993 average levels. The decline in 2007 appears to be reflective of the U.S. market. It is noted that imports were unusually high in 2006 partially due to increased demand and higher prices paid in the U.S. market in comparison to foreign markets.³¹ As a result, U.S. inventories increased in 2006. In 2007, import orders were slowed by the excessive inventory and foreign demand. It was emphasized in the *U.S. and International Market Outlook for 2007* that the origin of U.S. steel imports is evolving. It is noted that the shift in the origin of U.S. steel imports applies not only to simpler items like bars and rods but also to more-sophisticated products like oil country goods, cold-rolled coils, and hot-dip galvanized coils. Thus, in oil country goods the leader in 2006 was China; in cold-rolled coils the leaders were Brazil and China; in hot-dip coils India and China. The price of steel scrap dropped in 2007. Long-term expectations are that the market will rebound. Table 48 displays the 2005–2007 countries of origin for SNWW iron and steel imports. India is the seventh largest producer of steel in the world and supplied 26 percent of SNWW steel slab imports in 2007. Steel products are shipped from the Indian port of Dhamra on the eastern coast where channel deepening commenced in 2007. Dhamra will be the deepest port of India with a draught of 18 meters, which can accommodate super cape-size vessels up to 180,000 DWT. The master plan provides for 13 berths, capable of handling more than 83 million tons per annum of dry bulk, liquid bulk, breakbulk, and containerized cargo. The project is expected to be completed by March 2010.³²

Presently, the most common carriers used on the SNWW for the transport of steel slab and iron ore are LoLo bulkers in the 45,000 to 53,000 DWT range, with a maximum vessel size of 78,000 DWT. Review of the Lloyd's/Fairplay Vessel Register (2003) showed that 23 percent of bulk carriers constructed over the past decade are in the 66,000 to 78,000 DWT range. As noted, this is the same vessel type that is used for grain; however, the specific vessels are different with each cargo having dedicated carriers. Examination of the foreign ports of call for 1998–2001 SNWW tonnage showed that an average of 8 percent of tonnage was transported through world ports with channel depths of 44 to 47 feet. Examination of 2005–2007 routings shows a similar distribution of foreign ports as in 1998–2001. Vessel usage and general indicators, such as depths at trading ports and the design drafts for new vessel orders, suggests that, in the short-term, a minimum of 10 percent of present iron ore movements would utilize channel depths over 40 feet. Expansion of the Panama Canal is expected to increase the percentage to 50 percent by the year 2014. Project benefits were calculated assuming that 10 percent of 2015–2020 tonnage and 50 percent of 2020–2069 would be transported in vessels with loaded drafts between 40 and 49 feet.

3.10 LIMESTONE AND ROCK CARRIERS

SNWW aggregate tonnage primarily consists of imports of limestone, rock, and other raw building materials. For the period 2005–2007, 3 percent of U.S. limestone and rock imports were transported through the SNWW ports. Table 49 displays SNWW aggregate tonnage. Presently, the most common carriers used on the SNWW are in the 46,000 to 77,000 DWT range. Table 50 displays the fleet used for SNWW 2002–2007 aggregate imports. Presently nearly all tonnage is transported in vessels with design drafts over 40 feet. Current vessel usage and general indicators, such as depths at trading ports and the design drafts for new vessel orders, suggests that some 50 percent of iron ore movements would utilize channel depths over 40 feet due to the expansion of the Panama Canal. The shipments of clay and refractory materials are associated with vessels with loaded drafts over 37 feet and design drafts over 40 feet.

Table 49
SNWW Building Material Imports and Exports (1,000s of short tons)

3.11 WOOD PRODUCT CARRIERS

For 1998–2006, approximately 1 percent of U.S. wood product tonnage was transported through the SNWW ports. Wood products also represent 1 percent of the SNWW 1998–2006 foreign total. The largest wood product carriers used on the SNWW are in the 50,000 to 60,000 DWT range. The design drafts of these ships are right at 40 feet; and it was found that wood chip carriers, like container vessels, characteristically reach capacity in terms of volume before they reach their design drafts. Review of 2002–2006 data showed that the load patterns were the same as for 1998–2001. The nature of wood chip cargo suggests it is unlikely that the current fleet could be loaded to depths greater than 40 feet and, therefore, deepening benefits were not calculated for wood products. Discussion with industry representatives confirmed this. Additionally, review of the LRS showed that the maximum design draft

for wood chip carriers built between 1995 and the present is 39.4 feet. Analysis of the parcel sizes and 1995 to present construction and ships on order suggests that wood products are unlikely to realize benefits from channel depths over 40 feet in the near future. Analysis of 2002–2007 wood product movements and consultation with industry representatives confirmed these initial findings.

3.12 LIQUEFIED NATURAL GAS (LNG) FLEET

Discussion with industry representatives and review of the vessels on order revealed that LNG vessels with design drafts of 40 feet or more are being constructed. The existing vessel sizes and underkeel clearance requirements suggest that channel depths of 43 to 44 feet would be necessary. Table 51 displays the world LNG fleet, including vessels on order.

Table 51

4.0 COMMODITY AND FLEET FORECASTS

Commodity and fleet forecasts were prepared for crude petroleum and petroleum and chemical products, grain, iron and steel products, limestone and building materials, and LNG. The remaining oceangoing commodity groups, which were found either not to be transported in draft-constrained vessels at the current time or were of limited volumes, were analyzed in the aggregate. Estimation of total traffic was needed for the widening analysis and also provided critical input for the shore erosion effects evaluation performed by ERDC.

National forecast data and general indicators were assessed in relationship to the study area's historical commodity-specific tonnage flows for the purpose of evaluating the relationship between historical U.S. tonnage volumes and study area tonnage. The vessel fleet forecasts incorporate recent historical practices, which reflect continued and increased utilization of draft-constrained vessels under the without- and with-project futures.

The outputs of the commodity and fleet projections were based on forecasts published by Global Insight, USDOE's *EIA Annual Energy Outlook* (AEO2008) and (AEO2009); Global Insight, *The U.S. Economy, The 30-Year Focus*, First Quarter 2008 and Second Quarter 2009; USDA *Agricultural Baseline Projection Tables, USDA Baseline Projections Report to 2018*, February 2008 and February 2009; and from indices developed from historical trend data. The EIA forecasts extend through 2030. The Global Insight forecasts extend through 2035. The USDA forecasts extend through 2018.

The commodity forecasts presented in this document were initially prepared in 2008. The effect of 2009 EIA, Global Insight, and USDA 2009 forecast releases were evaluated and some changes were made to the SNWW projections based on the 2009 forecast releases. The effects of recent forecasts not incorporated into the base analysis are addressed in the sensitivity analysis.

4.1 REVIEW OF PETROLEUM FORECASTS

Table 52 presents the current range of U.S. crude petroleum import forecasts outlined in the AEO2008, AEO2009 and AEO2010. The forecasts presented include the AEO 2008 (January 2008), AEO2009 (March 2009), AEO2010 (May 2010) Global Insight, and Purvin and Gertz's. The AEO2010 data was received late in the report preparation process; therefore, discussion of it is not included in the text. The AEO2009 forecast shows U.S. crude oil imports declining at an annual rate of approximately -2.0 percent between 2007 and 2030. The AEO2009 forecast reflects the effect of the American Recovery and Reinvestment Act of 2009 in February 2009 and shows U.S. demand for liquid fuels growing by only 1 million BPD between 2007 and 2030 and shows no growth in oil consumption over the forecast period. Oil use is curbed due to the combined effects of a rebounding oil price, more-stringent corporate average fuel economy standards, and requirements for the increased use of renewable fuels. A key difference between the AEO and Global Insight forecasts is that the relative percentage crude oil and petroleum imports reflects higher volumes of products than the Global Insight forecast. Comparison of the relative distributions of U.S. and SNWW imports between crude oil and refined products shows that SNWW's

distribution reflects a significantly higher relative percentage of crude oil than products. Table 53 displays distributions of SNWW and U.S. relative percentages of crude petroleum versus refined products. Comparison of the SNWW and U.S. distributions shows that SNWW receives a significantly higher share of crude petroleum than the Nation as a whole. As a major refinery center, the SNWW distribution shown in Table 53 is expected to continue without- and with-project future conditions.

Another major difference between AEO and Global Insight is that the EIA reference forecast reflects higher domestic crude oil production throughout the projection period. Additionally, the EIA shows domestic production increasing rapidly instead of gradually. As noted on the EIA website, their forecast not only shows higher domestic production, it also shows rapid increase in domestic production.

In spite of differences in the relative distribution of crude oil versus products, analysis of the national and regional crude petroleum import volumes showed a high degree of correlation between study area and U.S. tonnage levels. The high correlation rates suggested that application of U.S. forecast trends to the study area is generally appropriate (Section 2); evaluations also showed that SNWW's overall rate of growth is higher than for the U.S. and Gulf Coast (see Table 8). Continuation of historical trends suggests that SNWW crude petroleum imports would grow at higher rates than the region (PADD III) and the Nation. Refineries in PADD III provide significant product supply to both the East Coast and Midwest. For example, about 60 percent of all gasoline produced in PADD III refineries is moved to other regions for consumption. In 2008, nearly half of the gasoline consumed in the East Coast region (PADD I)—about 1.6 million BPD—was supplied from PADD III. PADD III refineries supplied about 18 percent or approximately 0.5 million BPD of gasoline consumed in the Midwest (PADD II). PADD III also supplies a small amount of gasoline to the West Coast region (PADD V), mainly Arizona. Most of the gasoline volume moved from PADD III to those regions travels by pipeline (80 percent by pipeline into PADD I, 90 percent into PADD II, and virtually all into PADD V).

The historical trendline and anticipated 2012 completion of the 325,000 barrel per day crude petroleum refinery capacity in Port Arthur suggests that downward growth rate reflected in the AEO2009 forecast does not characterize SNWW's future. The Port Arthur and Beaumont terminals transport 400,000 BPD of waterborne crude oil via pipelines to inland refineries including refineries in Texas, Louisiana, Oklahoma, Ohio, Arkansas, and Kentucky.³³ The SNWW refineries supply 15 percent of the product on Colonial's system and 13 percent of the product on Explorer's system (see Figure 10). SNWW's capacity represents 6 percent of the U.S. total. Specific capacity is 572,000 BPD for Port Arthur and 577,000 BPD for Beaumont. SNWW capacity levels for 2009 are presently 12 percent higher than in 2004, and 31 percent higher than in 1994. The Motiva expansion of 600,000 BPD will result in a 52 percent increase in SNWW refinery capacity from the current volume of 1,149,000 BPD to 1,749,000 BPD. The Motiva expansion will make it the largest refinery in the U.S. and one of the largest in the world.

SNWW's crude oil imports were prepared using the Global Insight forecast shown in Table 52. The Global Insight's forecast reflects continuous increases in refinery processing gains through 2035. Refinery gains, which are measured by the differences in volumetric gains and are reflected by total outputs greater than input due to the processing of crude into products, were significant over the last 12 years (Figure 26). Review of the data presented on Figure 26 shows a maximum processing gain of 1.05 million BPD in 2004. Global Insight forecast of refinery gains exceed historical levels by approximately 5 percent in 2019 and 15 percent by 2030.

Other considerations in forecasting include the geographical source of imports or the use of oceangoing vessels versus pipeline, and, as noted, the share of conventional versus nonconventional liquids. Both the AEO and Global Insight project increases in nonconventional energy production and trade. SNWW

³³Martin Associates. 2006. Economic Impacts of the Sabine-Neches Waterway and Economic Benefits of Maintenance Dredging of the Waterway. Martin Associates, Lancaster, Pennsylvania.

presently receives some conventional Canadian crude by vessel and through existing pipelines; however, annual volumes are low due to pipeline limitations and market logistics that favor other locations.

Canadian crude oil has historically been consumed in five market areas that include Ontario, British Columbia, Washington State, U.S. Rocky Mountains, and U.S. Midwest.³⁴ The TransCanada Corporation is in the process obtaining permits for expansion to the Keystone Pipeline System. While the system that stretches from Alberta, Canada, to Cushing, Oklahoma, is completed, an additional extension from Cushing to the U.S. Gulf Coast is under evaluation. Financial commitments for the extensions to the Texas Gulf Coast are not expected before 2011.³⁵

4.2 SNWW CRUDE PETROLEUM FORECAST APPLICATION

Identification of the specific range of import volumes was estimated by incorporating the forecast volumes into a regression equation using SNWW imports as a function of U.S. imports. Table 54 displays SNWW's regression equation application using the Global Insight forecast results shown in Table 52. The equation is based on 1990–2007 data. An R Square of 0.903 was produced from the equation. The t-value and F statistic for the equation are significant at statistical confidence levels exceeding 99.999 percent. The resulting application shown in Table 54 includes the application of one standard deviation from the mean. The mean values range from 86,639 thousand short tons in 2019 to 101,016 thousand short tons in 2035. The band associated with the standard deviation produces import estimates of plus and minus

approximately 41 percent, which produces a 2035 minimum of 60,218 thousand and a maximum of 141,813 thousand sort tons, with 101,016 thousand representing the mean.

a/ SNWW 2019 Imports = $-41677.6 + (0.5456.66 * 638,425)$ with 638,425 short tons being U.S. imports in 2019.

The SNWW regression equation results presented in Table 54 reflect the inclusion of several variables that reduce future estimated volumes. One variable is the effect of Hurricane Rita. Declines in 2005–2007 imports are largely attributable to supply disruptions associated with Hurricane Rita, which devastated the SNWW region in September 2005. The hurricane surge resulting from Rita resulted in sand bars at the offshore Entrance Channel and silting of the Neches River Channel to Beaumont. Silting of the Neches River Channel severely limited transit of the upper reaches for several months and resulted in tonnage diversions to other ports due to loaded-draft limitations. The effect of shoals in the Entrance Channel and

silt deposits in the Neches River due to the hurricane surge had a particularly strong effect on crude petroleum traffic due to the use of large heavily loaded vessels. Comparison of SNWW crude petroleum tonnage with comparable ports is shown on Figure 27. The figure helps to illustrate the effect on short-term trends and resulting changes in the distribution of imports.

Figure 27
SNWW and Other Texas Ports
Crude Petroleum Imports (1,000s of short tons)

Source: USACE, *Waterborne Commerce of the U.S.*, 2005–2007, unpublished data.

Based on concerns from SNWW industry interests, the effect of excluding 2005–2007 data was examined. The results of excluding 2005–2007 produces a higher volume of long-term imports and reduces the standard error associated with the Y estimate (Table 55). The mean values range from 94,229 thousand short tons in 2019 to 110,765 thousand short tons in 2035. The band associated with the standard deviation produces import estimates of plus and minus approximately 21 percent.

Figure 28 displays the regression estimate associated with equations using SNWW imports as a function of U.S. imports. Figure 29 displays 1990–2004 actual imports and the statistical estimated, including the 95 percent confidence interval. Excluding 2005–2007 from the regression based forecast helps to account for the short-term effects of Hurricane Rita; however, there are other variables that are likely to result in higher future import volumes than the 1990–2004 based regression equation would suggest. The key variable that cannot be measured accounted for in regression is refinery capacity expansions. Construction on the 325,000 BPD crude petroleum refinery capacity in Port Arthur is expected to be completed in the first quarter of 2012. This addition will result in a 28 percent increase in SNWW refinery capacity from the current volume of 1,149,000 BPD to 1,473,000 BPD.

Other forecasting methods considered include trendline estimates. Table 56 presents the outputs of trendline estimates using 1980–2004 and 1990–2007 input data. As shown in Table 56, the mean values associated with the base are reasonable but the range of the 95 percentile confidence interval does not produce meaningful results.

Source: USACE, *Waterborne Commerce of the U.S.*, Part 2, 1980–2007.

Figure 30 displays comparison of the AEO2008, AEO2009, Global Insight, Purvin and Gertz, and 1980– and 1990–2007 trendline SNWW projection estimates. Comparison of the slopes associated with the SNWW’s 1980–2000 base data illustrates higher historical rate of growth for most years. The presentation shows that application of the AEO2009 forecast produces declining imports for 2010–2030. The other forecasts presented on Figure 25 show a range of increasing import volumes. SNWW high growth between 1990 and 2004 strongly affects SNWW’s future trendline. The Global Insight import estimates shown on Figure 30 correspond to the regression outputs shown in Table 55; these volumes were used for the base case. Sensitivity analyses were performed based on the AEO2009 forecast.

Figure 30
SNWW Crude Petroleum Import Forecast Comparisons

Source: USACE, *Waterborne Commerce of the U.S.*, Part 2, 1980–2006, Global Insight (2008), and EIA (2008).

Additional equations were calculated based on the inclusion of year in combination with the AEO2008, AEO2009, Global Insight, and Purvin and Gertz import forecasts. Those equations produced adjusted R squared values in the 85 to 90 percent range; however, they exhibited higher ranges of variances than the trendline output shown in Table 55. Other variables evaluated included world petroleum production. These variables performed poorly individually and in combination with U.S. imports and refinery capacity variables. It was concluded that U.S. crude oil imports by itself performed better statistically than any other single variable or combination of variables. Table 57 presents the SNWW crude petroleum import forecast.

4.3 PETROLEUM PRODUCT IMPORTS

Forecast of SNWW petroleum product imports and exports is based on analysis of regional data and national trends. Large increases for U.S. imports of gasoline and distillate occurred over the last 16 years, with the SNWW generally experiencing comparable or greater increases. For instance, SNWW 2004–2006 average distillate import volume of 1,668,000 short tons is 1800 higher than 1990–1992 levels. SNWW distillate imports presently make up 3.1 percent of the U.S. distillate import total. SNWW gasoline imports averaged 11,000 short tons for 1990–1992, with the 2004–2006 average increased to 1,696,000 short tons. Table 58 displays U.S. and SNWW 1994/1996 and 2004/2006 average import volumes by major commodity group. Inclusion of 2007 data reduces SNWW's most recent 3-year average to 4,202 thousand short tons from the 2004–2006 average of 5,057 thousand short tons shown in Table 58. In spite of downturns in 2007, SNWW experienced significant overall increases in gasoline and distillate imports (see Table 13). Inclusion of 2007 data reduces the 2004–2006 U.S. average by approximately 1 percent.

While SNWW 2002–2007 product imports are at historical highs, overall U.S. product imports are projected to decline from 2010–2030. Table 59 shows comparison of the AEO2008 projections with Global Insight's forecast. The Global Insight forecast shows product imports increasing after 2030.

4.4 FUEL OIL IMPORTS

Comparison of the national and regional fuel oil volumes shows some correlation between study area and U.S. product imports. While total product volumes are correlated with the U.S. levels, the specific correlations with SNWW's distillate and residual fuel oils are weaker. Regional growth for distillate and residual fuel is considerably higher than the U.S. rates. While the EIA notes in earlier publications that structural shifts occurred over the last few decades in the mix of products and that residual fuel oil imports are projected to decline and be replaced by unfinished gasoline and gasoline blending components, analyses conducted for the current SNWW waterway study show that PADD III residual fuel imports have continued to increase. Table 60 presents SNWW 1990–2006 residual and distillate fuel imports and the region's respective shares. Current indications suggest that PADD III and SNWW waterborne imports of distillate, which is a light product, will increase some in the future.

Table 60

Source: USACE, *Waterborne Commerce of the U.S.*, Parts 2 and 5, 1990–2007.

Figure 31 shows total U.S. distillate imports for 1990–2007, and Figure 32 presents a comparison of U.S. waterborne distillate imports with SNWW volumes. Comparisons of U.S. and SNWW residual fuel oil imports are shown on figures 33 and 34. Figure 31 includes waterborne and land route imports. As noted, Table 60 is limited to waterborne movements, and does not include Canadian products transported by pipeline, rail, or truck.³⁶ Overall, analyses of the EIA databases showed that approximately 16 percent of 2004–2006 U.S. product imports are from Canada.

³⁶ Unless otherwise noted, tables and figures only include waterborne traffic.

U.S. Imports of Residual Fuel,
Waterborne and Land Routes 1990–2007

Figure 34
U.S. and SNWW Residual Fuel Imports 1990–2007 (Waterborne Routes Only)

The percentage of U.S. petroleum products imported from Canada increased by 74 percent from 1994/1996 to 2004/2006. The EIA shows Canadian production of conventional fuel declining relative to its oil sand production. Historically, imports of products from Canada to the SNWW ports are low due to the relatively longer distances compared to other markets in the Midwest and the East Coast. Expectations about expansion of Canadian crude and products to the Gulf Coast are uncertain, but recognizably could significantly affect SNWW's tonnage forecast. PADD III imports of Canadian petroleum products decreased by 8 percent over the same period.

The AEO2008 is forecasting that 2006–2030 imports of “blending components” decrease by –1.1 percent. Blending components include oxygenates, but consist mainly of products that could be classified as finished gasoline in other jurisdictions or products that require little additional blending to be classified as finished gasoline. For purposes of the waterborne commerce classification, blending components are classified as gasoline. Distillate is contained in the EIA classification of “unfinished oils.” Unfinished or light oils are produced by partial refining of crude oil and include naphtha and lighter oils, kerosene and light gas oils, heavy gas oils, and residuum. Based on direct application of AEO and Global Insight anticipated trends, residual SNWW imports could decline; however, due to its use as an input in the refining process and for the production of specialized products, anticipated regional declines, if any, will be less than for the Nation. At the same time it is recognized that petroleum products contribute to a significantly smaller percentage of total petroleum imports (see Table 53) Comparison of 2002–2007 U.S. and PADD III residual fuel imports shown in Table 61 illustrates that while both U.S. and regional imports grew in 2007, regional growth was considerably higher. The presentation shows that PADD III residual fuel imports increased at significantly higher rates than the U.S. and East Coast rates. The East Coast is contained in PADD II and is presented here to illustrate its large market share and its weighted effect on national averages.

Light products and unfinished oils, including gasoline, naphtha, distillate, and, liquefied natural gas, are projected to increase at higher rates than heavy products. The EIA definition of unfinished oils includes light products. While imports of heavy products such as residual fuel oil are projected to decline and be replaced by unfinished gasoline and gasoline blending components, the market for residual may remain relatively high for SNWW and other Texas refinery centers that process heavy, or high-sulfur, crude petroleum. Texas Gulf Coast oil company transportation analysts verified that an increase in refined product imports would be necessary to meet processing needs and associated demand with growing imports for both light and heavy products. The Gulf Coast imports a significant amount of feedstock to support its role as the main U.S. refining and petrochemical center. The AEO forecast shows low growth for unfinished product imports, with an average annual growth rate of 0.1 percent from 2006 to 2030. Again, expectations are for slightly higher regional growth of unfinished products imports. An additional item worth noting is that the current U.S. volume of 0.69 million BPD represents an estimated 41 percent increase of the 2004 volume and, therefore, provides a significantly higher base level for the forecast application.

a/ Average annual growth rate (AAG).

Comparison of 2002–2007 U.S. distillate imports with PADD volumes show that while both U.S. and regional imports grew in 2007, growth for the U.S. Gulf Coast, as represented by PADD III, was considerably higher. Again, the variance in regional growth rates can be seen based on the data presented in Table 62. The presentation shows that distillate imports for PADD III increased relative to U.S. and East Coast rates.

SNWW fuel oil import forecasts are based on the assumption that the region will maintain its recent historical share of the U.S. market with imports increasing. Forecasts were prepared for distillate, residual

and gasoline imports. As shown in Table 62, the U.S. 2002–2007 average annual growth rate of 2.4 percent compares to the PADD III recent historical rate of 71.6 percent.

a/ Parts per million (ppm).

Table 63 displays SNWW distillate fuel oil import forecast. Comparison of SNWW 1994–1996 and 2004–2006 rates with those for the Nation showed that the region historically experienced higher growth rates than the Nation. A 1 percent growth rate was used for 2019–2069. While recognizably subject to uncertainty, the SNWW increases represent a new market, and short-term higher growth is anticipated. The effects of this uncertainty were evaluated in the sensitivity section of the Final Feasibility Report and are discussed in the risk section of this report. Figure 35 shows the SNWW forecast applications.

SNWW's low growth scenario assumes that regional distillate import growth will be comparable to the U.S. import rate. The scenario used for the benefit calculations was prepared using the expectation that the average annual growth rate for SNWW distillate imports would increase at approximately 1 percent annually through 2069. This forecast is included in the third column in Table 63.

Figure 35
 SNWW Distillate Imports 2000–2030
 (1,000s of Short Tons)
 Comparison of AEO2008 U.S. Forecast and SNWW Applications

Table 64 displays SNWW residual fuel oil import forecast. Due to uncertainty associated with residual imports, SNWW residual fuel import forecasts were assumed to grow at 1 percent annually between 2004/06 and 2069. While specific residual fuel import forecasts are not published by the EIA or Global Insight, Global Insight publishes a residual and distillate demand forecast. The growth rates associated with Global Insight's demand forecasts were considered, along with SNWW distillate and residual import tonnage, in estimating future imports. Table 65 summarizes Global Insight's residual and distillate fuel demand forecasts.

4.5 GASOLINE IMPORTS

SNWW gasoline imports increased significantly since the early 1990s, with current volumes exceeding 1.6 million short tons. SNWW gasoline imports presently compose approximately 3 percent of the U.S.

total waterborne gasoline imports. For the most recent 10-year period, approximately 90 percent of SNWW gasoline imports were shipped to Beaumont, with the remaining 10 percent to Port Arthur. Figure 36 presents a comparison of U.S. 2000–2006 gasoline imports with combined Beaumont and Port Arthur imports.

While U.S. gasoline imports have also increased dramatically, the EIA shows reductions in U.S. imports of gasoline blending components from 2006 to 2030. Increases in U.S. refinery capacity may be contributing to expected decline in the need for U.S. gasoline imports by allowing for increased domestic production. Over 98 percent of SNWW gasoline imports arrive by ship. In comparison, over 75 percent Midwest gasoline imports are transported by land from Canada. Canadian imports to the U.S. increased from 7 percent for 1994–1996 to 13 percent for 2004–2006.

Figure 36
U.S. and SNWW Waterborne Gasoline Imports and SNWW Gasoline Imports
(1,000s of Short Tons)

SNWW gasoline imports are expected to increase at slower rates than those recently experienced and, while future expectations are subject to a high level of uncertainty, regional imports forecasted to increase for the SNWW base scenario. The base scenario assumes that SNWW gasoline imports will grow at 1 percent annually from 2006 to 2069. Table 66 presents SNWW 2004–2069 gasoline import forecast. SNWW gasoline import forecast was assumed to grow at approximately 1 percent annually between 2004/06 and 2069. In its December 2007 report to Congress, the GAO³⁷ notes petroleum is a key impetus for growth in global trade in petroleum products and that there has been a structural surplus in production

³⁷ United States Government Accountability Office, Report to Congressional Requesters, GAO report number GAO-08-14 entitled 'Energy Markets: Increasing Globalization of Petroleum Products Markets, Tightening Refining Demand and Supply Balance, and Other Trends Have Implications for U.S. Energy Supply, Prices, and Price Volatility' released January 18, 2008. <http://www.gao.gov/text/d0814.html>.

of gasoline and a deficit in production of diesel in Europe. They note that the surplus of gasoline is largely the result of a “systematic switch” in European countries toward automobiles with diesel-powered engines, which are more efficient than gasoline-powered engines. European regulators promoted diesel fuel use in Europe by taxing diesel at a lower rate, and European demand for diesel fuel-powered vehicles rose. The European refining and marketing sector responded to this change in demand by importing increasing amounts of diesel and exporting a growing surplus of gasoline to the U.S. A conclusion was that the effect of this structural imbalance within the European Union will continue for the foreseeable future, and perhaps widen, resulting in more exports of European gasoline and blending components to the U.S.

Table 66

2004/2006–2069	0.9%	0.0%

4.6 PETROLEUM PRODUCT EXPORT FORECAST

U.S. petroleum product exports primarily consist of petroleum coke (47 percent), distillate fuel (16 percent), gasoline (16 percent), and residual fuel oil (13 percent). SNWW exports primarily consist of petroleum coke (67 percent) and gasoline (25 percent). Analysis of SNWW’s specific export groups, particularly petroleum coke and gasoline exports, show fair to good degrees of correlation between the study region and the U.S. For instance, the R square using 1990–2007 period data is 0.79 for petroleum coke and is 0.78 for gasoline.

4.7 PETROLEUM COKE EXPORTS

Published forecasts of U.S. coke exports are not available; however, indicators suggest an increased demand for coke. Ongoing construction of cokers in regions other than SNWW is indicative of increased demand. Increasing volumes of high-sulphur crude oil also suggest increasing volumes of residual coke.

Figure 37 illustrates the change in API index of U.S. crude petroleum imports.³⁸ Subsequently, analysis of the relationship between U.S. and SNWW petroleum coke exports and API indices associated with heavy crude oil demonstrated that coke exports are well correlated increasing U.S. imports of high-sulfur crudes (Figure 38).

Figure 37
U.S. Crude Petroleum Imports by API Gravity Classification (%)

³⁸ The API (American Petroleum Institute) gravity measures the relative density of oils. It serves as a rough measure of the quality of crude oils. The higher the API gravity number, the higher the API gravity, the lighter the compound. Light crude oils generally exceed 38 degrees API.

Figure 38
 SNWW and U.S. Petroleum Coke Exports and
 % of U.S. Crude Petroleum Imports by API Gravity Classification (%)

Analysis of the 1990–2007 relationship between U.S. petroleum coke exports and the percentage of crude petroleum imports with an API of 25 percent or less produced an adjusted R square of 0.94. The t value and F statistics associated with the equation is significant at the greater than 99.9 percent confidence levels. The relationship between SNWW petroleum coke exports and the API percentage produced an adjusted R square of 0.71, with a value of F statistic significant at the 99.99 confidence level.

Examination of 1990–2007 data showed that SNWW petroleum coke exports represents 14 percent of the U.S. waterborne exports, up from 4.6 percent in 1990. The U.S. is the world's largest supplier of petroleum coke. U.S. petroleum coke exports increased in 2008 by 3 percent over 2007 levels. The EIA shows refinery consumption and other domestic use of petroleum coke declining through 2030. At the same time, domestic production will increase based on the production of additional capacity and increased refinement of high-sulfur crude oil. Based on general indicators, including SNWW coker expansion, SNWW petroleum coke exports were assumed to follow SNWW and U.S. historical export trendlines. The refinement of high-sulfur crude oil, the processing of petroleum coke as a by-product, and the expansion of SNWW's coke-processing facilities supports this expectation. High-sulphur crudes are associated with both foreign imports of crude and Gulf of Mexico production.

Given the expectation of increased growth, a trendline using 1990–2005 SNWW exports as a function of time was used to represent the base forecast. Data for 2006–2007 were not originally available when the forecasts were prepared. Alternative forecasts using average annual growth rates were evaluated; however, the average annual growth exhibited variations. SNWW's 1990–1995 average annual growth rate is 36.5 percent, the 1995–2005 average annual growth rate is 1.3 percent, and the 2000–2005 average

annual rate is 11.8 percent. Growth rates based on 2-year point averages from 1990–2007 exports range from 3 and 10 percent. Figure 39 displays the 1990–2007 point averages.

Figure 39
SNWW Petroleum Coke Exports (1,000s of short tons)
1990–2007 Point Averages

Table 67 summarizes projections prepared using the 1990–2005 trendline, the 1995–2005 average annual growth rate of 1.3 percent, the 2000–2005 average annual growth rate of 11.8 percent, the 1990–2005 point averages of 3 and 10 percent, and the “no growth” forecast. SNWW transportations savings benefits were calculated using the forecast labeled “1990–2005 adjusted trendline.” A 2039–2069 average annual growth rate of 1 percent was used for all of the forecasts except the “1990–2005 trendline” and the “no growth forecast.” Figure 40 displays a comparison forecast trendlines shown in Table 66.

Figure 40
SNWW Petroleum Coke Export Forecast Scenarios
(1,000s of Short Tons)

4.8 GASOLINE EXPORTS

SNWW gasoline exports steadily increased since the early 1990s. For the most recent 3-year period, exports averaged 1.8 million short tons. Figure 41 shows SNWW's 1990–2007 trendline of gasoline exports. SNWW gasoline exports compose approximately 18 percent of the U.S. total waterborne gasoline exports. As shown on Figure 41, regional gasoline exports growth is strong, with the regional growth continuing to increase through 2007 when U.S. and PADD III exports volumes dropped slightly. Figure 42 displays 1982–2007 U.S. and PADD III export volumes.

For the most recent 3-year period, approximately 75 percent of SNWW gasoline imports were shipped to Beaumont and the remaining 15 percent to Port Arthur. Port Arthur's share increased from zero in 1990 to 28 percent in 2006. Most of SNWW gasoline exports are shipped to Mexico. The study region's share is more constant than the U.S. share, which declined some over the most recent 10-year period. Over 2005–2007, nearly 75 percent of U.S. gasoline exports were also transported to Mexico. For 2002–2004, 83 percent of U.S. gasoline exports were transported to Mexico. Over 95 percent of SNWW gasoline exports for the most recent 5-year period were shipped to Mexico.

Figure 41
SNWW Gasoline Exports
1,000s of short tons

Figure 42
U.S. and PADD III Gasoline Exports, 1982–2007
1,000s of Barrels

Comparison of U.S. and SNWW waterborne commerce records for gasoline exports showed a relatively strong level of correlation between the Nation and the region. The R square between 1990–2007 SNWW petroleum and U.S. gasoline exports is 0.71. PADD III gasoline exports produced an R square of 0.79. Published forecasts of gasoline exports are not available from the EIA or Global Insight. SNWW gasoline exports grew at an average annual rate of 27 percent from 1990 to 2007 and approximately 2.7 percent from 2004 to 2007. U.S. and PADD III 1990–2007 gasoline exports grew at an average annual rate of approximately 17 percent, with 2004–2007 U.S. and PADD III exports growing at rates comparable to the 1990–2007 rates. Trendline analysis of 1990–2007 SNWW gasoline exports as a function of time produced an adjusted R square of 0.92. Forecast of SNWW gasoline exports was evaluated based on comparison of the trendline and growth rate applications. Table 68 summarizes the gasoline export forecast applications evaluated for the SNWW study. SNWW's future gasoline exports were forecasted based on the 2004–2007 growth rate application (column 3, Table 68). Figure 43 displays a comparison of the forecasts evaluated.

Figure 43
U.S. and PADD III Gasoline Exports
1,000s of Short Tons 1990–2030

4.9 DISTILLATE EXPORTS

U.S. distillate exports increased at an annual rate of 14 percent between 1990 and 1994 and declined from 1994 through 2002 before increasing to 1991 levels. PADD III exports also followed a similar pattern. In 2006 and 2007, SNWW exports were comparable to 1990–1991 levels. Figure 44 shows U.S. and PADD III 1990–2007 distillate exports. Distillate fuel oil represents approximately 7 percent of SNWW’s 2004–2006 product exports. Approximately 80 percent of SNWW’s distillate exports were shipped from Port Arthur, with the remaining 20 percent shipped from Beaumont. Figure 45 shows comparison of U.S. and SNWW waterborne distillate exports

As shown on Figure 45, U.S. distillate exports increased dramatically between 2004 and 2006. SNWW distillate exports remained relatively flat from 1990 through 1995 before increasing to over 600,000 short tons in 1997 and 1998. Exports then dropped to near zero in 2000 before steadily increasing through 2005, with volumes down in 2006 and 2007, and 2007 exports totaling 345,000 short tons. While distillate is exported to countries all around the world, the largest share of SNWW distillate exports is shipped to Mexico. Review of 2004–2006 vessel records showed that the largest vessels are associated with shipments to Mexico. Review of International Energy Administration world trade data for 2006–2008 show an increase in U.S. trade with Mexico between 2006 and 2008. Comparison of the EIA’s first quarter 2008 product exports show an 18 percent increase over first quarter 2007. In its AEO2009 (SR/OIA/2009-03), the EIA shows U.S. petroleum product exports increasing at an average annual growth rate of 1 percent from 2006 through 2030. For forecasting purposes, SNWW’s 2004–2006 average tonnage was used as a base for the forecast application. In its December 2007 report to Congress, the GAO noted that petroleum product trade will continue to grow as global trends move towards increasing demand of lower sulfur fuel.

Figure 44
U.S. and PADD III Distillate Fuel Exports
1990–2007 Waterborne and Land Routes

Figure 45
U.S. and SNWW Distillate Fuel Exports
1990–2006 Waterborne

The indication is that lower sulfur fuel will necessitate increased processing as it becomes increasingly scarce. The GAO noted that strong demand for certain petroleum products, particularly distillates, will increase competition for and facilitate global trade of petroleum products in particular distillates. Based on its position as a major refinery center, expectations are that SNWW product exports will increase at a greater rate than the Nation. All indications are that refining and export of petroleum products will increase. Based on these indicators, an average annual growth rate of 2.5 percent was used for SNWW 2006–2069 exports. Table 69 summarizes the gasoline export forecast applications evaluated for the SNWW study. The first column presents U.S. distillate exports and application of the AEO2009 (SR/OIA/2009-03) petroleum product export forecast. The next column summarizes application of the AEO growth rates to SNWW’s 2004–2006 base. The AEO applications result in an average annual growth rate of 1 percent over 2004–2006 to 2029. The 2039–2069 volumes are based on continuation of a 1 percent growth rate. The third column summarizes application of a growth rate of 2.5 percent to the SNWW 2004–2006 base through 2039. The forecast in the last column is based on no growth beyond the 2004–2006 average. The forecast shown in column three was used for the benefit calculations. The 2039–2069 volumes for all growth forecasts are based on continuation of a 1 percent growth rate.

4.10 COASTWISE PETROLEUM PRODUCTS

SNWW domestic coastwise movements primarily consist of gasoline. Examination of vessel characteristics and geographic routings suggested that 10 to 20 percent of outbound coastwise shipment tonnage would benefit from channel depths over 40 feet. The draft-restricted product carriers are generally between 60,000 and 70,000 DWT with design drafts in the 41- to 43-foot range. As shown on Figure 46, SNWW coastwise movements increased steadily since the mid-nineties. Movements prior to 1995 primarily consisted of crude petroleum. Current movements consist almost exclusively of gasoline shipments. The majority of shipments are to Florida and the U.S. Northeast. As with product exports, based on SNWW's position as a major refinery center, expectations are that coastwise shipments are expected to increase at an increasingly steady rate based on the region's position as a major refinery center. Table 70 summarizes the SNWW coastwise forecasts evaluated for the SNWW study.

Figure 46
SNWW Coastwise Shipments
1995–2007 Waterborne

Table 70
SNWW Coastwise Movement Forecast Scenarios
(1,000s of Short Tons)

Year	SNWW Coastwise Movements 1998–2007 Trendline	SNWW Coastwise Movements 1% Growth	SNWW No Growth Beyond 2005–2007 Average
1990	8,906	8,906	8,906
1995	3,909	3,909	3,909
1996	5,386	5,386	5,386
1997	4,197	4,197	4,197
1998	4,284	4,284	4,284
1999	3,989	3,989	3,989
2000	3,863	3,863	3,863
2005	4,770	4,770	4,770
2006	5,438	5,438	5,438
2007	5,762	5,762	5,762
2010	6,121	5,595	5,323
2015	7,110	5,880	5,323
2019	7,901	6,119	5,323

2039	11,857	7,466	5,323
2049	13,834	8,248	5,323
2059	15,812	9,110	5,323
2069	17,790	10,064	5,323
Average Annual Growth Rates			
2005–2019	2.9%	1.0%	0.0%
2005–2069	1.8%	1.0%	0.0%

While review of the historical vessel movements showed that nearly half of petroleum product shipments was shipped in vessels with design drafts over 40 feet, the combination of U.S. tanker availability, depths at trading ports, parcel size demand, and industry discussion suggests that the tonnage that would utilize channel depths over 40 feet would not exceed 10 percent. Channel deepening benefits were calculated based on 10 percent of 2019–2069 tonnage.

4.11 REMAINING PETROLEUM PRODUCT EXPORTS

SNWW's remaining product exports include lube oil and naphtha, with each representing approximately 1.5 percent of total petroleum product exports and totaling less than 100,000 short tons from 1995 through 2006. The 2004–2006 export volumes for lube oil and naphtha were assumed to grow at 1 percent annually in future years.

4.12 CHEMICAL IMPORTS

The largest volumes, and the highest growth rates, for SNWW imports are for alcohols and ammonia, with present imports of these inorganic chemicals up by over 4,000 percent from the previous 10-year period. In comparison, U.S. chemical imports are currently over 200 percent higher than in the early 1990s. Currently, U.S. alcohol imports are over 500 percent higher than in the early 1990s, and ammonia imports are up by over 200 percent. Figure 47 displays U.S. alcohol and ammoniac imports for 1990–2007. For 2004–2007, Beaumont ammonia imports represented approximately 6 percent of the U.S. total, having increased from less than 5,000 short tons in the early 1990s to 460,000 short tons in 2006. The largest rates of growth for U.S. imports were for agricultural fertilizers. Fertilizers compose 33 percent of total chemical imports. While agricultural fertilizers are exported from SNWW, none are imported.

Figure 47
U.S. Alcohol and Ammonia Waterborne Imports 1990–2007
(1,000s of short tons)

Figure 48 displays SNWW 1990–2007 alcohols and ammonia imports. Eighty-nine percent of SNWW methyl alcohol imports comes from Trinidad, 8 percent comes from Chile, and the remaining 3 percent from Venezuela. The Trinidad plant represents the world's largest methanol production plant and is capable of producing 5,000 tons per day. The plant located in Punta Arenas, Chile, plans to triple its methanol production capacity by the end of 2008. Additionally, the Economic Research Service of the USDA notes that new plants are planned in West Africa and the Middle East, with those locations presently serving markets other than the SNWW.

U.N. studies suggest that worldwide demand will grow at 5 percent but indicate that the higher growths are expected to be associated with emerging markets. Analysis of the SNWW and national total indicated a reasonable level of correlation between the study area and the Nation; however, SNWW tonnage was equally correlated with year. Analysis of the 1990–2007 relationship between U.S. and SNWW chemical imports showed strong statistical correlation, with a corresponding adjusted R square of 0.82. An adjusted R square of 0.78 was produced when “year” was used instead of “U.S. imports.” The t value and F statistics associated with both of the equations are significant at the greater than 0.99 percent confidence levels. An average annual growth rate of 1 percent was used for SNWW 2006–2049 alcohol and ammonia imports. For forecasting purposes, SNWW’s 2004–2006 average tonnage was used as a base for the forecast application. SNWW’s alcohol and ammonia import forecast is displayed on Figure 49.

Figure 48
SNWW Alcohol and Ammonia Waterborne Imports 1990–2007
(1,000s of short tons)

Figure 49
SNWW Alcohol and Ammonia Imports 1995–2065
Waterborne (1,000s of Short Tons)

Future transition to larger and more fully loaded vessels for SNWW alcohol and ammonia imports was evaluated based on examination of vessel sizes and loaded drafts associated with other regional ports. These analyses showed that the loaded drafts associated with these commodities are generally less than 36 feet. The analyses also indicated that the use of vessel sizes constrained by the existing 40-foot channel depth is presently limited, with future transition being uncertain. While expectations concerning future chemical imports to SNWW are uncertain, larger and more deeply loaded carriers are presently being used.

4.13 CHEMICAL EXPORTS

Like imports, SNWW chemical exports grew at very fast rates. In 2006, SNWW exported 2.9 million short tons of chemicals, representing a record high. Review of 1990–2007 records show 1995–2007 exports had minimum exports of 724 thousand short tons in 1995. With few exceptions, SNWW exports steadily increased. In comparing SNWW's growth rates to U.S. rates, U.S. growth was slower but increased, with 2006 exports totaling 59 million short tons, up from 40 million in 1990.

SNWW's largest percentage increase was for fertilizer mixes, and the largest share of tonnage is associated with the organic compound and metallic salt commodity classifications (Table 17). U.S. exports of these commodities also increased. Figures 50 and 51 shows U.S. and SNWW metallic salts and organic compound exports for 1990–2006. For 2004–2006, SNWW exported 18 percent of the U.S. metallic salt waterborne total and 11 percent of the organic compound total. Based on these indicators, an

average annual growth rate of 2.5 percent was used for SNWW 2006–2039 metallic salts and organic compounds. A growth rate of 1 percent was used for 2039–2069. For forecasting purposes, SNWW’s 2004–2006 average tonnage was used as a base for the forecast application. Ten percent of future tonnage was forecasted to use channel depths over 40 feet. The transition to larger and more fully loaded vessels for 10 percent of future tonnage was based on general indicators associated with chemical vessel fleet trends summarized in the fleet forecast section (see Table 44). SNWW’s metallic salts and organic compound export forecast is displayed on Figure 52.

4.14 LIQUEFIED NATURAL GAS

LNG will play an increasingly important role in the natural gas industry and global energy markets in the next several years. Table 71 shows SNWW current and future capacity volumes for the SNWW facilities. Phase I of the Cheniere terminal is presently complete, and the first vessels arrived in April 2008. Phase 1 consists of 10.1 Bcf of LNG storage in three tanks, each with an LNG capacity of 160,000 cubic meters (m^3), and a maximum continuous regasification rate of 2.6 billion cubic feet per day (Bcf/d). Phase 2 will be built in stages. The first stage of Phase 2 will include the addition of fourth and fifth storage tanks, additional vaporizers that will bring the maximum continuous regasification rate up to 4.0 Bcf/d with a peak sendout capacity of 4.3 Bcf/d. In the future stages of Phase 2, a sixth storage tank may be added and related facilities will bring the total LNG storage volume to 20.2 Bcf.

Table 71
Distribution of Liquefied Natural Gas
Operational Capacity

Facility	Full Operational Output (Bcf/d)	Annual Output (Bcf)
Sabine Pass	3.360	1,226.40
Golden Pass	2.268	827.82
Port Arthur	2.520	919.80
Total SNWW	8.148	2,974.02

Construction of the Exxon Golden Pass LNG terminal is scheduled for completion by 2011. The Golden Pass facility, which is being constructed by ExxonMobil and Conoco Phillips, will consists of a dock and unloading facilities, 5 LNG storage tanks (≈ 17 Bcf), and vaporization capacity of 2.7 Bcf/d. The Port Arthur project consists of two ship berths, three to six storage tanks ($160,000 m^3$), and vaporization capacity of 1.5–3 Bcf/d. The LNG for the Golden Pass terminal is anticipated to be supplied primarily from the Ras Laffan 3 and the Qatargas 3 projects in Qatar, which will produce and process natural gas from Qatar's offshore North Field.

Construction of the Semptra terminal is anticipated after 2012. The Semptra LNG terminal will be capable of delivering between 1.5 and 3 Bcf per day of natural gas. The terminal will include two unloading docks for ships and three to six full containment storage tanks and associated equipment in order to transform the LNG back to its gaseous state. As noted, construction of this third facility is planned for after 2012. At full utilization, Sabine Pass and Golden Pass could handle 2.05 trillion cubic feet (Tcf) annually. The Semptra annual capacity increases regional capacity by 2.97 Tcf without pushing peak capacity.

There are about 40 LNG terminals that are either before the Federal Energy Regulatory Commission (FERC) or are being discussed by the LNG industry for North America. Six terminals are already operating on the East Coast, Puerto Rico, and Alaska. There are six onshore LNG terminals in the continental U.S., these are located in Everett, Massachusetts; Lake Charles, Louisiana; Elba Island, Georgia; Cove Point, Maryland; Cameron, Louisiana; Sabine, Texas; and Freeport, Texas. The Cameron,

Sabine, and Freeport terminals are new. In addition to these three terminals, the Northeast Gateway port offshore Massachusetts received its first supplies in 2008. With these four terminals now operational, U.S. capacity to receive LNG imports has increased from approximately 5.0 Bcf/d at the end of 2007 to about 9.1 Bcf/d as of the end of the year. The Sabine Pass facility adds 2.6 Bcf, or 29 percent to U.S. Bcf capacity.

In 2007, the U.S. imported an estimated 771 Bcf, or 21.2 million short tons, of LNG. Shipments to existing U.S. facilities in 2006–2008 came from Trinidad (64 percent), North Africa (22 percent), Western Africa (11 percent), Norway (2 percent), and the Middle East (1 percent). The EIA reported total LNG import shipments of 771 Bcf in 2007 to these terminals, with each importing similar volumes—each between 20 and 30 percent of the total. Imports in 2008 only reached 352 Bcf. Despite declines in 2008, the EIA expects U.S. LNG imports to increase to about 500 Bcf in 2009, up from 352 Bcf in 2008, and rise to about 740 Bcf in 2010. The 2008 fall in imported natural gas to the U.S. reflects the increased need for natural gas in other countries willing to compete for available global supplies. While U.S. imports increased in 2009 over 2008 levels, U.S. LNG import growth this year has been constrained because of increased LNG demand in Europe and delays and maintenance to new and existing LNG liquefaction capacity. With limited natural gas storage availability, recent data suggest that European inventory levels are now nearing capacity. The expectation is that LNG shipments may be redirected to U.S. ports in the coming months as prices in the European market become less attractive to LNG suppliers. A similar scenario may also occur in Canada, with natural gas pipeline imports increasing in the months ahead as Canadian storage facilities are topped off. The EIA notes that an increase in U.S. natural gas imports would likely be balanced by larger-than-expected declines in domestic natural gas production.

4.15 U.S. LNG IMPORT FORECAST

The EIA notes that annual U.S. LNG imports are projected to exceed 1 Tcf by 2015 but are expected to drop to 800 million cubic feet by 2030. Table 72 presents the LNG import forecasts outlined in the AEO2009. Short-term forecast revisions note that LNG imports are expected to increase to about 506 Bcf in 2009 from 352 Bcf in 2008, because of a combination of weak demand and growing supply in the global LNG market. Lower demand for LNG in Japan and South Korea has increased the amount of available LNG in the global market, leading to larger LNG purchases in China and Europe. However, with limited natural gas storage capacity in Asia and Europe, lower global demand is expected to increase available LNG cargoes for import by the United States.

The likelihood of a region's ability to capture a share of the LNG market is obviously subject to uncertainty; however, some sites, such as those on the SNWW, may have more-obvious advantages because of FERC approval, lack of public opposition, or locational advances (close access to international waters). The SNWW facilities have the advantage of FERC approval, relatively high levels of public and political support, and locational advances in terms of access to the U.S. Gulf. For the analysis, 20 percent of the U.S. waterborne LNG imports market was used for SNWW. Table 73 displays the expected distribution of imported by country of origin. The distribution was prepared based on industry input and

reflects a higher proportion of imports from Trinidad than the EIA forecast. The EIA is currently forecasting higher volumes from the Middle East than the distribution shown in Table 73.

4.16 GRAIN EXPORT FORECAST

Grain is exported from the Beaumont elevator located just below the Port of Beaumont main turning basin. While exports have exceeded 1 million short tons since 2003, recent volumes remain less than half the 1993 peak volume of 3.5 million. While relatively low in comparison to the Pacific Northwest and the Lower Mississippi, Beaumont has maintained a 1.4 to 1.7 percent share of the U.S. waterborne bulk grain export market. Table 74 displays Beaumont's 1990–2007 bulk grain exports by major product. Wheat

presently comprises 100 percent of Beaumont's grain exports for the most recent 4-year period. Beaumont's 2007 wheat exports represented 4.4 percent of the U.S. wheat export total.

Table 74
Beaumont Bulk Grain Exports and Percentage by Grain Type

Figure 53 shows wheat exports by U.S. geographic region for 2002–2007. Figure 54 shows Beaumont's share of the Texas Gulf Coast wheat exports for 2002–2007. Comparison of Beaumont wheat export volumes with other major U.S. grain export locations showed that Beaumont has maintained a consistent market share since 1996. Figure 55 displays 1990–2006 U.S. total wheat exports, U.S. production, and Beaumont wheat exports. While corn exports have historically been low, sorghum grain constituted 14 percent of Beaumont's bulk grain exports prior to 2003.

Figure 53
U.S. Wheat Exports by Region
(1,000s of Short Tons)

Figure 54
Beaumont Wheat Exports
(1,000s of Short Tons)

Figure 55
U.S. and Beaumont Wheat Exports and U.S. Wheat Production (short tons)

According to the U.S. Grains Council, the U.S. is currently positioned as the number two producer and number one exporter of sorghum on the world market. The U.S. share of the world sorghum trade has not dropped below 70 percent in more than a decade. World trade in sorghum is dominated by U.S. exports to Mexico. In the last 5 years, transportation of the commodities considered in this study (corn, sorghum, wheat, and soybeans) has shifted from maritime to overland.³⁹ Rail is the major overland transportation mode for all grains but sorghum. Sorghum is shipped by truck because of the proximity of the production areas in Texas's Rio Grande Valley to the border. Other importing countries and regions include Japan, Israel, South Africa, Spain, Morocco, and Eritrea.

Mexico is the world's third largest sorghum producer after Nigeria and the United States and the second largest world consumer after Nigeria. The United States is the only sorghum supplier to Mexico. Over the last 5 years, half of U.S. sorghum exports to Mexico were shipped by ocean through the U.S. Gulf, mostly from North Texas, South Texas, and the Mississippi River. The port of Veracruz is the major ocean point of entry. On average, trucks moved 30 percent and rail hauled 19 percent of sorghum shipped to Mexico. The top rail destinations for U.S. sorghum exports to Mexico in 2005 were Nuevo Leon, Veracruz, Estado de Mexico, Jalisco, and Guanajuato.⁴⁰ Texas (Laredo and El Paso) and Arizona (Santa Cruz) are the main rail entry points. The ports of Veracruz and Progreso are the major entry points by vessel. Half of the year's sorghum exports to Mexico occur between January and May, reaching a peak in April. The percentage of grain transported by oceangoing vessel declined from 60 percent in 2002 to 45 percent in 2006.

³⁹ USDA, U.S. Grain and Soybean Exports to Mexico – A Modal Share by Dalmy L. Salin, April 2008.

⁴⁰ Adcock, F. J. C. Parr Rosson III, and Alejandro Varela. 2007. Tracking U.S. Grain and Soybean Exports in Mexico. Center for North American Studies, Texas A&M University. <http://cnas.tamu.edu/AMS%20Final%20Export%20Report.pdf>

Analysis of Beaumont's grain exports does indicate reduction in shipments to Mexico and also shows that sorghum exports ceased after 2002. The specific reasons for Beaumont's drop in sorghum exports were not investigated; however, sorghum had composed a relative small share of Beaumont's grain. Analysis of Beaumont's 2004–2006 wheat exports by destination showed that the primary markets served are West Africa and the Middle East. Table 75 displays Beaumont's 1998–2006 wheat exports by destination.

Source: USACE, Navigation Data Center, detailed unpublished vessel records, 2004–2006.

Review of research conducted by Texas A&M University shows that the Gulf of Mexico ports are a major export outlet for U.S. wheat, in particular hard red winter wheat. Hard red winter wheat is railed from Kansas, Oklahoma, Texas, and Colorado for Texas export. Figure 56 displays the 1997–2006 relationship between wheat exports destination by state of origin and Beaumont's exports. The states of Kansas, Oklahoma, Texas, and Colorado originate virtually all of the 5 to 8 million tons of hard red winter wheat annually shipped to Texas Gulf ports. Transport of nearly all Texas Gulf grain exports is by unit train. The Burlington Northern Santa Fe, Missouri Pacific, Southern Pacific and Union Pacific railroads are used to transport wheat to export facilities in Brownsville, Corpus Christi, Galveston, and Houston.

The relative locations of the grain production areas to either rail lines or to the Mississippi River is the major determinant in the distribution of grain exports between the Texas Gulf Coast ports and the Lower Mississippi River.⁴¹ The U.S. Grains Council notes that while infrequent corn will move from Nebraska and Iowa to Texas ports during periods of Mississippi River low flow or of excess demand, red winter wheat from Louisiana, Mississippi, Arkansas, Missouri, Illinois, Indiana and other states in the Illinois and Ohio River basins tends to move via barge and rail through the Mississippi River ports.⁴² The Pacific Northwest is noted to have a freight advantage over the other U.S. Gulf for Asian destinations. The

⁴¹ Besslerand, David and Stephen W. Fuller, Transportation Research: Part E: Logistics and Transportation Review, Volume 36, Number 1: "Railroad Wheat Transportation Markets in the Central Plains: Modeling with Error Correction and Directed graphs", Department of Agricultural Economics, Texas A&M University.

⁴² U.S. Grains Council – Importer Manual, August 2004, Chapter 5, p. 64.

shorter distance from the Pacific Northwest to Asian destinations is mentioned as contributing to the willingness to pay a substantially higher price for feed grains delivered from that coast. While having an ocean freight advantage, the Pacific Northwest is noted as being relatively far from feed grains production areas.

Figure 56
Wheat Exports by State and Beaumont Exports, 1997–2006

*Constant 1990–1992 dollars. ftp://ftp-fc.sc.egov.usda.gov/Economics/priceindexes/Data/PPPI_CPI_CCI.xls.

Beaumont's tonnage forecast is based on application of the USDA's Baseline Projections Report February 2009 forecast. The forecast shown in Table 76 is based on Beaumont capturing between 4.4 percent and 7.8 percent of U.S. wheat exports, with 7.8 percent representing the 1990–2006 maximum and 4.4 percent representing the 2004–2006 average. The baseline forecast used for the transportation cost calculations is based on Beaumont capturing a 6.6 percent share of the U.S. export market. The transportation savings benefits are based on 30 percent of tonnage would load to drafts over 40 feet.

Table 76
Beaumont Wheat Export Forecast (2004–2069)

Year	U.S. Wheat Exports		Beaumont Wheat Exports	
	Bushels	Short Tons	Total Exports	Volume Used for Benefit Calculations
2004	1,066,000	31,980,000	1,208,333	–

2039	–	–	2,597,175	779,152
2049	–	–	2,868,896	860,669
2059	–	–	3,169,046	950,714
2069	–	–	3,500,599	1,050,180

The USDA is presently showing modest growth in wheat exports between 2006 and 2018/2019.⁴³ U.S. 2006–2018/2019 exports are forecasted to increase from approximately 990 million bushels in 2006 to 1,075 million bushels by 2014/2015 and remain constant at that level through the end of the forecast period in 2018/2019. Egypt maintains its position as the world's biggest importer of wheat, as imports climb slowly to nearly 9 million tons. Imports by developing countries in Sub-Saharan Africa, North Africa, and the Middle East rise to nearly 12 million tons and account for 45 percent of the total increase in world wheat trade. While the shares of the world wheat market held by Canada and the U.S. are noted to decline slightly and be offset by increases in the European Union, Ukraine, Russia, Australia, and Argentina, total U.S. wheat exports increase slightly. The USDA also notes that changing consumption patterns will boost wheat imports by some major importing countries. In Indonesia, strong economic growth and diversification of diets are projected to increase per capita wheat consumption. The USDA notes that for most developing countries there is little change in per capita wheat consumption but imports expand modestly because of population growth. Table 77 displays major destination ports for SNWW grain exports that can accommodate large bulk carriers.

An average of nearly 30 percent of Beaumont's 2000–2007 grain export tonnage was shipped in vessels with design drafts over 40 feet (Table 78). The maximum DWT presently used for grain exports is in the 60,000 to 70,000 DWT range. The vessels have design drafts between 42 and 43 feet. Until the early 1990s, grain carriers in excess of 100,000 DWT were used for the Texas bulk grain exports. The larger vessels were associated with the former Soviet Union and Northern Europe grain shipments. Currently, the maximum parcel sizes are in the 50,000 to 60,000 short tons range.

a/ February 2006, an updated trade route distribution was released but not presented (February 2009). Beaumont's wheat exports were assumed to continue Europe and the Mediterranean and expand to other markets as demand arises.

Note: Totals may not add due to rounding.

4.17 BREAKBULK IMPORT FORECAST

Analysis of the vessel fleets and utilization, and existing and future constraints associated with imports of aggregate products, such as iron ore, steel slab, limestone, and sand and gravel, and discussion with industry personnel suggested that 50 percent of limestone and sand and gravel, iron ore, and steel slab would be transported in vessels with loaded drafts over 40 feet (sections 3.9 and 3.10). Limestone and rock are classified as crude materials by WCSC. Iron ore and steel slab are classified as manufactured goods by WCSC. In addition to these classifications, crude materials are exported. SNWW's crude materials, primarily dry sulfur, clay, and refractory materials, are exported from SNWW. Table 79 displays SNWW's breakbulk tonnage forecast.

Discussion of the commodity-specific percentages is contained in the previous and following sections.

6.0 TRANSPORTATION SAVINGS BENEFITS

This section presents the transportation savings benefits. Transportation savings benefits were calculated for channel widening and deepening.

6.1 VESSEL OPERATING COSTS

The vessel operating costs are shown in tables 82 to 84. Table 82 displays the hourly operating costs for tankers. The hourly operating costs include fuel, labor, and maintenance. The costs used were obtained from deep-draft vessel operating cost EGM December 2008 update. The tanker costs were used for the crude petroleum, petroleum product, and chemical product transportation cost calculations. The maximum-sized vessels using the channel to Beaumont on a regular basis are in the 150,000 DWT class. The maximum size using the Taylor Bayou Port Arthur facilities are in the 110,000 to 116,000 DWT range. As previously noted, the Port Arthur fleet is smaller, in terms of DWT, because the existing width at the mouth of Taylor Bayou limits the allowable vessel size. The U.S. flag tanker costs contained in Table 82 were used for calculating the transportation costs for U.S. coastwise product movements. Table 83 displays the foreign flag bulk carrier operating costs which were used for the grain exports and imports of iron ore, metal products, limestone and rock. Table 84 displays the LNG vessel operating costs. The LNG costs were estimated in consultation with the Institute of Water Resources (IWR).

125,000	40	265,000	372.4	2,423	2,039

Source: Application of USACE, December 2008 Foreign Flag Tanker Costs presented in Economic Guidance Memorandum #08-04, Deep-Draft Vessel Operating Cost FY 2008, December 2008.

The LNG design vessel used by ERDC for the ship simulations consisted of a 140,000-m³ spherical-tank-type vessel 920 feet long, 142 feet wide, and 37.4 feet in draft, and a proposed 250,000-m³ membrane-type tanker 1,126 feet long, 177 feet wide, and 39.4 feet in draft. The LNG facilities are in the Sabine Pass Channel and Port Arthur reaches. The project design vessel for crude petroleum tankers using the entrance channel and going to Beaumont is 899 feet long and 164 feet wide. These dimensions correspond to a 158,000 DWT crude petroleum tanker.

6.2 UNDERKEEL CLEARANCE

Underkeel clearance is defined as the minimum clearance available between the deepest point on the vessel and the channel bottom, in still water. The SNWW project depth allows vessels to transit with a maximum draft of 40 foot fresh water subject to the most recent USACE's hydrographic report, prevailing weather, and tidal conditions.⁴⁴ Galveston District's dredging practice also provides 2 feet of

⁴⁴ <http://www.sabinepilots.com/index.html>.

advance maintenance and 2 feet of overdepth to the existing project depth of 40 feet mean low tide. The availability of advance maintenance and overdepth can provide an extra 4 feet of underkeel clearance. As the dredging cycle transpires, the stated project depth of 40 feet mean low tide and the range of underkeel clearance available on a period basis obviously varies and generally diminishes. Given these circumstances, it is also recognized that the dredging cycle is established with the goal of maintaining a minimum available project depth of 40 feet mean low tide. As indicated, the subsequent effect of the dredging cycle interval may result in a greater concentration of vessels loaded to 39 to 40 feet for the period closer to the completion of maintenance dredging. While the current analysis contained in this portion of the report does not include an investigation of the dredging history in relationship to vessel trips by loaded draft, the annual distributions of trips by draft from the pilots and USACE NDC were evaluated. Specifically, the pilots' policy was evaluated in relationship to the USACE and the pilot records of trips by loaded draft as a means of understanding existing underkeel clearance practices.

Data associated with the number of vessel trips by loaded draft was presented in Table 23 as part of the vessel utilization presentation (Section 3.3). Interpretation of the pilots' policy suggests that loaded drafts in excess of 40 feet should be rare, Table 23 shows this to be true, with few loaded drafts over 40 feet. Based on analysis of the Corps data and the pilots' records, vessels are loaded to a maximum draft of 40 feet.

While the pilots emphasize 3 feet of underkeel clearance, review of the waterborne commerce data shows some sailing drafts exceed 40 feet. The pilot emphasis of 3 feet of underkeel for liquid cargoes and review of the WCSC-WCUS data, which show a high number of vessels with loaded drafts over 37 feet, revealed discrepancies that showed uncertainty. Based on these findings, the transportation cost calculations were made based on 1 foot of underkeel clearance used for all vessels except LNG. Based on industry input a 4- to 6-foot underkeel clearance was used for LNG vessels. The indication from pilot discussion was that an absolute minimum of 4 feet underkeel clearance would be required and the preference was for 6 feet. The effects of varying underkeel clearance are addressed in detail in the Sensitivity section of this appendix (Section 8).

6.3 CHANNEL WIDENING BENEFITS

Reduction in delay benefits were calculated for channel widening and for holding area alternatives. The benefit estimates are based on comparison of transit times between project alternatives. Transportation costs for existing conditions, the without-project condition, and the project alternatives were calculated using 2004 SNWW traffic base. Pilot records for 2001 and 2004–2005 were obtained from the SPA. Vessel characteristics and related details were obtained from the USACE NDC detailed records.

In terms of channel width, there are three main traffic rules presently affecting vessel traffic. The traffic rules, which affect movements in the 400- and 500-foot project reaches, are instituted by the SPA for the purpose of helping to ensure safe navigation (Section 1, Table 3). The results of these rules provide for a safe channel and a relatively low accident rate; however, the rules affect a significant portion of traffic in the form of vessel delays. The traffic first rule is that vessels with combined beam widths equaling or

exceeding 50 percent of the channel width cannot meet each other. The second main rule is that vessels of 85,000 DWT or more will not meet vessels of 30,000 or more or with loaded drafts of 30 feet or more above buoys 29 and 30. The third rule is that vessels of 48,000 DWT or more with a loaded draft of 30 feet or more will not meet above buoys 29 and 30. Vessels going to existing port facilities in Port Arthur, Beaumont, and terminals in between are all affected by these traffic rules. The effect of the pilot rules in the existing 400- and 500-foot reaches is that inbound crude petroleum tankers that characteristically are in the 90,000 to 150,000 DWT range with beam widths between 135 and 145 feet and inbound loaded over drafts of 35 feet cannot meet an outbound tanker of a comparable size at a lesser or a blast draft nor can it meet a 106-foot-beam outbound chemical or product tanker.

The HarborSym model was used in evaluation of the Entrance Channel widening and the Neches River turning basin and anchorage features. The outputs from HarborSym were aggregated into Excel spreadsheets and are summarized in this section of the report. HarborSym is a planning-level model developed by the IWR to assist in economic analyses of channel widening improvements. HarborSym is an event-driven simulation model and includes data from user-specified transit rules that the model processes with each vessel call in order to calculate delays within the system. While not yet certified, the model is scheduled for review under the USACE certification system. The model is presently in the model certification process. The model is presently being used by several USACE district offices for channel-widening studies, and these outputs have undergone Agency Technical Review and USACE headquarters review.

As noted, channel widening was considered for the channel reaches from the Sabine Pass Channel inland through the Neches River Channel during the initial screening. The channel-widening alternatives evaluated include widening of the existing 500-foot Sabine Pass Channel and Port Arthur Canal and the 400-foot Sabine-Neches Canal and Neches River Channel. Table 85 presents the mileage from the offshore Entrance Channel to the jetty where the Sabine Pass Channel starts. The pilots board at either the Sabine Bar (SB) Buoy or the Sea Buoy. As shown from the mileage points in Table 85, the SB Buoy is farther seaward than buoys 29 and 30. Under present conditions, the pilots steer vessels from the SB Buoy or from buoys 29 and 30. Under present conditions, vessels with loaded drafts of 28 feet or more are piloted to and from SB Buoy, and vessels with lighter drafts are piloted from buoys 29 and 30. The effect of widening the Sabine Pass Channel to 500 feet will provide a continuous series of reaches for the inbound and outbound convoys to meet.

Table 85

Trinity Industries	57.2

In addition to channel widening, the proposed Neches River turning basin anchorages were identified based on user input as a less costly alternative to channel widening. These proposed features would be used to facilitate vessel passing. The turning basin and anchorages would all be located above mile 40 shown in Table 86. Current and future use of the existing turning basins and new holding and turning sites is outlined in Table 86. The table shows the cross-section stations and approximate mile, from the Sabine Bank to the turning basin anchorages.

Under existing and without-project future conditions, there are four federally maintained turning basins on the Neches River. These are TBA 1, TBA 4, TB 6, and the Beaumont Maneuvering Area. TBA 1, TBA 4, and TB 6 are used to turn Suezmax vessels. The maximum-sized vessels using the Beaumont Maneuvering Area are light Aframax vessels. The Beaumont Maneuvering Area is not currently designed for Suezmax vessels nor will it be under the with-project future. Under existing conditions, Suezmax vessels partially use the maneuvering area but also rely on the open channel in order to turn. This condition will continue under the with-project condition. In addition to the four federally maintained turning basins, light Aframax vessels presently use TBA 2, a privately maintained basin, for turning and anchorage.

Table 86
Neches River Turning Basin and Anchorage Features

Title	Location	Description	Station Number	Estimated Miles from Sea Buoy	CURRENT USE			PROPOSED USE

a/ Light vessels under emergency conditions.

b/ Under existing conditions, TB 5 is private and used by shallow-draft barges. A new turning basin is proposed immediately north of existing TB 5. This basin would be designed for loaded Suezmax tankers.

c/ For the "with-project future," anchorage basins 7 and 8 are designed for anchorage; however, the pilots intend to use anchorage basins 7 and 8 for both the anchorage and turning of Suezmax vessels.

While official publications note that there are no Federal anchorage areas on the Neches River Channel and that only emergency anchorage is permitted⁴⁵, analysis of the pilots' records showed that several sites are routinely used for temporary anchorage of light vessels. Table 87 displays the 2005 distribution of inbound vessels by docks and anchorage basins and suggests that the anchorages are used on more than emergency basis by light vessels. The pilots verified that the anchorages are used by light vessels (TBA 1, TBA 2, and TBA 4). The data shown in Table 87 indicate that 11 percent of vessels presently use unofficial anchorages. Of the total of 1,404 shown in Table 87, 161 vessels used the unofficial anchorages under existing conditions.

Seven federally maintained turning basins, including the Beaumont Maneuvering Area, and five anchorages are proposed under the with-project condition. TB 2, TB 3, and TB 5 would become Federal turning basins under the with-project condition. TB 1, TB 4, TB 6, and the Beaumont Maneuvering Area are existing Federal features, and they would be enlarged under the with-project condition. All of the anchorage basin components represent new Federal features (TBA 1, TBA 2, TBA 4, AB 7, and AB 8). Three of the basins (TBA 1, TBA 2, and TBA 4) are used for anchorage under existing conditions to a limited extent, but the limited anchorage component is not presently part of the Federal project. The pilots noted that under present conditions, the vessels are wedged in at those locations. Depth availability is limited to light-loaded or ballasted vessels. Additionally, while TBA 1, TBA 2, and TBA 4 currently provide anchorage function; they cannot serve as turning basins while vessels are anchored in them. The with-project condition would provide for concurrent use of TBA 1, TBA 2, and TBA 4 for both turning and anchorage of individual vessels.

As the titles indicate, some of the individual features will include a turning basin and an anchorage (TBAs 1, 2, and 4), and some just a turning basin (TB 3, TB 5, and TB 6) or an anchorage (AB 7 and AB 8). The SPA noted that the turning basin and anchorages, such as TBA 1, TBA 2, TBA 4, TBA 7, and AB 8 will be designed to enable a 48-foot loaded Suezmax tanker to use the inner portion of the feature as an anchorage and also allow a 48-foot loaded Suezmax tanker to turn in the turning basin section. While some of the features listed in Table 87 would be developed from existing basins (TBA 1, TBA 4, and TB 6) or are new basins (TBA 2, TB 3, TB 5, AB 7, and AB 8); the anchorage components of the features are essentially new and the proposed dimensions represent new dredging.

b/ USACE, NDC, Ports of Port Arthur, Beaumont, and Orange, Texas, NDC-01-P-5, Port Series, No. 22, Revised 2001.

The HarborSym model was used to evaluate widening of the Sabine Pass Channel and Port Arthur Canal and the turning basin and anchorage features. The HarborSym model results are for the baseline benefit calculations. Sensitivity analysis of the turning basin and anchorages was made using pilot interview data. Pilot interview data, including vessel log information and estimate of transit times, were crucial parts of building the SNWW HarborSym application. Model calibration is additionally crucial, and concerns about the ability of HarborSym to capture and model the pilots' anticipated behavior as it relates to the Neches River turning basin anchorage features were not resolved. There is a greater level of uncertainty associated with the Neches River anchorages than with the widening of the Sabine Pass Channel and Port Arthur Canal reaches. In reviewing the model outputs with the pilots, they found that the effects on transit times and vessel throughput associated with Sabine Pass Channel and Port Arthur Canal outputs were within their expectations. The time savings associated with the HarborSym Neches River turning basin and anchorage features runs are much lower than anticipated.

6.3.1 HarborSym Model

The HarborSym model is designed to create an event-driven simulation based on data stored in a database, instead of customization within a simulation environment. Included in these data are the user-specified transit rules that the model processes with each vessel call in order to calculate delays within the system. Users can define alternative sets of channel dimensions or rules reflecting harbor improvements to determine potential transportation cost savings resulting from reduced delays.

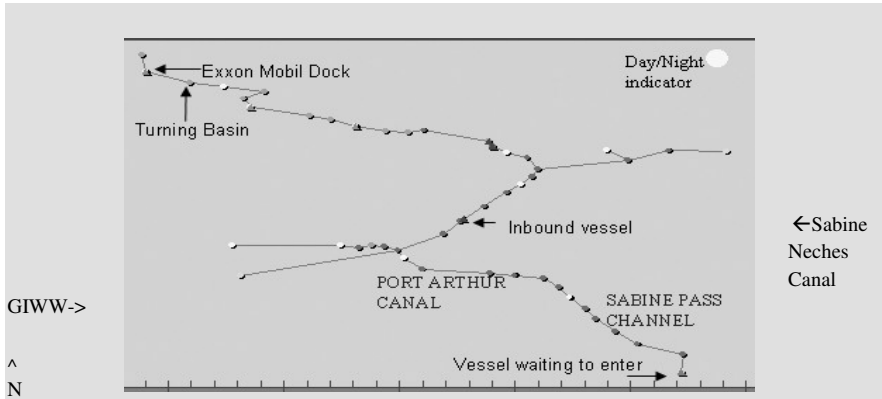

HarborSym outputs were crucial for aggregation and understanding of base condition delays. Pilot interviews were used to identify a wide range of information, including delay times. Vessel-class-specific delay times were obtained from the model output, with these inputs having been defined using pilot logs and extensive pilot interviews. A basic schematic of the SNWW from within the jetty starting at the Sabine Pass Channel is displayed on Figure 57. The key element in modeling the harbor system was replicating transit rules as listed in Table 3 of Section 1.

Inland waterway barge traffic was not included in HarborSym. Barge traffic moves through the Sabine-Neches Canal section of the SNWW. The Sabine-Neches Canal reach presently has a deep-draft project width of 400 feet, and deep-draft vessels do not meet other deep-draft vessels or tows in that reach. The project reach proposed for widening is the Sabine Pass Channel and the Port Arthur Canal, which is approximately 15 miles long and south of the Sabine-Neches Canal. Vessel-to-barge communication and the recently active VTM will help ensure that tow-barge and vessel transits do not overlap. Presently, every effort is made to avoid overlap of tow-barge and vessel transits.

Vessel-to-tow communication has greatly improved since the beginning of the study process. Additionally, the VTM is operational and very effective in planning vessel transits. Discussions with the tow industry, the VTM, and the deep-draft vessel pilots indicated that the relative impacts to tow-barge traffic are anticipated to be similar between the without- and with-project future due to vessel management. The with-project condition of channel deepening will provide the advantage of fewer oceangoing vessel trips for a given volume of traffic and, therefore, result in a net reduction in overall

congestion between the without- and with-project future conditions. The decision to forgo the barge shelf was made by the tow industry due to reconsideration of how vessels and barges would interact. The concern that was raised, but not physically modeled, was that the tow-barges could get pulled under or out into the channel as it either meets a deep-draft vessel or “held-up or idled” in the barge shelf. The tow operators originally thought that they wanted the shelf in case radio and/or other communication failed and a tow-barge could not clear the channel as a deep-draft vessel began its transit through the reach. An additional variable in deciding against the barge shelf was the activation of the VTM.

