Most of the area between the GIWW and the Gulf shoreline is covered with brackish marsh. Most of the marshes on and near the shoreline of Sabine Lake and Sabine Pass are brackish to intermediate, becoming fresher to the north with proximity to the Neches and Sabine rivers. There is generally a gradation from more open-water areas that are saline or brackish to the intermediate marsh areas. These intermediate marshes are encroaching on formerly freshwater areas, but in turn are being encroached upon by brackish waters and marshes.

By altering the natural hydrology, the GIWW and its levees have created a sharper (formerly more gradual) transition from fresh-intermediate water marshes north of the GIWW to brackish-saline marshes on the south side. There are some scattered fresh and intermediate marshes associated with the swales of the Chenier Plain. Some areas with relatively higher elevations support fairly freshwater areas that only seasonally support wetland communities (i.e., “wet prairies”). There are additional freshwater marshes in

the riparian zone of the Neches and Sabine rivers. The central part of the Sabine NWR previously supported more freshwater marshes. However, some of this area has been converted to intermediate and brackish marsh due to saltwater intrusion. This intrusion has encroached from the west (Sabine Lake), east (Calcasieu Lake), and south. Some large levied areas within the Sabine NWR (e.g., Pool 3) are being maintained as freshwater impoundments.

Shrub/Scrub Wetlands

These wetlands are generally located adjacent to marshes at somewhat higher elevations. Estuarine intertidal scrub-shrub wetlands are dominated by woody vegetation and periodically flooded by tidal waters. Common species include the black mangrove (*Avicennia germinans*) and big leaf sumpweed (*Iva frutescens*). Sea ox-eye daisy is a woody species that is frequently a co-dominant species in high salt marsh and is described in this report with the marshes.

Freshwater shrub-scrub wetlands are generally associated with riverine systems or in isolated depressional areas (e.g., swales). Common species include buttonbush (*Cephalanthus occidentalis*), rattlebean (*Sesbania* spp.), and alder (*Alnus* spp.).

Swamps (Forested Wetlands)

Two types of swamps or forested wetlands occur in the Chenier Plains of Texas and Louisiana (USFWS, 1998). These occur within the floodplains of waterways, primarily the Neches and Sabine rivers. One of these is a true swamp, which is flooded most or all of the year. It is dominated by bald cypress and tupelo gum trees (*Nyssa* sp.). Many swamp species, especially tupelo gum trees and many herbaceous species, are salinity-sensitive. Bald cypress is able to tolerate higher salinities than the other species. These swamps may occur streamside or in abandoned channels or other depressional areas within the floodplain. Swamps with mature sizable trees are considered to be rare and ecologically important because of the historical loss of swamp habitat from timber harvesting, saltwater intrusion, and a reduced growth rate in the subsiding coastal zone. The hardwoods have been logged repeatedly since the turn of the century (USACE, 1998a), so much of this community is secondary growth.

The other forested wetland is also located within the same floodplains. Common tree species of these bottomland hardwoods include water oak (*Quercus nigra*), red maple (*Acer rubrum*), eastern cottonwood (*Populus deltoides*), box elder (*A. negundo*), Carolina ash (*Fraxinus caroliniana*), overcup oak (*Q. lyrata*), sugar maple (*A. saccharum*), bald cypress, tupelo gum, and swamp privet (*Forestiera acuminata*). These are flooded seasonally at high-water events when the waterways overflow their banks. Some bottomland hardwood areas may not be true and/or CWA Section 404 jurisdictional wetlands, but may be more appropriately considered as dry-riparian communities.

Swamps provide unique habitat to many species. Wildlife foods in swamp habitats consist predominantly of soft mast, other edible seeds, invertebrates, and vegetation. Most swamp tree species produce soft mast or edible seeds. A variety of stand structure (overstory, shrub, herb layer) provides habitat for resting, foraging, breeding, nesting, and nursery activities. The hardwoods, especially the cypress trees, have been

logged repeatedly since the turn of the century and as recently as perhaps the 1950s (USACE, 1998a). Though much of the forest is secondary growth, the swamp and bottomland hardwood habitats have medium to high value for food and cover to resident and migratory fish and wildlife.

The hydrology determines the existence and quality of forested wetlands. Seasonal flooding with periodic drying cycles increases nutrient cycling, vertical structure complexity, and recruitment of dominant overstory trees. Seasonal flooding with abundant and consistent riverine/tidal input and water flow-through is considered to be optimal hydrologic characteristic. Optimal conditions for forested wetlands are discussed in the WVA (Appendix C). The WVA model considered several variables (e.g., tree species composition, stand maturity) to assess the overall condition and characterization of the forested wetlands.

Bottomland Hardwood Forests

Bottomland hardwood forests are located in river bottomlands, generally in the floodplain. They are commonly associated with and form mosaics of stands with cypress-tupelo swamps and other forested wetlands (e.g., water oak or ash flats); however, they may not actually be considered wetlands. In the lower Sabine and Neches watersheds, bottomland hardwood forests are found on an intricate network of sandy ridges interspersed with wet sloughs that have formed within the rivers' relict meanderbelts. These are highly productive and diverse ecosystems and serve many ecological functions.

Bottomland hardwood wildlife depends heavily on mast, other edible seeds, and tree buds as primary sources of food. Typical hard mast producers in the study area are oaks, pecan (*Carya illinoensis*), and other hickories. Soft mast and other edible seeds are produced by red maple, sugarberry (*Celtis laevigata*), green ash (*Fraxinus pennsylvanica*), boxelder (*A. negundo*), common persimmon (*Diospyros virginiana*), sweetgum (*Liquidambar styraciflua*), honeylocust (*Gleditsia triacanthus*), red mulberry (*Morus rubra*), bald cypress, tupelo gum, American elm (*Ulmus americana*), and cedar elm (*U. crassifolia*). Nonmast/inedible seed producers are eastern cottonwood, black willow (*Salix nigra*), and American sycamore (*Platanus occidentalis*).

Mature stands of bottomland hardwood are rare and ecologically important. Historical and ongoing timber harvesting has reduced the number of mature stands and increased the ecological importance of those that remain. These stands provide more hard and soft mast, other edible seeds, and buds than younger stands. They provide important wildlife requisites such as snags, nesting cavities, and medium for invertebrate production.

Upland Grasslands (including Coastal Prairies)

Virtually all (99 percent) of the original Gulf Coastal Prairies (commonly referred to as Cajun Prairies in Louisiana) community has been converted to agricultural, industrial or other uses although some remnants still exist (Smeins et al., 1991). Undeveloped upland grasslands usually have a mix of the original prairie species and introduced pasture species as well as various forbs and occasional shrubs such as honey mesquite (*Prosopis glandulosa*), eastern baccharis (*Baccharis halimifolia*), and southern wax-myrtle (*Myrica cerifera*). Hatch et al. (1990) list common species for Gulf Coast prairie as follows: little

bluestem (*Schizachyrium scoparium*), coastal bluestem (*S. scoparium* var. *littoralis*), yellow indiagrass (*Sorghastrum nutans*), eastern gammagrass (*Tripsacum dactyloides*), hairy awn muhly (*Muhlenbergia capillaris*), Texas wintergrass (*Stipa leucotricha*), panicgrasses (*Panicum* spp.), several *Paspalum* species, broomsedge (*Andropogon virginicus*), smutgrass (*Sporobolus indicus*), threeawn grasses (*Aristida* spp.), yankeeweed (*Eupatorium compositifolium*), western ragweed (*Ambrosia cumanensis*), prickly pear (*Opuntia* spp.), several aster species, Texas paintbrush (*Castilleja indivisa*), poppy mallows (*Callirhoe* spp.), phlox (*Phlox* spp.), bluebonnets (*Lupinus* spp.), and evening primrose (*Oenothera* spp.). Because of the higher rainfall and gradual transition to coastal marshes, the Coastal Prairies in the study area, particularly in Louisiana, switchgrass (*P. virgatum*) is more common than in Coastal Prairies farther west.

The upland grasslands, most of which have been converted to agricultural purposes (crops or pasture), are primarily north of the GIWW, inland of the coastal marshes. Upland grasslands also occur south of the GIWW in Louisiana on the uplands provided by Gum Cove and Perry Ridge (Fearn, 1995) and also in small, scattered patches in the uplands of the chenier complex. Only small, scattered remnants of coastal prairie may be found within the study area.

Upland and Nonwetland Riparian Woodlands and Forests

Several communities of upland forest occur in the study area, including the Coastal Live Oak-Sugarberry Series, Water Oak-Coastal Live Oak series, Loblolly Pine-Oak Series, and Chinese Tallow Woodland. The Coastal Live Oak-Sugarberry Series is essentially a maritime woodland or forest (woodlots/oak mottes) of the Upper Gulf Coast, which is unique to the Chenier Plain (USFWS, 1998). Associated species include yaupon, cedar elm, and ash (*Fraxinus* spp.) intermixed with open patches of little bluestem grasslands (Bezanson, 2001; Harcombe and Neaville, 1977; Texas Natural Heritage Program [TNHP], 1993). The Water Oak-Coastal Live Oak series is a mostly deciduous, riparian woodland of the floodplains and along bayous in the Upper Coastal Prairie, along the Sabine and Neches rivers. Associated species include pecan, cedar elm, sugarberry, yaupon, hawthorns (*Crataegus* spp.), and deciduous holly (*I. decidua*) (TNHP, 1993). The Loblolly Pine-Oak Series may include post, southern red, white, and water oaks (*Q. stellata*, *Q. falcata*, *Q. alba*, and *Q. nigra*). These occur on higher-elevation uplands that generally have acidic soils. This community often occurs as second growth or after disturbance and is highly variable and is a mix of pine and hardwood species (USFWS, 1998). Overstory species include loblolly pine, slash pine (*Pinus elliottii*), water oak, overcup oak, willow (*Salix* spp.), sweetgum, southern magnolia (*Magnolia grandiflora*), American elm, and sugarberry. Understory species include eastern red cedar (*Juniperus virginiana*), blackcherry (*Prunus serotina*), roughleaf dogwood (*Cornus drummondii*), sugarberry, American beautyberry (*Callicarpa americana*), and poison ivy (*Toxicodendron radicans*). These occur in scattered patches in the uplands in the north part of the study area, but also on Perry and Gum Cove ridges. Another woodland type has been created by the introduction of an exotic species, the Chinese tallow tree, which rapidly invades upland and fresh-brackish wetlands in disturbed areas or abandoned agricultural fields. These woodlands are virtual monocultures of tallow trees, but commonly include native species such as sugarberry, American elm, cedar elm, water oak, and ash (Bruce et al., 1995).

Beach/Ridge (includes barrier dune complex)

The current beach communities include a primary and secondary dune complex that is leeward of the unvegetated, beach sands of the shoreline. The primary dunes, located immediately landward of the beach, are taller and offer more protection from wind and hurricane storm surge than the secondary dunes. The secondary dunes, which are landward of the primary dunes, are not as tall and are more densely vegetated. Typical plant species of the primary dunes include sea oats (*Uniola paniculata*), bitter panicum (*P. amarum*), Gulf croton (*Croton punctatus*), beach morning glory (*Ipomea pes-caprae* var. *emarginata*), and fiddleleaf morning glory (*I. stolonifera*). Secondary dune species include marshhay/wiregrass, seashore dropseed (*Sporobolus virginicus*), seashore saltgrass, pennywort (*Hydrocotyle bonariensis*), and partridge pea (*Chamaecrista fasciculata*) (Britton and Morton, 1989; USFWS, 1998). Swales that occur between or within the primary and secondary dune complexes may support brackish-to-intermediate marsh vegetation. The ridge and swale topography of the Chenier Plain represents ancient beach systems. These occur behind the active beach system and exhibit alternating, linear, upland/transitional, and wetland features. The Gulf beach in the study area is heavily eroded and virtually nonexistent in places (e.g., Texas Point) where saline marshes can occur on the coastline.

3.9.5 Preparation of Baseline Data Set to Support the WVA Model

Since the primary impact expected with the proposed project is salinity intrusion, units used to evaluate impacts were defined to the greatest extent possible on hydrologic characteristics. Sensitive habitats that are hydrologically connected to waterways influenced by the proposed project were divided into hydro-units. Uplands and developed areas were excluded from the analysis. Baseline habitat types within each hydro-unit were then classified as marsh (fresh, intermediate, brackish, or saline), cypress-tupelo swamp, or bottomland hardwood. Habitat classification definitions were derived from Cowardin et al. (1979). Numerous other sources were used to map and characterize the wetlands. These are described in detail in Appendix C of this FEIS.

Baseline habitats for the Texas hydro-units were classified and mapped with the assistance of the Habitat Workgroup. The TPWD provided habitat mapping for the Keith Lake/Salt Bayou hydro-unit, the Lower Neches WMA (TPWD, 1992), and Cow Bayou (TPWD, 2004). The USFWS (2001) provided habitat maps of the McFaddin NWR and also mapped habitat types on the Neches River using the National Wetlands Inventory (NWI) data (USFWS and GLO, 1992), supplemented and revised as necessary on the basis of expert knowledge and field visits. All other Texas hydro-units were mapped by PBS&J using collapsed NWI data, reviewed and revised as necessary by the Habitat Workgroup.

Hydro-units and habitat types for Louisiana marsh habitats were drawn directly from mapping units developed for the Louisiana CWPPRA program (Chabreck and Linscombe, 1978; Linscombe, 2001; USGS-NWRC, 2004). Nonmarsh habitats on the Sabine River were mapped by PBS&J using NWI data, reviewed and revised by the Habitat Workgroup.

The existing vegetation and conditions, including detailed descriptions and maps for each hydro-unit, may be found in Appendix C (Section 7), so to avoid duplication, they are not included here.

3.10 AQUATIC ECOLOGY

3.10.1 Freshwater

The study area consists of both freshwater and marine ecosystems. The Sabine and Neches rivers and their tributaries were dominated by fresh water prior to the late 1800s, before Sabine Lake was opened for navigation. It is likely that Sabine Lake was almost entirely fresh, with the exception of saltwater intrusions that emanated from tidal surges during storms or during severe droughts (see Section 3.5 for additional discussions on hydrology). Thus, the biological communities have changed significantly within the past century due to the encroachment of salt water. Most of the tributaries adjacent to Sabine Lake are also influenced by salt water to some extent. Many of the deep navigational channels maintain predominant saltwater wedges that underlie freshwater inflows into the estuary. As a result of this, freshwater species adapted to stenohaline environments may be typically restricted to the upper reaches of the tributaries or occur above (on top of) the saltwater wedge. With high freshwater inflows, Sabine Lake and its tributaries often flush most of the salt water from the estuary resulting in a temporary expansion of freshwater habitat. However, with a return of normal freshwater inflows and tidal currents, Sabine Lake returns to a euryhaline (wide range of salinity) system.

Freshwater fauna typically occur in the tributaries of Sabine Lake including the Sabine and Neches rivers, Taylor, Cow, Adams, and Little Cypress bayous in Texas, Black and Johnson's bayous in Louisiana, as well as numerous other smaller tributaries. Rose City Marsh is predominantly a freshwater environment, and portions of Bessie Heights Marsh, distantly removed from the study area, contain low salinity. In addition, freshwater fauna can be found in the multitude of wetlands, oxbows, ponds, canals, and ditches within the study area.

3.10.1.1 Fisheries

Due to the variety of habitats and the typical diversity of southeastern United States streams, the study area has an exceptionally diverse fish community consisting of approximately 56 freshwater and 25 estuarine species (Hubbs, 1982; USACE, 1975b). Fishery surveys conducted by the TPWD on the Sabine and Neches rivers (TPWD, 1980, 1994) and Taylor, Hildebrand, Cow, Little Cypress, and Adams bayous (TPWD, 1985, 1995a, 1995b) confirm many of these species. Some of these species, including largemouth bass (*Micropterus salmoides*), channel catfish (*Ictalurus punctatus*), crappie (*Pomoxis* spp.), white bass (*Morone chrysops*), and sunfish (*Lepomis* spp.), are important recreational species. Although little information is available regarding angler use, all of these areas are extensively utilized by sport anglers (Driscoll, 2001). There is little to no commercial freshwater fishing on the Texas side of the study area (Young, 2001). Table 3.10-1 lists species collected by the TPWD from Bessie Heights Marsh using gill nets, and from the Neches River using bag seines (Tirpak, 2002). The number of data lines for gill nets represents the number of samples where at least one individual of that species was encountered per mesh size. The TPWD gill nets are 600 feet in length with 150-foot panels each of 3-, 4-, 5-, and 6-inch

mesh. For bag seines, the “number of data lines” represents the number of samples where at least one individual of that species was encountered. For each gear type, a higher number of lines indicate a higher encounter rate (not necessarily catch rate) for that species and gear.

The LDWF, Inland Fisheries Division, monitors fish populations with an emphasis on sport fish management on the Sabine River at Niblett’s Bluff and within associated bayous downstream of Niblett’s Bluff. A variety of freshwater species has been collected from this area including largemouth bass, spotted bass (*M. punctulatus*), bowfin (*Amia calva*), black crappie (*P. nigromaculatus*), spotted sucker (*Minytrema melanops*), golden shiner (*Notemigonus crysoleucas*), sunfish, blue catfish (*I. furcatus*), channel catfish, spotted gar (*Lepisosteus oculatus*), shad (*Dorosoma* spp.), and striped mullet (*Mugil cephalus*) (LDWF, var.). According to the LDWF (pers. comm. District Biologist, 2001), angling along the Sabine River is very popular, including tournament fishing for largemouth bass by local anglers.

3.10.1.2 Macroinvertebrates

Both benthic macroinvertebrates and plankton support the food chain in the freshwater zones. Food chains in the larger, slow-moving rivers, bayous, and backwater areas are similar to those found in lakes. In these systems, the food chain consists primarily of plankton, including microscopic algae (phytoplankton) and crustacea (zooplankton) that are suspended in the water column. Diverse communities of plankton occur throughout the freshwater system, but gradually shift to marine taxa as the water enters the estuarine areas. For the most part, plankton communities found in the study area are ubiquitous and common throughout the southern United States. Phytoplankton communities that occur in the freshwater zones of the study area typically include blue-green algae (Cyanophyta), green algae (Chlorophyta), and diatoms (Bacillariophyta). Zooplankton common to this same area include rotifers (Rotifera), calanoid and cyclopoid copepods (Copepoda), seed shrimp (Ostracoda), and *Daphnia* and *Ceriodaphnia* spp. (Cladocera).

In small streams or streams with higher water velocities, benthic macroinvertebrates are the primary basis of the food chain. Species composition in the rivers, bayous, and streams in the study area is similar to other southeastern United States rivers and streams. General groups of organisms commonly found in these areas include aquatic worms (Oligochaeta), scuds (Amphipoda), crayfish (Cambaridae), mayflies (Ephemeroptera), caddisflies (Trichoptera), water beetles (Coleoptera), midge flies (Chironomidae), water bugs (Hemiptera), dragonflies (Odonata), and mussels (Bivalvia).

Within the tidally influenced zones, where saltwater wedges or intrusion occur, the macrobenthic community is complex and dynamic (see subsection 3.10.2.1 for additional discussions). Community structure in the shallow margins of these tributaries may consist of those organisms common to freshwater environments due to the partitioning between fresh- and saltwater. However, these freshwater organisms are greatly affected by the encroachment of saltwater wedges. McKee and Wolf (1973) consider dissolved solids between 5,000 and 10,000 mg/L to be beyond the tolerance of most freshwater organisms. Persistent saltwater intrusion with saltwater wedges may allow for the encroachment of estuarine organisms.

Table 3.10-1
Species Collected by TPWD from Bessie Heights (Gill Nets) and Neches River (Bag Seines)
January 1986–June 2001

Family Name/Scientific Name	Common Name	Number of Data Lines	
		Gill Nets Bessie Heights	Bag Seines Neches River
HYDROZOA			
Hydractiniidae			
<i>Podocoryna carnea</i>	Smoothspined snailfur		1
CTENOPHORE			
Beroidae			
<i>Beroe ovata</i>	Sea walnut (comb jelly)		12
Bolinopsidae			
<i>Mnemiopsis mccradyi</i>	Phosphorus jelly		8
MOLLUSKS			
Mactridae			
<i>Rangia cuneata</i>	Atlantic rangia	2	10
CRUSTACEANS			
Penaeidae			
<i>Farfantepenaeus aztecus</i>	Brown shrimp		51
<i>Litopenaeus setiferus</i>	White shrimp		61
<i>Xiphopenaeus kroyeri</i>	Seabob		1
Palaemonidae			
<i>Palaemonetes pugio</i>	Daggerblade grass shrimp		1
<i>Palaemonetes</i> sp.	unidentified grass shrimp		40
<i>Macrobrachium ohione</i>	Ohio shrimp		5
Portunidae			
<i>Callinectes sapidus</i>	Blue crab	95	136
<i>Callinectes similis</i>	Lesser blue crab		8
Xanthidae			
Family mud crabs			2
Grapsidae			
<i>Sesarma reticulatum</i>	Heavy marsh crab		1
Cambariidae			
<i>Procambarus clarkii</i>	Red swamp crawfish		2
BRYOZOANS			
Gymnolaemata			
<i>Zoobotryon verticillatum</i>	Sauerkraut bryozoan	2

Source: A. Tirpak (2002).

Prior to the implementation of the CWA in the early 1970s, the Neches River, downstream of the saltwater barriers on the Neches River, and Pine Island Bayou were highly impacted by industrial wastewater effluent and saltwater encroachment. Studies by Harrel (1975, 1993), Harrel and Hall (1991), and Harrel et al. (1976) documented the impacts of increased salinity and depressed dissolved oxygen (DO) on benthic macroinvertebrates. The degree of impact was greater downstream in the industrialized portions of the river. Since the implementation of the CWA, water quality has improved with a significant reduction in biochemical oxygen demand (EPA, 1978); however, saltwater intrusion continues to be a problem for freshwater organisms in this area.

3.10.2 Marine

3.10.2.1 Estuarine Habitats and Fauna

3.10.2.1.1 Open-Bay

Sabine Lake, when compared to the other estuarine ecosystems in Texas, covers the smallest surface area (43,978 acres/68.6 square miles) and volume; however, it has the largest surrounding marshland (over 185,000 acres/288.6 square miles) (Armstrong et al., 1987; Blackburn et al., 2001). The average depth of Sabine Lake is 6 feet. Due to the large amount of freshwater inflow into Sabine Lake from stormwater runoff, return flows, and diversions, this estuary has the highest loading of nutrients than any other estuary in Texas (Armstrong et al., 1987). Due to its dynamic salinity (see subsection 3.5.5), Sabine Lake supports a diversity of fish species, plankton, and benthic organisms.

Plankton Assemblages. Phytoplankton (microscopic algae) are the major primary producers (plant life) in the open bay, taking up carbon through photosynthesis and nutrients for growth. Phytoplankton are fed upon by zooplankton (small crustaceans), fish, and benthic consumers. EH&A (1976), found that phytoplankton in Sabine Lake were comprised primarily of both freshwater and marine diatoms (45 percent) and green algae (36 percent). Species composition changed seasonally with minimum abundance occurring in the winter and maximum in the summer. Zooplankton were most abundant during the summer and early fall, coinciding with higher salinities. The dominant species was the copepod *Acartia tonsa* (85 percent), with several other marine copepods also present. Commensurate with higher salinities, the higher numbers were found in the lowest reaches of the estuary. Freshwater species, including rotifers and cladocerans, were the dominant taxa near the mouth of the rivers. Abundance of zooplankton was lowest in the winter and spring and highest in the summer and fall, which is the opposite in other estuaries (with the exception of Galveston Bay) (Armstrong et al., 1987; EH&A, 1976). Marine zooplankton abundance is apparently related to the greater inflow of fresh water into Sabine Lake and Galveston Bay during the winter and spring (Armstrong et al., 1987).

Nekton Assemblages. Nekton assemblages (organisms that swim freely in the water column) consist mainly of secondary consumers, which feed on zooplankton or juvenile and smaller nekton. Sabine Lake supports a diverse nekton population including fish, shrimp, and crabs. Some of these are resident species, spending their entire life in the bay, whereas others are migrant species spending only a portion of their life cycle in the estuary (Armstrong et al., 1987).

Dominant nekton species inhabiting the Sabine Lake estuary are Atlantic croaker (*Micropogonias undulatus*), white shrimp (*Litopenaeus setiferus*), brown shrimp (*Farfantepenaeus aztecus*), Gulf menhaden (*Brevoortia patronus*), bay anchovy (*Anchoa mitchilli*), red drum (*Sciaenops ocellatus*), blue crab (*Callinectes sapidus*), southern flounder (*Paralichthys lethostigma*), black drum (*Pogonias cromis*), striped mullet, sheepshead (*Archosargus probatocephalus*), and spotted seatrout (*Cynoscion nebulosus*), all of which are estuarine dependent (Chambers and Sparks, 1959; Parker, 1965; Reid, 1957). These species are ubiquitous along the Texas and Louisiana coast and are unaffected by changes in salinity. Seasonal differences occur in abundance with the fall usually being the smallest in biomass and number.

Newly spawned fish and shellfish begin migrating into the bay in winter and early spring with the maximum biomass observed during the summer months (Parker, 1965).

Recreational and Commercial Fisheries. Sabine Lake has the second-lowest percentage of the total commercial finfish harvest from all Texas bay systems (Culbertson et al., 2004). Table 3.10-2 lists the TPWD commercial landings for Sabine Lake from 1992 through 2001. From 1992 to 2001, an average of only 1,629 pounds of finfish were commercially harvested in Sabine Lake, with a value averaging \$1,540. The amount harvested has declined in recent years. Commercially caught species include Atlantic croaker, black drum, flounder, king whiting (*Menticirrhus americanus*), striped mullet, and sheepshead (Auil-Marshall et al., 2001; Culbertson et al., 2004).

The main commercially harvested shellfish species in Sabine Lake are blue crabs (Table 3.10-3). Sabine Lake sustains an important blue crab fishery in Texas and Louisiana. From 1997 through 2001, 27 percent of all blue crabs on the Texas coast were landed from Sabine Lake (Culbertson et al., 2004). From 1990 to 1999, over 1 million pounds of blue crabs were commercially harvested annually from Sabine Lake, with an annual value averaging \$843,273 (Culbertson et al., 2004). At one time, white shrimp made up a 330 ton/year fishery. In 1997, this fishery began to decline, possibly as a result of changes in freshwater inflow and concurrent isolation of wetlands from Sabine Lake. This decline was only observed in Sabine Lake while the white shrimp fishery in Galveston Bay and Lake Calcasieu remained the same (Sheridan et al., 1989). Eastern oysters (*Crassostrea virginica*) are not currently commercially harvested from Sabine Lake (see Table 3.10-2); however, they were harvested during 1986 and 1987 (Auil-Marshall et al., 2001).

The commercial landings data collected by the LDWF is shown in Table 3.10-3. From 1995 to 2005, an average of 10,375 pounds of finfish were commercially harvested from Sabine Lake, with a value averaging \$10,610. These species include alligator gar (*Lepisosteus spatula*) and blue catfish. Shellfish were only harvested in 2001 and 2002, and included 88,362 pounds of blue crab with a value of \$76,726 and 908 pounds of white shrimp with a value of \$1,223 (Kasprzak, 2007).

Due to the variety of both fresh and saltwater species, recreational fishing is Sabine Lake's largest recreational activity (Davis, 1996). The most sought after species include Atlantic croaker, black drum, gafftopsail catfish (*Bagre marinus*), red drum, sand seatrout (*Cynoscion arenarius*), sheepshead, southern flounder, and spotted seatrout (see subsection 3.10.1.1 for additional discussion on freshwater sport fish). Between May 1982 and May 1992, Sabine Lake (including Sabine Pass) accounted for 10 percent of the annual coastwide recreational fishing landings among bay systems. The majority of these species included Atlantic croaker, southern flounder, black drum, and gafftopsail catfish (Warren et al., 1994). The catch per unit effort in Sabine Lake is 0.35 fish per man-hour of fishing, second only to Galveston Bay. Annual fishing effort is estimated at 500,000 man-hours (Blackburn et al., 2001). The LDWF only collects recreational landings data on a statewide level; there are no data specific to Sabine Lake (Kasprzak, 2007).

Offshore fishing is also popular in the study area. The main recreational species are king mackerel (*Scomberomorus cavalla*), red snapper (*Lutjanus campechanus*), and sand seatrout. From May 1982 to May 1992, offshore recreational fishing in this area accounted for 4 to 7 percent of the annual coastwide private-boat fishing landings (Warren et al., 1994). The main commercially landed species include flounder, mullet, snapper, and blue crab (Table 3.10-4) (Culbertson et al., 2004). From 1997 to 2001, Sabine Lake represented less than 1 percent of the total annual coastwide finfish commercial landings (Culbertson et al., 2004).

3.10.2.1.2 Open-Bay Bottom

The open-bay bottom includes all areas of Sabine Lake not covered with oyster reefs (Lester and Gonzales, 2001) but does not include the bottoms of ship channels because they are so frequently disturbed by ship passage and maintenance dredging that they never establish a population even approaching a climax community. Benthic organisms are divided into two groups: epifauna, such as crabs and smaller crustaceans, which live on the surface of the bottom substrate, and infauna, such as mollusks and polychaetes that burrow into the bottom substrate (Green et al., 1992). Mollusks and other infaunal organisms are filter feeders that strain suspended particles from the water column. Others, such as polychaetes, feed by ingesting sediments and extracting nutrients. Many of the epifauna and infauna feed on plankton, and are then fed upon by numerous fish and birds (Armstrong et al., 1987; Lester and Gonzales, 2001). The open-bay bottom includes flat areas consisting of mud and sand that contribute large quantities of nutrients and food, making them one of the most important components of this habitat type. EH&A (1976) found that the dominant infauna organism throughout Sabine Lake was the clam (*Rangia cuneata*) and a polychaete of the family Capitellidae. *R. cuneata* was most abundant in areas of lower salinity, whereas polychaetes increased in abundance in areas of higher salinity (EH&A, 1976). Vittor & Associates (1997) found the dominant benthic taxa of Sabine Lake were the polychaetes, *Paraprionospio pinnata* (29.0 percent) and *Mediomastus* sp. (7.7 percent), the oligochaete, *Tubificoides heterochaetus* (23.2 percent), and the bivalve, *R. cuneata* (5.2 percent).

3.10.2.1.3 Oyster Reef

Eastern oyster reefs are present in several areas of Sabine Lake, Sabine Pass, and Keith Lake, and provide ecologically important functions. Oyster reefs are formed where a hard substrate and adequate currents are plentiful. Currents carry nutrients to the oysters and take away sediment and waste filtered by the oyster. Most oyster reefs are subtidal or intertidal and found near passes and cuts, and along the edges of marshes. Oysters can filter water 1,500 times the volume of their body per hour which, in turn, influences water clarity and phytoplankton abundance (Powel et al., 1992; Lester and Gonzalez, 2001). Due to their lack of mobility and their tendency to bioaccumulate pollutants, oysters are an important indicator species for determining contamination in the bay (Lester and Gonzalez, 2001).

Many organisms, including mollusks, polychaetes, barnacles, crabs, gastropods, amphipods, polychaetes, and isopods, can be found living on the oyster reef, forming a very diverse community (Sheridan et al., 1989). Oyster reef communities are dependent upon food resources from the open bay and marshes. Many organisms feed on oysters including fish, such as black drum, crabs (*Callinectes* spp.), and gastropods such as the oyster drill (*Thais haemastoma*) (Sheridan et al., 1989; Lester and Gonzales, 2001). When oyster reefs are exposed during low tides, shore birds would use the reef areas as resting places (Armstrong et al., 1987).

The majority of oyster reefs in the study area are located in the southern part of Sabine Lake near Blue Buck Point, in Sabine Pass, and in Keith Lake (GLO, 1996). Oysters are not commercially harvested from Sabine Lake. In Texas, all areas not specifically designated as Restricted, Conditionally Approved, or Approved by the Texas Department of State Health Services (TDSHS) are classified as Prohibited and closed for harvesting of molluscan shellfish (Heideman, 2002; TDSHS, 2008). Louisiana has designated Sabine Lake as a “Public Oyster Area.” Commercial harvesting is prohibited and public harvesting methods are restricted to tonging. However, Sabine Lake and its tributaries north of a line from Texas Point to Louisiana are closed to oyster harvesting.

3.10.2.1.4 Salt Marsh

Sabine Lake has the largest salt marsh coverage (over 185,000 acres) of any bay system in Texas (Blackburn et al., 2001). This emergent vegetation plays an important role in sustaining the health and abundance of life in the estuary. Emergent vegetation contributes to the productivity of the estuary by providing particulate matter, nutrients, structure, protection, substrate, habitat for estuarine species, flood control, and improved water quality. Salt marshes serve as spawning and nursery grounds for many fish and shellfish species (Sheridan et al., 1989; TPWD, 1997). As an example, Table 3.10-1 lists species that have been collected from Bessie Heights Marsh. Refer to subsection 3.9.2.1 for a more detailed description of this habitat type.

3.10.2.2 Offshore Habitats and Fauna

The Gulf is a partially enclosed, oceanic basin connected to the Atlantic Ocean by the Straits of Florida and to the Caribbean Sea by the Yucatan Canal. Numerous currents circulate water throughout the basin. Surface temperatures range from 57°F in January to 88°F in July (GMFMC, 2004). Salinities also vary seasonally ranging from 29 ppt near the coastline to 32 ppt in the open Gulf (Minerals Management Service [MMS], 1997). The nearshore area is predominantly composed of coarse sediments, while fine sediments are found in the deeper areas beyond the 260-foot contour (GMFMC, 2004). Sediment type plays an important role in determining community structure. Each species has optimal habitat and tolerance limits regarding sediment particle size and chemical composition that influences the distribution of fauna in nearshore waters (Britton and Morton, 1989).

3.10.2.2.1 Offshore Sands

There are few seagrasses or attached algae found in the offshore sands due to the strong currents and unstable sediments. Most of the bottom surface is populated with macroinfauna such as an occasional hermit crab, portunid crab, or ray. Even though there is little life on the sand surface itself, the overlying waters are highly productive. Phytoplankton are abundant, including microscopic diatoms, dinoflagellates, and other algae (Britton and Morton, 1989).

Much of the faunal diversity lies buried in the sand and relies on the phytoplankton for food. Bivalves found in offshore sands include the blood ark (*Anadara ovalis*), incongruous ark (*A. brasiliiana*), southern quahog (*Mercenaria campechiensis*), giant cockle (*Dinocardium robustum*), disk dosinia (*Dosinia discus*), pen shells (*Atrina serrata*), common egg cockle (*Laevicardium laevigatum*), cross-barred venus (*Chione cancellata*), tellins (*Tellina* spp.), and the tusk shell (*Dentalium texasianum*). One of the most common species occurring in the shallow offshore sands is the sand dollar (*Mellita quinquiesperforata*) as well as several species of brittle stars (*Hemipholis elongata*, *Ophiopsis elegans*, and *Ophiotrix angulata*). Many gastropods are common, including the moon snail (*Polinices duplicatus*), ear snail (*Sinum perspectivum*), Texas olive (*Oliva sayana*), Atlantic auger (*Terebra dislocata*), Salle's ager (*Terebra salleano*), scotch bonnet (*Phalium granulatum*), distroted triton (*Distrosio clathrata*), wentletraps (*Epitonium* sp.), and whelks (*Busycon* spp.). Crustaceans inhabit these waters including white and brown shrimp (both commercially caught species), rock shrimp (*Sicyonia brevirostris*), blue crabs, mole crabs (*Albunea* spp.), speckled crab (*Arenaeus cribrarius*), box crab (*Calappa sulcata*), calico crab (*Hepatus epheliticus*), and pea crab (*Pinothres maculatus*). The most abundant infaunal organism, with respect to the number of individuals, are the polychaetes (Capitellidae, Orbiniidae, Magelonidae, and Paraonidae) (Britton and Morton, 1989).

3.10.2.2.2 Artificial Reefs

In the Gulf, two types of artificial reefs exist, those structures placed to serve as oil and gas production platforms and those intentionally placed to serve as artificial reefs (GMFMC, 2004). The more than 4,500 oil and gas structures in the Gulf form unique reef ecosystems that extend throughout the water column providing a large volume and surface area, dynamic water-flow characteristics, and a strong profile (Dutton and Falk, 1981; Dokken, 1997; Stanley and Wilson, 1990; Vitale and Dokken, 2000). Fish are attracted to oil platforms because these structures provide food, shelter from predators and ocean currents, and a visual reference, which aids in navigation for migrating fishes (Bohnsack, 1989; Duedall and Champ, 1991; Meier, 1989; Vitale and Dokken, 2000). The size and shape of the structure affect community characteristics of pelagic, demersal, and benthic fishes (Stanley and Wilson, 1990). Many scientists feel that the presence of oil platform structures allows for the fish populations to grow, which increases fishery potential (Scarborough-Bull and Kendall, 1992).

The Texas Artificial Reef Program, administered by the TPWD, comprises three concepts. These are Rigs to Reefs, which provides for the recycling of obsolete petroleum platforms into permanent artificial reefs rather than allowing them to be taken ashore as scrap; Ships to Reefs, which at present only includes 12

Liberty Ships from the 1970s and the USTS *Texas Clipper*; and the Near Shore/Shallow Reef program, which is in water too shallow for rigs or ships and uses obsolete bridge and road-bed material and nonfunctional preformed concrete structures like culverts. There are three Near Shore/Shallow Reef sites that are relatively near the proposed new ODMDs for the Entrance Channel Extension: Basco's Reef, SALT Reef, and Sabine Reef (Appendix B). Basco's Reef (HI-117) is located 23 nautical miles from Sabine Pass in 50 feet of water and has received numerous donations. SALT Reef (HI-85, 18 nautical miles from Sabine Pass, 43 feet of water) and Sabine Reef (HI-117, 22 nautical miles from Sabine Pass, 36 feet of water) have not yet received donations but are formally part of the Artificial Reef Program. SALT Reef, which is closest to the proposed ODMDs, is 6.6 miles from ODMD B.

Artificial reefs are colonized by a diverse array of microorganisms, algae, and sessile invertebrates including shelled forms (barnacles, oysters, and mussels), as well as soft corals (bryozoans, hydroids, sponges, and octocorals) and hard corals (encrusting, colonial forms). These organisms (referred to as the biofouling community) provide habitat and food for many motile invertebrates and fishes (GMFMC, 2004).

Species associated with the platforms that are not dependent on the biofouling community for food or cover include the Atlantic spadefish (*Chaetodipterus faber*), lookdown (*Selene vomer*), Atlantic moonfish (*S. setapinnis*), creole-fish (*Paranthias furcifer*), whitespotted soapfish (*Rypticus maculatus*), gray triggerfish (*Balistes caprisus*), and lane snapper (*Lutjanus synagris*), all transients (move from platform to platform) and resident species (always found on the platforms) including red snapper, large tomatate (*Haemulon aurolineatum*), and some large groupers. Other resident species that are dependent upon the biofouling community for food or cover include numerous species of blennies, sheepshead, small grazers (butterflyfishes, Chaetodontidae). Highly transient, large predators associated with these structures include barracuda (*Sphyrna barracuda*), almaco jack (*Seriola rivoliana*), hammerhead sharks (*Sphyrna* spp.), cobia (*Rachycentron canadum*), mackerels (*Scombridae*), other jacks (*Caranx* sp.), and the little tunny (*Euthynnus alletteratus*) (GMFMC, 2004).

3.10.2.3 Essential Fish Habitat

The DEIS initiated EFH consultation under the Magnuson-Stevens Fishery Conservation and Management Act (MSFCMA). Congress enacted amendments to the MSFCMA (PL 94-265) in 1996 that established procedures for identifying EFH and required interagency coordination to further the conservation of federally managed fisheries. Rules published by the NMFS (50 CFR Sections 600.805–600.930) specify that any Federal agency that authorizes, funds or undertakes, or proposes to authorize, fund, or undertake an activity that could adversely affect EFH is subject to the consultation provisions of the above-mentioned act and identifies consultation requirements. A letter (Appendix A) was submitted to NMFS requesting a list of EFHs in the study area.

The GMFMC has identified the study area as EFH for adult and juvenile brown and white shrimp, red drum, red snapper, lane snapper, greater amberjack (*Seriola dumerilli*), king mackerel, Spanish mackerel

(*Scomberomorus maculatus*), cobia, Gulf stone crab (*Menippe adina*), gag grouper (*Mycteroperca microlepis*), scamp (*Mycteroperca phenax*), and adult gray snapper (*L. griseus*).

EFH is defined as “those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity.” When referring to estuaries, it is further defined as “all waters and substrates (mud, sand, shell, rock, and associated biological communities) within these estuarine boundaries, including the sub-tidal vegetation (seagrasses and algae) and adjacent tidal vegetation (marshes and mangroves)” (GMFMC, 2004). No Habitat Areas of Particular Concern (HAPC) identified by the GMFMC are located within the study area.

The following describes the preferred habitat, life history stages, and relative abundance of each EFH managed species based on information provided by GMFMC (2004). Table 3.10-5 describes EFH for each of these species.

Brown Shrimp. Brown shrimp eggs are demersal and are deposited offshore. The larvae begin to migrate through passes with flood tides into estuaries as postlarvae. Migrating occurs at night mainly from February to April, with a minor peak in the fall. Brown shrimp postlarvae and juveniles are associated with shallow vegetated habitats in estuaries, but are also found over silty sand and nonvegetated mud bottoms. Postlarvae and juveniles occur in salinity ranging from 0 to 70 ppt. The density of late postlarvae and juvenile brown shrimp are highest in marsh-edge habitat and submerged vegetation, followed by tidal creeks, inner marsh, shallow, open water, and oyster reefs. Muddy substrates seem to be preferred in unvegetated areas. Juvenile and subadult brown shrimp can be found from secondary estuarine channels out to the continental shelf, but prefer shallow estuarine habitats, such as soft, muddy areas associated with plant-water interfaces. Subadult brown shrimp migrate from estuaries, at night, on ebb tides during new and full moon phases in the Gulf. Their abundance offshore correlates positively with turbidity and negatively with hypoxia (low levels of oxygen in the water). Adult brown shrimp inhabit neritic Gulf waters (marine waters extending from mean low tide to the edge of the continental shelf) and are associated with silt, muddy sand, and sandy substrates (GMFMC, 2004). Adult brown shrimp are common within the Sabine Lake estuary during the spring and summer months, while juveniles are abundant in this area in the spring, summer, and fall.

Larval brown shrimp feed on phytoplankton and zooplankton. Postlarvae brown shrimp feed on phytoplankton, epiphytes, and detritus. Juvenile and adult brown shrimp prey on amphipods, polychaetes, and chironomid larvae, but graze on algae and detritus (Pattillo et al., 1997).

White Shrimp. White shrimp inhabit Gulf and estuarine waters and are pelagic or demersal, depending on their life stage. Their eggs are demersal and larval stages are planktonic, and both occur in nearshore Gulf waters. Postlarvae migrate into estuaries through passes from May to November with most migration occurring in June and September. Migration is in the upper 6.5 feet of the water column at night and at mid-depths during the day. Postlarval white shrimp become benthic once they reach the estuary. Here they seek shallow water with mud or sand bottoms high in organic detritus or rich marsh where they develop into juvenile white shrimp. Postlarvae and juveniles prefer mud or peat bottoms with large

quantities of decaying organic matter or SAV. Densities are usually highest along marsh edge and in SAV, followed by marsh ponds and channels, inner marsh, and oyster reefs. White shrimp juveniles prefer salinities of less than 10 ppt and occur in tidal rivers and tributaries. As white shrimp juveniles mature, they migrate to coastal areas where they mature and spawn. Adult white shrimp are demersal and inhabit soft mud or silt bottoms (GMFMC, 2004). Adult and juvenile white shrimp are abundant in the Sabine Lake estuary throughout the year. Adult white shrimp also occur throughout the Gulf to depths of about 131 feet.

White shrimp larvae feed on phytoplankton and zooplankton. White shrimp postlarvae feed on phytoplankton, epiphytes, and detritus. Juvenile and adult white shrimp prey on amphipods, polychaetes, and chironomid larvae, but also graze on algae and detritus (Pattillo et al., 1997).

Red Drum. Red drum occupy a variety of habitats, ranging from offshore depths of 131 feet to very shallow estuarine waters. Spawning occurs in the Gulf near the mouths of bays and inlets during the fall and early winter. Eggs usually hatch in the Gulf, and larvae are transported with tidal currents into the estuaries where they mature. Adult red drum use estuaries, but tend to migrate offshore where they spend most of their adult life. Red drum occur over a variety of substrates including sand, mud, and oyster reefs and can tolerate a wide range of salinities (GMFMC, 2004).

Estuaries are especially important to larval, juvenile, and subadult red drum. Juvenile red drum are most abundant around marshes, preferring quiet, shallow, protected waters over mud substrate or among SAV. Subadult and adult red drum prefer shallow bay bottoms and oyster reefs (GMFMC, 2004). Adult red drum that migrate into the Gulf are pelagic.

Estuaries are also important for the prey of larval, juvenile, and subadult red drum. Red drum larva feed primarily on shrimp, mysids, and amphipods, while juvenile red drum prefer fish and crabs. Adult red drum feed primarily on shrimp, blue crab, striped mullet, and pinfish (GMFMC, 2004). Within the Sabine Lake estuary, adult and juvenile red drum are common in the summer, fall, and winter, whereas in the Gulf, adult red drum are present year-round.

Gag Grouper. Gag grouper are demersal and are most common in the eastern Gulf. Eggs are pelagic and are spawned from December through April. Larvae are pelagic and most abundant in the early spring.

Postlarvae and pelagic juveniles move through inlets into high salinity estuaries from April through May, where they become benthic and settle into grass flats and oyster beds. Older juveniles move offshore in the fall to shallow reef habitat in depths of 3 to 165 feet. Adults prefer depths of 33 to 328 feet and utilize hard bottoms, oil platforms, and artificial reefs. Spawning occurs on the west Florida shelf from December through April (GMFMC, 2004).

Gag grouper feed on estuarine-dependent organisms such as shrimp, small fish, and crabs during their juvenile stages. As they mature and move farther offshore, they become opportunistic predators, feeding on a variety of fish and crustaceans (GMFMC, 2004). Adult gag grouper occur in Gulf waters within the study area.

Scamp. Scamp are demersal and widely distributed on shelf areas of the Gulf. Scamp eggs and larvae are pelagic and are spawned offshore in the spring. Juvenile scamp occur on shallow, nearshore hard bottoms and reefs in depths of 40 to 620 feet. Scamp spawn in aggregations from late February to early June.

Juvenile scamp feed on estuarine-dependent organisms such as shrimp, small fish, and crabs. As they mature and move offshore, they become opportunistic predators, feeding on a variety of fish and crustaceans (GMFMC, 2004). Adult scamp occur in Gulf waters within the study area.

Red Snapper. Red snapper are demersal and found over sand and rock substrates around reefs, and underwater objects to depths of 656 feet. However, adult red snapper prefer depths ranging from 131 to 360 feet (GMFMC, 2004). Spawning occurs in the Gulf from May to October, at depths of 60 to 122 feet over fine sand substrate. Larvae, postlarvae, and early juveniles occur from July through November in shelf waters. Early and late juveniles are often associated with underwater structures or small burrows, but are also abundant over barren sand and mud bottoms.

Juvenile red snapper feed on shrimp, but after age one, prey primarily on fish and squid. Of the vertebrates consumed, most are not obligate reef dwellers, indicating that red snapper feed away from reefs (GMFMC, 2004). All life stages of the red snapper occur in the Gulf waters within the study area.

Gray Snapper. Gray snapper can be demersal, structure, or mid-water dwellers inhabiting marine, estuarine, and riverine habitats. They inhabit depths to about 550 feet in the Gulf. Juvenile gray snapper are common in shallow water around SAV while adult gray snapper tend to congregate in deeper Gulf waters around natural and artificial reefs. Spawning occurs in the Gulf from June to August around structures and shoals. Their eggs are pelagic and the larvae are planktonic, both occurring in Gulf shelf waters and near coral reefs. Postlarvae migrate into the estuaries and are most abundant over *Halodule* and *Syringodium* grassbeds. Juveniles seem to prefer *Thalassia* grassbeds, seagrass meadows, marl bottoms, and mangrove roots, and are found in estuaries, bayous, channels, grassbeds, marshes, mangrove swamps, ponds, and freshwater creeks (GMFMC, 2004).

Juvenile gray snapper feed on estuarine-dependent organisms such as shrimp, small fish, and crabs. Gray snapper are classified as opportunistic carnivores at all life stages (Patillo et al., 1997). In estuaries, juvenile gray snapper feed on shrimp, larval fish, amphipods, and copepods. Adult gray snapper feed

primarily on fish, but smaller individuals will prey on crustaceans (GMFMC, 2004). Only adult gray snapper are found in the Gulf waters of the study area.

Lane Snapper. Lane snapper are demersal, occurring over all substrate types, but are most commonly found near coral reefs and sandy bottoms. Spawning occurs in Gulf waters from March through September. Nursery areas include mangrove and grassy estuarine habitats in southern Texas and Florida and shallow waters with sand and mud bottoms along all Gulf states. Juvenile lane snapper appear to favor grass flats, reefs, and soft bottoms to depths of 66 feet. Adult lane snapper occur offshore in depths ranging from 13 to 433 feet near sand bottoms, natural channels, banks, and artificial and natural structures (GMFMC, 2004).

Juvenile lane snapper feed on estuarine-dependent organisms such as shrimp, small fish, and crabs. Lane snapper are considered to be unspecialized, opportunistic predators, feeding on a variety of crustaceans and fish. However, adult lane snapper tend to prefer fish (GMFMC, 2004). Juvenile lane snapper are found in estuaries and marine waters, while adults are found only in marine waters.

Greater Amberjack. Greater amberjack occur throughout the Gulf to depths of 1,300 feet. Adults are pelagic and epibenthic, occurring near reefs and artificial structures. Spawning occurs offshore, and juvenile greater amberjack are associated with floating *Sargassum* and debris (GMFMC, 2004). Adult and juvenile greater amberjack are found in the Gulf within the study area.

King Mackerel. King mackerel are pelagic and found in Gulf waters from nearshore to 655 feet. Spawning occurs in the Gulf from May to October. Eggs are pelagic, occurring over depths of 98 to 590 feet. Nursery areas are located in marine waters with juveniles only occasionally entering estuaries (GMFMC, 2004).

While estuaries are important for most of their prey, king mackerel feed on a variety of fishes, but extensively utilizing herrings. Squid, shrimp, and other crustaceans are also fed upon by king mackerel. Adult and juvenile king mackerel are found in the Gulf within the study area.

Spanish Mackerel. Spanish mackerel are pelagic, inhabiting depths to 245 feet throughout the coastal zone of the Gulf. Adult Spanish mackerel are usually found from nearshore to the edge of the continental shelf. However, they may also migrate seasonally into estuaries with high salinity, but this migration is infrequent and rare. Spawning occurs in the Gulf from May through October. Larvae typically occur in the Gulf in depths ranging from 30 to 275 feet. Juveniles inhabit the Gulf surf, and sometimes estuarine habitats. However, juvenile Spanish mackerel prefer marine salinities and are not considered estuarine-dependent. Adult and juvenile Spanish mackerel are common in Sabine Pass from June through October. Juvenile Spanish mackerel prefer clean sand bottoms, but the substrate preferences of the other life stages are unknown (GMFMC, 2004).

While Spanish mackerel rarely use estuarine environments, estuaries are important for most of their prey. They feed on a variety of fishes, but extensively utilize herrings. Squid, shrimp, and other crustaceans are also fed upon by Spanish mackerel.

Cobia. Cobia are large, pelagic fish occurring from nearshore to depths of 131 feet near artificial and natural structure, including floating objects. In the study area, cobia occur only in the Gulf and do not use estuarine waters.

While cobia rarely use estuarine environments, estuaries are important for most of their prey. They feed on a variety of fishes, but extensively utilize herrings. Squid, shrimp, and other crustaceans are also fed upon by cobia.

Gulf Stone Crab. Gulf stone crabs occur in the study area, inhabiting the Gulf and the Sabine Lake estuary. Gulf stone crab seek cover under rock ledges, coral heads, dead shell, and grass clumps. They also inhabit burrows in seagrass flats and along the sides of tidal channels. Larval Gulf stone crabs are planktonic, suspended in the water column. Juvenile Gulf stone crabs prefer seagrass flats, channels, shell bottoms, sponges, and *Sargassum* mats. Once they reach a width of 0.5 inch, they live among oyster shells and rocks in shallow estuaries. Adult and juvenile Gulf stone crabs can tolerate a range of salinity; however, larvae require salinities from 30 to 35 ppt for optimal growth. Broad fluctuations in salinity and temperature can result in high mortality of larval Gulf stone crabs (GMFMC, 2004).

Gulf stone crabs are predatory throughout their life. Juvenile Gulf stone crabs feed on polychaetes, molluscs, and crustaceans. Adult Gulf stone crabs feed mainly on oysters and mussels, but also consume dead or decaying tissue and vegetable matter such as seagrass (GMFMC, 2004).

Gulf stone crabs are dependent upon fertile estuarine waters. High phytoplankton productivity in fertile estuarine waters results in food for oysters, worms, and other organisms, which, in turn, provide food for juvenile and adult stone crabs.

3.10.2.4 Ballast Water

Ballast water is loaded on empty ships to provide weight and stability while traveling from one port to the next. There are thousands of marine species that can be carried from port to port in ballast water, which may ultimately result in the introduction of unwanted aquatic species from foreign ports of origin (Global Ballast Water Management Programme, 2002). As a consequence, invasive, exotic species have been introduced into United States waters through ballast water. Ballast water is the largest single vector for nonindigenous species transfer (EPA, 2001). The USCG does not have a list of species of concern (SOC) that could potentially be introduced through ballast water into the study area (Allen, 2002). However, the EPA has compiled a list of invasive species that have the potential to be unintentionally introduced in Texas, although not necessarily through ballast water alone (Table 3.10-6) (EPA, 2001).

The USCG, under the provisions of the National Invasive Species Act, has implemented a program that consists of a suite of mandatory ballast water management protocols. All vessels, foreign and domestic, equipped with ballast water tanks that operate within U.S. waters are required to comply with 33 CFR Part 51 regarding management protocols. This includes submitting a ballast water exchange report to the National Ballast Information Clearinghouse (NBIC) to ensure compliance with the management requirements (USCG, 2006).

Table 3.10-6
Current and Potential Aquatic Species that Pose a Threat to Texas and Louisiana

Scientific Name	Common Name	Texas	Louisiana

Source: EPA (2001).

P = Potential threat; 4 = Current threat.

* = Cryptogenic (a species whose status as indigenous or nonindigenous remains unresolved).

According to the NBIC (2007) ballast water–reporting database, between 2000 and 2005, 1,279 ballast water exchange reports were submitted for the study area. Of these, 136 represented treated and 90 represented untreated discharges. Treated discharges consisted of either flow-through or empty/refill of ballast tanks.

3.11 WILDLIFE

Wildlife native to the study area include those that inhabit the Austroriparian Biotic Province (Blair, 1950). Diversity in the study area is high, with large numbers of vertebrate and invertebrate species. The Austroriparian Biotic Province is situated in the eastern portion of Texas and extends southward to the Gulf coast and east through Louisiana to the Atlantic Ocean. The vertebrate fauna of the Austroriparian Biotic Province in Texas and Louisiana, with few exceptions, is the typical vertebrate fauna of the Austroriparian Biotic Province eastward to the Atlantic seaboard. According to Blair (1950), at least 47 species of mammals, 29 species of snakes, 10 lizards, 2 land turtles, 17 anurans, and 18 urodeles occur or have occurred there.

3.11.1 Amphibians

Amphibians common to marsh habitats within the study area are the green treefrog (*Hyla cinerea*), American bullfrog (*Rana catesbeiana*), eastern narrow-mouthed toad (*Gastrophryne carolinensis*), Great Plains narrow-mouthed toad (*G. olivacea*), Blanchard's cricket frog (*Acris crepitans blanchardi*), squirrel treefrog (*H. squirella*), bronze frog (*R. clamitans*), and the southern leopard frog (*R. sphenoccephala utricularia*).

Amphibian species that are common to the upland grasslands include the Gulf Coast toad (*Bufo nebulifer*), southern leopard frog, and the northern spring peeper (*Pseudacris crucifer crucifer*).

Amphibian species that are commonly found in forest habitats include the gray treefrog (*H. versicolor*), eastern narrow-mouthed toad, squirrel treefrog, and the Great Plains narrow-mouthed toad (Blair, 1950).

3.11.2 Birds

Avian species known to occur year-round within the study area include herons and egrets (Family Ardeidae), gulls, terns, and skimmers (Family Laridae), Anhinga (*Anhinga anhinga*), turkey vulture (*Cathartes aura*), red-tailed hawk (*Buteo jamaicensis*), eastern screech-owl (*Megascops asio*), red-bellied woodpecker (*Melanerpes carolinus*), American crow (*Corvus brachyrhynchos*), tufted titmouse (*Baeolophus bicolor*), Carolina wren (*Thryothorus ludovicianus*), northern cardinal (*Cardinalis cardinalis*), northern mockingbird (*Mimus polyglottos*), house sparrow (*Passer domesticus*), and blue jay (*Cyanocitta cristata*). Winter migrants that reside within the study area may include the long-billed curlew (*Numenius americanus*), lesser yellowlegs (*Tringa flavipes*), least sandpiper (*Calidris minutilla*), mallard (*Anas platyrhynchos*), short-billed dowitcher (*Limnodromus griseus*), cedar waxwing (*Bombycilla cedrorum*), double-crested cormorant (*Phalacrocorax auritus*), yellow-rumped warbler (*Dendroica cornata*), American coot (*Fulica americana*), white-crowned sparrow (*Zonotrichia*

leucophrys), dark-eyed junco (*Junco hyemalis*), and the American goldfinch (*Spinus tristis*). Migratory waterfowl are known to be abundant in the study area. In the northern reaches of the study area and in the forested wetlands of Pine Island Bayou, wood ducks (*Aix sponsa*) can be found perching in tree cavities. In more-shallow areas, dabbling ducks, also known as “puddle ducks,” can be found in ponded wetlands closely associated with the Neches and Sabine rivers and their tributaries. During winter, they frequent the salt marshes along the immediate coastlines. Some of these species may include northern pintail (*Anas acuta*), American wigeon (*A. americana*), Northern shoveler (*A. clypeata*), green-winged teal (*A. crecca*), cinnamon teal (*A. cyanoptera*), mallard, and gadwall (*A. strepera*). Diving ducks, ducks inhabiting deeper waters such as Sabine Lake, may include redhead (*Aythya americana*), lesser scaup (*A. affinis*), and canvasback (*A. valisineria*). Common geese found foraging in the study area’s agricultural fields and freshwater wetlands as well as roosting in salt marshes include snow goose (*Chen caerulescens*), greater white-fronted goose (*Anser albifrons*), Ross’s goose (*Chen rossii*), and Canada goose (*Branta canadensis*).

Possible transient species that may occur in the study area during winter migration are chuck-will’s-widow (*Caprimulgus carolinensis*), chimney swift (*Chaetura pelagica*), ruby-throated hummingbird (*Archilochus colubris*), eastern kingbird (*Tyrannus tyrannus*), purple martin (*Progne subis*), yellow-throated warbler (*Dendroica dominica*), and the black-and-white warbler (*Mniotilta varia*) (Lockwood and Freeman, 2004).

According to the USFWS Texas Colonial Waterbird Census (USFWS, 2007), 25 documented rookeries occur within the study area. Table 3.11-1 provides information on nesting activities at these rookeries. No documented rookeries occur within the Louisiana portion of the study area (Clark, 2009).

3.11.3 Mammals

Common mammals that inhabit forest habitats in the study area include Virginia opossum (*Didelphis virginiana*), Brazilian free-tailed bat (*Tadarida brasiliensis*), nine-banded armadillo (*Dasypus novemcinctus*), swamp rabbit (*Sylvilagus aquaticus*), eastern red bat (*Lasiurus borealis*), eastern gray squirrel (*Sciurus carolinensis*), eastern fox squirrel (*S. niger*), white-footed mouse (*Peromyscus leucopus*), eastern woodrat (*Neotoma floridana*), northern raccoon (*Procyon lotor*), striped skunk (*Mephitis mephitis*), and coyote (*Canis latrans*).

Mammals common to upland grassland habitats within the study area include the least shrew (*Cryptotis parva*), hispid pocket mouse (*Chaetodipus hispidus*), pygmy mouse (*Baiomys taylori*), coyote, nine-banded armadillo, Baird’s pocket gopher (*Geomys breviceps*), eastern cottontail (*Sylvilagus floridanus*), hispid cotton rat (*Sigmodon hispidus*), and fulvous harvest mouse (*Reithrodontomys fulvescens*).

Mammals that are common to marsh habitat areas include the northern rice rat (*Oryzomys palustris*), nutria (*Myocastor coypus*), swamp rabbit, least shrew, coyote, striped skunk, Virginia opossum, bobcat (*Lynx rufus*), Attwater’s pocket gopher (*G. attwateri*), northern raccoon, and common muskrat (*Ondatra zibethicus*) (Blair, 1950).

3.11.4 Reptiles

Reptiles known to inhabit forested habitats in the study area are the little brown skink (*Scincella lateralis*), Texas ratsnake (*Elaphe obsoleta*), rough greensnake (*Opheodrys aestivus*), eastern gartersnake (*Thamnophis sirtalis sirtalis*), Texas coralsnake (*Micrurus tener*), and southern copperhead (*Agkistrodon contortrix contortrix*).

Reptiles common to upland grassland habitats include the three-toed box turtle (*Terrapene carolina triunguis*), ornate box turtle (*Terrapene ornata ornata*), green anole (*Anolis carolinensis*), prairie lizard (*Sceloporus consobrinus*), eastern six-lined racerunner (*Aspidoscelis sexlineata sexlineata*), little brown skink, diamond-backed watersnake (*Nerodia rhombifer rhombifer*), Texas ratsnake, Texas spotted whiptail (*A. gularis gularis*), prairie kingsnake (*Lampropeltis calligaster calligaster*), Mediterranean gecko (*Hemidactylus turcicus turcicus*), Texas coralsnake, and the western diamond-backed rattlesnake (*Crotalus atrox*).

Reptiles common to marsh habitats include the diamond-backed watersnake, snapping turtle (*Chelydra serpentina*), stinkpot (*Sternotherus odoratus*), Mississippi mud turtle (*Kinosternon subrubrum*), red-eared slider (*Trachemys scripta elegans*), Texas ratsnake, speckled kingsnake (*Lampropeltis getula holbrooki*), and the western cottonmouth (*Agkistrodon piscivorus leucostoma*) (Bartlett and Bartlett, 1999).

3.11.5 Insects

Common terrestrial insects that occur within the study area include the field cricket (*Gryllus* sp.), American cockroach (*Periplaneta americana*), wheel bug (*Arilus cristatus*), leaf-footed bug (*Leptoglossus phyllopus*), dog-day cicada (*Tibicen* sp.), green lacewing (*Chrysoperla* spp.), ground beetle (*Scarites subterraneus*), June beetle (*Phyllophaga* sp.), firefly (*Photinus* sp.), blister beetle (*Epicauta* sp.), boll weevil (*Anthonomus grandis*), Asian tiger mosquito (*Aedes albopictus*), deer fly (*Chrysops* sp.), house fly (*Musca domestica*), blow fly (*Calliphora* sp.), giant swallowtail (*Heracles cressphontes*), cloudless sulphur (*Phoebis sennae eubule*), snout butterfly (*Libytheana* sp.), honey bee (*Apis mellifera*), paper wasp (*Polistes carolina*), and the red imported fire ant (*Solenopsis invicta*) (Drees and Jackman, 1998).

3.12 THREATENED AND ENDANGERED SPECIES

Congress enacted the ESA (16 USC 1531 et seq.) of 1973, as amended, to provide a program for the preservation of threatened and endangered species and to provide protection for the ecosystems upon which these species depend for their survival. All Federal agencies are required to implement protection programs for these designated species and to use their authorities to further the purposes of the ESA. An endangered species is one that is in danger of extinction throughout all or a significant portion of its range in the U.S. A threatened species is one likely to become endangered within the foreseeable future throughout all or a significant portion of its range. The USFWS and NMFS are the primary agencies responsible for implementing the ESA. The USFWS is responsible for birds and terrestrial and freshwater species, while the NMFS is responsible for nonbird marine species.

The State of Texas also has regulations to protect endangered species (chapters 67, 68, and 88 of the TPWD Code and sections 65.171–65.184 and 69.01–69.14 of Title 31 of the Texas Administrative Code). These regulations, administered by the TPWD, prohibit commerce in threatened and endangered plants and wildlife and the collection of listed plant species from public land without a permit. In addition, the State of Louisiana, through the LDWF, provides protective status for all threatened and endangered species listed by the USFWS and also to those species listed as threatened or endangered by the State Natural Heritage Program. This assessment addresses State-listed threatened and endangered species; however, the ESA does not protect these species.

Only those species that the USFWS or NMFS lists as threatened and endangered have complete Federal protection under the ESA. Inclusion on the following lists does not imply that a species occurs in the study area, but only acknowledges the potential for occurrence. The USACE prepared a Biological Assessment (BA) to evaluate the potential impacts the SNWW CIP may have on federally listed threatened and endangered species (Appendix G1). The NMFS (n.d.), TPWD's Natural Diversity Database (NDD, 2005a, 2005b), TPWD (2010), and USFWS (2005c, 2009) provided county/parish-level lists of threatened and endangered species of potential occurrence in the study area (Table 3.12-1). In addition, NDD (2006) provided digital map data presenting specific locations of listed species within the study area.

Table 3.12-1
Threatened and Endangered Species¹ of Potential Occurrence
Within the Study Area

Common Name ²	Scientific Name ²	Status ³

¹ According to USFWS (2009), NMFS (n.d.), NDD (2005a, 2005b, 2006), and TPWD (2010).

² Nomenclature and taxonomic orders follow American Ornithologists' Union (AOU, 1998, 2000, 2002, 2003, 2004, 2005, 2006, 2007), Crother et al. (2000, 2001, 2003), Baker et al. (2003), Hubbs et al. (2008), NMFS (n.d.), USFWS (2009), TPWD (2010), and NDD (2005a, 2005b).

³ E = Endangered; species in danger of extinction throughout all or a significant portion of its range; T = Threatened; species which is likely to become endangered within the foreseeable future throughout all or a significant portion of its range; T/SA = Threatened because of similarity of appearance to other listed species; CH = Critical Habitat; SOC = Species of Concern (NMFS); species for which there is some information showing evidence of vulnerability, but not enough data to support listing at this time. These species are afforded no formal protection under the Endangered Species Act of 1973, as amended, but may be protected under other State or Federal laws; DL = Formerly listed as threatened or endangered, but due to significant population increases, has officially been removed from threatened or endangered status.

⁴ Recently removed from the Federal list of endangered and threatened species, the brown pelican, the peregrine falcon, and bald eagle retain their state status (74 FR 220:59443–59472; 64 FR 164:46542–46558; 72 FR 130:37346–37372). The brown pelican roosts and nests on islands and spill banks, the peregrine falcon is a statewide migrant in Texas, and bald eagles overwinter on several central Texas lakes (TPWD, 2010).

3.12.1 Insects

No federally listed threatened or endangered insect SOC potentially occur within the study area.

3.12.2 Flora

No federally listed threatened or endangered plant species or plant SOC potentially occurs within the study area.

3.12.3 Fauna

According to the NMFS (n.d), USFWS (2005c, 2009), NDD (2005a, 2005b), and TPWD (2010), 33 federally and/or State-listed threatened and endangered species, and 7 NMFS-designated SOC are of potential occurrence in Jefferson and Orange counties, Texas, and Calcasieu and Cameron parishes, Louisiana (see Table 3.12-1).

Twenty of the 40 species listed in Table 3.12-1 are federally listed as threatened and endangered. These include the endangered red-cockaded woodpecker (*Picoides borealis*), red wolf (*Canis rufus*), sei whale (*Balaenoptera borealis*), blue whale (*B. musculus*), finback whale (*B. physalus*), humpback whale (*Megaptera novaeangliae*), sperm whale (*Physeter macrocephalus*), West Indian manatee (*Trichechus manatus*), leatherback sea turtle (*Dermochelys coriacea*), loggerhead sea turtle (*Caretta caretta*), hawksbill sea turtle (*Eretmochelys imbricata*), Kemp's Ridley sea turtle (*Lepidochelys kempii*), green sea turtle (*Chelonia mydas*), and smalltooth sawfish (*Pristis pectinata*), as well as the threatened, piping

plover (*Charadrius melodus*), Louisiana black bear (*Ursus americanus luteolus*), Gulf sturgeon (*Acipenser oxyrinchus desotoi*), elkhorn coral (*Acropora palmata*), and staghorn coral (*A. cervicornis*). The USFWS lists the black bear (*U. americanus*) as threatened, only because of its similarity in appearance to the Louisiana subspecies of black bear. This designation, however, only applies within the historic range of the Louisiana black bear and not elsewhere.

Thirteen of the 40 species listed in Table 3.12-1 are identified by the TPWD as State-listed threatened species in Texas. These include brown pelican (*Pelecanus occidentalis*), peregrine falcon (*Falco peregrinus*), bald eagle (*Haliaeetus leucocephalus*), reddish egret (*Egretta rufescens*), white-faced ibis (*Plegadis chihi*), wood stork (*Mycteria americana*), swallow-tailed kite (*Elanoides forficatus*), sooty tern (*Onychoprion fuscatus*), Rafinesque's big-eared bat (*Corynorhinus rafinesquii*), Texas horned lizard (*Phrynosoma cornutum*), northern scarletsnake (*Cemophora coccinea copei*), timber rattlesnake (*Crotalus horridus*), and alligator snapping turtle (*Macrochelys temminckii*).

Seven of the 40 species listed in Table 3.12-1 are identified by NMFS as SOC: dusky shark (*Carcharhinus obscurus*), sand tiger shark (*Carcharias taurus*), night shark (*C. signatus*), saltmarsh topminnow (*Fundulus jenkinsi*), Warsaw grouper (*Epinephelus nigritus*), speckled hind (*E. drummondhayi*), and ivory tree coral (*Oculina varicosa*). These species do not receive Federal protection under the ESA.

3.12.3.1 Birds

The historic range of the red-cockaded woodpecker (endangered) included 34 east Texas counties. Currently, only 18 Texas counties support this species (Jackson, 1994; USFWS, 1995). Old-growth pines (60 to 70 years or more), often with the centers rotted by red-heart fungus, are the usual nesting sites, but younger, uninfected pines are also used (Hooper et al., 1980; Jackson, 1994). No known current populations occur in any of the study area counties or parishes, and suitable habitat is absent in the study area. Thus, the species is unlikely to occur in the study area.

The piping plover (threatened) is a small shorebird that inhabits coastal beaches and tidal flats. Approximately 35 percent of the known global population of piping plovers winters along the Texas Gulf Coast, where they spend 60 to 70 percent of the year (Campbell, 1995; Haig and Elliott-Smith, 2004). The piping plover population that winters in Texas breeds on the northern Great Plains and around the Great Lakes. The species is a common migrant and rare to uncommon winter resident on the upper Texas coast (Lockwood and Freeman, 2004; Richardson et al., 1998). The USFWS has designated critical habitat for the species in its nesting and wintering range (65 FR 41781–41812). Designation of critical habitat became final on July 10, 2001 (66 FR 36038–36143). Within Louisiana, the USFWS has designated critical wintering habitat for the piping plover along the entire shoreline from the east side of Sabine Pass (Texas-Louisiana border) east approximately 16 miles to the west end of Constance Beach (Unit LA 1, in part). No USFWS-designated Critical Habitat for the piping plover is present within the Texas portions of the project area.

The USFWS recently removed the peregrine falcon, the brown pelican, and the bald eagle from the Federal list of threatened and endangered species, but the Arctic subspecies (*F. p. tundrius*) and the bald eagle retain their State-listed status of threatened in Texas. The brown pelican retains its State-listed status of endangered in Texas. The Arctic subspecies of peregrine falcon is an uncommon migrant statewide and an uncommon winter resident along the Texas Gulf Coast, where it typically occurs near bays and estuaries (Lockwood and Freeman, 2004). Peregrine falcons may occur within the study area during migration; however, no suitable nesting or wintering habitat is present in the study area. NDD (2006) indicates no documented records from the study area; however, the species may occur in winter or as a transient during migration.

The brown pelican is a common resident along the Texas Gulf Coast, occasionally wandering inland during postbreeding in late summer and fall (Lockwood and Freeman, 2004). Brown pelicans breed on barrier, natural estuarine, or dredged material placement islands (Shields, 2002). Richardson et al. (1998) list the species as an abundant year-round resident on the upper Texas coast, which includes Jefferson County, Texas. Shields (2002) indicates that the species is a winter resident along the western Louisiana coast, but does not breed there. Brown pelicans are unlikely to nest in the study area, but are present throughout most of the year. In 2009, the USFWS removed the brown pelican from the list of threatened and endangered wildlife (74 FR 220; 59443–59472; December 17, 2009); however, the brown pelican still receives Federal protection under the Migratory Bird Treaty Act.

The bald eagle is present year-round in Texas and may be found breeding, wintering, and during migration. In Texas, bald eagles breed along the Gulf Coast and on major inland lakes and reservoirs. Additional numbers of bald eagles winter in these habitats. Bald eagles prefer large bodies of water surrounded by tall trees or cliffs, which they use as nesting sites. In 2007, the USFWS removed the bald eagle from the list of threatened and endangered wildlife (72 FR 130; 37345–37372; July 9, 2007); however, the bald eagle still receives Federal protection under provisions of the Bald and Golden Eagle Protection Act and the Migratory Bird Treaty Act. This species may be present within the study area.

The reddish egret (State threatened) is a common resident along the Texas coast. This species inhabits saline and freshwater habitats in all coastal counties, although it is more numerous southward. The reddish egret is also a rare postbreeding visitor over most of Texas, south of the Panhandle (Oberholser, 1974). It is possible that this species may occur within the study area in areas containing appropriate habitat.

The white-faced ibis (State threatened) is a medium-sized wading bird that inhabits freshwater marshes, sloughs, and irrigated rice fields, but also frequents brackish and saltwater habitats. White-faced ibis are permanent residents along the Texas Gulf Coast; however, nesting records exist for many scattered inland localities (Lockwood and Freeman, 2004; Ryder and Manry, 1994). The species is a common migrant/summer resident and uncommon winter resident on the upper Texas coast (Richardson et al., 1998). NDD (2006) indicates no documented records within the study area; however, the species is likely present year-round in the general area.

The wood stork (State threatened) is an uncommon to locally common postbreeding visitor to coastal Texas and inland waters in east and central Texas (Lockwood and Freeman, 2004). Wood storks historically bred in North America along the Gulf Coast from east Texas to Florida, but their range has significantly declined since the 1960s and their North American breeding range is now restricted to Florida, Georgia, and South Carolina (Coulter et al., 1999; Oberholser, 1974). In Texas, wood storks typically occur near freshwater or saltwater wetlands, lakes, or along rivers and streams. The USFWS lists the wood stork as federally endangered in Florida, Alabama, Georgia, North Carolina, and South Carolina, but not in Texas. Wood storks are uncommon to common in summer and fall along the upper Texas coast (Richardson et al., 1998). The species likely occurs in the study area during summer and fall.

The swallow-tailed kite (State threatened) is a medium-sized raptor that historically occurred along the coastal plains, interior lowlands, and riparian areas throughout the southeastern U.S. and Mississippi River Valley, west to central Texas (Meyer, 1995). Beginning in the late 1800s and early 1900s, this species' U.S. range dramatically decreased, likely because of forestry practices, which resulted in the loss of tall trees used for nesting. Today, swallow-tailed kites breed primarily in Florida, with scattered breeding populations in South Carolina, Georgia, Alabama, Mississippi, Louisiana, and southeastern Texas (Meyer, 1995). In Texas, the species is a rare to uncommon migrant throughout the eastern third of the state, with occasional migration records west to the eastern Edwards Plateau (Lockwood and Freeman, 2004). The species is a rare migrant in the study area, with the majority of records occurring between April and June (Richardson et al., 1998; Shackelford and Simons, 2000). NDD (2006) indicates no records within the study area; however, Shackelford and Simons (2000) indicate recent records of migrating birds, and the species may occur in the study area as a migrant.

The sooty tern (State threatened) is a largely pelagic (open ocean) species that nests on isolated tropical and subtropical islands (Schreiber et al., 2002). The species is a rare and local summer resident along the middle and lower Texas Gulf Coast from Matagorda County to Cameron County, where they nest in small numbers on natural and spoil islands, particularly in the Laguna Madre (Lockwood and Freeman, 2004; Oberholser, 1974). Sooty terns are rare in summer along the upper Texas coast (Richardson et al., 1998). It is unlikely that this oceanic species would regularly occur in the study area; however, their occurrence is possible.

3.12.3.2 Terrestrial Mammals

The red wolf (endangered) formerly inhabited a variety of wooded habitats including pine forests, bottomland hardwood forests, swamps, marshes, and coastal prairies (Schmidly, 2004). Most authorities consider the species extirpated, and red wolves are unlikely to occur in the study area.

The TPWD lists the Louisiana black bear (threatened) as a potentially occurring species in the study area, along with the black bear, because of its similarity in appearance to the Louisiana subspecies. The Louisiana black bear historically inhabited east Texas, Louisiana, and southern Mississippi, but now occurs only in small numbers in Mississippi and Louisiana (USFWS, 1992). The last Texas Pineywoods record of native black bear is from the late 1950s, near the town of Livingston in Polk County (Fleming,

1980). There are periodic reports of black bears from various counties of east Texas; however, these bears most likely represent individuals dispersing from neighboring areas in Louisiana (Taylor, 2000). According to Garner (1995), no recent documented sightings of black bears exist from the Texas Gulf Coast. It is unlikely that either subspecies of black bear would occur in the study area.

Rafinesque's big-eared bat (State threatened) occurs eastward from the Pineywoods of Texas throughout the southeastern U.S. This species roosts most frequently in hollowed trees, beneath bark, and under leaf litter, but often roosts in man-made structures such as buildings, wells, and barns (Schmidly, 1991, 2004). According to Schmidly (2004), documented records exist from Jefferson County, and the species may occur in the study area where appropriate habitat occurs.

3.12.3.3 Aquatic Mammals

NMFS identifies five endangered whale species of potential occurrence in the Gulf. These are the sei whale, blue whale, finback (or fin) whale, humpback whale, and sperm whale. These species are generally restricted to deeper offshore waters; therefore, it is unlikely that any of these five species would regularly occur in the study area (NMFS, 2003).

The West Indian (endangered) manatee historically inhabited the Laguna Madre, Gulf, and tidally influenced portions of rivers. It is currently, however, extremely rare in Texas waters, and the most recent sightings are likely individuals migrating or wandering from Mexican waters. Historical records from Texas waters include Cow Bayou, Sabine Lake, Copano Bay, the Bolivar Peninsula, and the mouth of the Rio Grande (Schmidly, 2004). In May 2005, a live manatee was photographed in the Laguna Madre near Port Mansfield (Blankinship, 2005). The West Indian manatee is chiefly a marine species; however, its occurrence in the study area is unlikely.

3.12.3.4 Reptiles

The leatherback sea turtle (endangered) is probably the most-wide-ranging of all sea turtle species. It occurs in the Atlantic, Pacific, and Indian oceans; as far north as British Columbia, Newfoundland, Great Britain, and Norway; as far south as Australia, Cape of Good Hope, and Argentina; and in other waterbodies such as the Mediterranean Sea (National Fish and Wildlife Laboratory [NFWL], 1980). The leatherback is mainly pelagic, inhabiting the open ocean, and seldom approaches land except for nesting (Eckert, 1992) or when following concentrations of jellyfish (TPWD, 2006), when it can be found in inshore waters, bays, and estuaries. It dives almost continuously, often to great depths. Leatherbacks nest primarily in tropical regions and only sporadically along the Atlantic and Gulf coasts of the continental U.S., with one nesting reported as far north as North Carolina (Schwartz, 1976). In the Atlantic and Caribbean, the largest nesting assemblages occur in the U.S. Virgin Islands, Puerto Rico, and Florida (NMFS, 2006a). No nests of this species have been recorded in Texas for at least 70 years (National Park Service [NPS], 2006); the last two, one from the late 1920s and one from the mid-1930s, were both from Padre Island (Hildebrand, 1982, 1986). Apart from occasional feeding aggregations such as the large one of 100 animals reported by Leary (1957) off Port Aransas in December 1956, or possible concentrations in the Brownsville Eddy in winter (Hildebrand, 1983), leatherbacks are rare along the Texas coast,

tending to keep to deeper offshore waters where their primary food source, jellyfish, occurs (NMFS and USFWS, 1992). There are no records of sea turtles nesting on Louisiana Point or anywhere in that area (Firmin, 2006), but documented records of leatherbacks exist from Jefferson County, Texas (Dixon, 2000); however, the species is unlikely to occur in the project area since only one has been captured by a relocation trawler (1.5 miles offshore of Aransas Pass), and there is no record of a take by a hopper dredge (NMFS, 2003).

The hawksbill sea turtle (endangered) is circumtropical, occurring in tropical and subtropical seas of the Atlantic, Pacific, and Indian oceans (Witzell, 1983). This species is probably the most tropical of all marine turtles, although it does occur in many temperate regions. The hawksbill sea turtle is widely distributed in the Caribbean Sea and western Atlantic Ocean, with representatives of at least some life history stages regularly occurring in southern Florida and the northern Gulf (especially Texas), south to Brazil (NMFS, 2006a). The hawksbill sea turtle generally inhabits coastal reefs, bays, rocky areas, passes, estuaries, and lagoons, where it occurs at depths of less than 70 feet. Like some other sea turtle species, hatchlings are sometimes found floating in masses of marine plants (e.g., sargassum rafts) in the open ocean (NFWL, 1980). In the continental U.S., the hawksbill sea turtles largely occur in Florida where they are sporadic at best. In 1998 the first hawksbill sea turtle nest recorded on the Texas coast was found at Padre Island National Seashore. This nest remains the only documented hawksbill sea turtle nest on the Texas coast (NPS, 2006; Shaver 2006). Elsewhere in the western Atlantic, hawksbills nest in small numbers along the Gulf Coast of Mexico, the West Indies, and along the Caribbean coasts of Central and South America (Musick, 1979). Texas is the only state outside of Florida where hawksbills are encountered with any regularity. Most of these sightings involve posthatchlings and juveniles, and are primarily associated with stone jetties. These small hawksbill sea turtles are believed to originate from nesting beaches in Mexico (NMFS, 2006a). There are no records of hawksbill sea turtles nesting on Louisiana Point or anywhere in that area (Firmin, 2006); no documented records of hawksbill sea turtles exist from Jefferson or Orange counties, Texas (Dixon, 2000), and they are not expected to be present in the project area.

The Kemp's ridley sea turtle (endangered) inhabits shallow coastal and estuarine waters, usually over sand or mud bottoms. Adults are primarily restricted to the Gulf, although juveniles may range throughout the Atlantic Ocean since they have been observed as far north as Nova Scotia (Musick, 1979) and in coastal waters of Europe (Brongersma, 1972). Almost the entire population of Kemp's ridley sea turtles nests on an 11-mile stretch of coastline near Rancho Nuevo, Tamaulipas, Mexico, approximately 190 miles south of the Rio Grande. Sporadic nesting has been reported from Mustang Island, Texas, southward to Isla Aquada, Campeche. Kemp's ridley sea turtles occur in Texas in small numbers and in many cases may well be in transit between crustacean-rich feeding areas in the northern Gulf and breeding grounds in Mexico. It has nested sporadically in Texas in the last 50 years. The number of nestings in Texas, however, has increased over the last decade from 4 nests in 1995 to 51 nests in 2005, 28 of which were from the Padre Island National Seashore (NPS, 2006; Shaver, 2006). Several of the ridley nests were from headstarted individuals. Such nestings, together with the proximity of the Rancho Nuevo rookery, probably account for the occurrence of hatchlings and subadults in Texas. Between 1996

and 2005, maintenance dredging in the Sabine Pass Entrance Channel by hopper dredges resulted in the lethal take of a Kemp's ridley sea turtle in 1997 (Rob Hauch, pers. comm., 2006). In 2006, maintenance dredging in the Sabine Bank Channel resulted in the lethal take of one Kemp's ridley sea turtle (USACE, 2006c). The species is of potential occurrence in the project area.

The loggerhead sea turtle (threatened) is widely distributed in tropical and subtropical seas, occurring in the Atlantic Ocean from Nova Scotia to Argentina, the Gulf of Mexico, the Indian and Pacific oceans (although it is rare in the eastern and central Pacific), and the Mediterranean Sea (Iverson, 1986; Rebel, 1974; Ross, 1982). In the continental U.S., loggerhead sea turtles nest along the Atlantic coast from Florida to as far north as New Jersey (Musick, 1979) and sporadically along the Gulf coast, including Texas. Like the worldwide population, the population of loggerhead sea turtles in Texas has declined. The loggerhead is the most abundant turtle in Texas marine waters, preferring shallow inner continental shelf waters and occurring only very infrequently in the bays. It is often seen around offshore oil rig platforms, reefs, and jetties. Loggerhead sea turtles are probably present year-round but are most noticeable in the spring when one of their food items, the Portuguese man-o-war, is abundant. Loggerheads constitute a major portion of the dead or moribund turtles washed ashore (stranded) on the Texas coast each year. Most of these deaths are the result of accidental capture by shrimp trawlers, where caught turtles drown and their bodies dumped overboard. In 1999, two loggerhead sea turtle nests were confirmed in Texas, while in 2000, five loggerhead sea turtle nests were confirmed (Shaver, 2000). For the last 5 years, up to five loggerhead sea turtle nest per year have been recorded from the Texas coast (Shaver, 2006). Between 1996 and 2005, maintenance dredging in the Sabine Pass Entrance Channel by hopper dredges resulted in the lethal take of a loggerhead sea turtle in 2002 (Rob Hauch, pers. comm., 2006). The species is of potential occurrence in the project area.

The green sea turtle (threatened) is a circumglobal species in tropical and subtropical waters. In U.S. Atlantic waters, it occurs around the U.S. Virgin Islands, Puerto Rico, and continental U.S. from Massachusetts to Texas. Major nesting activity occurs on Ascension Island, Aves Island (Venezuela), Costa Rica, and in Surinam. Relatively small numbers nest in Florida, with even smaller numbers in Georgia, North Carolina, and Texas (Hirth, 1997; NMFS and USFWS, 1991a, 1991b). The green sea turtle in Texas inhabits shallow bays and estuaries where its principal foods, the various marine grasses, grow (Bartlett and Bartlett, 1999). While green sea turtles prefer to inhabit bays with seagrass meadows, they may also be found in bays that are devoid of seagrasses. The green sea turtles in these Texas bays are mainly small juveniles. Adults, juveniles, and even hatchlings are occasionally caught on trotlines or by offshore shrimpers or are washed ashore in a moribund condition. Green turtle nests are rare in Texas. Five nests were recorded at the Padre Island National Seashore in 1998, none in 1999, and one in 2000 (Shaver, 2000). For the last 5 years, up to five nests per year have been recorded from the Texas coast (Shaver, 2006). Since long migrations of green sea turtles from their nesting beaches to distant feedings grounds are well documented (Green, 1984; Meylan, 1982), the adult green sea turtles occurring in Texas may be either at their feeding grounds or in the process of migrating to or from their nesting beaches. The juveniles frequenting the seagrass meadows of the bay areas may remain there until they move to other feeding grounds or, perhaps, once having attained sexual maturity, return to their natal beaches outside of

Texas to nest. There are no records of green sea turtles nesting on Louisiana Point or anywhere in that area (Firmin, 2006), but documented records of green sea turtles exist from Jefferson County, Texas (Dixon, 2000). It is of potential occurrence in the project area.

The Texas horned lizard (State threatened) occurs throughout the western two-thirds of the state in a variety of habitats, but prefers arid to semiarid habitats in sandy loam or loamy sand soils that support patchy bunch-grasses, cacti, yucca, and various shrubs (Dixon, 2000; Henke and Fair, 1998). Dixon (2000) shows historic records from the study area; however, because of the limited terrestrial habitat, it is unlikely they would occur in the study area.

The Northern scarletsnake (State threatened) inhabits loose, sandy soil of pine, hardwood, and mixed forest environments as well as adjacent open, agricultural fields, swamps, and stream banks of extreme east Texas (Tennant, 1998). Dixon (2000) shows historic records from the study area; however, because of the limited terrestrial habitat, it is unlikely they would occur in the study area.

The timber rattlesnake (State threatened) typically inhabits dense thickets and brushy areas along the floodplains of major creeks and rivers throughout the eastern third of Texas. It occurs in a variety of habitats including floodplains and riparian areas, swamps, upland pine and deciduous woodlands, abandoned farmland, and limestone bluffs (Werler and Dixon, 2000). This rattlesnake is most active during the summer and fall, with some activity noted in spring and as late as December (Werler and Dixon, 2000). Documented records exist from Jefferson County, Texas (Dixon, 2000); however, it is unlikely the species would occur in the study area because of the lack of suitable habitat.

The alligator snapping turtle (State threatened) is the largest North American freshwater turtle species. Alligator snapping turtles inhabit deep rivers, lakes, and large streams of the southeastern U.S. (Garrett and Barker, 1987). Documented records exist from Jefferson and Rusk counties, Texas (Dixon, 2000), but the species is unlikely to occur in the study area because of the lack of suitable habitat.

3.12.3.5 Fish and Amphibians

The smalltooth sawfish (endangered) historically was common throughout the Gulf from Texas to Florida, and along the east coast from Florida to Cape Hatteras. The current range of this species has contracted to peninsular Florida, and smalltooth sawfish are relatively common only in the Everglades region at the southern tip of the state. Smalltooth sawfish are usually found in shallow (typically less than 33 feet), warm (water temperatures exceeding 61°F) coastal waters, close to shore, over muddy and sandy bottoms. The most recent verified report of a smalltooth sawfish from Texas waters was in 1998. Since the smalltooth sawfish prefer shallow water, it is unlikely they would be encountered in the project areas that would be dredged.

The Gulf sturgeon (threatened) historically ranged along the northeastern Gulf, in major rivers from the Mississippi delta in Louisiana, east to Charlotte Harbor, Florida, and in marine waters of the central and eastern Gulf (NMFS, 2006b; USFWS and Gulf States Marine Fisheries Commission [GSMFC], 1995). Its current range extends from Lake Pontchartrain and the Pearl River in Louisiana and Mississippi east to

the Suwannee River in Florida. Sporadic records exist from as far west as the Rio Grande between Texas and Mexico, and as east and south as Florida Bay. As with other sturgeon species, the damming of rivers has been the most significant threat to the Gulf sturgeon (NMFS, 2006b). The study area is not within the known historic range of the Gulf sturgeon. Fish are mobile species and frequently occur outside of their normal ranges; however, it is unlikely that the species is present in the study area.

The dusky shark (SOC) is a large shark with a wide-ranging distribution in warm-temperate and tropical continental waters. It is coastal and pelagic in its distribution, where it occurs from the surf zone to well offshore. Habitat for this species does exist in the project area.

The sand tiger shark (SOC) has a broad inshore distribution. In the western Atlantic, this shark occurs from the Gulf of Maine to Florida, in the northern Gulf, in the Bahamas and in Bermuda. They are generally coastal, usually being found in the surf zone down to depths around 75 feet. They may also be found in shallow bays. They usually live near the bottom, but may be found throughout the water column. Their biggest threat is overfishing. Habitat for this species may exist in the project area.

The night shark (SOC) is a deepwater shark reported in waters from Delaware south to Brazil, including the Gulf. This shark is usually found at depths greater than 900 to 1,200 feet during the day and 600 feet at night. Habitat for this shark does not exist in the project area.

The saltmarsh topminnow (SOC) is endemic to the north-central coast of the Gulf from Galveston Bay eastward to western Florida. They tend to live in salt marshes and brackish water. This species requires shallow flooded marsh surfaces for breeding and feeding. Coastal erosion and loss of marsh is thought to be the greatest threat to this species. It is possible that this species occurs in the project area.

The Warsaw grouper (SOC) is a very large fish found in the deepwater reefs of the southeastern U.S. This fish ranges from North Carolina to the Florida Keys and throughout much of the Caribbean and Gulf to the northern coast of South America. This species inhabits deepwater reefs on the continental shelf break in waters 350 to 650 feet deep. Habitat for this species does not exist in the project area.

The speckled hind (SOC) inhabits warm, moderately deep waters from North Carolina to Cuba, including Bermuda, the Bahamas, and the Gulf. The preferred habitat is hard-bottom reefs in depths ranging from 150 to 300 feet. Habitat for this species does not exist in the project area.

3.12.3.6 Invertebrates

Elkhorn coral was listed as threatened on May 9, 2006 (71 FR 26852) and is found on coral reefs in southern Florida and the Bahamas, and throughout the Caribbean. Its northern limit is Biscayne National Park, Florida. This species is particularly susceptible to damage from sedimentation. Neither the project area nor the study area is located within the historical range for this species, nor does suitable habitat exist in the project vicinity.

Staghorn coral was listed as threatened on May 9, 2006 (71 FR 26852) and is found throughout the Florida Keys, the Bahamas, and the Caribbean islands. This coral occurs in the western Gulf, but it is absent from U.S. waters in the Gulf. Neither the project area nor the study area is located within the historical range for this species, nor does suitable habitat exist in the project vicinity.

Colonies of ivory tree coral (SOC) are found to depths of 500 feet on substrates of limestone rubble, low-relief limestone outcrops, and high-relief, steeply sloping prominences. The project area is not located within the historical range for this species, nor does suitable habitat exist in the project vicinity.

3.13 CULTURAL RESOURCES

Archival and historical research was conducted to develop a baseline level of knowledge for prehistoric and historic period cultural developments and to identify archeological and historical sites previously recorded in the SNWW project area. Among the research efforts, a review of published historical literature and previous archeological investigation reports yielded information useful for developing a general chronology of cultural developments across the region. Also, archeological reports and official site records maintained by State historic preservation offices in Texas and Louisiana were relied upon to identify previously recorded archeological and historical sites in the project area. Other sources of information included official industrial and agricultural census data as well as historical maps of the area prior to 1900 through 1955.

Cultural resources found in the project vicinity are generally of the following common types. Terrestrial prehistoric sites typically found in the SNWW CIP project vicinity consist of eroded or partially eroded prehistoric shell midden sites. The majority of shell middens are located along the main waterways, oxbows, and near the coast. Approximately 80 percent of these sites are comprised primarily of shells from the brackish-water clam (*Rangia cuneata*) mixed with sparse pottery shards and faunal food remains. Some sites located closer to the coast also contain shells from the eastern oyster. Historic terrestrial sites in the project vicinity are related primarily to Civil War military forts and outposts, although a few National Register structures such as the Sabine Pass Lighthouse and the Rainbow Bridge, are also present. The most typical marine sites in the project area are Civil War shipwrecks.

3.13.1 Prehistoric Chronology and Historic Context

3.13.1.1 Prehistoric Chronology

The prehistoric chronology of the Sabine Lake area is not well understood, as the area has received only limited testing (Aten, 1983). However, since the current project area is a part of the upper Texas coast, the three-phased chronological sequence that was developed for that region (Paleoindian to Archaic to Late Prehistoric) can be employed, with each transition marked by significant adaptations in technology and settlement patterns. Chronological designations are Before the Common Era (B.C.E.) and Common Era (C.E.) as per the *American Anthropological Association Style Guide* (2009).

Paleoindian (10,000 B.C.E. to 8000 B.C.E.) populations ranged over most of North America by the end of the Pleistocene. In the northern Gulf region, the Paleoindian culture is identified by the occurrence of large lanceolate, fluted projectile points. Typically, Paleoindian sites are considered to reflect low-density populations and hunter-gatherer subsistence strategies.

The Archaic period (6000 B.C.E. to C.E. 700) is typically subdivided into four components; the Early Archaic (6000 B.C.E. to 2500 B.C.E.), the Middle Archaic (2500 B.C.E. to 1000 B.C.E.), the Late Archaic (1000 B.C.E. to 300 B.C.E.), and the Transitional Archaic (300 B.C.E. to C.E. 700). Evidence of the Early Archaic is scarce along the upper Texas coast, due to either a decrease in human population or the lack of stratified excavations (Story et al., 1990).

Although there is a dearth of information on the Early Archaic along the upper Texas coast, other areas in North America have produced data pointing to a generalized hunting and gathering technology and a minimum band level social organization. Ricklis and Blum (1997) hypothesized that coastal sites were frequented during the winter months as part of a seasonal exploitation pattern.

Coastal sites and shell middens become more frequent during the Middle Archaic, expressing a unique subsistence activity. The Middle Archaic populations displayed a more involved method of seasonal exploitation, as documented by Voellinger (1990) at 41GV22. Evidence found at this site indicates early spring exploitation.

A hunting and gathering pattern of subsistence continued during the Late Archaic in Texas, with pre-Caddo sites marking the beginning of settled village life shortly after 500 B.C.E. in parts of East Texas, as well as a marked rise in bison exploitation as a game resource, as reflected in bison-kill sites in Central Texas.

The Transitional Archaic is marked by an increase in settlement sites, often having large burial mounds. Such sites mark the introduction of, and reliance upon, agriculture that leads to population growth and the emergence of social and political systems (Turner and Hester, 1985).

The Late Prehistoric period (C.E. 700 to C.E. 1600) is marked by the emergence of ceramics and terminates with European contact and interaction. While Aten (1983) has identified six chronological Late Prehistoric periods in the Galveston Bay area, he notes that the Sabine Lake area lacks sufficient controlled excavations to place it within this chronological sequence.

3.13.1.2 Historic Context

European interest in the coastal areas of Texas began almost as soon as the first Spanish explorers landed on the mainland of North America in 1513. Shortly thereafter, the Spanish crown began granting contracts to private investors to colonize and explore the new territory. One expedition led by a Spaniard Panfilo de Narváez ended in disaster. It is due to this unfortunate expedition that we have the earliest report of Europeans coming ashore in the vicinity of Sabine Pass (Weddle, 1985).

European activity in the region decreased over the next 100 years. It was not until the French explorer Rene Robert Cavalier, Sieur de La Salle entered Spanish territory in the northern Gulf in the late seventeenth century that the Spanish government hastened plans to colonize the area. The French continued to visit the region as they explored, established posts, and traded goods as far east as the Trinity River during the late 1600s and 1700s (Bolton, 1970). The early French and Spanish explorers relied on the Sabine and Neches rivers as their principal transportation route.

In 1763, Spain was given the Louisiana Territory by Louis XV of France; however, by 1802 the Spanish crown relinquished control of the Louisiana Territory back to France due to the territory's increasing demands on Spain's resources (Haggard, 1945). Less than 1 year later, Napoleon sold the territory to the United States.

With Louisiana in the hands of the U.S., Spain had a new problem at their border. The close proximity between Spanish and U.S. troops in the area of the Sabine River led to a great deal of tension and brought about an agreement between the two sides in 1806, whereby a strip of land was defined between the two countries that neither would rule. The land called the "Neutral Strip" extended between the Sabine River eastward to the Arroyo Hondo and from the Gulf to the 32nd parallel. The Neutral Strip was a wild ungoverned area open to smuggling, slave trade, and other criminal activity. The area also was the staging ground for military expeditions against Spanish Texas by ostensibly freelance organizations called filibusters (Haggard, 1945).

The Neutral Strip was abolished by the Adams-Onis Treaty of February 1821 whereby Spain relinquished its claims on the Sabine and Neches river area (Gibson et al., 1978). The treaty was ratified by the Mexican government that same year. Also in 1821, the Treaty of Cordova transferred Spanish Texas to the Republic of Mexico (Block, 1976). The land subsequently became a part of the Republic of Texas in 1836, at which time the Republic of Texas and the U.S. encouraged trade across the border formed by the Sabine River.

Goods were moved along the Sabine and Neches rivers as early as 1830 due to the economics of river versus overland transport (Chick, 1988). Settlement and economic use of the region increased from the early days of the Texas Republic through early statehood, and the rivers continued to be used as the primary transportation route until the Civil War.

After Texas's decision to secede from the Union on February 1, 1861, Sabine Pass became an important source of revenue and supplies for the Confederacy. Blockade-runners could operate virtually undetected out of Sabine Pass, shipping large amounts of cotton and other supplies to foreign markets and returning with coffee, sugar, munitions, and medical supplies. The U.S. recognized the importance of Sabine Pass to the Confederacy, and it soon became a focal point for the Union blockade of the Texas Gulf Coast.

Fearing a Union invasion during the Civil War, the citizens of Sabine Pass decided to build a fort to protect their town. Local residents, including many slaves, constructed a dirt and timber earthwork overlooking the Sabine River. On September 24, 1862, the fort was shelled by Union gunboats and

severely damaged. The following March, Major Josephus S. Irvine determined that the site was no longer useful (Block, 1976).

A new fort, Fort Griffin, was constructed a few miles away. With 30 engineers and 500 slaves, Major Julius Kellersberg constructed a triangular fort on an eminence overlooking the Sabine River. The fort was named for the commander of the Twenty-first Texas Battalion, Colonel William H. Griffin (Block, 1976).

Located across Sabine Pass opposite Fort Griffin, the Sabine Pass Lighthouse, which began operation in 1857, was an ideal observation post for the Confederate forces during the Battle of Sabine Pass. In September 1863, four Union gunboats leading a strong amphibious invasion force attacked Fort Griffin. At the Battle of Sabine Pass, Lieutenant Richard Dowling and a 46-man garrison disabled two of the attacking vessels and scattered the remainder of the Union ships (Block, 1976).

The U.S. strengthened its position at Sabine Pass with the arrival of the USS *Hatteras* and became more aggressive in the autumn of 1862. Union vessels conducted raids into the region as far north as Beaumont on the Neches River, destroyed much of the town of Sabine Pass, and bombarded and forced the temporary abandonment of Fort Griffin at Sabine Pass using both sail and steam vessels (Francaviglia, 1998). In January 1863, the Confederate forces fought back when they burned and destroyed the USS *Dan* near the Sabine Pass Lighthouse and captured the Union Vessel USS *Morning Light* and the schooner *Velocity* off Sabine Pass using the cotton-clad side-wheel steamers *Josiah H. Bell* and *Uncle Ben* (Francaviglia, 1998; Hardison, 1998).

The standoff between the two forces culminated with the Battle of Sabine Pass in September 1863. Under the direction of Lieutenant Richard W. Dowling, a 45-minute battle resulted in a Confederate victory. Lieutenant Dowling and his 46 men captured two gunboats, the USS *Sachem* and the USS *Clifton* and 350 prisoners, with an additional 61 U.S. soldiers and sailors missing or killed. Without losing a man, Dowling and the Guards prevented an invasion of Texas. The location of this battle is now preserved as the Sabine Pass Battleground and Historic Site (41JF36). A bronze statue of Dowling overlooks the 57.5-acre park.

The U.S. failed to establish itself in Texas during the war; however, the Union blockade did hinder the growth of burgeoning port cities in the state and all but decimated the economy of Sabine Pass for years to come (McGuff and Roberson, 1974).

3.13.2 Previous Investigations

3.13.2.1 Terrestrial Investigations and Recorded Sites

During 1939 and 1940, Gus Arnold of the University of Texas at Austin conducted an archeological survey in the region as a part of a larger east Texas study sponsored by the Works Progress Administration (Im, 1975). Arnold identified 28 sites within the project vicinity. Unfortunately, Arnold never published his results and the only record of his work exists as a Master of Arts thesis from the

University of Texas (Im, 1975). In this thesis, Im presents each site's general location, a short description, temporal components found, and a brief description of the artifacts (Im, 1975). Im noted the similarities between the ceramic artifacts collected by Arnold and those from the Lower Mississippi Valley and "supposed" (Im, 1975) that there were Mississippi Valley sherds among Arnold's collection. However, Im was not able to separate the Lower Valley sherds out of the collection, having particular difficulty in separating sherds dating to the Plaquemine and Coles Creek periods. Im concluded by noting that it seemed that sandy paste sherds occur more frequently early in the chronology and grog-tempered sherds later. Furthermore, he identified two culture areas in east Texas that he termed Caddoan and non-Caddoan with a boundary between the two areas located approximately 80 to 100 miles from the Gulf coast (Im, 1975).

After Arnold, McIntire (1958) recorded several sites in west Louisiana, and then used these sites to extend the Red River Chronology into that part of the state. In the late 1960s, Lawrence Aten and Charles Bollich undertook a survey in the Sabine Lake area of Louisiana and Texas (Aten and Bollich, 1969). Of the 14 sites visited by Aten and Bollich, four are within the project vicinity. Aten and Bollich (1969) attempted to order their ceramic artifacts by paste type (sandy paste and grog-tempered) with the assumption that sandy paste sherds would dominate the earlier assemblages. The authors (1969:Figure 4) concluded that both paste categories existed throughout the history of pottery making in the area with sandy paste sherds being a bit more numerous early in the sequence.

In 1973, the Texas Archeological Survey conducted an archeological survey along the Sabine and Neches rivers for the USACE (McGuff and Roberson, 1974). They visited 81 sites, 61 of which are located near the project area. McGuff and Roberson (1974) provided information on site description, condition, and impacts. Of the 81 sites visited, McGuff and Roberson (1974) listed 21 as potentially eligible for the National Register of Historic Places (NRHP).

In 1978, the USACE, Fort Worth District, sponsored two surveys of the lower Sabine River. The University of Southwestern Louisiana (now University of Louisiana, Lafayette) Center for Archeological Studies inventoried sites along the Sabine River from Toledo Bend Reservoir to the GIWW (Gibson, 1978). Gibson visited 12 sites in the project vicinity and determined that 10 of the sites were potentially eligible for National Register listing. In conjunction with the Gibson study, the University of New Orleans Archeological and Cultural Research Program inventoried sites along the Sabine River and its tributaries from the GIWW south to the Gulf (Beavers, 1978). Forty-two sites were visited by Beavers (1978), 19 of which are located in the project vicinity that he recommended for additional work.

The most recent archeological inventory was conducted by the Brazos Valley Research Associates for the City of Beaumont's Colliers Ferry Wetlands and Recreational Area and Nature Preserve (Moore and Aronow, 1993). No cultural resources were located during this survey, although they do discuss site 41JF1, which they noted was covered by 2 to 3 feet of dredged deposits.

While there has been a substantial amount of cultural resources inventory work done in the project area, there has been a distinct lack of more-detailed investigations involving archeological test excavations.

Several sites in the project vicinity have been subjected to some minimal level of formal testing: 41JF26, 41JF31 (Aten, 1983); 41OR58 (Rogers, 1991); 41CM141 (Servello and Blanchard, 1992); and 41JF11 and 41JF35 (Raab and Smith, 1983). Excavations were either limited to National Register eligibility testing or were not formally reported. The one site where extensive excavation has taken place is the Gaulding site (41JF27), excavated by the Texas Archeological Society (Aten and Bollich, 2002).

In addition to these traditional types of terrestrial archeological investigations, recent geological and remote-sensing investigations of submerged landforms located offshore have suggested that older prehistoric sites may have survived despite long-term inundation and sea level changes in the submerged relict Sabine River valley. A study by the MMS (Stright, 1990) located two possible *Rangia* midden sites approximately 16 miles offshore of the Louisiana/Texas border in the Gulf. Stright's work appears to confirm predictions published by Coastal Environments, Inc. (Pearson et al., 1986) that intact archeological sites may be located along relict tributaries associated with the now submerged Sabine River Valley.

3.13.2.2 Marine Investigations and Reported Shipwrecks

Several previous marine archeological investigations have occurred on the SNWW. Of these, four reports are pertinent to the current project. The four investigations discussed here are Bond and Foster (1993), Hoyt and Schmidt (1997), and Hoyt et al. (1994, 1998).

EH&A conducted a magnetometer survey on the lower Neches River in 1992 (Bond and Foster, 1993). Work was conducted under USACE permit number 19611 for the LNVA to identify possible shipwrecks at four potential saltwater barrier locations. Several magnetic anomalies were recorded during this survey, none of which were recommended as potential historic properties.

EH&A performed a remote-sensing survey of the Sabine Pass Channel and an assessment of the American Civil War-era shipwreck the USS *Clifton* (41JF65) under contract with the USACE in 1994 (Hoyt et al., 1994). Work was conducted in order to identify historic properties that might have been adversely affected by the USACE maintenance-dredging program and to locate and assess the wreck of the *Clifton*. EH&A was tasked with determining its potential for impacts during future jetty maintenance and repair activities (Hoyt et al., 1994). The remote-sensing survey recorded 26 localities that were recommended for diver investigation to identify whether they were historic shipwrecks. The report concluded that the wreck of the *Clifton* was eligible for listing in the NRHP. Further field investigations of the wreck, in the form of remote-sensing investigations and/or archeological excavation, were recommended should it be threatened by future projects.

EH&A followed up its 1994 work in the Sabine Pass Channel with diving assessments of the 26 localities identified in the previous work (Hoyt and Schmidt, 1997). This work was conducted in 1996 under contract with the USACE to determine whether the 26 localities were potential cultural resources. EH&A determined that 15 localities contained modern construction debris; 4 localities, although unidentified, were small and/or deeply buried objects not indicative of shipwrecks; 4 localities had been displaced or removed from the study area; 1 locality was located outside the impact area and within a previously

dredged area and therefore likely was modern in origin; and 2 (L25 and L26) remained unidentified and not fully investigated. The latter were located in an area where project dredging had been completed and therefore were not recommended for further investigation. However, EH&A recommended that additional investigations be conducted, should future plans include channel widening at this location, due in part to the localities' possible association with a recorded American Civil War shipwreck in the area.

EH&A conducted archival research, a remote-sensing survey, and a terrestrial survey in 1997 for the USACE (Hoyt et al., 1998). Work was conducted to identify possible cultural resources at a proposed site for the Neches River Saltwater Barrier, north of Beaumont in the vicinity of Pine Island Bayou. Archival research identified a single historic structure in the study area, a navigation light, which was not physically located during the survey. Numerous magnetic anomalies and side-scan sonar images were recorded during the remote-sensing survey. None of these anomalies was identified as possible cultural resources, and further archeological investigations were not recommended.

As part of the marine investigation, PBS&J researched several databases and secondary sources in order to produce a list of shipwrecks, archeologically sensitive areas, State Archeological Landmark (SAL) and NRHP sites potentially located within the study area. Such sources include PBS&J's shipwreck database, the shipwreck files at the Texas Historical Commission's (THC) Office of the State Marine Archeologist, the shipwreck files at the Louisiana Division of Archaeology (LDA), the NOAA Automated Wreck and Obstruction Information System, the MMS shipwreck database, the GLO's Resource Management Codes, the NPS's NRHP listings, the THC's SAL listings, and the THC's Historical Marker Program. In addition to these databases, cartographic resources such as NOAA's historical and modern navigation charts were useful in identifying possible shipwreck locations. Additional secondary sources such as Lytle and Holdcamper's (1975) Merchant Steam Vessels of the United States and the United States Bureau of Navigation's (various years) Merchant Vessel Losses of the United States were important sources for identifying historic and modern vessel losses.

PBS&J conducted a marine remote-sensing survey for the current FEIS along portions of the SNWW in Jefferson and Orange counties, Texas, and Cameron Parish, Louisiana, throughout February 2003. The survey covered the Outer Bar Channel, the Sabine Pass Jetty Channel, the Sabine Pass Channel, the Port Arthur Canal, the Sabine-Neches Canal, and the Neches River Channel. The survey included the assessment of potential historic properties, oyster reefs, pipelines and wells, and potential obstructions to navigation in the survey area. PBS&J's survey identified 27 potential historic properties, of which 15 would be impacted by the proposed project. Two previously recorded magnetic anomalies, L25 and L26 (Hoyt and Schmidt, 1997), were also identified as potential shipwrecks. PBS&J recommended that all 27 potential historic properties be avoided by bottom-disturbing activities. Anomalies for which avoidance is not feasible were recommended for further archeological investigations in the form of close-order remote-sensing surveys to aid differentiation between anomalies requiring diver assessment and anomalies associated with debris.

The results of the remote-sensing survey can be found in the report titled, *Historic Properties Identification, Oyster Reef Identification, and Pipeline and Obstruction Identification for the Sabine/*

Neches Waterway Widening and Deepening, Jefferson and Orange Counties, Texas, and Cameron Parish, Louisiana, prepared for the USACE by PBS&J dated September 2005 (Enright and Gearhart, 2005). Project plans have been modified since the study was conducted. The 27 anomalies located during the February 2003 survey are included on the current project plans.

The density of reported shipwrecks increases at the northwest corner of Sabine Lake where the SNWW divides near the mouth of the Neches River and Stewts Island. Farther up the Neches River, reported shipwrecks are present near Deer Bayou, Smith Bluff Cutoff, and Bethlehem Steel in Beaumont. In addition to these shipwrecks, the National Defense Reserve Fleet maintains a reserve of vessels on the Neches River near Beaumont that can be activated to help meet U.S. shipping requirements during a national emergency. Many are mothballed World War II naval vessels moved from the Reserve Naval Station Orange facility. This large fleet of intact and floating naval vessels may also extend into the old river channel that was cut off at Smith Bluff. Although not technically shipwrecks, many of these vessels are of sufficient age to meet NRHP eligibility requirements and may represent important World War II-era military developments associated with the study area.

A high density of reported shipwrecks is present in Sabine Pass. Sabine Pass and the adjacent Gulf coast are deemed to be archeologically sensitive in regards to the potential for historic shipwrecks, some of which include the CSS *Clifton*, three steam-driven vessels (*Pearl Plant*, USS *Dan*, and CSS *Sachem*), three sail-driven vessels (schooners *Manhasset* and *Revenge* and USS *Morning Light*), as well as an unknown quantity of jettisoned cargo lost in the area during the American Civil War. Sabine Pass is also home to the Sabine Pass Lighthouse, which is listed on the NRHP.

No remote-sensing survey has been conducted for the Sabine Bank Channel, the proposed Extension Channel, or the existing or proposed ODMDSs. The USACE researched the MMS files on known and potential historic shipwrecks in the Gulf portion of the SNWW project area. The MMS locations are only approximate because many wreck locations cannot be determined with certainty and are reported by lease block only. The approach corridor to Sabine Pass is a high probability area for shipwrecks. Numerous shipwrecks have been documented in the area including vessels that participated in the Battle of Sabine Pass during the American Civil War. Several shipwrecks have been reported in the vicinity of these anomalies, including *Terry Walker*, *Beulah*, *Esther*, *Kile No. 1*, *L.A. Burnham*, and one unidentified wreck (u128). Other wrecks reported in the general vicinity of the Outer Bar Channel include *Ella*, *Hattie*, *John Sealy*, *Manhasset*, USS *Morning Light*, and *Revenge*.

3.13.2.3 National Register Properties

There are two sites listed on the NRHP that are located adjacent to the proposed SNWW CIP: Rainbow Bridge and the Sabine Pass Lighthouse. Rainbow Bridge is the cantilever bridge crossing the Neches River just upstream from Sabine Lake. It allows SH 87 and SH 73 to connect Port Arthur with Bridge City. The Sabine Pass Lighthouse was described above. There is also one SAL (site 41JF65, the USS *Clifton*), also discussed above, that is located adjacent to the proposed SNWW CIP.

3.14 SOCIOECONOMIC RESOURCES

3.14.1 Introduction

This section presents detailed economic and demographic characteristics of the study area. Information evaluated within this section includes population, demographic, and community cohesion factors, employment, labor force characteristics, economics, tax base, land use, transportation, community services, aesthetics, future development and development restrictions, life, health, and safety, and Environmental Justice (EJ).

Two geographic levels have been selected to analyze the socioeconomic components of the proposed study area. These two levels have been chosen to capture more fully the socioeconomic setting and its relationship to the regional economy. These two geographic levels are the study area and the detailed study area.

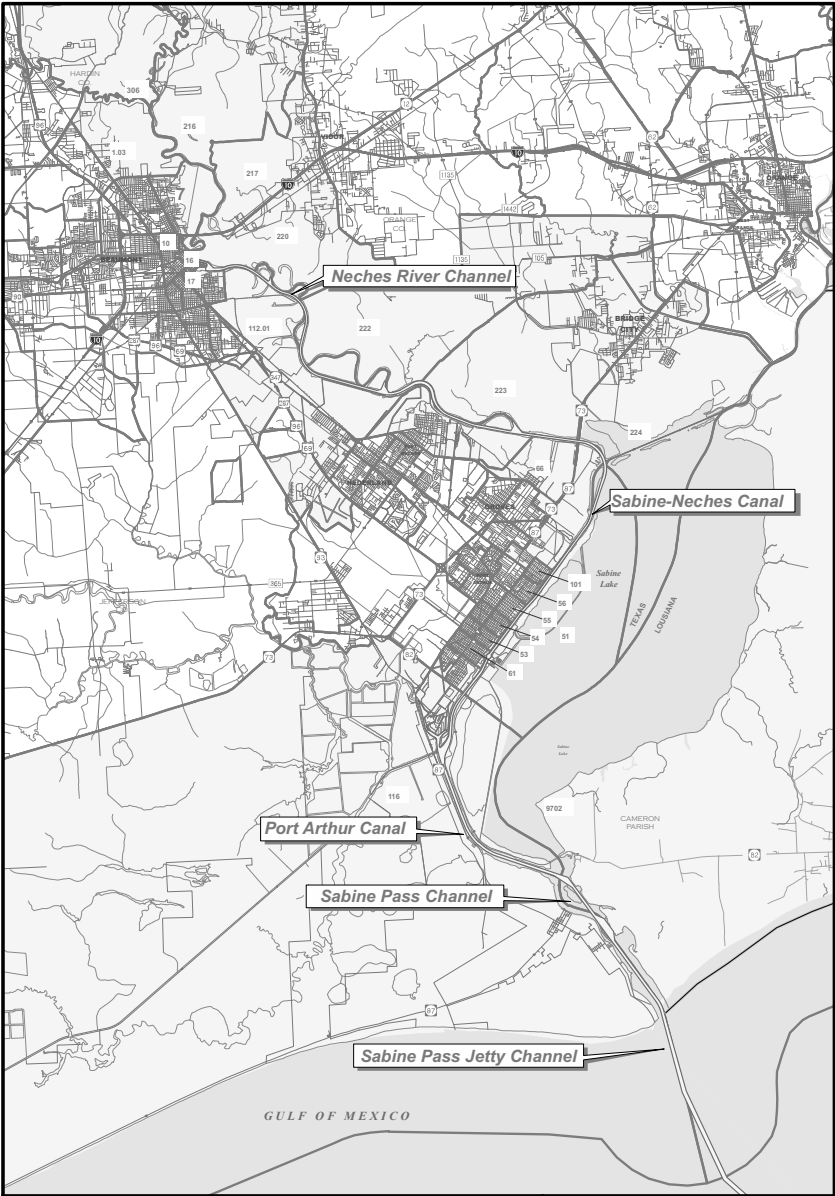

3.14.1.1 Study Area

For the purposes of this section, the following counties and parishes are used as units of socioeconomic analysis: Hardin, Jefferson, and Orange counties in Texas, and Cameron and Calcasieu parishes in Louisiana. Also the following cities are discussed: Beaumont, Port Arthur, Port Neches, Nederland, Vidor, Orange, and Bridge City in Texas; and Lake Charles in Louisiana. Also, census data and other socioeconomic data are provided for the BPA Metropolitan Statistical Area (MSA) (includes Hardin, Jefferson, and Orange counties, Texas), although some portions of these MSAs are not part of the study area. The Lake Charles MSA is the only other MSA within the study area, but it is not included because it includes only Calcasieu Parish (which is already discussed). Also, wherever it was possible, the Texas portion of the study area, and the Louisiana portion of the study area are discussed. In such cases, socioeconomic data are provided separately for all Texas counties and for all Louisiana parishes. Finally, some communities within the study area are discussed in more detail than others simply because they are located closer to areas affected by the proposed project, or areas near to the detailed study area, which is the second geographic level of analysis (below).

3.14.1.2 Detailed Study Area

The detailed study area for this section is defined differently than for other sections of this FEIS. The detailed study area, for this section, includes only census tracts that are within (or at least partially overlap into) the “detailed study area” that is shown on Figure 3.14-1 (2000 census tracts). The detailed study area, as defined within this section only, includes areas within a 1-mile-wide corridor of the areas proposed for ship channel improvements. Many of the census tracts included in this section overlap partly into the detailed study area, but cover much larger areas outside of the detailed study area. Therefore, the census data (provided by census tract) for the detailed study area include much larger populations than those that physically live within the detailed study area (areas included in the census tract level analysis are shaded yellow). These areas include incorporated areas of Beaumont, Port Neches, Nederland, Bridge City, and Port Arthur and unincorporated areas within Jefferson, Hardin, and Orange counties, Texas, and

3-111

Source: TIGER Census 2000 data.

(This page left blank intentionally.)

Cameron Parish, Louisiana. Finally, the census tract figure breaks up the detailed study area into the following subcategories based on the names of different segments of the ship channel (from north to south): Neches Channel, Sabine-Neches Channel, Port Arthur Channel, Sabine Pass Channel, and the Sabine Pass Jetty Channel.

3.14.2 Population and Community Cohesion

3.14.2.1 Historic and Projected Population

Table 3.14-1 presents the current and historic population data for the study area. From 1980 to 1990, population growth within the study area was negative, with only a few communities exhibiting positive population growth during the 1980s. Negative population growth in the study area during the 1980s is largely attributable to high unemployment rates, and economic problems within the region due to the 1980s “oil bust,” when manufacturing and construction industries within the study area (and other locations in Texas and Louisiana) suffered heavy economic losses and layoffs (Helen, 2002). During the 1980s the study area cities with the greatest population growth were Bridge City (6.5 percent increase) and Nederland (0.0 percent growth), while the greatest decreases in population were experienced in the City of Orange (at negative 12.9 percent) and Port Arthur (at negative 7.6 percent). Among study area counties and parishes, the greatest population growth during the 1980s occurred in Hardin County (at 1.5 percent growth) and Calcasieu Parish (at 0.5 percent growth), while the greatest decreases in population occurred in Jefferson County (at negative 4.6 percent) and in Orange County (at negative 4.0 percent). The population changes within the study area during the 1980s contrasted sharply with that of the State of Texas (at 19.4 percent), while it was fairly consistent with that of the State of Louisiana (at 0.3 percent) during this period. A possible reason for this trend is that the Texas economy, during the 1980s, was more diverse overall than the study area economy and that of the State of Louisiana, and therefore unemployment rates and economic losses were not as high, and out-migration of the population was not as prevalent.

Between 1990 and 2000 the study area population became positive again, with slow to moderate population growth (at 7.4 percent) occurring during this period. During the 1990s (especially during the late 1990s), the national economy had greatly improved, and within the study area less out-migration of population was occurring, as manufacturing and construction sectors were experiencing a partial recovery from the economic problems they had experienced during the 1980s. These sectors were retaining more of their employees, and the services sector was expanding, especially along the IH 10 corridor (Helen, 2002). During the 1990s the study area cities with the greatest population growth were Bridge City (6.0 percent increase) and Nederland (3.3 percent growth), while the greatest decreases in population were experienced in Orange (at negative 9.4 percent) and Port Arthur (at negative 0.9 percent). Among study area counties and parishes, the greatest population growth during the 1990s occurred in Hardin County (at 16.3 percent growth) and Calcasieu Parish (at 9.2 percent growth), while the slowest population growth occurred in Jefferson County (at 5.3 percent) and in Orange County (at 5.5 percent). The population changes within the study area during the 1990s contrasted sharply with that of the State of Texas (at 22.8 percent), while it was fairly consistent with that of the State of Louisiana (at 5.9 percent)

during this period. Much of this trend is attributable to the diversification of the study area economy relative to that of the states of Texas and Louisiana. The Texas economy was more diverse overall and was booming in the communications, high-tech, and services industries overall, and the population was expanding as a result. These trends were not occurring in the study area or the State of Louisiana to nearly the same degree.

Table 3.14-1
Study Area Population Trends, 1980–2000

Place	Population			Percent Change		
	1980	1990	2000	1980–1990	1990–2000	1980–2000
Beaumont	118,102	114,323	113,866	–3.2	–0.4	–3.6

*The Project Study Area population is calculated from a combined total of the Beaumont-Port Arthur MSA, the Lake Charles MSA, and Cameron Parish.

Table 3.14-2 provides population projections from 2000 to 2050 for Hardin, Jefferson, and Orange counties, Texas, and Calcasieu and Cameron parishes, Louisiana, the State of Texas, and the State of Louisiana. Generally, population within the study area counties and parishes is expected to be slow to moderate through year 2050.¹ The greatest population growth rates within the study area during this period are anticipated in Hardin County (average decade growth rate of 8.1 percent). The slowest population growth rates during this period are anticipated in Cameron Parish (average decade growth rate of negative 16.3 percent) and in Orange County (average decade growth rate of 3.3 percent).

¹Population projections for Calcasieu and Cameron parishes and the State of Louisiana for the years 2030 to 2050 were not available from the Louisiana State Data Center. Therefore, projections were made for these years based on average increases in population from the preceding 3 decades (for which projections were available). The average rate of growth that was used for these 3 decades for Calcasieu and Cameron parishes and the State of Louisiana were 5.7 percent, 1.3 percent, and 5.8 percent, respectively, for each decade from 2020 to 2050.

Table 3.14-2

There are a few factors that are likely to contribute to the slow to moderate population growth that is projected for the project study area from 2000 to 2050 (see Table 3.14-2). The population projections are based on socioeconomic trends in the last 30 years or so, which are likely to continue in the future. Namely, the study area's economy has grown at a slow to moderate rate over the past 2 decades, since the "oil bust" of the 1980s. During the 1980s, the study area's population growth was negative, as the manufacturing sector lost about 17,000 jobs, and many residents left the area to find better opportunities elsewhere. During the 1990s, the economic situation improved somewhat, but not enough to fully recover from major job losses in the 1980s. Population growth during the 1990s was slow to moderate in all communities of the study area, largely as a response to these economic trends. Population growth has been slow even as many large cities in Texas had booming economies during the late 1990s. Job growth occurred in the services, wholesale and retail trade, government, and medical services industries within the study area during this period, but not enough to offset lagging job growth in the manufacturing industry. Housing units were added at a relatively steady rate, but the average household size got smaller during the decade, so that the new housing units were not an indicator of rapid population growth. Many manufacturing companies upgraded or expanded their facilities, but with these improvements came mechanization of jobs, and this led to little growth in new jobs. Therefore, the study area economy has seen very few economic indicators that the economy is going to grow at a rate that is any different than what has occurred in the recent past. Without such growth in new jobs, it is unlikely that the study area population is going to grow any faster than slow to moderate, as it has done in the recent past. Without any economic indicators showing otherwise, analysts with the TWDB, and locally based population analysts believe that population growth within the study area would continue to be slow to moderate from 2000 to 2050 (Helen, 2002). Table 3.14-3 provides population figures for 2000 for the detailed study area. The total detailed study area population was 82,401 in 2000.

3.14.2.2 Demographics and Community Cohesion Factors

Being an intangible concept, the definition and, therefore, the measurement of community cohesion is not precise. There are certain factors, however, that can be measured and that can be interpreted to reflect community cohesion. The following community cohesion factors are presented within this section:

- Education and income
- Travel time to work
- Length of residence
- Degree of home ownership
- Age distribution

Education and Income. Table 3.14-4 shows educational attainment levels for detailed study area census tracts (2000), and provides a comparison with state, county and parish figures. In terms of higher education (bachelor's degrees and graduate or professional degrees), the highest levels of educational attainment in the study area are found in Calcasieu Parish (at 16.9 percent) and the lowest levels of educational attainment are found in Cameron Parish (at 7.9 percent). In terms of high school education, the highest levels of educational attainment in the study area are found in Hardin County (at 79.3 percent), and the lowest level of educational attainment is found in Cameron Parish (at 68.1 percent). The average of the detailed study area census tracts' highest educational levels attained are as follows: high school graduate (80.6 percent), bachelor's degree (6.6 percent), and graduate or professional degree (2.3 percent). In terms of high school education, the detailed study area was consistent with study area

Source: U.S. Census Bureau (2000b).

county and parish attainment levels, and higher than the State of Louisiana and the State of Texas. In terms of higher education, the detailed study area was relatively low as compared with study area county and parish attainment levels, and very low when compared with the State of Texas and the State of Louisiana. Considering the Texas and Louisiana portions of the study area (the total/average for the counties/parishes for each respective state within the study area), the 2000 Census data show that the Louisiana portion of the study area (at 12.4 percent) has a slightly lower level of educational attainment in terms of higher education when compared with the Texas portion of the study area (at 13.4 percent). In terms of high school education, the levels of educational attainment for the Texas and Louisiana portions of the study area are 84.8 and 80.0 percent, respectively.