Figure 57
SNWW HarborSym Network

6.3.1.1 Model Input Overview

HarborSym requires inputs associated with vessel traffic, channel dimensions, docks, reach length, entrance and exits, and topographic nodes. The point of entrance is the Gulf of Mexico. From the “entrance point,” the channel moves inward through a series of topographic nodes along the Sabine Pass Jetty Channel to the Sabine Pass Channel and then to the Port Arthur Canal and onward. Most topographic nodes are situated at the end of one channel reach and the start of another, such as the nodes on either end of the Sabine Pass Channel and the Port Arthur Canal. Some are at the junction of the Sabine-Neches Canal at the Neches River Channel and the junction of the Port Arthur Canal and Taylor Bayou. The Port Arthur Canal and Taylor Bayou junction is just north of the Port Arthur Canal junction with the GIWW. The topographic nodes generally reflect traffic rule changes.

For modeling purposes, docks are generally aggregated as a group. Moving in from the offshore entrance channel, the first dock destination on the Sabine Pass Channel is for Cheniere LNG and Offshore Marine. Moving into the next reach, the Golden Pass LNG, which is presently under construction, and the proposed Semptra terminal are contained in the next dock cluster located on the Port Arthur Canal. Within Taylor Bayou there are two major dock points with other docks within Taylor Bayou being grouped under

one of the two majors. At the lower end of the Neches River, several petroleum terminals are tied to a central dock destination. The Neches River Channel includes six center dock destinations.

Ten vessel types were defined and two or more classes per vessel type were defined. The vessel types are general cargo/RoRo, oil tanker, chemical tanker, LPG tanker, LNG tanker, bulk carrier, oceangoing tank/barge, tugboat, miscellaneous/other, and tug/barge. The vessel classes are based on vessel dimensions. Table 88 lists most of the major vessel classes and their associated DWT, beam width, and vessel operating costs. Additional variables, such as vessel length and load draft, were necessary inputs but are not shown in the table. Vessel loaded draft was tied to the “vessel call list,” which is another major level. The model structure contained several first level components and vessel characteristics and associated operating costs are included under the “vessel type heading.” Port traffic is a level one heading and it includes the vessel call list. Table 89 displays the general framework used for SNWW and shows most of the major line items. For nearly all of the items listed, additional levels of definitions and details are inputted. For example, under the reach heading, 48 reaches are defined. The general framework shown in Table 90 would be similar for other port studies.

6.3.1.2 Vessel Traffic Input

Vessel trip estimates were prepared for the 2000–2004-period base and for 2030–2040 average trips. The vessel classes were established based on the HarborSym vessel structure. The coding sheet corresponding to the vessel classes is presented in Table 14. The 2000–2004 period tonnage and the 2000–2004 fleet are presented in tables 91 and 92.

a/ LNG tonnage and vessels were included in the 2000/2004 HarborSym traffic analysis.

Tables 93 through 95 present the 2030–2040 period tonnage and trip data. A “widening and deepening alternative” would generate greater savings than widening. In regard to the pilot rules (see Table 3), rule 1 would change if the channel was widened and deepened. Rule 1 says that vessels with combined beam widths that equal or exceed one-half of the channel width are not permitted to meet day or night. If the channel was just widened, rules 3 and 4 would be relaxed as well. The effect of deepening and widening will likely be to result in vessels with loaded drafts of less than 40 feet being able to meet; however, vessels with loaded drafts over 40 feet would be much more restricted. While the vessel pilots indicated that the effect of deepening would mean a loss of some of the gains in terms of relaxing rules 3 and 4, a widening-only alternative would produce a lower number of vessels and could result in higher savings. The effects of deepening and widening on total transportation costs are discussed in the sensitivity section (Section 8).

6.3.1.3 Evaluation of Project Alternatives

The HarborSym model was run for existing conditions and each of the project alternatives. The widening alternatives included widening of the Sabine Pass Channel and Port Arthur Canal channel from 500 to 700 feet. Evaluation of widths less than 700 feet was also conducted. Widening of the Sabine Pass Channel and Port Arthur Canal reaches were evaluated with and without the Neches River turning basin and anchorage alternatives, and the turning basin anchorage features were evaluated on an incremental basis. The transportation cost savings associated with widening of the Sabine Pass Channel and Port Arthur Canal reaches and Neches River turning basin and anchorage features were evaluated based on a 40-foot channel depth.

An anticipated effect of widening the Sabine Pass Channel and Port Arthur Canal to 700 feet would be to allow a higher percentage of vessels in the proposed 700-foot reach. The effect of widening on rule 1 would be that a larger number of vessels with wider beam would be able to meet. Rule 2 would not change with widening as it applies to the Sabine-Neches Canal, which is shared by GIWW barge traffic. Widening of the Sabine-Neches Canal reach was evaluated during the early formulation stages; however, cargo docks are located on the west side of canal in the lower end of the reach, and the Port Arthur Hurricane Protection Levee, also on the west side, is located in the following section of this reach.

Anticipated costs associated with channel widening due to the Hurricane Protection Levee in the Sabine-Neches Canal and docks along the Sabine-Neches Canal and Neches River Channel reaches limited the extent of structural alternatives that were carried into detailed analysis. As part of plan formulation, the Neches River anchorage basins were introduced as a less costly alternative to widening of the Neches River Channel to Beaumont. The anchorages would be used to facilitate vessel passing. During the initial screening, extensive but intermittent widening was evaluated for the channel reaches from Sabine Pass Channel, inland through the Neches River Channel. This and the other alternatives were screened based on comparison of anticipated reductions in vessel delay costs and initial project construction cost estimates and the outputs of the ERDC ship simulation modeling. Widening of the Neches River reach

was found not be a cost effective alternative due to costly dock relocations and extensive dredging. Additionally, intermittent widening of the Neches River Channel did not perform well during ERDC ship simulation modeling. In comparison, the Neches River anchorages and Sabine Pass Channel and Port Arthur Canal widening features performed favorably. The results of the ERDC modeling showed that a minimum width of 700 feet through the Sabine Pass Channel and Port Arthur Canal would be necessary for the Suezmax and Aframax vessels to meet smaller vessels in the Sabine Pass Channel and Port Arthur Canal. The project design vessel is 899 feet long and 164 feet wide. These dimensions correspond to a 158,000 DWT Suezmax crude petroleum tanker. A loaded and a ballast design vessel could not successfully meet in the ERDC test of the 600-foot channel nor could the design vessel and a smaller 110,000 DWT Aframax tanker meet. Aframax tankers characteristically range from 90,000 to 120,000 DWT, and the Suezmax tankers characteristically range from 120,000 to 175,000 DWT.

6.3.1.4 Entrance Channel Widening Benefits

Evaluation of widening of the entrance channel to 700 feet through the Sabine Pass Channel and Port Arthur Canal showed that, using 2000–2004 traffic levels, vessels would save an average of 1.5 hours per round trip voyage, with an annual savings of \$3,487,322. Summary output from the HarborSym model associated with widening the Sabine Pass Channel and Port Arthur Canal to 700 feet is displayed in Table 96. The benefits of widening only through the Sabine Pass Channel totaled approximately \$2,269,264. Evaluation of Port Arthur by itself resulted in annual savings of approximately \$2,579,760. The widening benefits shown in Table 96 are for the existing 40-foot channel depth and 2000–2004 period traffic. The effect of reductions in total vessel movements resulting from channel deepening is evaluated in the sensitivity section of this appendix.

Examination of the output data shows that for the without-project condition, which reflects the inclusion of LNG carriers, vessels are in the system for 78.2 hours. The output also shows that expansion of the Entrance Channel will reduce the time in system to 76.7 hours. In reviewing the changes in delay times, it was found that there are large variances in throughput times. The minimum time for the without-project condition was on average 11.9 hours, and the minimum time for the with-project condition also averaged 11.9 hours. The larger crude oil tankers showed throughput savings for the with-project condition. For instance, Suezmax vessels took an average of 86.7 hours under the without-project condition and an average of 83.1 hours with the widened entrance channel. The addition of the LNG vessels will result in longer waiting times for several vessel classes. Without the LNG vessels, the average number of hours in the system was 66.4. The effect of introducing the LNG vessels increases total delay times but reduces average times because the LNG vessels represent a large increase in vessels that travel shorter distances than the existing tanker fleet going to the Neches River and, therefore, will not be subject to delays.

Table 96
SNWW HarborSym Output Annual Savings by Vessel Class (2004-Period Traffic), Widening Only

The benefits shown in Table 96 are based on widening only and are based on 2004-period traffic levels. Table 97 summarizes the average annual benefits for 2019–2069 for widening of the Sabine Pass Channel and the Port Arthur Canal. Table 98 displays the incremental economic summary data associated with the widening of the Sabine Pass Channel and the Port Arthur Canal. The results of the benefit-cost analysis indicated that widening was not an incremental justified feature.

Table 97
Sabine Pass Channel and Port Arthur Canal Widening Only
Average Annual Benefits (2008 Dollars at 4.375%)

Year	Sabine Pass Channel	Port Arthur Canal	Sabine Pass Channel and Port Arthur Canal
2004	2,269,264	2,579,760	3,487,322
2019	2,922,548	3,431,103	4,335,553
2029	3,738,979	4,431,691	5,486,406
2039	4,691,482	5,599,044	6,829,067

Item	Sabine Pass Channel and Port Arthur Canal
First Cost	78,448,000
Mitigation Cost	48,484,500
Interest During Construction	36,282,311
Total First Cost	163,214,811
Average Annual Construction Cost	8,091,727
Incremental Average Annual Operations and Maintenance (O&M) Cost	9,587,005
Total Average Annual Cost	17,678,733
Average Annual Benefits	6,338,991
Benefit to Cost Ratio	0.4

The benefit calculations are based on 2004-period historical and 2030-2040 projected traffic. The future traffic levels do not account for channel deepening. The effect on the reduction in total vessel movements resulting from channel deepening is evaluated in the sensitivity section of this appendix. For the sensitivity, HarborSym widening model was run based on the reduction in vessel trips as a result of channel deepening. The purpose of the sensitivity was to determine changes in the annual delays in relationship to widening and deepening of the Sabine Pass Channel and Port Arthur Canal. The change in vessel trips due to channel deepening was estimated based on the decrease in the number of trips

necessary to transport future tonnage. The model results show that the reduction in the number of vessel trips resulting from channel deepening has a significant effect on the net difference in the duration of vessel delays between the without- and with-project conditions. Further analyses based on various ranges of fleet forecasts indicate that the increase in benefits from scenarios that included either “deepening and widening” or “deepening and the turning basins” were primarily attributable to the reduction in trips due to channel deepening. These savings result from the reduction in trips based on vessels carrying additional cargo or the redistribution of vessel sizes based on the availability of a deeper channel and do vary significantly from the “widening only” benefits shown in Table 98. The effect of adding these savings to the project benefits is outlined in the sensitivity section (Section 8).

6.3.1.5 Neches River Holding Areas

Determination of the number of turning basins, turning basin anchorage combinations, and anchorages was initially made based on pilot interviews. The turning basins and turning basin anchorage combinations are used for both turning and for vessels to wait while others pass. The TBAs allow loaded vessels to await berths at the dock and will save the time that they originally would have spent “inbounding” when the berth became clear. With the TBAs, instead vessels only have to shift from one of these sites to a dock rather than awaiting an outbound ship to sail and to start in accordance with the traffic rules. The pilots said that they would trade vessels out between the Neches River “holding areas” and “docks,” thus violating established rules. According to ER 1105-2-100 and the Policy Digest, features such as turning basins can be in the Federal interest if they facilitate safe and efficient vessel navigation; this is clearly the case for the Neches River turning basins. In regards to incremental justification review concerns, there was considerably reluctance to allow anything less than the six turning basins; however, the pilots indicated that if priorities had to be placed on TBA construction, the priorities would be 1, 4, and 7. Next noted grouping was 1, 4, 5, and 7. It was emphasized that the priority was for all turning basin improvements. Current and without-project future use of the existing turning basins and new holding and turning sites is summarized in Table 99.

The pilots noted that the number of hours saved depends on the dock facility and that the benefits will be primarily for the crude oil tankers and some product carriers; however, all traffic would realize some savings. Pilot expectation is that the crude oil carriers would save about 7 hours. It also noted that the Panamax-size product carriers that load at ExxonMobil will save about 7 hours. The pilots noted that they did not expect a difference between the Aframax and Suezmax savings. The number of hours saved for vessels in the lower end of the Neches River Channel would be less.

Table 99
Neches River Proposed Turning Basin Anchorages

Description	Approximate Miles from Sabine Bank		Current Use
	Station	SB Buoy	
TBA 1 Turning Basin Anchorage 1	210+00	43.4	Limited with no anchorage
TBA 2 Turning Basin Anchorage 2	275+00	44.6	None
TB 3 Turning Basin 3	370+00	46.4	None
TBA 4 Turning Basin Anchorage 4	510+00	49.1	Limited with no anchorage
TB 5 Turning Basin 5	570+00	50.2	None
TB 6 Turning Basin 6	700+00	52.7	Turning Basin
TBA 7 Anchorage Basin 7	750+00	53.6	None
TBA 8 Anchorage Basin 8	850+00	56.5	None
Beaumont Maneuvering Area	975+00	58.8	Maneuvering Area

Pilot meetings conducted during the initial screening and during the HarborSym model building continued to show that the model was accurately calibrating existing conditions for the Entrance Channel reaches. In addition, the transit times were accurate for vessel throughput times. Discussion with the pilots after the runs were completed and review of the transit costs helped reconfirm that the model outputs for the Entrance Channel behavior were reasonably accurate for existing conditions as were expectations for the with-project condition; however, it was found that the model did not validate current or future use of the Neches River turning basins. The model results indicated a transfer in vessel delays from the present offshore location to the proposed siding locations. Detailed discussions with the vessel pilots initially revealed that the model was not set-up to account for pilots anticipated behavior of switching vessels between docks and holding areas. For this reason, HarborSym was not initially used for the Neches River turning basin analysis. In 2007–2008, modifications were made to the model in order to better capture the pilots anticipated behavior. The results of these modifications resulted in an increase in savings; however, the increase in savings is still significantly less than the pilots anticipated.

The model input is based on the assumption that the major difference in the Neches River without- and with-project conditions would be that, “as holding areas,” the “with project condition” would enable two vessels to be stored in TBA 1, TBA 2, TB 5, TBA 7, and TBA 8, instead of one small vessel in each. An additional item revealed at the meetings was that the maximum vessel size using the turning basins was the same for the without- and with-project conditions. Additionally, the model assumptions were based on “no change in Neches River transit rules” for the with-project condition. At the meeting, the pilots said that they would, in fact, trade vessels out between the Neches River “holding areas” and “docks” despite night rules and beam and depth restrictions. The indication was that “trading places” would be orchestrated to minimize the dangerous effects of violating established rules.

As an example of how the turning basins would be used, an inbound convoy would arrive on the Neches River Channel with the vessels going to docks on the upper end of the Neches leading the convoy. Each vessel would proceed to their respective dock and head into the berth (for the SNWW vessels turn after finishing at the dock). It takes about 1.5 hours to tie up at the docks, and loading or unloading takes about 18 hours, depending largely on cargo load. While the goal is for the vessel to get in and away from the dock within 24 hours, it is difficult to meet that goal, and vessel dock time frequently exceeds 30 hours. The goal of working to minimize unloading time or synchronizing it based on the other vessels in the convoy is an important consideration as the goal of completing dock time can be particularly crucial if another offshore convoy is set-up to come in. Under present conditions, the dockside convoy will leave its respective docks and head down the Neches River Channel. A vessel normally takes 2 hours to get from Exxon near the Beaumont Turning Basin at Neches River Station 990 to the lower end of the Neches River Channel (Station 240+00), a distance of about 14 miles. It was noted that outbound convoys often include one to two additional vessels. Under present condition, the vessels move down the Neches River Channel out to Buoy 29 and 30 in the Entrance Channel and into the 800-foot channel reach before they can meet single vessels with comparable dimensions or likewise an inbound convoy. Vessel meetings between inbound vessels and the outbound convoy are very restricted due to the combined beam and loaded-draft restrictions.

The pilots emphasized that the seven holding area improvements would allow loaded vessels to await berths and would save time that they originally would have spent in an inbound transit mode while the berth became clear. With the holding areas, vessels would only have to shift from the anchorage instead of awaiting the ship to sail and to start in accordance with the traffic rules. The pilots noted that the number of hours saved depends on the dock facility and that the benefits will be primarily for the crude oil tankers and some product carriers; however, all traffic would realize some savings. Pilot expectation is that the crude oil carriers would save about 7 hours. It also noted that the Panamax-sized product carriers that load at ExxonMobil will save about 7 hours. The pilots noted that they did not expect a difference between the Aframax and Suezmax savings. The number of hours saved for vessels in the lower end of the Neches River Channel would be lower.

The pilots noted that with the anchorages, future inbound convoys will include additional ships to await berths. Under present conditions, the size of an inbound convoy is limited due to berth space. When the berths are available, the vessels will switch from the holding area to a berth. They noted that it is quicker to put a vessel in an anchorage (approximately 20 minutes) than to dock (approximately 1 hour). Similarly, it is quicker to depart from anchorage than to undock and turn. The net result is that the convoys will move faster and include additional vessels.

The benefits of the turning basin features were evaluated based on pilot input and examination of the HarborSym output data associated with waiting times and other related variables. The initial focus of the discussions with the pilots was to understand present use of the turning basins and obtain clarification on the DWT, loaded drafts, beam, length, and number of vessels associated with each of the turning basins. Presently, the turning basins are used for vessel turning and holding of light vessels (i.e., loaded drafts less than 29 feet). Some turning basins are also used for holding light Aframax tankers, again with drafts

loaded to less than 29 feet. It was noted that Aframax tankers can be pushed into a turning basin; however, lack of maintenance dredging makes this practice less frequent and more difficult, but it will occur if a vessel, communication, or other breakdown situation requires.

The vessel arrivals and departures from the Neches River Channel are planned and/or orchestrated rather than random. Under present conditions, a new Neches River inbound fleet cannot come in until the outbound Neches River fleet has traveled down the Neches and has cleared the Jetty Channel and is in the Outer Bar Channel. Under the without-project condition, the vessels wait offshore. Under the with-project condition, they will also wait offshore; however, the sidings will allow a vessel to move to the dock and start unloading when, under the without-project condition, it would be waiting for an outbound convoy to clear the jetty channel. By widening the Entrance Channel through the Sabine Pass Channel, the inbound and outbound convoys have a longer reach in which to meet. By building the Neches River sidings, an inbound convoy can save a significant portion of the inbound transit time by being in the sidings and ready to move to the docks as the outbound convoy leaves. The convoy behavior will not change between the without- and with-project conditions. Table 100 presents the HarborSym output associated with the Neches River anchorages. Discussion with the pilots indicated uncertainty concerning shifting charges; therefore, the effect of their inclusion was evaluated. The benefits were calculation based on shifting costs being levied 50 percent of the time. Tables 101 and 102 summarize the average annual savings in comparison to the average construction cost. Table 101 is similar to Table 102 and presents the same combinations but differs in that the annual benefits reflect inclusion of “pilot shifting costs” for 100 percent of the time. The annual benefits presented in tables 101 and 102 do not reflect future growth and are based on 2004-period traffic levels. Analysis of the data presented in tables 101 and 102 shows that the combination of basins that include alternatives 1, 4, and 8 produce the highest net excess benefits among the alternatives evaluated.

Table 103 summarizes the project cost and benefits associated with the combination of 1, 4, and 8. The annual benefits presented in Table 104 are average annual numbers and reflect future growth based on 2019–2069 traffic levels. The benefit calculations are based on a project condition without deepening. The project construction cost is based on a project depth of 48 feet.

6.4 CHANNEL DEEPENING BENEFITS

The transportation costs and the savings associated with the proposed project depth increase were calculated using commodity-specific vessel class and trade route distributions. Transportation costs were calculated based on the channel depth alternatives and variables associated with vessel design drafts, maximum feet of light-loading, underkeel clearance, mileage traveled, and the number of hours to load and unload. Maximum vessel cargo capacities for crude oil and petroleum products were estimated based on review of the range of load factors obtained based on review from IWR Report 91-R-13, *National Economic Development Procedures Manual Deep Draft Navigation* (1991) and consultation with SNWW industry and the SPA. The IWR (1991) cargo capacity factors published in the deep-draft manual for dry bulk carriers and tankers are shown in Table 104. Consultation with industry and the pilots revealed that these estimates are reasonable. Table 105 presents representative round-trip mileage for the trade routes or junction points used for the transportation savings computations.

Table 104
Adjustments for Estimating Actual Vessel Capacity

Vessel DWT	Dry Bulk	Tanker
<20,000	0.90	0.90
20,000–70,000	0.92	0.92
70,000–120,000	0.95	0.95
>120,000	0.97	0.97

6.4.1 Transportation Savings Benefits for Channel Deepening

Transportation savings benefits from reductions in the vessel operating costs were calculated based on the relative difference in transportation costs between the without-project and with-project conditions. Transportation costs and savings were calculated for vessels that minimize transportation costs given trade route constraints. As previously noted, long-term fleet selection will continue to reflect goals of minimizing vessel operating costs. The basic procedure used to calculate transportation costs using 110,000 and 150,000 DWT foreign flag tankers as an example is illustrated in Table 106. Similar computations were made for appropriate distances and vessel sizes for each of the channel depth alternatives. The resulting costs-per-ton computations were calculated over the relevant range of vessels projected for each channel depth improvement, and the associated savings per ton were measured using the net differences in costs between the existing 40-foot channel and the depth alternative. Unless otherwise noted, the 2019–2069 tonnage forecasts used for the benefit calculations are shown in tables 81 and 82 summarizing the transportation savings benefits. Table 107 lists the terminal locations by channel and mileage point for the commodities included in the deepening analysis.

Table 106
Transportation Cost Calculation (South America to SNWW)

Channel Depth	40 feet	45 feet	50 feet	40 feet	45 feet	50 feet

a/ Anticipated to be constructed in 2012.

6.4.1.1 Crude Petroleum Imports

The costs per ton computations were calculated over the relevant range of vessels projected for each channel depth improvement. The associated savings per ton were measured using the net differences in costs between the existing 40-foot channel and the depth alternative. The transportation costs were calculated using foreign flag tankers (see Table 82). The distribution of tonnage between the ports of Beaumont and Port Arthur was assumed to reflect the relative historical tonnage shares. The sensitivity section of this appendix addresses the effects of Port Arthur's future share increasing relative to Beaumont's present share. Table 108 presents Port Arthur and Beaumont crude oil import forecasts.

SNWW Total	94,229	105,129	111,669	113,950	116,263	118,608
% Used for Benefits	95	95	95	95	95	95

An increase in the channel depth to Port Arthur from 40 to 45 feet would allow the existing range of 90,000 to 120,000 DWT vessels to carry approximately 20 percent more cargo. A depth increase from 40 to 50 feet or more would allow the same range of vessels to carry 35 percent more cargo. Table 109 displays the maximum cargo tons by vessel size and channel depth alternatives for representative vessels used in the analysis. Table 110 shows the number of shuttle vessels by channel depth alternatives necessary to offload a VLCC. The maximum loads shown in Table 109 and the number of shuttles shown in Table 110 are based on application of 1 foot of underkeel clearance. The effects of greater underkeel clearance are evaluated in the sensitivity analysis (Section 8). Shuttle vessels between 70,000 and 165,000 DWT were used for Beaumont's lightering cost calculations. Shuttle vessels between 70,000 and 120,000 DWT were used for Port Arthur's lightering cost calculations.

Table 111 summarizes the transportation cost by trade route used for the with- and without-project future condition calculations. The transportation costs for existing conditions and the without-project future are defined by the same range of vessel sizes. The existing range of vessels is concentrated between 75,000 and 120,000 DWT. The maximum vessel sizes presently used are in the 150,000 to 175,000 DWT range. Current distribution of crude oil imports by vessel size can be found in Section 3 (see tables 29, 31, and 32). There is a gap in the world tanker fleet between 175,000 and 250,000 DWT. The reason for the gap is that it is not cost effective to use tankers significantly larger than 175,000 DWT for channel depths of less than 55 feet (Section 3.5.1). An increase in channel depth of the SNWW would provide opportunity for the current range of vessels used for direct shipment and as shuttle vessels associated with offshore lightering to be more fully loaded.

The per ton transportation costs correspond to the least-cost method of shipment associated with the particular trade route. Review of the depths at trading ports and significant savings per ton indicate that a large share of crude petroleum tonnage from Mexico, Venezuela, and Trinidad would be loaded to vessel drafts over 40 feet.

Expectations concerning the percentage of Middle East and Africa movements are subject to greater uncertainty. Nearly all Middle East tonnage is lightered, and nearly all West Africa crude is lightened. The logistics associated with these offshore transfers introduces higher degrees of uncertainty than with direct shipment and, therefore, generates large cost variances.

Additionally, and as Table 111 illustrates, the cost savings for offshore transfer are lower than with direct shipment; however, distinct cost savings are apparent. The savings for lightering results from increases in shuttle loads due to greater channel depth in SNWW. For lightering, the effect of increasing channel depths at SNWW allows for the reduction in the number of shuttles necessary to totally lighter VLCCs. The savings for lightened movements results from decreases in offshore unloading time from the mother vessel to shuttles. For lightening, the mother vessel is substituting offshore unloading time for dock-side unloading time. Additionally, the shuttle vessel reduces its overall loading and unloading time.

Lightening generates comparatively lower savings than lightering because the latter produces the possibility of reducing the number of shuttles needed. Examination of the cost data also revealed that as channel depth increases, the resulting savings may introduce incentive to switch from lightening to direct shipment for movements from Africa and the North Sea. Table 112 presents the lightening and Table 113 presents the lightering costs. Historically, lightening was the most common choice for Africa and the North Sea movements; however, lightering has become more common for this route in recent years due to structural changes in oil production off the coast of West Africa. Lightering has always been the method of choice for Middle East movements. The small percentage of North Sea using SNWW tends to be lightered, and an increasing portion of West Africa crude is lightered. Lightering was assumed to represent the without- and with-project future choice for West Africa crude due to its relative low cost and increasing popularity. Comparison of the cost data in tables 112, 113, and 114 for the Africa and North Sea route demonstrates why lightening will continue for this route; however, method of shipment choices for West African crude will remain subject to a higher level of uncertainty than for other routes. The relative closeness in costs between the shipping methods, and the uncertainty associated “turnaround times” for completing offshore transfers means that direct shipment and lightening will continue as viable

options. At the same time, the effect of an SNWW deeper channel depth will reduce the cost differential and make direct shipment more cost competitive for Africa and North Sea routings and, therefore, may result in a greater frequency of direct shipment, with the uncertainty associated with offshore transfers being a key variable affecting shippers' decision.

Tables 114 and 115 display Beaumont and Port Arthur's transportation cost savings based on the least-cost shipping methods displayed in Table 111. For Port Arthur, the maximum vessel DWT used for the benefit calculations is less than 121,000 DWT. As previously noted, deepening of the channel leading to the Taylor Bayou terminal will enable the existing fleet to be more fully loaded, but it will not result in transition to larger vessels. The transportation costs shown in Table 111 and the savings shown in Table 115 reflect continuation of this limitation.

6.4.1.2 Petroleum and Chemical Product Transportation Savings Benefits

Reductions in the vessel operating costs for SNWW foreign petroleum product imports and exports and coastwise shipments were calculated based on the relative difference in transportation costs between the without-project and with-project conditions. For foreign imports and exports, transportation savings were calculated for petroleum product imports and exports and for chemical exports. Chemical imports were not found to be draft limited. As with crude petroleum, transportation costs and savings were calculated for vessels that minimize transportation costs given trade route constraints. Table 116 displays SNWW's petroleum product import forecast and the tonnage used for the benefit calculations. Table 117 displays the petroleum export forecast.

Table 123 summarizes the benefit calculations for coastwise product shipments and receipts. As noted, deepening of the channel leading to the Taylor Bayou terminal will enable the existing fleet to be more fully loaded but it will not result in transition to larger vessels. The transportation savings shown in Table 123 reflect continuation of this limitation. The maximum-sized coastwise vessels do not exceed Taylor Bayou's limitation. Transportation costs were estimated for 1-foot channel depth increments; however, the table presentations only include 40-, 45-, 47-, 48-, and 50-foot costs.

Table 123
SNWW Petroleum Product Coastwise Shipments and Receipts

6.4.1.3 Grain Exports Transportation Savings Benefits

Beaumont wheat exports compose 5 percent of the current U.S. total. Forecasts of future exports were estimated based on analysis conducted by the USDA. Beaumont's recent grain exports consist almost exclusively of wheat. Twenty-five percent of 2002–2006 grain export tonnage was shipped in vessels with design drafts over 40 feet. The maximum DWT presently used for grain exports is in the 60,000 to 70,000 DWT range. These vessels have design drafts between 42 and 43 feet. As previously noted, the median year of construction for the range of vessels presently used is 1985. Bulk carrier construction trends (see Table 47) suggest transition in the average DWT range up to the 80,000 to 94,000 DWT range. In the 1980s, grain vessels in the 135,000 to 150,000 DWT range were used for grain exports from

Beaumont and other Texas ports. These larger carriers transported grain to the former Soviet Union and to Northern Europe. Demand for large parcels and channel depth availability at the destination port could result in a return to 135,000 to 150,000 DWT vessels. Currently, the largest parcels from Texas ports are in the range of 40,000 to 60,000 short tons, and parcels of 10,000 to 20,000 short tons are typical. For grain shipped from the Canadian West Coast, it was noted that 40,000 DWT vessels are used for 10,000 parcels even though it is not cost effective. Reasons for small parcels could relate to specific demands not to commingle; however, that was not noted. Containerships are the most common vessel type used for Australian grain exported to Asian countries. Table 124 summarizes the per ton transportation cost associated with the range of bulk carriers expected to use the channel. Table 125 summarizes the grain exports for 2004–2007 and the annual transportation cost. Table 126 displays the annual tonnage forecast and the transportation savings. The transportation costs are based on the cost per ton (Table 124) multiplied by the annual tonnage (Table 125). The transportation savings benefits are based on 30 percent of tonnage would load to drafts over 40 feet (see Table 77). Port depth, trade route, historical vessel utilization data, and completion of the Panama Canal expansion were considerations used to identify the percentage of grain exports tonnage anticipated to benefit from the proposed SNWW depth increases.

Table 124
Beaumont Wheat Exports, Shipments to Europe, Mediterranean, and Far East
Total Cost Per Ton by Channel Depth (December 2008 Vessel Costs, in dollars) a/

DWT	Channel Depth (feet)						
	40	45	46	47	48	49	50
70,000	20.07	16.83	16.83	15.80	15.80	15.80	15.80
80,000	19.58	16.39	16.39	15.38	14.92	14.49	14.49
90,000	17.97	15.24	14.78	14.35	13.94	13.56	13.20
100,000	18.01	15.25	14.79	14.36	13.95	13.56	13.20
120,000	17.32	14.73	14.31	13.92	13.49	13.13	12.78

a/ Calculated based on a round-trip mileage of 18,000 and the foreign flag bulk carrier operating costs shown in Table 83.

The possibility of using containerships for grain transport is only being considered at a corporate level; however, the traditional use of bulk carriers provides a less expensive mode. Containerships for wheat and bulk grain transport have the noted advantage of increased versatility in the range of cargoes. The potential effect of using containerships through Beaumont or the transfer of bulk grain to another location is an uncertainty associated with grain export tonnage. The effect of this sensitivity is addressed in the sensitivity section (Section 8).

6.4.1.4 Crude Materials Transportation Savings

SNWW primary manufactured goods consist nearly exclusively of primary iron and steel products. Reductions in the vessel operating costs for SNWW steel slab and iron ore imports were calculated based on the relative difference in transportation costs between the without- and with-project conditions. As with the previous presentations, transportation costs and savings were calculated for vessels that minimize transportation costs given trade route constraints. Again, long-term fleet selection will continue to reflect goals of minimizing vessel operating costs. Port Arthur's breakbulk terminal is located outside the Taylor Bayou reach, and the bulk carriers are not subject to the beam and length limitations. However, the maximum beam width for the bulk carrier fleet is 106 feet. The design drafts for these vessels are generally less than 45 feet. The DWT range of bulk carriers used for the benefit calculations is 60,000 to 90,000. Larger vessels could be used but are not anticipated over the next 20 years. The maximum size presently being used is 78,000 DWT. The transportation savings calculations were based on average costs for the anticipated 60,000 to 90,000 DWT range.

Table 127 present the cost per ton transportation cost for the representative bulk carriers used to transport steel slab and iron ore. The costs shown are for Port Arthur and Beaumont. Based on existing port depths and vessel utilization, an estimated 10 percent of tonnage was projected to use channel depths over 40 feet for the years prior to 2014. By 2014, the expansion of the Panama Canal is expected to result in the existing base tonnage from the deepwater port of Lazaro Cardenas on the West Coast of Mexico to load to vessel drafts over 40 feet. At that time, an estimated 50 percent of tonnage is anticipated to be loaded to vessel drafts over 40 feet.

Table 127
SNWW Steel Slab and Iron Ore from South America and Far East and the
Mediterranean Cost Per Ton by Channel Depth (December 2008 Vessel Costs)

DWT	Channel Depth (feet)						
	40	45	46	47	48	49	50
Transportation Cost/Ton to Port Arthur							
60,000	17.63	14.60	14.13	13.66	13.66	13.66	13.66
70,000	15.60	13.08	12.68	12.29	12.29	12.29	12.29
80,000	15.22	12.74	12.35	11.96	11.60	11.26	11.26
90,000	14.12	11.95	11.60	11.25	10.94	10.63	10.35
Transportation Cost/Ton to Beaumont							
60,000	18.35	15.22	14.73	14.23	14.23	14.23	14.23
70,000	16.23	13.63	13.22	12.80	12.80	12.80	12.80
80,000	15.84	13.29	12.89	12.49	12.12	11.77	11.77
90,000	14.70	12.47	12.12	11.77	11.44	11.14	10.84

A representative weighted mileage for the applicable South America, Mediterranean, and Far East routes was used. The weighted mileage is approximately 14,000 miles round-trip. The mileage estimated was based on 2005–2007 routings (see Table 48). As previously noted, the tonnage forecast and average annual growth rate for 2002–2004 to 2069 tonnage was displayed in tables 80 and 81. Tables 128 and 129 summarize historical tonnage base and the annual transportation savings benefits for Port Arthur's steel slab and iron ore import tonnage.

Table 128
Port Arthur Steel Slab and Iron Ore from South America, Mediterranean,
and the Far East Historical Tonnage and Annual Transportation Cost by Ton
(\$1,000) (December 2008 Vessel Costs)

	Year	Total Exports	Used for Benefit Calculations
	2001	665,000	66,500
	2002	641,000	64,100
	2003	557,000	55,700
	2004	564,000	56,400
	2005	710,000	71,000
	2006	542,000	54,200
	2007	122,000	12,200
	2005–2007 Average	458,000	45,800

Transportation Cost by Vessel Size and Channel Depth Using 2005–2007 Average Tonnage a/							
DWT	40 feet	45 feet	46 feet	47 feet	48 feet	49 feet	50 feet
60,000	807	669	647	625	625	625	625

Average Savings		88	102	116	122	128	130

a/ The costs are based on the historical tonnage volume of 50.4 thousand short tons multiplied by the cost per ton shown in Table 127. The transportation cost of \$547,000 is the product of 50.4 thousand short tons times the difference in transportation costs for the channel depth alternatives.

Note: Application of data as presented may produce some differences due to rounding.

Table 131
 Beaumont Steel Slab and Iron Ore from South America and Far East
 and the Mediterranean Tonnage Forecast and Annual Transportation Savings
 (\$1,000) (December 2008 Vessel Costs)

		Tonnage Used for Benefit Calculations				
Year						
2002/2004	33,600					
2019	213,254					
2029	248,025					
2039	288,465					
2049	335,499					
2059	390,201					
2069	453,823					
Annual Transportation Savings by Year a/						
Year	45 feet	46 feet	47 feet	48 feet	49 feet	50 feet
2002/2004	88	102	116	122	128	130
2019	560	649	737	774	809	825
2029	652	755	857	900	941	960
2039	869	1,006	1,143	1,200	1,254	1,279
2049	1,175	1,360	1,546	1,623	1,697	1,730
2059	1,589	1,840	2,091	2,196	2,295	2,341
2069	2,150	2,489	2,828	2,970	3,105	3,166

a/ The savings for 2005/2007 are based on the difference in transportation costs from the previous table multiplied by the 2005/2007 tonnage. The savings for 2019–2069 are based on application of the tonnage growth to the 2005/2007 historical base.

Note: Application of data as presented may produce some differences due to rounding.

6.4.1.5 Crude Materials Transportation Savings Benefits

As with steel slab and iron ore, the DWT range of bulk carriers used for the aggregate rock and other crude materials benefit calculations are in the 60,000 to 90,000 DWT range. Larger vessels could be used but are not anticipated over the next 20 years. The maximum size presently being used is 78,000 DWT. The transportation savings calculations were based on average costs for the anticipated 60,000 to 90,000 DWT range. As with the previous presentations, transportation costs and savings were calculated for vessels that minimize transportation costs given trade route constraints. The DWT range of bulk carriers used for the benefit calculations are in the 60,000 to 90,000 DWT range.

The applicable tonnage forecast and average annual growth rate for 2002–2004 to 2069 was displayed in tables 80 and 81. The forecast includes imports and exports. Table 132 displays Port Arthur and Beaumont crude material imports and exports. Imports consist nearly exclusively of limestone, rock, and other building materials. Exports consist primarily of dry sulphur, clay, and refractory materials.

Based on existing port depths and vessel utilization, an estimated 50 percent of crude material imports and 10 percent of crude material exports was projected to use channel depths over 40 feet. A representative weighted mileage for the applicable South America and Far East was used. The weighted mileage is approximately 14,000 miles round trip. Table 133 present the cost per ton transportation cost for representative bulk carriers used to transport crude materials based on the trade routes shown.

Table 133

6.4.1.6 Liquefied Natural Gas Transportation Savings

Table 137 presents the trade route forecast used for the benefit calculations, Table 138 presents the per ton transportation cost. The bottom half of Table 138 presents the annual savings. The maximum loaded draft for LNG vessels is anticipated to be 40 to 42 feet. The majority of vessels will be loaded to 39 feet. The vessels will need from 3 to 6 feet underkeel clearance. The deepening benefits were therefore, believed to stop at a channel depth of approximately 43 feet. The benefits were calculated using 4 feet of underkeel clearance. Recalculation of the benefit estimates using 3 feet would reduce the average annual benefits by approximately 39 percent. Recalculation using 6 feet would increase the average annual savings by approximately 64 percent. Use of less than 4 feet of underkeel clearance is not expected for LNG vessels.

7.0 NED BENEFIT SUMMARY

Table 139 summarizes the transportation cost savings by major group. The majority of benefits are associated with imports of crude petroleum, LNG, and petroleum product and exports of petroleum products. Crude petroleum and petroleum products represent 84 percent of the benefits at the 45-foot depth and 89 percent at the 50-foot depth. LNG comprises 7 percent of benefits at the 45-foot depth and 4 percent at 50 feet. The LNG benefits are for facilities in the Sabine Pass Channel and Port Arthur Canal reaches. Distributions of the Taylor Bayou, Port Arthur, and Neches River deepening benefits are presented in Table 140.

Table 139
Total Average Annual Deepening Benefits (\$1,000s)
(50-Year Period of Analysis at 4.375%)
by Project Depth Alternative
(December 2008 Vessel Costs)

	45 feet	46 feet	47 feet	48 feet	49 feet	50 feet
Crude Petroleum Imports	41,130	48,650	53,411	61,081	66,173	68,759

Neches River Anchorages	2,153	2,153	2,153	2,153	2,153	2,153
Total Annual Benefits	83,844	95,856	104,303	115,074	122,875	127,696

Table 141 summarizes the benefit cost analysis, including the first cost of construction, net excess benefits, and the benefit to cost ratio (BCR) for the project alternatives. The results of the analysis indicate that the 49-foot channel depth represents the plan that most reasonably maximizes net excess benefits.

7.1 INCREMENTAL ANALYSIS

The project benefits start in the Sabine Pass Channel reach where the Cheniere LNG terminal is located.⁴⁶ The Port Arthur Canal reach follows the Sabine Pass Channel reach. The Golden Pass LNG terminal which is nearing completion, is located in the Sabine Pass Channel reach. An additional LNG terminal, Semptra, is permitted for construction in the Port Arthur Canal reach; however, due to uncertainty, the LNG transportation savings benefits (see Table 139) do not include Semptra. The Port Arthur Canal reach also provides access to the Taylor Bayou side channel and basin. The Port of Port Arthur facilities are located along the main portion of the Sabine-Neches Canal. The incremental analyses for channel improvements through Port Arthur excluding the Taylor Bayou side channel are shown in Table 142.

Table 142
Sabine Pass Channel, Port Arthur Canal, and Sabine-Neches Canal Incremental Analysis
Cost and Benefits (\$1,000s) by Channel Alternative
(50-Year Period of Analysis at 4.375%)
(December 2008 Vessel Costs)

	45 feet	46 feet	47 feet	48 feet	49 feet	50 feet
First Cost of Construction	510,640	564,696	618,751	672,807	725,314	777,822
Interest During Construction	48,541	54,539	60,538	66,536	71,713	76,889
Total Investment	559,181	619,235	679,289	739,343	797,027	854,711
Average Annual Cost	27,723	30,700	33,677	36,655	39,514	42,374
Deferred Construction (F&W)	174	188	201	215	221	227
Average Annual O&M	21,870	23,477	25,089	26,705	27,332	27,965

Benefit to Cost Ratios	0.3	0.2	0.2	0.2	0.2	0.2

Separable analysis of Taylor Bayou is shown in Table 143. The analysis presented in Table 143 shows that the BCRs for the Taylor Bayou increment are well above unity. Table 144 presents the Sabine-Neches and Taylor Bayou increments as a separable unit. Table 144 indicates that the BCRs for the segment through the Sabine-Neches Canal and including Taylor Bayou are below unity due to the inclusion of the Entrance Channel costs and exclusion of the Neches River benefits. Incremental analysis of the Neches River reach is shown in Table 145, and the BCRs are well above unity. Table 146 displays Neches River analysis excluding Taylor Bayou. Table 147 reflects exclusion of benefits from Taylor Bayou, LNG, and breakbulk. Table 148 presents calculation of the benefits and costs without inclusion of LNG.

⁴⁶ Reference to the facility locations can be found on Figure 1.

The results of the analysis presented in tables 142 through 148 show that the downstream benefits are not needed to justify the upstream costs. The analysis shows that each of the major reaches provides significant incremental benefits.

7.2 BENEFIT-COST RATIO AT 7 PERCENT

Calculation of benefits and costs at 7 percent interest is required by EC 11-2-194, commonly referred to as the budget Engineering Circular (paragraph 11). The 7 percent calculations are used for budget ranking purposes. Table 149 outlines the economic calculations at 7 percent.

8.0 SENSITIVITY ANALYSIS

Sensitivities were evaluated based on trade route variations, vessel underkeel clearance variance, the use of offshore or other pipeline alternatives, and the effect on vessel delays from reductions in vessel trips as a result of channel deepening. The effects of the sensitivities were evaluated in relationship to the BCRs, net excess benefits, and NED plan presented in Table 141. The effects of the combined sensitivities are also discussed.

8.1 UNDERKEEL CLEARANCE SENSITIVITY

Table 150 presents the results of a scenario using 3 feet of underkeel clearance instead of 1 foot for crude petroleum and petrochemical products. Table 151 presents the results of a scenario using 1 foot of underkeel clearance for vessels less than 100,000 DWT and 3 feet of underkeel clearance for vessels over 100,000 DWT. The underkeel clearance assumptions remain the same for the without- and with-project conditions. The basis for the second scenario is that as channel depth increases, vessel operators are likely to be more adverse to the risk associated with 1-foot underkeel clearance when operating larger vessels. Table 152 presents the results of using 1 foot of underkeel clearance for the without-project condition and 3 feet for the with-project condition.

The sensitivity presented in Table 152 is based on the assumption that vessel operators use the availability of a deeper channel depth to reduce the risk of operating with minimum underkeel clearance by insisting on greater underkeel clearance at vessels over 100,000 DWT under the with-project alternative. The transportation costs and savings for the scenario were run with the assumption that all crude and product carriers use 1 foot of underkeel clearance under the without-project condition and all carriers use 3 feet under the with-project scenarios. Table 139 presents the result on plan optimization.

8.2 OFFSHORE TERMINAL

This scenario evaluates a with- and without-project future represented by increased use of an offshore alternative or other pipeline alternative such as receipt of large volumes of Canadian crude by landside pipeline. These alternatives were evaluated as sensitivities, as plans for these projects are uncertain. Some industry representatives noted that for security reasons, access to more than one alternative is preferable. The logistics, including the use of other waterways and pipelines, necessary to receive feedstock during emergency situations is a part of emergency planning; however, the delivery costs associated with such alternatives exceed the costs associated with those of existing practices. The results of a scenario where 50 percent of future crude petroleum imports from West Africa and the Middle East use an offshore alternative are presented in Table 153. The results of the sensitivity indicate that the 48- and 49-foot deepening alternative project remain justified; however, the benefits are greatly reduced.

8.3 OFFSHORE TRANSFER TIME SENSITIVITY

This section evaluates the effects of using both increasingly optimal and less than optimal turnaround times for offshore lightering and lightening. Identification of the number of days used for the SNWW analysis was based on inputs from industry including data outlined in the Skaugen PetroTrans publication “Introduction to Lightering.”⁴⁷ Detailed discussion of the variables associated with crude petroleum methods of shipment was presented in Section 3.5.1. As noted in that section, SNWW crude petroleum transportation costs were calculated based on the mother vessel being offshore for 24 hours for each shuttle vessel used. The 24-hour period includes offloading from the mother vessel and associated logistics, including routine delays. Table 154 includes the minimum and maximum hours per shuttle evaluated for the sensitivity.

Table 154
Mother Vessel Offshore Hours Per Shuttle (Hrs)

	Hours
Minimum	18
Most Likely	24
Maximum	36

The most likely times are based on the assumption of optimal turnaround times with the arrival of the shuttle vessels being coordinated to avoid any delays. The minimum times are based on increasingly optimal turnaround time. Table 155 presents the results of the minimum offshore hours. The maximum times are based on quotes obtained from the lightering companies and industry. Table 156 presents the results of the less than optimal offshore hours.

8.4 VESSEL TRIP REDUCTION DUE TO CHANNEL DEEPENING

For this sensitivity, the HarborSym widening model was run based on the reduction in vessel trips as a result of channel deepening. The purpose of the sensitivity was to determine changes in the annual delays in relationship to widening of the Sabine Pass Channel and Port Arthur Canal. The change in vessel trips due to channel deepening was estimated based on the decrease in the number of trips necessary to transport future tonnage. These vessel trip calculations were used in the ERDC shoreline effect study. Vessel trip estimates were prepared using 2000–2004 trips and for 2030–2040 average trips (see tables 94 and 95). The results of the HarborSym model show that the reduction in the number of vessel trips resulting from channel deepening will have a significant effect on the net difference in the duration of vessel delays between the without- and with-project conditions. The transportation costs and savings associated with the sensitivity are outlined in Table 157.

Table 158 presents a comparison of the economic summary data for “widening with deepening” and widening as a separate feature. The economic summary data for widening as a separate feature was previously presented in Table 98. Additional analyses based on a range of fleet forecasts indicate that the increase in benefits from scenarios that included either “deepening and widening” or “deepening and the turning basins” were primarily attributable to the reduction in trips due to channel deepening. These savings result from the reduction in trips based on vessels carrying additional cargo or the redistribution of vessel sizes based on the availability of a deeper channel.

8.5 GRAIN EXPORT SENSITIVITY

The potential effect of using containerships through Beaumont or the transfer of bulk grain to another location is an uncertainty associated with grain export tonnage. For purposes of analysis, the effect of excluding transportation savings for grain exports was evaluated. The result of this sensitivity is summarized in Table 159.

8.6 DEPTH OPTIMIZATION SENSITIVITY REVIEW

This section provides a review of depth optimization. Current benefits calculations were reviewed in relationship to project construction costs. Benefit calculations for the range of channel depths between 43 and 50 feet continued to be maintained during the study process. While, detailed costs were not made for every channel depth increment after the initial optimization of benefits and costs were prepared, costs calculations for the 45-foot alternative were maintained as they were needed for cost allocation purposes. Comparison of recent project construction costs for the 45- and 50-foot channel depth increments and cost data for earlier study phases were used to estimate the project construction cost for 46, 47, and 49 feet. Detailed calculations were made for 45, 48, and 50 feet.

Comparison of the detailed cost values for 45, 48, and 50 feet with the inclusion of the interpolated values for 46, 47, and 49 feet with calculated transportation cost savings for 43, 45, 46, 47, 48, 49, 50, and 52 feet is displayed on Figure 58. The presentation shows that the average annual benefits by channel depth increase at a greater rate than costs. The results of this comparison suggest that channel depth alternatives less than 45 feet would not produce higher net excess benefits than the proposed 48-foot channel depth.

Figure 58
SNWW Depth Optimization Review

8.7 SUMMARY OF MAJOR SENSITIVITY EFFECTS

This sensitivity presents the results of using 1 foot of underkeel clearance for the without-project condition and 3 feet for the with-project condition and including the incidental benefits from reductions in vessel trips. Table 160 displays the project benefits for this scenario. The total benefits include the channel deepening and anchorage basin benefits outlined in Table 141 and the incidental reduction in delay benefits shown in Table 157. The annual savings for the without-project future without deepening is \$6,339,400. The annual savings for the without-project future that includes deepening to 48 feet is \$29,591,300. The results of the analysis indicate that the residual savings from the combined effect of widening and deepening is represented by the net difference of \$23,571,700. The savings for the 45-, 46-, and 47-foot depths was interpolated given a savings of zero at 40 feet and \$23,571,700 at 48 feet. The savings at 49 and 50 feet were assumed to be the same as at 48 feet.

9.0 REGIONAL ECONOMICS

This section provides a summary of regional benefits of port-related activity. Martin Associates' "Jefferson County Waterway and Navigation District – Study for Economic Impact Maintenance Dredging and Economic Impact of Deepening and Widening of the Sabine-Neches Waterway"⁴⁸ is the principal source used in preparation of this section. The Martin report includes evaluation of the economic impacts generated by marine activity in 2004. Economic impacts were estimated in terms of jobs, personal earnings, business revenue, and state, local, and federal taxes. Figure 59 outlines how the waterway activity impacts the local, regional, and Federal economies.

Figure 59
Flows of Economic Impacts through the Economy

Source: Martin Associates, "Jefferson County Waterway and Navigation District - Study for Economic Impact Maintenance Dredging and Economic Impact of Deepening and Widening of the Sabine-Neches Waterway" July 2006, Exhibit E-2, page 3.

As the figure indicates, the marine cargo and vessel activity generates revenue to firms providing marine services. This revenue results in a series of impacts including payroll, retained earnings, stockholder earnings, dividends and reinvestment, purchase of goods and services from local firms, as well as national and international firms (creating indirect jobs with these firms). Businesses also pay taxes from the business revenue.

Descriptions of the general job effects associated with port activity are defined as follows:

⁴⁸ Martin Associates, "Jefferson County Waterway and Navigation District - Study For Economic Impact Maintenance Dredging and Economic Impact of Deepening and Widening of the Sabine-Neches Waterway," August 2006.

Direct jobs are described as jobs with local firms providing support services to the waterway. These jobs are dependent upon this activity and would suffer immediate dislocation if the waterway activity were to cease. Direct jobs include employment with railroads and trucking companies, steamship agents, ship chandlers, warehouse operators, shipyards, and marine construction firms.

Induced jobs are described as jobs created locally and throughout the regional economy due to purchases of goods and services by those directly employed. These jobs are with grocery stores, the local construction industry, retail stores, health care providers, local transportation services, etc., and would also be discontinued if waterway activity were to cease.

Indirect jobs are described as jobs generated in the local economy as the result of local purchases by the firms directly dependent upon waterway activity. These jobs include jobs in local office supply firms, equipment and parts suppliers, maintenance and repair services, insurance brokers, business service contractors, and local utilities.

Cargo moving through marine terminals within the Jefferson County Waterway and Navigation District are noted to generate 83,692 jobs in Texas and Louisiana (Table 161). Of these, 14,987 are direct jobs generated by marine cargo and vessel activity. Wages and salaries associated with direct jobs were estimated to be \$877.7 million annually. Local and regional purchases made by the 14,987 direct job holders were estimated to result in an additional 13,628 induced jobs. An additional 55,077 indirect jobs are noted to be supported by \$3.7 billion in local purchases by businesses supplying services to marine terminals and marine-related businesses located along the SNWW. As the result of respending this income, an additional \$1.5 billion of income and consumption expenditures were created. The 55,077 indirect job holders in Texas and Louisiana received \$2.4 billion of indirect wages and salaries. In total, \$4.7 billion of direct, induced, and indirect personal wages and salaries and consumption expenditures were generated by maritime activity at marine terminals located within the Jefferson County Waterway and Navigation District.

The report also includes an assessment of the job impacts on a “per 1,000 ton basis,” which is noted to provide a tool for port planners to use in evaluating the relative importance of different commodities as economic generators. Table 162 presents the job impacts per 1,000 tons for each commodity moving through the public and private marine terminals. Tables 161 and 162 and Figure 59 are all displayed as presented in the Martin Associates report with minor formatting changes.

Source: Martin Associates, "Jefferson County Waterway and Navigation District - Study for Economic Impact Maintenance Dredging and Economic Impact of Deepening and Widening of the Sabine-Neches Waterway" July 2006, Exhibit II-2, page 18.

Examination of the data presented in Table 162 shows that containers and general cargo create the largest number of direct jobs per 1,000 tons, followed by steel, chemical products, and other dry bulk. The presentation also shows that the relatively large impact per 1,000 tons for containers and general cargo corresponds to a relatively small tonnage handled. In comparison, the number of jobs per 1,000 tons for crude petroleum and petroleum products is small despite the fact that crude petroleum generated the second largest direct job impact. The number of jobs and the jobs per 1,000s of tons for chemical products both rate relatively high. On a per 1,000 ton basis, chemical products generates nearly 0.5 jobs per 1,000 tons. In comparison, crude petroleum and petroleum products results in 0.06 jobs per 1,000 tons. Dry bulk and chemicals represent approximately 10 percent of total tonnage. The remaining 90 percent of tonnage consists of petroleum. The finding that some cargoes generate relatively small direct jobs per 1,000 tons of throughput reflects the fact that the handling of these cargoes is much less labor intensive than handling other commodities. For instance, the supporting infrastructure of agents, freight forwarders and customs house brokers, and warehousing and terminal operators is greater for some cargo.

9.1 OTHER INDICATORS

In addition to the Martin Associates report, Beaumont-Port Arthur Metropolitan Statistical Area (MSA) employment data was reviewed in order to assess the distribution of employment and short-term trends. Table 163 displays 2001–2007 MSA employment statistics. Manufacturing, retail trade, and construction are the largest private industry employers. Waterway-related employment is largely associated with private companies, and likely includes, in order of magnitude, transportation and warehousing, manufacturing, and wholesale trade. Additionally, mining employment, particularly offshore-related exploration, results in direct, indirect, and induced employment and income impacts. Analysis of the data presented in Table 163 shows positive job growth in all sectors directly related to waterway activity. The most notable growth rates are for mining (11 percent), wholesale trade (3.4 percent), and transportation and warehousing (3.3 percent). It is recognized that not all jobs associated with these sectors are directly related to the waterway.

9.2 SUMMARY AND CONCLUSIONS

While the incremental effects of the Federal action on employment and regional income are not addressed in the Martin Associates report, it is expected that construction of the Federal project will facilitate regional growth. The greatest effect on employment and income are expected to continue to be concentrated among dry bulk and chemical cargoes. Significant growth occurred over the last 10–15 years in these labor-intensive commodity groups. Additionally, overall total tonnage growth will allow for continued increases in regional employment and income.

ECONOMIC ADDENDUM

1.0 GENERAL

This addendum presents analysis of issues raised during the Independent External Peer Review (IEPR) (Battelle, 2010).

2.0 ANALYSIS OF LOOP AS A NON-STRUCTURAL ALTERNATIVE (IEPR COMMENT 1)

An offshore terminal has the potential of capturing 100 percent of all crude oil imports shipped from the routings represented by Middle East, Africa, North Sea, Mediterranean, and Brazil. Table 2A presents the tonnage that could potentially utilize an offshore terminal.

TABLE 2A						
SNWW Offshore Terminal Tonnage and Transportation Cost Savings						
Representative Trade Route	1,000's of Short Tons by Trade Routing					
	2019	2029	2039	2049	2059	2069

Europe/Africa	\$8.41	\$7.84	\$0.57			
Middle East	\$14.43	\$12.66	\$1.77			
Annual Transportation Savings						
Representative Route	2019	2029	2039	2049	2059	2069
Brazil	\$2,466	\$2,750	\$2,913	\$2,964	\$3,022	\$3,234
Europe & Africa	\$19,175	\$21,380	\$22,658	\$23,054	\$23,505	\$25,076
Middle East	\$55,894	\$62,321	\$66,045	\$67,201	\$68,515	\$73,093
Total	\$75,069	\$83,701	\$88,703	\$90,255	\$92,021	\$98,169

Table 2B provides a comparison of the transportation savings benefits between the channel deepening alternatives and an offshore oil terminal alternative. The cost for the offshore oil terminal and pipeline structure is estimated to be a first cost of \$1.8 billion based on the 2001 BOOTS construction cost estimate published by its sponsor and potential partners. The total annual cost estimates for the offshore alternatives are conservatively low. They do not include escalation of the original 2001 BOOTS estimate to 2010 costs, and they do not include estimated costs for operation and

maintenance (O&M), as we have no means of determining O&M costs for an offshore terminal. The table presents three offshore terminal funding scenarios. The first is based on SNWW users funding 100 percent of the terminal construction; the other scenarios are based on 50 and 25 percent funding. The project benefits are based exclusively on crude petroleum imports.

3. ANALYSIS OF CRUDE PETROLEUM IMPORTS BY VESSEL DRAFT (IEPR COMMENT 3)

The top section of Table 3A shows the relationship between crude oil design and loaded drafts. The second and third sections of Table 3A show the relative volume and percentage of tonnage transported in vessels with loaded drafts over 37 feet. Figure 3A illustrates the percentage increase in tonnage experienced on the SNWW between 1990 and 2008. While not exhibiting dramatic increases, the table and figure clearly shows a high concentration of loaded drafts over 37 feet for all years, with the percentage of tonnage loaded to drafts over 37 feet increasing from 60 percent in 1999 to 71 percent in 2008. Table 3B includes additional distribution summary data. Trends are more apparent from the second table which shows an average of 7 percent of 2006-2008 tonnage associated with design drafts under 40 feet, compared to an average of 15 percent for 1999-2001. For the 1999-2008 period, the use of vessels with design drafts less or equal to 40 feet ranged from 27 percent in 1990 to 2 percent in 2008, with a mean of 12 percent and median of less than 10 percent. The data show more efficient utilization patterns within the constraints of the existing channel depth, given uncertainties associated with spot market sales, variability in refinery input needs, congestion, and dock and pilot availability.

Estimation of how the Table 3A and 3B distributions might change given an increase in channel depth is difficult to discern based on the eight years of data; therefore, comparison to 1970-72 data was made in order to provide overall perspective. While the earlier data is unfortunately more general it provides a useful basis for evaluating overall changes (Table 3C). The change from 1970/72 to 2006/08 is dramatic and emphasizes how tanker load patterns evolved within a period of 35 years with no change in channel depth. As discussed in the Economic Appendix vessel trips have increased at a lower rate than tonnage because more cargo is transported per vessel, through a greater concentration of larger vessels. As outlined in the Appendix, expectations are that the number of vessels will increase as SNWW's cargo base diversifies due to LNG and increases in manufactured goods and dry bulk.

Table 3D provides a separate breakout of crude oil tanker trips included in Table 3C. SNWW 2006-2008 tonnage is down due to the effects of hurricanes and planned outages for refinery expansion; however, regional imports increased at significantly higher rates than the nation until 2004 (Figure 3B). The effect of the major hurricanes is illustrated in Figure 3C.

Source: Aggregated from U.S. Department of Energy Monthly Import Statistics, 2004-2010

As noted on page 99 of the Appendix, Hurricane Rita's surge resulted in sand bars at the offshore entrance channel and silting of the Neches River Channel to Beaumont, which severely limited transit of the upper reaches for several months and tonnage diversions to other ports well into 2006. The effect of shoals in the entrance channel and silt deposits on the Neches River had a particularly strong effect on crude petroleum traffic due to the use of large heavily loaded vessels.

Specific estimation of future expectations concerning the relationship between loaded and design drafts and future utilization were made based on strong long-term historical utilization of the existing channel, industry interest in channel deepening, the lack of constraints at the points of origin, increasing concentration of larger vessels (Table 3E), and reductions in transportation costs (Table 3F). These trends are indicative that load patterns will continue to become more efficient. A major advantage of the 45- to 50-foot channel depth alternatives is that they reduce the number of shuttles needed to lighter a VLCC (Economic Appendix, Table 110) by allowing the increasingly large concentration of 90,000 to 119,999 DWT vessels to be loaded more fully. Vessels in this group have design drafts between 45 and 49 feet (Economic Appendix, Table 33). Table 3F illustrates the large concentration of 90,000 to 119,999 DWT vessels and the dramatic increase in their use since 1980. As shown in the Appendix, the design drafts for all vessels groups except those less than 50,000 DWT exceed 40 feet. Examination of the 2008 SNWW 50,000 to 74,500 DWT group showed a design draft range of 39 to 48 feet, with a median of 45 feet. For the <50,000 DWT range, the maximum design draft was 43 feet and the median 37 feet.

*Data from SNWW 1981-period report shows that the largest vessel size in 1980 was 99,600. Indications are that the most common were 60,000 to 78,000 DWT.												

Table 3G displays the project average annual cost and benefits based on various assumptions associated with the percentage of crude petroleum imports that will be loaded to vessel drafts over 40 feet. The first column shows the benefits presented in Economic Appendix. The calculations in the remaining columns are based on alternative percentages. The results of this analysis, based on study region vessel utilization trends data from 1970-2008, industry expectations, and transportation cost savings indicate that it is reasonable to expect that a significant portion of future crude oil imports will be loaded to drafts over 40 feet given an increase in channel depth for the 50-year planning period starting in CY2019.

4.0 LNG MARKET SHARE (IEPR COMMENT 3)

The first part of this section addresses the basis for the market share. Table 4A displays the EIA U.S. LNG import forecast and the SNWW LNG forecasts that appear in the in the Economic Appendix (Table 72). As noted in the Appendix LNG permits were approved for the Cheniere Sabine Pass, Exxon-Mobil Golden Pass, and the Sempra Port Arthur Terminals. Cheniere opened in 2008 and Golden Pass is scheduled to open by 2011. Construction of the Sempra Terminal is planned after 2012.

TABLE 4A
U.S. and SNWW LNG Waterborne LNG Forecast
Short Tons

Year	U.S. Waterborne LNG Imports	SNWW Waterborne LNG Imports
2005	16,565,000	
2006	18,617,000	
2007	21,238,000	4,000
2008	12,072,000	39,000
2009	15,514,400	not available
2019	38,852,755	5,827,913
2020	38,045,447	9,511,362
2025	31,049,691	7,762,423
2029	24,698,681	6,174,670
2030	22,309,819	6,174,670
2069	22,309,819	6,174,670
Source: USACE, Waterborne Commerce of the U.S., Part 2, IWR-WCSC-2005-08, Parts 2 and 5 Navigation Data Center and the U.S. Department of Energy, 2009 Annual Energy Outlook, March 2009.		

As noted in the Appendix, the SNWW LNG forecast is based on a market share of 20 percent. Determination of the expected SNWW market forecast was based on evaluation of industry input, and a report prepared by Michael Gorecki of Alexander Aaron, Inc. in May 2007 for the Galveston District. The Alexander Aaron, Inc. report predicted that the distribution amongst the facilities would range from 28.6 to 41.5 percent. These percentages were based on SNWW LNG plant capacities in relationship to the U.S. total. The 28.6 percent share was based on SNWW having two LNG terminals and the 41.5 percent was based on SNWW having three LNG terminals. Table 4B displays the anticipated U.S. market share presented in the Alexander Aaron, Inc. report. These market shares were expected to be reasonable given construction progress and industry investments. As noted, construction is complete for the Cheniere Terminal and nearly complete for Golden Pass. The market analysis indicated that given two SNWW terminals, the region was likely to capture 28.6 percent of the U.S. LNG import market. The Galveston District used a lower percentage in order to account for uncertainty. The percentage used in the Appendix is 15 percent in 2019 and 25 percent for 2029-2069, with import tonnage remaining constant after 2030.

The remainder of this section addresses the effects of varying the market share used in the report. Table 4C displays the EIA U.S. LNG import forecast and a range of SNWW LNG forecasts.

50	1.3	1.2	1.3	1.3

The following tables summarize evaluation of the crude petroleum vessel utilization and LNG market share presented in Tables 4A and 4C.

In conclusion, the sensitivities presented in Tables 4A-4D indicate that project justification is much more sensitive to crude oil tanker vessel utilization than to LNG market share. The results of the analyses presented in Table 4D shows that if less than 60 percent of 2019-2069 crude oil imports are regularly loaded to drafts less than 40 feet, the BCR will fall below unity. While not shown in the table, the BCR remains at unity given a reduction in the LNG market share to one-half of the percentages of 15 percent in 2019 and 25 percent for 2029-2069 in combination with 65 percent of 2019-2069 crude oil imports being loaded to drafts over 40 feet. In conclusion, the tanker utilization data presented in Table 3A (1990-2008) and Table 3C (1970/72 and 2006/08) provide sufficient justification to reasonably conclude that the crude oil tanker fleet will continue to realize increased efficiencies under both the without and with project future.

In terms of the SNWW tonnage forecast and the use of the AEO forecasts, the EIA notes that the reasons for variations between the AEO and other forecasters are due to differences among the assumptions that underlie the different projections. For example, the AEO 2010 reference case generally assumes that current laws and regulations will continue through the projection period as enacted, whereas some of the other projections assume the enactment of new public policy over the next 25 years. For the SNWW analysis, the AEO forecast was utilized. The sensitivities analysis addresses the effects of lower forecasts which could occur for a variety of reasons, some of which may include policy changes not explicitly discussed in the Appendix.

5.0 CRUDE PETROLEUM TRADE ROUTE AND LIGHTERING ANALYSIS (IEPR COMMENT 4)

This response provides data and discussion concerning lightering volumes and trade route choices. These calculations were based on the assumption that 100 percent of crude oil imports from Middle East and Africa would be lightered. The transportation cost calculations were made on a cost-per-ton basis using the available specific vessel volumes lightered and given knowledge of the range of vessel sizes used. The specific distribution of shuttle vessels used for lightering and lightening is not known because the Corps' National Data Center data records do not provide that level of detail. However, the Economic Guidance Memorandum (EGM) deep-draft vessel operating costs were used to calculate and verify the most efficient range of vessels. Shuttle vessels used for lightering are 80,000 to 120,000 DWT vessels. The number of shuttle trips necessary to offload a 325,000 DWT class VLCC is shown in Table 110 of the Appendix. The volume unloaded at the lightering zone is constrained by channel depth and refinery input needs. Vessel size data were obtained from the detailed waterborne commerce statistics. The vessel sizes used for existing condition lightering are identified in the Appendix (Table 111). The vessel sizes

for existing condition lightening are identified in the Appendix (Table 112). Determination of the least costly method of shipment was based on comparison of direct shipment, lightering, and lightening costs using the Corps' EGM deep-draft vessel operating cost and optimal lightering turnaround data published in the Skaugen PetroTrans "Introduction to Lightering" along with periodic inquiries to the Skaugen PetroTrans company and other oil company personnel. Table 5A displays lightering cost components by major trade route for the segment from the foreign port of origin to the Gulf of Mexico lightering zone used in the Corps analysis.

15	Speed (knots)
\$2,114	Hourly Cost at Sea (Economic Guidance Memorandum)
\$1,377	Hourly Cost in Port Economic Guidance Memorandum)
24,917	Mideast Round Trip Mileage Via Cape to Lightering Zone
19,509	Mideast Round Trip Mileage Via Suez to Lightering Zone
11,488	Africa/North Sea Round Trip Mileage to Lightering zone
3,805	Venezuela Round Trip Mileage to Lightering Zone
1,220	Mexico Round Trip Mileage to Lightering Zone
\$82,710	Loading Cost at Origin Port (based on loading rate of 5,250 tons per hour)
\$3,593,602	Total Transportation Cost (Middle East via Cape)
\$2,831,596	Total Transportation Cost (Middle East via Suez)
\$1,701,409	Total Transportation Cost (Africa/North Sea)
\$618,847	Total Transportation Cost (Venezuela/Eastern South America)
\$254,612	Total Transportation Cost (Mexico)
\$11.40	Middle East Cost Per Ton via Cape
\$8.98	Middle East Cost Per Ton via Suez
\$5.40	Africa/North Sea Cost/ton
\$1.96	Venezuela/Eastern South America Cost/ton
\$0.81	Mexico Cost/ton

Table 5B displays the number of shuttles needed to fully load a 325,000 DWT vessel and Table 5C lists the number of hours needed to offload the 325,000 DWT vessel based on a range of shuttle vessels from 90,000 to 135,000 DWT. Based on per-ton transportation costs, this range represents the maximum efficiencies. Use of smaller shuttles is not cost effective when lightering (see Tables 5C-5H). In order to illustrate this point, a 42,500 DWT tanker is included in the Tables 5B-5G. Tables 5B-5E provide input data and Tables 5F and 5G display the cost per ton lightering cost for the Middle East and Africa/Mediterranean/ North Sea routing, respectively. The cost for direct shipment is presented in Tables 5H and 5I. Table 5H presents the direct shipment cost for Africa/North Sea/Mediterranean and Middle East routings. Table 5I presents the direct shipment cost for Mexico and Venezuela/Eastern South America.

TABLE 5B Number of Shuttles Needed to Unload a 325,000 DWT Tanker								
Channel Depth ft.	Shuttle Vessel DWT							
	42,500	90,000	110,000	115,000	120,000	125,000	130,000	135,000

Table 5J presents the lightening cost for the Africa/North Sea/Mediterranean route. Lightening represents a less costly shipping method than direct shipment for Africa/North Sea/Mediterranean routing; however, it is less competitive than lightering. As noted in the Appendix, lightening was historically the most common choice for Africa and the North Sea movements; however, it has become more common for the Africa/North Sea/ Mediterranean routes in recent years due to structural changes in oil production off the coast of West Africa. For this reason, the Africa/North Sea/Mediterranean cost calculations reflect lightering (Appendix, Table 111). Use of an average between lightering and lightening cost for this route may have been a more appropriate choice.

TABLE 5J SNWW Crude Petroleum Lightening Cost							
DWT: 165,000		Hourly Cost at Sea: \$1,439 (Appendix, p. 148)				Transportation Cost Per Ton: \$7.02 (Table 5A)	
Fully loaded cargo: 160,050 short tons		Hourly Cost in Port: \$922 (Appendix p. 148)

a/ Maximum cost reductions occur at the 46-foot channel depth.							
b/ There are some differences between the costs per ton shown here and what is presented in the Economic Appendix (Table 112), with these costs being slightly less than those presented in the table; however, lightening was still found to be higher relative to lightening.							

The remainder of this comment response addresses uncertainty pertaining to the trade route shipments of Venezuelan and other new routes such as Brazil. Application of the FY2008 EGM costs and the lightering company operational expectations of optimal turnaround times indicated that the resulting costs per ton suggested uncertainties. This uncertainty increased based on the release of the FY2008 vessel operating cost release, which showed a 17 percent drop in hourly costs for foreign flag tankers shown in the Appendix. Uncertainties associated with the transportation cost application are particularly high for routings that include Venezuela and Brazil because they have relatively short travel distance compared to the Middle East routes. For the Middle East, the relatively low FY2008 EGM costs showed that lightering is less costly than direct shipment. Additionally, the cost analyses for Africa crude showed that lightering is less costly than direct shipment, although by a comparatively smaller margin. However, the application for the Venezuelan routing revealed cost incentives to lighter which were not found using the higher vessel operating costs for the established optimal lightering turnaround time assumptions. As indicated, the cost of direct shipment is close to that for lightering and specifically relates to the operational assumptions based on optimal turnaround times and seamless logistics from the lightering company. The lightering company and industry indicate that it is not cost effective to lighter Venezuelan products.

Given the uncertainty associated with lightering logistics and associated transfer times, a sensitivity analysis was prepared evaluating the effect of minimum and maximum turnaround times. Table 5K displays columns showing both the mother vessel offshore unloading times and waiting times used for the analysis presented in the Economic Appendix, as well as the times for this sensitivity analysis. The times used in the Appendix suggest that multiple shuttles would be loaded simultaneously using innovations to be developed over the 2010-2069 future. However, these innovations were found not to be realistic for existing or future conditions. In the sensitivity analysis the offshore times are considered reasonable, given standard unloading time. For instance using a standard unloading rate of 5,250 tons per hour, it would take 60 hours to unload (lighter) a 325,000 DWT tanker $((325,000 * 0.97 \text{ capacity}) / (5,250 \text{ short tons per hour}))$. This sensitivity is included because of concerns that assumptions based on optimal offshore turnaround time, optimal scheduling of shuttle arrivals, and perhaps lower than realistic vessel operating cost, such as the Corps' FY08 tanker vessel operating costs being 17 percent lower than the FY07 release, result in criteria that is unrealistically conservative. The sensitivity was found to be representative of actual conditions while by comparison the times used for the base are not realistic.

An additional component modified for this sensitivity was to separate Venezuela products from those from Brazil. While shipments of crude oil from Brazil to SNWW are presently less than 1 percent, future expectations are that this will change. The Appendix analysis included Venezuela and Brazil as one

TABLE 5K Mother Vessel Combined Time Offloading and Waiting Between Shuttles				
	Mother Vessel Offshore Hours (Appendix)		Mother Vessel Offshore Hours (Sensitivity)	
Component	Lightering	<i>Lightening</i>	Lightering	<i>Lightening</i>
Minimum (hrs)	8	8	60	24
Most Likely (hrs) *	12	12	60 *	31 *
Maximum (hrs)	36	36	168	120
Hours Used for Calculation	12	12	96 *	30 *
*The most likely time for the mother vessel for lightering is based on a 325,000 DWT tanker, a cargo to short ton ratio of 0.97, and an unloading rate of 5,250 short tons per hour. The most likely time for the mother vessel for <i>lightening</i> is based on a 165,000 DWT tanker, a cargo to short ton ratio of 0.97, and an unloading rate of 5,250 short tons per hour. The hours used for calculation are based on a @risk triangular distribution using the minimum, most likely, and maximum values shown. The maximum values used as input into the @risk distribution are noted quotes from the lightering company.				

region. Table 5L displays the transportation cost with Brazil separated out from Venezuela. Table 5M displays the results of using the routing shown in Table 5L and the mother vessel sensitivity-based times from Table 5J (i.e. 96 hours offshore for the lightering mother vessel and 30 hours offshore for the lightening mother vessels).

Table 5N summarizes the data aggregated and incorporates the critical sensitivities evaluated under Comment 3. It was found in preparation of the response to Comment 4 that the duration of the VLCC offshore times used in the Appendix analysis was unrealistically low. For this aspect of the analysis, the sensitivity was found to be representative of actual conditions.

In conclusion, the results of the data and the additional sensitivities presented provide sufficient justification to reasonably conclude that the recommended plan for the 48-foot depth is economically justified.

6.0 CRUDE PETROLEUM MARKET SHARE AND TONNAGE FORECAST (IEPR COMMENT 6)

In overall terms and in spite of a recent decline in the SNWW share of the U.S. total, comparison of overall regional imports using 4-year averages from 1990-2009 shows that SNWW imports grew by 117 percent in comparison to a U.S. increase of 58 percent. During the period from 2004 to 2009, SNWW's refinery capacity increased from 6 percent to 6.5 percent (Economic Appendix, Table 10). Port Arthur refinery capacity in 2009 is nearly 13 percent higher than in 2004, with additional expansions scheduled. Motiva announced plans for a 325,000 barrel-per-day (BPD) refinery expansion in Port Arthur in December 2007. Additionally, expansion of the Motiva-Port Arthur refinery is currently underway and expected to be complete by 2012. Motiva's current capacity of 285,000 BBD will increase to 610,000 BBD until completion.

Source: Aggregated from U.S. Army Corps of Engineers, Waterborne Commerce of the U.S. and U.S. Department of Energy, Energy Information Administration data.

Regarding expectations concerning the region's percentage share of the U.S. market, SNWW's relative share has been affected by a combination of factors, both regional and national. Regionally, the share has been affected by hurricanes. Additionally, its relative share of the U.S. total has also been affected by the large influx of Canadian crude to the U.S. Midwest. Presently less than 1 percent of Canadian crude is transported to SNWW, with the majority of that being transported by vessel. Expansion of the Keystone TransCanada Pipeline to the U.S. Gulf Coast ports that include Port Arthur and Houston remains uncertain. SNWW refinery representatives do not foresee increases in their receipt of Canadian crude. While industry is noncommittal, interest in current pipeline delivery and the TransCanada Pipeline

Expansion was noted to be limited to the companies that buy excess oil for resale and transmittal to various SNWW, Texas City, and Houston refineries. This market is characteristically uncertain and small and the Gulf Coast represents a relatively high transmittal cost in comparison to markets in the U.S. Midwest. Texas imports of Canadian crude for 2005-2009 by pipeline and vessel averaged 1.1 percent, with a low of 0.6 percent in 2008 and a high of 1.5 percent in 2008. This issue's conclusion is that long-term expectations concerning the specific volume of Canadian crude that could be pipelined into the study region will remain uncertain in the short-term. Realization would depend upon high oil prices, among other factors. But with falling demand, falling crude oil prices, and carbon emission concerns, forecasts of future Canadian oil sands production have declined, as have expectations of likely volumes reaching the Gulf Coast in the near future.

The U.S. Department of Energy's Annual Energy Outlook 2007 (AEO 2007) forecast was used for the March 2007 Economic Appendix provided for IEPR. During the review period, the Galveston District continued to review new forecasts as they were released. The SNWW crude oil imports forecasts in the 2008 and 2009 draft reports reflect forecast modifications that are more conservative than the AEO 2007. The AEO 2008 showed a significant change from the AEO 2007 and from Global Insight's 2008 forecast release. The AEO 2008 release occurred at the same time that Motiva Port Arthur refinery expansion was announced. The Motiva expansion and SNWW's existing role as the largest waterway port of entry for petroleum suggested that Global Insight's slightly higher forecast was likely to be more reflective of long-term regional trends. Global Insight's 2008 forecast was subsequently used in the 2008 draft report and their 2009 forecast was used in current report.

In regard to differences between the AEO and Global Insight, the major difference between the two is that AEO forecasts much higher domestic crude oil production throughout the projection period than other noted forecasters. As noted in the AEO website, their forecast not only shows higher domestic production, it also shows a rapid increase in domestic production. Other differences pertain to the forecast price of crude oil. The figure below provides a comparison of the AEO 2010 Reference and low oil price based forecast with Global Insight's May 2010 price forecast release.

Table 6A displays the U.S. oil import data evaluated during 2008-09 preparation of the Appendix and since its submittal. Table 6B presents regression equation outputs using the AEO 2010 Reference and Low Price case scenarios. The regression equations were prepared using 1990-2007 and 1990-2008 base data.

Source: U.S. Department of Energy, AEO2008, 2008, and 2010. Global Insight 2035 forecast value was obtained from non-published back-up data obtained from Global Insight				

A comparison table of the BCRs based on the alternative forecasts was not prepared. It is recognized that SNWW import forecast is higher than all of the AEO 2009 and AEO 2010 projections, with the exception of the AEO 2010 Low Price scenario; however, the forecast for SNWW falls within the range of forecasts published by other recognized forecasters. As previously indicated, the Motiva expansion and SNWW's existing role as the largest waterway port of entry for petroleum suggested that the higher forecast would most reasonably reflect long-term trends for the study area.

ATTACHMENT 13.1 - Narrative

**SABINE-NECHES NAVIGATION CHANNEL
IMPROVEMENT PROJECT**

This MII estimate was prepared for the Feasibility Study of deepening the Sabine Neches Waterway to a depth of 48 feet. The work consists of deepening the navigation channel from the existing inland reaches to the Port of Beaumont from 40 to 48 ft; and extending the existing entrance channel by 13.2 miles into the Gulf of Mexico to a depth of 50 ft. The plan also consists of: 1) bend easing in the Sabine-Neches Canal and Neches River channel; 2) widening up to an additional 183 feet the Taylors Bayou Entrance channel and turning basins; and 3) Constructing new and enlarging/deepening existing turning and anchorage basins on the Neches River Channel. The entire plan involves dredging about 406,464 feet of channel. Quantities and design features were developed by the Galveston District (SWG) Engineering Branch.

This estimate was revised July 2009 using the latest price levels and the labor rates. During the update the marine fuel price was locked in at \$2.60/gal, (see attachment 13.2). This updated Mii estimate reflects changes in the scope. The major changes in scope are the removal of the widening of the entrance, removal of five turning basins, removal of two Beneficial Use (BU) sites, reduction of one BU, and the removal of the oyster reef. The estimate was escalated to October 2009 price levels in the Total Project Cost Summary Sheet (TPCS), (see attachment 13.4). The estimate was divided into 15 contracts, with each contract being subdivided into Non-Federal and Federal Costs. The costs were further organized in accordance with the work breakdown structure. The midpoint date of each account code for each of the construction contracts was provided by the project manager for developing the fully funded costs. The estimate was prepared in accordance with ER 1110-2-1302, dated 15 September 2008. The costs were escalated in accordance with the above Engineering Regulation and EM 1110-2-1304 dated 31 March 2009. All this data was input into the TPCS. The baseline estimate provides for all pertinent elements for a complete project ready for operations.

The original Independent Technical Review (ITR) of the cost estimate, construction schedules, and contingencies was performed in June 2006 by Mobile District, some minor revision were performed to the estimate in response to the comments. In July 2007 new requirements were published for the development of contingencies in Civil Works. A formal cost risk analysis for development of project contingences was done with the results presented in the Total Project Cost Summary Sheet (TPCS). Crystal Ball software was used to conduct the Cost Risk Analysis.

A formal Cost Risk Analyses was performed with the cooperation of the PDT and Cost Engineering Directory of Expertise (DX) of the Walla Walla District in August 2009. The risks were quantified and a cost risk model developed to determine a contingency at 80% confidence level (CL), (see attachment 13.3). For Hopper dredge work a 33% contingency was used for the 80% CL and for Pipeline dredge work a 30% contingency was used for the 80%. The estimate was escalated to October 2009 price level. The contingencies were used along with the updated estimate to revise the TPCS. An ITR Certification of Cost Estimate was provided by Cost Engineering DX for Civil Works, (see attachment 13.5). The Operation and Maintenance estimate was prepared in July 2009, with an effective pricing date of October 2009, (see attachment 13.6).

ACCOUNT CODE 01 – LANDS AND DAMAGES: Costs for this Account Code were provided by SWG, Real Estate Division.

ACCOUNT CODE 02 -- RELOCATIONS: A total of 42 pipelines would require relocation and 6 would require removal. The relocated lines were assumed to be directionally drilled, and bundled when possible. It is assumed that the lines which are currently abandoned in place will be removed from the limits of the new channel and disposed off-site. Relocation work is assumed to take place prior to dredging the new channel.

ACCOUNT CODE 12 -- NAVIGATION PORTS AND HARBORS: Dredge quantities were developed by the design engineer. It was assumed that the first 5 contracts would be done using one large hopper dredge per contract. The material from the hopper dredge would be placed in open water disposal. The remainder of the channel was assumed to be dredged using a 30" pipeline, with the material going into existing placement areas (PA's) or new PA's located along the waterway. The dredging cost was developed using CEDEP. The dredge production rates were reduced to account for the stiffer "new work" material to be encountered. The cost for mobilization and demobilization was developed using CEDEP, and assuming the pipeline dredge was based in New Orleans. The Dredging estimates were based on standard operating practices for the Galveston District which assumed conventional contracting practices of large business IFB's.

Included under the hopper dredge cost is the cost for Sea Turtle Protection. Included in this item are: 1) cost for two trawlers per hopper, 2) a sea turtle protection device fitted to the hopper, and 3) 24 hour monitoring survey.

The cost for creating a PA was included under this code of account. Part of the cost for creating a PA included clearing, grubbing, and stripping the area; as well as turfing the outside of the new levee. Labor rates and overhead costs were adjusted to reflect Region 6. Soil characteristics were provided by SWG, Engineering Division, Geotechnical and Structures Section.

Also, included under this account code were bridge dolphin fender systems. They are required for the MLK Hwy 82 Bridge located at Station 105+00 on the Sabine Neches Canal; as well as Hwy 87, (twin bridges), located at Station 93+00 on the Neches River. The cost for this work was provided by TXDOT. The cost for the Taylors Bayou sheet Pile Wall was also included under this account code.

Navigational aids are placed in accordance with U.S. Coast Guard Standards and all the quantities and cost data were provided by the Coast Guard.

ACCOUNT CODE 18 – CULTURAL RESOURCCE PRESERVATION: Cost for this account code was developed by the archeologist in SWG, Environmental Section, Planning and Environmental Branch.

ACCOUNT CODE 30 -- ENGINEERING AND DESIGN: The cost for this account was developed using the guidelines provided in the TPCS, with the agreement of the cost engineer and the project manager. In addition, the costs for survey and soil borings were provided by SWG, General Engineering Section and Geotechnical & Structures Sections in Engineering & Construction Division.

ACCOUNT CODE 31 -- CONSTRUCTION MANAGEMENT: The cost for this account was developed using the guidelines provided in the TPCS, with the agreement of the cost engineer and the project manager.

EXECUTIVE SUMMARY

PURPOSE

The purpose of this report is to document the results of the cost and schedule risk analysis (CSRA) performed for the Sabine-Neches Waterway (SNWW) Channel Improvement Project (CIP), located along the border between Texas and Louisiana. The CSRA reflects a feasibility level study under development by the U.S. Army Corps of Engineers (USACE), Galveston District.

BACKGROUND

The single alternative plan selected for recommendation is also the national economic development (NED) plan and the locally preferred plan (LPP). The recommended plan calls for the following modifications to the existing SNWW:

- Deepening of the SNWW to Beaumont to 48 feet.
- Widening the SNWW by 700 feet from offshore in the Gulf of Mexico to the Port Arthur Canal.
- Deepening and widening of Taylors Bayou channels and turning basins.
- Construction of several turning and anchorage basins on the Neches River Channel.
- Tapering Sabine Bank Channel from 800 feet wide (Station 23+300) to 700 feet wide.

SCOPE

The scope of the risk analysis report is to reflect the feasibility study and to calculate and present the cost contingencies at the 80 percent (P80) confidence level using the risk analysis processes as mandated by U.S. Army Corps of Engineers (USACE) Engineer Regulation (ER) 1110-2-1150, Engineering and Design for Civil Works, ER 1110-2-1302, Civil Works Cost Engineering, and Engineer Technical Letter 1110-2-573, Construction Cost Estimating Guide for Civil Works. The report presents the contingency results for both cost and schedule risks for all construction features at feasibility level development.

The major project construction scope is comprised of dredging, utilizing both hopper and pipeline dredges depending upon location in relationship to the Gulf and inland waterway. The project scope also includes some efforts contributing to sea turtle protection, navigational aids, and mitigation such as plantings and relocations by the sponsor(s). Within the feasibility study and in consideration of contract acquisition in accomplishing the project construction, the plan was separated into 15 distinct contract estimates. In each contract, dredging is the major effort, consequently, carrying the greatest risks. Separating the project into separate contracts results in the ability to more efficiently fund, procure, manage, and construct the separate contracts, thereby, reducing risks. The contracts studied within the CSRA are:

- Contract 1: Sabine Bank – Sta 165+00 to 132+00.
- Contract 2: Sabine Bank – Sta 132+00 to 95+734.
- Contract 3: Sabine Bank Channel – Sta 95+734 to 53+000.
- Contract 4: Sabine Pass Outer Bar Jetty – Sta 53+000 to 0+000.
- Contract 5: Sabine Pass Outer Bar Jetty Channel Sta 214-88 to 0+00.
- Contract 6: Sabine Pass Channel Sta 0+00 to 295+60.
- Contract 7: Port Arthur Canal & Taylor Bayou.
- Contract 8: Sabine Neches Canal Sta 0+00 to 170+00.
- Contract 9: Sabine Neches Canal Sta 170+00 to 592+93.
- Contract 10: Neches River Channel Sta 0+00 to 292+00.
- Contract 11: Neches River Channel Sta 292+00 to 716+00.
- Contract 12: Neches River Channel Sta 716+00 to 980+00.
- Contract 13: Dredging Sabine Lake.
- Contract 14: Channel to Orange.
- Contract 15: GIWW East of Orange.

RISK ANALYSIS PROCESS

As required by USACE, the CSRA was developed using the Crystal Ball software. The Crystal Ball software relies on Excel-based spreadsheets for its model development. All 15 contracts within the study consist of dredging work and were estimated using the USACE Cost Engineering Dredge Estimating Program (CEDEP), which is Excel based. Those same Excel-based estimates were used as the model basis for the Crystal Ball risk analysis, incorporating both cost and schedule.

Specifically related to this project, it became apparent that the contracts related to dredging carried similar risks with a separate distinction made regarding the use of hopper dredges and pipeline dredges in certain contracts. For this reason, the risk analysis utilized the same risk events identified within the risk register to support the risk models and resulting contingencies. The study did recognize that the limited availability of hopper dredges and their use further into the Gulf present a higher degree of some risks as compared to the pipeline dredging work. This resulted in slightly higher contingencies for the hopper dredges.

CONTINGENCY RESULTS

The USACE Cost Engineering Directory of Expertise (DX) for Civil Works recommends risk analyses output reflect the P80 confidence level in successfully completing the project. The following table reflects those results for the fifteen specific contracts. These contingencies are reflected within the Total Project Cost Summary.

Table ES-1. Contract Contingency Results - 80 Percent Confidence

Contract No.	Contract Description/Title	Type of Dredging Work	Contingency
Contract 1	Sabine Bank – Sta 165+00 to 132+00	Hopper	33%
Contract 2	Sabine Bank – Sta 132+00 to 95+734	Hopper	33%
Contract 3	Sabine Bank Channel – Sta 95+734 to 53+000	Hopper	33%
Contract 4	Sabine Pass Outer Bar Jetty – Sta 53+000 to 0+000	Hopper	33%
Contract 5	Sabine Pass Outer Bar Jetty Channel Sta 214-88 to 0+00	Hopper	33%
Contract 6	Sabine Pass Channel Sta 0+00 to 295+60	Pipeline	30%
Contract 7	Port Arthur Canal & Taylor Bayou	Pipeline	30%
Contract 8	Sabine Neches Canal Sta 0+00 to 170+00	Pipeline	30%
Contract 9	Sabine Neches Canal Sta 170+00 to 592+93	Pipeline	30%
Contract 10	Neches River Channel Sta 0+00 to 292+00	Pipeline	30%
Contract 11	Neches River Channel Sta 292+00 to 716+00	Pipeline	30%
Contract 12	Neches River Channel Sta 716+00 to 980+00	Pipeline	30%
Contract 13	Dredging Sabine Lake	Pipeline	30%
Contract 14	Channel to Orange	Pipeline	30%
Contract 15	GIWW East of Orange	Pipeline	30%

Note: Contingency % reflects an 80% confidence level.

Dredging Risks: The four most common risk concerns, related to dredging, carrying the greater risks were:

- Limited bid competition due to a shortage of dredge plants.
- Fuel price fluctuations, which greatly impact dredging costs.
- Limited geotechnical data of underwater materials.
- Scoping changes resulting in dredge quantity changes.

1. PURPOSE

The purpose of this report is to document the results of the cost and schedule risk analysis (CSRA) performed for the Sabine-Neches Waterway (SNWW) Channel Improvement Project (CIP), located along the border between Texas and Louisiana. The CSRA reflects a feasibility level study under development by the U.S. Army Corps of Engineers, Galveston District.

2. BACKGROUND

The single alternative plan selected for recommendation is also the national economic development (NED) plan and the locally preferred plan (LPP). The recommended plan calls for the following modifications to the existing SNWW:

- Deepening of the SNWW to Beaumont to 48 feet.
- Widening the SNWW by 700 feet from offshore in the Gulf of Mexico to the Port Arthur Canal.
- Deepening and widening of Taylors Bayou channels and turning basins.
- Construction of several turning and anchorage basins on the Neches River Channel.
- Tapering Sabine Bank Channel from 800 feet wide (Station 23+300) to 700 feet wide.

More in-depth project background information can be found within the Galveston District Feasibility Report.

3. SCOPE

The scope of the risk analysis report is to calculate and present the cost contingencies at the 80 percent confidence level using the risk analysis processes as mandated by U.S. Army Corps of Engineers (USACE) Engineer Regulation (ER) 1110-2-1150, Engineering and Design for Civil Works, ER 1110-2-1302, Civil Works Cost Engineering, and Engineer Technical Letter 1110-2-573, Construction Cost Estimating Guide for Civil Works. The report presents the contingency results for both cost and schedule risks for all construction features.

The major project construction scope is comprised of dredging, utilizing both hopper and pipeline dredges depending upon location in relationship to the Gulf and inland waterway. The project scope also includes some efforts contributing to sea turtle protection, navigational aids, and mitigation such as plantings and relocations by the sponsor(s). Within the feasibility study and in consideration of contract acquisition in accomplishing the project construction, the plan was separated into 15 distinct contract estimates. In each contract, dredging is the major effort, consequently, carrying the greatest risks. The advantage of separating the project into separate contracts results in the ability to more efficiently fund, procure, manage, and construct the separate contracts, thereby, reducing risks. The contracts studied within the CSRA are:

- Contract 1: Sabine Bank – Sta 165+00 to 132+00.
- Contract 2: Sabine Bank – Sta 132+00 to 95+734.
- Contract 3: Sabine Bank Channel – Sta 95+734 to 53+000.
- Contract 4: Sabine Pass Outer Bar Jetty – Sta 53+000 to 0+000.
- Contract 5: Sabine Pass Outer Bar Jetty Channel Sta 214-88 to 0+00.
- Contract 6: Sabine Pass Channel Sta 0+00 to 295+60.
- Contract 7: Port Arthur Canal & Taylor Bayou.
- Contract 8: Sabine Neches Canal Sta 0+00 to 170+00.
- Contract 9: Sabine Neches Canal Sta 170+00 to 592+93.
- Contract 10: Neches River Channel Sta 0+00 to 292+00.
- Contract 11: Neches River Channel Sta 292+00 to 716+00.
- Contract 12: Neches River Channel Sta 716+00 to 980+00.
- Contract 13: Dredging Sabine Lake.
- Contract 14: Channel to Orange.
- Contract 15: GIWW East of Orange.

4. METHODOLOGY/PROCESS

The risk analysis process for this study is intended to determine the probability of various cost outcomes and quantify the required contingency needed in the cost estimate to achieve any desired level of cost confidence. In simple terms, contingency is an amount added to an estimate (cost or schedule) to allow for items, conditions or events for which the occurrence or impact is uncertain and that experience suggests will likely result in additional costs being incurred or additional time being required. The amount of contingency included in project control plans depends, at least in part, on the project leadership's willingness to accept risk of project overruns. The less risk that project leadership is willing to accept the more contingency should be applied in the project control plans. The risk of overrun is expressed, in a probabilistic context, using confidence levels.

The USACE Cost Engineering Directory of Expertise (DX) for Civil Works guidance for cost and schedule risk analysis generally focuses on the 80-percent level of confidence (P80) for cost contingency calculation. It should be noted that use of P80 as a decision criteria is a risk adverse approach (whereas the use of P50 would be a risk neutral approach, and use of levels less than 50 percent would be risk seeking). Thus, a P80 confidence level results in greater contingency as compared to a P50 confidence level.

The risk analysis process uses *Monte Carlo* techniques to determine probabilities and contingency. The *Monte Carlo* techniques are facilitated computationally by a commercially available risk analysis software package (Crystal Ball) that is an add-in to Microsoft Excel. Cost estimates are packaged into an Excel format and used directly for cost risk analysis purposes.

In addition to broadly defined risk analysis standards and recommended practices, the risk analysis is performed to meet the requirements and recommendations of the following documents and sources:

- Engineering Regulation ER 1110-2-1150 dated August 31, 1999.
- Engineering Regulation ER 1110-2-1302 dated September 15, 2008.
- Engineering Technical Letter 1110-2-573 dated September 30, 2008.
- Memorandum from Major General Don T. Riley (US Army Director of Civil Works), dated July 3, 2007.
- Engineering and Construction Bulletin issued by James C. Dalton, P.E. (Chief, Engineering and Construction, Directorate of Civil Works), dated September 10, 2007.
- Cost and Schedule Risk Analysis Process guidance prepared by the USACE Cost Engineering DX.

Since the 15 contracts are dredging related, with the estimates developed within the USACE Cost Engineering Dredge Estimating Program (CEDEP), which is Excel based, the risk analysis used the CEDEP as the risk model basis, incorporating both cost and schedule. Noting that the hopper dredges carry somewhat different risks than the pipeline dredges, the two methods were modeled separately. The risk analysis results are provided in section 5.

4.1 Identify and Assess Risk Factors

Identifying the risk factors via the Project Development Team (PDT) is considered a qualitative process that results in establishing a risk register document. That risk register document then serves to support the quantitative study using the Crystal Ball risk software. Risk factors are events and conditions that may influence or drive uncertainty in project performance. They may be inherent characteristics or conditions of the project or external influences, events, or conditions such as weather or economic conditions. Risk factors may have either favorable or unfavorable impacts on project cost and schedule.

The qualitative risks are captured and placed within the risk register format. That format is the basis used for establishing the quantitative risks and developing the Crystal Ball risk model. Specifically related to this project, it became apparent that the contracts carry quite similar risks because the major efforts within each contract require dredging. For this reason, the risk analysis utilized the same risk events identified within the risk register to support the risk models and resulting contingencies. The study did recognize that the limited availability of hopper dredges and their use further into the Gulf present a higher degree of some risks as compared to the pipeline dredging work. This resulted in slightly higher contingencies for the hopper dredging.

4.2 Risk Register

A risk register is a tool commonly used in project planning and risk analysis. The risk register reflects the results of risk factor identification and assessment, risk factor quantification, and contingency analysis. It is important to note that a risk register can be an effective tool for managing identified risks throughout the project life cycle. As such, it is generally recommended that risk registers be updated as the designs, cost

estimates, and schedule are further refined, especially on large projects with extended schedules. Recommended uses of the risk register going forward include:

- Documenting risk mitigation strategies being pursued in response to the identified risks and their assessment in terms of probability and impact.
- Providing project sponsors, stakeholders, and leadership/management with a documented framework from which risk status can be reported in the context of project controls.
- Communicating risk management issues.
- Providing a mechanism for eliciting risk analysis feedback and project control input.
- Identifying risk transfer, elimination, or mitigation actions required for implementation of risk management plans.

The summary risk register in table 2 presents the risks related to the 15 contracts, considering internal and external risks. In the cases studied, the schedule analysis was incorporated into the cost analysis as another risk event related to productivity within the CEDEP estimates.

Table 2. Dredging Risk Register

Risk No.	Risk/Opportunity Event	Discussion and Concerns	Likelihood*	Impact*	Risk Level*	Measurement / Adjustments	Risk Applied to
1	Bid Competition	Corps studies have determined an expected dredge shortage due to the many anticipated projects scheduled in the Gulf region. Pipeline dredges, hopper dredges, and hopper dredges and pipeline dredges. Pipeline dredges are more prevalent; therefore, hopper dredges carry a greater risk in bidding competition. The Acquisition of pipeline dredges for construction durations helps alleviate some of this concern.	VERY LIKELY	SIGNIFICANT	HIGH	Limited Bid Competition Impacting Mobilization displacement of contractor markups.	Profit & Plant Acquisition
2	Type of Dredged Material	Limited Geotechnical data of the dredged material may result in the material being more difficult to dredge that would impact productivity.	LIKELY	MARGINAL	MODERATE	Productivity - Duration	Production
3	Dredged Quantity (prison)	Dredging commonly results in changed quantities resulting from inadequate underwater surveys and underwater changes over time. There is potential that the dredging material prism could change.	LIKELY	MARGINAL	MODERATE	Volumes - CY	Quantities
4	Scope Changes	As the designs are further developed, there is potential that the scope could change.	LIKELY	MARGINAL	MODERATE	Volumes - CY	Quantities
5	Weather	Severe weather in the Gulf region can cause delays and cost increases. The severity of the weather would impact the Gulf work for the hopper dredges more than the inland pipeline dredges.	UNLIKELY	SIGNIFICANT	MODERATE	Productivity - Duration	Production - Hopper
6	Schedule Constraints	Contract and environmental schedule constraints can impact the availability of resources that may be unavailable due to competing needs. The greater schedule concern would be funding availability which studied under a different risk.	UNLIKELY	MARGINAL	LOW	Duration	N/A
7	Labor Availability/Pricing	Gulf region labor rates are fairly low when compared to national rates. Slower economy should keep the rates reasonable with little impact.	UNLIKELY	MARGINAL	LOW	Hourly Wage Rates	N/A
8	Dredge Acquisition	Corps studies have resulted in an expected dredge shortage as compared to the many anticipated projects in the Gulf region. Less competition is likely, resulting in higher bids.	LIKELY	SIGNIFICANT	HIGH	Equipment Rates	Plant Acquisition & Ownership
9	Current Fuel Prices	Fuel price fluctuations continue, but have stabilized on a short-term basis. Fuel prices could be significantly impacted by fuel usage and cost. Current estimate uses current fuel pricing.	VERY LIKELY	SIGNIFICANT	HIGH	Fuel \$/Gall	Fuel
10	VE Opportunities	There seems to be little potential for efficiency gains with the dredging projects. "It is what it is."	VERY UNLIKELY	NEGLIGIBLE	LOW	Volumes - CY	N/A
11	Inflation Increases	Inflationary costs could impact project costs in the long term. Volatile fuel pricing on a dredge project could exceed standard OMB inflation rates. Current estimate fuel pricing is considered conservative.	LIKELY	MARGINAL	MODERATE	Escalation comparisons	Fuel

4.3 Quantify Risk Factor Impacts

The quantitative impacts of risk factors on project plans are analyzed using a combination of professional judgment, empirical data, and analytical techniques. Risk factor impacts are quantified using probability distributions (density functions), because risk factors are entered into the Crystal Ball software in the form of probability density functions.

Similar to the identification and assessment process, risk factor quantification involves multiple project team disciplines and functions. However, the quantification process relies more extensively on collaboration between cost engineering, designers, and risk analysis team members with lesser inputs from other functions and disciplines.

The following is an example of the PDT quantifying risk factor impacts by using an iterative, consensus-building approach to estimate the elements of each risk factor:

- Maximum possible value for the risk factor.
- Minimum possible value for the risk factor.
- Most likely value (the statistical mode), if applicable.
- Nature of the probability density function used to approximate risk factor uncertainty.
- Mathematical correlations between risk factors.
- Affected cost estimate and schedule elements.

In this study, the risk discussions focused on the similar moderate and high risks common to the 15 contracts. since the PDT was more interested in the contingency management per contract The resulting product from the PDT discussions is captured within a single risk register as presented in the section above. Note that the risk register records the PDT's risk concerns, discussions related to those concerns, and potential impacts to the current cost and schedule estimates. The concerns and discussions are meant to support the team's decisions related to event likelihood, impact, and the resulting risk levels for each risk event.

4.4 Analyze Cost Estimate and Schedule Contingency

Contingency is analyzed using the Crystal Ball software, an add-in to the Microsoft Excel format of the cost estimate and schedule. *Monte Carlo* simulations are performed by applying the risk factors (quantified as probability density functions) to the appropriate estimated cost and schedule elements identified by the PDT.

Contingencies are calculated by applying only the moderate and high level risks identified for each option (i.e., low-level risks are typically not considered but remain within the risk register to serve historical purposes as well as support follow-on risk studies as the project and risks evolve).

For the cost estimate, the contingency is calculated as the difference between the P80 cost forecast and the base cost estimate. Each option-specific contingency is then

allocated on a civil works feature level based on the dollar-weighted relative risk of each feature as quantified by *Monte Carlo* simulation. Standard deviation is used as the feature-specific measure of risk for contingency allocation purposes. This approach results in a relatively larger portion of all the project feature cost contingency being allocated to features with relatively higher estimated cost uncertainty.

5. RISK ANALYSIS RESULTS

5.1 Contingency Results at 80 Percent Confidence

The Cost Engineering DX recommends risk analyses output reflect the P80 confidence level in successfully completing the project. The following table reflects those results for the fifteen specific contracts. These contingencies are reflected within the Total Project Cost Summary.

Table 3. Contract Contingency Results - 80 Percent Confidence

Contract No.	Contract Description/Title	Type of Dredging Work	Contingency
Contract 1	Sabine Bank – Sta 165+00 to 132+00	Hopper	33%
Contract 2	Sabine Bank – Sta 132+00 to 95+734	Hopper	33%
Contract 3	Sabine Bank Channel – Sta 95+734 to 53+000	Hopper	33%
Contract 4	Sabine Pass Outer Bar Jetty – Sta 53+000 to 0+000	Hopper	33%
Contract 5	Sabine Pass Outer Bar Jetty Channel Sta 214-88 to 0+00	Hopper	33%
Contract 6	Sabine Pass Channel Sta 0+00 to 295+60	Pipeline	30%
Contract 7	Port Arthur Canal & Taylor Bayou	Pipeline	30%
Contract 8	Sabine Neches Canal Sta 0+00 to 170+00	Pipeline	30%
Contract 9	Sabine Neches Canal Sta 170+00 to 592+93	Pipeline	30%
Contract 10	Neches River Channel Sta 0+00 to 292+00	Pipeline	30%
Contract 11	Neches River Channel Sta 292+00 to 716+00	Pipeline	30%
Contract 12	Neches River Channel Sta 716+00 to 980+00	Pipeline	30%
Contract 13	Dredging Sabine Lake	Pipeline	30%
Contract 14	Channel to Orange	Pipeline	30%
Contract 15	GIWW East of Orange	Pipeline	30%

Note: Contingency % reflects an 80% confidence level.

5.2 CSRA Contingency Tables

Depicted below in table 4 are the CSRA contingency results, making separate distinction between the hopper and the pipeline dredges. The tables present the contingency values and percents at a 5 percent confidence level interval. The 80 percent confidence results were applied against the dredging activities within the Total Project Cost Summary. Since the 30 and 31 Feature Accounts (Planning, Engineering and Design and the Construction Management) are based upon a percentage of the construction costs, the same contingency was applied. The 01 Feature Account of Lands and Damages received a 25 percent contingency based upon the Galveston District's Real Estate Office.

Table 4. CSRA Contingency Tables

HOPPER DREDGE CONTINGENCY TABLE		PIPELINE DREDGE CONTINGENCY TABLE	
Confidence Level	Contingency	Confidence Level	Contingency
0%	-35%	0%	-11%
5%	-10%	5%	3%

100%	104%	100%	101%

5.3 Model Sensitivity Analysis and Output

The sensitivity analysis output indicates the risk events carrying the greatest potential variance in cost and schedule that also result in the greatest risks. For this report, the sensitivity results are presented, making separate distinction between the hopper dredges and the pipeline dredges.

Hopper Dredges: The greatest sensitivity related to risk concerns for the hopper dredging were concern for:

- Limited bid competition due to a shortage of hopper dredge plants reflected in greater contractor profit.
- Fuel price fluctuations, which greatly impact dredging costs.
- Limited geotechnical data of underwater materials
- Scoping changes resulting in dredge quantity changes.

Pipeline Dredges: The greatest sensitivity related to risk concerns for the pipeline dredging were concern for:

- Fuel price fluctuations that carry a greater risk for dredging activities.
- Limited bid competition resulting in greater contractor profits.
- Scoping changes resulting in dredge quantity changes.

USACE - GALVESTON DISTRICT
DRAFT FEASIBILITY REPORT**

COST ENGINEERING DX TPCS CERTIFICATION

As of 19 October 2009, the Walla Walla District, Cost Engineering Directory of Expertise (Dx) for Civil Works, certifies the feasibility level Sabine-Neches Waterway Channel Improvement Project developed by Galveston District for the values:

2012 Budget Amount:	\$1,100,935,000
Fully Funded Amount:	\$1,174,621,000

The Walla Walla Cost Dx representatives have provided an adequate Agency Technical Review (ATR) of the 2012 Budget and Total Project Cost, studying the project scope, report, cost estimates, schedules, escalation, and contingencies in accordance with ER 1110-2-1150 Engineering and Design for Civil Works Projects and ER 1110-2-1302 Civil Works Cost Engineering.

**REAL ESTATE PLAN
SABINE-NECHES WATERWAY
CHANNEL IMPROVEMENT PROJECT
JEFFERSON COUNTY, TEXAS**

1. General Background. This Real Estate Plan (REP) is the real estate work product of the U.S. Army Corps of Engineers, Galveston District, Real Estate Division (the "District") that supports project plan formulation for the Sabine-Neches Waterway Channel Improvement Project ("CIP"). It identifies and describes the lands, easements, and rights-of-way (LER) required for the construction, operation and maintenance of the proposed project, including those required for relocations, borrow material, and dredged or excavated material disposal. The REP also identifies and describes the facility/utility relocations that are necessary to implement the CIP. Further, the REP describes the estimated LER value, together with the estimated administrative and incidental costs attributable to providing project LER, and the acquisition process.

2. Project Type & Applicability. The feasibility study was conducted in response to the 5 June 1997 congressional resolution from the Committee on Environmental and Public Works, House of Representatives. The resolution states:

"The Secretary of the Army shall review previous reports on the Sabine-Neches Waterway published as Senate Document No. 80, 83rd Congress, Second Session; House Document No. 553, 87th Congress, Second Session; and other pertinent reports to determine the feasibility of modifying the channels serving the ports of Beaumont, Port Arthur, and Orange, Texas in the interest of commercial navigation."

3. Project Location. The Sabine-Neches Waterway is an approximate 64 existing mile federally authorized and maintained waterway located in Jefferson/Orange Counties in southeast Texas and Cameron Parish, Louisiana. The area surrounding the waterway is generally referred to as the "Golden Triangle" and is delineated by three major Texas seaports of Port Arthur, Beaumont and Orange. The Sabine-Neches Waterway provides deep-water navigation to these seaports, as well as for some shallow-draft tributary channels. The Sabine Pass, Sabine Lake, and Sabine River together form part of the boundary between the states of Texas and Louisiana. (See Exhibit "C" Map Sheet PA Index)

4. Scope and Content. The Sabine-Neches Waterway is a system of artificially widened and/or deepened channels that have been dredged from offshore through portions of the Sabine River and Lake, and the Neches River in Texas. The waterway is made up of 7 existing project reaches. From the Gulf of Mexico working upstream the reaches are: 1) Sabine Bank Channel, 2) Sabine Pass Outer Bar Channel, 3) Sabine Pass Jetty Channel, 4) Sabine Pass Channel, 5) Port Arthur Canal, 6) Sabine Neches Canal and 7) Neches River Channel. (See Exhibit "C" Map Sheet PA Index). The only connection with the Gulf of Mexico is a long narrow pass called Sabine Pass through which all tidal interchange occurs. Sabine Pass has been stabilized by jetties that extend more than 4 miles into the Gulf of Mexico. These jetties were constructed for navigational purposes. Proposed channel will have 8 reaches.

The feasibility report focused on alternatives from 45 feet to 50 feet for deepening of the Sabine-Neches Waterway from offshore to the Port of Beaumont. The alternatives were to deepen either 45, 46, 47, 48, 49, or 50 feet from the Gulf to Port of Beaumont, with up to 8 turning basins and selective widening. The Recommended Plan consists of a 49-foot deep navigation channel from the Gulf to the Port of Beaumont, with selective widening and 4 turning/anchorage basins.

5. Purpose The purpose of the REP is to identify the real estate requirements for the CIP and to estimate the costs of acquisition. The plan will also identify the estate to be acquired in the various tracts. In 2002, the local sponsor, the Jefferson County Navigation District, was renamed the Jefferson County Waterway and Navigation District (JCWND) and in 2007 the JCWND was renamed to the Sabine Neches Navigation District (SNND); the designation which is used throughout this report. The SNND already owns a majority of the lands needed for the CIP. The Sponsor will receive credit for the fair market value of any additional lands required, at the time they are made available to the Government for construction. The Sponsor will also receive credit for the administrative costs of acquisition for all lands acquired within 5 (five) years preceding the signing of the Project Cooperation Agreement (PCA).

6. Real Estate Requirements. The CIP Sponsor is required to furnish the lands, easements, and rights of way (LER) for the proposed cost-shared project. The real estate requirements must support construction as well as operation and maintenance of the project after completion. Of the eight reaches for the CIP starting with reaches one and two, **Sabine Bank Channel and Sabine Bank Extension**, all of the dredged material from this reach Sta53+000 to Sta165+000 will be deposited in offshore placement areas "A", "B", "C", "D", and offshore Site No. 1, (*See Exhibit "C" Map Sheet PA Index*). Reach three, **Sabine Pass Outer Bar Channel**, Sta53+000 to Sta0+000; all of the dredged material from this reach will be deposited in offshore Sites No. 2 and 3. (*See Exhibit "C" Map Sheet PA Index*) Reach four, **Sabine Pass Jetty Channel**, Sta0+000 to Sta215+29; the dredged material from this reach will all be deposited in offshore Site No. 4. (*See Exhibit "C" Map Sheet PA Index*) All of the placement areas which will be used for these three reaches are in navigable water and will be used by virtue of Navigation Servitude; therefore no real estate interests will be required. Reach five, **Sabine Pass Channel**, Sta0+000 to Sta295+00; the dredged material from this reach will be deposited in Placement Area Nos. 5 North, 5 South, 5C and 5B, an upland site containing 1,025.00 acres. This placement area will be acquired in fee. (*See Exhibit "C" Map Sheet PA 9*). Reach six, **Port Arthur Canal**, Sta0+00 to Sta326+24; the dredged material from this reach will be deposited in Placement areas 8 and 9, two upland sites. Placement area No. 8 contains 3,571.00 acres and is available by virtue Navigation Servitude, therefore no real estate interests is required. Placement area No. 9 contains 381.00 acres and is at the intersection of the Port Arthur Canal and the Gulf Intracoastal Waterway. Placement area 9a contains 166 acres will be acquired in fee. (*See Exhibit "C" Map Sheet PA 10*). Reach seven, **Sabine-Neches Canal**, Sta0+00 to Sta592+91; the dredged material from this reach will be deposited in Placement areas 8 and 11. These placement areas are along the Sabine- Neches Canal and were in navigable waters at one time. These Placement areas are now upland sites and are available by virtue of Navigation Servitude. Placement area 8 contains 3,571.00 acres and Placement area 11 contains 2,173.00 acres (*See Exhibit "C" Map Sheet PA 10 & 11*).

Neches River Channel is broken down into three reaches. Sta0+00 to Sta292+00, the material dredged from this reach will be deposited into placement areas 12, 13, 14, and 16 which total 1,051.00 acres and 17 which has 324 acres of upland placement areas. All of these placement areas with the exception of area 17 are owned by the local sponsor and therefore no real estate interests will be required. Placement area 17 will be acquired in fee. The second reach, Sta292+00 to Sta716+00, the material dredged from this reach will be deposited in placement areas 18, 18A, 21, 23, 23A and 24 which total 1,744.00 acres of upland placement areas. All of these areas are owned by the sponsor and therefore no real estate interests will be required. The third reach, Sta716+00 to Sta980+00, the material dredged from this reach will be deposited in placement areas 24A-187 acres, 25-643 acres, 25A-172 acres, 26-201 acres, 27A-129 acres, 27C-87 acres and 27D-55 acres. All these areas with the exception of placement area 26 and 27A, C and D are all owned by the local sponsor and therefore no real estate interests will be required. Placement areas 26 and 27A, C and D will be acquired in fee. (*See Exhibit "C" Map Sheet PA 14*). Within these three reaches, there are 4 turning basins of which only two will require the acquisition of land totaling 12.10 acres that will be acquired in perpetual channel improvement easement. (*See Exhibit "C" Map Sheet PA 14*). All of the placement areas currently owned by the local sponsor were acquired for the original SNWW project under a local cooperation agreement which required the sponsor to provide all LERRDs necessary for the project.

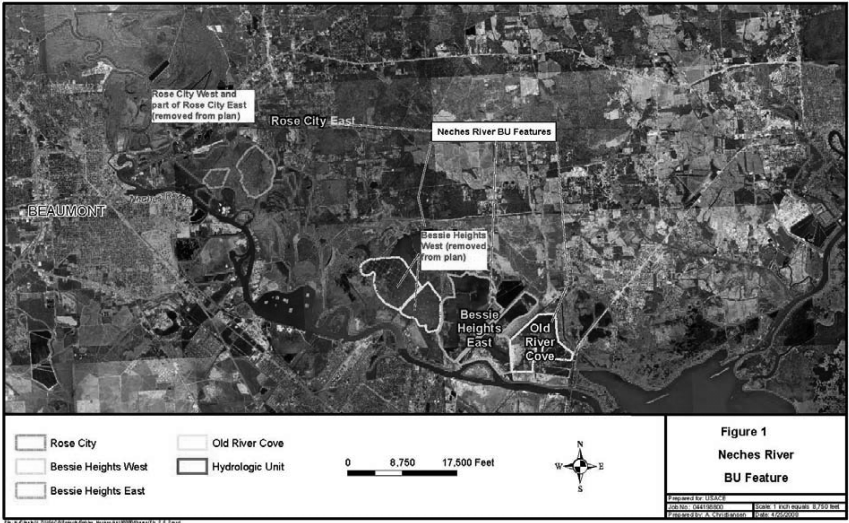

All DMMP beneficial use (BU) features proposed for inclusion in the DMMP of the Preferred Alternative are described in Table 2.4-13. Three former marsh areas on the Neches River (Rose City East, Bessie Heights East, and Old River Cove) would be combined into one large management feature called the Neches River BU Feature (see Figure 2.5-2). In the Gulf Shore BU Feature, maintenance material would be used to nourish Gulf shorelines at Texas and Louisiana Points (see Figure 2.5-3). The DMMP BU features are not being pursued as separable elements of an ecosystem restoration plan under Section 204 or 207 authorities. They are not ecosystem restoration measures, and as such, do not target a specific historical condition for the level of restoration. They are least-cost, environmentally acceptable placement features and are included as GNF of the DMMP.

The Neches River BU Feature would take advantage of new work material provided by the channel deepening project to build hydraulic containment levees within degraded, former marsh areas at Rose City East, Bessie Heights East, and Old River Cove. Each of these areas is referred to as a component of the overall Neches River BU Feature. Marsh would be created in each component using only new work, or a combination of new work and maintenance material. The Old River Cove component would be filled during initial construction with new work material, alone. In the Bessie Heights East component, maintenance material would be placed incrementally in 7 maintenance cycles over 28 years. At the Rose City East component, new work material would be used to construct containment levees and ridges, and then the marsh would be completed with the placement of maintenance material during the first maintenance cycle following construction. For the Neches River BU Feature as a whole, 2,853 acres of emergent marsh would be restored in areas that are now open water; 871 acres of improved shallow water habitat would be created by the formation of shallower ponds and interconnecting channels within the restored marshes; and 1,234 acres of existing fringing marsh would be nourished

Table 2.4-13
DMMP BU Features, SNWW Preferred Alternative

Beneficial Use Features	No.	Description	Size of Influence Area
Rose City East (component of Neches River BU Measure)	TX 3-1 East	Restoring 345 acres fresh marsh, 72 acres of shallow water, and nourishing 151 acres of existing marsh in two construction events. New work material from Neches River Channel will be used to restore 225-acre marsh, construct hydraulic containment levees and higher elevation features. Maintenance material from the first maintenance cycle will be used to restore an additional 120 acres of marsh.	Influence area – 568 acres
Bessie Heights East (component of Neches River BU Measure)	TX 5-2	Restores 679 acres of brackish and 1,190 acres of intermediate marsh, 660 acres of shallow water habitat and nourishes 651 acres of existing marsh. Marsh will be constructed with maintenance material from Neches River Channel for 28 years. New work material is used to build hydraulic containment levee.	Influence area – 3,180 acres
Old River Cove (component of Neches River BU Measure)	TX 6-1	Restores 639 acres of brackish marsh, 139 acres of shallow water habitat, and nourishes 432 acres of existing marsh with new work material from Neches River Channel. New work material used to construct hydraulic containment levee.	Influence area – 1,210 acres
Gulf Shore BU Feature (Texas and Louisiana Points)	TX 8-11 LA 5-2/6-2	Nourish 3 miles of Gulf shoreline on both sides of Sabine Pass, from 0.5 to 3.5 miles from East and West Jetties, using maintenance material from Sabine Pass Channel. Unconfined placement of maintenance material along shoreline every 3 years for 50-year period of analysis (8 placement episodes). Assume 50:50 split of material between Texas and Louisiana accomplished by alternating placement in Texas and Louisiana.	Affected shoreline 6.0 miles total

by winnowing fine-grained material from unconfined flows of dredged material effluent. The size of the Neches River BU Feature components and the magnitude of their ecological benefits are made possible by the large amounts of dredged material which would be generated by the proposed project, and extensive opportunities for beneficial use in the project area. The Gulf Shore Nourishment Feature would use material from regular maintenance dredging of the eastern section of the Sabine Pass Channel to nourish eroding marsh, and possibly create new saline marsh, along a total of 6 miles of shoreline on both sides of Sabine Pass at Louisiana and Texas Points. Material would be hydraulically pumped along a 3-mile reach of shoreline, from 0.5 to 3.5 miles from each jetty. The unconfined placement of material during each 3-year dredging cycle would alternate between Texas and Louisiana, so that materials would be placed on each state's shoreline every 6 years, for a total of 16 placement events over the 50-year period of analysis. Historic dredging records indicate that the material from Sabine Pass would average 51 percent silt, 31 percent clay, and 18 percent sand. The material would be hydraulically pumped into the near shore zone and some material would be expected to flow over existing marsh while the remainder flows into the nearshore waters. This mix of materials does not contain typical beach quality sand; however, resource agencies, which are listed in Table 1.6-1 of the FEIS, have agreed that returning the material to the littoral system would have a net beneficial effect, regardless of the material type.

The estates for the above mentioned tracts to be acquired are listed as below:

Fee Estate- Estate No. 1 Fee for Placement Areas

The fee simple title to (the land described in Schedule A) (Tract Nos. 5, 9, 17, 26, 27A, C and D), subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines; excepting and excluding from the taking all interests in coal, oil and gas or other minerals which are outstanding in parties other than surface owners and all appurtenant rights for the exploration, development and removal of said coal, oil and gas so excluded.

Channel Improvement Easement- Estate No. 8 for Turning Basins

A perpetual assignable right and easement to construct, operate, and maintain channel improvement works on, over, and across (the land described in Schedule A) (Tracts 1 through 8) for turning basins and for the purposes as authorized by the Act of Congress approved Water Resources Development Act 1999 (P.L. 106-53 SEC. 556), including the right to clear, cut fell, remove and dispose of any and all timber, trees, underbrush, buildings, improvements and/or other obstructions there from; to excavate; dredge, cut away, and remove any or all of said land and to place thereon dredged or excavated material; and for such other purposes as may be required in connection with said work of improvement; reserving, however, to the owners, their heirs and assigns, all such rights and privileges as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

7. **Borrow Material.** The proposed CIP does not require any borrow material.
8. **Access/Staging Area.** The proposed CIP does not require any access/staging areas. All of the proposed work will be performed within the existing right-of-way of the Sabine-Neches Waterway and existing roads and highways within the project area. No credit will be allowed for access/staging areas since these areas have already been provided for the previous project.
9. **Recreation Features.** The proposed project does not have any recreation features.
10. **Induced Flooding.** There is no induced flooding anticipated due to the construction of the project. The proposed CIP will be constructed within the existing right-of-way of the Sabine-Neches Waterway.
11. **Mitigation and DMMP BU sites.** The proposed CIP contains several mitigation and DMMP BU sites located within the project area. These sites consist of marsh creation, marsh nourishment and shore nourishment. Exhibit C shows the labeled sites on the Texas side and on the Louisiana side. (*See Exhibit "C" Map Sheet M 1*).
12. **Federally Owned Land & Existing Federal Project.** Some of the DMMP BU and mitigation sites are located on federally-owned land. The Gulf Shore BU Feature will nourish shoreline owned by the Texas Point National Wildlife Refuge. Two of the mitigation sites (LA 2-18B and LA 2Add B) are located in the Sabine National Wildlife Refuge.
13. **Navigation Servitude.** Navigation Servitude emanated from the Commerce Clause of the Constitution of the United States, Article I; Section 8, Clause 3. The servitude gives the Federal Government the right to use the "Navigable Waters" of the United States without compensation for navigation projects. These are non-transferable rights, and are not considered interest in real property. The CIP has 3,003 acres of mitigation and 3,294 acres of marsh restoration sites. These sites are marsh areas and are under the mean high water mark. Therefore, there is no real estate requirements associated with the mitigation effort, marsh restoration sites, or nourishment areas since the Government will exercise Navigation Servitude on the required submerged lands. A separate contract will be let for the construction of these sites.
14. **Public Law 91-646 Relocations.** There are no residential houses, businesses, or farms that would be required for relocation associated with PL 91-646.
15. **Assessment of Project Sponsor Land Acquisition Capabilities.** The sponsor has the authority and capability to furnish lands, easements and rights of way in accordance with the Feasibility Cost-Sharing Agreement. The sponsor is highly capable of performing the real estate acquisition required by this project. A copy of the capability assessment is attached as *Exhibit "A"*.
16. **Baseline Cost Estimate for Real Estate.** The cost estimate below reflects estimated Federal and Non-Federal real estate costs for the proposed 8 reaches which consists of a total of 14 contracts (see cost estimate) for the proposed navigation project. These costs

include land payments, acquisition administrative costs, surveying, mapping and administrative costs. The real estate costs for the CIP are estimated below:

REAL ESTATE

01/02 LANDS AND DAMAGES/RELOCATIONS

CONSTRUCTION CONTRACT #1 -NON-FEDERAL COSTS Sabine Bank Sta. 165+000 to 132+000

	Amount
Utility Relocations (50% of total Utility Relocations)	\$834,500
Contingency (33%)	\$275,500
Total Costs	\$1,110,000

CONSTRUCTION CONTRACT #3 -NON-FEDERAL COSTS Sabine Bank Sta. 95+734 to 53+000

	Amount
Utility Relocations (50% of total Utility Relocations)	\$497,500
Contingency (33%)	\$164,000
Total Costs	\$661,500

CONSTRUCTION CONTRACT #4 -NON-FEDERAL COSTS Sabine Pass Outer Bar Jetty Channel Sta. 53+000 to 0+000

	Amount
Utility Relocations (50% of total Utility Relocations)	\$828,500
Contingency (33%)	\$273,500
Total Costs	\$1,102,000

CONSTRUCTION CONTRACT #6 -NON-FEDERAL COSTS
Sabine Pass Channel Sta. 0+00 to 295+60

	Amount
Land Payments (MCACES line 11501)	\$700,000
Incidental Land Acquisition Expenses (total of MCACES lines 102, 103,105,112,113, 117)	\$127,000
Utility Relocations (50% of total Utility Relocations)	\$1,468,000
Contingency (25%-30%)	\$647,500
Total Costs	\$2,942,500

CONSTRUCTION CONTRACT #6 -FEDERAL COSTS
Sabine Pass Channel Sta. 0+00 to 295+60

	Amount
Administrative Expenses for Assistance, Review and Approval of NFS Land Acquisition (total of MCACES lines 102, 103,105,112, 113, 117)	\$102,000
Contingency (25%)	\$26,000
Total Costs	\$128,000

CONSTRUCTION CONTRACT #7 -NON-FEDERAL COSTS
Port Arthur Channel Sta. 0+00 to 326+24

	Amount
Land Payments (MCACES line 11501)	\$560,000
Incidental Land Acquisition Expenses (total of MCACES lines 102, 105,112,113,117)	\$79,000
Contingency (25%)	\$159,750
Total Costs	\$799,000

CONSTRUCTION CONTRACT #7 -FEDERAL COSTS
Port Arthur Channel Sta. 0+00 to 326+24

	Amount
Administrative Expenses for Assistance, Review and Approval of NFS Land Acquisition (total of MCACES lines 102, 105,108,112, 113, 117)	\$64,000
Contingency (25%)	\$16,000
Total Costs	\$80,000

CONSTRUCTION CONTRACT #8 & 9 -NON-FEDERAL COSTS
Sabine-Neches Canal Sta. 0+00 to 592+91

	Amount
Incidental Land Acquisition Expenses (total of MCACES lines 112,113,117)	\$140,000
Utility Relocations (50% of total Utility Relocations)	\$627,500
Contingency (25%-30%)	\$224,000
Total Costs	\$991,500

CONSTRUCTION CONTRACT #8 & 9 -FEDERAL COSTS
Sabine-Neches Canal Sta. 0+00 to 592+91

	Amount
Administrative Expenses for Assistance, Review and Approval of NFS Land Acquisition (total of MCACES lines 108, 112, 113, 117)	\$120,000
Contingency (25%)	\$30,000
Total Costs	\$150,000

CONSTRUCTION CONTRACT #10 -NON-FEDERAL COSTS
Neches River Channel Sta. 0+00 to 292+00

	Amount
Land Payments (MCACES line 11501)	\$20,000
Incidental Land Acquisition Expenses (total of MCACES lines 112,113,117)	\$90,000
Utility Relocations (50% of total Utility Relocations)	\$3,864,500
Contingency (25% - 30%)	\$1,187,500
Total Costs	\$5,162,000

CONSTRUCTION CONTRACT #10 -FEDERAL COSTS
Neches River Channel Sta. 0+00 to 292+00

	Amount
Administrative Expenses for Assistance, Review and Approval of NFS Land Acquisition (total of MCACES lines 108, 112, 113, 117)	\$85,000
Contingency (25%)	\$21,000
Total Costs	\$106,000

CONSTRUCTION CONTRACT #11 -NON-FEDERAL COSTS
Neches River Channel Sta. 292+00 to 716+00

	Amount
Land Payments (MCACES line 11501)	\$135,000
Incidental Land Acquisition Expenses (total of MCACES lines 102,105,112,113,117)	\$98,000
Utility Relocations (50% of total Utility Relocations)	\$7,840,000
Contingency (25% - 30%)	\$2,410,000
Total Costs	\$10,483,000

CONSTRUCTION CONTRACT #11 -FEDERAL COSTS
Neches River Channel Sta. 292+00 to 716+00

	Amount
Administrative Expenses for Assistance, Review and Approval of NFS Land Acquisition (total of MCACES lines 102,105,108, 112, 113, 117)	\$127,000
Contingency (25%)	\$32,000
Total Costs	\$159,000

CONSTRUCTION CONTRACT #12 -NON-FEDERAL COSTS
Neches River Channel Sta. 716+00 to 980+00

	Amount
Land Payments (MCACES line 11501)	\$775,000
Incidental Land Acquisition Expenses (total of MCACES lines 102,105,112,113,117)	\$168,000
Contingency (25% - 30%)	\$236,000
Total Costs	\$1,179,000

CONSTRUCTION CONTRACT #12 -FEDERAL COSTS
Neches River Channel Sta. 716+00 to 980+00

	Amount
Administrative Expenses for Assistance, Review and Approval of NFS Land Acquisition (total of MCACES lines 102,105, 112, 113, 117)	\$97,000
Contingency (25%)	\$24,000
Total Costs	\$121,000

Note: There are some administrative costs, both Federal and non-Federal costs, for utility relocations that are not presented separately in the tables. For those tables, the administrative costs for utility relocations are included as part of the contingency for that contract.

TOTAL--NON-FEDERAL LER plus UTILITY RELOCATION COSTS	\$24,430,500
LER Costs	\$3,617,000
Utility Relocation Costs	\$20,813,500
TOTAL -- FEDERAL COSTS	\$744,000

17. Acquisition Schedule. The acquisition of the LER necessary for the CIP is the responsibility of the sponsor, however, for the current project, the Sponsor owns all the lands required with the exception of six tracts which they are in the process of acquiring. Therefore, there is no need for an acquisition schedule. Significant time delays may be encountered if condemnation proceedings are required for land acquisitions.

18. Mineral Activity. Sabine Lake and the surrounding area along with the mitigation and the marsh restoration sites have considerable mineral activity. Mineral rights have not been transferred with property in the project area. Mineral rights need not be acquired with any lands required for the project. The State of Texas owns the mineral rights in most of the submerged lands in the project area. The Government's surface rights in the submerged lands required for the project emanates from the navigation servitude. The Navigation Servitude is the dominant estate and takes precedence over the mineral estate in the required submerged lands.

19. Relocation of Facilities/Utilities. A total of 104 pipelines have been identified crossing the SNWW navigation channels. Of the 104 pipelines, 46 require adjustment to meet the minimum required vertical and horizontal clearances for the Channel Improvement Project (CIP). (See Exhibit "D").

Pursuant to Section 101(a) of the Water Resources Development Act of 1986 (WRDA 86), as amended, the Sponsor is responsible for performing, or assuring the performance, of all relocations, including utility relocations, which are necessary for the CIP. All relocations, including utility relocations, are to be accomplished at no cost to the Federal Government.

Because the recommended plan consists of a 48-foot deep navigation channel, the CIP is a deep draft project. Therefore, in accordance with Section 101(a)(4) of WRDA 86, for all relocations of pipelines that are classified as "utility relocations," one-half of the cost of each such relocation shall be borne by the owner of the facility being relocated and one-half of the cost of each such relocation shall be borne by the Sponsor.

Consistent with the legislative history for Section 101 of WRDA 86, any pipeline, cable, or related facility located within the channel that must be relocated for the CIP is considered a utility relocation for the purpose of applying the cost sharing rule in Section 101(a)(4) of WRDA 86, as amended.

The Galveston District has concluded preliminarily that 41 of the 46 lines located within the channel must be relocated. Applying the definition of "utility" discussed above, such 41 relocations are classified as utility relocations for which the Sponsor must perform or assure performance with relocation costs to be shared equally between the Sponsor and the pipeline owners pursuant to Section 101(a)(4) of WRDA 86. Such relocation costs will not include any cost for upgrading or improving such facilities, which is to be borne by the facility owner.

If, following authorization of the CIP, the Sponsor is unable to reach an agreement with a pipeline owner as to the relocation of a particular pipeline, the Sponsor may request that the Corps exercise the navigation servitude, and revoke any existing Section 10 permit, to compel the owner to remove its line. The Corps will exercise the navigation servitude if the Sponsor has made a good-faith effort to negotiate with the pipeline owner for relocation of the line and

the Sponsor has made a showing that it has no authority to compel the relocation of the facility by the pipeline owner.

The exercise by the Corps of the navigation servitude, however, would not affect the cost-sharing formula for utility relocations established by the Congress in Section 101(a)(4) of WRDA 86. The Corps will not exercise the navigation servitude unless the Sponsor agrees in writing that such action will be at no cost to the Federal Government and will not affect the Sponsor's responsibility for payment of relocation costs under Section 101(a)(4). In addition, the Sponsor will be responsible for payment of the Corps' administrative costs associated with exercise of the navigation servitude.

For relocations that are not classified as "utility relocations," whether the Sponsor owes compensation to the facility owner turns on principles of just compensation under State law and whether any permits, licenses, or rights-of-way instruments have special provisions that as a matter of law may offset what compensation may otherwise be due. For such relocations, the Sponsor will negotiate with the pipeline or facility owners as to the amount of compensation that is required. As in the case of utility relocations, these relocations will be accomplished at no cost to the Federal Government.

The Galveston District also has concluded preliminarily that it will not be necessary to relocate 5 of the 46 lines because they are no longer necessary. Although such lines will need to be removed to construct the CIP, no replacement lines will be necessary. If an owner of such a line can be located, the Sponsor will contact the owner to reach a determination as to whether the owner has an interest in the existing line for which compensation is owed by the Sponsor. If the owner has a compensable interest, the Sponsor, as part of its requirement to provide lands, easements, and rights-of-way required for the CIP, will be responsible for acquiring this interest, at no cost to the Federal Government. The Sponsor will receive credit toward its additional 10 percent cash payment required by Section 101(a)(2) of WRDA 86 for the value of the interest acquired, and the Corps will revoke any existing Section 10 permit and remove the line as part of construction of the CIP, with the costs of the removal shared by the Corps and Sponsor as part of the costs of the general navigation features. If no compensation is owed to the owner of the line, or if the owner cannot be located, then the Corps will revoke any existing Section 10 permit and remove the line as part of construction of the CIP, with the costs of the removal shared by the Corps and Sponsor as part of the costs of the general navigation features.

The Sponsor will receive credit toward its additional 10 percent cash payment required by Section 101(a)(2) for the value of relocations provided under Section 101(a)(3) and for the costs of utility relocations borne by the Sponsor under Section 101(a)(4). Such credit will include any payment made by the Sponsor to the Corps associated with the Corps' exercise of the navigation servitude.

20. HTRW or Other Environmental Contaminants. HTRW is suspected in the vicinity of placement area 17 (Neches River Channel). Sponsor shall perform, or ensure performance of, any investigations for hazardous substances that the Government or the sponsor determines to be necessary to identify the existence and extent of any hazardous substances regulated under CERCLA (42 U.S.C. Sections 9601-9675), that may exist in, on, or under lands, easements and rights-of-way that the Government determines to be necessary for the construction or operation and maintenance of the general navigation

features. All cost for such investigations shall be included in total cost of construction of the general navigation features and cost shared in the Project Cooperation Agreement (PCA).

21. Attitudes of the Landowner. The sponsor is the owner of the majority of the CIP lands. As owners they are supportive and in favor of the project. No resistance to the project by the landowner is expected.

22. Sponsor Notification of Risks. A letter was transmitted to the Sabine Neches Navigation District (formerly Jefferson County Waterway and Navigation District) on the 24 of February 2003, advising them if for any reason, the Project Cooperation Agreement (PCA) never gets signed or if Congress fails to authorize or fund the CIP, any land they acquired or money they spent in their effort to acquire land will be at their sole risk. (*See Exhibit "B"*)

EXHIBIT "A"

APPENDIX 12-E

ASSESSMENT OF NON-FEDERAL SPONSOR'S
REAL ESTATE ACQUISITION CAPABILITY

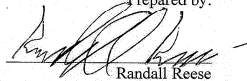

- I. Legal Authority:
 - a. Does the sponsor have legal authority to acquire and hold title to real property for project purposes? (yes/no)
 - b. Does the sponsor have the power of eminent domain for this project? (yes/no)
 - c. Does the sponsor have "quick-take" authority for this project? (yes/no)
 - d. Are any of the lands/interests in land required for the project located outside the sponsor's political boundary? (yes/no)
 - e. Are any of the lands/interests in land required for the project owned by an entity whose property the sponsor cannot condemn? (yes/no)
- II. Human Resources Requirements:
 - a. Will the sponsor's in-house staff require training to become familiar with the real estate requirements of Federal projects including P.L. 91-646, as amended? (yes/no)
 - b. If the answer to II.a. is "yes," has a reasonable plan been developed to provide such training? (yes/no)
 - c. Does the sponsor's in-house staff have sufficient real estate acquisition experience to meet its responsibilities for the project? (yes/no)
 - d. Is the sponsor's projected in-house staffing level sufficient considering its other work load, if any, and the project schedule? (yes/no)
 - e. Can the sponsor obtain contractor support, if required in a timely fashion? (yes/no)
 - f. Will the sponsor likely request USACE assistance in acquiring real estate? (yes/no) (If "yes," provide description)
 1. Condemnation of tract in Louisiana that has been ongoing for 7-8 years.
 2. Use of Navigational Servitude in pipeline removals and relocations.
- III. Other Project Variables:
 - a. Will the sponsor's staff be located within reasonable proximity to the project site? (yes/no)
 - b. Has the sponsor approved the project/real estate schedule/milestones? (yes/no)
- IV. Overall Assessment:
 - a. Has the sponsor performed satisfactorily on other USACE projects? **YES**

ER 405-1-12
Change 31
1 May 98

APPENDIX 12-E

- b. With regard to this project, the sponsor is anticipated to be:
(highly capable / fully capable / moderately capable / marginally capable /
insufficiently capable. If sponsor is believed to be "insufficiently capable",
provide explanation. **HIGHLY CAPABLE**
- V. Coordination:
- a. Has this assessment been coordinated with the sponsor?
(yes/~~no~~) **YES**
- b. Does the sponsor concur with this assessment?
(yes/~~no~~) (If "no", provide explanation) **YES**

Real Estate Division

Subject: Proposed Sabine Neches Waterway Project, Jefferson County, Texas

Mr. Paul Beard
Chairman
Jefferson County Navigation District
P.O. Box 778
Nederland, Texas 77627

Dear Mr. Beard:

It is our understanding, that you may begin acquiring rights-of-way and relocating pipelines in connection with the Sabine Neches Waterway Project prior to execution of the Project Cooperation Agreement (PCA) with the Federal Government. We appreciate your support for this proposed project but our regulations require us to inform you that **IF FOR ANY REASON, THE PCA NEVER GETS SIGNED OR IF CONGRESS FAILS TO AUTHORIZE OR FUND THE PROJECT, ANY LAND YOU ACQUIRED OR ANY MONEY YOU SPEND IN YOUR EFFORTS TO ACQUIRE LAND WILL BE AT THE SOLE RISK OF THE JEFFERSON COUNTY NAVIGATION DISTRICT.** Furthermore, for any property that qualifies for Federal participation in the project, your acquisition efforts must be in compliance with all of the provisions of P.L. 91-646, the Federal Relocation Assistance Law.

It has recently been determined that relocation of pipelines or utilities are considered as part of the Lands, Easements, and Rights-of-Way (LERRS) and can be accomplished prior to PCA execution at the sole risk of the Sponsor. It is also required that all relocations be supported by engineering cost estimates that meet project requirements as well as attorney's reports or opinions verifying that the pipeline or utility companies have compensable interests in the real property.

Please ensure that good records are kept regarding purchase price and real estate administrative expenses such as title evidence, surveys and appraisal fees. This will be necessary for you to receive credit in the event of Federal Authorization. Be advised that regulations dictate that credit will not be given for real estate administrative costs for properties acquired 5 years prior to execution of a PCA.

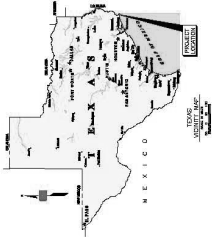

If you have any questions on any of the above please call Mr. Sal Arcidiacono of my staff at (409) 766-3803.

Sincerely,

Richard W. Harrison
Chief Real Estate Division

March 2011

ABSTRACT**FINAL ENVIRONMENTAL IMPACT STATEMENT
PROPOSED SABINE-NECHES WATERWAY
CHANNEL IMPROVEMENT PROJECT
SOUTHEAST TEXAS AND SOUTHWEST LOUISIANA**

The responsible agency for this action is the U.S. Army Corps of Engineers, Galveston District (USACE). The non-Federal sponsor is the Sabine Neches Navigation District (SNND). The U.S. Environmental Protection Agency, U.S. Department of the Interior – Fish and Wildlife Service, U.S. Department of Commerce – National Marine Fisheries Service, Texas General Land Office, and the Louisiana Department of Wildlife and Fisheries are cooperating agencies.

Abstract: This Final Environmental Impact Statement (FEIS) was prepared as required by the National Environmental Policy Act (NEPA) to present an evaluation of potential impacts of the proposed Sabine-Neches Waterway Channel Improvement Project (SNWW CIP). The proposed SNWW CIP is intended to improve the efficiency of the deep-draft navigation system while protecting the area's environmental resources. The FEIS addresses the potential direct, indirect, and cumulative impacts of the proposed project on the human environment, as identified during the public interest review, including placement of dredged material. All factors that may be relevant to the proposed project were considered, including plans for construction and operations, dredged material management and opportunities for beneficial uses, hydrology, salinity, and storm surges, terrestrial and aquatic habitats, endangered species, essential fish habitat, hazardous materials, air quality, shoreline erosion, cultural resources, socioeconomic considerations, safety, and economic effects. The alternatives analysis evaluated the No-Action, 3 nonstructural, and 120 structural alternatives. A recommended plan was selected that would deepen the SNWW to Beaumont to 48 feet and extend the Sabine Bank Channel an additional 13.2 miles, taper the Sabine Bank Channel from 800 feet wide (Station 23+300) to 700 feet wide (Station 25+800) through the end of the Sabine Bank Channel extension, deepen and widen Taylor Bayou channels and turning basins, and construct 3 new anchorage/turning basins on the Neches River. Beneficial use features and mitigation measures have been developed that effectively avoid or mitigate all environmental impacts. The public response to the findings of the Draft EIS have been addressed in the FEIS.

Comments on this FEIS must be postmarked by April 4, 2011.

Executive Summary

ES.1 INTRODUCTION AND AUTHORITY

The U.S. Army Corps of Engineers (USACE) has joined in an agreement with the Sabine Neches Navigation District (SNND) to prepare a Final Feasibility Report (FFR) and a Final Environmental Impact Statement (FEIS) for proposed improvements to the Sabine-Neches Waterway (SNWW). The proposed SNWW Channel Improvement Project (CIP) is intended to improve the efficiency of the deep-draft navigation system while protecting the area's coastal and estuarine resources. As authorized by the Senate Committee on Environment and Public Works Resolution, dated June 5, 1997, USACE has reviewed previous USACE reports on the SNWW and other pertinent reports to determine the feasibility of modifying the channels serving the Port of Beaumont and the Port of Port Arthur, Texas. The lead agency for the FEIS is USACE, with several cooperating agencies. This FEIS was prepared as required by the National Environmental Policy Act to present an evaluation of potential impacts associated with the proposed CIP.

ES.2 PURPOSE AND NEED

The purpose of the proposed CIP is to improve the transportation efficiency of the SNWW's deep-draft navigation system, while protecting the quality of the area's coastal and estuarine resources. Proposed channel improvements will support industry at ports within the SNWW navigation channel system, which are critical in the Nation's economy and military defense. Depth restrictions of the existing SNWW channel configuration and congestion in the channel prevent it from efficiently accommodating predicted future increases in crude oil imports. In addition to existing crude oil and petrochemical product facilities on the SNWW, one liquefied natural gas (LNG) facility began operations in 2008, and construction of a second facility is nearing completion; a third has received regulatory approval. In 2007, the Port of Beaumont handled about half of the military cargo deployed to and from the war in Iraq. The existing, congested SNWW cannot handle this level of increased use without compromising efficiency. Deep-draft vessels and barge traffic are restricted by narrow channel widths leading to constraints such as daylight-only and one-way sailing restrictions in specific reaches. Given the trend towards shorter, wider vessels and the congestion in the channel, deepening the channel could alleviate some of the congestion by allowing vessels to be more fully loaded and reducing the number of lightened and lightering vessels. The need to improve the SNWW must be weighed against the potential to affect significant environmental resources. The study area contains approximately 480 square miles of sensitive coastal habitats that are plagued by a high rate of wetland loss and extensive losses of interior coastal wetlands. These high rates of land loss provide opportunities to use dredged material beneficially for wetland restoration.

ES.3 DESCRIPTION OF THE PROPOSED ACTION AND ALTERNATIVES

Analysis of alternatives that could potentially meet the purpose and need for the proposed action included a systematic evaluation and consideration of environmental factors. Based on a three-phase screening

process (preliminary screening, second screening, and final screening of alternatives), nonstructural and structural alternatives were identified and evaluated relative to a No-Action Alternative. The No-Action Alternative carried forward for evaluation provides a basis against which all other alternative plans are measured. Thus, under the No-Action Alternative, the Federal Government and the non-Federal sponsor would not implement the proposed CIP. The 40-foot SNWW navigation channel would not be improved, and the objectives of improving the navigational efficiency of the waterway would not be met. Additionally, under the No-Action Alternative, benefits associated with proposed beneficial uses of dredged material for the proposed CIP would be substantially reduced. Nonstructural alternatives evaluated were (1) an alternative mode of commodity transport (i.e., an offshore oil terminal), (2) a vessel traffic system, and (3) modification of pilot rules. None of these alternatives increased the efficiency objective for all waterway users and were eliminated from further consideration.

Through the three-phase screening process, over 120 different combinations of various channel depths and widths were considered, with six depths (45, 46, 47, 48, 49, and 50 feet) evaluated in detail. The detailed evaluation included an economic evaluation to identify alternatives that maximized National Economic Development (NED) benefits, consistent with protecting the environment. Project benefits were based on reductions in transportation costs generated from more-efficient vessel loading and from reductions in vessel delays. The width of the channel was evaluated with a vessel simulation model conducted by the USACE Engineer Research and Design Center (ERDC) with input from the Sabine Pilots Association. Following the selection of a preferred channel alternative, a detailed evaluation of alternatives for the management of dredged material and the mitigation of ecological impacts was conducted. Least-cost analysis of dredged material placement and an incremental cost analysis of mitigation alternatives were conducted to select recommended placement and mitigation measures. The analysis of alternative dredged material placement⁷ components was performed in conjunction with planning for the avoidance and mitigation of impacts from channel improvements so that dredged material could be given a priority for potential use in mitigation efforts. Dredged material placement alternatives considered in the detailed evaluation included:

- Neches River Beneficial Use (BU) Feature
- Gulf Shore BU Feature
- Existing Active and Inactive Upland Placement Features (PAs)
- New upland PAs
- Existing Ocean Dredged Material Disposal Sites (ODMDSs)
- New ODMDSs

The Preferred Alternative proposes to increase the authorized depth of the channel from 40 to 48 feet along the entire 64-mile-long existing channel and add a 13.2-mile extension to the offshore channels into the Gulf of Mexico. The offshore navigation channels, known collectively as the Entrance Channel, are divided into the Extension Channel, the Sabine Bank Channel, the Sabine Pass Outer Bar Channel, and the Sabine Pass Jetty Channel. They would be deepened from 42 to 50 feet. The inshore channels (the Sabine Pass Jetty Channel, Sabine Pass Channel, Port Arthur and Sabine-Neches canals, and the Neches

River Channel) would be deepened from 40 feet to 48 feet. No modifications to the existing Sabine Pass Jetties are contemplated in conjunction with this project. Potential rehabilitation of the jetties is currently being studied, with the goal of preparing a long-range plan of modification needed to ensure that the jetties continue to function appropriately to support the Federal navigation channel.

Except for the one channel reach just beyond the jetties, the bottom width of the offshore Entrance Channel would be 700 feet wide. Since the existing Sabine Bank Channel is 800 feet wide, the bottom width of the deepened channel would be reduced to 700 feet wide. However, high currents passing around the mouth of the jetties require that the bottom width of the Sabine Pass Outer Bar Channel remain 800 feet wide, and therefore the deepened channel would be tapered to connect to the 700-foot Entrance Channel. With the exception of the Taylor Bayou basins and channels, the inshore channels would retain their existing 500 to 400 foot widths. The Taylor Bayou basins and channels would be widened to improve maneuverability for vessels using that facility. Neither the Sabine-Neches Canal nor the Neches River Channel would be systematically widened, but navigation efficiency would be improved with bend easings in both reaches and the addition or enlargement of turning and anchorage basins on the Neches River Channel. Project dimensions for the Preferred Alternative are provided in Table ES-1.