Table 3.14-5 provides the 1999 median family income for detailed study area census tracts and provides a comparison with county, parish, and state figures. The highest median family income within the study area is found in Hardin County (at \$37,612), while the lowest median family income is found in Cameron Parish (at \$34,232). All of the median family income figures for study area counties and parishes are higher than that of Louisiana (at \$32,566), and lower than that of Texas (at \$39,927). The detailed study area (average) median family income is \$28,884, which is substantially lower than the State of Texas, and study area counties and parishes, and lower than the State of Louisiana. The detailed study area census tracts with the highest median family income were Orange County tract 223 (at \$48,586) and tract 222 (at \$46,474), while the lowest median family incomes were found in Jefferson County tracts 16 (at \$11,833) and tract 53 (at \$13,803). Within the Texas and Louisiana portions of the study area, the Texas portion had a higher median household income (at \$36,635) than the Louisiana portion of the study area (at \$34,802).

Travel Time to Work. Table 3.14-6 provides 2000 average travel time to work data for the detailed study area census tracts and provides a comparison with county, parish, and state figures. The longest average travel time to work is found in Hardin County (at 29.2 minutes), while the shortest average travel time to work is found in Jefferson County (at 19.9 minutes). The average travel time to work for the detailed study area is 21.5 minutes, which is relatively low when compared with the study area counties and parishes, and is lower than both Texas and Louisiana. The detailed study area census tracts with the shortest travel time to work were Jefferson County tracts 16 (at 12.1 minutes) and 53 (at 15.1 minutes). The longest travel times to work were found in Jefferson County tracts 10 (at 28.4 minutes) and 116 (at 27.4 minutes). Commute times within the Texas portion of the study area are only slightly longer (at 23.6 minutes) than in the Louisiana portion of the study area (at 22.7 minutes).

Generally speaking, the prevailing movement of commuters is from study area suburbs towards Beaumont and Port Arthur, and to industrial employment centers in Bridge City and Orange. Major employers draw the largest number of commuters, and these are concentrated primarily along the ship channels within the study area. One major commuter movement is from Hardin County, south along SH 96/69/287 towards Beaumont in the morning, and returning northward from Beaumont to Hardin County in the afternoon. Also, in the mornings many of these commuters continue to travel south along SH 96/69/287 towards the Port Arthur area and employment locations along the ship channel, and return

northward in the afternoons. Another major commuter route is from suburban areas north of Orange, along SH 87/62 towards Orange and industrial employment centers in Orange County, and returning northward in the afternoons. Another important employment corridor is along SH 73/87 from the Port Arthur area towards industrial employment centers in Orange County in the mornings and back towards Port Arthur in the afternoons (Helen, 2002).

Length of Residency and Housing. Table 3.14-7 provides length of residence data for the study area population and compares them with county, parish, and state data. The “length of residency” category shows the year that residents moved into their household unit (as reported in the 2000 census). The 2000 census data show that a majority of residents living within the detailed study area census tracts moved into their homes between 1995 and 1998 (at 23.3 percent of housing units) and between 1999 and March of 2000 (at 17.9 percent of housing units). This trend was also true for residents of Jefferson County, Orange County, Calcasieu Parish, the State of Texas, and the State of Louisiana, although to slightly varying degrees. Also, significant percentages of detailed study area residents reported moving into their homes between 1980 and 1989 (at 16.7 percent of housing units). This trend was also true for residents of Orange County and Cameron Parish, with percentages that were slightly greater than in the detailed study area. It is noteworthy that Cameron Parish had substantial numbers of residents who moved into their homes from 1969 and earlier (at 18.1 percent of housing units). Finally, there is some variation among detailed study area census tracts in terms of household residency. Specifically, the following detailed study area census tracts had greater than 50 percent of residents moving into their homes before 1990: Jefferson County tracts 7, 51, 53, 54, 55, and 61. In the Texas portion of the study area, a majority of residents moved into their housing units between 1995 and 1998 (at 25.4 percent of housing units) and between 1999 and March of 2000 (at 18.9 percent). In the Louisiana portion of the study area, also, a majority of residents moved into their housing units between 1995 and 1998 (at 27.4 percent) and between 1999 and March of 2000 (at 20.4 percent).

Table 3.14-8 provides a tally of owner-occupied versus renter-occupied housing units for the detailed study area census tracts compared with study area counties, parishes and states, as reported by the 2000 census. The greatest percentage of owner-occupied housing units is found in Cameron Parish (at 85.1 percent), and the lowest percentage of owner-occupied housing units is found in Jefferson County (at 66.0 percent). Conversely, the highest percentage of renter-occupied housing units is found in Jefferson County (at 34.0 percent), and the lowest percentage of renter-occupied housing units is found in Cameron Parish (at 14.9 percent). The detailed study area was 72.3 percent owner-occupied housing units, and 27.7 percent renter-occupied housing units, which is a relatively low level of owner-occupied housing units compared with study area counties and parishes, and also lower than both Texas and Louisiana. The highest percentage of owner-occupied housing units within the detailed study area census tracts, is found in Orange County tracts 222 (at 89.0 percent) and 216 (at 87.8 percent), and the lowest percentage of owner-occupied housing units is found in Jefferson County tracts 16 (at 1.6 percent) and 1.03 (at 42.0 percent). The Louisiana portion of the study area has a slightly higher percentage of owner-occupied housing units (at 72.2 percent) than the Texas portion of the study area (at 70.6 percent).

Age Distribution. Table 3.14-9 shows the age characteristics of the detailed study area census tracts and provides a comparison with county-, parish-, and state-level data. Within the detailed study area census tracts, the median age in 2000 was 35.3, which is consistent with county and parish figures but higher than the State of Louisiana (at 34.0) and the State of Texas (at 32.3). In general, a majority of the detailed study area population is within the 25 to 34 (at 12.4 percent), the 35 to 44 (at 16.2 percent), and the 45 to 54 (at 14.1 percent) age cohorts. In the states of Texas and Louisiana, these same age cohorts represent a majority of the population, but to a lesser extent than in the detailed study area population. In Texas, the 25 to 34 cohort represents 15.2 percent, the 35 to 44 cohort represents 15.9 percent, and the 45 to 54 cohort represents 12.5 percent. In Louisiana, the 25 to 34 cohort represents 13.5 percent, the 35 to 44 cohort represents 15.5 percent, and the 45 to 54 cohort represents 13.1 percent. The Texas portion of the detailed study area has a slightly higher median age (at 35.9) than the Louisiana portion of the study area (at 34.8). In the Texas portion of the study area, a majority of the population is within the 35 to 44 age cohort (at 15.8 percent) and within the 45 to 54 age cohort (at 13.2 percent). In the Louisiana portion of the study area, a majority of the population is within the 35 to 44 age cohort (at 15.8 percent) and within the 45 to 54 age cohort (at 13.2 percent).

One reason that the study area population (including study area counties and parishes and the detailed study area census tracts) has a higher median age, and a larger “baby boomer” population than the states of Louisiana and Texas, is that opportunities for higher education are not as readily available within the study area, as compared with cities offering higher education in Louisiana and Texas. As a result, many young adults move away from the study area, for higher education opportunities elsewhere in Texas, Louisiana, or other states. Also, the spike in the “baby boomer”-aged population may be a result of families of “baby boomer” age returning to the study area (returning to where they grew up) after living elsewhere to pursue higher education and/or careers (Helen, 2002).

3.14.2.3 Demographics and Community Cohesion Factors Summary

Analysis of demographic and community cohesion factors within the study area and within the detailed study area suggests a moderate degree of community diversity. Study area counties and parishes exhibit low to moderate differences in levels of educational attainment. In terms of high school education, the detailed study area was consistent with study area counties and parishes. In terms of higher education, the detailed study area had achieved a relatively low level of educational attainment when compared with study area counties and parishes. There are some wide differences in levels of educational attainment among individual detailed study area census tracts. Study area median family income in 1999 by study area counties and parishes shows a fair amount of overall homogeneity. However, the detailed study area population had a substantially lower median family income than any of the study area counties and parishes. Also, median family incomes within the individual detailed study area census vary significantly, showing a high degree of community diversity. In terms of the median travel time to work, study area counties and parishes vary somewhat, varying from about 20 to 29 minutes. The detailed study area population has a relatively low average commute time when compared with the study area counties and parishes, and individual detailed study area census tracts show a relatively small degree of variation in commute times. In terms of length of household residency, the study area counties and parishes had a

Source: U.S. Census Bureau (2000).

majority of residents moving into their housing units relatively recently (since 1995). The only exception was Cameron Parish, where a large proportion of residents had moved into their housing units prior to 1970, although this has changed due to the devastating effects of Hurricane Rita on the parish. The detailed study area also had a majority of the households moving into their housing units since 1995, but there is a high degree of variability within individual census tracts related to the year that households moved into their housing units. The study area counties and parishes have a low degree of variation related to the percentage of housing units that are owner-occupied, with all counties and parishes having between 70 and 83 percent owner-occupied housing units. The detailed study area census tracts had a proportion of owner-occupied housing units that was lower than that of the study area counties and parishes. There was a high degree of variability in individual detailed study area census tracts in terms of the percentage of owner-occupied housing units, varying from 1.6 to 89 percent. In terms of median age, there was very little variation among study area counties and parishes, with the median age varying from 34.5 to 36.1. The average detailed study area median age was consistent with the study area counties and parishes. However, there was a moderate to high degree of variability among individual detailed study area census tracts in terms of median age, varying from 24.4 to 58.0. In general, the population living within the study area and the detailed study area demonstrated a moderate level of community diversity judging from the community cohesion factors evaluated in this section.

3.14.2.4 Environmental Justice

In compliance with Executive Order (EO) 12898 – Federal Action to Address EJ in minority populations and low-income populations, an analysis has been performed to determine whether the proposed project would have a disproportionately adverse impact on minority or low-income population groups within the detailed study area. The EO requires that minority and low-income populations do not receive disproportionately high and adverse human health or environmental impacts and requires that representatives of minority or low-income populations, who could be affected by the project, be involved in the community participation and public involvement process.

3.14.2.4.1 EJ Index Methodology

Three levels of analysis are provided to help determine whether there is potential for disproportionately high and adverse effects accruing to the population living within the detailed study area. These analyses were patterned after the EPA Region 6 model called the EJ Index, which depicts a survey of ethnicity and income within the study area (EPA, 2003). The raw data used to recreate the analysis are based on 2000 U.S. Census Bureau census tract–level data for ethnicity and tract-level data for income data (U.S. Census Bureau, 2000a, 2000b).

The EPA EJ Index model is a modification of the Region’s Human Health Risk Index Formula. The model uses GIS and census data to delineate the demographics within census tracts. The EJ Index model calculates the degree of vulnerability for the area based on population density and two socioeconomic criteria: a community’s percentage minority population and percentage of economically stressed households. This information is then compared with the calculated State index and a ranking criterion is

established. There are three ranking variables that comprise the EJ Index: population density, minority status, and economic status.

A score is assigned to each detailed study area tract that represents the population density. The criterion used to determine the population density score (from 0 to 4) is based on the number of persons per square mile. If a tract has no persons living within it, it is given a ranking score of 0, a population of 1 to 200 is ranked as 1, a population of greater than 200 but less than 1,000 is ranked as 2, a population of greater than 1,000 but less than 5,000 is ranked as 3, and a population of greater than 5,000 is ranked as 4.

A score is also assigned to each detailed study area tract that represents the percentage of minority population and the percentage of economically stressed persons. To establish the rankings for both the minority population and the percentage of economically stressed persons, each tract is assigned a score that represents how that tract compares to the state's percentage (SP). Therefore, a score of 1 indicates that the tract's average is less than or equal to the SP, a score of 2 indicates that the tract is greater than the SP, but less than or equal to 1.33 times the SP, a score of 3 indicates that the tract is greater than 1.33 times the SP, but less than or equal to 1.66 times the SP, a score of 4 indicates that the tract is greater than 1.66 times the SP, but less than or equal to 1.99 times the SP, and a score of 5 indicates that the tract is equal to or greater than twice the SP. The EJ Index score is established by multiplying the population density score with the minority status score and the economically stressed score.

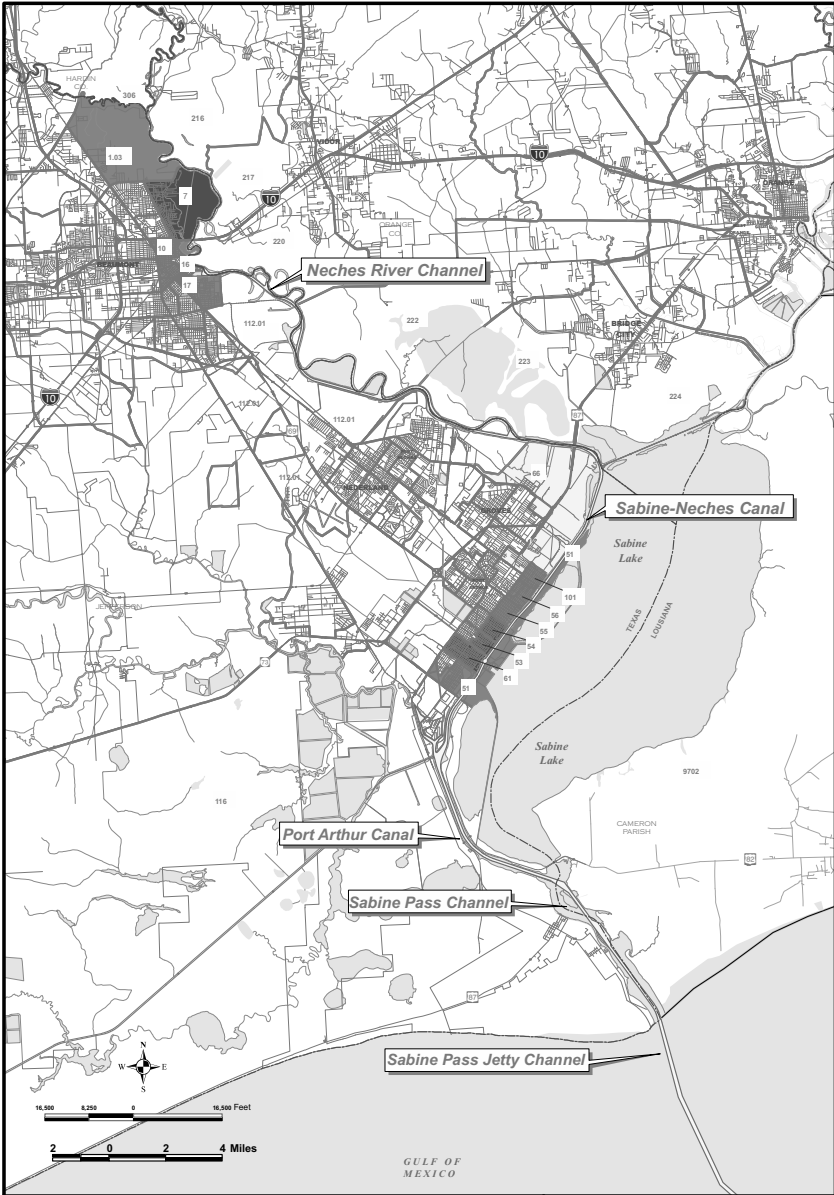

3.14.2.4.2 *Minority Status Degree of Vulnerability*

The Minority Status Degree of Vulnerability figure (Figure 3.14-2a) portrays the degree of vulnerability for minority status by detailed study area census tract. The percentages of minority populations that are living within census tracts that overlap into the detailed study area (entirely or partially) are compared with the respective SP of minority population. Tracts that are located within the State of Texas were compared with Texas's percentage of 47.5 percent, and tracts that are located within the State of Louisiana were compared with Louisiana's percentage of 37.4 percent. Minority status is defined to include all non-white as well as Hispanic-origin households. A ranking score (as described in the EJ Index Methodology) is assigned to each tract.

3.14.2.4.3 *Economic Status Degree of Vulnerability*

The Economic Status Degree of Vulnerability figure (Figure 3.14-2b) shows the percentage of economically stressed persons (or economically vulnerable) based on household income (the risk group is defined by the EPA – Region 6 as households with incomes less than \$15,000 per year). The percentage of economically stressed persons who are living within the detailed study area census tracts that overlap into the detailed study area (entirely or partially) are compared with the respective SP of economically stressed households. Census tracts that are located within the State of Texas were compared with Texas's percentage of 15 percent, and tracts that are located within the State of Louisiana were compared with Louisiana's percentage of 19 percent. A ranking score (as described in the EJ Index Methodology) is assigned to each tract.

3.14.2.4.4 *Potential Environmental Justice Index*

The Potential Environmental Justice Index figure (Figure 3.14-2c) shows a composite index incorporating population density, income, and ethnicity factors. Because the EJ Index is derived in part by the population of the project area, there is no county or state EJ Index number for comparison purposes.

3.14.2.4.5 *Environmental Justice Index Analysis*

The Minority Status Degree of Vulnerability figure (Figure 3.14-2a) shows that the detailed study area's population density (on average) is ranked as a 3, and the average percentage of ethnic minorities is 48.8 percent, which is substantially greater than all counties and parishes of the study area, greater than the State of Louisiana, and slightly greater than the State of Texas. The overall minority status for the detailed study area is ranked 3.

The Economic Status Degree of Vulnerability figure (Figure 3.14-2b) shows that the detailed study area census tracts have an average of 20.6 percent of the population that is economically stressed, which is slightly greater than in all study area counties and parishes, and the states of Texas and Louisiana. The overall economically stressed status is ranked 3.

The Potential Environmental Justice Index figure (Figure 3.14-2c) shows that the overall EJ Index for the detailed study area is 27. In addition to the EJ Index methodology, an analysis of the census tracts was also performed. The census tract data were used in this study to determine the potential for disproportionate effects to low-income and/or minority populations within the detailed study area and are presented in Table 3.14-10. The information is based on 2000 U.S. Census Bureau state, county, and census tract-level data for ethnicity and income (see Figure 3.14-1). All study area census tracts that overlap into the detailed study area (entirely or partially) were used in this analysis.

3.14.2.4.6 *Census Tract Analysis*

Within the detailed study area census tracts, the average percentage of African Americans is 26.7 percent, which is lower than the percentage of African Americans in Jefferson County (33.4 percent) and the State of Louisiana (32.2 percent), but is higher than the percentage of African Americans in Orange County (8.6 percent), Hardin County (6.9 percent), Cameron Parish (3.5 percent), Calcasieu Parish (23.5 percent), and the State of Texas (11.3 percent). Individual detailed study area census tracts with unusually high percentages of African Americans include the following: Jefferson County tracts 1.03, 7, 17, 51, 53, 54, 55, 61, and 66. The average percentage of Hispanics within the detailed study area is 9.6 percent, which is lower than Jefferson County (10.6 percent) and the State of Texas (32.0 percent), but is higher than the percentage of Hispanics in Orange County (3.5 percent), Hardin County (2.4 percent), Cameron Parish (2.1 percent), Calcasieu Parish (1.7 percent), and the State of Louisiana (2.4 percent). Individual detailed study area census tracts with unusually high percentages of Hispanics include the following: Jefferson County tracts 10, 56, and 101. The average percentage of "Other Race" population within the detailed study area is 4.1 percent, which is lower than the percentage of "other races" in Jefferson County (4.1 percent), the State of Louisiana (2.9 percent), and the State of Texas (4.3 percent), but is higher than

Source: U.S. Census Bureau (2000a, 2000g).

the percentage of “Other Race” population in Orange County (2.1 percent), Hardin County (1.8 percent), Cameron Parish (1.6 percent), and Calcasieu Parish (2.0 percent). Individual detailed study area census tracts with unusually high percentages of “Other Race” persons include the following: Jefferson County tracts 54, 55, and 56.

The average percentage of persons living below the poverty level within the detailed study area is 18.5 percent, which is lower than the percentage of people living below the poverty level in the State of Louisiana (19.0 percent), but is higher than the percentage of people living below the poverty level in Jefferson County (16.3 percent), Orange County (13.6 percent), Hardin County (11.1 percent), Cameron Parish (12.2 percent), Calcasieu Parish (15.0 percent), and the State of Texas (15.0 percent). Individual detailed study area census tracts with unusually high percentages of poverty status persons include the following: Jefferson County tracts 1.03, 7, 51, 53, 54, 61, 66, and 101.

3.14.2.4.7 *Results*

The results of the census tract analysis suggests that within the detailed study area census tracts, the potential for disproportionately high effects to ethnic minority populations is high, and the potential for disproportionately high effects to poverty status persons is moderate. The detailed study area exhibits a disproportionately high percentage of African Americans relative to other portions of the study area and the State of Texas. In addition, there are several detailed study area census tracts with exceptionally high percentages of African Americans. Also, the detailed study area has a moderately high percentage of Hispanics when compared with most counties and parishes within the study area and also the State of Louisiana. There are three detailed study area census tracts with unusually high percentages of Hispanics. Also, the detailed study area has an overall “Other Race” population that is slightly higher than four of the five study area counties and parishes. There are three detailed study area census tracts with unusually high percentages of “Other Race” population. The population living within the detailed study area census tracts has a moderately high percentage of poverty status when compared with most counties and parishes within the study area and the State of Texas. There are numerous census tracts within the detailed study area that have unusually high percentage of poverty status persons.

3.14.2.5 Port-Related Population

In subsection 3.14.3.3, the number of direct port-related employees for the Port of Beaumont, the Port of Port Arthur, and the Port of Orange is estimated at 41, 16, and 8, respectively, or a total of 65 direct employees for the three ports (Floyd, 2009; Myers, 2009). Applying a multiplier of 2.65 for the average household size within the study area, an estimate of the direct port-related population in the area is 172 persons. This represents only a very small fraction of the total population within the five-county study area.

Also, in subsection 3.14.3.3, it is estimated that total port-related employment in the port, manufacturing, and industrial industries is currently around 21,000. To estimate the population that is related to these industries, a multiplier of 2.65 was again applied to yield a port-related population of approximately

55,650 people. Since the study area consisted of 578,658 persons in 2000, this port/manufacturing/industrial population represents approximately 9.6 percent of the current study area population. This is an estimate of the population that has at least one family member that works in any of these industries that are either directly or indirectly linked to waterborne commerce. However, this estimate likely undercounts the population within the study area that is employed by companies that are suppliers to port, manufacturing, and industrial employers. Within the study area, outside vendors provide a wide diversity of expendables and services to these industries (Davis, 1996). Given that these estimates likely undercount the degree to which the local population depends on port, manufacturing, and industrial employment for its livelihood, it seems apparent that the a substantial portion of the population does depend on the these industries, probably at least 25 percent of the population. However, this dependency on port-related industry employment is less than it was before the 1980s “oil bust,” as the study area economy has made adjustments since the 1980s (Helen, 2002). Now the study area population relies to a greater extent on industries such as services, Federal, State, and local government, retail and wholesale trade, medical services, education, and Federal and State jails for its livelihood.

3.14.3 Economics

3.14.3.1 Historical Perspective

The SNWW forms a Y-shaped set of interlocking river channels and canals extending from the Gulf to Port Arthur, Beaumont, and Orange, Texas. Extensive construction to improve the waterways began with river and harbor acts of 1875, 1882, and 1896, when the mouth of the channel was deepened and jetties were built to prevent silting. Some improvements in the Sabine and Neches rivers were authorized in 1878, and the Port Arthur Canal and Dock Company began building a more suitable channel to Port Arthur in 1895. The Port Arthur Canal opened in 1899. The discovery of the Spindletop oil field in 1901 increased demand for deepwater navigation along the lower Sabine and Neches rivers. In response, Congress provided authorization and money in 1905 to complete the GIWW from New Orleans to Galveston Bay. This channel was dredged to a depth of 9 feet and a width of 100 feet and provided a direct connection with the Port Arthur Canal. By 1916 Congress approved the extension of the Port Arthur Canal, and a 25-foot-deep channel was completed to Beaumont in 1916 (known as the Neches Channel). Additional dredging and improvements extended the waterway to Orange (known as the Sabine Channel). By 1972, the SNWW was 40 feet deep and 400 feet wide (University of Texas, 2001).

A series of jetties, canals, rivers, and turning basins now compose the waterway. At the mouth of the channel is Sabine Pass, with jetties extending 3 miles into the Gulf. Twenty-four miles north, up the SNWW, is Port Arthur. The SNWW then splits. To the west, the Port of Beaumont is 19 miles up the Neches River from Port Arthur. To the east, the Port of Orange is 15 miles above the confluence of the Sabine and Neches rivers, via the Sabine Channel. The SNWW, the Neches Channel, the Sabine Channel, and the GIWW have all been tremendously important to development within the study area. The system supported more than 45,000,000 tons of cargo annually by the late 1930s, and over 40,000 vessels used the waterway by 1943. In 1979 well over 75,000,000 tons passed through the Sabine Pass jetties, making the Sabine-Neches shipping district the second largest in the State of Texas, behind that of Galveston-

Houston-Texas City (University of Texas, 2001). In 2007, the SNWW ranked 4th in the Nation in total tonnage, importing 141 million short tons. Individually, the Port of Beaumont ranked 5th nationally for domestic and total tonnage, and the Port of Port Arthur ranked 28th in the Nation (IWR-WCUS, 2007).

3.14.3.2 Employment

Table 3.14-11 provides employment by major industry sector and total employment for the study area for three Texas counties, two Louisiana parishes, the State of Texas, and the State of Louisiana. In Texas, a study of the fourth-quarter data for 2006 and 2008 show that total employment in Hardin County decreased from 12,616 to 12,527 (-0.7 percent), Jefferson County increased from 123,417 to 127,523 (3.3 percent), and Orange County increased from 22,493 to 23,275 (3.5 percent). Total employment in the State of Texas increased from 10,104,642 to 10,512,878 (4.0 percent) during this same period (Texas Workforce Commission [TWC], 2009).

In Louisiana, a study of the fourth-quarter employment data for 2006 and 2008 show that total employment in Calcasieu Parish increased from 85,506 to 87,877 (2.8 percent), and Cameron Parish increased from 2,501 to 3,046 (21.8 percent). Total employment in the State of Louisiana increased from 1,843,179 to 1,903,858 (3.3 percent) during this same period (Louisiana Department of Labor [LDOL], 2005, 2009).

In Texas, fourth-quarter TWC employment data for 2008 show that the leading economic sectors in Hardin County were government (20.1 percent), retail trade (15.5 percent), and construction (11.5 percent). For Jefferson County, leading sectors are construction (14.4 percent), government (14.1 percent), and manufacturing (12.2 percent). For Orange County, the leading sectors were manufacturing (23.7 percent), government (19.1 percent), and retail trade (13.3 percent). State of Texas leader sectors were government (16.9 percent), retail (11.5 percent), and manufacturing (8.7 percent) (TWC, 2009).

In Louisiana, data for 2008 show that the leading economic sectors in Calcasieu Parish were construction (12.9 percent) and retail trade (12.4 percent); leading sectors in Cameron Parish are transportation and warehousing (14.8 percent) and construction (13.2 percent); for the State of Louisiana, retail trade (12.0 percent) and manufacturing (8.0 percent) (LDOL, 2009).

Table 3.14-12 provides unemployment data for the study area including three Texas counties, two Louisiana parishes, the State of Texas, and the State of Louisiana. In Texas, a study of TWC unemployment data in 1998, 2001, 2003, 2006, and 2008 indicates that the highest unemployment rates were as follows: Hardin County (7.8 percent in 2003), Jefferson County (8.6 percent in 2003), Orange County (9.8 percent in 2001), and the State of Texas (6.7 percent in 2003). The lowest unemployment rates for these areas are as follows: Hardin County (5.3 percent in 2006), Jefferson County (6.1 percent in 2006), Orange County (5.9 percent in 2006), and the State of Texas (4.8 percent in 1998).

In Louisiana, LDOL data in 1998, 2001, 2003, 2006, and 2008 indicate that the highest unemployment rates were as follows: Calcasieu Parish (6.6 percent in 2003), Cameron Parish (6.4 percent in 2003), and the State of Louisiana (6.6 percent in 2003). The lowest unemployment rates were as follows: Cameron Parish (2.9 percent in 2006), Calcasieu Parish (3.3 percent in 2006), and the State of Louisiana (4.3 percent in 2006).

Table 3.14-13 provides a list of the top 20 major employers within the study area. The top employers are concentrated in the public education, health care, petrochemical, manufacturing, gambling, shipbuilding, Federal prisons, and other port-related industries. Together these top 20 (overall) employers provide over 41,000 jobs within the study area economy. Based on a labor force around 300,000 for the five-county/parish study area, this represents approximately 13.7 percent of employment within the five-county/parish study area. Among the top 20 employers, 8 of them are port-related employers (includes manufacturing employment), and these employers encompass 15,735 workers.

3.14.3.3 Port-Related Employment and Operations

Direct employment with the three study area ports, the Port of Beaumont, the Port of Port Arthur, and the Port of Orange, make up a very small fraction of the overall employment that is indirectly tied to port activities. Discussions with area port staff indicated that permanent full-time staff at the ports is as follows: Port of Beaumont (41 employees), the Port of Port Arthur (16 employees), and the Port of Orange (8 employees). Each of these ports also contracts with varying numbers of longshoreman to handle loading and unloading of cargo from ships when they are at port. Information on the average number of longshoremen was not readily available except in the case of the Port of Port Arthur where it was estimated that in an average month there are approximately 6,350 labor hours of employment, which is equivalent to approximately 40 full-time employees for that month, assuming a 40-hour-per-week schedule. Based on the yearly tonnage of cargo, it may be assumed that both the Port of Beaumont and the Port of Orange would have more longshoremen than the Port of Port Arthur (Bouillon, 2002; Davis, 2002; Floyd, 2009; Myers, 2009; Richard, 2002).

Conservative estimates of all port, manufacturing, and industrial-related employment, based on information from the U.S. Bureau of Labor Statistics indicates approximately 21,000 jobs in the study area in 2009 (TWC, 2009). It is likely, however, that an even greater number of port-related jobs exist within the area economy, as numerous small supplier companies provide goods and services to larger port, manufacturing, and industrial-related employers (Davis, 1996).

There are a few factors that have had effects on employment within port, manufacturing and industrial-related industries within the study area. One major factor that has led to relatively high unemployment levels within the study area has been a downturn in oil-related industries since the 1980s “oil bust.” During the 1980s, the study area experienced relatively high unemployment rates, as oil refineries and other manufacturing plants laid off as many as 17,000 workers. Since, the 1980s the manufacturing and other port-related industries have been slow to add large increases in the workforce, so unemployment rates did not fully recover even during the national economic boom of the 1990s. The particular “industrial mix” of the study area, which is heavily concentrated in manufacturing, port-related, construction, transportation, and public utilities, is also susceptible to employment volatility due to heavy reliance on contract labor. As new contracts are awarded, employees are contracted to accomplish the work, and when the project is completed, these companies would lay off their workforce until the next

contract is awarded unless current contracts can allow them to maintain staffing levels. In terms of competition for workers, the port-related, manufacturing, and industrial-related employers of the study area do not have to compete much with other industries in order to retain their workers. This is because overall these employers pay substantially higher wages than other industries that are important to the area, such as the services, retail and wholesale trade, and government services. Another factor affecting employment among manufacturing and port-related employers is an increased reliance on mechanized means of production. In many cases, large investments have been made to increase the size, capacity, and output of manufacturing plants and other port-related industries, but these expansions have led to relatively small increases in the number of employees (Crawley and Sanchez, 1999; Helen, 2002).

Table 3.14-14 provides a list of the top 10 industrial, manufacturing, and port-related employers in the study area. Collectively, these top 10 employers provide over 17,000 jobs to the area. Based on a labor force around 300,000 for the five-county/parish study area, this represents approximately 5.7 percent of employment within the five-county/parish study area.

Table 3.14-15 provides a list of the top 10 export commodities and import commodities at the Port of Beaumont, the Port of Orange, the Port of Port Arthur, and the Port of Sabine Pass. In terms of waterborne export commodities, 4 of the 10 top commodities being shipped are petroleum-based products, most of which are manufactured at plants located within the study area. The greatest export is petroleum coke at 3,777 short tons in 2003. In terms of waterborne import commodities, by far the single greatest waterborne commodity being received at these four study area ports (in terms of tonnage) is crude petroleum, at 69,260 short tons in 2003, or 91 percent of all inbound freight traffic tonnage. Examination of the top 10 import and export commodities provides a better understanding of the nature of the port-related economy within the study area. Because the single most important commodity (in terms of tonnage and value) being moved through the four ports is imported foreign crude petroleum, the price

of oil on the foreign market has very large implications in terms of economic success for study area manufacturing plants, and most other port-related businesses. If the price for a barrel of oil is either too low or too high, the entire manufacturing, and port-related sector of the study area economy as well as overall-employment levels, and economic activity within the study area can be adversely affected. Other important nonpetroleum based commodities (both imports and exports) include wheat, sand and gravel, waste and scrap materials, and iron and steel products.

Table 3.14-15
Top 10 Waterborne Export and Import Commodities – Ports of Beaumont,

*The number of short tons for each commodity represents a total of all Foreign, Canadian, Domestic-Coastwise, and Internal (inbound or outbound) tonnage for each commodity that is either an export or an import to the four study area ports.

3.14.3.4 Commercial Fishing

Commercial fishing within the Sabine Lake system is a relatively small contributor to the study area economy compared with other industry sectors. Table 3.14-16 compares the commercial fishing landings of the Sabine Lake system to all Texas bay systems in 2004. The total wholesale value for all finfish and shellfish landings in the Sabine Lake system in 2004 was \$623,160. It is noteworthy, however, that 2004 was not a particularly good year for commercial fishing in the Sabine Lake system. During the 1990s, 1992 had the greatest total value for all finfish and shellfish landings at \$6.0 million.

Table 3.14-16
Trends in Commercial Fishery Landings – Sabine Lake System
Compared with All Texas Bay Systems, 1999

	Sabine Lake System			All Texas Bay Systems	
	Weight (lbs) of Fish Landed	Wholesale (\$) Value of Fish Landed	% of Total (lbs) From All Texas Bay System Landings	Weight (lbs) of Fish Landed	Wholesale (\$) Value of Fish Landed
Black drum	0	0	0	1,717,000	1,444,000
Flounder	0	0	0	151,000	325,000
Sheepshead	0	0	0	68,000	28,000
Mullet	535	668	0.7	76,000	143,000
Other finfish	7,312	38,793	66.5	11,000	9,000
Total finfish	7,847	39,461	0.1	5,620,000	10,585,000
Shrimp, bait	0	0	0	1,330,000	3,666,000
Shrimp, commercial	344	355	<0.1	31,150,000	96,055,000
Total shrimp	344	355	<0.1	32,480,000	99,721,000
Blue crab	707,086	439,036	17.8	3,967,000	2,668,000
Eastern oyster	0	0	0	5,569,000	14,954,000
Squid	0	0	0	42,000	40,000
Total shellfish	707,430	439,371	7.4	9,578,000	17,662,000
Total finfish and shellfish	715,277	478,832	1.5	47,715,000	128,168,000

Source: TPWD (2005d).

The 2002 and 2003 Gulf annual commercial fishery statistics for Louisiana and Texas (NMFS, 2005) were reviewed. The commercial catch and the value of that catch for Louisiana were 1.3 billion pounds (\$307 million) and 1.2 billion pounds (\$294 million) for 2002 and 2003, respectively. The Texas catch was 93 million pounds (\$173 million) and 96 million pounds (\$168 million) for the same time periods. Menhaden were the dominant poundage in Louisiana, while shrimp accounted for most of the weight in Texas. Shrimp, in terms of value, were most dominant in both states. Commercial finfish catches in the Gulf result from beach seines (under certain circumstances), longlines, and incidental catch in shrimp trawls. The blue crab fishery is located in the bays as well as the Gulf. From 1982 to 1986, an annual average of 7.1 million pounds of blue crabs was landed in Texas at an annual average value of \$2.8 million. More species-specific commercial catch information is located in Appendix B ODMS, subsection 3.5.1.1.

3.14.3.5 Recreation

3.14.3.5.1 Recreational Fishing

Among sport-related activities, recreational fishing continues to be a major outdoor recreational activity. In 2006, 3.0 million people aged 16 and older fished in Texas. Between 2001 and 2006, the number of anglers increased by 25 percent, and fishing expenditures increased by 66 percent. Saltwater fishing increased by 33 percent, and freshwater fishing increased by 1 percent (USFWS, 2002e, 2006).

Sabine Lake, numerous wetlands, and the Gulf are sources of recreational fishing within the study area. The large variety of fresh and saltwater species in the area make fishing the most popular recreational activity within the marsh environment within the region. Recreational fishing in this area is a yearround activity that varies with the breeding cycle, water levels, fishing pressure, and aquatic-life productivity. Largemouth bass in inland waters and speckled trout in the Gulf and Sabine Lake are favorites among anglers in the area. Many local freshwater and saltwater anglers join fishing clubs, and enter contests for prize money. The estuarine-marsh-swamp environment provides the necessary nursery ground for an abundant seafood supply. More than 90 percent of the Gulf's finfish spend part of their lifecycle within the coastal zone. Although most species are commercially exploited, recreational anglers contributed more than \$420 million to the local economy (within southeastern Texas and southwestern Louisiana) in 2006, with more than half a million people involved in this leisure time activity (USFWS, 2003).

Also, crawfish are an important source of recreational fishing within freshwater wetlands and creeks within the study area (as well as throughout Louisiana). These crustaceans are collected from natural water areas and cultivated in ponds. In Louisiana and the Louisiana portion of the study area, the crawfish is more than a source of recreational fishing or even a food supply, but rather part of the local culture. Found in almost every ditch and harvested from large ponds, crawfish are utilized as food, bait, income, recreation, weed control, and as a literary topic (Davis, 1996).

3.14.3.5.2 Wildlife-Associated Recreation

Outdoor recreation is a booming business throughout the United States, and Texas and Louisiana offer many outdoor recreational activities. According to the USFWS 2006 National Survey of Fishing, Hunting, and Wildlife Associated Recreation, 29 percent of the total population of Louisiana and 26 percent of the total population of Texas was involved in wildlife-related recreation (USFWS, 2006).

Among the 1.2 million people who participated in wildlife-related recreation in the State of Louisiana in 2006, 91 percent were involved in sporting wildlife recreation (fishing, hunting, or both) and 60 percent were involved in wildlife-watching (feeding, photographing, and observing). Among the 6.0 million people who participated in wildlife-associated recreation in the State of Texas in 2006, 68 percent were involved in sporting wildlife recreation and 70 percent were involve in wildlife-watching (USFWS, 2006).

One of the benefits of outdoor recreation is the economic impact it has on a state and its regions. In Louisiana, over \$2.0 billion was spent on wildlife-associated activities (sporting yielded over \$1.7 billion and wildlife-watching yielded over \$312 million), and in Texas, almost \$2.3 billion was spent on wildlife-associated activities (sporting yielded almost \$1.3 billion and wildlife-watching yielded almost \$2.9 billion) (USFWS, 2006).

The Big Thicket National Preserve covers 106,684 acres of wetland, riparian and upland forest habitat within portions of Hardin and Orange counties, Texas, in the vicinity of the study area. It has been referred to as an "American Ark" because of the tremendous amount of biological diversity that occurs there. Recreational activities include auto touring, backpacking, biking, birdwatching, boating, camping,

fishing, hiking, horseback riding, hunting, interpretive programs, kayaking, nature walks, stargazing, swimming, and wildlife viewing. As a major recreational attraction of the area, the Big Thicket received 106,237 visitors in fiscal year 2004. The annual budget has decreased from \$2,266,000 in fiscal year 2002, to \$2,251,000 in fiscal year 2004 (USFWS, 2003). As with most attractions, money spent in the Big Thicket area would move into local economies. Many visitors to the Big Thicket National Preserve come as weekend visitors from the Houston metro area, and most visitors to the preserve spend money within the BPA MSA and the Lake Charles MSA (within the study area) on hotels, restaurants, entertainment, groceries, supplies, and sporting equipment. The popularity of outdoor recreation and “eco-tourism” within the study area is expected to increase over time, and with the increase in visitors to the area, there would be an increase in visitor spending within the local economy (Helen, 2002).

3.14.3.5.3 *Hunting*

The economic impact of hunting in Texas resulted in \$2.2 billion spent in Texas in 2006. Trip-related expenses totaled \$874 million, including \$338 million on food and lodging, \$336 million on transportation, and \$785 million for equipment rental. Hunting within the Louisiana portion of the study area is equally popular, with numerous seasonally occupied camps located primarily on private land, and leased to club members who often travel from metropolitan areas of Louisiana and Texas to waterfowl and deer hunting, among other game. Spending on hotels, restaurants, groceries, entertainment, supplies, and sporting goods by these hunting recreationists is a boon to both the economies of the BPA MSA and the Lake Charles MSA and is expected to increase over time as an important economic contributor (Helen, 2002).

In 2001, 6 percent of the U.S. population aged 16 and older were involved in hunting activities. An average of 18 days was spent by each hunter on their sport. The USFWS reports that the number of hunters has dropped by 7 percent between 1991 and 2001. The drop occurred primarily in small game and other animal hunting. Big game and migratory bird hunting numbers remained constant. Hunting-related expenditures also dropped by 12 percent. Neither the drop in hunters nor the drop in their expenditures is considered statistically significant (USFWS, 2002e).

3.14.3.5.4 *Wildlife Watching*

In 2006, 24 percent of the U.S. population aged 16 and older were involved in wildlife-watching activities. Between 2001 and 2006, people involved in wildlife-watching activities decreased by 7 percent. The USFWS differentiates between wildlife-watchers who participate around their homes and those who take trips to view wildlife. In spite of the decrease in the population of wildlife-watchers, their total expenditures have increased over the last 5 years by 16 percent, primarily due to equipment expenditures (USFWS, 2002e, 2006).

In 2006, expenditures related to wildlife-watching in the State of Louisiana were almost \$312 million, and in the State of Texas were almost \$2.9 billion. Expenditure totals include food and lodging, transportation, equipment, magazine subscriptions, membership dues, and contributions (USFWS, 2002e).

Wildlife-watching, particularly birding, is an extremely popular activity within the study area and in the nearby vicinity. The Great Texas Coastal Birding Trail (GTCBT) is a series of trails that links 308 bird-watching sites and many communities within 43 Texas counties on or near the Gulf Coast. The GTCBT offers boardwalks, parking pullouts, kiosks, and observation platforms for the comfort of wildlife-watchers. Participation in the GTCBT has grown by 33 percent overall between 2001 and 2002. Participation by youth teams has grown from one team to 97 teams in the 7 years of its existence (Scroggs, 2002; USFWS, 2002e).

There are several sections of the GTCBT that are located in or near the project study area. They are: Claiborne West Park, Lower Neches WMA and Bailey’s Fish Camp, Big Thicket National Preserve, Gore Store Road and Turkey Creek, Roy E. Larson Sandyland Sanctuary, Village Creek State Park, Tyrrell Park and Cattail Marsh, Tony Houseman State Park and WMA, Pleasure Island, J.D. Murphree WMA, Taylor Bayou, Sabine Pass, Sabine Pass Battleground State Historic Park and Texas Point, Texas Point NWR, Sabine Woods, Sea Rim State Park, and McFaddin NWR.

3.14.3.6 Tax Base

In Texas the state sales tax is 6.25 percent, with local sales/use tax not to exceed 8.25 percent (Texas Comptroller of Public Accounts, 2009). In Louisiana the aggregate rate of state sales tax is 4.00 percent, which consists of 3.97 percent Louisiana sales tax and 0.03 percent Louisiana Tourism Promotion District sales tax (Louisiana Association of Tax Administration, 2008). Within the general vicinity of the study area, local sales/use taxes are as shown in Table 3.14-17.

Table 3.14-17
Sales and Use Taxes by Study Area Jurisdictions, 2004*

Taxing Jurisdiction	City Rate (%)	County/Parish Rate (%)	Total Rate (includes State sales/use tax %)
City of Beaumont	1.25	0.50	8.25
City of Port Arthur	1.25	0.50	8.25
City of Port Neches	1.25	0.50	8.25
City of Groves	1.25	0.50	8.25

City of Bridge City	1.25	0.50	8.25
City of Orange	1.25	0.50	8.25
City of West Orange	1.25	0.50	8.25
City of Vidor	1.25	0.50	8.25
City of Lake Charles	2.25	2.25	8.75

Source: Texas Comptroller of Public Accounts (2005a, 2005b); Louisiana Department of Revenue (2005); Louisiana Economic Development (2005).
*2002 for Louisiana.

In Texas property is appraised, property tax is collected by local (county) tax offices or appraisal districts, and these funds are used to fund many local needs including public schools, city streets, county roads,

police, and fire protection (Texas Comptroller of Public Accounts, 2009). In Louisiana property is appraised, property tax is collected by local (parish) tax offices or Police Juries, and these funds are used for local schools and services. Table 3.14-18 provides a summary of property tax jurisdictions and tax rates for jurisdictions that affect large portions of the population living in the vicinity of the study area.

3.14.4 Land Use

The study area is approximately 1,900 square miles in area, and includes portions of Jefferson, Hardin and Orange counties, Texas, and Calcasieu and Cameron parishes, Louisiana. The study area includes nine municipalities: Beaumont, Port Neches, Nederland, Groves, Port Arthur, Bridge City, Vidor, Orange, and West Orange. Land uses for portions of the study area that are relatively close to the detailed study area are shown on figures 3.14-3a (Beaumont, Vidor, and vicinity), 3.14-3b (Nederland, Groves, Port Neches, Port Arthur and vicinity), and 3.14-3c (Sabine Pass and vicinity).²

The most currently available coverages were obtained from a variety of public agencies and private entities, and were integrated into a GIS using ArcView 3.2 and ArcView GIS. A land use/land cover coverage for the study area in 1990 was obtained from the USGS. This coverage was developed by the USGS through interpretation of satellite imagery (USGS, 1990). This land use/land cover coverage uses the Anderson system of classification, which categorizes land uses into 19 categories. Also, 1999 TxDOT county roads coverage (TxDOT, 1999a) and a 1999 parks coverage (derived from the TxDOT urban data) were obtained from Texas Natural Resource Inventory System (TxDOT, 1999b). Additional state parks and wildlife management areas (GLO, 1997) and wildlife refuge coverages (USFWS, 2001) for Texas were obtained from the GLO and USFWS. In addition, 1999 road and park coverages were obtained from the Louisiana Oil Spill Coordinator's Office for Cameron and Calcasieu parishes. A combination of these coverages was used as a working base map for aerial interpretation.

Within the study area, new urban development had occurred since 1990, so the land use/land cover coverage did not adequately capture areas of development since 1990. In order to address this issue, land use interpretation was conducted from working maps to identify and categorize land uses from areas that had been developed since 1990. Land use observations taken from a windshield survey of the study area, on October 2 and 3, 2001, were used to verify interpretation from the land use working maps. These new land use polygons were digitized and combined with the existing USGS land use/land cover coverage. In addition, the Anderson system of classification categories were aggregated for display in order to focus on urban land uses rather than vegetation types.

The study area includes all of Sabine Lake and portions of the Sabine and Neches rivers (flowing into Sabine Lake). The land use figures show the detailed study area that consists of the proposed areas for channel deepening within a 1-mile corridor and includes portions of land adjacent to the channel. The

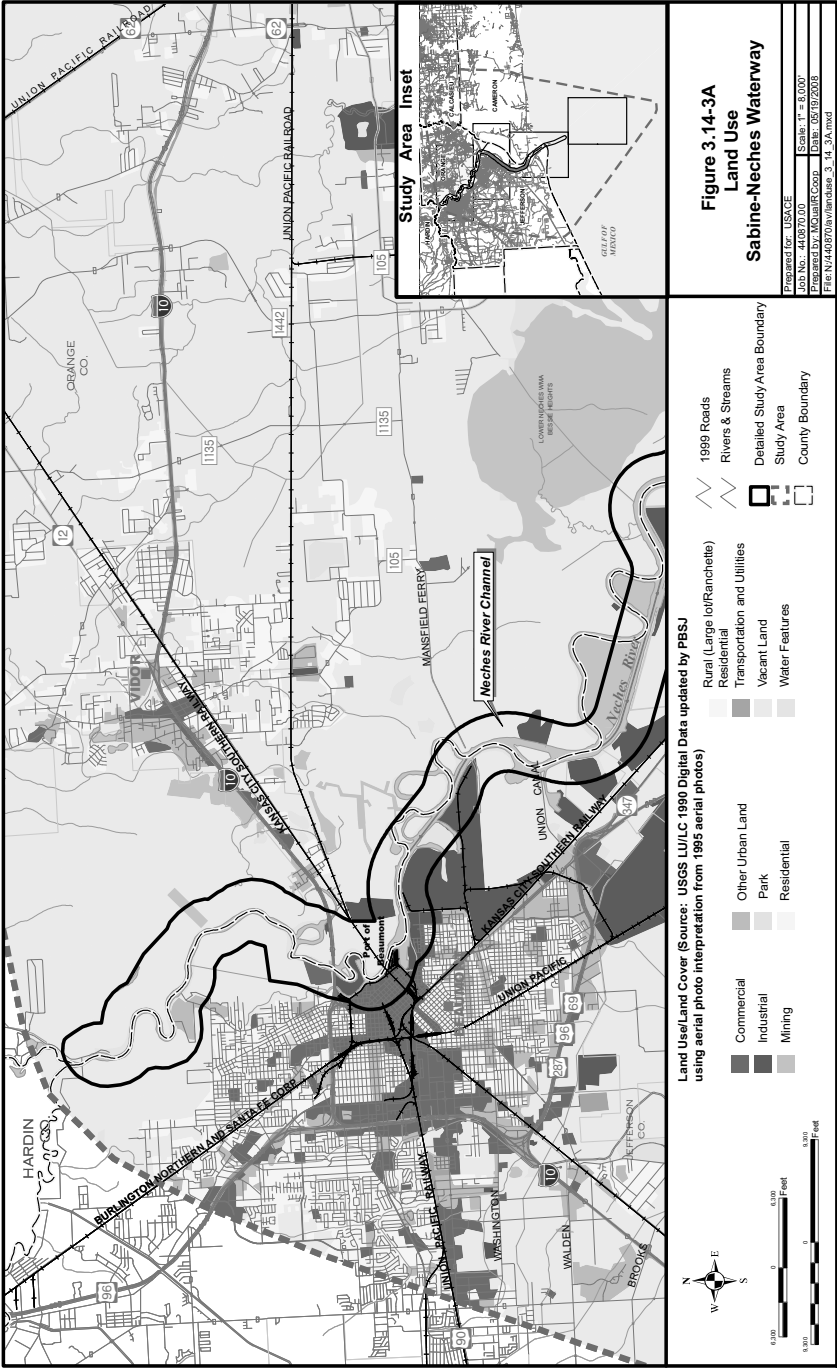

²Land use maps were developed for portions of the study area that are relatively close to the detailed study area, because these are the areas where potential effects (either beneficial or adverse) from project implementation may accrue to the local population.

(This page left blank intentionally.)

detailed study area is divided into the following subcategories: the Neches Channel, the Sabine-Neches Channel, the Port Arthur Channel, the Sabine Pass Channel, and the Sabine Pass Jetty Channel. Cities that are located adjacent to the detailed study area include Beaumont, Port Neches, Nederland, Groves, Bridge City, and Port Arthur.

As shown on Figure 3.14-3a, the City of Beaumont is located along the IH 10 corridor and along the western banks of the Neches Channel. Beaumont's downtown central business district (CBD) is located immediately west of the Neches Channel, and includes a variety of land uses including restaurants, retail shops, civic buildings, museums, hotels, and apartment buildings. The Beaumont CBD area includes the Art Museum of Southeast Texas, the Texas Energy Museum, the Jefferson County Courthouse, the Beaumont Civic Center, the Edison Plaza Museum, the Riverfront Park, the Fire Museum of Texas, and various other City of Beaumont and Jefferson County facilities. The Port of Beaumont is located on the southeast side of the CBD (at the intersection of Main Street and Blanchette Street) adjacent to the Neches Channel. Industrial sites in the Beaumont area are located adjacent to the Port of Beaumont along the Neches Channel, and to the southeast of the Beaumont city limits. Industrial uses in this area include Trinity Industries, ExxonMobile, Mobile Chemical, and North Star Steel.

Located east of Beaumont and along IH 10 is the City of Vidor. Vidor is a relatively small town with commercial uses located mainly along the IH 10 corridor. Residential neighborhoods of Vidor extend both north and south of the IH 10 corridor.

The City of Nederland is located southeast of Beaumont along the US Highway 287 corridor. This city is mostly residential in character with some commercial areas and parks. Industrial uses are located adjacent to Nederland to the north.

The City of Groves is located north of Port Arthur along SH 73. This relatively small city is mostly residential in nature and is bordered by heavy industrial uses to the northwest, north, northeast, and east.

Located along the southwest side of the Neches Channel is the City of Port Neches. This city includes older residential neighborhoods (located mostly near the Port Neches CBD), new subdivisions (mostly located on the southwest side of the city and near SH 347), commercial development along state highways and arterial roadways, and some civic buildings located mostly in the CBD. Industrial uses are located west and east of the city limits and along the Neches Channel. Notable industrial uses located to the west of Port Neches include Huntsman, Ameripol Synpol/Huntsman, Motiva Enterprises, and Air Liquide. Adjacent to the Neches River on the north side (north of Port Neches), land uses are mostly vacant land, with the exception of the Entergy – Sabine Plant.

North of the Sabine Pass area, the SNWW divides Pleasure Island and Sabine Lake from land areas west of the channel. Pleasure Island is a long narrow island that extends from the Sabine Pass area northward to the vicinity of the confluence of the Sabine and Neches rivers. The southern half of Pleasure Island consists primarily of vacant land. The northern half of Pleasure Island has some development in areas directly across from downtown Port Arthur. These developed areas consist of the Port Arthur Marina and

Yacht Club, the Pleasure Island Golf Course, Logans Park, City Hall Park, residential areas, and buildings and facilities operated by the USCG, the U.S. Army Reserve, the USACE, and Lamar University. SH 82 (T.B. Ellison Parkway) provides north-south access along Pleasure Island.

West of Pleasure Island and the Sabine-Neches Ship Channel is the City of Port Arthur. This area is characterized by heavy industry south, southwest, and north of the city. Land uses in the City of Port Arthur include commercial development mostly along state highways and arterial roadways, and residential neighborhoods, offices, and parks are interspersed throughout the city on collector and residential streets. Housing stock varies widely in terms of date of construction, size, and degree of maintenance. Civic buildings are located mostly in Port Arthur's CBD, which is located near the Sabine-Neches Ship Channel. Also located in the Port Arthur CBD is Lamar University – Port Arthur, and the Port of Port Arthur.

Notable industrial uses located east, southeast, and south of Port Arthur include Motiva Enterprises LLC, Huntsman, Ethyl Additives, Equilon, Premcor, Chevron, and the Texaco Terminal. Notable industrial uses that are located north of Port Arthur include Atofina, Horizon, Pabtex, R&R Marine Maintenance, and a variety of other industrial companies located either along SH 87/73 or adjacent to the SNWW.

Sabine Pass forms the southern entrance of the Sabine-Neches Ship Channel from the Gulf into the study area. In this area, on the Texas side (on the west side) of the Sabine Pass, is the Texas Point NWR and the Sabine Pass Battleground State Historical Park. Farther west along the Gulf coastline is Sea Rim State Park and the McFaddin Marsh NWR. This area is characterized by (mostly) undeveloped marshland and beaches, with numerous small lakes and wetland areas. The eastern side of Sabine Pass (the Louisiana side) consists almost entirely of undeveloped marshland and beaches. SH 82 parallels the Gulf coastline and connects with Johnson's Bayou, Holly Beach, Cameron, and the Calcasieu Lake area to the east.

In Louisiana, east of Sabine Lake, land is mostly vacant and consists primarily of wetland areas. The Sabine NWR makes up much of the land area in this portion of Cameron Parish. Very few roads or other urbanized land uses are located in this area.

3.14.4.1 Transportation

3.14.4.1.1 Roadways

Surface transportation in the vicinity of the study area is provided by a network of primary, secondary, and local roads. IH 10 is the primary artery of the BPA MSA. US 69, 90, and 287 and SH 347 also facilitate travel throughout the study area. As a result of the area's heavy dependence on industrial manufacturing, rail and sea transportation are vital within the area.

Transportation in Cameron Parish is served by two major state highways. The major north-south routes through the parish follow SH 27, which connects with IH 10 in Calcasieu Parish (16 miles north of the Cameron Parish border). The major east-west route through the parish is SH 82, which follows the Gulf Coast. Traffic on SH 27 and SH 82 must use the Cameron Ferry to cross the Calcasieu River Ship

Channel. Intercity bus service is provided only in Lake Charles and in Sulphur (Cameron Parish Police Jury, 2002). In Cameron Parish, IH 10 provides for east-west travel through the parish. SH 171 provides for travel to points north of Lake Charles.

3.14.4.1.2 Airports

There are no public general or commercial aviation airports in Cameron Parish. There are several private companies that have landing strips and offer helicopter services (primarily to the offshore oil and gas industry).

The Southeast Texas Regional Airport is located 10 miles south of Beaumont on US 69. This airport is served by Continental Express providing direct service to Houston and Dallas-Fort Worth. The Orange County Airport, located 3 miles southwest of Orange, serves general aviation needs for the study area. The Beaumont Municipal Airport serves the City of Beaumont and is located on US 90, 6 miles west of the city.

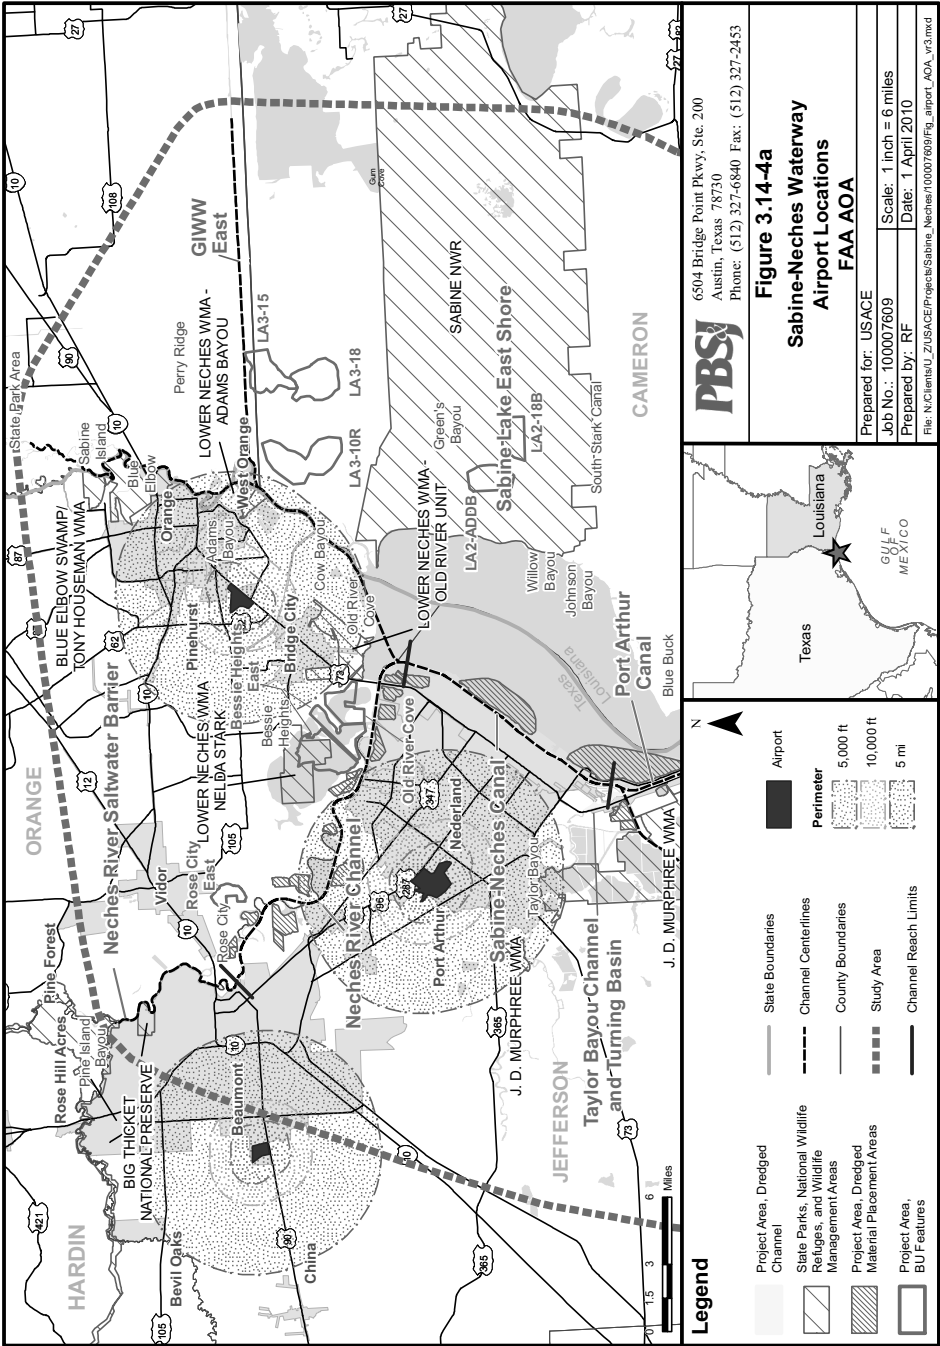

Due to the increasing concern about aircraft-wildlife strikes, the FAA has implemented standards, practices, and recommendations for holders of Airport Operating Certificates issued under Title 14, CFR Part 139, Certification of Airports, Subpart D (Part 139), to comply with the wildlife hazard management requirements of Part 139. Airports that have received Federal grant-in-aid assistance must use these standards.

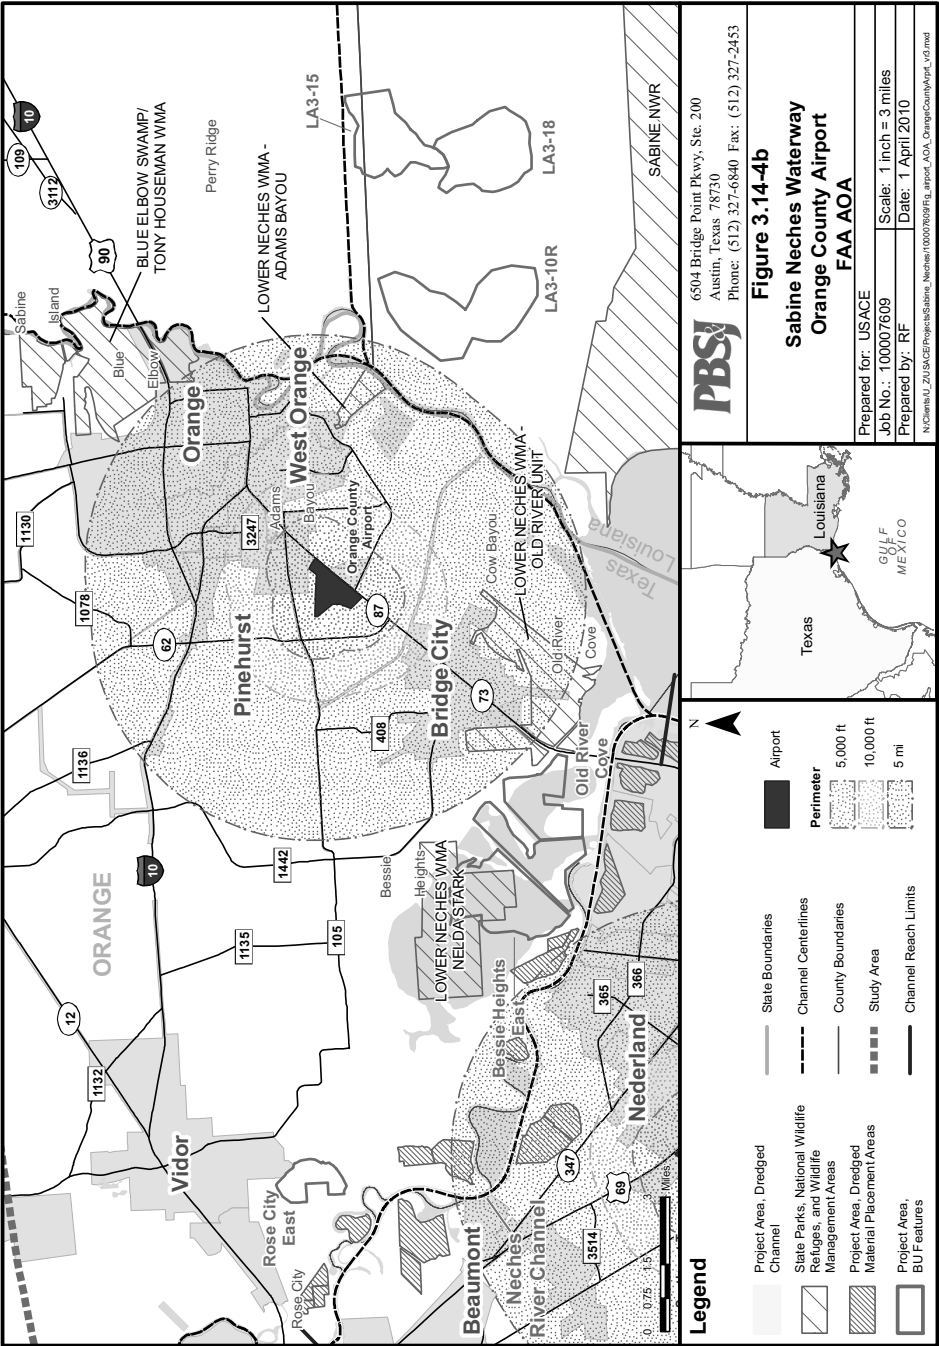

When considering proposed dredged spoil, BU features, and mitigation areas, developers must take into account whether the proposed action will increase wildlife hazards. The FAA recommends minimum separation criteria for land use practices that attract hazardous wildlife to the vicinity of airports. These criteria include land uses that cause movement of hazardous wildlife onto, into, or across the airport's approach or departure airspace or air operations area (AOA).

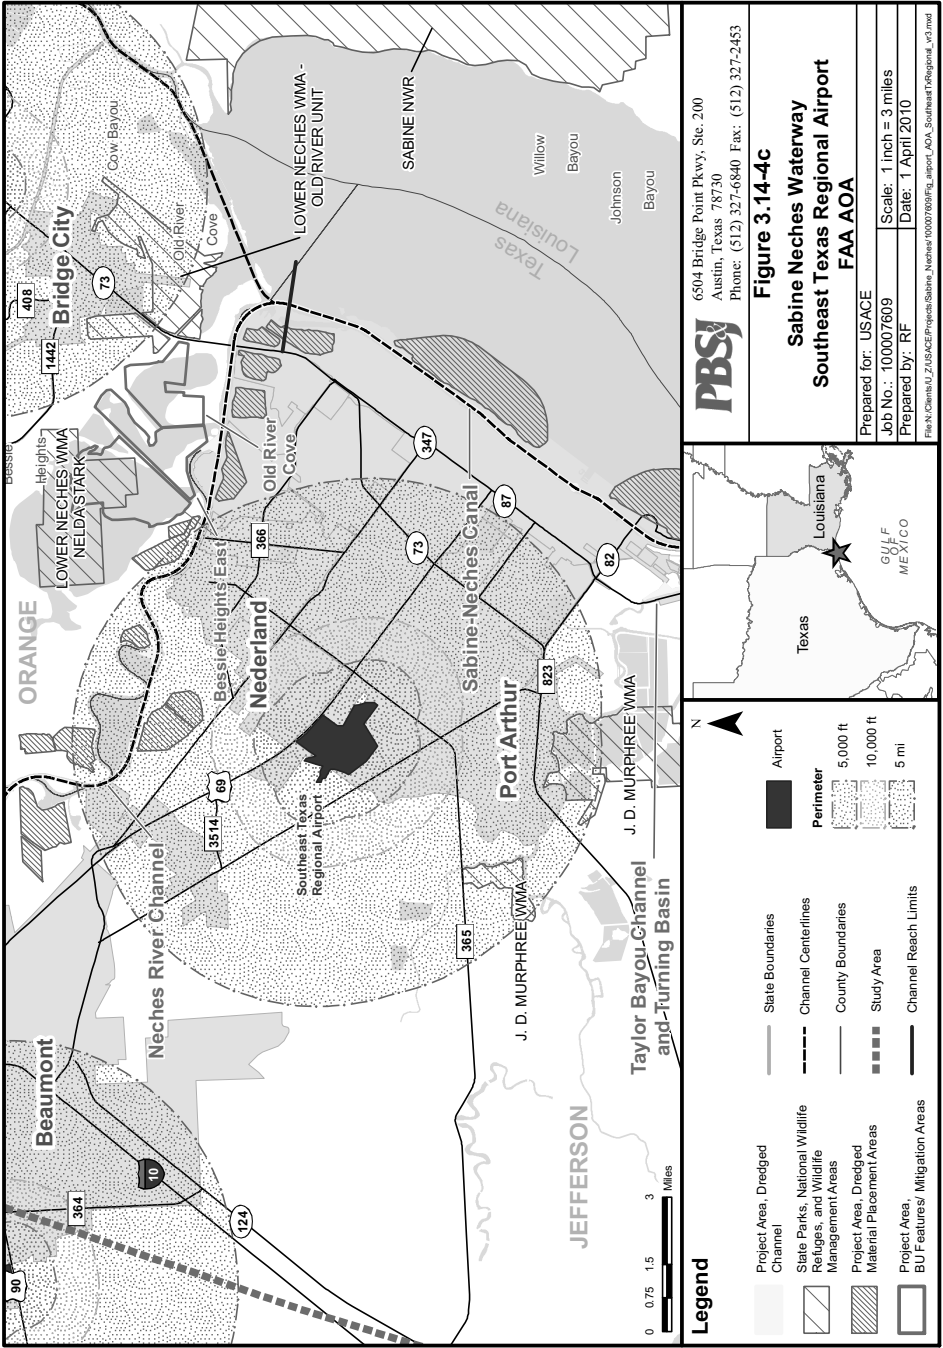

These separation criteria include:

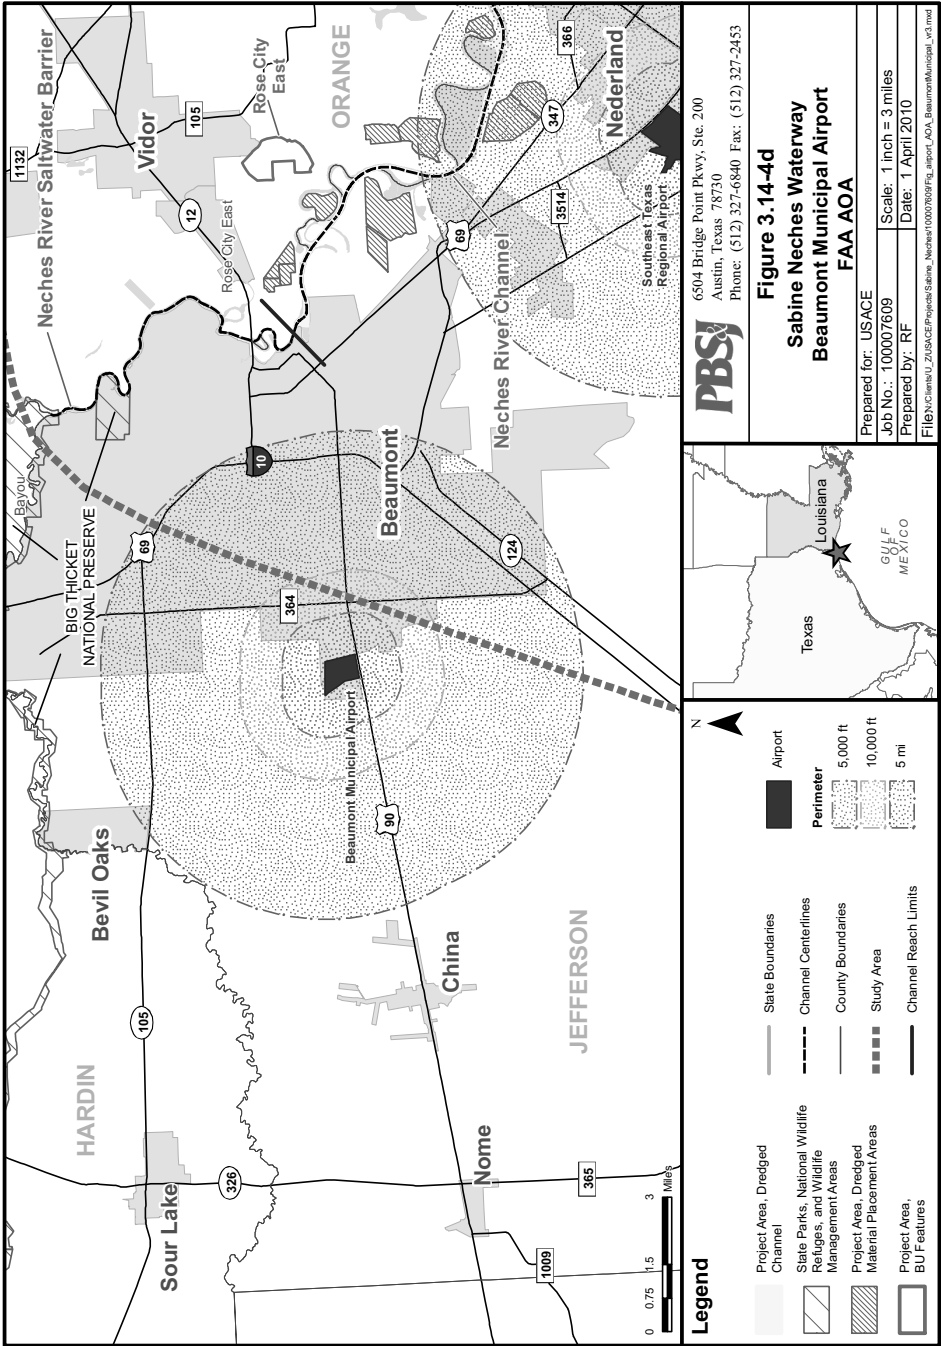

- Perimeter A: For airports serving piston-powered aircraft, hazardous wildlife attractants must be 5,000 feet from the nearest AOA (does not include any of the three airports within the study area);
- Perimeter B: For airports serving turbine-powered aircraft, hazardous wildlife attractants must be 10,000 feet from the nearest AOA (includes the three airports within the study area); and
- Perimeter C: 5-mile range to protect approach, departure, and circling airspace (includes the three airports within the study area).

Airports within the study area that must comply with these standards include the Orange County and Southeast Texas Regional airports and the Beaumont Municipal Airport, which is located just outside the study area (Figure 3.14-4a). Figures 3.14-4b–c show the perimeters around the AOA of 5,000 feet, 10,000 feet, and 5 miles surrounding these airports. Although the Beaumont Municipal Airport itself is not located within the study area, the 5-mile perimeter does fall within the study area (Figure 3.14-4d).

3.14.4.1.3 *Railways*

There is no rail service to Cameron Parish. Connections to three major freight rail systems (the Kansas City Southern Railway, the Union Pacific System, and the Southern Pacific Transportation Company) can be obtained in the nearby Lake Charles/Westlake/Sulphur metropolitan area of Calcasieu Parish. Amtrack Intercity Rail Passenger service is also available in Lake Charles.

Several rail carriers provide transportation within the study area, and form an important link to the Port of Beaumont, the Port of Port Arthur, and the Port of Orange. The four major rail carriers are Burlington Northern Santa Fe, Union Pacific, Kansas City Southern Railroad, and Tex Mex Rail Road. The Sabine River and Northern is a short-line railroad running through the area. Beaumont has 13 motor freight carrier terminals and 53 general freight carriers that serve the MSA's transportation needs (Texas A&M University, 2000).

3.14.4.2 *Community Services***3.14.4.2.1 *Fire, Police, and Emergency Medical Service***

Fire protection within the vicinity of the study area is handled by a combination of municipal and volunteer fire departments (VFD). Fire departments serving the study area include the Beaumont Fire Department, Nederland Fire-Rescue Department (includes the Nederland VFD), Port Arthur Fire Department, and the City of Groves Fire Department.

In Beaumont, fire protection is provided by the City of Beaumont Fire Department, which covers approximately 85 square miles and serves approximately 113,400 people. There are 229 paid personnel serving the city. This fire department responds to fire, medical, hazardous material, high-rise rescue, and dive rescue emergencies. The department includes 10 fire engines, 2 aerial pumpers, 2 aerial trucks, and 3 rescue trucks (City of Beaumont, 2009).

Fire protection within the city limits of Nederland is handled by the Nederland Fire-Rescue Department, which includes the Nederland VFD. Together, the Nederland Fire-Rescue Department and the Nederland VFD serve an area of approximately 4.5 square miles and approximately 17,400 residents who live within the City of Nederland and its Extraterritorial Jurisdiction (ETJ). There are 17 volunteer firefighters, and 6 of these personnel form a 6-person specialized rescue team. This fire department has the following equipment: three pumpers/engines, one 75-foot aerial truck, and one rescue truck. These fire departments respond to both fire and medical emergencies (City of Nederland, 2009).

In Port Arthur, fire protection is provided by the City of Port Arthur Fire Department, which covers an area of approximately 142 square miles serving approximately 57,800 people. There are 105 firefighters and 7 fire stations serving the residents and industrial areas of the city. This fire department responds to fire, medical, and hazardous materials emergencies. The services of this fire department are broken into the departments of Administration, Suppression, Training, Prevention, Communications, and Maintenance. This fire department includes the following equipment: seven fire engines, one snorkel, one

dive and high-angle rescue van, one hazardous materials truck, and several rescue boats (City of Port Arthur Fire Department, 2009).

Fire protection within the city limits of Groves is provided by the City of Groves Fire Department, which covers approximately 4 square miles and serves approximately 15,733 residents living within the city limits and its ETJ. The fire department responds to fire, medical, and hazardous materials emergencies. There are 14 paid firefighters and 25 volunteers operating from one fire station that is centrally located. This fire department includes the following equipment: three pumpers, one utility van, one utility pickup truck, one Chief's car, and one Assistant Fire Marshall's car (City of Groves, 2009).

The Insurance Services Office (ISO) ranks in accordance with the *Fire Suppression Rating Schedule* manual. The rankings are determined through the examination of three primary factors: the city's alerting system (i.e., 911 service and fire alarm systems) (10 percent); the fire department itself (50 percent); and the existing water system (40 percent). In Texas, the *Fire Suppression Rating Schedule* has been modified to include the following fire prevention activities: fire prevention code information, fire investigation, public fire safety education, construction code enforcement, attendance in Texas A&M's Fireman Training School, the number of certified volunteer firefighters available, and membership in the State Fire Marshall's Association or Texas Commission on Fire Protection. On the *Fire Suppression Rating Schedule* scale of 1 to 10 (1 being best), the ISO gives the City of Nederland Fire-Rescue Department a rating of 5, the City of Port Arthur Fire Department a rating of 3, and the City of Groves Fire Department a rating of 4 (Bradley, 2002).

3.14.4.2.2 *Public Services and Utilities*

Within the study area, a variety of entities provides electric utility, natural gas, water, wastewater, and solid waste disposal services. These services are summarized in Table 3.14-19.

3.14.4.2.3 *Regional Water Planning*

The TWDB has provided information pertaining to water supply, demand, and management direction for 16 Regional Water Planning Areas in Texas in the 2007 State Water Plan, *Water for Texas – 2007*, which was adopted by the Board on November 14, 2006. This State Water Plan document provides baseline information and planning policy related to the East Texas Region (Region I), which includes 20 counties of East Texas, including three counties (Hardin, Jefferson, and Orange) within the proposed project study area (TWDB, 2007).

The East Texas Region Planning Group identified water supply needs for 92 out of 165 water user groups in the region. The total needs by 2060 are about 1,261,320 acre-feet per year. There are 47 urban and rural municipalities and 18 irrigation and livestock user groups with needs in 2060. Estimated capital costs of recommended water management strategies for meeting needs over the 50-year planning horizon are about \$613 million (TWDB, 2007).

Table 3.14-19
Public Service and Utility Providers within the Study Area

	Electric Utility Service	Natural Gas Service	Water	Waste Water	Solid Waste Disposal Service
City of Beaumont	Entergy	Reliant Entex	City of Beaumont	City of Beaumont	City of Beaumont
City of Nederland	Entergy	Reliant Entex	City of Nederland	City of Nederland	City of Nederland
City of Port Neches	Entergy	Southern Union Gas	City of Port Neches	City of Port Neches	City of Port Neches
City of Groves	Entergy	Southern Union Gas	City of Groves	City of Groves	City of Groves
City of Port Arthur	Entergy	Southern Union Gas	City of Port Arthur	City of Port Arthur	City of Port Arthur
Unincorporated areas of Jefferson County	Entergy	Southern Union Gas and Reliant Gas			
Unincorporated areas of Hardin County

City of Orange			City of Orange	City of Orange	City of Orange
City of West Orange					
Unincorporated areas of Orange County	Entergy and Gulf States Utilities	Entex and United Texas Transmission			
Unincorporated areas of Calcasieu Parish	Entergy	Reliant Entex	Publicly provided by multiple water districts	Mechanical Sewer and Septic Systems	Waste Management Inc.
Unincorporated areas of Cameron Parish					

Sources: Entergy Louisiana (2002); City of Beaumont (2002); City of Bridge City (2002); City of Nederland (2005); City of Port Neches (2002); Bellard (2002); Cendercast (2002); Greater Orange Area Chamber of Commerce (2002).

The largest water user in the East Texas Region is steam electric, which accounts for 51 percent of the total demand of about 1.75 million acre-feet per year in 2060. Increases in steam-electric power generation, mining, and irrigation demands are also expected. Municipal water use for the region is projected to increase between 2010 and 2060, from about 151,000 acre-feet per year to 188,000 acre-feet per year. Five counties (including two study area counties), Angelina, Jefferson, Nacogdoches, Orange, and Smith, account for most of the total municipal use for the region in 2060. The cities (includes three study area cities) of Lufkin, Beaumont, Port Arthur, Nacogdoches, Orange, and Tyler are included in these counties. These cities would rely on increased groundwater and surface water production to meet

their needs. The only unmet needs in 2060 are 3-acre-feet per year for mining and 17 acre-feet per year for municipal uses (TWDB, 2007).

3.14.4.3 Aesthetics

The term aesthetics deals with the subjective perception of natural beauty in a landscape by attempting to define and measure an area's scenic qualities. Consideration of the visual environment includes a determination of aesthetic values (where the major potential effect of a project on the resource is considered visual) and recreational values (where the location of a proposed project could potentially affect the scenic enjoyment of the area). Aesthetic values considered in this study, which combine to give an area its aesthetic identity, include:

- topographical variation (hills, valleys, etc.)
- prominence of water in the landscape (rivers, lakes, etc.)
- vegetation variety (woodlands, meadows, etc.)
- diversity of scenic elements
- degree of human development or alteration
- overall uniqueness of the scenic environment compared with the larger region

The study area consists of a variety of terrain characterized by varying levels of aesthetic quality. The topography of the area is mostly flat to gently rolling, with very few outstanding elevational changes. Natural water features within the study area include the following: Sabine Lake, the Neches River (upstream of the Neches Channel), the Sabine River (upstream from the Sabine Channel), Black Marsh Lake, Black Bayou, Cow Bayou, Old River Bayou, numerous relatively small lakes, and many wetland areas. Also, the Gulf forms the southern border of the study area. Water features that are heavily used for waterborne commerce show a high degree of human development and alteration and include the following: the Neches Channel, the Sabine Channel, the Sabine-Neches Channel, the Port Arthur Channel, the Sabine Pass Channel, the Sabine Pass Jetty Channel, and the GIWW. Also some areas of Sabine Lake (especially on the Texas side of the lake) show a moderate degree of human development and alteration.

In general, in areas that are not urbanized, the study area exhibits a variety of vegetation types. Generalized vegetation within the study area is shown on Figure 3.9-1 and discussed in more detail in Section 3.9. Wetland areas are found surrounding Sabine Lake, along the Gulf Coast on both the Texas and Louisiana side, throughout most of the Louisiana portion of the study area and within the floodplain areas of the Sabine and Neches rivers/channels. Agricultural lands are found mostly in the western, northern, and northeastern portions of the study area. Forested or woodland upland areas are found primarily in the northern portion of the study area between the Sabine and Neches rivers.

However, the study area has also seen widespread human development, which can, depending on the type and scale, detract or add to the overall aesthetic quality (see figures 3.14-3a-c). Urban development

within the study area is concentrated in and around the following municipalities: Beaumont, Nederland, Port Neches, Groves, Port Arthur, Vidor, Bridge City, West Orange, and Orange. Land uses within the urbanized areas include a variety of residential neighborhoods, commercial or CBD districts, transportation systems (highways and railways), civic uses, parks, schools, port facilities, and heavy industry areas. The single largest detractor from the aesthetics of the study area is undoubtedly the heavy industry areas. There are large areas of heavy industry located near to the detailed study area (along the SNWW) southeast of Beaumont and in areas near Port Neches, Groves, and Port Arthur.

Generally speaking, the study area is not particularly distinguished in aesthetic quality from other adjacent areas within the region, although some areas within the region lack the vast waterbodies of the study area. The landscape exhibits a generally moderate to high level of impact from human development and alteration. No designated scenic views or scenic roadways were identified from the literature review or from field reconnaissance of the study area.

4.0 ENVIRONMENTAL CONSEQUENCES

This chapter is divided into 16 sections. Section 4.1 describes how the HS and WVA models were used to evaluate project impacts. Section 4.2 discusses risk and uncertainty in the application of these models. This is followed by separate sections that discuss project impacts to each category of physical, natural, cultural, and socioeconomic resources in the SNWW study. The chapter ends with a discussion of cumulative impacts in Section 4.16.

Environmental consequences analysis of the Preferred Alternative includes the assumption that the eight Neches River Turning and Anchorage Basins (Alternative G, Table 2.3-1) are a component of the SNWW CIP.

4.1 MODELING FUTURE WITHOUT AND WITH-PROJECT CONDITIONS

The evaluation of ecological impacts to the extensive wetland habitats in the study area was performed primarily with WVA models. These models provide quantitative estimates of changes to the quality and quantity of fish and wildlife habitat in the SNWW's wetland communities. The WVA is primarily driven by salinity predictions from the HS model. Both FWOP and FWP effects must be determined using the WVA models and the differences between the two calculated in order to determine the effects of the proposed project.

The HS model is described in detail in a separate report (Brown and Stokes, 2009). In brief, the HS model is a 3-dimensional TABS-MDS code that propagates flow and salinity throughout the model domain in response to many factors (e.g., tides, Gulf boundary conditions, winds, freshwater inflows). A 3-dimensional simulation was employed in the navigation channels and Sabine Lake, and 2-dimensional simulation (vertically integrated) was used in the shallow tributaries.

As described in Brown and Stokes (2009), the HS model was calibrated and verified using field observations collected by the ERDC during a long-term data collection effort at 16 stations in the study area from May 16, 2001, through January 10, 2002 (Fagerburg, 2003). The model tidal elevations, discharge measurements, current velocities, and salinities were compared to field data obtained during the period, and figures showing these comparisons can be reviewed in Brown and Stokes (2009). In general, the model performed reasonably well. The tidal elevations were comparable to field data near the coast with the level of agreement reduced somewhat in the upper reaches. Discharge and current velocity observations were also similar to model output at most but not all stations. The salinity comparisons were also reasonably close. It was noted that while salinity stratification was qualitatively correct, the model was somewhat more diffusive than observed and the amount of upstream salinity transport may at times be underestimated. However, a sensitivity analysis was conducted to investigate how well the model behaves under conditions when the flow is not changing rapidly. Since flow changes associated with the project would not be rapid, the behavior of the model under these conditions provides a better reflection of the gradual changes expected with the project. The model was found to behave better at most gages

under these conditions. Overall, the model provides a very detailed representation of the system and appears to be a suitable tool for evaluating project effects.

With the model developed and performance demonstrated against field data, the next step was using the model to quantify changes in the FWP and FWOP conditions. Two key components of this future evaluation are freshwater inflows and relative sea level change. After these components are described, the FWOP and FWP conditions are presented.

4.1.1 Freshwater Inflows

Freshwater inflow for the SNWW HS model's future conditions were developed using model outputs from Run 8 of the TCEQ Water Availability Models (WAM) for the lower Sabine and Neches rivers. For existing conditions, "Run 8 uses modified diversion amounts (maximum use for the last 10 years), year 2000 area-capacity parameters for major reservoirs, and assumed return flows. It also includes term water rights and provides the most realistic assessment of current streamflow conditions" (TWDB, 2007). The TWDB projected flows for the year 2060 by modifying Run 8 "to include projected increased demand from existing water rights, expected change to return flows, projected new strategies to come online before 2060, and estimated year 2060 storage capacities for major reservoirs" (TWDB, 2007).

The 2060 WAM runs were selected for use in the SNWW HS modeling because they were developed by the State's lead water planning agency, and they include future water supply strategies approved by the 2007 Texas State Water Plan (TWDB, 2007). The SNWW study area is included in Regional Plan I for the East Texas Region. The Region I water plan takes into consideration existing flows that are dedicated to the State of Louisiana as prescribed by the Sabine River Compact. All existing and proposed future strategies for meeting Texas's demand must be met by the Texas firm-yield share (750,000 acre-feet) of the total Sabine River flow, as appropriated under the use provision of Certificate of Adjudication No. 05-4658 (March 5, 1958). The 2060 WAM model does not attempt to predict future demand in the Louisiana portion of the Sabine Basin. This should not significantly affect future projections because the Louisiana portion of the basin is comprised primarily of undeveloped, coastal wetlands.

By 2060, Region I's population is projected to grow 36 percent, and water demands are projected to increase by 41 percent. The greatest increase (48 percent) is expected in the demand for water for manufacturing. Municipal demand is expected to grow 24 percent. The existing water supply is projected to decrease slightly by 2060, due primarily to reservoir sedimentation and a small decline in groundwater supply. Although the region as a whole appears to have enough supply to meet demands through 2060, the total water supply is not readily available to all users.

The regional plan recommends the following strategies to provide the additional water supply projected to be needed by 2060: (1) the construction of Lake Columbia reservoir in the Neches River watershed; (2) cooperation with Region C, which includes the Dallas-Fort Worth metropolitan area, in the use of surface water from Toledo Bend Reservoir and proposed Lake Fastrill; (3) expanded groundwater use by smaller communities; and (4) municipal conservation throughout the region.

The WAM outputs were developed using current patterns of precipitation and evaporation. The USACE did not modify the models to use projected precipitation or evaporation for SNWW future conditions because the Texas State Climatologist has recently concluded that it is impossible to predict with confidence what precipitation trends would be in Texas over the next half century (Nielsen-Gammon, 2009). Unlike precipitation, there is more consensus for a predicted temperature increase in Texas of close to 4°F by 2060. No attempt was made to change future temperatures in the model because resulting changes in evapotranspiration would be so small as to negligibly change modeling results.

Two freshwater inflow conditions, median and low, were developed for project evaluation. For both flow conditions, the ERDC provided salinities for all model stations and nodes for WVA modeling. Figure 4.1-1 illustrates the inflow values employed for the two major inflow sources for both the 10th percentile, low flow (dotted lines), and 50th percentile, median flow (solid lines), obtained from the WAM monthly output files.

Figure 4.1-1. SNWW Low and Median Inflow Hydrographs

These inflows were used for all impact analyses. The low inflow runs were conducted for 5 months, June through October, with June and July used for model spin-up. The spin-up months allow the model to reach a dynamic equilibrium for salinity and are not used in the analysis. The model output for the 3-month period from August through October was used for the low-flow sensitivity analysis. The median-flow simulation covered 6 months, April through September, with only 1 month, March, used for spin-up. The shorter spin-up period for the median flow was because the higher flow resulted in lower water residence times in the system. The median-flow output was used for all impact analyses.

Additional boundary conditions include flows in and out of the GIWW on the east and west boundaries of the study area, direct precipitation inputs, and the Gulf boundary condition salinity. Details are provided in Brown and Stokes (2009).

4.1.2 Relative Sea Level Rise

While the future rate of RSLR at the Sabine-Neches Estuary is very uncertain, it must be considered in project planning. Current USACE guidance (ER 1105-2-100; April 2000) stipulates that NRC (1987) should be used to determine the potential impacts of sea level rise on plan formulation and engineering structures. RSLR consists of two components: global (eustatic) sea level rise and local subsidence. The uncertainty inherent in the rates of eustatic sea level rise is evident in the variability of the different modeled rates given for the NRC (1987) projections and the Intergovernmental Panel on Climate Change (IPCC, 2007). A similar degree of uncertainty exists with the rate of local subsidence.

A detailed review of both eustatic and local subsidence rates was performed by the ERDC (Brown and Stokes, 2009). This review found the eustatic rate estimates range from 1.8 mm/year to 6.45 mm/year for the next 50 years. This study employs an estimate for eustatic rise (4.5 mm/year) that is in the middle of the range projected by NRC (1987) and in the high middle range of that predicted by IPCC (2007). In coastal Louisiana, estimates of the local subsidence component of RSLR were found to range from 0.4 to 0.6 mm/year based on basal peat measurements (Törnqvist et al., 2006), 2 to 5 mm/year as averaged from 48 years of tide gage data (Morton et al., 2006), and to 10 to 15 mm/year as measured from settling rates of established benchmarks (Shinkle and Dokka, 2004). The ERDC's review concluded that the lower rates were the most technically valid. These lower rates represent long-term trends in the subsidence rate, and seem to be the closest approximation of consensus concerning the local subsidence rate that is currently available.

Adding these to the NRC II projections for eustatic sea level rise yields a value for the RSLR in the SNWW study area over 50 years of 4.9 to 5.1 mm/year. The average of these, 5.0 mm/year is used for modeling purposes.

Therefore, the "most likely" value of RSLR to be used for the SNWW deepening study's 50-year period of analysis is 250 mm (0.82 foot). Adjusting this to account for the period of analysis beginning in 2019 and ending in 2069 (the new period of analysis for the SNWW reformulation), the "most likely" amount of RSLR by the year 2069 is 335 mm (1.1 feet).

Figure 4.1-2 illustrates the effect of RSLR on predicted FWOP salinity in the system with the low (10th percentile) flows. The two simulations illustrate the salinity difference between the FWOP salinities without RSLR and the FWOP salinities with RSLR. Both simulations use the same inflows (WAMs 2060 inflows). At most stations, the RSLR is predicted to cause average salinity to increase about 1 ppt.

Incorporating RSLR in the HS model raises water elevation uniformly by 1.1 feet, which in turn allows greater salt transport through the system. At Bessie Heights, the salinity increase with the low-flow inputs is 2.0 to 2.5 ppt. At the median inflows, the salinity increase from RSLR is 1.0 to 1.5 ppt.

Figure 4.1-2. Mean Salinity Values, Low-Flow Conditions

4.1.3 Application of HS Model to Predict Project Effects

Having established the HS model’s performance against field data and future conditions expected for freshwater inflows and RSLR, the next step is to use the model to predict changes in water elevations and salinity associated with project alternatives (the FWP condition). All simulations were performed using the low and median freshwater inflows and the 1.1 feet RSLR increase. Three types of project alternatives are considered: the 48-foot depth, other depth alternatives, and the effect of salinity mitigation measures.

4.1.3.1 Water Surface Elevations – 48 Foot Channel

Water surface elevation over the study area was largely unaffected by the deeper navigation channel. An exception to the general result is the upper end of the Neches River near the saltwater barrier. Figure 4.1-3 provides a sample of the tides with and without the 48-foot channel at this location. The average high-water elevation appears to increase by 0.067 foot.

4.1.3.2 Salinity Changes – 48-Foot Channel

The effect of the 48-foot navigation channel is to increase salinity over most of the study area. The increase is greater for the median flows than for the low flows, reflecting a greater salinity gradient at high inflows, which allows a greater effect from the density current. Tables 4.1-1 and 4.1-2 provide a statistical analysis of salinity differences at 17 stations throughout the system for the low- and median-

flow conditions. The tables provide the average differences between FWP and FWOP for surface, mid-depth, and bottom depths at each station.

Figure 4.1-3. Time Series of Tide at Neches River Salt Water Barrier – Low-Flow Case

The model salinity results are used for WVA modeling. The WVA requires input of “mean salinity” during the growing season and “mean high salinity” for impacts to fresh and intermediate habitats. The term “mean high salinity” is defined as the average of the highest 33 percent of consecutive salinity readings during a specified period of record. These two outputs of the HS model: mean and highest 33 percent, are the primary inputs to the WVA modeling.

4.1.3.3 Salinity Changes – Other Channel Depths

A model run with a 45-foot channel indicated that the salinity differences from the FWOP were similar to those with a 48-foot channel but lower in magnitude. To address salinity changes at other channel depths besides 48 and 45 foot, a quadratic equation was developed at each station based on model results at 0-, 5-, and 8-foot channel depth increase. This allowed the salinity change for each channel depth alternative to be predicted without having to model each deepening scenario independently.

4.1.3.4 Salinity Changes – Salinity Mitigation Measures

Three types of salinity mitigation measures were considered: large scale, small scale, and local. The large-scale measures are those such as Rose City, Bessie Heights East and West, and Old River Cove. These large-scale measures have the potential to influence the entire system and were modeled with the TABS-MDS model. The small-scale features were evaluated with a desktop model, and the local measures such as shoreline restoration or plugging of a logging canal were not modeled. The salinity results were used to develop WVA benefits for the wide array of mitigation measures that were evaluated during the preliminary screening of mitigation measures. The model runs for the large-scale measures were primarily concerned with reclamation of wetlands along the Neches River. Salinity reductions predicted by the modeling would only be effective if all of the proposed measures were adopted. Least-cost analyses resulted in the exclusion of Bessie Heights West, a large feature that contained about one-third of the proposed reclamation area. An FWP reduction in salinity is not forecast in conjunction with reclamation of the remaining components of the Neches River BU Feature because salinity effects of this revised BU plan have not been modeled, and the removal of Bessie Heights West would be expected to significantly reduce salinity benefits.

4.1.4 Application of the WVA Model

4.1.4.1 Comparison of the FWOP and FWP Conditions

The WVA methodology provides a comprehensive, quantitative estimate of FWP changes in the quality and quantity of emergent marsh, cypress-tupelo swamp, and bottomland hardwood forests.

Each WVA model consists of variables considered important to each habitat type and suitability indices (SI) for each variable. All of the variable SIs for a specific community (i.e., fresh/intermediate, brackish, or saline marsh; swamp; bottomland hardwood) are combined in a mathematical formula to calculate the Habitat Suitability Index (HSI), which represents the composite habitat quality of the wetland being evaluated. Within each HSI formula, important variables may be weighted relative to other variables in the formula. The HSI formulae employed for the SNWW ecological modeling are based on those developed by the CWPPRA Environmental Work Group (USFWS, 2002a, 2002b, 2002c).

The WVA methodology quantifies changes in specific wetland structural and functional characteristics determined to be significant indicators of habitat health and quality. It combines the effects of changes in wetland productivity and structure to calculate impacts measured as AAHU values. Future without project and FWP conditions for the period of analysis were projected using salinities from the HS model as input into the WVA model. The FWOP condition predicts changes expected to occur under the No-Action Alternative described in Section 3. The FWP condition addresses the changes expected to result from project construction, including impacts from the placement of dredged material, benefits of the BU features, and effects of the compensatory mitigation plan.

HSIs are established for the FWOP and FWP conditions for selected target years (TY) throughout the life of the project. Habitat units are calculated by multiplying these HSIs by the affected acreage at each target

year. The habitat units for the FWOP and FWP conditions totaled over the project life are divided by the total years of the project to determine AAHUs. Small changes in some variables like salinity, when applied to thousands of acres in the large hydrologic units in this study area, produce the changes in AAHUs shown tables 4.1-3 and 4.1-4 for Texas and Louisiana, respectively. The impacts or benefits of the project are then quantified by comparing AAHUs between FWP and FWOP conditions. This procedure fulfills the USACE requirement that compensation be evaluated using a unit of comparison that measures quality and quantity of habitat values over time.

The same procedure used to estimate FWP land loss was used to quantify the compensation associated with mitigation measures, which is described in detail in Chapter 5. Screened mitigation measures affected salinities in some areas, blocked shoreline retreat, and restored emergent marsh elevations in others. These changes were reflected in land loss tables specific to each mitigation measure as follows: (1) revised FWP land loss rates were calculated by substituting salinity values predicted by the HS model (Brown and Stokes, 2009) in the land loss rate formula for hydro-units on the Neches River; (2) acreages were adjusted in the land loss tables to account for the effect of mitigation measures, such as breakwaters or shoreline nourishment, which stopped or slowed existing shoreline retreat; and (3) acreages were adjusted in the land loss tables to add emergent marsh acres restored by the placement of dredged material or in-situ marsh terracing. Credit for marsh acreage was generally delayed by 1 year to allow time for planted and volunteer marsh vegetation to become established. This is based upon recent experience with CWPPRA and other marsh restoration projects in the lower Sabine and Neches watersheds where marsh plantings and natural vegetation rebounded quickly and robustly to create a stable marsh landscape.

Procedures to estimate the effects of mitigation measures deviate from the FWP land loss method in the specific instances where mitigation measures add mineral soils to degraded areas of former marsh. In these cases, the ICT projected that the loss rate for the mitigation areas would be lower because the addition of denser, mineral soils and the increase in marsh elevation would create a more stable landform. Accordingly, land loss rates due to the project were reduced by 50 percent in the land loss change spreadsheets for these areas. Other mitigation measures that did not involve the creation of a higher, more-stable landform were modeled using a land loss rate equivalent to the FWP rate.

4.1.4.2 Emergent Marsh Community Models

The EMCMS were used to evaluate saline, brackish, intermediate, and fresh marsh habitats in the study area. Variables included in the models were selected based upon their importance to fish and wildlife in coastal marsh ecosystems. A large number of species-specific HSI models for a variety of fish and shellfish, freshwater fish, birds, reptiles and amphibians, and mammals were reviewed and considered in the development of model assumptions. Six variables represent wetland habitat quality in the model:

	Totals		-5,453	-247		28,124	-412			

- V₁ percent of the wetland covered by emergent vegetation
- V₂ percent of the open water covered by SAV
- V₃ marsh edge and interspersed
- V₄ percent of the open-water area less than or equal to 1.5 feet deep
- V₅ salinity
- V₆ aquatic organism access

The reader is cautioned that straightforward comparisons of impacts associated with changes in salinity or other variables are not easily made between hydro-units. The varying AAHUs and acreage results are due to differences in project impacts, underlying conditions (i.e., existing land loss rate, marsh interspersed, SAV), and the size of the hydro-unit. Salinity is not the only determinant; changes in other variables can also have significant effects. Additional information about the weighting of variables is provided below. However, refer to Appendix C of the FEIS for detailed narratives of the FWOP and FWP conditions in each hydro-unit.

The primary focus of the SNWW application of the EMCM is the preservation of vegetated wetlands, but it is also recognized that some marsh restoration or protection strategies could have an adverse effect on aquatic organisms. Therefore, variables V₁ (percent emergent vegetation), V₂ (percent SAV), and V₆ (aquatic organism access) are grouped together and weighted more than the remaining variables. For all marsh models, V₁ receives the greatest weighting; however, the relative weights of V₁, V₂, and V₆ vary by marsh model to reflect different levels of importance between the marsh types.

The EMCM employs a split model format to account for the value of both marsh and open-water habitats. Two HSI formulas are calculated for each marsh type – one for emergent marsh habitat and one for open-water habitat. The HSI formula for emergent marsh contains the variables important for evaluating its habitat quality (V₁-percent coverage of emergent vegetation, V₃-marsh edge and interspersed, V₅-salinity, and V₆-aquatic organism access). The HSI formula for open-water habitat contains only the variables important to that habitat component (V₂-percent open water with SAV, V₃-marsh edge and interspersed, V₄-percent open water <1.5 feet deep, V₅-salinity, and V₆-aquatic organism access).

4.1.4.3 Swamp Community Model

The SCM uses variables that evaluate the ability of swamps to provide resting, foraging, and nesting habitat for a wide variety of wildlife species. In general, the swamp model can be applied if woody canopy cover is at least 33 percent of the surface area, and at least 60 percent of the canopy consists of any combination of bald cypress, tupelo gum, red maple, buttonbush, and/or planertree (*Planera aquatica*). The following four variables represent swamp habitat quality in the model:

- V₁ stand structure
- V₂ stand maturity
- V₃ water regime
- V₄ mean high salinity during the growing season

All of the SIs are combined in a mathematical formula, the HSI, which represents the composite habitat quality. Variables V_1 and V_3 (stand structure and water regime) are considered the most important variables in characterizing swamp habitat quality and therefore are weighted more than other variables. Variables V_1 and V_2 were adjusted for the dampening effect of salinity on tree growth, using output from the HS model. Variable V_4 (salinity) is weighted lower than the other variables.

4.1.4.4 Bottomland Hardwood Model

The BHM applies to forested wetlands that support a canopy of woody vegetation of which more than 40 percent of tree species consist of oaks, hickories, American elm, cedar elm, green ash, sweetgum, sugarberry, boxelder (*Acer negundo*), common persimmon (*Diospyros virginiana*), honeylocust (*Gleditsia triacanthos*), red mulberry (*Morus rubra*), eastern cottonwood (*Populus deltoides*), black willow (*Salix nigra*), and American sycamore (*Platanus occidentalis*). Variable selection for the model was based upon a review of various USFWS HSI models for bottomland hardwood wildlife. The following variables represent bottomland hardwood habitat quality in the model:

- V_1 tree species composition
- V_2 stand maturity
- V_3 midstory/understory
- V_4 hydrology
- V_5 size of contiguous forested area
- V_6 surrounding land uses
- V_7 disturbance

The model incorporates site-specific habitat quality features (tree species composition, forest stand structure, stand maturity, and hydrology) and landscape parameters (forest size, surrounding land use, and disturbance). Because the primary application of this model is to quantify the loss of ecological values due to changes in the site-specific conditions, variables that are likely to be affected by these changes (V_1 , V_2 , V_3 , and V_4) are considered more important than the landscape variables. Of the site-specific variables, V_1 (tree species composition) and V_2 (stand maturity) are considered equal and of greater importance than the other variables. Variable V_3 (understory/midstory) and V_4 (hydrology) are weighted less than V_1 and V_2 . The “landscape” variables (V_5 , V_6 , and V_7) are not weighted. Variables V_1 , V_2 , and V_3 were adjusted for the dampening effect of salinity on tree growth, using output from the HS model.

4.1.5 Storm Surge Sensitivity Modeling

The potential for proposed project features to increase storm surge impacts in the study area was analyzed with a storm surge sensitivity analysis (Wamsley et al., 2010). The ADCIRC model was run to estimate water levels for two worst-case hypothetical storms, both with and without proposed SNWW CIP project features in place. Project features evaluated by the modeling are the deeper navigation channel, proposed PAs with maximum levee heights, and two expanded PAs. The two simulated storms exhibited minimum central pressures of 900 millibars, offshore pressure radii between 14.9 and 18.4 nautical miles, and

forward speeds of 11 knots. Each produced water levels near or higher than the estimated 500-year level, and both would be considered extreme events. One storm tracked in the northwesterly direction, producing maximum surges of 18 feet near the coast at Sabine Pass and surges of 13–14 feet in Sabine Lake near Port Arthur, Texas. The second storm tracked in a north-northeasterly direction, producing maximum surges of over 20 feet near Sabine Pass and surges of 15 to 17 feet in Sabine Lake near Port Arthur.

The sensitivity analysis concluded that the greatest changes would occur north of Port Arthur along the Neches River. These changes are primarily due to the proposed increase in depth of the navigation channel. All changes are local, and there are no project-induced increases in surges away from the immediate vicinity of the navigation channel. Water levels in the marshes and open-water areas immediately north of the river would increase on the order of 4 to 8 inches or less. The modeling indicates some interior flooding would occur within the City of Port Arthur with both storms, both with and without the project. Changes in peak surge within the city for these two events, with the project in place, are caused by a slight increase in surge elevation and/or duration causing additional overtopping of the surrounding levee or internal topographic features. Peak surges for 100-year events are estimated to be approximately 9 feet in the Port Arthur area. Although simulations of less-intense events were not made as part of this study, in light of the 14- to 24-foot levees surrounding Port Arthur, significant interior flooding is not expected for the base condition. Any changes in peak surge on the order of inches should not cause any significant change in interior flooding for the with-project condition.

The Preferred Alternative for the SNWW CIP also includes ODMDS and marsh restoration measures. All of the existing and proposed ODMDSs are located several miles from the Gulf shoreline in water too deep to affect wave setup on the shoreline. The influences of marsh restoration on hurricane surge have been documented by Wamsley et al. (2009a, 2009b). Surges tend to slightly increase over and just seaward of the marsh as the surge propagation is slowed, which may result in reductions in peak water levels landward of marsh features. The impact of the proposed SNWW CIP marsh restoration features is relatively small and expected to modify peak surge levels locally by a minimal amount (Wamsley et al., 2010). No significant reductions or increases in surge level would be expected from either the marsh restoration or ODMDS.

4.2 UNCERTAINTIES ASSOCIATED WITH ECOLOGICAL MODELING FOR THE SNWW CIP

An analysis of risk and uncertainty associated with the WVA model application to the SNWW CIP has been performed in consideration of recommendations contained in the Actions for Change directive (USACE, 2006d). This analysis will facilitate risk-informed decision-making regarding the levels of ecological impacts and resulting recommended compensatory mitigation that were established using the models. The primary risks associated with ecological modeling for the SNWW CIP relate to the accuracy of the impact assessment and the cost of mitigation. Risks to human health or safety associated with ecological impacts are small. Incremental marsh loss attributable to the Preferred Alternative

(approximately 691 acres or about 2/5th of 1 percent of emergent marsh in the study area) would not affect the overall effectiveness of the coastal wetlands in buffering inland areas from storm surge effects.

An evaluation of the risks and uncertainties involved in application of the ecological model, on which the amount of proposed compensatory mitigation is based, is necessary to evaluate the adequacy of the recommended amount of ecological mitigation, and to support the recommended Federal investment. The reader is referred to Appendix C of this FEIS for the complete sensitivity analysis, including detailed methodology and analysis. A brief summary of the results of the analysis is presented below.

There are two types of uncertainty that have been identified for the predictive ecological modeling conducted in this study—uncertainty associated with model quality and performance, and uncertainty associated with model predictions. In regard to the first type of uncertainty, extensive technical review of the WVA models has been conducted to ensure that they are technically sound and defensible (LBG and TEA, 2008). The assessment determined that the concept and application of the models are sound for planning efforts. Theoretical approaches of the WVA models use scientifically established structural surrogates to evaluate wetland quality. The models' variables provide a reasonable description of the emergent marsh, swamp, and bottomland hardwood habitats, and are capable of evaluating project effects to habitat-based, functional processes that may be affected by the project. Based upon the results of this assessment, the Deep Draft Navigation Planning Center of Expertise, in consultation with the National Ecosystem Planning Center of Expertise, concurred with the findings of this assessment and approved the use of the WVA EMCM, BHM, and SCM for the SNWW feasibility study (Memorandum for Commander, HQ USACE [CECW-PC] and Commander, Southwest Division [CESWD-PDS] from the Director of Deep Draft Navigation Planning Center of Expertise [CESAD-PDS-P], dated June 30, 2009). This satisfies the requirements of EC 1105-2-407, as the WVA models were developed by a Federal agency other than the USACE, and are therefore subject to approval for use rather than certification.

Uncertainty associated with predictions of the WVA models (i.e., how different predictable outcomes could affect ecological impacts and costs) was evaluated by varying input values for the most significant variables. The WVA models do not include a direct way to measure risk, i.e., the model does not calculate a probability distribution that provides a statistically significant confidence level for the model projections. Since salinity is the driving force influencing WVA model predictions, salinity-related variables were targeted in one sensitivity analysis. The other analysis focused on an assumption underlying the valuation of the percent of emergent marsh cover. A range of possible outcomes associated with variable V_1 (percent of emergent marsh) in the EMCM, and variables V_4 and V_5 (salinity) in the SCM and EMCM, respectively, were evaluated to determine how uncertainties related to variable assumptions and values could affect impact predictions and compensatory mitigation decisions. Since the analysis was conducted to evaluate uncertainties with the recommended level of compensatory mitigation, the analysis was performed for the Louisiana hydro-units in which unavoidable impacts would occur.

4.2.1 Salinity Sensitivity

Because of uncertainties associated with HS model predictions of salinity impacts, a sensitivity analysis was performed to evaluate the full range of potential project effects. Salinity changes predicted with implementation of the Preferred Alternative were provided by the HS model. High- and low-salinity values bracketing the 95 percent confidence level were entered into WVA model for all habitats in Louisiana hydro-units. Ranges of AAHU impacts were then produced based on the 95 percent salinity range.

For cypress-tupelo swamps, the sensitivity analysis yielded a range of potential loss from 0 to 9 AAHUs, with no impact predicted to be most likely. The uppermost reaches of the Sabine River would remain essentially fresh; however, the Blue Elbow swamp near the GIWW could experience suboptimal salinities at the high end of the salinity range. Even at the maximum salinity, levels would not be suboptimal to the extent that sustainability of the swamp forest would be threatened. No impacts would be expected in the bottomland hardwood habitats at the maximum range of salinity predicted by the sensitivity analysis.

The largest range of potential impacts could occur within the intermediate marsh communities located east of Sabine Lake. AAHU losses for the intermediate marshes could range from 312 to 2,407 AAHUs, as compared to the FWP's most likely loss of 1,571 AAHUs. The highest potential salinities are suboptimal for most of the intermediate marshes east of Sabine Lake, and some exceed the maximum tolerance range. At the highest potential salinities, intermediate marshes in Willow Bayou, West Johnson's Bayou, and Sabine Lake Ridges would likely convert to brackish marsh about 20 years after project construction.

Impacts at the highest potential salinities would not threaten the sustainability of any of the other marsh communities over the period of analysis. Salinities remain within or close to the optimal range. For fresh marsh communities, AAHU losses could range from 8 to 477, as compared to the most likely loss of 78 AAHUs. For saline and brackish marshes combined, AAHU losses could range from 20 to 253, as compared to the FWP's most likely loss of 60 AAHUs.

The salinity sensitivity analysis of the WVA models demonstrated that there is a wide range of potential outcomes in AAHU losses attributable to uncertainties in salinity predictions. These outcomes range from a loss of 340 to 3,146 AAHUs within the 95 percent confidence range of salinity, the primary driver in the EMCM and SCM. After adjustments for the Gulf Shore BU Feature benefits (210 AAHUs) and the BU offset of impacts to Federal lands (340 AAHUs), losses could range from zero to 2,596 AAHUs. Based on the cost per AAHU of the recommended mitigation plan (\$77.5 million; 1,181 AAHUs), the cost of compensatory mitigation could range from \$0 to about \$170 million. The total predicted FWP loss of 1,499 AAHUs in Louisiana is based upon forecasts of the most likely salinity levels, and takes into account the potential FWOP effects of RSLR and changes in future freshwater inflows.

4.2.2 Percent Emergent Marsh Sensitivity Analysis

Ninety-nine percent of Louisiana impacts predicted by the ecological model were made using the EMCM. The most highly weighted variable in this model is V_1 (percent emergent marsh). This parameter is considered most significant because persistent emergent vegetation provides foraging, resting, and breeding habitat for a variety of coastal fish and wildlife species. Detritus from coastal marshes also provides a source of mineral and organic nourishment for organisms at the base of the food chain. Without the structure provided by the emergent marsh, the majority of the ecological benefits provided by this system disappears. Changes in the value of this parameter were predicted by relating changes in salinity to changes in marsh loss using a process that is described in Section 4.10. This sensitivity analysis explores the effects of an assumption that underlies the valuation of emergent marsh in this variable. The SNWW application of this model uses the same assumptions adopted by the EnvWG in its application of the model to CWPPRA restoration projects (USFWS, 2002b). In this model, optimal vegetative coverage is assumed to be 100 percent ($SI = 1.0$) for all marsh types. This assumption diverges from the general biological understanding that optimal cover falls in the 60 to 80 percent range, but it was adopted by the EnvWG to reflect CWPPRA's objective of long-term marsh creation and restoration. Questions have arisen as to whether maximizing the value of marsh coverage is appropriate for the SNWW application in which the primary purpose is the identification of project impacts and compensatory mitigation.

Selection of 100 percent marsh cover as the optimal habitat condition (V_1 -Original) for the SNWW application was based upon several factors. Maximizing the value of emergent marsh over associated shallow-water habitat is based upon the important ecological concept of long-term sustainability. With the SNWW project, marshes would continue to degrade over the 65-year period of analysis due to the effects of RSLR. Without the associated marshes, the small open-water areas would lose their value as nursery habitat, becoming open-bay or open-Gulf habitat. Restoration or mitigation projects generally need to maximize the creation of emergent marsh, so as to ensure the sustainability of the land itself.

To evaluate the effect of this assumption on the SNWW application, the EMCM was rerun for all of the Louisiana marsh communities using a revised formula for the variable in which optimal vegetative coverage ($SI = 1.0$) is assumed for a marsh coverage of 60 to 80 percent (V_1 -Revised). Overall, impacts using V_1 -Revised dropped by 3 percent. As would be expected, the smallest percentage changes occurred in marshes where the percent emergent marsh remained between 60 and 80 percent for both the FWOP and FWP conditions. If the V_1 -Revised formula were used to calculate the mitigation target for the recommended mitigation plan, the net loss would be 244 AAHUs. If V_1 -Revised were used to compute compensatory mitigation as it is currently designed, mitigation costs would increase by at least 42 percent to meet the V_1 -Revised mitigation target.

If the same mitigation measures were redesigned so that marsh fill would never exceed 80 percent, the amount of restored acres would drop from 2,696 to 2,215 acres. However, compensation as measured with the V_1 -Revised formula would increase and the net loss would be 167 AAHUs. Based upon the cost of the recommended mitigation plan, it is estimated that the total mitigation cost would be about 3 percent greater than the recommended mitigation plan. More significantly, the modified plan would restore about

18 percent fewer acres and do less to ensure the long-term sustainability of the marsh than the recommended mitigation plan.

4.2.3 Recommendations Resulting from WVA Model Sensitivity Analysis

The recommended compensatory mitigation plan is based upon the most likely range of salinity change as established by the HS model, scientifically based projections of changes in habitat resulting from the predicted salinity change, and the professional judgment and knowledge of the area by the large team of natural resource and engineering professionals who applied the WVA model to the SNWW CIP. The ICT HW contained professionals with expertise in wetland impact evaluation, marsh restoration, wetland forest management, aquatic habitat evaluation, freshwater and marine fisheries, terrestrial and avian wildlife biology, as well as natural resource management personnel from all of the protected lands in the study area.

In addition, the recommended mitigation plan maximizes the value of emergent marsh when measuring impacts and determining compensatory mitigation for project-related losses to this nationally significant, endangered resource. Without the structure provided by the emergent marsh, the majority of the ecological benefits provided by these systems disappear. For these reasons, no changes to the recommended mitigation plan are proposed as a result of this sensitivity analysis. It is recommended that Best Buy Plan #6 mitigation plan (described in Chapter 5) be selected as it incorporates the level of compensation needed to address the most likely impacts of the SNWW CIP.

4.3 PHYSIOGRAPHY AND GEOLOGY

4.3.1 No-Action Alternative

The No-Action Alternative would not impact physiography or geology within the study area. Alterations to bathymetry from maintenance dredging of existing ship channels, in addition to topographic changes from the placement of dredged materials at PAs, would continue under the No-Action scenario.

4.3.2 Preferred Alternative

The total estimated amount of dredged material generated from the proposed project would be approximately 98 mcy of new work material and approximately 650 mcy of maintenance material over 50 years after the project is constructed. This material would be placed in BU features, PAs, and ODMDs, as described in Section 2.5.

Impacts on local geology during dredging associated with the Preferred Alternative would include redistribution of existing sediment, local increases in turbidity, and potential changes in local scouring and shoaling rates. Net impacts on local geology would be minimal from these operations. Additionally, no impacts or modifications to geologic hazards such as faulting and subsidence are expected.

Two PAs would be created. The area where PA 24A would be created is currently a wetland habitat with a central upland ridge, which is set back from the shoreline of a Neches River oxbow and does not block overland flow to bottomland hardwoods along the shore. A critical section of marshhay cordgrass wetland was excluded from the proposed PA, and the boundaries were drawn to exclude bottomland hardwoods that line the Neches River oxbow west of the PA. The area where PA 18A would be created is already an upland area so there should be no topographic impact. Further information pertaining to specific PA descriptions and quantities of new work and maintenance material involved are presented in Section 2.4.

Three miles of shoreline located at Texas and Louisiana Points would be affected by the proposed Gulf Shore BU Feature (see Figure 2.5-2). Over the 50-year period of analysis, 16 placement episodes are expected, occurring in 3-year cycles, alternating between Texas and Louisiana. The Gulf Shore BU Feature would provide a regular source of predominantly fine-grained sediment that should contribute to mudflat accretion and periodically move onshore to become shore-attached through a process described by PIE (2003). On the western Louisiana and east Texas coasts, sediments accumulate as mudflats and underwater mudshoals (or “fluid mud”) in the nearshore region. Nearshore, fluid mud can be trapped against the shoreline by prevailing south and southwesterly winds, and storms carry the trapped muddy ooze onto the chenier shoreline. The presence of additional fine-grained sediments in the littoral system that would be provided by the BU feature should reduce the current erosion rate, and minimize the small increase in shore erosion predicted with the project (Gravens and King, 2003). In systems that have an abundant supply of fine-grained sediments, the nearshore seabed can be blanketed with fluid mud. The presence of additional muddy sediment in the nearshore environment may attenuate waves and lessen wave-induced erosion (Hsiao and Shemdin, 1980; Tubman and Suhayda, 1976; Wells and Kemp, 1986). Although the BU sediments would be largely fine grained, approximately 18 percent of maintenance material is expected to be sand. Sands that are deposited on shore would nourish and stabilize eroding marshes; sand deposited in the nearshore zone should stay in the nearshore environment, moving back and forth across the shoreface (Wamsley, 2008). More details on the expected behavior of the material can be found in subsection 2.5.3.2.

Three degraded marsh areas along the Neches River would be combined into the Neches River BU Feature. This large BU feature would use new work material and future maintenance material to benefit a total of 4,958 acres of degraded marsh on the lower Neches River by restoring 2,853 acres of emergent marsh; improving 871 acres of shallow water by creating shallower ponds and interconnecting channels; and nourishing 1,234 acres of existing fringing marsh by winnowing fine-grained material from unconfined flows of dredged material effluent. It would fulfill 53 percent of the restoration target set by the CEPRA 2004 plan update for the lower Neches River (GLO, 2004). Further information pertaining to this BU feature can be found in subsection 2.5.3.2.

Construction of mitigation measures in Louisiana would use sediment obtained from nearby waterbodies to restore marsh. The Willow Bayou Mitigation Measure would use sediment obtained from dredging the bottom of Sabine Lake to restore soils and marsh elevation to open-water areas in the marsh east of Sabine Lake. A 1.8-mile-long borrow trench in Sabine Lake would be dredged about 1,000 feet from the Sabine NWR shore and would average 1,030 feet wide by 7.5 feet deep. The borrow trench would be

continuous and parallel the current shoreline; the common longshore circulation pattern in Sabine Lake is expected to eventually fill the trench with Sabine River sediments. An access channel from the GIWW near the mouth of the Sabine River would be needed for the dredge to reach the proposed borrow trench area. The exact locations of the borrow trench and access channel would be determined in consultation with the ICT after PED bottom surveys of potential locations. Black Bayou Mitigation Measures LA 3-15B and LA 3-18B would hydraulically dredge accumulated material from the 30-foot-deep Lake Charles Deepwater Channel (co-located with GIWW in Louisiana) and use it to restore marsh in open-water areas south of the GIWW. While changes would occur to local bathymetry and topography during construction of the proposed project, these alterations would be expected to have negligible impacts on the regional physiography of the submerged and subaerial portions of the study area. No impacts associated with geologic hazards are expected, and impacts on local geology are expected to be minimal.

4.4 WATER QUALITY

4.4.1 No-Action Alternative

Under the No-Action Alternative, there would be no construction dredging; therefore, there would be no new work material for placement. While no turbidity or possibility for the release of undesired chemicals would occur, there would also be no opportunity for the creation of marshes using dredged material beneficially.

Under the No-Action Alternative, water quality would be as it is presently, as described in Section 3.3, with a gradual increase in salinity from RSLR in the future without the proposed project. There would be short-term increases in turbidity and the possibility of release of undesired chemicals during maintenance dredging, as there is now. All maintenance material is currently placed into PAs or ODMDs.

4.4.2 Preferred Alternative

USACE has received §401 State Water Quality Certification from Texas and Louisiana for this action. A CWA §404(b)(1) evaluation of the proposed action, provided in Appendix E, describes the effects of the proposed discharges. All relevant sediment and water quality data for both new work and maintenance dredging material were reviewed by a team of State and Federal resource agencies (ICT CW), including the TCEQ and LDEQ, and they found no cause for concern over water or sediment quality in any channel reach. New work sediments were deemed suitable for use in constructing restoration or mitigation sites, BU features, placement in ODMDs, and upland confined PAs. Maintenance material would be handled according to the DMMP. The DMMP measures, to the greatest degree possible, the use of dredged material as a beneficial resource. The Gulf Shore BU feature shares the material from Sabine Pass equally between the states. The new work and maintenance material used in the BU features of the Preferred Alternative would allow the restoration of approximately 4,958 acres of emergent marsh in Texas. It would also be used for beach nourishment on Texas and Louisiana Points.

The Preferred Alternative is the least environmentally damaging practicable alternative. As noted above, there should be little, if any, difference in inland turbidity or DO levels between the No-Action

Alternative and the Preferred Alternative. Best Management Practices would be employed during construction of restoration and mitigation areas. Significant detrimental environmental effects have not been noted in past construction and maintenance operations and are not expected with the Preferred Alternative since much of the construction and maintenance material would be used beneficially, and the rest would go into PAs or ODMDs. Short-term increases in turbidity may be caused by the unconfined flow of dredged material during construction of BU features and mitigation measures. There would be temporary, minor impacts from ocean placement at the new proposed ODMDs, as discussed in detail in Appendix B. Temporary water quality impacts may occur during borrow trench and access channel dredging in Sabine Lake and the Lake Charles Deepwater Channel for mitigation measures (see also sections 5.5.1, Willow Bayou Mitigation, and 5.5.2, Black Bayou Mitigation).

There is the possibility of contamination of the maintenance material by a spill or other event, as there is now, but deepening of the channel should reduce the probability of a spill by reducing the number of vessel trips. Additionally, the USACE routinely tests the elutriates prepared from maintenance material according to ITM and RIA protocols before dredging to ensure that there is no contamination. As noted in Section 3.3, past Tier I, Tier II, and Tier III evaluations of maintenance material elutriates with chemical analyses and water column bioassays have indicated no cause for concern.

4.5 SEDIMENT QUALITY

4.5.1 Surficial Sediments

4.5.1.1 No-Action Alternative

There would be no change in the quality of the surficial sediments of the project area unless there is an impact in the future without the proposed project.

4.5.1.2 Preferred Alternative

The quality of surficial sediments that would be dredged during construction of the Entrance Channel Extension is discussed in Appendix B. Extensive chemical analyses, bioassays, and bioaccumulation studies of this material were conducted in accordance with EPA Regulations and the *Ocean Testing Manual*. The data indicate that there are no causes for concern related to chemical contaminants and that these sediments are suitable for ocean placement. Similar testing was performed numerous times on maintenance material dredged from the 22-mile existing SNWW entrance channel, and these sediments were always found to be acceptable for ocean placement. The sediments to be dredged for the Extension Channel are located from 22 to 35 miles from shore, and thus are sufficiently far removed from known existing and historical sources of pollution on the inland portion of the SNWW to provide reasonable assurance that the material is not contaminated. The ICT CW (which included representatives from the EPA and USFWS) approved the use of the grab samples for SNWW bioassay and bioaccumulation samples, and agreed that the materials were suitable for ocean placement.

4.5.2 Maintenance Material

4.5.2.1 No-Action Alternative

The existing maintenance material was described in Section 3.4. The quantity and quality of this material would not be expected to change with the No-Action Alternative.

4.5.2.2 Preferred Alternative

The quantity of maintenance material is expected to increase by roughly 60 percent in the SNWW with the Preferred Alternative but the quality of this material would not be expected to change. While more maintenance material is expected to be dredged with the Preferred Alternative, the source and the method of placement would not change, except that much more of the maintenance material would be used beneficially. As noted above, project actions should decrease the probability of a spill. The USACE also routinely tests the maintenance material according to ITM and RIA protocols before dredging to ensure that the material is environmentally acceptable under all applicable regulations.

4.5.3 Summary

As summarized in subsection 3.4.2, recently tested sediment quality data presented in PBS&J (2004a) and from March 2008 and April 2009 indicates no cause for concern, related to the new construction dredging and dredged material placement. Although it was identified that one reach within the Neches River contained elevated levels of PAHs within the tested sediments, the elutriate tests for those sediment sampling stations did not reveal high concentrations of PAHs. Therefore, it can be concluded that PAHs are not expected to be released during dredging and/or placement, and it can be further concluded that there are no channel reaches within the SNWW that exhibit a chemistry cause for concern.

4.6 HYDROLOGY

4.6.1 No-Action Alternative

Under the No-Action Alternative that includes 1.1 feet of RSLR, there should be an increase from the present condition in the tidal circulation and water exchange with the Gulf, and a corresponding increase in sediment transport in the navigation channels. No significant change is expected in the direction or amount of longshore sediment transport. Longshore transport and wave modeling have been performed, and a sediment budget has been prepared for the study area in conjunction with a shoreline erosion study of the Texas coast from Sabine Pass through Galveston Island (King, 2007; Morang, 2006).

Shorelines will continue to retreat due to RSLR, and the rate can be expected to increase with an increase in the rate of RSLR. The highly erodible and weakly compacted soil on Pleasure Island and the east shore of Sabine Lake would likely continue to erode from tidal currents and wind waves. Vessel-generated waves and surges would continue to accelerate the process on Pleasure Island as in the past. Existing Gulf shoreline erosion of up to 40 to 50 feet/year on the Texas shoreline (King, 2007) and an erratic pattern of

accretion and erosion on the Louisiana shoreline (USACE, 2004a) would also continue, with the potential for significant increases due to climate change and sea level rise (IPCC, 2007).

The FWOP does include expected changes in water demands and supply strategies that are part of the 2007 Texas State Water Plan (TWDB, 2007) and permitted flows from upstream reservoirs. Existing Sabine River flows that are dedicated to the State of Louisiana by the Sabine River Compact are also taken into consideration.

4.6.2 Preferred Alternative

4.6.2.1 Circulation, Exchange, Inflows, Velocities

Under the Preferred Alternative, the same RSLR and inflow changes assumed in the FWOP will apply, and there would be a deeper navigation channel that will allow a greater amount of tidal circulation and exchange with the Gulf than is currently the case. The deepening project would cause only a minimal increase of water surface elevation over the study area; the average increase would be 0.8 inch (Brown and Stokes, 2009). The channel deepening results generally in increases in velocity along the entire channel; however, magnitudes are quite small, less than 0.5 foot per second in most cases (Parchure et al., 2005). The largest changes are observed in the Sabine-Neches Canal, but the absolute magnitudes are still small.

The potential for proposed project features to increase storm surge impacts in the study area was analyzed with a storm surge sensitivity analysis (Wamsley et al., 2010). The ADCIRC model was run to estimate water levels for two worst-case hypothetical storms, both with and without proposed SNWW CIP project features in place. Project features evaluated by the modeling are the deeper navigation channel, proposed PAs with maximum levee heights, and two expanded PAs. The sensitivity analysis concluded that the greatest changes would occur north of Port Arthur along the Neches River. These changes are primarily due to the proposed increase in depth of the navigation channel. All changes are local and there are no project-induced increases in surges away from the immediate vicinity of the navigation channel. Water levels in the marshes and open-water areas immediately north of the river would increase on the order of 4 to 8 inches or less. The modeling indicates some interior flooding would occur within the City of Port Arthur both with and without the project. Changes in peak surge on the order of inches should not cause any significant change in interior flooding for the with-project condition.

The Preferred Alternative for the SNWW CIP also includes ODMDS and marsh restoration measures. All of the existing and proposed ODMDSs are located several miles from the Gulf shoreline in water too deep to affect wave setup on the shoreline. The influences of marsh restoration on hurricane surge have been documented by Wamsley et al. (2009a, 2009b). Surges tend to slightly increase over and just seaward of the marsh as the surge propagation is slowed, which may result in reductions in peak water levels landward of marsh features. The impact of the proposed SNWW CIP marsh restoration features are relatively small and expected to modify peak surge levels locally by a minimal amount (Wamsley et al., 2010). No significant reductions or increases in surge level would be expected from either the marsh restoration or ODMDS.

The Preferred Alternative would not have an effect on freshwater inflows to the system. However, by increasing slightly the amount of tidal exchange, the inflows would be conveyed to the Gulf marginally faster than would be the case in the No-Action Alternative.

4.6.2.2 Sediment Transport

There are two main types of sediment transport in the system—sediment carried into the channels by heavy rains in the watershed and conveyed through the navigation channels, and sediment transport along the coast. Both are addressed here.

The low velocities near the bottom of the navigation channel offer conditions favorable for sediment deposition. The amount of sediment-laden runoff would be unchanged between the FWOP and FWP (Parchure et al., 2005). The slightly larger cross sections and lower current velocities would offer slightly better conditions for sediment to settle. This is one reason why the Preferred Alternative would require more maintenance dredging than the No-Action Alternative. Another reason is that the deeper channel will have a larger volume below the existing seabed, making it function as a larger sediment trap. Furthermore, the increased length of the channel results in higher dredging quantities for the offshore channel extension. Changes in salinity that also affect shoaling quantities are discussed in a later section.

The effect on Gulf shoreline change was investigated by Gravens and King (2003). Their shoreline impact study addressed the effects of changes in the wave climate produced by the deeper offshore channel and the changes in longshore sediment transport that would be expected from the altered wave climate. Under the Preferred Alternative, a deeper and longer entrance channel would have some effect on waves moving from the Gulf to the shore, and that would in turn exert an effect on the rate of longshore sediment transport.

The Gravens and King (2003) study also addressed a 45-foot alternative and noted that the effect of the Preferred Alternative (48-foot channel) would be intermediate and somewhat less than the 50-foot alternative. The direction of sediment transport is to the west on the Texas side of the channel and to the east on the Louisiana side, with little difference between existing conditions and the 50-foot channel. The effect of channel deepening is to reduce the westward transport on the Texas side and increase the eastern transport on the Louisiana side. The effect of channel deepening is to slightly reduce the net westward transport on the Texas side and the net eastern transport on the Louisiana side.

The Gulf Shore BU Feature proposes to restore 0.86 mcy of sediment to the littoral environment every 3 years using maintenance material from dredging the Sabine Pass Channel. Material placement during each 3-year dredging cycle would alternate between Texas and Louisiana, so that material would be placed on each state's shoreline every 6 years. Some material is expected to flow into the existing marsh while the remainder would flow into nearshore waters. This recurring action would nourish eroding marsh, restore sediment to the littoral zone, minimize projected FWP shoreline impacts, and potentially create new marsh. The BU dredged material is expected to be composed largely of unconsolidated muds. The fine-grained sediments are expected to initially be highly mobile, and some portion of the material would be rapidly lost from the vicinity of the shoreline. Because of the prevailing wave climate, the

mobile material within the surf zone should generally migrate to the west at both Texas and Louisiana Points (Wamsley, 2008). Transport processes identified by the Sabine Pass sediment budget (Morang, 2006) indicate that the material west of Sabine Pass would move toward the eroding shoreline at Texas Point. There, the additional fine-grained sediments could lower erosion rates through mudflat accretion and wave attenuation. A small quantity of material may migrate to the east and contribute to the Sabine Fillet at the west jetty (King, 2007; Morang, 2006). In Louisiana, the sand bar formed by BU sediments from the Cheniere LNG project may shelter the shoreline from wave energy sufficiently to allow fine-grained sediments to form a mudflat behind the sandbar (Nairn and Willis, 2002; PBS&J, 2004b). While a significant percentage of the sediment would be rapidly carried offshore, some is likely to move downcoast with the littoral current, enlarging the sand and mudflat already present at the east jetty.

4.6.2.3 Coastal Shoreline Erosion Impacts

The changes in sediment transport, while very small, can be expected to have some effect on the rates of shoreline erosion. Under the Preferred Alternative, there is a slight reduction in the erosion rate near the jetties. Near the jetties, the average rate of shoreline accretion was calculated to be as much as 60 feet/year. However, between 0.5 mile and 3 to 4 miles on either side of the jetties the erosion would be increased by less than 0.5 foot/year for a 50-foot project, and farther from the jetties than that, the change in the shoreline change would decrease to zero. The effect of the 48-foot channel on the Gulf shoreline between 0.5 mile and 3.5 miles from each jetty was estimated to be 0.42 foot/year based upon the 45- and 50-foot project effects.

The Gulf Shore BU Feature should have a positive effect on reducing shoreline erosion. The presence of additional fine-grained sediments in the littoral system, which would be provided by the BU feature, should reduce the current erosion rate and minimize the small increase in shore erosion predicted with the project. In systems that have an abundant supply of fine-grained sediments, the presence of additional muddy sediment in the nearshore environment may attenuate waves and lessen wave-induced erosion (Hsiao and Shemdin, 1980; Tubman and Suhayda, 1976; Wells and Kemp, 1986). Furthermore, the predominantly fine-grained sediment provided by this BU feature should contribute to mudflat accretion by periodically moving onshore and becoming shore-attached. On the western Louisiana and east Texas coasts, sediments accumulate as mudflats and underwater mudshoals (or “fluid mud”) in the nearshore region. Nearshore, fluid mud can be trapped against the shoreline by prevailing south and southwesterly winds, and storms carry the trapped muddy ooze onto the chenier shoreline (Morgan et al., 1958; Wells and Kemp, 1982, 1986). Accretion of the shoreline can then occur by poorly understood processes (Huh et al., 1991; King, 2007; PIE, 2003).

Although the BU sediments would be largely fine grained, approximately 18 percent of maintenance material is expected to be sand. Sands that are deposited onshore would nourish and stabilize eroding marshes, and sand deposited in the nearshore zone should stay in the nearshore environment, moving back and forth across the shoreface (Wamsley, 2008). Sand placed at Louisiana Point should remain on the shoreface where it was deposited; no significant amounts of sand are expected to enter the Jetty Channel. On erosive mud shorelines like those in the BU area, the sand percentage should increase and it

would form sandy lenses or a veneer over the mud shoreline substrate. As the sand lenses thicken, the sands help protect the underlying mud from further erosion (Nairn, 1992). However, in smaller quantities, sand can also accelerate erosion of a mud beach. If the consolidated mud is not covered by a sand veneer, any sand that is mobilized by wave action would act as a scouring agent (King, 2007).

4.6.2.4 Inland Shoreline Erosion Impacts

The primary area of concern for inland shoreline impacts is Pleasure Island along the confined channels of the Port Arthur and Sabine-Neches canals (Parchure et al., 2005). No increase in the existing erosion rate is predicted with the project for the eastern shore of Sabine Lake. The primary mechanism for shoreline erosion associated with the project is from passage of large vessels. Maynard (2003) investigated the mechanisms of ship-induced bank recession (shoreline erosion). The analysis employed a numerical model (HIVEL2D) to simulate the ship-induced velocity at the bank and employed information on the vessels in the existing and future fleets and information on the speeds that would be needed in both the No-Action and Preferred alternatives. The analysis focused on two sites on Pleasure Island; the north site is in the Sabine-Neches Canal, and the south site is in the Port Arthur Canal. The north site has no existing erosion protection, while the south site has riprap protection. Neither site will have a change in channel width. The analysis was calibrated to the existing rates of bank recession, and it used the model to account for differing numbers of vessel trips projected for the years 2030 and 2060 for both the No-Action and 50-foot alternatives. The Preferred Alternative is expected to have a lesser effect than the 50-foot alternative.

Maynard (2005) found that the rates of erosion are lower for the 50-foot alternative than for the No-Action Alternative at both the north and south sites for both 2030 and 2060 traffic levels. Overall, the effect of the Preferred Alternative should be to reduce the rate of erosion on inland channels relative to the No-Action Alternative because of fewer vessel trips that are predicted with the Preferred Alternative than in the No-Action Alternative.

4.6.3 Salinity

4.6.3.1 No-Action Alternative

Under the No-Action Alternative, the modeled RSLR of 1.1 feet is expected to increase salinity levels from the present condition. RSLR is expected to increase salinities up to 2 ppt in portions of the project area in the FWOP area. The complicated circulation and salinity patterns of the SNWW system would change substantially. Freshwater enters the system via several tributaries, including the Sabine River, the Neches River, and other smaller inflows. The Neches River flows directly into Sabine Lake and the Sabine-Neches Canal. The Sabine River flows into Sabine Lake, the Sabine NWR, and into Calcasieu Lake via the GIWW. During times of low flow, the direction of flow in the GIWW is reversed and higher salinity Calcasieu waters flow westward into the Sabine basin (Gammill et al., 2002).

The Sabine-Neches Canal connects the Neches River Channel to Sabine Pass, flowing through a narrow, confined channel between Pleasure Island on the east and Port Arthur on the west. This canal conducts

both fresh water from the rivers and Gulf waters intruding via tidal propagation through Sabine Pass. As a result, substantial salinity stratification forms in the Sabine-Neches Canal. Stratification contributes to salt water intruding up the Sabine-Neches Canal, into the northwest corner of Sabine Lake, and the lower reaches of the Neches River Channel. Consequently, observed salinity in Sabine Lake is highest at both the southern end (where it connects to Sabine Pass) and at the northern end (where it connects to the Sabine-Neches Canal). Lowest salinities are observed in the central and eastern portions of Sabine Lake, farthest from the hydraulic connection to sources of saline water.

Wide swings in salinity associated with shifts from periods of drought to high freshwater inflows would continue. Hydrologic conditions in some wetlands in the study area are managed with passive water control structures (rock weirs, flap-gate culverts, rock plugs, and rock dikes). FWOP conditions were developed using field salinity data collected with these structures in place. It is assumed these would continue to operate as they do today. A summary of water controls is below and they are described more fully in Section 3.5.

- In Louisiana, one large, rain-fed, freshwater impoundment (Pool 3) is located in the center of the SNWR, at the eastern edge of the SNWW study area (Gammill et al., 2002). A containment levee was constructed in 1951 around a large area of unbroken marsh. It is managed to hold fresh water at high levels, increasing the water-to-marsh ratio for wintering waterfowl habitat. Pool 3 was not included in the study area because it is hydrologically isolated from the surrounding wetlands. Two CWPPRA hydrologic restoration projects in the Black Bayou and Willow Bayou marshes east of Sabine Lake have been constructed (USFWS-LDNR, 2008a, 2008b). FWOP conditions in the Willow Bayou hydro-unit assume that all elements of Construction Unit 1 of the Willow Bayou Hydrologic Restoration Project are in place. The FWOP condition reflects a small reduction in the land loss rate due to the effects of the breakwater and in-situ terracing. Likewise, FWOP conditions in the Black Bayou hydro-unit include the projected effects of the Black Bayou Hydrologic Restoration Project. In WVA computations, land loss throughout the unit was reduced by two-thirds for the 20-year CWPPRA project life to reflect erosion protection and flow reductions with the GIWW shoreline protection. In addition, FWOP salinity in the intermediate marshes was expected to increase to 4.2 to 5.1 ppt, the salinity level projected to result from the Black Bayou hydrologic management measures (rock dike, rock weirs, and self-regulating tide gate).
- In Texas, saltwater barriers restrict saltwater intrusion from the GIWW into Taylor Bayou to the north and into the J.D. Murphree WMA to the south. Low rock weirs restrict flow on some smaller channels in the Texas Point NWR. FWOP conditions for the GIWW North, Salt Bayou, and Texas Point hydro-units were developed using field salinity data collected with these structures in place. Restrictions to the access of marine organisms caused by these structures were reflected in the EMCM variable (V_6) for aquatic organism access.

Mean salinities used in the FWOP condition of the WVA model are presented in tables 4.6-1 (Mean Salinity at Median Inflow) and 4.6-2 (Mean High Salinity at Median Inflow). The tables show salinities modeled at field sampling stations, and include a range of salinities calculated for the 95 percent confidence level. In general, empirical salinity data were used, when available, for the FWOP salinity parameter in the WVA model. HS model output was used when empirical data were not available. For

marshes inland and far from model nodes, the salinity gradient was estimated based upon empirical data from adjacent hydro-units, and local resource managers’ knowledge of the magnitude of water exchange with the larger channels and waterbodies.

Table 4.6-1
FWOP and FWP Mean Salinities and 95 Percent Confidence Range

Mean Salinity (ppt)/Median Flow					
Station Number	Data Collection Station	FWOP Mean Salinity	FWP 48-Foot Project Mean Salinity	FWP Mean Salinity 95% Confidence Range	
				Salinity (–2 SD)	Salinity (+2 SD)
1	Upper Neches River	0.0	0.0	0.0	0.0
2	Beaumont Turning Basin	0.1	0.2	0.0	0.7
3	Mouth of Neches River	3.4	4.2	2.9	5.5
5	Sabine River at Orange	0.4	0.6	0.0	1.5
6	Sabine-Neches Canal	12.8	14.4	12.0	16.8
7	Mouth of Sabine Pass	22.7	22.9	20.8	24.9
9	Mouth of Sabine River	5.3	6.6	5.2	8.1
10	South Sabine Lake	10.4	11.6	9.8	13.4
11	Black Bayou	4.1	5.2	3.7	6.6
14	Mouth of Johnson’s Bayou	5.1	6.7	5.5	7.9
15	Keith Lake Fish Pass	14.6	16.0	14.8	17.2

10	South Sabine Lake	17.5	18.7	16.3	21.1
11	Black Bayou	9.5	11.2	9.7	12.7
14	Mouth of Johnson's Bayou	10.5	12.7	11.9	13.5
15	Keith Lake Fish Pass	21.2	22.1	20.9	23.4
16	Mouth of Willow Bayou	8.7	10.6	8.3	13.0
17	GIWW West at Taylor Bayou	20.2	21.0	20.1	21.9

Although expected to occur only infrequently, when low flows, considered drought flows for the purpose of this analysis, occur during late summer and fall of some years, the HS model predicts substantially higher salinities (Table 4.6-3 Mean Salinity at Low Inflow). The HS model defines drought conditions as the 10th percentile of the WAM Run 8 2060 flows. At the upper reaches of the Neches River, the relative salinity increase as a result of low inflow is relatively small, only 0.1 ppt under the FWOP condition. Salinity in the Sabine River at Orange would increase from 3.8 ppt under the modeled existing condition to 4.9 ppt under the FWOP condition. The HS model predicts salinities throughout the remainder of the project area would range from 0.5 to 2.2 ppt higher during droughts under the FWOP condition than under existing conditions. Modeled FWOP salinity at Black Bayou during median flow is 4.1 ppt increasing to 15.6 ppt under drought conditions. Likewise, at the mouth of Willow Bayou, the predicted salinity increases from 4.3 ppt at median inflows to 14.6 ppt during drought under the FWOP condition. The HS model analysis (Brown and Stokes, 2009) reports that the largest salinity differences would occur in the Neches River near Bessie Heights and along the western shore of Sabine Lake. These analyses indicate that drought conditions cause substantial increases in salinity in the project area and that RSLR associated with the FWOP condition has relatively little additional affect on salinity during droughts.

Table 4.6-3
Mean Salinity Predicted by the Hydrodynamic-Salinity Model*

Mean Salinity (ppt)/Low Flow						
Station Numbers	Data Collection Station	Modeled Existing Condition	FWOP Mean Salinity	FWP 48-Foot Project Mean Salinity	FWP Mean Salinity Range	
					Salinity (-2 SD)	Salinity (+2 SD)
1	Upper Neches River	0.0	0.1	0.26	0.0	0.6
2	Beaumont Turning Basin	1.0	1.9	2.6	2.2	3.0
3	Mouth of Neches River	11.4	13.6	14.0	13.3	14.7
5	Sabine River at Orange	3.8	4.9	5.8	4.8	6.8
6	Sabine-Neches Canal	23.0	24.6	24.7	23.8	25.6
7	Mouth of Sabine Pass	28.9	29.4	29.1	28.4	29.7
9	Mouth of Sabine River	15.9	17.4	18.4	18.1	18.7
10	South Sabine Lake	21.7	23.3	23.2	22.1	24.3
11	Black Bayou	14.1	15.6	16.6	16.2	16.9
14	Mouth of Johnson's Bayou	15.0	16.9	17.9	17.6	18.2
15	Keith Lake Fish Pass	24.2	25.5	25.5	24.7	26.3
16	Mouth of Willow Bayou	12.7	14.6	15.6	15.2	16.0
17	GIWW West at Taylor Bayou	22.9	24.5	24.5	24.1	25.0

* Brown and Stokes (2009) – Under low-flow conditions (based on WAM Run 8 output for 2060 [TWDB, 2007]). All conditions assume intermediate RSLR of 1.1 feet.

4.6.3.2 Preferred Alternative

4.6.3.2.1 FWP Salinity Impacts

The Preferred Alternative would deepen the navigation channel and allow more tidal circulation and exchange with the Gulf than at present. Salinity would increase in much of the system, and the salinity wedge would extend farther upstream in the Neches River Channel. Increased salinity is expected to reduce health and biological productivity of a large area of intertidal marsh in Louisiana and Texas.

Salinity changes in the SNWW estuarine system were projected with the HS model described in sections 3.1 and 4.1 of this FEIS (Brown and Stokes, 2009). The HS model also determined that the average water surface elevation would be altered slightly by the channel deepening. The water surface is lower by less than an inch at Sabine Pass. The average water surface elevation is somewhat higher in the upper reaches of the Neches River, where the average elevation increase is about 0.8 inch. The change likely results from an increase in the landward extent of tidal propagation.

Two scenarios (low flow and median flow) were developed in the HS model to evaluate changes resulting from the project (see tables 4.6-1, 4.6-2, and 4.6-3). The HS modeling indicated that the highest average salinity increases for the Preferred Alternative over the FWOP condition are found in the following locations:

Low Flow:

- Neches River, near Rose City (approximately 0.7 ppt)
- Sabine River at Orange (approximately 0.9 ppt)
- Eastern shore of Sabine Lake (approximately 1.0 ppt)

Median Flow:

- Neches River near Bessie Heights (approximately 1.8 ppt)
- Keith Lake Fish Pass (approximately 1.4 ppt)
- Eastern Shore of Sabine Lake (approximately 1.4 to 1.6 ppt)

In addition to changes in salinity and stratification within the navigation channels and Sabine Lake, salinities in interior marshes were predicted with the HS model. The hydrologic effect of smaller channels in the marshes was included and salinity gradients were projected for wetland areas set back from the primary waterbodies. Modeling results indicated that salinity increases in the interior marshes, based upon average salinities, would be 1.0 ppt higher in the marshes east of Sabine Lake, and 0.1 to 1.8 ppt higher in the Neches River marshes. Salinities in the cypress-tupelo swamps in the upper Neches and Sabine River reaches were predicted to be about 0.3 ppt and 1.0 ppt higher, respectively. Salinity impacts are not expected to result from borrowing material from Sabine Lake and the Lake Charles Deepwater Channel/GIWW (for Willow and Black Bayou mitigation measures) because the borrow areas do not connect to the Sabine River Channel or the Calcasieu Ship Channel.

The potential for salinity impacts to be magnified in areas subjected to hydrologic management was considered by the ICT during application of the WVA model. In the Black Bayou hydro-unit, the new structures would not restrict flow sufficiently to impound water and exacerbate impacts of the 1.4 ppt increase in salinity within the intermediate marsh. Flow is considered to be essentially unrestricted because of the many remaining hydrologic access points. In Willow Bayou, water control structures proposed for Construction Unit 2 were eliminated when HS modeling determined that they would be ineffective. Control structures built in Construction Unit 1 would not restrict flow sufficiently to impound water. Like Black Bayou, flow is considered unrestricted because of the many remaining hydrologic access points. In Texas, saltwater barriers on Taylor Bayou and along the GIWW are actively managed and can be opened to accept flows from the GIWW when salinity levels inside the marshes are higher than the GIWW. Furthermore, flows in and out of the marshes affected by these barriers remain through smaller drainages and the larger Keith Lake Fish Pass and Texas Bayou.

An extensive literature review conducted for the Louisiana Coastal Areas Ecosystem Restoration Study (LCA Study) documented that increases in salinity negatively affect primary productivity of selected indicator species found in typical wetlands of the Louisiana coastal zone (Visser et al., 2004). These studies used measurements of productivity, including total biomass, stem/leaf elongation, and photosynthesis, gathered in greenhouse experiments on saturated soils. Linear regression equations were developed to predict percentage changes in habitat productivity per 1 ppt salinity increase for each major coastal vegetation community, regardless of inundation. For every 1 ppt increase in salinity, total primary

productivity of swamps was reduced by 8.4 percent, fresh marsh by 11.1 percent, intermediate marsh by an average of 6.8 percent, brackish marsh by 2.6 percent, and saline marsh by 2.1 percent. These relationships were used to predict land loss rate changes in the current study. The method and results of that analysis are presented in Section 4.10. Habitats in the SNWW study area are dominated by the same marsh and swamp vegetation species found in the western Louisiana coastal zone. Supporting references for salinity-related productivity changes in vegetation include:

- **Swamp** – co-dominant species bald cypress and tupelo gum (Conner et al., 1997; Megonigal et al., 1997; Mitsch et al., 1991; Pezeshki et al., 1987a, 1990)
- **Fresh marsh** – co-dominant species maidencane and bulltongue (Greiner LaPeyre et al., 2001; Hester et al., 2001; Howard and Mendelssohn, 1999; McKee and Mendelssohn, 1989; Pezeshki et al., 1987b, 1987c; Spalding and Hester, 2007; Willis and Hester, 2004)
- **Intermediate marsh** – co-dominant species bulltongue and marshhay cordgrass (Baldwin and Mendelssohn, 1998; Greiner LaPeyre et al., 2001; Howard and Mendelssohn, 1999, 2000; Pezeshki et al., 1987b; Spalding and Hester, 2007; Webb and Mendelssohn, 1996)
- **Brackish marsh** – co-dominant species marshhay cordgrass and seashore saltgrass (Bertness et al., 1992; Broome et al., 1995; Ewing et al., 1995; Greiner LaPeyre et al., 2001; Hester et al., 2001; Kemp and Cunningham, 1981; Parrondo et al., 1978; Warren and Brockelman, 1989)
- **Saline marsh** – Smooth cordgrass and blackrush (Bradley and Morris, 1992; Eleuterius, 1989; Gosselink, 1970; Linthurst and Seneca, 1981; Parrondo et al., 1978; Pezeshki and DeLaune, 1995).

4.6.3.2.2 *WVA Model Evaluation of Salinity Impacts*

The impact of salinity changes on the estuarine habitats in the SNWW study area was assessed with the WVA model. Optimal salinity ranges assumed by the WVA model for the various habitat types are as follows:

- Swamp and Bottomland Hardwood (≤ 1 ppt)
- Fresh Marsh (≤ 2 ppt) (upper limit of 4 ppt during March–November growing season)
- Intermediate Marsh (≤ 4 ppt) (upper limit of 8 ppt during March–November growing season)
- Brackish Marsh (≤ 10 ppt) (upper limit of 16 ppt as an annual average)
- Saline Marsh (≥ 9 and ≤ 21 ppt) (upper limit in excess of 24 ppt as an annual average)

The optimal salinity ranges in the WVA model were based upon established salinity tolerances of common vegetation communities and salinity ranges associated with life history requirements of fish and wildlife species utilizing the habitats. Information from 32 HSI species models (USFWS, 1980) for estuarine fish and shellfish, reptiles and amphibians, birds and mammals was relied upon in establishing the optimal ranges (USFWS, 2002a).

The WVA model assumes that periods of high salinity are most detrimental in fresh/intermediate marsh and swamp when they occur during the growing season. This assumption is supported by a recent summary of annual primary productivity by season and habitat type that was developed for the habitat-switching module of the LCA Study (Visser et al., 2004). In swamps, 75 percent of annual primary productivity occurs from March 1 through June 30, and no primary production occurs from November 1 through February 28 (Keeland and Sharitz, 1995). The seasonal productivity of fresh marsh is longer, with approximately 38 percent of annual productivity occurring from March 1 through June 30, and 48 percent occurring from July 1 through October 31 (Sasser and Gosselink, 1984). Seasonal productivity of intermediate marsh is very similar to that of fresh marsh, with somewhat lower productivity in the July through October months (Hopkinson et al., 1978).

Median flow has been used to model the effects of FWP salinity changes for all vegetative communities. Run 8 of the TCEQ's WAM was used to represent the median-flow condition for salinity modeling. The TWDB (2007) projected flows for the year 2060 by modifying Run 8 "to include projected increased demand from existing water rights, expected change to return flows, projected new strategies to come online before 2060, and estimated year 2060 storage capacities for major reservoirs" (TWDB, 2007). These WAM Run 8 inflows were developed using current patterns of precipitation and evaporation. The median-flow condition was modeled for the period from approximately April through September.

Model output included mean salinities used to model impacts to brackish and saline wetlands during their growth season. These marshes are most influenced by long-term, prevailing salinity conditions. The productivity of brackish marsh is relatively stable throughout the year, with only slightly lower productivity from November 1 through February 28 (Hopkinson et al., 1978). Nearly half of the annual productivity of saline marsh occurs from July 1 through October 31, 29 percent in late spring and summer, and 24 percent in late fall and winter.

The median flow was also used to evaluate possible effects on fresh and intermediate marshes and forested wetlands. However, because these systems are more sensitive than brackish and saline wetlands to relatively small seasonal salinity changes, mean high salinity is used as the salinity parameter for the WVA models. Mean high salinity is the roaming mean of the highest 33 percent of consecutive daily salinity values during the growing season calculated for a specific period of record. This statistic is applied to model effects of high salinity during the growing season, when episodes of sufficient duration would reduce productivity of these freshwater habitats (Hester et al., 1996, 2001; McKee and Mendelssohn, 1989).

In the EMCM, effects of salinity changes are reflected most directly by two variables: V_1 (percent emergent marsh) and V_5 (salinity); however, changes in salinity can also result in changes to variables V_2 (percent SAV coverage), V_3 (marsh edge and interspersions); and V_4 (percent shallow water). The model assumes even small changes beyond the optimal salinity range of a marsh result in a small change to the land loss rate. This effect is captured in V_1 and described in relation to vegetation impacts in Section 4.10. Variable V_5 focuses on the effects of salinity on vegetation; changes within the optimal salinity ranges of each regime are not considered an impact and do not change the SI score of "1.0." However, even small

salinity increases outside of the optimal range reduce the SI below “1.0.” This impact is based upon the assumption that small changes in salinity beyond the optimal range (suboptimal) for a specific hydrologic regime and its habitats affects the primary productivity of marsh grasses and forested wetlands.

FWOP and FWP salinities are presented for each hydro-unit in Texas and Louisiana in tables 4.6-4 and 4.6-5, respectively. Tables 4.6-6 and 4.6-7 present an acreage analysis by state and habitat type that identifies areas where FWOP and FWP salinities, respectively, are predicted to remain within, or extend into the suboptimal salinity range.

4.6.3.2.3 *Salinity Impacts by Vegetation Community*

Bottomland Hardwoods

Bottomland hardwoods in the study area are located on elevated ridges and natural river levees, as well as on upland terrace margins, most often separated from the navigation channels by fringing marsh or swamp. The study area contains 3,206 acres of bottomland hardwoods in Louisiana, and 5,458 acres in Texas. In the FWOP condition, this habitat is projected to remain within the optimal salinity range. The upper reach of the Sabine River is generally fresh, with salinity intruding only during times of drought and low freshwater inflow, or with tidal surges during hurricanes. Prevailing conditions are reflected in the median-flow scenario of the HS model, in which a FWOP salinity of 0 ppt is predicted in the Sabine River just south of IH 10. During FWP conditions, salinities would rise near the GIWW from a FWOP salinity of 2.5 ppt to a FWP salinity of 4.1 ppt. Upstream at the confluence of the Sabine and Old rivers, salinity is predicted to rise about 0.1 ppt under both the FWOP and FWP conditions.

The Sabine River watershed also contains bottomland hardwood communities located on the Texas side of the river in the Sabine Island (524 acres), Blue Elbow (189 acres), Cow Bayou (388 acres), and Adams Bayou (640 acres) hydro-units. FWOP and FWP salinity conditions for the Texas portions of Sabine Island and Blue Elbow are identical to those in Louisiana. Cow and Adams bayous enter the Sabine River south of the GIWW and receive runoff from developed areas south and west of the city of Orange. They have been rectified and deepened to provide shallow-draft access for oil field development vessels. The HS model projects FWOP mean salinity of about 0 ppt in Cow Bayou and 3.1 ppt in Adams Bayou. FWP salinities are predicted to range from about 1.0 ppt in Cow Bayou to 3.9 ppt in Adams Bayou. Although modeled salinities predicted under both the FWOP and FWP conditions are above the optimal range (≤ 1.0 ppt), in Adams Bayou the bottomland hardwoods are located on higher ridges or terrace margins, and are buffered from bayou salinities by intervening swamp and marsh.

In the Neches River watershed, the Neches River just south of IH 10 is normally fresh. The HS model predicts salinities in areas with bottomland hardwoods will remain near 0 in both the FWOP and FWP conditions. Several bottomland hardwood communities also occur south of IH 10 along the Neches River—1,775 acres in the Rose City hydro-unit, 293 acres in the Bessie Heights hydro-unit, and 197 acres in the Old River hydro-unit. FWOP mean annual salinities in these areas range from 0.3 ppt near Rose City to 1.5 ppt near Bessie Heights and Old River Cove. The bottomland hardwood stands are located well east of the river on the upland terrace margin and are not affected by salinity in the Neches River.

*Calculated using WVA Impacts Summaries from tables 4.1-3 and 4.1-4, Habitat Acreage from tables 4.1-3 and 4.1-4, Habitat Acreage from Table 7 in Appendix C.

The HW considered potential effects of brief salinity increases by adjusting growth rates of woody and herbaceous vegetation at rates correlated to the salinity SI in the SCM. Changes in salinity were reflected with changes in variables V_1 (tree species composition), V_2 (stand maturity), and V_3 (midstory/understory coverage) in consideration of potential impacts. Trees species found in the bottomland forest community such as oaks (*Quercus* spp.), hickories (*Carya* spp.), American elm, green ash, sweetgum, boxelder, etc., are generally sensitive to even low levels of salinity. Among many other adverse effects, salinity is known to cause a reduction in seed germination, with germination in many nonhalophytes inhibited by very small percentages of salt (Kozlowski, 1997). Woody plants usually are very sensitive during emergence and young seedling stages, but become progressively more tolerant with increasing age (Shannon et al., 1994). Given the small FWP salinity increase, only small reductions in growth rates were forecast, and no AAHU losses were projected by the BHM.

Cypress-Tupelo Swamps

Cypress-tupelo swamps in the study area occur streamside or in abandoned channels or other low areas within the floodplain. Approximately 6,641 acres of cypress-tupelo swamp are located in the Louisiana portion of the study area, and 10,157 acres in the Texas portion. Large continuous stands of swamp are present in the upper reaches of both the Sabine and Neches rivers, with thousands of acres protected in the Sabine Island and Blue Elbow Swamp WMAs. Smaller, isolated stands are found in the bottoms of small drainages along the upland margins, generally buffered from exposure to higher salinities by intervening marsh. Swamps are located in the same reaches of the river systems as the bottomland hardwoods, and experience the same FWOP and FWP predicted salinity conditions. Louisiana swamps in the study area are located in the Sabine Island (5,998 acres) and Blue Elbow (643 acres) hydro-units north of IH 10. During FWOP and FWP conditions, swamps in the Sabine Island hydro-unit would experience a salinity of 0.1 ppt. In the Blue Elbow hydro-unit, predicted salinity would increase from 0.6 ppt during FWOP conditions to 0.9 ppt during FWP conditions. No impacts to swamps in these areas are expected.

Swamps in the Texas portion of the study area occur in both the Sabine and Neches river watersheds. Swamps in the Sabine Island (1,194 acres) and Blue Elbow (2,548 acres) hydro-units straddle the border between the states, and thus the salinity changes reported for Louisiana swamps in these areas are the same in Texas. These predicted salinity changes are not expected to impact swamps in these areas. Swamps also occur in three hydro-units on the Texas side of the Sabine River watershed—Blue Elbow South (689 acres), Cow Bayou (110 acres), and Adams Bayou (115 acres). In the Neches River watershed, swamps occur in the hydro-units north of IH 10 (North Neches, 2,760 acres, and Neches-Lake Bayou, 2,277 acres), and a small swamp is located south of IH 10, at the upland margin of the Rose City hydro-unit (464 acres).

Under the median-flow condition, swamps in the Blue Elbow South hydro-unit are generally fresh with predicted salinities of 1.1 ppt in the FWOP condition and 1.7 ppt in the FWP conditions. Predicted salinity increases in Cow Bayou swamps from 0.0 ppt for the FWOP condition to 1.0 ppt for the FWP condition. The predicted salinities for Adams Bayou are higher, up to 3.1 ppt for the FWOP condition and

3.9 ppt for the FWP conditions. In total, FWP salinity increases in these swamps would result in the loss of 22 AAHUs.

The habitat switching module of the LCA Ecosystem Model projects that loss of swamp acreage would not be expected to occur until average annual salinities exceed 4 ppt, based on the literature review discussed above (Visser et al., 2004). None of the increases in salinity reported for the swamps in the Sabine River watershed would be expected to result in the conversion of swamp to marsh, and therefore the same swamp acreages were entered into the FWOP and FWP conditions of the SCM worksheets.

Fresh Marshes

Fresh marshes are widespread, but represent a smaller percentage of all marsh in the study area than intermediate and brackish marshes. Approximately 25,108 acres of fresh marsh occur in the Louisiana portion of the study area, and 15,697 acres occur in the Texas portion. In general, fresh marsh occurs along the Neches River, north of the GIWW in Louisiana and Texas, and in protected interior pockets of intermediate marsh throughout the study area. In the FWOP condition, 95 and 96 percent of this habitat in Texas and Louisiana, respectively, remain within the optimal salinity range. The proportion of fresh marsh predicted to remain in Texas within optimum salinities is 95 percent, with 94 percent remaining under the FWP condition. The WVA model predicts FWP AAHU losses of 173 AAHUs in the Neches River watershed and 111 AAHUs in the Sabine River watershed.

In Louisiana, fresh marshes are located in the Perry Ridge (18,859 acres), Southeast Sabine (2,634 acres), and Southwest Gum Cove (3,615 acres) hydro-units. Located north of the GIWW, Perry Ridge is by far the largest expanse of fresh marsh in the Louisiana study area. During most of the year, the Sabine River and the GIWW are fresh in the reaches adjacent to Perry Ridge. The Vinton drainage ditch provides hydrologic access to the eastern part of this area. However, in the FWP, salinities could increase in Perry Ridge from 1.7 ppt (FWOP) to 2.3 ppt (FWP).

The Southwest Gum Cove and Southeast Sabine hydro-units are located at the eastern edge of the SNWW study area, north and south of Pool 3, respectively. The northern hydro-unit is hydrologically connected to the GIWW through the Black Bayou Cutoff, and the southern unit is hydrologically connected to Sabine Lake through Willow Bayou. Average salinities during the growing season range from 1.2 ppt in the Southwest Gum Cove marsh to 1.7 ppt in the Southeast Sabine fresh marshes. Salinity in Southwest Gum Cove is projected to rise from 1.4 ppt (FWOP) to 2.0 ppt (FWP). Located closer to the coast, salinity in the Southeast Sabine hydro-unit is projected to rise from 2.1 ppt (FWOP) to 2.4 ppt (FWP).

In Texas, most of the fresh marshes are located in the Neches River watershed. However, smaller pockets occur in the Cow Bayou (1,775 acres) and Adams Bayou (599 acres) hydro-units in the Sabine River watershed. Mean annual salinities in these smaller bayous range from 0 ppt in the uppermost reaches to 3.5 ppt near the mouth of Cow Bayou. Adams Bayou salinity averages about 2.5 ppt. The HS model predicts salinity will increase to 4.0 ppt (FWOP) and 5.0 ppt (FWP) in Cow Bayou. In Adams Bayou, modeled salinities rise to 3.5 ppt (FWOP) and 5.0 ppt (FWP). FWP salinity would move from the

maximum of the fresh marsh optimal range to roughly the maximum of the optimal range for intermediate marsh in Adams Bayou.

In the Neches River watershed, all of the fresh marsh is located north of the GIWW. North of IH 10, approximately 436 acres of fresh marsh occur in the North Neches River hydro-unit, and 1,535 acres in the Neches-Lake Bayou hydro-unit. On the lower Neches River, fresh marsh occurs in the Rose City (3,327 acres), West of Rose City (492 acre), and Bessie Heights (2,147 acres) hydro-units. Nineteen percent of Rose City is open water, and a central expanse of tidally influenced mud flats is the site of eroded wetlands that were formerly fresh marsh and cypress-tupelo swamp. About half of the Bessie Heights hydro-unit is open water, averaging 2 to 3 feet in depth, that has developed in what was historically a large, mostly emergent, intermediate marsh. Salinities in these Neches River fresh marshes under the FWOP condition range from 0.0 in the North Neches River and Neches-Lake Bayou hydro-units to 1.5 ppt in Bessie Heights. Salinities would not be expected to change in the North Neches fresh marsh under the FWP condition. The greatest salinity increase projected for these marshes under the FWP condition is 0.5 ppt for the Bessie Heights marsh.

The GIWW North hydro-unit comprises three separate areas on the north side of the GIWW. All are located within the largest remaining coastal freshwater marsh in Texas (USFWS, 2005a). Most of this area is not hydrologically connected to the waterways, which form its southern and eastern boundary, the GIWW, and the Taylor Bayou Diversion Channel, respectively. FWOP salinities predicted by the HS model for the GIWW North fresh marsh average 2.5 ppt. PAs along the GIWW and levees, created when the waterways were originally dredged, serve as barriers along the banks of the waterway that protect the marshes from bank overwash. The TPWD data indicate that salinities in the fresh and intermediate marsh average 0.7 ppt. Areas selected for inclusion in the hydro-unit are likely to be affected by salinity increases associated with SNWW channel improvements. They are influenced by breaks in the levees and PAs, or through natural bayous that allow higher-salinity waters to enter the marsh system. Predicted salinity would increase to 2.5 ppt (FWOP) and 4.1 ppt (FWP) in portions of the fresh and intermediate marsh.

Intermediate Marshes

Intermediate marshes comprise the largest percentage of marshes throughout the study area, and most occur in Louisiana east of Sabine Lake. In total, approximately 133,000 acres of intermediate marsh occur in the Louisiana portion of the study area, and 39,500 acres in the Texas portion. Approximately 99 percent of Texas intermediate marsh (the majority of which is located in the Salt Bayou hydro-unit) is predicted to have salinities in the optimum range in the FWP condition. In Louisiana, about 94 percent of the intermediate marsh is predicted to have salinities in the optimum range under FWP conditions. The WVA model predicts FWP AAHU losses of 36 AAHUs in the Neches River watershed and 1,583 AAHUs in the Sabine River watershed.

In Louisiana, all but one of the hydro-units (Perry Ridge, 4,704 acres) are located south of the GIWW. Salinity in Perry Ridge intermediate marshes would rise from 4.5 ppt (FWOP) to 5.6 ppt (FWP).

Extensive intermediate marshes occur in the Louisiana portion of the study area south of the GIWW. These marshes are found in Willow Bayou (35,109 acres), Black Bayou (34,941 acres), West Johnson's Bayou (11,110 acres), Sabine Lake Ridges (9,270 acres), Southeast Sabine (5,400 acres), Southwest Gum Cove (6,605 acres), and East Johnson's Bayou (26,138 acres). The primary hydrologic connections to these marshes are the Black Bayou Cutoff/GIWW, Black Bayou/upper Sabine Lake, Willow Bayou/central Sabine Lake, and Johnson's Bayou (south-central Sabine Lake). Mean annual salinities at these hydrologic connections are 0.4 ppt in the GIWW, 2.8 ppt in Black Bayou, 4.3 ppt at Willow Bayou, and 6.3 ppt at Johnson's Bayou. However, mean annual salinities within these interior marshes are generally lower, ranging from 1.3 ppt in the northern marshes, through 2.0 ppt in the central marshes, to 6 ppt in the southern marshes. Black Bayou has the lowest projected salinity of these three marshes under the FWOP condition with a modeled salinity of 5.1 ppt and Willow Bayou has the highest with a FWOP salinity of 6.8 ppt. FWP salinities in these marshes are predicted to increase to 6.5 ppt in Black Bayou, 7.3 ppt in West Johnson's Bayou, and 7.7 ppt in Willow Bayou.

In hydro-units located farther from Sabine Lake (Southwest Gum Cove, Southeast Sabine, and East Johnson's Bayou), salinity increases of 0.3 to 1.1 ppt are expected under the FWP condition. However, salinities within the Southwest Gum Cove and Southeast Sabine hydro-units would remain within the optimal range. Salinity in East Johnson's Bayou is predicted to rise from 3.8 ppt (FWOP) to 4.8 ppt (FWP). For most of the intermediate marshes in this area, FWOP salinities during these higher-salinity periods are already at or beyond the high end of the optimal range, and FWP conditions move them further into the brackish range for at least several weeks a year.

In Texas, intermediate marshes are located on the lower Neches River (Bessie Heights – 6,913 acres, and Groves – 437 acres) and at Texas Point (1,631 acres). The Bessie Heights and Groves hydro-units are adjacent to the Neches River and fed by several hydrologic connections. Average salinity in Bessie Heights intermediate marsh is about 4.2 ppt during the growing season. Intermediate marshes in Bessie Heights are primarily located along its southern fringe, but are separated from the Neches River by upland PAs. About half of the Bessie Heights hydro-unit is open water, averaging 2 to 3 feet in depth, which has developed in a formerly large, mostly emergent, intermediate marsh. Salinity in Bessie Heights intermediate marsh is predicted to be 4.4 ppt (FWOP), increasing to 4.7 ppt (FWP). In the Groves hydro-unit, shallow, meandering streams cross the marsh and drain into the Star Lake Canal and Neches River. Mean annual salinities within the marshes themselves are close to the Neches River levels. In the portions of the Groves hydro-unit, FWP salinities are expected to rise from 4.0 ppt (FWOP) to 5.0 ppt.

At Texas Point, approximately 1,742 acres of intermediate marsh (with small pockets of fresh marsh) are located inland of the extensive brackish marsh in this hydro-unit. Marshes are hydrologically connected to the Sabine Pass Channel through Texas Bayou and a large, interconnected man-made canal. FWOP modeled salinities are 7.0 ppt. FWP salinity would increase to 7.8 ppt.

Intermediate marsh is also located along the lower third of Cow Bayou (1,144 acres) in the Sabine River watershed. Salinity under the FWP condition is projected to increase to 5.0 in parts of the Cow Bayou marshes from 4.0 ppt in the FWOP condition.

Brackish and Saline Marshes

Brackish marshes occur just inland of saline marshes along the coast and at Sabine Pass, and form fringing marsh around Sabine Lake, Keith Lake, Salt Bayou, and Old River Cove. In total, approximately 25,161 acres of brackish marsh occur in the Louisiana portion of the study area, and 32,201 acres in the Texas portion. Little to no change would be expected between the FWOP and FWP conditions with respect to the percentage of both brackish and saline marsh remaining within the optimal range. The WVA model predicts FWP AAHU losses of 131 AAHUs in the brackish marshes of the Neches River watershed and 23 AAHUs in the Sabine River watershed. For saline marsh, a FWP loss of 5 AAHUs would be expected at Texas Point, and a loss of 37 AAHUs would be expected at Louisiana Point.

In Louisiana, brackish marshes are found in the Willow Bayou (1,182 acres), Black Bayou (3,195 acres), West Johnson's Bayou (2,078 acres), Johnson's Bayou Ridge (2,744 acres), and Sabine Lake Ridges (15,962 acres) hydro-units. The hydrologic connections and mean annual salinities are generally the same as reported for intermediate marshes located east of Sabine Lake. However, brackish marshes in Sabine Lake Ridges and Johnson's Bayou Ridge are hydrologically connected to Sabine Pass through Lighthouse Bayou. Under average annual conditions, FWP salinities would remain within the optimal range (≤ 10 ppt), increasing an average of 1.4 ppt, and ranging from 5.3 ppt at Black Bayou to 8.6 ppt at Willow Bayou.

In Texas, brackish marshes occur in the Old River Cove (8,530 acres), GIWW North (647 acres), and the Texas Point (2,546 acres) hydro-units. About 30 percent of the Old River Cove hydro-unit is open water, and mean annual salinities are about 10.0 ppt. At GIWW North, salinity in some of the brackish marsh during late summer months is expected to rise from 10.8 ppt (FWOP) to 12.4 ppt (FWP). At Texas Point, FWOP mean salinity in the brackish marshes averages 9.8 ppt and FWP salinity is projected to rise to 10.6 ppt, just into the suboptimal range.

Saline marshes in the study area are restricted to the immediate coastal zone. In Louisiana, they occur in the Sabine Lake Ridges (3,767 acres) and Johnson's Bayou Ridge (370 acres) hydro-units. In the FWOP condition, 100 percent of this habitat in both Texas and Louisiana remains within the optimal salinity range. In Texas, 5,708 acres of saline marsh occur in the Texas Point hydro-unit. These areas are hydrologically connected to Sabine Pass and are generally protected from saltwater incursion from the Gulf by low shoreline ridges. FWP mean annual salinity is projected to rise an average of 0.8 ppt above the FWOP condition in these marshes, while remaining within the optimal range for saline marsh (≥ 9 and ≤ 21 ppt).

4.6.3.2.4 *Sensitivity to Potential Salinity Changes during FWP Drought Condition*

The HS model predicts salinities at 13 locations at median and low flow under the FWOP and FWP conditions (see tables 4.6-1 and 4.6-3). FWP salinities ranged from 0 to 22.9 ppt at median flows and from 0.26 to 29.1 ppt at drought flows. Salinities under the modeled existing condition during drought ranged from 0 to 28.9 ppt. The average salinity increase from FWOP to FWP conditions at the 13 stations was 1.0 ppt at median flows and only 0.5 ppt at low flows. This suggests that the relative effect of RSLR

on salinities is lower as drought conditions cause salinities to increase. The greatest salinity increases from FWOP to FWP conditions at low flow were estimated for the east shore of Sabine Lake, near Rose City on the Neches River, and the Sabine River at Orange, areas where the salinity is predicted to increase 0.7 to 1.0 ppt from the FWOP to the FWP condition. Predicted salinities in the portion of Sabine Lake adjacent to the Louisiana shore are projected to reach levels ranging from 15.6 to 17.9 ppt, under the FWP drought condition compared to a range of 12.7 to 15.0 ppt under the modeled existing drought condition.

FWP salinities under drought flows would average 8.2 ppt above FWP salinities at median flows. FWOP salinities under drought flows would average 8.9 ppt higher than FWOP salinities under median flows. Drought flows in the upper Neches River and Sabine River under the FWP condition are not likely to affect marshes in these areas since predicted salinities in the upper Neches River would be 2.6 and 5.8 ppt in the Sabine River at Orange. Salinities in adjacent marshes would be expected to be lower.

Possible impacts that may occur if predicted FWP salinities occur in the project area during drought will depend on the extent, frequency, and duration of low inflows. These possible impacts are difficult to predict because of the complexity of the project area ecosystem; uncertainty about future changes in major variables like inflow, temperature changes, and sea level rise; and limited understanding of ecosystem structure and function in the project area. There is currently substantial discussion in the scientific community regarding the role of tipping points in determining effects of ecosystem stressors. However, there are no current, reliable, studies describing salinity tipping points for marshes or wetlands in this part of Texas. It is clear that FWOP drought flows will substantially increase salinities above the modeled existing condition, over 8 ppt, but the FWP contribution to the additional salinity increase is small, averaging 0.5 ppt.

4.6.4 Groundwater Hydrology Impacts

4.6.4.1 No-Action

The No-Action Alternative would have no additional direct impacts to groundwater resources at or near the proposed study area beyond those that may result from existing dredging activities or placement of dredged material independent of this project. Any direct effects of those projects may result in local and regional changes (i.e., sedimentation, altered hydrology, or a relative rise in sea levels) over time and would be common to all alternatives considered in this FEIS. Their effects would be evaluated under their own environmental studies.

With the projected future effects of climate change, there is a potential for saltwater intrusion into shallow groundwater aquifers at or near the SNWW area due to a rise in sea levels. The USACE, Galveston District analyzed the potential for RSLR to affect aquifers in the study area (USACE, 2009b). If the sea level rises half an inch (0.04 foot), the freshwater/saltwater interface could potentially rise as much as 1.67 feet, which would not have a significant impact on a freshwater aquifer. However, for a 50-year assessment, sea level rise of 1.1 feet would cause the interface to rise up to 44 feet. For every foot the saltwater level rises, the height of free ground surface water reduces by a foot. As a result, the interface between saltwater and freshwater underground rises approximately 40 feet for every foot the sea level

risks. This could have a significant effect on the amount of fresh water in deep aquifers in the study area with or without the proposed project.

4.6.4.2 Preferred Alternative

The potential to affect groundwater hydrology in this project is related to construction and maintenance dredged material placement in 16 existing and 2 expanded upland PAs, as proposed in the Preferred Alternative. Groundwater hydrology potential effects may result in physical (ability to infiltrate and/or contact groundwater in area aquifers) and chemical (TDS or salinity) attributes of the dredged material.

In the area, the Gulf Coast aquifer is subdivided into the Chicot aquifer (uppermost) and the underlying Evangeline aquifer, separated by differences in lithology and permeability. Higher permeabilities are usually associated with the Chicot aquifer. The Chicot aquifer has been divided into an upper unit and lower unit, separated by a clay bed in some areas and, in other areas, merged into one large mass of interbedded and interconnected sand and clay.

No effects are anticipated to the lower unit of the Chicot, any portion of the Evangeline, or the massive portions of the upper Chicot aquifers because clay barrier layers are anticipated to prevent contact with dredged material. Therefore, no adverse effects are anticipated to groundwater wells documented by the TWDB in the area counties.

Dredged material produced by construction of the Preferred Alternative would be managed in accordance with the DMMP. PAs would be able to accommodate material from both construction and maintenance dredging over the 50-year period of analysis. More details can be found in the DMMP (Appendix D). The upper stratigraphic units of the upper Chicot aquifer may become saturated from newly discharged dredged material and/or precipitation stored within the PA. With time and as material is discharged into the PA, the water would evaporate and the solids of the dredged material would compact to form a low permeability cap over the substrate within the PA. This cap, composed of new work material, would form an effective barrier to future dredged material infiltration.

SNWW dredge elutriate, water, and sediment data were collected and archived by the USACE within 5 years of this project's initiation. Data from this set collected within the area's footprint were compared to the regulatory thresholds set through Texas and Louisiana WQS. These findings are discussed in detail in sections 3.3 and 3.4. Water and sediment samples were collected at locations that are most likely to have been impacted by industrial properties undergoing remedial action. No WQS or WQC was exceeded by water or elutriate samples from any of the three sampling sites, and none of the concentrations was noticeably higher in the channel samples than the reference samples. Therefore, no adverse potential effects are expected if groundwater in the upper Chicot aquifer comes into contact with water or elutriate from construction and maintenance dredged material.

In general, water from the SNWW project area ranges in salinity from essentially zero to that of 30 ppt. Groundwater quality data from the TWDB database indicates that groundwater from water wells completed in the Chicot aquifer within the project vicinity generally has TDS concentrations less than

200 mg/L (fresh) to more than 3,000 mg/L (brackish). Most of the groundwater from the Chicot aquifer has an average TDS concentration of less than 1,500 mg/L. In general, storage of saline/brackish water on an upland impoundment would suggest that impacts to the uppermost contact with land surface could occur. Additionally, if groundwater occurs in this uppermost level, then saline/brackish water may blend with shallow-occurring groundwater. Greater permeability of the land surface would contribute to faster surface water entry into the subsurface, and potentially into the groundwater. This would suggest that impacts to groundwater may be likely during the first placement of dredged material into the PA; however, over the life of a PA, solids in the dredged material settle to the bottom and create a layer of low-permeability material. This physical barrier would, in time, minimize the intermixing of surface and groundwater in that area. Most of the PAs in the project area are existing, previously used impoundments, with an established layer of low-permeability material. Two new areas are proposed in upland areas adjacent to the Neches River where salinity levels in the navigation channel are lower overall. No domestic or livestock wells are in the vicinity of the PAs, and no reported complaints by groundwater users have been registered in the area. No prior use of the PAs has resulted in known groundwater resource impacts, and no impacts are anticipated from additional placement through this project. Salinity increases from dredged material water infiltration to the upper Chicot is not a concern.

With the projected future effects of climate change, there is a potential for saltwater intrusion into shallow groundwater aquifers at or near the proposed study area due to a rise in sea levels. These impacts would be the same as the No-Action Alternative discussed above in subsection 4.6.4.1.

4.7 HAZARDOUS, TOXIC, AND RADIOACTIVE WASTE

4.7.1 No-Action Alternative

The No-Action Alternative would have no impact on hazardous materials associated with regulated facilities in the region. However, maintenance dredging of existing ship channels and from future channel deepening and/or widening projects, in addition to the placement of dredged materials at PAs, would continue under the No-Action Alternative. In the absence of project activity, the existing historic impacts related to area industry are also expected to continue.

4.7.2 Preferred Alternative

According to a review of regulatory agency database records and interviews conducted with regional TCEQ personnel, industrial activity has caused measurable impacts to the surface water, sediment, soil, and groundwater in localized areas within the study area. However, chemical analysis of sediment and surface water samples collected from the waterway indicate that these impacts have apparently been limited to the industrial facilities and adjoining properties (PBS&J, 2002). The nature and potential for any HTRW site to impact the surrounding environment varies considerably. The majority of the regulated facilities and incident locations identified in the regulatory agency database review do not pose an environmental concern for the project. However, several facilities within the study area do pose a greater potential to impact the environment. These facilities pose a potential concern based on the nature and

extent of contaminants at the site, their location relative to the PAs and the waterway, and the number of pathways in which the contaminants could reach the PAs and the waterway. The facilities that are considered priority HTRW sites of concern are summarized in Table 4.7-1; their locations are shown on Figure 4.7-1.

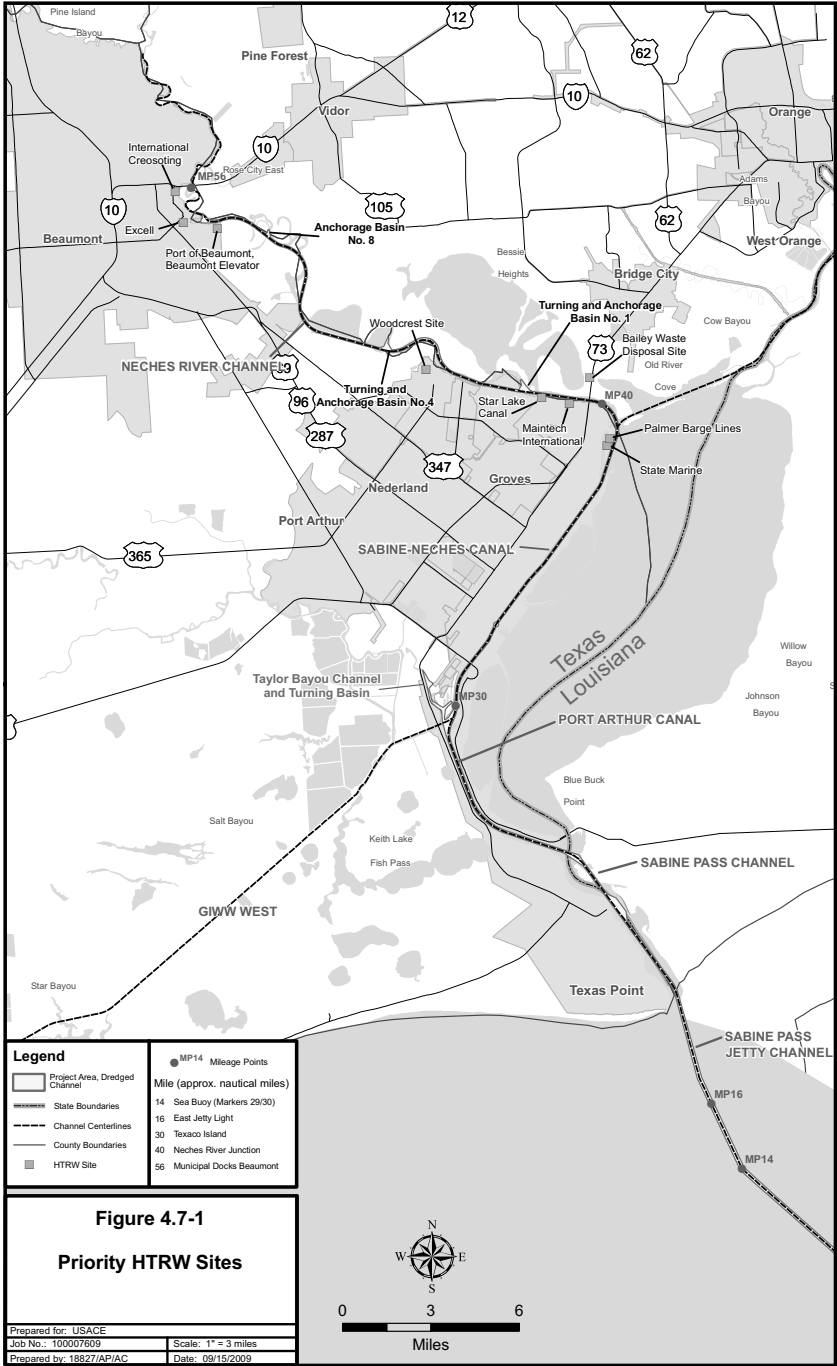

Table 4.7-1
Summary of Priority HTRW Sites within Sabine-Neches Waterway

Site Name	Site ID	Constituents of Concern	Media Impacted	Status
Bailey Waste Disposal Site	512	Arsenic compounds, benzene, phenols, pyridenes, naphthalenes, and chlorinated hydrocarbons	Surface water, groundwater, soil	Cleanup complete in 1998; Operation and Maintenance underway since 1999
State Marine	203	PAHs, metals	Surface water	Evaluation and cleanup are underway, but the nature and extent of contamination and the risks posed to human health and the environment are unknown
Palmer Barge Lines	548	Aluminum, barium, chromium, cobalt, iron, lead, magnesium, nickel, zinc, pesticides, VOCs, PAHs, PCP, and benzene	Surface water	Evaluation and cleanup underway since 2000; the EPA is considering various remedial alternatives
Star Lake Canal	471	Chromium, copper, PAHs, and PCBs	Surface water, sediments	Evaluation and cleanup underway since 2001, but the nature and extent of contamination and the risks posed to human health and the environment are unknown
International Creosoting	30	Arsenic, chromium, lead, creosote compounds, SVOC, and VOCs	Groundwater, sediment, soil, surface water	Clean up underway
Maintech International	410	PAHs	Groundwater, soil	Cleanup completed in 2000; undergoing Operation and Maintenance
Excell	28	TPH, benzene, toluene, ethylbenzene, and xylene	Groundwater	Investigation underway
Port of Beaumont, Beaumont Elevator	113	VOCs, herbicides, and pesticides	Groundwater, soil	Investigation underway
Woodcrest Site	584	VOCs	Soil	Investigation underway

Source: Banks Information Solutions (2002).

The USACE has determined that the 316-acre PA 17 is needed for future material disposal in conjunction with the Preferred Alternative and that PA 17 would be included in the DMMP; however, issues related to contaminated materials in a capped landfill and other waste disposal areas within this PA remain unresolved at this time. Pursuant to Department of the Army Engineering Regulation 1165-2-132, HTRW Guidance for Civil Works Projects, construction of civil works projects in HTRW-contaminated areas should be avoided. The non-Federal local sponsor has been notified that they are responsible for the investigation and remediation of HTRW issues for use of PA 17 for the project. Additional information is needed to fully identify and delineate onsite contaminants, and the EPA remedial investigations planned for the Star Lake Canal Superfund Site, which could potentially affect parts of PA 17, need to be completed. Surface and subsurface sampling and analysis would be necessary to identify and delineate contaminants of concern and to determine whether contaminants are present at levels of concern. Based upon available information at the time of this document's production, it is expected that PA 17 contaminant concerns would be resolved in time for its scheduled use in maintenance dredging; however,

(This page left blank intentionally.)

N:\Clients\USACE\Projects\Sabine_Neches\100007809\gofigs\Figure_4_7_1_v3.mxd

(This page left blank intentionally.)

if these issues are not resolved and PA 17 is not available, National Environmental Policy Act (NEPA) analysis and coordination would be performed to designate a new PA or expand an existing PA to replace the lost capacity.

A baseline evaluation of facilities that pose a potential concern to the project must also consider whether the release of contaminants is ongoing or has been effectively eliminated through remedial efforts. Based on these criteria, State Marine, Palmer Barge Lines, Star Lake Canal, and Beaumont Elevator continue to present an ongoing threat to impact the environment of the project area since these sites have not completed remedial activities. The remaining priority sites present a lesser threat due in part to either effective corrective action or distance to the waterway.

Based on the findings of the HTRW survey, there is the potential of encountering contaminated material during construction of the project. The contaminated material could increase project cost and/or lost time from discovery and remediation of the contaminated materials within the project area. The potential of encountering contaminated material appears to be greatest in areas adjacent to priority HTRW sites and in outfall canals adjacent to the SNWW. Surveys have been conducted to locate oil and gas wells and petroleum pipelines crossing the navigation channel (PBS&J, 2005). Prior to construction, additional pipeline surveys would be necessary for proposed BU features and mitigation measures.

The highest probability of residual contamination in water and sediments would be in the area of the Star Lake Canal outfall, the northern end of Pleasure Island, and near Taylor Bayou. According to TCEQ personnel, the Star Lake Canal and Taylor Bayou convey industrial wastewater effluent and stormwater to the SNWW. The sediment adjacent to the mouths of these canals could contain elevated levels of organic and inorganic compounds. Similarly, sediment adjacent to the State Marine and Palmer Barge Lines sites located near the north end of Pleasure Island could contain a variety of organic and inorganic compounds. These sources of potential contaminants are a result of migration and runoff of impacted groundwater and surface water into the waterway. However, based upon the recent chemical analysis of water and sediment collected within these channels, the potential for encountering contaminated material during dredging operations is considered minimal.

4.8 AIR QUALITY

This section provides a discussion of the air quality impacts associated with the No-Action and Preferred alternatives. The evaluation of air quality impacts associated with the proposed SNWW CIP was based on the identification of air contaminants and estimated emission rates for the Preferred Alternative. The air contaminants considered are those covered by the NAAQS (except for lead, which is not relevant to project emissions) including CO, O₃, NO_x, PM₁₀, PM_{2.5}, and SO₂. Air emissions were considered for channel improvement activities and placement of dredged material as well as emissions from vehicular traffic associated with the project employee commute. Project emissions were estimated based on preliminary assumptions regarding construction timing and equipment developed for this project. It is not within the scope of this analysis to perform the refined dispersion modeling necessary to predict

concentrations for each contaminant and alternative. Rather, the impact of emissions was analyzed relative to the existing inventory for air contaminant emissions in the BPA nonattainment area and the parishes of Cameron and Calcasieu.

The estimated air contaminant emissions, except O₃, were compared to the 2002 emissions inventory for the BPA ozone nonattainment area and for Cameron and Calcasieu parishes. Assuming an increase in air emissions would result in a corresponding increase in the ambient air concentration for that air contaminant, the ratio of the estimated emissions to the existing 2002 emissions for that contaminant provided a relative indication of the potential increase in ambient concentrations for the air contaminant. That difference was then compared to the NAAQS. As shown in Table 3.7-3 in subsection 3.7.3, monitored values indicate that concentrations of air contaminants (except O₃) for BPA are below the NAAQS over the period from 2004 to 2008. Because air emissions are generally dispersed with distance and time, a relatively small increase in emissions may be assumed to cause a correspondingly small increase in ambient air quality concentrations for that air contaminant, and it is therefore expected that the increase in emissions would not cause an exceedance of the NAAQS. Because authorization for the project is considered a Federal action, estimated emissions from the project were also considered in terms of the General Conformity Rules.

4.8.1 No-Action Alternative

No construction or new operating emission sources are associated with the No-Action Alternative. However, it is expected that air contaminant emissions would increase due to continued operational constraints on the existing system and projected increased ship traffic resulting both from growth of existing business and from new business.

4.8.2 Preferred Alternative

The evaluation of air quality impacts associated with the Preferred Alternative was based on the identification of air contaminants and estimated emission rates for this project alternative. Emissions inventories were estimated for project-related activities based on the schedule, dredging volumes, and other construction-related assumptions regarding construction timing and equipment developed for this project. The emission sources for this alternative would consist of marine vessel and land-based mobile sources that would be used during the channel improvement activities, as follows:

- **Marine Vessels.** Includes dredges (cutter and hopper), dredge support equipment (tugboats, survey boats, crew boats, and tenders), and shrimp trawlers; and
- **Land based.** Includes off-road (amphibious track hoe, dozer, dragline, excavator, and rolligon) and on-road (employee vehicles).

Air contaminant emissions associated with the channel widening would be primarily combustion products from fuel burned in equipment used for project dredging, support vessels, and dredged material placement equipment. Activities at dredged material placement sites would involve the use of earth-moving equipment. The marine vessel emissions sources are primarily diesel-powered engines. The off-road

construction equipment was assumed to be all diesel-powered, and on-road vehicles were assumed to be all gasoline-powered vehicles. Detailed emission estimates are provided in the General Conformity Determination (Appendix F).

4.8.2.1 Air Quality Analysis Results

The project construction emissions represent the estimated emissions from the activities associated with the Preferred Alternative. These activities would be considered one-time activities, i.e., the channel widening activities would not continue past the date of completion. Because of the high moisture content of the dredged material, it is expected that there would be no particulate matter emissions from the placement of dredged material in placement areas.

A summary of the total estimated annual emissions, in tons, resulting from the use of dredging equipment, support vessels, off-road equipment, and on-road equipment is presented in Table 4.8-1. A detailed summary of emissions can be found in the General Conformity Determination (Appendix F).

The total estimated annual emissions for each year of construction were compared to the 2002 emissions inventory for the BPA nonattainment area and the emissions inventory for Cameron and Calcasieu parishes. This comparison is presented in Table 4.8-2.

As shown on Table 4.8-2, air contaminant emissions from the Preferred Alternative would result in a relatively small increase in emissions above those from existing sources in the BPA and for Cameron and Calcasieu parishes. As a result, it is expected that air contaminant emissions from the combustion of fuel in equipment used for dredging and placement activities would also result in correspondingly minor short-term impacts on air quality in the immediate vicinity of the project area and even less as emissions are dispersed over the BPA and Cameron/Calcasieu areas.

4.8.2.2 General Conformity Applicability

For comparison with the thresholds defined in the General Conformity Rule, the estimated emissions of NO_x and VOC for each year for the project activities subject to the General Conformity are summarized in tables 4.8-3 and 4.8-4. For purposes of General Conformity, only air contaminant emissions that might occur within the BPA nonattainment area out to the 9-mile natural resources limit for the State of Texas were considered. The 9 nautical mile boundary is the seaward limit of the submerged lands of Texas as defined in the Submerged Lands Act (U.S. Code Title 43, Chapter 29, Subchapter II, § 1312). Emissions of carbon monoxide, sulfur dioxide, and particulate matter are not considered in the General Conformity evaluation as this area is in attainment with the NAAQS for each of those pollutants.

As shown in Table 4.8-3, estimated emissions of VOC for the Preferred Alternative are exempt from a General Conformity Determination because they are below the 100 tpy threshold for each year of anticipated activity. However, estimated NO_x emissions for the Preferred Alternative exceed the general conformity threshold, i.e., greater than 100 tpy, for all years of construction. Therefore, a General Conformity Determination for NO_x emissions would be required for these years.

Table 4.8-3
Summary of VOC Construction Emissions Subject to General Conformity

Year	Dredge and Support Equipment	Construction Equipment	Employee Vehicles	Total

To initiate the General Conformity process, the USACE, prepared a document entitled, “Draft General Conformity Determination, Sabine-Neches Channel Improvement Project.” This document was noticed for public comment and was submitted by the USACE to the TCEQ, the EPA, and other air pollution control agencies, as appropriate, concurrently with the DEIS. As part of the General Conformity process, the USACE made this document available to the public for review and comment for a period of 30 days. The TCEQ has provided written concurrence that emissions from the Preferred Alternative are conformant with the Texas SIP for the BPA (Appendix A1). Based on the TCEQ's comments, the

USACE has prepared a Final General Conformity Determination for the proposed SNWW CIP (Appendix F).

4.9 NOISE IMPACTS

Project-related noise impacts were evaluated by considering the noise emissions related to dredge and placement operations of the proposed channel improvement project at noise-sensitive land uses (residential, educational, health care, recreational). Potential noise impacts associated with dredging and placement activities were evaluated by modeling predicted noise levels as a function of distance between the noise-generating equipment and noise-sensitive land uses in the vicinity of the project area. Noise levels were calculated based on industry accepted standards and properties of noise attenuation.

4.9.1 No-Action Alternative

Under the No-Action Alternative, the channel would not be deepened to project specifications. However, the existing regime of maintenance dredging, which generally includes a cutterhead suction dredge and various tending/crew boats within the channel, would continue as normal. Table 4.9-1 summarizes dredging-related noise levels produced by equipment type.

Table 4.9-1
Typical Noise Levels

Equipment	Noise Level (dBA)
Cutterhead Dredge (at 160 feet)	79 ¹
Hopper Dredge (at 50 feet)	87 ²
Large Tug boat (at 50 feet)	87 ³
Small Tug Boat	72 ³
Bulldozer (at 50 feet)	82 ⁴
Bucket Crane (at 50 feet)	82 ⁴

¹ Geier & Geier Consulting (1997).
² Assumed same as large tug.
³ Epsilon Associates (2006)
⁴ FHWA (2006).

Potential short-term noise impacts related to the No-Action Alternative would occur during maintenance dredging activities throughout the channel’s length. Noise-sensitive land uses exist in various locations along both sides of the channel’s banks. These areas are concentrated in the cities of Port Arthur, Port Neches, and Beaumont. Other noise-sensitive land uses include recreational areas (J.D. Murphree State WMA, Sea Rim State Park, Sabine Pass Battleground State Park, and Pleasure Island) in the southern portion of the project. Table 4.9-2 summarizes the estimated noise levels produced by maintenance dredging activities at increasing distances from the ship channel. The No-Action Alternative would not result in permanent noise level increases, however, short-term impacts could be considered potentially significant at noise-sensitive land uses within 600 feet of maintenance dredging activities.

Table 4.9-2
Calculated Noise Levels of Maintenance Dredging

Distance From Center of Channel	Calculated Noise Level From Dredging Activities
160 feet	79 dBA (L _{eq})
300 feet	73 dBA (L _{eq})
600 feet	67 dBA (L _{eq})
1,200 feet	61 dBA (L _{eq})
2,400 feet	55 dBA (L _{eq})

4.9.2 Preferred Alternative

Under the Preferred Alternative, the channel would be deepened as described in Section 2.4. Equipment to be used for the proposed action would include separate crews consisting of a 30-inch hydraulic cutterhead dredge, three 500-horsepower tugboats, and one survey/crew boat within the channel. A large hopper dredge with tending boats would be used beyond the channel in the Gulf. However, noise levels associated with this portion of the project were not calculated since no noise-sensitive land uses are located beyond the channel. Although more than one crew could operate on the channel simultaneously, they would operate on separate reaches of the channel, and therefore would not be within the vicinity of noise-sensitive land uses at the same time. Dredging operations are expected to occur approximately 20 hours per day for a total of 7 years. Dredging activities would generate noise from a variety of equipment sources, however, the primary sources of equipment noise would include the dredges (with their associated pumps and generators) and tugboats (see Table 4.9-1). Smaller vessels, such as tending boats and survey boats, would not substantially contribute to the noise associated with dredging activities.

The proposed action under the Preferred Alternative is not expected to result in long-term noise impacts. No permanent noise sources would be installed as part of this project. In the short term, however, the proposed action could result in temporary elevated noise levels at noise-sensitive land use locations. Because the same type of equipment used for maintenance dredging would be used for the proposed action, short-term noise impacts related to the proposed action would be nearly identical to the short-term impacts that occur during current maintenance dredging, as discussed above in subsection 4.9.1. Table 4.9-2 summarizes the estimated noise levels produced by the proposed action at increasing distances from the ship channel. As is the case with current maintenance dredging, short-term impacts could be considered potentially significant at noise-sensitive land uses within 600 feet of the proposed project's dredging activities.

Reduction of the short-term noise levels could be achieved by using quieter-running equipment and by adding supplemental noise shielding around engines and pumps of the dredging equipment. Additional acoustical shielding panels could be used when the dredges operate in close proximity to residential areas. Additionally, dredging operations could be limited to daytime hours in proximity to residential areas. Limiting the hours of operation, however, would increase the length of the project significantly.

4.10 VEGETATION

4.10.1 No-Action Alternative

Under the No-Action Alternative, the combined effects of RSLR, shoreline recession, and interior marsh loss are expected to result in the significant loss of marsh and expansion of open-water areas, and this is likely to be exacerbated by the effects of global climate change. These processes would continue a trend of wetland loss that has been occurring in the study area in recent decades (Berman, 2005; Morton, 2003; Morton et al., 2005; Shinkle and Dokka, 2004; Titus and Narayanan, 1995). In Louisiana, a net land loss of 21 percent between 1978 and 2000 has been reported in the Chenier Plain subregion of coastal Louisiana, which includes the Sabine estuary (USACE, 2004a). In Texas, the most extensive losses of interior coastal wetlands in the state (12,632 acres between 1930 and 1978) have occurred in the Neches River delta. In total, over 90 percent of the emergent marshes in the Lower Neches River delta have been converted to open water, which is more than half of the total wetland loss in the State of Texas (Morton and Paine, 1990; Sutherlin, 1997; White et al., 1987). During this same period, NOAA documented a historical trend of mean sea level rise at its Sabine Pass tide gage of 0.2 inch/year over 48 years from 1958 through 2006 (USDC-NOAA, 2009), one of the highest on the Gulf Coast.

FWOP land loss projections for the SNWW project are based upon a single “most likely” estimate of 1.1 feet of RSLR by 2069. There is great uncertainty in the prediction of RSLR, which combines rates of global sea level rise and local subsidence. Uncertainties are related to the rate and degree of global climate change, including changes in the accumulation of greenhouse gases in the atmosphere, future trends in temperature and regional precipitation, the timing and quantity of freshwater inflows, sediment delivery to coastal marshes, and the rates of vegetative growth and biomass accumulation (Barras et al., 2004; IPCC, 2007; Langley et al., 2009; Nielsen-Gammon, 2009). In particular, some recent studies of geologic terrestrial and marine records support the plausibility of sea level rise on the order of 3.3 ± 1.64 feet by A.D. 2100 (Carlson et al., 2008; Rahmstorf, 2007; Rohling et al., 2008). Uncertainties in the rate of regional subsidence are related to the effect of anthropogenic factors such as oil, gas, and groundwater withdrawals, the compaction of deep reservoir rocks, the reactivation of surficial faults, and the erosion and/or accumulation of surface sediments (Gonzalez and Törnqvist, 2006; Milliken et al., 2008a, 2008b; Morton et al., 2006). This results in a very wide range of potential RSLR, calculated as stipulated by the most recent USACE relative sea level guidance (EC 1165-2-211, July 2009) to be between 0.3 and 2.8 feet over the period of analysis.

For this study, FWOP projections of land loss include the effects of rising salinities and shoreline recession associated with RSLR. Approximately 5,500 acres (7.5 percent) in Texas and 15,500 acres in Louisiana (10.5 percent) are forecast to be lost by 2069. In the near term, the marsh degradation process provides fisheries organisms with short-term benefits by releasing organic and mineral-rich sediments into the open-water system as the marsh is lost (Minello and Rozas, 2002). In the long term, the important ecological functions of the wetlands in the affected area would decline, resulting in the loss of fish and wildlife and their habitats, adverse effects on water quality, and reductions in erosion protection.

4.10.1.1 FWOP Shoreline Recession

The forecasted RSLR would result in the recession of Gulf and Sabine Lake shorelines in the SNWW study area. Potential problems associated with sea level change can be categorized into two classes; those of the open coast and large waterbodies where both water level and wave action are concerns, and those of inland tidal waters where wave action is usually much less severe (NRC, 1987). The NRC report discusses different approaches that can be used to model the change in shoreline configuration associated with RSLR. Two of those techniques were applied to project shoreline recession in the SNWW study area over the period of analysis (2019 through 2069).

The first technique is recommended for areas of active wave attack and erosion, and was applied to the Texas Gulf shoreline and the eastern shoreline of Sabine Lake. It is a historical trend analysis that includes an adjustment for higher future rates of RSLR. The second method was applied to the shorelines of interior lakes and inland waterways where the wave climate is subdued and the stable or accreting Louisiana Gulf shoreline (as described below). This method involves applying the projected change in sea level over the period of analysis to preexisting topography.

Two major factors influencing erosion and eventual shoreline profiles are fetch and exposure to predominant directions of wave approach (Wilson and Allison, 2008). In the SNWW study area, prevailing winds and wave approach are from the southeast; however, low-pressure weather systems (northers) frequently move across the upper coast from the north during winter months (Anderson, 2007). The portions of the study area most affected by these prevailing wind patterns are the Gulf shoreline and the eastern shore of Sabine Lake. In Sabine Lake, fetch and wave attack associated with prevailing southeasterly winds primarily affect the western shore, an area that is protected from erosion by riprapped levees around PAs 8 and 11. These levees are quite large and sufficiently high such that the rates of RSLR predicted here would have little to no effect. Winter northers, however, do affect the unprotected eastern shore of Sabine Lake (Greco and Clark, 2005; Parchure et al., 2005).

For the Gulf and east Sabine Lake shorelines, the historical trend, modified by the projected RSLR over the period of analysis, was used to project shoreline recession (NRC, 1987). Historical rates of change incorporate the inherent variability of the shoreline response based upon local coastal processes, local subsidence rates, coastline exposure, the local sedimentary environment, and eustatic sea level changes. This method assumes that the amount of recession during the historical record is directly correlated with the rate of sea level rise. Therefore, an accelerated rate of RSLR is assumed to result in a commensurate accelerated increase in shoreline recession. For example, a projected fourfold rise in the rate of RSLR in the study area would result in a fourfold increase in the recession rate. For the SNWW study area, the future rate of RSLR was forecast to be roughly 4.2 times the existing rate.

For this study, rates of existing historical Gulf shoreline change were obtained from several recent studies (Barras et al., 1994; BEG, 2009; USACE, 2004a). Most of the Texas shoreline in the study area experienced very high rates of shoreline retreat from the 1950s through 2002, ranging from -5 to -51 feet/year. However, small reaches near the SNWW west jetty and near Sea Rim State Park are stable

or accreting. The BEG (2009) has developed a projected shoreline for the upper Texas coast for the year 2056, based upon historical Gulf shoreline changes. The historical rate of change includes historic rates of RSLR but not the accelerated rates expected in the future. The projected shoreline retreat was adjusted to account for the accelerated rate of future RSLR by multiplying the width of the BEG shoreline retreat by the projected increase in the rate of RSLR and mapping a revised shoreline with GIS, adjusted as needed for controlling features such as roadways or large chenier ridges that are likely to block retreat.

A similar method was followed for Sabine Lake; however, in this case an average annual loss rate provided by the USFWS was applied as the baseline historical rate. Erosion on the east shore of Sabine Lake is caused primarily by wind-induced waves and soft sediments (Parchure et al., 2005). The historical rate was calculated with a GIS analysis of aerial photographs taken between 1978 and 2004 (Greco and Clark, 2005). This analysis estimated an average shoreline retreat rate of 4.5 feet/year for the Sabine Lake shoreline between the Sabine River and Willow Bayou. For the purposes of this analysis, the 4.5 feet/year rate is applied to the entire east Sabine Lake shoreline as shoreline retreat is also a problem along the Sabine Lake shoreline between Willow Bayou and Blue Buck Point (LCWCR/WCRA, 1998). The 4.5-foot/year rate was increased by a factor of 4.2 to account for the accelerated rate of RSLR, resulting in an estimated 1,200 feet of shoreline retreat by the year 2069. The current shoreline was recessed by this width, except where other controlling features such as levees, cattle walkways, or roadways would block retreat, and the lost acreage was calculated by GIS.

For the Louisiana Gulf shoreline in the study area, no change was projected through the year 2050 (Barras et al., 1994). The history of shoreline change for this area, developed in conjunction with the Louisiana Coastal Areas Ecosystem Restoration Report (USACE, 2004a), documented that the segment of the Chenier Plain shoreline between Sabine Pass and Ocean View Beach (located 6 miles beyond the 10-mile SNWW study boundary) prograded seaward at an average rate of +12.9 feet/year between 1883 and 1994. Between 1985 and 1995, the average rate of progradation slowed to +1.2 feet/year. The shoreline in the study area is dominated primarily by the effect of the Sabine Pass jetties, which intercept the westward-moving littoral drift and tend to trap sediment, creating a more stable shoreline than that nearer to Ocean View Beach. For this study, a stable shoreline through the period of analysis was assumed, and the projected RSLR at the Gulf shoreline (1.1 feet in year 2069) was applied to the preexisting topography using the GIS method described below.

For the Louisiana Gulf shoreline and the shorelines of all other major waterways and waterbodies in the study area, the second method was applied. Preexisting topography along shorelines was assumed to be fixed; current shoreline elevation was combined with the projected increase in sea level to project a new shoreline. The increase in sea level at the end of the period of analysis (year 2069) is equivalent to the change in water surface elevation projected by the HS model for the FWOP with RSLR condition; this change is +1.1 feet throughout the study area. Slope is a major controlling variable in the determination of shoreline changes using this method. Steep slopes would experience little shoreline displacement while gentle slopes would show a much larger lateral change. It is assumed that man-made features such as jetties, roads and highways, dikes and levees, bulkheads and fill would continue to be maintained at a

sufficient elevation that they would block shoreline retreat, and that current beneficial use projects that use dredged material to isolate interior wetlands from large waterways would be continued.

In the WVA EMCM, hydrologic unit acreages were adjusted to remove acres lost to RSLR-related shoreline recession for the FWOP land loss projection in the WVA model. This adjustment was made in the WVA land loss tables. The rate of acreage lost due to shoreline recession was assumed to be linear. The acres lost per year were subtracted from the base acreage before the revised land loss rate for the interior marsh was applied. This adjustment results in the removal of an equivalent amount of acres (lost due to RSLR only) from both the FWOP and FWP conditions. FWOP and FWP interior land loss rates were then applied to the remaining acreage, as described below, to determine the effect of salinity changes over the period of analysis in both the FWOP and FWP conditions.

In summary, the total acres of marsh forecast to be lost in the FWOP condition due to shoreline recession is 6,394 acres. The loss for each affected hydro-unit is shown in Table 4.10-1.

Table 4.10-1
Acres Lost to FWOP Shoreline Recession

HU #	HU name	Marsh Type	Marsh	Water	Total
Louisiana					
LA 2	Willow Bayou	Brackish	627	20	648
LA 3	Black Bayou	Brackish	621	9	630
LA 4	West Johnson's Bayou	Brackish	957	130	1,087
LA 5	Sabine Lake Ridges	Brackish	685	49	734

4.10.1.2 FWOP Interior Marsh Loss

4.10.1.2.1 Interior Marsh Loss

Land loss rates for interior marsh areas were adjusted to account for increasing salinity due to RSLR over the period of analysis using the land loss methodology of the WVA and a productivity-based land loss projection methodology based upon a salinity-vegetation productivity relationship developed for the habitat productivity component of the LCA Ecosystem Model (Visser et al., 2004).

The deepening project would result in a minimal increase in water elevation over the majority of the project area (averaging less than ½ inch). Thus no FWP impacts due to water elevation increases are anticipated. It is, however, assumed that all tidally influenced habitats would see a gradual increase in water elevation associated with a RSLR of 13.2 inches by 2069.

The effects of the projected rate of RSLR on coastal marshes are very difficult to predict. The RSLR rate at which marsh will convert to open water depends on the rate of marsh elevation gain by sediment accumulation and/or biological mechanisms such as biomass accumulation (Langley et al., 2009). Dams on both the Sabine and Neches rivers have decreased sediment deposition downstream in the coastal marshes, making biological processes very important in their long-term sustainability. It is possible that biomass accumulation would offset much if not all of the RSLR change in water surface elevation. “Primary productivity of salt marsh vegetation is regulated by changes in sea level, and the vegetation, in turn, constantly modifies the elevation of its habitat toward an equilibrium with sea level (Morris et al., 2002). A rise in relative sea level brings an increase in production and biomass density that enhances sediment deposition by increasing the efficiency of sediment trapping. This can lead to an absolute increase in the elevation of the marsh platform and result in a landward migration of the marsh (Gardner et al., 1992, Gardner and Porter, 2001). This may change total wetland area, depending upon local geomorphology and anthropogenic barriers to migration, such as bulkheads, canals, etc.

Existing coastal marshes appear to have adapted to historical ranges of mean sea level, and gradual changes in RSLR. There has been a decrease in the loss rate in the Sabine-Calcasieu area from 7.0 to 2.6 square miles (17.1 to 3.3 percent) (Barras et al., 1994). Furthermore, the high rate of RSLR in this region may be ameliorating, as the average increase at the Sabine Pass tide gage was 0.3 inch/year for the 41-year period between 1958 and 1999 compared to 0.2 inch/year for the 48-year period between 1958 and 2006 (USDC-NOAA, 2006, 2009). FWOP projections of coastal land loss in the Louisiana portion of the SNWW study area forecast relatively stable landforms and shorelines through 2050 (Barras et al. 1994), not accounting for the effects of tropical storms and hurricanes. In general, the interior marshes in the Louisiana portion of the SNWW study area appear to have stabilized and are not undergoing rapid conversion of large areas to open water like areas to the east in Louisiana (LCWCR/WCRA, 1998; USACE, 2004a). Recent Louisiana LIDAR data shows that existing marsh is higher than the projected RSLR for the period of analysis and thus should be able to withstand the gradual rise in elevation (Louisiana State University, 2009).

Similar large-scale FWOP land loss projections are not available for the Texas portion of the study area. However, this study assumed that the Texas portion would also remain relatively stable with respect to the effects of RSLR through the period of analysis because the same chenier landforms, marshes, and sediments are present throughout the study area. A GIS study of aerial photographs of the Salt Bayou/Keith Lake system confirmed that the open-water trend has slowed and possibly reversed itself in that area in recent years (TPWD, 2003). Texas interior marshes most at risk to the effects of RSLR are located in the Texas Point NWR and just outside and to the west of the SNWW study area in the McFaddin NWR. Most recently, marshes in these areas have been highly stressed due to the combined

effects of Hurricane Ike's storm surge and a subsequent drought, which caused prolonged high salinities throughout these marshes.

However, many different climatic, physical, and biological processes can affect the rate of accumulation. Recent experimental evidence suggests that increasing atmospheric CO₂ concentrations could stimulate biogenic mechanisms of elevation gain in a brackish marsh, and further, that this effect could be enhanced under salinity and flooding conditions expected with future RSLR (Langley et al., 2009). This response is further complicated by variations in sediment supply from river discharges and variations in primary production due to changes in nutrient loading, precipitation, temperature, and other factors (Morris et al., 2002). Gulf shoreline erosion associated with accelerated rates of RSLR may increase the amount of near shore sediment. Wilson and Allison (2008) have shown that material released by Gulf shoreline erosion remains nearshore rather than being dispersed into offshore waters, therefore remaining available for redeposition by tidal flooding or storm surge overwash. In addition to RSLR, future changes in climate would influence the quantity and timing of freshwater delivery to the coastal estuaries. At this time there is no consensus in the direction or amount of changes in precipitation in the study area, while a temperature increase of 4°F is likely by 2059 (Nielsen-Gammon, 2009). Whatever the net effect of climate change on basin runoff, most climate change projections agree that more frequent high-intensity rainfall events are likely. In most drainages, this type of event would most likely produce increased sediment runoff, and thus periodically increase sediment delivery to the coastal marshes. Uncertainties related to all of these processes could result in very different predictions of future marsh conditions.

It must be recognized that large areas of interior marsh could quickly convert to open water under certain extraordinary events. If RSLR accelerates to the extent that the coastal plant community cannot sustain an elevation within its range of tolerance, rates of primary production would decrease, resulting in an unstable and rapidly deteriorating marsh community (Morris et al., 2002). In addition, if shoreline recession cuts existing foredune formations, large areas of interior marsh could quickly be exposed to higher-salinity Gulf waters and wave attack. In this case, large marsh areas could quickly be lost to the Gulf.

The EMCM was used to forecast land loss in the emergent marshes of the study area. Variable V₁ (percent emergent marsh) of this model requires the projection of the number of acres of emergent marsh that would remain at the end of the period of analysis, both without and with the project. The WVA land loss methodology assumes that historical trends can be used to predict future land loss rates. Baseline historical land loss rates were determined by measuring changes over the most recent 15- to 20-year time period for which reliable data were available. These rates include the chronic, regional effects of subsidence, altered sediment delivery, global sea level rise, and tropical storms and hurricanes. They were calculated from a period that postdates high oil and gas extraction in the region and thus exclude subsidence that may be related to the higher rates of extraction, which have waned significantly in recent decades. After changes in acreages were calculated, the amount of emergent marsh that converted to open water was expressed as a percentage loss per year.

Increasing salinity levels associated with accelerating RSLR would be expected to reduce the primary productivity of the marsh and increase the land loss rate. Associating a decrease in primary productivity with an increase in salinity is based upon documented biological responses of inundated vegetation to salinity. The expected reduction in biological productivity of wetlands in the study area as a result of salinity stress is discussed in Section 4.6. Decreased plant productivity has been demonstrated to result from the interaction of excessive submergence and salinity. This interaction leads to a decrease in organic matter accumulation, which, in turn, results in greater submergence because the rate of increase in marsh elevation cannot keep up with the rate of submergence due to RSLR (Day and Templet, 1989; Day et al., 1995; DeLaune et al., 1994; Nyman et al., 1993; Spalding and Hester, 2007). The death of wetland vegetation often results, followed by peat collapse, erosion, and wetland loss (DeLaune et al., 1994; Gough and Grace, 1999; Salinas et al., 1986; Visser et al., 1999; Webb and Mendelssohn, 1996).

FWOP effects of RSLR to interior marsh areas are expected to be limited to the effects of increasing salinity. FWOP land loss rates were adjusted for the gradually rising salinity using the productivity-based land loss projection described below. Although emergent marshes throughout the tidally influenced portions of the study area would experience a gradual increase in water elevation associated with a RSLR of 1.1 feet by 2069, biomass accumulation was assumed to offset all of the RSLR increase in water surface elevation. The total amount of interior marsh expected to be lost in the FWOP condition, exclusive of the approximately 6,000 acres lost to shoreline recession, is approximately 15,000 acres.

4.10.1.2.2 *Productivity-Based Land Loss Projection*

In order to provide a science-based and systematic evaluation of the project effects for the SNWW WVA model application, the HW applied a productivity-based method of land loss projection that is based upon a salinity-productivity relationship developed for the habitat productivity component of the LCA Ecosystem Model (Visser et al., 2004). In the LCA Ecosystem Model, productivity algorithms were developed for all herbaceous and forested wetlands based on available published and unpublished data. That report documented extensive literature on the effect of salinity on the productivity of the dominant species in each of the habitats in this study area (see Section 4.6). These studies used various measurements of productivity, including total biomass, stem/leaf elongation, and photosynthesis, that were gathered using greenhouse experiments on saturated soils. To better illustrate the relationship of salinity and productivity, linear regression equations were developed that predict percentage changes in habitat productivity per 1 ppt salinity for each major coastal habitat type, regardless of inundation, as shown in Table 4.10-2. These predicted changes in primary productivity for every 1 ppt increase in salinity were used to predict land loss rate changes in the current study.

4.10.1.2.3 *Assumptions and Uncertainties of the Productivity-Based Land Loss Projection*

Relating changes in salinity to specific amounts of land loss is problematic. While there is extensive literature that relates increases in salinity to decreased productivity, vegetation stress, and eventual wetland loss, the USACE and the ICT are not aware of any studies that have documented specifically how much land loss is associated with specific increases in salinity. Similarly, no data are currently available

that relate salinity reduction with a reduction in land loss (Visser et al., 2004). Therefore, the HW assumed a direct linear correlation between decreased primary productivity due to salinity increases and increased land loss rates due the project (see Table 4.10-2). The HW considered increasing land loss rates for salinities that changed from optimal to suboptimal conditions and, conversely, also considered decreasing land loss rates in target years 20 to 50. The latter consideration is based upon historical observations that land loss rates generally stabilize and lessen a few decades after channel deepening projects are completed. Since the effects of these considerations would generally offset one another, the HW opted for the simpler 1:1 relationship.

Table 4.10-2
Productivity-Based Land Loss Projection

Habitat Type	% Productivity Lowered and Land Loss Rates Increased per 1 ppt Increase in Salinity
Fresh marsh	11.1
Intermediate Marsh	11.4 (<i>Sagittaria</i>), 2.3 (<i>Spartina patens</i>); mean = 6.8
Brackish	2.6
Saline	2.1

The relationship between productivity decreases and land loss rate increases is assumed to be linear; thus, a 1 percent decrease in productivity translates to a 1 percent increase in the land loss rate. For example, in Table 4.10-2, the productivity of fresh marsh decreases by 11.1 percent with every salinity increase of 1 ppt for fresh marshes. This translates to an 11.1 percent increase in the land loss rate for every 1 ppt increase in salinity. The following standard formula was applied to calculate FWP rates used in the WVA land loss spreadsheets.

$$\text{FWP land loss rate} = (((\text{fwp salinity ppt} - \text{fwop salinity ppt}) \times \text{percent productivity decrease per habitat type}) + 1) \times \text{baseline land loss rate}$$

4.10.1.3 FWOP SAV

The salinity change occurring with RSLR in the No-Action Alternative would be very gradual, and therefore the SAV community structure in the majority of intermediate marshes would likely change to include more salinity-tolerant species, such as widgeon-grass, pondweed (*Potamogeton pectinatus*), Eurasian watermilfoil, and freshwater eelgrass (USGS, 1997). It is expected that any SAV cover lost as a result of this change would be replaced by the salinity-tolerant SAVs continuing to grow within their tolerance range. As a result, no change in percent SAV cover would be expected during the period of analysis.

4.10.1.4 FWOP Effects of Hydrologic Management Structures

The hydrologic management of emergent tidal marsh has also been shown to contribute to land loss in nearby areas, such as the eastern section of the Sabine NWR, by increasing both salinity and the duration of inundation in managed marshes. The potential for hydrologic management in the study area to contribute to land loss is reviewed in subsection 4.6.3.2.1. None of the current hydrologic management

measures in the study area (the western Sabine NWR excluding Pool 3, the Black Bayou area, the Texas Point and McFaddin NWRs) lead to long-term ponding or significant delays in the ability of the wetlands to drain after periodic salinity incursions (i.e., droughts or hurricanes), and thus no adverse FWOP impacts associated with managed marshes would be expected.

4.10.1.5 FWOP Adjustments for CWPPRA Marsh Restoration Projects

FWOP adjustments to acreages for constructed or funded CWPPRA projects in the east Sabine Lake marshes (Clark et al., 2000; USFWS and NRCS, 2008a), at Black Bayou (USFWS and NRCS, 2008b), and at Perry Ridge (USGS-NWRC, 2002a, 2002b) were applied in the WVA land loss spreadsheets as had been done previously. Acres of restored marsh were added in the FWOP and FWP marsh (acres) columns in the target year in which they were completed.

4.10.2 Preferred Alternative

4.10.2.1 FWP Effects on Cypress-Tupelo Swamps and Bottomland Hardwood

The Preferred Alternative would have no direct construction impacts to bottomland hardwoods or swamps, and the FWP “most likely” salinity levels would not result in the loss of any swamp or bottomland hardwood forest acreage. In the swamp communities, salinities would exceed the optimal range at Adams Bayou and in the Blue Elbow South hydro-unit. However, FWP salinities would not exceed 4 ppt and thus would not be high enough to result in the conversion of swamp to marsh, or in the loss of forested wetland acreage (Visser et al., 2004). Bottomland hardwoods on the upland terrace margin near the mouth of the Neches River, along Adams Bayou, and at Perry Ridge would be exposed to occasional insults of salinities exceeding the optimal range, but at levels that are insufficient to cause a significant loss of productivity.

4.10.2.2 FWP Land Loss

4.10.2.2.1 FWP Shoreline Recession

Shoreline recession along the eastern shoreline of Sabine Lake would not be affected by the proposed project (Parchure et al., 2005). The deepening project does not significantly increase tidal amplitude, velocity, or water surface elevation and thus would cause no additional recession of the lake shoreline (Brown and Stokes, 2009).

Bank erosion along the SNWW navigation channels is not expected to increase in the FWP condition, and thus would not contribute to shoreline recession over the period of analysis (Maynard, 2005). Existing erosion of navigation channel banks is caused primarily by vessel wakes. It is predicted that the deeper channel would result in slightly fewer vessel trips than the FWOP condition and thus not increase erosion.

FWP erosion of the Gulf shoreline is predicted to increase slightly over the FWOP condition. A deeper and longer entrance channel would have some effect on waves moving from the Gulf to the shore, and that would in turn exert an effect on the rate of longshore sediment transport (Gravens and King, 2003). It

is predicted that this would result in the loss of 18 acres of Gulf shoreline within 4 miles from the jetties over the period of analysis.

4.10.2.2.2 *FWP Interior Marsh Loss*

FWP impacts would be expected to result when increased FWP salinities interact with FWOP submergence to cause a marginally higher land loss rate, exacerbating the process already occurring in the FWOP condition. The EMCM was used to forecast FWP land loss; rates were adjusted using the productivity-based projection to include the effect of gradually rising FWOP salinities and the abrupt FWP incremental salinity increase in TY 15 (the year of project completion). See tables 4.1-3 and 4.1-4 for the FWP impacts to wetland acres by habitat type in Louisiana and Texas, respectively, before the application of benefits from BU features.

Table 2.4-16 provides a summary of the project impact analysis and net losses/benefits after application of the BU plan benefits. In Louisiana, the WVA model forecasts that 691 more wetland acres in Louisiana would be lost over the period of analysis in the FWP condition. The highest losses are projected to occur in intermediate marsh (78.5 percent), with 8.5 percent in fresh marsh, 11 percent in brackish marsh, and 2 percent in saline marshes. Wetland losses in Louisiana are fully compensated by marsh mitigation measures described in Section 5.0. In Texas, the overall net change in wetland acreage is positive due to the benefits of the Neches River BU Feature. There is a net gain of 2,606 acres of emergent marsh, 12 percent fresh, 42 percent intermediate, and 46 percent brackish marsh.

4.10.2.2.3 *FWP SAV*

SAV impacts would be similar to expected changes in the FWOP condition. The SAV community structure in the majority of intermediate marshes would likely change to include more salinity-tolerant species, such as widgeon grass, pondweed, Eurasian watermilfoil, and freshwater eelgrass (USGS, 1997). An increase in salinity would occur with dredging of the Sabine Pass and Sabine Pass Jetty channels. The HS model projects that the incremental salinity increase would average 1.3 ppt near the mouths of Sabine and Keith lakes, 0.8 ppt in the east Sabine Lake marshes, 0.7 ppt on the lower Neches and Sabine rivers, and less than 0.15 ppt on the upper Neches and Sabine rivers. Since salinity change is a function of the total dredging template, the time required to reach a new FWP equilibrium would likely be considerable, ranging from a conservative minimum of several months to even a year, because each wetland would be responding to salinity inputs from multiple sources (Gary Brown personal communication, 2009). The most rapid change (on the order of 2 to 3 months) would likely occur in marshes immediately adjacent and open to tidal exchange with the navigation channel that has just been dredged. Because of the salinity effect of the existing navigation channel, wetlands adjacent to the channel are likely to contain SAVs with greater salinity tolerances, and thus would be able to adapt to the FWP change more easily.

The Neches River BU Feature and the Louisiana mitigation measures would likely cause SAV impacts because of temporary but greatly increased turbidity associated with the hydraulic placement of dredged material for marsh restoration. It was assumed that construction would result in the die-off of SAVs in the vicinity of placement activities during the year of construction, followed by quick rebounds associated

with increased nutrient input, and the creation of shallow, protected ponds within the restored marsh. No seagrass would be affected by the Gulf Shore BU Feature, and no impacts to other types of submerged aquatic vegetation are expected from channel deepening. Seagrasses and other types of submerged aquatic vegetation are not found along the margins of SNWW channel because conditions conducive for SAV growth (i.e., calm waters and low turbidity) are not present.

4.10.2.2.4 *Adjustments for Land Gains from BU Features and Mitigation Measures*

Marsh restoration proposed as BU features or compensatory mitigation adds mineral soils to degraded areas of former marsh. The addition of denser mineral soils and the increase in marsh elevation were assumed to create a more stable landform, and the increase in the land loss rate due to the project was reduced by 50 percent in the WVA land loss change spreadsheets. Other mitigation measures that did not involve the creation of a higher, more-stable landform were modeled using a land loss rate equivalent to the FWP rate.

4.11 AQUATIC ECOLOGY

The following presents a discussion of potential impacts to freshwater and marine communities from the No-Action and Preferred alternatives. A description of each community type discussed below can be found in Section 3.10.

4.11.1 Freshwater

Freshwater fauna adapted to low-salinity environments are generally restricted to the upper reaches of the tributaries of Sabine Lake and their distribution depends on the extent of freshwater inflow into the estuary. Portions of the tidal reaches of the Neches (downstream of the saltwater barrier) and Sabine rivers generally support freshwater fishes. The Rose City Marsh and the upper reaches of Bessie Heights Marsh that are farthest from the study area are also freshwater ecosystems under normal conditions. Other predominantly freshwater streams that flow into Sabine Lake or the tidal reaches of the Neches and Sabine rivers include Taylor, Cow, Adams, and Little Cypress bayous in Texas, and Black and Johnson's bayous in Louisiana. Additional descriptions of the existing environment are provided in Section 3.10.

Sabine Lake was predominantly a freshwater-dominated ecosystem prior to early navigation improvements, subsidence, oil and gas exploration, and subsequent marsh erosion. Saltwater intrusion into the lake and its tributaries is largely responsible for the transformation of the lake into a euryhaline environment. While most of this change occurred in the early part of the twentieth century, the peripheral marshes and tributaries have continued to change as a result of saltwater intrusion, although at a much slower rate than before.

In particular, specific impacts to the freshwater ecosystems within the study area include the degradation of Bessie Heights, Rose City, and Old River Cove marshes through subsidence, intrusion of salt water, and vegetation loss, which have caused substantial conversion of freshwater marsh to open water. As the organic soils that support marsh vegetation erode because of saltwater intrusion, open-water areas expand

and exposure to salt water increases along the remaining marsh edge. This process further facilitates encroachment of salt water into the tributaries of these marsh areas. These processes also impact other freshwater marsh and tributary areas adjacent to Sabine Lake.

The Rose City Marsh presently consists of freshwater habitats. There is little or no information that describes the present state of this freshwater ecosystem or its recreational benefits. However, anecdotal information indicates that a viable freshwater community exists in the open water, channels, and tributaries of the Rose City Marsh. This area supports some recreational fishing to an unknown extent.

The movement of saline water into Bessie Height Marsh is generally greater than Rose City Marsh since it is farther downstream and has more hydraulic connections to the Neches Ship Channel. The diversity, distribution, and importance of freshwater fauna in this area are not well known but are likely spatially restricted as a result of saltwater intrusion. Species that occur in the open-water portions of Bessie Heights Marsh tend to be euryhaline.

Marshes at Old River Cove are exposed to higher salinities than all other marshes on the Neches River tidal because of their location where the Neches Ship Channel connects with the Sabine-Neches Ship Channel. Like Bessie Heights, the distribution and role of freshwater fauna in this area are not well known; however, intrusion of saline water probably restricts their diversity and distribution. Much of this area is managed by TPWD as the Old River Unit of the Neches River WMA. A 2,500-acre area of controlled, isolated wetlands covers the eastern half of the marsh. Intake and outfall canals for a large power plant draw higher-saline waters from Old River Cove and discharge them into the Neches Ship Channel just upstream of the Rainbow Bridge. Salinities west of the outfall canal tend to be lower because this area is buffered by the bank of the canal and receives lower salinity overland flow from the Bessie Heights area. Widgeon grass is abundant in shallow waters west of SH 87, but SAVs are not common east of the highway. Roadside ditches and the utility canals provide access to estuarine species.

4.11.1.1 No-Action Alternative

Two factors are likely to influence freshwater communities in the FWOP scenario. It is possible there would be a long-term reduction in freshwater inflow to the estuary since the human population of the state is expected to double during the life of the proposed project. The doubling of the population may increase demand for freshwater inflow, which may in turn result in lower freshwater inflows to the estuary. The second factor is relative sea level rise, which is predicted to continue. RSLR would gradually increase salinities in portions of the estuary. In the absence of the project and associated marsh restoration projects, the loss of freshwater marsh habitats would likely continue, in part due to continued RSLR, although RSLR is not expected to significantly change salinities in freshwater portions of the project area. Salinities would likely increase in tributaries to the estuary, causing continued conversion of fresh water to brackish marsh, in turn, favoring colonization by euryhaline species. These changes would occur slowly under most circumstances, although catastrophic changes associated with events like hurricanes might cause changes to occur more rapidly. There is considerable uncertainty regarding freshwater inflows to the estuary in the future.

4.11.1.2 Preferred Alternative

The Preferred Alternative includes the Neches River BU Feature, which is designed to restore the elevation in the Rose City, Bessie Heights, and Old River Cove marshes. The restoration efforts would likely impact short- and long-term, existing open-water communities. A significant portion of the open water of each marsh would be converted to shallow marsh with emergent vegetation. This habitat conversion should reduce intrusion of salt water into portions of those marshes.

Short-term impacts would be associated with marsh construction. Placement of dredged material might result in an initial increase in turbidity in the marsh and nearby tributaries. Increased turbidity might result in a short-term reduction in the distribution of SAV in the Rose City and Old River Cove marshes. The initial placement of dredged material would aid in reducing saltwater intrusion and would create more areas of quiescent water allowing SAV to repopulate the areas quickly after construction of the mitigation marshes.

Long-term impacts include the conversion of open-water habitat to marsh habitat. Some recreational benefits exist in the present open-water areas of the marshes. Under normal conditions, Rose City and Bessie Height marshes are essentially open-water, shallow, brackish to freshwater lakes. The marsh restoration would significantly reduce the amount of open-water area. Additionally, the freshwater ecosystem would be protected from future saltwater intrusion. Restoration efforts in this area would maintain channels, drainages, and some open water, which would greatly improve the complexity and diversity of marsh habitats and improve the ecological and recreational benefits of this marsh.

The upper reaches of the Neches and Sabine rivers and their tributaries in the study area support valuable freshwater habitats. Modeling of potential salinity intrusion into the Neches and Sabine rivers associated with the project indicated that mean salinities on the upper Neches River would remain near existing conditions over most of the study area. However, slightly higher salinities are expected in swamps and fresh marsh communities on or near the Sabine River near the GIWW and in the extensive fresh marsh north of the GIWW in Texas. These potential changes are expected to cause small reductions in the health and biological productivity of freshwater habitats. Increases in salinity are expected to cause additional stress on some fresh and intermediate marsh vegetation, over approximately 173,750 acres of fresh and intermediate marsh in Texas and Louisiana over the study area as a whole. No loss of swamp or bottomland hardwoods is projected. Reduced growth of some trees in the cypress-tupelo swamps, particularly near the Sabine River, is expected as a result of the slight increase in salinity from the project. The loss of freshwater habitat would be expected to increase access to mineral-rich sediments and organic nutrients in the short term for estuarine fauna, leading to a temporary increase in productivity. But the increased productivity would decline as the freshwater habitats disappear, eventually leading to some reduction in freshwater fauna productivity (Minello and Rozas, 2002). The Neches River BU Feature is intended to create 4,958 acres of restored emergent marsh, improved shallow-water habitat, and nourished existing marsh in Rose City East, Bessie Heights East, and Old River Cove. The Neches River BU Feature is also intended to offset the direct loss of 86 acres of freshwater wetland used for the creation of

PA 24A. Once the project, including the DMMP BU features and compensatory mitigation, leads to an overall net gain in marsh habitat, no detrimental impacts to fauna are anticipated.

4.11.2 Marine

4.11.2.1 Estuarine Habitats and Fauna

4.11.2.1.1 *No-Action Alternative*

Under the No-Action Alternative, estuarine habitats and fauna would continue as described in subsection 3.10.2.1. However, it should be noted that the No-Action Alternative does not imply that there would be no dredging or placement activities. Maintenance dredging will continue as it has in the past.

4.11.2.1.2 *Preferred Alternative*

Due to the reproductive capacity and natural variation in phytoplankton populations, short-term, localized increases in turbidity associated with dredging within the project area are not expected to be significant (Brannon et al., 1978; May, 1973; Odum and Wilson, 1962). Under most conditions, fish and other motile organisms are only exposed to localized suspended-sediment plumes for short durations (minutes to hours) (Clarke and Wilber, 2000). Should marsh communities benefit from the Preferred Alternative, finfish and shellfish would also benefit. The potential for the deepening to cause widening at the top of cut as the side slopes adjust to the new project depth has been evaluated. The present 40-foot channel has been in existence since the early 1970s and has had adequate time for the dense clay sediments to stabilize. Deepening will be performed by making a box cut in the bottom of the existing channel. Some slumping of the side slope at the base of the channel may occur as the deeper channel stabilizes, but no slumping is expected at the top of cut. Therefore, no impacts to oyster reef located adjacent to the top of cut in Sabine Pass are expected. No emergent marsh or shallow bottom is present adjacent to the top of cut.

There are one-time effects of the borrow trench and access channel in Sabine Lake and dredging of accumulated sediments in the Lake Charles Deepwater Channel. The Preferred Alternative would impact approximately 275 acres (225 acres for the borrow trench and 50 acres for the access channel) of lake bottom within Sabine Lake, a designated Louisiana Public Oyster Area. Dedicated dredging of Sabine Lake would be performed to supply sediment needed to restore 687 acres of emergent marsh, improve 167 acres of shallow water, and nourish 1,112 acres of existing marsh within the 1,966 total acres in Willow Bayou Mitigation Areas LA 2-18B and LA 2-ADD B. Approximately 3.1 mcy of material would be dredged from a 1.8-mile-long trench in Sabine Lake, located at least 1,000 feet from the Sabine NWR shore, averaging 1,030 feet wide by 7.5 feet deep. The borrow trench would be continuous and parallel the current shoreline; the common longshore circulation pattern in Sabine Lake is expected to eventually fill the trench with Sabine River sediments. An access channel, approximately 8 miles long, from the GIWW near the mouth of the Sabine River would be needed for the dredge to reach the proposed borrow trench area. The exact locations of the borrow trench and access channel would be determined in consultation with the ICT after PED bottom surveys of potential locations. Also, accumulated material

would be dredged from the 30-foot Lake Charles Deepwater Channel, which is co-located with the GIWW in Louisiana (13 miles long by 125 feet wide beginning just past Pavel Island Channel and extending eastward, removing approximately 15 feet of accumulated sediment). The Lake Charles Deepwater Channel was completed in 1926 (USACE, 1998c) and the last known dredging occurred in 1940. Material would be hydraulically dredged and placed in Black Bayou Mitigation Areas LA 3-15B and 3-18B. The mitigation measure at West Black Bayou (LA 3-10R) would be constructed using maintenance material from the Sabine River Channel to Orange over a 30-year period. The Sabine River Channel dredging is a FWOP impact because it occurs as part of the normal maintenance dredging practices for the Sabine River Channel.

One-time impacts of the borrow trench and access channel dredging in Sabine Lake for the mitigation measures in Willow Bayou include an increase in water column turbidity during dredging activities; however, such effects are temporary and local. No further effects to water quality are expected. Benthic fauna would be removed due to evacuation of sediment during dredging activities; however, benthic organisms can rapidly recolonize, and no long-term effects are anticipated. Details of potential impacts from borrow trench dredging to benthos, salinity, SAV, oysters, and water quality are found in subsections 5.5.1 (Willow Bayou Mitigation) and 5.5.2 (Black Bayou Mitigation).

The potential for the removal of sediments from Sabine Lake for marsh mitigation to affect oyster reef has been evaluated. An oyster assessment was performed in 2006 (T. Baker Smith, Inc., 2006) near the area of the proposed Sabine Lake access channel and borrow trench in conjunction with an unrelated Department of Army permit application. Bottom types were found to consist of 90 percent firm mud and buried shell, 8 percent soft mud, and 0.7 percent exposed shell/reef. No live oyster reefs were found. Similar bottom types are expected in the area of the proposed access channel and borrow trench, which are located directly east of the surveyed area. Optimal salinities for oyster growth are from 10 to 15 ppt (Armstrong et al., 1987). Salinities in this area of Sabine Lake range from 1 to 6 ppt year-round, too fresh for oyster development (Fagerburg, 2003). During construction of the access channel and borrow trench, no impacts to extant live oyster reefs are likely. Nonetheless, prior to project implementation, a full water bottom assessment would be conducted by the USACE in accordance with the LDWF survey standards. This survey would be necessary in order for the LDWF to consider a waiver of compensation for impacts to the water bottoms of the Sabine Lake Public Oyster Area.

With the deepening of the channel, a small increase in salinity would be observed (see Section 4.6). Most organisms occupying these environments are ubiquitous along the Texas and Louisiana coast and can tolerate a wide range of salinities (Parker, 1965; Pattillo et al., 1997). Therefore, no adverse effects on fauna are expected due to changes in salinity that may result from the Preferred Alternative, except loss of habitat due to salinity impacts on marshes. Small increases in salinity under median-flow conditions would affect all tidally influenced brackish and saline marshes in the SNWW study area (approximately 37,000 acres). As discussed in Section 4.6, these potential changes are expected to cause small reductions in the health and biological productivity of these habitats. Increases in salinity are expected to cause additional stress on some marsh vegetation. However, since the project, including the DMMP BU features

and compensatory mitigation, leads to an overall net gain in marsh habitat, no detrimental impacts to fauna are anticipated.

There is little difference in the likelihood of oil spills with the No-Action or Preferred Alternative except that inclusion of bend easings should make channel transits safer. In the unlikely event a petroleum product spill should occur, however low the probability, adult crustaceans such as shrimp and crabs and adult finfish are probably mobile enough to avoid most areas of high oil concentrations. Larval and juvenile finfish and shellfish tend to be more susceptible to oil than adults and could be affected extensively by an oil spill during their active immigration periods. Due to their lack of mobility, they are less likely to be able to avoid these areas and could be negatively impacted if a spill were to occur. Benthic fauna may be killed, but phytoplankton may be adversely or favorably affected by oil spills. It is unlikely that an oil spill in the project area would result in significant, long-term impacts to either phytoplankton or benthic communities, since these organisms have the ability to recover rapidly from a spill due primarily to their rapid rate of reproduction and to the widespread distribution of dominant species.

4.11.2.2 Offshore Habitats and Fauna

4.11.2.2.1 No-Action Alternative

Under the No-Action Alternative, Gulf habitats and fauna would continue as described in subsection 3.10.2.2 with maintenance dredging and placement of dredged material in four designated ODMDS sites.

4.11.2.2.2 Preferred Alternative

Construction excavation removes benthic organisms from their habitat and sends them through the dredge into the hopper. Most cannot be expected to survive placement in the adjacent ODMDS. However, the benthic community can rapidly recolonize, both on the channel bottom and in open-water PAs. Since the benthic community occupying the channel bottom is continually disturbed by passing ships, maintenance dredging, while it may kill the organisms dredged, is not expected to change the community living there after recolonization.

Construction of the Extension Channel would physically disturb benthic communities in the proposed channel prism. Impacts to benthic organisms during maintenance dredging are expected to be minor. While there is some recolonization between cycles, sediments in the channel are continuously disturbed by passing ships. Placement of dredged material in the offshore placement site would bury those benthic organisms incapable of escaping or burrowing up through the dredged material. Organisms that are buried must vertically migrate or die (Maurer et al., 1986). Maurer et al. (1986) demonstrated that many benthic organisms were able to migrate vertically through 35 inches of dredged material under certain conditions; however, the species present in early successional stages of recovery are not the same as those buried by the dredged material. Although vertical migration is possible, most organisms at the center of the disturbance do not survive, but survivability was shown to increase as distance from the disturbance increased (Maurer et al., 1986). Benthic organisms would not long survive placement into upland PAs.

Potential beneficial effects of the suspended material associated with dredging operations include a resuspension of nutrients, absorption of contaminants in the water column, and addition of a protective cover allowing certain nekton to avoid predation (Stern and Stickle, 1978). As with the various detrimental effects, the importance of each of these latter effects would vary among groups and with the physiochemical parameters existing at the time and location of dredging and placement operations. Material to be dredged is not contaminated and should not pose contamination issues with respect to aquatic communities. Impacts in the new ODMDSs would be the same as those in the existing ODMDSs and are not expected to be significant.

4.11.2.3 Essential Fish Habitat

4.11.2.3.1 No-Action Alternative

Under the No-Action Alternative, EFH would continue as described in subsection 3.10.2.3 with periodic maintenance dredging and dredged material placement for the existing channel.

4.11.2.3.2 Preferred Alternative

EFH for adult and juvenile brown and white shrimp, red drum, gag grouper, scamp, red, gray, and lane snapper, greater amberjack, king and Spanish mackerel, cobia, and Gulf stone crab occur in the SNWW study area and may include estuarine emergent wetlands, estuarine mud, sand, and sand and shell substrates, SAV, estuarine and offshore water column. Shell substrate in the project area would be dredged with the Preferred Alternative. Open-bay bottom habitat would be impacted by the Preferred Alternative relative to the No-Action Alternative. In addition, Sabine Lake and the GIWW/Lake Charles Deepwater Channel would be impacted in one-time contracts to remove sediment for Willow and Black bayous mitigation measures, causing temporary increases in water column turbidity and removal of benthic fauna.

Initial placement operations would cover benthic organisms with dredged material in the ODMDS sites. Recovery of some benthic organisms would likely occur relatively quickly, although the assemblage in the dredged material might differ from the assemblage that existed at the PA prior to construction. Sheridan (1999) found that recovery of the benthic community would continue for at least 18 months for some parameters and beyond 3 years for others.

With the Preferred Alternative, increased water column turbidity during dredging would be localized and temporary. Teeter et al. (2003) found that the area of high turbidity extended roughly to the edge of the fluid mud flow, or about 1,300 to 1,650 feet from the discharge pipe. Modeling of dredged material discharge in the Laguna Madre determined that turbidity caused by dredging only lasts on the order of weeks to a few months, and therefore impacts to the estuarine and offshore water column would be minimal (Teeter et al., 2003). Material to be dredged is not contaminated and should not pose contamination issues with respect to EFH. Accidental spills have the potential to impact EFH, and larval and juvenile finfish could be affected significantly should a spill occur. Larval and juvenile finfish tend to be more susceptible to spills than adults and could be affected extensively by a spill during their active

immigration periods. Due to their lack of mobility, they are less likely to be able to avoid these areas and could be negatively impacted if a spill were to occur; however, there would be no increase in spill chances because of the larger channel and the fewer vessel trips that are predicted with the Preferred Alternative versus the No-Action Alternative.

The Preferred Alternative would temporarily and locally impact EFH species by turbidity; however, these impacts would be minimal since these species are motile enough to avoid areas of high turbidity. Benthos, as a food source, would be lost at the ODMDS sites until recovery occurs; however, these areas are small relative to the benthic habitat near Sabine Pass and any impacts would be negligible. Restored marsh and improved shallow-water habitat in the proposed mitigation and Neches River BU Feature total 13,053 acres of EFH creation, with 43 percent (5,636 acres) being emergent marsh. Approximately 1,828 acres of open water would be improved as EFH habitat by creating smaller, shallow-water pools and channels in which fetch and turbidity are reduced. In addition, another 5,589 acres of existing marsh within the influence areas targeted for mitigation measures and BU would be nourished by the winnowing of fine-grained sediments during unconfined placement of the dredged material.

The DEIS initiated EFH consultation under the MSFCMA. NMFS provided concurrence with the findings on March 8, 2010 (Appendix A3).

4.11.2.4 Ballast Water

4.11.2.4.1 No-Action Alternative

Under the No-Action Alternative, ship traffic in the SNWW would increase at rates predicted by the economic analysis.

4.11.2.4.2 Preferred Alternative

Although ship traffic would increase with the Preferred Alternative, the FWP increase would be less than the predicted growth of ship traffic under the No-Action Alternative, and therefore no additional impacts with respect to ballast water are expected. The economic analysis has determined that the maximum size of vessels using the deepened channel is not expected to increase; rather, vessels would be loaded to deeper drafts to take advantage of the increased depth. Therefore, an increase in the volume of ballast water is not expected. Furthermore, no changes in foreign ports of call are predicted.

4.11.2.5 Recreational and Commercial Fisheries

4.11.2.5.1 No-Action Alternative

Under the No-Action Alternative, recreational and commercial fisheries would continue as described in subsection 3.10.2.4. Additional discussion of impacts associated with normal maintenance dredging activities is discussed in subsection 4.11.2.5.2.

4.11.2.5.2 Preferred Alternative

Temporary and minor adverse effects from the proposed project and mitigation measures on recreational and commercial fisheries may result from altering or removing productive fishing grounds and interfering with fishing activity. Sheridan (1999) found that sheepshead, spotted seatrout, brown shrimp, pink shrimp (*Litopenaeus duorarum*), white shrimp, and blue crab numbers increased as SAV coverage improved following dredging, with few species collected at the site of the disturbance. Only spot (*Leiostomus xanthurus*), Atlantic croaker, and southern flounder were somewhat more numerous at the dredged material PA. However, the evaluation of effects on the estuarine habitats and fauna and Gulf habitats and fauna of the region (sections 4.10 and 4.12) concluded that no significant impacts to food sources for nekton were likely. Therefore, reductions of nekton standing crops would not be expected from the No-Action or Preferred Alternative. In particular, major species of nekton, including sciaenid fishes and penaeid shrimp, should not suffer any significant losses in standing crop. Recreational and commercial fishing would therefore not be expected to suffer from reductions in the numbers of important species from the Preferred Alternative.

Repeated dredging and placement operations may temporarily reduce the quality of recreational and commercial fisheries in the vicinity of dredging operations. This may result from decreased water quality and increased turbidity during project dredging and mitigation measures, as well as from a loss of attractiveness to game fishing resulting from loss of benthic prey. This condition is not permanent, and the quality of fishing in the vicinity of the channel and PAs should steadily improve after dredging is completed and would likely be similar to existing maintenance dredging, as under the No-Action Alternative. During project dredging and mitigation measures, game fish would leave prime recreational fishing areas for more-favorable, less-turbid locations; however, once dredging is completed, conditions would improve and game fish would return to the area. The additional habitat created by construction in the BU sites should provide additional recreational fishing opportunities. Construction activity in this portion of the channel should not significantly affect overall fishing in the general project area.

The impacts from the Preferred Alternative to both boat and wade-bank fishing would be temporary, potentially resulting in local disturbances, particularly along the edges of the channels. After dredging is completed, these areas should return to predredging conditions. A significant portion of the overall recreational fishing effort in the project area occurs in Sabine Lake and offshore; however, project dredging activities and mitigation measures should not significantly affect overall fishing.