Table ES-1
Project Dimensions for Preferred Alternative

Reach	Station	to	Station	Bottom Width (feet)	Project Depth (feet)
Extension Channel	165+443		95+734	700	50
Sabine Bank Channel	95+734		25+800	700	50
Sabine Bank Channel	25+800		23+300	700–800	50
Sabine Bank Channel	23+300		18+000	800	50
Sabine Pass Outer Bar Channel	18+000		0+000	800	50
Sabine Pass Jetty Channel	–214+88		0+00	800–500	48
Sabine Pass Channel	0+00		296+25	1355–500	48
Port Arthur Canal	0+00		325+84	1660–500	48
Sabine-Neches Canal	0+00		592+94	1050–400	48
Neches River Channel	0+00		980+00	400–1413	48
Taylor Bayou					
Entrance Channel	0+00		25+27	406–764	48
East Turning Basin	0+00		17+65	532–354	48
West Turning Basin	25+27		41+30	776	48
Connecting Channel	41+30		71+50	470–250	48
Taylor Bayou Turning Basin	71+50		106+25	1000	48

A total of 104 pipelines have been identified crossing the SNWW navigation channels. Of the 104 pipelines, 46 require adjustment to meet the minimum required vertical and horizontal clearances for the SNWW CIP. Bridge supports for the Martin Luther King Bridge over the Sabine-Neches Canal would be hardened because of the proximity of the new channel cut; supports for the Rainbow and Veterans Memorial bridges would not be affected. Bridge fender systems for all three bridges would be removed

and replaced to accommodate the new channel dimensions. The Port Arthur Hurricane Flood Protection Levee and utility power lines would not be affected.

Dredged material produced by construction of the Preferred Alternative and during maintenance dredging over the 50-year period of analysis would be managed in accordance with the Dredged Material Management Plan (DMMP). PAs proposed in the DMMP consist of upland PAs, ODMDSSs, and BU features. Construction of the Preferred Alternative is expected to yield approximately 98 million cubic yards (mcy) of new-work dredged material. Maintenance dredging over the 50-year period of analysis is expected to yield approximately 650 mcy of dredged material. Dredged material will be placed in 16 existing upland PA features and 2 new expansion cells at existing upland PAs (18A and 24A). For the Entrance Channel, material will be placed in four existing and four proposed ODMDSS features. Beneficial uses of dredged material in the DMMP consist of the Neches River BU Feature (Rose City East, Bessie Heights East, and Old River Cove) and the Gulf Shore BU Feature at Texas and Louisiana Points. Figures 2.4-1a–g in the FEIS show all the DMMP placement features proposed as part of the Preferred Alternative.

The Neches River and Gulf Shore BU features use dredged material beneficially to avoid and minimize all environmental impacts in Texas and some impacts in Louisiana. Compensatory mitigation in the form of marsh restoration is proposed for all unavoidable environmental impacts in Louisiana.

ES.4 POTENTIAL ENVIRONMENTAL IMPACTS

The FEIS addresses the potential impacts of the proposed project on human and environmental issues identified during the public interest review, including placement of dredged material. All factors that may be relevant to the proposed project were considered. Among those factors are salinity effects, effects to marshes and wetland forests, effects on threatened and endangered species, shoreline erosion, water and sediment quality, hazardous materials, air quality, cultural resources, socioeconomic effects, energy needs, safety, and in general, the welfare of the people of the United States. The following provides a brief description of potential impacts that were identified.

Physiography and Geology

Impacts on local geology during dredging and dredged material placement associated with the Preferred Alternative would include redistribution of existing sediment, potential increase of local scouring and shoaling rates, reduced erosion of inshore channel shorelines, and reduced erosion rates at Gulf shoreline nourishment areas compared to the No-Action Alternative. While local changes would occur to bathymetry and topography during construction and operation of the proposed project, these alterations would be expected to have negligible impacts on the regional physiography of the submerged and subaerial portions of the study area. No impacts associated with geologic hazards are expected, and impacts on local geology are expected to be minimal.

Water Quality

USACE has received Section 401 State Water Quality Certification from Texas and Louisiana for this action. Both states have determined that the requirements for water quality certification have been met and have concluded that the placement of fill material will not violate water quality standards of either state. The Preferred Alternative is the least environmentally damaging practicable alternative. It would result in little, if any, difference in long-term inland turbidity or dissolved oxygen levels when compared to the No-Action Alternative. Short-term increases in turbidity may be caused by the unconfined flow of dredged material during construction of BU features and mitigation measures. There would be temporary, minor impacts from ocean placement at the new ODMDSSs. Proposed channel improvements should increase safety, thus decreasing the probability of a spill.

Sediment Quality

Surficial sediments to be dredged during construction of the offshore Extension Channel have been determined to be suitable for ocean placement. Additionally, shoaled sediments and the construction material that would be dredged from the SNWW during construction of the Preferred Alternative was determined to be of sufficient quality to be used for beneficial uses.

Although the quantity of maintenance material dredged from the inland reaches of the SNWW is expected to increase significantly compared to the No-Action Alternative, the source of the maintenance material would not change, and the method of placement would not change, except that more of the maintenance material would be used beneficially. Past testing of maintenance material has indicated no cause for concern.

Hydrology

Under the Preferred Alternative, there would be a deeper channel that would allow a greater amount of tidal circulation and exchange with the Gulf and cause only a minimal increase of water surface elevation. Salinity would increase in much of the system by a maximum of about 2 parts per thousand, and the salinity wedge in the SNWW navigation channel would extend farther upstream in the Neches River. It is not expected to have an effect on freshwater inflows to the Sabine-Neches system. However, because the amount of tidal exchange would be slightly increased, the inflows would be conveyed to the Gulf marginally faster than would be the case in the No-Action Alternative. In regards to sediment transport, the Preferred Alternative would slightly reduce the net westward littoral transport on the Texas side and the net eastern littoral transport on the Louisiana side. The changes in sediment transport, while very small, can be expected to have some effect on the rates of Gulf shoreline erosion. Under the Preferred Alternative, there is a slight increase in the Gulf shoreline erosion rate between 0.5 mile and 3.5 miles from each jetty, but shoreline nourishment in the DMMP would replace shoreline that would be lost. The Preferred Alternative should also reduce the rate of erosion on inland channels relative to the No-Action Alternative by reducing the number of predicted vessel trips.

Because clay barrier layers are anticipated to prevent contact between water or elutriate from construction and maintenance dredged material and groundwater, no adverse effects are anticipated to the lower unit of the Chicot, any portion of the Evangeline, or the massive portions of the upper Chicot aquifers. Therefore, no adverse effects are anticipated to occur to groundwater wells documented in the project area counties.

The potential for proposed project features to increase storm surge impacts in the study area was analyzed with a storm surge sensitivity analysis. The greatest changes would occur north of Port Arthur along the Neches River due primarily to the proposed increase in depth of the navigation channel. All changes are local, and there are no project-induced increases in surges away from the immediate vicinity of the navigation channel. Changes in peak surge on the order of inches could occur with the project but should not cause any significant change in interior flooding.

Hazardous, Toxic, and Radioactive Waste (HTRW)

Findings of the HTRW survey indicate that there may be potential for encountering contaminated material during construction of the project, especially near industrial facilities that have not yet completed remediation efforts. Encountering contaminated material could increase project cost and/or lost time. However, based upon recent chemical analyses of water and sediment collected from within the channels, the potential for encountering contaminated material during dredging operations is considered minimal. The potential for oil and gas wells and petroleum pipelines to impact the project area is also minimal. A capped landfill has been found in PA 17 that is unrelated to dredged material or dredging activities. Issues related to possibly hazardous materials in the landfill must be resolved by the non-Federal sponsor before the PA can be used. Alternate PAs are available should this issue not be resolved in time for use.

Air Quality

Construction activities associated with the proposed CIP would result in emissions from combustion products from project dredging, support, and reuse/disposal equipment. Pollutant emissions from construction and dredging activities may result in short-term impacts on air quality in the immediate vicinity of the project site. Emissions of volatile organic compounds for the activities subject to USACE responsibility are exempt from a General Conformity Determination because they are below the 100-ton-per-year (tpy) threshold. Estimated nitrogen oxide (NO_x) emissions for activities subject to USACE responsibility would exceed the conformity threshold of 100 tpy for all years of construction. Therefore, USACE prepared a General Conformity Determination for NO_x emissions, which was submitted to the Texas Commission on Environmental Quality (TCEQ), U.S. Environmental Protection Agency (EPA), and other air pollution control agencies, as appropriate, to ensure conformity of this project with the State Implementation Plan (SIP). The TCEQ has provided written concurrence that emissions from the Preferred Alternative are conformant with the Texas SIP for the Beaumont-Port Arthur region (Appendix A1). Based on the TCEQ's comments, the USACE has prepared a Final General Conformity Determination for the proposed SNWW CIP (Appendix F).

Noise

The Preferred Alternative is not expected to result in long-term noise impacts because no permanent noise sources would be installed as part of this project and elevated noise levels would be short term, occurring during construction and maintenance dredging activities. Short-term impacts could be considered potentially significant at noise-sensitive land uses within 600 feet of dredging activities. Elevated noise levels are expected to be no different from those currently experienced during maintenance dredging activities. Therefore, no increase in noise impacts over levels associated with the No-Action Alternative is expected.

Vegetation

The Preferred Alternative would either directly or indirectly impact more than 220,000 acres of aquatic habitats in Texas and Louisiana. In Texas, negative impacts to productivity would occur over approximately 39,000 acres with a resulting loss of 412 Average Annual Habitat Units (AAHUs). The majority (380 AAHUs) are indirect productivity impacts that would occur to approximately 33,500 acres of intertidal marsh and swamp due to small increases in salinity from the proposed channel deepening. Direct impacts (32 AAHUs) are associated with the conversion of 86 acres of fresh marsh to upland PA 24A.

In Louisiana, negative indirect impacts to productivity would occur to approximately 182,000 acres of intertidal marsh due to small increases in salinities from the proposed channel deepening. The resulting total loss would be 1,709 AAHUs. No productivity or land loss impacts to Louisiana swamps are expected to occur.

The DMMP BU features (Neches River BU Feature in Texas and the Gulf Shore BU Feature in both Texas and Louisiana) would provide benefits that offset all impacts (-412 AAHUs) of the proposed plan in Texas and partially offset impacts in Louisiana. In Texas, construction of the Neches River BU Feature and the Texas portion of the Gulf Shore BU Feature would produce benefits totaling 1,068 AAHUs. Therefore, there would be a net gain of 656 AAHUs, which more than offsets all negative impacts that would occur in Texas. In Louisiana, the Gulf Shore BU Feature would provide benefits totaling 210 AAHUs. Given total Louisiana impacts of 1,709 AAHUs, there would be a net loss of 1,499 remaining in Louisiana after offsetting benefits of the Louisiana portion of the Gulf Shore BU Feature are applied.

After benefits of the BU features are applied to the project as a whole, the Preferred Alternative would result in the loss of 843 AAHUs over the future with-project condition. However, because the ecological benefits of the DMMP BU features would be primarily in Texas, additional compensatory mitigation beyond the total project loss of 843 AAHUs is proposed so that impacts in Louisiana would be compensated in Louisiana. The additional mitigation in Louisiana would result in a net gain of 338 AAHUs for the project as a whole and compensate for all losses in Louisiana with the exception of losses that would occur to Federal lands in the Sabine National Wildlife Refuge (SNWR). Exclusion of

the SNWR is based upon the definition of “coastal zone” in the Coastal Zone Management Act of 1972, as amended. “Excluded from the coastal zone are lands the use of which is by law subject solely to the discretion of or which is held in trust by the Federal Government, its officers or agents (16 USC § 1453).” Impacts to the SNWR would be fully offset by the Texas BU feature benefits.

A 1,159 AAHU loss would occur on non-Federal lands in Louisiana after taking into consideration the benefits of the DMMP. To offset this loss, a mitigation plan has been developed that will provide an ecological gain of 1,181 AAHUs in Louisiana. The mitigation plan would restore 2,783 acres of emergent marsh, improve 957 acres of shallow-water habitat, and nourish 4,355 acres of existing marsh.

Aquatic Ecology

The Preferred Alternative includes beneficial uses of dredged material that would restore the marsh elevations in the Neches River BU Feature. This is a large-scale feature that consists of marsh restoration in these major components: Rose City East, Bessie Heights East, and Old River Cove. These BU features are likely to have short- and long-term effects on the existing open-water communities. Shallow water or emergent marsh habitat would replace a significant portion of the open-water currently within each marsh. The marsh degradation process, which would proceed unchecked in the No-Action Alternative, would eventually adversely affect fishery productivity, while the restored marshes would improve nursery habitat and nutrient availability.

The total quantity of maintenance material from the inshore channels is expected to increase by 14 percent over the existing project, resulting in a similar increase in the duration of each maintenance dredging cycle; no change in the frequency of dredging cycles is anticipated. The total maintenance dredging quantity from the offshore channels is expected to increase by 120 percent, due to the 13.2-mile offshore channel extension and a predicted increase in the shoaling rate in existing channels. The increase in channel length and dredged material quantity will require the creation of four new ODMDSSs. The types of impacts to marine communities from the Preferred Alternative would be similar to maintenance dredging impacts expected for the No-Action Alternative, including short-term, localized increases in turbidity, which may reduce primary productivity. Proposed beneficial uses of dredged material that result in benefits to marshes in the study area would also benefit finfish and shellfish. Small increases in salinity expected to occur as a result of the Preferred Alternative are not expected to directly adversely affect fauna. Impacts to benthic organisms from dredging and placement of dredged material are not expected to be significant because recolonization is rapid, although the community composition in new PAs may be slightly different from pre-project conditions. The Preferred Alternative would temporarily and locally impact Essential Fish Habitat (EFH) species because of increased turbidity, although impacts are expected to be minimal. Concurrence was provided by National Marine Fisheries Service (NMFS) on March 8, 2010 (Appendix A3). In addition, the Preferred Alternative would result in net benefits to EFH through marsh creation and benefits to submerged aquatic vegetation. No Habitat Areas of Particular Concern are located in the study area. No adverse impacts to recreationally or commercially important aquatic species are expected, and no additional impacts with respect to ballast water are anticipated.

Construction of the Willow Bayou marsh mitigation areas would use material dredged from a 1.8-mile-long borrow trench parallel to the eastern shore of Sabine Lake. An access channel (approximately 8 miles long) would also be required for the dredge to travel from the Gulf Intracoastal Waterway near the mouth of the Sabine River to the borrow trench location. The exact locations of the borrow trench and access route would be determined in consultation with the Interagency Coordination Team after preconstruction, engineering, and design bottom surveys of potential locations. One-time impacts of the borrow trench and access channel dredging include a temporary increase in turbidity and the short-term loss of benthic fauna. No impacts to oyster reef are anticipated but a preconstruction survey of the borrow trench area would be performed to check this assumption. The probability that oyster reef will be found is very low. Salinities are too low in this area of Sabine Lake to support survival of oyster spat. In the small chance that reef is found, it would be small and localized and easily avoided by changing the access route at borrow area configuration. The common Sabine Lake circulation pattern is expected to prevent the development of hypoxic conditions in the borrow trench and transport Sabine River sediment to eventually fill the trench. Construction of the Black Bayou mitigation areas would use material from regular maintenance dredging of the Sabine River Channel and approximately 18 feet of material that has accumulated since construction of the 30-foot Lake Charles Deepwater Channel. The latter coincides with the Gulf Intracoastal Waterway between the Sabine River and Lake Charles, Louisiana. One-time impacts of both dredging operations would include a temporary increase in turbidity and short-term loss of benthic fauna. These mitigation areas would fully compensate impacts of the Preferred Alternative to the biological productivity of marshes in the affected area. The dredging activities needed to construct the mitigation areas are expected to have a net beneficial effect and cause no long-term impacts to biological resources and estuarine aquatic habitats. Long-term benefits of a higher, more-stable marsh in the mitigation areas would more than offset short-term impacts to turbidity and benthic organisms.

Wildlife

Direct impacts to wildlife from implementation of the Preferred Alternative include dredging impacts to bottom-feeding and pelagic organisms such as sea turtles, loss of habitat from one new placement area, and temporary impacts to shorebirds and their habitat from the regular placement of maintenance material on the Gulf shoreline. Indirect impacts to wildlife related to dredging and placement activities include a reduction of shorebird food supply from short-term increases in turbidity, risk of oil, chemical, or other hazardous material spill during construction, and temporary noise disturbances. However, beneficial uses of dredged material resulting in additional marsh habitat and beach nourishment would provide additional habitat for wildlife in the area.

Threatened and Endangered Species

Hopper dredging of the Entrance Channel is likely to adversely affect but not jeopardize the continued existence of loggerhead, Kemp's ridley, hawksbill, and green sea turtles. In the Biological Opinion (BO), the NMFS authorized the incidental lethal take of four sea turtles and identified reasonable and prudent measures to be adopted during construction. Potential impacts to sea turtles from maintenance dredging are covered by the Gulf Regional BO for USACE's dredging activities. Critical Habitat for wintering

piping plovers is present in the Louisiana portion of the Gulf Shore BU Feature. The U.S. Fish and Wildlife Service (USFWS) has concurred that the BU feature may affect, but is not likely to adversely affect, the species or its Critical Habitat because the Gulf Shore BU Feature would protect existing Critical Habitat. No other adverse effects to threatened and endangered plant or animal species have been identified.

Cultural Resources

While no specific impacts to historic properties have been identified at this time, the Preferred Alternative has the potential to adversely affect significant historic properties because numerous prehistoric and historic sites, structures, and shipwrecks are present in the project vicinity. A Historic Properties Programmatic Agreement has been negotiated and executed with the Texas and Louisiana State Historic Preservation Officers to ensure that significant historic properties are identified and mitigation, if necessary, is completed prior to project construction.

Socioeconomic Resources

Potential impacts to socioeconomic resources from the Preferred Alternative are not expected to be significant. Small changes in population growth are expected to occur as a result of the proposed CIP, and no disproportionately high or adverse impacts are expected to occur to minority or low-income persons. Development is likely to continue at the current rate resulting in no impacts to community values or housing in the study area, although land use patterns along the SNWW may change slightly in response to channel improvements. No negative impacts to the local economy are anticipated as a result of the Preferred Alternative, and the types of employment opportunities available in the area are not expected to change from current trends. No negative impacts are expected to occur to recreational resources or aesthetics within the study area.

Cumulative Impacts

Several past, present, and reasonably foreseeable future actions within the study area were identified for inclusion in the cumulative impacts analysis. Resources considered in the analysis included biological, ecological, physical, chemical, cultural, and socioeconomic resources for projects within the SNWW study area. Cumulative impacts from past, existing, and reasonably foreseeable projects, along with the Preferred Alternative, are not expected to have significant adverse effects within the study area. Impacts associated with the Preferred Alternative have been avoided or minimized by DMMP BU features or fully compensated by mitigation.

ES.5 AREAS OF CONTROVERSY AND UNRESOLVED ISSUES

USACE has evaluated the proposed SNWW CIP for consistency with the Louisiana coastal management program, and concluded that the Recommended Plan is fully consistent to the maximum extent practicable with the enforceable policies of the state's coastal management program. The Louisiana Department of Natural Resources (LDNR), Office of Coastal Management (OCM), found that the

SNWW CIP is conditionally consistent with their state program. Since conditional consistency as proposed by LDNR-OCM is not acceptable, LDNR-OCM has been notified that USACE will proceed with the project. This issue is discussed in detail in Section 6.0.

USACE coordination with the Louisiana Department of Wildlife and Fisheries (LDWF) has not been able to resolve issues related to the offset of project impacts to Federal lands with benefits from BU features in Texas, Louisiana Department of Wildlife and Fisheries (LDWF) requirements that the Recommended Plan include additional BU features, and royalty, license, and further assessment requirements concerning areas in Sabine Lake that would be affected by the removal of fill material for use in marsh mitigation. USACE has proposed that an assessment survey be completed, following the protocol established by LDWF, during the preconstruction, engineering, and design phase of the SNWW CIP.

In order for the four new ODMDSs to be approved for use, the EPA must publish a final rulemaking in the Federal Register. An FEIS for the proposed ODMDS and a Final Site Management and Monitoring Plan have been prepared and accepted by EPA for use in this rulemaking at a later date (Appendix B of the FEIS).

Coordination is ongoing with the Texas Point and Sabine National Wildlife refuges regarding construction activities related to the Gulf Shore BU Feature and proposed compensatory mitigation measures. The USFWS must determine whether these activities are compatible with the purposes of the refuges.

Issues related to hazardous materials in PA 17 (a capped landfill and other waste disposal areas within the PA) must be resolved by the non-Federal sponsor before the PA can be used as part of the Preferred Alternative. Alternative placement areas are available should PA 17 not be available for use.

ES.6 RELATION TO ENVIRONMENTAL REQUIREMENTS

The Preferred Alternative is in full compliance with the environmental requirements applicable to this stage of the planning process. A discussion of the applicable laws can be found in Chapter 7 of the FEIS.

1.0 NEED FOR AND OBJECTIVES OF ACTION

This chapter is divided into seven sections. Section 1.1 provides information on study authorities, project sponsors, cooperating agencies, and the location of the proposed project. Section 1.2 explains the purpose for, and need of, the proposed project, and Section 1.3 describes the existing project. Section 1.4 summarizes problems, needs, and concerns expressed by the public, resource agencies, and local governments at scoping meetings early in the study. Section 1.5 identifies planning objectives for the feasibility study, and Section 1.6 describes the resource agency coordination process and team. The chapter concludes in Section 1.7 with a description of resource management opportunities for dredged material.

1.1 STUDY AUTHORITY AND LOCATION

The Senate Committee on Environment and Public Works Resolution, dated June 5, 1997, authorized the U.S. Army Corps of Engineers (USACE) to review previous USACE reports on the Sabine-Neches Waterway and other pertinent reports to determine the feasibility of modifying the channels serving the Ports of Beaumont, Port Arthur, and Orange, Texas, in the interests of commercial navigation. These channels are collectively named the Sabine-Neches Waterway (SNWW). The Jefferson County Navigation District (JCND), non-Federal sponsor of the existing channels to Beaumont and Port Arthur, requested that the USACE initiate a reconnaissance study of potential channel improvements in September 1998. The reconnaissance investigation resulted in a finding that there was a Federal interest in the project and recommended that the study be continued into the feasibility phase. The JCND expressed its intent to act as the non-Federal sponsor for this phase of the study. The Final Feasibility Report (FFR) for the Sabine-Neches Waterway Channel Improvement Project (SNWW CIP) will determine whether improvements to the existing Federal navigation project are justified, and provide documentation needed to request Congressional authorization and funding for construction of the project. The Sabine River Channel to Orange, Texas, was not included in this FFR due to expectations of continued low utilization of the existing 30-foot channel. In 2002, the JCND was renamed the Jefferson County Waterway and Navigation District (JCWND), and in 2007, the JCWND was renamed the Sabine Neches Navigation District (SNND); the latter designation is used throughout the remainder of this document.

In March 2000, USACE and JCND signed an agreement to prepare an FFR and a Final Environmental Impact Statement (FEIS) for the proposed CIP. The lead agency for the FEIS is the USACE, with several cooperating agencies (Appendix A1). The U.S. Environmental Protection Agency (EPA) has agreed to be a cooperating agency for purposes relating to its authority to designate Ocean Dredged Material Disposal Sites (ODMDSs). The ODMDS FEIS, attached as Appendix B, provides the environmental analysis and public review required for subsequent EPA site designation. The National Marine Fisheries Service (NMFS), U.S. Fish and Wildlife Service (USFWS), Texas General Land Office (GLO), and Louisiana Department of Wildlife and Fisheries (LDWF) have agreed to be cooperating agencies with participation limited to meetings, teleconferences, and report review. The cost of the FFR and FEIS is shared by the USACE and the JCND.

The SNWW is located on the upper Texas Gulf Coast at the Texas-Louisiana state boundary (Figure 1.1-1). Sabine Pass, Sabine Lake, and the Sabine River together form the southern section of the boundary between the two states. The area surrounding the waterway is generally referred to as the “Golden Triangle,” which refers to the metropolitan area’s three major cities and their ports—Beaumont, Port Arthur, and Orange, Texas. The “Golden” refers to the wealth that came from the Spindletop oil strike in Beaumont in 1901. Several smaller cities also are located in the Golden Triangle, including Nederland, Port Neches, Groves, Bridge City, Vidor, and the City of Sabine Pass.

The project area is defined as those areas that will be directly affected by construction of the CIP, i.e., the proposed dredging footprint, existing and proposed placement areas (PAs) identified in the Dredged Material Management Plan (DMMP), and mitigation areas. The CIP refers to proposed plans for navigation improvements. Details of the Preferred Alternative for these improvements are provided in Section 2.4.

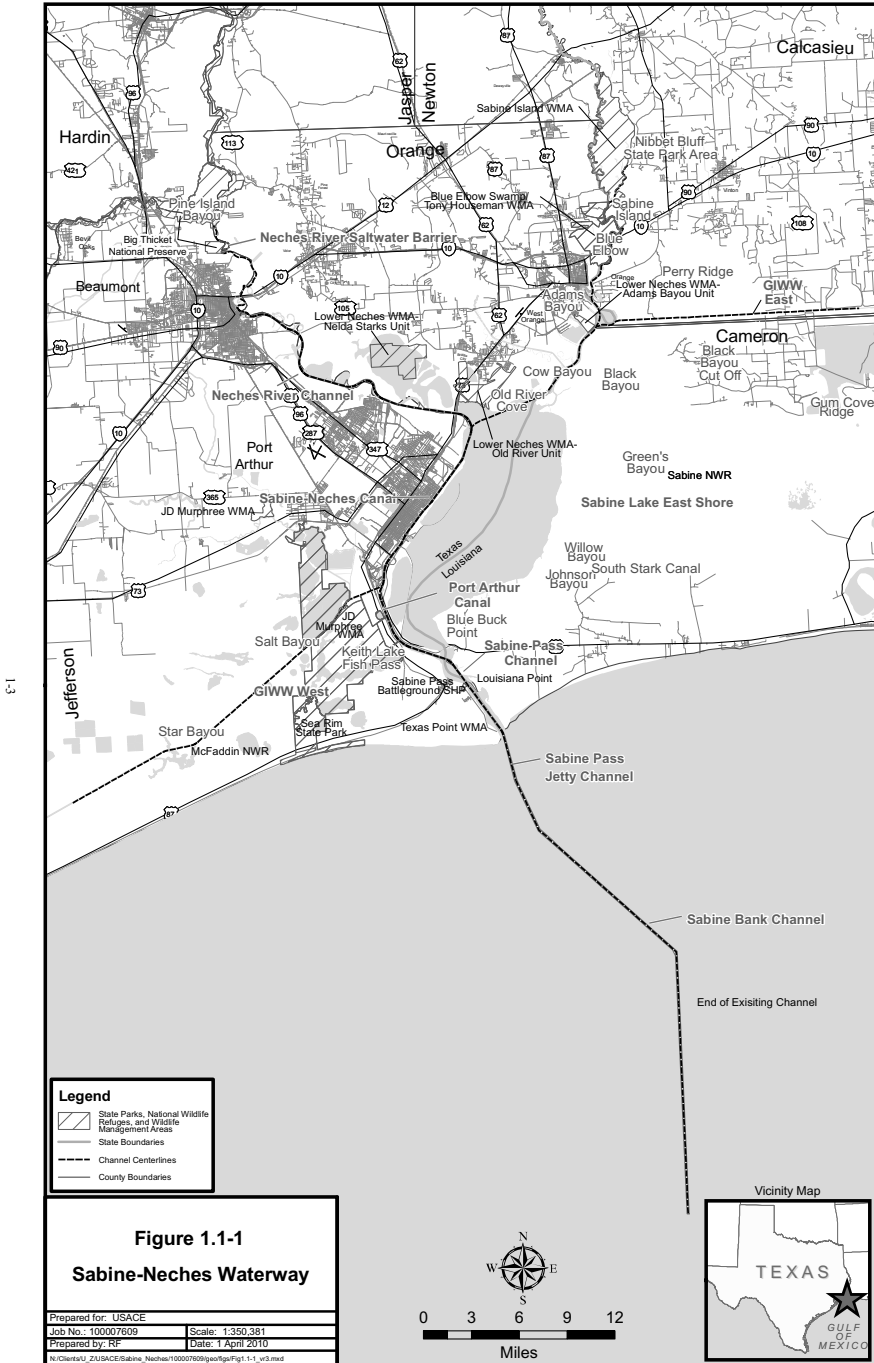

The study area includes a larger area for which environmental effects of alternatives have been analyzed (Figure 1.1-2). The study area encompasses a 2,000-square-mile area that contains the smaller project area and includes the following waterbodies and adjacent coastal wetlands: Sabine Lake and adjacent marshes in Texas and Louisiana, the Neches River Channel up to the Neches River Saltwater Barrier, the Sabine River Channel to the Sabine Island Wildlife Management Area (WMA), the Gulf Intracoastal Waterway (GIWW) west to Star Bayou, the GIWW east to Gum Cove Ridge, the Gulf of Mexico (Gulf) shoreline extending to 10 miles either side of Sabine Pass, and 35 miles offshore into the Gulf.

1.2 PURPOSE AND NEED

The purpose of the proposed CIP is to improve the transportation efficiency of the SNWW’s deep-draft navigation system, while protecting the quality of the area’s coastal and estuarine resources. Channel improvements are needed to support the SNWW’s critically important role in the Nation’s economy. In 2007, the SNWW ranked 4th in the Nation in total tonnage, importing 141 million short tons (Institute of Water Resources-Waterborne Commerce of the U.S. [IWR-WCUS], 2007). Individually, the Port of Beaumont ranked 5th nationally for domestic and total tonnage, and the Port of Port Arthur ranked 28th in the Nation (IWR-WCUS, 2007).

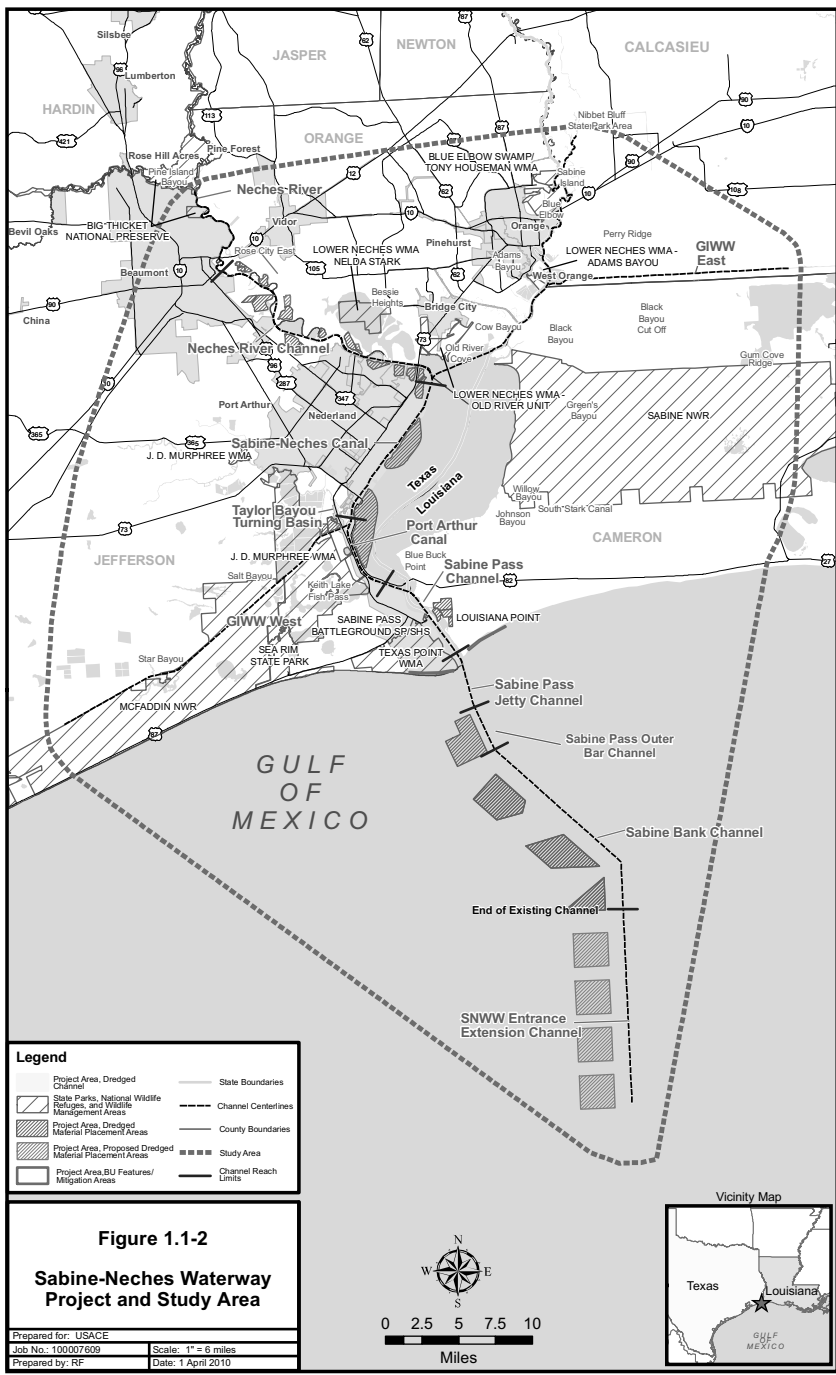

The Port of Beaumont’s public docks are located on the Neches River Channel, as well as several crude petroleum and product terminals. Port Arthur’s general cargo facilities are located on the Sabine-Neches Canal, and its crude petroleum and product terminals are located in the Taylor Bayou Basins. The Taylor Bayou Basins are located immediately south of Port Arthur at the junction of the Sabine-Neches Canal with the GIWW. In addition to its deep-draft traffic, the Sabine-Neches Canal serves as a through channel for shallow-draft barge traffic on the GIWW.

Sixty percent of the SNWW tonnage total comprises deep-draft movements, and the remaining 40 percent is shallow-draft GIWW traffic. There are 20 waterfront facilities in Port Arthur and 27 in Beaumont that receive and/or ship crude petroleum or petroleum/chemical products, making up the vast majority of

(This page left blank intentionally.)

(This page left blank intentionally.)

deep-draft movements on the waterway. The SNWW refineries also supply crude oil to the U.S. Department of Energy's "Big Hill Site" in Texas and the "Hackberry Site" in the Louisiana Strategic Petroleum Reserve. The waterway is the primary means of delivery for crude oil to four major refineries in Beaumont and Port Arthur. Domestic refineries on the Gulf Coast, the East Coast, and in the Midwest rely on the SNWW for 12 to 16 percent of waterborne crude oil deliveries (Martin Associates, 2006). Refined petroleum products are shipped from the SNWW via three major pipeline systems to 21 states east of the Rockies, including states as far away as Delaware, New Jersey, and Indiana. Other significant commodities and break bulk cargoes that are handled by the SNWW ports include petroleum coke, ammonia, sulphuric acid, metallic salts, liquid sulphur, bulk grain, manufactured iron and steel products, limestone, sand and gravel, and liquefied natural gas (LNG).

The SNWW's crude petroleum imports represent 4 percent of the U.S. total and 7 percent of the U.S. Western Gulf Coast region. From 1992 through 2005, crude petroleum imports on the SNWW grew at a 7.0 percent compound annual rate, compared to a 3.6 percent growth rate for the U.S. as a whole. Overall, commodity and breakbulk tonnage for the SNWW ports has also increased over this period. Grain exports have increased marginally since the middle 1990s, and Beaumont's 2005 to 2007 wheat exports represent 5 percent of the U.S. total. The waterway imported 14 percent of 2005 to 2007 U.S. pulp and waste paper products. Approximately 10 percent of 2005 to 2007 U.S. fertilizer and fertilizer mixes were exported from Beaumont.

During the early 2000s, permits were approved for Cheniere Energy's Sabine Pass, Exxon-Mobil's Golden Pass, and Semptra's Port Arthur LNG terminals. Construction of the Sabine Pass terminal was completed in April 2008 and operations began in April 2008. The Golden Pass LNG terminal was scheduled for completion in mid-2010 but has been delayed due to Hurricane Ike cleanup activities. Construction of the permitted Port Arthur facility is dependent upon the finalization of commercial arrangements. The SNWW LNG facilities are located in the Sabine Pass Channel and Port Arthur Canal; these reaches are presently 500 feet wide and would remain so in the without-project future. LNG vessels using the SNWW would be subject to strict U.S. Coast Guard (USCG) regulations and to local pilot rules, and all LNG vessel movements would be subject to one-way traffic. Since the Sabine Pass terminal opened, throughput has been low due to increased demand in other parts of the world. Long-term expectations are for prices to stabilize and shipments to the U.S. to increase, as LNG is expected to play an increasingly important role in the natural gas industry and global energy markets in the near and long-term future. The U.S. Energy Information Administration has raised its projections for LNG imports in 2009, citing falling demand elsewhere as new global production comes online.

The existing SNWW navigation channel system is congested. The existing 40-foot project depth was designed to efficiently and safely accommodate much smaller vessels than are being used today. The current 40-foot channel was completed in the late 1960s, and at that time, crude oil tankers averaging 40,000 dead weight tons (DWT) with loaded drafts of 36 feet were common. Vessels over 90,000 DWT are now used routinely for crude oil imports to both Beaumont and Port Arthur. In addition to larger vessels, the amount of vessel traffic on the SNWW has also increased. Both the SNWW and U.S. crude oil imports have risen steadily since the 1970s. The SNWW's 2002 to 2006 crude petroleum waterborne

imports comprised 12 percent of U.S. and 18 percent of Western Gulf Coast imports. The SNWW capacity presently represents 6 percent of the U.S. total. The SNWW capacity levels for 2009 were 12 percent higher than in 2004, and 31 percent higher than in 1994. Recent increases in the SNWW refinery capacity indicate that the region will gain an increasing share of U.S. totals.

With the current channel depth, there are draft restrictions on large vessels currently utilizing the channel. A majority of the tonnage carried on the SNWW is in deep-draft vessels, and the vast majority of the deep-draft traffic is composed of crude oil and petrochemical products. However, LNG, grain, and aggregate products, such as iron ore, steel slab, limestone, sand, and gravel, are also carried in draft-constrained deep-draft vessels. Currently at the SNWW, very large crude carriers transfer tonnage at an offshore location onto one or more shuttle vessels in a process called lightering. These very large carriers cannot enter the SNWW because of their size and draft. In addition, other large crude tankers presently offload a partial load offshore to a shuttle vessel or vessels, a process called lightening. These vessels then enter the SNWW with the shuttle vessels as they are small enough to navigate the SNWW with a lighter load.

The SNWW experienced strong growth over the past decade, with total tonnage increasing from an average of 102 million short tons for 1994 to 1996 to 141 million for 2004 to 2006. As imports have increased, the number of lightering and lightened vessels and product carriers has also increased, adding to shipping delays and congestion. The total number of inbound vessels on the SNWW is projected to increase in the short term at rates comparable to or higher than regional and national trends. Recent increases in the SNWW refinery capacity indicate the region will regain an increasing share of U.S. totals.

Ships are not only requiring deeper drafts, but the sizes of the vessels are wider. The vessel beams of both Port Arthur's and Beaumont's vessels cause them to be regularly impacted by the present 500-foot width of the Sabine Pass Jetty Channel and Port Arthur Canal. The most common crude oil tankers unloading at the Taylor Bayou Basins have design drafts of 45 feet and beams of approximately 124 feet. Tankers using the Taylor Bayou Basins are smaller than those offloading at terminals on the Neches River Channel because existing width at the mouth of Taylor Bayou, and the configuration of the docks within Taylor Bayou, limits the allowable vessel size. The maximum size vessels unloading at Port of Beaumont facilities on the Neches River Channel are approximately 900 feet long, with a beam width of 164 feet.

The Sabine Pilots Association has adopted transit rules to deal with the narrow channel, and these rules result in navigation constraints. These constraints include daylight-only and one-way sailing restrictions in specific reaches. The main restrictions place limitations on the combined beam widths and drafts for vessel meetings on the waterway. A major restriction is that vessels with combined beam widths in excess of 50 percent of the channel width cannot meet. The effects of these and other navigation restrictions cause significant delays along the waterway.

As a result of these rules, inbound vessels intending to use a specific dock must wait offshore until the outbound vessel at that dock sets sail, resulting in considerable delays because of the length of the inshore channel. In addition, vessels are now wider due to new double-hull requirements and to industry changes

to wider but shorter vessels, which makes vessel-meetings more difficult. The probability of accidents and other safety problems may increase with increases in both inland barge and deep-draft vessel traffic along the waterway. Channel deepening and additional turning and anchorage basins on the Neches River Channel could alleviate some of these congestion problems by permitting existing vessels to carry more cargo into port and reduce offshore vessel waiting times.

Congestion is increased during times when the SNWW serves an important military function. One of the busiest ports for military cargo in the world is located on the SNWW. The Port of Beaumont is the Nation's busiest Strategic Port of Embarkation, and it is the second largest commercial military out-load port worldwide. For the war in Iraq, it has handled approximately one-third of all the military cargo deployed to and from the war, which is more military cargo than any other U.S. port (Military Surface Deployment and Distribution Command, 2004, 2006). The SNWW must accommodate the military's increased use of newer and larger transport ships, which are three times the size of transport ships used in 1990. The SNWW contributes to national security in one other key aspect. Two terminals on the Neches River are connected by pipelines to underground storage facilities of the U.S. Department of Energy's Strategic Petroleum Reserves at Big Hill, Texas, and West Hackberry, Louisiana.

The need for improvements to the SNWW must be weighed against possible effects to significant environmental resources. The study area contains approximately 480 square miles of sensitive coastal habitats, which have experienced a high rate of wetland loss in recent decades. In Louisiana, a net land loss of 18 percent between 1978 and 2000 has been reported in the western Chenier Plain. In Texas, the most extensive losses of interior coastal wetlands in the state have occurred in the Neches River delta. Ninety percent of the emergent marshes in the Lower Neches River delta have been converted to open water, which is more than half of the total wetland loss in the State of Texas. These high land-loss rates provide opportunities for wetland restoration with the beneficial use of dredged material.

1.3 EXISTING PROJECT

The existing 40-foot SNWW project is a federally authorized and maintained waterway located in Jefferson and Orange counties, Texas, and Cameron and Calcasieu parishes, Louisiana (see Figure 1.1-1). However, the Sabine River Channel segment of the SNWW, which provides deep-draft access to the Port of Orange, is not included in the FFR. All subsequent references to the SNWW in this report focus on the 64-mile-long channel flowing through Jefferson and Orange counties, Texas, and Cameron Parish, Louisiana. The SNWW begins offshore, follows the west side of Sabine Lake and terminates just upstream of the Beaumont Turning Basin on the Neches River.

The SNWW is a system of widened and/or deepened channels (Table 1.3-1). Working inland from the Gulf, the reaches are (1) Sabine Bank Channel, (2) Sabine Pass Outer Bar Channel, (3) Sabine Pass Jetty Channel, (4) Sabine Pass Channel, (5) Port Arthur Canal, (6) Sabine-Neches Canal, and (7) Neches River Channel. The Sabine Bank through the Sabine Pass Jetty channels is sometimes referred to collectively as the Entrance Channel. The only connection with the Gulf is Sabine Pass, a long narrow pass, through which all tidal interchange occurs. The East and West Jetties extend approximately 4.1 miles into the

Gulf. They stabilize the Pass and provide protection for ships entering the landlocked channel. Maintenance material is placed in 16 upland confined PAs and 4 ODMDSSs in the Gulf. The FFR and DMMP (Appendix D) provide more-detailed descriptions and maps of the existing navigation channels and PAs.

Table 1.3-1
Existing SNWW Channel Dimensions

Channel Reach	Authorized Depth (feet)	Bottom Width (feet)	Length (miles)
Sabine Bank Channel	42	800	14.7
Sabine Pass Outer Bar	42	800	3.4
Sabine Pass Jetty Channel	40	800–500	4.0
Sabine Pass Channel	40	500–1133	5.6
Port Arthur Canal	40	500–1788	6.2
Sabine-Neches Canal	40	400–1060	11.3
Neches River Channel	40	400	18.6

In addition to deep-draft traffic, the SNWW serves as a through-channel for the shallow-draft GIWW. As it leaves Louisiana, the GIWW connects with the SNWW, approximately 3 miles below Orange, Texas, and follows the Sabine River Channel to Sabine Lake. The GIWW and Sabine River Channel cross the north end of Sabine Lake where they merge with the Sabine-Neches Canal at the mouth of the Neches River. The GIWW and Sabine-Neches Canal coincide through the confined channel reach between Pleasure Island and Port Arthur, where the GIWW connects with the Port Arthur Canal and exits the SNWW, continuing westward to Galveston Bay.

1.4 PROBLEMS, NEEDS, AND PUBLIC CONCERNS

To be responsive to the needs and concerns of all stakeholders and to ensure public involvement through an open, interactive process, the USACE and SNND developed a public involvement plan to be used during the feasibility phase of the SNWW CIP. The public outreach program was initiated in 2000 and included the following efforts:

- scoping meetings;
- public environmental restoration and beneficial use workshops;
- media trips;
- presentations at the Gulf of Mexico Fishery Management Council (GMFMC) Texas Habitat Protection Advisory Board;
- presentations at Southeast Texas Waterways Advisory Council (SETWAC) regular meetings;
- meetings with Sabine Pilots Association;
- presentation at the SETWAC 2007 meeting;
- meetings with SNWW industries; and

- public hearings.

A Notice of Intent to prepare a “Draft Environmental Impact Statement for Improvements to the Sabine-Neches Ship Channel Near Beaumont and Port Arthur, Texas” was published in the *Federal Register* (FR) on May 21, 2002 (67 FR 98:35801). Additionally, coordination with resource agencies was conducted through 11 meetings of the Interagency Coordination Team (ICT) and 30 technical working group meetings. More information about the ICT membership and activities is in Section 1.6. Detail about public outreach, meeting comments, and the ICT meetings and workshops can be found in Appendix A.

Existing water resource problems and needs in the study area were identified through coordination with Federal, State, and local agencies; area residents; waterway users; and the USACE and SNND. It should be noted that numerous concerns were raised during the public scoping meetings, letters received in response to those meetings, and a series of workshops with local public agencies and private organizations. The major issues and concerns identified through this process are discussed below. Summaries of the scoping meetings and copies of public comment letters are provided in Appendix A5. Some issues do not apply to the proposed CIP or are general concerns raised by the citizens of the area; these cannot be addressed in a project-specific FEIS. However, all of the concerns that are associated with the proposed CIP are addressed in this FEIS.

1.4.1 Navigation/Commerce

Waterway users are concerned that future increases in the Nation’s dependence on imported oil and the SNWW’s growing share of the import market will compound existing problems with transportation efficiency. The current 40-foot channel was completed in the late 1960s and, at that time, crude oil tankers averaging 40,000 DWT with loaded drafts of 36 feet were common. Vessels over 90,000 DWT are now used routinely for crude oil imports to both Beaumont and Port Arthur. Mother vessels in the 120,000 to 150,000 DWT range presently offload a partial load at the offshore lightering zone and then enter the SNWW along with the shuttle vessel. As imports have increased, the number of lightering vessels and product carriers has also increased, adding to shipping delays and congestion.

The existing narrow channel width creates congestion and transportation inefficiencies, resulting in potential problems with safety. Vessels are now wider due to new double-hull requirements and to industry changes to wider but shorter vessels. Wider vessels make meetings more difficult and, therefore, more dangerous. The SNWW is currently subject to transit rules, which are needed for the Sabine Pilots Association to safely guide large deep-draft tankers through the narrow channel. Increases in both inland barge and deep-draft vessel traffic along the waterway are expected to increase overall congestion and result in an increase in the likelihood of accidents. Historically, accidents on the SNWW are very low, due in large part to the existing pilot rules that minimize the probabilities of incidents involving deep-draft vessels. In 2006, two-thirds of the incidents involved shallow-draft tow transits. Overall, the ratio of incidents per transit was 1 percent or less for all transit types. Recently, installation of the Port Arthur vessel traffic service (VTS) is expected to reduce potential interactions between deep- and shallow-draft vessels.

It is believed that ship traffic through interior channel reaches contributes to existing shoreline erosion, and it is feared that a deeper channel will increase that erosion. Existing erosion is most severe along the Port Arthur and Sabine-Neches canals where the SNWW passes through a narrow, confined channel between Pleasure Island and Port Arthur. There is concern that a deeper channel would allow larger or more heavily laden vessels to use the waterway and cause additional erosion of channel shorelines.

The evaluation of alternatives other than a deeper navigation channel was urged in several comments. Suggestions included construction of a new port and pipeline terminal at the City of Sabine Pass. Others suggested that an offshore terminal similar to the Louisiana Offshore Oil Port (LOOP) be constructed. Both of these alternatives would avoid environmental impacts associated with channel improvements to the inland Port of Beaumont. It was also suggested that safety issues could be addressed by a vessel tracking and management system, rather than channel improvements.

1.4.2 Environmental

The primary environmental concern is the potential for the proposed CIP to increase saltwater intrusion and for higher salinity levels to further degrade marshes and cypress swamps in both Texas and Louisiana. The combined effects of subsidence and sea level rise (called relative sea level rise, or RSLR) are expected to increase the stress on existing marshes and worsen this trend. The public and resource agencies have identified severely stressed marsh areas at Texas Point and Salt Bayou in the Sabine Pass area, in the Neches River reach between Sabine Lake and Interstate Highway (IH) 10, and in the extensive marshes east of Sabine Lake. Marshes have been dying, due in large part to the combined effects of altered sediment delivery, saltwater intrusion, subsidence, and global sea level rise. Wetland loss results when sub-optimal salinities decrease biological productivity of marsh vegetation, leading to a decrease in organic matter accumulation, which, in turn, results in greater submergence because the rate of increase in marsh elevation cannot keep up with the rate of submergence due to RSLR (Day and Templet, 1989; Day et al., 1995; DeLaune et al., 1994; Nyman et al., 1993; Spalding and Hester, 2007). The death of wetland vegetation often results, followed by peat collapse, erosion, and wetland loss (DeLaune et al., 1994; Gough and Grace, 1999; Salinas et al., 1986; Visser et al., 1999; Webb and Mendelssohn, 1996). Cumulative effects of hydrologic alterations are also a concern, given that the existing project is believed to have contributed significantly to current wetland losses. Potential effects of increased salinities on cypress-tupelo swamps and bottomland hardwoods on the Neches and Sabine rivers at the upper margins of the study area have also been identified as significant potential impacts.

An associated issue is the deterioration of wildlife habitat and fishery nursery areas and the destruction of fish and wildlife resources that could occur as a result of increased wetland loss. Persistent emergent vegetation provides foraging, resting, and breeding habitat for a variety of coastal fish and wildlife species. Detritus from coastal marshes also provides a source of mineral and organic nourishment for organisms at the base of the food chain. The potential for proposed CIP impacts to oyster reef at Blue Buck Point at the mouth of Sabine Lake was also identified.

All or portions of the following federally and State-protected lands contain sensitive habitats that may be affected by the proposed CIP: the Sabine National Wildlife Refuge (NWR), the McFaddin NWR, the Texas Point NWR, the J.D. Murphree WMA, the Lower Neches WMA, the Tony Houseman WMA, and the Sabine Island WMA.

Potential impacts to threatened and endangered species are a concern, particularly dredging impacts to endangered sea turtles. The offshore channel deepening and extension will require the use of hopper dredges, which create particular hazards for sea turtles. Critical Habitat for the wintering piping plover is present in the study area.

Concern has been expressed that the proposed CIP could increase tidal amplitude and increase damage during storm surges by allowing the surge to inundate areas that have not been affected by previous storms. Potential for increased Gulf shoreline erosion is also a concern. In recent years, high shoreline erosion has caused substantial wetland losses on the Gulf shoreline from Texas Point westward to the vicinity of Sea Rim State Park.

The public has also expressed concern that dredging for the proposed CIP and the placement of dredged material will spread contaminated sediments or affect water quality. It is feared that new work dredging will release contaminants from past industrial discharges into the water column, or that areas selected for the beneficial use of dredged material could be polluted.

The beneficial use of dredged material to restore degraded marshes was encouraged by the public and resource agencies. The following sites were specifically identified as areas that could benefit: Rose City marsh, Bessie Heights marsh, Keith Lake marsh, marshes in the McFaddin NWR, east Sabine Lake marshes, and the Gulf shoreline at Texas Point and Holly Beach. Construction of a bird island in Sabine Lake was also suggested. The beneficial use of dredged material would reduce the need for new or expanded PAs and reduce potential wetland impacts.

The proposed CIP, including the Gulf ODMSs, could impact Essential Fish Habitat (EFH) for red drum; brown, white, and pink shrimp; Spanish mackerel; and estuarine water column and mud/sand bottoms. Potential effects to nursery and foraging habitat for economically important marine fishery species such as spotted sea trout, flounder, Atlantic croaker, black drum, Gulf menhaden, striped mullet, and blue crab also need to be evaluated for adverse effects associated with proposed water control structures.

It was suggested that environmental impacts as a consequence of the proposed CIP should be avoided if possible. A lock at Sabine Pass, a sill or constriction at the mouth of Sabine Lake, and smaller water control structures in the marshes east of Sabine Lake were suggested as methods to minimize or avoid impacts. Conversely, other comments warned of the potential harmful effects of water control structures that inhibit the movement of marine organisms into and out of intertidal marshes.

1.4.3 Socioeconomic

The Ports of Port Arthur and Beaumont expressed concern over the socioeconomic effects of not improving the SNWW. Both are concerned that the SNWW is close to reaching its capacity for vessel traffic movement. It was urged that direct and indirect economic and social benefits of the SNWW be fully evaluated.

Considerable concern was expressed by government agencies in Louisiana that the proposed CIP would have adverse effects on their state's environment while providing no economic benefits for Louisiana. Officials at the West Calcasieu Port, Harbor, and Terminal District urged that navigation improvements be evaluated on a regionwide basis, because channel improvements in Texas could put their facilities and the Port of Lake Charles at a competitive disadvantage. Cameron Parish officials expressed support for economic development that would benefit their constituents. Cameron Parish officials were also concerned that lands suitable for commercial development at Sabine Pass were being considered for use as PAs. Developable lands are limited on the Louisiana side of the SNWW, and all are needed to promote economic development.

Jefferson County Drainage District #7 expressed concern that channel widening and deepening could affect the structural integrity of the Port Arthur Hurricane Protection Levee, pump stations, and closure structures. The Texas Department of Transportation (TxDOT) expressed concern that increased erosion could adversely affect State Highways (SH) 82 and 87. Both are located immediately adjacent to the SNWW and are affected by present channel bank erosion. Additional erosion of SH 87 could destroy the only road access to the City of Sabine Pass.

The high concentration of petrochemical refineries and terminals in the study area means that a large number of pipelines are also present. Local industries are concerned that these pipelines will be affected by the proposed channel deepening and that they will be responsible for the cost of moving these pipelines to accommodate the deeper channel.

Socioeconomic impacts on commercial fisheries are also a concern. A small, commercial shrimp fleet operating out of Sabine Pass could be adversely affected if the proposed CIP adversely affects EFH. There is also a concern that environmental impacts could adversely affect sport fishing, which is a popular activity throughout the study area.

Several members of the general public expressed concern that the cost of this project will be large, that benefits will not be sufficient to outweigh costs, and that costs will be passed on to taxpayers in the form of higher taxes.

1.4.4 Historic Properties

There is concern that use of PA 5 will adversely affect public access to the Sabine Lighthouse, a National Register property. A road around the perimeter of the PA is currently the only access route to the Lighthouse. Changes or enlargements to this PA could limit or remove access to this historic property.

Concern has also been expressed about the potential for proposed CIP improvements to affect the Sabine Pass Battleground Park, Fort Griffin, and associated shipwrecks. These sites and shipwrecks are associated with important battles during the U.S. Civil War.

1.5 PLANNING OBJECTIVES

The planning objectives of the proposed CIP include improvement in the efficiency of the deep-draft navigation system and maintaining the ecological values of the area's coastal and estuarine resources. Economic efficiency would result from the passage of more fully loaded ships, a reduction in the need for lightering and lightening, and a decrease in vessel delays. Protection of the area's coastal and estuarine resources would result from the beneficial use of dredged material and full compensation for unavoidable environmental effects.

1.6 INTERAGENCY COORDINATION TEAM

An ICT comprising the Federal and State resource agency representatives from Louisiana and Texas was established at the beginning of the study to advise the USACE on matters related specifically to the environmental impact review. ICT agencies and representatives are listed in Table 1.6-1. Agencies were asked to designate one official member who was authorized to speak for the agency and make decisions in the group format. Representatives from other local and State agencies or governments also participated in the ICT in an advisory capacity: Jefferson and Orange counties, Texas; Cameron and Calcasieu parishes, Louisiana. The USACE ICT members ensured that decisions were made within the framework of the USACE planning process and in compliance with Federal law and policy, including guidance such as Planning in a Collaborative Environment (Engineer Circular [EC] 1105-2-409) and the Environmental Principles (Engineer Regulation [ER] 200-1-5). Insofar as was possible, given the USACE planning, policy, and schedule constraints, important decisions related to identifying and studying potential ecological impacts, and identifying alternatives for compensatory mitigation were made by consensus within the ICT. Toward the end of the planning study, remodeling and reanalysis were conducted by the USACE to incorporate the effects of a revised plan of navigation improvements, the projected future rate of RSLR, and future freshwater inflows. Because of schedule constraints, this modeling was performed without ICT consultation. However, the results of this reanalysis were coordinated with the ICT, and no changes in the recommended ecological mitigation plan resulted from the remodeling and reanalysis.

Technical work addressing specific environmental concerns or planning objectives was done by several smaller workgroups whose members were taken from the ICT. Each of these workgroups and its purpose is discussed separately below.

- The Restoration and Beneficial Uses Workgroup (RW) was created to develop ideas for ecosystem restoration and the beneficial use of dredged material in the study area. Although ecosystem restoration is not a study purpose, ideas for potential restoration projects were explored by this workgroup. The RW also reviewed suggestions provided during the public workshops for this purpose (Gulf Engineers and Consultants, Inc. [GEC], 2002).

- The Hydrodynamic and Salinity Modeling Workgroup (MW) provided data to assist the hydrodynamic salinity (HS) modeling and verification process and reviewed modeling results as part of the impacts evaluation. The modeling was conducted by the USACE's Engineer Research and Development Center (ERDC), reported in Brown and Stokes (2009).
- The Contaminants Workgroup (CW) evaluated water and sediment quality associated with the proposed CIP, including characterization of existing conditions in the project area and the results of physical and chemical analyses conducted. This evaluation is reported in PBS&J (2004a, 2004b).
- The ODMDS Workgroup (OW) was created to advise in the preparation of the Site Designation FEIS for the proposed ODMDSs. The OW reviewed existing data, recommended additional studies, reviewed the results of physical, chemical, and biological analyses, and reviewed the ODMDS FEIS, which is attached to this FEIS as Appendix B.
- The Habitat Evaluation Workgroup (HW) reviewed and classified existing habitat, performed field evaluations to document existing conditions, and developed and applied procedures for the prediction of without and with-project conditions using the Wetlands Value Assessment (WVA) ecological model. The HW also reviewed results of the ecological modeling and report, which is provided as Appendix C to the FEIS.

1.7 RESOURCE MANAGEMENT OPPORTUNITIES

Dredged material is now viewed as a regionally significant resource that can be put to positive use, rather than a waste by-product of channel improvements. The principles of Regional Sediment Management

(RSM) were applied to ensure that the dredged material arising from the SNWW CIP would be viewed as valuable resource, integral to economic viability and environmental sustainability of the region (Martin, 2002). In developing the DMMP for the project, this study searched for opportunities to achieve savings by coordinating projects, identified opportunities for beneficial use, and sought ways to contribute to coastal watershed goals related to sediment management. The large quantities of dredged material that would be generated by the proposed CIP created an ideal opportunity for the exploration of the beneficial use of dredged material. A series of public workshops and extensive ICT consultation evaluated a wide array of opportunities to use dredged material beneficially (GEC, 2002; Turner Collie & Braden, 2003). Potential uses of dredged material that were evaluated for this study included estuarine hydrologic and habitat restoration and ways to keep sediment in the system such as Gulf shoreline nourishment and offshore feeder berms. A complete description of alternatives for regional sediment management of the SNWW CIP dredged material is provided in Chapter 2.

2.0 ALTERNATIVES

This chapter is divided into five sections. The first discusses the history and process used in formulating alternatives that address planning objectives. Section 2.2 presents the preliminary screening of nonstructural and structural alternatives; the comparison of detailed structural alternatives follows in Section 2.3. Section 2.4 summarizes the results of the detailed screening and provides a full description of the Preferred Alternative. Section 2.5 describes and evaluates alternatives for the management of dredged material arising from construction and maintenance of the Preferred Alternative, and the incremental impacts and benefits of the DMMP. Placement features include beneficial use features, upland placement areas, and ODMDSs.

2.1 HISTORY AND PROCESS FOR FORMULATING ALTERNATIVES

The FFR, to which this FEIS is attached, provides a detailed description of the analysis of alternatives; however, a summary of this process is provided below. In this analysis, different ways of addressing identified problems, needs, and concerns were systematically evaluated while considering environmental factors. A three-phased screening process was used to identify the Preferred Alternative: 1) preliminary alternatives screening; 2) second screening; and 3) detailed evaluation of final alternatives. During preliminary screening, the expected “No-Action” Alternative was developed for comparison with other alternatives. This alternative was carried through the subsequent planning phases for comparison to other alternatives. Nonstructural and structural alternatives that could address planning objectives were also developed. The nonstructural alternatives evaluated the use of a VTS to alleviate transportation efficiency and safety concerns, the relaxation of existing pilot rules, and an alternative mode of commodity transport. For the structural alternatives, a wide array of structural channel improvements was evaluated. Over 120 different combinations of various depths and widths were analyzed during the preliminary screening. In the second phase, a more detailed evaluation of screened alternatives was performed. The final channel widths were determined during the second screening. With the exception of selective widening or bend easing in a few areas, no changes were made to the existing width of inshore navigation channels; the width of most of the offshore navigation channels and proposed extension were reduced from the existing width of 800 to 700 feet. Six channel depths (45, 46, 47, 48, 49, and 50 feet) with the set channel widths and from three to eight potential turning/anchorage basins on the Neches River Channel (Figure 2.1-1) were selected for the final detailed analysis. In accordance with the USACE Actions for Change initiative (USACE, 2006a), potential risks and uncertainties related to engineering, economic, and environmental analysis were evaluated throughout the alternatives analysis. Descriptions of these risks are discussed in the FEIS topic areas to which they relate, and they are also summarized in the FFR.

An economic evaluation of various deepening and widening alternatives was conducted to identify alternatives that maximized National Economic Development (NED) benefits. This evaluation is presented in detail in the FFR; only a brief summary is provided here. Project benefits were based on reductions in transportation costs generated from more-efficient vessel loading and from reductions in

vessel delays. Benefits and costs were calculated for Port Arthur and Beaumont depth alternatives of 43, 45, 47, 48, 50, 52, and 55 feet, and for other separable elements of the proposed CIP. The initial selection of the widening alternatives to be evaluated was based upon the results of a vessel simulation model conducted by the ERDC with input from the Sabine Pilots Association. The alternatives were subsequently screened based upon comparison of associated vessel delay costs and the initial construction cost estimates. Channel widening and turning anchorage basin benefits for deep-draft traffic were also evaluated by estimating benefits from delay reductions using an economic traffic model developed by the ERDC. Ecological mitigation costs for the six depth alternatives were interpolated based upon changes in salinity. The detailed evaluation of final alternatives concluded with the selection of a Preferred Alternative. Detailed evaluations of alternatives for the management of dredged material and the mitigation of ecological impacts were then performed for the Preferred Alternative. This evaluation concluded with the development of a DMMP and an ecological mitigation plan. The DMMP includes measures in which dredged material is used to restore wetland habitat, avoiding and offsetting impacts of the Preferred Alternative. The evaluation of alternatives for the management of dredged material and the recommended placement plan are described later in this chapter. The evaluation of mitigation alternatives that compensate for remaining unavoidable impacts to significant habitats and resources, and the recommended mitigation plan are described in Chapter 5 of this FEIS. Least-cost analyses of dredged material placement and an incremental cost analysis of mitigation alternatives were conducted to select recommended placement and mitigation measures; these analyses are presented in the FFR.

2.2 PRELIMINARY AND SECOND SCREENING

2.2.1 No-Action Alternative

The No-Action Alternative forms the basis against which all other alternative plans are measured. Under the No-Action Alternative, the Federal Government and the non-Federal sponsor would not implement the proposed CIP and the objectives of improving the navigational efficiency of the waterway would not be met.

It is expected that imports of crude oil and petroleum products would continue to expand to keep pace with the predicted national need for these products and the projected continuing declines in U.S. production. Vessel trips would increase to accommodate the higher imports, and higher costs associated with the current lightering and vessel movement limitations would continue. Increased vessel trips would exacerbate the existing channel bank erosion caused by vessel wakes in the confined channel reaches of the SNWW. It is projected that the existing trend in wetland losses would accelerate due to RSLR and altered hydrology and salinity levels caused by the existing SNWW navigation channels, the GIWW, and canals, levees, and water control structures associated with oil and gas exploration and production, logging, fishing, and hunting lands.

The No-Action Alternative would retain the 40-foot SNWW navigation channel with no improvements. The current channel dimensions do not allow the existing fleet to use the channel efficiently. Ships are limited by the current channel depth and width and safety limitations that result in one-way and daylight-

(This page left blank intentionally.)

only sailing restrictions. The need to lighter products and/or light load vessels increases overall vessel trips and shipping costs, and decreases the efficiency of the vessels using the waterway. The waterway is often congested because of frequent movements of lightered vessels carrying petroleum products from the Gulf to refineries on the Neches River Channel, and because of barge through-traffic using the GIWW. Vessels are now wider, placing limitations on the combined beam widths and drafts for vessel meetings on the waterway. Historically, casualty incidents on the SNWW channel are very low, due in large part to existing pilot rules that minimize the probability of incidents involving deep-draft vessels. Existing and proposed LNG facilities on the Sabine Pass Channel and Port Arthur Canal are subject to strict USCG regulations and to local pilot rules that prevent LNG vessels from meeting other vessel traffic. Increases in both inland barge and deep-draft vessel traffic along the waterway are expected to increase overall congestion and the likelihood of accidents. However, since the overall rate of casualty incidents is very low, the number of additional accidents in the future would also be low.

The No-Action Alternative would continue disposal activities for maintenance material from the 40-foot project in conformance with most, but not all, existing practices. In the FFR, the DMMP for the No-Action Alternative (the future without-project [FWOP] condition) is referred to as the Base Plan. The Base Plan forecasts disposal facility needs for all material that would be generated by maintenance dredging of the existing 40-foot project over a 50-year period of analysis. The 50-year analysis determined that additional capacity in upland PAs would be required, and it identified a least-cost beneficial use (BU) feature (the Gulf Shore BU Feature) that should be adopted as part of the Base Plan. The Gulf Shore BU Feature has also been included in the DMMP for the Preferred Alternative; it will be treated as a general navigation operation and maintenance (O&M) component.

No differences from existing offshore placement activities were identified for the Base Plan. The offshore channels (Sabine Bank Channel, Sabine Pass Outer Bar, and Sabine Pass Jetty Channel) would be maintained with a hopper dredge, and approximately 162 million cubic yards (mcy) of material would be placed in the four existing ODMDSs (sites 1–4). Bed sediments in the offshore channels vary from 4.3 percent sand and 95.7 percent silt plus clay in the Sabine Pass Outer Bar Channel to 24.3 percent sand and 75.7 percent silt plus clay in the Sabine Bank Channel (Parchure et al., 2005). These sites have sufficient capacity for the 50-year period of analysis as they are located in a dispersive environment where dredged material does not accumulate.

For the inshore Sabine Pass Channel, a cost analysis of placement alternatives in the FFR resulted in a change from traditional upland placement practices involving PA 5. Rather than placing all of the maintenance material from this channel into upland PA 5, the potential beneficial use of material from the channel section closest to the coast (Section 5) was evaluated to determine whether it could be used to nourish the Gulf shoreline on both sides of Sabine Pass (Gulf Shore BU Feature). Material from Section 6 of the Sabine Pass Channel would continue to be placed into PA 5 because the longer pumping distance to the coast makes shore nourishment cost prohibitive. The cost analysis determined that the Gulf Shore BU Feature is more cost effective than placing the material in the upland PA 5, and therefore it was adopted as part of the Base Plan.

Under the Base Plan, all of the inshore channels of the existing project (Sabine Pass Channel, Port Arthur Canal, Sabine-Neches Canal, and the Neches River Channel) would continue to be maintained by hydraulic pipeline dredge. Material from non-Federal dredging of private mooring and dock facilities would also continue to be placed in upland PAs along with the material from the Federal project. Existing management practices that utilize 16 upland PAs located adjacent to the channel from Sabine Pass to the Beaumont Turning Basin would continue. To contain 229.4 mcu of material over the 50-year period of analysis, the heights of existing PAs would be raised on a regular, recurring schedule in accordance with existing SNWW management practices. One new PA in the middle reach of the Neches River Channel (an expansion cell at PA 24A) would be needed to provide sufficient capacity for the period of analysis. On average, bed sediments vary in the inland channels from 38.3 percent sand and 61.7 percent silt plus clay in the Neches River Channel to 16.2 percent sand and 83.8 percent silt plus clay in the Port Arthur Canal (Parchure et al., 2005). Beneficial use features are not included in the Base Plan for the inland channels because the lack of suitable material makes construction and maintenance of containment levees more expensive than placing the material in existing PAs. However, Section 204 projects would be considered on a project-by-project basis if non-Federal sponsors express an interest in paying the incremental cost for such projects.

2.2.2 Nonstructural Alternatives

2.2.2.1 Vessel Traffic Service

The existing VTS along the SNWW was evaluated as a nonstructural alternative. Although this service is managed by the USCG and thus is not within the jurisdiction of the USACE, it was evaluated because it appeared to be a potential alternative to structural plans. VTS was authorized by certain sections of the Port and Waterways Safety Act of 1972; the Oil Pollution Act of 1990 made participation mandatory in areas serviced by existing and future VTS (USCG, 2008a). The purpose of VTS is to provide active monitoring and navigational advice for vessels in particularly confined and busy waterways. VTS is designed to expedite ship movements, increase transportation system efficiency, improve all-weather operating capability, and enhance vessel safety and marine environmental protection (SETWAC, 2007; USCG, 2008b).

The Vessel Traffic Center in Port Arthur became operational in 2005 and monitors every ship, vessel, or boat that attempts to enter or leave the SNWW and the GIWW in the Port Arthur service area. Infrared cameras, along with radar, radio-telephone reports from vessel operators, and satellite surveillance sensors on towers along the SNWW allow VTS controllers to zoom-in on vessel activity at a moment's notice. The satellite-based Automatic Identification System (AIS), required by the Maritime Transportation Security Act of 2002, assists the VTS by determining exactly what a specific commercial vessel is carrying, along with its speed, dimensions, and destination. Most commercial vessels using the waterway were required to have AIS equipment installed by the end of 2004 (Jackson, 2004). These include power-driven vessels 66 feet in length or longer; power-driven vessels of 100 gross tons or more carrying one or more passengers for hire; towing vessels 26 feet or longer while navigating all dredges and floating plant likely to restrict or affect the navigation of other vessels; and all vessels required to

participate in the Vessel Movement Reporting System. However, not all vessels are required to carry AIS; in particular, pleasure crafts, fishing boats, and warships are exempt.

Currently, VTS Port Arthur is a voluntary system operated in accordance with existing VTS regulations. Until rules regarding VTS Port Arthur are published, vessels are exempt from all VTS and Vessel Movement Reporting System requirements, except the requirement for AIS continuous broadcasts. When VTS Port Arthur is included in the VTS regulation, participation will become mandatory. At that time, VTS Port Arthur will be authorized to designate temporary reporting points and procedures, impose vessel-operating requirements, or establish vessel traffic routing schemes. During conditions of vessel congestion, restricted visibility, adverse weather, or other hazardous circumstances, VTS may control or manage traffic by specifying times of entry, movement, or departure to, from, or within a VTS area.

While the VTS will help congestion and improve safety to some degree, the USCG's traffic management role is limited to specific circumstances when the SNWW is congested or experiencing hazardous conditions. The VTS assists vessel operators in making independent decisions regarding the safe navigation of their vessels, for which they retain complete responsibility. In this sense, VTS should be considered primarily a navigational aid, a tool for mariners to use along with numerous other tools to facilitate safe navigation (USCG, 2008b).

2.2.2.2 Relaxation of Existing Pilot Rules

The SNWW is currently subject to transit rules that are needed for the pilots to safely guide large tankers through the narrow channel. These transit rules or restrictions are agreed upon by the shipping industry, supported by the USCG Captain of the Port Orders under the Ports and Waterways Safety Act of 1978, as amended, and administered by the Sabine Pilots Association (2007). An agreement enforcing these rules, dated January 12, 1981, will remain in force until the Sabine shipping industries, Sabine Pilots Association, and USCG agree to its revision or modification.

The existing 700-foot-wide offshore reach of the SNWW channel does not have vessel-meeting restrictions; however, in the narrower channel reaches, vessel-meeting restrictions are currently imposed. A general overview of the transit rules are:

- Daylight only sailing restrictions applied in specific reaches for vessels that exceed certain DWT, length, and breadth criteria.
- No meeting during nighttime sailing for vessels exceeding a given draft limitation.
- No meeting during either day or night, applied to vessels by DWT, length, breadth, and draft combinations.

Relaxation of the existing pilot rules for the waterway was considered as a nonstructural alternative early in the planning process. However, due to concerns about vessel handling and associated safety and that vessels utilizing the waterway are wider than those using the channel even 5 to 10 years ago, the Sabine Pilots Association would not consider relaxing the rules. The expectation for the with- and without-project future is that pilot rules will continue to limit the possibility of vessel meetings in the Sabine-

Neches Canal reach and that both vessel and shallow-draft tow movements will be scheduled through both VTS and communication between vessel pilots.

While vessel traffic is expected to increase under both the No-Action and future with-project (FWP) conditions, increases with a deeper channel are projected to be slightly lower because channel improvements will allow more deep-draft cargo to be carried with fewer vessel trips. Associated reductions in deep-draft vessel traffic would thereby serve to reduce the probability of casualties. However, since casualty occurrences in the SNWW are rare, the proposed improvements would not have a discernible effect on casualty rates. For LNG vessels, USCG safety rules will be the same with or without a deepened channel.

2.2.2.3 Alternative Mode of Commodity Transport

Offshore oil terminals were evaluated as an alternative mode to landside port delivery of crude petroleum. Three offshore terminal alternatives were considered in the analysis, one existing and two proposed. The decision to use an offshore terminal instead of lightering or constructing a deeper channel is complicated but largely depends on the relative cost per ton, relative market volumes, and facility accessibility. While a quantitative analysis of a LOOP alternative is beyond the scope of USACE planning study, the overall infrastructure requirements were examined to the extent possible. Pipeline capacities and necessary expansions were identified, and the reasons for current and past choices were evaluated as were expectations about future interest.

The existing offshore terminal, the LOOP, is America's first and only deepwater port. LOOP is presently operating at capacity and has been since 2005. In addition to new customers brought on due to infrastructure damages associated with the 2005 hurricanes, recent increase in the LOOP is tied to utilization associated with domestic production in the U.S. Gulf. Present use of LOOP consists of Louisiana-based refineries and U.S. Gulf Coast state domestic offshore production interests. LOOP's existing base of customers use it as one of several options for delivering crude oil to their Gulf Coast refineries. Access to LOOP for the SNWW market would require substantial investment as SNWW crude oil import volume nearly equals LOOP's capacity. LOOP's design capacity of 1.4 to 1.8 million barrels per day is only marginally higher than SNWW 2003 to 2005 crude petroleum import volume, which ranged from 1.1 to 1.3 million barrels per day (USACE, 2007a). The investment necessary for LOOP to process SNWW's entire crude petroleum throughput would require a doubling of capacity.

While all of SNWW's crude oil could not currently transfer to LOOP, some tonnage could be diverted. The SNWW users continue to consider LOOP along with other alternatives; however, continued practices suggest that LOOP is not a cost-effective alternative to the existing SNWW practice of its land-based ports. The volume of potential diversions depends upon various ranges of LOOP expansion or construction of a new facility. The large fixed cost of expansion, and associated financing costs, necessitate participation by a consortium of companies. The SNWW industries have not found the option of investing in LOOP, and the necessary associated infrastructure expansions, to be a cost-effective alternative to existing practices of either direct shipment or offshore lightering. The lack of incentive has

remained since the 1970s. An additional variable pertinent to the current evaluation is that LOOP would appear to be a less attractive cost option when compared to lower shipping costs that the SNWW improvement project is expected to provide.