Commercial fishing for shellfish (specifically blue crab) in Sabine Lake is very important; however, no significant long-term impacts are expected for the No-Action or Preferred Alternative.

4.12 WILDLIFE

4.12.1 No-Action Alternative

Existing dredging activities and placement of dredged material could result in sedimentation and altered hydrology, which could have a temporary, short-term, and localized impact on some species. On larger

temporal scales, the No-Action Alternative would result in no immediate direct impacts to the terrestrial wildlife species or wildlife habitats at or near the proposed study area. However, the combined effects of subsidence, saltwater intrusion, and wetland loss from sea level rise would convert estuarine and coastal habitats and their wildlife communities. These habitat changes are likely to be exacerbated by the effects of global climate change. In the absence of the project and associated marsh restoration projects, the loss of freshwater marsh habitats would likely continue due to RSLR. Salinities would likely increase in estuary tributaries, causing continued conversion of freshwater to brackish marsh, in turn favoring colonization by euryhaline species. Last, a long-term reduction in freshwater inflow to the estuary (since the human population of the state is expected to double during the life of the proposed project) could also result in coastal and estuarine habitat conversion.

4.12.2 Preferred Alternative

4.12.2.1 Dredging/Construction Activities

Direct effects of the proposed project are those associated with navigation channel improvements, and the placement of dredged material. They include (1) impacts to benthic organisms and their Gulf, estuarine, and riverine water-bottom habitats resulting from dredging to construct navigation improvements, ODMDSs, borrow areas for mitigation measures, and marsh restoration in shallow, open-water areas for BU features and mitigation measures; (2) dredging impacts to bottom-feeding and pelagic organisms such as sea turtles; (3) impacts to marshes and upland habitats from the enlargement of PAs; and (4) impacts to shorebirds and their habitat from the regular placement of maintenance material on the Gulf shoreline.

While dredging activities from the proposed project are unlikely to have a direct impact on terrestrial wildlife species, they may have an indirect impact. Such activities may cause temporary, local impacts to aquatic communities and habitats, including increased turbidity, which in turn may indirectly affect birds in the immediate vicinity by potentially reducing the availability of the food supply. These impacts are local and temporary and are not likely to be significant considering the overall availability of similar habitats in the general area and the mobility of the birds. The slightly increased possibility of accidental spills of oil, chemicals, or other hazardous materials during construction dredging activities also poses a threat to the aquatic community and, thus, the food source of many coastal birds in the area. Accidental spills could adversely affect phytoplankton and zooplankton assemblages, which make up the foundation of the aquatic food chain. While adult shrimp, crabs, and fish are mobile enough to avoid areas of high concentrations of pollutants, larval and juvenile finfish and shellfish are more susceptible to those threats. Any effects would be short term.

The noise of equipment and increased human activity during dredging activities may disturb some local wildlife, particularly birds, especially during the breeding season. Such impacts, however, should be temporary and without significant long-term implications. Salinity effects are unlikely, and most infaunal organisms in the area are relatively tolerant of salinity fluctuations.

Dredging activities for the channel improvement would occur adjacent to many of the rookeries noted in subsection 3.11.2; however, it is unlikely that dredging activities would result in impacts to these

rookeries since no placement would occur in the rookeries and the birds are accustomed to the noise of maintenance dredging.

Dredged material would be used beneficially for marsh creation in the Neches River BU Feature and for shore nourishment in the Gulf Shore BU Feature. Mitigation measures include marsh restoration in the Willow Bayou hydro-unit and in the Black Bayou hydro-unit. In addition, 16 existing and 2 new upland PAs would be used for construction and maintenance of the 48-foot project.

Placement of dredged material at these sites would have similar impacts to the dredging activities in that they would be unlikely to result in direct effects on terrestrial wildlife species but may have indirect effects. Temporary impacts to aquatic communities and habitat from increased sedimentation and turbidity would be expected. This in turn may affect birds and amphibians in the area by potentially reducing the availability of their local food supply temporarily. The impacts may be more noticeable if the sites are located near known bird rookeries. Noise and increased human activities during construction may temporarily affect terrestrial wildlife in areas adjacent to the restoration sites. Construction activities during the placement of material on the beach may temporarily preclude its use by wildlife; however, the duration of the activity would be temporary and the size of the construction area would not be large enough to cause any significant loss of habitat. These impacts would likely be minor and short term. The resultant additional marsh and beach restoration would provide additional habitat for wildlife in the area. Therefore, the proposed activity would not have adverse effects on terrestrial wildlife.

4.12.2.2 Operational Activities

Upon completion of the initial dredging activities associated with the project, few impacts are likely. Maintenance dredging activities would have similar temporary impacts as the initial dredging, but on a much smaller scale and for a shorter term. The number of vessels in the area would not increase or decrease; therefore, the potential for erosion of PAs would not change. The possibility of accidental oil or chemical spills would decrease because of safer navigability. Such spills pose a threat to the aquatic community and, thus, the food source of many coastal birds in the area. Impacts from noise and human activity are unlikely to be a factor.

Construction activities during the placement of dredged material at marsh creation sites and on beaches may temporarily preclude its use by wildlife; however, the duration of the activity would be temporary and the size of the construction area would not be large enough to cause any significant loss of habitat. The resultant additional marsh and beach restoration would provide additional terrestrial habitat for wildlife in the area. Therefore, the proposed activity would not have adverse effects on terrestrial wildlife.

4.13 THREATENED AND ENDANGERED SPECIES

A BA for this project has been prepared to fulfill the USACE requirements as outlined under Section 7(c) of the ESA of 1973, as amended, and is included in Appendix G1. The USACE is consulting with the NMFS and USFWS as required by Section 7(a)(2). NMFS issued a Biological Opinion (BO) on a previous similar project alternative. That opinion found that the proposed action was not likely to

jeopardize the continued existence of any endangered or threatened species or result in the destruction or adverse modification of critical habitat of such species (Appendix G2). While the project alternative changed, project-related impacts remained the same, and therefore the BO conclusion would remain the same.

4.13.1 No-Action Alternative

The No-Action Alternative would result in no immediate direct impacts to any endangered wildlife species or endangered species habitat at or near the proposed study area. The potential impacts to endangered sea turtles from maintenance dredging are covered by the BO for the USACE's maintenance dredging activities in the Gulf (NOAA, 2003), and therefore are not addressed in this FEIS.

4.13.2 Preferred Alternative

4.13.2.1 Dredging/Construction Activities

No federally or State-listed plant species are of potential occurrence in Jefferson or Orange counties, Texas, or Cameron or Calcasieu parishes, Louisiana (NDD, 2005a, 2005b, TPWD, 2010; USFWS, 2005c, 2009). Thus, the proposed project would not result in impacts to any threatened or endangered plant species.

The proposed project is unlikely to affect any threatened or endangered terrestrial species. Many are inland species that are not likely to occur in the affected areas, while others are migrants that pass through the region seasonally. Federally listed species likely occurring in the study area at some time of the year include the piping plover. Several threatened and endangered sea turtle species, of potential occurrence in study area waters, could be affected by project construction and maintenance activities. Potential impacts to threatened and endangered terrestrial and marine species have been assessed by the USACE in a BA presented in Appendix G1 of this FEIS.

Dredging activities, which would occur in open water, would not directly affect the wintering piping plover. The greatest potential for impacts to the wintering piping plover would be associated with the placement of dredged materials for shoreline nourishment activities in areas of suitable habitat (the Gulf Shore BU Feature). The USFWS has designated the entire shoreline between Constance Beach and Sabine Pass (Unit LA 1, in part) as critical habitat for the piping plover. Proposed beach nourishment activities at Louisiana Point would occur along approximately 3 miles of this unit, beginning approximately 0.5 mile east of Sabine Pass. Details of the Gulf Shore BU Feature beach nourishment activities are included in Section 4.2 of the BA (Appendix G1). A survey of both the Texas and Louisiana shore nourishment sites was conducted in July 2006 (see Attachment A to the BA). No habitat was found on the Texas side; the current shoreline within the proposed nourishment zone in Texas is an eroding marsh and contains no beach. In Louisiana, several areas suitable for piping plovers were identified. Large tidal sand/mudflats and sandbars located just offshore of Louisiana Point appeared to provide wintering piping plover feeding habitat. In addition, sandy beaches beginning 2 miles from the east jetty contain tidal flats with sparse vegetation suitable for feeding and roosting habitat. Placement of dredged

materials (i.e., Gulf shoreline nourishment) at Texas Point and Louisiana Point would not adversely affect piping plovers or designated Critical Habitat for the wintering piping plover. These impacts of placement activities would be temporary and local in nature. Some birds could be temporarily displaced, but there is sufficient habitat nearby to accommodate them. In general, the BU feature should result in positive effects on the piping plover by increasing the extent of suitable habitat in the study area. On the Louisiana side, where some Critical Habitat exists, additional beach may allow siltation to create some microtopographic relief on the backbeach, providing another primary constituent element for the Critical Habitat. Based on the facts listed above, the proposed project may affect but is not likely to adversely affect the piping plover or its Critical Habitat.

Loggerhead, Kemp's ridley, hawksbill, leatherback, and green sea turtles may be present in study area waters during certain times of the year. Thus, construction and postconstruction maintenance activities could result in impacts to the sea turtles, should they be present in the project area. A pipeline dredge would be used in those reaches of the SNWW inland of the Jetty Channel, and a hopper dredge would be used in the Sabine Pass Jetty Channel, the Sabine Pass Outer Bar Channel, the Sabine Bank Channel, and the Extension Channel. Sea turtles easily avoid pipeline dredges because of the slow movement of the dredge. The potential for incidental take of sea turtles by hopper dredges would be minimized by the use of draghead deflectors. Since new work dredging would require continuous hopper dredging for approximately 6 years, a winter dredging window for construction cannot be accommodated. Maintenance dredging has been conducted during all seasons between 1996 and 2005. Relocation trawling has been used since 2002, when maintenance dredging in the Sabine Bank Channel resulted in the lethal take of two sea turtles (Rob Hauch, pers. communication, 2006). In 2006, maintenance dredging in the Sabine Bank Channel resulted in the lethal take of one Kemp's ridley sea turtle (USACE, 2006c). Apart from direct mortality, dredging activities could have an impact on sea turtles through an increase in sedimentation and turbidity. There have been no reports of sea turtles nesting in the study area. Feeding opportunities within the proposed channel could attract sea turtles, where they might be exposed to additional risks from boat traffic, contaminants, fishing activities, tangled fishing lines, and accumulated plastic detritus, but that is true at the existing channel.

The effects on sea turtles of placing dredged material at the proposed ODMSs include (1) a collision potential from the vessel; (2) the deposition of dredged material on turtles and forage areas; and (3) the possibility of trash and debris from the dredge operation. Regarding the deposition of dredged material, modeling indicates that most of the dredged material is confined to a relatively small area. Because this is a short-term effect, and considering the mobility of the turtle species and the lack of limestone ledges in the proposed ODMSs, the sea turtles should easily be able to avoid a descending plume and available food sources should not be seriously reduced (NMFS, 2003). Regarding the vessel and debris possibility, it is the combined effect of many marine activities (e.g., oil spills, oil and gas operations, commercial fishing, marine transportation, etc.) that constitute the hazard and not a single activity such as a dredge operation. These activities, combined with natural predation and development on land, result in a cumulative adverse effect on sea turtles (Rosman, 1987). The Outer Bar Channel would be deepened at the existing width of 800 feet, and the width would quickly taper to 700 feet in the Sabine Bank Channel.

The dredging operation in the existing offshore channels is similar to, but of longer duration than, routine maintenance dredging. The Entrance Channel Extension would begin 18 miles offshore where sea turtles should be more dispersed than nearer the jetties. Only three lethal takes have been observed during maintenance dredging between 1996 and 2006, a period that entailed water temperatures ranging from 49.0 to 89.6°F. Based on the facts listed above, the proposed project may affect and is likely to adversely affect sea turtles. No critical habitat for sea turtles is present within the study area; therefore, the project is unlikely to adversely affect critical habitat.

4.13.2.2 Operational Activities

Upon completion of the initial dredging activities associated with the project, few impacts to endangered species or critical habitats are likely. Maintenance dredging activities would have similar temporary impacts as the initial dredging for recurring but shorter terms. The probability of accidental oil or chemical spills would decrease because there would be fewer vessel trips. Such spills pose a threat to the aquatic community and, thus, the food source for the piping plover. Impacts from noise and human activity are unlikely to be a factor. Maintenance dredging activities for the proposed project are covered by an existing agreement between the NMFS and USACE regarding the taking of sea turtles with hopper dredges, to ensure that significant impacts do not occur (NOAA, 2003).

4.13.2.3 USFWS Coordination and NMFS Biological Opinion

4.13.2.3.1 Piping Plover, Brown Pelican, and Bald Eagle

Placement of dredged materials (i.e., Gulf shoreline nourishment) at Texas Point and Louisiana Point would not adversely affect wintering populations of piping plovers or designated Critical Habitat for the piping plover. These activities should result in positive effects on the piping plover by increasing the extent of suitable habitat in the study area. On the Louisiana side, where Critical Habitat is designated, additional beach may allow siltation to create some microtopographic relief on the backbeach, providing another primary constituent element of the piping plover Critical Habitat. Based on the information listed above and presented in detail in the BA (Appendix G1), the Preferred Alternative is not likely to adversely affect the piping plover or its Critical Habitat.

The current Preferred Alternative eliminates proposed widening from the Sabine Pass Jetty Channel through the Port Arthur Canal, removes proposed beneficial use of dredged material at Bessie Heights West, and modifies the size and configuration of the Rose City BU feature. However, all other project features remain the same, and effects to threatened and endangered species and Critical Habitat have not changed. The USFWS, in letters dated March 20 and March 22, 2007 (Appendix A2), concurred that the deepening and widening 48-foot alternative was not likely to adversely affect the piping plover or its Critical Habitat. The USFWS Louisiana Field Office stated that no further ESA consultation would be required with its office unless changes are made to the scope or location of the project. Changes to the Preferred Alternative have not affected project impacts; therefore, no change is anticipated to the USFWS's "no effect" determination. The USFWS Clear Lake Field Office letter was silent on the need for further consultation. However, the USACE staff confirmed by telephone that no further ESA

consultation would be required unless changes are made to the scope or location of the project. The Clear Lake Field Office did recommend that steps be taken to determine whether bald eagles are nesting within or near the project area since the number of bald eagles in Texas is increasing. Prior to project construction, the USACE will check with the TPWD and local landowners to determine whether there have been recent bald eagle sightings and determine the need for surveys at that time.

The USFWS provided further guidance in a letter dated February 5, 2010, and recommended that all activity in Louisiana occurring within 2,000 feet of a brown pelican rookery be restricted to the non-nesting period (i.e., September 15 through March 31). However, because nesting periods vary considerably among Louisiana's colonies, it is possible that this activity window could be altered based upon the dynamics of the individual colony. Prior to project construction, the LDWF Fur and Refuge Division will be contacted to obtain the most current information about the nesting chronology of individual brown pelican colonies. In Texas, the USFWS recommended all activity occurring within 1,000 feet of a rookery be restricted to the non-nesting season.

4.13.2.3.2 *Sea Turtles*

Based on the facts listed above and presented in detail in the BA (Appendix G1), the Preferred Alternative may affect and is likely to adversely affect sea turtles. No Critical Habitat for sea turtles is present within the study area; therefore, the Preferred Alternative would not affect sea turtle Critical Habitat.

A BO, prepared by the NMFS for the previous 48-foot deepening and widening alternative, is presented in Appendix G2. The BO (dated August 13, 2007) concluded that the action, as proposed, was likely to adversely affect but is not likely to jeopardize the continued existence of loggerhead, Kemp's ridley, hawksbill, leatherback, or green sea turtles. The effects of the current Preferred Alternative on sea turtles are the same as those previously coordinated, and it is not anticipated that this determination would change. Although some short-term reduction in numbers and reproduction is expected, the anticipated take of sea turtles would not appreciably increase the risk of extinction of these species in the wild. The BO authorizes incidental lethal take of four turtles (three Kemp's ridley and one loggerhead or green sea turtle) during the course of the proposed project's hopper dredging. This estimate is based on the implementation of relocation trawling to prevent additional lethal takes by hopper dredges. Further, this opinion authorizes the per-fiscal-year non-lethal, non-injurious take (minor skin abrasions resulting from trawl capture are considered non-injurious), external flipper-tagging, and taking of tissue samples of 32 sea turtles in any combination, though 7 loggerhead, 21 Kemp's ridley, 1 hawksbill, 1 leatherback, and 2 green sea turtles would be expected in association with any relocation trawling conducted during the course of the proposed project.

NMFS determined that the following reasonable and prudent measures are necessary and appropriate to minimize impacts of the incidental take of sea turtles during the proposed action. Only incidental takes that occur while the following measures are in full implementation are authorized. For brevity, the reasonable and prudent measures are only summarized below. The reader is referred to the BO in Appendix G of this FEIS for the detailed measures, terms, and conditions.

Reasonable and Prudent Measures:**1. Temperature- and date-based dredging windows:**

- Hopper dredging activities shall be completed, whenever possible, between December 1 and March 31, when sea turtle abundance is lowest throughout Gulf coastal waters.
- Pipeline or hydraulic dredges, because they are not known to take turtles, must be used whenever possible between April 1 and November 30.

2. Observer Requirements: The USACE shall arrange for the NMFS-approved protected species observers to be aboard the hopper dredges to provide 100 percent monitoring of the hopper bin, screening, and dragheads for sea turtles and their remains between April 1 and November 30, and whenever surface temperature are 52°F or below.**3. Deflector Dragheads:** A state-of-the-art rigid deflector draghead must be used on all hopper dredges at all times.**4. Relocation Trawling:** Relocation trawling is required after the take of one sea turtle during the project. In general, it is also recommended as a useful conservation tool. The BO authorizes the per-fiscal-year nonlethal noninjurious take, external flipper-tagging, and taking of tissue samples of 32 sea turtles in any combination, though anticipates 7 loggerhead, 21 Kemp's ridley, 1 hawksbill, 1 leatherback, and 2 green sea turtles in association with any relocation trawling conducted during hopper dredging.**4.14 CULTURAL RESOURCES****4.14.1 No-Action Alternative**

Under the No-Action Alternative, archeological sites around the margins of eroding marsh areas would increasingly be exposed to the erosive effects of wind, tidal action, and RSLR as marshes convert to water, increasing fetch and erosive potential. Archeological sites along the SNWW navigation channel would continue to be exposed to the erosive forces of boat wakes; this would increase in the future as vessel trips rise to support projected imports under the current lightering requirements. Maintenance dredging of the SNWW would continue, with the potential to affect unidentified shipwrecks in or alongside the existing channel.

4.14.2 Preferred Alternative

The proposed CIP would not affect the two properties listed in the NRHP that are located near the project area (the Sabine Pass Lighthouse and the Rainbow Bridge) or the SAL, the USS *Clifton*, nor would it affect the submerged, offshore Sabine River Valley. Although the existing channel and ODMDs cross the center of the submerged valley, the footprint of the deeper channel and existing ODMDs would not be enlarged. The channel extension and new ODMDs are located south of the valley. The Sabine Pass Lighthouse, which is listed in the NRHP, is located in an area that would not be affected by channel improvements to the SNWW. Use of the nearby PA 5 would not limit or remove access to the lighthouse.

All areas that would be impacted by the SNWW CIP have not been assessed for their potential to contain properties eligible for the NRHP in accordance with the National Historic Preservation Act (NHPA). Therefore, the SNWW CIP has the potential to adversely affect eligible historic properties. The USACE has negotiated a Historic Properties Programmatic Agreement (HPPA) under 36 CFR 800.14(b) to govern subsequent investigations, to coordinate surveys of impact areas, to test potentially eligible sites (Table 4.14-1), and to manage data recovery or avoidance measures as necessary. A copy of the signed HPPA is provided in Appendix H of this FEIS.

Table 4.14-1
Terrestrial and Marine Historic Properties Potentially Adversely Affected
by the SNWW CIP

Resource	Location	Eligibility
Marine		
TB8.1	Neches River Channel	Potentially Eligible

IS2.1	Port Arthur Canal	Potentially Eligible
IS2.14s	Port Arthur Canal	Potentially Eligible
Terrestrial		
41JF29	Neches River	Potentially Eligible
41JF43	Neches River	Potentially Eligible
41OR10	Neches River	Potentially Eligible
41OR11	Neches River	Potentially Eligible
16CM26	Near LA 2-19B Mitigation Area	Potentially Eligible
16CM86	Within LA 3-10R Mitigation Area	Potentially Eligible
16CM103	Near LA 2-18B Mitigation Area	Potentially Eligible

Additional investigations are anticipated at this time, including survey of the proposed channel extension, areas affected by construction of the DMMP BU features, and areas affected by the construction of mitigation measures. No surveys are recommended for new or existing ODMDs as placement activities are not expected to adversely impact unrecorded wrecks that may be present, given the depth of water through which the material would settle, the expected depth of burial at the time of placement, and the dispersive nature of the seabed environment in this portion of the Gulf. Impacts to archeological sites in and around the margins of degraded marsh areas proposed as DMMP BU features or as mitigation measures would be avoided to the greatest extent possible. The restoration of currently eroding marsh areas would prevent the further erosion of sites by stabilizing landforms and creating protective marsh buffers.

Costs for additional terrestrial archeological survey and testing, and nautical archeological survey and dive assessments are included in the Engineering and Design cost of the project estimate. Funds for potential archeological data recovery are also included in the project cost estimate as a full Federal cost per Section 7 of PL 93-291. While no specific historic property impacts have been identified at this time, there is a high potential to affect a significant historic shipwreck. The highest potential for historic property data recovery is associated with channel deepening through Sabine Pass, the site of a significant Civil War naval battle. To cover estimated costs for historic property data recovery, funds have been included in the project cost estimate for potential data recovery projects during the construction phase.

4.15 SOCIOECONOMIC RESOURCES

4.15.1 No-Action Alternative

Under the No-Action Alternative, the study area would continue on its present course of economic development, population growth trends, and residential and industrial development patterns. The demand for community facilities, services, and housing would not increase within the study area since there is low projected population growth. The locations of these resources would generally follow development and land use plans identified by surrounding cities and Hardin, Jefferson, and Orange counties and Cameron and Calcasieu parishes. Because no property is likely to be removed from the tax rolls, the tax base would not be affected. The No-Action Alternative could possibly have a negative effect on the local economy within the study area. Transportation costs and operational inefficiencies with the existing ship channel could possibly change industry trends, thereby changing the number of employed persons.

Under the No-Action Alternative, the counties of Hardin, Jefferson, and Orange in Texas, and Cameron and Calcasieu parishes in Louisiana areas of the proposed project would continue to have slow to moderate population growth and moderately low commercial, residential, and industrial land development (see Section 3.14). The channel areas starting at the Port of Beaumont and continuing to the Gulf would continue to function as a leader in industrial facilities and international commerce in the study area. The ports would also continue to develop their industrial properties but at a slower rate than with the Proposed Alternative. Without the channel deepening, higher transportation costs and operational inefficiencies related to large vessels would continue. As a result, future growth at the ports would likely be slower and less than if the SNWW were improved.

4.15.2 Preferred Alternative

4.15.2.1 Population and Social Characteristics (Demographics)

The Preferred Alternative would not likely have an effect on population growth trends within the study area. Population in this area is projected to grow at a low rate. As a result of the Preferred Alternative, demand for community facilities, services, and housing would not increase in the study area. The location of these resources would generally follow development and land use plans currently identified. Most of the construction workers are likely to come from the labor force that is already living within Hardin,

Jefferson, and Orange counties, in Texas, and Cameron and Calcasieu parishes in Louisiana; therefore, immigration to the study area would be small. Over 72 percent of housing within the study area is occupied. Thus it is unlikely there would be an increase in single-family home construction. The projected population growth trend over 60 years for the study area has very little or no increase. Population growth for this area is not expected to change much from present. This alternative would have a minimal effect on the demographics of the study area.

4.15.2.2 Environmental Justice

The population living within the study area is primarily comprised of white persons (59.6 percent), followed by black or African American persons (26.7 percent), and Hispanic or Latino persons (9.6 percent); therefore, the proposed project would not be located within a minority area. Jefferson County consists of the highest minority populations of both African Americans (33.4 percent) and of Hispanic Origin (10.6 percent). In Jefferson County, census tracts 51 and 61 consist of the two highest populations of African American persons at 93.5 and 93.3 percent, respectively. Census tracts 101 and 56 in Jefferson County consist of the highest percentages of Hispanic persons at 45.3 and 41.4 percent, respectively. Both census tracts 51 and 61 in Jefferson County would be considered minority areas. The average median household income for the study area census tracts was \$28,884, which is above the Department of Health and Human Services (HHS) 2006 poverty guideline of \$20,000 for a family of four (HHS, 2006). The percent of persons living below poverty for the study area was 18.5 percent, which is higher than the State of Texas (15.0 percent), but is not more than 10 percent higher than the percent living below poverty for the Texas counties of Hardin (11.1 percent), Jefferson (16.3 percent), and Orange (13.6 percent), and Cameron Parish (12.2 percent) and Calcasieu Parish (15.0 percent) in Louisiana; therefore, the study area is not considered a low-income area.

The minority and low-income populations living within the study area would likely experience no adverse changes to the demographic, economic, or community cohesion characteristics within their respective neighborhoods as a result of the proposed project. Generally speaking, the populations living within the study area would not likely see any change from the proposed project. Therefore, the Preferred Alternative would not result in disproportionately high and adverse impacts on minority and low-income persons living within the study area.

4.15.2.3 Community Values

The Preferred Alternative would neither divide nor isolate any particular neighborhood nor separate residents from community facilities. It would likely have a negligible effect on population growth trends within the study area, and residential, commercial, and industrial development would likely continue at the same rate. Population in this area is projected to continue with its low growth rate, regardless of the proposed project, and demand for community facilities, services, and housing would continue at a rate that is consistent with the projected population growth. The location of these resources would generally follow development and land use plans identified by local jurisdictions. Therefore, the proposed project would not result in a negative impact to community values.

4.15.2.4 Housing

The Preferred Alternative is not expected to result in a substantial increase in population within the study area. In Calcasieu Parish, 10 percent of total housing is vacant, while in Cameron Parish there is 33 percent vacant housing. Hardin County consists of 10.2 percent vacant housing. Jefferson and Orange counties both have 9 percent vacant housing. Population growth is not expected to increase in the area; therefore, available housing would not affect the proposed project.

4.15.2.5 Economic Characteristics of Area Population

With the Preferred Alternative, as with the No-Action Alternative, the study area would continue to have large industrial facilities of the Neches Channel such as Trinity Industries, ExxonMobile, Mobile Chemical, and North Star Steel located near the Port of Beaumont. Other industries such as Huntsman, Ameripol Synpol/Huntsman, Motiva Enterprises, Air Liquide, and Entergy-Sabine Plant are located just north of Port Neches. The Preferred Alternative would not result in negative impacts to the local economy.

4.15.2.6 Leading Economic Sectors

The “industrial mix” in the study area of manufacturing, port-related, construction, transportation, and public utilities is typically reliant on contract labor. When a project is completed, companies would lay off their workforce until the next contract is awarded. In terms of competition for workers, the port-related, manufacturing, and industrial-related employers of the study area do not have to compete much with other industries because of the higher wages these employers offer over the services, retail, and wholesale trade and government services. Another factor affecting employment among manufacturing and port-related employers is the increased reliance on mechanized means of production. This type of production has a relatively small increase in the number of employees. During project construction, the study area may have a slight increase in construction employment and local purchases of construction materials but would be temporary, if any change at all.

4.15.2.7 Labor Force and Employment

The increase in jobs, economic output, and the tax base would be fairly slow and consistent with historical growth trends. The ports and their associated industries and international commerce currently serve an important role for the study area economy. These industries provide jobs, income, and a tax base for the area, and the effects reverberate within other industries such as housing, retail services, and wholesale trade. The Preferred Alternative would likely promote the development of industrial sites along the ship channel in Hardin, Jefferson, and Orange counties and Cameron Parish. This goal would be consistent with a steady historical trend towards increased reliance on these industries and these types of development within the region.

As previously discussed, the primary economic bases of the study area include petrochemical processing, construction, mineral extraction, tourism, commercial fishing, and agriculture. As a result of the proposed

project, the positive economic effects to the study area economy would be moderate at the least and substantial at best.

4.15.2.8 Personal Income

Within the study area census tracts, tract 16 in Jefferson County had the lowest per capita income (\$11,833) and tract 223 in Orange County had the highest (\$48,586). Tract 16 is located within Beaumont and would benefit very little, if any at all, from the Preferred Alternative.

4.15.2.9 Oil and Gas Production

SNWW refinery capacity presently represents 6 percent of the U.S. total; furthermore, SNWW's 2002–2006 crude petroleum waterborne imports comprised 12 percent of U.S. and 18 percent of Petroleum Administration Defense District (PADD III) imports (USACE, 2008b).

In addition to existing crude oil and petrochemical product facilities on the SNWW, one LNG facility began operation in 2008, and construction of a second facility is nearing completion; a third has received regulatory approval. It is anticipated that oil and gas production would continue to be a major employer and industry within the study area. The Preferred Alternative would provide the necessary transportation improvements that would continue to support the export of petroleum commodities as well as support predicted crude oil imports.

4.15.2.10 Public Finance

No impacts to public finance are anticipated from the Preferred Alternative.

4.15.2.11 Land Use

All proposed channel improvements for the Preferred Alternative occur in open-water locations (they would not affect any shoreline land uses). The only land use implications for the Preferred Alternative relate to upland PAs and indirect future land development, which may occur as a result of the proposed project.

Approximately 1,900 square miles of the study area includes portions of Jefferson, Hardin, and Orange counties, Texas, and Calcasieu and Cameron parishes, Louisiana. The study area includes nine municipalities: Beaumont, Port Neches, Nederland, Groves, Port Arthur, Bridge City, Vidor, Orange, and West Orange.

The greatest long-term land use consequence of the proposed project would likely be a change in future land uses that would occur in response to the improvements to the channel. These future land uses are not considered part of the proposed project but would be less likely to occur without it. When the Preferred Alternative is complete, the ports would have a deeper ship channel providing an incentive for new industrial development at all of the ports' properties, based on navigation cost savings. Future industrial development may include oil and gas refineries or upgrades, petrochemical plants or upgrades, LNG

plants, and bulk grain facilities. The long-term land use effects of these industrial facilities are largely unknown; however, given recent trends in the area, they would not likely lead to a substantial increase in demand for new housing development, new roads, commercial services, schools, or other services within Hardin, Jefferson, and Orange counties in Texas or Calcasieu and Cameron parishes in Louisiana.

Proposed land uses for the Preferred Alternative were evaluated to determine if they could increase wildlife hazards to aircraft using public use airports in the study area: the Beaumont Municipal Airport, the Southeast Texas Regional Airport, and the Orange County Airport (see figures 3.14-4a–d). All three airports sell Jet-A fuel, and it was therefore assumed that a separation distance of 10,000 feet for any of the hazardous wildlife attractants would apply, in addition to the 5-mile range to protect approach, departure, and circling airspace. Certain land use practices such as waste disposal facilities, water management facilities, golf courses, agricultural cropland, and dredged material placement areas can act as attractants to wildlife that pose a strike hazard. Some natural areas such as wetlands may attract wildlife species that are associated with aircraft strikes.

Project features of the Preferred Alternatives that could serve as attractants are PAs, BU marsh restoration areas, and marsh mitigation areas. None of these project features are located within the separation perimeters for the Beaumont Municipal Airport and the Orange County Airport. None of the BU and mitigation areas are located within separation areas for any of the three airports. However, all or portions of four PAs are located between the 10,000-foot and 5-mile perimeters of the Southeast Texas Regional Airport. All of PA 23/23A and PA 21 are located between the 10,000-foot and 5-mile perimeter; PAs 18 and 24 straddle the 5-mile perimeter. All are existing designated placement areas for the SNWW navigation project. Although they are designated PAs, at times during the dredging cycle they provide habitat for birds and wildlife species that pose a strike hazard. However, no new PAs would be constructed within the separation perimeters, and no change in land use is proposed in conjunction with the Preferred Alternative.

4.15.2.12 Recreation/Tourism

Among sport-related activities, recreational fishing, wildlife watching, and hunting continue to be major parts of the outdoor recreational activities in the study area. Sabine Lake, numerous wetlands, and the Gulf are sources of recreational fishing and wildlife watching. The construction of the Preferred Alternative would have minimal negative effects on recreation within the study area, and the proposed BU and mitigation marsh restoration areas are expected to have beneficial impacts to recreational activities in the area by providing additional habitat. The Neches River BU Feature will create 2,853 acres of emergent marsh, restore 871 acres of shallow-water habitat, and nourish 1,234 acres of existing marsh. Mitigation in Louisiana's Black Bayou and Willow Bayou watersheds would restore 2,783 acres of emergent marsh, 957 acres of shallow-water habitat, and nourish 4,355 acres of existing marsh. The Gulf Shore BU Feature at Texas Point and Louisiana Point would nourish 6.0 miles of Gulf shoreline. All of these locations would provide new habitat for native fish and wildlife species, providing more fishing and wildlife watching for this area, thus enhancing the life for recreational use.

4.15.2.13 Aesthetics

The Preferred Alternative would have a minimal effect on the overall visual quality within the study area. There would be no negative effect to the appearance of the shorelines that are adjacent to the proposed channel improvements except for temporary turbidity. The study area includes a variety of land uses, including residential neighborhoods, commercial or CBD, transportation systems (highways and railways), civic uses, parks, schools, port facilities, and heavy industrial areas. Some regions in the study area already show moderated human development. Generally speaking, the study area is not particularly distinguished in aesthetic quality from other adjacent areas within the region. The landscape exhibits a generally moderate to high level of impact from human development and alteration. The study area is not considered scenic as defined by Federal regulations by view or by roadway.

4.16 CUMULATIVE IMPACTS**4.16.1 Introduction**

The President's Council on Environmental Quality (CEQ) defines cumulative impacts as those impacts *"on the environment which result from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions."* Cumulative impacts can result from individually minor, but collectively significant, actions taking place over a period of time. Impacts include both direct effects (caused by an action, occurring at the same time and place as the action) and indirect effects (caused by the action, but removed in distance or later in time, and reasonably foreseeable). Ecological effects are those on natural resources and on the components, structures, and functioning of affected ecosystems, whether direct, indirect, or cumulative.

4.16.2 Method and Evaluation Criteria

The SNWW CIP FEIS follows a traditional cumulative assessment method as typically addressed under NEPA. To define the evaluation criteria and provide additional resource input to the USACE, SNND, and other project staff, an ICT comprised of resource agency representatives was established. The ICT, USACE, and SNND defined the cumulative impacts study area and evaluation criteria considered in this cumulative impacts assessment. This assessment is limited to the SNWW project area for the Preferred Alternative as defined in the Affected Environment section.

The ICT defined criteria and a project list of key past, present, and reasonably foreseeable actions. Criteria used to select projects identified as "reasonably foreseeable" for the purpose of this cumulative assessment are as follows:

- a) a Congressionally mandated study or project authorized by and specifically included in a Water Resources Development Act within the last 20 years, for which there is a readily available report that documents environmental consequences, or;

-
- b) a current or recently initiated Federal study for which there is a readily available report that documents environmental consequences, or;
 - c) a specific proposed or permitted, private (non-Federal, non-State, non-local government) Section 404 action or any aggregate of individual private Section 404 actions where the private action or actions required an environmental assessment (EA) or EIS for authorization and for which there is a readily available report that documents environmental consequences of the action or actions(s), or;
 - d) an existing or updated regional water plan or reservoir operating plan specifically related to the project area.

Projects that qualified as past, present, or reasonably foreseeable include several LNG and pipeline projects, regional water planning efforts, maintenance and operating plans and projects, habitat restoration and protection activities, and port improvements from the Gulf to the Port of Beaumont, along the SNWW. Project impacts are determined from the best publicly available information in existing documents. Not all projects are included in the impacts summary table and/or resource impact discussions because publicly available environmental documentation is insufficient to quantify and compare impacts; however, these project-specific influences may in time have additive impacts or benefits to resources in the area.

Using the above-defined criteria, the ICT defined the following projects as relevant past or present actions or existing conditions:

- SNWW 40-foot Project (maintenance dredging);
- GIWW –Texas Section, Main Channel and Tributaries, Maintenance Dredging;
- GIWW – Louisiana Section, Sabine Lake to Lake Charles;
- Neches River Saltwater Barrier Operating Plan;
- Toledo Bend Reservoir Operating Plan;
- Beneficial Uses of Dredged Material for Marsh Preservation, GIWW Port Arthur to High Island, Texas;
- Salt Bayou – McFaddin Ranch Wetlands Salt Water Control Project;
- SNWW Marine Organism Access between PA No. 11 and Sabine Lake, Texas;
- Several CWPPRA habitat protection and restoration projects;
- Sabine Pass LNG and Pipeline;
- Golden Pass LNG and Pipeline;
- Kinder Morgan Louisiana Pipeline; and
- Jefferson County Drainage District No. 6 (Diversion Channel from South Fork of Taylor Bayou, south to the GIWW).

Additionally, the ICT defined the following projects as reasonably foreseeable future actions:

- Port Arthur LNG and Pipeline;
- East Texas Regional Water (ETRW) Plan (as part of the approved Texas 2007 State Water Plan);
- Port of Beaumont Intermodal Improvements Projects, Northside and Southside;
- Keith Lake Section 1135 CAP;
- Sabine Pass to Galveston Bay Shoreline Erosion Feasibility Study; and
- Toledo Bend Reservoir relicensing.

Ongoing regional activities, initiatives, and programs may also affect local and regional drainage, navigation, flood control, and erosion control in the SNWW project area, but these actions/programs occur outside of the study area and/or effects are not project-related and cannot be quantified in this document. Programs under which such activities and initiatives may occur include the following:

- the GLO’s Coastal Management Program (CMP), including “Coastal Texas 2020” (a long-term, statewide initiative to promote Texas coastal environmental and economic health);
- Louisiana’s CMP;
- the USACE Galveston District navigation, flood control, and hurricane-flood protection programs, and regulatory efforts to protect wetlands and navigation channels;
- Jefferson County Drainage Districts (other than No. 6); and
- the Trinity Bay Conservation District.

Resource evaluation criteria include biological, ecological, physical, chemical, cultural, and socioeconomic resources for projects within the SNWW study area. The following resource parameters are addressed:

Physical Environment	Biological Attributes	Socioeconomic Attributes
Air Quality and Noise	Wetlands	Recreational Facilities/Areas
Topography and Bathymetry	Bottomland Habitat	Commercial/Recreational Fisheries
Soils	Terrestrial Vegetation	Ship Accidents/Spills
Sediment Quality	Submerged Aquatic Vegetation	Oil/Gas Production on Submerged Lands
Water Quality	Plankton/Benthos	Cultural Resources
Nutrients	Finfish/Shellfish	Public Health
Salinity	Mammals	Safety
Turbidity	Reptiles/Amphibians	Land Use
Contaminants	Threatened and Endangered Sp.	
Freshwater Inflow	Essential Fish Habitat	
Circulation/Residence	Migratory Birds	
Tidal Influence		

All impacts in the above categories that can be quantified from existing documents are displayed in Table 4.16-1. If an impact cannot be quantified, a qualification sourced from available documents (i.e., “benefit,” “net benefit,” No Impact, or Not Applicable) is presented in most instances for comparison. Project descriptions and cumulative impact assessment results follow.

Benefit or Net Benefit = Results which have an overall positive effect when compared to the FWOP (baseline, existing) conditions of the resource.

NI = no long-term impacts; NA = not available; UN = unavailable; I = impact

¹ Although not included in the table, several other projects are included in Section 4.16 Cumulative Impacts.

² Offset by engineering design, mitigation, data recovery, adaptive management plans/activities based on monitoring, procedures, and project controls.

³ Includes acreage from permit amendment applications.

4.16.3 Past or Present Actions

Petroleum-related industries, most prominently refining and crude oil terminal operations, dominate the area. These and other shipping-dependent industries, alongside commercial and recreational fisheries, agricultural production, and recreation and conservation areas (NWRs, State Parks, State Historic Sites, and WMAs), have influenced this area's land use history, navigation channel development and maintenance, coastal transportation trends, and regional economic and ecological importance to both Texas and Louisiana. The discussion of baseline conditions discussed in Section 3 of this FEIS presents conditions in the study area resulting from these past actions. Past projects considered in this cumulative impacts analysis include the current SNWW 40-foot Project maintenance and other related activities, which may influence or be influenced by natural and socioeconomic resources of the area.

4.16.3.1 Sabine-Neches Waterway 40-foot Channel (past and current condition)

Two of three major area seaports are included in the SNWW project area: Port Arthur and Beaumont. The Ports of Port Arthur and Beaumont rely on a series of artificially widened and/or deepened channels that were dredged from offshore in the Gulf, through Sabine Pass, around the western shore of Sabine Lake, and up the Neches River. Channel and port improvements began in 1885 when Army Engineers completed construction of the east and west jetties (Alperin, 1977). When the jetties produced a channel depth of 25 feet through Sabine Pass, the Kansas City, Pittsburg, and Gulf Railroad and the Port Arthur Channel and Dock Company dredged a 25-foot-deep by 75-foot-wide channel from Sabine Pass to Port Arthur in 1897. Located near the seminal 1901 Spindletop oil discovery, the cities of Beaumont and Port Arthur underwent rapid and substantial growth to accommodate the new petroleum industry. The Port Arthur International Public Port was established in 1899, and a 9-foot-deep canal was dug in the Neches River from the Port Arthur Ship Channel to Beaumont in 1908. The channel was deepened to 25 feet in 1916, and a turning basin was dredged in a bend of the Neches River. By this time, dock facilities had been developed along the Neches River waterfront, creating an inland port for the City of Beaumont. Beaumont's status as a shipping center was heightened in 1922 when the channel was deepened to 30 feet. In the 1940s, the channel was deepened to 36 feet and finally to 40 feet in the 1960s (Alperin, 1977). In 1912, a 25-foot navigation channel was constructed from the mouth of the Neches River, across the northern edge of Sabine Lake, and up the Sabine River to near the city of Orange, Texas. Called the Sabine River Channel, it was deepened to 30 feet in 1922 and remains that depth today. These deep-draft navigation channels are collectively known as the Sabine-Neches Waterway.

The shallow-draft GIWW coincides with portions of the SNWW in the study area. Construction of the GIWW between the Sabine River and Galveston Bay began in 1925. Originally 9 feet deep by 100 feet wide, it was later enlarged to its current dimensions of 12 feet by 125 feet. The segment of the GIWW from the Sabine River eastward 25 miles to the Calcasieu River in Lake Charles, Louisiana, was deepened to 30 feet by local interests and authorized as a Federal project in 1935 (USACE, 1998c). It provided a deepwater navigation channel to the Port of Lake Charles through the SNWW until the 30-foot depth was abandoned upon completion of the deep-draft Channel to Calcasieu in 1941; it is presently maintained at authorized GIWW dimensions of 12 feet by 125 feet.

The existing 40-foot SNWW project is a federally authorized and maintained waterway approximately 77 miles long, located in Jefferson and Orange counties, Texas, and Cameron and Calcasieu parishes, Louisiana. Currently, SNWW maintenance dredged material, approximately 8 mcy annually, is placed in 16 upland confined PAs and 4 ODMDSs in the Gulf (see Appendix D). There was no NEPA-process document for construction of the SNWW 40-foot project, which would provide information about impacts related to construction activities; however, the operational and maintenance impacts were addressed in an EIS in 1972. The Ecological Modeling Report (Appendix C) also discusses impacts of the current condition and FWOP. From these two sources, effects for this cumulative impacts analysis include the conversion and loss of wetlands, terrestrial vegetation, SAV, and wildlife habitats from the creation of PAs and saltwater intrusion. Relative to other Past and Present Actions, SNWW 40-foot Project impacts are presented in Table 4.16-1.

4.16.3.2 GIWW – Texas Section, Main Channel and Tributaries

The USACE, Galveston District published “Maintenance Dredging, Gulf Intracoastal Waterway, Texas Section – Main Channel and Tributary Channels” (an EIS) in October 1975. This document identified and evaluated the environmental impacts of continued maintenance dredging of the GIWW Texas Section and tributary channels. The proposed action was continued maintenance by periodic dredging of shoal deposits. The main channel was authorized at a 12-foot depth and a 125-foot bottom width. The typical means of dredging is by hydraulic pipeline dredge, with the exception of the Port Mansfield Channel that can be maintained by either pipeline or hopper dredge. At the time of the 1975 EIS, the environmental impact and adverse environmental effects of the proposed action were addressed based on the best available information (USACE, 1975a, 2004c).

As it leaves Louisiana, the GIWW connects with the SNWW approximately 3 miles below Orange, Texas. The GIWW then follows the Sabine River Channel and the Sabine-Neches Canal to the head of the Port Arthur Canal where it exits the SNWW and continues westward to Galveston Bay. Portions of GIWW Reach I (Sabine River to the Matagorda Ship Channel) and tributaries are within the SNWW project area. Specific impacts for the GIWW segments within the SNWW project area are not distinguishable in existing documents, which present impacts of larger reaches of the GIWW. Potential impact presentation of the entire GIWW in this document would not be comparable to other projects presented here; therefore, GIWW impacts are not included in Table 4.16-1.

4.16.3.3 Neches River Saltwater Barrier Operating Plan

From 1975 through 1997, the USACE, Galveston District, with cooperation from the LNVA, pursued a project to prevent saltwater contamination of surface water supplies while maintaining free and reasonable unobstructed use of the Neches River for existing and future navigation (USACE, 1997a). Temporary steel-sheetpile barriers installed and controlled by the local sponsor at two locations downstream from their freshwater intakes were environmentally and navigationally unacceptable. Environmental impacts were described in a 1975 FEIS and updated in a 1981 Supplement and 1997 EA; however, changes in environmental conditions and requirements necessitated an additional supplement.

The proposed project was revised in 1997 and relocated around river mile 29.7, downstream from the confluence of the Neches River and Pine Island Bayou, adjacent to the Big Thicket National Preserve. Installations and construction in approximately 60.4 acres include:

- an overflow dam with crown width of 300 feet in the Neches River;
- a sector gated 1,260-foot-long navigation bypass channel west of the river;
- a tainter gated 2,700-foot-long barrier structure in a diversion channel west of the navigation channel;
- an access levee road; and
- a service area west of the diversion channel.

Approximately 48.4 acres of the 60.4-acre project area involved vegetation removal and wetlands conversion, primarily in the form of cypress-tupelo swamp and bottomland hardwood habitats. The project identified the following environmental beneficial effects:

- set aside and protect 8.5 acres of cypress-tupelo swamp and additional modified mitigation strategy approved by the USFWS and USACE;
- prevent annual erosion and shoreline loss on the Big Thicket National Preserve;
- create 5 wetland acres around the “plug”;
- conserve groundwater; and
- protect an additional 10 miles of river and bayou wetlands from saltwater intrusion and downstream pollutant contamination.

Additional net benefits were found through additional studies (USACE, 1997a): agricultural (primarily rice, cattle, turf grass, and crawfish); recreation (bird-watching, hunting, fishing); industrial (cooling and processing); and municipal uses.

No long-term permanent effects to wildlife, aquatic life, threatened or endangered species, water quality, air quality, noise, floodplains, cultural resources, or prime farmlands were expected (USACE, 2003c). An FEIS supplement was prepared in July 1981. A draft Environmental Assessment (EA), contained in the December 1997 General Reevaluation Report, concluded that the recommended plan would not have significant adverse environmental effects. The final EA was completed in October 1998. Construction of the Saltwater Barrier Project was completed in 2003. Current operational impacts are not known at the time of this document’s production; however, impacts from the FEIS and the General Reevaluation Report are included in Table 4.16-1.

4.16.3.4 Salt Bayou – McFaddin Ranch Wetlands Salt Water Control Project

In 1992, the USACE, Galveston District, proposed modification of the GIWW by construction of a water control structure to improve fish and wildlife habitat on 60,000 acres of the wetlands of the McFaddin NWR, Sea Rim State Park, and J.D. Murphree WMA in Jefferson County, Texas (USACE, 1992). Prior

to construction of the GIWW, the SNWW, and the Keith Lake cut, the area contained fresh to brackish marshlands drained by bayous and lakes to Sabine Lake. Disrupted natural drainage patterns and introduced salt water from the Gulf increased salinity in these marshlands causing loss of SAV, erosion, conversion to open water, and reduced wildlife habitat values. Actions to repair these conditions included installation of a concrete water control structure with five gated culverts on the GIWW at Salt Bayou; new channel excavation; training levee construction with stone riprap; and damming the outlet channel. It was determined that this project would have no significant impact on water quality, federally listed threatened or endangered species, National Register eligible properties, or floodplains (USACE, 1992). The project was intended to have a beneficial effect on approximately 60,000 acres of publicly owned wetlands and migratory waterfowl habitat. Although the barrier is functioning as intended, rainwater runoff exiting through the single remaining tidal exchange point at the Keith Lake Fish Pass has been insufficient to block significant saltwater intrusion, and marsh loss is still occurring.

4.16.3.5 Beneficial Uses of Dredged Material for Marsh Preservation, GIWW – Port Arthur to High Island, Texas

In 2003, the USACE Galveston District proposed BU of routine periodic maintenance dredged material along part of the Port Arthur to High Island reach of the GIWW, a 17-mile reach, which crosses the McFaddin NWR and J.D. Murphree WMA in Jefferson County, Texas. For this project, BU included berm creation and restoration along the channel to restrict saltwater intrusion into adjacent freshwater to intermediate marshes. Additionally, dredged material in existing PA No. 4 was allowed to flow over the rear levee into adjoining marsh to offset effects of subsidence. PA No. 4 is located in both the McFaddin NWR and J.D. Murphree WMA; new PAs as a result of this project were located within the McFaddin NWR and consist of narrow discharge corridors along the southern bank of the GIWW (USACE, 2003d). This plan was developed with the USFWS and TPWD, stewards of the NWR and WMA, respectively.

Overall, dredged material discharge impacts to marsh elevation and temporary salinity impacts to vegetation were considered minor relative to preserving and restoring adjacent marshlands. Wildlife disturbance was short term and localized during dredged material discharge operations. It was anticipated that some species of freshwater fish would benefit from the action, and the action would not affect EFH. No federally listed or proposed species were likely to occur at the project site and several State-listed species may have benefited from habitat loss prevention, restoration, and preservation. No historic properties were affected.

The project actions have no significant effect on maritime traffic along this reach of the GIWW. Vehicular traffic to an adjacent hunting lodge was blocked for 1 to 2 weeks, outside of the hunting season, to accommodate the discharge pipe. During dredging, the area immediately around the dredge and pipeline are hazardous (presence of equipment, increase in service boat traffic); however, these impacts to public safety are minor.

The Port Arthur – High Island Beneficial Use of Dredged Material impacts summary is presented in Table 4.16-1 for comparison to the SNWW CIP and other past, present, and reasonably foreseeable projects.

4.16.3.6 Sabine-Neches Waterway: Marine Organism Access between Placement Area No. 11 and Sabine Lake

In 1997, the USACE, Galveston District, proposed relocation of two drop-outlet structures, which allow clarified decanted water to exit PA No. 11 during dredged-material discharge operations. The relocation intended to enhance estuarine connectivity between PA No. 11 and Sabine Lake Estuary System and productivity within PA No. 11, between dredging cycles, by opening PA No. 11 to tidal exchange with Sabine Lake. Additionally, the work included removal of two existing spillways and closure of the connection between the drainage ditches and the Sabine-Neches Canal. The project was determined to have no significant adverse effect on human environment, fish, wildlife, water quality, threatened or endangered species, or historical resources (USACE, 1997b).

4.16.3.7 TxDOT Emergency Action Permit for Fill Along the Sabine River

TxDOT held an emergency permit valid through 2008 to conduct shoreline stabilization activities, as needed. The permit was valid for approximately 9 miles along the east and west shorelines of the Port Arthur Ship Channel, along SH 87 from south of the GIWW to northeast of Keith Lake, and along SH 82 from east of the GIWW to east of Keith Lake, south of Port Arthur in Jefferson County, Texas.

4.16.3.8 Habitat Protection and Restoration Projects

CWPPRA (PL 101-646), also known as the Breaux Act, provides Federal funding through the USACE to five Federal agencies cooperating with local funding-match sponsors to preserve and restore wetlands in Louisiana (LCWCR, 1998). The Breaux Act also established the Coastal Wetlands Conservation Grant Program to help preserve and restore other coastal wetlands with matching Federal funding in the U.S. and to assist programs under the North American Wetlands Conservation Act, passed in 1989. The Breaux Act designates that 70 percent of its authorized funds go to Louisiana restoration projects, 15 percent to the Coastal Wetlands Conservation Grant Program, and 15 percent to North American Wetlands Conservation Act projects. The Breaux Act Louisiana projects typically have a 20-year or less “lifespan” from planning through implementation and monitoring. As of 2004, approximately 129 projects were active from 13 Priority Project Lists (USACE, 2005c). Four recent projects within the SNWW study area were considered for the cumulative impacts assessment. The effects of these projects on land loss were considered in the WVA model analysis of each hydro-unit (Appendix C); they are combined in Table 4.16-1 under “Habitat Restoration Projects” as they are similar in location, type, action, and effect. A brief description of each project included in this analysis follows.

4.16.3.8.1 East Sabine Lake Hydrologic Restoration Project

The USFWS, NRCS, and LDNR designed and implemented a restoration strategy to prevent elevated salinity in freshwater areas of the western Sabine NWR, from Pool 3 to the eastern shoreline of Sabine Lake in Cameron Parish, Louisiana (LCWCR, 2003). Two construction phases started in 2004 and included shoreline armoring, revegetation, terracing, dike and levee systems, and other water control

structure installations. Project actions are designed to prevent or restore events that affect the integrity and function of freshwater marsh areas in the refuge:

- prevent saltwater intrusion from the SNWW and the GIWW;
- restore natural water circulation;
- prevent rapid freshwater runoff;
- reduce marsh loss and subsidence, and
- reduce potential increased salinity from the Texas Water Plan (Senate Bill 1), the SNWW enlargement project, and the Neches River saltwater barrier north of IH 10.

The East Sabine Lake Hydrologic Restoration project area contains identified EFH for postlarval, juvenile, and subadult life stages of white shrimp, brown shrimp, and red drum (USFWS, 2004). The project area also provides important habitat for a number of economically important fishery species and migratory birds. The protected brown pelican may use the project area for feeding and/or loafing but is not known to nest in this area. The USFWS completed an intraservice Section 7 ESA consultation prior to issuing the Finding of No Significant Impact (FONSI) and Final EA and determined that the project would not adversely affect any threatened or endangered species within or adjacent to the project area. No cultural resources were identified within the work area. Habitat for fishery resources including EFH, migratory and resident waterfowl, wading birds, alligators, game mammals, furbearers, and brown pelican would be enhanced. Water quality and salinity are expected to show continual improvement. The total project effects/benefits include the following:

- 101.4 acres converted from shallow water to marsh, 1.4 acres filled by rock dike, and 163 acres of shallow water deepened for a total of 265.8 acres of shallow water filled or deepened; and
- 127.4 wetland acres protected and restored (USFWS, 2004).

4.16.3.8.2 *Black Bayou Hydrologic Restoration Project*

NOAA, NMFS, and LDNR sponsored and implemented a strategy to restore coastal marsh habitat and slow the conversion of wetlands to shallow, open water within a 25,529-acre wetland in Cameron and Calcasieu parishes, Louisiana (LCWCR, 2002a). The project area includes approximately 6,516 acres of fresh/intermediate marsh, 7,353 acres of brackish marsh, and 11,660 acres of open water (LDNR, 2003a). Tidally influenced intermediate and brackish marshes were threatened by saltwater intrusion and wave action amplified by the GIWW. Several actions were implemented:

- 22,600-foot rock dike constructed on the southern spoil bank of the GIWW;
- 70-foot bottom width barge bay weir in Black Bayou Cutoff Canal;
- 10-foot bottom width weirs with boat bays in Burton Canal and Block's Creek;
- old, collapsed weir replacement with fixed crest steel sheet-pile weir including a self-regulating tidegate; and
- in situ terracing in open-water areas to create elevated marsh and marsh plantings.

Construction activities were completed in December 2001, and marsh planting began in April 2002. Monitoring was conducted in 2003 under a revised plan (LDNR, 2003a). Mean salinity calculated from continuous recorders and discrete data did not show any large differences between project and reference areas or between preconstruction and postconstruction conditions. However, discrete salinities were monitored from June 1999 through March 2004, and data suggest that the impounded hydrologic area 1 was minimally effective in reducing mean salinity and sharp salinity increases compared to the areas outside the influence of the project structures (LDNR, 2007). California bulrush plantings installed in 2002 were variably successful. No significant change in the shoreline location over 3 years was evident from the 2003 data. SAV coverage was very high in most of the ponds sampled in 1999 and remained high in 2003. Dominant species found at both sampling times include Eurasian watermilfoil, southern naiad (*Najas guadalupensis*), and the algae *Nitella* sp. An annual inspection conducted in October 2005 by the LDNR indicated that the project was in good condition and functioning as intended and that features survived Hurricane Rita basically intact (LDNR, 2005a). As of December 2006, an inspection field trip with the LDNR and NMFS detected two small breeches: one on the rock dike along the GIWW and one on a plug along the GIWW. As a result, discussions are underway to develop a plan for corrective actions (LCWCR, 2006). The project created a total of 2,960 acres of wetlands, protected 634 acres for a net total of 3,594 acres; 2,812 AAHUs are expected for this project (LCWCR, 2002a).

4.16.3.8.3 Perry Ridge Shoreline Protection Project

In February 1999, the NRCS and LDNR completed a limestone riprap dike within a 4.3-mile reach of the GIWW north bank and the Vinton Drainage Canal (LCWCR, 2002b). This dike (12,000 linear feet) is offset from the vegetated shoreline by 60 feet and is designed to break navigation-induced wave action, prevent further shoreline erosion, and reduce salinity spikes by maintaining a freshwater pool behind the rocks. The dike protects approximately 1,203 acres of vegetated shoreline, which, in turn, benefits approximately 5,945 acres of intermediate marsh north of the shoreline. The original monitoring plan was implemented following construction and has been revised in 1998 and 2003 to conform to similar monitoring projects (LDNR, 2003b). Approximately 624 acres of AAHUs are expected (LCWCR, 2002b). Results of the 2005 Operations, Maintenance, and Monitoring Report (LDNR, 2005a) indicate that the average rate of shoreline accretion was 1.6 feet/year at project stations, while reference stations showed a continued rate of shoreline erosion at 0.8 foot/year.

4.16.3.8.4 GIWW – Perry Ridge West Bank Stabilization

In 2002, the NRCS and LDNR completed installation of approximately 34,652 linear feet of rock riprap and terraces along the northern bank of the GIWW between Perry Ridge and the Sabine River in Calcasieu Parish, Louisiana (LCWCR, 2002c). This section of the GIWW was dredged to allow the use of doublewide barges, and consequently, wake erosion intensified. In addition, the construction of the Calcasieu Ship Channel and the deepening of Sabine Pass have increased salinity and water currents within the GIWW. These activities have caused the GIWW shoreline to breach, thus impacting the interior marsh of the Perry Ridge West Bank project area. The shoreline protection was accomplished in three phases:

- 9,500 feet of rock riprap along the northern bank of the GIWW from Perry Ridge to its intersection with the Sabine River;
- 2,200 feet of rock riprap from the Sabine/GIWW intersection north along the Sabine River; and
- 22,952 linear feet of terraces in the shallow, open-water areas north of the GIWW to reduce fetch (distance a wave can travel) and allow recovery of the interior marshes. Terraces were vegetated with 9,400 trade-gallon-sized plantings of California bulrush.

The net benefit in the 1,132-acre project area would be protection and restoration of approximately 83 wetland acres over 20 years (LCWCR, 2002c). This project (CS-30) is directly west of the Perry Ridge Shoreline Protection Project (CS-24) discussed above. According to the 2005 Operations, Maintenance, and Monitoring Report (LDNR, 2005b), visual observations indicate an increase in the SAV species in the project area and potential for accretion.

4.16.3.9 Sabine Pass LNG and Pipeline Project

The Federal Energy Regulatory Commission (FERC) issued an Order on December 21, 2004, granting approval under Section 3(a) of the Natural Gas Act (NGA) for Sabine Pass LNG, L.P.'s proposal (FERC Docket No. CP04-47-000) to construct and operate Phase I facilities at the LNG import terminal and granting approval under Section 7(c) of the NGA for 16 miles of 42-inch-diameter pipeline and associated facilities (called the Sabine Pass Pipeline). This order was based on, among other analyses, the FEIS, Sabine Pass LNG, and Pipeline Project (Phase I Project FEIS) published in November 2004 (FERC, 2004). Sabine Pass LNG, L.P., has subsequently applied for, and the FERC issued, an EA in May 2006 to expand facilities at the terminal (Phase II) (FERC, 2006a). The Sabine Pass LNG Terminal received its first shipment of LNG in April 2008.

The Sabine Pass LNG import terminal in Cameron Parish, Louisiana, includes the following:

- LNG ship unloading berths;
- LNG transfer, storage, and vaporization;
- packaged natural gas turbine/generator sets;
- ancillary utilities, buildings, and service facilities; and
- a new 16-mile, 42-inch-diameter pipeline system to deliver natural gas to existing pipeline infrastructure (FERC, 2004).

As documented in the FEIS, the Sabine Pass LNG project was expected to affect approximately 540 acres of open land, consisting of coastal prairie and grasslands, wetlands, and a Dredged Material Placement Area (DMPA). Approximately 35 acres were converted to open water, 36 acres were converted from shallow water to deep water, and 341 acres were affected by operational facilities. Construction and operation were anticipated to have minimal effects to geological and soil resources; no prime farmland soils were affected. No significant effects were anticipated to groundwater resources or public or private water supply wells. Surface water impacts included dredging approximately 4.5 mcy from the berth area

and 69,000 cy from the construction dock area. Materials were moved to an unconfined BU area near Louisiana Point. Maintenance dredging is expected to occur every 4 to 7 years. Protective measures would be implemented to minimize impacts to surface waters. Although project actions resulted in temporary decreased water quality during and following dredge placement, potential future dredging benefits may include the following:

- Creation of a wave barrier to decrease wave energy along the shoreline, resulting in decreased shoreline erosion;
- Accretion of shoreline from redeposition of dredged material;
- Increased shallow-water habitat for marine and bird species that use shallow-water areas for foraging;
- Reoxygenation of sediments;
- Increase in wetland vegetation at water/shoreline interface due to increased shallow water and decreased wave energy; and
- Accretion of wetland habitats as high tide or storm events carry sediments into wetland areas

Approximately 156 acres of wetlands were expected to be affected by the LNG terminal development. Permanent wetland impacts included conversion of 17.4 acres of emergent wetland and 30 acres of DMPA to LNG terminal facility and 3.8 acres emergent wetland for a mainline valve on the pipeline. Less than 1 acre of forested wetland was converted to emergent wetland for pipeline operation. Additional wetlands impacts (approximately 27 acres) and mitigation (62 acres) were proposed when the USACE and LDEQ approved a permit amendment for Phase II (USACE, 2006d).

Wetlands in the Sabine Pass LNG and Pipeline project areas are designated as EFH for brown and white shrimp, red drum, and Spanish mackerel. Temporary EFH impacts during construction of the LNG terminal and pipeline totaled approximately 83 acres. Operation of the LNG and pipeline facilities was expected to permanently impact 15 acres of brackish marsh and mudflat wetlands and convert 36 acres of shallow open-water EFH to deep-water habitat. Wetland and EFH mitigation was proposed to enhance or create 73-wetland acres onsite, concurrent with the start of construction.

Of the 12 potentially occurring Federal- and State-listed threatened and endangered species, only the piping plover and brown pelican potentially occurred within the LNG project area. Critical habitat for the piping plover is designated at Louisiana Point, near the BU area for this project. With protective measures, construction and operation of the LNG terminal and pipeline facility were not expected to likely adversely affect either species or designated critical habitat. LNG ship encounters in the open water of the Gulf during transport create potential adverse effects to sperm whales, Kemp's ridley sea turtles, loggerhead sea turtles, green sea turtles, and leatherback sea turtles. As with the terrestrial species, protective measures and reporting procedures minimize these impacts.

At the time of construction, there were no residences within 1 mile of the LNG terminal location, and no residences within 50 feet of the pipeline work areas. No visual impacts were expected. No recreational

facilities were directly impacted by construction or operation. It was anticipated that areas along the LNG ship route and around the terminal slip would be exposed to a potential temporary hazard during ship transit and while at the berth.

No prehistoric or historic cultural resources were located in the area of potential effect at the time of the FEIS publication; however, additional deep-water archeological testing and some remaining testing along the proposed pipeline route were conducted following the issuance of the FEIS. No known archeological sites or historic properties were affected by use of the Louisiana Point BU dredge disposal area. Construction air emissions were expected to be short term without adverse effect to regional air quality. Operational air quality was anticipated to exceed NO₂ and CO thresholds and was subject to State air permitting requirements.

The following plans were implemented to minimize impacts to potentially affected resources:

- Upland Erosion Control, Revegetation, and Maintenance Plan;
- Wetland and Waterbody Construction and Mitigation Procedures;
- Spill Prevention, Containment, and Countermeasures Plan;
- Aquatic Resources Mitigation Plan;
- Environmental Construction Plan and Procedures; and
- NOAA Vessel Strike Avoidance and Injured/Dead Protected Species Reporting (Strike Avoidance Policy).

The Sabine Pass LNG and Pipeline impacts summary is presented in Table 4.16-1, in comparison to the SNWW CIP and other past, present, and reasonably foreseeable projects.

4.16.3.10 Golden Pass LNG and Pipeline

In July 2005, FERC authorized (with conditions) Golden Pass LNG Terminal LP and Golden Pass Pipeline LP construction and operation of an LNG receiving and transportation facility northeast of Sabine Pass, Texas, adjacent to the Port Arthur Canal in Jefferson County, Texas (FERC, 2005). The project was designed to import, store, and deliver foreign-source LNG to natural gas markets and includes a marine ship berthing area, LNG storage tanks and vaporization facilities, and a natural gas pipeline. The 122.4-mile natural gas pipeline was completed in April 2009, 1 year ahead of schedule (FERC, 2006b). The pipeline would cross Jefferson, Orange, and Newton counties, Texas, and Calcasieu Parish, Louisiana. Although the facility was expected to open in mid 2009, damage caused by Hurricane Ike pushed the anticipated opening into 2010 (*Wall Street Journal*, 2008).

Measures would be taken to minimize impacts to soil and geological resources. Approximately 2.8 acres of prime farmland would be permanently affected. No impacts are anticipated to groundwater resources. Primary impacts to surface waters would be from construction, including dredging 6.3 mcy for the LNG terminal; this action would create approximately 63.9 acres of open water and convert 43 acres of shallow water to deep water. Maintenance dredging is expected to occur every 2 years and would result in an

average of 410,000 cy per year. Dredged material would be pumped to PA 8 or PA 9, and approximately 1.2 mcy would be beneficially used for wetland restoration in the J.D. Murphree WMA. The proposed pipeline would cross the J.D. Murphree WMA. Approximately 0.5 acre of eroded shoreline would be reclaimed by filling the shallow-water area adjacent to the canal. Pipeline construction would minimize impacts to surface waters in 19 crossings using 31 horizontal directional drills.

It is anticipated that clearing and construction would affect approximately 2,007 acres of palustrine wetlands, estuarine emergent marsh, upland prairie, forest, agriculture and pastureland, and open-water/channel shoreline habitat. Approximately 239 acres of forested uplands and wetlands would be converted to herbaceous cover. Permanent vegetation effects would be approximately 227 acres for the LNG terminal and access road and 712 acres for the pipeline easement, aboveground facilities, and access roads (FERC, 2006b).

Golden Pass would affect approximately 399 wetland acres: 109 acres lost to LNG terminal facility development; 64 acres converted from forested to herbaceous or lost for aboveground facilities and access roads; and 226 acres affected by pipeline construction. Approximately 83 acres of forested wetlands would be cleared for pipeline right-of-way (ROW); of this, 40 acres would be maintained as herbaceous wetland within the ROW and the remaining 43 acres would eventually return to forested wetland areas. Pipeline construction would cross 14.9 miles of the J.D. Murphree WMA and nearly 1 mile of the Sabine Island WMA. The impacts to the forested wetland areas are considered permanent because of the time required for those wetlands to naturally recover to preproject conditions. Three years of invasive species control would be performed along the pipeline route to facilitate native species' success. Routing would minimize wetlands impacts on J.D. Murphree WMA, and directional drilling would minimize impacts to the Sabine Island WMA. Permanent impacts to wetlands would be mitigated through the following actions:

- creation of approximately 244 acres of vegetated wetland within the J.D. Murphree WMA;
- purchase of an 829-acre tract (195.5 acres forested wetlands, 7.6 acres emergent and scrub shrub wetlands, 18.8 acres forested riparian corridor, and 603.2 acres upland mixed-age pine stands) adjacent to the Big Thicket National Preserve; and
- purchase of 50 acres from The Nature Conservancy's Southwest Louisiana Pine Wetland Mitigation Bank to compensate for the forested wetland impacts within the Calcasieu River watershed.

The Golden Pass projects would affect just over six marshland acres designated as EFH for several life stages of red drum, Spanish mackerel, and white and brown shrimp. Deep, open-water EFH may be created by berth and marine basin dredging, providing habitat for some lifestages of some species. Of 15 potentially occurring federally and State-listed threatened and endangered species, the projects may affect only the red-cockaded woodpecker.

Thirty-three residences are within 1 mile of the proposed LNG terminal. Visual and land use impacts would occur in limited areas; however, Golden Pass would implement special construction techniques to

minimize land use impacts to affected residences. The Texas State Historic Preservation Officer (SHPO) has concurred that no historic properties would be affected by the LNG terminal; however, the pipeline system consultation is not complete. Investigations and consultation indicate that buried cultural resources and the viewshed and cultural landscape of historic structures may be affected by the pipeline system.

The following plans would be implemented to minimize impacts to potentially affected resources:

- Spill Prevention, Containment, and Countermeasures Plans;
- Storm Water Pollution Prevention Plan;
- Upland Erosion Control Plan;
- Revegetation and Maintenance Plan;
- Wetland and Waterbody Construction and Mitigation Procedures; and
- Aquatic Resources Mitigation Plan.

The Golden Pass LNG and Pipeline impacts summary is presented in Table 4.16-1, in comparison to the SNWW CIP and other past, present, and reasonably foreseeable projects.

4.16.3.11 Kinder Morgan Louisiana Pipeline

Kinder Morgan Louisiana Pipeline LLC has obtained authorization to construct and operate a 140-mile pipeline system in Cameron, Calcasieu, Jefferson Davis, Acadia, and Evangeline parishes, Louisiana (FERC, 2006a; 2007). The proposed Kinder Morgan Louisiana Pipeline is designed to transport regasified natural gas from the Sabine Pass LNG Terminal to various intrastate and interstate natural gas pipeline systems, delivering a peak day capacity of not less than 3,395,000 decatherms.

The pipeline system would consist of three pipelines and associated pipeline support facilities, including pig launchers and receivers and metering equipment. Leg 1 of the pipeline consists of approximately 130 miles of 42-inch-diameter pipeline originating at a receipt point within the Sabine Pass LNG Terminal and terminating at an interconnection with an existing Columbia Gulf Transmission interstate pipeline in Evangeline Parish, Louisiana. Leg 2 is an approximately 0.4 mile of 36-inch-diameter pipeline originating at a receipt point in the Sabine Pass LNG Terminal and terminating at an interconnection with the existing Natural Gas Pipeline Company of America north of the LNG terminal. The third pipeline originates at the termination point of Leg 1 and would not have impacts within the SNWW study area. Fifteen new lateral pipelines from the proposed pipeline interconnecting sites to existing interstate pipelines are expected to be constructed by separate entities.

The FEIS was issued in April 2007 (FERC, 2007). Specific resource impact information for the Kinder Morgan Louisiana Pipeline is included in Table 4.16-1. The corridor for Leg 1 is located in the SNWW study area; it commences from the Sabine Pass LNG terminal, proceeds north across Sabine Lake, up the Sabine River, and then turns eastward along the GIWW. The corridor in Sabine Lake was designed to avoid impacts to the extensive oyster reefs near Blue Buck Point and does not impact other oyster reef or habitat. Pipeline construction was expected to result in permanent impacts to 0.8 acre of brackish marsh in

the SNWW study area. Compensatory mitigation for these wetland impacts consisted of marsh restoration and preservation through the creation of 5,511 linear feet (2.53 acres) of wave-dampening terraces.

4.16.3.12 Jefferson County Drainage District No. 6 Taylor Bayou Flood Reduction Project

The Jefferson County Drainage District No. 6 (JCDD6) received a Department of Army permit in 2007 to construct flood control improvements to Green Pond Gully, Willow Slough, and Taylor Bayou, southwest of the city of Beaumont, in Jefferson County, Texas (USACE, 2006e, 2007c). Actions will include regional detention and levee construction, channel improvements, and the construction of a diversion channel (known as the Needmore Diversion Channel) from near the confluence of the North and South Forks of Taylor Bayou south to the GIWW. The Green Pond Detention Basin, levee construction, channel modifications, and Needmore Diversion Channel will be undertaken as part of flood reduction measures for the Taylor Bayou watershed. The Green Pond Detention Basin will be a 9,000-acre, aboveground detention facility located between Lawhorn Road, Farm-to-Market Road 365, South China Road, and Gallier Canal, with a maximum storage capacity of 15,000 acre-feet. The Needmore Diversion Channel is a 63,000-foot-long, 14-foot-deep, 200-foot-wide bottom channel within a 1,000-foot-wide ROW extending from near the confluence of the North and South forks of Taylor Bayou to the GIWW. Rectification of several man-made channel restrictions are included along portions of the North Fork of Taylor Bayou at Craigen Road, SH 124, IH 10, between Crystal Lakes, and between IH 10 and Green Pond Gully to restore and improve the flood flow characteristics of the waterway. The project will result in the direct impact to 692.4 acres of jurisdictional wetlands and 337.2 acres of nonjurisdictional low-to-high-quality forested and medium-to-high-quality herbaceous wetlands.

To offset impacts for the project, the JCDD6 has agreed to preserve 538 acres of wetlands adjacent to Spindletop Bayou and an additional 1,926 acres of forested wetlands and uplands within the Green Pond facility. An additional 7,000 acres will have restricted land use to preserve the area from development. A total of 44 acres of wetlands and riparian forest within or adjacent to the Needmore Diversion (40 acres of wetland shelf within the channel and 4 acres of riparian wooded corridor along the east border of the channel from Taylor Bayou south to Willow Slough) will also be created. In total, mitigation will consist of the preservation of approximately 2,464 acres of wetlands and wetland forests and the creation of 44 acres of wetlands and riparian forest to compensate for impacts to approximately 692 acres of jurisdictional waters and wetlands. To ensure that impacts to water quality in Taylor Bayou are minimized, the project design includes a flap gate structure at the Needmore Diversion Channel's south end to eliminate the possibility of saltwater intrusion in periods of reduced freshwater inflows and during storm surge events. In addition, the diversion channel's input from the South Fork of Taylor Bayou will be controlled to take only floodwaters above elevation 5.2 feet mean sea level ensuring that normal flows of Taylor Bayou are not impacted and only severe flood events are reduced in size and duration by the proposed diversion channel. At issuance, all required Federal, State, and/or local authorization or certifications had been obtained except for water quality certification and coastal zone consistency certification. JCDD6 stated that the project is consistent with the Texas CMP goals and policies and would be conducted in a manner consistent with that program and that water quality certification would be obtained from TCEQ.

A historic properties investigation has been conducted within the permit area, and no sites determined eligible for or listed on the NRHP are within the permit area or affected area. No known threatened and/or endangered species or their critical habitats are likely to be adversely affected by the proposed work. The action is not anticipated to have a substantial adverse impact on EFH or federally managed fisheries in the Gulf. Specific resource impact information for the Taylor Bayou Flood Reduction Project is included in Table 4.16-1.

4.16.4 Reasonably Foreseeable Future Actions

4.16.4.1 Port Arthur LNG and Pipeline

Port Arthur LNG, L.P., and Port Arthur Pipeline, L.P., proposed construction of a new LNG import terminal and pipeline system in Jefferson County, Texas (FERC, 2006c). The facility includes LNG ship unloading berths, LNG storage and vaporization, and a new 73-mile, 36-inch-diameter natural gas pipeline system to deliver the natural gas to existing interstate and intrastate pipeline systems. The project was authorized by FERC in 2006 and would be constructed in two phases over approximately 10 years.

Geological resources would be minimally affected. Erosion control devices and plans would reduce shoreline erosion and flooding effects from storm events. Adverse effects to groundwater and water supplies are not anticipated. Impacts to surface waters would be primarily from the 6.7 mcy of material dredged for the LNG ship berths and turning basin, pumped to an existing DMPA onsite for beneficial reuse. Approximately 82 acres of land would be converted to open water. Fourteen areas would be horizontally directionally drilled to minimize potential adverse water quality effects from the pipeline crossing several major waterbodies.

Clearing and construction would impact 1,497 acres of palustrine, scrub-shrub, and forested wetlands; estuarine emergent marsh; coastal prairie/grasslands; coastal woodlands/upland forests; agriculture and pastureland; disturbed lands; and, open-water/channel shoreline habitats. Operational (permanent) vegetation impacts would include approximately 198 acres for the LNG terminal and 87 acres (forest to herbaceous conversion) for the pipeline. Construction of the proposed LNG facility and pipeline would result in impacts to approximately 391 acres of wetlands, of which 96 acres would be permanent (83 acres for LNG terminal facility and 13 acres for the pipeline). Approximately 13 acres of the pipeline system permanently impacted wetlands would be converted from forested to herbaceous cover. The remaining 295 acres of impacted wetlands would be restored and allowed to revegetate to preconstruction conditions.

The Port Arthur LNG terminal and pipeline projects would affect a total of 456 acres of estuarine and deep-water habitats designated as EFH for several life stages of red drum, Spanish mackerel, white and brown shrimp, and bonnethead shark (*Sphyrna tiburo*). Eighty-two acres of deep, open-water EFH may be created by berth and marine basin dredging, providing habitat for some lifestages of some species. Of 22 potentially occurring Federal- and State-listed threatened and endangered species, the projects are not likely to adversely affect any of these species or their designated critical habitats.

No residences occur within 1 mile of the proposed LNG terminal and three residences occur within 50 feet of the proposed pipeline work area. Land use and visual impacts are likely. Site-specific construction plans would be implemented to minimize effects to these residences during construction. No direct effects are anticipated to the private, State, and Federal recreation and conservation areas in the Louisiana or Texas. CZMP consistency determinations have been issued by Louisiana and Texas. Two cultural sites within the terrestrial portion of the proposed construction area have been assessed as potentially eligible for listing in the NRHP. Additionally, seven magnetic and/or acoustic anomalies have been detected where the pipeline would cross Sabine Lake. Studies and avoidance/mitigation measure planning efforts are in progress.

If unmitigated, direct and indirect emissions during the LNG terminal operation would exceed de minimis air quality conformity thresholds. Mitigation measures would be implemented, preventing increase of emissions with respect to future baseline emissions. Operational risks to public health and safety would be none to minimal, depending on the location and activity. The moving safety zone, moored vessel security zone at the terminal, and one-way traffic areas would affect other commercial and recreational traffic using the SNWW.

The following minimization and protection plans would be implemented to address unavoidable impacts:

- Spill Prevention, Containment, and Countermeasures Plans;
- Storm Water Pollution Prevention Plan;
- Upland Erosion Control Plan;
- Revegetation and Maintenance Plan;
- Wetland and Waterbody Construction and Mitigation Procedures;
- Aquatic Resources Mitigation Plan (primarily for wetlands); and
- LNG Vessel Management and Emergency Plan.

The Port Arthur LNG and Pipeline impacts summary is presented in Table 4.16-1, in comparison to the SNWW CIP and other past, present, and reasonably foreseeable projects.

4.16.4.2 East Texas Regional Water Plan

The 2007 Texas State Water Plan is the eighth water plan developed by TWDB as a part of its core mission to ensure that sufficient, clean, and affordable water supplies are available for the citizens of the State of Texas and that those water supplies foster a healthy economy and environment (TWDB, 2007). The plan was developed from May 2005 to August 2006 and approved in November 2006. The state plan includes participation from 16 regional groups (TWDB, 2007).

The ETRW Planning area includes all or part of 20 counties, from Beaumont, Port Arthur, and Orange counties north to Tyler County, spanning from the Texas-Louisiana border east to the Trinity River Basin boundary. Three surface water river basins (Sabine, Trinity, and Neches) and four aquifers (Gulf Coast,

Carrizo-Wilcox, Sparta, and Queen City) serve the water uses in the region. The Neches-Trinity Coastal Basin and approximately 1 square mile of the Cypress Creek Basin are also partially encompassed in the planning area. The 2006 ETRW Plan that was adopted as part of the 2007 Texas State Water Plan seeks to address a projected 41 percent increase in water demand from 2010 to 2060 through several strategies (TWDB, 2007):

- construction of a new reservoir, Lake Columbia (Eastex) on Mud Creek (tributary of the Angelina River) in Cherokee County, Texas (approximately 187,839 acre-feet);
- negotiated use of adjacent Region C surface water supplies, Toledo Bend Reservoir (existing), and Lake Fastrill (not yet constructed on the Neches River);
- expanded groundwater use based on long-term sustainability;
- municipal conservation through plumbing code implementation and public education to save over 20,600 acre-feet of water annually by 2060;
- City of Athens indirect reuse of wastewater discharge, returning a portion of treated wastewater to Lake Athens, the city's primary water supply; and
- policy recommendations.

The ETRW Plan is consistent with protection of agricultural, public, park, oil, gas, and coal production resources. The development of Lake Columbia and Lake Fastrill may affect several resource classes, including timber, State- and Federal-threatened and/or endangered species, water resources, and others; however, these reservoirs would not be within the SNWW project area. Lake Columbia is anticipated to inundate approximately 10,000 acres. Lake Fastrill would inundate approximately 24,950 acres, including a portion of the proposed USFWS North Neches NWR. Site-specific information to identify wetlands, bottomland hardwoods, ecologically significant stream segments, Sabine-Neches estuary freshwater inflow needs, cultural resources, and prime farmland sites is currently not available. Because specific resource impact information is not available at this time, strategies discussed in the ETRW Plan are not included in Table 4.16-1.

4.16.4.3 Port of Beaumont Intermodal Improvement Projects

Both the Southside and Northside intermodal improvements projects have received funding from the H.R. 3 Transportation Bill. The Southside Project would provide infrastructure modifications and facilities expansion for direct intermodal interchange, transfer, and access for the Port of Beaumont to improve access and operation capabilities. The project would include rail holding tracks and loading ramps, and would increase the port's railcar storage capacity by about 75 percent. Operational efficiency and security would be enhanced by relocating the interchange tracks to expanded facilities at the terminal (Port of Beaumont, 2005a).

The Northside Intermodal Improvements Project would fund development and construction of an access road to connect IH 10 to port-owned property on the north bank of the Neches River. Additional funding was received for a rail infrastructure improvement project under a Federal program designed to promote air quality and congestion reduction (Port of Beaumont, 2005b).

These projects, combined, are expected to:

- Enhance the port's capacity for railcars
- Improve the port's ability to handle military cargo
- Enhance security for military and other cargo
- Increase the efficiency of port operations
- Make downtown riverfront property available for commercial development
- Provide significant growth opportunities for development of the port's northbank property in Orange County, Texas

In addition to projects outlined above, additional Port of Beaumont improvements include:

- A general cargo wharf
- A new dock office
- A new building for the port's military customers
- Repairs of bulkheads and upgrades of lots
- New double layberth for military vessels and new 90,000-square-foot transit shed on the Orange County, Texas, side
- Extend main Harbor Island east wharf with new transit shed on Beaumont side – new 680-foot extension to Harbor Island wharf, and linking railroad tracks on the new wharf to existing tracks. Project is meant to relieve berth congestion at the terminal.

Specific resource impact information is not available at this time; therefore, the Port of Beaumont intermodal improvement projects' potential impacts are not included in Table 4.16-1.

4.16.4.4 Keith Lake Fish Pass Ecosystem Restoration Section 1135 CAP

Keith Lake Fish Pass is located in Jefferson County, Texas, approximately 15 miles south of Port Arthur and intersects SH 87. The pass is approximately 0.3 mile south of the GIWW and on the west bank of the Sabine-Neches Ship Channel south of Port Arthur. The pass connects Keith Lake to the Port Arthur Canal and is part of a drainage system that impacts about 60,000 acres of wetlands (10,000 acres of coastal marsh habitat) in McFaddin NWR, Sea Rim State Park, and J.D. Murphree WMA in the Neches River delta. At 10,000 acres, the Keith Lake watershed contains approximately 8 percent of existing Texas coastal estuarine marshes. Assuming no increase in the rate of marsh loss from the most recent estimates, approximately 3,460 acres (or 35 percent) of brackish marsh in the Keith Lake watershed would be lost during the next 50 years (USACE, 2002).

Area marsh has been adversely affected by saltwater intrusion and high-energy inflows resulting from an obsolete and unrefurbishable 1933 USACE structure and the impacts of the 1974 USDA "water exchange pass" project, now known as the Keith Lake Fish Pass. The pass was created to improve water circulation into the Salt Bayou Drainage system and was a 3,600-foot straight-line canal, 155 feet wide and 5 feet

deep with 2:1 side slopes. Higher-than-expected water volume and velocity have eroded the pass to 240 feet wide and 7 feet deep since 1977. The cut has improved the amount and variety of marine species in the area; however, the marsh system has been degraded by high salinity levels and hydraulic energy impacts from the ship channel.

Emergent coastal wetland habitats and wetland soils loss has been accelerated in Jefferson County, Texas. Open water is formed when salt-intolerant vegetation dies and the underlying organic topsoil material erodes away before the succession of salt-tolerant vegetation can take place. The area is vital nesting and brooding habitat for mottled ducks, with an increasing amount of nesting by fulvous whistling duck (*Dendrocygna bicolor*) and black-bellied whistling ducks (*D. autumnalis*). Several species of migratory birds traveling the Central Flyway use the area as a rest stop or staging area.

Jefferson County, Texas, and USACE, Galveston District, with support from the TPWD, GLO, and TWDB, are studying ways to reduce the amount of saltwater intrusion and decrease high-energy inflows entering the marsh, thus slowing marsh habitat loss. The goal of the study and any recommended conservation measure is to sustain and protect over 60,000 acres of brackish coastal marshes within the Saltwater Bayou Watershed, including approximately 2,600 acres in the Keith Lake system. As yet, undetermined measures must assist in achieving the objective presented in the Salt Bayou Project Joint Management Concept Plan for Sea Rim State Park, McFaddin NWR, and J.D. Murphree WMA (August 1990). The TPWD is developing alternatives and potential impact information for the Keith Lake Fish Pass project is not currently available to include in Table 4.16-1.

4.16.4.5 Sabine Pass to Galveston Bay Shoreline Erosion Project

The purpose of the Sabine Pass to Galveston Bay Shoreline Erosion Feasibility Study is to address the severe shoreline erosion occurring along the upper Gulf Coast of Texas between the SNWW (Sabine Pass) and the Galveston Entrance Channel (Galveston Bay) and the entire Gulf shoreline of Galveston Island (USACE, 2004b). The study area consists of approximately 90 miles of Gulf shoreline in Jefferson, Chambers, and Galveston counties along the upper Texas coast from Sabine Pass to San Luis Pass at the western end of Galveston Island. The major problems identified in the reach to the north of Galveston Bay result from shoreline erosion and include the potential destruction of nationally significant wetlands, loss of land and damage to homes and commercial properties, and significant damage to SH 87. The Sabine Pass to Galveston Bay Shoreline Erosion Project is in the planning stages, and no information regarding potential impacts is available for Table 4.16-1.

4.16.4.6 Toledo Bend Reservoir Relicensing

Toledo Bend Reservoir is located on the Sabine River in Texas and Louisiana and forms a portion of the boundary between the two states. The reservoir is approximately 65 miles long and inundates land in Newton, Sabine, Shelby, and Panola counties, Texas, and Sabine and DeSoto parishes, Louisiana. Toledo Bend Reservoir has 1,200 shoreline miles, normally covers an area of 185,000 acres, and has a controlled storage capacity of 4,477,000 acre-feet. The reservoir was constructed by SRA-TX and Sabine River Authority of Louisiana (SRA-LA) for water supply with secondary uses of hydroelectric power

generation and recreation. On December 12, 2002, the SRA-TX approved an application to TCEQ to amend Certificate of Adjudication No. 05-4658 to include the right to divert 293,300 acre-feet per year of the available portion of the stored Texas water from Toledo Bend Reservoir for multiple use (municipal, industrial, agricultural) (SRA-TX and LNVA, 2006). TCEQ is mandated to consider environmental flows (instream and freshwater needs) during permit evaluations for new reservoirs or amended water rights.

The SRA-TX and SRA-LA have initiated the process to renew the FERC license that allows the generation of hydroelectric power. The current FERC license expires October 14, 2013. The intention of SRA-TX and SRA-LA is to continue current operations as a hydropower peaking unit during the summer months. However, as water supply sales increase, hydropower generation may be reduced.

The Authorities submitted a Notice of Intent to file an application for a new license and request designation as non-Federal representatives in September 2008, and a Proposed Study Plan in July 2009 to FERC (SRA, 2009), but specific resource impact information is not available at this time; therefore, the Toledo Bend Reservoir Operating Plan and potential FERC relicensing potential impacts are not included in Table 4.16-1.

4.16.4.7 Cameron Parish Dredge Project

Cameron Parish Gravity Drainage District #7 proposes to dredge 6,970 feet of Johnson's Bayou to remove debris and sediments deposited during Hurricane Ike. Material would be placed into an upland confined PA. No wetland impacts would occur. Also, preliminary coordination determined no substantial effects, and no effects to EFH and threatened or endangered species, respectively. Information available is minimal, and this project is not included in Table 4.16-1.

4.16.4.8 Taylor Bayou Canal Seven Gate Saltwater Barrier

Located at the existing Taylor Bayou Canal Seven Gate Saltwater Barrier at the intersections of the Taylor Bayou Canal and Taylor Bayou, the SNND proposes to construct four additional saltwater gates. This effort would include 137-x-40-foot pile-supported slap and gate walls, 98 feet of concrete wing wall, 3,000 cy of riprap, 6,500 feet of 8-inch conduit, replacement of the control building (which was destroyed by Hurricane Ike), and 50,000 cy of material acquired from dredging. Impacts would involve 2.3 acres of wetland. Information available is minimal, and this project is not included in Table 4.16-1.

4.16.4.9 Study Area Habitat Protection and Restoration Actions

Four projects are currently planned in the study area that target protection and restoration of wetlands and include the Star Bayou/Rose City Mitigation Bank, and three restoration and enhancement projects at McFaddin NWR.

The Star Bayou/Rose City Mitigation Bank would require dredging of Star Bayou (400-x-200-foot area) to acquire 26,000 cy of material. This material would be used to construct, restore, and enhance wetland areas at part of another ongoing mitigation effort in the Rose City Marsh Complex Habitat Restoration

Area. Although temporary impacts may occur from dredging, the project would result in long-term beneficial effects to wetlands in the study area.

The USFWS proposes to rehabilitate earthen levees and install water control structures at two locations on McFaddin NWR. The first project, Big Hill Unit Restoration, would involve acquisition of 534,000 cy of dredged material for 8,900 feet of levee rehabilitation along Lost Bayou. Also, 400 feet of new levee would be created. Water control structures would be used to manipulate freshwater inflows from Willow Slough, and general aquatic habitat management. Although 0.18 acre of wetlands would be filled through these actions, the overall long-term effect of the project would result in net benefits to the study area wetland complexes.

The second project, Clam Lake Restoration Project, would create a 625-square-foot levee with control structures within wetlands. Material for levees would come from immediately adjacent areas. Although the project would fill 2.94 acres of marsh and excavate another 3.67 acres, project goals include saltwater intrusion protection for 1,500 acres of wetlands within the Wild Cow Bayou Unit, restoration of 248 acres of marsh, and enhancement of 730 acres of wetlands adjacent to 10-mile Cut.

The third project on McFaddin NWR would involve the placement of 12,132 linear feet of graded rock serving as a breakwater structure for protection along an eroded shoreline along the north side of the GIWW. The breakwater would be approximately 25 feet wide at the base, 3.5 feet high in the center, 20 to 40 feet from the existing eroded bank, resulting in 43,570 cy of fill below the mean high tide line. No direct wetland impacts would occur, and the breakwater may have beneficial effects to adjacent wetlands.

Information on these four protection and restoration projects was limited and only included wetland impacts (or indirect effects) that would all be beneficial to study area wetland complexes. No other information regarding potential project effects associated with the cumulative impacts analysis was available, and thus these projects are not included in Table 4.16-1.

4.16.4.10 Sabine Lake Oil and Gas Projects

Eight oil and gas projects are planned for Sabine Lake that would impact regulated waters and include four exploration wells (El Paso E&P Co.), three flowlines (El Paso E&P Co.), and one oil and gas drilling, production, and transportation facility (Shoreline Southeast LLC).

Four exploration wells occurring in Sabine Lake would involve minimal discharge of materials into regulated waters. All four projects combined are anticipated to impact a total of 0.14 acre of bay bottom, and no mitigation is proposed. These projects would not cause long-term detriment to the study area's aquatic resources.

The three proposed flowlines in Sabine Lake are 6-inch diameter and would be jetted into place about 3 feet below mudline. All of these projects combine for a total of 0.43 acre of impacts to bay bottom, and no mitigation is proposed. These projects would not cause long-term detriment to the study areas aquatic resources.

Information on these Sabine Lake oil and gas projects was limited and only included regulated waters impacts. No other information regarding potential project effects associated with the cumulative impacts analysis was available, and thus these projects are not included in Table 4.16-1.

4.16.5 Cumulative Impacts Results

The following sections provide discussion of the potential cumulative impacts summarized in Table 4.16-1, which may result from the Preferred Alternative combined with past, present, and reasonably foreseeable actions within the Study Area.

4.16.5.1 Ecological and Biological Resources

Ecological and biological resources are expected to experience short-term temporary adverse effects resulting from increased turbidity, disturbed bottom, and placement of dredged material during construction and maintenance operations. Some permanent impacts are expected to wetlands; however, these are to be offset by the benefits of BU features and compensatory mitigation for each project considered in this assessment.

4.16.5.1.1 Wetlands

All projects considered in this analysis have compensatory measures and/or minimization or mitigation plans to address wetland loss and/or impacts. In total, the restoration activities, purchased-and-protected areas, and created wetlands offset impacts within and adjacent to the project area, resulting in a net gain of wetland acres (approximately 10:1). This net gain is not always type-for-type; conversion of forested wetlands is considered permanent loss given the time it takes to recover mature forested wetlands and the high potential for invasive species colonization. Overall, cumulative impacts to wetlands are not expected to be significant with implementation of the Preferred Alternative's Mitigation Plan.

4.16.5.1.2 Bottomland Forest

The Preferred Alternative causes no loss of forested wetland acreage (either swamp or bottomland hardwood) throughout the study area. Salinity impacts to the forested wetlands on the Neches River are avoided by DMMP hydrologic and marsh restoration on the river. Salinity impacts to swamps on the Sabine River are related to a minor decrease in the function of the ecological system, as conservatively estimated in the WVA model (Appendix C) by comparison to maximum growth under optimal conditions. The loss in function is considered to be negligible since projected salinity levels are within the tolerance levels of the swamps.

4.16.5.1.3 Terrestrial Vegetation

Terrestrial vegetation impacts occur on most projects considered in this cumulative impacts assessment. Clearing for construction, ROW maintenance (trimming and mowing), prescribed burning, conversion to open water, and dredged material placement may affect terrestrial vegetation. The conversion of forested areas to herbaceous cover or open land or water is the most significant impact as the time to recover forest

vegetation communities is significantly longer than that to recover herbaceous habitats, without active intervention. Additional impacts stem from the invasion of non-native fast-colonizing species in disturbed areas.

Upland vegetation on any PA would be covered by dredged material deposition; however, this vegetation consists of mostly opportunistic species, which would recolonize easily once the site has been dewatered. Herbaceous cover impacted typically recovers in a reasonable timeframe with the implementation of erosion control measures. Several of the projects considered in this assessment have invasive species monitoring and control measures, forest land impact minimization actions, or net beneficial actions (such as native prairie restoration and prescribed burning or replanting disturbed areas), which can reduce the loss of native terrestrial vegetation.

In the Preferred Alternative, a total of 86 acres of marsh would be converted to upland confined PAs. The loss of biological function and acreage is fully compensated by DMMP restoration plans resulting in a net increase in coastal marsh acreage in the project area. Cumulatively, the SNWW does not contribute to terrestrial vegetation loss or impacts.

4.16.5.1.4 *Submerged Aquatic Vegetation*

Physical impacts to SAV may result from projects augmenting marshlands, protecting shoreline, and affecting wetlands. Additionally, increased salinity resulting from the Preferred Alternative and other projects included in this analysis could affect submerged vegetation and related habitats. Marsh restoration and DMMP restorations and nourishment measures offset adverse effects associated with the Preferred Alternative. Additionally, the Preferred Alternative would increase the amount of shallow-water areas and reduce wave action in certain areas, making conditions more conducive to SAV recruitment and growth, effectively resulting in a net increase of SAV in the study area.

4.16.5.1.5 *Plankton and Benthos*

Placement of dredged material in offshore placement sites would bury benthic organisms incapable of escaping or burrowing up through the dredged material. Only the dredge projects considered in this document would affect benthic organisms in the study area through this method. Recolonization is expected; however, benthic community structure and abundance may be altered as early successional recovery stages are not necessarily the same as those buried by excavated materials. Additionally, repeated localized dredging in one place may prevent full benthic community development and shift community structure since overall benthic impacts affect a very small percentage of water bottom in the study area. It is possible that the new community would still provide adequate food source for the aquatic community. Excavation would increase turbidity levels and may provide cover benefits to certain organisms. In general, all projects considered in this cumulative impacts assessment have the potential for short-term negative impacts; none of the coverage or turbidity impacts are expected to adversely affect benthic organisms or plankton. Minimization and mitigation measures to restore, enhance, and augment estuarine environments and shorelines would likely provide a net benefit to these organisms.

4.16.5.1.6 *Essential Fish Habitat*

The Sabine Pass LNG and Pipeline, Golden Pass LNG and Pipeline, and the Preferred Alternative have the potential to affect EFH through excavation and dredged material placement in open-water PAs. These activities could affect food sources in EFH and increase turbidity. Dredged material associated with these projects that would be placed in open-water sites would not contain contaminants, as determined by the EPA and USACE review and permitting. Additionally, loss of shallow-water habitats from some of the projects' activities considered in this analysis may adversely affect EFH for lifestages of several species; however, the Preferred Alternative's proposed actions would result in a net benefit to EFH through marsh creation and reduced impacts to SAV.

4.16.5.1.7 *Threatened and Endangered Species*

Most of the projects included in this assessment are not expected to or did not significantly impact federally listed threatened or endangered species. In general, the species potentially most affected are sea turtles during hopper dredging activities and piping plover during dredged material placement. While turtle mortality is a possibility, the USACE-NMFS sea turtle avoidance and documentation procedures established for hopper dredging activities and applied during all projects using hopper dredges significantly reduce the likelihood of adversely affecting protected sea turtles. In relevant projects' assessment documents, piping plover populations and designated Critical Habitat were determined to not be affected. Food species potential impacts are short term and recoverable, based on all assessments.

4.16.5.2 *Physical and Chemical Resources***4.16.5.2.1 *Air Quality***

Objectionable odors (mercaptan, hydrogen sulfide) may result from construction and maintenance excavation and/or dredging of sediments containing high concentrations of organic matter. Several of the projects in this assessment document that NO_x and CO emissions would occur during dredging and/or excavation equipment activities. These activities are considered temporary and intermittent. Most of the projects considered in this analysis lie within or adjacent to the BPA Ozone 8-hour Nonattainment Zone, which includes Jefferson and Orange counties. All projects within the study area with the potential to affect air quality must conform to the TCEQ SIP. Coordination and compliance with the TCEQ and EPA would result in no significant cumulative impacts to air quality within the study area.

4.16.5.2.2 *Noise*

Temporary noise impacts would result from construction and maintenance dredging activities, which would change with location, depending on the section being dredged. It is unlikely that dredging would occur for more than one of the reviewed projects at one time.

4.16.5.2.3 *Topography, Bathymetry, Soils, Sediment Quality*

Terrestrial and marine contours would be permanently changed in construction and maintenance dredging projects, but not by most of the LNG and pipeline projects (which state that temporarily impacted project areas would be returned to preconstruction contours). Topography and bathymetry would be cumulatively changed (increased) in upland and offshore PAs as a result of dredged material deposition. Most soil impacts in all projects are considered temporary and/or recoverable given best construction and erosion control practices, including protection measures implemented as a result of stormwater permitting and water quality certification. No significant impacts to sediments or from sediments are expected, except that there may be an increased risk of spill during construction of the reasonably foreseeable projects included in this analysis.

4.16.5.2.4 *Water Quality*

For those projects that include dredging activities, dredging and placement operations are expected to temporarily degrade water quality in the project vicinity through increased turbidity and nutrient releases from the sediment. Dredging placement is not expected to affect water quality as much of the construction and maintenance material would be used beneficially and the rest would go into PAs. For the most part, salinity increases for the projects considered in this analysis were negligible, within natural fluctuation ranges, or offset by mitigation or protective measures. Increased ship traffic in the study area could increase the risk of a toxic spill; however, that risk is offset by the increased safety in the channel expected from the widening and deepening of the SNWW. LNG and pipeline projects presented in this analysis would implement water quality control measures (soil erosion prevention and control, spill prevention and response plans, and runoff containment).

4.16.5.2.5 *Sediment Quality*

None of the projects reviewed for this assessment are expected to impact sediment quality. For projects where contaminant spills or leaks are a potential adverse effect, prevention and response plans would be implemented. None of the sediment analyses conducted for this project identified cause for concern.

4.16.5.2.6 *Shoreline/Bank Erosion*

Shoreline fluctuations along the Gulf, natural waterways, and constructed navigation channels within the study area are ongoing. While some of the erosion and change can be attributed to natural causes, these can be exacerbated by unmitigated wave action, destabilized shoreline, loss of vegetation, and other factors. Such factors are generally a result of increased frequency and size of ship traffic (enhancing wave action), conversion of shallow gradual water – shoreline transition areas to deeper, open water, and upland activities and development, which can increase runoff and erosion. The Preferred Alternative is expected to reduce the number of vessel trips when compared to the number of trips expected with the No-Action Alternative, thus reducing the potential for increased wave action. Some of the habitat restoration projects reviewed are expected to decrease shoreline erosion in small, localized areas.

Additionally, beach and shoreline nourishment as part of projects' mitigation measures, slow the rate of erosion and shoreline loss in specific areas.

4.16.5.3 Cultural and Socioeconomic Resources

4.16.5.3.1 Economy

All of the channel enhancement, maintenance, LNG, and pipeline projects are expected to have a net benefit to the regional economy.

4.16.5.3.2 Recreational Facilities/Areas

Although some of the projects considered in this analysis create conditions that contribute to shoreline erosion, vegetation loss, and land use impacts throughout their project areas, many public recreation lands owned by the USFWS (Texas Point NWR, McFaddin NWR), TPWD (Tony Houseman WMA, J.D. Murphree WMA, units of the Lower Neches River WMA), TxDOT, and LDWF (Sabine Island WMA) benefit from many of the mitigation and minimization measures. Cumulative and coordinated wetland enhancement and restoration efforts on public lands, increased access to public waters, and habitat creation contribute to habitats, which support recreational activities (bird watching, hunting, fishing). The Preferred Alternative's DMMP restoration measures and marsh mitigation would result in a net benefit to those recreational areas by creating substantial marsh acreage.

4.16.5.3.3 Commercial and Recreational Fisheries

None of the projects reviewed would adversely impact commercial or recreational fisheries (see also subsection 4.16.5.1.6, Essential Fish Habitat). The Preferred Alternative DMMP and marsh mitigation measures would provide a long-term net benefit to fisheries by the creation of new nursery areas.

4.16.5.3.4 Ship Accidents/Spills

The LNG and pipeline projects, in combination with this project's Preferred Alternative, are expected to increase the number of large vessels using the area's navigable waterways (i.e., SNWW, GIWW, Neches River). It is anticipated that the deepening of the SNWW under the Preferred Alternative, in combination with the other dredging and port projects reviewed in this analysis, would have a net benefit on shipping safety; therefore, the potential for accidents and spills is likely to decrease.

4.16.5.3.5 Public Health and Safety

Most of the LNG and pipeline projects, in addition to this project, increase the potential for large ship traffic in inhabited areas along project area waterways. No adverse impacts are anticipated for these projects, although, small recreational craft traffic and other channel users may experience delays and reduced mobility with increases in ship traffic throughout the project area.

4.16.5.3.6 Cultural Resources

Activities associated with any of the reviewed projects have the potential to adversely affect unknown cultural resources by altering the integrity of the location, design, setting, materials, construction, or association contributing to a resource's significance (related to National Register eligibility criteria). No known sites on the NRHP would be impacted by projects reviewed in this analysis; however, projects that are eligible under NRHP criteria have been identified and could be affected. Discovery of potentially protected features/sites during construction and maintenance activities would require verification and further coordination with the SHPO.

4.16.6 Conclusions

Cumulative impacts from past, existing, and reasonably foreseeable future projects, along with the Preferred Alternative, are not expected to have significant adverse effects within the study area. Many of the projects within the study area are part of the continued port and shipping industry development. Some projects considered in this assessment are beneficial to certain natural resources (predominantly wetlands and the species dependent on them) and add to the diversity and health of publicly held recreation and conservation areas, migratory bird habitats, EFH, and other sensitive coastal resources. Impacts associated with the Preferred Alternative have been fully offset by compensatory mitigation measures. In addition, the Preferred Alternative would have net beneficial effects on wetlands, water quality, and SAV with the construction of extensive BU features on the Neches River and the Gulf shoreline.

5.0 MITIGATION PLAN

This chapter discusses the evaluation of mitigation measures for the Preferred Alternative, and presents the Recommended Mitigation Plan that has been developed in consultation with the appropriate resource agencies. Mitigation is necessary because unavoidable impacts to nationally significant intertidal wetlands remain after efforts to minimize impacts were exhausted. Net project impacts and benefits after application of DMMP BU feature benefits, are summarized in Table 5.1-1.

Table 5.1-1
Net Project Impacts and Benefits by Average Annual Habitat Units

	Bottomland Hardwood	Swamp	Fresh Marsh	Intermediate Marsh	Brackish Marsh	Saline Marsh	Totals
Preferred Alternative Impacts (negative AAHUs)							
Texas	0	-2	-6	-8	-31	-	-12
Louisiana	0	0	-8	-571	-3	-7	-709
Total Project Impacts	0	-2	-96	-619	-54	-2	-121
Preferred Alternative Benefits (positive AAHUs)							
Texas	0	0	284	433	235	222	1,068
Louisiana	0	0	0	0	0	210	210
Total Project Benefits	0	0	178	433	235	432	1,278
Net Project Benefits or Impacts (AAHUs)	0	-2	-6	-186	81	390	-43

This chapter is divided into six sections: Section 5.1 summarizes Federal policy and regulatory requirements for mitigation plans, and mitigation objectives that were followed in the plan's development. Section 5.2 provides a brief history of the development and coordination of the Recommended Mitigation Plan, including application of the HS and WVA models. Section 5.3 summarizes FWP impacts of the Preferred Alternative after benefits of the DMMP BU features have been applied. Section 5.4 discusses the evaluation of alternatives for compensatory mitigation, and presents the cost effective/incremental cost analysis (CE/ICA) of mitigation alternatives. Section 5.5 describes the Recommended Mitigation Plan that compensates for unavoidable salinity impacts.

5.1 SUMMARY OF PROJECT IMPACTS

Unavoidable indirect impacts of the Preferred Alternative in Louisiana remain after all benefits of the DMMP BU features have been applied. Although the SNWW channel is located primarily in Texas, large indirect impacts may occur due to small increases in salinity levels causing an increase in wetland loss and a decrease in biological productivity in aquatic habitats of both Texas and Louisiana. Remaining impacts in Louisiana may affect approximately 182,000 acres (284 square miles) of tidal, emergent marsh habitats, resulting in a total loss of 1,709 AAHUs (a 1.8 percent loss from the FWOP condition). The important ecological functions of the wetlands in the affected area would decline as increases in salinity levels affect marsh communities, and the fish and wildlife that depend upon this habitat. The slightly

higher salinities may lead to the loss of 691 acres of marsh, associated SAV and shallow-water habitat, as stressed emergent marsh converts to open water. Some direct effects of the Preferred Alternative's navigation improvements were not captured and quantified by the WVA modeling. However, a full impact analysis has been performed for these effects, and they have been determined to be minor and temporary. These impacts include (1) impacts to water quality and benthic organisms and their Gulf, estuarine, and riverine water-bottom habitats resulting from dredging to construct the navigation improvements, the creation of new offshore ODMDSs, the borrow area trench for Willow Bayou mitigation areas, and marsh restoration in shallow, open-water areas; (2) potential dredging impacts to bottom-feeding and pelagic organisms such as sea turtles; and (3) potential impacts to shoreline birds and their habitat from the placement of maintenance material on the Gulf shoreline.

Potential adverse effects to threatened and endangered sea turtles during hopper dredging to construct the Entrance Channel would be addressed by the adoption of reasonable and prudent measures to avoid impacts that are established in the BO for the CIP. No other adverse effects to threatened and endangered species have been identified.

5.2 MITIGATION PLANNING

In the evaluation of alternatives for the SNWW CIP, ecological impacts of the Preferred Alternative have been avoided and minimized to the greatest extent practicable, as required by national policy (Section 906(d), WRDA 86), national environmental laws and executive orders, and the USACE regulations (ER 1105-2-100). The results of proposed actions to minimize impacts are presented in detail in Chapter 2. Unavoidable impacts to significant resources that remain are compensated to the extent justified as described below.

5.2.1 Compliance with Federal Requirements

Implementation guidance for Section 2036(a) of WRDA 07 (Mitigation for Fish and Wildlife and Wetlands Losses), issued August 31, 2009, requires that the Preferred Alternative contain a specific plan to mitigate fish and wildlife losses since it has been determined that the Preferred Alternative would have unavoidable impacts after benefits of the DMMP BU features are applied. Adverse impacts to ecological resources that are caused by a proposed project must be avoided or minimized to the extent practicable, and remaining unavoidable impacts must be compensated to the extent justified. The Preferred Alternative must contain sufficient mitigation to ensure that the CIP would not have more than a negligible adverse impact on significant ecological resources.

Central to this requirement is the determination of significance, as mitigation is required only for impacts to significant resources. Significance must be based upon the contribution of the resource to the Nation's economy and technical, institutional, and/or public recognition of the value of the resource. Criteria for determining significance include, but are not limited to, scarcity or uniqueness of the resource from a national, regional, State, or local perspective. The USFWS Habitat Stewardship Program has identified estuarine intertidal emergent wetlands as one of three nationally recognized "scarce and vulnerable"

wetland habitats. These are the same sensitive wetland habitats (saline, brackish, intermediate, and fresh marsh) addressed by the Mitigation Plan.

These habitats are also considered significant and vulnerable by the CWPPRA, Public Law 101-646 (Title III) and the North American Waterfowl Management Plan (2004). The Texas Land and Water Resources Conservation Plan (TPWD, 2005e) recognizes the Gulf coastal marshes in Tier One of high priority ecoregions and considers these habitats to be the most threatened of the State's two high diversity ecoregions. Significant marsh habitat on the Lower Neches River and along the Texas Point shoreline have been declared "critical erosion areas" by the Texas Coastwide Erosion Response Plan. Furthermore, coastal marshes in the Louisiana portion of the study area are recognized as threatened and vulnerable by the Louisiana Coast 2050 Plan (LCWCR/WCRA, 1998), the LCA Ecosystem Restoration Study (USACE, 2004a), and the Louisiana Comprehensive Master Plan (LCPRA, 2007; USACE, 2008a).

Although mitigation technically includes avoiding and minimizing project impacts to ecological resources, this chapter focuses on actions that are typically considered compensatory mitigation, i.e., rectifying impacts by restoration, preservation, or maintenance activities during the life of the project, or replacing fish and wildlife resources that have been adversely affected. Replacements are generally made "in-kind," but substitutions, or replacements "out-of-kind," are also acceptable mitigation if they are at least equal in value and significance to the resources lost. The purchase of credits from mitigation banks established by others was considered as an option in providing compensatory mitigation for the Preferred Alternative. Only two existing mitigation banks were identified in the lower Sabine and Neches watersheds. Neither was available for use as the credits from one were sold out and the other was developed for the exclusive use of a State agency.

The WVA model (Appendix C) quantifies impacts to all habitats in the study area and provides a means to establish the appropriate amount of compensating mitigation. Recommended mitigation measures must be justified by CE/ICA, which identifies the least-cost mitigation plan by demonstrating that the value of the last increment of losses prevented, reduced, or replaced is at least equal to the costs of the last added increment.

The USACE regulations (ER 1105-2-100) recognize wetland resources for special consideration in mitigation planning, and these are the type of resources that could suffer long-term impacts from the Preferred Alternative. Impacts to wetlands must be fully mitigated, and projects must meet the goal of no net loss of wetlands. The Mitigation Plan described below fulfills the special requirements for wetlands. These plans also contribute to multiagency regional plans (Louisiana Coast 2050; a TPWD regional management plan for J.D. Murphree WMA, Sea Rim State Park, Texas Point, and McFaddin NWR; and the North American Waterfowl Plan) by restoring and preserving scarce and vulnerable wetlands and wildlife habitat, and using dredged material beneficially to the greatest extent possible.

5.2.2 Compensatory Mitigation Objectives and Target

The following objectives were established to evaluate mitigation measures considered for the SNWW CIP. The objectives were developed by the USACE in consultation with the ICT.

- Minimize salinity impacts to the SNWW affected area
- Maximize the use of dredged material in marsh restoration measures
- Meet goal of no net loss of wetlands
- Replace lost habitat quality on a one-to-one basis as measured by AAHUs
- Replace habitats in-kind to the extent practicable
- Mitigate losses in the state where they occur
- Share dredged material from Sabine Pass equally between Louisiana and Texas

These objectives reflected the most significant expected impacts of the CIP, widespread interest in potential beneficial uses of dredged material, the national policy objective to prevent wetland loss, and the USACE requirements to fully compensate for unavoidable project adverse effects. The last objective is related to the fact that the CIP affects resources from two states. While this FEIS evaluates impacts on the SNWW coastal and estuarine system without regard to state boundaries, the mitigation plan complies, to the greatest extent practicable, with the CZMP for each state. Under the Coastal Zone Management Act (CZMA), states with approved coastal management programs have jurisdiction within their coastal boundaries to ensure compliance with their programs. The CZMA and its implementing regulations require that Federal activities comply to the maximum extent practicable with these programs. In Louisiana, the Louisiana State and Local Coastal Resources Management Act functions as the state coastal management program for CZMA purposes. Compensatory mitigation is used to offset any net loss of wetland ecological value after efforts have been made to avoid or minimize impacts. Furthermore, the CWPPRA requires Federal agencies to ensure that maintenance or modification of navigation projects be consistent with the purposes of the restoration plan submitted under CWPPRA. Louisiana has adopted a Coastal Wetlands Conservation Plan under this authority with a goal of no net loss of wetlands in coastal areas of Louisiana as a result of development activities. The proposed SNWW mitigation plan would provide additional compensatory mitigation beyond the total project loss of 843 AAHUs so that impacts in Louisiana would be compensated in that state. There is, however, a significant exception to this requirement. Federal lands are excluded from coverage under the CZMA, and this means that compensatory mitigation for impacts to Federal lands may be developed without regard to state boundaries.

Since the CZMA does not apply to Federal lands, excess Texas BU benefits could be used to compensate for impacts to Federal lands in Louisiana. The only lands affected by this exclusion are located in the Sabine NWR. While the Texas Point and McFaddin NWRs in Texas would also be affected by salinity increases associated with the project, two DMMP BU features (the Neches River and the Gulf Shore BU features) provide benefits that offset all project impacts in Texas (including impacts to both NWRs) and provide excess benefits of 656 AAHUs. The DMMP BU features fulfill Texas's CZMP requirements to

avoid and minimize impacts to the coastal zone, such that no compensatory mitigation for Texas state resources is needed.

Total SNWW project impacts to the Sabine NWR are –340 AAHUs. When these are removed from the total project impacts in Louisiana (–1,499 AAHUs), the mitigation target proposed for compliance with Louisiana’s CZMP is –1,159 AAHUs. Table 5.1-2 illustrates this calculation. Since all mitigation measures for the SNWW would be located in Louisiana, the new mitigation target would compensate for total project losses of –843 AAHUs by providing 1,159 AAHUs of compensatory mitigation.

Table 5.1-2
FWP Compensatory Mitigation Target for Louisiana

Units (AAHUs)	Texas	Louisiana	Project
Net FWP Benefits/Impacts			
Total Impacts (negative)	–12	–709	–121
Total BU Benefits (positive)	1,068	210	1,278
Net FWP Benefits (positive) or Impacts (negative)	656	–499	–43
Excess Texas Benefits Applied to Federal Lands (Louisiana)			
Excess Texas Benefits	656		
Sabine National Wildlife Refuge Impacts	–40		
Net Excess Texas Benefits	316		
Compensatory Mitigation Target			
Net Impacts by State and Project		–499	–43
Federal Impacts Compensated with Texas Excess Benefits		340	
FWP Compensatory Mitigation Target		–159	–43

5.3 **RESOURCE AGENCY COORDINATION OF THE
RECOMMENDED MITIGATION PLAN**

Since the primary environmental concerns are the interrelated issues of saltwater intrusion, marsh loss, and destruction of wildlife habitat and fishery nursery areas, the ICT formed two workgroups to oversee the development and application of models used to evaluate salinity changes and ecological effects of the CIP. The MW participated in the development and review of the HS model, and the HW participated in the selection and application of the ecological model. Both models played an integral role in the development of FWOP and FWP conditions and were used to compare the effectiveness of restoration and mitigation measures.

Any ICT agency interested in participating was invited to attend these workshop meetings. Representatives from the following agencies participated in one or both of the workgroups:

- USFWS Clear Lake (Texas) Field Office
- USFWS – Louisiana Field Office
- USFWS – Chenier Plain NWR complex
- USFWS – Sabine NWR

- NMFS – Galveston, Texas
- NMFS – Baton Rouge, Louisiana
- EPA Region 6
- GLO
- TWDB
- TPWD
- TPWD – J.D. Murphree WMA
- LDNR
- LDWF
- SRA-TX
- USACE (Galveston District and ERDC-CHL)

Concerns that a deeper navigation channel would bring higher salinity in the Sabine Lake estuarine system were addressed with a 3-dimensional HS model that predicts changes in salinity, circulation, and water elevation due to proposed channel improvements. The modeling was performed by the ERDC's CHL worked closely with the MW to calibrate and verify the base model for initial modeling. The modeling was revised in 2009 to incorporate changes resulting from external and USACE reviews. The MW reviewed the ERDC's model calibration and verification process, and the revised modeling results.

The SNWW ICT established the HW to apply the WVA model; representatives from 14 agencies regularly attended and agreed upon data used as inputs for the model. Over 30 ICT and workgroup meetings were conducted from 2001 to 2006, and one meeting was held in 2009. The USFWS-Louisiana Ecological Field Office provided assistance to ensure that WVA methodology (USFWS, 2002b) was followed properly and that WVA model Excel worksheets were being used appropriately. The USACE conducted an in-house quality check for worksheet accuracy. In 2009, changes in the proposed project and HS modeling necessitated that the WVA modeling be revised. Due to schedule constraints, the USACE performed the modeling without ICT involvement, basing it as closely as possible on methods and assumptions used by the ICT in the original modeling. The results of this remodeling were coordinated with the ICT. A quality check was also performed for the revised worksheets.

5.4 EVALUATION OF ECOLOGICAL MITIGATION MEASURES

5.4.1 Preliminary Screening of Alternatives

A large number of potential mitigation measures were evaluated, but the majority were eliminated during preliminary screening. Measures were generally of two types: measures to reduce or avoid salinity intrusion and measures to restore or protect habitat. Salinity effects for large-scale measures affecting the estuary as a whole were evaluated with the HS model; a desktop model was developed for alternatives affecting smaller, localized drainages (Brown and Stokes, 2009). Ecological benefits were evaluated for most of the measures using the WVA model; some were eliminated early in the process because they

were not feasible or implementable. Screening-level costs were based upon conceptual designs and costs for similar structures that had been constructed recently by the USFWS. Final costs were only developed for mitigation measures ultimately included in the Mitigation Plan.

5.4.1.1 Measures to Reduce Salinity Intrusion

Since impacts of the Preferred Alternative would be related primarily to salinity increases associated with a deeper SNWW navigation channel, extensive efforts were made to identify mitigation measures that could minimize or eliminate the projected increase in salinity intrusion. Measures were formulated that affected the estuary as a whole, or smaller, localized areas within specific wetlands.

Sabine Pass Lock and Dam

The construction of a lock and dam at Sabine Pass was considered to address increases in saltwater intrusion from the proposed deepening and widening of the SNWW. The lock and dam were not considered to be a project alternative because the structures would not improve navigation efficiency, but it was believed they could minimize salinity impacts. The existing SNWW navigation channel through Sabine Pass is 40 feet deep and 500 feet wide. Large ocean-going petroleum and chemical product tankers regularly transit the waterway. Placing a lock in the channel would create new transit delays as discussed below.

The structures anticipated for salinity control would consist of two navigation locks within the current SNWW navigation channel. Figure 5.4-1 presents a conceptual drawing of the lock and dam alternative. A connecting levee would be required from the east lock wall to the Louisiana side of the pass, and a dam would be required to close the old river channel on the Texas side. This dam would be constructed from the cutoff island to the Texas shoreline immediately upstream of the City of Sabine Pass. It would consist of a reinforced concrete sill positioned at elevation -25 feet mean low tide (MLT), with a set of tainter gates. The tainter gates would be closed under normal conditions, but would open to allow the discharge of upstream floodwaters. A levee would also be required to connect the west end of the dam to higher ground.

The lock and dam would prevent continuous saltwater intrusion from the Gulf by blocking the deeper navigation channel and old river channel, while allowing two-way ship traffic and periodic discharges of upstream floodwaters. The lock and dam structure would create a pool behind the structures with a 3- to 5-foot increase in water elevations over current conditions. The pool is necessary to create the hydraulic head pressures required for the lock to function properly.

There are significant engineering challenges to be met in designing the large locks required to accommodate the large ships, which would use the proposed CIP. The width and depth of the lock chamber would be larger than any other known lock constructed in the U.S., and therefore additional research and data would be needed in order to design and construct the large lock gates and machinery.

With respect to impacts on navigation, the locks would not have a direct effect on the deepening benefits of the proposed project, but would significantly reduce the navigational efficiency of the existing or proposed channel. A preliminary economic analysis estimated that annual delay costs for both inbound and outbound trips would be approximately \$7 million. This estimate did not include queuing effects. In reality, slowdowns due to the locks would generate additional delays and queues would form. The vessel delay and personnel cost would need to be treated as added costs for the lock feature. The delays associated with a lock would lead to additional cost and result in a loss of business for the ports of Port Arthur and Beaumont.

From an environmental standpoint, the proposed lock and dam would have both positive and negative environmental impacts on the region. On the positive side, the lock would significantly reduce saltwater intrusion through Sabine Pass into the upriver wetlands systems. Such reduction in saltwater intrusion would ameliorate degradation caused by current saltwater intrusion and permit slow reestablishment of some of the former fluvial freshwater wetlands that existed prior to initial channelization of the river. These freshwater wetlands would likely support increased freshwater sports fishing opportunities, waterfowl, and perhaps some cypress-tupelo swamp acreage.

However, the proposed lock and dam would produce negative environmental impacts as well. Reducing saltwater inputs upstream and flooding existing marshes would significantly decrease productivity of the existing saline and brackish marshes, as the obligate higher-salinity marsh plants are gradually lost in the freshwater conditions. In addition, even before significant loss of marshes upstream of the lock, many largely marine species would be physically precluded from reaching the nursery marsh areas by the lock. Therefore, many commercial, sportfish, and shellfish species would likely decrease in abundance.

The lock alternative was eliminated from further consideration on the basis of navigation economics, environmental, and cost factors. The lock alternative would reduce navigation benefits and result in higher vessel transportation costs. Environmental benefits associated with control salinity intrusion would be partially offset by significant impacts associated with restricting ingress/egress of marine organisms. Finally, significant engineering challenges associated with construction of such a large structure would result in high costs, estimated in excess of \$2 billion.

Sabine Lake Sill

Three versions of a sill or weir at the mouth of Sabine Lake were modeled with the HS model (Brown and Stokes, 2009): a submerged sill at -10 feet MLT; a stepped, submerged sill ranging from -2.5 feet MLT at the shore to a -10-foot MLT boat bay in the center; and an emergent sill with a -10-foot MLT boat bay in the center of the channel. This alternative was eliminated from further consideration when modeling determined that a sill provided little, if any, salinity mitigation, except for some reduction in salinity at the southwest end of Sabine Lake. This is likely because the principal pathway for salinity transport into the system is via the Sabine-Neches Canal at the northwest corner of Sabine Lake. In addition, the more restrictive versions created unacceptably high velocities through the mouth of Sabine Lake and unacceptably high water elevations in the southern part of Sabine Lake during flood events.

Structural Water Control

Nineteen various water-control structures were proposed to control salinity intrusion into the marshes east of Sabine Lake and west of Sabine Pass (see Appendix C). The ERDC developed desktop models to evaluate changes in salinity achieved by these structures (Brown and Stokes, 2009), and the WVA model was applied to evaluate their ecological benefits. Various combinations of a sheet pile wall, a large rock weir, earthen plugs, and channel fill were evaluated for Texas Bayou in the Texas Point NWR. Large, adjustable salinity control structures and large rock weirs were evaluated for Willow Bayou, Three Bayou, Black Bayou, Greens Bayou, and the Right Prong of Black Bayou. Smaller rock weirs and low rock liners were assessed for numerous smaller channels in the Willow Bayou and Black Bayou hydro-units. Earthen plugs in logging canals and submerged pipeline ROWs were suggested as a means of reducing salinities within swamps at Blue Elbow and the Sabine Island WMA. NMFS was concerned that proposed water control structures could adversely affect EFH and other aquatic resources by blocking or reducing marine fishery access to the Louisiana marshes east of Sabine Lake. It is possible that structures could cause salinities to be higher in managed areas during droughts or after storm surges. Ultimately, all of the proposed water control structures were eliminated from further consideration when WVA modeling yielded net negative benefits (i.e., impacts). Salinity reductions were generally modest and could not overcome the adverse effects of restrictions to marine organism access.

Ensuring Freshwater Inflow

Purchasing freshwater flows from both the SRA-TX and LNVA was investigated as a potential mitigation measure. Contracts could be negotiated for the 50-year period of analysis that require annual payments for a specific volume of flow, which was determined with the HS model. The alternative was eliminated from further consideration because there is no guarantee that the mitigation flow would be available when it is needed most—during periods of low flows or drought, when the incremental salinity increase associated with the deeper navigation channel would have its greatest adverse effect. The new allocation would be subordinate to preexisting water rights and subject to changes in priorities by State water plans. Ultimately, there is no guarantee that sufficient flows, although contracted and paid for annually, would be provided at the expense of human needs.

Marsh Creation

Several measures were considered in which marshes would be used to constrict flows and thereby reduce salinity intrusion from the navigation channel. Marsh creation was evaluated for the following locations: (1) upstream and downstream of the mouth of Sabine Lake, (2) a specific shoreline reach of the Port Arthur Canal, (3) an eroded area at the head of the west jetty, (4) eroding islands between the Sabine-Neches Canal and the northwest corner of Sabine Lake, and (5) the mouths of channels draining Rose City and Bessie Heights. Some of these alternatives were eliminated from further consideration when HS modeling determined they were not effective at reducing salinities. Others were eliminated because they would block access to private property, cause backwater flooding, or create safety problems with navigation.