LOOP is located offshore of Grande Isle, Louisiana, in 110 feet of water. Grande Isle is 302 miles east of Port Arthur and Beaumont. LOOP was organized in 1972 as a Delaware corporation and converted to a limited liability company in 1996. Marathon Ashland Pipe Line LLC, Murphy Oil Corporation, and Shell Oil Company are LOOP's owners. LOOP is the only port in the U.S. capable of offloading deep-draft tankers known as Ultra Large Crude Carriers (ULCC) and Very Large Crude Carriers (VLCC). Along with offloading crude from VLCCs, LOOP also offloads smaller tankers. LOOP consists of three single-point mooring buoys used for the offloading of crude tankers and a marine terminal consisting of a two-level pumping platform and a three-level control platform.

A 48-inch-diameter pipeline connects the LOOP Marine Terminal located 23 miles offshore in the Gulf to the Clovelly, Louisiana, storage facilities. Clovelly is approximately 260 miles east of the SNWW Port Arthur and Beaumont facilities. Four pipelines connect the onshore storage facility to refineries in Louisiana and along the Gulf Coast. The Clovelly facility provides interim storage for crude oil before it is delivered via connecting pipelines to refineries on the Gulf Coast and in the Midwest. The oil is stored in eight underground caverns leached out of a naturally occurring salt dome. In 1996, one cavern was dedicated to the production streams coming in from the deepwater Gulf.

The domestic offshore crude oil system uses the same distribution system used by the foreign barrels. The caverns are capable of storing approximately 50 million barrels of crude oil (a barrel of oil is equal to 42 U.S. gallons). In addition, LOOP has an aboveground tank farm consisting of six 600,000-barrel tanks. LOOP operates the 53-mile, 48-inch LOCAP pipeline that connects LOOP to CAPLINE (Amoco Cushing-Chicago Pipeline Company) at St. James, Louisiana. CAPLINE is a 40-inch pipeline that transports crude oil to several Midwest refineries. St. James is 227 miles east of Port Arthur and Beaumont. LOOP is connected to over 50 percent of the U.S. refinery capacity and has offloaded over 7 billion barrels of foreign crude oil since its inception.

LOOP is designed to handle 1.4 million barrels per day, but depending on the sizes of ships being serviced, it can handle 1.8 million barrels per day. The variance relates to the pumping rates of the tankers using the facility. Larger tankers tend to have faster pumping rates, with some capable of pumping 80,000 barrels per hour. Smaller tankers may only be able to pump 35,000 barrels per hour. When fully operational, LOOP is generally the largest point of entry for crude oil imports into the U.S. About 13 percent of all waterborne foreign imports pass through LOOP each day. Again, LOOP's design capacity of 1.4 to 1.8 million barrels per day is only marginally higher than the SNWW 2003 to 2005 crude petroleum import volume, which ranged from 1.2 to 1.4 million barrels per day. Of the SNWW's approximate 1.3 million barrels per day import volume, terminals on the SNWW transport approximately 400,000 barrels per day of waterborne crude oil via pipelines to inland refineries including refineries in Texas, Louisiana, Oklahoma, Ohio, Arkansas, and Kentucky (Martin Associates, 2006). In total, the SNWW delivers approximately 12 to 16 percent of the crude oil supplied to domestic refineries east of

the Rockies. Refineries supplied via the SNWW provide transportation fuels and other products to consumers along the Gulf Coast, East Coast, and in the Midwest regions. The SNWW ports presently receive about 1 percent of their daily input through LOOP. Additional offshore and landside infrastructure would be necessary for an increase in volume to take place.

Although there are some competing markets, the SNWW and LOOP generally serve parallel markets, with LOOP consistently processing very large volumes and SNWW serving relatively smaller parcels. The sizes of the VLCCs using LOOP typically exceed 300,000 DWT, whereas the maximum-sized vessels using the SNWW are 175,000 DWT. The maximum design draft of these vessels is 55 feet or less. The minimum-sized crude oil tankers using the SNWW are in the 70,000 to 80,000 DWT range and have design drafts between 40 and 48 feet. LOOP's foreign petroleum imports are from the Middle East, whereas the SNWW's market consists of direct shipments from Mexico and Venezuela and lightened mother vessels and shuttles. It has been noted that the cost effectiveness of LOOP lessens for small vessel sizes. The SNWW has the ability to serve a more general market and range of users. In discussions with local port and oil industry personnel, it is noted that LOOP and similar proposals serve crude petroleum but do not serve a full range of petroleum and bulk cargoes that use the SNWW.

The most-immediate obstacle to increased use of LOOP or a new offshore facility is lack of major limitations for direct connection from LOOP to SNWW. A marginal increase in the SNWW's use of LOOP from its present 1 percent share would require LOOP pipeline connection modifications involving multiple pipelines and multiple companies. Such an investment may generate the necessity for higher throughput charges, which, in turn, may make access less cost effective than in the past. An industry analyst noted that, to a large extent, the companies demand that each segment, including pipeline transportation, stand on its own economically (Rabinow, 2004). The long-term availability of LOOP since the 1970s and low participation by the SNWW companies indicate that LOOP and new offshore terminal proposals have not provided the market utilization incentives for significant shares of the SNWW crude oil to shift towards these alternatives. The long-term trend is for domestic refining capacity to become more concentrated in regional centers and for imports of petroleum products to grow. This trend is evident with the SNWW with crude oil import tonnage exceeding that of any other U.S. port and being equal to LOOP. Imports of refined products and partially refined crude oil have grown significantly as have the use of draft-constrained vessels for transporting these cargoes.

In 2001, construction of a new terminal (called the Bulk Oil Offshore Transfer System, or BOOTS) offshore of Sabine Pass, Texas, was proposed. The relatively long distance from LOOP to the SNWW and the need for additional infrastructure suggest that a facility closer to the SNWW would be an attractive alternative to LOOP for SNWW channel improvements. However, the BOOTS facility has not yet been constructed, and the regulatory permit application is inactive. The USCG has had no update on the proposal and does not expect a submittal. At the present time, the potential user of the proposed project is the terminal proponent. They noted that their participation as sole supporter is not feasible financially. It was specifically noted that their feedstock needs were not sufficient to finance the expansions to LOOP.

The BOOTs project proponent was contacted, and it was found that a new location farther down the Texas coast near Freeport is presently being considered. Access by the SNWW refineries to the proposed Texas Offshore Ports System (TOPS) would have advantages over LOOP. There is an existing pipeline from Freeport to Texas City; however, its connection to Port Arthur would necessitate a new pipeline from Texas City to SNWW, a distance of approximately 75 miles. Industry indications are that the use of an offshore Freeport terminal would not serve as the exclusive supplier, just as LOOP is not the exclusive supplier for the Louisiana markets. TOPS would reduce the vessel traffic on the Neches River by reducing the number of shuttle vessels coming into the SNWW from the offshore lightering zone. However, a disagreement among the partners recently led to the withdrawal of two of the three companies from the partnership.

In a general discussion with industry, a representative noted that offshore oil terminal projects surface periodically, but the cost of these alternatives keeps them from moving beyond the initial planning stage. It is noted that the attractiveness of offshore alternatives over existing use of the SNWW is diminished by its ability to only serve one commodity (i.e., crude petroleum). It was added that the various crude oil blends and grades of oil introduce a range of additional concerns that add to throughput costs. The pipelines and associated infrastructure requirements vary between potential users, and mingling of products and grades of crude is complex and difficult to facilitate. The construction of an offshore terminal that can meet the needs of various users is a challenge with the costs to realize multiparty usage creating an impasse to these proposals moving beyond the initial planning stage. Recognition of the cost of multiple pipelines necessary to meet the needs of the large base of customers necessary to finance these project alternatives has resulted in a stalemate in the decision process.

Expansion of LOOP, construction of a new offshore facility such as BOOTs or TOPS, or an unloading terminal along the Sabine Pass or Port Arthur Canal reaches would reduce the vessel traffic on the Neches River. The reduction in ship traffic resulting from LOOP, BOOTs, or TOPS would reduce the economic viability of the SNWW deepening and widening project. However, past and present trends in infrastructure and fleet investments indicate that industry intends to continue using the Neches River Channel. An increase in the number of specially designed SNWW vessels was recently completed by one company, and another has invested in Neches River dock modifications for the larger “Aframax” and “Suezmax” vessels. The focus of immediate private-sector petroleum vessel investments is concentrated on SNWW improvements rather than offshore or on the Sabine Pass Channel or Port Arthur Canal. Ongoing consultation with industry continues to show that commitments to offshore terminal investment have not materialized. During the 30 years since LOOP has become operational, several Texas Gulf Coast channel improvement projects have been completed and the benefits have been accrued. Offshore terminals would not accommodate products other than crude oil, and a significant proportion of benefits for the Neches River Channel project improvement are from refined petroleum products. The offshore terminal was found not to meet the efficiency objective for all waterway users as it addressed the needs of only one user and commodity (crude oil). For these reasons, this alternative was eliminated from further consideration.

2.2.3 Structural Alternatives

Six different channel depths (43, 45, 48, 50, 53, and 55 feet) were evaluated in combination with several different widening scenarios during preliminary and second alternatives screening. Widening the upper reaches of the SNWW to 500 feet through the Port of Beaumont was evaluated, as were selective widening alternatives of different widths for specific reaches. This analysis resulted in over 120 variations of alternative depths and widths. Costs were estimated for all of these variations and compared to benefits during this initial screening process. An incremental analysis of benefits for separable elements of the project was also conducted. Preliminary analysis indicated that approximately 65 percent of the project benefits were associated with the upstream Beaumont area and 35 percent with the Port Arthur area; therefore, continuing improvements up the Neches River to Beaumont was economically justified. The initial screening determined that depths of 45 feet and greater had higher net excess benefits than depths less than 45 feet. The initial analysis also showed slightly higher net excess benefits for the 52-foot and 55-foot depths than for depths between 45 and 50 feet. However, because the rate of change in net excess benefits for depths over 50 feet was relatively small, and due to the non-Federal sponsor's budget constraints, only depths between 45 and 50 feet were advanced for final screening. Ecological benefits and mitigation costs were not calculated for the 120 plus variations during the preliminary and second screening. However, the array of structural improvements was assessed for potential effects to the environment in a nonquantitative manner.

Deepening and widening combinations that were evaluated during preliminary screening are listed below.

- Maintain existing 40-foot depth with 500-foot width, and 3 existing turning basins, to Port of Beaumont;
- Deepen the entire waterway from the Gulf to the Port of Beaumont at depths of 43, 45, 48, 50, 53, and 55 feet with an extension of the Entrance Channel ranging from 5 to 25 miles in length and no widening;
- Deepen the entire waterway, considering the various depths (43, 45, 48, 50, 53, and 55) with an extension of the Entrance Channel ranging from 5 to 25 miles in length, and widen the Sabine-Neches Canal to Beaumont to match the 500-foot-wide channels in the lower reach;
- Deepening but not widening of the Taylor Bayou Channels and Basins at the various depths (43, 45, 48, 50, 53, and 55).

Two of the preliminary structural alternatives were found to be infeasible due to technical, economic, and environmental constraints, and were therefore not advanced into the second screening:

- Widening the entire existing channel from Sabine Pass to the Port of Beaumont, at widths varying from 500 to 700 feet, was found to be infeasible because a widening-only alternative would not provide the additional draft needed to increase navigation efficiency for the largest number of waterway users. In addition, this alternative would have had significant ancillary effects such as the destruction of large amounts of emergent land and wetlands, the disruption or displacement of

a large number of existing docks and berthing facilities, the relocation of bridge supports for existing highway bridges, and the creation of many new PAs.

- Selective widening only (widening only certain reaches of the channel) was eliminated because it would provide even fewer navigation benefits than the widening-only alternative discussed above

During the second alternatives evaluation, several widening combinations were evaluated. Each of the following was evaluated for deepening options of 43, 45, 48, 50, 53, and 55 feet with an extension of the Entrance Channel from 8 to 16.5 miles.

- Maintain existing 500- to 400-foot width of the inshore channels to Port of Beaumont at depths of 45, 48, and 50 feet;
- Reducing the deepened Sabine Bank Channel from 800 feet wide to 700 feet wide through the end of the extension channel;
- Selective widening (600- and 700-foot widths) from Sabine Pass Channel station 180+00 to Port Arthur Canal station 275+00 (long reach);
- Selective widening (600- and 700-foot widths) from Sabine Pass Channel Station 265+00 to Port Arthur Canal Station 85+00 (short reach);
- Selective widening (500-, 600-, and 700-foot widths) in the Sabine-Neches Canal;
- Selective widening (600- and 700-foot widths) in the Neches River Channel. Deepening and widening of the Taylor Bayou Channels and Basins;
- Constructing a 12-foot-deep by 150-foot-wide barge shelf from the Port Arthur Junction Area to the mouth of the Neches River; and
- Adding various combinations of up to eight turning basins and/or anchorage basins on the Neches River Channel.

Several of these alternatives were eliminated at the conclusion of the second screening. The alternative mode of commodity transport (LOOP and BOOTS) and the VTS alternatives would help with improving safety along the existing channel (by reducing vessel traffic or better managing the traffic). However, these alternatives do not address the navigational efficiency of the waterway and would not allow the vessels utilizing the channel to load more fully. The potential relaxation of the current transit rules by the pilots was evaluated but screened out as not implementable because the pilots do not support this course of action. Therefore, all of the nonstructural plans were eliminated from further consideration. The widening alternatives included widening of the Sabine Pass and Port Arthur Canal channel from 500 to 700 feet. Although the widening in combination with the deepening of the channel was economically justified, the widening alone did not provide a benefit to cost ratio equal to or greater than 1.0. Therefore, the widening alternative for this reach was not an incrementally justified feature and was eliminated from further evaluation. Depths less than 45 feet and greater than 50 feet were also eliminated from further

screening, because the economic analysis indicated that the NED depth was likely between 48 and 50 feet.

In summary, since structural alternatives (e.g., deepening the channel) were the only alternatives that would fully address the project objective of navigational efficiency, only the No-Action Alternative and some structural alternatives for improvements to the SNWW navigation system were carried forward for detailed analysis. Among all of the structural alternatives, only six depths (45, 46, 47, 48, 49, and 50 feet) were carried forward into detailed evaluation.

2.3 EVALUATION OF FINAL ALTERNATIVES

2.3.1 Alternatives Advanced for Final Screening

At the conclusion of the second screening, only the No-Action Alternative and six structural alternatives for improvements to the SNWW deep-draft navigation system were advanced into detailed screening. The barge shelf alternative was dropped from further consideration when implementation of the VTS improved communication between deep-draft vessels and barges, thereby providing a nonstructural solution for the barge shelf. The three nonstructural alternatives for deepening the deep-draft channel had been eliminated from further consideration, as described above. Structural alternatives evaluated during this final screening phase are listed below. Comparative channel dimensions and dredging quantities are provided in Table 2.3-1.

- Deepening the SNWW to Beaumont to 45, 46, 47, 48, 49, or 50 feet (Alternatives A through F, respectively, in Table 2.3-1) with an extension of the Entrance Channel ranging from 8 to 16.5 miles in length, a 700-foot-wide Sabine Bank and Extension Channel, and deepening and widening the Taylor Bayou Channels and Basins.

Adding various combinations of up to eight turning basins and/or anchorage basins to the 45-, 46-, 47-, 48-, 49-, and 50-foot Neches River Channel deepening alternatives (Alternative G).

2.3.2 Comparison of Alternatives and Selection of the Preferred Alternative

The selection of the Preferred Alternative (Alternative D) from the alternatives listed above was based upon a comparison of economic, engineering, environmental, and socioeconomic factors presented in Table 2.3-1. The economic analysis presented in Chapter V of the FFR identified the alternative described below as the plan that maximizes net excess benefits for deepening the SNWW. The Preferred Alternative is called the Selected Plan, and ultimately, the Recommended Plan, in the FFR. The Preferred Alternative, presented as the last alternative in subsection 2.3.1, is described in detail below:

Deepening of the SNWW to Beaumont to 48 feet with a 13.2-mile-long by 700-foot-wide Sabine Bank and Extension Channel, existing 500- to 400-foot-wide jetty and inshore channels with the exception of deepening and widening of Taylor Bayou Channels and Basins, and the addition of Neches River Turning/Anchorage Basins 1, 4, and 8 (see figures 2.4-1a–g).

While the economic analysis determined that the 49-foot alternative is the NED plan, the 48-foot alternative is preferred by the non-Federal sponsor and will be recommended as the Locally Preferred Plan. Structural modifications of the Preferred Alternative meet the planning objective for increased navigational efficiency, and DMMP BU features and compensatory mitigation measures effectively avoid or mitigate all unavoidable environmental impacts.

Costs were estimated for all of the alternatives and used to determine the benefit-to-cost ratio in the economic analysis. Included in the costs were dredging, levee construction, relocations (including utility relocations), and O&M costs for the 50-year period of analysis. Ecological mitigation costs for the six depth alternatives were estimated using HS model salinity projections for the 40-, 45-, and 48-foot channel depths. Salinity was chosen as the best factor on which to base interpolations of mitigation costs because it is the primary driver in the ecological modeling that was used to determine the compensatory mitigation plan. The cost interpolation assumed that there would be a linear relationship between predicted salinities for each channel depth at the end of the period of analysis and the cost of mitigation.

Direct ecological effects associated with navigation channel improvements under all proposed alternatives and the placement of dredged material consist of:

- Impacts to benthic organisms and their Gulf, estuarine, and riverine water-bottom habitats would be similar for all alternatives. Benthic organisms are expected to quickly rebound from the short-term impacts of channel dredging, the use of offshore PAs, and the Sabine Lake borrow trench/access channel associated with compensatory mitigation in Louisiana.
- Dredging impacts to bottom-feeding and pelagic organisms such as sea turtles may occur with hopper dredging of offshore channel reaches for all alternatives, but reasonable and prudent measures to avoid impacts would be instituted with an avoidance plan.
- Impacts to marsh would result from the enlargement of one PA under the No-Action Alternative and two PAs under all other alternatives. The new PAs would be small, and the incremental cost associated with one additional PA is too small to affect alternative selection. Most PAs would be enlarged by raising levee heights, which means that the footprint of PA impacts would be similar for all alternatives.
- Impacts to shorebirds and their habitat would result from the regular placement of maintenance material on the Gulf shoreline under all alternatives, including the No-Action Alternative. Birds would be temporarily displaced to nearby habitat during each placement episode. These impacts would be minor and temporary, and the number and footprint of each placement episode would be the same for each alternative.

Indirect effects provide the primary ecological impact of all structural alternatives. Although the SNWW channel is located primarily in Texas, large indirect impacts may occur in both Texas and Louisiana due

to small increases in salinity levels causing an increase in wetland loss rates and a decrease in biological productivity in aquatic habitats of the study area. HS modeling indicates that none of the depth alternatives would result in significant impacts to swamp and fresh marsh habitats in the upper reaches of the Sabine and Neches rivers. Salinity impacts of the six depth alternatives to the vast saline through intermediate marshes would be similar, with an average difference between the 45- and 50-foot alternatives of less than 0.5 parts per thousand (ppt).

2.3.3 Sensitivity of Project Alternatives to Relative Sea Level Rise

“Coastal Sensitivity to Sea-Level Rise: A Focus on the Mid-Atlantic Region” (U.S. Climate Change Science Program [USCCSP], 2009) synthesizes the state of knowledge regarding possible effects of RSLR on coastal ecosystems and communities. Areas of the Nation’s coast are experiencing submergence of low-lying lands, erosion of shores, and conversion of wetlands to open water as a result of RSLR. Studies suggest the rate of RSLR has increased recently and is likely to continue to increase in vulnerable areas. Forecasting impacts of RSLR on specific coastal areas is difficult because of the complexity of coastal ecosystems and ecological processes and uncertainty about regional variation in RSLR. According to USCCSP (2009:1), “Existing studies of sea-level rise vulnerability based on currently available elevation data do not provide the degree of confidence that is optimal for local decision making.”

Circular No. 1165-2-211, Water Resources Policies and Authorities Incorporating Sea-level Change Considerations in Civil Works Programs (USACE, 2009a), requires the USACE to incorporate “the direct and indirect physical effects of projected future sea-level change in managing, planning, engineering, designing, constructing, operating, and maintaining USACE projects. . . .” In fulfillment of this requirement, the sensitivity of project alternatives to the full range of potential FWOP changes in sea level has been evaluated. There are a wide range of potential effects related to the full range of RSLR, but the sensitivity of project alternatives would be more limited. In particular, alternatives were evaluated to determine whether the purpose and function of navigation features could be undermined, whether environmental impacts might be exacerbated, and how economic benefits and costs might be affected by sea level change. Nonstructural alternatives were evaluated but eliminated in the second screening; they are therefore not addressed in this analysis.

In order to meet the requirements of Circular No. 1165-2-211, this section evaluates effects of the full range of possible RSLR rates, which were developed in accordance with a specific methodology prescribed in the guidance. RSLR rates that may be appropriate for the project area are discussed in detail in Section 3.3 of Appendix C to this FEIS. The range of RSLR was determined using both tide gage and basal peat data for the local subsidence component of RSLR. Tide gage data reflect the effects of recent historical subsidence. The average rate of RSLR measured at the Sabine Pass tide gage was 0.2 inch/year for the 48-year period between 1958 and 2006 (U.S. Department of Commerce [USDC]-National Oceanic and Atmospheric Administration [NOAA], 2006, 2009). However, there is significant scientific debate concerning the validity of tidal records with respect to the projection of future subsidence rates in the northwest Gulf coastal plain. The relative influence of historic anthropogenic activities in this area (e.g., oil and gas withdrawal) is difficult to quantify. If these activities contributed significantly to recent

observations of subsidence, then significant reductions in these activities may result in rapid deceleration of subsidence rates, returning them to long-term average rates best represented by the basal peat data. Deriving RSLR estimates using both basal peat and tide gage data, possible RSLR rates were estimated for the period from 2019 to 2069 to range from 0.3 to 2.8 feet. Possible low, intermediate, and high rates are as follows:

- 0.3 foot, Low (1.83 millimeters [mm]/year), based on basal peat subsidence rates
- 0.7 foot, Intermediate (4.27 mm/year), based on basal peat subsidence rates
- 1.1 feet, Intermediate (6.71 mm/year), based on tide gage subsidence rates (This value was used in the hydrodynamic-salinity modeling of the estuary for this project.)
- 1.5 feet, Intermediate (9.14 mm/year), based on tide gage subsidence rates
- 2.2 feet, High (13.44 mm/year), based on basal peat subsidence rates
- 2.8 feet, High (17.07 mm/year), based on tide gage subsidence rates

An intermediate rate of RSLR (1.1 feet by year 2069) was used as the “most likely” estimate of RSLR in the alternative analysis for this project, in accordance with the USACE planning guidance. The following discussion describes possible ways that high and low RSLR might affect the project alternatives and the recommended action. There are relatively little data and analysis currently available that would permit a detailed, quantitative analysis of the impacts of each of the possible RSLR scenarios on the project alternatives. Ways in which different RSLR rates might affect project design and impacts are presented in Table 2.3-2.

In general, the functioning of the navigation features associated with all alternatives (channel depths of 45 through 50 feet, turning/anchorage basins, PAs/ODMDSs, and the BU features) would not be significantly affected by the full range of potential sea level change. Construction dredging would occur within 10 years and would not be affected by future rates of RSLR. While shoaling rates toward the end of the period of analysis could increase due to an enlarged cross section and greater saltwater penetration, this small effect would probably be offset by increased overall water depths. PAs and BU features have been designed to accommodate sea level changes through the high RSLR range. PAs are located at sufficiently high elevations to withstand the potential rise, and appropriate erosion control measures are included. BU features are located well inland on the Neches River, and they have been designed with erosion control features that would survive the full range of RSLR. The addition of mineral soils and higher marsh elevations would provide stable landforms. Biomass accumulation and sediment from adjacent terrace margins should enable restored marsh vegetation to maintain itself even with the high RSLR rate.

The protection of human health and improvements in safety are not project objectives and therefore potential effects on calculated risk are not applicable. RSLR does not affect the functioning of the various depth alternatives or vessel safety. At the intermediate and high rates of RSLR, a significant increase in

Table 2.3-2
Relative Sea Level Rise Sensitivity of Project Alternatives

Sensitivity of Design				Sensitivity of Impacts		
Navigation Channel Alternatives A-G	DMMP (PAs/ODMDSs)	DMMP (BU Features)	Mitigation Measures	Human Health/Safety	Environmental Impacts	Economic Costs/Benefits
<p>Low Rate (0.3 feet over 50 years)</p> <p>No significant effect for any depth alternative. Low range of future RSLR is lower than recent historical rate.</p>	DMMP: no change to existing shoaling rate and maintenance dredging expected. All PAs designed for intermediate RSLR rate.	All BU features were designed to accommodate intermediate RSLR; low rate would have no effect.	All mitigation measures were designed to accommodate intermediate RSLR; low rate would have no effect.	RSLR does not affect the functioning of the various depth alternatives or vessel safety. Small increase in tidal surge penetration due to low RSLR rate would be expected; tidal surge protection is not a project objective. No increase in tidal surge impacts due to project.	Primary project impact is result of greater salinity intrusion. Salinity difference for low RSLR is within one standard deviation of the salinity difference between FWOP and FWP.	Benefits and costs of the deepened navigation channel would be the same as FWP forecast.
	<p>Intermediate Rate (0.7 to 1.5 feet over 50 years)</p> <p>No significant effect for any depth alternative. Rising water depth offset by increased shoaling. Potential impacts to Sabine Pass water surface elevation is within range used for engineering design of all PAs. No effect to ODMDSs.</p>	Possible RSLR rise is within range used for engineering design of all BU features.	Possible RSLR rise is within range used for engineering design of all mitigation measures.	RSLR does not affect the functioning of the various depth alternatives or vessel safety. Intermediate increase in tidal surge penetration due to RSLR rate; tidal surge protection is not a project objective. No increase in tidal surge impacts due to project.	Salinity impacts were based upon RSLR of 1.1 feet. Salinity difference for range of intermediate RSLR rates is within one standard deviation of the salinity difference between FWOP and FWP.	Benefits and costs of the deepened navigation channel for the full intermediate range would be the same as FWP forecast.
<p>High Rate (2.8 feet over 50 years)</p> <p>No significant effect for any depth alternative. Possible small increase in armoring may be needed for some PAs. No significant effect to ODMDSs.</p> <p>depth alternatives resulting from enlarged cross section and greater saltwater penetration. Potential impacts to Sabine Pass Jetties addressed by separate O&M major rehabilitation project.</p>	DMMP: small increase in levee heights and/or armoring may be needed for some PAs. No significant effect to ODMDSs.	Addition of mineral soils and higher marsh elevations provides more-stable landforms. Biomass accumulation may enable restored marsh vegetation to remain stable relative to high RSLR rate. Erosion control features would survive the full range of RSLR.	Addition of mineral soils and higher marsh elevations provides more-stable landforms. High rate of RSLR could result in submergence and erosion of restored marsh. Monitoring and adaptive management plan have been developed to identify corrective actions that might be needed toward the end of the period of analysis.	RSLR does not affect the functioning of the various depth alternatives or vessel safety. High rate of RSLR would increase tidal surge penetration; tidal surge protection is not a project objective. No increase in tidal surge impacts due to project.	Potential salinity increase with high range of RSLR is still within one standard deviation of the salinity difference between FWOP and FWP. No significant increase in salinity impacts would be expected.	Benefits of the deepened navigation channel would be the same as FWP forecast. No facilities used by shipping industry would be rendered ineffective by the high range of RSLR. O&M costs could increase slightly toward the end of the period of analysis, but not enough to reduce benefit to cost ratio below parity.
	<p>High Rate (2.8 feet over 50 years)</p> <p>No significant effect for any depth alternative. Possible small increase in armoring may be needed for some PAs. No significant effect to ODMDSs.</p> <p>depth alternatives resulting from enlarged cross section and greater saltwater penetration. O&M costs could increase slightly toward the end of the period of analysis, but not enough to reduce benefit to cost ratio below parity.

tidal surge penetration would be expected, but this would not affect project alternatives because tidal surge protection is not a project objective. Furthermore, HS modeling has determined that little or no increase in water surface elevation would be expected due to the deeper navigation channel.

The primary impact of RSLR on this project may be its potential impact on mitigation measures proposed for the Louisiana marshes along the east side of Sabine Lake. These mitigation measures are planned for marshes that could experience submergence and erosion at the high RSLR rate. In recent decades, marshes in the study area have been able to keep up with rates of 5.6 to 6.5 mm/year, suggesting that these marshes may be able to sustain themselves through rises in the intermediate range of RSLR (4.3 to 9.1 mm/year). The high rate of RSLR (17.1 mm/year) could threaten long-term survivability. Sustainability thresholds are determined by local physical, chemical, climatologic, and hydrologic conditions and cannot be extrapolated to other regions. However, as an example, studies in the mid-Atlantic region indicate that the tipping point for coastal ecosystems could range from an RSLR of as low as 2.0 mm/year to as high as 10 mm/year (USCCSP, 2009). There are relatively little data and analysis currently available that would permit a detailed, quantitative analysis of the impacts of the full range of potential RSLR on the SNWW ecosystem and project alternatives.

A monitoring and contingency/adaptive management plan has been developed to identify corrective actions that could be necessary decades after initial marsh construction (Appendix J). Corrective actions proposed in the contingency plan assume that the low to intermediate rates of RSLR will occur; the high rate is assumed to be unlikely. If monitoring determines that the extent of vegetation coverage does not meet ecological success criteria specified in the monitoring plan, manual planting would be employed to restore the requisite acres of emergent marsh. The ICT would determine whether marsh planting is needed and if so, to what extent and in which areas. Relocation of the mitigation areas to areas that would be protected from the potential effects of the full range of RSLR is not feasible. All intertidal marshes in the study area would be similarly affected by the sea level change because of the extremely low slope of the coastal plain. The option of purchasing credits in a mitigation bank was investigated; however, no mitigation banks exist for this area and resource type.

2.4 PREFERRED ALTERNATIVE

The description of the Preferred Alternative in this section is divided into two primary components, navigation channels improvements and associated elements, and dredged material placement features. Requirements for compensatory mitigation are covered in Chapter 5. General navigation features of the Preferred Alternative consist of navigation channels and basins, and bridge reinforcements. Other project elements required to complete project construction are Aids to Navigation; lands, easements, rights-of-way, and relocations (LERRs); and deep-draft utility relocations. The 50-year DMMMP for both new work and O&M consists of ODMDSS, upland PAs, and the Neches River and Gulf Shore BU features. Detailed descriptions for project components are provided later in this chapter.

2.4.1 Navigation Channel Improvements

The description of proposed improvements begins at the farthest point offshore and moves inshore to the Beaumont Turning Basin. Project dimensions for the Preferred Alternative are provided in Table 2.4-1 and all channel sections and stationing are shown on figures 2.4-1a–g.

Table 2.4-1
Project Dimensions for Preferred Alternative

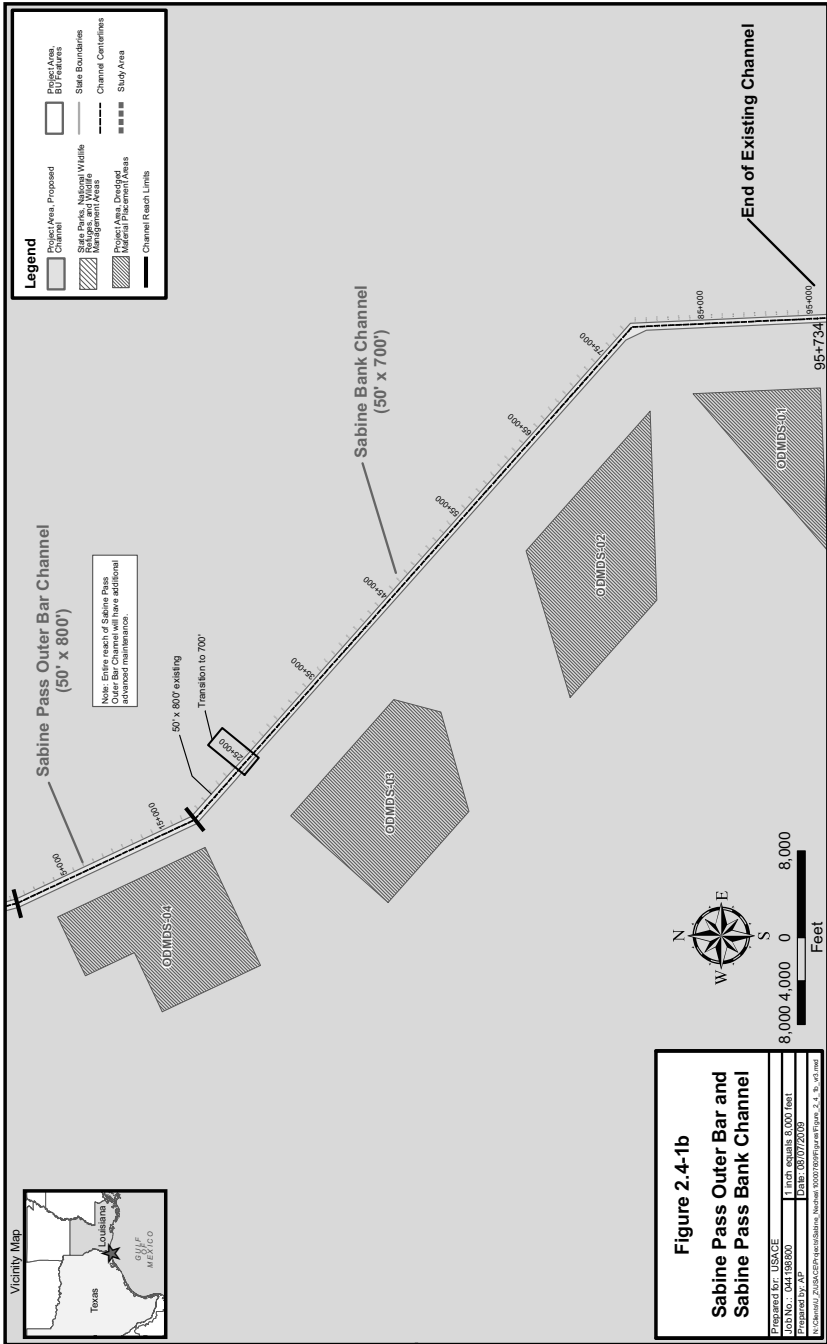

Reach	Station	to	Station	Bottom Width (feet)	Project Depth (feet)	Side Slope*
Extension Channel	165+443		95+734	700	50	1V/2H
Sabine Bank Channel	95+734		25+800	700	50	1V/2H
Sabine Bank Channel	25+800		23+300	800–700	50	1V/2H
Sabine Bank Channel	23+300		18+000	800	50	1V/2H
Sabine Pass Outer Bar	18+000		0+000	800	50	1V/10H
Sabine Pass Jetty Channel	–214+88		0+00	800–500	48	1V/2H
Sabine Pass Channel	0+00		296+25	1,355–500	48	1V/2H
Port Arthur Canal	0+00		325+84	1,660–500	48	1V/2H
Sabine-Neches Canal	0+00		592+94	1,050–400	48	1V/2H
Neches River Channel	0+00		980+00	400–1,413	48	1V/2H
Taylor Bayou						
Entrance Channel	0+00		25+27	406–764	48	1V/2H
East Turning Basin	0+00		17+65	532–354	48	1V/2H
West Turning Basin	25+27		41+30	776	48	1V/2H
Connecting Channel	41+30		71+50	470–250	48	1V/2H
Taylor Bayou Turning Basin	71+50		106+25	1,000	48	1V/2H

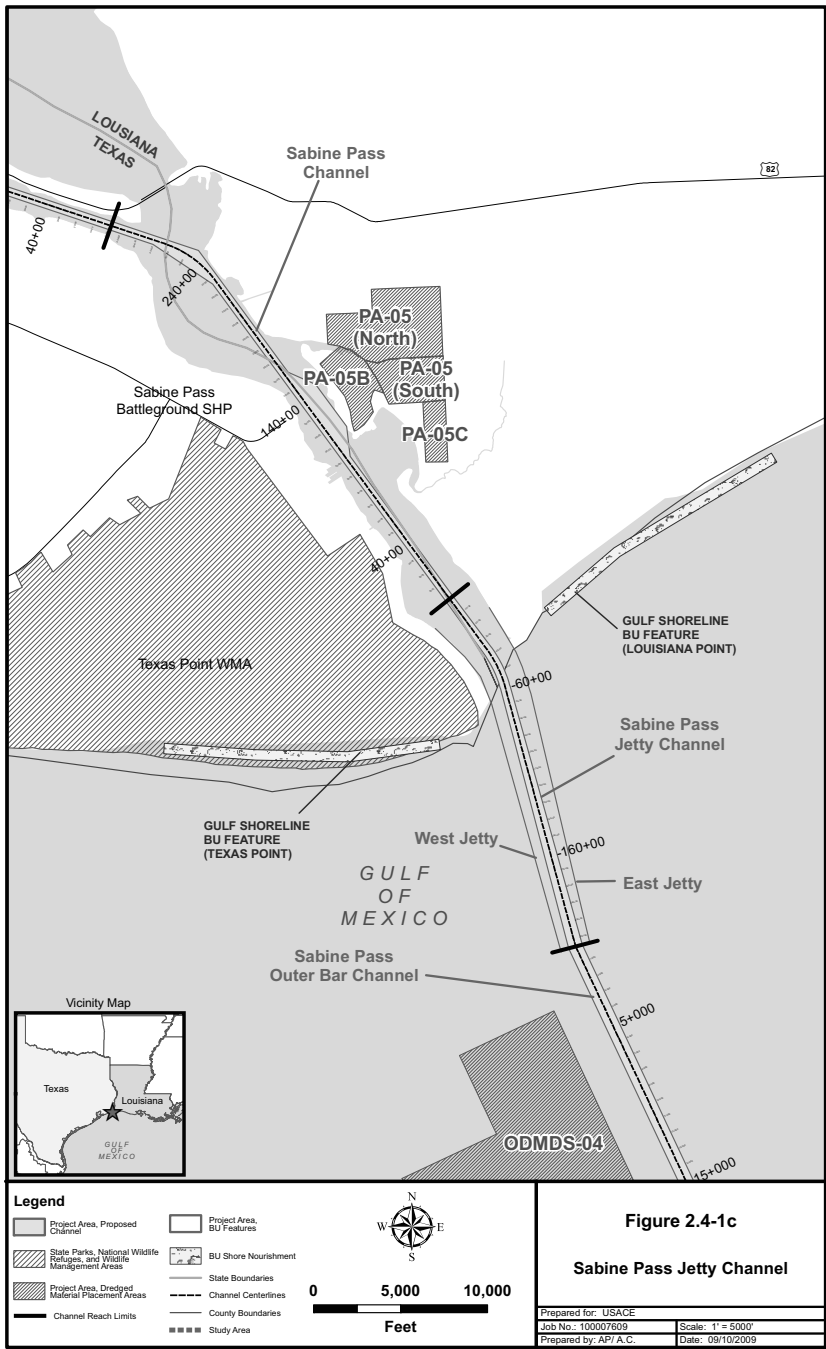

*Vertical to horizontal distance.

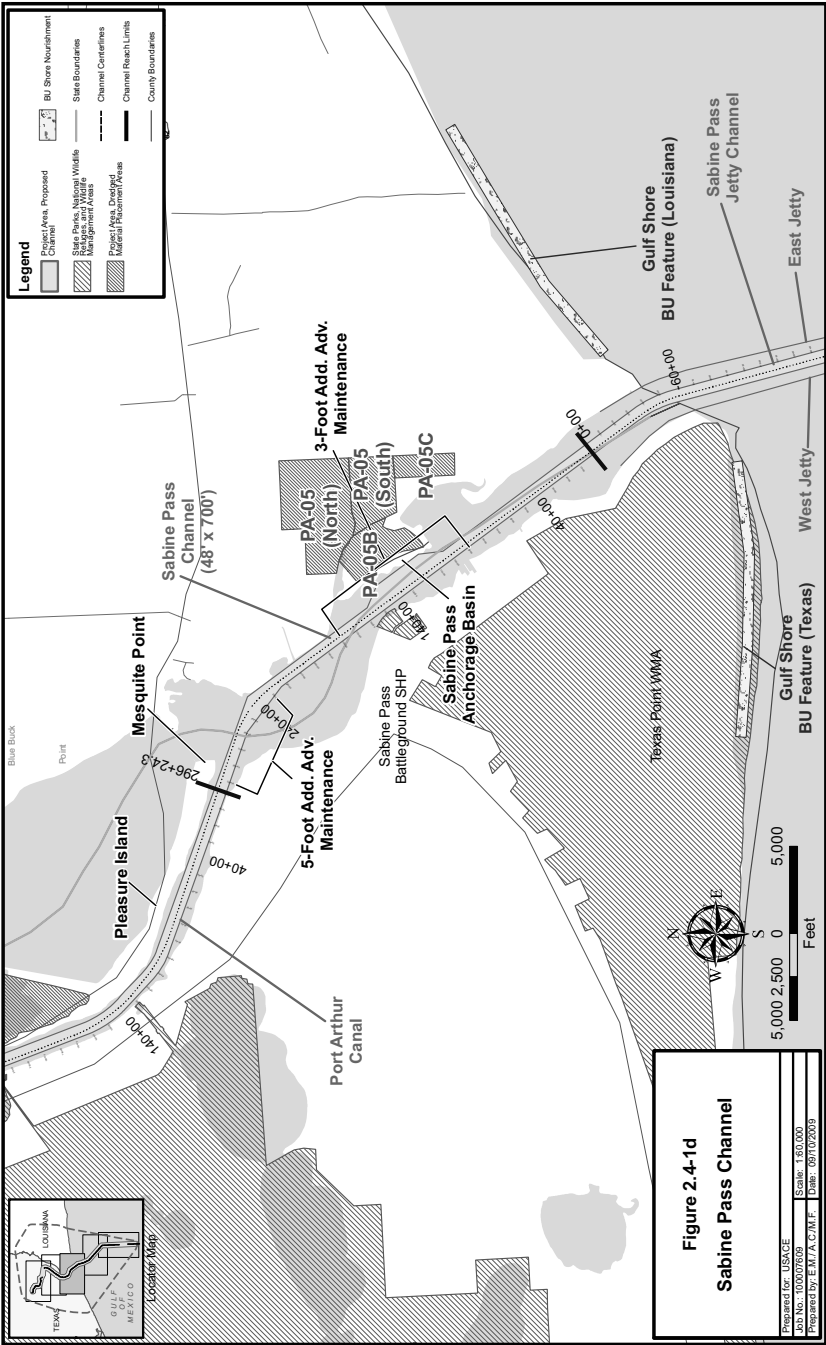

The authorized depth of the channel in the Preferred Alternative would increase from 40 to 48 feet along the entire existing channel, and the offshore entrance channel would extend 13.2 miles farther into the Gulf. The Sabine Pass Jetty Channel, Sabine Pass Channel, Port Arthur and Sabine-Neches canals, and the Neches River Channel would be deepened from 40 to 48 feet. The authorized depth of the existing offshore Entrance Channel (Sabine Pass Outer Bar Channel and Sabine Bank Channel) is currently 42 feet; the additional depth is needed to accommodate fluctuations in offshore surface water elevation. These channels and the proposed Sabine Bank Extension Channel would be deepened from 42 to 50 feet.

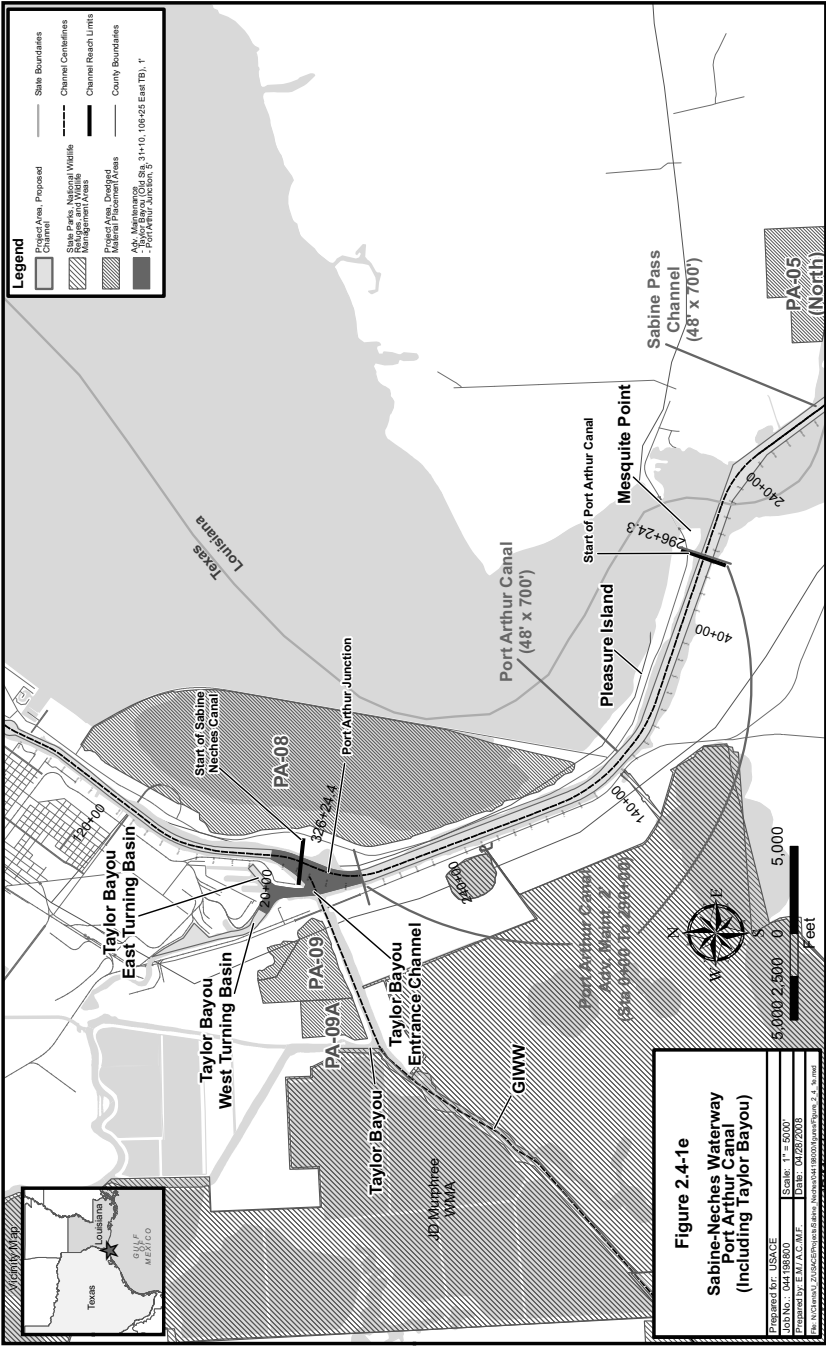

This would increase the SNWW from 64 miles to approximately 77 miles in length. No modifications to the existing Sabine Pass Jetties would be required as part of the CIP.

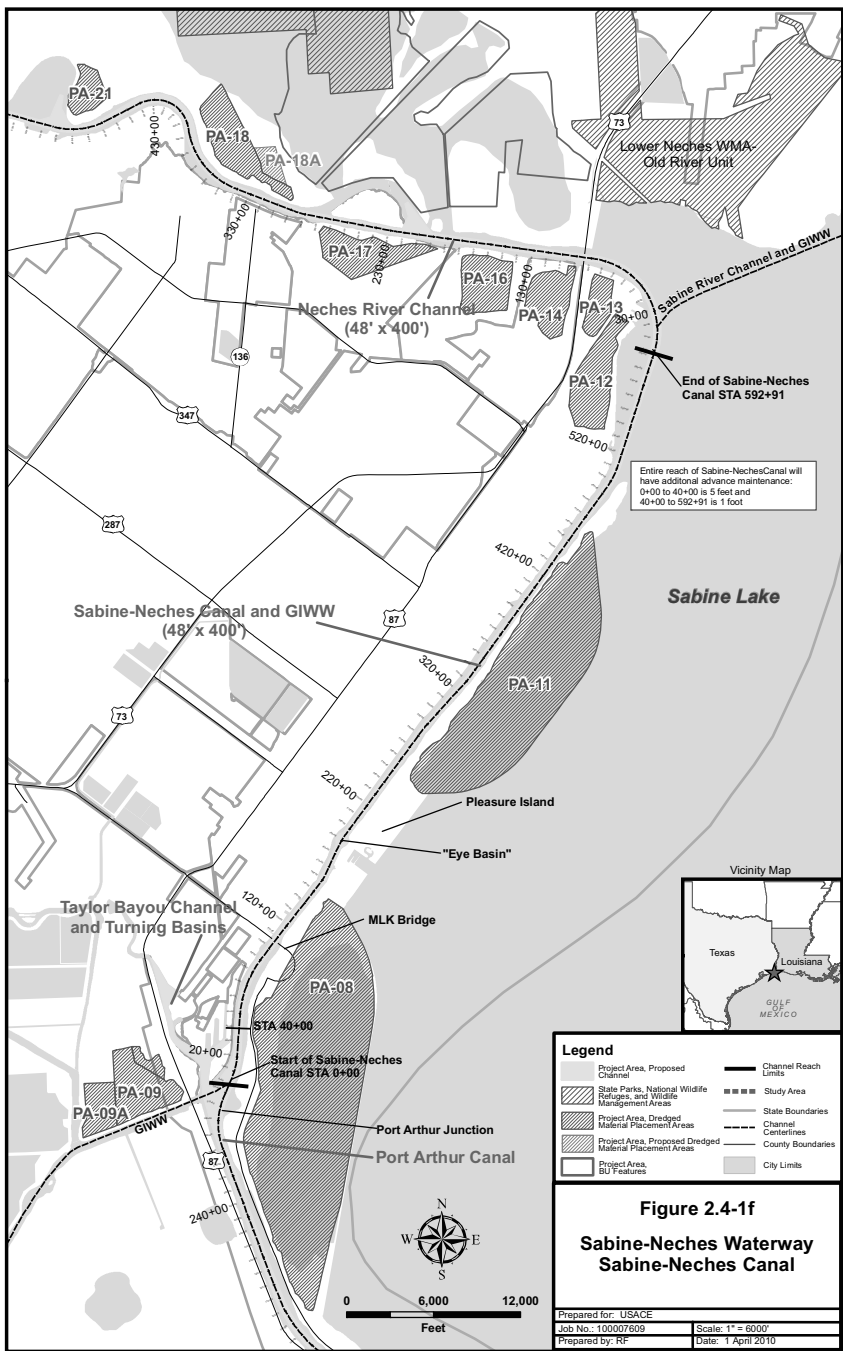

The Sabine Pass Jetty Channel and the majority of the inshore channels (Sabine Pass Channel, Port Arthur Canal, Sabine-Neches Canal, and Neches River Channel) would remain at their existing widths. With the exception of wider sections at anchorages or channel intersections, these channels transition from 500 feet wide between the jetties to 400 feet wide upstream of the Martin Luther King (MLK) Bridge on the Sabine-Neches Canal and Neches River Channel. The Taylor Bayou Channels and Basins would also be widened and deepened to 48 feet. Although the Sabine-Neches Canal and Neches River

Channel would not be widened, navigation efficiency would be improved with short stretches of selective widening and bend easings in both reaches, and the addition or enlargement of one anchorage and two turning/anchorage basins on the Neches River Channel.

The Preferred Alternative would generate an estimated 98 mcy of new work and 650 mcy of maintenance material over the 50-year period of analysis (Table 2.4-2). The annual maintenance dredging quantities in the SNWW will increase from an average of 8.1 mcy for the current 40-foot project to 13.0 mcy for the proposed 48-foot project.

Table 2.4-2
New Work and 50-Year Maintenance Quantities for Preferred Alternative

	Channel Reach	New Work Quantities (cy)	50-Year Maintenance Quantities (cy)
Offshore	Sabine Bank Extension	18,737,000	36,216,000
	Sabine Bank Channel	15,358,000	96,371,000
	Sabine Pass Outer Bar Channel	5,923,000	223,650,000
	Sabine Pass Jetty Channel	2,978,000	13,527,000
Inshore	Sabine Pass Channel	6,723,000	34,781,000
	Port Arthur Canal*	11,697,000	82,858,000
	Sabine-Neches Canal	11,944,000	73,245,000
	Neches River Channel	25,014,000	89,725,000
Total Quantities		98 mcy	650 mcy

*Includes Taylor Bayou channels and basins.

cy = cubic yards

Dredging depths will actually be deeper than the authorized depth when allowances for overdepth and advanced maintenance are included. Allowable overdepth is an additional depth outside the required dredging template that is permitted to allow for inaccuracies in the dredging process. Allowable overdepth for the existing channel varies between 1 and 2 feet. The Preferred Alternative would maintain a constant 2 feet of allowable overdepth for all channel reaches. Advance maintenance is the practice of dredging deeper than the authorized channel dimensions to provide for the accumulation and storage of sediment. In critical and fast-shoaling areas, it is required to avoid frequent redredging and to ensure the reliability and least overall cost for operating and maintaining the project authorized dimensions. The existing SNWW project has a constant 2-foot advance maintenance depth, and the Preferred Alternative assumes a minimum 2-foot depth for all channel reaches. During the Final Alternatives evaluation phase, an analysis was performed to identify potential with-project changes in dredging frequencies, and to determine whether an increase in advance maintenance would be required. As a result, an increase in advance maintenance (ranging from 1 to 5 feet) was proposed for some portions of some channel reaches to allow the proposed dredging frequency to remain the same as the existing O&M dredging frequency. The full potential dredging depth is provided in the description for each reach below. The full potential depths of each channel reach (including allowable overdepth, advance maintenance, and additional

advance maintenance) were included in the HS modeling. Each channel reach is divided into different sections for dredging contracts. These sections are shown on the Engineering Plates in the FFR.

2.4.1.1 Sabine Bank Extension Channel

This channel would lengthen the existing offshore entrance channel approximately 13.2 miles at a bottom width of 700 feet (Figure 2.4-1a). The additional length is required to reach a water depth in the Gulf equal to the proposed channel depth. The proposed offshore depth is 50 feet, but advance maintenance and allowable overdepth would add a total of 4 more feet, bringing the total dredged depth of the Extension Channel to 54 feet. It would be constructed by hopper dredge beginning at the end of the Sabine Bank Channel, and it would extend into the Gulf at the same bearing as the Sabine Bank Channel. An overview of the project details for the Sabine Bank Extension is listed in Table 2.4-3.

Table 2.4-3
Project Details of Sabine Bank Extension

Length of Reach	13.2 miles (new)
Project Depth	50 feet
Bottom Width	700 feet
Advance Maintenance	2 feet
Allowable Overdepth	2 feet
New Work Material	18,737,000 cy
Placement Areas	ODMDSs A, B, C, and D
Beneficial Use of Dredged Material	None
Maintenance Material (50-year quantity)	36,216,000 cy
Increase in Maintenance Material	36,216,000 cy
Placement Areas	ODMDSs A, B, C, and D
Beneficial Use of Dredged Material	None

2.4.1.2 Sabine Bank Channel

This 14.7-mile-long channel would be deepened from 42 to 50 feet using a hopper dredge (Figure 2.4-1b). When advance maintenance and allowable overdepth are added to the proposed 50-foot depth, the Sabine Bank Channel would be dredged to 54 feet. The bottom width of the Sabine Bank Channel is currently 800 feet; it would remain 800 feet wide for the first mile past the end of the Outer Bar Channel, and then it would taper from 800 feet to 700 feet over the next 0.5 mile. The Sabine Bank Channel would continue the 700-foot bottom width for approximately 13.2 miles to its connection with the Extension Channel. Since the existing channel is 800 feet wide, new channel markers would be required to mark the tapered transition and the remainder of the narrowed Sabine Bank Channel. An overview of the project details for the Sabine Bank Channel reach is listed in Table 2.4-4.

Table 2.4-4
Project Details for Sabine Bank Channel Reach

Length of Reach (sections 1, 2)	14.7 miles (no change)
Project Depth	50 feet
Bottom Width	800 feet then narrow to 700 feet
Advance Maintenance	2 feet
Allowable Overdepth	2 feet
New Work Material	15,358,000 cy
Placement Areas	ODMDSs 1 and 2
Beneficial Use of Dredged Material	None
Maintenance Material (50-year quantity)	96,371,000 cy
Increase in Maintenance Material	45,549,000 cy
Placement Areas	ODMDSs 1 and 2
Beneficial Use of Dredged Material	None

2.4.1.3 Sabine Pass Outer Bar Channel

This 3.4-mile-long channel would be deepened from 42 to 50 feet using a hopper dredge (see Figure 2.4-1b). This portion of the channel has higher-velocity eddies moving around the end of the east jetty, which causes sediment to settle out as the currents cross the navigation channel, creating a higher shoaling rate. Due to the high shoaling rate, advance maintenance amounts would be increased to maintain current maintenance dredging cycles. When advance maintenance and allowable overdepth are added, the Outer Bar Channel could be dredged to 58 feet. The Outer Bar Channel would remain at its current 800-foot bottom width due to strong crosscurrents just beyond the end of the jetties. An overview of the project details for the Sabine Pass Outer Bar Channel reach is listed in Table 2.4-5.

Table 2.4-5
Project Details for Sabine Pass Outer Bar Channel Reach

Length of Reach (Section 3)	3.4 miles (no change)
Project Depth	50 feet
Bottom Width	800 feet
Advance Maintenance	2 feet
Allowable Overdepth	2 feet
Additional Advance Maintenance	4 feet
New Work Material	5,923,000 cy
Placement Areas	ODMDS 3
Beneficial Use of Dredged Material	None
Maintenance Material (50-year quantity)	223,650,000 cy
Increase in Maintenance Material	123,965,000 cy
Placement Areas	ODMDS 3
Beneficial Use of Dredged Material	None

2.4.1.4 Sabine Pass Jetty Channel

This 4.1-mile-long channel would be deepened to 48 feet using a hopper dredge (Figure 2.4-1c). When advance maintenance and allowable overdepth are added, the Sabine Pass Jetty Channel could be dredged to 52 feet. The channel would gradually taper from the existing 800-foot width at the jetties' mouth to the existing 500-foot width. No impacts to the jetties would be associated with the proposed improvements. An overview of the project details for the Sabine Pass Jetty Channel reach is listed in Table 2.4-6.

Table 2.4-6
Project Details for Sabine Pass Jetty Channel Reach

Length of Reach (Section 4)	4.1 miles (no change)
Project Depth	48 feet
Bottom Width	800 to 500 feet
Advance Maintenance	2 feet
Allowable Overdepth	2 feet
New Work Material	2,978,000 cy
Placement Areas	ODMDS 4
Beneficial Use of Dredged Material	None
Maintenance Material (50-year quantity)	13,527,000 cy
Increase in Maintenance Material	2,142,000 cy
Placement Areas	ODMDS 4
Beneficial Use of Dredged Material	None

2.4.1.5 Sabine Pass Channel

This 5.6-mile-long channel begins just north of the jetties and extends upstream to Mesquite Point on Pleasure Island (Figure 2.4-1d). It would be deepened to 48 feet and constructed with a hydraulic pipeline dredge. Advance maintenance would vary in different sections of the Sabine Pass Channel to account for differences in shoaling rates. The maximum dredging depth for two reaches of this channel (Station 0+00 to Station 100+00, and Station 180+00 to Station 230+00) would be 52 feet. Due to additional advance maintenance required to maintain existing O&M dredging cycles, the reaches from Station 100+00 to Station 180+00 and Station 230+00 to the end of the Sabine Pass Channel at 296+25 would be dredged to a depth of 55 feet. The bottom width of the Sabine Pass Channel would remain 500 feet. The Sabine Pass Anchorage is located in this reach and its footprint would be reduced in size because it has never been fully utilized. The width would be decreased from 1,500 feet to 855 feet, and the length remains 8,200 feet. The angle of approach would remain the same. An overview of the project details for the Sabine Pass Channel reach is listed in Table 2.4-7.

2.4.1.6 Port Arthur Canal (including Taylor Bayou Channels and Turning Basins)

This 6.2-mile-long canal begins near Mesquite Point and ends at the Port Arthur Junction Area with the Taylor Bayou channels (Figure 2.4-1e). The Junction Area serves as a turning basin and has an irregular shape where the Taylor Bayou channels and the GIWW merge with it. The Port Arthur Canal would be deepened to the proposed depth of 48 feet with a hydraulic pipeline dredge. Advance maintenance would

vary in different sections of the Port Arthur Canal to account for differences in shoaling rates. The reach from Station 00+00 to Station 290+00 would be dredged to a maximum depth of 53 feet. The remaining part (Port Arthur Junction) between Stations 290+00 and 325+84 would be dredged to a maximum depth of 57 feet. The bottom width of the Port Arthur Canal would remain 500 feet up to the Junction Area. An overview of the project details for the Port Arthur Canal reach (including Taylor Bayou) is listed in Table 2.4-8.

Table 2.4-7
Project Details for Sabine Pass Channel Reach

Length of Reach (sections 5 and 6)	5.6 miles (no change)
Project Depth	48 feet
Bottom Width	500 feet
Advance Maintenance	2 feet
Allowable Overdepth	2 feet
Additional Advance Maintenance	Station 100+00 to Station 180+00 is 3 feet Station 230+00 to Station 295+61 is 3 feet
New Work Material	6,723,000 cy
Placement Areas	PA 5
Beneficial Use of Dredged Material	None
Maintenance Material (50-year quantity)	34,781,000 cy
Increase in Maintenance Material	4,191,000 cy
Placement Areas	none
Beneficial Use of Dredged Material	Gulf Shore Beneficial Use Feature

Table 2.4-8
Project Details for Port Arthur Canal Reach (including Taylor Bayou)

Length of Reach (sections 7 and 8)	6.2 miles (no change)
Project Depth	48 feet
Bottom Width	Varies (widest is 500 feet)
Advance Maintenance	2 feet
Allowable Overdepth	2 feet
Additional Advance Maintenance	(PA Canal) Station 0+00 to 290+00 is 1 foot (PA Canal) Station 290+00 to 326+37 is 5 feet (Taylor Bayou) Station 0+00 to 31+00 is 5 feet (Taylor Bayou) Station 31+00 to 106+25 is 1 foot
New Work Material	11,697,000 cy
Placement Areas	PAs 8 and 9
Beneficial Use of Dredged Material	None
Maintenance Material (50-year quantity)	82,858,000 cy
Increase in Maintenance Material	5,391,000 cy
Placement Areas	PA 8 and 9
Beneficial Use of Dredged Material	None

Located at the confluence of the Port Arthur Junction Area, the GIWW, and the mouth of the original Taylor Bayou, the Taylor Bayou Channels and Turning Basins consist of several sub-reaches: Entrance Channel, East Turning Basin, West Turning Basin, Connecting Channel, and the Taylor Bayou Turning Basin. Several significant changes are proposed for this area. When advance maintenance and allowable overdepth are added to the proposed 48-foot depth, all of the Taylor Bayou Channels and Basins could be dredged to 53 feet. The Taylor Bayou portion of the Junction Area, between Taylor Bayou Stations 0+00 and 41+20, would be dredged to 57 feet. The Taylor Bayou Entrance Channel and the West Turning Basin bottleneck curve would be widened, and a structural wall would protect local railroad tracks. Changes for each sub-reach are detailed below.

- **Taylor Bayou Entrance Channel.** The new bottom width widens on the west side of the channel. The channel would be widened to 444 feet at new Station 10+00. The new bottom width would taper back to the existing width by the end of the first curve at Station 28+38.
- **East Turning Basin.** The right side width would decrease 16 feet as the new depth extends down the existing side slope.
- **West Turning Basin.** The width of the existing bottleneck has been increased up to 120 feet on the west side, between new stations 33+00 and 55+00. The west bank of the basin would be protected by a structural wall, preventing impacts to the local railroad tracks present in this area.
- **Connecting Channel.** The West Turning Basin widening would taper back to the existing width in the Connecting Channel, between stations 55+00 and 67+00.
- **Taylor Bayou Turning Basin.** No changes would be made to the existing dimensions, but the basin would be deepened to the proposed 48-foot depth. Existing shore protection belonging to a local facility near Station 90+00 would be affected by penetration by the top-of-cut for the new depth.

2.4.1.7 Sabine-Neches Canal

The 11.2-mile-long canal begins at the Port Arthur Junction Area and ends just south of the mouth of the Neches River (Figure 2.4-1f). The GIWW shares this canal with the deep-draft channel. It would be deepened to the proposed depth of 48 feet with a hydraulic pipeline dredge. When advance maintenance and allowable overdepth are added, stations 0+00 to 40+00 could be dredged to 57 feet, and the remainder of the canal through Station 592+91 could be dredged to 53 feet.

The bottom width of this canal would be selectively widened in three separate sections. The bottom width of the most-downstream curve (stations 0+00 to 20+00) would be widened to 500 feet on the east side of the channel, and then promptly tapered to the existing 400-foot width prior to the MLK Bridge (SH 82). The canal would be widened to 450 feet adjacent to the Port of Port Arthur, with gradual tapering upstream and downstream between stations 120+00 and 170+00. The third widening section would begin to taper at Station 565+00, gradually widening to 500 feet and remaining that width to the end at Station 592+91.

Bend easing is proposed for three areas in the Sabine-Neches Canal to improve ship maneuverability: stations 265+00 to 305+00, stations 350+00 to 395+00, and stations 500+00 to 520+00. The bend easing between stations 350+00 to 395+00 would eliminate a wiggle in the alignment and shift the footprint of the canal 10 feet east of the existing alignment up to Station 520+00.

Changes are also recommended for the canal bottom adjacent to the Port Arthur Dock and the “Eye Basin.” The canal toes adjacent to the Port of Port Arthur would be moved approximately 10 feet to the east while keeping the same bottom width of 450 feet. The diameter of the turning point (“Eye Basin”) at Station 190+00 would be decreased by 16 feet. An overview of the project details for the Sabine-Neches Canal reach is listed in Table 2.4-9.

Table 2.4-9
Project Details for Sabine-Neches Canal Reach

Length of Reach (sections 9 and 10)	11.2 miles (no change)
Project Depth	48 feet
Bottom Width	varies 400 to 500 feet
Advance Maintenance	2 feet
Allowable Overdepth	2 feet
Additional Advance Maintenance	Station 0+00 to 40+00 is 5 feet Station 40+00 to 592+91 is 1 foot
New Work Material	11,944,000 cy
Placement Areas	PA 11
Beneficial Use of Dredged Material	None
Maintenance Material (50-year quantity)	73,245,000 cy
Increase in Maintenance Material	13,122,000 cy
Placement Areas	PAs 8 and 11
Beneficial Use of Dredged Material	None

2.4.1.8 Neches River Channel

This 18.5-mile-long channel begins just south of the mouth of the Neches River (Figure 2.4-1g). It would be deepened to the proposed depth of 48 feet to Station 980+00 with a hydraulic pipeline dredge. Advance maintenance would vary in different sections of the Neches River Channel to account for differences in shoaling rates. Between stations 0+00 and 440+00, the maximum dredged depth would be 52 feet; between stations 440+00 and 978+00, it would be 54 feet. While the overall bottom width of 400 feet does not change for the majority of the channel length, the first curve at the mouth of Neches River (between stations 0+00 and 75+00) would be widened to 500 feet, and then tapered back to 400 feet prior to the SH 87 twin bridges. The channel also will be widened to 500 feet between turning basins No. 1 and No. 2. An overview of the project details for the Neches River Channel reach is listed in Table 2.4-10.

Three basins will be added or enlarged on the Neches River Channel. All would be dredged to the proposed depth of 48 feet, plus the advance maintenance and allowable overdepth associated with the specific channel reach in which they are located.

Table 2.4-10
Project Details for the Neches River Channel Reach

Length of Reach (sections 11–18)	18.5 miles (no change)
Project Depth	48 feet
Bottom Width	400 feet (majority of channel) 500 feet Station 0+00 to 75+00
Advance Maintenance	2 feet
Allowable Overdepth	2 feet
Additional Advance Maintenance	Station 440+00 to 978+00 is 2 feet
New Work Material	25,014,000 cy
Placement Areas	PAs 12, 13, 14, 16, 18, 21, 23, 24, 25, 26, 27
Beneficial Use of Dredged Material	Neches River BU Feature
Maintenance Material (50-year quantity)	89,725,000 cy
Increase in Maintenance Material	23,277,000 cy
Placement Areas	PAs 12, 13, 14, 16, 17, 18, 21, 23, 24, 25, 26, 27
Beneficial Use of Dredged Material	Neches River BU Feature (Rose City East and Bessie Heights East only)
Turning Basins/Anchorage Areas	1 New; 2 Enlarged; 5 No change

- Turning and Anchorage Basin No. 1 would be located in an old river oxbow at the east end of Texaco Island near Station 210+00. The Turning Basin would enlarge the existing basin from 1,000 to 1,350 feet in diameter. A new Anchorage Basin, 250 by 1,100 feet in size, would be added.
- Turning and Anchorage Basin No. 4 would enlarge an existing turning point at Station 510+00 from 1,000 to 1,350 feet in diameter. A new Anchorage Basin in the old river oxbow at Station 500+00 would be 250 by 1,100 feet in size.
- Turning Basin No. 6 is an existing basin at Station 700+00. It would retain the same dimensions and would not be deepened to the proposed depth of 48 feet. Maintenance dredging would continue at the existing depth.
- The new Anchorage Basin No. 8 would be located at Station 850+00. The 250-x-1,000-foot basin is located in an old river oxbow.
- The Beaumont Maneuvering Basin's overall dimensions would remain the same as the existing project. Located near Station 975+00, it would be deepened to the proposed 48-foot depth.

2.4.1.9 Bridge Reinforcements and Fenders

Deepening and selective widening improvements to the SNWW navigation channels would affect existing fender systems of the Rainbow Bridge and Veterans Memorial Bridge over the Neches River Channel on SH 87 and the MLK Bridge over the Sabine-Neches Canal on SH 82. Bridge fender systems on both sides of the channel would require removal and replacement. None of the bridges would cause an unreasonable obstruction to navigation, and thus would not require modification or replacement pursuant to the Truman-Hobbs Act. However, existing MLK Bridge piers would be armored to protect them from erosion and maintain the proposed 400-foot channel width.

2.4.1.10 Aids to Navigation

Many of the existing aids to navigation within the waterway would require removal and replacement. The upstream reach from the Beaumont Maneuvering Basin and the vicinity of SH 87 on the Neches River Channel would not require changes in the navigation aids. Ranges and buoys would not need to be replaced along the Port Arthur Canal, Sabine Pass Channel, and Sabine Pass Jetty Channel. However, aids along the remainder of the waterway would need to be relocated, and new aids will be required along the Extension Channel.

2.4.1.11 Lands, Easements and Rights-of-Way

The non-Federal Sponsor is required to furnish the LERR for the proposed cost-shared project. The real estate requirements must support construction as well as operation and maintenance of the project after completion. A summary of the real estate requirements for each channel reach is provided in Table 2.4-11. Specific details of the real estate requirements can be found in the Real Estate Plan, Appendix 3 of the FFR.

Table 2.4-11
Real Estate Requirements for Placement Areas

	Real Estate Requirement
Channel Reach	
Sabine Bank Extension	Navigational servitude
Sabine Bank Channel	Navigational servitude
Sabine Pass Outer Bar Channel	Navigational servitude
Sabine Pass Jetty Channel	Navigational servitude
Sabine Pass Channel	Acquire in Fee (PA 5)
Port Arthur Canal	Navigational servitude (PA 8) Acquire in Fee (PA 9)
Sabine-Neches Canal	Navigational servitude (PAs 8, 11)
Neches River Channel	Owned by Sponsor (No-Action) (PAs 12, 13, 14, 16, 18, 18A, 21, 23, 23A, 24, 24A, 25, 25A) Acquire in Fee (PAs 17, 26, 27A, 27C, 27D) Turning Basins – two will require the acquisition of land in perpetual channel improvement easement
Louisiana Mitigation Areas	
Willow and Black Bayou Areas	Navigational servitude

2.4.1.12 Relocations

The following assumptions were made to identify pipelines that could be affected by the recommended plan and to develop associated costs. The individual circumstances of each pipeline will be evaluated by USACE in consultation with non-Federal sponsor and the pipeline owner during the preconstruction, engineering, and design (PED) and Construction phases, and decisions regarding necessary actions will be made individually for each pipeline at that time. Feasibility engineering guidelines indicate that pipelines with a minimum of 8 feet of cover for trenched lines or 5 feet of cover for directionally drilled

lines would not be adjusted. Pipelines that do not meet the minimum cover requirement would be required to be adjusted.

The adjusted pipelines must be located 20 feet below the authorized 48-foot depth. The 20 feet includes any advance maintenance and allowable overdepth. The relocation of active pipelines is assumed to be installed with directional drilling, and bundled where possible.

A total of 104 pipelines have been identified crossing the SNWW navigation channels. Of the 104 pipelines, 46 require adjustment to meet the minimum required vertical and horizontal clearances for the SNWW CIP.

Pursuant to Section 101(a) of the Water Resources Development Act (WRDA) of 1986, as amended, the Sponsor is responsible for performing, or assuring performance, of all relocations, including utility relocations, which are necessary for the CIP. All relocations, including utility relocations, are to be accomplished at no cost to the Federal Government.

The USACE, Galveston District has concluded preliminarily that 41 of the 46 lines located within the channel must be relocated and are classified as utility relocations for which the Sponsor must perform or assure performance. In accordance with Section 101(a)(4) of WRDA 86, one-half of the cost of each such relocation will be borne by the owner of the facility being relocated and one-half of the cost of each such relocation will be borne by the Sponsor. Such relocation costs will not include any cost for upgrading or improving such facilities, which is to be borne by the facility owner.

For more specific information regarding the utility relocations, and preliminary conclusions regarding the remaining 5 lines that must be removed but not replaced, see the FFR, Real Estate Plan, Appendix 4.

DMMP marsh restoration at Bessie Heights and mitigation marsh restoration measures east of Sabine Lake were assumed to require no relocations. However, since oil production is active in some of these areas, additional pipeline searches and coordination with pipeline owners would be required prior to construction to avoid impacts.

No relocations would be required for overhead power utilities, highway bridges, the Port Arthur Hurricane Flood Protection Levee, or its associated pump stations and closure structures.

2.4.2 Dredged Material Placement Areas

Dredged material produced by construction and operation of the Preferred Alternative over the 50-year period of analysis would be managed in accordance with the DMMP. More details can be found in the DMMP presented in Appendix D of this FEIS. The total new work construction quantity was presented in Table 2.4-2. Information on proposed maintenance quantities is important in evaluating potential project impacts. Table 2.4-12 provides a reach-by-reach comparison of maintenance quantities for the existing project (No-Action Alternative) and the Preferred Alternative. Disposal features proposed for the

Preferred Alternative consist of beneficial use features, upland PA features, and ODMDs. The location of all disposal features is shown on Figures 2.4-1a–g.

Table 2.4-12
Existing and Proposed Maintenance Dredging Quantities

Channel Reach	Existing 50-Year Maintenance Quantities (cy)	Proposed 50-Year Maintenance Quantities (cy)
Sabine Bank Extension	0	36,216,000
Sabine Bank Channel	50,822,000	96,371,000
Sabine Pass Outer Bar Channel	99,685,000	223,650,000
Sabine Pass Jetty Channel	11,385,000	13,527,000
Sabine Pass Channel	30,590,000	34,781,000
Port Arthur Canal	88,249,000	82,858,000
Sabine-Neches Canal	60,123,000	73,245,000
Neches River Channel	66,448,000	89,725,000
Total Quantities	407 mcy	650 mcy

2.4.2.1 Quantities and Types of Dredged Material

Construction of the Preferred Alternative would require the development of significantly more PA capacity than currently exists for the SNWW project. The existing project uses 16 upland PAs and 4 ODMDs. Construction of the Preferred Alternative would generate 98 mcy of new work material. Shoaling is projected to increase with the Preferred Alternative for several reasons (Parchure et al., 2005). The Entrance Channel would extend an additional 13.2 miles into the Gulf, and this would result in higher offshore dredging quantities. The deeper channel would have a greater cross-sectional area, making it function as a larger sediment trap; and higher salinities would increase flocculation and the deposition of suspended sediment.

Maintenance dredging is therefore projected to increase for the entire channel, from 407 to 650 mcy over the 50-year period of analysis. Expressed as average annual quantities, quantities will increase from 8.1 to 13.0 mcy per year (an increase of approximately 60 percent). Fifty-seven percent of the maintenance quantities for the Preferred Alternative would originate from the offshore channels, and 43 percent from the inshore channels. As would be expected with the offshore channel extension, maintenance dredging volumes for the offshore channel would increase more than the inshore reaches, with an increase from 162 to 370 mcy and 251 to 281 mcy, respectively. Additional capacity for the offshore reaches could be obtained by designating new ODMDs, and the designation of four new ODMDs is being sought (see Appendix B).

Finding areas suitable for the development of new upland PAs along the inshore reaches was difficult. The majority of land adjacent to the SNWW is either covered by residential and industrial development and existing PAs, or is coastal wetland. For this reason, considerable effort was directed toward evaluating alternatives for the placement of dredged material. Maintenance material would be used to the

greatest extent possible in the resulting DMMP. A discussion of the process used to evaluate these alternatives, and a description of alternatives considered, is provided in Section 2.5.

2.4.2.2 DMMP Beneficial Use Features

All DMMP BU features proposed for inclusion in the DMMP of the Preferred Alternative are described in Table 2.4-13. Three former marsh areas on the Neches River (Rose City East, Bessie Heights East, and Old River Cove) would be combined into one large management feature called the Neches River BU Feature (see Figure 2.5-1). In the Gulf Shore BU Feature, maintenance material would be used to nourish Gulf shorelines at Texas and Louisiana Points (see Figure 2.5-2). The DMMP BU features are not being pursued as separable elements of an ecosystem restoration plan under Section 204 or 207 authorities. They are not ecosystem restoration measures, and as such, do not target a specific historical condition for the level of restoration. They are least-cost, environmentally acceptable placement features and are included as general navigation features (GNF) of the DMMP.

The Neches River BU Feature would take advantage of new work material provided by the channel-deepening project to build hydraulic containment levees within degraded, former marsh areas at Rose City East, Bessie Heights East, and Old River Cove. Each of these areas is referred to as a component of the overall Neches River BU Feature. Marsh would be created in each component using only new work, or a combination of new work and maintenance material. The Old River Cove component would be filled during initial construction with new work material alone. In the Bessie Heights East component, maintenance material would be placed incrementally in seven maintenance cycles over 28 years. At the Rose City East component, new work material would be used to construct containment levees and ridges, then the marsh would be completed with the placement of maintenance material during the first maintenance cycle following construction. For the Neches River BU Feature as a whole, 2,853 acres of emergent marsh would be restored in areas that are now open water; 871 acres of improved shallow-water habitat would be created by the formation of shallower ponds and interconnecting channels within the restored marshes; and 1,234 acres of existing fringing marsh would be nourished by winnowing fine-grained material from unconfined flows of dredged material effluent. The size of the Neches River BU Feature components and the magnitude of their ecological benefits are made possible by the large amounts of dredged material that would be generated by the proposed project, and extensive opportunities for beneficial use in the project area.

The Gulf Shore Nourishment Feature would use material from regular maintenance dredging of the eastern section of the Sabine Pass Channel to nourish eroding marsh, and possibly create new saline marsh, along a total of 6 miles of shoreline on both sides of Sabine Pass at Louisiana and Texas Points. Material would be hydraulically pumped along a 3-mile reach of shoreline, from 0.5 to 3.5 miles from each jetty. The unconfined placement of material during each 3-year dredging cycle would alternate between Texas and Louisiana, so that materials would be placed on each state's shoreline every 6 years, for a total of 16 placement events over the 50-year period of analysis. Historic dredging records indicate that the material from Sabine Pass would average 51 percent silt, 31 percent clay, and 18 percent sand. The material would be hydraulically pumped into the nearshore zone and some material would be

expected to flow over existing marsh while the remainder flows into the nearshore waters. This mix of materials does not contain typical beach-quality sand; however, resource agencies have agreed that returning the material to the littoral system would have a net beneficial effect, regardless of the material type.

Table 2.4-13
DMMP BU Features, SNWW Preferred Alternative

Beneficial Use Features	No.	Description	Size of Influence Area
Rose City East (component of Neches River BU Measure)	TX 3-1 East	Restoring 345 acres fresh marsh, 72 acres of shallow water, and nourishing 151 acres of existing marsh in two construction events. New work material from Neches River Channel will be used to restore 225-acre marsh, construct hydraulic containment levees and higher elevation features. Maintenance material from the first maintenance cycle will be used to restore an additional 120 acres of marsh.	Influence area – 568 acres
Bessie Heights East (component of Neches River BU Measure)	TX 5-2	Restores 679 acres of brackish and 1,190 acres of intermediate marsh, 660 acres of shallow-water habitat, and nourishes 651 acres of existing marsh. Marsh will be constructed with maintenance material from Neches River Channel for 28 years. New work material is used to build hydraulic containment levee.	Influence area – 3,180 acres
Old River Cove (component of Neches River BU Measure)	TX 6-1	Restores 639 acres of brackish marsh, 139 acres of shallow-water habitat, and nourishes 432 acres of existing marsh with new work material from Neches River Channel. New work material used to construct hydraulic containment levee.	Influence area – 1,210 acres
Gulf Shore BU Feature (Texas and Louisiana Points)	TX 8-11 LA 5-2/6-2	Nourish 3 miles of Gulf shoreline on both sides of Sabine Pass, from 0.5 to 3.5 miles from East and West Jetties, using maintenance material from Sabine Pass Channel. Unconfined placement of maintenance material along shoreline every 3 years for 50-year period of analysis (8 placement episodes). Assume 50:50 split of material between Texas and Louisiana accomplished by alternating placement in Texas and Louisiana.	Affected shoreline 6.0 miles total

2.4.2.3 Upland Placement Areas

Sixteen existing and two expanded upland PAs proposed for use with the Preferred Alternative are listed in Table 2.4-14. Existing upland PAs would be used to the greatest extent possible; however, the expansion of some existing PAs would also be required. The locations of each PA are shown on figures 2.4-1d–g, and the evaluation of PA impacts is presented in subsection 2.5.3.3.

2.4.3 Impact Analysis and Mitigation Needs Summary for the Preferred Alternative

A full summary of the impact analysis and compensatory mitigation needs for the Preferred Alternative is presented in Table 2.4-16 for each state. The calculation of impacts and benefits of the DMMP BU features and mitigation measures are described in Section 2.5 and throughout Section 4 of this FEIS.

Table 2.4-14
Upland Placement Areas, SNWW Preferred Alternative

Placement Area	Additional Cell(s)	Size (acres)	Associated Waterway Section**
5	N&S, B and C	957	Sabine Pass Channel (sections 5 and 6)
8		3,570	Port Arthur Canal (sections 7 and 8)

4	3,444	Active	Section 4

2.4.4 Critical Assumptions

Critical planning and environmental assumptions were made in the evaluation of the benefits and impacts of the Recommended Plan. Table 2.4-17 provides a brief summary of the major assumptions, the scientific basis or rationale behind each assumption, and an indication of the consequences if the assumptions turn out not to be valid.

Table 2.4-16
Summary of the Impact Analysis and Compensatory Mitigation Needs for the Preferred Alternative

	Texas	Louisiana	Project as Whole
Impact Analysis (AAHUs*)			
Negative Impacts (–) Before DMMP BU	–412	–1,709	–2,121
Positive Impacts Resulting from DMMP BU	1,068	210	1,278
Net Gain or Loss (–) After DMMP BU	656	–1,499	–843
Offset of Impacts to Louisiana Federal Lands from Excess Texas BU Benefits	–340	340	NA
Net Gain or Loss (–) After BU Benefits	316	–1,159	–843
Compensatory Mitigation (AAHUs)			
Total Compensation	0	1,181	1,181
Net Gain After BU Benefits & Mitigation	316	22	338
Impact Analysis (Acres)			
Size of Potential Impact Area	58,649	197,530	256,179
Area with No Impacts	19,421	15,247	34,668
Area of Direct Impacts	86	0	86
Area of Indirect Impacts	39,228	182,283	221,511
Net Acres of Land Loss (–) before DMMP BU	–247	–691	–938
Total Shoreline Influenced by DMMP BU	3 miles	3 miles	6 miles
Total Acres Affected by DMMP BU	4,958	0	4,958
Created Emergent Marsh	2,853	0	2,853
Improved Shallow Water	871	0	871
Nourished Existing Marsh	1,234	0	1,234
Compensatory Mitigation (Acres)			
Total Acres Affected by Mitigation	0	8,095	8,095
Created Emergent Marsh	0	2,783	2,783
Improved Shallow Water	0	957	957
Nourished Existing Marsh	0	4,355	4,355
Total Acres Affected by DMMP BU and Mitigation	4,958	8,095	13,053
Created Emergent Marsh	2,853	2,783	5,636
Improved Shallow Water	871	957	1,828
Nourished Existing Marsh	1,234	4,355	5,589

*AAHU = Average annual Habitat Units

Table 2.4-17
Critical Assumptions

Assumption	Rationale for the Assumption	Consequences if Assumption Becomes Invalid
FWOP Condition		
Louisiana Coastal Wetlands Planning, Protection, and Restoration Act (CWPPRA) Projects in operation at Willow Bayou, Black Bayou, and Perry Ridge for remainder of project life.	Ecological effects of CWPPRA projects (reductions in land loss rates and/or salinity) based upon changes projected in environmental assessments.	If ecological benefit of CWPPRA project is less than expected, then FWOP salinity and land loss impacts would be slightly higher than expected; conversely, if ecological benefits are higher, FWOP impacts would be slightly lower than expected.
Most likely rate of RSLR estimated to be 1.1 feet in the study area by year 2069. Full potential range of RSLR estimated to be from 0.3 to 2.8 feet over period of analysis.	Eustatic sea-level rise based upon mid- to high mid-range projected by National Research Council (NRC) and Intergovernmental Panel on Climate Change (IPCC), respectively. Local subsidence component based upon long-term trends obtained from basal peat analysis. Full potential range calculated as required by Circular No. 1165-2-211.	Little consequence if RSLR is lower than expected. High rate of RSLR could result in small increase in maintenance dredging and PA levee heights for existing project; increase in hurricane tidal surge elevation; an increase in land loss due to submergence of intertidal marshes; and salinity increase. Functioning of navigation channel would not be affected; improvements at some dock facilities might be needed.
Future freshwater inflows assumed for HS modeling are slightly higher on Neches River than existing inflows; about the same as existing inflows on the Sabine River.	Future freshwater inflows were based upon demand projections and supply strategies approved by the 2007 Texas State Water Plan.	Little consequence if inflows are higher than projected. If inflows are lower than expected, FWOP ecological impacts would be higher than expected and more areas would be experiencing suboptimal salinities.
Changes in land loss rates are driven by the interaction of salinity and submergence, resulting in a reduction in plant productivity, leading to a decrease in plant growth, plant death, followed by peat collapse and wetland loss. Assumed linear relationship between change in salinity due to RSLR and change in FWOP land loss rate.	The salinity-vegetation productivity relationship is based upon algorithms developed for dominant wetland vegetation species in the study area. The algorithms were developed for the Louisiana Coastal Areas Ecosystem Restoration Study using data from a large number of professional studies.	If the relationship between salinity and land loss is different from that projected, FWOP land loss would be higher or lower than current estimates.
FWP Condition (Preferred Alternative)		
RSLR – same as FWOP because deepening project causes only negligible increase in water surface elevation.	FWP water surface elevation change determined by ERDC HS modeling.	Little consequence if RSLR is lower than expected. No FWP effect on maintenance dredging, PA levee heights, or tidal surge penetration. At high rate, all areas suitable for marsh mitigation could be susceptible to submergence. DMMP BUs protected by containment structures.
Additional land loss would result primarily from the interaction of higher FWP salinities with FWOP RSLR. Assume direct linear relationship between salinity and land loss changes.	Associating land loss with salinity increases is based upon well-documented biological responses of inundated vegetation to salinity change. No data are currently available that relate specific salinity changes to specific land loss rate changes.	If the relationship between salinity and land loss is different from that projected, FWP impacts would be higher or lower than current estimates.

Table 2.4-17, cont'd

Assumption	Rationale for the Assumption	Consequences if Assumption Becomes Invalid
Cost Estimates		
Cost estimate of the Preferred Alternative utilized appropriate probabilities of risk.	Cost risk analysis was performed using required forecasting and analysis tools. Cost contingencies developed by this analysis have been included in the total project cost estimate.	An increase in total project cost, exclusive of price level changes, of more than 20 percent of the total project cost stated in the authorizing legislation would require Congressional authorization.
It was assumed that up to 5 pipeline dredges would be available for use at one time for inshore channel dredging, and mitigation and BU marsh creation. Offshore dredging assumes use of only one hopper dredge at a time.	Assume offshore hopper dredge production averaging 7.9 mcy/yr; inshore pipeline dredge production of 7.2 mcy/year; and no more than 550 acres/year of mitigation or BU marsh creation by any one dredge.	If the assumed production rate is too high, or if the assumed number of dredges is not available, then construction would take longer and the total cost of construction would increase.
Funding		
Sufficient funding streams would be available to construct the Preferred Alternative over the assumed construction periods and to provide long-term operation and maintenance.	USACE planning policy states that plans should be developed without funding constraints. Federal funding priorities are difficult to predict.	Total project cost could be higher because of longer construction schedule. Inadequate O&M funding could cause an increase in navigation costs or adversely affect monitoring of mitigation and BU features.

2.5 EVALUATION OF ALTERNATIVES FOR THE MANAGEMENT OF DREDGED MATERIAL

2.5.1 Regional Sediment Management Objectives and Scope

The principles of RSM were applied in evaluating alternatives for the placement of dredged material from the proposed SNWW CIP. RSM is an approach for managing projects involving sand and other sediments derived from dredging and other activities in riverine, estuarine, and coastal systems (USACE, 2006b). Its major objective is the retention of sand or other sediments in natural aquatic systems, thereby supporting a more sustainable process and potentially reducing project costs (Martin, 2002). RSM incorporates many of the principles of watershed planning, but applies them in the context of dredging and other activities that influence sediment resources. It broadens the problem-solving perspective from a project-specific scale to a larger spatial and longer-term perspective. This requires the integration of a broad range of disciplines and collaborative partnerships among stakeholders. The USACE authorities and policies that support implementation of RSM are discussed in Technical Note No. 8 for the RSM Demonstration Program (USACE, 2003a).

The geographic focus of an RSM analysis is a sediment system, on a scale that is relevant to issues (e.g., dredged material management or processes like erosion or shoaling) that have been identified by stakeholders in the region. The RSM study area essentially coincides with the SNWW study area and contains riverine, estuarine, and coastal environments. It is large enough to facilitate understanding of sediment processes and behavior and the inherent interconnectedness of all parts of a sediment system. The RSM study area includes the existing 65-mile-long SNWW navigation channel that extends from

22 miles offshore in the Gulf, through a jettied entrance at Sabine Pass, up artificial canals on the west side of Sabine Lake, and finally up the Neches River Channel to the City of Beaumont. The SNWW area of analysis incorporates all of the existing and proposed navigation and placement features, and significant inflows and structures that affect the system. The littoral portion of the study area extends from Holly Beach, Louisiana, to Sea Rim State Park in Texas, roughly a distance of 40 miles. It extends into the Gulf along the existing Entrance Channel, proposed channel extension, and ODMDSs for a distance of roughly 40 miles; and it extends inland from the coastline approximately 40 miles to incorporate the tidally influenced reaches of the Sabine and Neches rivers watersheds and Sabine Lake.

The Texas Coastwide Erosion Response Plan has identified several parts of the study area as “critical erosion areas” because of impacts to habitats and traffic safety from ongoing erosion, and has called for an increase in the beneficial use of dredged material from the SNWW project to help address these issues. The plan was developed as part of the Texas Coastal Erosion Planning and Response Program (CEPRA) (GLO, 2004, 2005). The program has identified the Gulf shoreline between Texas Point and Sea Rim State Park as a critical erosion area. It attributes the erosion, in part, to a lack of sediment coming down the Sabine and Neches rivers, and the interruption of longshore sediment transport by the SNWW jetties. The CEPRA Plan recommends that long-term regional sediment management be utilized, along with highway realignment and beach dune restoration, to protect the important coastal evacuation route of SH 87 in Jefferson County. As described below, the Gulf Shore BU Feature will provide a long-term, RSM approach to restoring some sediment to the littoral zone in this area of high erosion. In Orange County, the CEPRA Plan calls for restoration of 9,400 acres of marsh in the Lower Neches River using dredged material to raise soil elevations in the former marsh areas that have become open water. These are the same marsh areas (i.e., Rose City, Bessie Heights, and Old River Cove) that have been combined into the Neches River BU Feature. The evaluation of these beneficial use features is described more fully later in this chapter.

2.5.2 Description of the SNWW Sediment System

2.5.2.1 Geomorphology

The modern coast of the northwest Gulf is the product of dramatic processes that occurred at the end of the Holocene sea level rise. The lowstand occurred approximately 20,000 to 18,000 years before present (B.P.) when the sea level was about 350 feet lower than today. Rapid sea level rise occurred until 7,000 to 6,000 years B.P., and then slowed to reach the modern stillstand about 3,000 years B.P. (Blum et al., 2002; Frazier, 1974; Nelson and Bray, 1970). The offshore shoal area of Sabine Bank is a relict shoreline that formed during this period. As the sea level rose, the Sabine and Neches rivers backfilled incised valleys that had developed during the lowstand. The Chenier Plain on both sides of Sabine Pass was created with sediment transported by the westernmost of the Mississippi River’s major distributaries (Byrnes and McBride, 1995). The Mississippi River never flowed directly through this region, and thus much less erosion of the Pleistocene surface occurred (Penland and Ramsey, 1990). Rather than the hundreds of feet of silty sediment that overlays the Pleistocene surface in the Louisiana coastal plain to the east, the Pleistocene surface lies beneath about 49 feet of sediment in the Chenier Plain region. It is composed of a

series of parallel beach ridges that evolved as a series of prograding mudflats intermittently reworked into sandy or shelly ridges. Sabine Lake formed in the elongated drowned river valley of the Sabine River. The Sabine River and the Neches River empty into the northeast and northwest corners, respectively, of Sabine Lake.

The modern Gulf shoreline from Holly Beach to Sea Rim State Park is composed of mudflats, mud washover flats, clay marsh platforms, sandy washover flats, and some sandy beaches (Louisiana Department of Natural Resources [LDNR], 1997; PBS&J, 2006; USACE, 1971a). The low marshy areas on the east and west sides of Sabine Pass are known as Louisiana and Texas Points, respectively. Both shorelines within 10 miles of Sabine Pass are entirely undeveloped, and public access is limited. In Texas, a section of SH 87 has been abandoned since 1989 due to shoreline erosion. Most of the shoreline in the Texas portion of the study area is located within the Texas Point NWR. In Louisiana, SH 82 crosses Sabine Lake where the lake begins its constriction into Sabine Pass, and does not approach the coastline until it nears the small community of Johnson's Bayou. The property south of SH 82 is privately held, with the exception of the SNWW PA 5 on Sabine Pass. Recreation and wildlife preservation have been the major uses of the area; however, recently the new Sabine Pass LNG facility has been constructed on the waterway northwest of PA 5.

The only major inlet in the sediment system is Sabine Pass, the jettied entrance for the SNWW. These navigation structures extend seaward, blocking longshore sediment transport and carrying sediment out of the littoral zone. The Sabine Pass Jetties were built between 1883 and 1885 with east and west completion lengths of 25,000 feet (4.7 miles) and 22,000 feet (4.2 miles), respectively (Alperin, 1977). Longshore transport of sediments from the east is also affected by navigation jetties at Calcasieu Pass (USACE, 2004a). Construction on the east jetty at Calcasieu Pass began in 1893 and the west jetty in 1986 (USACE, 1961). Over the next 45 years, east and west Calcasieu jetties reached 10,500 feet (2 miles) and 8,200 feet (1.6 miles), respectively.

Offshore of Sabine Pass, the bottom slope averages 6 feet per mile until roughly 1 mile offshore, after which it steadily decreases to an average 1 foot per mile through roughly 10 miles offshore (White et al., 1987). Thus, for most of its extent the shelf is gently sloping and (with the exception of Sabine Bank) is relatively featureless. The Sabine Bank is the principal topographic feature with approximately 25 feet of relief. Sandy muds and clay muds predominate the surface inner shelf region; however, the surface of virtually the entire area is covered by a sheet of sand approximately 2 feet thick (Anderson and Wellner, 2002; PBS&J, 2004b). An extensive outcrop of Beaumont clay is located nearshore and within 2 feet of the sediment surface, beginning near Sea Rim State Park and extending westward (Nelson and Bray, 1970). The Beaumont clay is derived from coastal and deltaic plain silts and clays that were deposited on the continental shelf during the previous lowstand. The clay outcrops from a complex, eroding scarp face with relief of approximately 2 feet (Pacific International Engineering [PIE], 2003).

Sabine Bank is the only area that contains significant quantities of beach-quality sand (Morton et al., 1995). It is an elongated feature, located approximately 17 miles south of the mouth of Sabine Pass and oriented roughly parallel to the coast (Blum et al., 2002). The main body of the bank (Sabine West Bank)

is 20.5 miles long, and water depths over the bank range average 39 feet below mean low water. The existing SNWW Entrance Channel passes approximately 0.75 mile to the east of its eastern edge. A smaller body of Sabine Bank (Sabine Bank East), approximately 10.5 miles long, is located east-northeast of the SNWW channel. Existing ODMDs 1 and 2 are located north and south of the eastern end of the Sabine West Bank, sufficiently distant that materials placed there do not flow onto them. All of the four existing and four proposed ODMDs are evenly spaced on the west side of the existing and proposed extension channel. They were located on the west side of the channel so they will be downstream of the most prevalent circulation currents in the northwest Gulf.

2.5.2.2 Wind, Tides, and Circulation

The hydrodynamic regime in the northwestern Gulf results from a complex interaction of tides, meteorological driving forces, freshwater inflows, and Coriolis acceleration. Both local conditions and the overall Gulf circulation pattern affect the area. In addition, major storms profoundly influence waves, tides, currents, and sediment movement.

The combination of a broad continental shelf and low waves in the Gulf allows local winds to play a more dominant role in shoreline dynamics in this area than on most other beaches around the U.S. (King, 2007). Local winds can directly modify longshore currents within the surf zone and in the nearshore environment. The average wind direction from a buoy off Sea Rim State Park is from the south-southeast (PIE, 2003). However, wind direction is more southerly in summer months and more southeasterly at other times of the year. Average speeds are fairly constant at 9 to 13 miles per hour throughout the year, reaching maximum in April and May.

Astronomical tides are generally small in the Gulf. They vary from diurnal to semidiurnal as a function of the moon's declination, with an average amplitude of approximately 1 foot (King, 2007). During average conditions, waves in the nearshore are depth-limited and controlled by water levels, the mild nearshore slope, and the possible presence of a soft mud bottom (PIE, 2003). The coast of the Chenier Plain between Sabine Pass and Calcasieu Pass is also microtidal, with tides ranging from 2.0 to 2.4 feet. Waves come from the south about 16 percent of the time and from the south-southeast 28 percent of the time (Byrnes and McBride, 1995).

A major feature that dominates circulation in the eastern Gulf is the Loop Current, a continuation of the Yucatan Current which enters the Gulf through the Yucatan straits. There are two important semipermanent currents that diverge from the Loop Current; the one in the northwestern Gulf circulates counterclockwise (Rouse et al., 2004). Inner-shelf currents in the Gulf off the Louisiana and upper Texas coast flow westward and move downcoast during the late fall, winter, and early spring. This flow is highly responsive to wind forcing and may briefly reverse direction and flow upcoast. This reversal typically occurs during late spring, so that for a month or more the mean current in this area may be eastward. During the summer, when winds are weaker, the coastal waters are highly stratified, and surface flows may not flow in the same direction as near-bottom currents.

Bottom currents have a strong effect on sediment movement on the shelf. A study of water velocities needed to cause rapid erosion on sediments similar to those in the study area found a critical erosion velocity of 0.47 knot, with little variation among sand, silt, or clay (Moherek, 1978). The bottom ocean currents near Sabine Pass should have sustained bottom velocities of at least twice the critical erosion velocity for several days each year. Within approximately 40 miles of the Gulf Coast in this area, bottom current will reach a maximum velocity of about 3.9 knots every 3 years and sustain velocities of 1 knot or greater for several days once a year (EPA, 1982). Pre- and postdredging surveys of the existing ODMDs off Sabine Pass provide corroborating evidence of this sediment movement. Maintenance material from recurrent dredging placement episodes disperses after each placement and does not accumulate.

2.5.2.3 Coastal Shoreline Erosion Impacts

The changes in sediment transport, while very small, can be expected to have some effect on the rates of shoreline erosion. Under the Preferred Alternative, there is a slight reduction in the erosion rate near the jetties. Near the jetties, the average rate of shoreline accretion was calculated to be as much as 60 feet/year. However, between 0.5 mile and 3 to 4 miles on either side of the jetties, the erosion would be increased by less than 0.5 foot/year for a 50-foot project and farther from the jetties than that, the shoreline change would decrease to zero. The effect of the 48-foot channel on the Gulf shoreline between 0.5 mile and 3.5 miles from each jetty was estimated to be 0.42 foot/year based upon the 45- and 50-foot project effects.

The Gulf Shore BU Feature should have a positive effect on reducing shoreline erosion. The presence of additional fine-grained sediments in the littoral system, which would be provided by the BU feature, should reduce the current erosion rate and minimize the small increase in shore erosion predicted with the project. In systems that have an abundant supply of fine-grained sediments, the presence of additional muddy sediment in the nearshore environment may attenuate waves and lessen wave-induced erosion (Hsiao and Shemdin, 1980; Tubman and Suhayda, 1976; Wells and Kemp, 1986). Furthermore, the predominantly fine-grained sediment provided by this BU feature should contribute to mudflat accretion by periodically moving onshore and becoming shore-attached. On the western Louisiana and eastern Texas coasts, sediments accumulate as mudflats and underwater mudshoals (or “fluid mud”) in the nearshore region. Nearshore, fluid mud can be trapped against the shoreline by prevailing south and southwesterly winds, and storms carry the trapped muddy ooze onto the chenier shoreline (Morgan et al., 1958; Wells and Kemp, 1982, 1986). Accretion of the shoreline can then occur by poorly understood processes (Huh et al., 1991; King, 2007; PIE, 2003).

Although the BU sediments would be largely fine grained, approximately 18 percent of maintenance material is expected to be sand. Sands that are deposited onshore would nourish and stabilize eroding marshes and sand deposited in the nearshore zone should stay in the nearshore environment, moving back and forth across the shoreface (Wamsley, 2008). Sand placed at Louisiana Point should remain on the shoreface where it was deposited; no significant amounts of sand are expected to enter the Jetty Channel. On erosive mud shorelines like those in the BU area, the sand percentage should increase, and it would form sandy lenses or a veneer over the mud shoreline substrate. As the sand lenses thicken, the sands help

protect the underlying mud from further erosion (Nairn, 1992). However, in smaller quantities, sand can also accelerate erosion of a mud beach. If the consolidated mud is not covered by a sand veneer, any sand that is mobilized by wave action would act as a scouring agent (King, 2007).

2.5.2.4 Inland Shoreline Erosion Impacts

The primary area of concern for inland shoreline impacts is Pleasure Island along the confined channels of the Port Arthur and Sabine-Neches canals (Parchure et al., 2005). No increase in the existing erosion rate is predicted with the project for the eastern shore of Sabine Lake. The primary mechanism for shoreline erosion associated with the project is from passage of large vessels. Maynard (2005) investigated the mechanisms of ship-induced bank recession (shoreline erosion). The analysis employed a numerical model (HIVEL2D) to simulate the ship-induced velocity at the bank and employed information on the vessels in the existing and future fleets and information on the speeds that would be needed in both the No-Action and Preferred alternatives. The analysis focused on two sites on Pleasure Island; the north site is in the Sabine-Neches Canal, and the south site is in the Port Arthur Canal. The north site has no existing erosion protection, while the south site has riprap protection. Neither site will have a change in channel width. The analysis was calibrated to the existing rates of bank recession, and it used the model to account for differing numbers of vessel trips projected for the years 2030 and 2060 for both the No-Action and 50-foot alternatives. The Preferred Alternative is expected to have a lesser effect than the 50-foot alternative.

Maynard (2005) found that the rates of erosion are lower for the 50-foot alternative than for the No-Action Alternative at both the north and south sites for both 2030 and 2060 traffic levels. Overall, the effect of the Preferred Alternative should be to reduce the rate of erosion on inland channels relative to the No-Action Alternative because of fewer vessel trips that are predicted with the Preferred Alternative than in the No-Action Alternative.

2.5.2.5 Longshore Transport

In general, the longshore movement of littoral sediments in the study area is from the east to the west (King, 2007; Morang, 2006; USACE, 2004a). In the recent past, the estimated net longshore sediment transport to the west ranged from 47,000 to 97,000 cy/year east of Sabine Pass (USACE, 1971a). West of Sabine Pass, the typical yearly net longshore sediment transport is to the southwest (Carothers and Innis, 1960; Mathewson, 1987; USACE, 1971b), with an occasional reversal of direction at Sea Rim State Beach (King, 2007; Mason, 1981). At Sea Rim State Park, the typical net transport to the southwest was about 70,600 cy/year; for the atypical reversal to the northeast, the net transport rate was 35,000 cy/year (Mason, 1981). Another study of coastal geomorphology and shoreline erosion in Jefferson County was conducted by PIE (2003) in conjunction with ongoing studies of erosion impacts to SH 87. PIE calculated longshore sediment transport using both Galveston Buoy and Wave Information Study data. In general, the gross sediment transport rate was found to be higher toward Galveston Island. Transport divergence was indicated near Sea Rim State Park, in the vicinity of two areas of high erosion along Texas Point.

Longshore transport and wave modeling have been performed, and a sediment budget has been prepared for the study area in conjunction with a shoreline erosion study of the Texas coast from Sabine Pass through Galveston Island (King, 2007; Morang, 2006). These studies have confirmed that the littoral system in the study area is dominated by fine-grained sediments. The shorelines along Texas and Louisiana Points are primarily composed of consolidated mud (King, 2007; USACE, 2004a). Farther to the west, the consolidated mud substrate is overlain by sand veneers and is only occasionally exposed. Aside from the prevalence of fine-grained sediments along Texas Point, there was no real trend in median grain sizes in the study area. In Louisiana, the shoreline is similar to those found in Texas for about 2 miles east of the jetty and then it transitions to a sandy beach that reaches toward Ocean View Beach. Sediment transport and deposition are distinctly different on mud shorelines than on sandy beaches (King, 2007). Once eroded, cohesive sediments (clays and silts) are generally carried in suspension until deposited in a less-energetic environment (e.g., deeper water outside the surf zone or in wave-sheltered areas such as quiet bays and estuaries), and so are lost to the littoral system.

On sand beaches, the mobilized sand generally stays within the active profile. This is the primary reason that most of the world's beaches are composed of sediments having diameters greater than 0.10 mm. The depth of closure, or the sedimentologically active zone, has recently been determined to be approximately 19.7 feet deep off the upper Texas coast (King, 2007). Sand deposited any deeper than this point is unable to move any closer to shore. On the Texas side of Sabine Pass, this is roughly 3 to 4 miles from shore; off Louisiana Point, this point is roughly 2 to 3 miles from shore.

In regions like the study area that have large supplies of fine-grained sediments, the nearshore seabed can be blanketed with thick, unconsolidated, gel-like, mud oozes called "fluid mud." There are numerous anecdotal reports of the presence of floating rafts of "fluid mud" on the Gulf's surface west of the Atchafalaya River mouth in Louisiana, and off Texas Point and Sea Rim State Park (Block, 1984; PIE, 2003). Nearshore, the fluid mud can be trapped against the shoreline by prevailing south and southwesterly winds, and storms carry the trapped muddy ooze onto the chenier shoreline (Morgan et al., 1958; Wells and Kemp, 1982, 1986). Accretion of the shoreline can then occur by poorly understood processes (Huh et al., 1991; King, 2007).

2.5.2.6 Shoreline Descriptions

Jefferson County and Cameron Parish coastlines in the study area are mainland beaches fronting a chenier plain that formed from a Pleistocene promontory overlain by Holocene marginal deltaic sediments (King, 2007; USACE, 2004a). The upland area adjacent to the coast is a relatively flat, gently sloping terrain with marsh elevations of 1 to 2 feet mean sea level and ridge elevations of 5 to 6 feet mean sea level. Saline marsh vegetation covers the upland area behind the eroding shoreface. In the Texas Point NWR, a fillet of muddy substrate that was created by rapid deposition over approximately the last 100 years lies seaward of the chenier ridges. For the period between 1883 and 1970, the net accretion was documented at 2,225 feet (Morton, 1975). The fillet of recent deposits recedes rapidly and disappears approximately 0.5 mile from the West Jetty, where the Chenier Plain again fronts the Gulf until it ends about 18 miles from Sabine Pass (PIE, 2003).

The shoreline in the Texas Point NWR (between Sabine Pass and Sea Rim State Park) is a muddy shoreface composed of consolidated mud (King, 2007; PIE, 2003). A thin veneer of sand thrown up onto the marsh edge by storms covers some areas of the mud substrate. Farther west, the Sea Rim State Park area is a sediment transport convergence zone, and the beach typically has a substantial veneer of sand. In Louisiana, the coastline for approximately 10 miles east of the jetty contains tidal sand/mudflats, sand bars and sandy beaches with tidal flats (PBS&J, 2006). A narrow tidal sand/mud flat, ranging from 30 to 450 feet in width, extends for about 1.5 miles east of the jetty, and then transitions to a sandy beach. These beaches vary in width from 50 to 300 feet and end at an eroded, low mud bank shoreline. A sand bar is present in the nearshore zone that is the result of the beneficial placement of dredged material by Cheniere Energy in conjunction with construction of the Sabine Pass LNG facility. The 10-to-150-foot-wide bar begins about 0.5 mile from the jetty and extends for about 1 mile to the east. It lies roughly parallel to the shore, between 4,000 and 1,200 feet offshore.

2.5.2.7 Historical Shoreline Change in the Study Area

The northwest Gulf Coast system is sand starved, and essentially no modern-day sand is being delivered to these beaches (Lee, 2003; Morang, 2006; Morton, 1977). The only coarse-grained sand reaching the Texas shores appears to originate from the erosion of underlying Pleistocene barrier-strand plain deposits, which contain lenses of fine-grained and poorly sorted sands in massive clay and silt deposits (Isphording et al., 1989). The lack of delivery of coarse-grained sand during the modern stillstand has contributed significantly to shoreline erosion in the area. The very limited coarse-grained load of the Sabine and Neches rivers is deposited in bay-head deltas in Sabine Lake rather than on the coast (Mason, 1981; Morang, 2006; USACE, 1971b). Therefore, the limited sand in the northwest Gulf coastal system either migrated up the shoreface with the Holocene sea rise or was eroded from relict Pleistocene deposits.

Chronic erosion is believed to be associated with the diversion of sand and other sediment resulting from channelization and regulation of the Mississippi and Atchafalaya rivers to the east, and the Sabine and Neches rivers in Texas. The Calcasieu and Mermentau rivers also do not supply coarse-grained sediments, and the Cameron jetties deflect the little material that does exist away from the Holly Beach area, so that it accumulates to the west at Long Beach, Louisiana's westernmost sandy beach (LDNR, 1997; USACE, 2004a). The Sabine Pass jetties also intercept sediment moving westward in the littoral drift, creating a wide, muddy, tidal flat next to the east jetty (PBS&J, 2006; USACE, 2004a). On the Texas side, a 0.5-mile-wide fillet of silt and mud, located immediately adjacent to the west jetty, intercepts sediments moving from the west during periodic reversals near Sea Rim State Park in the dominant longshore movement (PIE, 2003).

Shoreline change has been extensive in this region and continues to be an ongoing problem. In the area between Ocean View Beach and the Sabine jetties, the shoreline prograded seaward at an average rate of +12.9 feet/year between 1883 and 1994. Recently, however, accretion has slowed to +1.2 feet/year, and the behavior of this shoreline has become erratic, with change rates varying between -13.2 and +14.7 feet/year (USACE, 2004a). East of Ocean View Beach, the 10-mile-long coastline to Holly Beach fronts a series of chenier and beach ridges that provided a foundation for roadways and commercial

development before it was essentially destroyed by Hurricane Rita in 2001. Persistent erosion in this area, on the order of –4.3 feet/year between 1985 and 1998, was recorded here prior to the hurricane (USACE, 2004a). Hurricane Rita’s storm surge at Louisiana Point was 10.6 feet as recorded by U.S. Geological Survey (USGS) sensors (Farris et al., 2007). The surge deposited 3.3 feet of new sediment on the Hackberry Beach chenier ridge and inundated thousands of acres of coastal marsh. Bar welding to the lower shoreface was also evident (Guidroz et al., 2006). Immediately after the storm, hundreds of acres of marshay cordgrass marsh in Cameron Parish appeared to have been severely impacted by extensive flooding of high-salinity waters. When the water finally subsided, the vegetation in many areas appeared dead, and the marsh had areas that were 30 to 50 percent devegetated. Over time, porewater salinity levels should decline as rainwater flushes salinity from the system (Farris et al., 2007). On the Texas side of Sabine Pass, a 0.5-mile stretch of shoreline adjacent to the west jetty is aggrading at a rapid rate, but beyond this narrow zone to the west, is an active erosion zone extending approximately 15 miles to the vicinity of Sea Rim State Park (Morang, 2006). This eroding stretch of the Jefferson County coastline is experiencing the largest erosion rate on the upper Texas coast, up to 40 to 50 feet/year (King, 2007). It has been identified as a “critical erosion area” by the Texas Coastwide Erosion Response Plan because of threats to traffic safety and wildlife habitat. Shoreline erosion has destroyed a portion of SH 87, an important hurricane evacuation route, and is eroding coastal wetland habitat at Texas Point and McFaddin NWRs (GLO, 2004, 2005).

2.5.2.8 Sabine Pass Sediment Budget

New littoral transport rates have recently been calculated for the Sabine Pass littoral zone. The Sabine Pass sediment budget (Morang, 2006) applied shoreline change statistics that were computed from changes in sediment volume for littoral cells, using cross-shore profiles that were projected with an ERDC modeling study (King, 2007). The sediment budget focused on characterizing sediment movement in the coastal segments of the navigation channel and nearby Texas shoreline. Accurate estimates of the percentage of total transport that is suspended sediment load from the inshore area were not available. Six of the 23 cells defined for this study are relevant to this discussion—three cells (the Sabine Pass Channel, the Sabine Jetty Channel, the Sabine Outer Bar Channel) were used to analyze sediment movement in the navigation channels through Sabine Pass and past the jetties; three other cells (the Sabine Fillet, Texas Point NWR, and Sea Rim State Beach) were used to calculate sediment movement along the littoral zone westward of Sabine Pass. A summary of the sediment budget results is presented in Table 2.5-1.

2.5.2.9 Existing Project Shoaling and Sediment Transport Conditions

The following summary of shoaling and sediment transport conditions for the existing SNWW includes all segments of the existing SNWW navigation system. The analysis of channel sections covered by the sediment budget (see Table 2.5-1) is derived primarily from Morang (2006); dredging cycle lengths, velocity data, average percentages of sediment sizes, and dredging quantities for channel reaches not covered by the sediment budget were obtained from the SNWW Sediment Study (Parchure et al., 2005); other supporting analyses are identified as the data are presented. The discussion begins with the upstream end of the SNWW (the Neches River Channel) and moves downstream through the confined Sabine-

Neches and Port Arthur canals, the Sabine Pass Channel, and then offshore into the Sabine Pass Jetty Channel, the Sabine Pass Outer Bar Channel, and the Sabine Bank Channel. Finally, the interaction of the channel and adjacent shoreline sections is described.

Table 2.5-1
Sediment Budget for Sabine Pass (adapted from Morang, 2006)*

Cell	Sources and Quantity (1,000 cy per year)	Sinks and Quantity (1,000 cy per year)	PA/ODMDS and Quantity (1,000 cy per year)
Sabine Pass Channel	866.7 (approximately 20% sand) from Port Arthur Canal and Sabine Lake	274.2 mud and sand into Jetty Channel	592.5 into PA 5
Sabine Pass Jetty Channel	274.2 (mud and minor sand) from Sabine Pass Channel	Unknown quantity of fine-grained material carried in suspension offshore	289.1 to ODMDS 4 (dispersed by shelf circulation, storm and tidal currents)
	14.9 (mud) offshore		
Sabine Outer Bar Channel	Unknown amount from Sabine Jetty Channel (possible mud input)		1722.6 to ODMDS 3 (dispersed by shelf circulation, storm and tidal currents)
	1,722.6 from undetermined source (littoral sediments and/or ODMDS)		
Sabine Fillet	25.1 longshore transport from Texas Point NWR (west)	14.9 longshore transport (mud & minor sand) to Jetty Channel	
		10.2 shoreline growth at Sabine mud fillet	
Texas Point NWR	434.2 from beach erosion (+90% mud)	152.0 overwash losses	
		173.7 mud lost offshore	
		25.1 longshore transport of mud to east	
		83.5 longshore transport to west (sand & shell)	
Sea Rim State Beach	83.5 longshore transport from Texas Point NWR (east)	117.7 beach growth at Sea Rim State Beach	
	34.3 longshore transport from McFadden NWR (west)		

*Sediment Budget quantities are based on 25 years of data from Galveston District's Dredging Database. SNWW CIP without-project shoaling quantities are based on data from 1967 to 2001. A cross check and conversion verified that the quantities are similar.

2.5.2.9.1 *Neches River Channel*

Dredging cycles on the Neches River Channel vary from 3 to 4 years along the eastern half of the channel near Sabine Lake to 6 years along the western segment near Beaumont. Approximately 3.1 mcy/cycle are dredged from eastern channel sections 11, 12, 13, 14, and 15 and placed into PAs 12, 13, 14, 16, 18, 21, 23, and 23A. Approximately 3.3 mcy/cycle are dredged from western channel sections 16, 17, and 18 and placed in PAs 24, 25, 25A, 26, 27A, 27C, and 27D near Beaumont. Peak ebb and flood velocities are low (0.8 foot/second and 0.3 foot/second, respectively). Bed sediments average 62 percent silt and clay and 38 percent sand.

2.5.2.9.2 *Sabine-Neches and Port Arthur Canals*

These canals traverse the confined channel segment between the City of Port Arthur and Pleasure Island. Sabine-Neches Canal sections 9 and 10 are dredged every 4 years. Approximately 3.7 mcy/cycle are placed in PAs 8 and 11. Bed sediments average 78 percent silt and clay and 22 percent sand. Port Arthur Canal Section 7 is dredged every 3 years and approximately 1.8 mcy/cycle are placed in PA 8. Section 8 and the Taylor Bayou Channels and Basins are dredged every 2 years; approximately 2.3 mcy/cycle are placed in PAs 8, 9, and 9A. Peak ebb and flood velocities are 2.6 and 2.2 feet/second, respectively. Bed sediments average 84 percent silt and clay and 16 percent sand. The junction of the Port Arthur Canal, Taylor Bayou Channel, and the Sabine Pass Channel is an existing dredging hot spot, often requiring dredging more frequently than the 2-year cycle. This is due, at least in part, to a rapid decrease in velocity as the flows move into the much wider junction. In addition, existing erosion along the channel side of Pleasure Island may be returning sediment to the system (Parchure et al., 2005).

2.5.2.9.3 *The Sabine Pass Channel*

Channel sections 5 and 6 are dredged every 3 years and approximately 1.9 mcy/cycle are placed in PA 5. Bed sediments average 70 percent silt and clay and 30 percent sand. There are no obvious sand sources because the banks of the channel are low mudflats. Little sand reaches the open coast from the Sabine and Neches rivers because Sabine Lake is an efficient sediment trap and most of its coarse material is deposited in the lake or trapped in the lower alluvial reaches of the rivers. Since the dredged material is removed from the system, some mechanism must be replenishing the sand. It may be delivered to this channel by unusually high runoff from Sabine Lake or the Port Arthur Canal. Although ebb and flood velocities are roughly equal through this section, lower velocities are present where Sabine Lake discharges into the channel; shoaling rates are higher than average around this discharge point. Peak ebb and flood velocities in the remainder of the channel are 4.0 and 3.2 feet/second, respectively. Negligible amounts of material come from the littoral system, entering the channel and moving upstream. Conversely, plumes of fine-grained material can be seen moving through the pass into the Gulf in satellite images. This material disperses over the continental shelf and does not contribute to the littoral budget.

2.5.2.9.4 *The Sabine Pass Jetty Channel*

Section 4 is self-scouring and needs far less frequent maintenance dredging than the other coastal reaches. Ebb velocities are high, peaking at about 3.5 feet/second, and flood velocity reaches 3.0 feet/second. Despite this jetting action, on the average about 1.1 mcy/cycle of dredged material are placed in ODMDS 4 in a 5-year dredging cycle. Sediment delivered by the Sabine Pass Channel is predominantly silt and some sand, and about 5 percent of the total transport comes from the littoral system. A small boat cut in the east jetty may allow material carried by the longshore current moving west from Louisiana to enter the channel (PBS&J, 2004b). Bed samples average 89 percent clay and silt and 11 percent sand. Before- and after-dredging bathymetry surveys have demonstrated that the material placed offshore in the ODMDS does not accumulate; it disperses quickly after placement in the offshore environment.

2.5.2.9.5 *The Sabine Pass Outer Bar Channel*

Section 3 is the first 3.4 miles of navigation channel outside of the jetties. Ebb velocities fall rapidly as the channel discharges over the Outer Bar. Peak ebb velocities fall from about 3.5 feet/second within the jetties to 2.7 feet/second just beyond the jetties, to 1.3 feet/second near the intersection with the Sabine Bank Channel. Peak flood velocities of 3.0 feet/second within the jetties fall to 2.4 feet/second just beyond the jetties, and to 0.4 foot/second at the end of the channel reach. It appears that little material moves from the Sabine Pass Jetty Channel into the Sabine Outer Bar channel, based upon the balance of material entering versus what is removed by dredging. Yet, the shoaling rate in this section is very high. Approximately 1.9 mcy/cycle are removed yearly and placed in ODMDS 4. Bed samples average 96 percent silt and clay and 4 percent sand. The source of the sediment is undetermined. Existing and proposed ODMDSs are located west of the channel because the mean current flow in this area is westward most of the year. However, this flow reverses and moves eastward for a month or longer during the late spring (Rouse et al., 2004). During periods of reversal, sediment may drift back into the channel from ODMDS 4. However, typical flow patterns move ebb flows to the south/south-southwest just beyond the jetties, and flood flows generally come from the east (Parchure et al., 2005). Furthermore, anecdotal accounts from the Sabine Pilots Association report a strong east to west current crossing just outside the jetties in the vicinity of ODMDS 4 (Webb, 2003).

2.5.2.9.6 *The Sabine Bank Channel*

Sections 1 and 2 (totaling 6.6 miles long) extend the navigation channel into the open Gulf. They are dredged every 4 years, and approximately 4.2 mcy/cycle are placed in ODMDSs 1 and 2. Bed sediments average 76 percent silt and clay and 24 percent sand. Ebb and flood velocities are nearly equal (ranging between 0.25 and 0.70 foot/second), but the velocity pattern is erratic. Rapid shoaling is not a problem in this reach, and no other management concerns are known.

2.5.2.9.7 *Adjacent Gulf Shorelines*

At Louisiana Point, the littoral current has supplied sufficient sediment in the recent past to cause shoreline progradation between Ocean View Beach and the Sabine jetties (USACE, 2004a), and create a

wide tidal mudflat against the jetty (PBS&J, 2006). Some fine-grained sediment from this westward littoral current may be entering the Sabine Pass Jetty Channel through a small boat cut in the east jetty (PBS&J, 2004b).

All but the easternmost wedge of Texas Point (the Sabine Fillet) is undergoing severe beach erosion, with shoreline retreat of up to 1,150 feet between 1974 and 2000. Shoreface sediment losses are approximately 434,200 cy/year (see Table 2.5-1). Longshore transport to the west carries 20 percent to Sea Rim State Beach (PIE, 2003), 35 percent is lost to overwash, and 40 percent is carried offshore. Approximately 6 percent moves eastward, carried by periodic reversals in the dominant longshore current (King, 2007; PIE, 2003). The west jetty intercepts about 40 percent of the total eastward transport, creating a ½-mile-wide fillet of silt and mud against the jetty; the remainder is carried into the Sabine Pass Jetty Channel.

In contrast to Texas Point, Sea Rim State Beach is located in a convergence zone and receives 117,700 cy/year (see Table 2.5-1) of littoral material from both the east and west. About 70 percent is carried by longshore transport from the east at Texas Point, and 30 percent comes from McFaddin NWR to the west. The accreting beach is composed of sand (0.10 to 0.14 mm in size) and shell fragments, underlain by mud.

2.5.3 Analysis of Sediment-related Problems and Opportunities

This section describes RSM problems and opportunities that were identified by the SNWW study and presents the results of a preliminary screening that was designed to identify potential beneficial uses for the dredged material that would be generated with the Preferred Alternative.

The principles of RSM were applied to ensure that the dredged material arising from the SNWW CIP would be viewed as a valuable resource, integral to economic viability and environmental sustainability of the region. In developing the DMMP for the project, this study searched for opportunities to achieve savings by defining sediment-related problems, coordinating projects, and identifying opportunities for beneficial use (Martin, 2002). The large quantities of dredged material that would be generated by the Preferred Alternative created an ideal opportunity for the exploration of the beneficial use of dredged material. A series of public workshops and extensive ICT consultation evaluated a wide array of opportunities to use dredged material beneficially (GEC, 2002; Turner Collie & Braden, 2003).

A variety of private stakeholders, State and Federal resource agencies, and USACE engineering and scientific experts identified the following existing and FWOP sediment-related problems in the region:

- Lack of sand in the littoral system
- Interruption to the littoral system caused by SNWW jetties
- Extensive shoreline erosion at Texas Point
- Erratic accretion and erosion at Louisiana Point
- Rapid shoaling in the Sabine Pass Outer Bar Channel
- Rapid shoaling in the Port Arthur Junction

- Erosion of west side of Pleasure Island
- Erosion of Sabine Lake eastern shore
- Lack of sediment recharge to, and continuing loss of, sediment from emergent marshes

The following FWP impacts that could potentially be addressed with the beneficial use of dredged material or other project elements were also identified:

- Project impacts associated with the creation of new ODMDs for the Extension Channel
- Project impacts associated with the creation of new upland PAs to accommodate new work material and increased quantities of maintenance material over the period of analysis
- Project impacts associated with a small increase in Gulf Coast shore erosion within 3.5 miles of each jetty
- Project impacts to cypress-tupelo swamps and intertidal marshes from reductions in biological productivity due to project-induced salinity increases and marsh loss
- Additional advance maintenance due to a higher than average increase in shoaling in the Sabine Pass Outer Bar Channel, one section of the Sabine Pass Channel, the Port Arthur Junction, and portions of the Neches River Channel

2.5.3.1 Preliminary Screening – Features Eliminated From Consideration

Opportunities to use dredged material beneficially to address these sediment-related concerns were suggested by public workshop participants and the ICT and/or developed by the USACE technical studies. These suggestions resulted in the evaluation of a wide array of BU features, which could reduce or avoid salinity impacts, restore or replace degraded wetlands, create new terrestrial or marine habitat, and return sediment to the littoral zone. Table 2.5-2 lists all features that were considered and eliminated during preliminary screening and the reason for dropping them from further consideration. The incremental cost estimates presented in the table were developed during preliminary screening; they are based upon 2005 cost levels and use \$2.05/gallon for marine diesel. Incremental costs are the additional costs that would be needed to use the material beneficially, over and above the normal costs of dredging and placement in designated PAs or ODMDs. It is likely that the actual costs would be much higher than estimated here.

The feasibility of using new work and/or maintenance material was considered for all features. In the analysis for the inshore reaches, PA containment levee construction was the first priority for the use of new work material, followed by beneficial use opportunities. In the offshore reaches, opportunities for beneficial use of new work material were evaluated and eliminated before material was committed to existing and proposed ODMDs. For maintenance material in both inshore and offshore reaches, priority was given to beneficial use if it could be demonstrated to be the least-cost alternative.

Table 2.5-2
Dredged Material Beneficial Use Features Eliminated from Consideration

Feature Description	Reason for Elimination
Hydrologic Restoration	
Marsh islands isolating Sabine-Neches Canal from Sabine Lake	Increased salinities in Black Bayou and up the Sabine River
Marshes constricting flow at mouth of Sabine Lake (north and south of SH 82 swing bridge)	Ineffective at reducing salinities Increases velocities through mouth of Sabine Lake
Marshes constricting flow along the side of the Port Arthur Canal	Ineffective at reducing salinities High cost relative to amount of marsh acres created
Construction of channel islands blocking flow from bayous emptying Neches River marshes at Rose City and Bessie Heights	Potential to cause backwater flooding Obstructed channel access for private landowners Navigation safety concerns
Filling canal at Texas Bayou using new work material from Sabine Pass Channel	Ineffective at reducing salinities because access still provided by Texas Bayou
Emergent Marsh Restoration	
Marsh restoration using new work material from Neches River Channel to restore marsh in Rose City West	Area is being developed as a mitigation bank; no longer available for restoration
Marsh restoration using new work material from Neches River Channel to restore marsh in Bessie Heights West	Would be feasible but cost exceeds Traditional Placement Plan Preliminary estimate of incremental cost – \$581K Sponsor has not been identified
Marsh restoration using new work material along the east shore of PAs 8 and 11 at Pleasure Island	Unacceptable location; interferes with levee maintenance
Marsh restoration north of Keith Lake using new work material from the Neches River Channel	Would be feasible but cost exceeds Traditional Placement Plan Preliminary estimate of incremental cost – \$472K Sponsor has not been identified
Marsh restoration north of Keith Lake using maintenance material from Port Arthur Canal	Would be feasible but cost exceeds Base Plan Preliminary estimate of incremental cost – \$300K Sponsor has not been identified
Marsh restoration in Texas Point NWR using new work material from Sabine Pass Channel to restore marsh behind subsided jetty section.	Would be feasible but cost exceeds Traditional Placement Plan Preliminary estimate of incremental cost – \$445K Sponsor has not been identified
Wildlife Habitat Creation	
Bird island constructed in Sabine Lake using new work material from Sabine-Neches Canal	Would be feasible but cost exceeds Traditional Placement Plan Preliminary estimate of incremental cost – \$1.9 million Sponsor has not been identified
Returning Sediment to Littoral Zone	
Texas or Louisiana Point shore nourishment using new work material from Section 5 of the Sabine Pass Channel	Would be feasible but cost exceeds Traditional Placement Plan Preliminary estimate of incremental cost – \$6.6 million Sponsor has not been identified
Texas or Louisiana Point shore nourishment using new work material from sections 5 and 6 of the Sabine Pass Channel	Would be feasible but cost exceeds Traditional Placement Plan Preliminary estimate of incremental cost – \$19.5 million Sponsor has not been identified
Stockpiling new work material from Extension channel for future beneficial use	Not feasible because material would disperse rapidly and not be available for use at a later date
Transporting sediment from new work dredging of the Extension Channel to the Texas or Louisiana littoral zone	Would be feasible but cost exceeds Traditional Placement Plan Preliminary estimate of incremental cost – \$86.3 million Sponsor has not been identified
Marine Habitat Restoration	
Construction of topographic high in littoral zone with new work material	Topographic elevation would be temporary Incremental costs (\$268 million) make it economically infeasible

Given the large amount of dredged material that would be generated with the proposed project, considerable effort was expended to identify areas that could benefit from its beneficial use. All degraded marsh areas near the SNWW were investigated to determine whether least-cost beneficial use features could be developed. No interior marsh areas in need of nourishment or restoration were identified adjacent to Sabine Pass in Louisiana. Areas in Louisiana that could benefit from beneficial use of dredged material are all located in the marshes east of Sabine Lake. However, these were found to be too distant from the navigation channel to permit cost-effective use of dredged material from the SNWW navigation channels. Numerous degraded marshes in Texas with potential for beneficial use were identified adjacent to the navigation channel. They are located in the Texas Point NWR adjacent to the Sabine Pass Channel, in the J.D. Murphree WMA adjacent to the Sabine-Neches Canal, and in areas of the Neches River WMA and private lands adjacent to the Neches River Channel. The Gulf shoreline at Texas and Louisiana Points is close enough to the navigation channel to allow cost-effective beneficial use of dredged material. The shoreline on the Texas side of Sabine Pass was also identified as a high priority area for beneficial use because of high ongoing erosion in this area.

Several hydrologic restoration features that were intended to prevent higher FWP salinities in portions of the study area were eliminated early in the screening process. They were modeled using the HS model and found to be either ineffective at reducing salinities or to have significant unintended impacts. For example, marsh islands constructed with new work material were proposed as a means of isolating the salinity wedge in the Sabine-Neches Canal from Sabine Lake. Modeling determined that the islands did block the flow into the lake, but forced a salinity wedge to travel up the Sabine River Channel, potentially affecting cypress-tupelo swamps in that watershed. Other proposed BU features that were unsuccessful in reducing salinities are described in Table 2.5-2.

A large number of conceptual designs for emergent marsh restoration throughout the study area were initially identified as possible compensatory mitigation measures. Because of their proximity to the navigation channel, several marsh restoration features in Texas were also evaluated to determine whether they would be less costly than traditional placement. Only the Neches River and Gulf Shore BU features were determined to be less costly than using upland PAs for new work (Traditional Placement Plan) or maintenance material (Base Plan). These features and the cost analysis are presented in detail later in this chapter. Marsh restoration features considered but eliminated included marsh restoration in Texas Point NWR using new work material from the Port Arthur Canal or the Sabine Pass Channel, and at Bessie Heights West using new work material from the Neches River Channel. Another feature used new work material for marsh restoration in the part of Old River Cove marsh that lies east of the intake canal. All were found to be feasible but more costly than traditional upland placement. The preliminary incremental costs for these features were relatively low, ranging from \$300,000 to \$581,000, but no sponsor has been identified to share the incremental cost.

The creation of new wildlife habitat using new work material from the Sabine-Neches Canal was also explored. This feature would provide needed nesting habitat for colonial waterbird species such as cormorant, pelican, heron, egret, spoonbill, gull, tern, and skimmer. These birds regularly nest in large numbers along the Texas and Louisiana coasts, frequently on bay islands, both natural and manmade.

Despite the presence of excellent waterbird habitat in the Sabine NWR, no colonies have been documented in Louisiana within the study area. The lack of isolated, predator-free islands is believed to be a primary cause for this lack of nesting habitat. It was proposed that an island be constructed in the middle of Sabine Lake with new work material from the Sabine-Neches Canal. This feature was eliminated when the cost was found to be approximately \$2 million higher than the use of traditional upland PAs, and no sponsor was identified to share the incremental cost.

Several features were evaluated that would return sediment normally placed in upland PAs or ODMDSs to the littoral zone. Conceptual plans were developed for shore nourishment at Texas and Louisiana Points using new work material from Section 5 or sections 5 and 6 of the Sabine Pass Channel. The features were found to be feasible but cost \$6.6 and \$19.5 million, respectively, more than upland placement in PA 5. Stockpiling dredged material in ODMDS 4 for later use was also investigated. Like all other SNWW ODMDSs, material placed at this site disperses quickly after placement. Although it is closest to shore, the dispersed material in ODMDS 4 is not likely to migrate into the littoral zone because it is located beyond the depth of closure. It is expected that any material stockpiled within ODMDS 4 would be unavailable for use within 3 months of placement. Since stockpiling assumes that the beneficial use need will not be immediate or short term, it was concluded that this feature is not a viable alternative. Transporting and discharging coarser-grained sediments from the new work dredging of the Extension Channel (stations 117+000 to 146+000) into the littoral zone offshore of Texas or Louisiana Point was also evaluated. A hopper dredge with pump-out capability could be used to dredge the channel, move as close as possible to shore, and pump the material via a connecting pipeline to a discharge point within the 14-foot-depth contour. Discharging the material at or inshore of the depth of closure should guarantee the reintroduction of sediments within the littoral zone, where natural processes will beneficially distribute the sediments. It is estimated that the incremental cost of this action would be about \$86.3 million. While feasible, this BU feature is much more costly than placement in the proposed ODMDSs B and C. No sponsor has been identified to share the incremental cost of the feasible BU features discussed above.

The creation of new marine habitat in the form of a “topographic high” offshore of Louisiana Point was also investigated. This feature would involve the beneficial use of new work material from the deepened Sabine Bank and Extension channels to create a new refuge or feeding locale for fish and shrimp. The material would be dredged as usual with a hopper dredge and then transported far enough upcurrent to prevent redeposition in the navigation channel. The material would be dropped in mounds forming a series of rows over a large area, roughly 2.0 by 2.5 miles. The actual ecological benefits of such a feature off the Texas coast have not been demonstrated. A similar feature was constructed outside of Galveston Bay, but no monitoring was conducted to determine whether any benefits accrued. In addition, the feature would be temporary because the dispersive processes acting on the ODMDSs would also be present here. It was eliminated from further consideration when it was estimated that the incremental cost of the temporary habitat would be approximately \$268 million.

2.5.3.2 Detailed Evaluation of Disposal Features

After the preliminary screening, BU features that appeared to be least-cost alternatives for the beneficial use of dredged material in reducing with-project salinities, restoring marsh, or providing shoreline nourishment were advanced for detailed evaluation. Water and sediment sampling and bioaccumulation studies have established that dredged material from all SNWW navigation channels is suitable for beneficial use (PBS&J, 1999, 2002, 2004a). The ecological benefits of the following beneficial use features were evaluated and quantified using the WVA model, and these benefits were used to minimize project impacts as described below. A description of the WVA model is provided in Chapter 4. In addition, numerous existing upland PAs were evaluated for use with the Preferred Alternative. All BU alternatives to ODMDSs were eliminated during the preliminary screening. Existing and proposed ODMDS sites were therefore evaluated for the placement of all material from the offshore channel reaches.

2.5.3.2.1 Neches River BU Feature

Three former marsh areas on the Neches River have been combined into one large management feature, called the Neches River BU Feature (Figure 2.5-1), to provide flexibility in the use of new work and maintenance material from the several construction reaches of the Neches River Channel. The primary objective of this combination feature would be to beneficially utilize dredged material to restore emergent marsh in an area that has suffered dramatic, widespread loss of marsh. The BU feature would utilize new work and maintenance material that would otherwise be removed from the sediment system and stored in upland, confined placement areas.

The Neches River BU Feature would offset all indirect salinity impacts to Texas wetland habitats on the Neches and Sabine rivers (Hydrologic Units [HUs] TX 3 through TX 8, and TX 10 through TX 13) by restoring 2,853 acres of emergent marsh, improving 871 acres of shallow water by creating shallower ponds and interconnecting channels, and nourishing 1,234 acres of existing fringing marsh by winnowing fine-grained material from unconfined flows of dredged material effluent (Table 2.5-3). The BU feature thus provides benefits to a total of 4,958 acres of degraded marsh on the lower Neches River, or 53 percent of the restoration target set by the CEPRA 2004 plan update for the lower Neches River (GLO, 2004). The BU feature also offsets the direct impact of converting 86 acres of freshwater wetlands to a confined placement area (PA 24A). The size of the Neches River BU Feature components and the magnitude of their ecological benefits are made possible by the large amounts of dredged material that will be generated by the proposed project and extensive opportunities for beneficial use in the project area.

Table 2.5-3
Acreage Restored by Each Component of Neches River BU Feature

Components of the Neches River BU Feature	Restored Emergent Marsh	Improved Shallow- Water Habitat	Nourished Existing Marsh	Total Influence Area
Rose City East	345	72	151	568
Bessie Heights East	1,869	660	651	3,180
Old River Cove West	639	139	432	1,210
Total	2,853	871	1,234	4,958

2.5.3.2.2 *Gulf Shore BU Feature*

The use of dredged material was also evaluated for Gulf shoreline nourishment at Texas and Louisiana Points (Figure 2.5-2). Over the 50-year period of analysis, maintenance material would be hydraulically pumped from Section 5 of the adjacent Sabine Pass Channel onto a total of 6 miles of shoreline on both sides of Sabine Pass. Some material is expected to flow over existing marsh while the remainder will flow into nearshore waters. Material placement during each 3-year Sabine Pass Channel dredging cycle would alternate between Texas and Louisiana, so that material would be placed on each state's shoreline every 6 years. This recurring action would nourish eroding marsh, minimize projected FWP shoreline impacts, and potentially create new marsh. As this BU feature is located within the Texas Point NWR, USACE has requested that the USFWS prepare a compatibility determination for the proposed activity. See correspondence dated January 23, 2007, in Appendix A1 of the FEIS.

Texas Point is undergoing severe beach erosion, with shoreline retreat of up to 1,150 feet between 1974 and 2000 (King, 2007; Morang, 2006). This is the highest rate of shoreline loss on the upper Texas coast and a CEPRA "critical erosion area" (GLO, 2005). In Louisiana, persistent erosion along the shoreline between Ocean View and Holly Beach, on the order of -4.3 feet/year between 1985 and 1998, was recorded here prior to Hurricane Rita (USACE, 1971a, 2004a). Nearer to Louisiana Point, significant accretion over the last 100 years has slowed to +1.2 feet/year, and the behavior of this shoreline has become erratic, with some areas eroding and some aggrading (USACE, 2004a).

Historic dredging records indicate that the maintenance material from Sabine Pass will average 51 percent silt, 31 percent clay, and 18 percent fine sand (USACE dredging data base). This mix of materials does not contain typical beach-quality sand, but the material types and composition are similar to what is present on the shorelines today. Narrow beach fronts of silt or clay lie seaward of eroding overwash marsh terraces (PBS&J, 2006). Given the unusual characteristics of this sand-starved system, returning the material to the littoral system is likely to have a net beneficial effect, regardless of material type. The longshore transport in this system contains primarily fine-grained sediments, but these sediments have been shown to accumulate in the near shore zone and result in shoreline accretion by, as yet, poorly understood processes (King, 2007; Morang, 2006).

The Gulf Shore BU Feature will provide a regular source of predominantly fine-grained sediment that should contribute to mudflat accretion and periodically move onshore to become shore-attached through a process described by PIE (2003). On the western Louisiana and east Texas coasts, sediments accumulate as mudflats and underwater mudshoals (or “fluid mud”) in the nearshore region. Nearshore, fluid mud can be trapped against the shoreline by prevailing south and southwesterly winds, and storms carry the trapped muddy ooze onto the chenier shoreline. The northwest Gulf is a microtidal, storm-dominated environment. In a typical year there are about 20 to 30 frontal passages generating waves, surges, and wind-driven currents, with most frequent waves from the southeast about 3 to 4.5 feet in height (PIE, 2003).

Mudflat accretion on the western Louisiana coast appears to correlate with periods of high sediment influx from the Atchafalaya River and the passage of large storm systems. Up to 1,000 feet of accretion along a 4.5-mile segment of shoreline in western Louisiana occurred over a few days during the passage of Hurricane Aubrey (Morgan et al., 1958). Another study reports that accretion in western Louisiana occurs most frequently during storms and that it can be very rapid (Wells and Kemp, 1986). Huh et al. (1991) report that surge deposits of gel-like mud become stranded on the upper shoreface during storms. These deposits can dry and crack, forming mud cobbles that help to armor the shoreline. Fluid mud and mudflat accretion at the shoreline has also been observed on the Jefferson County shoreline. At Sea Rim State Beach in June 2002 (PIE, 2003), shoreline features were observed that resembled the storm surge deposits of fluid mud and mud cobbles reported above.

The presence of additional fine-grained sediments in the littoral system that will be provided by the BU feature should reduce the current erosion rate and minimize the small increase in shore erosion predicted with the project (Gravens and King, 2003). In systems that have an abundant supply of fine-grained sediments, the nearshore seabed can be blanketed with fluid mud. The presence of additional muddy sediment in the nearshore environment may attenuate waves and lessen wave-induced erosion (Hsiao and Shemdin, 1980; Tubman and Suhayda, 1976; Wells and Kemp, 1986). There are also anecdotal reports of Gulf areas off Louisiana and Texas Points being safe havens for vessels during storms due to the near-total attenuation of waves (Block, 1984; King, 2007; Wells and Kemp, 1986).

The BU dredged material is expected to be composed largely of unconsolidated muds. These fine-grained sediments are expected to initially be highly mobile and some portion of the material will be rapidly lost from the vicinity of the shoreline. As demonstrated by another BU project at Texas Point (USACE, 2000), a significant percentage will also flow onshore and nourish existing marsh along the eroding beachfront. Because of the prevailing wave climate, the mobile material within the surf zone should generally migrate to the west at both Texas and Louisiana Points (Wamsley, 2008). Transport processes identified by the Sabine Pass sediment budget (Morang, 2006) indicate that the material would move toward the eroding shoreline at Texas Point. There, the additional fine-grained sediments could lower erosion rates through the mudflat accretion and wave attenuation processes described above. A small quantity of material may migrate to the east and contribute to the Sabine fillet at the west jetty (King, 2007; Morang, 2006).

In Louisiana, the sand bar formed by BU sediments from the Cheniere LNG project may shelter the shoreline from wave energy sufficiently to allow fine-grained sediments to form a mudflat behind the sandbar (Nairn and Willis, 2002). While a significant percentage will be rapidly carried offshore, some is likely to move downcoast with the littoral current, enlarging the sand and mudflat already present at the east jetty. Potential impacts of elevated levels of total suspended solids (TSS) are expected to be similar to those that resulted from the Cheniere LNG BU project (PBS&J, 2004b). A temporary increase in suspended silt/clay was expected during the first 8 to 9 months following placement. After the termination of placement activities, TSS was expected to decrease for about 18 months when concentrations reached background levels. Modeling conducted for the Cheniere project indicated that it will take 9 years before the silt and clay component of Cheniere BU material become totally suspended and are removed from the littoral zone. Since the Gulf Shore BU Feature proposes a placement episode every 6 years, all the fine-grained sediments would not have been removed before new material is added. This should result in the retention of some portion of the fine-grained sediment, and thus facilitate mudflat accretion through the processes described above. During and after each placement episode, most of the resuspended silt and clay are expected to enter the Sabine Pass Jetty Channel through the shallow boat cut, but deposition in the channel is not expected. It should remain in suspension and be transported back into the Gulf.

Although the BU sediments will be largely fine grained, approximately 18 percent of maintenance material is expected to be sand. Sands that are deposited on shore will nourish and stabilize eroding marshes; sand deposited in the nearshore zone should stay in the nearshore environment, moving back and forth across the shoreface (Wamsley, 2008). Sand placed at Louisiana Point should remain on the shoreface where it was deposited; no significant amounts of sand are expected to enter the Jetty Channel. On erosive mud shorelines like those in the BU area, the sand percentage should increase and it will form sandy lenses or a veneer over the mud shoreline substrate. As the sand lenses thicken, the sands help protect the underlying mud from further erosion (Nairn, 1992). However, in smaller quantities, sand can also accelerate erosion of a mud beach. If the consolidated mud is not covered by a sand veneer, any sand that is mobilized by wave action will act as a scouring agent (King, 2007).

It is acknowledged that the behavior of the BU sediments within this complex littoral system cannot be predicted with certainty over the period of analysis, especially given the potential for strong storms to affect the coastal environment. However, there is sufficient knowledge of general processes and baseline conditions to support evaluation of potential impacts and benefits. Furthermore, the engineering feasibility and potential environmental benefits have been demonstrated by successful recent BU projects at Texas and Louisiana Points (PBS&J, 2004b; USACE, 2000). All of this information was used to establish explicit assumptions about the expected behavior of the BU material in the quantification of project impacts and benefits using the WVA model, as described in Appendix C of the FEIS. The WVA model analysis assumed that 60 percent of the pumped quantity will remain in the existing marsh and on the shallow nearshore slope in front of the existing shorefront immediately after material placement. Since the material is unconsolidated and prone to erosion, only 50 percent of that material was assumed to remain by the end of each 6-year cycle. It was further assumed that the regular addition of material every 6 years would slow the resuspension of fine sediments and result in the accumulation of some new marsh

by the end of the period of analysis. No attempt was made to account for the effect of large storm systems. No long-term impacts to vegetation or benthic sediments were assumed to result from nourishment episodes. NWR personnel reported that the marsh vegetation at Texas Point rebounded quickly and with renewed vigour after being covered with up to 1 foot of material by the Texas Point BU project (Walther, 2005). Potential impacts to Critical Habitat for the wintering piping plover are expected to be beneficial in the long term, with short-term displacement during disposal activities. Benthic invertebrate fauna residing in the intertidal and tidal impact zones will be smothered, but studies have shown the impact to be similar to that resulting from natural events such as storms and hurricanes (Saloman and Naughton, 1977; Simon and Dauer, 1977). Following the burial, the resident species should recover quickly because of their short life cycle, high reproductive potential and the rapid recruitment of larvae and motile macrofauna from nearby unaffected areas (Nelson and Pullen, 1988).

2.5.3.3 Upland Placement Features

2.5.3.3.1 Existing Active PAs

Existing PAs were evaluated to determine whether they possessed sufficient capacity for new work and maintenance material over the 50-year period of analysis. All of the upland PAs were reviewed by the ICT for potential impacts to environmental resources, and no further environmental review was recommended for existing PAs that were in active use. Existing and proposed upland PAs are shown on figures 2.4-1d–g.

2.5.3.3.2 Existing Inactive PAs

Field visits were made to existing PAs that had been inactive in recent years (PAs 23A, 26, 27C, and 27D). Inactive PAs were visited to determine whether habitat and connectivity had developed since their last use such that they were contributing to the function of adjacent wetlands. No field visits or further review of new PA 18A and inactive PA 25A were recommended by the HW as they were known to contain low-quality, upland habitat. Observations made during the field visits are summarized below.

Existing PA 23A (269 acres) is a leveed upland area east of PA 23, covered by a secondary growth of tallow and black willow forest. Existing PA 26 (192 acres) is a leveed oxbow of the Neches River south of Rose City; it is covered primarily with cattail, phragmites, and palmetto in low spots and yaupon (*Ilex vomitoria*), privet, pine, and tallow on slightly higher elevations. Existing PA 27C (87 acres) is located on the upland west of Rose City, southwest of 27A and south of 27D. It is covered by a secondary upland forest of mixed loblolly pine (*Pinus taeda*), water oak (*Quercus nigra*), and sweetgum (*Liquidambar styraciflua*); most of the larger trees have been wind-thrown by recent storm events. Existing PA 27D (35 acres) is a leveed upland area adjacent to 27A. Its water table is kept artificially high by runoff from an adjacent industrial facility. This artificial water table supports dense California bulrush, fringed on the eastern side by a narrow corridor of second-growth cypress, sweetgum, and tallow. Both 27C and 27D are situated on the north side of the Neches River opposite the Beaumont Turning Basin. All of these areas have been modified extensively by past placement activities and associated levee systems that have artificially altered the hydrology. Surrounding levees hold water and isolate the areas from adjacent

waterbodies, preventing them from contributing to the function of the adjacent wetlands and riparian corridor. All contain degraded habitat with low habitat values, primarily roosting habitat for birds and some wildlife cover. Renewed use of these areas would not constitute a significant adverse change to the existing environmental condition.

2.5.3.3.3 Areas Considered for PA Expansion

The quantities of dredged material projected for the Preferred Alternative necessitated additional PA capacity. Areas adjacent to existing PAs 14, 16, and 24 were evaluated to determine their suitability as PAs. The proposed expansion areas were designated as PAs 14A, 16A, 18A, and 24A. The HW evaluated these areas with aerial photographs and field inspections; descriptions and evaluations provided below were based upon those observations.

PA 14A (82 acres) is located south of existing PA 14, on the south side of the Neches River near its mouth. It is a relatively undisturbed wet meadow of marshhay cordgrass (*Spartina patens*) containing numerous small ponds. The area floods during seasonally high tides and heavy storms, providing intermittent hydrologic connectivity to the riparian corridor. It provides habitat for numerous native wildlife species and is covered by a valuable intermediate wetland. It was determined that use of this area would be a significant adverse change to existing conditions. The USACE reevaluated needs along the lower Neches River and dropped it from further consideration for use as a PA.