5.4.1.2 Measures to Restore or Protect Habitat

The HW also evaluated a wide array of measures, which utilized marsh restoration, inshore shoreline protection, and Gulf shore nourishment to compensate for wetland loss or protect from increased erosion. The most effective of these in terms of costs and ecosystem benefits were ultimately selected for inclusion in the Recommended Mitigation Plan; those described below were eliminated during preliminary screening.

Marsh Restoration Measures

Thirty-nine combinations of measures and scales of marsh restoration were evaluated. Screening was based upon an informal analysis of benefits determined by the WVA model and costs developed by the USACE. All possible sources of material for marsh restoration were considered (submerged in situ soils, new work and maintenance material from the nearest SNWW channel reaches, sediments from Sabine Lake, Sabine River Channel maintenance material, and accumulated material in the Lake Charles Deepwater Channel/Louisiana GIWW). Locations evaluated for restoration were (1) a degraded marsh area near the head of the West Jetty in the Texas Point NWR; (2) Old River Cove east of the power plant intake canal; (3) the eastern shores of PAs 8 and 11 on Pleasure Island; (4) an old logging canal north of Texas Bayou; (5) a large open-water area south of the Louisiana GIWW and east of Black Bayou Cutoff; and (6) a small, confined open-water area at the northeast corner of the Louisiana GIWW and Black Bayou Cutoff. The large open-water area on the GIWW east of the Black Bayou Cutoff was eliminated because the area was approved for an in situ marsh-terracing project under CWPRA Project CS-27. Different scales of marsh fill and source material were used within the same footprints in Willow and Black bayous to create different alternatives. Most of the alternatives were eliminated because they produced unacceptably low benefits when compared to costs. Small scales of in situ marsh terracing and marsh creation using dredged material located in the Willow and Black bayou hydro-units were eliminated because of low benefits. Twelve larger scales of the same alternatives were advanced for further screening due to their higher benefits and improved cost effectiveness.

Inshore Shoreline Protection

Twenty-one combinations of shoreline protection measures and scales were evaluated in the preliminary screening. Measures were developed for two locations: the eastern shore of Sabine Lake and the north shore of the GIWW in Texas.

For the GIWW shoreline, two separate reaches of rock breakwater (2.4 miles long and 1.5 miles long) were proposed to stabilize areas where low banklines allow higher-salinity waters from the GIWW to enter the large expanse of fresh and intermediate marsh north of the GIWW. Benefits were assessed using the WVA model, based upon an assumed salinity reduction in the marshes protected by the breakwater. The alternative was eliminated because of low benefits in relation to cost. IWR-PLAN comparison revealed it was less cost effective than other alternatives.

For the Sabine Lake shoreline, a foreshore dike was proposed for the Sabine Lake shore between Willow Bayou and the mouth of Black Bayou. This alternative was evaluated in three scales of 3, 4.4, and 8.6 miles in length. Two material types were evaluated for the breakwater: barged-in rock and earthen material obtained from Sabine Lake sediments adjacent to the breakwater. Each of these alternatives was also evaluated at three distances from the Sabine Lake shore: 150, 250, and 500 feet. Finally, marsh restoration behind the dikes was also proposed. Marsh would be created behind the earthen and rock alternatives, 150 feet from the shore using Sabine Lake sediments from the access channel required for construction, and new work material from the SNWW channel was evaluated for the 250- and 500-foot scales. Benefits determined by the WVA were based on the creation of new marsh and the elimination of shoreline retreat. Initially, the rate of shoreline retreat was determined by a GIS analysis of satellite images by the USFWS (Greco and Clark, 2005). However, the rate of shoreline retreat was later revised to incorporate the most likely rate of RSLR, and a forecasted 1.1-foot rise in water surface elevation. Costs of the different measures were estimated by the USACE, including additional costs to raise the dike to accommodate RSLR. All of these alternatives were eliminated because costs were high when compared to benefits.

Gulf Shore Nourishment

Eleven measures and scales of Gulf shoreline nourishment were evaluated for Texas and Louisiana Points. The measures were developed in an effort to find the most-cost-effective combination of pumping distance, material type, and length of shoreline nourishment. All of the alternatives were constrained by the requirement that both new work and maintenance material be split evenly between Texas and Louisiana. All but one assumed unconfined placement of dredged material along the current shoreline using a hydraulic pipeline dredge. One alternative envisioned construction of a confined cell along the Texas Point shoreline using new work and maintenance materials. This alternative was eliminated early in the screening because of excessively high costs. Alternatives relying upon unconfined placement of either new work or maintenance material from Sabine Pass sections 5 or 5 and 6 were evaluated for ½-, 2-, and 3-mile-long shoreline reaches. All would begin ½ mile from each jetty, avoiding areas near the jetties where the accretion rate is high. Cost effectiveness analysis determined that the 3-mile-long scale of the maintenance material alternative was the least-cost alternative for the placement of dredged material, and therefore it was adopted as part of the DMMP. One alternative that uses new work material to nourish shoreline at Louisiana Point was advanced for further screening as a potential mitigation alternative.

5.4.2 Final Screening of Ecological Mitigation Measures

The Mitigation Plan was selected using the USACE certified version of IWR-PLAN software. IWR-PLAN uses the tools of CE/ICA to weigh the costs of mitigation plans against their nonmonetary output. A mitigation plan is defined as a group of mitigation measures. Cost-effectiveness analysis is used to identify least-cost plans, and incremental cost analysis identifies the subset of cost-effective plans that are superior financial investments, called “best buys plans.” Best buys plans are the most efficient plans at producing the output variable (in this case, AAHUs); they provide the greatest increase in the value of the output variable for the least increase in cost.

Mitigation measures advanced for final screening with IWR-PLAN are listed in Table 5.4-1. For the CE/ICA, the measures were expressed as Solutions A through M, and each solution was evaluated at different scales (Table 5.4-2). Two categories of solutions were evaluated:

- 1) Marsh restoration in the Willow and Black bayou areas; and
- 2) Gulf shore nourishment.

The footprint of several marsh restoration solutions is identical; they propose marsh restoration in the same physical area using different sources of sediment (i.e., in situ material, SNWW new work material, and dedicated dredging from Sabine Lake). Solutions with identical footprints are not combinable with other solutions and were identified as such in IWR-PLAN. Other solutions reflect different placement sequences and combinations for the various open-water locales within Willow Bayou or Black Bayou. These were developed in an effort to identify combinations that have more-cost-effective pumping distances. One alternative (LA 2-18C) was duplicated in the IWR-PLAN solutions, with the cost for dredging varied by the size of dredge (i.e., an average size dredge versus the largest, most powerful dredge that could access the area, the *California*). Scales are defined by adding increments of acreage restored, varying the amount of sediment used in the restoration, or the length of shoreline protected or nourished.

Table 5.4-2 contains incremental costs and output for all solutions and scales included in the analysis. The IWR-PLAN code for each solution and the scales of that solution are indicated in the first column, and a brief description of each solution is provided in the second column. For example, the first solution is Willow Bayou in situ terracing (Solution A). This solution has four scales (A₁-A₄), which increase in acres incrementally through the four scales. Scale A₁ restores 38 acres of emergent marsh; Scale A₂ creates an additional 26 acres for a cumulative total of 47 acres for both scales A₁ and A₂. The third column provides a unique identification number for each solution and scale that was used for mapping and tracking through cost estimating and ecological modeling. The fourth column provides the cumulative AAHU output associated with the cumulative acres being restored, and the fifth provides the cumulative average annualized cost.

Variables used in the analysis were nonmonetary ecological benefits established by WVA modeling (expressed in AAHUs) and average annualized costs. These costs include the first cost of construction, costs for marsh plantings, postconstruction monitoring, and 50-year annualized O&M costs. The costs of alternatives that involve the use of maintenance material over one or multiple dredging cycles were amortized over the 50-year period of analysis, using dredging-cycle projections based on historical dredging data and the discount rate in effect at that time.

Table 5.4-1
Mitigation Alternatives Evaluated in Final Screening

<i>Marsh Restoration - In Situ Terracing</i>			
Description of Alternative			
“Duck-wing”-shaped earthen terraces built with in situ material using amphibious excavator. Each terrace is 1,000 feet long; 100-foot gap between terraces; approximately 500 feet between each row of terraces. Terraces should have 15-foot-wide tops at +2.0 feet NAVD88 and 4:1 side slopes.			
Hydro-Unit	No.	Size of Influence Area	Emergent Marsh Created
Willow Bayou	LA 2-16(A)	Influence area – 1,831 acres in north part of Greens Lake; located within the same footprint as LA 2-16(B) and LA 2-16(C)	38 acres
	LA 2-17(A)	Influence area – 2,297 acres in southern part of Greens Lake; located within the same footprint as LA 2-17(B) and LA 2-17(C)	45 acres
	LA 2-18(A)	Influence area – 680 acres in area north of Willow Bayou canal; located within the same footprint as LA 2-18(B) and LA 2-18(C)	11 acres
	LA 2-19(A)	Influence area – 1,809 acres in area west of Deep Bayou; located within the same footprint as LA 2-19(B) and LA 2-19(C)	28 acres
<i>Marsh Restoration – Sabine Lake Dedicated Dredging</i>			
Description of Alternative			
Hydraulically dredged material from Sabine Lake (dedicated dredging) to restore marsh and shallow-water habitat in open-water areas of marsh. Borrow trench located 500 feet from shore, excavated approximately 7.5 feet deep; width and length vary for each scale. Assume unconfined flow of maintenance material, frequent movement of pipe, and few training or containment structures.			
Hydro-Unit	No.	Size of Influence Area	Emergent Marsh Created
Willow Bayou	LA 2-16(B)	Influence area – 1,831 acres in north part of Greens Lake; borrow trench approximately 1,000 feet wide x 2 miles long	822 acres
	LA 2-17(B)	Influence area – 2,297 acres in southern part of Greens Lake area; borrow trench approximately 1,250 feet wide x 2 miles long	1,035 acres
	LA 2-18(B)	Influence area – 680 acres in area north of Willow Bayou Canal; borrow trench approximately 700 feet wide x 0.8 mile long	251 acres
	LA 2-19(B)	Influence area – 1,809 acres in area west of Deep Bayou; borrow trench approximately 1,200 feet wide x 1.8 miles long	719 acres
	LA 2 ADD B	Influence area – 1,285 acres in area north of Willow Bayou Canal; borrow trench approximately 1,000 feet wide x 1.25 miles long	436 acres

Table 5.4-1, cont'd

<i>Marsh Restoration – SNWW New Work Material</i>			
Description of Alternative			
Use new work material from SNWW Section 10 to restore emergent marsh and shallow-water habitat in open water in north part of Greens Lake area. Assume unconfined flow of new work material, frequent movement of pipe, and few training or containment structures.			
Hydro-Unit	No.	Size of Influence Area	Emergent Marsh Created
Willow Bayou	LA 2-16(C)	Influence area – 1,831 acres in north part of Greens Lake area; located within the same footprint as LA 2-16(A) and LA 2-16(B)	822 acres
	LA 2-17(C)	Influence area – 2,297 acres in southern part of Greens Lake area; located within the same footprint as LA 2-17(A) and LA 2-17(B)	1,035 acres
	LA 2-18(C)	Influence area – 680 acres in area north of Willow Bayou Canal; located within the same footprint as LA 2-18(A) and LA 2-18(B)	251 acres
	LA 2-19(C)	Influence area – 1,809 acres in area west of Deep Bayou; located within the same footprint as LA 2-19(A) and LA 2-19(B)	719 acres
	LA 2-ADD C	Influence area – 1,285 acres in area north of Willow Bayou Canal; located within the same footprint as LA 2-ADD B	436 acres
<i>Marsh Restoration – Channel to Orange Maintenance Material</i>			
Description of Alternative			
Hydraulically pump maintenance material from the Channel to Orange (Sabine River) between East Pass and the GIWW into areas north of Black Bayou to restore emergent marsh in degraded marsh and open-water areas. Assume unconfined flow of maintenance material, frequent movement of pipe, and few training or containment structures. Material would come from maintenance dredging of the Sabine River Channel.			
Hydro-Unit	No.	Size of Influence Area	Emergent Marsh Created
Black Bayou	LA 3-10R	Influence area – 2,465 acres; restoring 132 acres every 5 years, TY 5 thru TY 30 (total of 6 cycles, ending TY 30)	792 acres

Table 5.4-1, cont'd

<i>Marsh Restoration - GIWW Dedicated Dredging</i>			
Description of Alternative			
Dedicated dredging of adjacent GIWW to restore emergent marsh and shallow-water habitat; percent of open water restored to emergent marsh is different in A and B scales. Assume unconfined flow of hydraulically pumped material that has accumulated in GIWW (formerly the 30-foot Deepwater Channel to Lake Charles), frequent movement of pipe, and few training or containment structures.			
Hydro-Unit	No.	Size of Influence Area	Emergent Marsh Created
Black Bayou	LA 3-15(A)	Influence area – 1,788 acres in area west of Black Bayou Cutoff Canal; assume 60 percent of open water restored to emergent marsh	546 acres
	LA 3-18(A)	Influence area – 1,877 acres in large area of open water south of LA 3-15; assume 60 percent of open water restored to emergent marsh	497 acres
	LA 3-15(B)	Influence area – 1,788 acres area west of Black Bayou Cutoff Canal; assume 75 percent of open water restored to emergent marsh	683 acres
	LA 3-18(B)	Influence area – 1,877 acres in large area of open water south of LA 3-15; assume 75 percent of open water restored to emergent marsh	621 acres
<i>Gulf Shoreline Nourishment</i>			
Description of Alternative			
Nourish Gulf shoreline at Louisiana Point; length of nourished shore and number of placement cycles vary. Material pumped along shoreline using hydraulic pipeline dredge. Assume 50:50 split of material between Texas and Louisiana. Assume 60 percent retention of material after initial placement; 50 percent of newly added acres remain at end of 6 years.			
Hydro-Unit	No.	Size of Influence Area	Length of Shoreline
Sabine Lake Ridges	LA 5-3	Nourish 0.5 to 1.0 mile from east jetty; assume one-time unconfined placement of new work material from SNWW Section 5; all added acres eroded away by TY 51	0.5 mile
	LA 5-1 and 6-1	Nourish 0.5 to 3.5 miles from east jetty; assume one-time unconfined placement of new work material from SNWW Section 5; all added acres eroded away by TY 51	3.0 miles
	LA 5-5	Nourish 0.5 to 3.5 miles from east jetty; assume one-time unconfined placement of new work material from SNWW sections 5 and 6; all added acres eroded away by TY 51	3.0 miles

5.4.3 Selection of the Best Buy Mitigation Plan

The result of the incremental analysis is illustrated on Figure 5.4-2 and in Table 5.4-3. Ten best buy plans were identified, with incremental costs ranging from \$2,716 to \$19,935 per AAHU. Line 1 is the No-Action Plan, with no cost and no output. The first column numbers the plans in order of cost effectiveness, with the most cost-effective plan (Plan 2) shown on the second line. Column 2 in Table 5.4-3 lists the codes for all solutions included in each best buy plan, as determined by the incremental cost analysis. The mitigation alternatives advanced for final screening (discussed previously) are the solutions evaluated by IWR-PLAN. Refer to Table 5.4-2 for a description of the mitigation measure represented by the codes shown in column 2. Column 3 shows the incremental output (in AAHUs) of the solution, which is added with each new best buy plan. Column 4 shows the average annual cost associated with the incremental output (the last solution added) of each best buy plan.

Figure 5.4-2. Results of CE/ICA Analysis

Table 5.4-3
Incremental Cost of Best Buy Plan Combinations (Ordered by Output)

Counter	Plan Alternative	Output (AAHUs)	Cost (\$1.00)	Average Cost	Incremental Cost	Inc. Output (\$1.00)	Inc. Cost Per AAHU
				(\$1.00/AAHU)	(\$1.00/AAHU)		
1	No-Action Plan	0.00	0.00				
2	A0B0C0D0E0F0G0H0I0J0K1L0M0	307.00	833,787.00	2,715.9186	833,787.0000	307.0000	2,715.9186
3	A0B0C0D0E0F0G0H1I0J0K1L0M0	505.00	1,587,504.00	3,143.5723	753,717.0000	198.0000	3,806.6515
4	A0B0C0D0E0F0G0H1I0J0K2L0M0	815.00	2,833,144.00	3,476.2503	1,245,640.0000	310.0000	4,018.1935
5	A0B0C0D1E0F0G0H1I0J0K2L0M0	967.00	3,454,021.00	3,571.8935	620,877.0000	152.0000	4,084.7171
6	A0B0C0D2E0F0G0H1I0J0K2L0M0	1,181.00	4,465,620.00	3,781.2193	1,011,599.0000	214.0000	4,727.0981
7	A0B0C0D3E0F0G0H1I0J0K2L0M0	1,600.00	6,778,538.00	4,236.5863	2,312,918.0000	419.0000	5,520.0907
8	A0B0C1D3E0F0G0H1I0J0K2L0M0	2,045.00	9,573,089.00	4,681.2171	2,794,551.0000	445.0000	6,279.8899
9	A0B0C2D3E0F0G0H1I0J0K2L0M0	2,537.00	12,759,111.00	5,029.2121	3,186,022.0000	492.0000	6,475.6545
10	A0B0C2D3E0F0G0H1I0J0K2L0M2	2,591.00	13,129,173.00	5,067.2223	370,062.0000	54.0000	6,853.0000
11	A0B0C2D3E0F0G0H1I0J0K2L0M3	2,627.00	13,846,826.00	5,270.9654	717,653.0000	36.0000	19,934.8056

Best Buy Plan 2, shown on line 2, consists of Solution K₁; it has the lowest cost per AAHU (\$2,716) of all the best buy plans and consists of only the first scale of that solution, with an output of 307 AAHUs. Best Buy Plan 3 adds Solution H₁ to Solution K₁, with an incremental output of 198 AAHUs for Solution H₁, and a total output of 505 AAHUs for the plan. Best Buy Plan 4 consists of Solutions H₁ and K₂; in this case, the difference between total output for this plan and Best Buy Plan 3 (H₁ and K₁) is the incremental output between K₂ and K₁ (815 – 505 = 310 AAHUs). The cumulative output for each successive group of plans is shown in Column 3. The first plan with the cumulative total that exceeds the mitigation target is generally selected as the Best Buy Mitigation Plan.

The incremental annualized cost per unit of output (Column 5) is calculated by dividing total average annual cost for each incremental solution by the output from that solution. For Best Buy Plan 4, the total annualized cost of K₂ (in this case, \$1,245,640) is divided by the incremental output (310 AAHUs) to obtain \$4,018. Average annual costs were developed for all solutions that were analyzed with IWR-PLAN. These costs include the first cost of construction, marsh plantings, monitoring, and 50-year annualized O&M costs. They are not provided in this document, except as incremental costs per habitat unit, but are available upon request.

Best Buy Plan 6 (Solutions D₂, H₁, and K₂ – shown in bold in tables 5.4-2 and 5.4-3) appears to be an efficient mitigation plan since it reaches the mitigation target of 1,159 AAHUs (Table 5.4-4) by providing a total of 1,181 AAHUs. Best Buy Plan 6 consists of emergent marsh restoration in two Willow Bayou areas (totaling 607 acres) and three areas in the Black Bayou area (totaling 2,096 acres). Best Buy Plan 7 was also evaluated to determine whether its considerable additional benefits were worth the comparatively small incremental cost. Best Buy Plan 7 provides 420 additional AAHUs (719 more acres restored in Willow Bayou) by adding Solution D₃ for an additional average annual cost per unit of output of \$4,237 (total average annual cost of \$2,312,918). Since the estimated total first cost of this increment is \$39,275,000 (screening-level cost) and Best Buy Plan 6 meets the mitigation target, Best Buy Plan 7 was deemed not worth the additional investment.

Table 5.4-4
Recommended Mitigation Plan

Recommended Mitigation Plan	Mitigation AAHUs
Willow Bayou	
LA 2-18 B Marsh Restoration (Sabine Lake dredging)	152
LA 2-ADD B Marsh Restoration (Sabine Lake dredging)	214
Black Bayou West	
LA 3-10R Marsh Restoration (Sabine River Channel maintenance material)	198
Black Bayou East	
LA 3-15 B Marsh Restoration (GIWW dredging)	307
LA 3-18 B Marsh Restoration (GIWW dredging)	310
Total Compensation	1,181
FWP Mitigation Target	-1,159
Net Benefits After Compensation	22

5.5 RECOMMENDED MITIGATION PLAN

The CE/ICA selected Best Buy Plan 6 as the most efficient combination of mitigation measures to compensate for the indirect impacts of the Preferred Alternative. It provides 1,181 AAHUs, which is 10 AAHUs more than the mitigation target. It is important to remember that additional compensatory mitigation would be provided in Louisiana beyond the total 843 AAHUs impacts of the Preferred Alternative. The mitigation plan would result in a net gain of 338 AAHUs for the project as a whole.

Unavoidable impacts of the SNWW CIP remain only in Louisiana; all CIP impacts in Texas are minimized and offset by the DMMP, and no mitigation is required. Therefore, all of the mitigation measures in Best Buy Plan 6 would be located in Louisiana. The mitigation plan consists of restoring five degraded marsh areas east of Sabine Lake near Willow and Black bayous, Louisiana (Table 5.5-1, Figure 5.5-1). Each of these alternatives is described in detail below. The recommended Mitigation Plan compensates for the Preferred Alternative’s salinity increase and associated losses in marsh and productivity by marsh creation activities that would influence a total of 8,095 acres of Louisiana marshes in the Willow and Black Bayou watersheds. The plan would restore 2,783 acres of emergent marsh in existing open-water areas within the marsh, improve 957 acres of shallow-water habitat by creating shallower, smaller ponds and channels within the restored marsh, and stabilize and nourish 4,355 acres of existing marsh located in and around the marsh restoration zone. The amount of recommended mitigation is based upon the amount of marsh acreage that could be lost as a result of the project, and the additional amount that would need to be restored in order to fully compensate for adverse changes to biological function of the remaining marsh throughout the affected area over the 50-year period of analysis. More than a one-to-one ratio of created marsh to natural marsh is needed to fully compensate for the loss of marsh productivity caused by the CIP. Studies by NMFS (Minello, 2000; Minello and Webb, 1997) have shown that created marshes are not functionally equivalent to natural marshes for all estuarine species for as much as 15 years after the marshes are planted. In total, these measures would produce 1,159 AAHUs and provide full compensation for all impacts of the CIP. The USACE and the ICT would monitor all of the mitigation areas as described by the monitoring plan presented in Appendix I.

Table 5.5-1
Recommended Mitigation Plan – Acreage Analysis

Mitigation Measure	AAHUs	Total Influence Area (acres)	Nourished Existing Marsh (acres)	Restored Open Water (acres)	Restored Emergent Marsh (acres)
Willow Bayou					
LA 2-18B	152	681	367	63	251
LA 2-ADD B	214	1,285	745	104	436
Subtotal	366	1,966	1,112	167	687
Black Bayou West					
LA 3-10R	198	2,465	1,317	356	792
Black Bayou East					
LA 3-15B	307	1,788	878	227	683
LA 3-18B	310	1,876	1,048	207	621
Subtotal	617	3,664	1,926	434	1,304
Total Mitigation	1,181	8,095	4,355	957	2,783

Specific performance criteria for the marsh restoration areas were established in consultation with the ICT: (1) placed material would be 60 to 80 percent vegetated with native, typical, emergent marsh 5 years after each placement of material; (2) marsh would remain intact and 60 to 80 percent vegetated with native, typical, emergent marsh through the 50-year period of analysis; and (3) invasive, noxious, and/or exotic plants would compose less than 4 percent of marsh cover at year 2 and year 5.

5.5.1 Willow Bayou Mitigation

Recommended Willow Bayou mitigation measures (LA 2-18B and LA 2-ADD B) are located within the boundaries of the Sabine NWR (see Figure 5.5-1). The USACE has requested that the USFWS prepare a compatibility determination for the proposed activity. See correspondence dated January 24, 2007, in Appendix A1. Material dredged from a borrow trench in Sabine Lake would be used to restore 687 acres of emergent marsh within open-water areas, improve 167 acres of shallow-water habitat, and nourish 1,112 acres of existing marsh within the total influence area of 1,966 acres (see Table 5.5-1). Small ponds and sinuous, interconnected channels would be created to maintain tidal connectivity, increase marsh edge, and create protected areas for SAV. Approximately 1,966 acres of existing marsh in the influence area would also be renourished by winnowing fine-grained suspended solids during placement events. Marsh would be constructed by the unconfined flow of dredged material from a hydraulic pipeline. Frequent pipe movement and careful elevation control would be necessary to obtain the appropriate marsh elevations. In order to maximize edge in the marsh, topographic relief would be created by varying the final elevation of material placement, and planting with appropriate native flora at each elevation. The varied topography would allow for differences in duration of tidal inundation, create different floral communities, and maximize biodiversity. Tidal creek channels would be constructed in the marsh creation area after the dredged material has settled. These would be needed to return the area to normal tidal regime, facilitate marine organism access, and allow water and nutrients to flow into the area.

The dedicated dredging would take approximately 3.1 mcy of material from a 1.8-mile-long borrow trench in Sabine Lake. The borrow trench would be located at least 1,000 feet from the Sabine NWR shore and would average 1,030 feet wide by 7.5 feet deep. The borrow trench would be continuous and parallel to the current shoreline, in line with the common longshore circulation pattern in Sabine Lake. The circulation is expected to prevent the development of hypoxic conditions that would be detrimental to aquatic organisms, and would eventually fill the trench with Sabine River sediments. An access channel, approximately 8 miles long, from the GIWW near the mouth of the Sabine River would be needed for the dredge to reach the proposed borrow area. The exact locations of the borrow trench and access channel would be determined in consultation with the ICT after PED bottom surveys of potential locations. The USACE and ICT would monitor these mitigation areas in accordance with the specific success criteria and monitoring plan presented in Appendix J.

S-23

(This page left blank intentionally.)

One-time impacts of the borrow trench and access channel dredging would include an increase in water column turbidity during dredging activities; such effects are temporary and local to nekton, phytoplankton, and water quality. A hydraulic pipeline dredge would be used to minimize turbidity. For further information, see subsection 4.11.2.1. No further effects to water quality and related organisms would be expected. Benthic fauna would be removed due to excavation of sediment during dredging activities; however, benthic organisms can rapidly recolonize and no long-term effects are anticipated. Due to low salinity (1 to 6 ppt) in this area of Sabine Lake, live oyster reefs are not likely (Fagerberg, 2003). A study by T. Baker Smith, Inc. (2006) found no live oyster reefs in this area. SAV cover is not likely to be found in this area due to the prevalence of shallow, turbulent, and turbid water.

5.5.2 Black Bayou Mitigation

For the Black Bayou West (LA 3-10R) mitigation measure, material from maintenance dredging of the Sabine River Channel between East Pass and the GIWW would be used to restore a large area of marsh north of Black Bayou and west of Rusty Vincent Lake (see Figure 5.5-1 and Table 5.5-1). Maintenance dredging of the Sabine River Channel is considered a separate project within the SNWW system, with a different non-Federal sponsor. It is a without-project condition for the SNWW CIP, and therefore only the incremental cost associated with placing the material in the marsh is included in the cost estimate for the Preferred Alternative. Material removed during regularly scheduled maintenance dredging of this channel would be hydraulically pumped into a large degraded marsh area west of Rusty Vincent Lake. This area is close to the navigation channel, minimizing pumping distance and cost. Marsh restoration in LA 3-10R would be accomplished in six 5-year dredging cycles beginning by the first year of the completion of CIP construction. Each dredging cycle would pump approximately 526,000 cy of material to create 132 acres; a total of 792 acres of emergent marsh would be created over 30 years; 356 acres of shallow-water habitat would be improved, and 1,317 acres of existing marsh would be nourished within the total 2,465 acres influenced by the unconfined flow of dredged material.

For the Black Bayou East (LA 3-15B and LA 3-18B) mitigation measures, marsh restoration would be accomplished in two areas just west of the Black Bayou Cutoff Canal using dedicated dredging of accumulated material in the Lake Charles Deepwater Channel/GIWW (see Figure 5.5-1 and Table 5.5-1). The Lake Charles Deepwater Channel was constructed in 1926 and coincides along its entire 24.9-mile length with the GIWW between the Sabine River and Lake Charles (USACE, 1998c). Communications with the New Orleans District indicate the depth of the 30-foot channel has been reduced to approximately 12 feet due to sedimentation.

Dedicated dredging of the Lake Charles Deepwater Channel for the Black Bayou mitigation efforts would remove and kill benthic organisms; however, constant ship traffic in the shallow channel is an ongoing disturbance to these organisms. Recovery of benthic organisms would be rapid (Sheridan, 1999). No impacts to salinity would be expected because the dredged section would not connect with the Sabine River Channel or the Calcasieu Ship Channel; therefore, there would be no connection with the saltwater wedge in the Calcasieu Ship Channel (there is no Sabine River wedge; Brown and Stokes, 2009) It is

expected that sediment would accumulate over time, refilling the channel to its current depth of approximately –12 feet.

Approximately 10.5 mcy of material would be pumped from a 13-mile stretch of the GIWW approximately 125 feet wide (the width of the GIWW/Deepwater Channel) into the two areas. The first (LA 3-15B) would be located adjacent to the GIWW and would have the shortest pumping distance; the second would be located south of LA 3-15B, and pumping would move to it after the first is complete. A total of 1,304 acres of emergent marsh would be restored, 434 acres of shallow-water habitat would be improved, and 1,926 acres of existing marsh would be nourished within the total 3,664 acres influenced by the unconfined flow of dredged material.

Marsh would be constructed by the unconfined flow of dredged material from a hydraulic pipeline. Frequent pipe movement and careful elevation control would be necessary to obtain the appropriate marsh elevations. In order to maximize edge in the marsh, topographic relief would be created by varying the final elevation of material placement, and planting with appropriate native flora at each elevation. The varied topography would allow for differences in duration of tidal inundation, create different floral communities, and maximize biodiversity. Tidal creek channels would be constructed in the marsh creation area after the dredged material has settled. These would be needed to return the area to the normal tidal regime, facilitate marine organism access, and allow water and nutrients to flow into the area. The USACE and ICT would monitor these mitigation areas in accordance with the specific success criteria and monitoring plan presented in Appendix J.

5.5.3 Comparison of Recommended Mitigation Plan to Mitigation Planning Objectives

The net benefits of the Mitigation Plan are shown in tables 5.4-4 and 5.5-1. Compensatory mitigation was considered only after impacts were minimized and offset by DMMP BU features. The DMMP features maximize, to the greatest degree possible, the use of dredged material as a beneficial resource, and share the material from Sabine Pass equally between the states. The mitigation plan (+1,181 AAHUs) fully compensates for AAHU losses to state resources in Louisiana and results in a net gain of 338 AAHUs for the project as a whole. Impacts to East Sabine Lake marshes are replaced in-kind by the marsh mitigation plans in Willow and Black bayous. Minor productivity impacts to cypress-tupelo swamp on the Sabine River near the GIWW are not matched in-kind. The ICT considered this to be acceptable since the loss in function is negligible. Projected FWP salinity levels are within the tolerance levels of these swamps, and the CIP causes no loss of swamp acreage.

5.5.4 Performance Criteria for DMMP Restoration/Nourishment and Mitigation Areas

5.5.4.1 Design and Construction

General performance criteria for marsh design and construction for DMMP BU features and Louisiana mitigation measures are presented below. Reference marshes would be located near to mitigation sites so

that vegetation, salinity regime, and hydrology would be directly comparable. Specific criteria would be developed during the PED phase.

Goals and Objectives

- To create intertidal marshes compatible with the surrounding natural environment using dredged material.
- To reach consistent and similar intertidal fluctuations that mimic existing nearby marshes to provide habitat suitable for local species to survive and grow.
- To create a sustainable habitat that would withstand environmental conditions and anthropogenic impacts for the period of analysis.

Methods

- Build or reinforce existing containment levees adjacent to large canals with mechanically dredged, in situ material. Keep containment levees to the minimum necessary to prevent filling of adjacent navigable canals.
- Place hydraulically dredged material within degraded marsh areas and allow unconfined flow over larger influence areas.
- Frequently move pipe to prevent the accumulation of unsuitably high elevations of material.
- Allow fine-grained sediments to winnow through fringing marsh while material settles at discharge locations.
- Shape the material where required and plant vegetation to sustain the intertidal habitat over time.

Standards

- A sustainable marsh habitat maintained.
- Marsh elevations and geotechnical factors shall fall within certain parameters set in the design.
- Marsh water depths, water quality, water temperatures, DO levels, and salinity of the created marsh shall be favorable to expected flora and comparable to those in reference marshes.
- Water displacement over the tidal cycle shall be similar to reference marshes.

Monitoring and Contingency Plans

Monitoring and contingency plans for the mitigation measures and DMMP BU features are presented in Appendix J. The monitoring and contingency plans for mitigation measures and BU features have been developed in accordance with recent implementing guidance for sections 2036 (a) and 2039, respectively, of WRDA 07, and the monitoring plans for beneficial use of dredged material in Texas and Louisiana as required by the Section 2039 guidance.

The monitoring plans identify specific ecological success criteria to be used in determining whether the mitigation and BU DMMP features have been successful. Details of the monitoring plan for all of the

mitigation sites in Louisiana and the BU features are presented in tables 3 and 4, respectively, of Appendix J. These tables present the key monitoring parameters, periodicity, costs, and responsible parties.

Periodic monitoring to determine the success of marsh mitigation measures and DMMP BU features would continue until the Division Commander determines that the ecological success criteria of the mitigation and DMMP BU features have been met. This determination would be based upon monitoring results and ICT consultation reports provided by the District Engineer. The ICT would be consulted annually to determine progress in the planning, construction, and postconstruction evaluation of the ecological success of these features.

5.5.4.2 Implementation

Upon authorization of the CIP, the USACE would use its Navigational Servitude to obtain access for construction of the Texas and Louisiana DMMP BU features and the Louisiana mitigation measures, for the purposes of planning, construction, and postconstruction monitoring. Landowners would be advised of the need for access. All restored areas would remain jurisdictional wetlands and continue to be subject to the Servitude; therefore, conservation easements would not be required. Agencies on the ICT have requested the opportunity to provide input to the future engineering, design, construction, and monitoring of the project. The ICT would participate in the detailed planning of the marsh creation areas during the PED phase, monitor construction of the mitigation areas, and participate in planning and conducting postconstruction monitoring.

6.0 CONSISTENCY WITH TEXAS AND LOUISIANA COASTAL MANAGEMENT PROGRAMS

In an effort to encourage states to better manage coastal areas, Congress enacted the CZMA in 1972. Texas and Louisiana both have developed and continue to implement federally approved coastal zone management programs and plans (TCMP and LCMP, respectively). States with approved plans have the right to review Federal activities (including private activities that require Federal permits) to determine whether they are consistent to “the maximum extent practicable” with the policies of the state’s coastal zone management program. Appendix I addresses the compliance of the Preferred Alternative in this FEIS with the TCMP and LCMP in full detail.

In summary, coastal natural resource areas (CNRAs), would be affected by the Preferred Alternative. The Preferred Alternative is a result of evaluating six project designs, several mitigation approaches, and beneficial uses of dredged material. Evaluations were made by an ICT and involved extensive modeling of ecological functions based on potential impacts, RSLR, and mitigative measures. The alternatives evaluations included attempts to minimize and avoid CNRAs to the maximum extent practicable and provide overall benefits to the ecosystem functions.

No net loss of coastal wetlands was a specific goal of the SNWW CIP ICT and alternatives evaluation. Several components of the DMMP and mitigation plan involve restoration, protection, and enhancement of coastal wetlands. The Neches River BU Feature would restore 2,853 acres of emergent marsh, nourish 1,234 acres of existing marsh, and improve 871 acres of shallow-water habitat. Additionally, the mitigation plan consists of restoring five degraded marsh areas east of Sabine Lake near Willow and Black bayous, Louisiana. This mitigation measure would restore 2,783 acres of emergent marsh in existing open-water areas within the marsh, improve 957 acres of shallow-water habitat by creating shallower, smaller ponds and channels within the restored marsh, and stabilize and nourish 4,355 acres of existing adjacent marsh.

USACE has evaluated the proposed SNWW CIP for consistency with the Texas and Louisiana coastal management programs, and concluded that the Recommended Plan is fully consistent to the maximum extent practicable with the enforceable policies of both state programs. An ICT comprised of Federal and State resource agency representatives from Texas and Louisiana assisted USACE over a nearly 10-year period to perform appropriate scientific studies and modeling needed to ensure that the proposed project avoids and minimizes environmental impacts to the greatest extent practicable. USACE in particular notes that State and Federal agencies including USFWS, NMFS, TPWD, TCEQ, LDEQ, and the EPA have expressed no outstanding concerns with the project. By letter dated March 30, 2010, the Texas Coastal Coordination Council concurred with the USACE consistency determination. By letter dated March 31, 2010, the LDNR Office of Coastal Management (OCM) found that the SNWW CIP is conditionally consistent with their state program. The finding requires that USACE submit an additional consistency determination no later than the time at which draft contract plans and specifications are circulated for internal review. A requirement of the conditional consistency is the submission of additional detailed

information on topics that “would include, but not be limited to, the topics of storm surge, bar channel deepening, salinity, borrow from Sabine Lake, mitigation plans and adequacy, and pipeline relocation.” The letter also notes that the USACE letter to LDNR-OCM, dated March 19, 2010, does not constitute an adequate resolution to the issues described. USACE consulted with LDNR (as a member of the ICT) concerning technical issues raised in this letter, and issues originally approved by LDNR as a member of the ICT are now being reopened. USACE maintains that the issues, as summarized below, have been adequately addressed. Since USACE finds that the Recommended Plan is consistent to the maximum extent practicable with the enforceable policies of the LCMP, USACE does not accept conditional consistency as proposed by LDNR-OCM. By letter dated April 26, 2010, USACE notified LDNR of its finding and that it will proceed with the project.

Storm Surge

LDNR asserts that the effects of the deeper shipping channel and the borrow of material from the GIWW and Sabine Lake may be significant and have not been modeled thoroughly enough to identify all potential impacts. ERDC-CHL was consulted about the need to model the salinity effect of borrowing material from the GIWW and Sabine Lake relative to salinity impacts. Neither feature was expected to increase salinity impacts, and so they were not included in the HS modeling.

ERDC was also consulted on the potential for ODMDSs to increase wave set-up and erosion on Louisiana shores. ODMDS sites are located too far from shore and in water too deep to affect the Louisiana shore. Waves of any consequence present within a thousand feet of the shoreline are generally depth limited because of the mild nearshore slope and the presence of a soft mud (PIE, 2003). The closest ODMDS (#4) is located between 3.8 and 6 miles from Louisiana in 34 to 43 feet of water. Appendix B discusses previous monitoring of this ODMDS and studies of bottom ocean currents in the region that have determined the dredged material would disperse between placement cycles and not accumulate, and thus would not affect wave set-up or erosion.

ERDC has just completed a sensitivity analysis of potential storm surge impacts from the deeper shipping channel and placement areas (Wamsley, Cialone, and McAlpin, 2010). The analysis is discussed in more detail in subsection 4.6.2.1. The analysis clearly and unequivocally identifies no impact to Louisiana from the deflection of storm surges by the higher PA levees or from the deeper navigation channel. Therefore, further modeling to identify impacts is not necessary.

Bar Channel Deepening

Modeling of potential impacts on wave climate has been performed by ERDC-CHL as reported by Gravens and King (2003). The report has been presented on the USACE, Galveston District’s SNWW webpage since 2003, and it is reported in here in subsection 4.6.2.2. The modeling addressed the changes in the wave climate that would be produced by a deeper and longer offshore channel, including the Outer Bar Channel. In the first 2 miles east of Sabine Pass, the net eastward transport would be slightly reduced (by a maximum of about 1,400 cy/year), and farther east there would be essentially no change. For a

50-foot project, between ½ mile and 3–4 miles of the east jetty, the accretion would decrease by less than 0.5 foot/year, and farther from the jetties than that, the change in the shoreline would decrease to zero. This small impact would be more than offset by the proposed Gulf Shore BU feature's regular shoreline nourishment at Louisiana Point.

Salinity

LDNR asserts that the SNWW salinity modeling used questionable assumptions and boundary conditions, and data collected over a short and nonrepresentative time period. Boundary conditions and assumptions were developed by ERDC and coordinated with the ICT in numerous meetings of the ICT and its MW from 2000 to 2004, and the revised HS modeling presented at the last ICT meeting on August 27, 2009. While LDNR participated in most of the MW meetings, and all prior ICT meetings, no representatives from LDNR attended the last ICT meeting. The ICT presented no objections to the revised modeling at this meeting. The HS modeling for the Preferred Alternative has been subjected to extensive agency technical review (ATR) and independent external peer review (IEPR). ATR identified no significant concerns. The primary IEPR concern related to the need to include the effects of relative sea level rise. This was included as demonstrated in the latest the HS modeling report (Brown and Stokes, 2009). As part of the ICT, LDNR participated in the development of modeling assumptions and reviewed the modeling results. No negative comments were received prior to the consistency determination coordination.

Borrow Site in Sabine Lake

LDNR has requested more information on design details regarding the proposed Sabine Lake borrow trench for the Willow Bayou mitigation areas. USACE has agreed to provide all of the information (i.e., geotechnical information on borrow quality, analysis of potential access channels, and disposal plans) needed to develop detailed engineering plans during the PED phase. Designs would minimize impacts to the maximum extent practicable. This FEIS (subsection 5.5.1) fully evaluates potential impacts of the access channels and borrow area and has determined that impacts would be minimal and temporary.

LDNR also requires that mitigation of oyster seed ground impacts must be accomplished to the satisfaction of LDWF. The exact locations of the borrow trench and access channel would be determined in consultation with the ICT after PED bottom surveys of potential locations. The proposed route of the access channel was chosen to keep dredging impacts to a minimum; it takes advantage of deeper water in the center of the lake, thereby minimizing dredging and bottom impacts. Due to low salinity in this area of Sabine Lake, live oyster reefs are not likely (Fagerberg, 2003; T. Baker Smith, 2006). Nevertheless, as stated in subsection 5.5.1 and in the USACE letter dated March 4, 2010, to LDWF, USACE has proposed that a water-bottom survey of the borrow and access channel areas be conducted during the PED phase of the project. In the unlikely event that oyster reef is encountered, plans will be revised to avoid impacts.

LDNR-OCM asserts that royalty payments and license issues over sediment resources must be resolved with LDWF before LDNR-OCM can concur that the final design is consistent, to the maximum extent

practicable, with Louisiana Coastal Resources Program. USACE maintains that the United States is not bound by Louisiana statute (R.S. 56:2011) pursuant to the Supremacy Clause of the United States Constitution, and that Louisiana is not entitled to compensation under the Fifth Amendment, pursuant to the doctrine of Navigation Servitude. This servitude gives the Federal Government the right to use the "Navigable Waters" of the United States without compensation for navigation projects. In a letter dated March 19, 2010, on the issue of payment of royalties, the USACE provided a detailed legal and policy analysis to support the conclusion that no royalty payments are proper or allowable under current Federal law.

Mitigation Plans and Adequacy

LDNR asserts that details of the proposed mitigation are insufficient to determine whether all potential losses will be adequately compensated. USACE disagrees—mitigation site locations have been finalized, and conceptual designs are sufficient to support ecological modeling of the compensatory mitigation. USACE has agreed to work with the ICT (which includes LDNR) to obtain all of the information needed to develop detailed engineering plans, including geotechnical data relevant to site design, during PED.

LDNR asserts that the proposed mitigation plan falls at least 318 AAHUs short of replacing the anticipated habitat losses to Louisiana, and that additional mitigation will have to be performed in Louisiana to offset this deficit. USACE maintains that the proposed mitigation plan would more than compensate for all impacts of the proposed SNWW CIP. LDNR has questioned the use of benefits from BU features in Texas to offset impacts in Louisiana (see Table 5.1-2). In Louisiana, the benefits of BU measures offset the loss of 210 AAHUs to private lands along the coast at Louisiana Point, and the loss of 340 AAHUs to Federal land in the SNWR. Exclusion of the Federal SNWR is based upon the definition of "coastal zone" in the Coastal Zone Management Act of 1972, as amended. "Excluded from the coastal zone are lands the use of which is by law subject solely to the discretion of or which is held in trust by the Federal Government, its officers or agents (16 USC §1453)." The net impact of the project to non-Federal lands in Louisiana after application of BU benefits is the loss of 1,159 AAHUs, and the proposed mitigation plan would provide 1,181 AAHUs in order to fully and separately compensate losses to these lands. Furthermore, the Louisiana marsh mitigation measures would compensate for the predicted loss of 691 acres in Louisiana over 50 years by the restoration of 2,783 acres of emergent marsh, the improvement of 957 acres of shallow-water habitat, and the nourishment of 4,355 acres of existing marsh. Since the marsh restoration is several times greater than the predicted marsh loss, there would be no net loss of wetlands.

LDNR has also questioned the benefits of the Gulf Shore BU feature at Louisiana Point, and asserts that additional mitigation in Louisiana will be required unless acceptable technical justification of the projected benefits is provided. The benefits of the BU feature in Louisiana were established by WVA modeling accomplished by the ICT, of which LDNR was a part. The technical justification presented in Appendix C, subsection 8.3.1.2 and WVA modeling were reviewed and accepted by the ICT. The monitoring plan (Appendix J) would determine whether benefits are being reached as predicted.

Pipeline Relocation

A total of 104 pipelines have been identified crossing the SNWW navigation channels. Of the 104 pipelines, 46 require adjustment to meet the minimum required vertical and horizontal clearances for the SNWW CIP. The individual circumstances of each pipeline will be evaluated by USACE in consultation with the non-Federal sponsor and the pipeline owner during the PED and Construction phases, and decisions regarding necessary actions will be made individually for each pipeline at that time. Costs of pipeline relocations have been included in the economic analysis of potential project benefits. Direct and indirect economic benefits of the proposed deepening will accrue to all users of the SNWW, including the energy industries, and to the regional economy in Louisiana as established by an independent economic analysis (Martin Associates, 2006). The economic analysis presented in FFR Section V.F establishes that there would be a net economic benefit to the country from the proposed project. Minimal impacts to Louisiana industries are anticipated because construction would work around pipeline relocations as needed to accommodate all parties for a safe, effective, and minimally disruptive working plan.

(This page left blank intentionally.)

7.0 CONSISTENCY WITH OTHER STATE AND FEDERAL PLANS AND REGULATIONS

This FEIS has been prepared to satisfy the requirements of all applicable environmental laws and regulations and has been prepared using the CEQ NEPA regulations (40 CFR Part 1500–1508) and the USACE’s regulation ER 200-2-2 (*Environmental Quality: Policy and Procedures for Implementing NEPA*, 33 CFR 230). The USACE will follow provisions of all applicable laws, regulations, and policies related to the proposed actions, including those for which applicability, review, and enforcement are their responsibility. Additionally, the local sponsor may be required to secure local municipal permits as a “Land, Easements, Rights-of-Way, Relocation, and Disposal Areas” requirement. The following sections present brief summaries of Federal environmental laws, regulations, plans, and coordination requirements applicable to this FEIS.

7.1 NATIONAL ENVIRONMENTAL POLICY ACT

This FEIS has been prepared in accordance with CEQ regulations in compliance with NEPA provisions. All impacts on terrestrial and aquatic resources have been identified, significant adverse impacts requiring mitigation have been identified, and mitigation has been proposed.

7.2 RIVER AND HARBOR ACT OF 1899

Sections 9 (33 USC 401) and 10 (33 USC 403) are related to structural construction and dredge-and/or-fill activities, respectively, within U.S. navigable waterways. The USACE authorizes permits under this statute. While the agency would not issue a permit for its own actions, the USACE would meet and be consistent with all applicable elements of the statute. Additionally, the USACE and ICT determined that dredged material testing was required under the related Regulatory Guidance Letter 06-02 (*Guidance on Dredged Material Testing for Purposes of Section 404 of the Clean Water Act, Section 10 of the Rivers and Harbors Act, and Section 103 of the Marine Protection, Research, and Sanctuaries Act of 1972*, July 6, 2002). Results are presented in sections 3.3 and 3.4.

7.3 CLEAN WATER ACT

USACE has received §401 State Water Quality Certification from Texas and Louisiana for this action. Both states have determined that the requirements for water quality certification have been met and have concluded that the placement of fill material will not violate water quality standards of each state. The Preferred Alternative is the least environmentally damaging practicable alternative. A CWA §404(b)(1) evaluation of the proposed action, provided in Appendix E of this FEIS, describes the effects of the proposed discharges. Short-term increases in turbidity may be caused by the unconfined flow of dredged material during construction of BU features and mitigation measures. Proposed channel improvements should decrease the number of vessel trips, thus decreasing the probability of a spill.

Appendix E of this FEIS contains the §401(b)(1) evaluation needed for state water quality certification. All relevant sediment and water quality data for both new work and maintenance dredging material were reviewed by a team of State and Federal resource agencies (the CW of the ICT), including the TCEQ and LDEQ, and they found no cause for concern over water or sediment quality in any channel reach. New work sediments were deemed suitable for use in constructing BU or mitigation sites and upland confined PAs, although excess new work material would have to be placed in upland confined PAs. Maintenance material would be handled according to the DMMP. The DMMP measures maximize, to the greatest degree possible, the use of dredged material as a beneficial resource, and share the material from Sabine Pass equally between the states.

7.4 CLEAN AIR ACT of 1970

The CAA is the comprehensive Federal law that regulates air emissions from area, stationary, and mobile sources. An analysis of estimated air contaminant emissions from equipment (including dredges and support equipment such as tugboats, runabouts, and tenders, as well as land based equipment such as bulldozers and employee vehicles) associated with the proposed CIP is expected to result in short-term impacts on air quality in the immediate vicinity of the project area, but no long-term impacts are expected. Emissions of VOC for the project are exempt from a General Conformity Determination because they are below the general conformity threshold of 100 tons per year. However, estimated NO_x emissions for the Preferred Alternative exceed the general conformity threshold; i.e., greater than 100 tpy, for all years of construction.

Pursuant to Section 176 of the CAA Amendments of 1990, the USACE prepared a document entitled, “Draft General Conformity Determination, Sabine-Neches Channel Improvement Project.” This document was noticed for public comment and was submitted by the USACE to the TCEQ, the EPA, and other air pollution control agencies, as appropriate, concurrently with this DEIS. As part of the General Conformity process, the USACE made this document available to the public for review and comment for a period of 30 days. The TCEQ has provided written concurrence that emissions from the Preferred Alternative are conformant with the Texas SIP for the BPA (Appendix A1). Based on TCEQ’s comments, the USACE has prepared a Final General Conformity Determination for the proposed SNWW CIP (Appendix F).

7.5 NATIONAL HISTORIC PRESERVATION ACT OF 1966

Compliance with the NHPA of 1966, as amended, requires identification of all NRHP-listed or NRHP-eligible properties in the project area and development of mitigation measures for those adversely affected in coordination with the Texas and Louisiana SHPOs and the Advisory Council on Historic Preservation. As indicated in Section 3.13, this project would not impact NRHP-listed properties or SALs; however, it may potentially adversely impact terrestrial and marine historic properties eligible for listing in the NRHP. This FEIS has been coordinated with the Texas and Louisiana SHPOs. An HPPA (Appendix H) has been executed among the Texas and Louisiana SHPOs, the SNND and USACE to address subsequent investigations, coordinate surveys of impact areas, test potentially eligible sites, and manage data recovery or avoidance measures as necessary. Tribal coordination, required by the NHPA, has been

conducted. Tribes with historical or cultural ties to the region were contacted early in the study to identify their interests and concerns. The draft Programmatic Agreement has also been coordinated with the Tribes. No Tribes have requested to become consulting parties, and no impacts to Tribal land or traditional cultural properties have been identified.

7.6 ENDANGERED SPECIES ACT

Potential impacts to federally listed threatened and endangered species have been assessed by the USACE in a BA. The BA determined that several federally listed species of sea turtles and wintering populations of the piping plover and its Critical Habitat could potentially be affected by project construction or operation. The BA concluded that the Preferred Alternative would not jeopardize the continued existence of piping plovers or result in the adverse modification of its designated Critical Habitat. Potential impacts to sea turtles from hopper dredging were identified, and interagency consultation under Section 7 of the ESA was initiated. NOAA/NMFS responded with a BO as outlined under Section 7(c) of the ESA of 1973, as amended. The BA and BO are presented in Appendix G of this FEIS; other related correspondence is present in Appendix A2. While the project alternative changed, project-related impacts remained the same and therefore the BO conclusions would remain the same.

Potential impacts to the wintering piping plover would be associated with implementation of the Gulf Shore BU Feature. The recurring placement of dredged material for shoreline nourishment would affect areas of designated Critical Habitat. The USFWS has designated the entire shoreline between Constance Beach and Sabine Pass (Unit LA 1, in part) as Critical Habitat for wintering piping plover. Proposed beach nourishment activities at Louisiana Point would occur along approximately 3 miles of this unit, beginning approximately 0.5 mile east of Sabine Pass. No designated Critical Habitat, or even suitable habitat, is present along the Texas portion of the Gulf Shore BU Feature. The USFWS, in letters dated March 20 and March 22, 2007 (Appendix A2), concurred that the Preferred Alternative is not likely to adversely affect the piping plover or its Critical Habitat and the brown pelican. The USFWS Louisiana Field Office stated that no further ESA consultation would be required with its office unless changes are made to the scope or location of the project. The USFWS Clear Lake Field Office letter was silent on the need for further consultation. However, the USACE staff confirmed by telephone that no further ESA consultation would be required unless changes are made to the scope or location of the project. The Clear Lake Field Office did recommend that steps be taken to determine whether bald eagles are nesting within or near the project area since the number of bald eagles in Texas is increasing. Prior to project construction, the USACE would check with the TPWD and local landowners to determine whether there have been recent bald eagle sightings and determine the need for surveys and further coordination at that time.

The USFWS provided further guidance in a letter dated February 5, 2010, and recommended that all activity in Louisiana occurring within 2,000 feet of a brown pelican rookery be restricted to the non-nesting period (i.e., September 15 through March 31). However, because nesting periods vary considerably among Louisiana's colonies, it is possible that this activity window could be altered based upon the dynamics of the individual colony. Prior to project construction, the LDWF Fur and Refuge

Division will be contacted to obtain the most current information about the nesting chronology of individual brown pelican colonies. In Texas, the USFWS recommended all activity occurring within 1,000 feet of a rookery be restricted to the non-nesting season.

Loggerhead, Kemp's ridley, hawksbill, leatherback, and green sea turtles may be present in the study area waters during certain times of the year. Construction and postconstruction maintenance activities involving the use of hopper dredges could result in impacts to sea turtles. No critical habitat for sea turtles is present in the study area, and there have been no reports of sea turtles nesting in the study area, as most of the shoreline is an eroding, muddy marsh. The NMFS has concluded that hopper dredging during construction and maintenance is likely to adversely affect but is not likely to jeopardize the continued existence of loggerhead, Kemp's ridley, hawksbill, leatherback, or green sea turtles. The Opinion authorizes incidental lethal take of four turtles (three Kemp's ridley sea turtles and one loggerhead or green sea turtle) during the course of the proposed project's hopper dredging. Only incidental takes that occur while the specified reasonable and prudent measures are in full implementation are authorized. These measures specify that (1) dredging should be completed, whenever possible, within specified temperature and date-based dredging windows; (2) NMFS-approved protected species observers must provide 100 percent monitoring during certain date and temperature-determined periods; (3) rigid deflector dragheads must be used on hopper dredges at all times; and (4) relocation trawling is required after the take of one sea turtle during the project. The Opinion authorizes the per-fiscal-year nonlethal noninjurious take, external flipper-tagging, and taking of tissue samples of 32 sea turtles in any combination in association with any relocation trawling conducted during hopper dredging. Maintenance-dredging activities for the proposed project are covered by an existing agreement between the NMFS and USACE regarding the taking of sea turtles with hopper dredges to ensure that significant impacts do not occur (NOAA, 2003).

7.7 MIGRATORY BIRD TREATY ACT AND MIGRATORY BIRD CONSERVATION ACT

The Migratory Bird Treaty Act of 1918 (as amended) extends Federal protection to migratory bird species; among other activities, nonregulated "take" of migratory birds is prohibited under this Act in a manner similar to the ESA prohibition of "take" of threatened and endangered species. Additionally, EO 13186, "Responsibility of Federal Agencies to Protect Migratory Birds," requires Federal activities to assess and consider potential effects of their actions on migratory birds (including, but not limited to, cranes, ducks, geese, shorebirds, hawks, and songbirds). The effect of the Preferred Alternative on migratory bird species has been assessed. The USFWS has concurred that the Preferred Alternative is not likely to affect designated piping plover habitat at Louisiana Point. DMMP marsh restoration and Louisiana marsh mitigation areas would result in a net increase in migratory bird habitat in the project area. Construction contracts would include instructions to avoid impacts to migratory birds and their nests from construction-related activities. The Migratory Bird Conservation Act (16 USC 715–715d, 715e, 715f–715r; 45 Stat. 1222) establishes a Migratory Bird Conservation Commission to approve areas of land or water for acquisition as reservations for migratory birds and is not applicable to the project.

7.8 FISH AND WILDLIFE COORDINATION ACT OF 1958

The Fish and Wildlife Coordination Act directs Federal agencies to consult with the USFWS and relevant state wildlife resource agencies regarding potential impacts to wildlife from proposed improvements like the proposed SNWW CIP. The intent of this consultation is to help prevent the loss of and damage to wildlife resources from water development projects. USACE has consulted with the USFWS throughout the ICT process, and as a result, USFWS recommendations have been incorporated into the final impact assessment and the BU and compensatory mitigation plans for the Preferred Alternative. The USFWS submitted a Coordination Act Report (CAR) that affirms the USACE impact assessment and approves the proposed BU and mitigation plans. The CAR, dated March 16, 2010, is presented in Appendix A3.

7.9 NATIONAL WILDLIFE REFUGE SYSTEM IMPROVEMENT ACT OF 1997

The National Wildlife Refuge System Improvement Act of 1997 amended the National Wildlife Refuge System Administration Act of 1966 to improve management of the NWR System. An amendment to the 1966 Act requires that each refuge administrator review any proposed new use of a refuge to determine whether its use is compatible with the purposes of the refuge and consistent with public safety. Since the proposed Willow Bayou mitigation measures LA 2-18 and LA 2-ADD B are located in the Sabine NWR, and the proposed Gulf Shore BU Feature at Texas Point is located in the Texas Point NWR, the USACE has requested compatibility determinations from each refuge manager. Each refuge must identify the effects of the proposed use on refuge resources and provide an opportunity for public review and comment.

7.10 MARINE MAMMAL PROTECTION ACT OF 1972

The Marine Mammal Protection Act was passed in 1972 and amended through 1997. It is intended to conserve and protect marine mammals and establish the Marine Mammal Commission, the International Dolphin Conservation Program, and a Marine Mammal Health and Stranding Response Program. The Preferred Alternative is in compliance with this Act. No impacts to marine mammals are expected.

7.11 FISHERY CONSERVATION AND MANAGEMENT ACT OF 1996

Congress enacted amendments to the MSFCMA (PL 94-265) in 1996 that established procedures for identifying EFH and required interagency coordination to further the conservation of federally managed fisheries. EFH consists of those habitats necessary for spawning, breeding, feeding, or growth to maturity of species managed by Regional Fishery Management Councils in a series of Fishery Management Plans. Rules published by the NMFS (50 CFR sections 600.805–600.930) specify that any Federal agency that authorizes, funds, or undertakes, or proposes to authorize, fund, or undertake an activity that could adversely affect EFH is subject to the consultation provisions of the above-mentioned Act and identifies consultation requirements. Sections 3.10 and 4.11 of this FEIS were prepared to address EFH in the project area and to initiate consultation under the Act. Any detrimental impacts of the Preferred

Alternative on EFH are minor and temporary, but the project would provide indirect benefits since the project, including the DMMP restoration sites, would lead to an overall net gain in marsh habitat. The NMFS, by letter dated March 8, 2010, has concurred with the FEIS assessment of EFH impacts, and concurs that the proposed BU features and mitigation will offset the adverse impacts to EFH and provide a net-benefit to federally managed fisheries. No further consultation under the MSFCMA with NOAA or NMFS is required.

7.12 FEDERAL WATER PROJECT RECREATION ACT

The Federal Water Project Recreation Act of 1995 requires consideration of opportunities for outdoor recreation and fish and wildlife enhancement in planning water resource projects. The beneficial uses included in the project for the construction and maintenance material include uses requested by various recreational groups, environmental groups, and State and Federal regulatory agencies. All would benefit one or more of the items listed above.

7.13 MARINE PROTECTION, RESEARCH, AND SANCTUARIES ACT OF 1972

This Act requires a determination that dredged material placement in the ocean would not reasonably degrade or endanger human health, welfare, or amenities or the marine environment, ecological systems, or economic potential (shellfish beds, fisheries, or recreational areas). Maintenance and construction dredged material proposed for placement at the existing and new ODMDs, designated by the EPA under Section 102 of Marine Protection, Research, and Sanctuaries Act (MPRSA), is subject to evaluation using the ocean dumping environmental criteria. The proposed new ODMDs are outlined in Appendix B. The conclusion of the ODMD Designation FEIS (Appendix B) was that the Preferred ODMDs met all of the 5 general and 11 specific criteria listed in 40 CFR 228.5 and 228.6 and are therefore acceptable under the MPRSA. All material transported for ocean disposal would be evaluated pursuant to the EPA Ocean Dumping Regulations and Criteria (Section 103). Use of the ODMDs would be in accordance with an approved Site Monitoring and Management Plan (SMMP).

7.14 COASTAL ZONE MANAGEMENT ACT

In an effort to encourage states to better manage coastal areas, Congress enacted the CZMA in 1972. Texas and Louisiana both have developed and continue to implement federally approved coastal zone management programs and plans (TCMP and LCMP, respectively). States with approved plans have the right to review Federal activities (including private activities that require Federal permits) to determine whether they are consistent to “the maximum extent practicable” with the policies of the state’s coastal zone management program. Appendix I addresses the compliance of the Preferred Alternative in this FEIS with the TCMP and LCMP in full detail.

In summary, CNRAs would be affected by the Preferred Alternative. The Preferred Alternative is a result of evaluating six project designs, several mitigation approaches, and beneficial uses of dredged material. Evaluations were made by the ICT and involved extensive modeling of ecological functions based on

potential impacts, RSLR, and mitigative measures. The alternatives evaluations included attempts to minimize and avoid CNRAs to the maximum extent practicable and provide overall benefits to the ecosystems functions.

No net loss of coastal wetlands was a specific goal of the ICT and alternatives evaluation. Several components of the DMMP and mitigation plan involve restoration, protection, and enhancement of coastal wetlands. The Neches River BU Feature would restore 2,853 acres of emergent marsh, nourish 1,234 acres of existing marsh, and improve 871 acres of shallow-water habitat. Additionally, the mitigation plan consists of restoring five degraded marsh areas east of Sabine Lake near Willow and Black bayous, Louisiana. This mitigation measure would restore 2,783 acres of emergent marsh in existing open-water areas within the marsh, improve 957 acres of shallow-water habitat by creating shallower, smaller ponds and channels within the restored marsh, and stabilize and nourish 4,355 acres of existing adjacent marsh.

USACE has evaluated the proposed SNWW CIP for consistency with the Texas and Louisiana coastal management programs, and concluded that the Recommended Plan is fully consistent to the maximum extent practicable with the enforceable policies of both state programs. The Texas Coastal Coordination Council has concurred with the USACE consistency determination. The LDNR-OCM found that the SNWW CIP is conditionally consistent with their state program. Since conditional consistency as proposed by LDNR-OCM is not acceptable, LDNR-OCM has been notified that USACE will proceed with the project. This issue is discussed in further detail in Section 6.0.

7.15 COASTAL BARRIER IMPROVEMENT ACT OF 1990

This act is intended to protect fish and wildlife resources and habitat, prevent loss of human life, and preclude the expenditure of Federal funds that may induce development on coastal barrier islands and adjacent nearshore areas. The Coastal Barrier Improvement Act of 1990 was enacted to reauthorize the Coastal Barrier Resources Act (CBRA) of 1982. The Gulf shoreline at the Texas Point NWR is designated as an “otherwise protected area” (unit T01P). The Gulf shoreline in the Louisiana portion of the study area contains no CBRA-designated units. Exceptions to the Federal expenditure restrictions also include maintenance or constructed improvement(s) to existing Federal navigational channels and related structures (e.g., jetties), including the disposal of dredged materials related to maintenance and construction (The Center for Regulatory Effectiveness, n.d.); therefore, the Preferred Alternative is exempt from the prohibitions identified in the act.

7.16 FARMLAND PROTECTION POLICY ACT OF 1981 AND THE CEQ MEMORANDUM PRIME AND UNIQUE FARMLANDS

In 1980, the CEQ issued an Environmental Statement Memorandum “Prime and Unique Agricultural Lands” as a supplement to the NEPA procedures. Additionally, the Farmland Protection Policy Act was passed in 1981, requiring consideration of those soils, which the USDA defines as best suited for food, forage, fiber, and oilseed production, with the highest yield relative to the lowest expenditure of energy

and economic resources. The NRCS concurred that the “prime farmland if drained” soil mapped in PA 24A is not Important Farmland, and provided the Farmland Conversion Impact Rating Form indicating an exemption.

7.17 EXECUTIVE ORDER 11988, FLOODPLAIN MANAGEMENT

The Preferred Alternative includes the development of two new PAs (PA18A and PA24) and the Neches River BU Feature within the floodplain of the Neches River. Alternatives to avoid the adverse effects of developing the two new PAs in the floodplain were evaluated, and it has been determined that this is the only practicable alternative. The Neches River BU Feature would construct marsh in areas of open water within the floodplain that formerly were emergent marsh; they would remain jurisdictional wetlands after construction. Development in the BU areas would be controlled by Section 404 regulations, and their construction would not be expected to induce growth in the floodplain. BU alternatives were evaluated in consideration of existing drainages to ensure that restored wetland areas would not induce flooding. This FEIS fulfills public notification requirements as it provides an explanation of why these project features are proposed to be located in the floodplain and provides an opportunity for the public to comment on these plans.

7.18 EXECUTIVE ORDER 11990, PROTECTION OF WETLANDS

This EO directs Federal Agencies to avoid undertaking or assisting in new construction in wetlands, unless no practical alternative is available. One of the two new PAs proposed for development (PA 24A) would result in the conversion of 86 acres of wetlands to a confined PA. Alternatives to avoid the loss of 86 acres of wetlands were evaluated, and it has been determined that this is the only practicable alternative. The Preferred Alternative’s Neches River BU Feature would result in a net gain in wetlands along the lower Neches River, and the ecological benefits of this feature would more than offset the loss of 86 wetland acres due to the construction of PA 24A. The Neches River BU Feature would construct marsh in areas of open water within the floodplain that formerly were emergent marsh; they would remain jurisdictional wetlands after construction. The Neches River BU Feature would improve water quality, inhibit erosion and sediment loss, and restore habitat for fish and wildlife species, improving the long-term productivity of the lower Neches River ecosystem.

7.19 EXECUTIVE ORDER 13112, INVASIVE SPECIES

Under EO 13112, Federal agencies may not authorize, fund, or carry out actions that it believes are likely to cause or promote the introduction or spread of invasive species unless the agency has determined and made public its determination that the benefits of such actions clearly outweigh the potential harm caused by invasive species. Related to project development and implementation, Federal agencies whose action(s) may affect the status of invasive species are required to use relevant programs, information, and authorities to do the following:

- prevent the introduction and/or spread of invasive species;
- accurately monitor invasive species populations related to their area of effects;

- provide restoration for natural vegetation communities adversely affected by invasive species;
- provide environmentally sound control of invasive species; and
- consult with the Invasive Species Council and ensure their actions are consistent with the Invasive Species Management Plan.

Although ship traffic would increase with the Preferred Alternative, the increase would be less than the predicted growth of ship traffic under the No-Action Alternative, and therefore, no additional impacts with respect to ballast water are expected. Furthermore, no changes in foreign ports of call are predicted.

7.20 EXECUTIVE ORDER 12898, ENVIRONMENTAL JUSTICE

This EO directs Federal agencies to determine whether the Preferred Alternative would have a disproportionate adverse impact on minority or low-income population groups within the project area. The Preferred Alternative would not significantly affect any low-income or minority population (Section 4.12).

7.21 COMPREHENSIVE ENVIRONMENTAL RESPONSE, COMPENSATION, AND LIABILITY ACT AND RESOURCE CONSERVATION AND RECOVERY ACT

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) of 1980 (as amended) was designed to help clean up the nation's inactive hazardous waste sites. There are a variety of different requirements included in this sweeping legislation. CERCLA also requires industries to disclose to their communities what hazardous substances they use and store. CERCLA authorized the EPA to remediate polluted sites; for this purpose it created Superfund to pay for site cleanups when there is no clear-cut responsible party. The EPA can also pursue potentially responsible parties to make them pay for response and remediation activities. Superfund, 40 CFR 302–310, authorized the EPA to respond to and remedy polluted sites and created Superfund to pay for site cleanups when a responsible party could not be identified.

The RCRA of 1976 (as amended) provides for comprehensive cradle-to-grave regulation of hazardous waste and authorizes environmental agencies to order the cleanup of contaminated sites. Since 1984, it has also called for the extensive regulation of underground storage tanks and the cleanup of contamination caused by leaking tanks. In addition, RCRA addresses the environmental problems associated with nonhazardous solid waste and encourages states to develop solid waste management programs, regulate solid waste landfills, and eliminate open dumps. Federal facilities are required to comply with Federal, State, and local regulations and requirements on solid and hazardous waste and underground storage tanks to the same extent as private parties. RCRA contains provisions on a number of other topics, such as resource recovery, used oil management and recycling, small town environmental planning, and plastic ring carriers. While most RCRA provisions focus on the protection of human health, its wide-ranging attempts to prevent, reduce and eliminate pollution have an obvious, if largely unstated, effect on wildlife protection as well.

These acts require the reporting of hazardous, toxic, and radioactive waste and prescribe specific handling and remediation requirements. A records search was performed to identify possible RCRA and CERCLA sites in or near the project area, and these are described in the FEIS. An evaluation of the potential for these sites to impact the proposed project was conducted, and yielded the following concern. Contaminant issues affecting PA 17 must be resolved by the non-Federal sponsor before the PA can be used as part of the preferred alternative. Alternative placement areas are available should this not be resolved in time for use.

7.22 FEDERAL AVIATION ADMINISTRATION – HAZARDOUS WILDLIFE ATTRACTANTS ON OR NEAR AIRPORTS

In accordance with FAA AC 150/5200-33 and the Memorandum of Agreement among the FAA, the USACE, and other Federal agencies (July 2003), the Preferred Alternative was evaluated to determine if proposed land uses could increase wildlife hazards to aircraft using public use airports in the study area. Potential attractants (four existing PAs) were found to be located between the 10,000-foot and 5-mile perimeters of the Southeast Texas Regional Airport in Beaumont, Texas. No new PAs would be constructed within the separation perimeters, and no change in land use is proposed in conjunction with the Preferred Alternative. USACE provided this information to the FAA, and concluded that continued use of the four existing PAs does not constitute a change in land-use and is compatible with airport operations.

7.23 TEXAS CHENIER PLAIN NATIONAL WILDLIFE REFUGE COMPLEX COMPREHENSIVE CONSERVATION PLAN

The Texas Chenier Plain NWR Complex is four units administered by the USFWS: Anahuac NWR, McFaddin NWR, Texas Point NWR, and Moody NWR. These units are located along the upper Texas Gulf Coast in Chambers, Jefferson, and Galveston counties. Only the Texas Point NWR is located within the SNWW study area. The Refuge Complex's aquatic habitats (open-water and near-shore Gulf habitats), freshwater to saline marshes, riparian habitats, coastal woodlots, rice fields, native prairies, cheniers and coastal beach, and dune habitats harbor over 300 bird species, 75 species of freshwater fish, and 400 species of salt and brackish water finfish and shellfish.

Long-term, large-scale alterations to the region—over 100,000 acres of coastal wetland loss in 25 years; loss and conversion of more than 99 percent of the historic tallgrass prairie along the Louisiana and Texas Gulf Coasts for agriculture, residential, and commercial uses; increases in nonnative plant and animal species; loss or severe restriction of freshwater and sediment inflows and increased saltwater intrusion; and ongoing threats from sea level rise and land subsidence—have prompted the USFWS to act to facilitate the long-term protection of natural resources in the region.

The Texas Chenier Plain National Wildlife Refuge Complex Comprehensive Conservation Plan (CCP) provides a 15-year vision to identify and propose solutions to significant problems that may adversely affect the populations and habitats of fish, wildlife, and plants and the actions necessary to correct or

mitigate such problems (USFWS, 2008a). The CCP has four goals: (1) conserve, enhance and restore the refuge's coastal wetlands to provide habitat for native fish and wildlife; (2) conserve, enhance and restore the refuge's coastal prairies and coastal woodlands to provide habitat for native fish and wildlife; (3) implement a comprehensive biological program to guide and support conservation effort for all native fish, wildlife, and plant species; and (4) work with others on a landscape level to address threats to natural biological diversity, ecological integrity, and environmental health on the Refuge Complex. Specific strategies will include habitat restoration, protection, and land acquisition from willing sellers.

The Preferred Alternative would impact the goals of the CCP by causing small increases in salinity and land loss, and related decreases in productivity within the intermediate, brackish, and saline marshes of the Texas Point NWR. However, losses quantified by the WVA model would be more than offset by gains from the regular beneficial use of dredged material for shoreline nourishment at Texas Point. This BU feature complies with another goal of the CCP—the restoration of sediment supply to the Gulf's nearshore littoral zone at Texas Point NWR through the beneficial use of dredged material. Other CCP goals (restoration of hydrology by reducing saltwater intrusion with rock weirs or earthen plugs in Texas Bayou, and using dredged material to restore mineral sediment to interior marsh) were thoroughly evaluated in the screening of BU and mitigation measures. Construction of rock weirs or earthen plugs at Texas Bayou were determined to be ineffective in reducing saltwater intrusion. The beneficial use of dredged material to restore interior marsh would be feasible, but the cost would exceed the Traditional Placement Plan. The latter goal could be pursued if a non-Federal sponsor offers to pay the incremental cost of construction. The SNWW CIP does not conflict with any of the refuge expansion goals of the Texas Point NWR.

7.24 SABINE NATIONAL WILDLIFE REFUGE COMPLEX COMPREHENSIVE CONSERVATION PLAN

The Sabine NWR is part of the Southwest Louisiana National Wildlife Refuge Complex, which also includes Cameron Prairie and Lacassine NWRs to the east within Cameron Parish, and Shell Keys NWR in Iberia Parish. Only the western portion of the Sabine NWR (portions of Unit 5, excluding Pool 3, Unit 6, and Unit 7) is located within the SNWW study area. The refuge contains a diversity of habitat including extensive coastal marshes and open water, wooded ridges and levees, canals, ponds, and bayous. The refuge provides habitat for many species of wildlife, including ducks, geese, alligators, muskrats, nutria, raptors, wading birds, shorebirds, blue crabs, shrimp, and finfish. It is one of the primary overwintering refuges for waterfowl in the Mississippi Flyway.

Overall, the greatest risk to fish, wildlife, plants, and their habitats in the Chenier Plain ecosystem is from extensive wetland habitat degradation and loss that has occurred over the past century. Wetlands in the Chenier Plain declined 16 percent from the mid-1960s to 1990. These habitat losses have led to commensurate impacts on wildlife populations, especially those dependent on wetlands. These losses have prompted the USFWS to implement a 15-year protection plan to facilitate wetland preservation and restoration, a most important wildlife conservation priority of the Gulf Coast ecosystem.

The CCP provides a 15-year vision to identify and propose solutions to significant problems that may adversely affect the populations and habitats of fish, wildlife, and plants and the actions necessary to correct or mitigate such problems (USFWS, 2008b). CCP primary goals include (1) maintaining, restoring, and enhancing unique coastal wetland habitats on the refuge to provide favorable conditions to improve species diversity and richness of migratory birds and native terrestrial and aquatic species; and (2) maintaining healthy and viable wildlife and fish populations on the refuge to contribute to the purpose for which it was established.

The Preferred Alternative would impact the first goal of the CCP by causing small increases in salinity and land loss, and related decreases in productivity within the intermediate, brackish, and saline marshes of the refuge. However, losses as quantified by the WVA model would be more than offset by gains from the regular beneficial use of dredged material for shoreline nourishment at Louisiana Point and other BU features associated with the project in Texas. In addition, it is proposed that two of the compensatory mitigation measures proposed for the SNWW CIP be located within the Sabine NWR. These measures would employ one of the management strategies recommended by the CCP—using dredged material to restore mineral sediment to emergent marsh in degraded areas of the refuge. In the long term, these mitigation areas would contribute to the restoration of habitat and maintenance of healthy fish and wildlife populations in the refuge.

7.25 TEXAS COASTWIDE EROSION RESPONSE PLAN

The Texas Coastwide Erosion Response Plan has identified several parts of the study area as “critical erosion areas” because of impacts to habitats and traffic safety from ongoing erosion, and has called for an increase in the beneficial use of dredged material from the SNWW project to help address these issues. The plan was developed as part of the CEPRA (GLO, 2004, 2005). The program has identified the Gulf shoreline between Texas Point and Sea Rim State Park as a critical erosion area. It attributes the erosion, in part, to a lack of sediment coming down the Sabine and Neches rivers, and the interruption of longshore sediment transport by the SNWW jetties. The CEPRA Plan recommends that long-term regional sediment management be utilized, along with highway realignment and beach dune restoration, to protect the important coastal evacuation route of SH 87 in Jefferson County. In Orange County, the CEPRA Plan calls for restoration of 9,400 acres of marsh in the Lower Neches River using dredged material to raise soil elevations in the former marsh areas that have become open water. The Preferred Alternative would address some of the ongoing problems by using maintenance material for shoreline nourishment at Texas Point and by restoring and nourishing approximately 5,000 acres of marsh in the Lower Neches River floodplain.

7.26 LOUISIANA COAST 2050

In Louisiana, the Coast 2050 is a comprehensive, ecosystem-based restoration plan, completed in 1998 to address coastal wetland loss throughout southern Louisiana. Planning involved Federal, State, and local entities, landowners, environmentalists, wetland scientists, and others in the development of an integrated,

multiple-use approach to ecosystem management. A major funding source for these projects comes from the Federal CWPRA. The SNWW is located in Region 4 of this plan.

The goals of Coast 2050 are to:

- Sustain coastal ecosystem with the essential functions and values of the natural ecosystem
- Restore the ecosystem to the highest practicable acreage of productive and diverse wetlands
- Accomplish this restoration through an integrated program that has multiple use benefits

In the Sabine Lake area, Coast 2050 strategies include:

- Maintain Sabine River inflow
- Beneficial use of dredged material for marsh creation
- Seasonally operated locks at the mouths of navigation channels to relieve salinity stress on marshes

Detailed strategies for specific areas are described in the Coast 2050: Toward a Sustainable Coastal Louisiana (LCWCR/WCRA, 1998). The USACE, New Orleans District, and LDNR prepared the *Louisiana Coastal Area Feasibility Study* to provide the necessary technical data required to implement the conceptual plan of the Coast 2050 document (USACE, 2004a). The Preferred Alternative would impact the first goal of the Coast 2050 Plan by causing small increases in salinity and land loss, and small decreases in productivity. However, these losses would be fully compensated by marsh restoration mitigation measures in the Willow and Black bayou watersheds.

7.27 LOUISIANA COASTAL AREAS ECOSYSTEM RESTORATION STUDY AND PLAN

The LCA Ecosystem Restoration Study (USACE, 2004a) documented the most critical human and natural needs of the endangered Louisiana coastal area, identified short- and long-term critical priorities, and recommended large-scale, long-term studies that were beyond the scope of that study. The eastern half of the SNWW study area is located in the western part of Region 4, the Chenier Plain. Without any preservation or restoration actions, the report predicted that Sabine Lake wetlands would continue to experience severe wetland deterioration and land loss due to increased salinity levels and marine influences from the SNWW and the GIWW, relative sea level change, tropical storms, oil and gas infrastructure, sediment reduction/vertical accretion deficit, and saltwater intrusion resulting from diminished freshwater inflow.

For Region 4 as a whole, existing rates of habitat loss are predicted to continue, resulting in the loss by 2050 of 9.8 percent of existing fresh marsh, 16.3 percent of intermediate marsh, 100 percent of saline marsh, and 33.3 percent of swamp habitat. Brackish marsh and open water are predicted to increase by 46.5 and 11.4 percent, respectively. This would reduce habitat diversity and result in a long-term loss of an estimated 37 square miles of land loss.

The LCA report did not recommend any near-term critical restoration features for congressional authorization or additional study in Region 4. While beneficial use of dredged material from the Calcasieu Channel is recommended for wetlands adjacent to that channel, no beneficial use projects are identified for the marshes along the eastern shore of Sabine Lake. A long-term, large-scale study of freshwater and sediment management in the Chenier Plain was recommended and this would include the portion of the SNWW study area east of Sabine Lake and the Sabine River. The Preferred Alternative does not include any features that would conflict with future restoration features. Impacts of the proposed project would be fully compensated by the marsh mitigation measures.

7.28 LOUISIANA’S COMPREHENSIVE MASTER PLAN

Louisiana has developed a coastal master plan that integrates planning for ecosystem restoration and hurricane protection in planning for a sustainable coast (LCPRA, 2007). The master plan establishes a clear set of priorities for comprehensive coastal protection in Louisiana. In the Chenier Plain, the plan notes that navigation channels and canals have allowed salt water to penetrate inland, destroying fringe marsh and impinging on freshwater lakes. The plan recommends the development of a new plan to develop appropriate measures to address these impacts. Portions of the plan that affect the SNWW study area are as follows. The Chenier Plain Freshwater and Sediment Management and Reallocation Plan suggests managing river and surface fresh water supplies to ensure availability of fresh water throughout the year. This management would also permit the delivery of fresh water to areas exposed to saltwater stress. It is suggested that the GIWW could be used as a conduit to distribute fresh water from the Atchafalaya River toward marshes to the west. The plan also seeks to maintain the integrity of freshwater resources by raising and fortifying selected portions of SH 82, installing segmented offshore breakwaters to protect the barrier shoreline, fortifying dredged material banks along the GIWW, and placing saltwater barriers on the SNWW to manage salinity levels. The plan recognizes that safe and efficient navigation must be maintained when implementing such a project. It suggests that a barrier could be operated periodically to manage saltwater intrusion events. Marsh restoration using dredged material from maintenance dredging of navigation channels is also recommended. In planning hurricane protection structures, the plan emphasizes nonstructural solutions such as flood insurance, elevating and retrofitting structures, and revising building codes. No structural solutions for hurricane protection are recommended for the study area. The State’s Annual Plan would be the vehicle for presenting yearly scheduling and cost information about proposed projects. The Preferred Alternative does not include any features that would conflict with restoration priorities of this plan. Impacts of the proposed project would be fully compensated by marsh mitigation measures.

7.29 LOUISIANA COASTAL PROTECTION AND RESTORATION

In February 2008, the Louisiana Coastal Protection and Restoration Draft Technical Report was released for public review and comment (USACE, 2008a). The study was conducted as a joint effort of the Federal government and the State of Louisiana to investigate and integrate hurricane risk reduction and coastal restoration for south Louisiana. The purpose of the report is to describe the progress that the USACE has

made in this effort, which is mandated by the Energy and Water Development Appropriation Act of 2006 and the Department of Defense, Emergency Supplemental Appropriations to Address Hurricanes in the Gulf of Mexico, and Pandemic and Influenza Act, 2006. Additional time would be needed for the USACE to complete the comprehensive hurricane analysis and design for south Louisiana due to engineering, environmental, and economic complexities. The Louisiana Coastal Protection and Restoration effort is closely tied to Louisiana's Comprehensive Master Plan discussed above. The report does not make recommendations for project authorizations, appropriations, or nongovernmental decisions. It describes methodologies used to perform the technical evaluation and the process used to engage stakeholders.

One of the most significant accomplishments is the development and application of numerical models that replicate hurricane surges and determine the statistical frequency of events along the entire Louisiana coast. This effort has vastly improved the ability of the USACE to evaluate hurricane threats along the northern Gulf coast, including storm surge and wave effects. The Louisiana Coastal Protection and Restoration effort also quantified the risk reduction benefits provided by wetlands. The Louisiana coast is divided into planning units that generally correspond to previously defined subregions. Planning Unit 4 corresponds to Region 4, the Chenier Plain.

Hurricane modeling determined that certain areas of the Gulf are more likely to experience higher-intensity storms. Southeastern Louisiana, Mississippi, and western Alabama were shown to have a higher probability of severe-storm occurrence than elsewhere along the Gulf. The probability of a hurricane greater than Category 2 on the Saffir-Simpson Scale hitting the Gulf coastline in the SNWW study area is 2 percent in any 1 year, half that of the highest probability zone (4 percent in any 1 year). Hurricane Rita is a close comparison to a 100-year storm based on size, intensity, and track. It produced a peak storm surge with an approximately 90-year return interval, compared to the 400-year storm surge of Hurricane Katrina. The Louisiana Coastal Protection and Restoration storm surge modeling projects that a water surface height in the SNWW study area (east of Sabine Lake) with a 100-year storm would range from 15 feet near the coast to 11 feet north of the GIWW near Orange, Texas. Storm surge effects would be felt in the Sabine River valley far north of the current study area. For a 400-year storm, water elevations would range from 19 feet near the coast to 12 feet north of the GIWW near Orange, Texas.

Planning Unit 4 Alternatives located within the SNWW study area are limited to two types: (1) construction of a 12-foot-high levee along the entire GIWW alignment, ending at the Sabine River; and (2) marsh restoration in the marshes east of Sabine Lake. The coastal restoration alternative includes marsh restoration in two areas that are proposed as compensatory mitigation measures for the SNWW CIP (LA 3-10R and LA 3-15). Coastal restoration scored relatively highly in minimizing environmental impacts but did not appear to be a cost-effective measure. The potential for channel deepening proposed in the Preferred Alternative was evaluated with HS modeling conducted for this study. The results of this analysis indicated there would be no significant increase in storm surge effects.

7.30 NORTH AMERICAN WATERFOWL MANAGEMENT PLAN

The purpose of the North American Waterfowl Management Plan (NAWMP, Plan Committee, 2004) is to sustain abundant waterfowl populations by conserving landscapes through partnerships that are guided by sound science. The 2004 Plan establishes a new 15-year horizon for waterfowl conservation in North America by assessing and defining needs, priorities, and strategies needed to promote waterfowl conservation in the twenty-first century. The SNWW study area is located in the Gulf Coastal Prairie, an area of continental significance to North American ducks, geese, and swans as it lies within the Central Flyway. The plan focuses on habitat conservation at a continental scale and identifies general objectives for habitat conservation in five key priority regions, including the Gulf Coast Prairie Region. The beneficial use of dredged material to restore degraded marshes is specifically identified as a habitat conservation strategy in this plan. The Preferred Alternative would contribute to plan goals with the restoration and nourishment of approximately 5,000 acres of emergent marsh in the Lower Neches River floodplain and regular shoreline nourishment at Texas and Louisiana Points.

8.0 ANY ADVERSE ENVIRONMENTAL IMPACTS WHICH CANNOT BE AVOIDED SHOULD THE PREFERRED ALTERNATIVE BE IMPLEMENTED

The Preferred Alternative would result in minor adverse impacts to benthos and fish from dredging and placement of dredged material but these impacts are temporary. Although the SNWW channel is located primarily in Texas, large indirect impacts may occur due to small increases in salinity levels causing an increase in wetland loss and a decrease in biological productivity in aquatic habitats of both Texas and Louisiana. In Texas, 33,500 acres of intertidal marsh and swamp are expected to be indirectly impacted due to the slight salinity increase as a result of the proposed action. Biological productivity may be reduced over approximately 39,000 acres of tidal marsh and swamp in Texas, with the potential loss of 247 acres of emergent marsh, including 86 acres of fresh marsh that would be converted to an upland PA. Impacts in Louisiana may affect approximately 182,000 acres of tidal, emergent marsh, and potentially result in the loss of about 691 additional acres of marsh within the area of tidal influence. This includes 86 acres of wetland habitat that would be converted to an upland PA. The BU features and compensatory mitigation address wetland loss by restoring a total of 5,636 acres of emergent marsh, 1,828 acres of improved shallow-water habitat, and nourishing 5,589 acres of existing marsh, which more than compensates for wetland losses resulting from a small increase in salinity and enhances the long-term productivity of the study area's ecosystem.

8. Any Adverse Environmental Impacts Which Cannot Be
Avoided Should The Preferred Alternative Be Implemented

(This page left blank intentionally.)

9.0 ANY IRREVERSIBLE OR IRRETRIEVABLE COMMITMENTS OF RESOURCES INVOLVED IN THE IMPLEMENTATION OF THE RECOMMENDED PLAN

The primary impact of the Preferred Alternative is an indirect impact associated with a small increase in salinity and an associated reduction in biological productivity over approximately 211,500 acres of intertidal marsh and swamps in Texas and Louisiana, and the potential resultant loss of about 691 acres of marsh within the area of tidal influence of the SNWW. Benefits of the Neches River BU Feature more than offset the direct impact of conversion of 86 acres of fresh marsh to a confined PA (PA 24A) and the indirect impact of the increase in salinity over 39,000 wetland acres in Texas. The Neches River BU Feature restores 2,853 acres of emergent marsh, improves 871 acres of shallow-water habitat, and nourishes 1,234 acres of existing marsh, providing benefits that offset all project impacts in Texas and all but the loss of 843 AAHUs in Louisiana. The indirect effect of a small increase in Gulf shoreline erosion in both states (totaling approximately 15 acres over the period of analysis) is minimized by the Gulf Shore BU Feature. Compensatory mitigation for unavoidable impacts in Louisiana restores 2,783 acres of emergent marsh, improves 957 acres of shallow-water habitat, and nourishes 4,355 acres of existing marsh in the Willow and Black bayou areas. The BU features and compensatory mitigation address wetland loss by restoring 5,636 acres of emergent marsh, 1,828 acres of shallow-water habitat, and nourishing 5,589 acres of existing marsh, which more than compensates for worst-case wetland losses resulting from a small increase in salinity and enhances the long-term sustainability of the study area ecosystem. Since there would be a time lag before the restored marshes become established and ecologically functional, there would be a temporary loss of productivity during the interim period. Benthic organisms in the Gulf that are buried during initial and subsequent use of the ODMDs would recover quickly after each use. The productivity of expanded PAs on the Neches River and the Sabine Lake bottom taken for borrow material would be temporarily disrupted, but would shortly be transformed into different habitats that would contribute to the long-term productivity of the SNWW estuary.

(This page left blank intentionally.)

10.0 RELATIONSHIP BETWEEN LOCAL SHORT-TERM USES OF MAN'S ENVIRONMENT AND THE MAINTENANCE AND ENHANCEMENT OF LONG-TERM PRODUCTIVITY

BU features and compensatory mitigation provided under the Preferred Alternative address wetland loss by restoring 5,636 acres of emergent marsh, 1,828 acres of shallow-water habitat, and nourishing 5,589 acres of existing marsh, which more than compensates for worst-case wetland losses resulting from a small increase in salinity and enhances the long-term productivity of the study area ecosystem. Since there would be a time lag before the restored marshes become established and ecologically functional, there would be a temporary loss of productivity during the interim period. Benthic organisms in the Gulf that are buried during initial and subsequent use of the ODMDSs would recover quickly after each use. The productivity of expanded PAs on the Neches River and the Sabine Lake bottom taken for borrow material would be temporarily disrupted, but would shortly be transformed into different habitats that would contribute to the long-term productivity of the SNWW estuary.

10. Relationship Between Local Short-Term Uses of Man's Environment
and the Maintenance and Enhancement of Long-Term Productivity

(This page left blank intentionally.)

11.0 ENERGY AND NATURAL OR DEPLETABLE RESOURCE REQUIREMENTS AND CONSERVATION POTENTIAL OF VARIOUS ALTERNATIVES AND MITIGATION MEASURES

NEPA regulations in 40 CFR 1502.16(e) and (f) require a discussion of project energy requirements and natural or depletable resource requirements, along with conservation potential of alternatives and mitigation measures in an EIS.

Under the No-Action Alternative, the energy requirements for maintaining the channel would continue as before. However, the navigation requirements for energy (fuel) to transport commercial products is likely to increase in the future as commerce increases and more traffic increases congestion and navigation time into and out of regional ports. Air quality impacts are likely to increase with an increase in navigation traffic congestion and travel time along the SNWW.

The Preferred Alternative is expected to reduce energy (fuel) requirements for transporting products on a ton/mile basis by deepening the channel and providing bend easings:

- ships can be more heavily loaded with cargo; and
- fewer vessel trips would be required in lightering of crude oil from large ships offshore.

Energy (fuel) would be required to deepen the channel, but this is a short-term impact. Energy to maintain the deeper channel is expected to increase by roughly a factor of two, with the increase in shoal material expected for the larger channel. This increase in fuel requirement is expected to be more than offset by fuel savings in ship traffic in the larger channel and should help reduce air quality impacts slightly over the No-Action Alternative, especially since the largest increase in shoaling is offshore. Increased efficiency in moving petroleum and other petroleum-based commodities to the local refineries is expected to help conserve natural or depletable resources in the future. The reduced energy requirements of the more-efficient channel would result in a smaller increase in transportation costs in the future, which reduces overall production costs for the consumer.

12.0 LIST OF AGENCIES AND ORGANIZATIONS TO WHOM COPIES OF THE FINAL STATEMENT ARE SENT

12.1 PUBLIC INVOLVEMENT PROGRAM

The USACE and SNND involved the public through public meetings and other outreach throughout the history of this project. A proactive approach was taken to inform and involve the public, resource agencies, industry, local government, and other interested parties about the project and to identify any public concerns.

The first public scoping meeting was held on May 24, 2000, at the John Gray Center Auditorium, Lamar University, Beaumont, Texas. The purpose of this meeting was to inform the public about the initiation of the feasibility study and to solicit comments on navigation concerns, alternatives to be addressed, and environmental issues and concerns.

The second public scoping meetings were held on May 28, 2002, at the Best Western Hotel, Lake Charles, Louisiana, and May 29, 2002, at the John Gray Center Auditorium, Lamar University, Beaumont, Texas. The purpose of these meeting were to inform the public about study progress and to solicit comments on environmental issues such as changes in salinity and circulation, changes in fresh- and saltwater marshes, water and sediment quality, erosion along the channel, threatened and endangered species impacts, and beneficial use of dredged materials.

Other various forms of outreach utilized during this project included early regulatory agency coordination, ICT, RW, MW, CW, OW, and HW meetings, public workshop to obtain ideas for BU of dredged material, media trips down the waterway, presentations at the GMFMC Texas Habitat Protection Advisory Panel, meetings with the Sabine Pilots Association, presentation at the 2007 Southeast Texas Leaders meeting, meetings with SNWW industries, individual contacts, press releases, and comment forms.

DEIS Public Hearings were conducted on January 26, 2010, at the Beaumont Civic Center in Beaumont, Texas, and on January 27, 2010, at the Lake Charles Civic Center in Lake Charles, Louisiana, to solicit comments and information from the public. Approximately 51 people attended the meeting in Beaumont, and 19 in Lake Charles. An open house was conducted prior to the Public Meetings, which included table-top poster presentations and discussions among the USACE, the SNND, USACE consultants, and the public. Formal presentations were made by SNND and USACE during the public meetings, and then oral comments were taken from the public. These comments were considered when finalizing the FEIS. Transcripts of the DEIS public meetings are presented in Appendix K.

12.2 REQUIRED COORDINATION

The FEIS is being circulated to all known Federal, State, and local agencies. Interested organizations and individuals are also being sent notice of availability. A list of those who are being sent a copy of this

12. List of Agencies and Organizations to Whom Copies of the Final Statement Are Sent

document, along with a request to review and provide comments on the documents, is provided in Section 12.3.

12.2.1 PUBLIC VIEWS AND RESPONSES

Public views and concerns expressed during this study have been considered during the preparation of this FEIS. The views and concerns were used to develop planning objectives, identify significant resources, evaluate impacts of various alternatives, identify potential PAs, and identify a plan that is socially and environmentally acceptable. Important concerns expressed included the beneficial use of dredged material and recreational opportunities.

Development of alternatives is explained in Section 2. The recommended plan takes into consideration the expressed objectives, views, and concerns of the resource agencies and public. Public comments received are addressed Appendix A5.

12.3 STATEMENT RECIPIENTS

The following list includes agencies, organizations, and public that were sent a copy of these documents and/or the Notice of Availability with a request to review and provide comments.

(This page left blank intentionally.)

13.0 LIST OF PREPARERS

Name/Title	Experience	FEIS Area of Responsibility
U.S. Army Corps of Engineers, Galveston District		
Janelle Stokes, Regional Environmental Specialist	25 years, Environmental Impact Assessment and Impact Analysis, Cultural Resource Coordination, Archeological Research and Surveys	Project coordination, report preparation, CE/ICA analysis, WVA modeling
Carolyn Murphy, Chief, Environmental Section	27 years, Environmental Impact Assessment and Impact Analysis, Planning and Environmental Resources, Archeological Research and Surveys	Document review
Richard Medina, Chief, Planning and Environmental Branch	35 years, Environmental Impact Assessment and Impact Analysis, Planning and Environmental Resources	Document review
Rob Hauch, Physical Scientist	26 years, Environmental Impact Assessment and Impact Analysis; Dredged Material, Water, and Sediment Quality Analyses	Appendix B preparation assistance, project review
Kristy Morten, HTRW Specialist	28 years, HTRW and Biological Analysis	HTRW, document review
Nicole Minnichbach, Staff Archeologist	7 years, Archeology	Archeology section preparation and review
Nancy Young, Civil Engineer	10 years, Civil Engineer	Engineering design of BU features and mitigation measures
John Damm, Geotechnical Engineer	20 years, Geotechnical Engineer	Engineering design of BU features
Ryan Brown, Geotechnical Engineer	3 years, Geotechnical Engineer	Engineering design of BU features
U.S. Environmental Protection Agency		
Barbara Keeler	30 years of coastal environmental science and NEPA experience for EPA, currently serving as the Region 6 Coastal & Wetlands Planning Coordinator.	Served as the EPA Regional lead for technical and policy EIS review. Participated in this effort as the EPA representative on the Habitat Workgroup and the Sabine-Neches Interagency Coordination Team.
Stephen Bainter	30 years environmental related activities experience, to include experiences in positions as the Municipal Whole Effluent Coordinator, Water Quality Permitting Specialist, and Water Quality Standards Coordinator for EPA Region 6. Currently assigned as EPA Region 6's Ocean Dumping Coordinator.	ODMDS EIS and SMMP technical review.

Name/Title	Experience	FEIS Area of Responsibility
U.S. Environmental Protection Agency, concluded		
Renee Bellew	9 years environmental related activities experience, currently serving as a Water Quality Standards Coordinator for EPA Region 6. Participated in this effort while as the EPA Region 6's Ocean Dumping Coordinator.	ODMDS EIS technical and policy review.
PBS&J		
Martin Arhelger, Vice President, Project Director	30 years, Environmental Assessment and Impact Analysis	Project Manager, water and sediment quality
Angela Bulger	8 years, NEPA Compliance and Coordination	Assistant Project Manager, document coordination
Tony Risko	18 years, Coastal Engineering	Assistant Project Manager
Lisa Vitale, Marine Biologist	15 years, Marine Biology	Assistant Project Manager, Marine Fisheries/EFH, document coordination and production, quality control
Tomas Dixon, Senior Scientist	8 years, Wildlife and Protected Species	Wildlife and threatened & endangered species, BA and CMP preparation
Derek Green, Biologist, Wildlife Specialist	24 years, Environmental Assessment and Analysis	Wildlife and habitat, threatened and endangered species, sea turtle analysis
Erik Huebner, Senior Scientist	10 years, Wildlife and Protected Species	Wildlife and threatened & endangered species
Tommy Adamski, Senior Environmental Planner	10 years, Planning	Noise analysis
Wendy Connally, Ecologist	4 years, Environmental Assessment and Analysis	Cumulative Impacts and QA/QC
Kathy Calnan, Ecology, Botany	16 years, Vegetation Analysis and Impacts	Vegetation Analysis
Dave Buzan, Aquatic Biologist	30 years, Aquatic Biology, Vegetation Analysis and Impacts	Freshwater Fisheries, Vegetation Analysis
Ruben Velasquez, Senior Engineer	30 years, Air Quality	Air Quality, General Conformity
Bob Gearhart, Archeologist, Magnetometer and Side-Scan Sonar Specialist	22 years, Marine Archeology	Marine archeology
Steve McVey, Geologist, HazMat Specialist	12 years, Environmental Geology	HTRW Analysis
Tricia LaRue, Environmental Planner	5 years, Planning and Socioeconomics	Socioeconomics
Michael Hettenhausen, Environmental Planner	2 years, Planning and Document Review	General ecology, document review
Eric Monshaugen, GIS Specialist	4 years, GIS	GIS data/figures
Chris Vidrick, Senior Word Processor	30 years, Word Processing	Word processing, document formatting and review
Bob Bryant, Lead Word Processor	18 years, Word Processing	Word processing, document formatting and review
Linda Nance, Technical Editor	35 years, Editing	Technical document editing

Name/Title	Experience	FEIS Area of Responsibility
Independent Technical Review		
Philip M. Payonk, Chief, Environmental Resources Section, CESAW-TS-PE	27 years Environmental Impact Assessment and Impact Analysis; Dredged Material, Water, and Sediment Quality Analyses; Ocean Disposal Coordinator	Environmental Impact Review; compliance with environmental laws and regulations
Bernard E. Moseby, Economist, CESAM-PD-FE	21 years Economic Analysis, Deep Draft Navigation	Review of Mitigation Measures CE/ICA
Carl E. Dyess, Dredging Project Manager, CESAM-OP	18 years, Dredging Operations Manager	Review of operations and maintenance plans
Wade A. Ross, Supervisory Hydraulic Engineer, CESAM-EN- HH	16 years, Hydraulic Engineer, Deep Draft Navigation	Review of hydrology and hydraulics issues
Dennis E. Mekkers, Hydraulic Engineer, CESAM-EN-HH	12 years, Structural Hydraulic Design, Tidally Influenced Wetlands Modeling and Restoration	Review of HS models
Naomi R. Fraenkel, Civil Engineer, CENAN-PL-F	5 years, Deep Draft Navigation Planning	Review of plan formulation
James A. Wagoner III, Assistance District Counsel, CESAM-OC	18 years, Real Estate Attorney	Real estate issues review
Wallace W. Brassfield, Cost Engineer, CENWW-EC-X	40 years, Construction Cost Estimating	Project costs review

Sabine-Neches Waterway Channel Improvement Project Coordination

1.0 INTRODUCTION

U.S. Army Corps of Engineers (USACE) and the Sabine Neches Navigation District (SNND) (formerly the Jefferson County Waterway Navigation District [JCWND]) developed a public involvement plan to be used during the feasibility phase for the Sabine-Neches Waterway Channel Improvement Project (SNWW CIP). The goal of this public involvement plan was to ensure that USACE and the SNND were responsive to the needs and concerns of all stakeholders and to ensure public involvement through an open, interactive process. Stakeholders include all the various publics that could be affected or are interested in the project. The plan helped USACE and the SNND provide information to, and obtain information from, the stakeholders.

Coordination with resource agencies was conducted primarily through Interagency Coordination Team (ICT) and technical working group meetings. Resource agencies and the study team meet regularly throughout the study process. Over 30 workgroup meetings and 10 ICT meetings were held.

1.1 PROGRAM OBJECTIVES

- a. Enhance public understanding of the study, the range of alternatives studied, and the recommended plan for the project.
- b. Identify all stakeholders and the best ways to communicate with each.
- c. Learn the public's desires, needs, and concerns and make them known to decision-makers.
- d. Explain the planning process and study progress.
- e. Provide for consultation before decisions are reached.
- f. Provide information about the results of environmental studies.
- g. Obtain views and concerns on proposed beneficial use areas, and mitigation features.
- h. Solicit the public's views and comments for consideration in the decision-making process.
- i. Disseminate study information and results in a wide variety of formats.

1.2 PROGRAM ACTIVITIES

To this end, a pro-active outreach program was initiated to ensure that the public, resource agencies, industry, local government, and other interested parties were informed about the project and that any concerns were identified and addressed.

Each of activities listed here is described individually below. The program included:

- scoping meetings
- public workshops to obtain ideas for ecosystem restoration and the beneficial use of dredged material
- media trips by boat down the waterway

- presentations at the Gulf of Mexico Fisheries Management Council's Texas Habitat Protection Advisory Panel
- presentations at regular meetings of Southeast Texas Waterway Advisory Council (SETWAC)
- meetings with Sabine Pilots
- presentation at the 2007 SETX meeting
- meetings with SNWW industries

2.0 PUBLIC SCOPING MEETINGS

2.1 PUBLIC SCOPING MEETING IN 2000

2.1.1 Meeting Summary

A public scoping meeting was held May 24, 2000, commencing at 7:00 p.m. The meeting was announced in local newspapers and with a public notice dated April 20, 2000. The location of the meeting was:

John Gray Center Auditorium
Lamar University
855 E. Florida Ave, Beaumont, Texas

The purpose of the meeting was to inform the public about the initiation of the feasibility study and to solicit comments on navigation concerns, alternatives to be addressed, and environmental issues and concerns. The meeting was attended by 43 persons, as well as representatives of SNND and USACE.

The meeting was conducted by Colonel Nicholas Buechler, Commanding Officer, USACE, Galveston District. Paul Beard, Chairman of the SNND, gave the welcoming address. Col. Buechler explained the purpose and procedures of the meeting and introduced the speakers. Tom Jackson, General Manager of SNND, presented an overview of the development of the Sabine-Neches Waterway and explained the navigation needs that gave rise to the feasibility study. Richard Tomlinson, Project Manager with the Galveston District, presented an overview of the study process.

The meeting was then opened to comments from the public and resource agencies. The issues raised by the speakers that they would like to see addressed in the context of the Draft EIS are as follows:

1. Salinity intrusion, particularly into marshes on the east side of Sabine Lake, the Sabine National Wildlife Refuge (NWR), and upstream on the Sabine and Neches Rivers
2. Effects on wildlife and fisheries which are associated with marsh loss
3. Project effects on tidal amplitude
4. Potential increases in inland reach of storm surges
5. Potential increases in erosion along the channel and along the coast

6. Beneficial use of dredged materials to restore marsh
7. Beneficial use of dredged materials to restore beaches and dunes
8. Establishment of a lock at Sabine Pass as an alternative to the project
9. Deepening through to Sabine Pass and then establish a pipeline distribution center at Sabine Pass as an alternative to deep draft channel improvements to Beaumont.
10. Potential decreases in marshes because of increased needs for placement areas.
11. Potential decreases in sports and shrimp fisheries
12. Effects of relocating approximately 70 pipelines
13. Overall cost of project as it relates to benefits, and the potential to increase taxes
14. Potential impacts to facilities on Pleasure Island such as the TPWD Wildlife Coastal Research Facility and the Corps of Engineers Port Arthur Area Office
15. Potential for restoring the historical hydrology and ecological diversity of the Sabine estuarine system
16. Socioeconomic effects of not improving the channel
17. Identify direct and indirect socioeconomic benefits of channel
18. Evaluate need for new turning basins, berthing areas, and passing zones
19. Who will be responsible for the local cost, both for construction and maintenance of channel improvements and placement areas?
20. Effects on navigation safety

The major concern of the participants was the potential for the project to increase salinity intrusion and further accelerate the decline of existing marshes.

The meeting was adjourned at 8:04 p.m.

2.1.2 Post-Meeting Comments

Several written statements were received by USACE in the month following the meetings. Additional issues that were not raised in the meetings include:

1. Salinity intrusion, particularly into Tony Houseman State Park and Wildlife Management Area (WMA), Lower Neches WMA, J. D. Murphree WMA, and Sea Rim State Park and other habitats of concern such as Sabine Lake, intertidal and fresh marshes at Taylor Bayou, along the GIWW, swamps and bottomland hardwoods, and the Sabine and Neches Rivers
2. Potential impacts to the Sabine Pass Battleground
3. Need for 3-dimensional hydrodynamic modeling of potential salinity and circulation changes
4. Mitigative measures should not adversely affect ingress and egress of marine organisms that use the estuary as part of their life cycle.
5. Studies should incorporate anticipated changes in fresh water inflow
6. Potential impacts to oyster reefs and Blue Buck Point
7. Consistency determination with the Louisiana Department of Natural Resources
8. Cumulative and secondary effects of hydrologic alterations to the coastal ecosystem
9. Beneficial uses of dredged material should be considered for the following areas: Bessie Heights marsh, backdune marshes at the Texas Point NWR, beach

nourishment at Holly Beach and Texas Point, marshes in McFaddin NWR, and marshes within the Lower Neches WMA and J.D. Murphree WMA.

10. Impacts to endangered sea turtles
11. Effects on Essential Fish Habitat (EFH) for postlarval, juvenile and adult red drum, brown shrimp, white shrimp, pink shrimp, postlarval and juvenile Spanish mackerel; categories of habitat that could be affected include estuarine emergent wetlands, estuarine water column, and estuarine mud/sand bottoms.
12. Potential effects to nursery and foraging habitat for economically-important marine fishery species such as spotted seatrout, flounder, Atlantic croaker, black drum, Gulf menhaden, striped mullet and blue crab.
13. Consideration of a submerged sill or constriction at the mouth of Sabine Lake, and water control structures in the wetlands east of Sabine Lake
14. Concern that the Sabine-Neches waterway is close to reaching its capacity for vessel traffic movement

2.2 PUBLIC SCOPING MEETINGS IN 2003

2.2.1 Meeting Summaries

Two public scoping meetings were held in late May 2002. The meetings were announced in the Notice of Intent to Prepare a Draft EIS for Improvements to the Sabine-Neches Ship Channel near Beaumont and Port Arthur, Texas (Federal Register, Volume 67, No. 98, Tuesday, May 21, 2002). A copy of the Notice of Intent is located at the end of this introductory section, before Appendix A-1. The meetings were also announced in local newspapers and with a public notice which was mailed to all persons on the study mailing list.

2.2.1.1 Public Meeting on May 28, 2002

Best Western Hotel
2600 Moeling Street, Lake Charles, LA
Commencing 7:00 pm

The purpose of the meeting was to inform the public about study progress and to solicit comments on environmental issues such as changes in salinity and circulation, changes in fresh and saltwater marshes, water and sediment quality, erosion along the channel, threatened and endangered species impacts, and beneficial use of dredged materials. The meeting was attended by 20 persons, as well as representatives of the non-Federal sponsor (the Jefferson County Waterway and Navigation District or SNND) and USACE.

The meeting was conducted by Dr. Lloyd Saunders, Chief of Planning, Environmental, and Regulatory Division of the Galveston District. Paul Beard, Chairman of SNND, gave the welcoming address. Dr. Lloyd Saunders explained the purpose and procedures of the meeting and introduced the speakers. Tom Jackson, General Manager of SNND, presented an overview of the development of the Sabine-Neches Waterway and explained the navigation needs that gave rise to the feasibility study. Lizette Richardson, Project Manager with the Galveston District, presented an overview of the study process, including the way in which the study is

responding to issues raised in the May 2000 public meeting. Janelle Stokes, Environmental Lead with the Galveston District, explained the Draft EIS as a component of the feasibility study and the ICT that was formed to promote effective teamwork on the EIS among state and federal agencies.

The meeting was then opened to comments from the public. The issues raised by the speakers that they would like to see addressed in the context of the EIS are as follows:

1. Consistency determination with the Louisiana Department of Natural Resources.
2. Coordination with the Louisiana Coastal Restoration program.
3. Coordinated planning with Calcasieu Ship Channel.
4. Greater consideration for Louisiana interests and concerns.
5. Increased participation of private sector on ICT.
6. Additional opportunities for the public to express opinions on the project.
7. Beneficial use of dredged materials for beach restoration.
8. Consideration of beneficial use recommendations from workshops.
9. Marsh preservation and restoration.
10. Shoreline and channel erosion.
11. Saltwater intrusion.
12. Potential for increased storm surges.
13. Impacts to endangered species.
14. Impacts to migrating birdlife.
15. Potential for pollution of water-bearing sands because of increased dredging.
16. Potential toxicity of dredged materials.
17. Effects of dredging on water quality and fisheries.
18. Loss of shallow-water habitat through dredged material disposal; effects of ocean dredged material disposal sites.
19. Expropriation of land in Louisiana for placement areas, particularly land suitable for economic development.
20. Potential for changes in state boundaries because of spoil disposal in Sabine Lake.
21. Consideration of project alternatives such as a pipeline to an offshore oil port.
22. Establishment of a lock at Sabine Pass to stop saltwater intrusion.
23. Effect of a lock at Sabine Pass on ingress and egress of estuarine species.
24. Restoration of access to Sabine Lighthouse.
25. Establishment of a collision control system on the channel.

The major concern of the participants was the potential for the project to further accelerate the decline of the marshes in Louisiana and the smallness of the population in the coastal area to speak for those marshes.

The meeting was adjourned at 8:05 p.m.

2.2.1.2 Public Meeting on May 29, 2002

John Gray Center Auditorium
855 E. Florida Ave, Beaumont, Texas
Commencing 7:00 pm

The purpose of the meeting was to inform the public about study progress and to solicit comments on environmental issues such as changes in salinity and circulation, changes in fresh and saltwater marshes, water and sediment quality, erosion along the channel, threatened and endangered species impacts, and beneficial use of dredged materials. The meeting was attended by 34 persons, as well as representatives of the SNND and USACE.

The meeting was conducted by Lloyd Saunders, Chief of Planning, Environmental, and Regulatory Division of the Galveston District. Paul Beard, Chairman of SNND, gave the welcoming address. Lloyd Saunders explained the purpose and procedures of the meeting and introduced the speakers. Tom Jackson, General Manager of SNND, presented an overview of the development of the Sabine-Neches Waterway and explained the navigation needs that gave rise to the feasibility study. Lizette Richardson, Project Manager with the Galveston District, presented an overview of the study process, including the way in which the study is responding to issues raised in the May 2000 public meeting. Janelle Stokes, Environmental Lead with the Galveston District, explained the Draft EIS as a component of the feasibility study and the ICT that was formed to promote effective teamwork on the Draft EIS among state and federal agencies.

The meeting was then opened to comments from the public. The issues raised by the speakers that they would like to see addressed in the context of the EIS are as follows:

1. Beneficial use of dredged materials to restore marsh.
2. Beneficial use of dredged materials to restore beaches.
3. Beneficial use of dredged materials to create bird islands in Sabine Lake.
4. Salinity intrusion, particularly into freshwater marshes.
5. Potential for increases in storm surges.
6. Potential contaminants in dredged materials.
7. Cumulative impacts of sediments, circulation, and salinity on marshes.
8. Erosion along the channel.
9. Effect of project on operating procedures for the saltwater barrier.
10. Decrease in marshes because of increased needs for placement areas.
11. Maintenance of remaining nursery areas in existing placement areas in Sabine Lake.
12. Establishment of a pipeline at Sabine Pass as an alternative to the project.

The major concern of the participants was the potential for the project to further accelerate the decline of the marshes.

The meeting was adjourned at 7:42 p.m.

2.2.2 Post-Meetings Comments

Several written statements were received by USACE in the month following the meetings. Additional issues that were not raised in the meetings include:

1. Potential effect of project on Jefferson County Drainage District No. 7 Hurricane Flood Protection System.
2. Effect of project on human populations, particularly downstream water supplies, air quality, water quality and quantity, wetlands and floodplains, hazardous materials and wastes, non-hazardous solid waste and other materials, noise, occupational health and safety, and land use and housing.
3. Cumulative impacts of all past, present, and proposed projects in the area in relation to the proposed project.
4. Harmful effects of "beneficial use" proposals, particularly the creation of islands in marine or brackish environments.
5. Consideration of mitigation costs in project feasibility assessment.
6. Effect of project on floodplain development.
7. Potential for increased tidal amplitudes.
8. Impacts to neo-tropicals, wading birds, waterfowl, terns, skimmers, brown pelicans, and sandpipers.
9. Impacts on 404B1 areas such as wildlife reserves, management areas, rookeries, wetlands, oyster reefs, mud flats, sandbars, and beaches.
10. Socioeconomic impacts on sport and commercial fisheries, hunting, crabbing, shrimping, tourism, oystering, and other recreational activities.
11. Determine dredging risks to sea turtles.
12. Elevate dredged material disposal areas above sea level and use plantings to create wildlife habitat.
13. Make dredged material disposal areas subject to public servitude.
14. Determine gulf shoreline impacts from possible changes in near-shore currents and wave patterns.
15. Impacts to paddle fish, sea turtles, oyster reefs, Western Sand Darter, and Western Hill Splitter Mussel.
16. Impacts to flora, particularly loss of wetlands from plant community changes.
17. Potential toxicity of dredged materials in beneficial use projects.
18. Potential for introduction of exotic species.
19. Increased national security costs from increased shipping traffic.

2.3 PUBLIC MEETING SUMMARIES

Two public meetings were held in late January 2010. The meetings were held in Beaumont, Texas, and Lake Charles, Louisiana. The meetings were noticed as "Notice of Public Meeting and Availability of Draft Environmental Impact Statement (EIS) for Sabine-Neches Waterway Proposed Channel Improvement Project, Draft Environmental Impact Statement for Texas Ocean Dredged Material Disposal Sites Designation and Draft General Conformity Determination" in local newspapers.

A notification mailer was mailed to all persons on the study mailing list. The mailing list contained a wide array of elected officials, environmental organizations, historic resource organizations, commercial groups, recreational groups, public bodies, fishermen, hunters, and landowners. Over 400 notices were sent out.

Additionally, letters of invitation were mailed and emailed to public officials.

2.3.1 Public Meeting on January 26, 2010

The Beaumont Civic Center
701 Main Street
Beaumont, Texas 77701

The purpose of the meeting was to inform the public about the release of the Draft EIS, Draft EIS for Ocean Dredged Material Disposal Sites Designation, and Draft General Conformity Determination, and solicit comments. The meeting was attended by 51 persons. The meeting was hosted by the non-Federal sponsor, the Sabine-Neches Navigation District (SNND) and the U.S. Army Corps of Engineers (USACE) Galveston District.

From 5:30-7:00 P.M., an informal open house was open to the public. Members of the public viewed displays and spoke with the USACE and PBS&J employees who were available at the display stations. There were four display stations:

1. Recommended Plan-Navigation Improvements
2. Alternatives Evaluated
3. Technical Studies
4. Environmental Impacts and Mitigation

All display materials were sourced from the Draft EIS and the Draft Feasibility Report.

The formal public meeting was conducted by Colonel David Weston, Commanding Officer of the Galveston District, and commenced at 7 P.M. Randall Reese, General Manager of SNND, made a brief introduction of SNND members present and then introduced Colonel Weston. Colonel Weston introduced USACE employees and provided a brief overview of the project and the study. Byron Williams, Project Manager with the Galveston District, explained the purpose and procedures of the meeting and introduced the speakers. Clayton Henderson, Assistant General Manager of SNND, presented an overview of the development of the Sabine-Neches Waterway and explained the navigation needs that gave rise to the feasibility study. Sheri Willey, Project Manager with the Galveston District, presented an overview of the study process. Janelle Stokes, Environmental Lead with the Galveston District, presented the environmental portion of the study.

The meeting was then opened to comments from the public. The issues that the speakers would like to see addressed in the context of the Draft EIS are as follows:

1. Potential impacts on pipeline operations and cost estimates for pipeline relocations

2. Request for an extension of the comment period to at least April 26, 2010
3. Request for an extension of the comment period for at least 120-days
4. Potential problems of proposed dredge sites and respective impacts on fisheries
5. Increased salinities and unnatural increased water flow in coastal marshes and wetlands and Sabine Lake, as well as the impacts on the proximate wildlife habitats
6. Increased marketability and accessibility for larger ship traffic and concurrent increased safety margins
7. Increased economic stimulation through job creation
8. Permitting issues for relocation or removal of existing pipelines

The major concerns of the participants were the environmental impacts (increased salinity) and pipeline relocation.

The meeting was adjourned at 8:07 P.M.

2.3.2 Public Meeting on January 27, 2010

The Lake Charles Civic Center
Jean Lafitte Room
900 Lakeshore Drive
Lake Charles, LA 70601

The purpose of the meeting was to inform the public about the release of the Draft EIS, Draft EIS for Ocean Dredged Material Disposal Sites Designation, and Draft General Conformity Determination, and solicit comments. The meeting was attended by 19 persons. The meeting was hosted by the non-Federal sponsor, the SNND and the USACE Galveston District.

From 5:30-7:00 P.M., an informal open house was open to the public. Members of the public viewed displays and spoke with the USACE and PBS&J employees who were available at the display stations. There were four display stations:

1. Recommended Plan-Navigation Improvements
2. Alternatives Evaluated
3. Technical Studies
4. Environmental Impacts and Mitigation

All display materials were sourced from the Draft EIS and the Draft Feasibility Report. The formal public meeting was conducted by Colonel David Weston, Commanding Officer of the Galveston District, and commenced at 7 P.M. Randall Reese, General Manager of SNND, made a brief introduction of SNND members present and then introduced Colonel Weston. Colonel Weston introduced USACE employees and provided a brief overview of the project and the study. Byron Williams, Project Manager with the Galveston District, explained the purpose and procedures of the meeting and introduced the speakers. Clayton Henderson, Assistant General Manager of SNND, presented an overview of the development of the Sabine-Neches Waterway and explained the navigation needs that gave rise to the feasibility study. Sheri Willey, Project Manager with the Galveston District, presented an overview of the study process. Janelle

Stokes, Environmental Lead with the Galveston District, presented the environmental portion of the study.

The meeting was then opened to comments from the public. The issues that the speakers would like to see addressed in the context of the Draft EIS are as follows:

1. Formation of an ICT for the development of the final Beneficial Use sites and mitigation plan
2. Potential costs of relocating pipelines
3. Potential flooding impacts from storm events if the channel is deepened
4. More spoil used beneficially
5. Potential impacts of problems caused by deepening channels
6. Increased salability of the waterway
7. Compatibility with the world's largest LNG carriers

The major concerns of the participants were the effects of deepening the channel and pipeline relocation.

The meeting was adjourned at 8:00 P.M.

2.3.3 Pre-Meeting Comments

Written comments were received by the USACE in the months leading up to the release of the Draft EIS, Draft EIS for Ocean Dredged Material Disposal Sites Designation, and Draft General Conformity Determination.

1. Louisiana Department of Wildlife and Fisheries (LDWF) will not concur in plans to mitigate in Texas for wetland impacts occurring in Louisiana. Additional mitigation measures should be implemented to offset the current 318 AAHU deficiency.
2. New work material from the Sabine Pass Channel and Sabine Pass Jetty Channel should be used beneficially to create, restore, or nourish emergent marsh in the vicinity of the project.
3. No fill material shall be dredged from state-owned water bottoms in Louisiana without a license issued by LDWF.
4. Adverse impacts to the public oyster area in Sabine Lake from the mitigation areas, including any access channels, must be addressed.
5. Potential creation of hypoxic conditions in dredged water bottoms and increased shoreline erosion rates through increased wave energy or sinking of the shoreline to fill the excavated trench.
6. Further justification of the 'no change' determination for Further Without Project.
7. Commitment of the local sponsor and interagency coordination.
8. Potential negative impact on marine life in the dredge containment compartments used for the dredging in the deepening and widening of the waterways.
9. Identification of location for Natural Resources Conservation Services to evaluate the proposed areas as required by the Farmland Protection Policy Act
10. Potential economic impacts on coastal low-income communities

2.3.4 Post-Meeting Comments

Written comments were received by USACE in the month following the public meetings. They were received as emails, comment forms, and letters.

1. Placement of spoil in relation to jetties in Texas and Louisiana
2. Potential bias in the research because it was conducted by USACE. A nonaffiliated research team should be implemented
3. Need for the project
4. Any deepening or widening will make our waterway more competitive for business that uses larger ships and automatically adds additional safety margins for the existing shipping already present.
5. Potential impacts on pipeline operations, pipeline relocations, and the costs associated
6. Request of an extension of the comment period to April 10, 2010, at the earliest
7. Need for the project
8. Any deepening or widening will make our waterway more competitive for business that uses larger ships and automatically adds additional safety margins for the existing shipping already present.
9. Potential impacts of placement of spoil near the Sabine Jetties
10. Identification and location of the 42 pipelines that may require relocation
11. Potential costs of relocating pipelines and cost sharing between pipeline owners and project sponsor
12. Request of an extension of the comment period to no earlier than April 10, 2010
13. Potential relocation of pipelines and actual costs to a pipeline owner regarding relocation
14. Request of an extension of the comment period to May 10, 2010
15. Potential concerns about modeling for storm surges, bar channel deepening, salinity, the proposed mitigation for unavoidable impacts to wetland habitats, and the potential impacts to extant energy
16. Increased economic shipping efficiency
17. Recommended literature regarding geoarchaeology in the Sabine Lake area
18. Coordination request with pipeline owners and operators
19. The relocation of a significant number of pipelines must be preceded by a comprehensive and coordinated planning process regarding the relocation.
20. The project may impact pipeline operations in other ways besides relocation.
21. Request identification of the pipelines that will be impacted by the project, the owner of each such pipeline, and the costs for removing or relocating each such pipeline
22. Request for additional documents to understand the proposed project's impact on pipeline operations, including a projected timeline from when the relocations may actually be needed
23. Request confirmation of the cost-sharing requirement that half the pipeline relocation costs must be borne by the pipeline owner and the other half by the local sponsor of the project
24. Request a 60 day extension of the comment period
25. Potential costs, safety and environmental risks, and interruption of gas/diesel supplies, as a result of relocation and removal of pipelines

26. Deepening will potentially increase damage done by storm surges
27. The Draft EIS fails to provide: (1) the project's economic value to the State of Louisiana; (2) resolution to conflicting modeling results and how much marsh could/would be lost or adversely affected by the project due to higher salinity levels than projected; (3) full mitigation plan or compensation for projected losses of intertidal marsh in most of the Louisiana portion of the study area including Cameron Meadows; and (4) resolution to the conflict between navigation needs in Texas, the project's acknowledged detrimental impacts to Louisiana marshes, and ongoing publicly supported and funded coastal restoration efforts in Louisiana.
28. Request for the list of the 42 deep-draft utilities designated for relocation
29. Request for a cross-section where a 10-inch diameter hydrogen pipeline crosses the Neches River (292+00). Additionally requests the GPS coordinates of both existing Neches River centerline and the proposed Neches River centerline
30. Request for further description of the hydraulic pipeline dredge process

3.0 ENVIRONMENTAL RESTORATION / BENEFICIAL USE WORKSHOPS

3.1 PURPOSE

One of the purposes of the study is to maintain and restore the natural environment in the Study Area. A series of public workshops was held in late 2001 and early 2002 to secure suggestions for environmental restoration and beneficial uses of dredged material from interested organizations and individuals. This section will describe the procedures that were used to initiate and conduct the workshops and their outcome.

3.2 RESTORATION WORKGROUP

The ICT created a Restoration Workgroup (RW) to gather, evaluate, and recommend ideas for environmental restoration and beneficial use. At its first meeting in June 2001, the RW identified the brainstorming workshops used by the Beneficial Users Group (BUG) in the Houston-Galveston Navigation Project as the appropriate format for the SNWW Workshops.

The RW also identified a number of environmental organizations, historic resource organizations, commercial groups, and recreational groups in Texas and Louisiana that should be invited to participate in the workshop process and stipulated that this list should be expanded. A contact list was developed identifying the addresses and telephone numbers for many of these organizations. Recommendations were given on how various groups should be approached to achieve efficiency in the workshop process. Organizations were not to be mixed in the workshops in recognition of their differing goals and interests.