PA 16A (202 acres) is located west of existing PA 16 on the south side of the Neches River near its mouth. It is covered by intermediate marsh and crisscrossed by shallow streams and small ponds. It has never been leveed and receives tidal circulation through a natural bayou connecting to the Neches River and the Star Lake Canal, which forms its western boundary. Dominant wetland plants are marshhay cordgrass, several varieties of bulrush, cattail, and widgeon-grass (*Ruppia maritima*). The vegetation community and hydrologic connectivity to adjacent wetlands in the riparian corridor make this a high-quality native marsh providing important habitat for native fish and wildlife. The USACE determined that use of this area would be a significant adverse change to existing conditions. The EPA includes the 16A area in a preliminary area of concern for the Star Lake Canal Superfund Site (EPA, 2006). An EPA feasibility study to determine the nature and extent of contamination is under way. The area has been dropped from further consideration for use as a PA.

PA 18A (71 acres) is located north of existing PA 18. It is a disturbed upland area containing low-quality scrub habitat. Based upon HW review of an aerial photograph of the proposed expansion area and knowledge of the area, the area was determined to be suitable for use as a PA.

PA 24A (187 acres) is located north of the Maritime Administration's Reserve Fleet area. The area contains a central upland ridge with surrounding wetland components. The northern portion of the area is hydrologically connected to the Neches River, but hydrologic connections to the southern half of the site are restricted by prior levee and road construction. Wetlands in the area contain small open-water pockets but are primarily densely vegetated with California bulrush (*Scirpus californicus*), common reed (*Phragmites australis*), and marshhay cordgrass. Observed aquatic vegetation in shallow-water ditches

includes common salvinia (*Salvinia minima*), water smartweed (*Polygonum hydropiperoides*), and white pond lily (*Nyphaea odorata*). Ninety-five percent of the overstory on the upland ridge is a secondary growth of invasive Chinese tallow (*Sapium sebiferum*) with occasional bald cypress (*Taxodium distichum*), red maple (*Acer rubra*), sweetgum, and American holly (*I. opaca*) composing about 5 percent of the overstory. The upland ridge is not hydrologically connected to adjacent riparian habitat and has very little mast forage. Wildlife value is limited to roosting habitat for birds and some wildlife cover. Wetlands in the northern portion and in swales surrounding the upland ridge are a higher quality fresh marsh habitat; the majority of the marshhay cordgrass wetland is located in the northern section. In order to minimize impacts to wetlands, the USACE redrew the proposed boundary of the PA to exclude 144 acres of the marshhay cordgrass in the northern section, reducing the proposed PA from 331 acres to 187 acres.

The proposed project's need for PA capacity in this reach of the SNWW requires that 86 acres of the lower quality wetlands in the southern portion of the area be converted to an upland PA. Impacts to the upland ridge would not constitute a significant adverse change to the existing environmental condition because of the low quality of that habitat. The conversion of 86 acres of freshwater wetlands to a confined PA is included in the predicted impacts of the Preferred Alternative. The WVA model quantified the loss of marsh function and acres due to this conversion as a loss of 32 AAHUs. The impact is fully offset by benefits of the DMMP Neches River BU Feature.

2.5.3.4 ODMDS Features

Four ODMDSs (Nos. 1–4, see Figure 2.4-1b) are currently in use for the existing SNWW project. Alternatives for the placement of new work material and the increase in maintenance material resulting from the construction of a deeper and longer offshore channel have been evaluated in an ODMDS Site Designation FEIS, which is included as Appendix B to this FEIS. Appendix B evaluates alternatives for the selection of new ODMDSs, including the use of the existing ODMDSs for the proposed CIP and beneficial use sites.

The existing ODMDSs were evaluated to determine whether they could accommodate all new work and maintenance material from the Preferred Alternative. Although it was determined that they were large enough to hold all the material, the 13.2-mile length of the channel extension would make the cost of hauling all new work and maintenance material to existing ODMDSs prohibitively expensive. Designation of four new ODMDSs (Nos. A–D, see Figure 2.4-1a) will be necessary. The best locations for the new sites were determined using the “zone of siting feasibility” screening technique, which delineates economically feasible sites that are sufficiently removed from ecologically sensitive or incompatible use areas to eliminate or minimize adverse impacts.

The ODMDSs FEIS found no significant environmental impacts related to the use of existing and proposed ODMDS sites for the SNWW Preferred Alternative. Analysis of northwestern Gulf circulation patterns confirmed that the existing and proposed ODMDSs were properly located on the west side of the navigation channel. Before- and after-dredging bathymetry surveys have demonstrated that the material

placed offshore in the ODMS does not accumulate; it disperses quickly after placement in the offshore environment.

The USACE and EPA have cooperated in the preparation of an FEIS for the proposed ODMSs; this document is Appendix B of the FEIS. Public comment on the proposed ODMSs was requested concurrently with comments on the SNWW CIP. If the FFR and FEIS are approved by the USACE and the Recommended Plan is authorized by the U.S. Congress, the EPA will publish a rule-making in the *Federal Register* that establishes SNWW ODMSs A, B, C, and D for use in conjunction with construction and operation of the 48-foot project.

2.5.4 Incremental Environmental Impacts and Benefits of the DMMP

Incremental DMMP impacts of the proposed 48-foot project are discussed in detail in Section 4 of the FEIS, but are summarized here. The incremental impact consists of marsh lost with construction of one new upland placement cell (PA 24A), low-quality scrub habitat lost with the construction of another upland placement area (PA 18), and four new ODMSs (A–D). No impacts are anticipated with improvements to existing upland PAs that are needed to provide additional capacity for the 50-year period of analysis, since improvements are limited to increasing containment levee heights. The DMMP BU features have net ecological benefits that are described below.

2.5.4.1 Methods and Objectives

The DMMP BU features described above provide ecological benefits, which offset project impacts. The benefits were used to reduce or minimize project impacts before remaining, unavoidable impacts were quantified, and compensating mitigation was developed. The WVA model was used to quantify impacts to all affected habitat types in the study area and establish the appropriate amount of offsetting DMMP benefits by habitat type. An HS model was used to evaluate and quantify salinity impacts and benefits of the BU plan. The WVA model is summarized in Section 5 and described in detail in Appendix C of the FEIS. The HS model is also summarized in Section 5, but it is described in detail in Brown and Stokes (2009). Evaluation of beneficial use alternatives was conducted within the ICT and technical workgroups in meetings conducted from 2001 to 2006. The BU plan was revised by the USACE in 2009 to reflect changes necessitated by project reformulation and revised HS modeling.

The DMMP benefits contribute to multiagency regional plans (the Texas Parks and Wildlife Department [TPWD] regional management plan for J.D. Murphree, Sea Rim State Park, Texas Point NWR, and McFaddin NWR, see Keith Lake: the Texas Coastwide Erosion Response Plan [GLO, 2004, 2005]; the Louisiana Comprehensive Management Plan [Louisiana Coastal Protection and Restoration Authority (LCPR), 2007; USACE, 2008a]; the Louisiana Coast 2050 Plan [Louisiana Coastal Wetlands Conservation and Restoration Task Force and the Wetlands Conservation and Restoration Authority (LCWCR/WCRA), 1998], and the North American Waterfowl Management Plan [NAWMP Plan Committee, 2004]), by restoring and preserving scarce and vulnerable wetlands and wildlife habitat, nourishing eroding Gulf shorelines, restoring sediment to the littoral zone, and using dredged material

beneficially to the greatest extent possible. The DMMP also complies with the Coastal Zone Management Plans (CZMP) for each state by sharing dredged material from the Sabine Pass Channel to accomplish regular shoreline nourishment. The Gulf Shore BU Feature shares this resource equally between the states because it is dredged from a channel that straddles the state boundary.

2.5.4.2 Offsetting and Minimizing Ecological Impacts

BU features included in the DMMP provide benefits that offset and minimize all indirect and direct impacts (-412 AAHUs) of the Preferred Alternative in Texas (Table 2.5-4) and partially offset impacts in Louisiana (Table 2.5-5). In Texas, construction of the Neches River BU Feature and the Texas portion of the Gulf Shore BU Feature will produce benefits totaling 1,068 AAHUs. Therefore, there will be a net gain of 656 AAHUs, which more than offsets all negative impacts that occur in Texas. Impacts that are offset include the direct loss of 32 AAHUs for the conversion of fresh marsh to upland PA 24A. The majority of the offset Texas impacts are in the Neches River watershed, but approximately 16 percent are losses to cypress-tupelo swamp (-22 AAHUs) and fresh and intermediate marsh (-45 AAHUs) in the Sabine River watershed. In Louisiana, the Gulf Shore BU Feature provides benefits totaling 210 AAHUs. Given total Louisiana impacts of 1,709 AAHUs, there is a net loss of 1,499 AAHUs remaining in Louisiana after offsetting benefits of the Louisiana portion of the Gulf Shore BU Feature are applied.

It is important to note that the impacts presented here do not include all impacts of the Preferred Alternative in Texas as FWP impacts in Texas's Salt Bayou (TX 9) hydro-unit are not included. Jefferson County, Texas, and USACE, with support from the TPWD, GLO, and Texas Water Development Board (TWDB) have been studying ways to reduce the amount of saltwater intrusion, decrease high-energy inflows, and minimize impacts to larval fish access in an ongoing Section 1135 Continuing Authorities Program (CAP) study for the Salt Bayou hydrologic unit. When the Keith Lake Section 1135 CAP study was begun in 2003, it seemed likely that the CAP study and construction would be completed before the SNWW CIP could be authorized and constructed. The Keith Lake Section 1135 study was therefore considered separable from the SNWW CIP, and for planning purposes, it was assumed that a water control structure at Fish Pass would be part of the future without-project condition for the SNWW CIP.

Incremental impacts of the SNWW CIP will be calculated for the Salt Bayou unit of the SNWW study area when WVA modeling is completed for the Keith Lake Section 1135 study. It is possible that the excess DMMP benefits (316 AAHUs) of the SNWW CIP will cover all incremental project impacts. However, if it is determined that additional mitigation is needed, then USACE and the non-Federal sponsor of the SNWW CIP will initiate consultation with resource agencies, identify and incrementally justify additional compensatory mitigation for the Salt Bayou unit, and prepare a supplemental environmental impact statement.

With adoption of the DMMP, all FWP impacts in Texas will be offset, and no compensating mitigation is proposed in conjunction with construction of the Preferred Alternative. Impacts in Louisiana are minimized to the greatest extent possible by the DMMP, but unavoidable impacts of -1,499 AAHUs remain. When the impacts and DMMP benefits are not subdivided by state but are applied to the project as a whole, a loss of 843 AAHUs remains (Table 2.5-6). A mitigation plan, described in Section 5, has been developed to compensate for unavoidable impacts of the Preferred Alternative.

3.0 AFFECTED ENVIRONMENT

This chapter is divided into 14 sections. Section 3.1 describes the models that were used to characterize existing conditions, and evaluate impacts as presented in Section 4. A description of the environmental setting follows in Section 3.2, followed by separate sections on the physical, natural, cultural, and socioeconomic resources in the SNWW study area that could be affected by the proposed project.

3.1 MODELING EXISTING CONDITIONS

Since the primary environmental concerns identified during the scoping process are the interrelated issues of saltwater intrusion, marsh loss, and destruction of wildlife habitat and fishery nursery areas, engineering and ecological models were used to characterize existing conditions related to these concerns, thereby establishing a baseline against which changes associated with project alternatives could be measured. Several engineering models were used to evaluate physical systems and processes in the study area, and an ecological model was used to evaluate the biological effects of project alternatives on habitat.

3.1.1 Hydrodynamic Salinity

Concerns that a deeper navigation channel would increase salinity in the Sabine Lake estuarine system were addressed with a 3-dimensional HS model that predicts changes in salinity, circulation, and water elevation due to proposed channel improvements. The ERDC's Coastal and Hydraulics Laboratory (CHL) worked closely with the ICT to calibrate and verify the base model for use in this system. The ICT reviewed the ERDC's model calibration and verification process, provided data and information on hydrologic connectivity, marsh elevation, and bathymetry, and reviewed modeling results as part of the impacts evaluation. For the baseline conditions, modeling was performed using actual depths rather than authorized project depths.

The ERDC's CHL applied an established 3-dimensional estuarine model (ERDC-modified TABS Multi-Dimensional Numerical Modeling System) to compute hydrodynamics and salinity transport for the proposed CIP. The HS model covers the entire study area from the Salt Bayou watershed on the west to near Gum Cove Ridge in Louisiana on the east, and inland to north of IH 10. The model includes forcing due to tides, freshwater inflows, wind, Coriolis, and density gradients due to salinity variation, and accounts for precipitation and evaporation. The code uses a finite-element formulation, which gives it flexibility in matching complex geometry. Over the last decade, the code has been extensively used for a variety of the USACE field projects, including the Houston-Galveston Navigation Channels project, New York Harbor, St. Johns River, Florida, and Atchafalaya Bay in Louisiana. Two of the special features of the code, wetting/drying and "marsh porosity," enable successful modeling of wetlands. A description of the model and its output is provided in a report by the ERDC-CHL (Brown and Stokes, 2009).

HS model salinities were verified against salinity data from June to December 2001. The modeling report provided standard deviations for each of the original modeling stations; these provide a measure of the uncertainty inherent in the model predictions. For the baseline condition, model outputs were provided for all original sampling locations.

3.1.2 Other Engineering Models

Several other engineering models were conducted to characterize other existing physical processes in the study area, and to provide baseline information for the assessment of impacts. The most significant of these are:

Ship Simulation. The ship simulation was used to determine navigation and safety impacts due to anticipated changes in vessel sizes as a result of the proposed channel widening (Webb, 2003). The main objective of the study was to determine whether the “design” ship could safely operate within the width and depth of the proposed channel dimensions. The simulation was conducted on a channel depth of 50 feet with varying widths. Additional ship simulation was conducted to determine the navigation and safety implications of reducing the offshore entrance channel to a 700-foot width.

Sediment Study. A desktop engineering model was applied to determine anticipated shoaling rates along the waterway and estimate any increases in channel erosion (Brown and Stokes, 2009; Parchure et al., 2005). Results from the study were used to estimate the quantity of maintenance material arising from structural alternatives. Erosion concerns along Pleasure Island and East Sabine Lake were also addressed by the analysis. An additional study effort was performed along the Pleasure Island reach and Sabine-Neches Canal to determine whether the channel velocities in these areas would result in increased channel erosion.

Vessel Effects Study. A vessel effects study was conducted to determine the potential erosional effects to Pleasure Island from vessel traffic in the Port Arthur and Sabine-Neches canals (Maynard, 2005). Project vessel traffic was modeled with HVEL2D, a two-dimensional finite element model designed specifically to simulate flow in typical high-velocity channels. The model has been used since the mid-1980s and is maintained by the ERDC-CHL.

Gulf Shoreline Effects Study. This ERDC-CHL study was conducted to determine potential erosion impacts to the Gulf shoreline that could be associated with deepening and extending the Entrance Channel. The study area extended 10 miles from the jetties into Texas and Louisiana (Gravens and King, 2003). The STWAVE and GENESIS models were applied to examine wave conditions within a bathymetry grid extending 20 miles along the shoreline and evaluate changes to the shoreline.

3.1.3 Wetland Value Assessment Model

The WVA model suite uses a quantitative habitat-based assessment methodology developed to prioritize Louisiana coastal restoration projects submitted for funding under Coastal Wetlands Planning, Protection and Restoration Act (CWPPRA) (Louis Berger Group and Toxicological & Environmental Associates [LBG and TEA], 2008). The WVA model is a modification of the widely used Habitat Evaluation Procedure (HEP) models developed by the USFWS (1980). It was developed by the Environmental Workgroup (EnvWG) of the Planning and Evaluation Subcommittee of Louisiana’s CWPPRA Technical Committee (USFWS, 2002a). The WVA methodology employs a community approach that assumes that optimal conditions for all fish and wildlife within a specific type of coastal wetland habitat can be

characterized by a group of significant variables, and that existing or future conditions can be compared to that optimum, providing an index of habitat quality similar to those developed under the well-established HEP. Using this methodology, several habitat-specific community models have been developed by the EnvWG, and three were selected for use in this study: the Emergent Marsh Community Model (EMCM), the Swamp Community Model (SCM), and the Bottomland Hardwood Model (BHM). The EMCM can be applied to four coastal marsh communities—fresh, intermediate, brackish, and saline marsh. Hereafter in this report, the term “WVA model” applies to the three components of the WVA model suite (EMCM, SCM, and BHM) that are used in this study. The results of the WVA model, measured in AAHUs, can be combined with cost data to provide a measure of the effectiveness of the proposed project in terms of annualized cost per AAHUs gained.

A WVA Procedural Manual was prepared by the EnvWG to provide guidance in the use of the WVA model (USFWS, 2002b). In addition, a separate procedural manual was prepared for the EMCM (USFWS, 2002c). The BHM and the SCM (LDNR, 1993) were developed outside of the CWPPRA arena and are periodically used by the EnvWG for CWPPRA project evaluation. The original BHM (LDNR, 1993) was utilized for this study. The SCM was subsequently updated by the EnvWG and the updated version was used here (USFWS, 2002d). The SNWW Habitat Workgroup chose to apply the WVA model as formulated by the EnvWG and LDNR because the habitats and environmental stressors in the SNWW study area are the same as those for which they were developed. Appendix C of the FEIS maps and characterizes all significant habitats in the study area, explains how the WVA model evaluates project impacts and benefits, and describes the methods and assumptions used in the modeling process.

The WVA model provides a comprehensive, quantitative measure of FWP changes in the quality and quantity of emergent wetlands and associated aquatic habitat in the SNWW study. However, it was not developed for use in conjunction with aquatic habitats in large waterbodies. Baseline conditions for aquatic habitats in the SNWW study area that are not associated with emergent wetlands were not characterized with the WVA model or any other ecological model. It was determined that use of an ecological model to characterize and evaluate impacts for these resources would not be necessary, due to the nature of the impacts and conditions specific to the study area; more information relative to this decision is presented in Section 4. However, aquatic habitats in the Sabine and Neches rivers, Sabine Lake, the SNWW and GIWW navigation channels, and offshore in the Gulf are described in this section to the extent necessary to compare to FWP alternatives.

The WVA model was chosen as the most appropriate ecological model for the SNWW project based on a number of factors. Although the WVA model was developed specifically to apply to habitat types present in the Chenier Plain region of the Louisiana coastal zone, the same types of coastal habitat (emergent coastal marsh, bottomland hardwoods, and cypress-tupelo swamp) are present throughout the Sabine-Neches coastal watershed in both Texas and Louisiana, and in fact are a continuation of the same system (Daigle et al., 2006; Griffith et al., 2004). In addition, the areas contain the same fish and wildlife communities, similar soils, and topography, and the Sabine-Calcasieu basins share an interconnected hydrology. Furthermore, the types of variables measured by the WVA model are sensitive to the types of changes that have been identified as the highest concerns by resource agencies and the general public for

the SNWW project. Specifically, these are potential changes in salinity, stress and death of marsh vegetation, and further loss or degradation of already stressed coastal marshes. The variables measured by the WVA model are also recognized scientifically and technically as important in characterizing overall habitat quality. Variables utilized in the WVA model outputs could be combined across the different habitat types. A final factor is that variables were established such that data were easily estimated or collected from existing data sources. This was especially important because the study area is exceptionally large (over 2,000 square miles), and therefore extensive field data collection efforts were not practical. The size and habitat diversity of the study area made application of other ecological models very difficult. Other ecological models, such as the Hydrogeomorphic Approach and HEP models, were considered and rejected because extensive field data collection required by these models was not feasible given time and budget constraints.

An ICT was established that (1) identified environmental issues and concerns; (2) evaluated the significance of fish and wildlife and other ecosystem features; (3) recommended and reviewed environmental studies; (4) evaluated potential impacts; and (5) recommended and evaluated potential mitigation measures. The ICT defined the study area as all areas possibly affected by the proposed project. Potential environmental effects in adjacent coastal wetlands were analyzed for an extensive area including Sabine Lake and adjacent marshes in Texas and Louisiana, the Neches River Channel up to the new Neches River Saltwater Barrier, the Sabine River Channel to the Sabine Island WMA, the GIWW west to Star Bayou, the GIWW east to Gum Cove Ridge, the Gulf shoreline extending 10 miles either side of Sabine Pass, and offshore in the Gulf, 15 miles beyond the end of the current channel.

A subcommittee of the ICT, the HW, developed input data and applied the WVA model. The subcommittee analysis provided data on baseline and FWOP conditions and, as explained later in this document, project impacts and mitigation for specific areas. The use of the WVA model and other information provided by the ICT produced a great amount of detailed data regarding the existing and potential future conditions of the study area. This information is included in this chapter's description of the affected environment.

The WVA model created vegetation categories and mapping units in order to describe baseline or existing conditions and predict future conditions with and without the proposed project under various scenarios including various possible mitigation projects. All habitats hydrologically connected to waterways influenced by the proposed channel improvements were divided into "Hydrologic Units" (hydro-units). Hydro-unit boundaries were based upon small watershed divides, or on the basis of other topographic features that serve as hydrologic separators. Vegetation categories were mapped within each of these hydro-units. The WVA methodology for determining the vegetation baseline is briefly described below. Section 4.1 describes the modeling methodology for determining impacts and mitigation plans. See Appendix C for the detailed methodology.

FWOP projections of land loss were developed as a baseline against which project-induced changes could be measured. Base land loss rates were determined by measuring changes of emergent marsh and open-water areas using Geographic Information System (GIS) software between images from 2 or more years.

The time between images generally spanned the most recent 15- to 20-year time period for which reliable data were available. This time period generally fell between the years 1978 and 2001.

After changes in acreages were calculated, the amount of emergent marsh that converted to open water was expressed as a percentage loss per year. Adjustments to FWOP land loss rates were made to account for constructed or funded CWPPRA projects in the east Sabine Lake marshes (Clark et al., 2000; USFWS and Natural Resources Conservation Service [NRCS], 2003), at Black Bayou (LDNR, 1993), and at Perry Ridge (USGS-National Wetlands Research Center [NWRC], 2002a, 2002b), the effects of RSLR on shoreline recession, and RSLR, as described in Appendix C of this FEIS. A spreadsheet that calculates land loss annually was used for all projections.

The WVA model has been assessed for use in conjunction with the SNWW project, as required by EC 1105-2-407. The WVA model is not a USACE corporate model, and therefore certification is not required, but the model must be approved for use. This approval was provided by the Deep-Draft Center for Expertise based upon the results of a model assessment (LBG and TEA, 2008). The assessment evaluated the application of the three WVA model components (EMCM, SCM, and BHM) that were used to quantify impacts and benefits of SNWW CIP alternatives, including BU features and compensatory mitigation. The assessment determined that the model was theoretically appropriate and correctly applied, and it has been approved for use for the SNWW study.

3.2 ENVIRONMENTAL SETTING

3.2.1 Study Area

The SNWW is located in Jefferson and Orange counties in southeast Texas, and Cameron and Calcasieu parishes in southwest Louisiana. The project area includes the SNWW from the Gulf through the jettied channel at Sabine Pass, through the Port Arthur Canal, Sabine-Neches Canal, and Neches River Channel to the Port of Beaumont. Included is the area covered by the possible addition of 13.2 miles of new channel extending beyond the end of the existing channel into the Gulf. The Sabine River Channel, which extends from the mouth of the Neches River to the Port of Orange, is not currently being considered for channel modification and is not addressed in this FEIS.

The study area includes the SNWW and a much broader geographical range covering approximately 2,000 square miles inland. Due to potential additional saltwater intrusion into the Sabine Lake estuary resulting from the CIP, hydrologic features associated with the SNWW and Sabine Lake are an important consideration. In addition, beneficial use of dredged material may include efforts outside of existing PAs and may include areas well outside of the SNWW.

3.2.2 Physiography

The study area is located in the Austroriparian Biotic Province (Blair, 1950), which extends from east Texas along the Gulf Coast plain to the Atlantic coast, and the Outer Coastal Plain Mixed Forest Physiographic Province (McNab and Avers, 1994). The study area is characterized by a diversity of

features that are a result of the natural transition between marine and freshwater environments and anthropogenic impacts. The Sabine and Neches rivers consist of flat to gently rolling surface topography with poorly drained floodplains that include dense bottomland forests with extensive complexes of interconnecting coastal prairie, wetlands, and bayous. Farmers and ranchers are the principal users of these prairie and upper marsh areas. Developable uplands are mostly restricted to the west side of the estuary. All of the cities and towns in the study area are located in Texas on the west side of Sabine Pass, Sabine Lake, and upland areas north of Sabine Lake. The timberlands in the flood-prone areas are used primarily as wildlife habitat with some areas commercially lumbered on a small scale. The topography of the study area is essentially featureless, except for the surface expression of four salt domes: Big Hill, Fannett, and Spindletop, Texas, and Hackberry, Louisiana. This area once supported major petroleum reserves, but now only produces limited quantities of oil and gas (USACE, 1982).

Aten (1983:15–20) provides the following description of the northwestern Gulf coast that gives a good description of the study area as well:

...[this area] strikes many visitors as a monotonous repetition of prairies and marshes interspersed with an occasional swamp, barrier beach, or forest. . . . it is a highly dynamic environment that has taken on much of its present form concurrent with human occupation. . . . The basic genesis of the coastal zone land surfaces is that of a series of major river deltas coalesced into an extensive and continuous deltaic plain during the Late Pleistocene. Superimposed on this massive accumulation of deltaic material . . . are the effects of more recent events, such as Late Pleistocene-Holocene sea level fall and rise, and the formation of the modern river deltas, estuaries, . . .

. . . Inland . . . are sandier and slightly rolling terrains . . . [that] support pine and hardwood forests. . . .

. . . The major natural hazard in the area is flooding, which results either from overflow in rivers or from storm tides . . . the tidally influenced waters of the estuaries and streams supported [prehistorically] enormous populations of shellfish, fish, birds, reptiles, and mammals . . . over 125 animal taxa have been recovered archaeologically as food remains. . . .

Due to the abundance of rainfall in this region, the rivers and bayous of this reach provide substantial freshwater inflow into Sabine Lake. However, instream flows to this reach have been altered from their natural hydrograph due to major impoundments in the middle and upper Sabine and Neches River basins. Similar to Aten's (1983) description of the region, most of the Sabine and Neches rivers reach is tidally influenced (Mantz and Dong, 1996). Despite abundant rainfall, navigational dredging has allowed saltwater intrusion into these rivers and bayous (USACE, 1998a) resulting in saltwater wedges typically overlaid with influent fresh water.

The Sabine Lake area is a dynamic estuary only recently subject to extensive flood and ebbs of tidal currents and extensive mixing of fresh and sea water. Sabine Lake was formed from the flooding of an ancient river valley (Kane, 1959) and was later separated from the Gulf by the advancement of the Gulf

shoreline and deposition of the beach ridge/mudflat complex known as the Chenier Plain (Gould and McFarlan, 1959). High-volume freshwater inflow into Sabine Lake helped maintain Sabine Pass as a narrow and relatively shallow link between the Gulf and Sabine Lake (Morton, 1996).

The Gulf in the study area consists of open seas, coastline, and a dredged channel extending from the jettied Sabine Pass seaward. This area is dominated by the Mississippi River Delta. When the Mississippi River occupied one of its western courses, sediment deposits were carried westward by littoral currents that built the Chenier Plain (Davis, 1996). Since the Mississippi River has been emptying through its eastern delta lobe, little new sediment has been reaching the Chenier Plain (USACE, 1975a).

3.2.3 Geology

The regional surface geology of the Gulf Coast region consists of sedimentary beds ranging in age from late Eocene to recent, which lie as bands nearly parallel with the coast. Recent deposits form the coastline and successive beds crop out toward the interior. Due to the age of exposure of the rocks, the outcrop areas are successively more eroded and dissected toward the interior. The Pleistocene and Recent formations still retain much of their depositional surface (Texas Water Commission, 1963).

The thick sequence of sedimentary rocks and unconsolidated sediments beneath the present-day Gulf Coastal Plain reflect cyclic marine and continental deposition in the region through the Jurassic, Cretaceous, and Tertiary periods, culminating with predominantly fluvial deposits at the end of the Tertiary period. This pattern continued through the Pleistocene Epoch (i.e., early Quaternary period, about 2 million years before present), during which sedimentation was largely controlled by sea level fluctuations associated with repeated glacial and interglacial episodes (Van Siclen, 1975). During the Holocene, the fluvial Sabine Valley became an estuarine system, eventually becoming completely inundated by the rising sea level. During this interval, an estuarine-lagoonal system became dominant (Pearson et al., 1986).

The primary physiographic environments of the study area consist of two major Pleistocene depositional systems and five major Holocene depositional systems. The major Pleistocene systems include the fluvial-deltaic systems and barrier-strandplain systems. These two systems form the Coastal Zone within the study area, generally at elevations greater than 10 feet above sea level (Brown et al., 1973). The five major Holocene depositional systems include the fluvial systems, strandplain-chenier systems, offshore systems, marsh-swamp systems, and bay-estuary-lagoon systems. The Coastal Zone is underlain by sedimentary deposits that originated in ancient but similar physiographic environments. These ancient sediments were deposited by the same natural processes that are currently active in shaping the present coastline. These processes include longshore drift, beach wash, wind deflation and deposition, tidal currents, wind-generated waves and currents, and levee, point-bar, and flood basin deposition (Brown et al., 1973).

The Quaternary-aged Beaumont Formation covers the entire inland study area and is overlain by the younger Deweyville Formation and Alluvium within the Neches and Sabine River valleys. Quaternary

Alluvium and isolated barrier island deposits outcrop along the coastline. The environments responsible for the deposition of the Beaumont Formation primarily include stream channel, point bar, natural levee, backswamp, and coastal marsh and mudflat deposits. The Beaumont Formation is composed of clay with interbedded silt and sand. Similarly, the environments responsible for the deposition of the Quaternary-aged Deweyville Formation include point bar, natural levee, stream channel, and backswamp deposits. The Deweyville Formation is composed of sand, silt, and clay, with some gravel. The Quaternary Alluvium, which is found immediately adjacent to existing river courses and along the Gulf Coast shore, was deposited primarily in point bar, natural levee, stream channel, backswamp, coastal marsh, mudflat, and narrow beach deposits and is composed of clay, silt, and locally abundant organic matter (Bureau of Economic Geology [BEG], 1982).

3.2.4 Climate

The climate of the study area is both tropical and temperate (Soil Conservation Service, 1965). Prevailing winds are generally from the south and southeast with an average speed of about 10 to 11 miles per hour. In the winter months, cold air masses bring in polar air and prevailing northerly winds. Temperatures are moderated by the influence of the winds from the Gulf, resulting in mild winters and relatively cool summer nights. The mean daily temperature ranges from the mid-50s (degrees Fahrenheit [°F]) in December and January to the mid-80s in the summer months. The temperature rarely drops below 22°F or rises above 98°F. Relative humidity levels average approximately 78 percent throughout the year (USACE, 1975a). Another effect of the nearness of the Gulf is abundant rainfall distributed throughout the year. The average annual rainfall is about 52 inches, with monthly precipitation averaging from 3.2 inches to about 6.6 inches. Snow and sleet seldom occur. Heavy fog occurs on an average of 29 days per year. Clear days during the year average about 117; partly cloudy days, 191; and cloudy days, 57. The growing season, or the average period from the last frost in spring to the first frost in fall, is about 294 days.

3.3 WATER QUALITY

The Texas Commission on Environmental Quality (TCEQ), formerly the Texas Natural Resource Conservation Commission (TNRCC), and the Louisiana Department of Environmental Quality (LDEQ) have designated certain larger streams or bayous, or segments thereof, as “classified” segments for the purpose of developing water quality criteria (WQC) specific to each segment. Within the study area, there are 25 classified assessment units (subsegments of the primary stream segments), 6 in Louisiana and 19 in Texas. Table 3.2-1 lists segment-specific water quality standards (WQS) for all stream segments in the study area.

3.3.1 Water and Elutriate Chemistry

As with all industrialized areas, there is potential for chemical contamination within the Sabine-Neches Estuary. Numerous petroleum-related industries are found along the SNWW, including refineries and transshipment docks near Port Arthur and Beaumont. Petroleum products and crude oil are shipped and

pipled on- and offshore in this area (Long, 1999). However, based on available data, there is no indication of current water or elutriate contaminant problems along the SNWW. Discussions on hazardous, toxic, and radioactive substances in the study area can be found in Section 3.6.

Stream segments 601, 703, and 2411 constitute the SNWW, and none of these segments are classified as nonsupporting on the Clean Water Act (CWA) Section 303(d) list of impaired waters. While several impaired stream segments (0501, 0508, 0511, 0701, and 0704) are located within the study area boundaries, they would not be affected by the direct or indirect effects of channel deepening or construction of any project features and therefore are not evaluated further.

The USACE has collected and archived a significant amount of water and sediment chemistry data. These data are grouped by channel stations (see figures 2.4-1a–g). Also included is a discussion of elutriate, which provides information on those constituents that are dissolved into the water column during dredging and placement. Since the elutriate represents the dissolved concentrations that would be expected in the water column, they are compared to the Texas Surface Water Quality Standards (TWQS), provided by the TCEQ for the protection of aquatic life, Louisiana Surface Water Quality Standards (LWQS), and EPA WQC. Since the values are from grab samples from a marine environment, the acute marine TWQS are used for comparison. Parameters analyzed are listed in Table 3.2-2.

3.3.1.1 Entrance Channel

Historical water and elutriate data for detected compounds from 1993, 1995, 1996, 1998, and 2004 are presented in PBS&J (2004a, 2004b) and Appendix B. Chromium was the only metal found above detection limits in 1993 elutriate samples in channel station, PA stations, and reference stations. However, all concentrations were well below the LWQS and TWQS for chromium. No parameters were detected in 1993 water samples. Barium was not detected in 1993, but was detected in water samples at all stations in 1995, 1996, and 1998 and in elutriate samples at most stations in 1995, 1996, and all stations in 1998. Chromium was detected at one station and copper at two stations for water in 1995. The copper value in the water sample from station S-SB-95-DA4 (26.5 micrograms per liter [$\mu\text{g/L}$]) was above the LWQS (3.63 $\mu\text{g/L}$), the TWQS (13.5 $\mu\text{g/L}$), and the Gold Book WQC (2.9 $\mu\text{g/L}$). However, S-SB-95-DA4 is a PA site located over 2 miles offshore from the end of the jetties. No copper was detected in the elutriate sample. Other metals found above detection limits in 1996 included copper in elutriate samples and zinc in both water and elutriate samples. In 1998, arsenic, cadmium, chromium, copper, and zinc concentrations were found above detection limits in water and elutriate samples, and selenium was detected in water samples only. The water copper concentration at the reference station S-SB-98-REF3+4 (3.9 $\mu\text{g/L}$) was above the LWQS and the WQC, but the copper concentration in the elutriate was below the detection limit. Barium concentrations were higher in elutriate samples than in water samples, indicating a potential release of barium into the water column during dredging and placement. Zinc concentrations for water and elutriates were higher in 1996 than in 1998, although all samples were below the LWQS and TWQS. In the 2004 sampling of the Entrance Channel, while copper, nickel, and zinc appeared to increase slightly upon elutriate preparations and selenium decreased slightly, no LWQS, TWQS, or WQC were exceeded for any channel stations. The proposed Entrance Channel Extension was

also sampled in 2004 (Attachment B of Appendix B), and no WQC were exceeded for any channel station water or elutriate sample (stations were all in Federal waters and WQS were not pertinent for comparison).

Table 3.2-2

Phenanthrene			X
Pyrene			X
Total organic carbon	X	X	X
Total PAH			X
Total polychlorinated biphenyls (PCBs)			X
Total petroleum hydrocarbons (TPH)		X	X

For organics in 1998, total petroleum hydrocarbon (TPH) was found above detection limits in two elutriate samples, and ammonia, which was not measured until 1996, was found in high concentrations for both water and elutriate samples. Total organic carbon (TOC) was not measured until 1990, but was found above detection limits for water and elutriate samples at most stations for all years sampled.

Bioassays have been conducted on samples collected from the Entrance Channel (Espey, Huston & Associates, Inc. [EH&A], 1979, 1983a, 1983b; PBS&J, 1999, 2004b; and Appendix B). Survival of organisms exposed to the liquid phase (water) and suspended particulate phase (elutriate) of sediments from the SNWW Entrance Channel was greater than 50 percent in all of these reports. Therefore, no 96-hour LC_{50} (the concentration of a substance that is lethal to 50 percent of test organisms after a continuous exposure of 96 hours) could be calculated. In such cases, the LC_{50} is assumed to be equal to 100 percent and the dredged material would not be predicted to be acutely toxic to water column organisms since the Limiting Permissible Concentration for water column toxicity/suspended particulate phase has been met (EPA/USACE, 2003). As noted in Appendix B, this also applies to the Entrance Channel Extension.

3.3.1.2 Sabine Pass Channel

Historical water and elutriate data for detected compounds from 1987, 1990, 1992, and 1998 are presented in PBS&J (2004a). Lead and zinc were the only metals found above detection limits in 1987 at all stations in water and elutriate samples. One water sample from station S-SP-87-06 contained 98.0 $\mu\text{g/L}$ of zinc that slightly exceeds the WQC (85.0 $\mu\text{g/L}$), the LWQS (90 $\mu\text{g/L}$), and the TWQS (92.7 $\mu\text{g/L}$). However, the elutriate value was low indicating no release of zinc to the water column during dredging or placement. Metals were not detected in 1990, and in 1992 the only metal found above detection limits was cadmium (in water) at station S-SP-92-06. In 1998, barium and zinc concentrations were found above detection limits for water and elutriate and were consistently higher in the elutriate samples. This contrasts to the 1987 samples, in which elutriate values were normally lower than water concentrations. Arsenic was detected at most stations in water and two stations for elutriate; cadmium and nickel were found in water only. All values, except the zinc value noted above, were below the WQC, LWQS, and TWQS.

Oil and grease were detected in 1987 in water and elutriate samples. Ammonia, which was not measured until 1996, was found above detection limits in all elutriate samples for 1998. For the organics, in 1987 fluoranthene was above detection limits at one station. TOC was detected in all water and elutriate samples during 1992, and elutriate concentrations were consistently higher than water concentrations.

3.3.1.3 Sabine-Neches Canal

Historical water and elutriate data for detected compounds from 1984, 1987, 1989, 1990, 1994, 1995, 1996, 1997, and 1998 are presented in PBS&J (2004a). Copper was the only metal found above detection limits in 1984; zinc was detected in 1987 water and elutriate samples; and metals were not detected in 1989 water and elutriate. In 1990, chromium was detected in water at one station, and zinc at two water and four elutriate stations. Barium and zinc were detected in water and elutriate samples in 1994. In 1995, barium was detected in all water and elutriate samples. One elutriate at station S-SN-95-15 contained high barium (1,096.0 $\mu\text{g/L}$). There are no WQC, LWQS, or TWQS for barium, but the Gold Book Criterion for barium in domestic water supplies (EPA, 1986) is 1,000 $\mu\text{g/L}$. Copper in elutriate samples at two stations was detected at levels greater than the WQC (2.9 $\mu\text{g/L}$) and the WQS (3.63 $\mu\text{g/L}$) but not the TWQS

(13.5 µg/L) (6.6 µg/L, S-SN-95-13 and 5.0 µg/L, S-SN-95-17). Barium and zinc were also found above detection limits in 1996 in water and elutriate samples. In 1997, barium, cadmium, copper, and nickel were found at most or all stations in water and elutriate; chromium was found in water only; selenium at one station in water; and zinc at all stations for water and one station for elutriate. In 1998, barium and zinc were found in all water and elutriate, and cadmium at one station for water. Except for the 1995 samples noted above, all values were below the WQC, LWQS, and TWQS. Recent sampling and testing within the Sabine-Neches Canal detected nickel in water sample S-SN-08-04A, and arsenic, copper, nickel, and zinc in sample S-SN-08-4A. However, all concentrations of detected metals were below the WQC, TWQS, and LWQS values. In addition, bis(2-ethylhexyl)phthalate was detected at 2.31 milligrams per liter (mg/L) in the elutriate sample.

Oil and grease were detected in 1984 and 1987 in water and elutriate samples. Ammonia was above detection limits for all but one water sample in 1996 and all water and elutriate samples in 1998. For the organics, in 1997 TPH was above detection limits at one station (S-SN-97-02). TOC was detected in all or most water and elutriate samples in 1990, 1994, 1995, 1996, and 1997. Detected concentrations in the historic data for TOC were similar in value for all water and elutriate samples. Both ammonia and TOC were detected in the March 2008 water and elutriate samples. However, ammonia concentrations were below the WQC values for both water and elutriate.

3.3.1.4 Port Arthur Turning Basins

Historical water and elutriate data for detected compounds from 1984, 1987, 1989, 1992, 1994, 1996, and 1998 are presented in PBS&J (2004a). Arsenic was found above detection limits for 1984 and 1998 for elutriate samples only. Barium, for which analyses were not conducted before 1993, was detected for both water and elutriate in 1994, 1996, and 1998 (highest concentrations in 1998); cadmium was found in water samples in 1998; lead in one elutriate sample in 1992; and nickel in 1992 (elutriate only) and 1998 (water only). Copper was detected in both water and elutriates in 1984 and elutriates only in 1992 and 1998. Copper in both elutriate samples for 1984 (5.0 µg/L at stations S-PATB-84-08 and S-PATB-84-09) and one from 1992 (9.4 µg/L at station S-PATB-92-10) exceeded the WQC (2.9 µg/L) and LWQS (3.63 µg/L). One copper value from station S-PTBA-92-08 in 1992 (27.9 µg/L) exceeded the WQC, TWQS (13.5 µg/L), and LWQS. Copper was detected only once in either medium, in 1996 and 1998, below the WQC, LWQS, and TWQS. Zinc was detected in 1987 for water and elutriate, in 1992 at one station for elutriate, in 1994 and 1998 for both media. No zinc values exceeded the WQC, LWQS, or TWQS. Metals were not above detection limits for water or elutriate in 1989. Recent sampling and testing in March 2008 within the Port Arthur Turning Basin detected arsenic, nickel, and zinc in water samples, and arsenic, copper, nickel, and zinc in elutriate samples. However, all concentrations of detected metals were below the WQC, TWQS, and LWQS values.

TOC was above detection limits in water and elutriate samples for all stations in 1992, 1994, and 1996 (PBS&J, 2004a). Detected concentrations in 1996 were lower than the 1992 and 1994 samples, which were similar in value for both water and elutriates. Oil and grease were detected in 1984 and 1987 for water and elutriate samples. All oil and grease values were similar except for an increased concentration

at station S-PATB-87-08 of 40.0 mg/L. No organics were detected for any year for water or elutriate samples. Ammonia was detected in all elutriate samples in 1998. Both ammonia and TOC were detected in the March 2008 water and elutriate samples. However, ammonia concentrations were below the WQC values for both water and elutriate.

3.3.1.5 Taylor Bayou Turning Basin

Historical water and elutriate data for detected compounds from 1989, 1994, 1996, and 1998 are presented in PBS&J (2004a). Of the metals, arsenic was found in both water and elutriate at two stations in 1998. Barium was above detection limits in both media in 1994, 1996, and 1998 (highest concentrations in 1998). Cadmium was found in all water samples and nickel in two water stations in 1998. Zinc was detected in 1994 and 1996 in both water and elutriates at all stations and in 1998 for all elutriate samples only (1998 concentrations were the highest). No WQC, LWQS, or TWQS were exceeded. Metals were not above detection limits for water or elutriate in 1989.

TOC was above detection limits for water and elutriates for all stations in 1994 and 1996, and in 1998 for water only (PBS&J, 2004a). No other organics were detected for any year in water and elutriate samples. Ammonia was detected in all elutriate samples in 1998, as has been seen with all reaches sampled of the SNWW.

3.3.1.6 Port Arthur Canal

Historical water and elutriate data for detected compounds from 1987, 1989, 1990, 1992, 1994, 1996, and 1998 are presented in PBS&J (2004a). For the metals, lead and zinc were found above detection limits in both water and elutriate samples in 1987. Zinc was the only metal detected in 1990, and the elutriate value at station S-PA-90-05 (550.0 µg/L) was well above the WQS (85.0 µg/L), LWQS (90.0 µg/L), and TWQS (92.7 µg/L). Since zinc was not detected in water at that station or in the water or elutriate samples 500 feet up and down stream, and the sediment zinc concentration was not high relative to nearby stations, this value appears to be an error. In 1992, lead was the only metal found above detection limits in the elutriate sample. Barium and zinc were detected in both water and elutriates in 1994, and in 1996 barium was found in both media and zinc in elutriate only. For 1998, arsenic was detected in water samples only at 4 of 14 stations; barium in all water and all but one elutriate sample; cadmium in most water and one elutriate sample; copper in most water samples; and nickel at 4 stations. Zinc was also detected in all water and elutriates, at the highest concentrations when compared to historic values. None of the WQC, LWQS, or TWQS was exceeded. Recent sampling and testing in March 2008 within the Port Arthur Canal detected nickel in water samples, and arsenic, copper, nickel, and zinc in elutriate samples. However, the concentrations of metals in both the water and elutriate samples were below the WQC, TWQS, and LWQS values.

Oil and grease were only detected in water and elutriate samples in 1987. TOC was above detection limits in water and elutriate samples for all stations in 1992, 1994, and 1996. No other organics were detected in any year for water and elutriate samples. Ammonia was detected in one elutriate sample (S-PA-98-01) in

1998. Both ammonia and TOC were detected in the March 2008 water and elutriate samples. However, ammonia concentrations were below the WQC values for both water and elutriate.

3.3.1.7 Neches River Channel

Historical water and elutriate data for detected compounds from 1988, 1990, 1994, 1995, and 1997 are presented in PBS&J (2004a). The 1995 stations were sampled in March and September of that year. Of the metals, zinc was detected in water samples from all or most stations in 1990, 1994, and 1997, and elutriate samples in 1994 and 1995 at most stations. However, all concentrations were well below the WQC, LWQS, and TWQS for zinc. Barium was detected in 1994, 1995, and 1997 at all water and elutriate stations. Cadmium was detected in water and elutriate samples from 1997; nickel was detected in three elutriate samples in 1995 and water in 1997; and lead in one elutriate sample (S-NR-95-21, September) in 1995. In 1995 (September), chromium was detected in two water samples and most elutriate samples. Copper was found in all 1995 (September) elutriate samples; all were well above the TWQS (13.5 µg/L), WQC (2.9 µg/L), and LWQS (3.63 µg/L) ranging from 23.8 µg/L to 55.6 µg/L. However, copper concentrations were below detection limits during the March sampling. No metals were detected in water and elutriate in 1988. Except for the copper concentrations noted above, all values were below WQC, LWQS, and TWQS. Recent water and elutriate sampling and testing in the Neches River Channel occurred in April 2009. Results of the tests show all metal concentrations below WQC, LWQS, and TWQS values.

TOC was above detection limits for water and elutriate samples for all stations in 1990, 1994, 1995, and 1997 (PBS&J, 2004a). No other organics were detected in any year for water and elutriate samples. Both ammonia and TOC were above detection limits for water and elutriate in the April 2009 samples. Chrysene (1.16 µg/L), benzo(a)anthracene (0.45 µg/L), benzo(k)fluranthene (0.53 µg/L), and benzo(a)pyrene (0.51 µg/L) were also found in an elutriate duplicate sample from April 2009. There are no WQSS for these PAHs. However, ammonia concentrations were below the WQC for both water and elutriate.

3.3.1.8 Sabine River Channel

Historical water and elutriate data for detected compounds from 1990 and 1995 are presented in PBS&J (2004a). Of the metals, zinc was detected in two of seven water samples and three of seven elutriate samples, but all concentrations were below TWQS, LWQS, and WQC. No other metals were detected in 1990 water and elutriate samples. In 1995, barium was above detection limits in all water and elutriate samples. Copper was detected in all elutriate samples, which were all above the WQC (2.9 µg/L) and LWQS (3.63 µg/L), ranging from 5.0 µg/L to 7.5 µg/L. Lead was also found in elutriates at one station (S-SR-95-04) but at concentrations well below the LWQS, TWQS, and WQC.

TOC was not detected in 1990, but was found above detection limits in all water and elutriate samples in 1995. No other organics were detected in 1990 or 1995.

3.3.1.9 GIWW – Port Arthur to High Island

Historical water and elutriate data for detected compounds for 1983 and 1993 are presented in PBS&J (2004a). Arsenic was the only metal detected in 1983, and it was found in all water and elutriate samples; however, it was not detected in 1993. In 1993, barium and zinc were found above detection limits in all water and elutriate samples, and in most cases elutriate concentrations were higher than water concentrations. All concentrations were less than the LWQS, TWQS, and WQC.

Oil and grease were detected in water and elutriate samples in 1983. TOC was above detection limits for water and elutriates for all stations in 1993 (PBS&J, 2004a). Ammonia was detected in most elutriate samples from 1983, but in none from the GIWW from 1993.

3.4 SEDIMENT QUALITY

Data collected by the USACE since 1983 were analyzed to determine the sediment quality of the SNWW. These samples of maintenance material are collected periodically before a maintenance-dredging event, following noncontaminating procedures approved by the USACE and EPA. Reference station material, for comparison with the maintenance material, is collected from areas in the vicinity of and similar to the maintenance material stations, but which have not been impacted by dredging and dredged material placement. For example, the reference station for the Upper Neches River Channel bioassays and chemistry was located in an oxbow off the channel and surrounded by nonindustrial land; the Lower Neches River Channel reference station was located in the Bessie Heights area where the channel material would be used beneficially; the Sabine-Neches Canal reference station was located in east Sabine Lake, near the Sabine NWR; and offshore reference stations were located in designated reference areas, up-current of the channel (PBS&J, 2004a; Appendix B).

There are no sediment quality criteria with which to compare concentrations in the sediment; however, there are several different guidelines that are used to look for a cause for concern in sediment samples. One guideline is the Effects Range Low, or ERL. ERL were developed by a technique that demonstrates no cause and effect from the chemicals in the data set. When ERL derived from sets of data from different areas are compared, the results are inconsistent (USACE, 1998b). Since the ERL are not based on cause and effect data, they are used only to determine a possible “cause of concern.” The ERL presented here are those given in the NOAA 1999 Screening Quick Reference Tables (Buchman, 1999). Where applicable, reference stations were examined, and in most cases, concentrations were within a factor of five relative to these stations, which is normal, as an examination of years of data collected from maintenance material along the waterway of Texas will show (USACE database). Also, while “higher than” is used in the following discussion, this only means that one concentration is numerically higher than another. However, there was no replication for these samples, and statistical significance, if any, could not be determined.

The need for determining a “cause for concern” is based on the guidance documents developed by the EPA and USACE. Specifically, the *Inland Testing Manual* (ITM) (EPA/USACE, 1998) and the Regional Implementation Agreement (RIA) (EPA/USACE, 2003), which are guidance manuals in EPA Region 6

for inland (including bays) and ocean placement of dredged material, respectively, use a structured hierarchical procedure for determining data needs relative to decision-making. This involves a series of tiers or levels of intensity of investigation—the tiered approach. Typically, tiered testing involves decreased uncertainty and increased available information with increasing tiers. This approach is intended to ensure the maintenance and protection of environmental quality, as well as the optimal use of resources. Specifically, least effort is required in situations where clear determinations can be made whether unacceptable adverse impacts are likely or not likely to occur based on available information. Most effort is required where clear determinations cannot be made with available information. The tiered approach to testing in this ITM and RIA must be initiated at Tier I. The tiered approach is designed to aid in generating physical, chemical, toxicity, and bioaccumulation information, but not provide more information than is necessary to make factual determinations. Tiered testing results in environmental protection by producing a more efficient compilation of necessary evaluations at reduced costs, especially to low-risk operations. Disposal operations that obviously have low environmental impact generally should not require intensive investigation to make factual determinations.

It is necessary to proceed through the tiers only until information sufficient to make factual determinations has been obtained. For example, if the available information is sufficient to make factual determinations, no further testing is required. The initial tier (Tier I) uses readily available, existing information (including all previous testing). More-extensive evaluation (tiers II, III, and IV) may be needed for materials that have a clear potential for impact or for which Tier I information is inadequate to determine the lack of potential for impacts. Tier II is concerned solely with sediment and water chemistry, including comparison of elutriates to WQSs and WQC. Tier III is concerned with well-defined, nationally accepted toxicity and bioaccumulation testing procedures. Tier IV allows for case-specific laboratory and field testing, and is intended for use in unusual circumstances. The approach is to enter Tier I and proceed as far as necessary to make factual determinations, i.e., there must be enough information available to make determinations on water column impact, benthic toxicity, and benthic bioaccumulation. The tests in the ITM and RIA reflect the present state-of-the-art procedures for dredged material evaluation.

The need to determine a “cause for concern” is driven by the tiered approach. If a “cause for concern” arises, sufficient information must be gathered to determine whether the dredged material is acceptable for in-bay or ocean placement. Therefore, the ERL is used as a tool to determine whether there might be a concern with the dredged material, as WQS were used for elutriates. The WQS are standards that must be met whereas the ERLs have no statutory authority.

3.4.1 Sabine-Neches Waterway

3.4.1.1 Entrance Channel

Historical sediment data for detected compounds from 1993, 1995, 1996, 1998, and 2004 are presented in PBS&J (2004a, 2004b) and Appendix B. Of the metals, chromium, copper, lead, and nickel were detected at all stations for all years. At PA station S-SB-93-DA3, in 1993, copper was detected at a concentration of 70.0 milligrams per kilogram (mg/kg), much greater than the concentrations found at the reference

stations, channel stations, and other PA stations and the DA3 station in 1995. Therefore, it appears to be an aberrant value. Cadmium was detected at all stations in 1993 and 1998; barium and zinc in 1995, 1996, and 1998 at all stations; and arsenic was detected in 1998 at all stations. The zinc concentrations in 1995 were slightly higher than the reference stations. In 2004, the most-inshore station (adjacent to ODMD5 4) tended to have the highest sediment concentration, and the ERL for arsenic was exceeded at this station. However, the elutriate concentration was well below WQS and WQC, and bioassays indicated no toxicity. There were no trends in the data, and no ERL were exceeded by samples from the Entrance Channel Extension in the 2004 samples. The sediments at the channel stations were mostly silt and clay, whereas sediments from the reference and PA stations generally contained a higher sand content. Since trace metal concentrations tend to be positively correlated to silt/clay concentrations, slightly higher metals concentration would be expected in the channel sediments.

Of the organics, TOC was detected only in 1998 but at high concentrations when compared to the reference station. The TOC values were so much higher that there was likely a change in methodology in 1998 because an error in units would not account for the difference. Total volatile solids (TVS) and ammonia (both not measured until 1993) were detected in 1996 and 1998. The reference stations were below detection limits for TVS and in 1998 for ammonia only. However, concentrations of TVS were at least five times the detection limits and ammonia concentrations were also above detection limits in 1996 (S-J-96-DA4) and in 1998 (S-J-98-02, S-J-98-03, and S-SB-98-02). Total sulfides, which was not measured until 1993, were detected in 1998 at most stations at concentrations higher than the reference stations (S-SB-98-REF3&4) that had concentrations below detection limits.

Solid phase bioassays were conducted on Entrance Channel sediments in 1999 (PBS&J, 1999) and in 2004 (PBS&J, 2004b) and on Entrance Channel Extension sediments in 2004 (Appendix B). In all cases, there were no tests in which survival in the Reference Control was greater than survival in the treatments and the difference exceeded 10 percent (20 percent for the amphipods), requiring statistical analysis. Therefore, the survival data from the solid phase bioassay indicate no potential for environmentally unacceptable toxic impacts to benthic organisms from the placement of dredged material from the Entrance Channel or Entrance Channel Extension. Bioaccumulation data in 2004 likewise indicated no expectation of adverse impacts to benthic organisms from the placement of Entrance Channel or Entrance Channel Extension dredged material.

3.4.1.2 Sabine Pass Channel

Historical sediment data for detected compounds from 1987, 1990, 1992, and 1998 are presented in PBS&J (2004a). Arsenic was above detection limits at one station in 1987 and at all stations in 1998. Chromium, copper, nickel, and zinc were detected at all stations in 1987, 1990, 1992, and 1998. Lead was found in 1987, 1992, and 1998 at all stations. Oil and grease were detected only in 1987 but at all stations; TOC was detected at all stations in 1998 (see subsection 3.3.1.2); total PCBs were detected at two stations in 1987; and TVS was detected in 1998 at all stations. Ammonia was detected at all stations in 1998 with the concentration at station S-SP-98-04 (21.4 mg/kg) much higher than at the other stations.

3.4.1.3 Sabine-Neches Canal

Historical sediment data for detected compounds from 1984, 1987, 1989, 1990, 1994, 1995, 1996, 1997, and 1998 are presented in PBS&J (2004a). Arsenic was detected in 1984, 1987, and 1997 at all stations; barium at all stations from 1994 to 1998; chromium in 1987 through 1997 at all stations; copper at every station for all years except 1998; lead in 1987 and 1994 to 1998 at all stations; mercury in 1997 at most stations; nickel in 1989, 1990, 1997, and 1998 at all stations; and zinc in all years at every station. These values were roughly in the same range in all years. However, one station in 1990 (S-SN-90-09) had a copper concentration of 40.0 mg/kg, much higher than the other stations for which values ranged from 3.3 mg/kg to 8.1 mg/kg. This anomalous value of copper does not indicate a cause for concern, since values were lower in subsequent years. Recent sediment samples collected in March 2008 within the Sabine-Neches Canal showed an arsenic concentration slightly greater (9.7 mg/kg) than the ERL value (8.2 mg/kg). All other detected metal concentrations were below the ERL values.

For the organics, TOC was detected in 1994, 1995, 1997, and 1998 with the concentrations in 1998 higher than in previous years (see subsection 3.3.1.3). Oil and grease were detected in 1984 (highest concentration) and 1987; total PAHs only in 1987; and the PAHs, fluoranthene and benzo(a)pyrene in 1987 and 1989 (highest concentration). In 1997, the PAHs, phenanthrene, pyrene, benzo(a)anthracene, and chrysene, plus TPH were detected at most stations. TVS and ammonia were detected at most stations in 1996 through 1998. Total sulfides were only detected in 1996 at three out of seven stations. All values were roughly in the same ranges in all years. Both ammonia and TOC were detected in the March 2008 sediment sample (S-SN-08-04A).

3.4.1.4 Port Arthur Turning Basins

Historical sediment data for detected compounds from 1984, 1987, 1989, 1992, 1994, 1996, and 1998 are presented in PBS&J (2004a). Arsenic was above detection limits in 1984, 1987, and 1998 at all stations, except for one in 1984. Barium was also found in 1994, 1996, and 1998 at all stations. Chromium, copper, lead, nickel, and zinc were detected in 1987, 1989, 1992, 1997, 1996, and 1998 at all stations, with the exception of lead, which was not detected in 1989. These values were roughly in the same ranges in all years. Recent sediment samples collected and tested in March 2008 detected arsenic concentrations in all samples slightly greater than the ERL value of 8.2 mg/kg. The arsenic concentrations in the samples ranged from 8.7 to 11.9 mg/kg. In addition, one sediment sample (S-PATB-08-08) had a copper concentration (49.6 mg/kg) that slightly exceeded the ERL value of 34.0 mg/kg. Chrysene (at 65.3 micrograms per kilogram [$\mu\text{g/kg}$] vs. ERL = 384 $\mu\text{g/kg}$), butylbenzylphthalate (66.9 $\mu\text{g/kg}$ vs. no ERL), and pyrene (at 68.5 $\mu\text{g/kg}$ vs. ERL = 665 $\mu\text{g/kg}$) were found in sample S-PATB-08-08 in March 2008.

TOC was found in 1994 and 1998 at all stations, the 1998 concentrations being much higher than in 1994 (see subsection 3.3.1.4). Total PAH, fluoranthene, and benzo(a)pyrene were detected in 1987 at all stations. Fluoranthene was found at a higher concentration (24.1 mg/kg) at station S-PATB-87-09 than at the other stations. Benzo(a)pyrene was also found at two of three stations in 1989; benzo(e)pyrene in

1996, at one of three stations; and ammonia in 1998, at all stations. Also, oil and grease, in 1984 and 1987, and TVS in 1998, were detected at all stations. Both ammonia and TOC were detected for all sample stations in March 2008.

3.4.1.5 Taylor Bayou Turning Basin

Historical sediment data for detected compounds from 1989, 1994, 1996, and 1998 are presented in PBS&J (2004a). For the metals, chromium, copper, nickel, and zinc were found in all years at all stations. Zinc concentrations were higher in 1994 and 1998, when compared to the 1989 data; however, there are not enough data to indicate a trend. The concentration of copper at station S-PATB-89-12 was 70.0 mg/kg, much higher compared to the data from other years, including later years and, interestingly, at the same anomalous concentration found at S-SB-93-DA3 (see subsection 3.3.1.1). Therefore, there is no trend of increasing copper concentrations with time. Barium was detected in 1994, 1996, and 1998 at all stations, and arsenic in 1998 at all stations. The barium values were roughly the same ranges in all years.

TOC was detected in all 1994 and 1998 samples, the greatest concentrations occurring in 1998 (see subsection 3.3.1.5). Naphthalene was found at one station in 1996; benzo(a)pyrene at one station each in 1989 (14.1 mg/kg) and 1996 (41.5 mg/kg); and benzo(e)pyrene in 1996. Ammonia and TVS were detected in 1998 at all stations.

3.4.1.6 Port Arthur Canal

Historical sediment data for detected compounds from 1987, 1989, 1990, 1992, 1994, 1996, and 1998 are presented in PBS&J (2004a). Nickel and zinc were found in all years at all stations; chromium and copper in all years at most stations; and lead was found in all years (except 1990) at all stations. Arsenic was detected in 1987 at one station and in 1998 at all stations; and barium was detected in 1994, 1996, and 1998 at all stations. All values were in the same range in all years, with the exception of barium in 1994 and 1996, which had more-elevated concentrations than in 1998 values. Recent sediment samples collected and tested in March 2008 detected arsenic concentrations slightly in excess of ERL values for stations S-PA-08-02 (8.95 mg/kg) and S-PA-08-07 (dup) (9.82 mg/kg). All other metals detected had concentrations below ERL values.

Oil and grease were detected in 1987 at all stations. TOC was found in 1994, 1996, and 1998 at all stations, with the 1998 values being the highest (see subsection 3.3.1.6). In 1987, total PAH and fluoranthene were detected at one station, and benzo(e)pyrene was detected in 1996. Ammonia and TVS were detected at station S-PA-98-01 in 1998. Both ammonia and TOC were detected in all samples tested in March 2008.

3.4.1.7 Neches River Channel

Historical sediment data for detected compounds from 1988, 1990, 1994, 1995, and 1997 are presented in PBS&J (2004a). Chromium, copper, nickel, and zinc were found at most or all stations for each year.

Lead was also detected in all years, except 1990, and at most stations, consistent with what was found at the other reaches for this same year. Arsenic was detected in 1988 and 1997 at most stations; barium was detected in 1994, 1995, and 1997 at all stations; and cadmium was detected at most stations in 1988 and 1997. Two stations (S-NR-88-21 and S-NR-88-18) exhibited greater copper concentrations (30.0 mg/kg) when compared to the other stations. Barium concentrations were higher in 1994 than in subsequent years. All other concentrations fell within similar ranges for all years.

Recent sediment sampling and testing occurred in the Neches River on April 1, 2009. Results of the tests showed arsenic at four sample stations (S-NR-09-05, -06, -10, and -11) slightly exceeding ERLs. The exceeded values ranged from 8.37 to 9.41 mg/kg, as compared to the arsenic ERL of 8.2 mg/kg. All other detected concentrations for the remaining metals were below ERL values. Both ammonia and TOC were found above the detection limits in April 2009.

TOC was above detection limits for 1994, 1995, and 1997 at most stations, with concentrations in 1994 the highest (95.0 to 622.0 mg/kg). Naphthalene, fluoranthene, and benzo(a)pyrene were detected in 1994 and 1995 at a few stations. The concentrations of benzo(a)pyrene in 1994 ranged from 36.0 to 533.0 mg/kg, at higher concentrations than in other years. The greatest concentration of fluoranthene occurred in 1995 at station S-NR-95-19 at 266.8 mg/kg. Total PAH, acenaphthene, and benzo(e)pyrene were above detection limits in 1995. Concentrations of acenaphthene at some stations are high (ranging from 81.4 to 321.9 mg/kg) relative to other stations. Also, TPH, TVS, and ammonia were found above detection limits at in 1997.

3.4.1.8 Sabine River Channel

Historical sediment data for detected compounds from 1990 and 1995 are presented in PBS&J (2004a). In 1990, chromium, copper, nickel, and zinc were above detection limits at all stations. One copper concentration at station S-SR-90-05 was higher (40.0 mg/kg) than at the other stations, but all other concentrations were within the same ranges. In 1995, barium, chromium, copper, lead, nickel, and zinc were above detection limits at all stations. Mercury was found at stations S-SR-95-02 (0.26 mg/kg) and S-SR-95-06 (0.36 mg/kg). Benzo(a)pyrene was found in 1990 at one station at a concentration of 10.0 mg/kg.

3.4.1.9 GIWW – Port Arthur to High Island

Historical sediment data for detected compounds for 1983 and 1993 in the Port Arthur to High Island segment of the GIWW are presented in PBS&J (2004a). Chromium, copper, lead, nickel, and zinc were above detection limits in both years at most stations. Arsenic was also detected in 1983 at all stations; and barium and cadmium were detected at all stations in 1993. All values were roughly the same for both years. TOC was found in 1993 at all stations, with higher concentrations at stations GIP-PAHI-93-17 (528.0 mg/kg) and GIP-PAHI-93-33 (204.0 mg/kg). Ammonia was also above detection limits in 1983 at all stations.

3.4.2 Summary

In summary, an examination of the sediment data presented in PBS&J (2004a), and sediment data recently collected in March 2008 and April 2009, indicates no cause for concern, with the possible exception of elevated PAHs in one reach of the Neches River. There are nine sites listed in Table 3.3-1 that are considered to be priority Hazardous, Toxic, and Radioactive Waste (HTRW) sites, and there is a reach of the Neches River (stations 750 + 000 to 950 + 000, see Figure 2.4-1g) that has higher sediment PAH concentrations than other reaches of the SNWW, but the location of the sites in Table 3.3-1 do not correlate to the higher-PAH reach of the Neches River. Additionally, none of those PAHs are found in the elutriate samples from the higher-PAH reach of the Neches River (Section 3.3), so there is no indication that those PAHs would be released during dredging and/or placement. Taking all of this information into account, there appear to be no reaches of the SNWW that exhibit a cause for concern.

Table 3.3-1
Summary of Priority HTRW Sites within Sabine-Neches Waterway

Site Name	Site ID	Constituents of Concern	Media Impacted	Status
Bailey Waste Disposal Site	512	Arsenic compounds, benzene, phenols, pyridenes, naphthalenes, and chlorinated hydrocarbons	Surface water, groundwater, soils	Cleanup complete in 1998; Operation and Maintenance underway since 1999
State Marine	203	PAHs, metals	Surface water	Evaluation and cleanup are underway, but the nature and extent of contamination and the risks posed to human health and the environment are unknown
Palmer Barge Lines	548	Aluminum, barium, chromium, cobalt, iron, lead, magnesium, nickel, zinc, pesticides, volatile organic compounds (VOCs), PAHs, pentachlorophenol (PCP), and benzene	Surface water	Evaluation and cleanup underway since 2000; the EPA is considering various remedial alternatives
Star Lake Canal	471	Chromium, copper, PAHs, and PCBs	Surface water, sediment	Evaluation and cleanup underway since 2001, but the nature and extent of contamination and the risks posed to human health and the environment are unknown
International Creosoting	30	Arsenic, chromium, lead, creosote compounds, semivolatile organic compounds (SVOC), and VOCs	Groundwater, sediment, soil, surface water	Clean up underway
Maintech International	410	PAHs	Groundwater, soils	Cleanup completed in 2000; undergoing Operation and Maintenance
Excell	28	TPH, benzene, toluene, ethylbenzene, and xylene	Groundwater	Investigation underway
Port of Beaumont, Beaumont Elevator	113	VOCs, herbicides, and pesticides	Groundwater, soils	Investigation underway
Woodcrest Site	584	VOCs	Soil	Investigation underway

3.5 HYDROLOGY

The study area is located within the Neches-Trinity Coastal Basin, the lower Neches River Basin, the lower Sabine River Basin, and the Calcasieu/Sabine River Basin. The Sabine River Basin is long and narrow with a length of approximately 300 miles. The basin has a watershed area of about 9,756 square miles, including 7,396 square miles in Texas. The Sabine River flows southeasterly from its source in Hunt County, Texas, for about 165 miles to the Texas-Louisiana border in the vicinity of Logansport, Louisiana. From there, the river flows in a southerly direction to Sabine Lake and the Gulf. Land surface elevations in the Sabine River watershed vary from a few feet above sea level near the coast to approximately 700 feet above mean sea level at the headwaters. The Sabine River Tidal section is 24 miles long starting from the confluence with Sabine Lake in Orange County to West Bluff in Orange County. Three large tributaries drain into the Sabine River Tidal section within the study area. These tributaries are Little Cypress, Cow, and Adams bayous.

The Neches River originates in southwest Van Zandt County and flows southeasterly through the Piney Woods of east Texas to the confluence with the Angelina River. The upper Neches River has a watershed of about 7,451 square miles and is approximately 150 miles in length. The Neches River Tidal section is 27 miles long starting from the confluence with Sabine Lake in Orange County to a point 7 miles upstream of IH 10 in Orange County. The hydrology of the Neches River Tidal segment is influenced by tidal and freshwater exchange with Sabine Lake and the Sabine-Neches Canal at the lower end of the stream segment, and by freshwater inflows from Pine Island Bayou and the Neches River at the upper end of the stream segment.

Sabine Lake is formed by the confluence of the Neches and Sabine rivers. The lake is 68.7 square miles in size and is fairly shallow, averaging about 4 to 6 feet in depth. The lake is located at the east side of the SNWW from Port Arthur and Pleasure Island. Sabine Lake has a drainage area of approximately 50,000 square miles in Texas and Louisiana that results in freshwater inflow of about 13 million acre-feet per year (McFarlane, 1996). Between Sabine Lake and the Gulf lies Sabine Pass. It is 2.1 square miles in size and is located from the end of the jetties at the Gulf to SH 82.

In addition to the Neches and Sabine rivers, Sabine Lake and the SNWW are fed by a number of smaller watercourses from both the Texas and Louisiana sides of the lake. From Louisiana, several smaller watercourses including Greens Bayou, Johnson's Bayou, Willow Bayou, Three Bayou, Lighthouse Bayou, Starks Canal, Hog Island Gully, West Cove Canal, and Black Bayou drain the Sabine NWR area and provide water exchange between the Sabine Lake and Calcasieu Lake systems. From Texas, the smaller waterbodies contributing to Sabine Lake and the SNWW include Old River Bayou draining to Old River Cove at the north end of Sabine Lake; Bessie Heights Canal draining the Bessie Heights Marsh area; Taylor Bayou draining the Big Hill Reservoir area and the J.D. Murphree WMA; the Keith Lake Channel draining surrounding lakes and marshland to the SNWW; Salt Bayou draining the McFaddin NWR and Sea Rim State Park; and Star Lake draining the southern areas of the McFaddin NWR and surrounding area. Of these smaller waterbodies, the following areas are of particular concern to this study:

- Bessie Heights Canal, located on the Neches River approximately 10 miles upstream of Rainbow Bridge, drains the Bessie Heights Marsh area and the Bessie Heights Oil and Gas Field. There are numerous small canals associated with the development of the oil field feeding into Bessie Heights Canal. These smaller canals have caused increased saltwater intrusion into the marshlands of the Bessie Heights area.
- Salt Bayou, located in southern Jefferson County, feeds Salt Lake and drains the McFaddin NWR to the eastern portion of the GIWW. A water control structure, known as the Salt Bayou Structure, located at the outlet of Salt Bayou into the GIWW prevents saltwater intrusion via the GIWW into the surrounding marshlands that were affected by the deepening of the GIWW and SNWW. The Salt Bayou Structure works in conjunction with the Salt Lake Structure at Perkins Levee to control salinity levels in the McFaddin NWR, Sea Rim State Park, and the J.D. Murphree WMA. The Salt Bayou system is affected by the SNWW through the opening at the Keith Lake Fish Pass.
- Black Bayou estuary and eastern shoreline of Sabine Lake located in Cameron and Calcasieu parishes. This area has suffered significant erosion and loss of marsh area. According to the Louisiana Coast 2050 report (LCWCR/WCRA, 1998), the Black Bayou mapping unit had lost 4,900 acres of marshland between 1978 and 1990 because of altered hydrology and wave/wake erosion.
- Willow Bayou estuary, located in Cameron Parish primarily in the Sabine NWR. This area has suffered significant Sabine Lake shoreline erosion and loss of interior marsh. From 1974 to 1990, 1,140 acres were lost (LCWCR/WCRA, 1999).

Eleven water quality segments, as designated by TCEQ, are included in the Sabine River, Neches River, Sabine Lake, and Sabine Pass. While these segments do not necessarily pertain to hydrology, they are useful for delineating waterbodies for discussion purposes. These include:

Segment	Identification
0501	Sabine River Tidal
0501B	Little Cypress Bayou
0502	Sabine River Above Tidal
0508	Adams Bayou Tidal
0508A	Adams Bayou Above Tidal
0511	Cow Bayou Tidal
0511A	Cow Bayou Above Tidal
0601	Neches River Tidal
0601A	Star Lake Canal
2411	Sabine Pass
2412	Sabine Lake

Upstream of Sabine Pass (excluding the Sabine and Neches river segments) is the Neches-Trinity Coastal Basin and the Sabine River Basin, which include the following major waterbodies or segments as designated by TCEQ. However, some of these waterbodies do not drain into the SNWW.

Segment	Identification
0701	Taylor Bayou Above Tidal
0701D	Shallow Prong Lake
0702	Intracoastal Waterway Tidal
0702A	Alligator Bayou
0703	Sabine-Neches Canal Tidal
0704	Hillebrandt Bayou
0704A	Willow Marsh Bayou
0704B	Kidd Gully
110301	Sabine River confluence with Old River below Sabine Island WMA to Sabine Lake
110302	Black Bayou from boundary between segments 1103 and 1106 to Sabine Lake
110303	Sabine River
110303	Sabine Pass
110602	Black Bayou – Intracoastal Waterway to boundary between segments 1103 and 1106
110701	Sabine River Basin Coastal Bays and Gulf Waters to the State 3-mile limit

The coastal watersheds along SNWW are generally flat and consist of coastal forested wetlands and marshes, and prairies. The extensive marshlands occur in areas less than 5 feet above mean sea level and extend inland 4 to 15 miles along the entire Gulf shoreline. Marshes and associated swamps extend up the reaches of the Sabine and Neches rivers.

Although the geomorphology of the system indicates that the Sabine Lake estuary was historically a freshwater environment, a survey of the Sabine River by the USACE in 1879 suggests Sabine Lake may have had at least periods of natural saltwater intrusion. Description of plant communities near the mouth of the Sabine River at Sabine Lake indicated the absence of riparian vegetation typical of freshwater rivers in this region and the presence of salt-tolerant plants (USACE, 1980). It is likely that saltwater intrusion may have occurred with tidal surges from Gulf storms resulting in an estuarine environment.