A draft letter was mailed to organizations which described the study: the purpose, procedures, and restrictions of the workshops, and what would be done with the workshop results. To insure adequate geographic coverage, workshop notifications appeared in newspapers in Baton Rouge and Lake Charles, Louisiana, and in Beaumont, Port Arthur, and Orange, Texas. A draft notice was prepared for newspaper and website use. A number of small communities in Texas and

Louisiana were identified for potential workshops if meetings with organizations did not produce adequate geographic coverage.

The workshops were intended to solicit suggestions for environmental restoration and beneficial use throughout the Study Area, producing recommendations that could be used in the SNWW feasibility planning process, but also providing a database of recommendations that could be used by other studies and organizations. Recommendations were later evaluated for economic and technical feasibility by the Habitat Evaluation Workgroup (HW).

3.3 CONSULTING FIRM

Gulf Engineers & Consultants, Inc. (GEC), a Baton Rouge consulting firm experienced in public involvement, USACE procedures, and water resources projects, was secured to organize and conduct the workshops. This was done because of the time-consuming nature of the effort and the short timeframe for completion. GEC secured the services of a local contact in Texas to avoid any possibility of perceived geographic bias. USACE control of contractor activities was secured through the establishment of a close working relationship between the Contracting Officer's Representative and GEC, through continuous reporting by GEC, and through attendance at all of the workshops by Galveston District personnel or their representatives.

3.4 PRELIMINARY ACTIVITIES

Preliminary efforts were devoted to document review, an internet search, attendance at a public meeting concerning the Bessie Heights Marsh, and a visit with the SNND. The principal documents reviewed were the plan of action designed by the Restoration Workgroup, the SNWW reconnaissance report, the scoping meeting minutes, the project study plan, correspondence that had been sent to the Galveston District in connection with the feasibility study, and Louisiana's *Coast 2050* report. An internet search was used to check information on the contact list, to identify additional potential participant organizations, and to identify local chapters. The search also produced information on how the two states were approaching coastal planning, on some of the significant issues, and on some of the specific proposals that had already been developed for coastal restoration. The Bessie Heights Marsh public meeting was attended because it was concerned with an environmental restoration project in the study area in Texas and in order to gain a sense of procedural difficulties that might be encountered in the workshops. The visit with the SNND resulted in an extensive tour of the study area's navigation and environmental features, including site visits to some of the existing dredged material disposal areas.

3.5 CONTACTS

The initial list of potentially interested parties prepared by the RW included 11 organizations in Texas and 5 in Louisiana. GEC added to this list five organizations and groups in Texas and six in Louisiana, all of which were approved for contact by the USACE. The final list contained a wide array of environmental organizations, historic resource organizations, commercial groups, recreational groups, public bodies, fishermen, hunters, and landowners.

The organizations were contacted by telephone in November. Telephone logs were kept of all contacts. The contacts were used to explain the nature of the workshops and the function of GEC in relation to the Galveston District and to determine whether the organization was interested in participating in the process and wanted more information in the form of a letter from the Galveston District. The response to the telephone contacts was highly favorable.

On receiving confirmation from an organization or group that it would like to have a workshop, information on date, time, place, and composition was transmitted by e-mail from GEC to USACE, which transmitted the information to the Restoration Workgroup members.

3.6 NEWSPAPER NOTICES

The RW identified the Beaumont Enterprise, Orange Leader, Port Arthur News, Lake Charles American Free Press, and Baton Rouge Advocate as daily newspapers in which public notices of the workshops should be placed. GEC identified the weekly *Beaumont Examiner* as an additional suitable placement medium. The draft workshop notice that had been prepared by the Restoration Workgroup was placed in these newspapers during the week of November 12, 2001 (one day in the *Baton Rouge Advocate*, two days in the *Beaumont Examiner*, and three days in the others). During its November 16, 2001 meeting, the RW indicated that the notice should also appear in the newspaper of record for Cameron Parish (the *Cameron Pilot*), which was done during the week of November 19, 2001 (3 days). The notices achieved the objective of giving everyone an opportunity to participate in the process.

3.7 WORKSHOP ORGANIZATION AND PROCEDURES

Most of the workshops were organized by the responding organizations or groups; that is, GEC did not need to call a number of people to establish attendance at most of the workshops. Most of the workshops were held in conjunction with regular organizational meetings. The Galveston District prepared electronic files of recent aerial photographs of the study area, a constructed hardcopy map showing the study area boundaries and the channel, Mylar-covered hardcopy older topographic maps of the east and west portions of the study area, and four Mylar-covered hardcopy maps of recent aerial photographs of the immediate vicinity of the channel. Suggestions were numbered, beginning with one at the first workshop and continuing sequentially through the last, to avoid the difficulties that participants would have in recording large numbers on the Mylar-covered maps. The suggestions were later compiled by GEC into one master list.

Suggestions were hand recorded and the locations of suggestions were recorded on the Mylar-covered hardcopy maps, of which the two topographic maps proved most useful (with the west portion used in Texas meetings and the east portion used in Louisiana meetings). The electronic maps were used in the workshops to provide greater clarification for specific suggestions and their locations when needed. Tape recorders were not used because of the emphasis on anonymity of suggestions.

In addition to the GEC facilitator, all of the workshops were attended by at least one USACE representative, almost all were attended by at least one RW representative, and some were

attended by the SNND. At each workshop, GEC gave a brief presentation on the project, the purpose of the workshop, how the workshop results would be used, and the ground rules. It was stressed that the workshop was not for expressing opinions on the merits of the project, that the suggestions made by the workshop participants could refer to any place in the study area, that the suggestions did not need to be limited to problems and opportunities related to the SNWW project, that the suggestions should not be limited by concerns of technical or economic feasibility, that all suggestions would remain anonymous with respect to the person making the suggestion and the meeting at which the suggestion was made, and that the suggestions would be used to create a database that would be used in conjunction with the project but also by a wide variety of agencies, organizations, and groups.

3.8 WORKSHOP RESULTS

Sixteen workshops were held, attended by a total of 168 persons who participated in the making suggestions. A number of organizations declined to participate; the major reason for nonparticipation in the process was insufficient interest on the part of organization members. Of the 16 workshops, 10 were held in Texas and six in Louisiana. One meeting in Texas and one in Louisiana was attended by participants from both states. The discrepancy between the number of meetings in Texas and Louisiana was the result of organization availability and response. The total number of Louisiana participants was actually about the same as the number of Texas participants.

The participants produced 244 suggestions, which were concerned with marsh restoration, beach and dune restoration, chenier restoration, hydrologic restoration, salinity control, erosion control, island construction, land restoration and development, road restoration, recreation and cultural development, use of sediment sources, use of placement areas, and nonstructural measures. There were a number of repeated suggestions, which provide some idea of the preference for various proposals. The 244 suggestions, listed below, are presented in no particular order. Specific locations related to each suggestion are labeled with the suggestion number on figures 1-3.

1. Deposit dredged materials in open water areas within the marshes (affected by subsidence, erosion, and saltwater intrusion) at Texas Point NWR.
2. Deposit dredged materials at Lafitte's Landing 1 and 2 (south end of Pleasure Island, lakeside, along shoreline and by marina) to provide shoreline erosion control and wetland creation.
3. Deposit dredged materials at Pleasure Island Marina for shoreline erosion control and marsh creation.
4. Construct a salinity control structure at the Keith Lake Fish Pass/SNCC intersection to reduce saltwater intrusion while allowing for unhindered navigation and marine organism ingress/egress.
5. Construct a system (depending on hydrologic model) of berms or levees (terraces) north of Pleasure Island in the gap and restore the island along the Sabine-Neches Canal to protect the lake from higher salinities in the channels.

6. Restore the hydrologic connection (freshwater sheetflow) at Salt Bayou between the marshes north and south of the GIWW.
7. Construct a structure on the east part of Salt Bayou to restore freshwater flow to marshes south of the GIWW.
8. Deposit dredged materials, particularly those with higher sand content, linearly along the shoreline from Texas Point NWR westward through McFaddin NWR.
9. Deposit dredged materials, particularly those with higher sand content, linearly along the shoreline east of the entrance channel.
10. Create gaps in both entrance channel jetties to increase sediment transport to Gulf shorelines.
11. Stabilize the shoreline on the east edge of Texas Point NWR at gaps in the jetty north of pilot station and repair the jetty.
12. Construct a two to six acre bird island or islands, at least five feet high with a sheltered lagoon, in the north part of Sabine Lake near Sidney Island at least one mile offshore.
13. Establish salinity controls, including the restoration of historic flow volumes, in Texas Bayou and associated channels connecting to the SNWW on Texas Point NWR through such things as low-level rock weirs, plugging man-made channels, water control structures, and/or other channel modifications.
14. Deposit dredged materials in open water areas and degraded marshes in the east part of the Salt Bayou watershed north and south of Keith Lake.
15. Stabilize the shoreline in any reaches of the GIWW projected to have increased salinities as a result of the project.
16. Establish erosion control on the Taylor Bayou outfall canal shoreline, primarily on the south bank.
17. Stabilize the banks of the GIWW in Louisiana, particularly the south bank, because the north bank has been largely stabilized through two coastal restoration projects.
18. Protect the cypress swamp area south of the Neches River Saltwater Barrier from possible excessive salinities by installing structures, terraces, or other hydrologic components.
19. Use high sand content dredged materials from offshore, including existing disposal areas, for beach enhancement purposes.
20. Implement the East Sabine Lake Hydrologic Restoration Project to protect approximately 35,000 acres of brackish to intermediate marsh in the west part of the Sabine NWR and adjacent lands from elevated salinities by such things as water control structures at major bayous and canals and earthen terraces in existing shallow-water areas.
21. Construct a gate on the Sabine Pass Channel or a sill offshore to establish hydrologic control.
22. Restore the interior hydrology of Salt Bayou marshes south of the GIWW on TPWD land.
23. Construct a low-level rock weir or similar structure at the causeway to prevent excessive salinities from entering the lake.
24. Construct salinity controls in the brackish marsh regions east of the intersection of Lighthouse Bayou and the Sabine Pass Channel.

25. Deposit dredged materials from the SNWW in large, shallow, open-water areas in the west part of the Sabine NWR north and south of the Willow Bayou Canal and in the Greens Lake area.
26. Deposit dredged materials from the SNWW on the east shoreline of Sabine Lake at the Sabine NWR and adjacent lands.
27. Deposit dredged materials from the SNWW in the open-water areas of the Greens Lake area to create marshes.
28. Establish salinity control between the GIWW and the Sabine River to protect the Louisiana side.
29. Establish salinity control west of the Hwy. 87 bridge and the GIWW to protect the Texas side.
30. Use new work materials one-time offshore that would degrade to feeder berms.
31. Establish topographic relief offshore.
32. Establish nearshore feeder berms for shoreline protection.
33. Protect and stabilize the Middle Marsh Drain Ditch.
34. Restore the saltwater guard lock at the north end of Pleasure Island.
35. Establish salinity control at the mouth of Cow Bayou.
36. Establish salinity control at the mouth of Adams Bayou.
37. Establish salinity control on the Old Ferry Road Borrow Ditch.
38. Establish salinity control at Old River Bayou.
39. Create terraces in the Entergy Power Plant Marsh.
40. Isolate the Entergy outfall canal by recreating the historic canal berms.
41. Use dredged materials to create terraces and mounds and backfill canals in the Bessie Heights Marsh.
42. Restore the natural hydrology of the Bessie Heights Marsh by restoring the natural bayou and closing the two canals.
43. Divert some of the stormflow in Anderson Gully into the Bessie Heights Marsh.
44. Restore the cypress swamps in the Rose City Oilfield through hydrologic restoration, salinity control, and beneficial use of dredged materials.
45. Plug the Hwy. 87 borrow ditch to restore flows to Nig Bayou.
46. Protect the shoreline on the north side of Old River Cove.
47. Use dredged materials to create mounds and terraces in Old River Cove.
48. Use dredged materials in the Old River Unit of the Lower Neches River WMA.
49. Use dredged materials in the open-water areas of the Burton Canal Marsh east of the Sabine River and the Burton Canal.
50. Use dredged materials in the open-water areas of the marsh east of Phoenix Lake.
51. Protect and restore the north shore of Keith Lake.
52. Construct a structure in the Sabine River at Orange to protect the cypress-tupelo swamps upstream if Sabine Compact withdrawals are implemented.
53. Use dredged materials to create a bird island north of the causeway.
54. Use dredged materials to restore marsh elevations in the interior of the Salt Bayou Marsh south of the GIWW.
55. Divert the Neches River through the Bessie Heights Marsh into Sabine Lake by leveeing the channel.
56. Create a substrate for oysters in south Sabine Lake to restrict salinity and flow.

57. Construct a navigation lock at Sabine Pass, which would resolve many of the problems, particularly saltwater intrusion, in the Sabine Lake area.
58. Construct a low-level rock weir constriction at the mouth of Sabine Lake at the causeway to reduce saltwater intrusion.
59. Implement the East Sabine Lake Hydrologic Restoration Project (a CWPPRA project) to provide salinity control on the east shore of Sabine Lake.
60. Implement the NRCS Public Law 566 rock weirs along the length of Black Bayou.
61. Construct a salinity control structure at the mouth of Black Bayou.
62. Use dredged materials between Pleasure Island and Sabine Island to create an earthen barrier that would protect Sabine Lake from saltwater intrusion from the channels.
63. Use dredged materials to restore the marsh in the Old River Unit south of Bridge City.
64. Remove Placement Area 11 at the north end of Pleasure Island to restore the estuarine bottom and reestablish public access to state waterbodies.
65. Remove Placement Area 8 at the south end of Pleasure Island to restore the estuarine bottom and reestablish public access to state waterbodies.
66. Use dredged materials to restore the marshes north and south of Keith Lake.
67. Use dredged materials to restore the marshes in the Greens Bayou area.
68. Use dredged materials to restore the marshes in the Willow Bayou area.
69. Establish an earthen barrier with water control structures along the entire east edge of Sabine Lake to protect the marshes from salinity intrusion and wave action.
70. Use dredged materials to restore the marshes north of Lighthouse Bayou.
71. Construct a structure at the mouth of Lighthouse Bayou to reduce salinity intrusion.
72. Use dredged materials to restore the marshes south of Perry Ridge.
73. Provide greater opportunities for fishing (for example, piers) to compensate for the decline of boater access to Sabine Lake from Louisiana that has been brought about by hydrologic restoration projects.
74. Stabilize the shoreline on the east side of Sabine Lake using boudin bags (geotextile tubes filled with dredged materials).
75. Use dredged materials to restore the marshes northwest of the Black Bayou Oil and Gas Field.
76. Maintain Sabine River freshwater flows into Sabine Lake in keeping with the Coast 2050 strategy.
77. Establish a navigation lock on the GIWW at Gum Cove Ridge to reduce saltwater intrusion to the east.
78. Use dredged materials to enhance the existing marsh strip and refurbish the deteriorated rock barriers on the south side of the GIWW in the Gum Cove Unit 13 area.
79. Use dredged materials to restore the marshes and establish a bird island south of the GIWW in the Gum Cove Unit 13 area.
80. Provide shoreline protection and hydrologic restoration for the fresh marsh east of the Sabine River and between the GIWW on the south and the Sabine Island WMA on the north.
81. Create terraces and use dredged materials to restore marshes between Perry Ridge and the Sabine River.

82. Protect the marshes between the Sabine NWR and Sabine Pass by protecting the shoreline of Sabine Lake and establishing salinity controls on Madame Johnsons Bayou, Forge Bayou, Greens Bayou, and Johnsons Bayou in keeping with the East Sabine Lake Hydrologic Restoration Project.
83. Use dredged materials to restore marsh in all open-water areas east of Sabine Lake where it is feasible to pump them, and construct terraces to restore marsh in all open-water areas east of Sabine Lake where it is not feasible to pump dredged materials (note: not location specific).
84. Use dredged materials and construct terraces in the open-water areas of the Black Bayou Cutoff Canal area.
85. Restore the hydrology and prevent saltwater intrusion at the oil field ditch and lateral ditches running west from the Black Bayou Cutoff Canal.
86. Establish a state park in the area east of Lighthouse Bayou and south of Hwy. 82 (contingent on private property donation and not necessarily including the lighthouse).
87. Use dredged materials to restore eroded beaches in the vicinity of the 15-mile marker from the Louisiana line (that is, in the Dunn Beach and Martin Beach areas).
88. Construct an earthen barrier on the east bank of the Sabine River from the GIWW to Sabine Island to eliminate saltwater intrusion.
89. Use dredged materials to restore the marshes in the area north of the GIWW and west of the Gray and Vinton drainage canals.
90. Use one-time placement of dredged materials in various areas to create coastal forest and chenier habitat (note: not location specific).
91. Use dredged materials to create cheniers on the high marsh from Louisiana Point to Holly Beach.
92. Use dredged materials to restore marshes in the Bessie Heights Marsh area.
93. Provide erosion control along the channel on the north portion of Pleasure Island.
94. Provide erosion control along the channel on the extreme south portion of Pleasure Island.
95. Use dredged materials to restore the north end of Pleasure Island where Sabine Lake is breaking through.
96. Use dredged materials to restore the southern tip of the peninsula north of the northern tip of Pleasure Island.
97. Provide erosion control using concrete revetment on the west side of the Port Arthur Canal across from Placement Area 11 in the vicinity of the vessel repair facility.
98. Use dredged materials to close the gap between the channel and Sabine Lake north of Pleasure Island.
99. Use dredged materials to close the gaps between the islands at the north end of Sabine Lake.
100. Elevate Hwy. 87 with dredged materials near Sabine Pass.
101. Provide erosion control along the channel on the south portion of Pleasure Island in the vicinity of Placement Area 8.
102. Use dredged materials to restore the marsh on the south end of Humble Island.
103. Use dredged materials to restore the marsh on the south side of the GIWW below Taylor Bayou.
104. Use dredged materials to restore the marshes north of the GIWW in Louisiana.

105. Restore access to the Sabine Lighthouse and stop erosion in the immediate area.
106. Use dredged materials to build developable land on the north side of the Neches River from Beaumont downstream.
107. Use dredged materials to build up the area near Hwy. 82 and the causeway so that a bridge can be built over the channel directly linking Hwy. 82 and Hwy. 87.
108. Use dredged materials to restore the eroding beach in the vicinity of Peveto Beach.
109. Breach the levees and use dredged materials to restore the manmade lakes within Sabine NWR to their original marsh condition.
110. Use dredged materials to fill in oilfield service canals wherever they are contributing to salinity intrusion into Louisiana's marshes (note: not location specific).
111. Use dredged materials to build islands offshore on both sides of the channel for migratory birds that would simulate the function of a natural delta.
112. Use dredged materials to build islands for migratory birds in Sabine Lake far enough from shore to protect from predators.
113. Use dredged materials to construct cheniers in Louisiana and Texas, planting them with oaks and other vegetation that occur on natural cheniers.
114. Use dredged materials to restore cheniers in Louisiana and Texas (perhaps by removing the existing top layer of sand and shell, depositing dredged materials, and they relaying the sand and shell on top), with easements to protect them for bird use.
115. Use dredged materials to buffer cheniers in Louisiana and Texas that are in danger of disappearing.
116. After placing dredged materials in new placement areas, shape and contour the areas so that they appear natural, and plant native vegetation to support wildlife (note: not location specific).
117. Shape and contour existing dredged material placement areas so that they appear natural, and plant native vegetation to support wildlife (note: not location specific).
118. Construct recreational amenities, particularly primitive campgrounds, on cheniers and on placement areas that have been filled (note: not location specific).
119. Construct a lock at Sabine Pass to prevent saltwater intrusion into Sabine Lake.
120. Construct a bulkhead on the channel side of Pleasure Island from the intersection of the SNWW and the GIWW to the north end of the island.
121. Mine dredged materials from Placement Area 8 to build up the 43 acres at the south end of Pleasure Island owned by the port and then replace with new dredged materials.
122. Preserve the productive shallow-water areas of the two placement areas on Pleasure Island by depositing dredged materials on top of the existing levees, particularly near the channel, and develop the land for recreational use.
123. Use dredged materials to build up the land on the southern portion of Pleasure Island from Placement Area 8 to the south end of the island on the lakeside and bulkhead the channel side.
124. Provide erosion control for all of Pleasure Island on the channel side.
125. Use dredged materials to rebuild the approximately one-quarter mile of land at the north end of Pleasure Island that has completely eroded away and protect it with erosion control structures.

126. Use dredged materials to build up the land on Pleasure Island directly across from the Taft Avenue Extension to preserve its potential as a location for a second bridge to the island.
127. Construct a new salinity control structure on the north side of the GIWW at the point where Salt Bayou intersects the GIWW.
128. Use dredged materials to restore the beach and create dunes south of McFaddin NWR between Sea Rim State Park and High Island.
129. Use dredged materials to rebuild the island at the McFadden Bend Cutoff (Reserve Fleet area across from Sun Terminal) that was lost to erosion.
130. Use dredged materials to restore Bessie Heights Marsh and construct salinity control structures to protect the marsh.
131. Construct a salinity control structure on the Keith Lake Fish Pass.
132. Limit salinity intrusion into Keith Lake by using dredged materials to fill in the cuts that have been made into the lake on its north side.
133. Build vegetated dunes and institute ongoing erosion control and beach nourishment for the eroded beach in the vicinity of McFaddin NWR.
134. Construct a structure at the channel end of the Pilot Station Cut to limit saltwater intrusion.
135. Construct a structure at the channel end of the Texas Bayou Cut to limit saltwater intrusion.
136. Construct a structure at Keith Lake Fish Pass to limit saltwater intrusion.
137. Investigate the potential for mining existing placement areas for high-quality dredged materials that can be used in various restoration projects (note: not location specific).
138. Use maintenance dredging materials from the GIWW to restore the eroded beach in the vicinity of McFaddin NWR.
139. Use dredged materials from the lower portion of Taylor Bayou for marsh restoration and beach nourishment.
140. Mine the high-quality sediments from behind the dam at Steinhagen Lake (outside of the study area) for use in marsh restoration and beach nourishment projects in the study area.
141. Modify the jetty system to restore the longshore current and deposition of materials along the beach west of the channel.
142. Use the high-quality materials from offshore channel dredging to restore the eroded beach in the vicinity of McFaddin NWR.
143. The beach in the vicinity of McFaddin NWR is being eroded because the longshore current is deflected outward by the jetties and then turns back sharply toward the beach. Build a longshore parallel jetty system to minimize the assault on the beach by the inwardly turning longshore current.
144. Because it is of higher quality, use dredged materials from the GIWW for beach restoration west of the channel rather than for other purposes.
145. Reinforce the shoreline all along the channel to reduce erosion and the need for maintenance dredging.
146. Implement the Drainage District 6 proposed Taylor Bayou Diversion Channel project west of the present diversion channel and from Taylor Bayou to the GIWW to alleviate flooding.

147. Use dredged materials to restore the eroding beach south of McFaddin NWR to protect Hwy. 87.
148. Pump sand from offshore to restore the eroding beach south of McFaddin NWR to protect Hwy. 87.
149. Restore the Rose City Marsh in keeping with the plan of action submitted by TNRCC, which involves breaking the open-water areas into cells with levees and restoring one cell at a time with dredged materials.
150. Preserve the oxbow above the Rose City Marsh, with possible donation or easement and recreation link with mainland.
151. Close the breaks into the marsh on the southeast bank of Keith Lake that are contributing to saltwater intrusion.
152. Resolve the problem of too much fresh water in the Blind Lake area where the TPWD levee and the GIWW are interrupting sheetflow, perhaps by constructing a drainage canal to the GIWW.
153. Reduce saltwater intrusion into Bessie Heights Marsh by separating the marsh from the Neches River by building a levee along the riverbank and rebuilding the levee on the GSU canal.
154. Reduce saltwater intrusion by building a levee across the old dredged material placement area to Bird Island Bayou.
155. Restore the Mires Bayou area by building levees to close the oxbow at both ends, which would limit saltwater intrusion.
156. Protect the Texas Point marshes by constructing a longshore rock jetty and placing dredged materials along the beach behind the jetty.
157. Use dredged materials to restore marshes throughout the study area that have been converted to open-water areas, as seen by comparing historic to contemporary maps (note: not location specific).
158. Constrict the channel to about 250 feet at Sabine Pass to reduce saltwater intrusion into Sabine Lake.
159. Construct a lock at Sabine Pass to eliminate saltwater intrusion into Sabine Lake.
160. Deposit dredged materials southeast of the lighthouse to create a raised area or dunes that would protect the lighthouse from storm surges and assist in erosion control.
161. Place dredged materials southeast of the lighthouse along the mudflats and slightly inshore at an elevation of about three feet to protect the lighthouse.
162. Control coastal erosion west of Johnsons Bayou by the placement of materials from offshore channel dredging.
163. Use every opportunity presented by the present and proposed projects to preserve the lighthouse for future generations (note: not site or recommendation specific).
164. Construct a saltwater barrier at the mouth of Lighthouse Bayou to limit saltwater intrusion into the marsh.
165. Construct an emergent or submerged rock barrier north of the causeway to limit saltwater intrusion into Sabine Lake.
166. Build a levee or separate salinity control structures from Blue Buck Point east to limit saltwater intrusion into the marshes through the numerous small ditches and oilfield canals.

167. Construct an erosion control structure and rebuild the land with dredged materials in the eroding cove on the east side of the lake and north of the causeway.
168. Construct an erosion control structure and rebuild the land with dredged materials in the eroding cove on the east side of the lake and south of the causeway.
169. Construct a lock at the mouth of the channel to eliminate saltwater intrusion into Sabine Lake.
170. Build placement areas to a reasonable level, then move on to other areas, allowing the old placement areas to vegetate or be used for development (note: not location specific).
171. Use dredged materials to restore the eroding beaches from Texas Point to High Island.
172. Use dredged materials for dune restoration south of Hwy. 87 if it is ever rebuilt.
173. Use dredged materials for marsh restoration in the Bessie Heights Marsh.
174. Use dredged materials for marsh restoration in Keith Lake wherever open-water areas are emerging.
175. Use dredged materials for marsh restoration in the Salt Bayou watershed north and south of the GIWW.
176. Use dredged materials to build up low-lying land suitable for development that is not marshland (note: not location specific).
177. Because most dredged materials contain pollutants, continue to put them in placement areas rather than using them for ostensibly beneficial purposes (note: not location specific).
178. Any beach-quality sand that is available should be used to restore the eroding beaches from Texas Point to High Island.
179. Use dredged materials to construct a road to the Sabine Lighthouse.
180. Use dredged materials to restore the beaches east of the channel.
181. Construct a lock at the mouth of the channel to eliminate saltwater intrusion into Sabine Lake.
182. Construct a revetment or levee and fill in back with dredged materials to restore the eroding cove at the mouth of Lighthouse Bayou.
183. Remove Point Hunt Island in the channel to allow a straight passage for vessels so that the land to the east is not subjected to collisions.
184. Use dredged materials to fill in the open-water areas in Sabine NWR.
185. Use dredged materials to further build up the potentially developable land on the east side of the channel and investigate ways to modify present restrictions on development.
186. Constrict the channel at Sabine Pass to reduce saltwater intrusion into Sabine Lake.
187. Construct a weir in the vicinity of the causeway to reduce saltwater intrusion into Sabine Lake.
188. Construct a series of small islands between the north end of Pleasure Island and Sabine Island to reduce saltwater intrusion into Sabine Lake from the channel.
189. Use the higher-quality dredged materials obtained through offshore dredging for marsh and beach restoration.
190. Use dredged materials to restore the shoreline and Hwy. 87 between Texas Point and High Island.

191. Continue to insure freshwater inflow into Sabine Lake from the Neches and Sabine rivers (note: not location specific).
192. Construct a public boat launch on the Louisiana side of the causeway at the site of the present deteriorated boat ramp to provide access to Sabine Lake from Louisiana.
193. Rehabilitate the old boat launch at the burned out bridge on old Hwy. 90.
194. Rebuild the deteriorating islands between the north end of Pleasure Island and Sabine Island to reduce saltwater intrusion into Sabine Lake from the channel.
195. Construct substrates for oysters in Sabine Lake to renew oyster production.
196. Ensure that future restoration and beneficial use projects comply with Louisiana mandates and Louisiana's Coast 2050 plan (note: not location specific).
197. Stabilize the levees of the GIWW throughout its entire extent in the Louisiana portion of the study area.
198. Restore the levees on the Vinton Drainage Canal.
199. Use dredged materials to restore road access to the Sabine Lighthouse.
200. Construct a lock in Sabine Pass to eliminate saltwater intrusion into Sabine Lake.
201. Use dredged materials for erosion control on both sides of the channel from Sabine Pass to the north end of Pleasure Island.
202. Stabilize the shoreline of the entire Neches River channel.
203. Stabilize the lake shoreline and replenish adjacent marshes in the area from Blue Buck Point to Johnsons Bayou, leaving the bayous open.
204. Construct a structure within the causeway to slow tidal flows in and out of the south end of Sabine Lake.
205. Construct a lock at the mouth of the Sabine River to regulate freshwater flows into Sabine Lake from Toledo Bend Reservoir.
206. If the SNWW project is approved, develop a joint Louisiana-Texas plan to deal with any unforeseen problems that might occur (note: not location specific).
207. Use dredged materials for beach restoration from Texas Point to High Island.
208. Construct a fishing pier in connection with the improved boat launch on the Louisiana side of the causeway.
209. Construct a large parking area in connection with the improved boat launch on the Louisiana side of the causeway.
210. Construct a structure at the mouth of Lighthouse Bayou to limit saltwater intrusion.
211. Use dredged materials to restore the beach from Louisiana Point to Constance Beach.
212. Use dredged materials to reinforce the roadbed of Hwy. 82 along the Louisiana coast.
213. Use dredged materials to enhance the beach at Louisiana Point.
214. Use dredged materials to restore Fina Anchorage Island created by the cutoff in the Neches River.
215. Use dredged materials for chenier restoration in Louisiana, including planting of native vegetation to provide habitat for neotropical migratory songbirds.
216. Use dredged materials to restore deteriorating marshes in the chenier plain.
217. Use dredged materials to construct new cheniers in Louisiana.
218. Establish salinity control on the bayous and canals entering Sabine Lake from Louisiana.
219. Use dredged materials to restore cheniers on the Texas side of the channel.

220. Use dredged materials to restore beaches and dunes along the Louisiana coast to provide bird habitat.
221. Move Hwy. 87 one thousand feet inland from the beach from Texas Point to High Island, build a dune structure, and fill in the area with dredged materials to slow erosion.
222. Stockpile dredged materials and mine them for beneficial use when needed (note: not location specific).
223. Use dredged materials (sand and mud) to restore the coastline west of Texas Point.
224. Use dredged materials to restore the marshes north of Keith Lake.
225. Restore the marshes from Bessie Heights Marsh to Rose City Marsh as one marsh system.
226. Fill manmade ditches within the Texas marshes (Sea Rim Pintail Flats Marsh, Lower Neches Marsh, Bessie Heights Marsh, Texas Point Marsh, McFaddin Marsh, Meyers Bayou Marsh, etc.) to restore the historic hydrology and salinity (note: not location specific).
227. Construct a saltwater barrier at Sabine Pass.
228. Construct water control structures at the mouth of every canal and bayou in Texas that connects with the channel (Pilot Station, Texas Bayou, Keith Lake Fish Pass, Bessie Heights, Lower Neches, etc.) to restore the historic hydrology, and use dredged materials to fill the canals after water control is accomplished (note: not location specific).
229. Use dredged materials to raise Hwy. 87 from the GIWW bridge south to Sabine Pass.
230. Reconstruct Hwy. 87 from the GIWW bridge south to Sabine Pass to allow sheetflow under the road.
231. Use dredged materials to build up eroding areas on Pleasure Island while avoiding any damages to the lake.
232. Develop a comprehensive study of the best possible restoration of the marsh system from Bessie Heights Marsh to Rose City Marsh.
233. Transport dredged materials outside of the study area so that they can be more widely used, for example at Rollover Pass (note: not location specific).
234. Use dredged materials to create vegetated dunes and restore the beaches from Texas Point to High Island.
235. Mine existing placement areas for materials to build dunes and restore beaches along the Texas coast (note: not location specific).
236. Use dredged materials to build a barrier island from Texas Point to Rollover Pass.
237. After historic hydrology and salinity have been reestablished (as per 226 and 228) in Texas' degraded marshes (Sea Rim Pintail Flats Marsh, Lower Neches Marsh, Bessie Heights Marsh, Texas Point Marsh, McFaddin Marsh, Meyers Bayou Marsh, etc.), build land masses and islands, with coarse dredged sand used to establish bird grit sites (note: not location specific).
238. Use dredged materials to construct a bird island in Sabine Lake.
239. Use the higher-quality materials from offshore dredging for beach restoration.
240. Construct water control structures at the mouth of every canal and bayou in Texas that connects with the channel (Pilot Station, Texas Bayou, Keith Lake Fish Pass, Bessie Heights, Lower Neches, etc.) to restore the historic hydrology, and use

- dredged materials to fill the canals after water control is accomplished (note: not location specific).
241. Use dredged materials to create vegetated dunes and restore the beaches from Texas Point to High Island.
 242. Use dredged materials from the SNWW and from Entergy's canal dredging to restore the declining marshes on Entergy property.
 243. Use dredged materials to levee Entergy's outflow canal to keep sediment out of the canal and to keep the flow of water from eroding the marsh.
 244. Use dredged materials in any fashion that would keep saltwater from intruding into the marshes on Entergy property.

3.9 Post-Workshop Activities

After each workshop, suggestions were clarified on the basis of the various sets of notes that had been taken, were provided sequential numbers for each succeeding workshop, and were placed in the electronic database. The locations of suggestions on the hardcopy maps were assigned sequential numbers for each succeeding workshop, transferred to the electronic maps, and checked for precision in keeping with the suggestions. This information was e-mailed to the Galveston District. The Mylar overlays served as a permanent record of the suggestions from each workshop. Finally, the suggestions and their locations were organized electronically by category. The following maps show the 244 suggestions in terms of their categorical designations.

4.0 SNWW RIVER TRIPS

The SNWW study team members and resource agencies were given an introductory boat tour of the proposed project area on September 13, 2000. SNND Board Member Sonny Sherman provided a houseboat for the trip. Representatives from all ICT agencies were invited to travel down the SNWW from Beaumont to Sabine Pass. They were accompanied by USACE study team members who provided introductory information on the proposed project.

A boat trip from Beaumont to Sabine Pass down the SNWW was held for public news media on September 23, 2003. SNND Board Member Sonny Sherman provided a houseboat for the trip. Media from the entire Study Area were invited to travel and observe the channel, and speak with team members, resource agencies, and the SNND. The objective of these trips was to generate public interest in the project and encourage greater participation in public meetings.

5.0 TEXAS HABITAT PROTECTION ADVISORY PANEL MEETINGS

Status updates on the preparation of the Draft EIS were presented at Texas Habitat Protection Advisory Panel (AP) Meetings on December 9, 2003, and December 6, 2005. The AP was briefed on alternatives, technical workgroup activities, and H-S and WVA modeling procedures and results. The Preferred Alternative (48x700 ft project) was presented to the AP on September 26, 2006. The AP is composed of persons from recreational and commercial fishing groups, conservation organizations, academia, and state and federal resource agencies who meet to

review and discuss fishery habitat issues. It is one of eight regional fishery management councils established by the Magnuson-Stevens Fishery Conservation and Management Act of 1976.

6.0 SOUTHEAST TEXAS WATERWAY ADVISORY COUNCIL (SETWAC) MEETINGS

USACE representatives regularly attended SETWAC meetings to provide status updates of the project. SETWAC is a "harbor safety committee" established by the U.S. Coast Guard (USCG) in 1997. SETWAC is a public forum to facilitate discussion and exchange of views and advice among all stakeholders on a wide range of issues relevant to ports on the Sabine and Neches Rivers. Topics discussed at the meetings include, but are not limited to, communications, traffic management, anchorages, and other topics dealing with safety, efficiency, preservation, and improvement of the transit and usage of the Sabine-Neches Waterway System. Members of SETWAC include the USCG, USACE, the SNND, the Ports of Beaumont, Orange, Port Arthur and Sabine, public safety and emergency management agencies from surrounding local governments, commercial fishing associations, petrochemical plants and terminals along the SNWW, the Sabine Pilots Association, harbor tug companies, shipping agents and operating companies, and vessel repair companies.

7.0 LEADERSHIP OF SOUTHEAST TEXAS CLASS OF 2007 CONFERENCE

On January 25, 2007, representatives from USACE, SNND, the Sabine Pilots Association, and Bracewell and Giuliani provided updates regarding the proposed SNWW CIP to this conference in Orange, Texas. The central topic for the conference was the proposed CIP. USACE and SNND provided an overview and current status of the feasibility study and EIS.

8.0 SABINE PILOTS ASSOCIATION (SPA)

USACE and SNND met with members of the SPA several times throughout the preparation of the EIS. The purpose of the meetings was to obtain information on transit rules, transit times, and safety and other operational issues. Specific changes in depth and width, and specific navigational features such as turning basins and anchorages were discussed.

9.0 INDUSTRIAL USERS OF THE SNWW

USACE and SNND met with representatives from local industry several times throughout the course of this study. The meetings were held to identify specific needs of the industries in regard to use of the SNWW. Current and projected future needs were explored.

10.0 FUTURE PUBLIC INVOLVEMENT ACTIVITIES

Following completion of the Final Feasibility Report and the Final Environmental Impact Statement, additional public involvement activities will be initiated:

- Distribution to agencies and organizations for review and comment (see distribution list in FEIS Section 12.3);
- Presentation of the Preferred Alternative to local governments; and
- Publication of the FEIS Notice of Availability in the Federal Register, announcing the public comment period.

May 5, 2000

Major Randy L. Turner, Deputy District Engineer
Department of the Army
Galveston District Corps of Engineers
P. O. Box 1229
Galveston, TX 77553-1229

Dear Major Turner:

I am writing in reference to the Notice of Studies and Initial Public Meeting for Sabine-Neches Waterway, Texas Feasibility Study. We are concerned about increases in saltwater and tidal intrusion into the swamps and fresh to intermediate marshes of the Calcasieu-Sabine Basin east of Sabine River and Sabine Lake that may result from this navigation project.

There are more than a hundred square miles of fragile coastal marsh and swamp in southwestern Louisiana that rely on freshwater from the Sabine River for their productivity. These marshes have already suffered catastrophic losses over the past 50 years due to hydrologic alterations and, as a result, there is a sizeable state and federal restoration effort underway to ensure that the remaining wetlands will continue to support renewable fish and wildlife resources for future generations. There are, in fact, a large number of coastal restoration projects that have been constructed or are in various stages of planning/implementation that would be affected by significant salinity changes in the Sabine estuary. Wetlands of the Calcasieu/Sabine estuary are already stressed by the well-documented effects of navigation channel-induced saltwater intrusion.

We expect that this feasibility study will include a thorough analysis of the environmental effects of the existing navigation project as well as the incremental effects of any proposed project modification. You are probably aware that ongoing water planning activities under Texas Senate Bill 1 are evaluating diversion of the Sabine River from or below Toledo Bend Reservoir. Reductions in Sabine River stream flow and increased saltwater intrusion may cause significant adverse impacts to the estuarine system in both states. It is critical that this feasibility study evaluate the potential cumulative impacts to the Louisiana and Texas coastal marsh ecosystem from these hydrologic alterations.

We are very interested in being involved in the planning and decision-making process for this study and await notice from the Galveston District as to how we can appropriately participate in the study's environmental assessment of the southwest Louisiana marshes. In the meantime, please send us a copy of the project Reconnaissance Study so that we can fully understand the scope of the project and the nature of the federal interest that has been identified as justifying further study. Please contact me at (225) 342-7308 should you have any questions or like to discuss this further.

Sincerely,

Bill Good, Ph.D.

Re: Notice of Studies and Initial Public Meeting for Sabine-
Neches Waterway, Texas, Feasibility Study

Dear Major Turner:

The Louisiana Department of Wildlife and Fisheries is very interested in the above reference study and the impacts to the natural resources of Louisiana. We request that your agency keep us informed on the study and any meetings and/or field trips concerning this study.

This agency strongly supports the beneficial use of dredged material to restore wetlands within the Sabine River Basin. There are areas within Louisiana that we would suggest this dredged material be placed to restore some of the marsh lost.

Mr. Fred Dunham of my staff is assigned to this study and can be reached at (225) 765-2367, fax (225) 765-2452, or by e-mail dunham_fo@wlf.state.la.us.

Sincerely,

Colonel Nicholas J. Buechler
 U.S. Army Corps of Engineers
 P.O. Box 1229
 Galveston, Texas 77553-1229
 ATTN: Mr. Frank Garcia

Dear Colonel Buechler:

This is in response to Public Notice dated April 20, 2000 requesting comments on the feasibility phase of the Sabine-Neches Waterway (SNWW) Study. The SNWW connects the harbor facilities in Beaumont, Port Arthur, Orange, and Sabine Pass in Jefferson and Orange Counties, Texas, and Cameron and Calcasieu Parishes Louisiana with the Gulf of Mexico. This waterway also connects the Gulf Intracoastal Waterway (GIWW) in Calcasieu Parish, Louisiana to the GIWW in Jefferson County, Texas. Following are comments of the U.S. Fish and Wildlife Service, which have been coordinated with our Texas Chenier Plain and Louisiana Sabine National Wildlife Refuges and our Lafayette, Louisiana field office.

The Public Notice states that 3 alternatives being considered are channel deepening from the Gulf of Mexico to Beaumont, channel widening from Port Arthur to Beaumont, and using dredged material to enhance Bessie Heights and Rose City Marshes. Our comments are intended to provide the Corps with Service concerns regarding possible impacts to important native fish and wildlife habitats in the Sabine, Neches, and Calcasieu River Basins which could be affected by modifications to the SNWW.

Salinity intrusion into important wetland habitats --- The Service's main concern from any channel modifications are that increased salinity intrusion from an enlarged ship channel could affect freshwater and brackish wetland habitats already stressed by high salinity levels. These habitats include important freshwater wetlands at Taylor's Bayou, wetlands adjacent to the Gulf Intracoastal Waterway (GIWW) in Texas and Louisiana, cypress-tupelo wetland forests along the Neches River and north of the GIWW in Louisiana, large tracts of freshwater and brackish marsh east of Sabine Lake within Sabine National Wildlife Refuge, and marshes west of Sabine Lake at Lower Neches Wildlife Management Area (Texas Parks and Wildlife Department), and J.D. Murphree Wildlife Management Area.

This is your future. Don't leave it blank. - Support the 2000 Census.

Colonel Nicholas J. Buechler

These habitats are some of the richest, in terms of productivity, diversity, and habitat value, in North America. Collectively, they provide important wintering habitat for over 2 million waterfowl annually and contribute hundreds of millions of dollars to the regional economy annually through recreational hunting and fishing, tourism, commercial fisheries, fur trapping, and outdoor recreation. These wetlands are today adversely impacted by elevated levels of salinity introduced through the SNWW and the Calcasieu Ship Channel, 40 miles to the east. Salinity intrusion from these two sources has, during the past 50 years, caused shifts in native wetland communities towards saline marsh, a less diverse marsh type. Recent studies by Louisiana Department of Natural Resources have shown large amounts of marsh loss adjacent to manmade channels and canals throughout the area. This marsh loss and marsh alteration is presently causing millions of dollars in economic losses annually to the coastal counties of Jefferson and Orange and the parishes of Cameron and Calcasieu. As these wetlands provide habitat for some of our most valuable trust-mandated natural resources, the Service will not support any channel enlargement project which causes significant additional increases in salinity to adjacent inland marsh and swamp communities.

Therefore, the Service recommends that the Corps conduct three-dimensional hydrodynamic modeling studies to predict changes to salinity regimes, tidal amplitudes, hydroperiods, and marsh flooding durations within the lower Sabine and Neches River drainages from SNWW project modifications. The Service would like to participate in this modeling work group.

The Louisiana Department of Natural Resources (DNR) is presently contracting with Dr. Ehad Meselhe at the University of Louisiana at Lafayette for an H3D model to be used to predict similar changes in this region. There is available an extensive set of data on water salinities within these wetland habitats of concern, specifically in Sabine National Wildlife Refuge, McFaddin National Wildlife Refuge, Texas Point National Wildlife Refuge, J.D. Murphree Wildlife Management Area, Sabine Lake proper, Lake Bayou cypress swamp near Beaumont, Blue Elbow cypress swamp on the Sabine River, and Sabine Island Wildlife Management Area (Louisiana Department of Wildlife and Fisheries). Any model utilized can and should be able to be verified by accurately reproducing known climatic events within these or similar sites.

Additionally, the Service recommends that model iterations include a reasonable array of freshwater inflow scenarios reflecting historic extremes and include reasonable engineering and beneficial uses features designed to reduce predicted future and present salinity conditions. These should include: a navigational lock or gate near Sabine Pass, waterway restrictions at important salinity intrusion points such as the lower end of Sabine Lake, Keith Lake Channel, Pleasure Island boat pass, the GIWW west of the SNWW, the re-establishment of the Sabine Lake shoreline south of the GIWW, and the GIWW east of Sabine Lake. And, model scenarios should include a reasonably foreseeable array of scenarios predicting cumulative losses of Sabine River freshwater inflows caused by withdrawals under current Texas Senate Bill 1 (Texas Water Plan). Again, the Service would like to participate in the development of the model, its verification, and in analysis of its results throughout project planning.

This is your future. Don't leave it blank. - Support the 2000 Census.

Beneficial uses features --- Additional beneficial uses features using project-generated dredged material to restore previously degraded or lost wetland habitat should be investigated in the event channel modifications can be designed so as to not cause increased salinity problems. Potential beneficial uses project sites include Bessie Heights Marsh, backdune marshes at Texas Point National Wildlife Refuge, beach nourishment at Holly Beach and Texas Point, marshes at McFaddin National Wildlife Refuge, and marshes within the Lower Neches and J.D. Murphree Wildlife Management Areas.

Impacts to Kemp's Ridley Sea Turtle --- Stranding records indicate the nearshore waters off Sabine Pass contain a seasonally large population of this most endangered sea turtle species. Project designs will have to include adequate monitoring and protection mechanisms to insure turtles are not killed during channel dredging within the jetty channel reach.

Thank you for the opportunity to provide input during this early stage of project planning. We look forward to working with your staff closely during the coming months to insure that our important native coastal fish and wildlife resources are conserved by careful planning and wise project design. Our Service "team", which will be working on the SNWW project, includes Darryl Clark (Lafayette Field Office, 337/291-3111), Phil Glass (Clear Lake Field Office, 281/286-8282), Andy Loranger and Patrick Walther (Texas Chenier Plain NWR, 409/267-3337), and Chris Pease (Sabine NWR, 318/762-3816). Please do not hesitate to call any of them, or me at 281/286-8282 if you have questions or if these recommendations require clarification.

Sincerely,

for

Carlos H. Mendoza

June 23, 2000

Colonel Nicholas J. Buechler
 District Engineer, Galveston District
 Department of the Army, Corps of Engineers
 P.O. Box 1229
 Galveston, Texas 77553-1229

Dear Colonel Buechler:

The National Marine Fisheries Service (NMFS) has reviewed the "Notice of Studies and Initial Public Meeting for Sabine-Neches Waterway, Texas Feasibility Study," dated April 20, 2000, requesting comments on the feasibility phase of the Sabine-Neches Waterway (SNWW) Study. The Feasibility Study will examine channel deepening from the Gulf of Mexico to Beaumont, channel widening from Port Arthur to Beaumont, and using dredged material to enhance Bessie Heights and Rose City Marshes.

The proposed channel modification will affect Essential Fish Habitat (EFH) for postlarval, juvenile, and adult red drum (*Sciaenops ocellata*), brown shrimp (*Penaeus aztecus*), white shrimp (*Litopenaeus setiferus*), and pink shrimp (*Penaeus duorarum*), postlarval and juvenile Spanish mackerel (*Scomberomorus maculatus*). Categories of EFH which may be affected if the project is constructed will include estuarine emergent wetlands, estuarine water column, and estuarine mud/sand bottoms. Detailed information on red drum, mackerel, shrimp, and other Federally managed fisheries and their EFH is provided in the 1998 amendment of the Fishery Management Plans for the Gulf of Mexico prepared by the Gulf of Mexico Fishery Management Council (GMFMC). The 1998 generic amendment was prepared as required by the Magnuson-Stevens Fishery Conservation and Management Act (MSFCMA) (P.L. 94-265).

In addition to EFH designated for shrimp, Spanish mackerel, and red drum, wetlands adjacent to Sabine Lake, and the lower Sabine-Neches River watershed, provide nursery and foraging habitat that supports various forage species and economically-important marine fishery species such as spotted seatrout (*Cynoscion nebulosus*), flounder (*Paralichthys spp.*), Atlantic croaker (*Micropogonias undulatus*), black drum (*Pogonias cromis*), Gulf menhaden (*Brevoortia patronus*), striped mullet (*Mugil cephalus*) and blue crab (*Callinectes sapidus*). These estuarine-dependent organisms serve as prey for other fisheries managed under the MSFCMA by the GMFMC (e.g., red drum, mackerels, snappers, and groupers) and highly migratory species managed by the NMFS (e.g.,

billfishes and sharks). Wetlands also provide habitat for many benthic animals, including marine worms and crustaceans, which are important components of the estuarine food web. Furthermore, wetlands provide other estuarine support functions, including: (1) providing a physically recognizable structure and substrate for refuge and attachment above and below the water surface; (2) improving water quality by trapping sediments and assimilating pollutants; (3) preventing erosion; (4) collecting organic and inorganic material by slowing currents; and (5) providing nutrients and detrital matter to the Sabine Lake estuary.

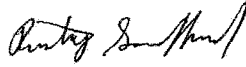

The NMFS is concerned that the proposed channel deepening and widening will increase salinity, alter the hydroperiod, and increase the tidal amplitude in the lower Sabine-Neches watershed. This could adversely impact brackish and intermediate marshes within the lower Sabine-Neches watershed and could result in significant marsh loss within the watershed. Therefore, NMFS recommends that the Corps conduct a three-dimensional hydrodynamic modeling study to evaluate potential changes to salinity regimes, tidal amplitudes, hydroperiods, and marsh flooding duration. The model should include all major drainages within the lower Sabine and Neches River watershed and Sabine Lake, including the Gulf Intracoastal Waterway to Calcasieu Lake, and an assessment should be made to determine what affects the proposed channel deepening and widening will have on marshes in the lower watershed. Model iterations should include a reasonable array of freshwater inflow scenarios to reflect present hydrology and a reasonably foreseeable array of scenarios predicting cumulative losses of Sabine River freshwater inflows caused by withdrawals under current Texas Senate Bill 1 (Texas Water Plan). The model runs should compare the present channel configuration with the proposed deepened and widened channel, including any reasonable engineering and beneficial use features designed to reduce predicted salinity increases. NMFS would like to participate in the development of the model, its validation, and in analysis of its results throughout project planning.

For your information, the Louisiana Department of Natural Resources (DNR) is presently contracting with Dr. Ehad Meselhe at the University of Louisiana at Lafayette for an H3D model to be used to predict similar changes in this region. There is available an extensive set of data on water salinities within these wetland habitats of concern, specifically in Sabine National Wildlife Refuge, McFaddin National Wildlife Refuge, Texas Point National Wildlife Refuge, J.D. Murphree Wildlife Management Area, Sabine Lake proper, Lake Bayou cypress swamp near Beaumont, Blue Elbow cypress swamp on the Sabine River, and Sabine Island Wildlife Management Area (Louisiana Department of Wildlife and Fisheries).

Additional beneficial use features using project-generated dredged material to restore previously degraded or lost wetland habitat should also be investigated. Potential beneficial use project sites include Bessie Heights Marsh, back dune marshes at Texas Point National Wildlife Refuge, beach nourishment at Holly Beach and Texas Point, marshes at McFaddin National Wildlife Refuge, and marshes within the Lower Neches and J.D. Murphree Wildlife Management Areas.

If we may be of further assistance, please contact Mr. Rusty Swafford of our Galveston Facility at (409) 766-3699.

Galveston, Texas 77553-1229

RE: C000171, Galveston District, Corps of Engineers, Sabine-Neches Waterway Study, Southeast Texas and Calcasieu and Cameron Parishes, Louisiana

Dear Mr. Garcia:

This letter is in response to the Notice of Studies and Initial Public Meeting for the Sabine-Neches Waterway, Texas Feasibility Study. Our preliminary comments are presented below, however, it will be necessary for the Galveston District to submit a Consistency Determination on this project before we can make a final decision on the project. For timely review, we suggest that you submit the Consistency Determination at the same time that the Draft EIS is published.

In the past, Louisiana has experienced vast amounts of wetland loss, a large part due to saltwater intrusion following development of navigational channels. For this reason, we are especially concerned that deepening of the Sabine-Nechez channel may have similar devastating effects on wetlands in southwestern Louisiana. We strongly recommend that the Galveston District conduct hydrological simulation modeling of the saltwater effects likely to result from this project, and that features such as a saltwater lock be included in the study of alternatives.

We recommend that the feasibility study provide full need and justification for the project, and that a thorough analysis of all environmental effects of the existing navigation channel and project alternatives be conducted and presented in the study findings. Possibilities for beneficial use of the dredged material to create wetlands should be fully explored as Louisiana has a no-net wetlands loss policy. Further, we expect the Galveston District to address any potential cumulative and secondary effects that these hydrological alterations will have on the coastal ecosystem, and provide compensatory mitigation for any wetland losses that may result.

EXECUTIVE DIRECTOR

Colonel Nicholas J. Buechler
U. S. Army Corps of Engineers
P.O. Box 1229
Galveston, Texas 77553-1229
ATTN: Mr. Frank Garcia

Dear Colonel Buechler:

Texas Parks and Wildlife Department (TPWD), acting in the public trust, has considerable fish and wildlife interests and public recreation interests in the area influenced by any proposed navigation improvements. TPWD's habitat ownerships within these potentially impacted areas include the Tony Houseman State Park and Wildlife Management Area at Blue Elbow Swamp, Lower Neches Wildlife Management Area, J. D. Murphree Wildlife Management Area, Sea Rim State Park, and Sabine Pass Battleground. These lands total approximately 40,000 acres of wetland habitats in Orange and Jefferson Counties. Additionally, habitats of particular interest in the potentially affected area include Sabine Lake; fresh, intermediate and brackish marshes under other public or private ownerships; swamps and bottomland forests associated with the Sabine and Neches watershed basins; and the rivers and tributaries of the basins. These habitats have suffered substantially from salt-water intrusion due to increased navigation channel depths, small access channels into marshes, subsidence, and reduced marsh re-nourishment due to navigation channels and dams. Any increase in salinity will only increase the rate of habitat loss and thus is not acceptable.

Texas Parks and Wildlife requests that the Corps of Engineers implement the following recommendations regarding the proposed Feasibility Phase of the Sabine-Neches Waterway (SNWW) Study.

- The Corps should develop a three-dimensional hydrodynamic model that will reflect potential changes associated with the deepening and widening of the navigation channels, including the three depths of 45, 50, and 55 feet. The model should include the watershed basins to the west to State Highway 124, extend north upstream to existing dams on the Neches and Sabine Rivers. The model should also extend eastward to the Calcasieu Ship Channel.

Col. Nicholas Buechler
Page 2

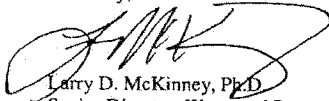

- Include in the model mitigative measures that could compensate for changes in salinity for each proposed depth. For example, submerged locks or barriers to salt water intrusion at the mouth of Sabine Pass should be considered. Major mitigative measures located in a few strategic locations could reduce the need for structural measures scattered along every tributary or embayment opening. Mitigative measures should not adversely affect ingress and egress of marine organisms that utilize estuaries as part of their life cycle. It is important that the diversity and productivity of Sabine Lake and its associated marshes and swamps are not degraded by the navigation improvements but are maintained or improved.
- Feasibility studies should incorporate anticipated changes in freshwater inflows into the estuary as anticipated from State water planning process (SB-1) actively underway at this time. The water plan for the State will be finalized in 2001. While this planning process is now underway, the timeline for the plan is to year 2050 allowing anticipated changes in freshwater inflows to be evaluated.
- In addition to measuring changes in salinity, modeling efforts should assess and incorporate changes in the following variables:
 - 1) tidal amplitude,
 - 2) anticipated relative sea level rise,
 - 3) temperature,
 - 4) primary productivity (phytoplankton) of Sabine Lake,
 - 5) nutrient utilization and water flushing rate (hydroperiod) in Sabine Lake,
 - 6) marsh hydroperiod as well as the flooding regime, and
 - 7) sediment transport within the basins and along the shoreline west of Sabine Pass.
- Modeling efforts should also measure the impact to the following "target" species:
 - rangia clam
 - white shrimp
 - Atlantic croaker
 - blue crab
 - Southern flounder
 - mottled duck
 - pig frog
 - American alligator
 - muskrat

Col. Nicholas Buechler
Page 3

- Specific habitat types that should be considered in the modeling effort include:
 - Cypress-tupelo swamp
 - Freshwater marsh
 - Intermediate marsh
 - Brackish marsh
 - Oyster reefs (Blue Buck Point)
- State cultural and historical sites (Fort Griffen) along the mouth of Sabine Pass should be assessed.
- The Corps should establish a beneficial uses group (BUG) for this project. Additionally, the Corps should use a process similar to the one used for the Houston Ship Channel project by developing an Interagency Coordination Team (ICT).

The Department appreciates the opportunity to provide comments and is interested in participating in the modeling work group, ICT, and/or BUG. Questions can be directed to Woody Woodrow in the Upper Coast Conservation Office (281) 461-4071 Ext. 22 or Rollin MacRae in Austin at (512) 389-4639.

Sincerely,

Larry D. McKinney, Ph.D.

re: Point of Contact for the Sabine-Neches Waterway Widening and Deepening Feasibility Study Interagency Coordination Team (ICT)

Dear Ms. Murphy:

Thank you for your letter of July 13, 2000 inviting my office to nominate someone for the Sabine-Neches Feasibility Study. This proposed project is of concern to my office both as it relates to regulatory issues, i.e. federal consistency determinations, and restoration issues, i.e. potential impacts of increased channel size on the quantity and quality of coastal wetlands. My office has two divisions, Coastal Management Division and the Coastal Restoration Division, which handle regulatory and restoration issues, respectively. Ideally, I would appoint a representative from each division to address these different aspects of the proposed project. These representatives would have been Mr. Greg DuCote from CMD and Mr. Steve Gammill from CRD. However, as you have requested a single point of contact, I nominate my Deputy Assistant Secretary, Mr. Gerry Duszynski, as our ICT Representative. He will call upon Mr. DuCote and Mr. Gammill for assistance, as appropriate.

Sincerely,

 A handwritten signature in dark ink, appearing to read "James Hanchey".

James "Randy" Hanchey, P.E.
Assistant Secretary

cc: Dr. Bill Good, Administrator, CRD
Dr. Terry Howey, Administrator, CMD
Mr. Gerry Duszynski, Deputy Assistant Secretary, OCRM
Mr. Steve Gammill, Geoscience Supervisor, CRD
Mr. Greg DuCote, Program Manager, CMD

May 28, 2002

Ms. Janelle Stokes
Environmental Section, Planning Branch
Planning Environmental and Regulatory Division
P.O. Box 1229
Galveston, Texas 77553-1229

Dear Ms. Stokes:

We saw in Federal Register Notice 67 FR 35801 dated May 21, 2002 that the Army Corps of Engineers intends to prepare a Draft Environmental Impact Statement (DEIS) to address the Improvements to the Sabine-Neches Ship Channel Near Beaumont and Port Arthur, Texas. We understand the study will evaluate several widening and deepening alternatives to improve a deep-draft navigation channel that connects harbor facilities in the Beaumont and Port Arthur area with the Gulf of Mexico. We are responding on behalf of the Department of Health and Human Services (DHHS), U.S. Public Health Service.

We are also particularly concerned that the DEIS provide detailed information on the dredged sediments, including plans for testing and characterizing contaminated hazardous and toxic bottom sediments prior to removal. We also are interested in planned disposal locations of these removed sediments and the potential impacts that these materials may have on human populations or potential downstream water supplies.

While we have no specific comments to offer at this time, the following areas are of particular concern to us and should be addressed if appropriate for this DEIS.

I. Air Quality

- dust control measures during project construction, and potential releases of air toxins
- potential process air emissions after project completion
- compliance with air quality standards

II. Water Quality/Quantity

- special private or public potable water supply considerations, including ground and surface water resources
- compliance with water quality and waste water treatment standards
- ground and surface water contamination (e.g. runoff and erosion control)
- body contact recreation

III. Wetlands and Flood Plains

- potential contamination of underlying aquifers
- construction within flood plains which may endanger human health
- contamination of the food chain

IV. Hazardous Materials/Wastes

- identification and characterization of hazardous/contaminated sites
- safety plans/procedures, including use of pesticides/herbicides; worker training
- spill prevention, containment, and countermeasures plan

Page 2 - Ms. Janelle Stokes

V. Non-Hazardous Solid Waste/Other Materials

- any unusual effects associated with solid waste disposal should be considered

VI. Noise

- identify projected elevated noise levels and sensitive receptors (i.e. residential, schools, hospitals) and appropriate mitigation plans during and after construction

VII. Occupational Health and Safety

- compliance with appropriate criteria and guidelines to ensure worker safety and health

VIII. Land Use and Housing

- special consideration and appropriate mitigation for necessary relocation and other potential adverse impacts to residential areas, community cohesion, community services
- demographic special considerations (e.g. hospitals, nursing homes, day care centers, schools)
- consideration of beneficial and adverse long-term land use impacts, including the potential influx of people into the area as a result of a project and associated impacts
- potential impacts upon vector control should be considered

While this is not intended to be an exhaustive list of possible impact topics, it provides a guide for typical areas of potential public health concern which may be applicable to this project.

Thank you in advance for your consideration. Please send a copy of the DEIS to the following address for our review and comment:

Carolyn E. Murphy, Chief
Environmental Section
U.S. Army Corps of Engineers
Galveston District
P.O. Box 1229
Galveston, Texas 77553-1229

Dear Ms. Murphy:

This responds to the U. S. Army Corps of Engineers notice of intent, to prepare a Draft Environmental Impact Statement for the improvements to the Sabine-Neches Ship Channel near Beaumont and Port Arthur, Texas, published in the May 21, 2002, Federal Register.

Since June 2001, the U.S. Fish and Wildlife Service (Service) Clear Lake, Texas and Lafayette, Louisiana Ecological Services Field Offices have been actively involved with the Corp of Engineers, Galveston District, other Federal and State environmental resource agencies in both states, and the project sponsor in the planning efforts for the Sabine-Neches Ship Channel Improvements project. Service involvement includes participation in the Interagency Coordination Team's Beneficial Uses Group and the Salinity Modeling Group. The Service will prepare a Draft Fish and Wildlife Coordination Act Report detailing its analysis of project impacts and mitigation requirements. This draft report will be completed in 2003.

The Service looks forward to further coordination with the Galveston District and others on the planning of this project.

Sincerely,

Geoffrey J. Quinlan
Regional Director

Subject: Sabine-Neches Waterway (Channel Improvements to Beaumont)
Environmental Impact Statement (EIS)

Dear Ms. Murphy:

The Environmental Protection Agency (EPA), Region 6, appreciates your invitation to become a cooperating agency in the preparation of the subject EIS. EPA is very interested in the proposed project and will participate in the National Environmental Policy Act (NEPA) process regarding our specific programs and responsibilities, to the extent possible, including: 1) Section 309 of the Clean Air Act (CAA) in review of the EIS for compliance with NEPA and Council on Environmental Quality (CEQ) guidelines; 2) Section 404 of the Clean Water Act (CWA) in the evaluation of impacts on wetlands and waters of the United States; and if applicable, 3) Section 102(c) of the Marine Protection, Research, and Sanctuaries Act (MPRSA) regarding the possible designation of an environmentally acceptable ocean dredged material disposal site (ODMDS). However, we are currently unable to participate as a cooperating agency.

Section 309 of the CAA and Section 404 of the CWA

The EIS for the proposed project should: 1) clearly demonstrate the Federal need for the proposed project, particularly when balanced against the Federal interest in coastal restoration; 2) analyze less environmentally damaging practicable alternatives to the proposed project; 3) fully evaluate potential adverse wetland impacts associated with increased salinity, tidal amplitude, and vessel traffic; 4) evaluate any adverse impacts to the on-going deltaic land formation occurring at the mouth of the Sabine-Neches outlet; and 5) evaluate the potential for induced development of port, harbor, and associated ship-building facilities.

Section 102(c) of MPRSA

It is unclear at this time if a new ODMDS would be required for the proposed project. For example, it is possible that 'new work' materials removed in connection with the proposed channel enlargement could be disposed of for beneficial use in coastal waters that are not subject to Section 102(c) of the MPRSA. Since any new EPA ODMDS designation would be subject to NEPA review, the following EIS Sections may provide the technical evaluation and related information in order for EPA to designate, if necessary, an environmentally acceptable and feasible site:

Internet Address (URL) - <http://www.epa.gov/earth1r6/>

Recycled/Recyclable - Printed with Vegetable Oil Based Inks on Recycled Paper (Minimum 30% Postconsumer)

Introduction - including ODMDS components in the background and project description, problems (e.g., suspended fluff or flocculation), and purpose and need.

Alternatives - including ODMDS in the history and process of formulating and screening options. Evaluate the environmental impacts of the reasonable ODMDS alternatives, including the beneficial use of dredged material to the maximum extent practicable. These could include:

1) ODMDS alternative sites (i.e., deep water, mid-shelf, and shallow water sites, including the currently designated ODMDS; and

2) beneficial use options such as, but not limited to: a) wetlands creation; b) pumping into confined disposal where the material may dewater and compact; c) other beneficial uses of dredged material, such as creation of beach feeder berms, or beach nourishment; and d) an alternative of cost-sharing.

Affected Environments and Environmental Consequences - including relevant ODMDS areas under the applicable affected resources, and the environmental consequences associated with and resulting from the applicable ODMDS activities. The Draft EIS could also provide an analysis of the secondary impacts of ODMDS disposal, including but not limited to: 1) the effects on coastal loss, erosion and/or subsidence; and 2) reductions, if any, in the long-term productivity of the coastal ecosystem. These Draft EIS impact analyses and discussions could be summaries or conclusions taken from the actual work products in the Appendices.

Appendices - including ODMDS work products, such as: 1) the evaluations based on the five general (40 CFR 228.5) and 11 specific (40 CFR 228.6) criteria; 2) environmental site screening study; 3) modeling components for new construction and new maintenance materials; 4) contaminant and/or sediment studies; 5) site management and/or monitoring plans; and 6) a State Coastal Zone Consistency Determination.

We look forward to working with you and your staff on this EIS. Please keep us informed regarding future coordination activities and meetings, which will be very helpful in our discussion of travel and resource commitments. If you have any questions, feel free to contact me at (214) 665-8150 or Mike Jansky at (214) 665-7451.

Sincerely yours,

Robert D. Lawrence, Chief
Office of Planning and
Coordination (6EN-XP)

DEPARTMENT OF THE ARMY

P.O. BOX 1229
GALVESTON, TEXAS 77553-1229

REPLY TO
 ATTENTION OF.

February 10, 2004

Ms. Estelle A. Bulka
 Acting Chief, Office of Planning and Coordination
 U.S. Environmental Protection Agency
 Region 6
 1445 Ross Ave., Suite 1200
 Dallas, Texas 75202-2733

Dear Ms. Bulka:

The Galveston District, Corps of Engineers, would like to invite the U.S. Environmental Protection Agency, Region 6 (EPA), to participate as a Cooperating Agency in the development of an Environmental Impact Statement (EIS) for the Sabine-Neches Waterway Feasibility Study (Channel Improvements to Beaumont). Our non-federal partner for this study is the Jefferson County Waterway and Navigation District. It has become apparent during the initial phases of this study that the designation of new ocean dredged material disposal sites (ODMDS) will be necessary to accommodate maintenance material for the offshore channel extension that will accompany channel deepening should the project be authorized. We propose that this EIS serve as a vehicle for EPA to prepare and develop environmental criteria for ocean disposal activities and to designate new or expanded ocean disposal sites associated with the proposed improvements, and to satisfy the requirements of Section 102 of the Marine, Protection, Research, and Sanctuaries Act. Additionally, if beneficial uses are identified for the disposal material, the District will have to consider and develop criteria for placing material under Section 404 of the Clean Water Act.

A combined EIS with EPA as a Cooperating Agency is preferred by this agency because preparation and coordination of a separate ODMDS EIS could seriously impact the completion schedule for this study. We have sufficient time to conduct required field work and prepare an ODMDS appendix for our combined EIS before the tentatively scheduled January 2005 completion of the preliminary draft. Public meeting(s) will be held in late summer/early fall to acquaint the public with the recommended plan in advance of releasing the draft for public review. Should you choose not to be a Cooperating Agency for this EIS, preparation of a separate EIS specifically for ODMDS designation will be necessary. Although we will also conduct the required analyses and prepare a preliminary draft EIS for EPA's coordination and issuance, time required to complete the separate process would likely delay issuance of the SNWW DEIS beyond the current schedule of April 2005.

In accordance with Section 1501.6 of the Council on Environmental Quality (CEQ) Regulations for Implementing the National Environmental Policy Act (NEPA), we hereby formally request that the EPA become a Cooperating Agency. To formalize the request, we are enclosing two originals of a proposed Cooperating Agency Agreement between the EPA and the Galveston District Corps of Engineers. If you agree to the terms of the agreement, please sign them and return one original to us.

If you should have any questions regarding this request and the agreement, please contact Ms. Janelle Stokes of my staff at (409) 766-3039.

Sincerely,

Lloyd H. Saunders, Ph.D.
Chief, Planning, Environmental
and Regulatory Division

Enclosure

**Environmental Impact Statement (EIS) for the Feasibility Study of the Sabine-Neches
Waterway Project (Channel Improvements to Beaumont, Texas)**

COOPERATING AGENCY AGREEMENT

between

**The Corps of Engineers (CE)
Galveston District
The Lead Agency**

and

**The U.S. Environmental Protection Agency (EPA)
Region 6
The Cooperating Agency**

INTRODUCTION

This agreement outlines the responsibilities agreed to by the above two Federal agencies with respect to the preparation of both the Draft and Final Environmental Impact Statements for the Feasibility Study of the Sabine-Neches Waterway Project (Improvements of the Channel to Beaumont) with the Jefferson County Waterway and Navigation District as the local sponsor. The project study area is in the vicinity of Beaumont, Port Arthur, and Sabine Pass, Texas. The Galveston District CE has initiated development of an EIS to determine the environmental impacts of proposed channel improvements as well as environmental impacts of alternatives to the proposed action. The EIS will cover a full range of reasonable alternatives so that the CE decision-maker(s) will be aware of the full range of impacts of a final decision. The EIS will also serve as a vehicle for the EPA to prepare and develop environmental criteria for ocean disposal activities and to designate new or expanded ocean disposal sites associated with the proposed improvements and to satisfy the requirements of Section 102 of the Marine, Protection, Research, and Sanctuaries Act.

COOPERATING AGENCY RESPONSIBILITIES

1. The Cooperating Agency (EPA) will participate in the scoping and public meeting process and will consult with the lead agency as appropriate so that the discussion is consistent with the planned alternatives, to the extent resources allow.
2. The comments EPA provides to the CE under this agreement will be advisory, with the exception of final recommendations regarding ocean dredged material disposal site (ODMDS) designations. EIS conclusions specifically related to compliance with Section

102 of the Marine Protection, Research and Sanctuaries Act (MPRSA) will be the responsibility of EPA.

3. EPA will assist the CE in the preparation of the Environmental Impact Statement for the portions specifically related to Section 102 of MPRSA.
4. EPA will participate in field visits at the lead agency's request, to the extent resources allow.
5. This agreement will appear in all documents in which the EPA is designated as a cooperating agency.
6. EPA's participation as a cooperating agency does not affect its commenting role established under Section 309 of the Clean Air Act.
7. EPA will conduct all rulemaking required for formal designation of the ODMDS.

LEAD AGENCY RESPONSIBILITIES

1. The lead agency (CE) will forward to EPA a summary of all comments received during the preparation of the documents including those arising out of the scoping process, public meetings and circulation of the EIS's.
2. When necessary, the CE will conduct an in-house meeting with EPA staff to solicit views and input on regulatory and/or significant environmental issues associated with the proposed actions.
3. The CE is the lead agency and is responsible for final decisions in the draft and final EIS's and their publication. The lead agency will consult with EPA but will retain sole responsibility for determination of which overall project alternative is selected and what mitigation will be included in the project.
4. EPA will be given a complete and final copy of both the Draft and Final EIS's for review prior to final lead agency approval and distribution of the documents.
5. EPA will be promptly informed of all schedule changes that would affect timely completion of the EIS documents.
6. A statement that describes the extent of EPA's role as a cooperating agency will be placed in the introduction section of the EIS.
7. If budget shortfalls prohibit EPA travel associated with EIS coordination activities, the lead agency will consider the option of funding travel or meeting with Regional Staff at the Region 6 Office in Dallas, Texas.

8. This agreement shall become effective upon the date it is signed by both parties. This agreement may be amended upon written agreement executed by both parties. This agreement is terminated when the lead agency Record of Decision is signed or when written notice is given by either agency.

DEPARTMENT OF NATURAL RESOURCES
OFFICE OF COASTAL RESTORATION AND MANAGEMENT

February 23, 2005

Janelle Stokes, Environmental Lead, SNWW Feasibility Study
U.S. Army Corps of Engineers, Galveston District
CESWG-PE-PR
P.O. Box 1229
Galveston, Texas 77553

Dear Ms. Stokes:

The Louisiana Department of Natural Resources, Office of Coastal Restoration and Management, wishes to enter the following comments into the official record of the Sabine-Neches Waterway (SNWW) Navigation Improvement Interagency Coordination Team. It is this Agency's expectation that each outstanding item will be addressed thoroughly and satisfactorily.

1. All environmental documents meant to satisfy NEPA and/or NOAA Coastal Zone Management Act (CZMA) Federal Consistency requirements must contain full and complete analyses of feasible alternatives. Analyses shall include alternative project types for the movement of hydrocarbon products upstream and downstream of the SNWW. The documents must give a full, fair, and accurate accounting of past, present, and future uses and users of the waterway. They must show that other alternatives would or would not meet the economic needs of the users and the goals of the project. The lessening of impacts from the construction of either alternative within the cost benefit analysis must also be taken into account.
2. Consistency with Louisiana's coastal management program will only be determined by a full review of the complete Consistency Determination submitted by the U.S. Army Corps of Engineers, Galveston District, pursuant to state and federal CZMA programs. That review will address the extent to which the recommended project has avoided, minimized, and compensated for impacts.
3. Mitigation measures for the navigation improvement project should include enforceable minimum Sabine River flow requirements.

For additional information, please contact William K. "Kirk" Rhinehart at (225) 342-2179.

Sincerely yours,

Gerald M. Duszynski
Acting Assistant Secretary

Environmental Section

Christy Lavergne
Louisiana Department of Wildlife and Fisheries
Marine Fisheries Division
P.O. Box 98000
Baton Rouge, LA 70898-9000

Dear Ms. Lavergne:

The Galveston District, Corps of Engineers, and the Jefferson County Waterway and Navigation District are in the final stages of preparing a draft feasibility report and environmental impact statement for the Sabine-Neches Waterway, Texas and Louisiana, Channel Improvement Project (SNWW CIP). Representatives of the Louisiana Department of Wildlife and Fisheries (LDWF) and other Louisiana resource agencies have participated with Texas and Federal agency representatives on an Interagency Coordination Team (ICT) which has evaluated impacts and developed mitigation measures for the Selected Plan of navigation improvements. Decisions on project impacts and compensatory mitigation were made by the ICT's designated workgroup with the full participation and concurrence of your agency's representatives. However, the LDWF ICT representatives (Mr. Kyle Balkum and Mr. Michael Harbison) have recommended that we contact you to obtain official comments from your agency regarding: 1) our assessment of the proposed dedicated dredging in Sabine Lake to supply sediment for marsh restoration proposed as mitigation; and 2) mitigation of impacts to oyster reef in Sabine Pass.

Complete details of project impacts and mitigation have been coordinated at length with the ICT. The Draft Environmental Impact Statement, currently scheduled for public review in late 2006, will be provided for your agency's formal review and comment at that time. A brief project summary is provided here to provide a context for the separate resolution of these two issues. The primary components of the Selected Plan for the SNWW CIP consist of deepening the existing inland reaches of the navigation channel from 40 to 48 ft to the Port of Beaumont, extending the existing entrance channel into the Gulf of Mexico at a depth of 50-ft, and widening the existing channel to 700 ft through Sabine Pass to the Taylor's Bayou Turning Basin near Port Arthur, Texas. The primary impacts to Louisiana are indirect impacts to Louisiana's intertidal wetlands associated with increased salinities. Ecological modeling of impacts has determined that 499 acres of intertidal marsh in areas east of Sabine Lake will be lost over 50 years due to salinity increases associated with the deeper navigation channel. The proposed mitigation plan developed by the ICT's Habitat Restoration Workgroup will restore a total of 3,502 acres of

emergent marsh in the Sabine National Wildlife Refuge (SNWR) and the Black Bayou area as full compensation for project impacts to Louisiana (USACE, 2006). The Black Bayou mitigation measures will restore 2,096 acres of emergent marsh in three open-water areas using maintenance material from the Channel to Orange over the 50-year project life, and a one-time dedicated dredging of accumulated material in the Lake Charles Deep Water Channel/GIWW. No issues requiring separate resolution have been identified by the LDWF ICT representatives concerning the Black Bayou mitigation measures.

Sabine Lake Dedicated Dredging

The portion of the mitigation to be conducted in the SNWR would consist of the restoration of 1,406 acres of emergent marsh. Dedicated dredging of Sabine Lake would be performed to supply the soils needed to restore marsh acreage and elevation, and mitigate for projected salinity increases in this area. A map showing the area of dedicated dredging and marsh restoration areas is Enclosure 1. The SNWW mitigation measure involves the one-time removal of Sabine Lake sediments by hydraulic pipeline dredge and the pumping of this material into three separate open water areas of the SNWR.

The area proposed for dedicated dredging is located within the Sabine Lake Public Oyster Area. However, the affected portion of Sabine Lake is too fresh to support viable oyster populations. Sabine Lake salinities in the vicinity of Willow Bayou averaged 5.3 parts per thousand (ppt) from 1984 to 1993 (Paille, 1996). Mean 1966 to 2000 salinities from stations located on the SNWR suggested that average Sabine Lake spring salinities are less than 3 ppt, summer salinities range from 3 ppt to 6 ppt, fall salinities are slightly greater than 6 ppt, and winter salinities range from 3 ppt to 6 ppt for the mid-eastern portion of Sabine Lake near SNWR (Louisiana Coastal Wetland Conservation and Restoration Task Force, 2002). Salinity sampling conducted in 2001 in support of hydrodynamic modeling for the SNWW Feasibility Study (Fagerburg, 2003) recorded summer salinities ranging from 3 ppt to 6 ppt at the northern end of Sabine Lake, and fall salinities primarily ranging from 1 ppt to 6 ppt, with one month of higher salinities averaging 9 ppt. The hydrodynamic model developed for the Feasibility Study revealed that observed salinity in Sabine Lake is highest at both the southern end (where the lake connects to Sabine Pass near Blue Buck Point) and at the northwestern corner (where the lake connects to the Sabine-Neches canal). The lowest salinities are observed in the central and eastern portions of the lake, which are furthest from the hydraulic connection to sources of saline water. (Brown et al., 2006).

Optimal salinity for oysters in Louisiana is from 10 to 15 ppt. Oyster larvae are killed below 10 ppt; salinities above 15 ppt are tolerated by oysters, but oyster predation by the oyster drill and others (i.e., *Perkinsus*) significantly increases above that salinity level (Breithaupt and Dugas 1979). Davis (1958) observed that oyster larval settlement and spat development occurred at salinities between 5 and 35 ppt. Adult oysters are able to withstand brief periods of salinities less than 5 ppt, but feeding, growth, and reproduction are severely reduced at those levels (Galtsoff 1964). Thus salinities in the vicinity of the East Sabine Lake Project area (6 ppt or lower) are in the marginal lower range for oyster production. Therefore, while not impossible, it is very

unlikely that oyster larvae, spat, and adults will be able to survive within the existing project area salinity regimes, except during drought years.

Sabine Lake oyster reefs are located in the southern portion of the lake in the vicinity of Blue Buck Point and the Highway 82 Causeway. Although there appear to be no published reports nor regular sampling programs of Sabine Lake oyster production, some unpublished data is available. Sampling conducted by the Texas Parks and Wildlife Department in the Blue Buck Point reef area from 1986 to 1991 (Mambretti personal communication, 2003) and a sonar survey of the southern third of Sabine Lake conducted in conjunction with a proposed Department of Army permit (Stelly personal communication, 2003) have mapped oyster reef in this area. In addition, the remote sensing survey documented that oyster reefs are concentrated in the Blue Buck Point vicinity and taper off quickly to the north. Because of the lower salinities in the upper two-thirds of Sabine Lake, it is unlikely that oyster reefs extend beyond the southern third of Sabine Lake. The dedicated dredging proposed here would occur at least 3.5 miles inland from the nearest mapped occurrence of oyster reefs in the southern portion of Sabine Lake near Blue Buck Point.

The dedicated dredging would take approximately 6.0 million cubic yards of material from a borrow trench in Sabine Lake located from 500 to 1500 ft from the SNWR shore. The borrow trench would extend north from near Willow Bayou for a distance of 3.9 miles, and average 1,030 ft wide by 7.5 feet deep. Trench ends would be sloped to gradually reconnect bottom elevations to the existing lakebed. The borrow trench would be continuous and parallel to the lake shoreline, in line with the common long-shore circulation pattern present in Sabine Lake. This circulation is expected to prevent the development of hypoxic conditions that would be detrimental to aquatic organisms. It is expected that the canal would eventually fill with Sabine River sediments. An access canal would also be needed for the pipeline dredge to reach the proposed borrow canal construction area. This canal would access the area from the section of the GIWW which crosses north Sabine Lake, and is shown the attached map.

USFWS and LDWF representatives on the ICT Habitat Restoration Workgroup have agreed that the proposed mitigation measure, based on application of the Wetland Value Assessment methodology, would have a net beneficial effect and cause no serious impacts to oysters and other biological resources and estuarine lake habitat. The Workgroup as a whole has approved adoption of the proposed action as a mitigation measure. Long-term benefits of a higher, more stable marsh would more than offset short-term impacts to benthic organisms during the one-time dredging episode. Dedicated dredging in Region 4 was approved in the CWPPRA Coast 2050 Plan (LCWCR/WCRA, 1998) as a common restoration strategy for wetland creation, as it furthers a strategic goal of ensuring vertical accumulation of coastal marshes relative to sea level rise and subsidence. The Coast 2050 plan was approved by participating state and Federal agencies, and all 19 coastal parishes.

Sabine Pass Oyster Impacts

One of the few direct impacts associated with channel widening and deepening proposed by the Selected Plan would be the loss of 7.3 acres of oyster shell reef on the Louisiana side of the Sabine Pass navigation channel. The reefs, mapped in 2003 by a remote sensing and oyster sampling survey undertaken for the SNWW feasibility study (Enright, 2003), are not located within a designated Louisiana Public Oyster Area or an Oyster Lease Area. Side-scan sonar and systematic sampling with a steel shell dredge mapped 60.1 acres of oyster reef within the remote-sensing survey corridor in Louisiana, 7.3 acres of which lie within the top-of-cut of the Selected Plan's 48 ft deep x 700 ft wide channel. A map of these reefs is provided as Enclosure 2. The shell dredge sampling recorded counts of live and dead American oysters (*Crassostrea virginica*), and half shells within 37 100-foot long transects (Enclosure 3). Twelve of these transects yielded no live or dead oysters, and few to no half shells. The remainder contained from 2 to 43 live oysters, or an average of 12 live oysters in each sample. The Sabine Pass Channel will be enlarged using a 30-inch cutterhead hydraulic pipeline dredge. Excavated material and sea water will be suctioned into the hydraulic pipeline and deposited in an existing, upland placement area on the east side of Sabine Pass. Material will not be side cast on the remaining oyster reef beyond the top-of-cut of the widened channel. We propose to compensate for the biological impacts associated with the loss of 7.3 acres of existing reef by the creation of an equivalent amount of new oyster reef. Details such as location, pad thickness, and reef material can be determined through ICT consultation.

Based upon the hydrologic, biological and geophysical data summarized above, we request a finding that: 1) project activities of the Selected Plan for the SNWW CIP will not adversely impact Public Oyster Area resources and oyster habitat and that all relevant survey/assessment requirements have been satisfied for the Sabine Lake dedicated dredging for marsh restoration; and 2) that the proposed mitigation is adequate compensation for impacts to 7.3 acres of oyster in Sabine Pass. If you have any questions, please do not hesitate to call Ms. Janelle Stokes at 409-766-3039.

Sincerely,

Dolan Dunn

RE: Sabine-Neches Waterway mitigation project in Sabine Lake, Louisiana

Mr. Dunn:

We are in receipt of your July 21, 2006 letter concerning the above captioned project. We have reviewed additional information related to the project, including the proposed mitigation plan that involves dredging approximately six million cubic yards of water bottoms from Sabine Lake, Louisiana for potential marsh creation/restoration in the adjacent Sabine National Wildlife Refuge. We have also reviewed written correspondence and Interagency Coordination Team information concerning the project that occurred over the past few years. It is clear from this information that the project's purpose is economically driven, and the environmental component stems only from the required mitigation for impacts associated with possible salinity increase in Sabine Lake. Although mitigation will serve as potential marsh creation/restoration on the Sabine National Wildlife Refuge, water bottom habitat within Sabine Lake will be impacted by dredging activities in the mitigation borrow area. As proposed, the required mitigation involves trading potential habitat creation/restoration in one area (Sabine NWR) for potential habitat degradation in another (Sabine Lake).

As you are aware, Sabine Lake is a public oyster area and this agency is mandated to diligently protect and conserve such areas. We exercise these protective measures regardless of the water bottom type (i.e. reef, sand, mud, etc.) or the current presence/absence of live oyster resources. In addition, it has been our long-standing practice that water bottoms associated with a proposed project within a public oyster area must be assessed prior to project implementation, and that compensation is required for impacts to those water bottoms.

Therefore, in order for this agency to consider a waiver of compensation for impacts to the water bottoms of the Sabine Lake public oyster area in relation to the mitigation borrow site, a full water bottom assessment must be performed and submitted to this agency prior to project implementation. A copy of the water bottom assessment protocol to be followed is attached for your information.

Sabine-Neches Waterway Corps Letter
Page 2 of 2

In addition, Louisiana Revised Statutes 56:2011-2015 outlined provisions relative to the dredging of fill material from water bottoms owned by the state of Louisiana and royalties thereon. No fill material shall be dredged from state-owned water bottoms unless a permit for that removal is issued by the Louisiana Department of Wildlife and Fisheries (LDWF). A severance royalty for each cubic yard of material removed from state-owned water bottoms shall also be paid to the state through LDWF. The proposed compensatory mitigation plan includes a proposal to sever approximately 6.0 million cubic yards of water bottom material (approximate severance value: \$1,200,000) from Sabine Lake, a state-owned water bottom, and placement of the material on federally owned and managed property. Therefore, pursuant to R.S. 56:2011-2015, LDWF requests that the project applicant apply for a permit and pay the appropriate severance royalties for the proposed removal of material from state-owned water bottoms.

Thank you for providing us with the opportunity to comment on your mitigation plan. Please contact Patrick Banks at 225.765.2370 or by email at pbanks@wlf.louisiana.gov if you have additional questions concerning the water bottom assessment requirements. For more information concerning the fill material permit process involving the removal of state-owned water bottoms, please contact Biologist Assistant Division Administrator Robert Love at 225.765.2814.

Sincerely,

W. Parke Moore, III

 Houston, TX. 77058

Dear Mr. Parris:

The Galveston District, Corps of Engineers, and our non-federal sponsor, the Jefferson County Waterway and Navigation District, would like to invite your agency to participate as a cooperating agency in the development of an Environmental Impact Statement (EIS) for the Sabine-Neches Waterway (SNWW) Feasibility Study. Navigation improvements are being proposed for the existing 65-mile long deep draft channel from the Gulf of Mexico to the Port of Beaumont on the Neches River. Environmental effects are being analyzed for adjacent intertidal marshes and forested wetlands in a large surrounding area which includes Sabine Pass and Sabine Lake, adjacent marshes in Texas and Louisiana, tidally influenced portions of the Neches and Sabine Rivers, and a proposed 13-mile long channel extension in the Gulf of Mexico. The Draft EIS is currently scheduled for publication in the summer of 2007.

We are required by the Council on Environmental Quality (CEQ) Regulations for Implementing the National Environmental Policy Act (NEPA) (40 CFR Part 1501.6) and subsequent policy guidance to invite all agencies with "jurisdiction by law" or who have "special expertise with respect to any environmental issue" to participate in the preparation of our NEPA documents as cooperating agencies. Previously, we understood that inviting your participation in our SNWW Interagency Coordinating Team informally accomplished the substance of this requirement. However, we are now required to send agencies a written invitation to participate as a cooperating agency; those that agree will be identified on the cover page of the SNWW EIS.

We request that you provide a written response to this invitation. For non-federal agencies which agree to become a cooperating agency, we will develop a memorandum of agreement to formalize expected roles and responsibilities. If you should have any questions regarding this request, please contact Janelle Stokes of my staff at (409) 766-3039.

Sincerely,

 Carolyn Murphy

Benjamin Tuggle
Regional Director
U.S. Fish and Wildlife Service
Southwest Region (2)
P.O. Box 1306
Albuquerque, N.M. 87103

Dear Dr. Tuggle:

This letter requests a compatibility determination for the beneficial use of dredged material for shoreline nourishment in the Texas Point National Wildlife Refuge (TPNWR), Jefferson County, Texas. This activity is being recommended in conjunction with the proposed Sabine-Neches Waterway (SNWW) Channel Improvement Project, Jefferson and Orange Counties, Texas, and Cameron Parish, Louisiana. The Galveston District is currently preparing a draft feasibility report and environmental impact statement which recommends enlargement of the existing navigation project to a proposed 48 x 700 foot channel.

As part of this project, shoreline nourishment is proposed for 3 miles of the Gulf of Mexico shoreline within the TPNWR, from 0.5 to 3.5 miles from the West Jetty, using maintenance material from the Sabine Pass portion of the SNWW navigation channel. The location of the proposed shoreline nourishment is shown on Enclosure 1. The Dredged Material Management Plan (DMMP) for the proposed project includes unconfined placement of maintenance material along the shoreline every 6 years for the 50-year project life (8 placement episodes). Shoreline nourishment at Texas Point will alternate with shoreline placement on the Louisiana Gulf shoreline, east of the SNWW. Rapid shoreline retreat in the TPNWR is resulting in substantial loss of wetlands. Additional shoreline erosion of approximately 0.42 feet per year is projected in conjunction with the proposed extension of the SNWW entrance channel. The proposed shoreline nourishment would protect the shoreline from existing erosion and eliminate the projected increase in erosion over the project life.

It is expected that the maintenance material from Sabine Pass will reflect the historical average of 51 percent silt, 31 percent clay, and 18 percent sand. The material would be hydraulically pumped into the near shore zone; some material is expected to flow over existing marsh while the remainder flows into the nearshore waters. Marsh plantings would occur as soon as possible on the inland half of the emergent berm to assist in stabilization. Experience with a similar project at Texas Point indicates that a majority of the dredged material will dissipate quickly during each placement event; however, some will remain and form a shelf on the shallow nearshore slope in front of the existing marsh edge.

Unconfined placement on the shoreline will have a net beneficial effect on this environment. Although placement events will temporarily impact shallow near shore waters and eroding marsh, benthic organisms in the nearshore zone will quickly rebound from the short term impact, as will marsh areas along the shore front which are nourished with additional sediment. Material added to the shoreline with these nourishment episodes will stabilize the eroding shoreline, and add sediment to the longshore current which will nourish areas to the west that are eroding at even greater rates. The potential for the nourishment activity to affect threatened and endangered species has been evaluated. No designated or proposed critical habitat would be affected. The federally-listed, endangered piping plover (wintering population) and sea turtles may occur in the shoreline nourishment area. No impacts to the wintering population of the piping plover are expected, however, because there is no intertidal beach or sand flat along this shoreline and therefore there is no wintering habitat for piping plover. The absence of a sand beach also negates potential for sea turtle nests in the nourishment zone. A contaminants assessment prepared for this project has determined that sediments and water from the SNWW are suitable for beneficial uses. Sediment and water sampling will be conducted prior to each maintenance cycle to ensure that these materials remain suitable for shoreline nourishment.

The proposal for shoreline nourishment at TPNWR was developed in coordination with Mr. Andy Loranger (Texas Chenier Plain National Wildlife Refuge Complex, 409/267-3337) and Mr. Phil Glass (Clear Lake Ecological Field Office, 281/286-8282). It was also recommended by the SNWW Interagency Coordination Team, a group of federal and state agencies which have reviewed impact assessments and recommended restoration and mitigation measures for the proposed SNWW project. Furthermore, the shoreline nourishment feature is included in the Draft Coordination Act Report for the project, which will be completed shortly.

Based upon the information presented above, we request your concurrence that the proposed shoreline nourishment is compatible with the major purposes of the TPNWR. If you have any questions, please contact Ms. Janelle Stokes at 409/766-3039.

Sincerely,

Carolyn Murphy

Environmental Section

Sam Hamilton
 Regional Director
 U.S. Fish and Wildlife Service
 Southeast Region (4)
 1875 Century Blvd. #400
 Atlanta, Georgia 30345

Dear Mr. Hamilton:

This letter requests a compatibility determination for marsh restoration in the Sabine National Wildlife Refuge (SNWR), Cameron Parish, Louisiana. This activity is being recommended as compensatory mitigation for unavoidable impacts of the proposed Sabine-Neches Waterway (SNWW) Channel Improvement Project, Jefferson and Orange Counties, Texas, and Cameron Parish, Louisiana. The Galveston District is currently preparing a draft feasibility report and environmental impact statement which recommends enlargement of the existing navigation project to a proposed 48 x 700 foot channel.

As part of the proposed project, 3 separate areas totaling 3,775 acres have been selected as marsh restoration sites in the SNWR's Willow Bayou unit (Enclosure 1). Intermediate marsh in the proposed restoration areas has been converting to open water at a rapid pace. Salinity increases associated with a deeper SNWW navigation channel are expected to exacerbate this trend. The proposed mitigation compensates for this loss by restoring a total of 1,406 acres of emergent intermediate marsh within the 3 restoration sites.

The marsh would be restored by the addition of mineral soil removed by hydraulic pipeline dredge from the bottom of Sabine Lake. Borrow areas would be located at least 500 feet from shore. Material would be placed by the unconfined flow of dredged material from a hydraulic pipeline. Pipeline routes would follow existing canals and levees wherever possible. Within the restoration area, frequent pipe movement and careful elevation control would be necessary to obtain the appropriate marsh elevation. Tidal creek channels would be constructed in the marsh creation area after the dredged material has settled to return the area to normal tidal regime, facilitate marine organism access, and allow water and nutrients to flow into the area.

This extensive marsh restoration effort will result in the displacement of currently shallow open water habitat. While some open water habitats are valuable and may be critical in some instances in maintaining fisheries productivity, intertidal marshes are critically important in maintaining this productivity over time as they provide more food and cover for juvenile fishery organisms than open water habitats. The potential for the marsh restoration activities to affect threatened and endangered species was evaluated. No designated or proposed critical habitat would be affected. None of the federally-listed species identified for Cameron Parish are

expected to occur in the restoration areas. A contaminants assessment for the proposed Federal project identified no contaminated sites or sediments in the vicinity.

The proposal for marsh restoration in the SNWR was coordinated with Mr. Donald Voros (Southwest Louisiana National Wildlife Refuge Complex, (337/598-2216), Mr. Terry Delaine (Sabine National Wildlife Refuge, (337/558-5574), Mr. Roy Walter (Southwest Louisiana National Wildlife Refuge Complex, (337/598-2216) and Mr. Darryl Clark (Louisiana Field Office, (337/291-3111). It was also recommended by the SNWW Interagency Coordination Team, a group of federal and state agencies which have reviewed impact assessments and recommended restoration and mitigation measures for the proposed SNWW project. Furthermore, the marsh restoration measure is included in the Draft Coordination Act Report for the project, which will be completed shortly.

Based upon the information presented above, we request your concurrence that the proposed shoreline nourishment is compatible with the major purposes of the SNWR. If you have any questions, please contact Ms. Janelle Stokes at 409/766-3039.

Sincerely,

Carolyn Murphy

Colonel David C. Weston
District Engineer
Galveston District, Corps of Engineers
Department of the Army
P. O. Box 1229
Galveston, Texas 77553-1229

Dear Colonel Weston:

Thank you for your letter of January 23, 2007, inviting NOAA's National Marine Fishery Service (NMFS), Southeast Region, to participate as a cooperating agency in developing the environmental impact statement for the Sabine-Neches Waterway Feasibility Study. The project proposes to implement navigation improvements for the existing 65-mile long deep draft channel from the Gulf of Mexico to the Port of Beaumont on the Neches River.

The NMFS Southeast Region accepts the invitation from the Department of the Army to serve as a cooperating agency on this project. However, due to staffing and travel funding constraints, our participation may be limited to review and comment on draft documents, teleconferences, and occasional travel for meetings. I appreciate your request for NMFS Southeast Region's assistance in the development of this environmental document. If we may be of further assistance, please contact Mr. Rusty Swafford, of our Habitat Conservation Division, Galveston field office, at (409) 766-3699.

Sincerely,

A handwritten signature in dark ink, appearing to read "Roy E. Crabtree".

Environmental Section

Billy Eakin
Regional Manager
Louisiana Department of Environmental Quality
Southwest Regional Office
1301 Gadwell
Lake Charles, LA 70615

Dear Mr. Eakin:

The Galveston District, Corps of Engineers, and our non-federal sponsor, the Jefferson County Waterway and Navigation District, would like to invite your agency to participate as a cooperating agency in the development of an Environmental Impact Statement (EIS) for the Sabine-Neches Waterway (SNWW) Feasibility Study. Navigation improvements are being proposed for the existing 65-mile long deep draft channel from the Gulf of Mexico to the Port of Beaumont on the Neches River. Environmental effects are being analyzed for adjacent intertidal marshes and forested wetlands in a large surrounding area which includes Sabine Pass and Sabine Lake, adjacent marshes in Texas and Louisiana, tidally influenced portions of the Neches and Sabine Rivers, and a proposed 13-mile long channel extension in the Gulf of Mexico. The Draft EIS is currently scheduled for publication in the summer of 2007.

We are required by the Council on Environmental Quality (CEQ) Regulations for Implementing the National Environmental Policy Act (NEPA) (40 CFR Part 1501.6) and subsequent policy guidance to invite all agencies with "jurisdiction by law" or who have "special expertise with respect to any environmental issue" to participate in the preparation of our NEPA documents as cooperating agencies. Previously, we understood that inviting your participation in our SNWW Interagency Coordinating Team informally accomplished the substance of this requirement. However, we are now required to send agencies a written invitation to participate as a cooperating agency; those that agree will be identified on the cover page of the SNWW EIS.

We request that you provide a written response to this invitation. For non-federal agencies which agree to become a cooperating agency, we will develop a memorandum of agreement to formalize expected roles and responsibilities. If you should have any questions regarding this request, please contact Janelle Stokes of my staff at (409) 766-3039.

Sincerely,

A handwritten signature in cursive script that reads "Carolyn Murphy".

Dear Ms. Murphy:

This letter is in reply to your request for a compatibility determination for the beneficial use of dredged material for shoreline nourishment in the Texas Point National Wildlife Refuge, Jefferson County, Texas. This is a project that the Fish and Wildlife Service supports. I will do a compatibility determination on this project. Our compatibility determinations require a 30-day public review, so I would like to coordinate it with the public review of the Corps' Environmental Impact Statement that addresses this project as well. Please keep me informed as to when the EIS will go out for public comment and I will put the compatibility determination out for public comment at the same time.

If this is not acceptable to you, or you would like to discuss this further, please call me at (409)971-2909.

Sincerely

Colonel David C. Weston
U.S. Army Corps of Engineers, Galveston District
P.O. Box 1229
Galveston, Texas 77553

Dear Colonel Weston:

This letter supersedes our March 20, 2007, letter in response to your request that the Fish and Wildlife Service (Service) participate as a National Environmental Policy Act (NEPA) cooperating agency for the Sabine-Neches Waterway (SNWW) Feasibility Study. As your staff is aware, the Service has participated as an active member of the Interagency Coordination Team (ICT) for the SNWW study since 2002. As part of the ICT, Service biologists have helped in mapping important native fish and wildlife areas, determining hydrological parameters for hydrodynamic/salinity modeling, developing mitigation and beneficial use sites and methods, and preparing impact assessments.

We welcome the opportunity to continue our participation in NEPA document preparation and planning for the SNWW project as a cooperating agency. If you have any questions feel free to contact me or Mr. Phil Glass, staff biologist, at our Clear Lake Field Office.

Sincerely,

Stephen D. Parris
Field Supervisor, Clear Lake ES Field Office

Ms. Teresa Bruner
Southwest Region Regional Administrator
Federal Aviation Administration
Southwest Region
2601 Meacham Boulevard
Fort Worth, TX 76137-4298

Dear Ms. Bruner:

The US Army Corps of Engineers, Galveston District and the Sabine Neches Navigation District (non-federal sponsor) are conducting a study of potential navigation improvements to the Sabine-Neches Waterway (SNWW). The SNWW is located in Jefferson and Orange Counties in Texas and Cameron Parish in southwest Louisiana (Figure 1). A preliminary draft environmental impact statement has identified a Preferred Alternative (PA) that would deepen the SNWW from the Gulf of Mexico through the jettied channel at Sabine Pass, through the Port Arthur Canal, Sabine-Neches Canal, and Neches River Channel to the Port of Beaumont from 40 to 48 feet. Dredged material from deepening and continued maintenance of inland channel reaches would be placed in 16 existing upland placement areas (PAs) and three marsh restoration features. Mitigation for unavoidable project impacts would also restore marsh in five existing degraded marsh areas east of Sabine Lake and the Sabine River.

Upon review of FAA AC 150/5200-33, we have determined that certain components of the Preferred Alternative (use of existing upland PAs, proposed marsh restoration features, and marsh mitigation areas) could serve as wildlife attractants. We have mapped the locations of three local public use airports (the Southeast Texas Regional Airport, the Orange County Airport, and the Beaumont Municipal Airport) to determine if project features meet or conflict with minimum separation criteria for potentially hazardous land use practices. Figure 2 shows the 5,000-foot, 10,000-foot, and the 5-mile range perimeters around the three airports in the project vicinity. No PAs, marsh restoration features, or marsh mitigation areas are located within the separation perimeters for the Orange County Airport or the Beaumont Municipal Airport.

All or portions of four existing upland PAs (PA 18, 21, 23-23A, and 24) are located outside the 10,000-foot criteria, but partially or wholly within the 5-mile perimeter of the Southeast Texas Regional Airport; no marsh restoration features or marsh mitigation areas are located with the 5-mile separation perimeter for this airport (Figure 3). The four upland PAs were

originally designated for use for the SNWW Navigation Project in 1975, and will be used for disposal of dredged maintenance material (spoil) on average every four to six years, as they are now, with the exception of PA 23A. PA 23A, although designated in 1975, has not been used recently, but will be used for the improved project. All four PAs provide some habitat for birds and wildlife species at times between the dredging cycles. No new PAs are proposed within the separation perimeter.

Based upon the information presented above, we request your review and concurrence that continued use of these four existing PAs does not constitute a change in land-use and is compatible with airport operations, and that it is not necessary to submit FAA Form 7460-1 for this project. If you have any questions regarding the project, please contact Janelle Stokes at (409) 766-3039.

Sincerely,

A handwritten signature in cursive script, appearing to read "Carolyn Murphy".

Subject: LNU--Farmland Protection, Draft Environmental Impact Statement
for the Sabine-Neches Waterway Channel Improvement Project
Texas Ocean Dredged Material Disposal Site Designation
Jefferson and Orange Counties, Texas

We have reviewed the Draft Environmental Impact Statement for the Sabine-Neches Waterway Channel Improvement Project/Texas Ocean Dredged Material Disposal Site Designation in Jefferson and Orange Counties, Texas, as outlined in your letter of March 5, 2010. This is part of the National Environmental Policy Act (NEPA) evaluation for the U.S. Army Corps of Engineers.

The soil mapped in the proposed project area is not Important Farmland and is, therefore, exempt from the FPPA. We have completed a Farmland Conversion Impact Rating (form AD-1006) indicating the exemption.

We are enclosing the completed AD-1006 for the project indicating the approval status. Thank you for the resource materials you provided. If you have any questions please contact Micki Yoder at (254) 742-9826, Fax (254) 742-9859.

Sincerely,

Temple, Texas 76501-7602

Dear Mr. Gohmert,

As requested by your letter of January 14, 2010, we are hereby providing additional information on the precise location of Tentatively Recommended Plan features for the Sabine-Neches Waterway Channel Improvement Project, Southeast Texas and Southwest Louisiana. A map is enclosed that locates the navigation channel, placement areas and marsh restoration areas relative to hydric soils and prime farmland in the study area (Enclosure 1). All of the project features are located within existing waterways, unclassified areas, or in hydric soil areas with the exception of 49 acres in proposed Placement Area (PA) 24A, which is classified as "Prime Farmland Soil When Drained."

We have completed Form AD-1006 (Farmland Conversion Impact Rating) and the site has received a total Part VI point score of 37 (Enclosure 2). Neither the site nor the areas around it are currently being farmed, and it is adjacent to urban areas and an existing leveed PA. We are proposing to convert the 49 acres to a leveed PA for the containment of dredged material from the adjacent Sabine-Neches Waterway Navigation Channel.

We request your evaluation of the proposed action's impacts as required under the Farmland Protection Policy Act. If you have any questions, please contact Ms. Janelle Stokes at 409/766-3039.

Sincerely,

Carolyn Murphy

Subject: Draft Environmental Impact Statement for the Sabine-Neches Waterway Channel Improvement Project, Texas and Louisiana

Dear Ms. Stokes:

The U.S. Department of the Interior has reviewed the U.S. Army Corps of Engineers, Galveston District's Draft Feasibility Study (DFS) and Draft Environmental Impact Statement (DEIS) for the proposed Sabine-Neches Waterway Channel Improvement Project. The Corps proposes to deepen and maintain, for 50-years, the existing 64-mile-long by 40 feet-deep inland Sabine-Neches channel to 48 feet-deep with 4 feet of additional advanced and overburden dredging (52 feet-deep total), deepen the existing Sabine-Neches Gulf of Mexico channel from 42 feet-deep to 50-feet-deep with 4 feet of additional advanced and overburden dredging (54 feet-deep total), and dredge a 13.2 mile-long new Gulf of Mexico channel 54-feet-deep by 700-feet-wide. Existing channel widths of 400 to 500 feet-wide for the inland reach and 700 feet-wide for the Gulf reach will not be changed.

Project benefits include more efficient vessel loading/off-loading and reduced navigation delays by accommodating larger vessels. In order to compensate for environmental impacts to fish, wildlife and wetland resources, the project includes beneficial use (BU) of dredged material in a Dredged Material Management Plan (DMMP) in Texas, beneficial use at the Louisiana Point and Texas Point Gulf shorelines, and BU and compensatory mitigation in the form of marsh restoration using dredged material on Sabine National Wildlife Refuge and in marshes north of Black Bayou, LA.

We reviewed the information provided, and offer the following comments in accordance with provisions of the National Environmental Policy Act (NEPA) of 1969 (83 Stat. 852; 42 U.S.C. 4321 et seq.), the Endangered Species Act (ESA) of 1973 (87 Stat. 884, as amended; 16 U.S.C. 1531 et seq.), the Migratory Bird Treaty Act (40 Stat. 755, as amended; 16 U.S.C. 703 et seq.),

Bald and Golden Eagle Protection Act (BGEPA) (54 Stat. 250, as amended, 16 U.S.C. 668a-d), and the Fish and Wildlife Coordination Act (FWCA) (48 Stat. 401, as amended, 16 U.S.C. 661 et seq.).

The draft Feasibility Report and DEIS provide an excellent description of fish and wildlife resources within the study area, the purpose and need for the proposed action, program objectives, critical needs and opportunities, and potential risks and uncertainties. Implementation of the greater than \$1.2 billion, 50-year Sabine-Neches Waterway Channel Improvement Project (SNWW CIP) would increase economic shipping efficiency by deepening the existing channel to allow larger vessels (primarily crude oil) to access and dock at the ports of Port Arthur and Beaumont. The Sabine-Neches Waterway (SNWW) provides 12% of the nation's crude oil transportation and an average of 141 million tons of shipping per year (2004-2006). Larger vessels must lighten their loads in the Gulf of Mexico and are prevented from two-way traffic in inland parts of the Sabine-Neches waterway. These practices cause transportation delays and increased costs.

The Galveston District established an Interagency Coordination Team (ICT) composed of Federal and state agency representatives from Texas and Louisiana to review the SNWW CIP's environmental impacts and recommend BU and mitigation. The Louisiana and Clear Lake Texas Ecological Services Field Offices represented the U.S. Fish and Wildlife Service on that ICT. The Corps and the ICT evaluated over 120 different combinations of depths (from 43 to 55 feet-deep) and widths. Three alternatives were carried forward after the analysis: the no-action alternative, a deepening and widening alternative, and the preferred alternative. In the no-action alternative, it is assumed that the SNWW enlargement would not be implemented and the existing shipping delays would continue. Channel dredging and disposal activities, including existing beneficial use projects, would continue in accordance with the current Federal standard. The Preferred alternative would increase the existing SNWW channel depth by 12 feet in the inland and Gulf channels (52 feet and 54 feet respectively), including advanced and overdraft dredging.

Specific Comments

DEIS 2.4.2 Dredged Material Placement Areas, Page 2-45; 2.4.2.2 DMMP Beneficial Use Features, Page 2-46; 5.5 Recommended Mitigation Plan, Pages 5-21 to 5-26 – The FWS recommends the creation of an interagency work group (i.e., Interagency Coordination Team) during post-authorization planning, and continue the work group through the detailed planning and construction phases. The work group would execute important design, inspection, and monitoring functions for habitat creation features.

The FWS recommends that the Corps implement a DMMP BU and mitigation monitoring program to consist of aerial photography interpretation, elevation, and vegetation surveys to be conducted periodically during the project life to ensure that the BU and mitigation is successful at offsetting project impacts during the project life. In addition, the FWS recommends the creation and implementation of an invasive species control plan that addresses both invasive flora and fauna in the project area.

DEIS 2.4.2 Dredged Material Placement Areas, Pages 2-45 to 2-46; 5.0 Mitigation Plan, Pages 5-20 to 5-26 - SNWW Dredged Material Management Plan (DMMP) that will use dredged

material from the SNWW channel beneficially, restoring 3,190 acres of marshes adjacent to the lower Neches River and 337 acres at the Texas Point Gulf shoreline, for a net + 3,280 acres (+ 656 AAHUs) benefit in Texas. Louisiana Point Gulf shoreline beneficial use with dredged maintenance material from the SNWW CIP (+ 337 acres), BU and compensatory mitigation [+ 2,783 acres (1,181 AAHUs)] yields a net + 2,429 acres (+ 22 AAHUs) in Louisiana. We concur that the beneficial use and compensatory mitigation fully compensates for predicted SNWW CIP impacts to wetlands within the project area.

In accordance with the January 2003 Partnership Agreement for Water Resources and Fish and Wildlife between the FWS and the Corps, sufficient continuous funding should be provided to the FWS to fulfill our responsibilities under Section 2(b) of the FWCA throughout post-authorization planning and evaluation for individual beneficial use projects. Accordingly, to ensure that optimum fish and wildlife resource benefits are achieved, the FWS will continue to work closely with the Corps and the States of Louisiana and Texas throughout the plan implementation process as a member of the ICT during the detailed design and implementation phase. Our findings and recommendations for each of the mitigation projects approved for implementation will be provided in draft and final supplements to this DEIS under the authority of the FWCA. Fulfillment of Section 7 of the ESA of 1973 (87 Stat. 884, as amended; 16 U.S.C. 1531 et seq.) responsibilities would also be accomplished at that time.

DEIS 3.12 Threatened and Endangered Species, Pages 3-94 to 3-95 – The FWS actively participated in the development and review of the Biological Assessment of the SNWW's effects on threatened and endangered species. In the FWS's March 22, 2007, letter, the FWS Lafayette, Louisiana, Field Office concurred with the Corps' determination that the SNWW CIP project would not be likely to adversely affect the threatened Louisiana black bear (*Ursus americanus luteolus*), endangered West Indian manatee (*Trichechus manatus*), endangered brown pelican (*Pelecanus occidentalis*), endangered interior least tern (*Sterna antillarum*), endangered red-cockaded woodpecker (*Picoides borealis*), threatened bald eagle (*Haliaeetus leucocephalus*), and threatened piping plover (*Charadrius melodus*), and its designated critical habitat in Louisiana. Minor project revisions would not result in additional effects to those species beyond what was already considered; therefore our determinations remain unchanged.

Brown pelicans (*Pelecanus occidentalis*) occur throughout the study area and are currently known to nest on Rabbit Island in Calcasieu Lake in southwestern Louisiana. Although no brown pelican nesting sites are known to occur within the proposed project area, they may occasionally use portions of the project area that contain suitable habitat (i.e., Sabine Pass Channel, Louisiana Point) for feeding and/or loafing. The brown pelican was officially removed from the List of Endangered and Threatened Species on December 17, 2009. For additional information please refer to the following links:
http://www.fws.gov/home/feature/2009/pdf/brownpelicanfinaldelisting11-10-09_to_OFR.pdf
http://www.fws.gov/home/feature/2009/pdf/brown_pelicanfactsheet09.pdf.

Although the brown pelican was officially removed from the List of Endangered and Threatened Species, it continues to be protected under the Migratory Bird Treaty Act (MBTA). Accordingly, the FWS recommends all activity in Louisiana occurring within 2,000 feet of a brown pelican rookery be restricted to the non-nesting period (i.e., September 15 through March 31). However, nesting periods vary considerably among Louisiana's brown pelican colonies, so it is possible that this activity window could be altered based upon the dynamics of the individual

colony. The Louisiana Department of Wildlife and Fisheries' Fur and Refuge Division should be contacted to obtain the most current information about the nesting chronology of individual brown pelican colonies. In Texas, the FWS recommends all activity occurring within 1,000 feet of a brown pelican rookery be restricted to the non-nesting season.

The bald eagle (*Haliaeetus leucocephalus*) occurs throughout the study area. Since bald eagles often nest and forage on river channels and reservoirs, steps should be taken to determine whether bald eagles may be nesting within or near the project area. While the bald eagle was officially removed from the List of Endangered and Threatened Species on July 9, 2007, it is still afforded protection under the MBTA and the Bald and Golden Eagle Protection Act.

Twenty-three species, including cormorants, pelicans, herons, egrets, spoonbills, gulls, terns, and skimmers, regularly nest in large numbers along the Texas and Louisiana coasts, frequently on both natural and manmade bay islands. The Texas Colonial Waterbird Census indicates that there are 25 documented rookery sites, with an estimated 2,835 nesting pairs annually since 1995, located within the study area. Colonial waterbirds are an important wildlife resource along the Gulf Coast and in the project area because of their abundance, their economic significance to the tourism industry, and their status as indicators of aquatic ecosystem health.

In recent years, the majority of successful Texas colonies have been located on islands wholly or partially maintained by dredged material. The FWS recommends using project-dredged material to construct a 2-to 12-acre, colonial waterbird nesting island located at least 1 mile from the shore in Sabine Lake. This island should include a sloping sand beach protected by a rock breakwater. The FWS can assist in the final design, location and management of the island.

DEIS 4.0 Environmental Consequences, Pages 4-1 to 4-81 – Salinity and water level hydrodynamic and Wetland Value Assessment models, reviewed and approved by the ICT, predicted a loss of 691 acres [-1,709 Average Annual Habitat Units (AAHUs)] and – 247 acres (-412 AAHUs) for Louisiana and Texas wetlands adjacent to Sabine Lake over the 50-year project life. Beneficial use and compensatory mitigation plans were developed by the ICT to compensate for these losses.

DEIS 4.11.2 Marine; 4.11.2.1.2 Preferred Alternative, Page 4-70 – If oyster reefs are encountered during project implementation, the Galveston Corps should replace any reefs damaged by the project on a 1:1 basis with suitable bottoms within Sabine Pass or in the southern portion of Sabine Lake. Oyster habitat mitigation should be accomplished concurrently with channel construction, and should consist of at least a 1-foot thick layer of shell or suitable cultch material (i.e., limestone or fly-ash rock), and should be followed up at one (1) year post-construction with bottom profiling survey and grab sampling to insure adequate relief (minimum average 0.5 feet above bay and pass bottom) and oyster spat coverage. This mitigation is not needed if no Sabine Lake or Pass oyster habitat is disturbed by project features.

DEIS 5.5 Recommended Mitigation Plan, Pages 5-21 to 5-26 – The FWS concurs with Willow Bayou Unit mitigation Alternative "B," restoring marsh on the Sabine NWR through dedicated dredging of material from Sabine Lake and placing that material in open water areas on that Refuge north of the Willow Bayou Canal. However if Alternative "B" should not prove viable, the FWS recommends that Alternative "C," beneficial use of new work material from the SNWW, be used to restore marsh on Sabine NWR, or the rock breakwater shoreline stabilization

measures, or Sabine NWR terracing measures be implemented as long as the acres protected/restored and AAHUs gained fully compensate for project impacts.

The FWS recommends that the Corps construct the Sabine-Neches project mitigation at the same time as waterway enlargement construction is performed and that the Corps require protective easements on privately owned lands where Sabine-Neches BU and mitigation is to be performed to ensure that the habitat restoration and enhancement work is not compromised by future development activities. 14

The FWS recommends the construction of tidal creek channels (or trenasses) at least 10 feet-wide and 2 feet-deep in the restored marsh, 6 months to a year, if necessary, after disposal in order to return the area to natural hydrology for tidal movement and estuarine aquatic organism access to the restored marshes. The tidal creeks could be constructed by tracking marsh buggy track-hoes, or similar equipment, over proposed creek channel routes. The dredged material pipeline for marsh restoration (i.e., Willow Bayou and Black Bayou Units mitigation) should be placed in existing canals and waterways to the greatest extent practicable to minimize marsh damage. 15

DEIS 5.5.1 Willow Bayou Mitigation, Table 5.5-1 Recommended Mitigation Plan, Page 5-22 - The FWS recommends that the Corps review their calculations for volumes of dredged material needed to achieve the listed Louisiana mitigation and questions whether the Corps would be able to achieve the degree of marsh restoration depicted in the recommended mitigation plan with unconfined placement of dredged material. 16

The FWS recommends that the Sabine Lake borrow area be located at least 1,000 feet westward of the eastern Sabine Lake shoreline to minimize borrow area shoreline impacts. The Corps should acquire a refuge Special Use Permit from the Sabine NWR (Don Voros, Manager, Southwest Louisiana Refuges Complex, 1428 Hwy 27, Bell City, LA 70630; 337-598-2216) to coordinate the final planning for the dedicated dredging marsh restoration mitigation on Sabine NWR. 17

DEIS 5.2.2 Agency Participation, Page 154 – The FWS will provide a revised FWCA Report in February 2010, which will provide additional recommendations. Many of the FWS's draft SNWW FWCA recommendations have been addressed in the DFR and DEIS. 18

Comments from the National Park Service

The potential environmental impacts that are of concern to Big Thicket National Preserve are that a deeper channel in Sabine Lake and the Neches River will increase the influence of Gulf tides, increase salinity, and raise water surface elevation at Preserve lands within the study area, leading to degradation of freshwater marsh, bottomland hardwood forest habitat, and salinity effects to cypress-tupelo swamps. The effects of the deeper channel, in concert with potential reductions in freshwater in-flows from the Neches River during times of subsistence or dry base flow (i.e., drought) could cause damage to salinity-intolerant species including tupelo trees and benthic macroinvertebrates. 19

Big Thicket National Preserve acquired lands by donation from The Conservation Fund in April 2009 (http://www.conservationfund.org/news/big_thicket_land_gift) including approximately 20

6,000 acres of cypress-tupelo swamp, bottomland hardwood forest, and freshwater marsh that lie below the Saltwater Barrier, at the upper margins of the project study area. The new Preserve lands, which are not identified anywhere in the DEIS as being part of the Preserve, are referred to in the DEIS as hydrologic units "TX-1 North Neches River" and "TX-2 Neches-Lake Bayou." Preserve lands comprise much of these two units, mainly on the east side of the Neches River, extending south to Interstate Highway 10 (I-10). The DEIS notes severely stressed marshes, marsh subsidence, and wetland loss in the Neches River reach between Sabine Lake and I-10, directly adjacent to the Preserve. Our concern is that the Preserve may become the new frontline separating intact and degraded systems, or that worsening conditions and wetland loss may spread northward and engulf areas of Big Thicket National Preserve.

Areas of the Preserve would be influenced by the proposed project according to analysis in the DEIS: the Hydrodynamic-Salinity model (Table 4.6-3) forecasts an increase in salinity in the upper Neches River from 0.1 ppt to 0.26 ppt under low flow conditions; salinities in the cypress-tupelo swamps in the upper Neches reaches are predicted to increase by 0.3 ppt; and surface water elevations are expected to increase an average of 0.8 inch in the upper reaches of the Neches River due to greater tidal influence. These conditions have the potential to reduce primary productivity in Preserve freshwater marsh habitat, reducing biomass, and leading to eventual submergence and loss.

We would like to see discussion of how the channel deepening would affect the magnitude of tidal and storm surge from Tropical storms, greater consideration for mitigation measures to prevent long-term and short-term increases in salinity in the Neches River and adjacent freshwater marsh habitat, and modeling of salinities and freshwater inflows for dry base flow and subsistence flow conditions that are described in the Sabine and Neches Rivers and Sabine Lake Bay, Basin and Bay Expert Science Team Environmental Flows Recommendations Report (November 2009).

On page 3-148 Big Thicket National Preserve should be described as 106,684 acres, and being in portions of seven counties in southeast Texas (Hardin, Jefferson, Orange, Tyler, Polk, Jasper, and Liberty). Throughout the document, Preserve lands should be represented on maps and figures that show refuges and other conservation lands. Additionally, the DEIS was apparently sent to the Preserve at a pre-Hurricane Rita address that is no longer in use. Please send future correspondence to:

Todd W. Brindle, Superintendent
Big Thicket National Preserve
6044 FM 420
Kountze, TX 77625

If you have any questions or if we can be of any further assistance in providing maps or other information, please contact David Roemer, Chief of Resources Management, Big Thicket National Preserve, at (409) 951-6820.

We appreciate the opportunity to comment on the draft SNWW CIP DFR and DEIS. If your staff has questions regarding our comments, please feel free to contact me at (505) 563-3572.

Sincerely,

RESPONSE TO COMMENTS

Comment No.	Response
1	Thank you for your comment.
2	If the proposed project is approved, U.S. Army Corps of Engineers (USACE) would continue working with the existing Interagency Coordination Team (ICT) during preconstruction, engineering, and design (PED), construction and operation of the project. Specific ICT involvement relative to the design, inspection and monitoring of beneficial use (BU) features and mitigation measures are described in the Sabine-Neches Waterway Channel Improvement Project (SNWW CIP) Mitigation and Beneficial Use Monitoring Plan (Final Environmental Impact Statement (FEIS) Appendix J).
3	FEIS Appendix J presents the SNWW CIP Mitigation and Beneficial Use Monitoring Plan. The frequency and periodicity of aerial photography and interpretation and vegetation surveys are specified in the plan. Construction contracts would ensure that elevations appropriate for marsh survival are achieved by the initial construction. The plan includes monitoring and control of invasive, noxious and/or exotic plants.
4	The FEIS has been revised to note that the USFWS concurs that the beneficial use features and compensatory mitigation fully compensate for predicted SNWW CIP impacts.
5	USACE looks forward to continuing our work with the USFWS throughout post authorization planning. The U.S. Fish and Wildlife Service (USFWS) Coordination Act Report (CAR) is presented in FEIS Appendix A3.
6	The FEIS sections on Endangered Species impacts and coordination have been revised to note that minor project revisions subsequent to the original coordination do not change the March 22, 2007 determination.
7	The threatened and endangered species section of the FEIS will be updated to reflect the fact that the brown pelican was officially removed from the List of Endangered and Threatened Species on December 17, 2009.
8	Draft EIS (DEIS) Section 7.7 (Migratory Bird Treaty Act and Migratory Bird Conservation Act) states that construction contracts will include instructions to avoid impacts to migratory birds (including brown pelicans) and their nests from all activities related to the SNWW CIP. During the preparation of plans and specifications, USACE will check with designated state agencies to obtain the most current information about nesting colonies. All construction activity in Louisiana occurring within 2000 ft of a brown pelican rookery will be restricted to the non-nesting period. In Texas, all activity occurring within 1,000 feet of a rookery will be restricted to the non-nesting season.
9	During the preparation of plans and specifications, USACE will check with state and federal agencies to obtain the most current information about bald eagle nests in the SNWW CIP construction areas.
10	Creation of a bird island in Sabine Lake using dredged material from the proposed SNWW CIP was evaluated and eliminated from consideration when the cost was found to be about \$ 2 million higher than the use of existing placement areas, and since no non-Federal sponsor has been identified to share the incremental cost (see DEIS Section 2.5.3.1).
11	USACE concurs that project impacts, as determined by the Wetland Value Assessment (WVA) model and reviewed by the ICT, are a predicted loss of 691 acres (-1709 AAHUs) in Louisiana and a loss of 247 acres (-412 Average Annual Habitat Units [AAHUs]) in Texas, prior to application of BU feature benefits and compensatory mitigation (See DEIS Table 2.4-16 and Section 4.1.4.1)
12	FEIS Section 4.11.2.1.2 evaluates the potential for impacts to oyster reef by the proposed SNWW CIP. No impacts to oyster reef are anticipated in Sabine Pass because the channel is not being widened and no slumping is expected at the top of cut. No impacts to oyster reef in Sabine Lake are

	anticipated because salinities are generally too low to support spat growth, as confirmed by recent survey. Furthermore, as stated in FEIS Section ES.5 and Section 5.5.1, USACE has proposed that a water bottom survey of the borrow and access channel areas in Sabine Lake be conducted during the preconstruction engineering and design (PED) phase of the project. In the unlikely event that oyster reef is encountered, plans will be revised to avoid impacts.
13	The FEIS has been revised to note that the USFWS concurs with the selected Willow Bayou mitigation plan, which would use material from the dedicated dredging of Sabine Lake. If the proposed SNWW ICT is approved, USACE would continue consultation with the ICT (which includes USFWS) during the PED phase to perform and evaluate geotechnical analyses of the proposed source material.
14	USACE plans to construct the proposed Willow Bayou, Black Bayou East and first phase of Black Bayou West concurrently with proposed channel deepening. The remaining 5 phases of the Black Bayou West mitigation measure would be completed over approximately the next 30 years in conjunction with maintenance dredging of the Sabine River Channel. The Black Bayou East and West mitigation measures are located on private property. USACE has determined that conservation easements are not required because all restored areas would remain jurisdictional wetlands and would continue to be subject to the navigational servitude (Feasibility Report [FR] Section VIII.E).
15	The FEIS Section 5.5.1 description of proposed mitigation measures includes tidal creek channels, as recommended by USFWS. USACE will consult with the ICT (which includes USFWS) during PED to minimize impacts to existing marsh during construction of the mitigation measures.
16	As recommended, USACE has reviewed our calculations for volumes of dredged material required for Louisiana mitigation measures, and it has been determined that the calculations are sufficient for the feasibility level of design.
17	FEIS Section 5.5.1 states that the borrow trench would be located at least 1000 feet from the SNWR shoreline, and that the exact location of the trench would be determined in consultation with the ICT (which includes USFWS) during PED. USACE has requested a compatibility determination from the SNWR for the proposed Willow Bayou mitigation area.
18	The USFWS's revised CAR, dated March 2010, is presented in FEIS Appendix A-3. USACE responses to the CAR are presented in the same appendix.
19	Potential impacts of the deeper navigation channel to hydrounits containing the newly acquired areas of the Big Thicket National Preserve downstream of the Neches River Saltwater Barrier were evaluated by ERDC's Hydrodynamic Salinity modeling (HS model) (Brown and Stokes 2009). This modeling, summarized in FEIS Section 4.1, incorporated Year 2060 future flow projections that are based upon assumptions of the 2007 Texas State Water Plan and projected effects of relative sea level rise. As described in FEIS Sections 4.1.2.2, Table 4.1-1, and Section 4.6.3.2.2, no project impacts are expected during median or low flows.
20	The new preserve lands were acquired by the National Park Service (NPS) during the final preparation of the DEIS, and thus were not identified in that document. See response to comment 19 concerning potential for proposed SNWW CIP to affect these areas of the Big Thicket National Preserve.
21	See response to comment 19 above.
22	A sensitivity analysis using the ADCIRC model was performed to determine what effect the proposed SNWW CIP might have on surge levels in the study area (Wamsley et al., 2010). The results of this analysis are presented in FR Chapter VIII, FEIS Section 4.1.5. Given the fact that impacts of the proposed SNWW CIP are related primarily to salinity intrusion, extensive efforts have already been made to identify effective mitigation measures that could minimize or eliminate the projected increase in salinity. The results of this effort are presented in FEIS Section 5.4.1.1. The HS modeling performed for this study by ERDC employed a state-of-the-art model to evaluate potential salinity impacts for both median and low flows, and the technical adequacy of the HS modeling has been sustained by Agency Technical Review (ATR) and Independent External Peer Review (IEPR). USACE believes that further HS modeling is not warranted.
23	The acreage of the Big Thicket National Preserve has been changed to reflect this updated information. Text has been changed to clarify that Big Thicket National Preserve is located within portions of Hardin and Orange counties, Texas in the vicinity of the study area.

24	New preserve lands have been included in FR/FEIS maps, and are discussed in FR (Chapter 1, Sensitive Areas), FEIS Section 3.9.2, and FEIS Appendix C, Section 1.5.1.
25	The mail list has been updated to reflect this information.

GENERAL LAND OFFICE

JERRY PATTERSON, COMMISSIONER

February 8, 2010

Colonel David C. Weston
 U. S. Army Corps of Engineers
 P.O. Box 1229
 Galveston, Texas 77553-1229

RE: Sabine Neches Waterway Improvement Project

Dear Col Weston:

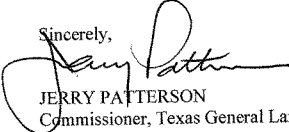

The proposed project consists of the deepening and expanding of navigation channels in the Sabine Neches Waterway and placement of the associated dredge material. Based on the information contained in the Draft Environmental Impact Statement and the Feasibility Report, much of the proposed dredging and dredge material placement is located on state owned submerged lands.

The General Land Office (GLO) and School Land Board are responsible for managing and authorizing the use of state owned submerged land dedicated to the Permanent School Fund. While Navigational Servitude covers the project and no lease or easement will be required, there may be impacts that the GLO will need to address. Based on a review of the project, there appear to be multiple pipelines with easements authorizing their placement on state owned submerged land that will be impacted. Also the project may impact current mineral leases and future mineral leases on state land that are managed by the GLO.

The GLO is requesting an additional 90 days (until May 10, 2010) to review the Draft Environmental Impact Statement to determine the impact the project will have on state mineral leases and pipeline easements, and other possible impacts from the project. The GLO has also been contacted by representatives for the pipeline operators who will be impacted by this project and who are also seeking additional time to evaluate this proposal. This seems like a reasonable request given the amount of state owned submerged land that will be impacted by the project. After a complete review, the GLO may have additional comments and concerns about the project.

If you have any questions concerning this request, please contact Deputy Commissioner Rene D. Truan at (512) 463-5200 or by e-mail at rene.truan@glo.state.tx.us.

Sincerely,

 JERRY PATTERSON
 Commissioner, Texas General Land Office

RE: Resolution Concerning the Sabine-Neches Waterway Channel Project

Dear Ms. Stokes:

The attached Resolution supporting the Sabine-Neches Waterway Channel Project was approved by the Board of Directors at its February 16, 2010 meeting. Please call me at 409-892-4011 if you have any questions or if you need additional information.

Yours very truly,

A handwritten signature in cursive script that reads 'Scott Hall'.

Scott Hall, P.E.
General Manager

STATE OF TEXAS

§

LOWER NECHES
VALLEY AUTHORITY

COUNTY OF JEFFERSON

§

BE IT REMEMBERED at a meeting of BOARD OF DIRECTORS OF THE LOWER NECHES VALLEY AUTHORITY held on the 16th day of February, 2010, on motion made by Director Kathleen Jackson and seconded by Director Jordan Reese, the following Resolution was adopted:

Resolution Concerning the Sabine-Neches Waterway Channel Project

WHEREAS, the U.S. Army Corps of Engineers (USACE), in concert with Sabine-Neches Navigation District has proposed a project to deepen the Sabine-Neches Waterway; and

WHEREAS, USACE has prepared a study analyzing the feasibility and environmental impacts of the proposed improvement to the Sabine-Neches Waterway that serves the ports of Beaumont and Port Arthur, Texas and the proposed improvements reasonably accommodate environmental concerns; and

WHEREAS, the USACE study clearly demonstrates the necessity for these improvements to provide a safe and efficient waterway that will accommodate the current and future needs of our ports and industry; and

WHEREAS, the project is also critical for the National Defense, and the proposed improvements are clearly cost effective and will enable our ports to facilitate the handling of vital military cargo; and

WHEREAS, the project would provide a positive economic benefit and would benefit the people of Jefferson County, the State of Texas, and many States beyond our region;

NOW THEREFORE, be it resolved that the Board of Directors of the LOWER NECHES VALLEY AUTHORITY urge all elected officials and citizens to support this project and the adoption of the plan for these improvements as proposed.

AND BE IT FURTHER RESOLVED that the Corps affirm its plan and submit the plan to its headquarters for finalization.

PASSED AND ADOPTED by the Lower Neches Valley Authority Board of Directors this 16th day of February, 2010.

President

Secretary

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY

REGION 6

1445 ROSS AVENUE, SUITE 1200
DALLAS, TX 75202-2733

FEB 18 2010

Mr. Dolan Dunn
Chief, Planning, Environmental &
Regulatory Division
New Orleans District
U.S. Army Corps of Engineers
P.O. Box 60267
New Orleans, LA 70160-0267

Dear Mr. Dunn:

In accordance with our responsibilities under Section 309 of the Clean Air Act, the National Environmental Policy Act (NEPA), and the Council on Environmental Quality regulations for implementing NEPA, the U.S. Environmental Protection Agency (EPA) Region 6 office in Dallas, Texas, has completed its review of the Draft Environmental Impact Statement (DEIS) for the Sabine-Neches Waterway Channel Improvement Project, Southeast Texas and Southwest Louisiana and the DEIS for the Sabine-Neches Waterway Channel Improvement Project, Texas Ocean Dredged Material Disposal Sites Designation.

EPA rates the DEIS as "LO", i.e., EPA has a "Lack of Objections" to the proposed action described in the DEIS. EPA has enclosed detailed comments for further consideration in the development of the Final EIS and asks that these comments be responded to in that document.

Our rating of this DEIS will be published in the Federal Register according to our responsibility under Section 309 of the Clean Air Act to inform the public of our views on proposed Federal actions. If you have any questions, please contact me at (214) 665-7451 or by e-mail at jansky,michael@epa.gov.

EPA appreciates the opportunity to review the DEIS. Please send our office two copies of the Final EIS when it is sent to the Office of Federal Activities, EPA (Mail Code 2252A), Ariel Rios Building, 1200 Pennsylvania Ave, N.W., Washington, D.C. 20460.

Sincerely yours,

A handwritten signature in cursive script, reading "Cathy Gilmore", is written over a horizontal line.

**DETAILED COMMENTS
ON THE
DRAFT ENVIRONMENTAL IMPACT STATEMENT FOR THE
SABINE NECHES WATERWAY CHANNEL
IMPROVEMENT PROJECT
SOUTHEAST TEXAS AND SOUTHWEST LOUISIANA**

The Region 6 Office of the EPA has reviewed the DEIS and Draft Feasibility Report prepared by the Galveston District of the Corps for the Sabine-Neches Waterway Channel Improvement Project. We currently have only one outstanding issue to raise which is that the Draft U.S. Fish and Wildlife Service Coordination Action Report is pending and the results of that report should be used to make any necessary adjustments to the mitigation and dredged material disposal plans for the tentatively selected plan.

2

Five years ago, EPA Region 6 set up a NEPA Cooperating Agency agreement with the Galveston Corps District for this project. The Corps was starting feasibility studies on a channel expansion and they knew that, in addition to options for widening and deepening, they would look at extending the channel out into the Gulf for 13-17 more miles. That distance would make it expensive to transport material to the four existing Ocean Dredged Material Disposal Sites (ODMDS) and they might propose an additional four more ODMDS's further out and along the expanded channel.

EPA Region 6 and the Galveston District Corps set up a process whereby the Corps' channel improvement DEIS (which would involve a new DMMP devised by an interagency team) would contain an appendix that would essentially be a stand alone ODMDS DEIS, including a Site Management and Monitoring Plan (SMMP). As a NEPA Cooperating Agency and a member of the Interagency Coordination Team and various sub-committees, Region 6 could direct the analyses for the ODMDS work. The thought was that if the Corps did the analyses and NEPA documentation as we instructed, the Region could then basically take a "ready to go" NEPA document prepared by the Corps, make any revisions as necessary, publish it as an EPA ODMDS DEIS (if necessary), and follow with EPA rulemaking. This could optimize project planning and public involvement, as well as making effective use of federal funding.

As a member of the interagency team, Region 6 worked for several years on the dredged material disposal plan (DMMP), beneficial use (BU) options, salinity change analyses, and wetland mitigation issues. The Region has followed the development and analysis of project alternatives. We support the project planning process that was used, which included an evaluation of non-structural alternatives and which applied the principles of Regional Sediment Management in evaluating alternatives and in developing the DMMP for the tentatively selected plan.

The tentatively recommended plan would result in an estimated 98 million cubic yards of new work dredged material and 650 million cubic yards of maintenance material over the 50-year period of analysis. Disposal of this material would be managed in accordance with the new DMMP, which is described in these documents. The DMMP includes an extensive BU plan that

would direct the use of both new work and maintenance dredged material to restore degraded marshes and to nourish Gulf shorelines.

BU features of the DMMP (Neches River and Gulf shoreline features) would minimize and offset all direct and indirect marsh impacts in Texas by creating 2,853 acres of emergent marsh vegetation, improving 871 acres of open water habitat, and nourishing 1,234 acres of existing marsh. Therefore, no compensatory mitigation is proposed to offset projected wetland impacts from the tentatively selected plan in Texas. Unavoidable losses to marshes in Louisiana are fully mitigated, according to WVA analyses, by marsh creation in the Willow Bayou and Black Bayou watersheds east of Sabine Lake. In addition to offsetting projected wetland habitat losses, the mitigation plan would compensate for the projected salinity increase and associated losses in biological function and productivity by marsh creation in the Willow and Black Bayou watersheds.

Region 6 supports the decision not to recommend the creation of a topographic high offshore of Louisiana Point as an additional mitigation measure, using new work material dredged the Sabine Bank and Extension Channels. The ecological benefits of such a feature have not been sufficiently demonstrated and, if the projected benefits were realized, they would be short-lived. Additional information would be needed to justify the associated project feature expense.

Additional Comments

On Page I-21, under Outdoor Recreation, the total state revenues from wildlife associated activities in Louisiana should be \$3.0 billion with sporting revenues of \$1.4 billion and wildlife watching bringing in \$1.6 billion.

EPA is concerned about salinity increases in the upper Neches and the Blue Elbow Swamp mitigation bank area and other "sensitive" freshwater wetlands along the channels that are subject to tidal influences. We recommend that even though the Corps models indicate only slight increases in salinity due to widening of the channel, that the Corps monitor salinity increases and vegetative response before, during, and after project completion. We are specifically concerned about Baldcypress/Tupelo plant communities that may be sensitive to only slight increases in salinity. EPA suggests a 10-year annual monitoring plan.

Finally, the Document appears to adequately address the potential adverse effects of the Ocean Dredged Material Disposal Sites and therefore this EIS will suffice EPA's NEPA responsibilities to use in designating the four ODMDS at a later date.

If you have any other questions about this review, please give me a call. Thank you for the opportunity to provide comments at this stage in the process.

RESPONSE TO COMMENTS

Comment No.	Response
1	The FEIS has been revised to note that the EPA has rated the project as "LO," which means that it has no objections to the proposed SNWW CIP.
2	The USFWS CAR, dated March 16, 2010, has been included in the FEIS, Appendix A along with USACE responses to the report. USFWS concurred with the USACE mitigation and BU plans for the proposed SNWW CIP.
3	USACE notes U.S. Environmental Protection Agency (EPA) concurrence in the Ocean Dredged Material Disposal Sites (ODMDS) BU alternatives analysis related to the creation of a topographic high using new work material. USACE did not adopt this alternative.
4	The text has been revised to correct the total economic impact of wildlife-related activities in Louisiana.
5	Salinity monitoring is conducted by many state and Federal agencies throughout the SNWW study area. It is expected that this data will be available for use in assessing future conditions within the study area.
6	USACE will note in the FEIS that EPA has approved the ODMDS FEIS for use in designating the four new ODMDS at a later date.

RE: **C20090667**, Coastal Zone Consistency
U. S. Army Corps of Engineers, Galveston District
Direct Federal Action
Draft EIS for the Sabine-Neches Waterway Improvements Project, Southeast Texas and Southwest, **Louisiana**

Dear Mr. Dunn:

This office has received the above referenced federal application for consistency review with the approved Louisiana Coastal Resources Program in accordance with Section 307(c) of the Federal Coastal Zone Management Act of 1972, as amended. NOAA Regulations on Federal Consistency, at 15 CFR '930.41(a), allow 60 days for the review of Direct Federal Activities, and at '930.41(c)(b) allow additional review time upon mutual agreement between the Federal agency and the State Coastal Zone Program. Please be advised that, by this letter, Interagency Affairs/Field Services Division and the Galveston Corps District have mutually agreed to extend the State review time to March 12, 2010.

A final determination will be made within the authorized time period, ending March 12, 2010. If you have any questions please call Brian Marcks of the Consistency Section at (225) 342-7591.

Sincerely yours,

Gregory J. DuCote

Re: Sabine-Neches Waterway Channel Improvement Project Draft Feasibility Report and Draft Environmental Impact Statement

Dear Ms. Stokes:

As described in the Public Notice, dated December 18, 2009, the applicant, Sabine Neches Navigation District, proposes the Channel Improvement Project (CIP) to deepen and widen the Sabine-Neches Waterway (SNWW). The project is located along the Texas and Louisiana border, in Jefferson and Orange counties in southeast Texas and Cameron Parish, Louisiana.

In addition to the information contained in the public notice, the following information is needed for review of the proposed project. Responses to this letter may raise other questions that will need to be addressed before a water quality certification determination can be made.

1. Title 30, Texas Administrative Code (TAC), Chapter 279.11(c)(1), states that "No discharge shall be certified if there is a practicable alternative to the proposed discharge which would have less adverse impact on the aquatic ecosystem," As noted in the Draft Feasibility Report, the primary environmental concern is increased saltwater intrusion and further degradation of marshes and cypress marshes as a result of the CIP. In addition, the Draft Environmental Impact Statement (DEIS) acknowledges in Section 3.5.3 the accelerated marsh deterioration and increased saltwater intrusion in the Calcasieu/Sabine River Basin. The DEIS identifies approximately 174 structures water control structures that had been constructed as of 1990 to address marsh deterioration, saltwater intrusion, and erosion within the project study area. Please provide a clear demonstration that no practical alternatives exist for the proposed project. Please complete the enclosed 401 Certification Questionnaire and Alternatives Analysis Checklist.

Ms. Janelle Stokes
U.S. Army Corps of Engineers
USACE Sabine-Neches Waterway Draft EIS 124121809
Page 2
March 9, 2010

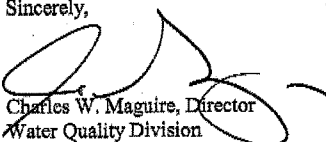

2. Section 3 (Affected Environment) of the DEIS states that there are 19 classified stream segments in Texas within the study area. However, only nine classified segments and their respective water quality standards are listed in Table 3.2-1. It should be noted that Sabine Pass (Segment No. 2411) and Sabine Lake (Segment No. 2412) are also located within the CIP study area and their designated uses are contact recreation, oyster waters, and exceptional and high aquatic life use, respectively. Please provide a complete list of the classified water segments and their appropriate designated uses and water quality criteria for the CIP study area.
3. Section 3.3.1 of the DEIS states that "based on available data, there is no indication of current water or elutriate contaminant problems along the SNWW." However, numerous classified segments (e.g. Segments No. 0501, 0508, 0511, 0701, and 0704) are currently listed as non-supporting on the Clean Water Act Section 303(d) list for impaired waters. Constituents of concern include low dissolved oxygen levels, bacteria, chlorophyll-*a*, ammonia, and nutrients. In addition, Segment 0702 (Intracoastal Waterway Tidal) is listed on the draft 2010 Texas 303(d) list as non-supporting for dioxin in edible tissue and PCBs in edible tissue. Please provide a complete list of the waterbodies (classified and unclassified) in the study area that have been identified as non-supporting or with concerns for non-attainment or screening levels with regard to applicable water quality standards.
4. Section 3.10.2.1 of the DEIS provides a list of the dominant nekton species inhabiting the Sabine Lake estuary. The species list includes white shrimp (*Litopenaeus setiferus*) and the discussion of the nekton assemblage concludes that all the listed species "are ubiquitous along the Texas and Louisiana coast and are unaffected by changes in salinity." However, subsequent paragraphs in this section note the significant decline in the white shrimp fishery and attribute the decline to "changes in freshwater inflow and concurrent isolation of wetlands from Sabine Lake." A current update of the status of this commercially important species and the species' response to salinity variations should be included in both the DEIS and Draft Feasibility Report.
5. Section 4.16 (Cumulative Effects) of the DEIS concludes that "past, existing, and reasonably foreseeable future projects, along with the Preferred Alternative, are not expected to have significant adverse effects within the study area." Quantifiable impacts are summarized in Table 4.16-1 and numerous categories and potential benefits or impacts in the table are noted with an * or ** symbol. The meaning or significance of these symbols is unclear with respect to categories (e.g., Past and Present Actions*) and individual assessments (e.g., NT*, Minimal*, 79 ac**, etc.). Please provide clarification and an explanation of the purpose intended.

Ms. Janelle Stokes
U.S. Army Corps of Engineers
USACE Sabine-Neches Waterway Draft EIS 124121809
Page 3
March 9, 2010

6. Texas Commission on Environmental Quality (TCEQ) requires that total suspended solids (TSS) concentrations in effluent associated with dredging activities be controlled to a maximum of 300 milligrams per liter (mg/L). Please provide a list of best management practices (BMPs) and operational procedures that will be used to minimize TSS levels during dredging operations and the placement of dredged material.
7. As noted in the Draft Feasibility Report and DEIS, members of the Interagency Coordination Team (ICT) and the agencies and organizations represented on the ICT, have extended substantial time and resources during the DEIS development process. Please provide an overview and tentative schedule for the inclusion ICT members and organizations in the resolution of outstanding project issues and the development of the Final EIS for the proposed project.

The TCEQ looks forward to receiving and evaluating other agency or public comments. Please provide any agency comments, public comments, as well as the applicant's comments, to Mr. Robert Hansen of the Water Quality Division MC-150, P.O. Box 13087, Austin, Texas 78711-3087. Mr. Hansen may also be contacted by e-mail at rhansen@tceq.state.tx.us, or by telephone at (512) 239-4583.

Sincerely,

Charles W. Maguire, Director
Water Quality Division
Texas Commission on Environmental Quality

March 19, 2010

Environmental Section

Mr. Charles W. Maguire
 Director
 Water Quality Division
 Texas Commission on Environmental Quality
 P.O. Box 13087
 Austin, Texas 78711-3087

Dear Mr. Maguire:

Reference is made to your letter dated March 9, 2010 regarding the Sabine-Neches Waterway Channel Improvement Project (SNWW CIP) Draft Feasibility Study and Draft Environmental Impact Statement (DEIS), issued for public and agency review on December 24, 2009. In response to several requests, Galveston District (District) extended the public comment period to March 12, 2010. An Interagency Coordination Team (ICT) comprised of Federal and State resource agency representatives from Texas and Louisiana has assisted Galveston District in modeling and analyzing environmental impacts, and selecting beneficial use (BU) and mitigation measures for the Tentatively Recommended Plan. The Texas Commission on Environmental Quality (TCEQ) has had a representative on the ICT since its inception in 2000 through the last ICT meeting on August 27, 2009. Although TCEQ has been unable to send a representative to most of these meetings, the District has kept your agency apprised of studies and models performed to evaluate potential environmental impacts of the SNWW CIP. We offer the following information to assist you in review of the proposed project.

1. You have requested that Galveston District complete a "401 Certification Questionnaire and Alternatives Analysis Checklist" and demonstrate that no practicable alternatives exist for the proposed project. We understand that TCEQ requires this form to facilitate Section 401 reviews of U.S. Army Corps of Engineers Section 404 permit applications. The Galveston District is not applying for a permit to construct this Federal project, and therefore completion of this form should not be required.

However, we understand that your agency requires information in order for you to complete Section 401 review. All of the questions posed by the certification questionnaire and alternatives analysis checklist are answered by information presented in the Draft Feasibility Report (DFR), the Draft Environmental Impact Statement (DEIS), and DEIS Appendix E (Section 404(b)(1) Evaluation). For example, questions concerning impacts to state surface waters (1.A of the Questionnaire) are answered by information provided by DEIS Appendix E, and the compensatory mitigation plan (Questionnaire 1.B) is described in DEIS Section 5.5. Information regarding the alternatives analysis is provided in DFR Chapter IV and DEIS Chapter 2.0. These

chapters provide a thorough description of the alternative evaluation process, the specific alternatives that were evaluated (including non-structural alternatives, project alternatives with smaller dimensions, and the no-action alternative), and the rationale for selecting the Tentatively Recommended Plan.

A thorough description of salinity control structures that were evaluated in the screening of mitigation alternatives is provided in DEIS Section 5.4. None of the salinity control structures were selected because the net effect of the structures was determined to be negative. Beneficial salinity effects were modest and could not overcome the adverse effects of restrictions to marine organism access. The alternatives analysis provided in the DFR/DEIS clearly demonstrates that there is no practicable alternative to the proposed discharges which would have less adverse impact to the aquatic ecosystem.

2. FEIS Section 3.3 and Table 3.2-1 will be revised to provide a complete list of the classified water segments, their designated uses and water quality criteria. The DEIS reference to 19 classified stream segments refers to the total number of assessment units (sub-segments of the primary stream segments) in the study area. The number is correct, but the text will be corrected to refer to assessment units instead of stream segments. This number already includes Segments 2411 (Sabine Pass) and 2412 (Sabine Lake). Table 3.2-1 currently identifies all of the primary stream segments in the study area, with the exception of Segments 2411 and 2412. Table 3.2-1 will be revised to include Segments 2411 and 2412, their designated uses and water quality criteria.

3. As noted in your comment, Section 3.3.1 of the DEIS states that "...based on available data, there is no indication of current water or elutriate contaminant problems along the SNWW." The SNWW refers to the Sabine-Neches Waterway navigation channel, not the entire study area. We believe that a complete listing of impaired waterbodies in the study area would not be relevant to the assessment of environmental impacts of the Tentatively Recommended Plan. However, we will add the following information to FEIS Section 3.3.1 as clarification. "Stream segments 601, 703, and 2411 comprise the SNWW and none of these segments are classified as non-supporting on the Clean Water Act Section 303(d) list of impaired waters. While several impaired stream segments (0501, 0508, 0511, 0701, 0704) are located within the study area boundaries, they would not be affected by the direct or indirect effects of channel deepening or construction of any project features and, therefore are not evaluated further."

4. The DEIS discusses the decline of the white shrimp fishery in the study area, attributing the decline to "changes in freshwater inflow and concurrent isolation of wetlands from Sabine Lake." The Tentatively Recommended Plan would not affect freshwater inflows or increase the isolation of wetlands from Sabine Lake. The proposed beneficial use feature that restores significant marsh acreage on the Neches River and the marsh restoration proposed as compensatory mitigation east of Sabine Lake would provide a net benefit to marine and estuarine fish and wildlife species. None of the other resource agencies with the expertise and responsibility for marine fisheries and essential fish habitat expressed a concern over the effects.

of the projected small salinity increase on white shrimp, and therefore an analysis of this species' responses to salinity variations is not warranted.

5. The superscripts, footnotes and abbreviation of terms for Table 4.16-1 (Impact Summary for Past, Present, and Reasonably Foreseeable Project with Publicly Available Information) will be revised in the FEIS to make the table easier to use. To help you interpret the DEIS table, we offer the following:

Single asterisks after the column headings "Past or Present Actions" and "Reasonably Foreseeable Actions." refer to the footnote included with the table. "Although not included in the table, several other projects are included in Section 4.16 Cumulative Impacts." The reason a particular project is not included in the table is provided in the text description of each project.

Single asterisks in table cells referred to a footnote that was inadvertently left out of the table: "**Offset by engineering design, mitigation, data recovery, adaptive management plans/activities based on monitoring, procedures, and project controls." Likewise, double asterisks referred to another absent footnote: "**Includes acreages from permit amendment applications.

Cell contents are further explained below:

"Benefit" or Net Benefit refers to results which have an overall positive effect when compared to the FWOP (baseline, existing) condition of the resource. "Benefit" infers direct benefit and "Net Benefit" infers a culmination of resource-related effects which are advantageous to the resource category as a whole.

NI = No long-term impacts; NA = Not Applicable; UN = Unavailable; I = Impact

6. The TCEQ requirement that total suspended solid (TSS) concentrations in effluent associated with dredging activities be controlled to a maximum of 300 milligrams per liter could only be met for confined placement areas where outlet structures control the ponding of water and the settling of TSS before release. The management of TSS during the proposed unconfined discharge of dredged material for the Neches River and Gulf Shore BU features cannot meet this standard, but Best Management Practices (BMPs) would be utilized to minimize TSS to the maximum extent practicable. DEIS Appendix E, Part I.f (page E-13) states that BMPs, such as silt curtains, may be implemented where appropriate to control and reduce turbidity during dredging and placement. Part II.c.(4) on page E-19 states that BMPs, such as temporary containment levees/spill boxes or silt curtains could be utilized to minimize impacts during discharged to construct BU marsh restoration features. Galveston District coordination with the ICT (of which TCEQ is a member) of the proposed SNWW CIP would continue after project approval to obtain resource agency input into the identification of BMPs and the development of plans and specifications for BU features and compensatory mitigation measures.

7. All ICT member agencies were provided the opportunity to comment on the Preliminary DEIS (September 29, 2009) and the publically released DEIS (December 24, 2009) to ensure that

resource issues were adequately and appropriately addressed. ICT involvement prior to completion of the Final EIS for the SNWW CIP will be limited to consistency review by representatives from the following Coastal Coordination Council member agencies: Texas General Land Office, Texas Parks and Wildlife Department, Texas Water Development Board, Texas Commission on Environmental Quality and the Texas Department of Transportation. This review will be conducted pursuant to the Coastal Coordination Act's Implementation Rules 31 TAC §506.28 "Guidance for Conducting Consistency Reviews in Coordination with an Interagency Coordination Team," issued on December 11, 2003. Galveston District has requested concurrence that the Tentatively Recommended Plan for the SNWW CIP is consistent, to the maximum extent practicable, with the Texas Coastal Management Program goals and policies. The ICT would remain active through the preconstruction, engineering and design (PED) and project construction phases to provide input during the development of plans and specifications for BU features and mitigation measures, and on BMPs as described in response 6 above. The ICT would continue into the operations phase to ensure that the BU and mitigation measures have been constructed as specified in the DEIS and that the goals of the compensatory mitigation plan have been fully achieved.

In conclusion, we hope this additional information will be helpful in your review. We trust that we have provided sufficient information for you to provide §401 State Water Quality certification. However, we would be happy to meet with you to provide further information if needed. All public and agency comments on the DEIS and our responses will be available for your review when they are presented in the FEIS. Please do not hesitate to contact Ms. Janelle Stokes at 409/766-3039 should you need further assistance.

RE: **C20090667**, Coastal Zone Consistency
U. S. Army Corps of Engineers, Galveston District
Direct Federal Action
Draft EIS for the Sabine-Neches Waterway Improvements Project, Southeast Texas and Southwest, **Louisiana**

Dear Mr. Dunn:

This office has received the above referenced federal application for consistency review with the approved Louisiana Coastal Resources Program in accordance with Section 307(c) of the Federal Coastal Zone Management Act of 1972, as amended. NOAA Regulations on Federal Consistency, at 15 CFR '930.41(a), allow 60 days for the review of Direct Federal Activities, and at '930.41(c)(b) allow additional review time upon mutual agreement between the Federal agency and the State Coastal Zone Program. Please be advised that, by this letter, Interagency Affairs/Field Services Division and the Galveston Corps District have mutually agreed to extend the State review time to March 26, 2010.

A final determination will be made within the authorized time period, ending March 26, 2010. If you have any questions please call Brian Marcks of the Consistency Section at (225) 342-7591.

Sincerely yours,

Gregory J. DuCote

Re: Draft Environmental Impact Statement for the Sabine-Neches Waterway Channel Improvement Project, Southeast Texas and Southwest Louisiana and the Draft Environmental Impact Statement Sabine-Neches Waterway Channel Improvement Project, Texas Ocean Dredged Material Disposal Site Designation

Dear Ms. Stokes:

Texas Parks and Wildlife Department (TPWD) staff has reviewed the above referenced documents provided to our agency on December 18, 2009. TPWD staff has also participated in the Interagency Coordination Team (ICT) for this project. Through the ICT process TPWD was able to provide our input into the project design, beneficial use components and mitigation options. As a result of this process, our agency comments have been incorporated into the Draft Environmental Impact Statement and we have no outstanding issues with the project.

Without proper execution of the mitigation plan and beneficial use features, this project would have deleterious impacts on an already significantly altered and fragile Sabine Lake coastal ecosystem. Therefore, we cannot stress enough the importance of continued coordination with our agency through the planning, engineering and design phase, the construction phase, and the maintenance phase of this project. We strongly recommend that the U.S. Army Corps of Engineers and the Sabine Neches Navigation District adopt the Beneficial Use Group model developed for the Houston Ship Channel project to facilitate this coordination.

We appreciate the opportunity to participate in the ICT process for this project and fully endorse use of the ICT process to facilitate federal projects that avoid and minimize impacts on the natural resources of Texas.

Questions can be directed to Mr. Jamie Schubert, Upper Coast Ecosystem Assessment Team Leader at (281) 534-0135.

Sincerely,

Ross Melinchuk
Deputy Executive Director, Natural Resources

RE: Sabine-Neches Waterway Channel Improvement Project – DEIS

Dear Ms. Stokes:

The professional staff of the Louisiana Department of Wildlife and Fisheries (LDWF) has reviewed the Sabine-Neches Waterway Channel Improvement Project Draft Environmental Impact Statement (EIS). As a Cooperating Agency and a member of the Interagency Coordination Team, LDWF submits the following recommendations. These recommendations shall be given thorough consideration and be individually and adequately addressed in the Final EIS.

Compensatory Mitigation

The U.S. Army Corps of Engineers (USACE) intends to restore more marsh in Louisiana than the project is predicted to destroy over the initial 50-year project life. Despite this, there remains a 318 AAHU deficiency in Louisiana. **The 318 AAHU deficiency indicates that project construction, including beneficial use and mitigation measures, is expected to result in an overall loss of fish and wildlife habitat quality in Louisiana.**

USACE proposes to use excess Texas BU benefits to offset this deficiency of compensatory mitigation in Louisiana. **LDWF will not concur in plans to mitigate in Texas for wetland impacts occurring in Louisiana.**

Therefore, LDWF recommends that additional mitigation measures be implemented in Louisiana to offset the current 318 AAHU deficiency.

Beneficial Use

LDWF recommends that new work material from the Sabine Pass Channel and Sabine Pass Jetty Channel be used beneficially to create, restore, or nourish emergent marsh in the vicinity of the project. Instead of using only maintenance material composed of fine-grained sediment, the new work material, composed predominantly of clay, should be placed along the shoreline at Louisiana Point. New work material would have a greater likelihood of remaining in the existing marsh and on the shallow nearshore slope in front of the shoreline than maintenance material.

LDWF License to Dredge; Royalties

LDWF's legal staff is investigating USACE's claim that the Supremacy Clause of the U.S. Constitution allows USACE to avoid acquiring a license from, and pay royalties to, LDWF for dredging state owned water bottoms.

Ms. Stokes
 Page 2
 March 11, 2010

Public Oyster Areas

Sabine Lake in Louisiana is a public oyster area and LDWF is mandated to diligently protect and conserve such areas. It has been a long-standing practice that water bottoms associated with a proposed project within a public oyster area must be assessed prior to project implementation, and that compensation is required for impacts to those water bottoms. Adverse impacts to the public oyster area from the mitigation dredging areas, including any access channels, must be assessed. The applicant shall contact LDWF's Heather Finley at 225-765-2956 or hfinley@wlfr.la.gov for further information.

4

LDWF has consistently asserted that these recommendations must be satisfactorily addressed by USACE. Unfortunately, the DEIS failed to do so. LDWF will continue to urge USACE to correct the inequitable wetland mitigation plan and to adequately address all other outstanding LDWF concerns. Please do not hesitate to contact LDWF's Kyle Balkum at 225-765-2819 should you need further assistance.

Sincerely,

Robert A. Barham
 Secretary

RESPONSE TO COMMENTS

Comment No.	Response
1	Please see USACE response in letter dated March 4, 2010. USACE maintains that all impacts have been fully compensated. Therefore, this will be reported as an unresolved issue in the FEIS.
2	Please see USACE response in letter dated March 4, 2010. USACE has explained that the beneficial use of new work material was thoroughly explored by the FEIS, and that dredged material would used to the maximum extent practicable in the proposed SNWW CIP. Therefore, this will be reported as an unresolved issue in the FEIS.
3	Please see USACE response in letter dated March 4, 2010. USACE understands that this issue is still under review by Louisiana Department of Wildlife and Fisheries (LDWF). If it is not resolved prior to publication, it will be reported as an unresolved issue in the FEIS.
4	Please see USACE response in letter dated March 4, 2010. USACE has proposed that a water bottom survey of the borrow area and access channels be conducted after project approval. In the event that oyster reef is encountered, plans would be revised to avoid impacts. Therefore, this will be reported as an unresolved issue in the FEIS.

RE: Sabine-Neches Waterway Feasibility Study DEIS

Dear Ms. Stokes:

The professional staff of the Louisiana Department of Wildlife and Fisheries (LDWF) has reviewed the preliminary Sabine-Neches Waterway Feasibility Study Draft Environmental Impact Statement (DEIS). Based upon this review, LDWF staff submits the following comments below. These comments, shall require thorough consideration and be individually and adequately addressed in the DEIS.

Compensatory Mitigation

Excess Texas BU Benefits are being used to offset a deficiency of compensatory mitigation in Louisiana. **LDWF will not concur in plans to mitigate in Texas for wetland impacts occurring in Louisiana.** LDWF recommends that additional Louisiana mitigation measures be implemented to offset the current 318 AAHU deficiency.

Beneficial Use

The tentatively Recommended Plan would result in an estimated 98,000,000 cubic yards of new work material (i.e., material dredged during initial channel deepening and widening). With the exception of a portion of the material dredged from the Neches River Channel in Texas, all new work material would be pumped to upland placement areas and ocean dredged material disposal sites, not used beneficially.

Of particular concern to LDWF is the Sabine Pass Channel segment which begins just north of the jetties and extends 5.6 miles upstream to Mesquite Point, Texas and the Sabine Pass Jetty Channel which begins at the jetties and extends 4.1 miles downstream. All 9,701,000 cubic yards of new work material from these segments (6,723,000 cubic yards from Sabine Pass Channel and 2,978,000 cubic yards from Sabine Pass Jetty Channel) would be pumped to upland placement areas or ocean dredged material disposal sites. **LDWF recommends that new work material from the Sabine Pass Channel and Sabine Pass Jetty Channel be used beneficially to create, restore, or nourish emergent marsh in the vicinity of the project.**

LDWF License to Dredge; Royalties

Sabine Lake and Sabine Pass in Louisiana are state owned water bottoms. No fill material shall be dredged from state owned water bottoms without a license issued by LDWF. A royalty payment, based on cubic yards, shall also be made to LDWF. The applicant shall contact LDWF's Mike Windham at 504-284-5268 or cwindham@wlf.la.gov for further information.

Ms. Stokes
 Page 2
 October 23, 2009

Public Oyster Areas

Sabine Lake in Louisiana is a public oyster area and LDWF is mandated to diligently protect and conserve such areas. It has been a long-standing practice that water bottoms associated with a proposed project within a public oyster area must be assessed prior to project implementation, and that compensation is required for impacts to those water bottoms. Adverse impacts to the public oyster area from the mitigation dredging areas, including any access channels, must be assessed. The applicant shall contact LDWF's Heather Finley at 225-765-2956 or hfinley@wlf.la.gov for further information.

LA2-ADD B/LA2-18B

LDWF needs more information about the access channel and borrow trench for LA2-ADD B/LA2-18B. For instance, why was the proposed route chosen? Why not a more direct route? What is the depth of the channel? What is the depth and length of the borrow trench? What is the distance from shore of the borrow trench? All of these questions are a concern due to the potential to create hypoxic conditions in dredged water bottoms and increase shoreline erosion rates through increased wave energy or sinking of the shoreline to fill the excavated trench.

WVA Modeling – Submerged Aquatic Vegetation (SAV)

The WVA model predicts no change in the percentage of SAV cover for either Future Without Project (FWOP) or Future With Project (FWP) condition despite increases in salinity. However, the FWP results in adverse impacts to native SAV in two hydrologic units (i.e., TX 3 and LA 1). Furthermore, the salinity ranges appear high for some of the species and, according to discussions at the August 27, 2009 ICT meeting, some native SAV species were not included in the analysis. More work is necessary to justify the "no change" determination for FWP or else adverse impacts need to be accounted for in the WVA model and adequate and appropriate mitigation provided.

The Louisiana Department of Wildlife and Fisheries appreciates the opportunity to review and provide recommendations to you regarding this proposed activity. Please do not hesitate to contact LDWF's Kyle Balkum at 225-765-2819 should you need further assistance.

Sincerely,

Robert J. Barkham
 Secretary

Environmental Section

Mr. Robert J. Barham
Secretary
Louisiana Department of Wildlife and Fisheries
Office of Wildlife
P.O. Box 98000
Baton Rouge, Louisiana 70898-9000

Dear Mr. Barham:

Reference is made to the letter dated October 23, 2009 from your agency regarding the preliminary Sabine-Neches Waterway Channel Improvement Project (SNWW CIP) Feasibility Study and Draft Environmental Impact Statement (DEIS). The DEIS, issued for public and agency review on December 24, 2009, included your comments and identified them as unresolved issues in the DEIS Executive Summary (Section ES.5, page ES-10). An Interagency Coordination Team (ICT) comprised of Federal and State resource agency representatives from Texas and Louisiana has assisted Galveston District in modeling and analyzing environmental impacts, and selecting beneficial use (BU) and mitigation measures for the Tentatively Recommended Plan. The Louisiana Department of Wildlife and Fisheries (LDWF) has had a representative on the ICT since its inception in 2000. For your convenience, we are providing responses to each of your comments with this correspondence.

Compensatory Mitigation

The proposed mitigation plan would more than compensate for all impacts of the proposed SNWW CIP. Benefits of the BU measures are being used to offset impacts in both Texas and Louisiana. DEIS Table 5.1-2 provides a summary accounting of BU benefits and compensatory mitigation for the proposed project. In Louisiana, the benefits of BU measures offset the loss of 210 average annual habitat units (AAHUs) to private lands along the coast at Louisiana Point, and the loss of 340 AAHUs to Federal land in the Sabine National Wildlife Refuge. Although the net impact of the project as a whole after application of all BU benefits (including significant other BU benefits in Texas) is the loss of 843 AAHUs, the proposed mitigation plan would provide 1,181 AAHUs in order to fully compensate for the loss of 1,499 AAHUs to non-Federal lands in Louisiana. The marsh mitigation measures would compensate for the predicted loss of 691 acres in Louisiana over 50 years by the restoration of 2,783 acres of emergent marsh, the improvement of 957 acres of shallow water habitat and the nourishment of 4,355 acres of existing marsh. Since the marsh restoration is several times greater than the predicted marsh loss, there would be no net loss of wetlands.

Beneficial Use

The ICT participated in an exhaustive search for least-cost beneficial use opportunities throughout the project area. The screening of potential BU measures is described in the DEIS

-2-

Section 2.5.3. Given the large amount of dredged material that would be generated from the proposed SNWW CIP, considerable effort was expended to identify areas in both Texas and Louisiana that could benefit from its beneficial use. All degraded marsh areas near the SNWW navigation channels, including the marshes inland from Louisiana Point, were investigated. The ICT identified no interior marsh areas in need of nourishment or restoration adjacent to Sabine Pass in Louisiana. Areas in Louisiana that could benefit from BU measures are all located in marshes east of Sabine Lake. However, these were found to be too distant from the navigation channel to permit cost effective use of dredged material from the SNWW navigation channels.

The tentatively-recommended BU plan includes the only measure in Louisiana that was identified as a least costly method of disposal. The Gulf Shore Nourishment Feature would use material from regular maintenance dredging of the eastern section of the Sabine Pass Channel to nourish eroding marsh along shorelines at Louisiana Point and Texas Point. Maintenance material would be hydraulically-pumped along a 3-mile reach of shoreline (from 0.5 to 3.5 miles from each jetty) during each 3-year dredging cycle. The unconfined placement would alternate between Texas and Louisiana, so that dredged material would be placed on each state's shoreline every 6 years, for a total of 16 placement events over 50 years. Dredging and pumping costs for new work material are higher, and therefore shoreline nourishment during construction in the Sabine Pass Channel would be more expensive than placement in the existing Placement Area (PA) 5. The Sabine Pass Jetty Channel would be dredged by hopper dredge; beneficial use of this material would require double handling and would cost more than placement in the existing Ocean Dredged Material Disposal Site (ODMDS) A. Current Corps of Engineers guidance requires that a cost share sponsor be identified for any environmentally beneficial use of dredged material that is not the least costly method of disposal. No potential non-federal sponsors have been identified for BU measures that are not the least costly method of disposal. The proposed BU plan uses dredged material to the maximum extent practicable to protect and nourish the Gulf shoreline, and existing upland PA5 and ODMDS A would be utilized rather than creating new placement areas.

LDWF License to Dredge; Royalties

Galveston District maintains that the United States is not bound by Louisiana statute (R.S. 56:2011) pursuant to the Supremacy Clause of the United States Constitution, Article VI, paragraph 2, and that Louisiana is not entitled to compensation under the Fifth Amendment, pursuant to the doctrine of Navigation Servitude. This servitude gives the Federal Government the right to use the "Navigable Waters" of the United States without compensation for navigation projects. The connection between the navigation project and the proposed removal of fill from Sabine Lake is simple. The removal of fill material for the Willow Bayou marsh mitigation areas would not be necessary but for construction of the proposed project.

Public Oyster Area

Galveston District understands that the area proposed for the one-time borrow area and access channel are located within the Sabine Lake Public Oyster Area. While the area is designated as a public oyster area, several recent bay bottom assessments conducted in the vicinity by Department of Army permit applicants have identified no live oyster reefs in the area. Nevertheless, as stated in DEIS Section ES.5 and Section 5.5.1, we propose that a water bottom survey of the borrow and access channel areas be conducted after approval of the Chief of Engineer's report, during the preconstruction engineering and design (PED) phase of the project. In the unlikely event that oyster reef is encountered, plans will be revised to avoid impacts.

LA2-ADD B/LA2-18B

DEIS Section 5.5.1 answers many of the questions posed by your letter. "The dedicated dredging would take approximately 3.1 million cubic yards of material from a 1.8-mile-long borrow trench in Sabine Lake. The borrow trench would be located at least 1,000 feet from the Sabine National Wildlife shore and would average 1,030 feet wide by 7.5 feet deep. The borrow trench would be continuous and parallel to the current shoreline, in line with the common long shore circulation pattern in Sabine Lake. The circulation is expected to prevent the development of hypoxic conditions that would be detrimental to aquatic organisms, and would eventually fill the trench with Sabine River sediments. An access channel, approximately 8 miles long, from the GIWW near the mouth of the Sabine River would be needed for the dredge to reach the proposed borrow area. The exact locations of the borrow trench and access channel would be determined in consultation with the ICT after PED bottom surveys of potential locations." The proposed route of the access channel was chosen to keep dredging impacts to a minimum; it takes advantage of deeper water in the center of the lake, thereby minimizing dredging and bottom impacts. The depth of the access channel would be dependent upon water depth and the draft of the dredge. ICT coordination during the PED phase would ensure that LDWF concerns with these features are adequately addressed.

WVA Modeling – Submerged Aquatic Vegetation (SAV)

DEIS Appendix C, Section 4.2 describes the WVA modeling of the variable "Percent Submerged Aquatic Vegetation." The WVA model documentation described in DEIS Appendix C, Section 2.6.1.2, defines SAV as any of the diverse array of floating-leaved and submerged aquatic plants that are typically found in a study area. SAV coverage is included as an important model variable because SAV provides important food and cover to a wide variety of fish and wildlife. The model evaluates the percentage of open water that is dominated by aquatic vegetation, without consideration as to whether it is native or invasive. The WVA modeling utilized an inventory of SAV species in the study area that was prepared using recent monitoring reports and other available literature. Potential project impacts would be related to the increase in salinity that would occur with deepening of the SNWW navigation channel. As described in DEIS

Section 4.2.1, one native and one invasive SAV species out of 10 species present in LA 1 would be affected by the predicted salinity change. It is expected that any SAV cover lost due to the gradual salinity change would be replaced by salinity tolerant SAV species continuing to grow within their tolerance ranges. As a result, no actual impact to percent SAV cover would be expected. The best available scientific information was used to establish salinity ranges for the evaluation; differences in scientific opinion regarding these ranges are readily apparent in the literature. No new information has yet been provided by LDWF or any other resource agency and, therefore, we see no reason to revise the WVA modeling at this time.

We hope this additional information will be helpful to your agency in evaluating the SNWW CIP Draft EIS. The issues and area of concern raised by your letter have been individually and adequately addressed in the DEIS. Please do not hesitate to contact Ms. Janelle Stokes at 409/766-3039 should you need further assistance.

Sincerely,

Carolyn Murphy

 Good morning,

A couple of you requested additional information on the ICT process for consistency concurrence. I'm attaching the 2003 CCC Guidance for ICT Consistency Review. It describes the approved process that we would like to follow for the SNWW CIP. If you have further questions about this, I believe Ms. Tammy Brooks, GLO Coastal Management Program, (512) 463-9212 may be able to provide additional information.

And please don't hesitate to call me if you have any other questions or concerns. <<CCC_Guidance_ICT_Consistency_Review_2003.pdf>>

Re: Comments on December 2009 Draft Documents for Sabine-Neches Waterway Channel Improvement Project

Dear Ms. Stokes:

The Sabine River Authority of Texas (SRA-TX) appreciates this opportunity to provide its comments on the December 2009 draft documents for the Sabine-Neches Waterway Channel Improvement Project. The SRA-TX has been an active participant in the USACE Interagency Coordination Team and is familiar with the proposed project.

The SRA-TX was created by the Legislature in 1949 as an official agency of the State of Texas. SRA-TX was created as conservation and reclamation district with responsibilities to control, store, preserve and distribute the waters of the Sabine River and its tributary streams in Texas for useful purposes. The Texas portion of the Sabine River Basin originates in Texas with headwaters east of Dallas and flows southeast to the Stateline near Logansport, Louisiana where waters are divided equally between the two States. The total drainage area of the Basin is 9,756 square miles which includes all or part of twenty-one counties in Texas (about 76 percent of the basin) and seven parishes in Louisiana (about 24 percent of the basin). The downstream reach ends at the confluence of the Sabine River with Sabine Lake. The STA-TX, the Sabine River Authority, State of Louisiana (SRA-LA) and the Sabine River Compact Administration all have responsibilities relating to the waters of the Sabine Basin.

The SRA-TX has taken an active role in water supply and water quality protection activities for many years, including work with regional state water planning groups, drought planning, and water conservation. As a partner in the Texas Clean Rivers Program since the program's inception, SRA-TX collects water quality data throughout the Sabine River Basin under a state-approved quality assurance project plan and the data is accepted by the state for standards compliance assessment. SRA-TX monitors water quantity and quality for SRA-TX and SRA-LA in Toledo Bend Reservoir and the Lower Sabine River Basin. SRA-TX has actively participated in review of state water quality standards, nutrient standards development, waste load evaluations, and industrial and municipal permit compliance monitoring. SRA-TX is

currently gathering available data and conducting studies on the Lower Sabine River relevant to the renewal of its Federal Energy Regulatory Commission (FERC) license for the Toledo Bend Hydropower facility. Other recent environmental flows work includes several years of work with Senate Bill 2, Texas Instream Flow Program and Senate Bill 3, Sabine and Neches Rivers and Sabine Lake Bay Basin and Bay Area Stakeholder Committee and Expert Science Team. As a part of these environmental flows activities, the SRA-TX has maintained that solutions for preservation and protection of the ecology of Sabine Lake and the surrounding wetlands should be based on retarding saltwater intrusion into the wetlands which has resulted from numerous secondary channels in Texas and Louisiana.

Over the past 130 years, secondary channels emanating from the open waters of Sabine Lake, the tidal waters of the lower Sabine and Neches Rivers as well as the Gulf Intracoastal Waterway have exposed the adjacent wetlands (bottomland hardwoods, cypress-tupelo swamps and open marshes) to increased tidal exchange of higher salinity water from the Gulf of Mexico via the Sabine-Neches Waterway to areas such as Bessie Heights, Keith Lake and the Sabine National Wildlife Refuge. SRA-TX agrees that wetlands mitigation/habitat restoration efforts outlined in the report will need the beneficial use of dredged material to re-establish marsh elevations along with revegetation in order to rebuild these areas. However, SRA-TX believes saltwater intrusion into these areas will require more control structures to retard saltwater intrusion and slow freshwater drainage from wetland areas back into Sabine Lake and the lower Sabine and Neches Rivers. In this regard, SRA-TX requests additional consideration be given to such control structures to mitigate wetland loss resulting from secondary channels.

1

Thank you again for this opportunity to submit our comments. We have also attached specific comments for your consideration. Please contact our office if further details or clarification is needed.

Sincerely,

A handwritten signature in dark ink, appearing to read 'Jack W. Tatum'. The signature is fluid and cursive, with a large initial 'J' and 'W'.

Jack W. Tatum
Water Resources Manager

Volume II, Draft Environmental Impact Statement for Sabine-Neches Waterway Channel Improvement Project

p.3-28

3.5.3.1 Flow Diversions

The area within Calcasieu/Sabine River Basin has experienced accelerated marsh deterioration and conversion to shallow open water as a result of the construction of Calcasieu Ship Channel, the SNWW, and the GIWW, ~~land subsidence from mineral extraction, and relative sea level rise~~. Efforts to combat the increased flow of saltwater into the area include both structural and vegetative methods. A 1990 inventory of water control structures along the perimeter and interior of the Calcasieu/Sabine River Basin located 174 structures.

2

Comment [JDPI]: It's inaccurate to describe inflows from the Sabine and Neches Rivers in terms of the reservoirs. 56% of fresh water entering Sabine Lake originated from watersheds and direct precipitation other than flows passing through Sam Rayburn and Toledo Bend dams 147 miles upstream of Sabine Lake.

3

4

SRA Comment: The Recommended Plan includes beneficial use of dredge material but doesn't include water control structures such as those listed in section 3.5.3.1 to restrict the flow of saltwater into the marshes. The SRA-TX understands the need for beneficial use of dredge material and recognizes cost/benefits analyses have been done to select mitigation options that are most cost-effective, however these beneficial use areas aren't expected to prevent saltwater from entering the marshes. Marsh perimeter control structures reduce tidal hydraulics and erosion of surface sediments, restrict inflows from Sabine Lake, and retain fresh water from rainfall and local watersheds.

5

p. 4-112

4.16.4.6 Toledo Bend Reservoir Relicensing

Toledo Bend Reservoir is located on the Sabine River in Texas and Louisiana and forms a portion of the boundary between the two states. The reservoir is approximately 65 miles long and inundates land in Newton, Sabine, Shelby, and Panola counties, Texas, and Sabine and DeSoto parishes, Louisiana. Toledo Bend Reservoir has 1,200 shoreline miles, normally covers an area of 185,000 acres, and has a controlled storage capacity of 4,477,000 acre-feet. The reservoir was constructed by Sabine River Authority of Texas and Sabine River Authority, State of Louisiana (SRA-LA) for water conservation, supply, with secondary uses of

6

hydroelectric power generation, and recreation. On December 12, 2002, the SRA-TX approved an application to the TCEQ to amend Certificate of Adjudication No. 05-4658 to include the right to divert 293,300 acre-feet per year of the available unappropriated portion of the stored Texas water from Toledo Bend Reservoir for multiple use (municipal, industrial, agricultural) (SRA-TX and LNVA, 2006). TCEQ is mandated to consider environmental flows (instream and freshwater needs) during permit evaluations for new reservoirs or amended water rights.

The SRA-TX and ~~Louisiana~~ SRA-LA (Authorities, hereafter) ~~propose to revise their FERC license to eliminate~~

~~peaking hydropower generation during the summer months at Toledo Bend Reservoir.~~ With this proposed change, water would be used for public water supply.

~~The SRA-TX and LNVA commissioned Sabine~~

~~Lake: Ecological Condition of the Sabine-Neches Estuary report (SRA-TX and LNVA, 2006) to facilitate preparation of the FERC pre-application document for relicensing new operations (an EIS would be required to evaluate the impacts of such a change).~~ If the Toledo Bend Reservoir were to be operated solely as a public water supply, the hydropower operational increase in freshwater inflows to Sabine Lake during the summer months would not occur, resulting in a flow regime similar to pre-reservoir or naturalized conditions (SRA-TX and LNVA, 2006). The current FERC license expires October 14, 2013 (SRA-TX and LNVA, 2006).

7

Comment [JDP2]: The new license will not eliminate summertime hydropower peaking.

Comment [JDP3]: This document was an important reference in the FERC Pre-Application Document but wasn't commissioned for that purpose.

~~The SRA-TX and SRA-LA (Authorities, hereafter) have initiated the process to renew the FERC license which allows the generation of Hydro-electric generation. The current FERC license expires October 14, 2013. The intention of the Authorities is to continue current operations as a hydropower peaking unit during the summer months. However, as water supply sales increase, hydropower generation may be reduced resulting in a flow regime that is more similar to pre-reservoir or naturalized conditions.~~

Comment [JDP4]: A comment on the FERC license renewal process.

Volume IV, Draft Environmental Impact Statement for Sabine-Neches Waterway Channel Improvement Project

Appendix J, SNWW CIP Mitigation/Beneficial Use Monitoring Plan

The SRA-TX recommends long-term salinity monitoring as a part of the Monitoring Plan to evaluate accuracy of the prediction model, subsequent assumptions that were made on the basis of salinity modeling, and the ultimate success potential for adopted mitigation measures.

Mr. Jack Tatum
 Water Resources Manager
 Sabine River Authority of Texas
 P.O. Box 579
 Orange, TX 77631

RESPONSE TO COMMENTS

Comment No.	Response
1	Given the fact that impacts of the proposed SNWW CIP are related primarily to salinity intrusion, extensive efforts have been made to identify effective mitigation measures that could minimize or eliminate the projected increase in salinity and tidal amplitude. The results of this effort are presented in FEIS Section 5.4.1.1. None of the salinity control structures were selected because the net effect of the structures was determined to be negative. Beneficial salinity effects were modest and could not overcome the adverse effects of restrictions to marine organism access.
2	The FR was revised as suggested.
3	Totals in FR Table I-2 have been corrected.
4	The effect of relative sea level rise (which by definition includes subsidence from any cause) on existing interior marshes is discussed in FEIS Section 4.10.1.2.1. Existing coastal marshes appear to have adapted to gradual changes in sea level rise, and in recent years there has been a decrease in the loss rate in the Sabine-Calcasieu area. The text has not been revised.
5	See USACE response to Comment 1.
6	The FEIS was revised as suggested.
7	The FEIS has been revised.
8	Salinity monitoring is conducted by many state and Federal agencies throughout the SNWW study area. It is expected that this data will be available for use in assessing future conditions within the study area.

 P.O. Box 1229
 Galveston, Texas 77553

Ms. Stokes,

The Texas Water Development Board (TWDB), as a member of the interagency coordination team for the Sabine-Neches Waterway Channel Improvement Project (SNWW CIP) and as a member of the Coastal Coordination Council (CCC), concurs that the tentatively recommended plan for the SNWW CIP is consistent with the Texas Coastal Management Program's goals and policies regarding *Dredging and Dredged Material Disposal and Placement* (TAC §501.25).

We have reviewed the analysis of compliance for the goals and policies related to TAC §501.25 *Dredging and Dredged Material Disposal and Placement* (Appendix I-1 of the Draft Environmental Impact Statement) and agree that the plans for beneficial use of dredged material meet the goals and policies of the Texas Coastal Management Plan. If you have further questions, please contact me at 512-936-0825 or at junji.matsumoto@twdb.state.tx.us.

RE: **C20090667**, Coastal Zone Consistency
U. S. Army Corps of Engineers, Galveston District
Direct Federal Action
Draft EIS for the Sabine-Neches Waterway Improvements Project, Southeast Texas and Southwest, **Louisiana**

Dear Mr. Dunn:

This office has received the above referenced federal application for consistency review with the approved Louisiana Coastal Resources Program in accordance with Section 307(c) of the Federal Coastal Zone Management Act of 1972, as amended. NOAA Regulations on Federal Consistency, at 15 CFR '930.41(a), allow 60 days for the review of Direct Federal Activities, and at '930.41(c)(b) allow additional review time upon mutual agreement between the Federal agency and the State Coastal Zone Program. Please be advised that, by this letter, Interagency Affairs/Field Services Division and the Galveston Corps District have mutually agreed to extend the State review time to March 31, 2010.

A final determination will be made within the authorized time period, ending March 31, 2010. If you have any questions please call Brian Marcks of the Consistency Section at (225) 342-7591.

Sincerely yours,

Gregory J. DuCote

 Subject: Consistency Determination for SNWW Channel Improvement Project

Dear Tammy/Jamie/Junji/Robert and Raul,

The consistency review for the proposed SNWW CIP project will be conducted pursuant to the Coastal Coordination Act's Implementation Rules 31 TAC §506.28 "Guidance for Conducting Consistency Reviews in Coordination with an Interagency Coordination Team," issued on December 11, 2003. The Corps of Engineers, Galveston District, has established an interagency coordination team (ICT) that includes as voting members representatives from the following Coastal Coordination Council member agencies: Texas General Land Office, Texas Parks and Wildlife Department, Texas Water Development Board, Texas Commission on Environmental Quality and the Texas Department of Transportation.

Please provide by return email your agency's concurrence that the Tentatively Recommended Plan for the SNWW CIP (as described in the Draft Environmental Impact Statement and Draft Feasibility Report, issued on 24 December 2009) is consistent, to the maximum extent practicable, with the Texas Coastal Management Program goals and policies. Please respond to this request as soon as possible because the deadline for receiving comments on the Texas consistency determination is 12 March 2010.

Thank-you

RE: Water Quality Certification (WQC 100330-01/AI 104985/CER 20100001)
Sabine-Neches Waterway Channel Improvements Project
Cameron Parish

Dear Ms. Stokes:

We have received notice of your application for a 401 Water Quality Certification to dredge waterbottoms and place spoil material for marine vessel access improvements, along Sabine Pass in southwestern Cameron Parish. Prior to processing the certificate, this office requires:

1. A proof of publication of the Public Notice in **THE ADVOCATE** of Baton Rouge. 1
2. A proof of publication of the Public Notice in **THE AMERICAN PRESS** of Lake Charles. 2
3. Assurance that any excavated material will be, to the best of your knowledge, free of contaminants and/or will be disposed of in an approved landfill. 2
4. A list of landowners, adjacent to the project site. 3

Be sure to include our reference number (WQC 100330-01/AI 104985) on all responses. Please send all correspondence to the Louisiana Department of Environmental Quality to the following address:

Louisiana Department of Environmental Quality
Water Permits Division
P.O. Box 4313

Attn: Water Quality Certifications

Enclosed are copies of public notices to be published by you one time in the official State Journal, THE ADVOCATE of Baton Rouge and THE AMERICAN PRESS of Lake Charles. (As provided for by LRS 30:2074 A(3), the cost of this publication is to be at your expense). PLEASE REQUEST THAT THESE NEWSPAPERS FURNISH US WITH PROOFS OF PUBLICATION OF THIS NOTICE TO THE FOLLOWING ADDRESS:

Louisiana Department of Environmental Quality
Water Permits Division
P.O. Box 4313
Baton Rouge, LA 70821-4313
Attn: Water Quality Certifications

A ten-day period after the date of publication will allow for public comment. After this ten-day period has expired, a decision as to whether to grant the certificate will be made in accordance with LAC 33:IX.1507.A-E and provisions of Section 401 of the Clean Water Act.

If we haven't received this information within 30 days from the date of this letter, your application will be considered inactive. If you have any questions, please call Jamie Phillippe at 225-219-3003.

Sincerely,

RESPONSE TO COMMENTS

Comment No.	Response
1	Public notices meeting the requirements of Louisiana Department of Environmental Quality (LDEQ) have been published in the these newspapers.
2	Information on the potential for contaminants in the dredged material is provided in FEIS Section 3.4 and Section 4.5. In consideration of LDEQ requirements, Sabine Pass sediment was compared to Louisiana’s RECAP non-industrial Screening Standards. All detected analytes were below the lowest value for the respective standard. PBS&J also compared water and elutriate results to the Louisiana Water Quality Standards (WQS), and found no exceedances.
3	Information on adjacent landowners is provided in FEIS Section 5.5.4.2, page 5-28 and FR, Appendix 4, Section 21.

Attn: Water Quality Certifications

Dear Mr. Phillippe:

Reference is made to your letter dated March 30, 2010 regarding Galveston District's request for §401 Water Quality Certification for the proposed Sabine-Neches Waterway Channel Improvement Project (SNWW CIP). We offer the following information to assist in your continuing review.

- You requested proof of publication for public notices in THE ADVOCATE of Baton Rouge and THE AMERICAN PRESS of Lake Charles. Upon review, we found that Galveston District's original public notice publications had not included the Baton Rouge newspaper, and had not required that comments concerning water quality certification be sent directly to your agency. Therefore, we have initiated new notices in both newspapers utilizing the draft language you provided. The public notices were published in THE ADVOCATE of Baton Rouge on April 5, 2010, and in THE AMERICAN PRESS of Lake Charles on April 6, 2010. We have requested that both newspapers furnish your office proofs of publication, and the public notice directs that comments be sent directly to you.
- You requested assurance that any excavated material will be, to the best of our knowledge, free of contaminants and/or disposed of in an approved landfill. The SNWW CIP Draft Environmental Impact Statement (DEIS) Section 3.4 and Section 4.5 discuss sediment analyses conducted for the proposed project, and conclude that there are no causes for concern related to contaminants. We have compared the Sabine Pass sediment data presented in the DEIS with the Louisiana RECAP non-industrial Screening Standards. All detected analytes were below the lowest value for the respective standard. The DEIS compared water and elutriate results to the Louisiana water quality standards, and found no exceedances. This information will be added to the SNWW CIP §404(b)(1) evaluation, Section II.d (Contaminant Determinations).

- You requested a list of landowners adjacent to the project site in Louisiana - the Sabine Pass Channel and Placement Area 5 in Cameron Parish. The SNWW CIP DEIS Section 5.5.4.2 and Draft Feasibility Report, Appendix 4 (Real Estate Plan) provide adjacent landowner information.

In conclusion, we hope this additional information will be helpful in your review. We trust that we have provided sufficient information for you to provide §401 State Water Quality certification. However, we would be happy to meet with you to provide further information if needed. Please do not hesitate to contact Ms. Janelle Stokes at 409/766-3039 should you need further assistance.

Sincerely,

A handwritten signature in cursive script that reads "Carolyn Murphy". The signature is written in dark ink and is positioned above the printed name and title.

**Re: Sabine - Neches Waterway Improvements Project
CMP # 10-0048-F2**

Dear Ms. Murphy,

As required by 31 T.A.C. § 506.28(b), the Coastal Coordination Council (Council) issues this consistency agreement for the Sabine - Neches Waterway Improvements Project (Project), a federal development project conducted by the US Army Corps of Engineers (USACE).

USACE established an interagency coordination team (ICT) for the Project pursuant to 31 T.A.C. § 506.28(b). Its duties included advising the USACE on the consistency of the Project and included among its voting members a minimum of three Council member agency representatives. A majority of the Council member agency representatives on the ICT found the Project to be consistent, to the maximum extent practicable, with the CMP goals and policies. USACE adopted the ICT consensus position on consistency and submitted it to the Council as its consistency determination for the Project. None of the Council member agency representatives on the ICT objected to USACE's consistency determination in writing within 15 days after the close of the public comment period.

Therefore, the Council accepts and adopts the consistency determination for the Project as submitted by the USACE in accordance with 31 Texas Administrative Code § 506.28(b). 1

Sincerely,

Tammy S. Brooks
Consistency Review Coordinator
Texas General Land Office

DEPARTMENT OF NATURAL RESOURCES

OFFICE OF COASTAL RESTORATION AND MANAGEMENT

March 12, 2010

Dolan Dunn
Chief, Planning, Environmental & Regulatory Division
Dept. of the Army
Galveston District, Corps of Engineers
P. O. Box 1229
Galveston, TX 77563-1229

RE: Draft Feasibility Report and Draft EIS for the Sabine – Neches Waterway Improvements Project, Southeast Texas and Southwest Louisiana

Dear Mr. Dunn:

The Louisiana Department of Natural Resources, Office of Coastal Management (LDNR OCM), has reviewed the above-referenced Draft Feasibility Report and Draft EIS for the Sabine – Neches Waterway Improvements Project, and we offer the following comments. The Consistency Determination submitted by your agency for the proposed activity continues to be under review by this Office; the issues noted below will have to be resolved prior to the construction phase, in order for OCM to concur that the final design is consistent, to the maximum extent practicable, with the Louisiana Coastal Resources Program in accordance with Section 307(c) of the Coastal Zone Management Act of 1972, as amended.

In addition, the Louisiana Office of Coastal Protection and Restoration (OCPR) has commented to LDNR that there are significant uncertainties about the compliance of the Draft Report's Tentatively Recommended Plan (TRP) with the attached "Louisiana's Integrated Ecosystem Restoration and Hurricane Protection: Comprehensive Master Plan for a Sustainable Coast" (Master Plan). Since conformance with the Master Plan is an enforceable policy of the State of Louisiana's coastal management program, it is essential that these uncertainties are addressed so that Master Plan compliance can be more accurately determined prior to final project design.

Storm Surge:

- Effects of the deeper shipping channel, Gulf Intracoastal Waterway (GIWW) deepening, and borrow area excavation in Sabine Lake may be significant and have not been modeled thoroughly enough to identify all potential impacts.
- Upland confined disposal sites on the Texas side of the project may create a barrier to storm surge, redirecting water to Louisiana that under present circumstances goes to Texas. Though

Coastal Management Division • Post Office Box 44487 • Baton Rouge, Louisiana 70804-4487

(225) 342-7591 • Fax (225) 342-9439 • <http://www.dnr.state.la.us>

An Equal Opportunity Employer

OCM acknowledges that the areas which are threatened by this potential inundation are not heavily populated, storm surge does adversely affect coastal resources.

- * Offshore disposal sites from the bar channel dredging may alter storm currents, potentially increasing set-up and erosion on Louisiana shores.

Bar Channel deepening:

- * Modeling of potential impacts on wave climate and resulting shoreline impacts was not performed. There is no objective means of estimating potential impacts to the Gulf shoreline due to the bar channel deepening.

Salinity:

- * Modeling of potential salinity changes used questionable assumptions and boundary conditions, and data collected over a short and non-representative time period, casting doubt on the reliability of the model results.

Borrow Site in Sabine Lake:

- * Specific site locations must be identified.
- * Flotation access channel route must be identified.
- * Disposal plans for material removed from the access channel route must be described.
- * Disposal plans for access channel material and overburden, if any, from borrow site(s) must be described.
- * Mitigation must be accomplished for submerged aquatic vegetation and oyster seed ground impacts to the satisfaction of LDWF.
- * Effects of excavation on wave and tidal climate and potential shoreline erosion must be more thoroughly modeled and evaluated.
- * Geotechnical information on borrow quality should be collected and evaluated.
- * Royalty payments and license issues over sediment resources must be resolved with LDWF.

Borrow Site in Gulf Intracoastal Waterway:

- * Geotechnical data must be collected and analyzed for sediment suitability.
- * Geotechnical data must be collected and analyzed for slope stability.
- * Shoreline stabilization plans must be proposed.
- * The location and configuration of the channel bottom to be left undisturbed to prevent salt water intrusion must be fully described. Analysis of its response to routine scour as well as storm surge, over the project life, must be presented.

Mitigation:

- * In general, the details of proposed mitigation are insufficient to determine whether all potential losses to the coastal resources of Louisiana will be adequately compensated.
- * Disposal site final locations and design are not identified.
- * Geotechnical data for disposal site design must be collected and evaluated.
- * Mitigation project lifetime maintenance and repair must be addressed. Can the Local Sponsor do such work in Louisiana?
- * Average Annual Habitat Units (AAHUs) generated by proposed mitigation fall at least 318 AAHUs short of replacing the anticipated habitat losses to Louisiana. Additional mitigation will need to be performed in Louisiana to offset this deficit.
- * 210 AAHUs are claimed to be created by the shoreline deposition of bar channel maintenance material onto the Gulf shoreline east of the Sabine jetties. The material has only 18% sand; it

is unlikely that such fine grained material will remain in place for the project life and the DEIS notes that the effects of large storm systems were not included in the consideration. Even with periodic maintenance, the ability of such a deposit to provide 210 AAHUs is questionable. Additional mitigation in Louisiana will be required to make up for those AAHUs unless an acceptable technical justification of the projected benefits is provided.

Pipelines:

- * Plats showing all pipelines affected by the deepening of the navigation channel, GIWW, flotation access channel and borrow site must be provided. The Galveston District must also provide a plan for the re-location of any pipelines that might be required as a result of the recommended plan and each of the alternatives.
- * Any potential impacts to Louisiana industries as a result of pipeline re-locations or other construction and/or maintenance related activities must be fully evaluated, and minimized and/or mitigated.

As ever, the Office of Coastal Management appreciates the opportunity to comment on this proposed project, and we look forward to working with your staff to resolve these many issues. If you have any questions please call me at (225) 342-5052.

Sincerely yours,

Gregory J. DuCote

**Office of Coastal Protection and Restoration Master Plan Consistency Comments on
Tentatively Recommended Plan for Sabine-Neches Waterway Channel Improvement
Project**

March 11, 2010

The U.S. Army Corps of Engineers' (USACE) Galveston District is conducting a feasibility study of the Sabine-Neches Waterway Channel Improvement Project in Southeast Texas and Southwest Louisiana. Louisiana Office of Coastal Protection and Restoration (OCPR) staff reviewed the December 2009 Draft Environmental Impact Statement (EIS) and Draft Feasibility Report (Draft Report), and had telephone conversations with USACE Galveston District personnel about aspects of those documents. That review indicates there are still significant issues and uncertainties relative to the consistency of the Draft Report's Tentatively Recommended Plan (TRP) with "Louisiana's Integrated Ecosystem Restoration and Hurricane Protection: Comprehensive Master Plan for a Sustainable Coast" (Master Plan). While we are not stating at this time that the TRP is inconsistent with the Master Plan, it is essential that these issues and uncertainties be sufficiently addressed prior to final project design so Master Plan consistency can be more accurately determined.

The following comments identify key uncertainties and deficiencies and offer recommendations for addressing them prior to a final consistency determination to be provided by the USACE to the Louisiana Department of Natural Resources pursuant to the Coastal Zone Management Act. These comments are grouped by relevant components of the Master Plan.

Master Plan Objective #1

Reduce economic losses from storm based flooding to residential, public, industrial, and commercial infrastructure, assuring that assets are protected, at a minimum, from a storm surge that has a 1% chance of occurring in any given year.

OCPR technical staff has serious concerns about the adequacy of the modeling of storm surge impacts on the Louisiana portion of the study area. The current standard for storm surge impacts to still water elevation and waves during tropical storm events uses "coupled" ADCIRC/STWAVE modeling. To date, such evaluations have not been performed for the TRP. Such modeling should include the project's "annual" impacts not only occurring under the "normal" tidal conditions, but also considering statistically based evaluations using appropriate sets of storms to establish the project's impacts for multiple return interval conditions so that the total damages/impacts/benefits are established (integrated over the full realm of return intervals). Verbal communications with USACE personnel suggest that three storms (with two scenarios) will be modeled. OCPR staff does not believe that the number of storms currently planned for

modeling is sufficient to adequately assess impacts. Thus, formal assurances by the USACE are needed, indicating that sufficient modeling of project-related storm surge and wave impacts will be performed prior to completion of final design, and that the results and methodology will be provided to the State of Louisiana for further review.

The USACE modeling has not demonstrated that spoil placement and consequent increased elevation of upland confined disposal sites on the Texas side will not deflect storm surge to the Louisiana side. Such modeling is needed to determine whether project-induced changes to storm surge and wave conditions could cause economic damages to Louisiana infrastructure. Offshore disposal sites created from dredging the bar channel may create partial barriers to storm currents, potentially increasing set-up on Louisiana shores under "normal" annual conditions and under larger tropical storm events.

Master Plan Objective #3

Provide habitats suitable to support an array of commercial and recreational activities coast-wide.

Adverse habitat impacts are to be offset via restoration of 2,783 acres of marsh, nourishment of 4,355 acres of existing marsh, and improvement of 957 acres of shallow water habitat. However, we are concerned that, under the TRP, adverse impacts to coastal wetlands in Louisiana will not be fully mitigated within Louisiana. The TRP assigns 318 Average Annual Habitat Units (AAHUs) of "excess benefits", resulting from the beneficial use of dredged material in Texas, to Louisiana in order to mitigate impacts to wetlands on the federally owned Sabine National Wildlife Refuge, located in Louisiana. From a Master Plan consistency standpoint, we believe that it is inappropriate to apply "excess benefits" in that manner; those impacts will still occur within Louisiana's boundaries, so the mitigation should occur within those boundaries.

OCPR technical staff also has concerns about the amount of mitigation projected to result from beneficial use of dredged material along the Gulf shoreline near Louisiana Point. Since the involved materials are predominantly clays and silts (less than 20% sand), OCPR technical staff are not convinced this project feature will achieve a net benefit of 210 AAHUs. A full explanation of the calculation of these benefits should be presented, as additional mitigation in Louisiana will be required if those projections cannot be adequately justified.

Elevation surveys and geotechnical information/analysis/design will be required to determine if the borrow quantities and fill areas are adequately designed to help ensure the success of the mitigation plan in fully compensating for project impacts.

Given the above issues and uncertainties, the USACE should provide written assurance that the final mitigation project plans and designs will fully offset project impacts to Louisiana's coastal wetlands (including impacts to federal lands within Louisiana); that assurance should provide for review and concurrence by the State of Louisiana.

The Ecological Model assumes that the marshes in western Cameron Parish will recover to existing conditions following a storm event; based on observations following Hurricane Rita, OCPR technical staff do not believe that assumption is correct.

OCPR has concerns that project's alteration of seafloor, lake and channel topography may result in significant adverse effects on additional marshes in Louisiana if storm surge into those marshes is increased by the project's enlarged channel dimensions.

The Ecological Model states that drainage in the Chenier Plain marshes (under normal conditions) is "... impaired by numerous hydrologic modifications such as the GIWW [and] the SNWW." These marshes are primarily brackish and intermediate types. OCPR technical staff has concerns that removal of borrow material for marsh creation from the GIWW channel bottom, as well as some of the borrow excavation within Sabine Lake, will introduce greater levels of salinity into these marshes during normal tidal conditions, possibly resulting in marsh vegetation die-offs and conversion of marsh to open water.

Changes to the tides, storm surge and wave conditions associated with the project could potentially increase shoreline erosion rates, and increase storm surge and salinity-induced changes to surrounding marshes.

Of the 16 total hydrologic monitoring sites, 7 were located in Louisiana. Of those 7 sites, 3 sites (#7, #9, and #12) experienced equipment malfunctions resulting in 1.5 to 8 months of lost data, thus limiting comparison of the data to other sites.

The salinity model report concludes that the project would result in only a 0 to 2 parts per thousand (ppt) salinity change impact. However, OCPR technical staff has several concerns regarding use of the modeling results referenced in the December 2009 Draft Report to reach conclusions on project impacts and related habitat mitigation needs for the TRP. USACE Galveston District personnel have indicated that there is no plan to perform additional modeling work. Key OCPR concerns include:

1. No access to data reports on which some of the initial and boundary conditions were based.
2. Data collection involved very short periods to judge the effectiveness of model calibration and verification.
3. Modeling used little salinity information outside the channels to perform the calibration and verification.
4. The model generally performed poorly in salinity predictions as compared to salinity measurements in the channels and lakes. In some cases, differences between predicted and measured salinity ranged from 5 to 15 ppt. Attempts were made to reconcile the differences by "introducing salinity" into the modeling effort.

5. The model domain ignored the boundary/interaction between the Calcasieu and Sabine basins.
6. It appears that most of the marsh in Louisiana was not modeled and only limited areas were considered in an ad hoc way (ignoring over-marsh flows); this approach will not capture project impacts on the marsh for larger tropical storm and hurricane salinity impacts.
7. The project will deepen the channel to 48 feet, not including 2 more feet of advanced maintenance and another 2 feet of allowable over-depth. Thus, during larger tidal and tropical storm events the channel could be 52 feet deep rather than 48 feet. Louisiana's marshes are susceptible to damages from salinity increases during larger tropical storms, so it is very likely that this modeling approach will underestimate damages to the marshes resulting from the channel deepening. The modeling effort also ignores the potential impacts associated with major hurricane (Ike/Gustav) years. Complicating the evaluation is the use of future relative sea level rise conditions that tend to "muddy the waters" regarding the estimated project impacts.
8. Pool 3 in Sabine National Wildlife Refuge was not included in the study (p. 4-26) because it has historically been a freshwater impoundment, hydrologically isolated from the surrounding marsh. The containment levees were breached in 2005 as a result of Hurricane Rita. Therefore, this area should be considered in the model since it will be impacted by the project. Because of extensive landscape alterations resulting from Hurricanes Rita and Ike (land loss, vegetation stress and instability of the soils), the conditions in the model may not apply.
9. The modelers were apparently not aware of the existence of Louisiana's Coast Wide Reference Monitoring System. OCPH has 15 CRMS sites in the impacted area. It would be prudent to review the available data to assess the reasonableness of model baseline assumptions compared to the 2007 non-storm and 2008 storm (Ike/Gustav) years.

We recommend that the USACE provide a written commitment to rectify the above deficiencies in their Dec. 2009 salinity modeling not later than the engineering and design phase of the project, and to include language in the final feasibility study report indicating that additional adverse salinity impacts to wetlands anticipated as a result of that additional salinity modeling will be fully mitigated at project cost.

Master Plan Recommendations

The Master Plan recommends stabilizing key areas along the Chenier Plain's bay and lake shorelines that, if breached, would have catastrophic results for the landscape.

It is not clear that the USACE has evaluated the potential effects of excavating marsh creation material at the proposed borrow sites on shoreline erosion and bank stability. The results of those evaluations should be provided, and included in the impacts and mitigation analyses. The borrow source(s) may need to be moved to eliminate such impacts, depending on the results.

The Master Plan seeks to maintain the integrity of freshwater resources by fortifying and maintaining spoil banks along the GIWW and placing saltwater barriers at deep draft shipping channels to manage salinity levels

Potential effects of excavating the GIWW borrow source, such as on shoreline erosion and slope stability, should be evaluated and included in the impacts and mitigation analyses. The recommended project plan should include installing shoreline stabilization measures along the GIWW borrow site, or avoiding use of that site, if those evaluations disclose such a need. The recommended project plan should also ensure the continued function of the salinity plug at the western boundary of the GIWW segment to be used as a borrow site.

BOBBY JINDAL

SCOTT A. ANGELLE
SECRETARY

State of Louisiana
DEPARTMENT OF NATURAL RESOURCES
OFFICE OF COASTAL RESTORATION AND MANAGEMENT

March 31, 2010

Dolan Dunn
Chief, Planning, Environmental and Regulatory Division
Dept. of the Army
Galveston District, Corps of Engineers
P. O. Box 1229
Galveston, TX 77563-1229

RE: **C20090667**, Coastal Zone Consistency
Galveston District, Corps of Engineers
Direct Federal Action
Feasibility Study and Draft Environmental Impact Statement for the Sabine-Neches Waterway Channel Improvement Project, **Cameron Parish, Louisiana**

Dear Mr. Dunn:

The above referenced project has been reviewed for consistency with the approved Louisiana Coastal Resource Program (LCRP) as required by Section 307 of the Coastal Zone Management Act of 1972, as amended. This office finds that the project, as proposed in the application, is conditionally consistent with the LCRP.

Pursuant to NOAA regulations on federal consistency at 15 CFR 930.4(a)(1), a conditional consistency concurrence must include the conditions which must be satisfied; an explanation of why the conditions are necessary to ensure consistency with specific enforceable policies of the management program, and an identification of the specific enforceable policies.

Explanation of necessity:

The Louisiana Department of Natural Resources (LDNR) Office of Coastal Management (OCM) has concluded, based on staff review and comments from the Louisiana Office of Coastal Protection and Restoration, the Louisiana Department of Wildlife and Fisheries, and other agencies, that the Draft Feasibility Study and Environmental Impact Statement for the Sabine-Neches Waterway Channel Improvement project is generally consistent with the LCRP provided that the conditions described herein are met. As outlined in our comment letter of March 12, 2010, the project as described lacks many significant details as to design features and locations, potential impacts, and the means by which these impacts will be avoided, reduced, minimized, and compensated for. This would include, but not be limited to, the topics of storm surge, bar channel deepening, salinity, borrow from Sabine Lake, mitigation plans and adequacy, and pipeline relocation. Further, the

Coastal Management Division • Post Office Box 44487 • Baton Rouge, Louisiana 70804-4487
(225) 342-7591 • Fax (225) 342-9439 • <http://www.dnr.state.la.us>
An Equal Opportunity Employer

adequacy of completed and planned modeling of potential salinity changes, storm surge, and other impacts is of significant concern, and must be conducted in a way in which this State can have full confidence in the analytical results. Please note in particular that your response letter, dated March 19, 2010, does not constitute an adequate resolution to the issues described.

Conditions:

In order to be consistent, to the maximum extent practicable with the LCRP, the Corps of Engineers-Galveston District must prepare an additional consistency determination, which will be submitted to LDNR pursuant to 15 CFR 930 Subpart C, when this project has reached a point in the planning or design process where all project elements can be described in detail, but modifications may still be made if necessary to achieve full consistency with the LCRP. This will be no later than the time at which the draft Contract Plans and Specifications are circulated for internal Corps review. This subsequent consistency determination will include the draft Plans and Specifications as well as detailed information sufficient for the evaluation of all proposed actions for consistency with the LCRP and the Master Plan.

Enforceable policies:

Louisiana's State and Local Coastal Resources Management Act (SLCRMA) and the Louisiana Administrative Code (LAC) address the requirements for information necessary for the review of consistency determinations in several places. Relevant enforceable policies may be found in Coastal Use Guidelines in the Louisiana Administrative Code Title 43, Part I:

§701 F Information regarding the following general factors shall be utilized by the permitting authority in evaluating whether the proposed use is in compliance with the guidelines:

1. type, nature, and location of use;
2. elevation, soil, and water conditions and flood and storm hazard characteristics of site;
3. techniques and materials used in construction, operation, and maintenance of use;
4. existing drainage patterns and water regimes of surrounding area including flow, circulation, quality, quantity, and salinity; and impacts on them;
5. availability of feasible alternative sites or methods of implementing the use;
6. designation of the area for certain uses as part of a local program;
7. economic need for use and extent of impacts of use on economy of locality;
8. extent of resulting public and private benefits;
9. extent of coastal water dependency of the use;
10. existence of necessary infrastructure to support the use and public costs resulting from use;
11. extent of impacts on existing and traditional uses of the area and on future uses for which the area is suited;
12. proximity to and extent of impacts on important natural features such as beaches, barrier islands, tidal passes, wildlife and aquatic habitats, and forest lands;

13. the extent to which regional, state, and national interests are served including the national interest in resources and the siting of facilities in the coastal zone as identified in the coastal resources program;
14. proximity to, and extent of impacts on, special areas, particular areas, or other areas of particular concern of the state program or local programs;
15. likelihood of, and extent of impacts of, resulting secondary impacts and cumulative impacts;
16. proximity to and extent of impacts on public lands or works, or historic, recreational, or cultural resources;
17. extent of impacts on navigation, fishing, public access, and recreational opportunities;
18. extent of compatibility with natural and cultural setting;
19. extent of long term benefits or adverse impacts.

G. It is the policy of the coastal resources program to avoid the following adverse impacts. To this end, all uses and activities shall be planned, sited, designed, constructed, operated, and maintained to avoid to the maximum extent practicable significant:

2. adverse economic impacts on the locality of the use and affected governmental bodies;
4. alterations in the natural concentration of oxygen in coastal waters;
5. destruction or adverse alterations of streams, wetland, tidal passes, inshore waters and waterbottoms, beaches, dunes, barrier islands, and other natural biologically valuable areas or protective coastal features;
7. alterations of the natural temperature regime of coastal waters;
8. detrimental changes in existing salinity regimes;
10. adverse effects of cumulative impacts;
11. detrimental discharges of suspended solids into coastal waters, including turbidity resulting from dredging;
15. fostering of detrimental secondary impacts in undisturbed or biologically highly productive wetland areas;
16. adverse alteration or destruction of unique or valuable habitats, critical habitat for endangered species, important wildlife or fishery breeding or nursery areas, designated wildlife management or sanctuary areas, or forestlands;
17. adverse alteration or destruction of public parks, shoreline access points, public works, designated recreation areas, scenic rivers, or other areas of public use and concern;
18. adverse disruptions of coastal wildlife and fishery migratory patterns;
19. land loss, erosion, and subsidence;
20. increases in the potential for flood, hurricane and other storm damage, or increases in the likelihood that damage will occur from such hazards;

21. reduction in the long term biological productivity of the coastal ecosystem.

NOAA Regulations at 15 CFR 930.4(a)(2) state that the Federal agency shall modify its project proposal pursuant to the State agency's conditions. The Federal agency shall immediately notify the State agency if the State agency's conditions are not acceptable. Section 930.4(b) states that, if the requirements of §930.4(a)(1) through (3) are not met, all parties shall treat the State agency's conditional concurrence as an objection pursuant to §930 Subpart C.

Finally, pursuant to §930.63(e), your agency has the opportunity to appeal this conditional concurrence/objection to the Secretary of Commerce within 30 days after receipt of this conditional concurrence/objection.

OCM appreciates the opportunities provided by the Galveston District to review this important project. OCM is fully aware of the importance of navigation to this state and the nation and is committed to working together to enable the project to be completed in a manner which does not adversely affect the coastal resources of the state. We anticipate that our participation in future work by the Interagency Coordination Team (ICT) will identify those specific issues which will require detailed assessment by the Corps prior to our final review for consistency with the LCRP.

If you should have any questions on this matter, please contact me at (225) 342-5052.

Sincerely yours,

Gregory J. DuCote

RESPONSE TO COMMENTS

Comment No.	Response
1	USACE does not consider the condition to be acceptable. USACE has concluded that the proposed SNWW CIP is fully consistent to the maximum extent practicable with the enforceable policies of the Louisiana Coastal Resource Program, though LDNR-OCM objects. This agency has gone to great lengths to demonstrate that we have fulfilled these requirements as demonstrated by nearly ten years of coordination with LDNR and LDWF through the SNWW ICT, and extensive studies and modeling described in our letter of March 19, 2010.

Environmental Section

Mr. Gregory J. DuCote
 Administrator
 Interagency Affairs/Field Services Division
 Louisiana Department of Natural Resources
 Office of Coastal Management
 P.O. Box 44487
 Baton Rouge, Louisiana 70804-4487

Dear Mr. DuCote,

Reference is made to your letters dated February 5, 2010 and March 12, 2010 regarding the Sabine-Neches Waterway Channel Improvement Project (SNWW CIP) Draft Feasibility Study and Draft Environmental Impact Statement (DEIS), issued for public and agency review on December 24, 2009. In response to several requests, Galveston District (District) extended the public comment period to March 12, 2010. An Interagency Coordination Team (ICT) comprised of Federal and State resource agency representatives from Texas and Louisiana has assisted Galveston District in modeling and analyzing environmental impacts, and selecting beneficial use (BU) and mitigation measures for the Tentatively Recommended Plan. The Department of Natural Resources (LDNR) has had a representative on the ICT since its inception in 2000 through the last ICT meeting on August 27, 2009. The District has consulted with LDNR (as a member of the ICT) concerning most of the technical issues raised in these letters, and many issues originally approved by LDNR as a member of the ICT are now being reopened. Nevertheless, we would like to work with you in resolving the concerns of the Louisiana Department of Natural Resources, Office of Coastal Management (LDNR-OCM) and the LDNR Office of Coastal Protection and Restoration (OCPR) and offer the following point-by-point response to issues discussed in both letters.

Storm Surge

LDNR asserts that the effects of the deeper shipping channel and the borrow of material from the Gulf Intracoastal Waterway (GIWW) and Sabine Lake may be significant and have not been modeled thoroughly enough to identify all potential impacts. The Coastal Hydraulic Laboratory at the Corps of Engineer's Engineering Research and Development Center (ERDC-CHL) was consulted about the need to model the salinity effect of borrowing material from the GIWW and Sabine Lake relative to salinity impacts. Neither feature was expected to increase salinity impacts and so they were not included in the hydrodynamic salinity (HS) modeling.

ERDC was also consulted on the potential for offshore dredged material disposal sites (ODMDS) to increase wave set-up and erosion on Louisiana shores. In a teleconference on February 5, 2010, ERDC explained to LDNR personnel that the ODMDS sites are located too far from shore and in water too deep to affect the Louisiana shore. Waves of any consequence

present within a few hundred meters of the shoreline are generally depth limited because of the mild nearshore slope and the presence of a soft mud (Pacific International Engineering, 2003, Coastal geomorphology of a non-barrier Gulf of Mexico beach: Analysis for protection of Highway 87 and McFaddin NWR in Jefferson County, Texas). The closest ODMDS (#4) is located between 3.8 and 6 miles from Louisiana in 34-43 ft of water. It is used by the existing project for maintenance dredging of the Sabine Pass Jetty Channel. MDFATE modeling (DEIS Appendix B) has shown that it will accommodate new work and maintenance material from the proposed project with mounding to a maximum of 5 to 7.5 feet at the time of placement. Previous monitoring of this ODMDS and studies of bottom ocean currents in the region have determined that the material would disperse between placement cycles and not accumulate. Therefore the height of material placed in this (and all other) SNWW ODMDS would not affect wave set-up or erosion. Further modeling is not warranted.

ERDC has just completed a sensitivity analysis of potential storm surge impacts from the deeper shipping channel and placement areas (Wamsley, Cialone and McAlpin, 2010, Surge Sensitivity Analysis for Sabine Neches Water Navigation Project, ERDC-CHL). The results of this analysis were also presented to LDNR in the March 3, 2010, teleconference. The analysis clearly and unequivocally identifies no impact to Louisiana from the deflection of storm surges by the higher PA levees or from the deeper navigation channel. Therefore, further modeling to identify impacts is not necessary.

Bar Channel Deepening.

LDNR's assertion that modeling of potential impacts on wave climate was not performed is incorrect. Modeling has been performed by ERDC-CHL as reported by Gravens and King (2003, Shoreline impacts study for Sabine-Neches Project) and this fact was communicated to LDNR in the 2/5/2010 teleconference; a link to the report was emailed to them that same day. The report has been presented on SWG's SNWW webpage since 2003, and it is reported in the DEIS in Section 4.6.2.2. Furthermore, the ERDC modeling report was reviewed and approved by ICT (which included LDNR). The Gravens and King (2003) modeling report addressed the changes in the wave climate that would be produced by a deeper and longer offshore channel, including the Outer Bar Channel, to which we assume the comment relates. In the first two miles east of Sabine Pass, the net eastward transport would be slightly reduced (by a maximum of about 1400 yds³/yr), and further east there would be essentially no change. For a 50 ft project, between a half mile and 3-4 miles of the east jetty, the accretion would decrease by less than 0.5 ft/yr, and further from the jetties than that, the change in the shoreline change would decrease to zero. This small impact would be more than offset by the proposed Gulf Shore beneficial use (BU) feature's regular shoreline nourishment at Louisiana Point.

Salinity

LDNR asserts that the SNWW salinity modeling used questionable assumptions and boundary conditions, and data collected over a short and non-representative time period. Boundary conditions and assumptions were developed by ERDC and coordinated with the ICT in numerous meetings of the ICT and its modeling workgroup from 2000-2004, and the revised HS

modeling presented at the last ICT meeting on August, 27, 2009. While LDNR participated in most of the Modeling Workgroup Meetings, and all prior ICT meetings, no representatives from LDNR attended the last ICT meeting. The ICT presented no objections to the revised modeling at this meeting. The HS modeling (both original and revised) has been subjected to extensive agency technical review (ATR) and Independent External Peer Review (IEPR). ATR identified no significant concerns. The primary IEPR concern related to the need to include the effects of relative sea level rise. This was added in the revised HS Model analysis (Brown and Stokes, 2009, Numerical Model Study of Potential Salinity Impacts Due to Proposed Navigation Improvements to the Sabine-Neches Waterway, Texas, ERDC-CHL).

Borrow Site in Sabine Lake

LDNR lists several types of information that are needed prior to construction. In our February 5, 2010 teleconference, the District stated that we would work with the ICT (which includes LDNR and the Louisiana Department of Wildlife and Fisheries [LDWF]) to obtain all of the information (i.e. geotechnical information on borrow quality, analysis of potential access channels and disposal plans) needed to develop detailed engineering plans during preconstruction, engineering and design (PED). The need for wave climate modeling to support design considerations would be determined at that time. Designs would minimize impacts to the greatest extent possible. The DEIS (Section 5.5.1) fully evaluated potential impacts of the access channels and borrow area and determined that impacts would be minimal and temporary.

LDNR states that mitigation of oyster seed ground impacts must be accomplished to the satisfaction of LDWF. DEIS Section 5.5.1 evaluates the potential impacts by the proposed access route/borrow area. The dedicated dredging would take approximately 3.1 million cubic yards of material from a 1.8-mile-long borrow trench in Sabine Lake. An access channel, approximately 8 miles long, from the GIWW near the mouth of the Sabine River would be needed for the dredge to reach the proposed borrow area. The exact locations of the borrow trench and access channel would be determined in consultation with the ICT after PED bottom surveys of potential locations. The proposed route of the access channel was chosen to keep dredging impacts to a minimum; it takes advantage of deeper water in the center of the lake, thereby minimizing dredging and bottom impacts.

Benthic fauna would be removed when the borrow sediment is excavated; however, benthic organisms can rapidly recolonize and no long-term effects are anticipated. Due to low salinity (1 to 6 parts per thousand [ppt]) in this area of Sabine Lake, live oyster reefs are not likely (Fagerberg, 2003, Field Data Collection Summary Report for the Sabine-Neches Waterway Study, ERDC). A study by T. Baker Smith, Inc. (2006, Oyster Assessment for Proposed Locations, Flow Lines and Facilities to Serve the Ballard Well SL 17131 No. 1 and the MF 102080 Well No. 1, Sabine Lake, Cameron Parish, Louisiana, and Jefferson County, Texas) found no live oyster reefs in this area. Submerged aquatic vegetation (SAV) is not likely to be found in this area due to low salinities and shallow, turbulent water. Nevertheless, as stated in DEIS Section ES.5 and Section 5.5.1 and in our letter dated March 4, 2010 to LDWF, we propose that a water bottom survey of the borrow and access channel areas be conducted after

approval of the Chief of Engineer's report, during the PED phase of the project. In the unlikely event that oyster reef is encountered, plans will be revised to avoid impacts.

LDNR states that mitigation of SAV impacts must be accomplished to the LDWF. In our letter dated March 4, 2010 to LDWF, the District agreed to reevaluate SAV impacts if additional information on potential SAV impacts is provided. To date, no additional information has been provided by LDWF or any other agency. DEIS Appendix C, Section 4.2 describes the Wetland Value Assessment (WVA) modeling of the model variable "Percent Submerged Aquatic Vegetation." The WVA model documentation described in DEIS Appendix C, Section 2.6.1.2, defines SAV as any of the diverse array of floating-leaved and submerged aquatic plants that are typically found in a study area. SAV coverage is included as a model variable because it provides important food and cover to a wide variety of fish and wildlife. The model evaluates the percentage of open water that is dominated by SAV, without consideration as to whether it is native or invasive. The WVA modeling utilized an inventory of SAV species in the study area that was prepared by the District using recent monitoring reports and other available scientific literature. Potential project impacts would be related to the increase in salinity that would occur with deepening of the SNWW navigation channel. As described in DEIS Section 4.2.1, one native and one invasive SAV species out of 10 species present in LA 1 would be affected by the predicted salinity change. It is expected that any SAV cover lost due to the gradual salinity change would be replaced by salinity tolerant SAV species continuing to grow within their tolerance ranges. As a result, no actual impact to percent SAV cover would be expected. The best available scientific information was used to establish salinity ranges for the evaluation; differences in scientific opinion regarding these ranges are readily apparent in the literature. As no new information has yet been provided, we see no reason to revise the WVA modeling at this time.

LDNR asserts that royalty payments and license issues over sediment resources must be resolved with LDWF before the OCM can concur that the final design is consistent, to the maximum extent practicable, with Louisiana Coastal Resources Program. The District maintains that the United States is not bound by Louisiana statute (R.S. 56:2011) pursuant to the Supremacy Clause of the United States Constitution, and that Louisiana is not entitled to compensation under the Fifth Amendment, pursuant to the doctrine of Navigation Servitude. This servitude gives the Federal Government the right to use the "Navigable Waters" of the United States without compensation for navigation projects. The applicability of the Navigation Servitude has been interpreted broadly to include not only traditional navigation projects, such as locks and dams, but also to apply when actions are in furtherance of aesthetic, ecological, environmental, economic or commercial public interests in navigable waterways, United States v. 967,905 Acres in Cook County, 447 F. 2d 764, 771 (8th Cir. Min., 1971). The landmark decision United Transmission Co. v. U.S. Army Corps of Engineers, 772 F. Supp 952 (E.D. Tex., Jul 11, 1991), 7 F. 3d 436 (5th Cir. Tex., Nov 18, 1993, 512 U.S. 1235 (U.S. Jun 27, 1994) Cert. Denied, upheld the Corps' authority to exercise the Navigation Servitude and its "§10 permit authority," as codified in §10 of the Rivers and Harbors Act, 33 U.S.C. §401 et seq., to effect the removal of obstructions to navigation, even though the Federal project was authorized, not for navigation, but for flood control.

Additionally, the State of Louisiana has no compensable interest under the Fifth Amendment, because its interests are subservient to the dominant Navigation Servitude. This is illustrated in a recent case before the United States Court of Appeals, Federal Circuit (July 31, 2009), Northwest Louisiana Fish & Game Preserve Commission v. United States 2009 WL 2341986 (C.A.Fed.) In this case, the State of Louisiana alleged that the U.S. Army Corps of Engineer's construction and operation of the Red River Navigation Project caused a severe hydrilla and coontail infestation in Black/Clear Lake, making some parts of the Lake useless for recreation. The Court held that "the Government's navigational servitude is derived from the principle that all navigable waters in the United States are considered public property, Owen v. United States, 851 F.2d 1404, 1408 (Fed Cir. 1998) (en banc). This court has acknowledged the extraordinary priority given to navigable waters, noting that they are under the 'exclusive control of the federal government.' Id. . . . The dominant servitude defines the limits within which Congress can work to improve navigation without creating an obligation to pay just compensation under the Fifth Amendment." Owen, 851 F.2d at 1408. The Court concluded that "because the Commission's interest is subservient to the Government's dominant servitude, it is not compensable under the Fifth Amendment, 2009 WL 2341986 (C.A.Fed.), p. 5. For the SNWW CIP, an evaluation of the connection between the removal of fill material for the Willow Bayou marsh mitigation areas and the navigation purpose of the underlying project is simple. But for construction of the proposed project, the environmental mitigation and BU marsh restoration would not be necessary.

Borrow Site in GIWW

LDNR lists several types of information that are needed prior to construction. In our February 5, 2010 teleconference, the District stated that we would work with ICT (which includes LDNR) to obtain all of the information (i.e. geotechnical information on sediment suitability and slope stability, and complete an analysis of the "salinity plug" in the GIWW at its intersection with the Sabine River) needed to develop detailed engineering plans. Designs would minimize impacts to the greatest extent possible; instability of emergent shorelines is not anticipated because dredging would remove accumulated maintenance material only, as described in DEIS (Section 5.5.2). In situ sediments beside and below the existing GIWW channel would not be disturbed. However, should analyses determine that stabilization of small areas is needed; the District would propose stabilization plans at that time.

Mitigation

LDNR asserts that details of the proposed mitigation are insufficient to determine whether all potential losses will be adequately compensated. The District disagrees – mitigation site locations have been finalized despite the LDNR assertion to the contrary and conceptual designs are sufficient to support ecological modeling of the compensatory mitigation. In our February 5, 2010 teleconference, the District stated that we would work with the ICT (which includes LDNR) to obtain all of the information needed to develop detailed engineering plans, including geotechnical data relevant to site design, during PED. LDNR was referred to DEIS Appendix J for a description of the mitigation monitoring and contingency plan, which describes the role and responsibilities of the non-Federal sponsor, the Sabine-Neches Navigation District (SNND).

LDNR asserts that the proposed mitigation plan falls “at least 318 Average Annual Habitat Units (AAHUs) short of replacing the anticipated habitat losses to Louisiana” and that additional mitigation will have to be performed in Louisiana to offset this deficit. The District maintains that the proposed mitigation plan would more than compensate for all impacts of the proposed SNWW CIP. Benefits of the BU measures are being used to offset impacts in both Texas and Louisiana. DEIS Table 5.1-2 provides a summary accounting of BU benefits and compensatory mitigation for the proposed project. In Louisiana, the benefits of BU measures offset the loss of 210 average annual habitat units (AAHUs) to private lands along the coast at Louisiana Point, and the loss of 340 AAHUs to Federal land in the Sabine National Wildlife Refuge. Although the net impact of the project as a whole after application of all BU benefits (including significant other BU benefits in Texas) is the loss of 843 AAHUs, the proposed mitigation plan would provide 1,181 AAHUs in order to fully and separately compensate for the loss of 1,499 AAHUs to non-Federal lands in Louisiana. Exclusion of the Federal lands (i.e. the Sabine National Wildlife Refuge) is based upon the definition of “coastal zone” in the Coastal Zone Management Act of 1972, as amended. “Excluded from the coastal zone are lands the use of which is by law subject solely to the discretion of or which is held in trust by the Federal Government, its officers or agents (16 U.S.C. § 1453).” Furthermore, the Louisiana marsh mitigation measures would compensate for the predicted loss of 691 acres in Louisiana over 50 years by the restoration of 2,783 acres of emergent marsh, the improvement of 957 acres of shallow water habitat and the nourishment of 4,355 acres of existing marsh. Since the marsh restoration is several times greater than the predicted marsh loss, there would be no net loss of wetlands.

LDNR also questions the benefits of the Gulf Shore BU feature at Louisiana Point, and asserts that additional mitigation in Louisiana will be required unless acceptable technical justification of the projected benefits is provided. The benefits of the BU feature in Louisiana were established by WVA modeling accomplished by the ICT, of which LDWF and LDNR were a part. The technical justification presented in DEIS Appendix C, Section 8.3.1.2 and WVA modeling were reviewed and accepted by the ICT. The monitoring plan (DEIS Appendix J) would determine if benefits are being reached as predicted.

Pipelines

All pipelines in project construction areas would be identified during PED. Plans for pipeline relocations would also be developed at that time. Costs of pipeline relocations have been included in the economic analysis of potential project benefits. Direct and indirect economic benefits of the proposed deepening will accrue to all users of the SNWW, including the energy industries, and to the regional economy in Louisiana as established by an independent economic analysis (Martin Associates, 2006, Economic Impacts of the Sabine-Neches Waterway and Economic Benefits of Maintenance Dredging of the Waterway). The District’s economic analysis presented in FR Section V.F establishes that there would be a net economic benefit to the country from the proposed project. Minimal impacts to Louisiana industries are anticipated because construction would work around pipeline relocations as needed to accommodate all parties for a safe, effective and minimally disruptive working plan.

Attachment “Office of Coastal Protection and Restoration Master Plan Consistency Comments on Tentatively Recommended Plan for Sabine-Neches Waterway Channel Improvement Project, March 11, 2010.

Many of the comments in this attachment repeat or expand on bulleted comments in the letter. Responses below address comments that were not already addressed by responses to LDNR-OCM comments above.

Master Plan Objective #1

LDNR states that OCPR technical staff have serious concerns about the adequacy of the storm surge modeling of potential impacts to the Louisiana portion of the study area. The storm surge sensitivity analysis of two “worst case” storms ((Wamsley, Cialone and McAlpin, 2010, Surge Sensitivity Analysis for Sabine Neches Water Navigation Project, ERDC-CHL) was provided to LDNR by email on March 2, 2010. The analysis clearly demonstrates that the proposed project would have no impacts in Louisiana, so there is no need to perform the full scale ADCIRC/STWAVE modeling requested by LDNR. This modeling would be needed to fully evaluate impacts, if impacts had been identified. Since none were identified using a worst-case analysis, further modeling is not justified. The sensitivity analysis clearly demonstrates that the proposed SNWW CIP would not contribute to economic losses in Louisiana from storm based flooding to residential, public, industrial and commercial infrastructure, and thus complies with Master Plan Objective # 1.

Master Plan Objective #3

The majority of the LDNR comments under this objective are covered by District responses to the OCM comments. However, the OCPR comment also contains a number of specific questions and assertions regarding the HS salinity modeling, demands for additional salinity modeling, and a demand that the feasibility study include language “indicating that additional adverse salinity impacts to wetlands anticipated as a result of that additional salinity modeling will be fully mitigated at project cost.” The District maintains that the HS modeling (Brown and Stokes, 2009) is technically and scientifically sound and that salinity impacts have been adequately addressed by the DEIS. The District would be happy to arrange for ERDC-CHL to present and discuss details of the modeling effort with your staff at your convenience. The HS model has undergone several technical reviews (by the ICT, the US Army Corps of Engineers Center of Deep Draft Navigation, and an independent peer review by outside academics) and we are confident that it is a technically sound tool for the evaluation of project impacts. With the proper execution of the proposed mitigation plan and BU features, the proposed SNWW CIP would not conflict with Objective #3: “provide habitats suitable to support an array of commercial and recreational activities coast-wide.”

- LDNR asks that USACE provide written assurance that the final mitigation project plans and designs will fully offset project impacts in Louisiana’s coastal wetlands. Additional assurance should not be necessary, as the FEIS and Record of Decision will obligate the

District and non-Federal sponsor to provide the compensatory mitigation described in these documents.

- One of LDNR's assertions relates to the previous HS modeling report (Brown et al., 2006) in which calibration and verification differences were reconciled by "introducing salinity." These problems were resolved by the revised HS modeling (Brown and Stokes, 2009). The LDNR claim that they were not given access to the latest HS modeling report is incorrect. LDNR did not request access to the report and a final version of this report was not available until late February, 2010. A copy of this report is provided with this letter.
- The LDNR comments question issues such as model calibration and verification, the duration and extent of data collection, and the treatment of marshes in the model. ERDC employed a state-of-the-art model to evaluate potential salinity impacts, and the technical adequacy of the HS modeling has been sustained by ATR and IEPR.
- LDNR asserts that "most of the marsh in Louisiana was not modeled." All of affected marsh in Louisiana was modeled, and the ICT (including LDNR representatives) were involved in determining what areas were modeled.
- LDNR asserts that the HS Modeling did not include the actual dredging depth (48 ft plus 2 ft advance maintenance and 2 ft allowable overdepth). This assertion is incorrect. The full 52 ft of potential dredging depth is included in the modeling
- The LDNR asserts that inclusion of predictions of relative sea level rise (RSLR) conditions "tend to muddy the waters" regarding estimated project impacts. Inclusion of RSLR is required to appropriately determine future without project conditions, a requirement of the US Army Corps of Engineers planning process.
- LDNR asserts that Pool 3 in the SNWR must be included in the HS model because breaches to the containment levee caused by Hurricane Ike would result in impacts from the proposed project. In a recent communication with the SNWR and US Fish and Wildlife Service (USFWS) personnel, that agency reports that the only hurricane-caused breach, a 6 to 7 foot opening in the SE corner of Pool 3, was repaired 3 to 4 months ago by an oil company doing work on the SNWR. Two 6-foot wide bays on each of two 14-bay variable crest weir water control structures located in the northwest and eastern containment levees of the Pool are currently left open for fisherman access and rainwater discharge. Salt water intrusion at these locations is not an issue because most of the water flow is discharging out of the Pool and because of the bay's small size (6 feet wide). It is possible for tidal surges from tropical storms or hurricanes to enter the Pool, but on average tides, water can only currently enter via the two 6-foot wide bays per water control structure. These openings are not sufficient to cause salt water intrusion problems in the Pool. There are no current plans for the USFWS to maintain or raise the Pool levees. They have been inspected and future maintenance noted but, to the knowledge of the SNWR manager, the levee maintenance has not been funded.

The major salt water intrusion route to the Pool is from Calcasieu Lake to the east. This is not an issue because the southeast gap has been repaired and the fisherman boat bays are not significant in size (2, 6-foot wide bays). The projected salinity increases from the

SNWW CIP would not be a threat to increasing salinities from the west into the Pool because of its hydrologic isolation. Pool 3 was originally eliminated from the Sabine-Neches project area because it was, and remains, hydrologically isolated from the west via the Pool levees even though it contains two water control structures operated as weirs. The model predicted that net salinity increase caused by the Sabine-Neches project in the hydrologic units surrounding the Pool would be from 0.5 ppt to 1.0 ppt (Southeast Sabine = 0.5 ppt, Southwest Gum Cove = 0.9 ppt, Sabine Lake Ridges brackish marsh = 0.6 ppt, East Johnsons Bayou = 1.0 ppt). These salinity increases would not be likely to cause saltwater intrusion in the Pool under the current scenario of intact levees with 2, 6-foot wide bays opened at each of 2 water control structures. Therefore, Pool 3 remains hydrologically isolated from the Sabine-Neches influence area. Furthermore, USFWS believes that re-doing the Sabine-Neches hydrologic model for this reason is not warranted.

Master Plan Recommendations

The exact location of the proposed borrow trench in Sabine Lake would be determined during PED by the District in consultation with the ICT. It would be sited so as to avoid increasing erosion to the shoreline, and therefore would not result in breaches to the Chenier Plain's bay and lake shorelines. The need for wave climate modeling to support design considerations would be determined in consultation with the ICT during PED.

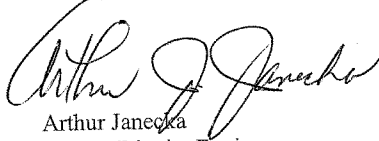

The proposed SNWW CIP would not adversely affect "spoil banks" along the GIWW or the freshwater resources protected by them. Geotechnical investigations during PED would obtain all information needed to evaluate the stability of the emergent GIWW shoreline during proposed borrow activities. If an adverse effect is identified, the borrow activity would be modified to avoid those impacts. Similarly, geotechnical information would be obtained to support the detailed design of the "salinity plug" in the GIWW near the Sabine River.

In conclusion, I hope this additional information will be helpful in resolving your concerns regarding the proposed SNWW CIP and the studies report in the DEIS. The DEIS has provided sufficient information, including numerous scientific analyses and numerical modeling studies, to demonstrate that the proposed DEIS complies with the National Environmental Policy Act and that the proposed SNWW CIP is in compliance, to the maximum extent practicable, with the Coastal Zone Management Act, and other applicable laws and regulations. Several other state and federal agencies have found that the DEIS provides sufficient information for their reviews. The USFWS (letter dated February 5, 2010), National Marine Fisheries Service (letter dated March 8, 2010), Texas Parks and Wildlife Department (letter dated March 11, 2010), and the Environmental Protection Agency (letter dated February 18, 2000) have expressed no outstanding concerns with the proposed project.

If, after review of the information provided herein, your agency still has concerns, I request that you explain how the proposed activity would be inconsistent with the specific enforceable policies (including citations) of your coastal management program, and provide

alternatives, which if adopted would allow the proposed SNWW CIP to proceed in a manner consistent to the maximum extent practicable with the cited enforceable policies. I would like to reiterate that Galveston District has been working through the ICT process with LDNR and 12 other state and Federal agencies for 10 years to perform the appropriate scientific studies and modeling needed to ensure that the proposed project avoids and minimizes environmental impacts to the greatest extent practicable. We stand ready to continue working with ICT during the PED phase to resolve your concerns and develop detailed designs for the Louisiana mitigation measures and BU feature. Please do not hesitate to contact Ms. Janelle Stokes at 409/766-3039 should you need further assistance.

Sincerely,

Arthur Janeczka

REPLY TO
 ATTENTION OF

April 26, 2010

Environmental Section

Mr. Gregory J. DuCote
 Administrator
 Interagency Affairs/Field Services Division
 Louisiana Department of Natural Resources
 Office of Coastal Management
 P.O. Box 44487
 Baton Rouge, Louisiana 70804-4487

Dear Mr. DuCote:

Reference your letter dated March 31, 2010 to Mr. Dolan Dunn of my staff. The letter discusses the Louisiana Coastal Resource Program (LCRP) consistency review of the U.S. Army Corps of Engineers, Galveston District (the District) consistency determination for the Sabine-Neches Waterway Channel Improvement Project (SNWW CIP). The Louisiana Department of Natural Resources, Office of Coastal Management (LDNR-OCM) found that the proposed SNWW CIP is conditionally consistent with the LCRP. The finding requires that USACE submit an additional consistency determination no later than the time at which draft contract plans and specifications are circulated for internal District review.

A requirement of the conditional consistency is the submission of additional detailed information on topics that "would include, but not be limited to, the topics of storm surge, bar channel deepening, salinity, borrow from Sabine Lake, mitigation plans and adequacy, and pipeline relocation." The District has gone to great lengths to coordinate the proposed project and supporting environmental studies addressing these issues with LDNR, as demonstrated by nearly ten years of analysis and coordination with LDNR through the SNWW Interagency Coordination Team. Through this coordination process we have successfully resolved numerous issues raised by the State of Louisiana, State of Texas, and Federal agencies that participated in the review of the project.

The District has evaluated the proposed SNWW CIP for consistency with the LCRP, and has concluded that the Recommended Plan is consistent to the maximum extent practicable with the enforceable policies of Louisiana's coastal management program. Conditional consistency as proposed in your letter is not acceptable, and you

are hereby notified that, in compliance with 15 CFR 930.43 (d) (2), this agency finds that the proposed action is consistent to the maximum extent practicable with the enforceable policies of the Louisiana program, and we will proceed with the project.

Sincerely,

A handwritten signature in black ink, appearing to read "D. C. Weston", with a stylized flourish at the end.

RE: **U. S. Army Corps of Engineers, Galveston District**
Notice of Public Meeting of the Draft Environmental Impact Statement (DEIS)
for Sabine-Neches Waterway Proposed Channel Improvement Project, Southeast
Texas and Southwest Louisiana

Dear Ms. Stokes:

This office has received your December 19, 2009, letter stating that the referenced Draft report was prepared in accordance with the National Environmental Policy Act (NEPA) of 1969, Section 102(2)(c) as amended. This document is presently under public review, with written comments to be postmarked by February 10, 2010. This Department would like to request to extend the comment period an additional 90 days to May 10, 2010, in order for this Office to fully evaluate the project and all appurtenant documentation. It is a large body of information and we are trying to be very diligent and thorough in our review. We are particularly concerned about modeling for storm surges, and salinity, the proposed mitigation for unavoidable impacts to wetland habitats, and the potential impacts to extant energy infrastructure and any potential for disruption of services/delivery of product that Louisiana's industries rely on. A more detailed, though not necessarily complete, list of areas of concern is attached.

Please let us know as early as possible if such a time extension for our comments meets with your approval.

If you have any questions please contact me at 225.342.5052 or
Gregory.ducote@la.gov.

Sincerely yours,

A handwritten signature in dark ink, appearing to read "Gregory J. DuCote".

An Equal Opportunity Employer

Storm Surge:

- Effects of the deeper shipping channel, deeper GIWW, and borrow area in Sabine Lake may be significant and have not been appropriately modeled.
- Upland confined disposal sites on the Texas side of the project may create a barrier to storm surge, redirecting it to Louisiana.
- Offshore disposal sites from the bar channel dredging may create partial barriers to storm currents, potentially increasing set-up on Louisiana shores.

Bar Channel deepening:

- Modeling of potential impacts on wave climate and resulting shoreline impact must be performed.

Salinity:

- Modeling efforts are still under review by staff.
- Existing data from CRMS stations evidently was not used in modeling.
- Input parameters may not have been optimal.

Borrow Site in Sabine Lake:

- Justify the selected floatation access channel route. What alternatives were evaluated?
- Describe the disposal of material removed from the access channel route. Were impacts (e.g., SAVs) evaluated & mitigated?
- Mitigation for SAVs and oyster seed ground impacts is required by LDWF. These must be successfully addressed.
- Effects of excavation on wave climate and potential shoreline erosion should be evaluated.
- Geotechnical information on borrow quality should be collected and evaluated.
- Royalty payments and license issues over sediment resources must be resolved with LDWF.

Mitigation:

- Disposal site design must be presented.
- Geotechnical data for disposal site design must be collected and evaluated.
- Mitigation project lifetime maintenance and repair must be addressed. Who will perform? Can the Local Sponsor (TX) do such work in Louisiana?

GIWW deepening for borrow:

- Geotechnical data must be collected and analyzed for sediment suitability.
- Geotechnical data must be collected and analyzed for slope stability.
- Shoreline stabilization plans must be proposed.
- The design and analysis of the proposed salt water plug must be presented.

Pipelines:

- Plats showing all pipelines affected by the deepening of the navigation channel, GIWW, floatation access channel and borrow site must be provided.
- Discussion of impacts to this energy infrastructure and plan for addressing same
- Impacts to Louisiana industries must be fully evaluated and minimized.

Janelle,

Attached please find the LDWF comment letter on the DEIS for the Sabine-Neches Waterway Improvement Channel Project. Our agency has a Memorandum of Understanding with the LDWF whereby this agency requires that the applicant agree to the specifications included in their official comment letter to us to obtain consistency concurrence with our agency on a given project. Please provide information that you will comply with these LDWF specifications, revise the project to meet these specifications, or work with LDWF to resolve any differences you may have with them that are agreeable to LDWF. LDWF normally informs us when they are in agreement with such resolutions of any differences you may have.

Brian Marcks
 Consistency Analyst
 LDNR/OCM

RE: Consistency Number: C20090667
Applicant: Corps of Engineers - Galveston District
Notice Date: December 28, 2009

Dear Mr. Ducote:

The professional staff of the Louisiana Department of Wildlife and Fisheries (LDWF) has reviewed the Consistency transmittal and preliminary Draft Environmental Impact Statement (EIS) for the Sabine-Neches Waterway Channel Improvement Project. LDWF has also been an active participant on the project Interagency Coordination Team since 2005.

At this time, LDWF has identified several issues that require further consideration by the natural resource and regulatory agencies. These outstanding issues are identified and described in the attached letter, dated October 23, 2009, submitted to Ms. Janelle Stokes.

LDWF requests that you accept this letter and the attached letter as our comments on the proposed project. We believe that each issue shall require thorough consideration and be individually and adequately addressed in the EIS.

The Louisiana Department of Wildlife and Fisheries appreciates the opportunity to review and provide recommendations to you regarding this proposed activity. Please do not hesitate to contact LDWF Permits Coordinator Dave Butler at 225-763-3595 should you need further assistance.

Sincerely,

Jimmy L. Anthony
Assistant Secretary

TEXAS COMMISSION ON ENVIRONMENTAL QUALITY

Protecting Texas by Reducing and Preventing Pollution

April 15, 2010

Ms. Janelle Stokes
 Regional Environmental Specialist
 United States Army Corps of Engineers, Galveston District
 P.O. Box 1229
 Galveston, Texas 77553-1229

Re: General conformity concurrence for the Sabine-Neches Waterway Channel Improvement Project

Dear Ms. Stokes:

This letter provides general conformity concurrence for the proposed Sabine-Neches Waterway Channel Improvement project. The Texas Commission on Environmental Quality (TCEQ) reviewed the project in accordance with Title 40 Code of Federal Regulations Part 93, and Title 30 Texas Administrative Code (TAC) § 101.30 of the TCEQ general rules. The proposed project is located in the Beaumont-Port Arthur (BPA) area and is classified as moderate nonattainment for the 1997 ozone standard, and emissions are expected to be above the 100 tons per year *de minimis* threshold. Therefore, a general conformity analysis is required.

The TCEQ has determined, pursuant to 30 TAC §101.30(h)(1)(E)(i)(I), that emissions from the proposed project will not exceed the emissions from the applicable state implementation plan, the BPA Rate-of-Progress adopted by the TCEQ Commission on October 27, 2004, and approved by the United States Environmental Protection Agency on February 22, 2006. This general conformity determination is based upon information provided in a September 2009 Draft General Conformity Determination prepared for the U.S. Army Corps of Engineers (USACE).

In support of the ozone National Ambient Air Quality Standard, the TCEQ suggests the USACE adopt pollution prevention and/or reduction measures in conjunction with this and future projects, such as the following:

- encourage construction contractors to apply for Texas Emission Reduction Plan grants;
- establish bidding conditions that give preference to clean contractors;
- direct construction contractors to exercise air quality best management practices;
- direct contractors that will use tugboats during construction to use clean fuels;
- direct operators of the assist tugboats used in maneuvering dredge vessels to use clean fuels;
- select assist tugs based on lowest nitrogen oxides (NO_x) emissions instead of lowest price; or
- purchase and permanently retire surplus NO_x offsets prior to commencement of operations.

Ms. Janelle Stokes
Page 2

Thank you for providing the necessary information and staff assistance for our review. We would also appreciate update(s), as appropriate, as this project moves forward. I look forward to working with you in the future on any upcoming projects you may have that affect air quality in your district. If you require further assistance on this matter, please contact Mr. Koy Howard at (512) 239-2306 or kohoward@tceq.state.tx.us.

Sincerely,

TEXAS COMMISSION ON ENVIRONMENTAL QUALITY

Protecting Texas by Reducing and Preventing Pollution

April 19, 2010

Ms. Janelle Stokes
U.S. Army Corps of Engineers
Galveston District CESWG-PE-RE
P.O. Box 1229
Galveston, Texas 77553-1229

Re: Sabine-Neches Waterway Channel Improvement Project §401 Water Quality Certification

Dear Ms. Stokes:

This letter is in response to the United States Army Corps of Engineers – Galveston District (Corps) correspondence dated March 19, 2010, requesting §401 State Water Quality Certification and the Public Notice dated December 18, 2009, on the Sabine Neches Navigation District proposal to deepen and widen the Sabine-Neches Waterway (SNWW). The SNWW Channel Improvement Project (CIP) is located along the Texas and Louisiana border, in Jefferson and Orange counties in southeast Texas and Cameron Parish, Louisiana.

The Texas Commission on Environmental Quality (TCEQ) has reviewed the public notice and related application information provided by the Corps. On behalf of the Executive Director and based on our evaluation of the information contained in these documents, the TCEQ certifies that there is reasonable assurance that the project will be conducted in a way that will not violate Texas surface water quality standards.

The Sabine Neches Navigation District proposes to increase the authorized depth of the channel from 40 to 48 feet along the entire 64-mile-long existing channel and add a 13.2-mile extension to the offshore channels into the Gulf of Mexico. The purpose of the CIP is to improve the transportation efficiency of the SNWW's deep-draft navigation system and support industry at ports within the SNWW navigation channel system.

SNWW CIP proposed mitigation incorporates the Neches River and Gulf Shore Beneficial Use features of the Dredged Material Management Plan (DMMP) and all components of Best Buy Mitigation Plan 6, including emergent marsh restoration in two areas of Willow Bayou (totaling 607 acres) and three areas in the Black Bayou region (totaling 2,096 acres).

Ms. Janelle Stokes
U.S. Army Corps of Engineers
USACE Sabine-Neches Waterway Draft EIS 124121809
Page 2
April 19, 2010

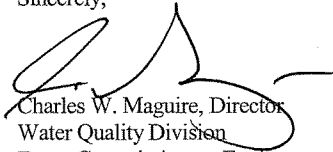

The TCEQ has reviewed this proposed action for consistency with the Texas Coastal Management Program (CMP) goals and policies in accordance with the regulations of the Coastal Coordination Council and has determined that the proposed action is consistent with the applicable CMP goals and policies.

This certification was reviewed for consistency with the CMP's development in critical areas policy {Title 31, Texas Administrative Code (TAC), Chapter (§) 501.23} and dredging and dredged material disposal and placement policy {31 TAC §501.25}. This certification complies with the CMP goals {31 TAC §501.12(1, 2, 3, 5)} applicable to these policies.

No review of property rights, location of property lines, nor the distinction between public and private ownership has been made, and this certification may not be used in any way with regard to questions of ownership.

If you require additional information or further assistance, please contact Mr. Robert Hansen, Water Quality Assessment Section, Water Quality Division (MC-150), at (512) 239-4583.

Sincerely,

A handwritten signature in black ink, appearing to read "Charles W. Maguire", is written over the typed name and title.

Charles W. Maguire, Director
Water Quality Division

Ms. Janelle Stokes
Attachment 1 – Dredge and Fill Certification
USACE – Sabine-Neches Waterway Draft EIS 124121809
Page 1 of 3
April 19, 2010

WORK DESCRIPTION: As described in the public notice dated December 18, 2009, and additional information provided by the Corps, dated March 19, 2010.

SPECIAL CONDITIONS: None

GENERAL: This certification, issued pursuant to the requirements of Title 30, Texas Administrative Code, Chapter 279, is restricted to the work described in the December 18, 2009, Draft Environmental Impact Statement and Draft Feasibility Report. This certification may be extended to any minor revision of the Environmental Impact Statement (EIS) when such change(s) would not result in an impact on water quality. The Texas Commission on Environmental Quality (TCEQ) reserves the right to require full joint public notice on a request for minor revision. The applicant is hereby placed on notice that any activity conducted pursuant to the EIS and COE project authorization which results in a violation of the state's surface water quality standards may result in an enforcement proceeding being initiated by the TCEQ or a successor agency.

STANDARD PROVISIONS: These following provisions attach to any permit or project authorization issued by the COE and shall be followed by the permittee or any employee, agent, contractor, or subcontractor of the permittee during any phase of work authorized by the COE.