3.5.1 Freshwater Flows

The SNWW contains perennial freshwater flow from both the Neches and Sabine rivers and their tributaries as well as tidal flow from the Gulf. The USGS maintains a set of gauge stations in the study area (<http://waterdata.usgs.gov/tx/nwis/rt>), including:

USGS 08041000	Neches River at Evadale, Texas
USGS 08041500	Village Creek near Kountze, Texas
USGS 08041700	Pine Island Bayou near Sour Lake, Texas
USGS 08030500	Sabine River near Ruliff, Texas
USGS 08042522	Taylor-Alligator Bayou Pump Station near Port Arthur, Texas

Of these, the USGS gauge near Evadale on the Neches River (08041000), with peak flow records from 1884 to present, and the gauge near Ruliff on the Sabine River (08030500), with peak flow records from 1924 to present, contain the flow data that can best describe the freshwater inflow into the study area. The Evadale gauge has a drainage area of 7,951 square miles, and the Ruliff gauge has a drainage area of

9,329 square miles. Both gauges are upstream of Sabine Lake. Peak flow records for the Evadale and Ruliff gauges range from 5,890 cubic feet per second (cfs) on October 30, 1970, to 125,000 cfs in 1884 and 11,100 cfs on June 11, 1981, to 121,000 cfs on May 22, 1953, respectively. Typical dry weather flows on both the Sabine and Neches rivers each average about 1,200 cfs. Information developed by the Waterway Experiment Station of the USACE (Vicksburg District) indicated that 10 percentile flows range from 57,100 to 418,500 acre-feet/month; mean flows range from 342,400 to 1,540,000 acre-feet/month; and 90 percentile flows range from 612,500 to 3,302,000 acre-feet/month.

3.5.2 Water Exchange Patterns between Calcasieu and Sabine Lakes

Water exchange between Calcasieu and Sabine lakes occurs through the marsh of the Sabine NWR, located between Calcasieu and Sabine lakes and midway between the GIWW to the north and the Gulf to the south. The GIWW, North Line Canal, Central Canal, and South Line Canal provide hydrologic connections between the two lakes, as shown on Figure 3.5-1. With the exception of a few freshwater marsh impoundments, the area south of the GIWW is tidally influenced, and water level and flow direction can vary daily with tide, wind, stormwater runoff, river stage, barometric pressure, and control-structure operations. Studies of the area have shown that wind is the primary force affecting the flow patterns between the two lakes, resulting in flow patterns that overpower the effects of lunar tides (Paille, 1996).

During prolonged periods of strong southeast and south winds (typically occurring prior to frontal passage), a large volume of Gulf water is forced into Calcasieu and Sabine lakes, raising water levels in the area. The rise in water levels in the lakes causes strong incoming flows to occur in the surrounding marshes. The large area of marsh and shallow open water extending northward from Backridge Canal to Hackberry can also experience a push of water northward. This northward push of water causes water levels in the southern end of the open-water area to lower, facilitating flow into the area from Calcasieu Lake via Hog Island Gully and Kayo Bayou. In addition, the Roadside Canal flows strongly toward the southern end of the open water, importing water from Calcasieu Lake via the Headquarters Canal and West Cove Canal water control structures. During these wind conditions, Backridge Canal flows northward toward the southern end of the open area. At the northern end of the open-water area, these high-tide conditions result in discharge of water through Rycade Canal toward Black Lake. The discharge through Rycade Canal is often very strong as a result of substantial head differential that can be created by the wind-induced lowering of water levels in the southern portion of Black Lake. North Line Canal conveys large volumes of water from wind-induced high-tide areas within the Sabine NWR toward Sabine Lake by way of Black Bayou (Paille, 1996).

During prolonged periods of strong northerly winds (typically occurring after frontal passage), water levels in the nearshore Gulf and within Calcasieu and Sabine lakes lower, often resulting in a continuous outflow from Calcasieu and Sabine lakes. The large area of marsh and shallow open water extending northward from Backridge Canal to Hackberry can also experience a push of water southward and, thus, raising water levels in the southern end of the open water and lowering water levels in the northern end. This southward push of water in the open water often results in a strong flow toward Calcasieu Lake due

FIGURE 3.5-1

MAP OF HYDROLOGIC CONNECTIONS BETWEEN
SABINE LAKE AND CALCASIEU LAKE

Source: Paille, 1996

to the lowering water levels in the lake caused by the outgoing flows. The Backridge and Roadside canals can convey large volumes of water from the high-water-level areas toward Calcasieu Lake via Headquarters Canal and West Cove Canal water structures. Flow patterns in Rycade Canal can vary, however, with the North Line Canal west of Beach Canal typically draining west toward Sabine Lake (Paille, 1996).

During summer months, when winds are typically light and variable, lunar tides generally dominate the flows between Calcasieu and Sabine lakes. Normal flow patterns for ebb tides are similar to frontal passage and for flood tides are similar to conditions prior to frontal passage, but in smaller magnitudes. During ebb tide, GIWW, North Line Canal, Central Canal, and South Line Canal drain the Sabine NWR marsh area simultaneously toward both Calcasieu and Sabine lakes, with no-flow sections in each canal that vary with wind, water levels, river stages, and control-structure operation (Paille, 1996).

3.5.3 Flow Diversion, Demands and Discharges

3.5.3.1 Flow Diversions

Flow patterns and salinity in Sabine Lake, surrounding marshes, and tributaries have changed as a result of navigational dredging. In 1876, a sandbar was removed from Sabine Pass to aid in navigation, which consequently facilitated saltwater intrusion into Sabine Lake (USACE, 1975a, 1998a). Since then, channel deepening and widening has exacerbated saltwater intrusion into Sabine Lake and surrounding marshes and tributaries. In addition, Sabine Lake, Calcasieu Lake in Louisiana, and surrounding waterbodies have been connected through man-made canals and the GIWW. Tidal currents emanating from the Gulf transport seawater through Sabine Pass into Sabine Lake and adjacent waterbodies. Although the lake and associated waterbodies are low-energy environments, wind-generated currents strongly influence water movement within the system (Paille, 1996). As a result, a complex hydraulic relationship has developed within this area.

Several saltwater barriers in the study area restrict saltwater intrusion into upstream areas. In Texas, along Taylor Bayou, two saltwater barriers and sets of navigation locks are located approximately 2 miles upstream of the mouth of Taylor Bayou. Originally installed for irrigation purposes, the saltwater barriers along Taylor Bayou now primarily serve as a preventative measure for stopping saltwater intrusion into freshwater marshes and maintaining water level for recreation purposes (JCND, 2002). Additionally, the TPWD also maintains several small saltwater barriers in various locations along the GIWW for the purpose of protecting freshwater marshes and habitat within the J.D. Murphree WMA (JCND, 2002). Saltwater intrusion from the GIWW is controlled by water control structures at Perkins Levee and the opening of Salt Bayou to the GIWW (USACE, 1992), but the marshes remain open to the salinity influence of the SNWW through the Keith Lake Fish Pass. The GIWW structures are manually controlled by the TPWD and can be opened to help drain the area when the marshes have been flooded with higher-salinity waters during hurricanes. In the Texas Point NWR, low rock weirs have been constructed on several small channels in the intermediate and brackish marshes; however, unrestricted flow still is provided through the largest stream in the hydro-unit, Texas Bayou.

The area within the Calcasieu/Sabine River Basin has experienced accelerated marsh deterioration and conversion to shallow open water as a result of the construction of the Calcasieu Ship Channel, the SNWW, and the GIWW. Efforts to combat the increased flow of salt water into the area include both structural and vegetative methods. A 1990 inventory of water control structures along the perimeter and interior of the Calcasieu/Sabine River Basin located 174 structures. Examples of these water-control structures include (Marcantel, 1996):

Location	Description
Louisiana SH 82 at Calcasieu Ship Channel	Three-barrel structure allows only one-way flow into Calcasieu Ship Channel
Louisiana SH 27 at Holly Beach, Louisiana	Two-barrel structure allows only one-way flow into the roadside ditch along Louisiana SH 82
Structure at First Bayou	Bulkhead structure with two bays managed so that two-way flow is possible until salinity levels reach or exceed 7 ppt in the road ditch along west Louisiana SH 27
Hog Island Gully	Fixed crest weir with tainter arm gate that remains open until salinity levels reach 12 ppt in Brown Lake (on the north end of the Sabine NWR)
West Cove Canal	Fixed crest weir with tainter arm gate that remains open until salinity levels reach 12 ppt in Back Ridge Canal of the West Cove Canal structure
Headquarters Canal	Single-barrel structure where gates remain open until salinity levels reach or exceed 12 ppt in Brown Lake
Rycade Canal	Bulkhead structure with seven bays managed so that flap gates are allowed to operate when water levels in interior marshes are above marsh level and/or salinity at the structure reaches or exceeds 5 ppt
Gray's Ditch Levee/Cattle Walkway	Levee has two openings (one at unnamed bayou and one at Willow Bayou) and forms a barrier along the east bank of Sabine Lake
Deep Bayou	Two-barrel structure allows one-way flow out of Deep Bayou into Johnson's Bayou
South Starks Canal	Three-barrel structure allows one-way flow to the east

More recently, two CWPPRA hydrologic restoration projects have been completed in the Black Bayou and Willow Bayou marshes east of Sabine Lake:

- The East Sabine Lake Hydrologic Restoration Project (CWPPRA Project No. CS-32), approved in 2001, has nearly been completed (USGS-NWRC, 2004). Project goals include the reduction of salinities within interior marshes, encouragement of submerged aquatic vegetation (SAV) development, hydrologic restoration of historic flows, reduction of turbidity in open-water areas, and the restoration and protection of marsh through earthen vegetative terraces. Construction Unit 1, completed in 2006, includes a rock weir at Pines Ridge Bayou, two flapgate culverts at Bridge Bayou, a rock plug at Double Island Gully, a 3,000-foot-long foreshore rock dike along the Sabine Lake shore north of Willow Bayou, and approximately 32 miles of vegetated earthen terraces in large shallow open-water areas south of Greens Lake and south of Willow Bayou Canal. Hydrodynamic modeling of proposed Construction Unit II water control structures (fixed crest weirs with boat bays) at Right Prong, Greens, Three, and Willow bayous was completed in 2004 (USFWS-LDNR, 2008a). The modeling predicted that the proposed structures would have very little effect on reducing project area salinities, and therefore Construction Unit 2 components were deleted from the restoration plan in 2006. The Pines Bayou weir was rehabilitated in 2007

due to heavy damage from Hurricane Rita. Four 50-foot-wide gaps were also installed in 2007 in the breakwater near Willow Bayou. Additional in situ earthen terraces are also planned.

- The Black Bayou Hydrologic Restoration Project (CWPPRA Project No. CS-27) was constructed in 2001 for the purpose of restoring coastal marsh habitat and slowing the conversion of wetlands to shallow open water. The project limits the amount of saltwater intrusion into the surrounding marsh and canals from Black Bayou and the GIWW and reduces erosion caused by wave action from nearby boats and tides (USGS-NWRC, 2002c). These elements are (1) approximately 4.3 miles of rock foreshore dike along the south shore of the GIWW; (2) the Black Bayou Cut-off Canal rock weir with boat bay; (3) the Burton Canal weir with boat bay; (4) the Block's Creek rock weir with boat bay; and (5) a self-regulating tide gate for the NO-13 unit wetlands. The objective of the tide gate is to divert fresh water from the GIWW and create a hydrologic head that maximizes freshwater retention time and reduces saltwater intrusion and tidal action. Terracing and vegetative plantings are also planned as part of the CWPPRA project.

Flows into Sabine Lake have been greatly altered from their natural hydrograph due to major impoundments in the middle and upper Sabine and Neches river basins. The flow regime of the lower Sabine River is affected by Toledo Bend Reservoir, which provides electric power, flood control, and irrigation water. Playing a lesser role, but nevertheless affecting water availability in the Sabine River, are a number of smaller reservoirs upstream of Toledo Bend Reservoir in Texas. The larger of these impoundments include lakes Tawakoni, Fork, Cherokee, Martin Creek, and Murval. Additionally, the flow regime of the lower Sabine River is affected by two diversion canals near Sulphur, Louisiana, which were constructed to provide municipal, industrial, and irrigation water to Calcasieu Parish in Louisiana and Orange County in Texas. The diversion pumps currently operate at 20 percent of their capacity that results in an average daily flow of 336 cfs to Calcasieu Parish and 560 cfs to Orange County.

The flow regime of the Neches River is strongly influenced by Sam Rayburn Reservoir and to a lesser extent by B.A. Steinhagen Reservoir. Other reservoirs that affect water availability within the Neches River are upstream of Sam Rayburn Reservoir and include lakes Palestine, Tyler, Jacksonville, Striker, and Nacogdoches.

Saltwater intrusion in the Neches River became a problem with the construction of the first deepwater navigation channel to Beaumont in 1915 (USACE, 1998a). Since that time, salt water has threatened freshwater intakes on the Neches River. In the past, temporary saltwater barriers and freshwater discharges (up to 2,500 cfs) from Sam Rayburn Reservoir were used to prevent encroachment of salt water (Lower Neches Valley Authority [LNVA], 2002; USACE, 1998a). A saltwater barrier was constructed on the Neches River immediately downstream of the confluence of the Neches River and Pine Island Bayou (USACE, 2004b). Operation of the new saltwater barrier will preclude the need for large freshwater releases from Sam Rayburn Reservoir during periods of drought, resulting in a net reduction of freshwater inflow into Sabine Lake (LNVA, 2002; Mosier, 2002). However, provisions for maintaining environmental flows to protect high-quality wetlands downstream of the saltwater barrier during periods of drought are currently being developed (Mosier, 2002). Under this plan, special gate operations for wildlife and environmental management will be coordinated with the USACE. This will include providing enough freshwater inflow to maintain a specific conductance of 2,800 microsiemens or less

(within 10 feet of the surface) at the IH 10 bridge near Beaumont. While freshwater habitats in the Neches River will be maintained by the operation of the new saltwater barrier, it is likely that freshwater inflows into Sabine Lake will be less under drought conditions than historical inflows.

In May 2007, the Texas House of Representatives and Senate passed HB3 and SB3, respectively, which was signed by the Governor on June 15, 2007 (Texas Legislature Online [TLO], 2007). The “Environmental Flows” Act took effect on September 1, 2007 (TLO, 2007). The Act creates an administrative process to determine environmental flow needs for the rivers, bays, and estuaries of Texas. After the needs are established, TCEQ is required to develop and adopt rules to (1) provide environmental flow standards necessary to support the ecology of every river and bay system in Texas; (2) establish an amount of unappropriated water that would be set aside for satisfying the environmental flow standards; and (3) create a process for reducing the amount of water that would be available under a water rights permit, issued after the bill’s effective date, to protect the environmental flow standards. TCEQ identified the lower Sabine River as one of the first tier of instream flow studies to be initiated. TCEQ has contracted with the Sabine River Authority of Texas (SRA-TX) for assistance in the Lower Sabine Priority Instream Flow Study. Based on the results of this study, TCEQ will establish environmental flow standards for the Sabine River/Neches River/Sabine Lake system by September 1, 2010.

3.5.3.2 Freshwater Demands and Discharges

Water demands and supplies have been analyzed for the East Texas Region (Region I), consisting of 20 counties as far north as Smith County that includes the City of Tyler (TWDB, 2007). The projected regional water demand for the year 2010 is 896,455 acre-feet. Manufacturing represents 45 percent of the amount and irrigation is 25 percent. Municipal and county demand represents 21 percent of that amount. This demand is projected to increase by 41 percent by the year 2060. Water supply projected for 2010 is 1,158,261 acre-feet, with 80 percent of the supply from surface water. The remainder of the supply is from groundwater. While demand is projected to slightly exceed the existing supply by the year 2060, the recommended water management strategy for the region would result in an additional 324,756 acre-feet of supply (TWDB, 2007). The plan anticipates expanded exports of water to Region C (Dallas-Fort Worth area).

During dry conditions, stream flow is influenced by the discharge from permitted wastewater treatment plants or point sources along tributaries. For the Neches-Trinity Coastal Basin, which includes Taylor Bayou, there are 89 permitted point sources that have a combined permitted flow of 214 million gallons per day (MGD), or 330 cfs. The Neches River Basin has 225 point sources for a combined permitted flow of 1,341 MGD, or 2,070 cfs; and the Sabine River Basin has 166 point sources for a combined permitted flow of 1,647 MGD, or 2,550 cfs. While actual discharges are usually much smaller than the permitted flows, and not all of these point sources are located within the study area, some of the discharges would affect salinity levels in the study area during drought periods.

3.5.4 Tides

Tides in the SNWW and Sabine Lake are dominated by the tides emanating from the Gulf, but lag by about 1 hour from offshore to Sabine Pass and by 4 to 5 hours from offshore to the upper reaches of the SNWW. Normal tidal fluctuation in the study area is small with a diurnal range of 1 to 2 feet (Mantz and Dong, 1996).

The Texas Coast Ocean Observation Network (TCOON) maintains tide gauge stations at Sabine Pass, Mesquite Point, Port Arthur, Rainbow Bridge, and Orange. These gauges vary in length of record from 5 to 10 years. The statistics of tidal records at these TCOON gauges can be found on the TCOON website (<http://lighthouse.tamucc.edu/TCOON/HomePage>). A tidal range varying from 1.03 feet at Sabine Pass to 0.65 foot at Orange can be derived from the tide records. These ranges are typical of the Gulf coast area.

Water levels in the SNWW are also influenced by the prevailing winds from the south-southeast. Water levels generally rise slightly with winds out of the south and south-southeast and fall, sometimes significantly, with winds from the north or northwest. Water surface elevations in the SNWW can vary greatly when driven by wind and storm activity. Water levels as low as -4 feet during strong northwesterly winds and as high as +16 to +18 feet during hurricane surges have been observed.

3.5.5 SNWW and Salinity

Tidal flow originating from the Gulf influences the tidal regime of the SNWW, including Sabine Lake and Calcasieu Lake. During periods of drought, the flow in the Neches and Sabine rivers can drop drastically and a saltwater wedge can proceed farther upstream of both the Sabine and Neches rivers from the Gulf (LNVA, 2002; SRA-TX, 2002). While saltwater intrusion has been detected in salinity samples in the Sabine River Tidal reach, a definite saltwater wedge has not been identified because of the fluctuation of freshwater inflows from upstream. A definite saltwater wedge is evident in the Neches River, and a new saltwater barrier located approximately 30 stream-miles upstream of Rainbow Bridge has been installed to prevent saltwater intrusion north of the Port of Beaumont (see subsection 3.5.3.1 for additional discussion).

The strength and intensity of winds and intensity of rainfall influences salinity levels in the SNWW, Sabine Lake, and Calcasieu Lake. The salinity of the water ranges from approximately 34 ppt in the open Gulf to 0 ppt in the upper reaches of the Neches and Sabine rivers. Sabine Lake is predominantly brackish with salinity ranging from 15 ppt at Sabine Pass to 0 ppt at the northern end of the lake near Rainbow Bridge. Calcasieu Lake is also brackish, but generally experiences salinity levels higher than those found in Sabine Lake. Given that both lakes are tidally influenced and water exchange patterns between the two lakes vary with tides and wind, the fluctuating salinity levels can often be extreme. The Sabine NWR and the waterways connecting the two lakes also experience fluctuating salinity levels, however, generally, not in the extremes observed within the two lakes. Sabine Lake relies on freshwater inflow from the Neches and Sabine rivers, while Calcasieu Lake relies primarily on the Calcasieu River for freshwater

inflow. The Sabine NWR relies primarily on rainfall for fresh water, and its salinity increases during periods of drought as the salinity in the two lakes rises (Paille, 1996).

During drought periods, salt water can travel more easily through the deeper SNWW than shallower Sabine Lake, thus the northern reach of the lake and associated marshlands can have the unique condition of having greater salinity levels than those areas to the south. This is because salt water traveling in the SNWW can enter northern marshes that typically have salinity levels buffered by freshwater inflows from the Sabine and Neches rivers. Saltwater entering the northern marshes can result in build-up of salinity concentrations. During periods of normal rainfall, high-salinity water transported by the SNWW is buffered by discharges from upstream reservoirs that have little effect on the salinity levels of Sabine Lake and the surrounding marshes. On the other hand, during periods of high flows, the SNWW and Sabine Lake can experience occasional freshwater conditions (very low salinity levels) due to large quantities of fresh water entering the system from the Sabine and Neches rivers (Coalition to Restore Coastal Louisiana, 2002).

Fifty-six stations provide salinity data measured from the monitoring stations within the study area. Data from the stations can be obtained from TCEQ's Standard Water Quality Monitoring (SWQM) database, which is used to support the Texas Clean Rivers Program and the preparation of Texas Water Quality Inventory (TCEQ, 2002). The locations of these stations range from the USCG station in Sabine Pass upstream to all the tributaries (e.g., Black Bayou, Cow Bayou, Adams Bayou) to the upper reaches of the Neches and Sabine rivers in the study area, and in the GIWW east of the Sabine River and west of Port Arthur. Salinity, as a function of depth from several stations along the SNWW, is of particular interest because the heavier salt water tends to move upstream along the bottom of the deep, stratified channel while freshwater flowing on top of the saltwater current moves downstream. The data from the project area show a clear trend of reduced bottom salinity when moving upstream along the SNWW, from about 25 ppt at Sabine Pass to about 15 ppt at IH 10 on Neches River near Beaumont and 10 ppt at the upper portion of Sabine Lake near the confluence with the Sabine River. The stations at the GIWW (about 7 miles upstream of Sabine Pass) and at Topco Dock (about 6 miles upstream of the GIWW) have bottom salinities of about 23 ppt and 20 ppt, respectively. These values clearly show the level and extent of salinity intrusion along SNWW.

3.5.6 Groundwater Hydrology

Groundwater in the project area is withdrawn from the Gulf coast aquifer system. The Gulf coast aquifer consists of complexly interbedded clays, silts, sands, and gravels of Cenozoic age, which are hydrologically connected to form a large, leaky artesian aquifer system that extends from the Rio Grande northeastward across the Gulf Coastal Plain past the Louisiana-Texas border. In the project area, the Gulf coast aquifer is subdivided into several parts, of which the Chicot aquifer is the uppermost (Figure 3.5-2). The Chicot aquifer consists of the Willis, Lissie (Montgomery and Bently), and Beaumont formations, and overlying alluvial deposits. The Chicot aquifer includes all deposits from the land surface to the top of the underlying Evangeline aquifer. The physical basis for separation of the Evangeline and Chicot aquifers is the difference in lithology and permeability (Wesselman, 1971). In some area, clay beds

Figure 3.5-2. Geologic and Hydrologic Units within the Project Area

System	Series	Stratigraphic Unit		Hydrologic Unit		
		Texas	Louisiana			
Quaternary	Holocene	Quaternary Alluvium		Chicot Aquifer	Upper Unit	Gulf Coast Aquifer
	Pleistocene	Beaumont Clay				
		Lissie Formation	Montgomery Formation		Montgomery Formation	
			Bently Formation		Bently Formation	
		Willis Sand			Willianna Formation	
Tertiary	Pliocene	Goliad Sand		Evangeline Aquifer		
	Miocene	Fleming Formation		Burkeville Aquiclude		

separate the aquifers, but these beds are not continuous. The higher permeabilities are usually associated with the Chicot aquifer.

The Chicot aquifer has been divided into an upper unit and lower unit. These units are separate by a clay bed; however, in some parts of the study area, the upper and lower units merge to form one large mass of interbedded and interconnected sand and clay. The upper unit of the Chicot typically consists of a basal sand overlain by clay. Most of the sand is part of the Montgomery Formation, and the clay is part of the overlying Beaumont Formation. The lower unit generally consists of two or more massive sands separated by clay. Northwestward, the sands thin and the clay content of the lower unit increases.

The Evangeline aquifer underlies the Chicot aquifer and is the lowermost unit containing fresh to slightly saline groundwater within the project area (see Figure 3.5-2). The Evangeline aquifer consists of the Goliad Sand and upper portions of the Fleming Formation. The aquifer is underlain by the Burkeville aquitard, which forms the lower confining unit for the Evangeline aquifer.

Water well records kept by the TWDB for Orange and Jefferson counties indicate that the majority of water wells in the project area are completed in the upper and lower units of the Chicot aquifer. Of the wells installed in the Chicot, most are completed in the lower unit typically at depths between 400 and 800 feet. Wells completed in the upper unit of the Chicot aquifer were typically completed at depths ranging from 15 feet or less to 300 feet. Groundwater is reportedly used for domestic, public supply, stock, and industrial purposes.

Groundwater recharge to the aquifers occurs by precipitation onto outcrop areas and vertical leakage from overlying aquifers. However, most precipitation runs off and becomes stream flow or evaporates immediately and only a small fraction of the total rainfall recharges the surficial aquifer. Regional groundwater flow in the aquifers is generally southeastward from outcrop areas towards areas of natural discharge (Gabrysch and McAdoo, 1972; Wesselman, 1971). However, superimposed upon this natural discharge regime is artificial discharge caused by groundwater pumping. Because of groundwater development, water levels have declined and cones of depression around areas of groundwater pumping have developed altering the natural flow pattern, and groundwater now flows towards these centers of pumping.

Groundwater quality in the Chicot aquifer varies widely across the study area. In general, the water in the aquifer increases in salinity in the southern part of the study area near the coastline. Groundwater quality data from the TWDB database indicate that groundwater from water wells completed in the Chicot aquifer within the project vicinity generally has total dissolved solids (TDS) concentrations less than 200 mg/L (fresh) to more than 3,000 mg/L (slightly to moderately saline). Most of the groundwater from the Chicot aquifer has an average TDS concentration of less than 1,500 mg/L. Chloride concentrations typically ranged from less than 50 mg/L to over 600 mg/L and averaged around 450 mg/L.

3.5.7 Erosion

Several locations in the study area are experiencing significant erosion: the side of Pleasure Island bordering the Port Arthur and Sabine-Neches canals, the eastern shore of Sabine Lake, and the Gulf shoreline in Texas and Louisiana. Each of these areas is discussed below.

The rate of erosion of the Pleasure Island shoreline varied between 4.2 and 16.5 feet per year during the 20-year period 1974 through 1993 (Parchure et al., 2005). Erosion appears to be caused predominantly by surges, stern waves, and rapid drawdown resulting from vessel traffic within the constricted Sabine-Neches waterway (Maynard, 2005). The fetch is limited for the constricted waterway; wind waves are, therefore, relatively small in magnitude and not likely to contribute significantly to existing erosion rates. In addition, the highly erodible and weakly compacted soil on Pleasure Island makes it vulnerable to erosion from any source.

Marsh loss caused by wind-induced wave action is also occurring along the east Sabine Lake shoreline north of Willow Bayou at an average rate of 4.7 feet/year (Greco and Clark, 2005). Visual observations and GIS analyses confirm that the shoreline near the Willow Bayou mouth has shifted towards Willow Bayou leaving a narrow strip of land, which may be on the order of only 30 to 50 feet wide, separating Willow Bayou and Sabine Lake. Tall natural grass grown on this strip of land has not been able to arrest the erosion because the grass roots are not able to hold the soil firmly attached to them. Sabine Lake has a large water surface area, which provides sufficient fetch for significant wave generation and, in the shallow-water depths, the waves breaking on the shore have sufficient energy to cause serious erosion.

Texas Point is undergoing severe beach erosion, with shoreline retreat of up to 1,150 feet between 1974 and 2000 (King, 2007; Morang, 2006). This is the highest rate of shoreline loss on the upper Texas coast and a CEPRA “critical erosion area” (GLO, 2005). In Louisiana, persistent erosion along the shoreline between Ocean View and Holly Beach, on the order of –4.3 feet/year between 1985 and 1998, was recorded here prior to Hurricane Rita (USACE, 1971a, 2004a). Nearer to Louisiana Point, significant accretion over the last 100 years has slowed to +1.2 feet/year, and the behavior of this shoreline has become erratic, with some areas eroding and some aggrading (USACE, 2004a). Hurricane Rita deposited 3.3 feet of new sediment on the Hackberry Beach chenier ridge, and reworked sediment was observed bar welded to the lower shoreface (Farris et al., 2007; Guidroz et al., 2006). Hurricane Ike eroded the beach ridge at the McFadden NWR (Federal Emergency Management Agency, 2008). Impacts to this ridge increase the probability that interior marshes will be exposed to saltwater intrusion in the near future.

3.6 HAZARDOUS, TOXIC, AND RADIOACTIVE WASTE

The purpose of the HTRW assessment is to identify indicators of potential hazardous materials or waste issues relating to the study area. A review was conducted of databases maintained by Federal, State, and local regulatory agencies, an aerial photographic review, and interviews with officials from the TCEQ and the USACE to determine the location and status of HTRW sites regulated by the State of Texas and the EPA. A review was also conducted of oil and gas wells and pipelines located within the study area. These

data were obtained from the Texas Railroad Commission (RRC) and the LDNR. Support data for the assessment can be found in PBS&J (2002).

The scope of the regulatory information search included the following Federal and State databases: the National Priority List (NPL); the State Equivalent Priority Sites (State Sites or SPL); Comprehensive Environmental Response Compensation and Liability Information System (CERCLIS) Database; Resource Conservation and Recovery Act (RCRA) Generators and Violators List (RCRA-G); RCRA Corrective Actions List (CORRACT); RCRA Treatment, Storage, or Disposal List (RCRA-TSD); TCEQ and LDEQ Underground and Aboveground Storage Tank Database; Leaking Underground Storage Tank Listings (LUST); City/County and Parish Solid Waste Landfill listings (SWL); Emergency Response Notification System (ERNS) database; TCEQ and LDEQ Spills Incident Information System database; National Pollution Discharge Elimination System (NPDES) database; Toxic Release Inventory System (TRIS) database; and Facility Index System (FINDS) database. A total of 1,789 records were identified within the study area during the various regulatory agency database searches. Several of the records are associated with the same facility or property (e.g., a facility/property containing multiple petroleum storage tanks is also the site of several reported spills or emergency response actions). The 1,789 database records are associated with a total of 598 facilities or properties within the study area. On the basis of results of the regulatory agency database searches, the following sites are located within the study area:

- 4 NPL sites;
- 33 CERCLIS sites, 30 sites with No Further Remedial Action Planned designation;
- 9 CORRACT sites;
- 151 RCRA-G sites;
- 11 RCRA-TSD sites;
- 776 petroleum storage tanks at 289 facilities;
- 74 LUST sites;
- 4 State Voluntary Cleanup sites;
- 515 reported ERNS actions at 93 facilities/properties;
- 414 reported spills at 22 facilities/properties;
- 45 TRIS listings associated with 30 facilities;
- 221 FINDS database listings associated with 207 facilities/properties; and
- 2 unpermitted (inactive) municipal SWL.

Aerial photographs of the study area were used to examine the historical use of the SNWW and the surrounding watershed. The photographs depict portions of the study area as it appeared in 1930, 1938, 1955, and 1956. The aerial photographs were obtained from Tobin International, Ltd. Examination of aerial photography indicated that development within the study area was, as it is today, predominantly located west of the Sabine and Neches rivers. Development occurs in the urban centers of Texas that

include Beaumont, Port Arthur, Port Neches, Nederland, Orange, West Orange, Bridge City, and Rose City. The remainder of the Texas portion of the study area is vacant, undeveloped land. With the exception of Vinton, the Louisiana portion of the study area is vacant, undeveloped land. The study area includes a variety of land uses, which include highly developed residential-urban, industrial, recreational, and vacant, undeveloped range-pasture or WMAs.

Urban development within the study area is located adjacent to major highways. An industrial corridor composed of petroleum refineries, petrochemical plants, ship docks, shipyards, ship builders, grain elevators, PAs, warehouses, wastewater treatment plants, and a power plant parallels the SNWW. Utilization of vacant, undeveloped land is for agriculture and oil and gas production. For additional discussion on land use, see subsection 3.14.4.

According to information derived from regulatory agency records and TCEQ regional officials, regional industrial activity has caused measurable impacts to the surface water, sediment, soil, and groundwater in the study area. However, chemical analyses of sediment, elutriate, and surface water samples collected from the waterway indicate that these impacts have apparently been minimal (sections 3.3 and 3.4). The nature and potential for any HTRW site to impact the surrounding environment varies considerably. The majority of the regulated facilities and incident locations (i.e., spills and releases) identified in the regulatory agency database review do not pose a significant environmental concern for the project. However, several facilities within the study area do have a greater potential to impact the environment. These facilities are considered a potential threat based on the nature and extent of contaminants at the site, the location relative to the waterway, and the number of pathways in which the contaminants could reach the waterway. The facilities that are considered priority HTRW sites of concern are summarized in Table 3.3-1.

A baseline evaluation of facilities that pose a potential threat to the project must also consider whether the release of contaminants is ongoing or has been effectively eliminated through remedial efforts. Based on these criteria, State Marine, Palmer Barge Lines, Star Lake Canal, and Beaumont Elevator continue to present an ongoing threat to impact the environment of the study area. The remaining priority sites present a lesser threat due in part to either effective corrective action or distance to the waterway. Detailed site information of each of these facilities is provided in PBS&J (2002).

State Marine (Site ID No. 203) and Palmer Barge Lines (Site ID No. 548) are located on Pleasure Islet south of channel station 250+00 and north of PA 11. These sites are reported to have impacted surface water and are currently undergoing cleanup and evaluation. Star Lake Canal (Site ID No. 471) is located adjacent to the boundary of the cities of Port Arthur and Port Neches, Texas, and midway between PAs 16 and 17. The canal conveys stormwater and industrial wastewater from adjoining industrial facilities and discharges the water to the Neches River near the midpoint of channel stations 130+00 and 230+00. The canal is reported to have impacted surface water and is currently undergoing cleanup and evaluation. The Beaumont Elevator (Site ID No. 113) is located at 1745 Buford Street and adjacent to the waterway west of channel station 930+00. The site is reported to have impacted soil and groundwater and is currently undergoing an investigation.

The Star Lake Canal priority site has potential to affect PA 17. PA 17 is located adjacent to the Neches River in Port Neches, Texas, at river station 260+00. The 392-acre parcel on the west bank of the Neches River has been used as a PA for dredged material for over 40 years. A recent environmental survey of the property identified Recognized Environmental Conditions on the tract including a capped landfill, waste disposal areas containing unknown substances, asbestos-containing material, lead, and furfural. These sites are located inside and close to the southwest boundary of PA 17.

Also, another potential HTRW concern has been identified on adjoining land. A recently updated EPA Region 6 fact sheet (EPA Publication date March 6, 2006) for the Star Lake Canal Superfund Site indicates the Potentially Responsible Parties are planning Remedial Investigations (RI) and a study to determine the nature and extent of contamination. Heavy metals, PCBs, and PAHs have been identified as having migrated or have the potential to migrate to Molasses Bayou, Star Lake Canal, the Neches River, and Sabine Lake. Pentachlorophenol and toxaphene have been found in Jefferson Canal sediments (EPA, 2006). The preliminary area of concern lies outside the eastern and southern boundaries of PA 17.

The Star Lake Canal Superfund site consists of contaminated surface water and sediments in the Star Lake Canal, adjoining Jefferson Canal, and Molasses Bayou (EPA, 2006). The Jefferson Canal and the Star Lake Canal have served as industrial wastewater and stormwater outfalls since the late 1940s. Although the Star Lake Canal borders PA 17, the current configuration of PA 17 distances it from the canal. PA 17 has been leveed to contain dredged material for at least 36 years, as indicated by a 1969 aerial photo. The levee system also acts as a barrier to encroachment of surface water and sediments outside the PA.

RRC files indicate that there are a total of 6,951 permitted well sites located within the study area. These well sites include 6,073 vertical wells and 878 directional wells. The database indicates that the vertical well sites include the following types/status:

- 1,370 are listed as active producing oil/gas wells;
- 2,372 as plugged;
- 1,861 as dry holes;
- 7 as permitted locations;
- 158 as shut-in wells;
- 35 as storage wells;
- 57 as injection wells;
- 28 as saltwater disposal wells;
- 1 as a brine mining well; and
- 184 well sites listed as miscellaneous well types.

One thousand ninety-eight of the producing vertical wells are listed as oil wells, 168 are listed as gas wells, and 104 are listed as producing oil and gas.

The database indicates that directional well sites include the following types/status:

- 226 active producing oil/gas wells;
- 291 plugged wells;
- 202 dry holes;
- 10 injection wells;
- 5 permitted locations;
- 90 shut-in wells;
- 2 storage wells;
- 8 saltwater disposal wells;
- 1 brine mining well; and
- 43 well sites were listed as the miscellaneous well types.

One hundred fifty-eight of the producing directional wells are listed as oil wells, 50 are listed as gas wells, and 18 are listed as producing oil and gas.

A total of 533 pipeline systems were identified within the study area. Five hundred seventeen (517) of the pipelines are listed as active, 16 are listed as inactive. The pipelines are reported to transport the following material:

- 314 transport natural gas;
- 49 crude oil;
- 91 oil and gas;
- 8 LPG;
- 161 gas and condensate; and
- 1 pipeline system was listed as idle.

While the RRC pipeline database is the most comprehensive account of pipelines in the State of Texas, this database does not include every existing pipeline. Therefore, a remote sensing survey for pipelines, wells, and other obstructions in the SNWW navigation channel has been conducted (PBS&J, 2005); field survey data have been matched with the results of record searches that are reported in PBS&J (2002).

3.7 AIR QUALITY

3.7.1 Regulatory Context

The Clean Air Act (CAA), which was last amended in 1990, regulates air emissions from area, stationary, and mobile sources. The CAA requires the EPA to establish National Ambient Air Quality Standards (NAAQS) for pollutants considered harmful to public health and the environment and establishes two types of national air quality standards. Primary standards define the maximum levels of air quality that the

EPA judges necessary, with an adequate margin of safety, to protect public health, including the health of “sensitive” populations such as asthmatics, children, and the elderly. Secondary standards define the maximum levels of air quality that the EPA judges necessary to protect public welfare, including protection against decreased visibility and damage to animals, crops, vegetation, and buildings. Air quality is generally considered acceptable if pollutant levels are less than or equal to these established standards on a continuing basis.

The EPA has established NAAQS for seven principal pollutants, called “criteria” pollutants, in 40 Code of Federal Regulations (CFR), Part 50. The criteria pollutants are carbon monoxide (CO), nitrogen dioxide (NO₂), ozone (O₃), lead (Pb), inhalable particulate matter (PM) with an aerodynamic diameter less than or equal to a nominal 10 microns (PM₁₀), fine particulate matter with an aerodynamic diameter less than or equal to a nominal 2.5 microns (PM_{2.5}), and sulfur dioxide (SO₂). These standards are summarized in Table 3.7-1.

Table 3.7-1
National Ambient Air Quality Standards

Air Constituent	Averaging Time	NAAQS Primary	NAAQS Secondary
Sulfur Dioxide (SO ₂)	3 hours	0.50 ppm	0.5 ppm
	24 hours	0.14 ppm	
	Annual Arithmetic Mean	0.030 ppm	
Particulate Matter (PM ₁₀)	24 hours	150 µg/m ³	150 µg/m ³
Particulate Matter (PM _{2.5})	24 hours	35 µg/m ³	35 µg/m ³
	Annual Arithmetic Mean	15 µg/m ³	15 µg/m ³
Nitrogen Dioxide (NO ₂)	Annual Arithmetic Mean	0.053 ppm	0.053 ppm
Carbon Monoxide (CO)	1 hour	35 ppm	---
	8 hours	9 ppm	---
Lead (Elemental) (Pb)	Calendar	1.5 µg/m ³	1.5 µg/m ³
	Quarter		
	Arithmetic Mean		
	Rolling 3-Month Average	0.15 µg/m ³	0.15 µg/m ³
Ozone (O ₃)	1 hour	0.12 ppm	0.12 ppm
	8 hour (1997 standard)	0.08 ppm	0.08 ppm
	8 hour (2008 standard)	0.075 ppm	0.075 ppm

Source: 40 CFR, Part 50, National Primary and Secondary Ambient Air Quality Standards.

--- = An ambient air quality standard has not been promulgated.

ppm = parts per million.

µg/m³ = micrograms per cubic meter.

CO is a colorless and practically odorless gas primarily formed when carbon in fuels is not burned completely (Lewis, 1987). It may temporarily accumulate at harmful levels, especially in calm weather during winter and early spring, when fuel combustion may reach a peak and CO is chemically more stable due to the low temperatures. Transportation activities, indoor heating, industrial processes, and open burning are among the anthropogenic (man-made) sources of CO.

NO₂, nitric oxide (NO), and other oxides of nitrogen are collectively called nitrogen oxides (NO_x). These compounds are interrelated, often changing from one form to another in chemical reactions. NO₂ is

commonly measured in ambient air monitors. NO_x emissions are generally emitted in the form of NO , which is oxidized to NO_2 . The principal anthropogenic sources of NO_x are fuel combustion in motor vehicles and stationary sources such as boilers and power plants. Reactions of NO_x with other atmospheric chemicals can lead to the formation of O_3 .

Ground-level O_3 is a secondary pollutant, formed from daytime reactions of NO_x and (volatile organic compounds (VOCs) rather than being directly emitted by natural and anthropogenic sources. VOCs are released in industrial processes and from evaporation of organic liquids such as gasoline and solvents. Ozone contributes to the formation of photochemical smog.

Pb is a heavy metal that may be present as dust or fumes. Dominant industrial sources of Pb emissions include waste oil and solid waste incineration, iron and steel production, lead smelting, and battery and lead alkyl manufacturing. The lead content of motor vehicle emissions, which was the major source of lead in the past, has significantly declined with the widespread use of unleaded fuel.

The NAAQS for particulate matter is based on two different particle diameter sizes: PM_{10} and $\text{PM}_{2.5}$. PM_{10} are small particles that are likely to reach the lower regions of the respiratory tract by inhalation. $\text{PM}_{2.5}$ is particulate matter that is considered to be in the respirable range, meaning these particles can reach the alveolar region of the lungs and penetrate deeper than PM_{10} . There are many sources of particulate matter, both natural and anthropogenic, including dust from natural wind erosion of soil, construction activities, industrial activities, and combustion of fuels.

SO_2 is a colorless gas with a sharp, pungent odor (Lewis, 1987). SO_2 is emitted in natural processes, such as volcanic activity, and by anthropogenic sources such as combustion of fuels containing sulfur and the manufacture of sulfuric acid.

The CAA requires the EPA to assign a designation of each region of the U.S. regarding compliance with the NAAQS. The EPA categorizes the level of compliance or noncompliance with each criteria pollutant as follows:

- Attainment – area currently meets the NAAQS
- Maintenance – area currently meets the NAAQS, but has previously been out of compliance
- Nonattainment – area currently does not meet the NAAQS

Ozone nonattainment areas are further classified as extreme, severe, serious, moderate, or marginal depending on the severity of nonattainment.

The TCEQ has the responsibility for developing a plan for maintaining or attaining the NAAQS. This plan, which was submitted to and approved by the EPA, is called the State Implementation Plan (SIP). Similarly, the LDEQ has the responsibility for developing the SIP for Louisiana. For areas that are in nonattainment with the NAAQS, the SIP describes how the area would reach attainment of the air quality standards. The SIP sets emissions budgets for point sources such as power plants and manufacturers,

areawide sources such as dry cleaners and paint shops, off-road mobile sources such as boats and lawn mowers, and on-road sources such as cars, trucks, and motorcycles.

As previously noted, the project study area includes Jefferson and Orange counties. These counties are within an area designated as the Beaumont-Port Arthur (BPA) Air Quality Control Region (AQCR). Ozone is the only criteria pollutant from which the BPA fails to meet the NAAQS. The EPA has classified the BPA area as a “serious” nonattainment area under the 1-hour NAAQS for ozone and a “moderate” nonattainment area with regard to the 8-hour NAAQS for ozone. Under the current attainment classification, the BPA has until June 15, 2010, to attain the 8-hour NAAQS for ozone. However, 8-hour ozone data for 2005, 2006, and 2007 indicate that the BPA area is monitoring attainment of the standard. As a result, the TCEQ adopted a SIP revision that includes a Redesignation Request and a Maintenance Plan for the BPA area (TCEQ, 2008). This maintenance plan is currently pending review by the EPA.

Calcasieu Parish is in the Lake Charles AQCR and Cameron Parish is in the southern Louisiana-southeast Texas AQCR. These parishes are currently classified as being in attainment with the NAAQS for all criteria pollutants.

3.7.2 Conformity of Federal Actions

As required by the CAA, the EPA has also promulgated rules to ensure that Federal actions conform to the appropriate SIP. Two rules were promulgated: (1) the Transportation Conformity Rule (40 CFR Part 93); and (2) the General Conformity Rule (40 CFR Part 51, Subpart W). The Transportation Conformity Rule applies to the Federal Highway Administration (FHWA)/Federal Transit Authority projects within maintenance or nonattainment areas. The General Conformity Rule applies to Federal actions, except FHWA and Transit Authority actions, within maintenance or nonattainment areas.

The CAA prohibits Federal agencies from funding, permitting, or licensing any project that does not conform to an applicable SIP. The purpose of this General Conformity requirement is to help ensure that Federal agencies consult with State and local air quality districts to assure these regulatory entities know about the expected impacts of the Federal action and have considered or will include expected emissions in their SIP emissions budget.

The General Conformity Rule provides for emission thresholds above which a General Conformity Determination would be required. For the BPA ozone nonattainment area, which is classified as “moderate” under the 8-hour ozone standard, the emissions threshold is 100 tons per year (tpy) of NO_x or of VOC. Therefore, if the total emissions from the project are estimated to be equal to or greater than this threshold for NO_x or VOC, the USACE must prepare a General Conformity Determination showing how the project conforms or would conform with the SIP for that pollutant, prior to undertaking the action. Even if emissions of NO_x or VOCs are below these levels, a conformity determination would also be required if the increase in emissions due to the project would equal or exceed 10 percent of the total emissions of those pollutants for the entire nonattainment area (i.e., the project is considered a regionally significant action). The General Conformity Determination was submitted to the TCEQ and the EPA for

review concurrently with the DEIS. The TCEQ has provided written concurrence that project emissions are consistent with the most currently approved SIP emissions budgets for the BPA nonattainment area. As Cameron Parish and the Lake Charles area are in attainment with the NAAQS, a general conformity determination would not be required for these areas.

3.7.3 Air Quality Baseline Condition

Table 3.7-2 is a summary of emissions for the BPA and Cameron/Calcasieu parishes based on the currently available air emissions inventory information provided by the EPA. The emissions information for each pollutant is broken out by category: area source, highway, off-highway, and point source emissions based on emissions inventory information for 2002. Although this emissions inventory is not current, it contains the most recent data available, and it provides a base from which to compare the proposed project emissions.

Air pollutants within and near the project area are measured by numerous air monitoring stations. Most of the stations in the region measure the concentrations of criteria air pollutants, as well as temperature, wind velocity, wind direction, and other meteorological parameters. The monitors operate continuously and are routinely calibrated and maintained to assure quality data. Monitoring data (2004 through 2008) for counties in the BPA nonattainment area and for Cameron and Calcasieu parishes are presented in Table 3.7-3 to provide an indication of monitored pollutant concentrations relative to the NAAQS.

As previously noted, the BPA area is classified as a “serious” nonattainment area under the 1-hour NAAQS for ozone and a “marginal” nonattainment with the 8-hour NAAQS for ozone. According to the TCEQ, 8-hour and 1-hour ozone design value trends for the BPA ozone nonattainment area from 1991 to 2007 show decreases in both the 8-hour and 1-hour ozone design values. The design values are used in the evaluation of attainment with the ozone standards. The 8-hour ozone design value has decreased by 17.8 percent over the past 17 years, and the 1-hour ozone design value has decreased by 28.7 percent over the past 17 years. The decreases in ozone have occurred despite increases in population in the BPA area. Eight-hour ozone monitoring data for 2005, 2006, and 2007 indicate that the BPA area is monitoring in attainment of the standard. Monitoring data for Calcasieu Parish (Lake Charles Area) also indicate levels above the 8-hour standard.

3.8 NOISE

3.8.1 Fundamentals and Terminology

Noise is defined as unwanted sound that disrupts or interferes with normal activities, or that diminishes the quality of the environment. Noise is usually caused by human activity and is added to the natural, or ambient, acoustic setting of an area. Exposure to high levels of noise over an extended period can cause health hazards such as hearing loss; however, the most common human response to environmental noise is annoyance. Individuals respond to similar noise events differently based upon various factors that may

¹ Selection of monitored values is based on criteria established in 40 CFR, Part 50. Parameters and data reported here represent those available in EPA's Aerometric Information Retrieval Database (AIRData): "AIRData-Monitor Values Report" as of September 2009.

² Data for Hardin County and Cameron Parish were not available in EPA Air Data Report.

³ 2004–2008 available data to date.

include the existing background level, noise character, level fluctuation, time of day, the perceived importance of the noise, the appropriateness of the setting, and the sensitivity of the individual.

Sounds of the same pressure but different frequencies are not perceived by the human ear as equally loud. The human ear is less sensitive to low frequencies and extremely high frequencies, and most sensitive to the mid-range frequencies that correspond with human speech. Therefore, in order to measure sound in a manner similar to human perception, an adjustment known as “A-weighting” is used. All regulatory agencies require that measurements be taken using the A-weighted sound level (dBA).

Although A-weighted sound measurements indicate the level of environmental noise at any given time, community noise levels vary constantly. Typical noise environments consist of numerous noise sources that vary and fluctuate over time. Because of the varying noise levels within a community, it is necessary to use a descriptor called the equivalent sound level (L_{eq}). L_{eq} provides a way to describe the average sound level, in decibels (dB), for any time period under consideration.

Another measurement descriptor of the total noise environment is the Day-Night Sound Level (L_{dn}), which is the A-weighted equivalent sound level for a 24-hour period with an additional 10 dB weighting imposed on the equivalent sound levels occurring during nighttime hours (10:00 P.M. to 7:00 A.M.). For example, an environment that has a measured daytime equivalent sound level of 60 dBA and a measured nighttime sound level of 50 dBA, would have a weighted nighttime sound level of 60 dBA ($50 + 10$), and an L_{dn} of 60 dBA. Numerous Federal agencies including the EPA, Department of Defense, Department of Housing and Urban Development, and Department of Transportation/Federal Aviation Administration (FAA) have adopted this descriptor in assessing environmental impacts. Regulatory agencies generally recognize an L_{dn} of 55 dBA as a goal for the outdoor noise environment in residential areas. Studies have found that outdoor noise environments across the U.S. range from approximately 40 L_{dn} in rural residential areas, to nearly 60 L_{dn} in older urban residential areas, to as much as 90 L_{dn} in congested urban settings (EPA, 1974).

3.8.2 Affected Environment

Noise-sensitive receptors are facilities or areas where excessive noise may disrupt normal activity, cause annoyance, or loss of business. Land uses such as residential, religious, educational, recreational, and medical facilities are more sensitive to increased noise levels than are commercial and industrial land uses. Noise-sensitive receptors in the vicinity of the study area are located in the cities of Port Arthur, Port Neches, and Beaumont. The existing noise environment of these communities is affected by a number of sources, most of which are transportation related (i.e., barges, roadway, railway, etc.). Waterborne transportation activities that currently contribute to the region’s ambient noise environment include barges, commercial fishing/shrimping vessels, sport and recreation boats, and current maintenance dredging of the canal. Other sources that contribute to the existing noise environment of these communities include activities at nearby commercial enterprises, such as restaurants, marinas, activities at commercial fishing and shrimping businesses, and numerous heavy industrial uses. Ambient noise levels

measured in other Texas coastal communities with a similar degree of activity generally ranged between 60.9 and 65.1 L_{dn} (HFP Acoustical Consultants, Inc., 2002).

3.9 VEGETATION

3.9.1 Introduction

The study area is located within the Gulf Coast Prairies and Marshes and Pinewoods Vegetation Areas (Hatch et al., 1990). A generalized map of the vegetation and land cover types appears on Figure 3.9-1. Maps of each hydro-unit are provided in Appendix C. The vegetation communities include saline to fresh marshes, swamps, bottomland hardwood forests, upland grasslands, and forests. The study area includes an important ecosystem called the Chenier Plain (aka strandplain). Chenier is derived from a French word that means “a place where oaks grow.” Cheniers are paleo-beach ridges that parallel the shoreline (USFWS, 1998; White et al., 1987) fanning out (diverging) where they are cut by river mouths. This “fanning out” pattern occurs near Sabine Pass. The ridges are topographically higher than the surrounding area because they are composed of coarse-grained material (sand and shell) that is more resistant to erosion. The formation and maintenance of the cheniers depends on the input of sand deposited by rivers, transported by westerly longshore currents, and reworked by storms. The upland habitat of the cheniers supports the Coastal Live Oak-Sugarberry Series (*Quercus virginiana-Celtis laevigata*), a maritime woodland or forest (woodlots/oak mottes) of the Upper Gulf Coast that is unique to the Chenier Plain and should be considered sensitive habitat (USFWS, 1998). The modern Chenier Plain system occurs in Louisiana and Texas where the linear ridges and swales are evident in topography and vegetation communities. Transitional and upland vegetation communities occur on the ridges, and wetland communities occur in the interridge swales. The Chenier Plain is separated from the Pleistocene Prairie Complex to the north by a broad low area, which is dominated by brackish marshes (LCWCR/WCRA, 1998).

A band of saline and brackish marshes parallels the coast immediately landward at the beach/dune complex and shore areas. This area is widest in the Mississippi delta and narrows to the west. This east-to-west narrowing is evident in the study area. The wetland communities extend up river, bayou, and creek floodplains, becoming increasingly fresh upstream. The forested wetlands occur in the fresher areas of these floodplains and are primarily cypress-tupelo swamps. These swamps occur along with bottomland hardwood forests and other wetlands within the floodplains. Uplands predominate in the north (especially the northwestern) part of the study area and include grassland and forests. Most of the nonforested upland has been converted to agricultural land. The upland forest is predominantly a pine-oak mix forest (USFWS, 1998; White et al., 1987). Chinese tallow, an exotic, invasive species that has been a management problem since the 1970s, occurs in both upland and bottomland areas, especially in disturbed areas such as fallow croplands.

(This page left blank intentionally.)

3.9.2 Protected and Sensitive Habitats in the Study Area

The term “sensitive habitat” should not be confused with the term “critical habitat.” Critical habitat is a legal term with respect to the Endangered Species Act (ESA) and refers to a specific geographic area identified by the USFWS for a federally protected species (see Section 3.12). Sensitive habitat is a subjective term, not a legal term, and generally refers to the vulnerability of a habitat. Spatial extent, uniqueness, endemic quality, or vulnerability to ongoing pressures or imminent changes may make a habitat environmentally sensitive (e.g., large historical losses as with the coastal prairie or fresh marsh losses due to saltwater intrusions). For various reasons the following habitats that occur in the study area should be considered sensitive.

The study area contains a high concentration of significant coastal wetlands. The ICT identified 109,175 acres (171 square miles) in Texas and 197,530 acres (309 square miles) in Louisiana of coastal marsh, bottomland hardwood, and cypress-tupelo swamp habitats, which are addressed in the impact evaluation and described in detail in the following subsections.

3.9.2.1 Texas Portion of the Study Area

In Texas, beginning at the coast and working inland, the following protected and sensitive habitat areas are present within the study area:

- Approximately 10,000 acres of fresh to salt marsh in the Chenier Plain west of Sabine Pass, the majority of which consists of the Texas Point NWR. This NWR is part of the Texas Chenier Plain NWR complex (USFWS, 2005a). This area is indicated as hydro-unit (HU) TX 8 on Figure 3.9-1.
- 55,700 acres of fresh to salt marsh located west of the Sabine River between Texas Point and the mouth of the Neches River (TX 7 and 9). Much of this area is protected by the J.D. Murphree WMA and the McFaddin NWR. Managed by the TPWD, the J.D. Murphree WMA totals 24,250 acres of fresh, intermediate, and brackish water wetlands in the Texas Chenier Plain (TPWD, 2005a). It is located just inland of the Texas Point WMA and extends north of the GIWW. The eastern half (approximately 23,000 acres) of the McFaddin NWR is also part of the study area. This NWR is also part of the Texas Chenier Plain NWR complex. The McFaddin NWR protects one of the largest remaining freshwater marshes on the Texas coast and thousands of acres of intermediate to brackish marsh (USFWS, 2005a). It is located adjacent to and just west of Texas Point WMA.
- 22,100 acres of fresh, intermediate, and brackish marshes and 2,850 acres of cypress-tupelo swamp and bottomland hardwoods on the Neches River from the mouth of the river where it empties into Sabine Lake to the City of Beaumont (TX 3 through 6). Approximately 9,580 of these acres consist of open-water areas resulting from breaking and eroding marsh in the marshes at Rose City, Bessie Heights, and Old River Cove. The Nelda Stark Unit and Old River units of the Lower Neches River WMA (TPWD, 2005b) are located in this area.
- 6,490 acres of Neches River cypress-tupelo swamp and bottomland hardwoods and 1,970 acres of fresh marsh between the City of Beaumont and the new Neches River Saltwater Barrier near Pine Island Bayou (TX 1 and 2). A USACE-approved, privately operated, wetlands mitigation bank (the Neches River Cypress Swamp Preserve) is located within this area (USACE, 2005a).

- 4,771 acres of cypress-tupelo swamps, bottomland hardwood, and fresh and intermediate marshes on Cow and Adams bayous (TX 10 and 11). The Adams Bayou Unit of the Lower Neches River WMA (TPWD, 2005b) is located in this area.
- 689 acres of cypress-tupelo swamp west of the Sabine River and south of IH 10 (TX 12).
- 2,737 acres of cypress-tupelo swamp and bottomland hardwoods in the Blue Elbow Swamp (LA/TX 2). Located north of IH 10 and west of the Sabine River, this area is owned by TxDOT and managed as the USACE-approved Blue Elbow Mitigation Bank (USACE, 2005b). The area includes the Tony Houseman WMA, managed as a cooperative effort between the TxDOT and TPWD (TPWD, 2005c).
- 2,277 acres of cypress-tupelo swamp and bottomland hardwoods west of the Sabine River, across from the Sabine Island WMA in Louisiana (LA/TX 1).
- 6,000 acres of cypress-tupelo swamp, bottomland hardwood forest, and freshwater marsh below the Saltwater Barrier, on Big Thicket National Preservelands in Texas (TX1 and 2).

3.9.2.2 Louisiana Portion of the Study Area

In Louisiana, beginning at the coast and working inland, the following protected and sensitive habitat areas are present within the study area (LCWCR/WCRA, 1998; USGS-NWRC, 2004):

- 71,470 acres of saline, brackish and intermediate marshes in the Louisiana Chenier Plain habitat at Louisiana Point, Blue Buck Point, and Johnson's Bayou areas (LA 4, 5, 6, and 9). Sensitive areas include Sabine Lake Ridges (33,472 acres of chenier ridge, and saline, brackish, and intermediate marsh), Johnson's Bayou Ridge (4,089 acres of saline and brackish marshes, and chenier ridges), West Johnson's Bayou (13,190 acres of brackish and intermediate marsh), and East Johnson's Bayou (26,719 acres of chenier ridge, and fresh, intermediate, and brackish marsh).
- 44,325 acres of brackish, intermediate, and fresh coastal marsh in the western half of the Sabine NWR (LA 3 and 7). The Sabine NWR, as a whole, contains 124,511 acres of fresh, intermediate, and brackish marsh between Calcasieu and Sabine lakes in southwest Louisiana (USFWS, 2005b). Approximately 13,744 acres of marsh within this study area has degraded to open water. This sensitive area contains the Willow Bayou mapping unit (36,291 acres) and 8,034 acres in the west section of the Southeast Sabine mapping unit.
- 46,511 acres of brackish, intermediate, and fresh marsh in an area north of Willow Bayou and south of the GIWW (LA 2 and 8). This sensitive area contains the Black Bayou mapping unit (36,291 acres) and 10,220 acres of fresh and intermediate marsh in the Southwest Gum Cove mapping unit.
- 25,721 acres of fresh and intermediate marsh and bottomland hardwood habitat in the Perry Ridge mapping unit, north of the GIWW and east of the Sabine River (LA 1).
- 650 acres of cypress-tupelo swamp and bottomland hardwoods in the Blue Elbow Swamp, east of the Sabine River and north of IH 10 (LA/TX 2).
- 7,039 acres of cypress-tupelo swamp and bottomland hardwoods in the Sabine Island WMA, north of the Blue Elbow Swamp and east of the Sabine River (LA/TX 1).

3.9.3 Historical Changes

The coastal wetlands of the Calcasieu and Sabine river basins were historically an unbroken stand of coastal wetlands including fresh to brackish marshes and swamps (Marcantel, 1996). Most of the brackish marshes bordered Calcasieu and Sabine lakes. In the 1940s and 1950s, this ecosystem began to fragment and exhibit other significant alterations, due in part to the construction of several major navigation channels (Calcasieu Ship Channel, GIWW, SNWW), which increased salinity throughout the estuary, including the lakes and surrounding marshes (Marcantel, 1996). The presence of the GIWW and activities along the GIWW made several changes to previous hydrologic conditions. Levees associated with the GIWW and other channels changed drainage patterns, flooding some areas, and blocking sheet flow across extensive areas of marsh. Several miles of Salt Bayou, north of Shell Lake, were lost. Taylor Bayou was rerouted to join the GIWW. Concrete water control structures were placed on both sides of the canal at Star Lake, at the outfall of Salt Bayou and the GIWW, and at Little Keith Lake Cut on Port Arthur Canal, which eventually became inoperable (Sutherlin, 1997).

Petroleum exploration has also caused hydrologic changes in the area. Four major oil fields were developed in Texas marshes west of Sabine Lake beginning in the mid-1920s: Bessie Heights (Neches River), Rose City (Neches River), Clam Lake (McFaddin NWR), and Shell Lake (Sea Rim State Park). Gum Island (La Belle Ranch) was developed in Louisiana, east of Sabine Lake. Levees, roads, and canals associated with these operations, as well as accelerated subsidence caused by subsurface water and petroleum extraction, have changed hydrology and contributed to the conversion of marshes to open water (Sutherlin, 1997). The extensive construction of channels for navigation, petroleum exploration, hunting, fishing, and trapping throughout the area has increased saltwater intrusion into the interiors of the marshes (Marcantel, 1996).

The Chenier Plain in the area of Calcasieu and Sabine lakes has been identified as one of the two Louisiana coastal zones that has experienced the most severe land loss. More than 25 percent of the marsh was lost between 1933 and 1990 within the Sabine, Calcasieu, and Mermentau basins (LCWCR/WCRA, 1998). According to the LCWCR/WCRA report, a 1994 study by Barras et al. found that the westernmost area of Louisiana lost approximately 15,950 acres (18 percent) of marsh between 1978 and 1990.

Currently, within the State of Louisiana, there are approximately 3,800 square miles of marsh and over 800 square miles of swamp. It is predicted that approximately 600 square miles of marsh and 400 square miles of swamp would be lost by conversion to open water by the year 2050 (LCWCR/WCRA, 1998). The Calcasieu/Sabine Basin had 317,100 acres of marsh and 170 acres of swamp in 1990. Using current restoration levels, there would be a net loss of 38,400 acres by 2050; however, no swamp loss is predicted (LCWCR/WCRA, 1998).

According to Morton and Paine (1990), Sutherlin (1997), and White et al. (1987), the most extensive losses of interior coastal wetlands in Texas have occurred along the Neches River delta where 12,632 acres of marshes have been converted to open water. This is more than 90 percent of the marshes in the lower Neches River delta. Contributing factors include subsidence associated with subsurface

petroleum and groundwater extraction, eustatic sea level rise, altered hydrology that caused saltwater intrusion, and decreases in sediment and/or nutrient supply.

The inflow of fresh water, primarily from the Sabine and Neches rivers, buffers the salt water emanating from the Gulf; that is, the salt water coming inland, via the SNWW and other channels, is buffered by discharges of fresh water from reservoirs on the Sabine and Neches rivers. Saltwater coming up the Calcasieu Ship Channel is only buffered by rainfall, so the surrounding marshes of the ship channel and Calcasieu Lake are more vulnerable to saltwater intrusion. There is more-active management to protect wetlands from saltwater intrusion around Calcasieu Lake than Sabine Lake (Marcantel, 1996). See Section 3.5 for further discussion on the hydrology.

Saltwater intrusion and its impact on marshes have been managed, in part, by the use of water control structures. In 1990 there were 174 water control structures identified in the Calcasieu and Sabine River basins (Marcantel, 1996). See Section 3.5 of this FEIS for more information regarding water control structures and other hydrologic alterations.

The construction of the GIWW and activities associated with the SNWW had several effects, some of which are:

- altered habitat associated with Salt Bayou (north of Shell Lake);
- severed Salt Bayou north of Star Lake;
- altered course of Taylor Bayou to join GIWW;
- constructed concrete water control structures on both side of canal at Star Lake, at outfall of Salt Bayou and the GIWW, and at Little Keith Lake Cut on Port Arthur Canal, which eventually became inoperable;
- altered habitat and land loss in the Black Bayou watershed;
- altered habitat and land loss in the Willow Bayou watershed;
- shoreline erosion along the banks of the GIWW; and
- blocked sheet flow across marshes.

Roads and levees also altered hydrologic patterns, particularly in the coastal zone where a small change in topographic relief can significantly alter surface hydrology. Openings and water control structures associated with these features also affect the hydrology. Important features include:

- Louisiana SH 27 along east boundary of the Calcasieu/Sabine River Basin (north to south orientation);
- SH 82 (Calcasieu Ship Channel to Sabine Pass) along south boundary forms barriers along the east and south perimeters;
- Rycade Canal (south of Black Lake);
- Gray's Ditch levee/cattle walkway (north to south, Pines Ridge – Johnson's Bayou) forms a barrier along east bank of Sabine Lake (Marcantel, 1996); and

- SH 87 and SH 73 altered hydrology in Orange and Jefferson counties (Sutherlin, 1997).

Wildlife management units within the river basins use levees and other water control structures to manage areas for specific habitat types (Marcantel, 1996):

- Pool 3A on Sabine NWR is managed as a freshwater marsh.
- Round Lake and Lost Lake in the J.D. Murphree WMA are managed as fresh marsh.

According to Morton (1996), the marshes on the eastern shoreline of Sabine Lake and Sabine Pass have remained essentially natural in contrast to the more developed west side that has been greatly altered by the SNWW and associated ports. Also, most of the western shore of Sabine Lake has been elevated by placement of dredged material, and shorelines have been armored to protect against erosion associated with the predominant southeastern winds.

According to Marcantel (1996), the overall condition of the marshes within the Calcasieu/Sabine River Basin have been improving. This is attributed to above-average rainfall and the stabilization of tidal fluctuations and water salinity. Marcantel (1996) warns that the salinity in Sabine Lake needs to continue to be stabilized to avoid the level of management required in Calcasieu Lake. As discussed in Section 3.5, freshwater inflows from the Sabine and Neches rivers are largely moderated by flood control structures and freshwater impoundments upstream. A freshwater inflow study was prepared to establish the basic requirements of the ecosystems of the floodplains and the estuary (Kuhn and Chen, 2005).

Land loss has occurred at high rates in recent decades (Berman, 2005; Morton, 2003; Morton et al., 2005; Shinkle and Dokka, 2004; Titus and Narayanan, 1995). In Louisiana, a net land loss of 21 percent between 1978 and 2000 has been reported in the Chenier Plain subregion of coastal Louisiana, which includes the Sabine estuary (USACE, 2004a). In Texas, the most extensive losses of interior coastal wetlands in the state (12,632 acres between 1930 and 1978) have occurred in the Neches River delta. In total, over 90 percent of the emergent marshes in the Lower Neches River delta have been converted to open water (Morton and Paine, 1990; White et al., 1987), which is more than half of the total wetland loss in the State of Texas (Sutherlin, 1997).

Underlying causes of coastal land loss can be divided into two general categories, natural and man-induced (Morton, 2003). Natural causes include erosion, sediment reduction, submergence due to relative sea level rise, and wetland deterioration. Induced causes include construction and dredging in the coastal zone, upstream dams, river channelization, changes to overland sheet flow, fluid extraction, and climate alterations. NOAA has documented a trend of mean sea level rise at Sabine Pass of 0.2 inch/year from 1958 through 1999 (USDC-NOAA, 2009). The reader is referred to Appendix C for further discussion of the rates and cause of RSLR and coastal land loss.

3.9.4 Wetland and Aquatic Vegetation Communities

The following paragraphs include general descriptions of the wetland (including aquatic) vegetation communities that occur in the study area. The descriptions include ecological functions, historical trends,

and vulnerabilities. Detailed descriptions of the vegetation communities within each hydro-unit are provided in the Ecological Modeling Report (Appendix C, Section 7.0), so to avoid duplication, they are not included here.

Submerged Aquatic Vegetation

SAV provides important food and cover to a wide variety of fish and wildlife. SAV beds are associated with many kinds of marshes from saline to fresh, as well as in open bay waters. Fresh and intermediate marshes, in particular, often support diverse communities of submerged and floating leaved vegetation. Brackish marshes can support aquatic plants that provide food and cover for several species of fish and wildlife. Although amounts are generally less than those that occur in fresh or intermediate marshes, certain species such as widgeon grass, coontail, and milfoil can be abundant under some conditions, and widgeon grass, in particular, is an important food source for waterfowl. Low-salinity saline marshes may contain widgeon grass, which tolerates a wide range of salinities. Open-water areas in saline marshes generally contain sparse aquatic vegetation and are primarily important as nursery areas for marine organisms.

To a large extent, seagrass distribution in Texas parallels the precipitation and inflow gradients along the Texas coast. Seagrasses are common along the middle to lower coast where rainfall is low and evaporation is high. This correlates with average baywater salinities above 20 ppt. Conversely seagrass is scarce in bays of the upper coast where rainfall and inflows are high and salinities are lower (TPWD, 1999). These areas are also more turbid, which also limits sunlight penetration for seagrass growth (TPWD, 1999).

The TPWD (1999) reports that well-known annual species often occur in at least portions of all Texas bays except for Sabine Lake. However, the low-salinity-tolerant species, widgeon grass, technically not a seagrass because it tolerates very low salinity, can be found in protected parts of the Sabine Lake system. In addition, other SAV found in the study area include Eurasian watermilfoil (*Myriophyllum spicatum*) and freshwater eelgrass (*Vallisneria americanum*). Most available data on distributions of SAV for the Texas Gulf Coast are for seagrass meadows of the Laguna Madre (Onuf, 1995; Pulich et al., 1997; Quammen and Onuf, 1993). Few data are available for the upper Texas coast (Adair et al., 1994). Polyhaline species (18 to 30 ppt) found in the study area include widgeon grass; mesohaline species (5 to 18 ppt) include Eurasian watermilfoil, a nonnative invasive species, and freshwater eelgrass.

Baseline values for SAV, used in the EMCM, were based largely upon previous observations by Habitat Workgroup members in the hydro-units that they manage or regulate, and data collected for CWPPRA or other restoration projects in or near the areas under evaluation.

SAV cover and species type can and do change rapidly in response to a complex interaction of many conditions (e.g., salinity, freshwater introduction, nutrient input, turbidity, water depth, fetch).

Marshes and Flats

Coastal marshes include a variety of wetland communities (species assemblages) that are differentiated by salinity, elevation, and soil regimes. Marshes range from saline, brackish, intermediate, to fresh water. Soil saturation is highly correlated with elevation and influences the type of marsh community that an area supports. The terms *Low* and *High* reflect this relationship and may actually reflect only small changes in elevation, but may be significant when compared to the broad, flat areas of the coast. These plant communities, as well as unvegetated flats, commonly form intricate mosaics of the various communities associated with these subtle changes in topography.

Flats may be sparsely vegetated. In general, less than 30 percent vegetative cover will distinguish a flat from a marsh. Tidal flats are periodically flooded by tidal waters. The term flat includes sandbars, mudflats, and other nonvegetated or sparsely vegetated habitats also called salt flats. Sparse vegetation that occurs on salt flats may include glasswort (*Salicornia* spp.), saltwort (*Batis maritima*), and shoregrass (*Monanthochloe littoralis*).

These wetlands serve many ecological functions. Persistent emergent vegetation provides foraging, resting, and breeding habitat for a variety of coastal fish and wildlife species. Detritus from coastal marshes also provides a source of mineral and organic nourishment for organisms at the base of the food chain. Loss of emergent coastal marsh is a serious existing condition in the study area, and it is assumed that this loss would continue due to RSLR (USDC-NOAA, 2009). Existing and potentially accelerated marsh loss associated with channel deepening has been identified as one of the highest concerns by resource agencies and the general public. Mitigation measures should, therefore, maximize emergent marsh creation, maintenance, and protection.

Important features of marshes include the amount of marsh edge (linear distance of open water/vegetation interface) and interspersed that reflects the relative amount of marsh to open water and the degree to which open water is dispersed throughout the marsh. Interspersion is an important characteristic for fresh water and estuarine fish and shellfish nursery and foraging habitat in all marsh types. The marsh/open-water edge provides cover for postlarval and juvenile organisms.

Deeper water is assumed to be less biologically productive than shallow water because sunlight, oxygen, and temperature are reduced as depth increases. Shallow water also provides better bottom access for waterfowl, better foraging habitat for wading birds, and more-favorable conditions for the growth of aquatic vegetation.

Increase in salinity associated with the existing navigation project are one of the most important factors affecting coastal land loss in the study area. As salinity increases, biological productivity in the marsh is reduced thereby increasing vulnerability to land use.

Access by estuarine-dependent fishes and shellfishes, as well as other aquatic organisms, is important in assessing the quality of marsh systems. It is assumed that a high degree of hydrologic connectivity with adjacent systems provides high organism access, as well as providing greater nutrient exchange. Brackish

and saline marshes are assumed to be more important than fresh/intermediate marshes as habitat for estuarine-dependent fish and shellfish.

White and Tremblay (1995) summarize many factors that have contributed to marsh loss in the study area. In most cases, marsh loss occurs by conversion of the marshes to open water. In the lower Neches River Valley, this conversion is caused by subsidence and faulting (sometimes related to oil and gas production), dredged canals, alteration of hydrologic regime (due to channelization and placement of dredged material), decreased input of fluvial sediment (due to upstream dams), and construction of artificial levees. Similar factors are responsible for marsh loss in the Sabine River Basin.

Since 2000, there have been large areas of die-off in the low salt marshes on the Gulf Coast, commonly called Brown Marsh phenomenon (LDNR, 2002a). The area most severely impacted is east of the study area, between the Mississippi and Atchafalaya rivers. Although the causes are unknown, it is believed to be a combination of factors, including weather regimes, and is currently under study.

Low marshes for all salinity types are distinguished by the species composition. Indicator species by marsh type appear below (LDNR, 2002b; McKee et al., 2006; USFWS, 1998). More-extensive species lists appear in Visser and Sasser (1998) and White et al. (1987). Additional descriptions of these marsh types appear in Appendix C, Section 7.0.

Saline Marsh

- Smooth cordgrass, oystergrass (*S. alterniflora*) – dominant species in low marsh
- Seashore saltgrass (*Distichlis spicata*)
- Blackrush (*Juncus roemerianus*)
- Saline marsh aster (*Symphyotrichum tenuifolius*, syn. *Aster t.*)
- Glasswort – dominant species in high marsh
- Marshhay cordgrass, wiregrass (*S. patens*)
- Sea ox-eye daisy (*Borrchia frutescens*)

Brackish Marsh

- Saltmarsh bulrush (*Scirpus robustus*) – (co-)dominant species in low marsh
- Marsh pea (*Vigna luteola*)
- Waterhemp (*Amaranthus tamariscinus*)
- Seashore saltgrass – (co-)dominant species in high marsh
- Dwarf spikerush (*Eleocharis parvula*)
- Marshhay cordgrass, wiregrass – (co-)dominant species in high marsh

Intermediate Marsh

- Seashore paspalum (*Paspalum vaginatum*) – (co-)dominant species in low marsh
- Olney bulrush (*Schoenoplectus americanus*, syn., *Scirpus a.*) – (co-)dominant species in low marsh
- California bulrush, giant bulrush – (co-)dominant species in low marsh
- Common reedgrass, roseau cane (*P. australis*) – (co-)dominant species in low marsh
- Sand spikerush (*E. montevidensis*)
- Marshhay cordgrass, wiregrass – (co-)dominant species in high marsh
- Bulltongue (*Sagittaria lancifolia*)

Freshwater Marsh

- Maidencane (*Panicum hemitomen*) – (co-)dominant species in low marsh
- Giant cutgrass (*Zizaniopsis milacea*) – co-dominant species in low marsh
- Bulltongue – (co-)dominant species in low marsh
- American lotus (*Nelumbo lutea*)
- Watershield (*Brasenia schreberi*)
- Duckweed (*Lemna* spp.)
- Fanwort (*Cabomba caroliniana*)
- Squarestem spikerush (*E. quadrangulata*) – co-dominant species in high marsh
- Marshhay cordgrass, wiregrass – co-dominant species in high marsh

In general, the saline marshes are located nearest to the Gulf shoreline. In this area they tend to be linear features, which grade into brackish marshes with increasing distance from the shoreline. Some occur near Sabine Pass in the swales of the Chenier Plain.