1. The water quality of wetlands shall be maintained in accordance with all applicable provisions of the Texas Surface Water Quality Standards including the General, Narrative, and Numerical Criteria.
2. The applicant shall not engage in any activity which will cause surface waters to be toxic to man, aquatic life, or terrestrial life.
3. Permittee shall employ measures to control spills of fuels, lubricants, or any other materials to prevent them from entering a watercourse. All spills shall be promptly reported to the TCEQ by calling the State of Texas Environmental Hotline at 1-800-832-8224.
4. Sanitary wastes shall be retained for disposal in some legal manner. Marinas and similar operations which harbor boats equipped with marine sanitation devices shall provide state/federal permitted treatment facilities or pump out facilities for ultimate transfer to a permitted treatment facility. Additionally, marinas shall display signs in appropriate locations advising boat owners that the discharge of sewage from a marine sanitation device to waters in the state is a violation of state and federal law.
5. Materials resulting from the destruction of existing structures shall be removed from the water or areas adjacent to the water and disposed of in some legal manner.
6. A discharge shall not cause substantial and persistent changes from ambient conditions of turbidity or color. The use of silt screens or other appropriate methods is encouraged to confine suspended particulates.
7. The placement of any material in a watercourse or wetlands shall be avoided and placed there only with the approval of the Corps when no other reasonable alternative is available. If work within a wetland is unavoidable, gouging or rutting of the substrate is prohibited. Heavy equipment shall be placed on mats to protect the substrate from gouging and rutting if necessary.

Ms. Janelle Stokes

Attachment 1 – Dredge and Fill Certification

USACE – Sabine-Neches Waterway Draft EIS 124121809

Page 2 of 3

April 19, 2010

8. Dredged Material Placement: Dredged sediments shall be placed in such a manner as to prevent any sediment runoff onto any adjacent property not owned by the applicant. Liquid runoff from the disposal area shall be retained on-site or shall be filtered and returned to the watercourse from which the dredged materials were removed. Except for material placement authorized by this permit, sediments from the project shall be placed in such a manner as to prevent any sediment runoff into waters in the state, including wetlands.
9. If contaminated spoil that was not anticipated or provided for in the permit application is encountered during dredging, dredging operations shall be immediately terminated and the TCEQ shall be contacted by calling the State of Texas Environmental Hotline at 1-800-832-8224. Dredging activities shall not be resumed until authorized by the Commission.
10. Contaminated water, soil, or any other material shall not be allowed to enter a watercourse. Noncontaminated stormwater from impervious surfaces shall be controlled to prevent the washing of debris into the waterway.
11. Storm water runoff from construction activities that result in a disturbance of one or more acres, or are a part of a common plan of development that will result in the disturbance of one or more acres, must be controlled and authorized under Texas Pollutant Discharge Elimination System (TPDES) general permit TXR150000. A copy of the general permit, application (notice of intent), and additional information is available at: http://www.tceq.state.tx.us/nav/permits/wq_construction.html or by contacting the TCEQ Storm Water & Pretreatment Team at (512) 239-4671.
12. Upon completion of earthwork operations, all temporary fills shall be removed from the watercourse/wetland, and areas disturbed during construction shall be seeded, ripped, or given some other type of protection to minimize subsequent soil erosion. Any fill material shall be clean and of such composition that it will not adversely affect the biological, chemical, or physical properties of the receiving waters.
13. Disturbance to vegetation will be limited to only what is absolutely necessary. After construction, all disturbed areas will be revegetated to approximate the pre-disturbance native plant assemblage.
14. Where the control of weeds, insects, and other undesirable species is deemed necessary by the permittee, control methods which are nontoxic to aquatic life or human health shall be employed when the activity is located in or in close proximity to water, including wetlands.
15. Concentrations of taste and odor producing substances shall not interfere with the production of potable water by reasonable water treatment methods, impart unpalatable flavor to food fish including shellfish, result in offensive odors arising from the water, or otherwise interfere with reasonable use of the water in the state.
16. Surface water shall be essentially free of floating debris and suspended solids that are conducive to producing adverse responses in aquatic organisms, putrescible sludge deposits, or sediment layers which adversely affect benthic biota or any lawful uses.

Ms. Janelle Stokes

Attachment 1 – Dredge and Fill Certification

USACE – Sabine-Neches Waterway Draft EIS 124121809

Page 3 of 3

April 19, 2010

17. Surface waters shall be essentially free of settleable solids conducive to changes in flow characteristics of stream channels or the untimely filling of reservoirs, lakes, and bays.
18. The work of the applicant shall be conducted such that surface waters are maintained in an aesthetically attractive condition and foaming or frothing of a persistent nature is avoided. Surface waters shall be maintained so that oil, grease, or related residue will not produce a visible film of oil or globules of grease on the surface or coat the banks or bottoms of the watercourse.
19. This certification shall not be deemed as fulfilling the applicant's/permittee's responsibility to obtain additional authorization/approval from other local, state, or federal regulatory agencies having special/specific authority to preserve and/or protect resources within the area where the work will occur.

Attention: Janelle Stokes

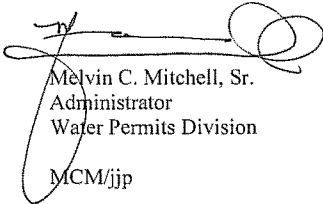

RE: Water Quality Certification (WQC 100330-01/AI 104985/CER 20100001)
Sabine-Neches Waterway Channel Improvements Project
Cameron Parish

Dear Ms. Stokes:

The Louisiana Department of Environmental Quality (the Department) has reviewed your application to dredge waterbottoms and place spoil material for marine vessel access improvements, along Sabine Pass in southwestern Cameron Parish.

Based on the information provided in the application, the Department made a determination that the requirements for a Water Quality Certification have been met and concludes that the placement of the fill material will not violate water quality standards of Louisiana as provided for in LAC 33:IX.Chapter 11. Therefore, the Department hereby issues a Water Quality Certification to the U.S. Army Corps of Engineers- Galveston District.

Sincerely,

Melvin C. Mitchell, Sr.
Administrator
Water Permits Division

Project	Sabine-Neches Waterway Feasibility Study and EIS
Date	July 30, 2002
Invoice Number	02073001

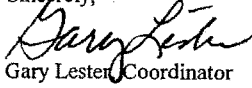

Personnel of the Habitat Section of the Fur and Refuge Division have reviewed the preliminary data for the captioned project. In reviewing our database, many rare, threatened, or endangered species or critical habitats were found within the area of the captioned project that lies in Louisiana. I have attached tables containing the information for these element occurrence records, along with explanations of the data fields. Please refer to the LNHP data utilization agreement for restrictions regarding the use of these data. Element occurrence location information is given as point data and do not reflect the local extent of the occurrence. In addition, the precision of the location information may be limited. Please refer to the precision data field which defines the precision to which the element occurrence as described can be located on a topographic map. Due to the preliminary nature of the request, and the fact that no specific project details were given, the Louisiana Natural Heritage Program is unable to make specific comments concerning the project's impact on these species at this time. It will be necessary for you to contact us as your project progresses and specific project details are available, so that we may make the necessary comments in the future. In addition, please be aware that a manatee (*Trichechus manatus*) was observed in the Sabine River North of the I-10 Bridge in November of 1999. The manatee is listed as endangered on both the federal and state species lists. Your project area is in the Louisiana Department of Wildlife and Fisheries Sabine Island Wildlife Management Area (WMA). Please Contact the WMA Manager John Robinette at 318-491-2575 to coordinate activity. Your project area is in the USFWS Sabine National Wildlife Refuge. Please contact USFWS Wildlife Biologist Diane Borden-Billiot at 318-762-3816 to coordinate activity. Your project area is in the coastal zone. Contact the State of Louisiana Department of Natural Resources Coastal Management Division to determine if a coastal use permit is required. The Sabine Pass Lighthouse State Commemorative Area occurs in your project area. No other state or federal parks, wildlife refuges, scenic streams, or wildlife management areas are known at the specified site within Louisiana's boundaries.

The Louisiana Natural Heritage Program has compiled data on rare, endangered, or otherwise significant plant and animal species, plant communities, and other natural features throughout the state of Louisiana. Heritage reports summarize the existing information known at the time of the request regarding the

An Equal Opportunity Employer

location in question. This report does not address the occurrence of wetlands at the site in question. Heritage reports should not be considered final statements on the biological elements or areas being considered, nor should they be substituted for on-site surveys required for environmental assessments. The Louisiana Natural Heritage Program requires that this office be acknowledged in all reports as the source of all data provided here. If you have any questions or need additional information, please call Louisiana Natural Heritage Program Data Manager Jill Kelly at (225) 765-2643.

Sincerely,

A handwritten signature in cursive script, appearing to read "Gary Lester".

Gary Lester, Coordinator
Natural Heritage Program

LOUISIANA NATURAL HERITAGE PROGRAM (LNHP)

DATA UTILIZATION AGREEMENT

We are pleased to provide you with information on the occurrence of threatened and endangered species. Do to the dynamic nature of the LNHP database and the sensitivity of some of the information however, some precautions are necessary in your use of the information.

Please sign and date below and return this document if you are in agreement with the conditions listed below for utilization of the LNHP database.

This agreement allows Dave Munson of PBS&J, 206 Wild Basin Road, Suite 300, Austin, Texas 78746 use of the LNHP records, at \$20.00 per quad, for the Sabine-Neches Waterway Feasibility Study and EIS. The information supplied by the LNHP shall be used only for this project. As an employee of PBS&J, Dave Munson is authorized to sign this agreement.

PBS&J shall not use computer and hard copy files of LNHP data for any other projects, and PBS&J shall not release any copy of the LNHP data files to another party, without written consent of the LNHP Director.

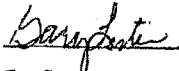

All maps and graphs generated by PBS&J, using information provided by the LNHP shall reference in the legend the LNHP program as the source of the data. All text generated by PBS&J using information provided by the LNHP shall reference on the title or acknowledgement page the LNHP program as the source of the data, and the date the data were provided.

The quantity and quality of data collected by the LNHP are dependent on the research and observations of many individuals. In most cases, this information is not the result of comprehensive or site-specific field surveys; many natural areas in Louisiana have not been surveyed. The LNHP database represents a compilation of information extracted from published and unpublished literature, museums and herbaria, field surveys, personal communications, and other sources. Records for new occurrences of plants and animals are continuously being added to the database and other occurrence records may change as new information is gathered. For these reasons, PBS&J is authorized to use the data for a period of one year from the date the data are received. At that time, PBS&J shall delete all computerized files containing the LNHP data, or enter into another data utilization agreement with the LNHP.

The LNHP cannot provide a definitive statement on the presence, or absence, or condition of biological elements in any part of Louisiana. LNHP reports summarize the existing information known to the LNHP at the time of the request regarding the biological elements or locations in question. They should never be regarded as final statements on the elements or areas being considered, nor should they be substituted for on-site surveys required for environmental assessments.

The LNHP and the State of Louisiana shall not be liable for any damages or loss whatsoever, to any person or legal entity, or property resulting from the use of the data specified here. PBS&J and/or any person or legal entity which receives said information from PBS&J agrees to indemnify and hold harmless the LNHP and the State of Louisiana from and against any and all claims, demands and causes of action of any description in favor of any person for damage or loss whatsoever to persons, legal entities, or property arising from the use of the data specified herein and/or any person or legal entity which receives said information from PBS&J.

Information provided by this database transfer may not be published without prior written approval of the LNHP, and the LNHP must be credited as an information source in these publications.

Louisiana Natural Heritage Program Biological Conservation Database Field Definitions

EOCODE – (Element Occurrence Code) Represents a unique code for each element in the database

LONG – Longitude of the centrum of the element occurrence. Element Occurrence data is given as point information for the centrum of the occurrence, at this time we can not supply information about the local extent of the occurrence.

LAT – Latitude of the centrum of the element occurrence. Element Occurrence data is given as point information for the centrum of the occurrence, at this time we can not supply information about the local extent of the occurrence.

PRECISION - Precision to which the element occurrence as described can be located on a topographic map.

S = Seconds (accuracy of locality mappable within a three-second radius)

M = Minute (within a one minute radius, approximately 2 km or 1.5 miles from centerpoint)

G = general (to quad or place name precision only, precision within about 8 km or 5 miles)

SNAME – (State Name) The appropriate element name recognized in the state using standard scientific binomial (or trinomial) nomenclature

SCOMNAME– (State Common Name) Common name of the element that is recognized at the state level

USESA – (United States Endangered Species Act) Appropriate standard abbreviation for the U.S. federal register category for the element as proposed or determined by the U.S. Fish and Wildlife Service or the National Oceanic and Atmospheric Administration (marine species)

GRANK– (Global Rank) The global element rank which best characterizes the relative rarity or endangerment of the element worldwide.

SRANK – (State Rank) The state element rank which best characterizes the relative rarity or endangerment of the element in the state.

LASTOBS – (Last Observation) Date the element occurrence was last observed extant at this site; not necessarily date site was last visited.

EXPLANATION OF RANKING CATEGORIES EMPLOYED BY NATURAL HERITAGE PROGRAMS NATIONWIDE

Each element is assigned a single global rank as well as a state rank for each state in which it occurs. Global ranking is done under the guidance of NatureServe, Arlington, VA. State ranks are assigned by each state's Natural Heritage Program, thus a rank for a particular element may vary considerably from state to state. Federal ranks are designated by the U.S. Fish & Wildlife Service under the provisions of the Endangered Species Act of 1973.

FEDERAL RANKS (USFWS FIELD):

LE = Listed Endangered

LT = Listed Threatened

PE = Proposed endangered

PT = Proposed Threatened

C = Candidate

PDL = Proposed for delisting

E (S/A) or T (S/A) = Listed endangered or threatened because of similarity of appearance

XE = Essential experimental population

XN = Nonessential experimental population

No Rank = Usually indicates that the taxon does not have any federal status. However, because of potential lag time between publication in the Federal Register and entry in the central databases and state databases, some taxa may have a status which does not yet appear.

(Rank, Rank) = Combination values in parenthesis = The taxon itself is not named in the Federal Register as having U.S. ESA status; however, all of its infraspecific taxa (worldwide) do have official status. The statuses shown in parentheses indicate the statuses that apply to infraspecific taxa or populations within this taxon. *THE SPECIES IS CONSIDERED TO HAVE A COMBINATION STATUS IN LOUISIANA*

(PS) = partial status = Status in only a portion of the species' range. Typically indicated in a "full" species record where an infraspecific taxon or population has U.S. ESA status, but the entire species does not. *THE SPECIES DOES NOT HAVE A STATUS IN LOUISIANA*

(PS, Rank) = partial status = Status in only a portion of the species' range. The value of that status appears because the entry with that status does not have an individual entry in NatureServe. *THE SPECIES MAY HAVE A STATUS IN LOUISIANA*

GLOBAL ELEMENT RANKS:

G1 = critically imperiled globally because of extreme rarity (5 or fewer known extant populations) or because of some factor(s) making it especially vulnerable to extinction

G2 = imperiled globally because of rarity (6 to 20 known extant populations) or because of some factor(s) making it very vulnerable to extinction throughout its range

G3 = either very rare and local throughout its range or found locally (even abundantly at some of its locations) in a restricted range (e.g., a single physiographic region) or because of other factors making it vulnerable to extinction throughout its range (21 to 100 known extant populations)

G4 = apparently secure globally, though it may be quite rare in parts of its range, especially at the periphery (100 to 1000 known extant populations)

G5 = demonstrably secure globally, although it may be quite rare in parts of its range, especially at the periphery (1000+ known extant populations)

GH = of historical occurrence throughout its range; i.e., formerly part of the established biota, with the possibility that it may be rediscovered (e.g., Bachman's Warbler)

GU = possibly in peril range-wide, but status uncertain; need more information

G? = rank uncertain. Or a range (e.g., G3G5) delineates the limits of uncertainty

GQ = uncertain taxonomic status

GX = believed to be extinct throughout its range (e.g., Passenger Pigeon) with virtually no likelihood that it will be rediscovered

T = subspecies or variety rank (e.g., G5T4 applies to a subspecies with a global species rank of G5, but with a subspecies rank of G4)

STATE ELEMENT RANKS:

S1 = critically imperiled in Louisiana because of extreme rarity (5 or fewer known extant populations) or because of some factor(s) making it especially vulnerable to extinction

S2 = imperiled in Louisiana because of rarity (6 to 20 known extant populations) or because of some factor(s) making it very vulnerable to extinction

S3 = rare and local throughout the state or found locally (even abundantly at some of its locations) in a restricted region of the state, or because of other factors making it vulnerable to extinction (21 to 100 known extant populations)

S4 = apparently secure in Louisiana with many occurrences (100 to 1000 known extant populations)

S5 = demonstrably secure in Louisiana (1000+ known extant populations)

(B or N) may be used as qualifier of numeric ranks and indicating whether the occurrence is breeding or nonbreeding)

SA = accidental in Louisiana, including species (usually birds or butterflies) recorded once or twice or only at great intervals hundreds or even thousands of miles outside their usual range

SH = of historical occurrence in Louisiana, but no recent records verified within the last 20 years; formerly part of the established biota, possibly still persisting

SR = reported from Louisiana, but without conclusive evidence to accept or reject the report

SU = possibly in peril in Louisiana, but status uncertain; need more information

SX = believed to be extirpated from Louisiana

SZ = transient species in which no specific consistent area of occurrence is identifiable

September 14, 2004

National Marine Fisheries Service
Southeast Regional Office
Mr. Andreas Mager
9721 Executive Center Drive north
Saint Petersburg, Florida 33702-2449

Dear Mr. Mager,

The U.S. Army Corps of Engineers, with the Jefferson County Navigation District (JCND) as the local sponsor, has proposed a project to widen and deepen the Sabine-Neches Waterway. The Sabine-Neches Waterway (SNWW) is located in Jefferson and Orange counties in Texas and borders Cameron and Calcasieu Parishes in southwest Louisiana. The project area includes the SNWW from the Gulf of Mexico through the jettied channel at Sabine Pass, through the Port Arthur Canal, Sabine-Neches Canal, and Neches River Channel to the Port of Beaumont, including an additional 17 miles of new channel extending beyond the end of the existing channel into the Gulf of Mexico. The Sabine Channel, that extends from Sabine Lake to the Port of Orange is not being considered for channel modification.

The study area is larger than the project area due to potential environmental affects and has been developed through consultation with the project Interagency Coordination Team (ICT). The study area is illustrated on the attached map.

PBS&J is currently developing the Biological Assessment (BA) for the proposed project and thereby is requesting your office provide any information regarding federally protected species within the study area. Your comments will be an important consideration in the development of the BA and in the assessment of potential project impacts.

PBS&J looks forward to receiving information from your office and appreciates your time and effort required in responding to this request. Please contact Mike Horvath or me at 512 327-6840 if you have any questions or require additional study area information.

Sincerely,

The U.S. Army Corps of Engineers, with the Jefferson County Navigation District (JCND) as the local sponsor, has proposed a project to widen and deepen the Sabine-Neches Waterway. The Sabine-Neches Waterway (SNWW) is located in Jefferson and Orange counties in Texas and borders Cameron and Calcasieu Parishes in southwest Louisiana. The project area includes the SNWW from the Gulf of Mexico through the jettied channel at Sabine Pass, through the Port Arthur Canal, Sabine-Neches Canal, and Neches River Channel to the Port of Beaumont, including an additional 17 miles of new channel extending beyond the end of the existing channel into the Gulf of Mexico. The Sabine Channel, that extends from Sabine Lake to the Port of Orange is not being considered for channel modification.

The study area is larger than the project area due to potential environmental affects and has been developed through consultation with the project Interagency Coordination Team (ICT). The study area is illustrated on the attached map.

PBS&J is currently developing the Biological Assessment (BA) for the proposed project and thereby is requesting your office provide any information regarding state protected species within the study area. Your office (Mr. Gary Lester) initially responded to our data request in 2002 (attached), however, we are currently updating our agency contacts. Please provide written response since your comments will be an important consideration in the development of the BA and in the assessment of potential project impacts. If there has been no change since your 2002 response, please let us know and we will utilize your earlier information.

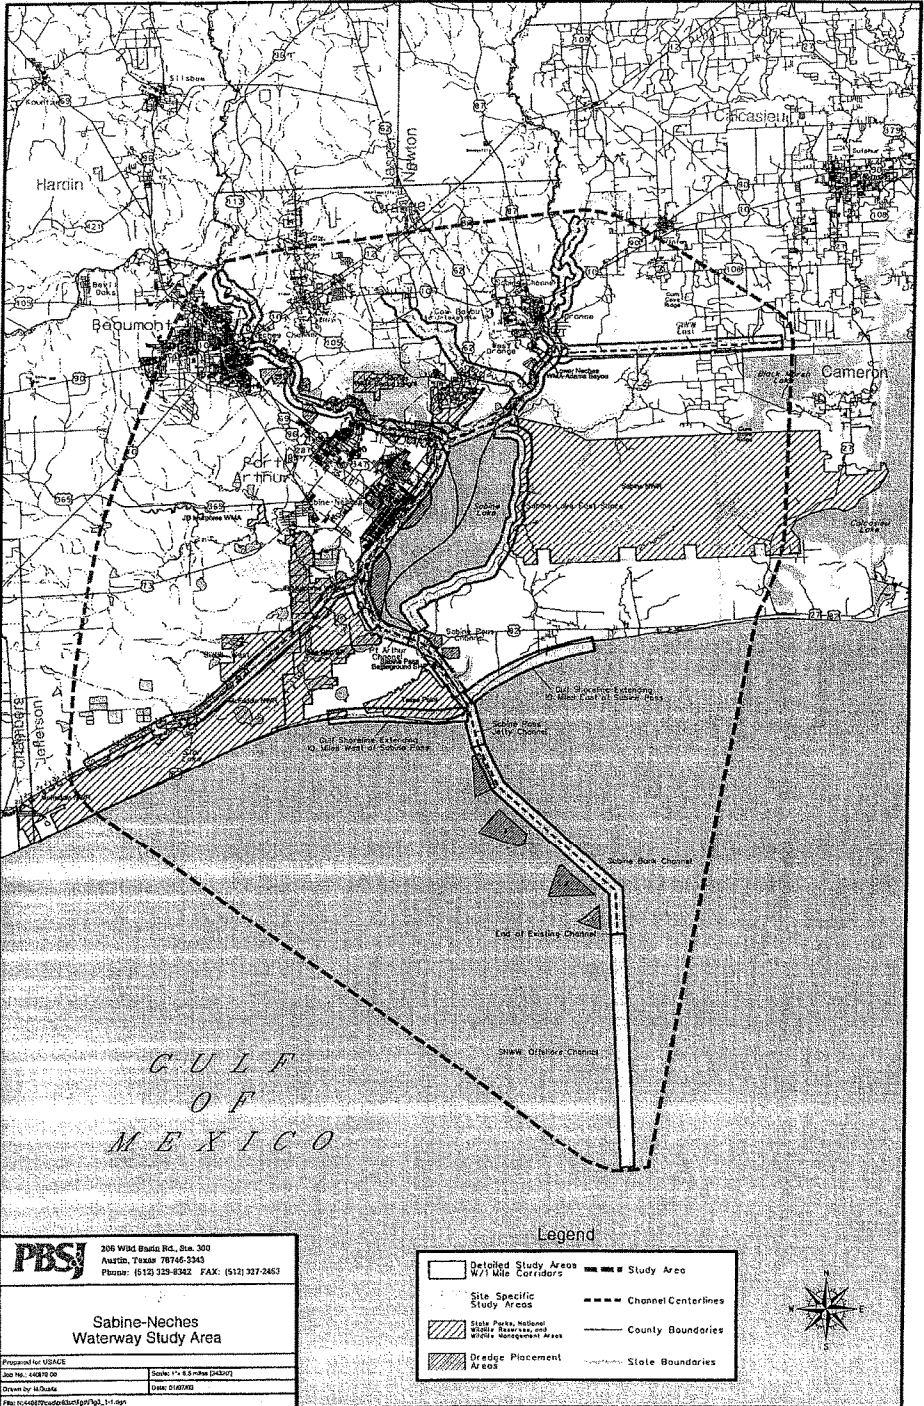

PBS&J looks forward to receiving information from your office and appreciates your time and effort required in responding to this request. Please contact Mike Horvath or me at 512 327-6840 if you have any questions or require additional study area information.

Sincerely,

A handwritten signature in dark ink, appearing to read 'Martin Arhelger'.

Austin, Texas 78730

Dear Mr. Arhelger:

Please reference your September 14, 2004, letter requesting information regarding threatened and endangered species that may occur within the proposed study area for the Sabine-Neches Waterway (SNWW) project. The U.S. Army Corps of Engineers (Corps) has proposed to widen and deepen the SNWW bordering Jefferson and Orange Counties in Texas, and Calcasieu and Cameron Parishes in Louisiana. The proposed project area would include the SNWW from the Gulf of Mexico, passing through the jettied channel at Sabine Pass, the Port Arthur Canal, Sabine-Neches Canal, and Neches River Channel to the Port of Beaumont, and an additional 17 miles of new channel extending beyond the end of the existing channel into the Gulf of Mexico. The U.S. Fish and Wildlife Service's (Service) Lafayette, Louisiana, Field Office has reviewed the information provided, and offers the following comments on the Louisiana-portion of the proposed project, in accordance with provisions of the Endangered Species Act (ESA) of 1973 (87 Stat. 884, as amended; 16 U.S.C. 1531 et seq.), and the Migratory Bird Treaty Act (MBTA; 40 Stat. 755, as amended; 16 U.S.C. 703 et seq.). For information regarding Federal-trust resources in Texas, please contact the Service's Houston, Texas, (i.e., Clear Lake) Field Office (17629 El Camino Real, Suite 211, Houston, TX 77058-3051, phone: 281-286-8282).

West Indian manatees (*Trichechus manatus*) may rarely occur along the Gulf coast in southwestern Louisiana during the summer months (i.e., June through September). They have declined in numbers due to collisions with boats and barges, entrapment in flood control structures, poaching, habitat loss, and pollution. Cold weather and outbreaks of red tide may also adversely affect these animals.

Bald eagles (*Haliaeetus leucocephalus*) nest in Louisiana from October through mid-May. Although we are not aware of active eagle nests within the proposed project area, there is an inactive nest located on the east side of the Sabine River and south of Interstate Highway 10; nests that are not currently listed in our database may also be present within areas containing suitable habitat. Eagles typically nest in bald cypress trees near fresh to intermediate marshes or open water. Major threats to this species include habitat alteration, human disturbance, and environmental contaminants (i.e., organochlorine pesticides and lead).

Bald eagles usually return to the same nest year after year, but they may also use alternate nests in the same general vicinity in different years. Bald eagles are most vulnerable to disturbance during courtship, nest building, egg laying, incubation and brooding (roughly the first 12 weeks of the nesting cycle). Disturbance during this critical period may lead to nest abandonment, cracked and chilled eggs, and exposure of small young to the elements. Human activity near a nest late in the nesting cycle may also cause flightless birds to jump from the nest tree, thus lessening their chance of survival. Should the proposed project or associated work activities encroach within 1,500 feet of an eagle nest during the nesting season (October through mid-May), further ESA consultation with this office will be necessary. We further caution that the proposed activity should not damage any portion of the eagle nest trees, including their root systems (i.e., through soil compaction or disturbance).

Federally listed as endangered, brown pelicans (*Pelecanus occidentalis*) feed along the southwestern Louisiana coast in shallow estuarine waters, using sand spits and offshore sand bars as rest and roost areas. Major threats to this species include chemical pollutants, colony site erosion, disease, and human disturbance. Should you determine that the proposed project may directly or indirectly affect brown pelicans, further ESA consultation with this office will be necessary.

Federally listed as threatened, the piping plover (*Charadrius melodus*), as well as its designated critical habitat, occur along the southwestern Louisiana coast. Piping plovers winter in Louisiana, and may be present for 8 to 10 months. They arrive from the breeding grounds as early as late July and remain until late March or April. Piping plovers feed extensively on intertidal beaches, mudflats, sand flats, algal flats, and wash-over passes with no or very sparse emergent vegetation; they also require unvegetated or sparsely vegetated areas for roosting. Roosting areas may have debris, detritus, or micro-topographic relief offering refuge to plovers from high winds and cold weather. In most areas, wintering piping plovers are dependent on a mosaic of sites distributed throughout the landscape, because the suitability of a particular site for foraging or roosting is dependant on local weather and tidal conditions. Plovers move among sites as environmental conditions change.

On July 10, 2001, the U.S. Fish and Wildlife Service designated critical habitat for wintering piping plovers. In Louisiana, the proposed project would be located adjacent to Unit LA-1, a unit which includes "... the land from the seaward boundary of mean low low water to where densely vegetated habitat, not used by the piping plover, begins and where the constituent elements no longer occur. . ." (50 CFR Part 17, Volume 66, No. 132, Page 36127). Designated critical habitat identifies specific areas that are essential to the conservation of the species. The primary constituent elements for piping plover wintering habitat are those habitat components that support foraging, roosting, and sheltering and the physical features necessary for maintaining the natural processes that support those habitat components. Constituent elements are found in geologically dynamic coastal areas that contain intertidal beaches and flats (between annual low tide and annual high tide), and associated dune systems and flats above annual high tide. Important components (or primary constituent elements) of intertidal flats include sand and/or mud flats with no or very sparse emergent vegetation. Adjacent unvegetated or sparsely vegetated sand, mud, or algal flats above high tide are also important, especially for roosting plovers. Major threats to this species include the loss and degradation of habitat due to

development, disturbance by humans and pets, and predation. Should you determine that the proposed project may directly or indirectly affect the piping plover or its critical habitat, further ESA consultation with this office will be necessary.

Endangered and threatened sea turtles forage in the near-shore waters, bays and sounds of southwestern Louisiana. The National Marine Fisheries Service (NMFS) is responsible for aquatic marine threatened or endangered species. Please contact Mr. Eric Hawk (727/570-5312) in St. Petersburg, Florida, for information concerning those species in the aquatic environment.

The proposed project area may encompass areas containing suitable nesting habitat for colonial wading birds. Colonies that are not currently listed in the database maintained by the Louisiana Department of Wildlife and Fisheries may also be present. That database is updated primarily by monitoring the colony sites that were previously surveyed during the 1980s. Until a new, comprehensive coast-wide survey is conducted to determine the location of newly-established nesting colonies, we recommend that a qualified biologist inspect the proposed project area for the presence of undocumented nesting colonies during the nesting season. To minimize disturbance to colonial nesting birds, the following restrictions on activity should be observed:

1. For colonies containing nesting wading birds (i.e., herons, egrets, night-herons, ibis, and roseate spoonbills), anhingas, and/or cormorants, all activity occurring within 1,000 feet of a rookery should be restricted to the non-nesting period (i.e., September 1 through February 15, depending on species present).
2. For colonies containing nesting gulls, terns, and/or black skimmers, all activity occurring within 650 feet of a rookery should be restricted to the non-nesting period (i.e., September 16 through April 1, depending on species present).
3. We recommend that on-site contract personnel be informed of the need to identify colonial nesting birds and avoid impacting them during the breeding season.

The Service's Sabine National Wildlife Refuge (NWR) is located along the eastern bank of the Sabine Lake. Please be aware that the National Wildlife Refuge System Improvement Act of 1997 (16 U.S.C. 668dd through 668ee) requires that activities on NWRs must be compatible with NWR purposes. Please contact the Sabine NWR Manager at 337/762-3816 for additional information, and to ascertain the need for a NWR Special Use Permit for that portion of the proposed project.

The proposed project may also affect the Black Bayou Hydrologic Restoration (CS-27), Gulf Intracoastal Waterway – Perry Ridge West Bank Stabilization (CS-30), and East Sabine Lake Hydrologic Restoration (CS-32) Projects. Those projects are authorized by the Coastal Wetlands Planning, Protection, and Restoration Act (CWPPRA). The Service recommends avoiding direct impacts to specific project features (e.g., canal plugs, rock dikes, levees, water control structures, diversion canals, etc.). The exact locations of specific project features may be obtained at <http://www.lacoast.gov/projects/list.asp>, which contains detailed information on those CWPPRA projects. Please be aware that Section 303(d) of CWPPRA requires that all Federal activities be

consistent with the purposes of that Act and take into account the need to protect the public investment in the above-listed CWPPRA projects.

We appreciate the opportunity to provide comments during the early planning stages of the proposed action. If you have any questions or require further information on the Louisiana portion of the proposed project, please contact Brigitte Firmin (337/291-3108) of this office.

Sincerely,

David M. Bernhart
Assistant RA for Protected Resources
Southeast Regional Office
National Marine Fisheries Service
263 13th Avenue South
St. Petersburg, FL 33701

Dear Mr. Bernhart:

This letter is in regard to a proposed Federal project for the widening and deepening of the Sabine-Neches Waterway (SNWW) in Jefferson and Orange Counties, Texas, and Cameron Parish, Louisiana. The Galveston District is currently preparing a draft feasibility report and environmental impact statement which recommends enlargement of the existing navigation project to a proposed 48 x 700 foot channel.

We have prepared a Biological Assessment (BA) for the proposed work as both listed species and critical habitat are located within the affected area. A description of the proposed project is provided in the BA. We have concluded that the proposed project is likely to adversely affect the federally-listed endangered loggerhead, Kemp's ridley, and hawksbill sea turtles, and threatened green sea turtles. The proposed project will have no effect on federally-listed endangered whales and West Indian manatee, or the threatened Gulf sturgeon. The proposed project will have no affect on critical habitat.

Since the proposed project may affect federally-listed species, we request initiation of formal consultation pursuant to 50 CFR 402.14, to evaluate the effects of the proposed project on threatened and endangered sea turtles. In accordance with Section 402.14(g)(5), we also request that a draft copy of the biological opinion be furnished.

We appreciate your continued cooperation in allowing us to fulfill our responsibilities under the Endangered Species Act. Should you require any additional information during review of the enclosed BA, please call Ms. Janelle Stokes at 409/766-3039.

Sincerely,

Carolyn Murphy

Field Supervisor
U.S. Fish and Wildlife Service
Clear Lake Ecological Services Field Office
17629 El Camino Real, Suite 211
Houston, Texas 77058

Dear Mr. Parris:

This letter is in regard to a proposed Federal project for the widening and deepening of the Sabine-Neches Waterway (SNWW) in Jefferson and Orange counties, Texas, and Cameron Parish, Louisiana. The Galveston District is currently preparing a draft feasibility report and environmental impact statement which recommends enlargement of the existing navigation project to a proposed 48 x 700 foot channel.

We have prepared a Biological Assessment (BA) for the proposed work as both listed species and critical habitat are located within the affected area. A description of the proposed project is provided in the BA. We have concluded that the proposed project is not likely to adversely affect the federally-listed, endangered piping plover and its designated critical habitat at Louisiana Point, Louisiana. The piping plover and its critical habitat will experience a beneficial effect from the proposed project resulting from habitat enhancement (i.e., shoreline nourishment) through the beneficial use of dredged material. The proposed project will have no effect on the federally-listed, endangered brown pelican. No other federally-listed species are likely to occur, and no other designated critical habitat is located in the project area.

We are hereby requesting your written concurrence, pursuant to the informal consultation procedures prescribed in 50 CFR 402.13, that the proposed action is not likely to adversely effect federally-listed species or designated critical habitat. We appreciate your continued cooperation in allowing us to fulfill our responsibilities under the Endangered Species Act. Should you require any additional information during review of the enclosed BA, please call Ms. Janelle Stokes at 409/766-3039.

Sincerely,

Carolyn Murphy

March 20, 2007

Carolyn Murphy
Chief, Environmental Section
Department of the Army
Galveston District, Corps of Engineers
P. O. Box 1229
Galveston, TX 77553-1229

Dear Ms. Murphy:

This responds to your letter of February 21, 2007, regarding a proposed Federal project to widen and deepen the Sabine-Neches Waterway (SNWW) in Jefferson and Orange counties in Texas, and Cameron Parish in Louisiana. These comments apply only to the proposed project within the borders of the State of Texas.

The proposed project includes deepening the Sabine Pass Jetty Channel, the Sabine Pass Channel, Port Arthur Canal, Sabine-Neches Canal, and the Neches River Channel to the Port of Beaumont from 40 to 48 feet; deepening the SNWW Entrance Channel in the Gulf from 42 to 50 feet; widening the Sabine Pass Jetty Channel, the Sabine Pass Channel, and the Port Arthur Canal to the junction with Taylors Bayou from 500 to 700 feet; deepening the Taylors Bayou Navigation Channel and turning basins to 48 feet; dredging two new anchorage basins, two new turning basins, and three turning and anchorage basins on the Neches River Channel. As mitigation, the Dredged Material Management Plan (DMMP) will include the use of dredged material to restore three degraded marsh areas on the Neches River (Rose City, Bessie Heights, and Old River Cove); restore six degraded marsh areas near Willow and Black Bayous, Louisiana; and nourish Gulf shorelines at Texas and Louisiana Points to create new saline marsh along a 3-mile stretch of shore.

The Biological Assessment indicates that a 2006 survey along the proposed shore nourishment areas found no suitable habitat for piping plovers on the Texas side. Placement of dredged material on an eroding bank should create suitable habitat where none currently exists, resulting in a beneficial effect for the species. Therefore, we concur that the proposed project may affect but is not likely to adversely affect the piping plover.

Although the brown pelican is a year-round resident along the upper Texas coast, including Jefferson and Orange counties, no active nesting sites are known to occur in the vicinity of the

**TAKE PRIDE
IN AMERICA**

proposed project. Therefore, we concur that the project is not likely to adversely affect the brown pelican.

The Biological Assessment indicates that, as of 2003, no bald eagle nests were known to exist in Jefferson or Orange Counties. Two nesting territories have since been discovered in Orange County, but neither is in the immediate vicinity of the project area. The number of bald eagles nesting in Texas is increasing and often the locations of their nests are not known. Since bald eagles often nest and forage on river channels and reservoirs, steps should be taken to determine whether bald eagles may be nesting within or near the project area. These steps may include talking to local landowners and/or lessees about bald eagle sightings and surveying suitable habitat during the nesting season for bald eagles and their nests.

These comments are provided in accordance with Section 7 of the Endangered Species Act (87 stat. 884 as amended; 16 U.S.C. 1531 et seq.). If the project changes or additional information on the distribution of listed or proposed species becomes available, the project should be reanalyzed for effects not previously considered.

If you have any questions, or if we can be of further assistance, please call Kathy Nemec of my staff at 281/286-8282.

Sincerely,

A handwritten signature in black ink that reads "Stephen D. Parris". The signature is fluid and cursive, with the first letters of the first and last names being capitalized and prominent.

March 22, 2007

Ms. Carolyn Murphy
Chief, Environmental Section
U.S. Army Corps of Engineers
Post Office Box 1229
Galveston, Texas 77553-1229

Dear Ms. Murphy:

Please reference your February 21, 2007, letter requesting: (1) our review of the U.S. Army Corps of Engineers' (Corps) biological assessment (BA) of the Sabine-Neches Waterway (SNWW) Channel Improvements project, and (2) our concurrence with the Corps' determination that the proposed project is not likely to adversely affect the threatened Louisiana black bear (*Ursus americanus luteolus*), endangered West Indian manatee (*Trichechus manatus*), endangered brown pelican (*Pelecanus occidentalis*), endangered interior least tern (*Sterna antillarum*), endangered red-cockaded woodpecker (RCW, *Picoides borealis*), threatened bald eagle (*Haliaeetus leucocephalus*), and threatened piping plover (*Charadrius melodus*) and its designated critical habitat. The proposed SNWW project would be located in Jefferson and Orange Counties, Texas, and Cameron Parish, Louisiana.

The U.S. Fish and Wildlife Service's (Service) Lafayette, Louisiana, Field Office has reviewed the information you provided, and offers the following comments on the Louisiana portion of the proposed project only, in accordance with provisions of the Endangered Species Act (ESA) of 1973 (87 Stat. 884, as amended; 16 U.S.C. 1531 et seq.). Please note that the Service's Houston, Texas, (i.e., Clear Lake) Field Office (17629 El Camino Real, Suite 211, Houston, TX 77058-3051, phone: 281-286-8282) is the lead Service point of contact for the proposed project, and should be contacted for information concerning Federal trust fish and wildlife resources within the Texas portion of the proposed project.

According to the BA, the proposed SNWW project would involve:

1. deepening the Sabine Pass Jetty Channel, the Sabine Pass Channel, the Port Arthur Canal, the Sabine-Neches Canal, and the Neches River Channel to the port of Beaumont from 40 to 48 feet;
2. deepening the existing SNWW Entrance Channel in the Gulf of Mexico from 42 to 50 feet, plus advance maintenance and allowable over-depth, and constructing a 13.1-mile-long extension of the offshore entrance channel;
3. widening the Sabine Pass Jetty Channel, the Sabine Pass Channel, and the Port Arthur Canal to its junction with Taylors Bayou from 500 to 700 feet;

4. bending easings in three areas on the Sabine-Neches Canal and three areas on the Neches River Channel;
5. deepening the Taylors Bayou Navigation Channel and turning basins to 48 feet, and widening the entrance and connecting channels to improve vessel maneuverability;
6. dredging two new anchorage basins, two new turning basins, and three turning and anchorage basins on the Neches River Channel, as well as reducing the existing Sabine Pass anchorage basin in size by approximately 50 percent;
7. beneficially using dredged material to restore three degraded marsh areas on the Neches River and nourish Gulf shorelines at Texas and Louisiana Points;
8. restoring six degraded marsh areas near Willow and Black Bayous, Louisiana;
9. adding four new Ocean Dredged Material Disposal sites in the Gulf along the 13-mile-long channel extension; and,
10. using 16 existing upland placement areas and two new expansions of existing placement areas for construction and maintenance of the proposed project.

Dredging in the Sabine Pass Jetty Channel would be conducted by a hopper dredge, while the remaining inshore channels would be constructed with hydraulic pipeline dredges. Direct project effects are those associated with navigation channel improvements and the placement of dredged material, including impacts to benthic organisms and their Gulf, estuarine, and riverine water-bottom habitats; dredging impacts to bottom-feeding and pelagic organisms (e.g., sea turtles); impacts to marshes and upland habitats from the enlargement of placement areas; and, impacts to shorebirds (e.g., brown pelican, piping plover) and their habitat from the regular placement of maintenance material on the Gulf shoreline. Indirect project effects are an anticipated increase in salinity and the projected loss of 716 acres of tidal marsh resulting from its conversion to open water. The Corps does not anticipate any effects to federally listed species as a result of salinity increases or marsh loss.

According to the BA, beneficially using dredged material to nourish a 3-mile-long portion (mile 0.5 to 3.5) of the Gulf shoreline would result in beach nourishment at Louisiana Point every 6 years (i.e., each 3-year dredging cycle would alternate between Texas and Louisiana Points). The material would average 51 percent silt, 31 percent clay, and 18 percent sand, and would be hydraulically pumped via a pipeline into the nearshore zone, such that some material is expected to flow over existing marsh and shoreline while the remainder flows into the nearshore waters. Marsh planting would occur as soon as possible on the inland portion of the emergent berm to assist stabilization of the material. Based on past experience with similar projects, the Corps expects that dredged material will dissipate quickly during a placement event, with 60 percent remaining to form a shelf on the shallow nearshore slope in front of the existing marsh edge. Since the material would be unconsolidated and is prone to erosion, the Corps estimates that 50 percent of the material that remains after each placement event would erode away by the end of

the 6-year cycle. Over the 50-year life of the project, however, beach nourishment activities using maintenance dredging material from the Sabine Pass Channel would result in the creation of new saline marsh and beach habitat at Louisiana Point. Because of natural erosional processes along Louisiana Point and the dynamic coastal/beach system, it is difficult to estimate how many acres of marsh and beach habitat would be created over the life of the project.

The Corps has determined that the proposed SNWW project would not affect the Louisiana black bear, interior least tern, RCW, or bald eagle because those species are unlikely to occur in the project area due to lack of suitable habitat. According to our records, the Service confirms that we do not have records of those species occurring within the proposed project areas in Louisiana; therefore, we concur with the Corps' determination that the proposed project would not affect those species. In addition, our records indicate that the West Indian manatee rarely occurs along the southwestern portion of the Louisiana Gulf coast; therefore, we also concur with the Corps' determination that the proposed project is not likely to adversely affect that species. Specific comments regarding project-related effects to the brown pelican and the piping plover, as well as its designated critical habitat, are discussed below.

Louisiana Point is the southwestern tip of the Louisiana Gulf coast shoreline. It is an uninhabited mixture of marsh and beach shoreline. The area has been heavily eroded by natural processes due to increasing tidal prism, insufficient volumes of sediment supplied by littoral currents, land subsidence, and sea-level rise (Boesch 1982). Although increases in the tidal prism may be primarily responsible for enlargement of tidal passes, the insufficient supply of sand available to rebuild eroded areas has also contributed to increased tidal pass widths and shoreline retreat (Louisiana Coastal Wetlands Conservation and Restoration Task Force and the Wetlands Conservation and Restoration Authority 1999). Where insufficient supplies of sand prevail, measures to maximize sand retention, such as sand fencing and vegetative planting, are needed to effectively rebuild and maintain these eroded areas.

According to the BA, Louisiana Point currently consists of an eroded shoreline that extends for approximately 2 miles from the east jetty. A sandy beach, varying from 50 to 300 feet in width, begins approximately 2 miles east of the east jetty and extends east beyond the proposed beach nourishment project area. Shoreward of the beach is an eroded shoreline with occasional flats containing extensive stands of dense vegetation. A 1.65-mile-long tidal sand/mudflat is located approximately 1,500 feet offshore of Louisiana Point at its western end, and extends such that it gradually meets the shoreline at its eastern end. A 1-mile-long offshore sand bar that extends from 4,200 feet offshore at its western end to 1,200 feet offshore at its eastern end is also located offshore of Louisiana Point.

As you know, brown pelicans feed in shallow estuarine waters, and use sand spits and offshore sand bars as rest and roost areas. Brown pelicans are currently known to nest on Rabbit Island in Calcasieu Lake in southwestern Louisiana. Although no brown pelican nesting sites are known to occur within the proposed project area, they may occasionally use those portions of the proposed project area that contain suitable habitat (e.g., Sabine Pass Channel, Louisiana Point) for feeding and/or loafing. Any pelicans that may be feeding or loafing in the project area during construction (and future maintenance dredging activities) are likely to be temporarily displaced to nearby suitable habitat, but they would not be permanently excluded from using the project

area. Based on that information, the Service concurs with your determination that the proposed project is not likely to adversely affect the brown pelican.

The threatened piping plover, as well as its designated critical habitat, occur within the beach nourishment portion of the proposed project area. Piping plovers winter in Louisiana, and may be present for 8 to 10 months annually. They arrive from the breeding grounds as early as late July and remain until late March or April. Piping plovers feed extensively on intertidal beaches, mudflats, sand flats, algal flats, and wash-over passes with no or very sparse emergent vegetation; they also require unvegetated or sparsely vegetated areas for roosting. Roosting areas may have debris, detritus, or micro-topographic relief offering refuge to plovers from high winds and cold weather. In most areas, wintering piping plovers are dependent on a mosaic of sites distributed throughout the landscape, because the suitability of a particular site for foraging or roosting is dependant on local weather and tidal conditions. Plovers move among sites as environmental conditions change, and studies have indicated that they generally remain within a 2-mile-long area.

According to the BA, the Corps would initially require approximately 4.75 years to complete the entire proposed project, with several contractors working simultaneously, and maintenance dredging would occur every 3 years following completion of the initial project features. The beach nourishment portion of the proposed project would temporarily affect approximately 1.5 miles of sandy beach on the Gulf shoreline, and it is the only feature that has the potential to affect piping plovers. Because plovers may be present in the project area for 8 to 10 months on an annual basis, the initial beach nourishment event (and subsequent events every 6 years) would likely occur when wintering piping plovers are present and utilizing suitable habitat at Louisiana Point. According to the BA, an offshore sand bar and an offshore sand/mudflat located less than 1 mile from the proposed beach nourishment area contain suitable piping plover habitat. Suitable piping plover habitat also exists along the Gulf shoreline adjacent to the beach nourishment project area. Although studies indicate that wintering piping plovers generally remain within a 2-mile-long area, sufficient roosting and foraging habitat would be available for them to disperse into on those offshore features or the adjacent shoreline during construction activities and future maintenance dredging. Such disturbance would be temporary in nature and would not permanently exclude piping plovers from utilizing the nearby habitats or the project area. In addition, the proposed project would result in creation of additional suitable habitat (i.e., beach habitat) over the 50-year life of the project. Furthermore, construction activities would also have no long-term effect on the existing water quality conditions within the proposed project areas because any increase in turbidity from dredging and placement of material on/near the shoreline would be temporary in nature, and the site would return to normal turbidity levels shortly after construction is complete. Based on that information, the Service also concurs with the Corps' determination that the proposed project is not likely to adversely affect the piping plover.

On July 10, 2001, the Service designated 137 areas along the coasts of North Carolina, South Carolina, Georgia, Florida, Alabama, Mississippi, Louisiana, and Texas as critical habitat for wintering piping plovers (66 FR, No. 132). Those areas consist of approximately 165,211 acres of mapped area along the Gulf and Atlantic coasts, as well as margins of interior bays, inlets, and lagoons. Piping plover designated critical habitat identifies specific areas that are essential to the

conservation of the species. The “primary constituent elements” (PCEs) for piping plover wintering habitat are those habitat components that support foraging, roosting, and sheltering and the physical features necessary for maintaining the natural processes that support those habitat components. Constituent elements are found in geologically dynamic coastal areas that contain intertidal beaches and flats (between annual low tide and annual high tide), and associated dune systems and flats above annual high tide. The PCEs of intertidal flats include sand and/or mud flats with no or very sparse emergent vegetation. Adjacent unvegetated or sparsely vegetated sand, mud, or algal flats above high tide are also important, especially for roosting plovers. Major threats to this species include the loss and degradation of habitat due to development, disturbance by humans and pets, and predation.

The proposed project would be located within Critical Habitat Unit LA-1 which encompasses the Texas/Louisiana border to Cheniere au Tigre (including Louisiana Point). At the time of designation, that Unit consisted of approximately 6,548 acres (approximately 89.87 miles of shoreline). Specifically within the proposed beach nourishment project area, piping plover critical habitat includes “. . . the land from the seaward boundary of mean low low water [MLLW] to where densely vegetated habitat, not used by the piping plover, begins and where the constituent elements no longer occur” (66 FR, No. 132, Page 36127). Because of the dynamic coastal system, the current acreage of the entire Unit is unknown. Nonetheless, the proposed project would temporarily affect and restore approximately 3.0 miles of shoreline, of which 1.5 miles contains PCEs of piping plover critical habitat.

Critical habitat may be adversely affected if the proposed action affects the ability of the PCEs to support foraging, roosting, and sheltering, or the physical features necessary to maintain the natural processes that support those elements. Due to the nature of the proposed activities, temporary effects to existing piping plover critical habitat would occur during the initial beach nourishment event and once every 6 years for future maintenance dredging events. Construction and future periodic maintenance of the proposed project would temporarily impact (i.e., once every 6 years for 50 years), but not eliminate, a total of approximately 1.5 miles of existing piping plover critical habitat. After each beach nourishment event, and over the 50-year life of the project, additional piping plover critical habitat would be created, but due to natural erosional processes and the dynamic coastal/beach system at Louisiana Point, an exact acreage has not been estimated. During the future without the proposed SNWW project, the complete loss of existing piping plover critical habitat within that project area would be expected due to current erosion of the shoreline.

In the short-term (i.e., immediately post-nourishment event), the proposed project area would provide less than ideal habitat over the next few months until wave actions have redistributed the dredged material and wind action has deposited sand within the dynamic coastal/beach environment. Existing and newly created foraging habitat immediately post-construction would not be suitable until benthic organisms recolonize those areas. Meanwhile, adjacent critical habitat on the offshore mudflat, offshore sand bar, and adjacent beach would provide sufficient habitat for the piping plover. In the long-term (i.e., 50 years post-construction) and later, the Corps expects that the proposed project area would mimic existing critical habitat that was formed by natural coastal processes. Therefore, the Corps expects that any temporary impacts to piping plover critical habitat should eventually be restored, and that such restored habitat would

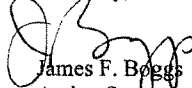

have a longer predictable existence due to increased stability of the shoreline, such that, the overall beach nourishment portion of the proposed project would benefit the piping plover and its designated critical habitat.

According to the BA, the Corps has determined that the proposed project is not likely to adversely affect designated piping plover critical habitat because a portion of the Louisiana Gulf shoreline would be temporarily impacted, but the overall effects of adding sediment to the shoreline would create new critical habitat and extend the longevity and availability of existing piping plover critical habitat within the proposed project area. According to our calculations, the proposed project would impact less than 2 percent of the PCEs within Critical Habitat Unit-LA1, and even less than that of the total designated critical habitat on the Atlantic and Gulf coasts. In addition, over the designed life of the project, the longevity of critical habitat PCEs would be increased by maintenance of the natural processes that support those elements. Based upon the above information, project-related effects to piping plover critical habitat would be insignificant and temporary in nature; therefore, the Service also concurs with the Corps' determination that the proposed project is not likely to adversely affect the piping plover's designated critical habitat.

No further ESA consultation with the Service's Lafayette, Louisiana, Field Office would be required for the proposed action unless there are changes in the scope or location of the project features, or the project has not been initiated within one year. If the proposed action has not been initiated within one year, follow-up consultation should be accomplished with the Service prior to making expenditures to ensure that the threatened and endangered species information is up-to-date. If the scope or location of the proposed action is changed, re-initiation of consultation should occur as soon as such changes are made.

We appreciate the Corps' continued cooperation in the conservation of threatened and endangered species and their designated critical habitat. If you have any questions or require additional information, please contact Brigitte Firmin (337/291-3108) of this office.

Sincerely,

James F. Boggs

Colonel Steven P. Haustein
 District Engineer, Galveston District
 Department of the Army, Corps of Engineers
 Post Office Box 1229
 Galveston, Texas 77553-1229

Dear Colonel Haustein:

NOAA's National Marine Fisheries Service (NMFS) has been involved with the evaluation of the environmental impacts of the proposed deepening of the Sabine-Netches Waterway (SNWW) led by staff of the Galveston District (GD) under the auspices of the Sabine-Netches Waterway Re-Evaluation Study. Water control structures across numerous hydrologic connections between Sabine Lake and Louisiana wetlands have been proposed as a potential mitigation alternative to compensate for the anticipated wetland loss resulting from the deepening of the SNWW. The NMFS is concerned that the proposed project, and in particular this potential mitigation alternative, may adversely affect essential fish habitat (EFH) and other aquatic resources of national importance.

The GD convened a SNWW Habitat Workgroup that estimated that channel deepening could result in 497 and 468 acres of wetland loss in Louisiana and Texas, respectively. These impacts were based on an average increase in salinity estimated to be 0.78 parts per thousand (ppt) in Louisiana and 0.98 ppt in Texas, as predicted by modeling conducted by the Corps of Engineers' Engineer Research and Development Center. A maximum increase of 2.5 ppt was projected for some wetlands within the overall study area. Water control structures across many of the tidal connections between Sabine Lake and the marshes in Louisiana are being considered as a mitigation alternative to reduce saltwater intrusion in an effort to prevent the estimated wetland loss.

Marine fishery productivity in Louisiana annually rates second only to Alaska in terms of pounds produced and dockside value (NMFS 2004). At least 90 percent of that production is from species that are dependent on coastal wetlands as nursery, resting, and foraging habitats for at least a portion of their life cycle. These wetlands also have been identified under the Magnuson-Stevens Fishery Conservation and Management Act as essential fish habitat (EFH) for a variety of federally managed species, such as brown shrimp, white shrimp, red drum, and Spanish mackerel. In addition, other estuarine-dependent species serve as prey for other fish managed under the Magnuson-Stevens Act by the Gulf of Mexico Fishery Management Council (e.g., mackerels, snapper, and groupers) and highly migratory species managed by the NMFS (e.g., billfishes and sharks).

The installation and operation of water control structures has been shown to significantly impact marine fishery access to, use of, and production on, wetlands behind those structures (Herke et al. 1992, Rogers et al. 1992, and Rogers and Herke 1995). While it is still early in the planning stage and the exact type of structures and operational plan for each are unknown, it is likely that a structure which would have a significant impact on the water salinity of the area would not provide an adequate level of fishery access to, and production on, the affected wetlands (Rogers et al. 1994). As such, it is unclear how mitigation that would adversely impact marine fishery production could compensate for an action that also could have negative impacts on habitat supportive of those resources.

The NMFS also is concerned that although the installation of water control structures may buffer salinity changes in the marsh, they also may cause salinities to be higher in managed areas during droughts or following storm surges. Rogers et al. (1994) identified four studies where salinities were slightly higher inside the managed area, two where there were no significant difference in salinities, and three where salinities were buffered. Unpublished data from the Cameron Creole Watershed Project, located on the eastern side of Calcasieu Lake in Louisiana, suggest lake water level and rainfall have a greater influence over water salinities in the marsh than water control structures. Other studies in Louisiana have shown higher water salinities in the marsh interior during droughts or following storm surges (Rogers et al. 1992, Bourgeois 1997). Given such uncertainties, it is unclear how the installation of water control structures can be expected to offset increased salinities that may result from the deepening of the SNWW to a level sufficient to compensate for the induced wetland loss.

The installation of water control structures and implementation of marsh management activities also has been shown to impact factors that help maintain healthy marshes. Monitoring data from the East Mud Lake project, constructed under the auspices of the Coastal Wetlands Planning, Protection, and Restoration Act, showed decreases in marsh vegetation cover, greater subsidence, higher water levels, and longer periods of flooding inside the management area than outside in unmanaged marsh (Weifenbach and Clark 2000). Other studies document similar problems with prolonged flooding and higher salinity, as well as reduced sediment deposition and accretion in managed marsh compared to unmanaged marsh (Boumans and Day 1994; Meeder 1989). These effects can result in reduced wetland plant growth and increased stress in marshhay cordgrass and smooth cordgrass (Koch and Mendelssohn 1989), and contribute to wetland loss (Cahoon and Groat 1990).

Finally, the NMFS is concerned about the cumulative impacts of marsh management activities on the wetlands connected to Sabine Lake and the associated impact to marine fishery productivity. The proposed structures would semi-impound most of the remaining tidally-influenced area between Sabine Lake and Calcasieu Lake. This would contribute to the large cumulative impacts of structural marsh management in the Calcasieu-Sabine estuary on commercial and recreational marine fishery productivity. According to the New Orleans District's analysis of permit data, 98,266 acres of the Calcasieu-Sabine Basin have been affected by completed, partially implemented, or implementable marsh management projects (U.S. Army Corps of Engineers

APR 19 2005

1996). That EIS found that nowhere in the Louisiana coastal zone is there such an extensive effort to place an entire sub-basin under some form of hydrologic management. The Science Advisory Board convened by the Environmental Protection Agency found that ecosystem-level cumulative impacts to fisheries productivity could result from multiple structural marsh management projects that reduce available marsh habitat within an estuary (Sanzone and McElroy 1998).

In view of the above, the NMFS urges the GD to consider less environmentally damaging alternatives than structural marsh management to avoid, minimize, or mitigate impacts associated with the proposed deepening of the SNWW. While we do not consider hydrologic management to be a suitable mitigative option, we are committed to continue working cooperatively with the stakeholders to investigate and implement alternative measures to maintain wetland health while sustaining marine fishery productivity.

We appreciate your consideration of our comments.

Sincerely,

Miles M. Croom

RE: Sabine-Neches Waterway Project
PBS&J Job Number 440870

Dear Mr. Swafford:

PBS&J has contracted with the Galveston District of the U.S. Army Corps of Engineers (Galveston District) to prepare the EIS for the Sabine-Neches Waterway Project (project) located in Jefferson and Orange Counties, Texas and Calcasieu and Cameron Parish, Louisiana. The Galveston District is engaged in a potential widening and deepening of the Sabine-Neches Waterway. The project sponsor is the Jefferson County Navigation District. Alternatives are in the process of being developed.

PBS&J is collecting data for the EIA. The level of detail for our assessment will be as necessary to describe existing conditions and to provide analysis of future conditions due to project impacts. The project study area is in the vicinity of Beaumont, Port Arthur, and Sabine Pass, Texas and encompasses the entire 75-mile long deep draft channel from the Gulf of Mexico through a jettied channel at Sabine Pass, through the Port Arthur Canal, Sabine-Neches Canal, and Neches River Channel to Beaumont and adjacent areas that may be affected by proposed project alternatives.

PBS&J is submitting this letter to request information on Essential Fish Habitat occurring in the project area, which should be addressed for the project, and any conservation recommendations you may have. Please call me at (512) 342-3389 if you have any questions or need additional information.

Sincerely,

March 8, 2010

Ms. Carolyn Murphy
Chief, Environmental Section
Department of the Army, Corps of Engineers
P.O. Box 1229
Galveston, Texas 77553-1229

Dear Ms. Murphy:

The NOAA National Marine Fisheries Service has reviewed the Draft Environmental Impact Statement for the Sabine-Neches Waterway Channel Improvement Project Southeast Texas and Southwest Louisiana. We have reviewed the proposed plans and associated essential fish habitat assessment and NMFS concurs with the Corps of Engineers' determination that the proposed project will temporary adversely impact essential fish habitats due to physical disruption and increased turbidity during dredging, as well as potentially causing secondary impacts to essential fish habitats from slightly increasing salinities in some areas of the Sabine Lake watershed affect living marine resources. We also concur that the proposed beneficial use of dredged material to mitigate and restore 13,052 acres of tidal marsh habitats, as well as the enhancement of approximately 1,828 acres of open water ponds and 5,589 acres of marsh, will offset the adverse impacts to essential fish habitats and provide a net-benefit to Federally managed fisheries. Therefore, NMFS has no comments to provide regarding the proposed plans and no further consultation under the Magnuson-Stevens Fishery Conservation and Management Act with the NOAA National Marine Fisheries Service is required. 1

If we may be of further assistance, please contact Mr. Rusty Swafford of our Galveston Facility at (409) 766-3699.

Sincerely,

Miles M. Croom

Dear Colonel Weston:

This letter transmits our revised Sabine-Neches Waterway Channel Improvements Project, Jefferson and Orange Counties, Texas and Cameron Parrish, Louisiana, Fish and Wildlife Coordination Act Report that addresses changes in the scope of the project, sea level rise, long term monitoring and mitigation. This report provides the U.S. Fish and Wildlife Service's recommendations for mitigation of unavoidable impacts to important fish and wildlife resources in the Sabine-Neches Waterway area, and recommendations for long-term management of mitigation and beneficial uses sites.

We appreciate the opportunity afforded us to assist in planning this large and important Federal project, and appreciate the efforts of your staff in considering coastal Texas and Louisiana fish and wildlife resources. We are providing copies to the other environmental agencies, including Texas Parks and Wildlife Department, Louisiana Department of Fisheries and Wildlife, Louisiana Department of Natural Resources, National Marine Fisheries Service, U.S. Environmental Protection Agency, Texas General Land Office, and Texas Council on Environmental Quality.

Please contact me or Donna Anderson at 281/286-8282 or Darryl Clark at 337/291-3111 if you have comments or questions. Thank you.

Sincerely,

Edith Epling

**SABINE-NECHES WATERWAY CHANNEL IMPROVEMENTS PROJECT,
JEFFERSON AND ORANGE COUNTIES, TEXAS, AND CAMERON PARISH,
LOUISIANA**

The Sabine-Neches Waterway (SNWW) is a Y-shaped commercial waterway comprised of interlocking natural river channels and manmade canals. The waterway presently extends from the Gulf of Mexico, through the Sabine Jetties, 63.8 miles northward across the western edge of Sabine Lake, at 100 square (sq) miles in area the fifth largest estuary in Texas (White et al. 1987), to Port Arthur and Beaumont on the old Neches River Channel and to Orange on the Old Sabine River Channel (Figure 1). Present dimensions are 42 X 800 feet (ft) in the 22-mile Entrance Channel, 40 X 500 ft in the 5.6-mile Sabine Pass Channel, 40 X 500 ft in the 6.2-mile Port Arthur Canal, 40 X 400 ft in the 11.3-mile Sabine-Neches Canal, and 40 X 400 ft in the 18-mile Neches River Channel. General tonnage moved along the SNWW has generally risen during the 1990's from 38 thousand tons in 1990 to 81 thousand tons in 2000. Primary commodities shipped via the SNWW are crude oil (60,810 tons imported in 2000), gasoline (3,710 tons exported), petroleum coke (3,329 tons exported), fuel oil (2,470 tons exported), sand and gravel (1,056 tons imported), and wheat (753 tons exported) (USACE 2000). Since the 2002 Iraq War, the Ports of Orange and Beaumont have been the largest shippers of military supplies in the country.

This revised report addresses changes in the scope of the project, sea level rise modeling, long term monitoring and mitigation.

Background and History of the Sabine-Neches Waterway

The United States expanded into and incorporated Texas during the early 1800's. U.S. Army expeditions explored Texas rivers and began rudimentary navigation improvements, mostly removal of long-established log jams. The first survey of the Sabine Pass area, in 1853, found channel depths of 5 ft, but with a soft mud bottom allowing steamships of up to 10 ft draft to pass. Construction began to deepen inland portions of the waterway shortly after the River and Harbors Act of 1875 and continued in segments until 1896, when the mouth of the channel at Sabine Pass was deepened (6 ft-deep by 70-100 ft-wide) and the jetties were constructed to prevent silting (Alperin 1977, Gammill et al. 2002).

Historic records show that, from 1840 through the early 1920's, 32 sawmills operated in the lower Sabine-Neches River areas (PBS&J 2003). Several of the beneficial use wetland sites selected for the current project still show marked effects of logging from this era, including radial "star" logging canals, vast scrub/shrub swamp with numerous old tree stumps, and a few still-barren mud flats.

The discovery of the Spindletop oil field in 1901 increased the demand for deepwater navigation. In 1916, Congress approved the extension of the Port Arthur Canal, and a 25-ft deep channel was completed to Beaumont. Subsequent dredging extended the

Proposed Alternatives for SNWW Deepening Project

Figure 1 shows the proposed project alignment, existing and proposed new terrestrial disposal areas, mitigation sites, outstanding designated natural areas, and beneficial use features. Shaded channel drawings illustrate proposed new dimensions.

Channel dimensions varying from 43 to 55 ft in depth were analyzed incrementally and in combination by Corps economists to determine feasibility. The selected (National Economic Development or NED) plan is as follows: 2

Existing Gulf of Mexico Entrance Channel to Beaumont - deepen existing 64-mile channel from 42 to 48 ft within the existing widths, including 2 ft of advanced maintenance and 2 ft of overdepth throughout the waterway, with some isolated segments of additional advanced maintenance.

Extend Gulf of Mexico Channel (13.2 miles) – extend the existing Gulf of Mexico portion of the Sabine-Neches Channel 13.2 miles to a depth of 48 feet, 2 ft of advanced maintenance and 2 ft of overdepth dredging.

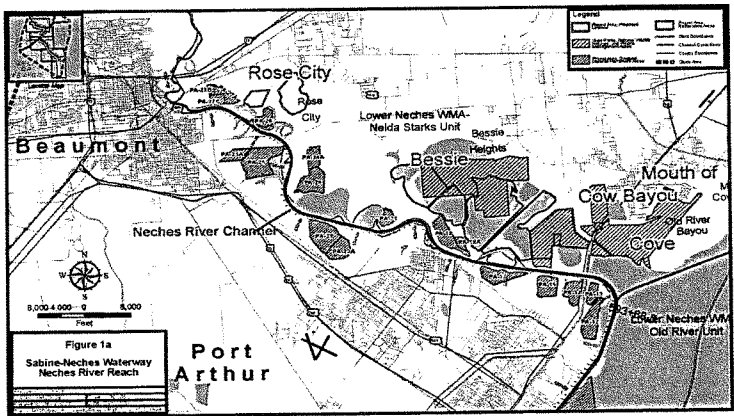

Figure 2 Placement areas and beneficial use sites

Description of SNWW Study Area

The vegetative communities of southeast Texas and southwest Louisiana have been thoroughly described in several authoritative books and numerous technical articles, including O'Neil 1949, Blair 1950, Bezanson 2001, Harcombe and Neaville 1977, Smeins et al. 1991, TNHP 1993, Visser and Sasser 1998, Visser et al. 2000, Gosselink et al. 1979, and Chabreck 1972.

State and Federally-designated natural areas in the project area, important because of the large areas of native fish and wildlife habitat and recreational opportunities they represent as well as their inherent susceptibility to project-induced salinity changes, are shown and discussed as well. We summarize major community types in Texas and Louisiana, provide updated acreage

estimates, update recent changes to the current project and other channelization projects, and provide the U.S. Fish and Wildlife Service's recommendations as to project-related impacts and minimization measures.

Sabine Lake and Offshore Gulf of Mexico

At 69 sq miles of open water, Sabine Lake is the smallest of the six major Texas bay systems in both areas and volume. Its 6-ft average depth is similar to other Texas estuaries. However, its 289 sq miles of adjacent marshes composes the largest wetland system in Texas (Fisher et al. 1973). The region's high (55.8 in.) annual rainfall and two large river systems make it, on average, the freshest estuarine system in Texas. Average salinities, as verified by the TABS/MDS modeling effort for this project, ranges from fall lows of 3 parts per thousand (ppt) in the upper portion of the lake at median river flow to highs of 15 ppt in the lower lake. At low flow conditions (average of lowest 20 percent of historic flows), these salinities rise to 12 ppt in the upper lake and 21 ppt in the lower lake. Historic drought conditions have produced salinities in excess of 28 ppt in the lower lake.

Due to this dynamic salinity regime, Sabine Lake supports several rich and diverse fish, plankton, and invertebrate benthic communities. Heavy seasonal growths of both freshwater and marine phytoplankton, mostly diatoms (45 percent total biomass), along with the ubiquitous green algae (36 percent total biomass) occur and are heaviest in the summer (Espey, Huston and Associates 1976). Zooplankton is most abundant during summer and early fall, which is similar to what occurs in Galveston Bay but opposite from what is found in the more southerly and higher salinity mid- and lower coast bays. Copepods are by far the dominant species group (over 95 percent total biomass). Dominant infaunal benthic organisms consist of the *Rangia* clam, capitellid polychaetes, and *Tubificoides* oligochaetes (Vittor and Associates 1997).

Aquatic fauna has changed since the original manmade opening of Sabine Pass from a freshwater system similar to that currently present in the upper Neches and Sabine Rivers portions of the study area, to a saline/brackish system typical of Galveston Bay and other Texas estuaries. Important forage and predator fish are typified by alligator gar (*Lepisosteus spatula*), ladyfish (*Elops saurus*), finescale menhaden (*Brevoortia gunteri*), gizzard shad (*Dorosoma cepedianum*), bay anchovy (*Anchoa mitchilli*), river carpsucker (*Carpionodes carpio*), hardhead catfish (*Arius felis*), channel catfish (*Ictalurus punctatus*), Gulf killifish (*Fundulus grandis*), white bass (*Morone chrysops*), largemouth bass (*Micropterus punctulatus*), black crappie (*Pomoxis nigromaculatus*), crevalle jack (*Caranx hippos*), pigfish (*Orthopristis chrysoptera*), spotted seatrout (*Cynoscion nebulosus*), black drum (*Pogonias cromis*), striped mullet (*Mugil cephalus*), Spanish mackerel (*Scomberomorus maculatus*), southern flounder (*Paralichthys lethostigma*),

and lizardfish (*Synodus foetens*). These species represent fresh, marine, and euryhaline assemblages. Commercial finfish harvest is insignificant at only an average of 2,186 pounds worth \$1,385 annually. Recreational fish harvest is much more important, with an estimated 500,000 man-hours of fishing and is second only to Galveston Bay (Blackburn et al. 2001).

Important nektonic shellfish are blue crab (*Callinectes sapidus*), white shrimp (*Litopenaeus setiferus*), brown shrimp (*Farfantepenaeus aztecus*), and swamp crayfish (*Procambarus clarkii*). The Sabine Lake blue crab fishery accounts for almost 25 percent of the total Texas commercial landings, with over one million pounds landed annually, for a total value of \$665,600 (Texas Parks and Wildlife Department 2007).

Mussel diversity and abundance has substantially declined due to increased salinities caused by ship channel construction, elevated turbidity levels, and hydrologic alterations from upstream reservoir operations (Howells et al. 1996).

Sabine Lake formerly had large, commercially harvested oyster beds. These have been reduced in recent years to Sabine Pass, extreme lower Sabine Lake, Keith Lake Fish Pass and immediately adjacent to Keith Lake. Oysters have not been commercially harvested since the late 1970s.

Calcasieu-Sabine Basin, LA

The Calcasieu-Sabine basin is the westernmost of the nine coastal hydrologic basins in Louisiana and comprises the western portion of Louisiana's Chenier Plain. It extends from just east of Calcasieu Lake to Sabine Lake, with the Gulf Intra-Coastal Waterway (GIWW) and Gulf of Mexico forming its northern and southern boundaries. The 630,000-acre Calcasieu-Sabine Basin contained 435,600 acres of coastal wetlands in 1932 (Louisiana Coastal Wetlands Conservation and Restoration Task Force 1993). The Sabine sub-basin includes the area from the western shoreline of Calcasieu Lake westward to Sabine Lake. The western half of the sub-basin is within the influence area of the SNWW.

The largest wetland problem in the basin is the conversion of marshes to open water as a result of human hydrologic alterations (channelization, levees) and natural causes (i.e., subsidence and wave action). Channelization for navigation canals causes saltwater intrusion into fresher intermediate and fresh marshes, which can result in vegetation die-off and conversion of marsh to open water. The Calcasieu-Sabine Basin lost over 122,000 acres (30 percent) of marsh from 1932 to 1990 (Dunbar et al. 1992). The 318,000-acre Sabine sub-basin (220,000 acres of marsh) lost over 84,000 acres of marsh (38.5 percent) since 1932 due to human-induced and natural causes. Another 38,400 acres of Calcasieu-Sabine Basin marshes (12.1 percent) are projected to be lost by 2050, for a total projected loss of 160,400 acres from 1932 to 2050 (Louisiana Coastal Wetlands Conservation and Restoration Task Force and the Wetlands Conservation and Restoration Authority 1999).

Vegetative Communities

Freshwater swamp and marsh --- Both freshwater swamp and freshwater marsh, often occurring in intermeshing context within large wetland tracts, occur in abundance within the northern half of the project area in both Texas and Louisiana. Table 1 gives approximate acreages of marsh and swamp types, broken down by drainage and habitat type.

Primary swamp type is cypress-tupelo swamp, which is characterized by common baldcypress (*Taxodium distichum*) and tupelo gum (*Nyssa aquatica*) overstory, and numerous aquatic understory species such as bulltongue (*Sagittaria lancifolia*), swamp lily (*Crinum americanum*), pickerel weed (*Pontederia cordata*), smartweed (*Polygonum sp.*), and blue iris (*Iris sp.*). Large tracts of cypress-tupelo swamp occur in permanently and semi-permanently flooded areas along the Neches River north of Interstate (I-) 10 and along the Sabine River north of I-10 and total approximately 16,798 acres in the extended study area (PBS&J 2003).

Swamp scrub and freshwater marsh are often intermixed within cypress-tupelo tracts, either in natural meander scars or in areas completely logged in the past which have not reforested. The 1,750-acre tract immediately east of downtown Beaumont and north of I-10 is a good example of an area crisscrossed by logging ("star") canals dug in the early 1900's for extraction of commercially valuable baldcypress, which has not yet completely reforested and remains in freshwater marsh/scrub-shrub. Primary plant species here are buttonbush (*Cephalanthus occidentalis*), rattlesnake bean (*Sesbania drummondii*), box elder (*Acer negundo*), swamp privet (*Foresteria acuminata*), cattail (*Typha latifolia*), and Virginia tea (*Itea virginica*). Approximately 278 acres of shrub/scrub and 40,805 acres of freshwater marsh (mostly in Louisiana) are in the project area. Beneficial use areas at Rose City Marsh (project hydrologic unit TX3) will target freshwater marsh/scrub shrub habitat, although cypress-tupelo swamp should be the long term goal, due to its high productivity and recreational value to wetland users, primarily waterfowl hunters, fishermen, and birdwatchers.

Bottomland hardwood forest --- Higher, intermittently-flooded strips of land immediately adjacent to the riverine ridge and to meander lakes (oxbows) are often forested by mature bottomland hardwood forest. The largest tracts are at the extreme upper end of the project area, just south of the Neches River saltwater barrier (Figure 1), and along the Sabine River north of I-10, within Sabine Wildlife Management Area (600+ acres). PBS&J (2003) estimated total acreage of this habitat type within the immediate project area at only 323 acres, but approximately 8,664 acres lie within the extended study area. Bottomland hardwood forest has long been identified as one of the most productive habitat types for wildlife in North America, often harboring up to four times the density and diversity of bird, mammal, and herpetofauna species of upland forests. More recently, bottomland hardwood forests in the northern Gulf of Mexico region have been identified as critical fall and spring migrant stopover habitat for huge numbers, perhaps the majority, of the more than 130 species of North America's neotropical migrant songbirds (Gauthreaux 1971).

Intermediate marsh --- This marsh type is located between brackish and fresh marsh. Intermediate marsh has an irregular tidal regime, is oligohaline, and is dominated by narrow-leaved, persistent species such as marshhay cordgrass (*Spartina patens*). Plant diversity and soil organic matter content is higher than in brackish or saline marshes. This marsh is characterized by a diversity of species, many of which are also found in freshwater and brackish marshes. Characteristic species include roseau cane (*Phragmites australis*), bulltongue (*Sagittaria lancifolia*), coastal water hyssop (*Bacopa monnieri*), spikesedge (*Eleocharis* spp.), Olney's bulrush (*Schoenoplectus americanus*), California bulrush (*Schoenoplectus californicus*), American bulrush (*Schoenoplectus pungens*), saltmarsh bulrush (*Bulboschoenus robustus*), deer pea (*Vigna luteola*), seashore paspalum (*Paspalum vaginatum*), switch grass (*Panicum virgatum*), bearded sprangletop (*Leptochloa fascicularis*), camphor-weed (*Pluchea camphorata*), Walter's millet (*Echinochloa walteri*), fragrant flatsedge (*Cyperus odoratus*), alligator weed (*Alternanthera philoxeroides*), southern naiad (*Najas guadalupensis*), big cordgrass (*Spartina cynosuroides*), and gulf cordgrass (*S. spartinae*). Two other major autotrophic groups in intermediate marsh are epiphytic and benthic algae. Intermediate marsh occupies the least acreage of any of the four marsh types. Salinity averages about 3.3 ppt. This marsh type is very productive of many species of wildlife and is important to larval and postlarval marine organisms. This marsh community may change to either fresh or brackish marsh if salinity shifts. An estimated 172,853 acres of intermediate marsh occurs within the project study area (included in project hydrologic units).

Brackish marsh --- This wetland area located between the high-salinity saline marshes near the Gulf of Mexico and the intermediate areas further removed from the Gulf constitutes an estimated 62,000 acres, or 37 percent, of the 169,321 acres of "estuarine" wetland study area. Brackish marsh is generally considered "slightly salty"; with salinity levels varying over a wide range from location to location. In coastal Louisiana and Texas, the typical brackish marsh vegetation pattern occurs in areas within approximately the 4 to 15 ppt normal salinity range. Common, usually dominant, vegetation in these areas is saltmarsh bulrush (*Bulboschoenus robustus*), seashore saltgrass (*Distichlis spicata*), marshhay cordgrass (*Spartina patens*), dwarf spikerush (*Eleocharis parvula*), waterhemp (*Amaranthus australis*), and marsh pea (*Vigna luteola*). Large tracts of brackish marsh occur in the (formerly fresh) lower Neches River basin, on both the J.D. Murphree Wildlife Management Area (WMA) and McFaddin National Wildlife Refuge (NWR) south of the GIWW and north of State Highway (SH) 87, and on the Sabine NWR east of Sabine Lake. Brackish marsh areas have cyclically high waterfowl populations, especially in years following high-salinity events when freshwater levels return to normal and periodic "blooms" of prime food plants such as widgeongrass (*Ruppia maritima*) and *Paspalum* sp. occur. Furbearers such as muskrat, formerly an important commercially-harvested animal in the project area, also occur in cyclically high numbers. Brackish marshes have suffered some of the highest rates of marsh loss due to subsidence and loss of organic materials as formerly fresh areas are subjected to salinity intrusion, resulting in plant loss.

Saline marsh --- Salt marsh covers an estimated 9,845 acres within the project area, largely along the Gulf shorelines and adjacent to Sabine Pass, lower Sabine Lake, the GIWW nearest the SNWW and some areas in the lower Neches River. Dominant plants in the salt marsh are smooth cordgrass (*Spartina alterniflora*), seashore saltgrass, blackrush (*Juncus roemerianus*), saltmarsh aster (*Aster tenuifolius*), and glasswort (*Salicornia* sp.). Gulf coastal salt marshes are often almost exclusively smooth cordgrass-dominated and comprise important marine nursery habitat, probably due to its ready access to estuaries, though wildlife populations are less diverse than in nearby intermediate and freshwater marshes.

Table 1 Acreages of major wetland types in SNWW project area (modified by USFWS from PBS&J 2003)

Wetland type	Ac. within 5,000 ft. of SNWW, tributary Channels, and Sabine Lake	Ac. within major study area
Bottomland hardwood and scrub	975	4,862
Estuarine (saline and brackish) marsh	13,530	169,321
Fresh marsh	13,812	146,417
Aquatic beds, fresh or estuarine	404	4,433
Cypress or cypress-tupelo swamp	1,110	3,265
Open water	35,182	206,894
TOTAL	65,013	535,192

4

Fish and Wildlife Resources

Fish and Shellfish --- Project-area marshes and associated open-water habitats provide important habitat (i.e., nursery, escape cover, feeding grounds) for a variety of freshwater and estuarine-dependent fish and shellfish. Most of the economically important saltwater fishes and crustaceans harvested in Louisiana spawn offshore and then use estuarine areas for nursery habitat (Herke 1995). Nekton use of estuaries is largely governed by the seasons (Day et al. 1989). Different species use the same locations in different seasons, and different life stages of the same species use different locations. Aquatic species diversity peaks in the spring and summer, and is typically low in the winter. Some marine species which use estuaries as nursery habitat also have estuarine dependent life stages, typically larvae and juveniles. Larvae or juveniles immigrate into the project area during incoming tides and take advantage of the high productivity of the estuary.

Species typical of low-salinity areas include largemouth bass (*Micropterus salmoides*), crappie (*Pomoxis nigromaculatus*), bluegill (*Lepomis macrochirus*), gar (*Lepisosteus spatula*), and blue catfish (*Ictalurus furcatus*). Species found in higher salinity areas, such as the project area, include Atlantic croaker (*Micropogonias undulates*), Gulf menhaden (*Brevoortia patronus*), bay anchovy (*Anchoa mitchilli*), red drum (*Sciaenops ocellatus*), black drum (*Pogonias cromis*), southern flounder (*Paralichthys lethostigma*), blue crab (*Callinectes sapidus*), Gulf stone crab (*Menippe adina*), brown shrimp (*Penaeus aztecus*), and white shrimp (*Penaeus setiferus*) (Louisiana Coastal Wetlands Conservation and Restoration Task Force and the Wetlands Conservation and Restoration Authority 1999).

Waterfowl --- Southeast Texas (Jefferson and Orange Counties) and southwest Louisiana (Cameron Parish) contain some of the most important and heavily utilized waterfowl habitats remaining on the Gulf coast, with many of these areas located adjacent to or a short distance from the SNWW. Important Texas habitat tracts are located within Texas Point NWR, McFaddin NWR, J. D. Murphree WMA, and on privately owned marsh and swamp tracts along the Neches River. Important Louisiana tracts are located within Sabine NWR east of Sabine Lake, the Cameron Prairie NWR east of Calcasieu Lake and Rockefeller State Wildlife Refuge at Grand Chenier. More detailed descriptions of these publicly-owned refuges are provided in the *Protected (State and Federal) Natural Sites in Project Area* section of this report.

Waterfowl use and economic impacts from hunting and outdoor-related activities in the immediate project area are impressive. The U. S. Fish and Wildlife Service's Mid-Winter Waterfowl Census numbers for 2004-2005 were very low compared to previous years, probably due to high-salinity marsh conditions. January 2005 flight lines over McFaddin NWR and Texas Point NWR counted 27,964 geese and 12,688 ducks. Peak 2005 estimates for Sabine NWR were 125,000 geese and 200,000 ducks (McFaddin/Sea Rim NWR files). McFaddin NWR hosted 1,470 hunter-days who harvested 3,694 ducks and 76 geese during the 2005-2006 season. Texas Point NWR hosted 338 hunter-days who took 501 ducks and 28 geese during the 2005-2006 season. J.D. Murphree WMA hosted 1,997 hunter-days taking 5,014 ducks and 93 geese for the 2005-2006 season. The 2.5 birds per hunter-day was one of the highest ratios of any Texas public hunting area. Sabine and Cameron Prairie NWRs did not have recent hunting statistics readily available, but did have 2006 waterfowl survey data. Cameron Prairie NWR flight(s) during January 2006 counted 63,198 ducks, and Sabine NWR flight(s) counted 143,455. Total southwest Louisiana refuge flight(s), which include Lacassine NWR (58 miles east of Sabine Lake) counted an impressive 523,454 ducks, an almost 100 percent increase over January 2005 counts and indicative of the improving conditions in coastal marshes following Hurricane Rita in September 2005. The (small) Sabine Island WMA hosted 114 hunter-days during 2005-2006, taking "approximately" 50 ducks (Robinette 2007). Numerous waterfowl guides in Texas and Louisiana host hunters on private marshes, rice fields, and coastal marshes in the Jefferson County/Cameron Parish area. Private lands hunters almost certainly account for more hunting days and greater harvest than those on public areas.

The 2001 National Survey of Fishing, Hunting, and Wildlife-Associated Recreation (USDOI 2003) show hunter participation and expenditures by state, but not by county or region. In 2001, 1.2 million hunters in Texas (both resident and non-resident) spent 14.2 million days afield and an estimated \$1.5 billion. Of these, approximately 500,000 hunters, or 42 percent, hunted migratory birds, primarily waterfowl. While these statistics are not compiled by county, a large proportion of waterfowl hunters have historically used the marshes within the SNWW project area.

Cameron Parish, Louisiana is one of the most popular waterfowl hunting regions of the U.S., both in terms of numbers of hunters and hunter success. In 2001, an estimated 333,000 Louisiana hunters spent approximately \$446 million. Approximately 144,000 or 44 percent of these were migratory bird hunters, and of these, a sizeable proportion hunted in Cameron Parish.

Colonial Waterbirds---Twenty-three species of cormorant, pelican, heron, egret, spoonbill, gull, tern, and skimmer regularly nest in large numbers along the Texas and Louisiana coasts, frequently on bay islands, both natural and manmade. In recent years, the majority of successful

Texas colonies have been located on islands wholly or partially maintained by dredged material (Glass 1994). Colonial waterbirds are an important wildlife resource on the Gulf Coast and in the project area because of their abundance (an estimated 2,835 nesting pairs annually since 1995 in the project area), their economic significance to the tourism industry, and their status as indicators of aquatic ecosystem health. Since 1973, the Texas Colonial Waterbird Society has conducted annual censuses of all coastal Texas colonies and maintains a comprehensive database which provides annual census numbers and colony locations (TCWC 2006).

While locations of most important Texas colonies are on small offshore islands (TCWC 2006), most of those in the SNWW project area are in semi-protected industrial sites and other semi-urban sites. Sydney Island, a formerly important nesting island in upper Sabine Lake, has become inactive in recent years, probably due to predator invasion (Bailey, personal communication).

Regional waterbird population trends are a more accurate picture of waterbird population health than comparing individual colony counts from specific years, since nesting populations are known to shift frequently in response to predation, habitat conditions, parasite levels, and human disturbance. For purposes of comparison, Jefferson and Orange Counties, Texas, and Cameron Parish, Louisiana are considered the project area, and county (parish) dimensions are probably appropriate considering known waterbird home ranges and habitat use (Custer et al. 1978). In 2005, Jefferson and Orange Counties contained 10 known colonies with a total estimated population of 8,462 nesting pairs belonging to 13 species. Only one species of gull or tern was present, in comparison to Galveston Bay, where most years the laughing gull comprises over 50 percent of the nesting pairs (TCWC 2006). Most of the nesting birds belong to the heron, egret and ibis families, which are important components of freshwater marsh and swamp systems.

Nearby coastal Louisiana, while replete with excellent wading bird and other waterbird habitat (124,511 marsh acres in Sabine NWR alone), is devoid of even mid-sized (100 nesting pairs or greater) colony sites. Because we do not have a yearly coastal Louisiana dataset comparable to the TCWC, we used the May/June 2000 USGS colonial waterbird flight survey summary (Michot et al. 2004). This survey, conducted by Federal and state wildlife personnel at infrequent intervals since 1980, located only two small colonies totaling an estimated 106 nesting pairs belonging to four species. Waterbird experts have long concluded that successful nesting habitat must be geographically isolated and free from land-based predators (Soots and Landin 1978).

Because of the lack of large, multi-species waterbird colonies within huge habitat tracts in the project area, it seems logical that new, well-protected and managed offshore islands would be utilized by nesting colonial waterbirds. Recent experience in Galveston, Matagorda, Corpus Christi, and Nueces Bays supports this supposition.

Protected (State and Federal) Natural Sites in Project Area

The unique geographic location of the project study area at the confluence of the Central and Mississippi migratory bird flyways and its inherent natural diversity is reflected in the fact that six major state or Federally-protected parks and refuges are located here. Figures 3 and 4 show these protected areas. This list does not include private, city, or county parks and refuges.

McFaddin National Wildlife Refuge --- This 55,000-acre U.S. Fish and Wildlife Service (Service) refuge was established in 1980 and contains the largest tracts of coastal freshwater marsh remaining in Texas. The 5,400-acre White Marsh tract was added in 2000. Most of McFaddin NWR is saline to brackish marsh. It was probably was a freshwater marsh prior to GIWW construction in the 1940's and erosion and subsidence in the 1970's. Large freshwater areas still exist in interior areas west of Clam Lake (Figure 2). McFaddin NWR hosts approximately 10,000 visitors annually, including 2,400 annual hunter-days of waterfowl hunting. The degradation of SH 87 along the coastline during a 1993 hurricane has reduced visitation.

Texas Point National Wildlife Refuge --- Managed as a unit of McFaddin NWR, this 8,900-acre tract lies entirely between the Gulf of Mexico beach and SH 87 and to the west of Sabine Pass. It is almost entirely saline marsh, brackish marsh, and moist saline (*Spartina patens* or marsh hay) prairie. The small brackish to saline lakes and large marsh hay meadows attract seasonally large duck and goose populations. SNWW project hydrologic unit TX-8 (Figure 1) is entirely within Texas Point NWR.

Sea Rim State Park --- This Texas Parks and Wildlife Department (TPWD)-administered, 4,141-acre tract lies south and east of McFaddin NWR. The headquarters is located and most visitations occur within the 5.2-mile long Gulf beach frontage tract located to the south of SH 87. This state park contains important beach dune, backdune marsh and prairie, and freshwater wetlands and is especially important as spring neotropical migrant songbird and waterbird habitat due to its location. Dedicated in 1977, it has been closed awaiting repairs since Hurricane Rita in September 2005.

J.D. Murphree Wildlife Management Area --- This State of Texas WMA is composed of three separate tracts (Big Hill, Hillebrandt, and Lost Lake Units) totaling 24,250 acres lying east of McFaddin NWR and on both the north and south sides of the GIWW. It was purchased from the McFaddin family in 1950. The fresh, intermediate, and brackish marshes of this WMA are some of the most important migrant and stopover habitat in the Central Flyway and host upwards of 50,000 ducks per year. Some marsh tracts are managed to maintain intermediate to freshwater marsh characteristics optimum for waterfowl. Round Lake, a 500-acre natural lake within a protective levee system constructed in the 1960s when salinity intrusion first became a serious problem, contains some of the highest-quality freshwater aquatic habitat remaining on the upper Texas coast. Large flocks of canvasback (*Aythya valisneria*) traditionally use this area on a seasonal basis (Sutherlin 1996). J.D. Murphree is in project hydrological units TX-7 and TX-9.

Lower Neches Wildlife Management Area --- The 7,998-acre Nelda Starks Unit and the Old River Unit are located along the Neches River north of the SH 87 (Rainbow) bridge, immediately north of the confluence of the Neches River and Sabine Lake. These brackish marshes have suffered considerable losses, accelerated during the 1960s from land subsidence and salinity intrusion into formerly freshwater systems. Two projects at Bessie Heights have restored over 250 acres of subsided open water habitat back to emergent marsh, a hopeful sign that this trend is being reversed. The WMA is in project hydrological unit TX-10.

Sabine Island Wildlife Area --- This 8,743-acre unit is on the east side of the lower Sabine River, just upstream from IH-10 and the GIWW. It is managed by the Louisiana Department of Wildlife & Fisheries. It is heavily forested with primarily cypress-tupelo swamp intermixed with

pine-hardwood ridges and oak-hickory-pecan bottomland forest. Numerous creeks, sloughs, and backwater swamps cross the area. As with all the forested portions of the project area, it provides invaluable spring stopover habitat for neotropical migrant songbirds. It lies within project hydrological unit LA-/TX-1.

Sabine National Wildlife Refuge --- This huge (124,511-acre) Louisiana refuge lies immediately east of Sabine Lake. It is important to the project due to its large size, wetland diversity, and its potential for protecting the sensitive intermediate marsh systems located within one mile of the eastern Sabine Lake shoreline from the negative impacts of increased salinities (see *Project Impacts* chapter). An interesting portion of the refuge is Sabine Pool #3, a 26,000-acre, leveed impoundment which is managed to support entirely freshwater marshes. The type of fresh marsh system enclosed within the completely leveed Sabine Pool #3, with its inherent high diversity of aquatic plants and bird life, would have been much more widespread in the project area before the SNWW and GIWW intruded into these systems.

Sabine NWR is comprised of seven management units containing fresh, intermediate, brackish, and saline marsh. Hydrologic management on the refuge is focused primarily on controlling salinity and minimizing tidal fluctuations through the construction and operation of levees, weirs, and gated structures. Managers strive to achieve a balance between reducing wetland plant waterlogging and saltwater intrusion stresses, and providing access for estuarine fish and shellfish organisms to interior marshes during critical life-cycle events.

Figure 3 Federal and State protected areas within study area – Sabine Pass

Figure 4 Federal and State protected areas within study area – Mid Sabine Lake

Existing SNWW Disposal Areas

Thirteen (13) existing, designated, or proposed dredged material disposal areas lie alongside the 67-mile SNWW right-of-way (Figure 1). Habitat within these areas ranges from offshore Gulf of Mexico marine habitat (disposal areas (DA) 1-4), high-quality intermediate marsh (DA 16A), relatively undisturbed *Spartina patens* wet meadow (DA 14A), leveed scrub-shrub partially wetland community (DA 23A), and several previously used, wholly or partially-leveed sites with somewhat disturbed upland and wetland communities (DAs 24A, 26, 27A, 27C, and 27D).

5

Disposal areas 1-4 lie four to 30 miles offshore to the west of the SNWW channel. Dredged material has been placed in these areas repeatedly during the past 40 years. However, winnowing and ocean currents tend to redistribute placed sediments, and bottom composition ranges from coarse sands to soft muds. Typical bottom invertebrate communities consist of *Polychaete* and *Oligochaete* worms, clams (*Mercenaria sp.*), arks (*Anadara sp.*), sand dollar (*Mellita quinquesperforata*), brittle stars (*Hemipholis sp.*), blue crab (*Callinectes sapidus*), and box crab (*Calappa sulcata*). Nektonic invertebrates include white shrimp (*Litopenaeus setiferus*), brown shrimp (*Farfantepenaeus aztecus*), and peppermint shrimp (*Lysmata wurdemanni*). Important and common fish are Gulf trout (*Cynoscion nothus*), Lane snapper (*Lutjanus synagris*), Spanish mackerel (*Scomberomorus maculatus*), and cobia (*Rachycentron canadum*).

Dominant wetland plants in intermediate marsh sites such as at DA 16A are salt-marsh bulrush, Olney's bulrush (*Schoenoplectus americanus*), California bulrush (*Schoenoplectus californicus*), black needlerush (*Juncus roemerianus*), marsh-hay cordgrass (*Spartina patens*), *Paspalum vaginatum*, narrow-leaf cattail (*Typha angustifolia*) and widgeon-grass (*Ruppia maritima*). These dominants and the circulation pattern and elevation are indicative of relatively undisturbed high-quality intermediate marsh. As such, this area provides excellent wetland habitat for furbearing mammals, native reptiles, resident waterbirds, and migrant waterfowl, in addition to providing nursery habitat and detrital input for marine fisheries.

Wet shrub/scrub communities, such as at DA 14, are of mixed successional states, indicating altered and fluctuating water regimes. Typical understory plants include ferns, common reed (*Juncus sp.*), California bulrush (*Schoenoplectus californicus*), frogfruit (*Phyla lanceolata*), blackberry (*Rubus sp.*), and *Aster sp.* The lack of large open-water areas or natural circulation patterns and the dense thicket-like forest structure inhibit this site's value for native wildlife. However, it has potential for management and contains some native wildlife habitat values for mid-story songbirds such as *Empidonax flycatcher*, cardinal, yellow-rumped warbler, and common blackbird, and small numbers of waterfowl such as wood duck.

Methods of Study

Project Area Wetland Analysis

Early in project planning, Service biologists delineated and quantified wetland communities adjacent to the SNWW channel and mapped tributaries, including relatively small creeks and sloughs, which could serve as conduits for salinity intrusion into sensitive aquatic communities. This information can be used to measure future impacts from salinity increases into fresh or intermediate systems, after hydrodynamic/salinity modeling results became available. It can also be used to identify potential wetland impacts from channel enlargement and potential sites of salinity intrusion that would need to be corrected or mitigated.

Corps of Engineers Hydrodynamic/Salinity Model

The SNWW project presented a complicated and difficult set of conditions for estimating project-related impacts to fish and wildlife resources and to wetland communities. The potentially affected ecosystem is huge, complex (both in terms of its hydrology and its biology), and interconnected. Within the 1,035,154-acre vegetated portion (including agricultural lands) of the study area (Table 1), six major wetland types (including special aquatic sites such as beaches) total 706,632 acres or approximately 68 percent of all lands exclusive of development (PBS&J 2003). Wetlands and special aquatic sites can be categorized into six major vegetative community types (Table 1).

Six major hydrological features in the project area potentially allow high-salinity Gulf of Mexico waters to enter ecologically sensitive ecosystems: Sabine Pass, Sabine-Neches and Port Arthur Canals, Gulf Intracoastal Waterway, Sabine River, Neches River, and Sabine Lake (Figure 1).

The entire SNWW system exhibits complex circulation and salinity patterns. This is due to the two large and numerous small freshwater rivers and tributary streams, the huge storage basins (including the 43,978-acre Sabine Lake, the 11,363-acre Bessie Heights Marsh, and the 5,817-acre Rose City basin) which serve as salinity-retention basins, the numerous smaller circulation channels into adjacent ecosystems, the deep manmade canal systems, and the large active tidal pass (Sabine Pass).

Because of these factors, the Interagency Coordination Team (ICT) determined that a state-of-the-art numerical model calculating salinity and hydrodynamic changes from channel modifications would be necessary to estimate project impacts. The TABS-MDS model was extensively modified from its original format, the RMA 10 model by Resource Management Associates (King 1993), to compute hydrodynamics, salinity transport, and sediment transport for alterations to large-scale waterways from navigation projects such as the Houston-Galveston Navigation Channels, Texas. The TABS-MDS Hydrodynamic/Salinity Model (HS) was used to predict salinity changes for each project hydrological unit.

The ICT utilized the model to develop the present, future without project, and future with project salinity scenarios essential for the predictive Wetland Values Assessment (WVA) methodology. Because WVA methodology incorporates salinity changes in assessing habitat quality, it is appropriate for this project, because salinity impacts to important freshwater systems upstream from channel enlargement are considered among the most serious potential project impacts.

The project area "profile" incorporated into the TABS/MDS model matrix included 15 hydrologic sampling stations, which were sampled for the nine-month period from January to September 2002, and 38 H/S model nodes, or mathematical model calculation "output" points. The physical sampling stations were at: 1) Pine Island Bayou, 2) Neches River at Rose City, 3) Neches River at Bessie Heights, 4) Mouth of Sabine River at GIWW, 5) Sabine River at I-10 bridge, 6) Pleasure Island MLK bridge, 7) Texas Point, 8) upper Sabine Lake at Black Bayou, 9) lower Sabine Lake at Buck Point, 10) Black Bayou at East Pass, 11) Black Bayou at GIWW, 12) Star Lake at GIWW, 13) Johnson's Bayou inside mouth, 14) Keith Lake Fish Pass, and 15) Willow Bayou inside mouth. The planned offshore Gulf of Mexico sensor was not deployed due to sea conditions, but background Gulf data was readily available from NOAA sources. The 38 H/S model "output" nodes ranged from the Neches River Saltwater Barrier south to Johnson's Bayou in Louisiana, and included Cow Bayou, Adams Bayou, Black Bayou, the GIWW west to Taylor's Bayou and east to Black Bayou and 14 stations in the vast, and potentially sensitive, marsh tracts east of Sabine Lake. This frequency of model "output" nodes allowed the ICT to refine estimates of salinity changes to relatively small aquatic habitat tracts.

Changes to salinity were incorporated into habitat productivity change calculations for each of the three aquatic habitat types as one of five variables, with salinity negatively affecting productivity, thus accelerating interior marsh loss. Since the TABS-MDS code was designed to measure alterations to salinity from channel modifications, it was considered the best tool to use for the present project. Other models were considered, including the Sabine Basin-Calcasieu Ship Channel Hydrodynamic Model developed by Dr. Ehab Meselhe of the University of Louisiana-Lafayette. However, the TABS-MDS model as developed by Corps' Engineer Research and Development Center (ERDC-WES) was considered the most sensitive and appropriate.

Sea Level Rise

Sea level rise in the Sabine Neches estuary systems is very uncertain. In the fall of 2008, the Corps began to incorporate relative sea level rise (RSLR) into the SNWW HS modeling. This report used "most likely" scenarios of 0.5 meter, 1.0 meter and 1.5 meters over a 100 year period for possible changes for projects. The National Research Council (NRC) committee recommended that these rates be revisited every decade to incorporate additional data. The 2008

modeling efforts used the NRC II curve as it presented the most likely sea level rise changes for the project (Table 2).

On July 1, 2009, the Corps issued new guidance that requires that relative sea level rise changes be incorporated into all Corps coastal activities. In addition, the Corps reviewed sea level rise predictions suggested by the Intergovernmental Panel on Climate Change (IPCC 2007). The IPCC 2007 report assumes sea level rise on the premise that thermal expansion contributes to 70-75 percent of the rise. Should the ice sheets in Greenland and Antarctica melt faster than the current rate, these sea level projections will be obsolete. Table 2 illustrates predicted sea level rise by the NRC and the IPCC.

Table 2 National Research Council and Intergovernmental Panel on Climate Change rates of sea level rise

Eustatic Sea Level Rise Estimates	50 years	100 years
Existing rate	60 mm (1.2 mm/yr)	120 mm (1.2 mm/yr)
NRC I	130 mm (2.6 mm/yr)	400 mm (4.0 mm/yr)
NRC II	225 mm (4.5 mm/yr)	780 mm (7.8 mm/yr)
NRC III	322.5 mm (6.45 mm/yr)	1125 mm (11.25 mm/yr)
IPCC AR4 - Scenario B1: lower end of range	90 mm (1.8 mm/yr)	180 mm (1.8 mm/yr)
IPCC AR4 - Scenario A1B: mid range of all scenarios	190 mm (3.8 mm/yr)	380 mm (3.8 mm/yr)
IPCC AR4 - Scenario A1F1: high end of range	295 mm (5.9 mm/yr)	590 mm (5.9 mm/yr)

(Corps 2009b)

Under these new guidelines, several changes were made to the existing Wetland Value Assessment (WVA) model (discussed in the next section) to account for RSLR. Shoreline recession, interior marsh loss, salinity, marsh edge, percent shallow water and depth and duration of tidal flooding data were all incorporated into the model. For a full discussion of the variables, see USACE 2009a.

After further consideration, the Corps used a 1.1 foot RSLR as a most likely scenario. After the model had been run with the additional parameters and variables, results showed that swamps and bottomland hardwoods within the project area would experience an increase in depth and duration of tidal flooding as well as the substrate being exposed at low tide and longer seasonally. Additionally, the model showed that marsh elevation would maintain equilibrium with rising sea level and the interior marshes would not be submerged. Further, results showed that in Texas 86 acres of fresh marsh would be converted to upland and almost 39,000 acres would experience lower productivity and higher land loss rates from the indirect effects of increased salinity. Future without project (FWOP) land loss would increase from 7.5 percent to 8.2 percent through Time Year (TY) 65 and there would be a net loss of 412 Annual Average Habitat Units (AAHUs). In Louisiana, there would be no direct impacts to oyster reefs. Indirect impacts of higher salinity over 182,000 acres would result in lower productivity and higher land

loss. The FWOP land loss through TY 65 would increase from 10.5 percent to 11.5 percent and there would be a net loss of 1,709 AAHUs.

Wetland Value Assessment (WVA) Ecological Model(s)

The Wetland Values Assessment (WVA) methodology was developed in the early 1990's in Louisiana for assessment and rating of wetland restoration projects by the Coastal Wetlands Planning, Protection and Restoration Act (CWPPRA) Environmental Work Group interagency team. The WVA methodology (USFWS 2002a and 2002b) was considered appropriate for SNWW project analysis by the ICT because it incorporates large-scale measurements of predicted changes to salinity and vegetation of coastal Louisiana habitats identical to those of the project area. The WVA methodology has been certified by the Corps for use in the ecological evaluation of the SNWW project and is currently under review for acceptance nationwide as an evaluation model to evaluate the impacts and benefits of Corps public works projects.

The WVA methodology requires predictions within model units, including predictions of future changes to land loss rates. Therefore, the interagency team determined historic land loss rates for each wetland habitat type within each project hydrologic unit by GIS comparison of historic aerials from the past 20 to 25 years. From this, FWOP land loss rates, then a FWP (future with project) land loss rate and projected historical rates over the 50-year project life were established using the Productivity-based Land Loss Increase Method modified from Visser et al. 2004a and 2004b. This salinity-effect information was then used in the WVA models (USFWS 2002b) by marsh habitat type. This method is based on a direct linear correlation between decreased primary productivity due to salinity increases with increased land losses due to the project. There was some concern, based on knowledge of specific Louisiana coastal marsh tracts for which detailed historic information was available, that Visser's methods might underestimate losses when salinities exceed "optimal" ranges for a particular marsh type. However the interagency evaluation group agreed to use the Visser productivity method because it was science based. Tables 3 and 4 show the estimated salinity changes and habitat losses for the Texas and Louisiana hydrologic units, respectively. The Corps and the ICT members agreed early in project planning that habitat losses should be tabulated and mitigated, if required, independently for Texas and Louisiana resources (Tables 3 and 4). Figure 5 shows locations of the HU's. Numbering proceeds generally from north to south.

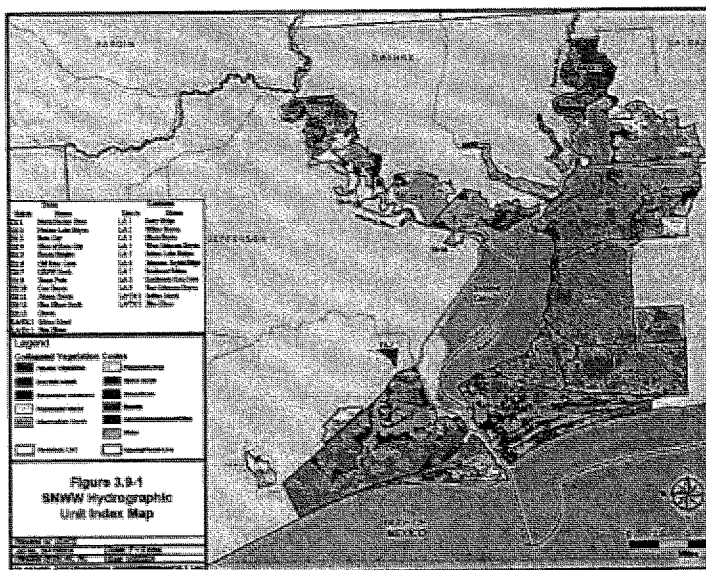

Figure 5 Hydrologic Unit Locations

In July 2009, the Corps received new compliance items to be incorporated into the both the HS and WVA models. RSLR and fresh water inflows were to be integrated into both models. The WVA model assessment was performed to comply with the new Corps model certification regulations.

The WVA methodology incorporates seven community habitats: 1) fresh/intermediate marsh, 2) brackish marsh, 3) saline marsh, 4) bottomland hardwood forest, 5) barrier headland, 6) freshwater swamp, and 7) coastal Chenier/ridge. The three marsh models, the freshwater swamp model, and the bottomland hardwood model were used for project analysis. Table 3 summarizes place names, habitat classifications, and approximate acreages of habitat tracts analyzed under each WVA habitat classification, with findings. Results are expressed in average annual habitat units (AAHU's) and acreages (+ or -) and are used to compute required mitigation and benefits of beneficial use (BU) features.

It should be noted that, as with any numerical model of ecological functions, exact numerical output should be interpreted with caution. Positive and negative habitat trends, as judged from known historic responses to similar causes, should be considered in addition to model outputs. The ICT reviewed the literature to determine past responses to salinity changes and erosion within large marsh tracts, such as at Bessie Heights, Keith Lake, and Black Bayou, to determine if changes predicted by the model were reasonable. The Service considered model output in terms of acres affected to be more significant than AAHUs, therefore acres were given more weight in selecting mitigation. In all cases, the mitigation and BU plan compensate for projected AAHU and habitat losses for each project hydrologic unit, for each wetland habitat type, and within each state. Table 5 summarizes project impacts by habitat type.

Eighty-two percent of the Sabine-Neches Enlargement project Texas AAHU impacts are predicted to occur in fresh (-206 AAHUs) (50 percent) and brackish marshes (-131 AAHUs) (32 percent). Seventy-eight percent of the acreage (541 acres) and 91 percent of the AAHU impacts (1,571 AAHUs) are predicted to occur in Louisiana intermediate marshes. Few to no impacts are expected in swamp and bottomland hardwood habitats in Texas (0 acres, -22 AAHUs swamp), and Louisiana (0 acres, -44 AAHUs swamp). Eleven and 8.4 percent of the Louisiana acreage impacts are predicted to occur in brackish and fresh marshes, respectively (Table 5).

SNWW Project Impacts

General salinity-related impacts to aquatic communities (Texas and Louisiana)

In the initial phases of project planning and interagency coordination, the Service and the other resource agencies expressed concerns that further salinity intrusion into the largest remaining tracts of high-quality fresh, intermediate, and brackish marshes on the Texas and Louisiana Gulf coast would likely be the SNWW project's greatest negative impact (USACE 2009).

Further, the Service considered alterations of salinities in the upper Neches and upper Sabine watersheds to be of higher concern than alterations of salinity to the higher-salinity, lower watershed marshes adjacent to Gulf of Mexico and GIWW waters. This is because undisturbed swamps and fresh marshes are composed of diverse assemblages of aquatic plants adapted to fresh water. These communities are tolerant of only a very few parts per thousand of salt over a very short time period. They are acutely affected by the sudden addition of only a few parts per thousand of salt (Reid and Wood 1976). For example, cypress-tupelo swamps on the lower Neches River system, in the vicinity of what is now Bessie Heights Marsh, disappeared within only a few years of original SNWW and GIWW construction, almost certainly from acute rises in salinity levels (Sutherlin 2005). This is typical for fresh to intermediate swamp and marsh systems (Brown and Montz 1986). Of course, concurrent localized events related to oilfield brine water discharges and logging directly impacted these forests also.

The brackish to saline marshes south of the GIWW in Texas and within a mile or so of Sabine Lake and the Gulf of Mexico in Louisiana are generally less diverse, are composed of plant species adapted to a wider range of salinities and are capable of tolerating salinities above 6 ppt on a semi-permanent basis. Increased salinities have been shown to be deleterious to brackish and even saline marsh by decreasing plant productivity, diversity, and by indirectly increasing marsh erosion (Visser et al. 2004b), and should be mitigated. However, they are not considered as sensitive to salinity changes as the fresher aquatic systems further upstream because salinity-induced plant stress in those locations is less likely to result in immediate marsh die-off.

Many scientific literature reports have concluded that increased salinities are detrimental to most fresh, intermediate and some brackish species of wetland vegetation (Hester et al. 2002). Hester et al. (2002) reviewed over 100 scientific studies concerning the salinity and water logging effects on 22 wetland species. All specimens of *Leersia oryzoides* died at salinities of 6, 9, and 12 ppt (Flynn et al 1995). Salinities of 15 ppt were lethal to both *Leersia oryzoides* and *Panicum hemitomon* (maidencane) in the field (McKee and Mendelssohn 1989). *Panicum hemitomon* stem height was reduced at 6 ppt and aboveground tissue mortality was seen in maidencane at

salinities of 12 ppt in greenhouse treatments (Howard and Mendelssohn 1999a). *Panicum hemitomon* was not able to recover total and below ground biomass associated with increased salinities (Howard and Mendelssohn 1999b). Hester et al. (1998) reported lethal salinity levels from 7.6 to 12 ppt for *P. hemitomon*. Bulltongue (*Sagittaria lancifolia*), a dominant fresh marsh species, is found at average salinities of 0.3 ppt (White 1983). *Sagittaria lancifolia* biomass was reduced at 6 ppt (Baldwin and Mendelssohn 1998), tissue damage occurred at 4.8 ppt (McKee and Mendelssohn 1989), growth decreased at 4 ppt (La Peyre 2001), and 2.9 ppt decreased photosynthesis and was lethal (Pezeshki et al. 1987a). Duck potato (*Sagittaria latifolia*), a common arrowhead, experienced tissue wilting and chlorosis at 6 ppt (Holm and Sasser 2001).

Marshhay cordgrass (*Spartina patens*), the most common intermediate and low salinity brackish marsh grass species, has a salinity range of 0 to 4 ppt (Taylor et al. 1997). As salinity increased from < 1 ppt to 6 ppt, net photosynthesis, leaf conductivity, and root and shoot dry weights decreased (Bandyopadhyay et al. 1993). Salinities of 15 to 25 ppt decreased *S. patens* height, foliage and root dry weight (Pezeshki and DeLaune 1991), increased salinities from 0 to 22 ppt decreased stomatal conductance by 54 percent and net photosynthesis by 43 percent (Pezeshki et al. 1987b), salinities of 30 ppt decreased photosynthesis by 36 percent (Bertness et al. 1992), and Broome et al. (1995) found a decrease in stem length and number at salinities greater than 10 ppt. Cattail (*Typha latifolia*) had decreased biomass at salinities of 1.8 ppt, total biomass was significantly depressed at 18 ppt after 3 weeks, and total mortality was observed at salinities of 18 ppt after 4 months (Hootsmans and Wiegman 1998).

The HS model input was chosen by the modeling committee to provide conservative estimates of salinity changes associated with channel enlargement. Low flow changes were calculated using the three-month period exhibiting lowest flows of the simulation period, ranging from 400 to 800 cubic feet per second (cfs) on the Sabine River and 400 to 500 cfs on the Neches River. These are significantly lower than mean flows. Median flow salinities were calculated for a six-month period, not including late winter and early spring (usually higher rainfall) months.

Hydrodynamic/salinity model results are summarized by hydrologic unit in Tables 3 and 4 for Texas and Louisiana respectively. Salinity impacts are summarized in habitat acres by net with-project acreage loss and maximum projected salinity change by habitat type and hydrologic unit. Table 5 summarizes projected salinity-related habitat losses by habitat type within each state by acres and AAHUs. Following are summaries of the Service's analysis of potential project-related salinity impacts, by hydrologic units in Texas and Louisiana.

Salinity related impacts to aquatic communities

Texas Habitat Areas

A review of the impacts associated with the most recent modeling efforts suggest that Texas will have a conversion of 86 acres of fresh water marsh to upland at DA 24A. Indirect impacts suggest higher salinities over approximately 39,000 acres, resulting in lower productivity. In addition, the model indicates that there will be no salinity impacts in swamps/bottomland hardwoods/fresh water marsh north of I-10. Salinity increases range from 0.3 to 1.8 ppt, with the highest impacts in fresh water marsh at GIWW North and Adams Bayou, and brackish marsh in Old River Cove and GIWW North.

Upper Neches River

North Neches River (Project HU TX 1) --- This 4,143-acre unit has 2,760 acres of cypress-tupelo, 384 acres of fresh water marsh, 412 acres of bottomland hardwood forests, 127 acres of open water and the remainder is scrub/shrub and upland habitats. The large riverine flows and seasonal flooding that this area is exposed to would continue and only a negligible increase in water surface elevation would be expected in the FWP. The HS model indicates that no FWP salinity impacts and no loss of bottomland hardwood, marsh or swamp habitat acreage are expected to occur. As a result, there are no AAHU losses for hydrologic unit TX 1.

Neches Lake Bayou (Project HU TX 2) --- This 5,707-acre unit is located immediately downstream from TX 1 and contains 2,277 acres of cypress-tupelo swamp, 1,270 acres of fresh marsh, 1,040 acres of bottomland hardwood forests, with the remainder scrub/shrub and upland habitats. Habitats and fish and wildlife resources in this unit are very similar to TX 1. The large riverine trough flows and seasonal flooding that this area is exposed to would continue in the FWP and only a negligible increase in water surface elevation would be expected. The HS model indicates that no FWP salinity impacts and no loss of bottomland hardwood, marsh or swamp habitat acreage are expected to occur. As a result, there are no AAHU losses for hydrologic unit TX 2.

Rose City (Project HU TX 3) --- This 5,805-acre unit has 2,323 acres of fresh marsh, 1,775 acres of bottomland hardwood forests, 464 acres of cypress-tupelo, 1091 acres of open water, with the remainder other upland habitats. FWP impacts are associated with a 0.5 ppt salinity increase and would result in the loss of three acres of fresh marsh, with no losses in the bottomland hardwood or swamp areas. Also, the SNWW Dredged Material Management Plan proposes to expand an existing placement area in this unit. This expansion would result in the conversion of 85 acres of fresh marsh and 1 acre of open water to a confined upland placement area and the loss of 32 AAHUs.

West of Rose City (Project HU TX 4) --- This 493-acre unit contains 395 acres of fresh marsh and 97 acres of open water habitat. The marshes are remnants of larger marshes impacted by the industrial facilities and Corps placement area in the unit. Impacts associated with the project will be minimal. Salinity changes are expected to be minimal (0.5 ppt) with a loss of one acre of fresh marsh resulting in no change in AAHU's for this unit.

Lower Neches River

Bessie Height (Project HU TX 5) --- Bessie Heights is an 11,363-acre hydrologic unit and is the sight of the most contiguous loss of marsh in Texas. The unit contains 2,018 acres of fresh marsh, 1,932 acres of intermediate marsh, and 293 acres of bottomland hardwoods. FWP impacts would be associated with small increases in salinity (0.5ppt) and the loss of two acres of fresh marsh and one acre of intermediate marsh. These impacts would result in a total loss of 14 AAHUs for the unit.

Old River (Project HU TX 6) --- This unit is approximately 11,851 acres and contains 5,240 acres of brackish marsh and 230 acres of fresh and intermediate marsh on the periphery. There is a 199-acre tract of bottomland hardwood in one corner of the unit and 3,620 acres of the unit is open water. Increases of salinity to 13 ppt and the loss of 46 acres of brackish marsh result in a total loss of 116 AAHUs for the unit.

Gulf of Mexico to North of GIWW

GIWW North (Project HU TX 7) --- This 5,907-acre unit is comprised of three units located on the north side of the GIWW and all are within the largest remaining coastal freshwater marsh in Texas. There are 4,541 acres of fresh marsh, 588 acres of brackish marsh, 129 acres of intermediate marsh and 195 acres of open water. TPWD baseline salinities range from 0.7 to 0.9 ppt during the growing season in fresh and brackish marshes, respectively. Project impacts expect an increase in salinity to 4.0 ppt in fresh marsh and 1.6 ppt in brackish marshes. Sixty-three acres of fresh and two acres of brackish marsh will be lost. Project impacts will result in a total loss of 148 AAHUs in this unit.

Texas Point (Project HU TX 8) --- This unit is 11,422 acres and lies adjacent to the SNWW at Sabine Pass and extends for almost 13.5 miles along the Gulf of Mexico. The Texas Point NWR lies completely within this unit. This unit contains 4,898 acres of saline marsh, 2,398 acres of brackish marsh, 1,605 acres of intermediate marsh, 100 acres of fresh marsh, 1,413 acres of other upland areas, and 1,008 acres of open water. Baseline salinities for this area average 5.75 ppt for intermediate, 8.5 ppt for brackish and 12.5 ppt for the saline marshes. It should be noted that periodic hurricanes and tropical depressions do inundate these areas with high salinity waters, but usually are then punctuated by long periods of freshwater recovery (Gooch 1996). However, the potential for a 0.56 ppt increase to affect standing crop of fresh/intermediate marsh via inflow points at the (Service-estimated) six tidal creeks and bank failure points is certainly real. This pattern tends to serve the beneficial function of removal of surplus above-ground vegetation, much like periodic wildfires in prairie regions, thus allowing highly productive new-growth vegetation to recover, to the benefit of wildlife populations. This is different from encroachment of chronic, slightly higher salinity levels in these communities, which has been shown to alter vegetation patterns to a less diverse and less productive state for wildlife (Palmisano 1972).

Project impacts would include increases in salinity, interior land loss and shoreline retreat increases. Salinities are expected to move to 7.8 ppt, 10.6 ppt and 14.6 ppt for the intermediate, brackish and saline marshes, respectively. Expected land losses are 6 acres, 5 acres and 17 acres for intermediate, brackish and saline marshes, respectively. Shoreline retreat is expected to increase to 0.42 ft/yr between 0.5 and 3.5 miles west of the jetty. These impacts are expected to result in a loss of 31 AAHUs in this unit.

Salt Bayou (Project HU TX 9) --- This 55,044-acre unit is adjacent to the SNWW between TX 8 and the GIWW. The majority of this unit lies within the J.D. Murphree WMA and the McFaddin NWR. The Salt Bayou unit has been extensively impacted by human development, i.e. oil exploration, cattle grazing and the construction of levees and ditches to create waterfowl hunting opportunities. This development has led to increases in the amount of open water and has decreased the amount of emergent marsh with causes most likely being the increases in salt water intrusion. Predicted losses of salinity increases from 6.9 ppt to 9.6 ppt for the brackish marsh and to 7.4 for the intermediate marsh include 49 acres of brackish marsh and 202 acres of intermediate marsh are expected. The 251 acres of brackish/intermediate marsh loss in Salt Bayou is not included in project compensation requirements because it was agreed that the Section 1135 Water Resources Development Act (WRDA) Keith Lake Fish Pass project, a TPWD/Corps cooperative project supported by the Service, would protect this entire HU from project-induced salinity increases. In fact, current project design alternatives would reduce

salinities within this HU by as much as 10 ppt. **The Service will monitor SNWW deepening progress along with the Section 1135 Keith Lake Fish Pass Project and will recommend additional habitat compensation should the Keith Lake project fail to materialize.**

Cow Bayou (Project HU TX 10) --- Cow Bayou flows into the Sabine River approximately three miles north of its confluence with Sabine Lake. This 4,990-acre unit comprises a narrow riparian corridor and its entire length is confined by development and Bridge City. There are two upland placement areas, 1,436 acres of fresh water marsh, 1,445 acres of intermediate marsh, and 110 acres of cypress-tupelo swamp located within the unit. A salinity increase of 1.0 ppt is expected in the swamps and fresh water marshes in the upper reaches. Salinity increases of 1.0 ppt (Table 3) are expected for both fresh water and intermediate marshes in the lower reaches. Fresh water and intermediate marsh loss are expected to be six acres and three acres, respectively, for a loss of 30 AAHUs.

Adams Bayou (Project HU TX 11) --- Adams Bayou flows into the Sabine River approximately 5 miles north of Sabine Lake. This 1,679-acre unit is comprised of a narrow riparian corridor. There are 516 acres of fresh marsh and 640 acres of bottomland hardwood forests. Cypress tupelo comprises only 115 acres in this unit. Swamp communities are expected to see salinity increases of 0.8 ppt and fresh marshes will see an increase of 1.5 ppt (Table 3). Though somewhat compromised and intruded-upon by urban areas and past oilfield development, these are important habitat areas heavily used by local residents for recreation. These increases translate into a loss of three acres for fresh water marshes. No loss of swamp or bottomland hardwood acres is expected, however, the increased salinity is expected to have an overall impact on the health of the system. Increased herbaceous coverage and slowing of tree growth is expected. These impacts reflect a loss of 19 AAHUs.

South of Blue Elbow Swamp (Project HU TX 12) --- This entire section (698 acres) of the lower Sabine River drainage system is composed of cypress-tupelo swamp. This habitat type is predicted to suffer no actual acreage loss from the 0.6 ppt salinity increase during low flow periods. Although no loss in swamp acreage is expected, the increase in salinity will cause a reduction in the overall health and productivity of the swamp. Expected impacts are a reduction of over story and a slowing in the rate of trunk diameter growth. This expected impacts result in a loss of 18 AAHUs.

Groves, Neches River (Project HU TX 13) --- This small (437-acres) intermediate marsh unit lying west of the Neches River shows a baseline salinity of 3.0 ppt and FWP impacts would increase salinities 1.0 ppt to 4.0 ppt. This translates to three acres of projected intermediate marsh loss and a loss of 3 AAHUs.

Texas portion of shared HU's (Project HU LA/TX 1 and 2) --- LA/TX 1 and 2 are predicted to have, at a maximum, 0.0 and 0.3 ppt salinity increases, causing insignificant habitat losses. The ICT Environmental Work Group biologists thought that such small predicted maximum salinity increases would not significantly percolate into adjacent, higher bottomland areas since bottomland flooding is almost always accompanied by increased freshwater events. Adjacent cypress-tupelo swamps would likewise be buffered from any slight channel salinity increases by large volumes of surface fresh water. Because impacts are expected to be negligible, there is no expected land loss and no loss of AAHUs.

Salinity-related impacts to aquatic communities (Louisiana)

Louisiana Habitat Areas

Perry Ridge (Project HU LA 1) --- This large (28,094-acres) unit lying immediately north of the GIWW and west of the Sabine River contains the largest freshwater marsh tract (18,859 acres) in the project area. Because of projected salinity increases in the upper and eastern Sabine Lake, it is considered potentially at risk from project-induced salinity intrusion. Significant (2,158 acres) bottomland forests also occur here. A small predicted salinity change (-0.3 ppt) at this unit's boundary extrapolates to predicted losses of 50 acres (-65 AAHU's) of fresh marsh and 12 acres (-53 AAHU's) of intermediate marsh (Table 4). The bottomland hardwood portion of the unit would not be affected by increased water levels enough to suffer damages from slightly increased salinities. Also, as is the case for upper Neches and lower Sabine Rivers (TX) units, higher water levels are normally associated with increased freshwater river flows and high rainfall events, conditions which would be reflected under the High Flow model scenario.

A shift toward more brackish marsh habitat occurred from 1949 to 1968. In 1968, there was a 10 percent decrease in fresh marsh and the unit was 55 percent intermediate and 20 percent brackish marsh, possibly caused by saltwater intrusion from the SNWW via Sabine Lake and the GIWW. The unit currently includes 27 percent intermediate marsh (7,370 acres), 29 percent fresh marsh (7,820 acres), 1 percent swamp (170 acres), and 30 percent open water (8,190 acres). The remaining 14 percent includes upland, ridge, swamp, forest, or developed land (3,751 acres) (Louisiana Coastal Wetlands Conservation and Restoration Task Force and the Wetlands Conservation and Restoration Authority 1999).

Willow Bayou (Project HU LA2) --- This huge (36,291 acres) unit lies east of Sabine Lake and is bordered by Pine Ridge on the north, Sabine Lake on the west, the Burton-Sutton Canal on the east, and the Starks South Canal on the south. Most (35,100 acres) of its marsh acreage is classified as intermediate and is therefore potentially sensitive to minor salinity changes. The modeled FWP -0.9 ppt salinity increase is predicted to cause a loss of 102 acres (-328 AAHU's) of intermediate marsh during project life. The relatively small amount (1,182 acres) of brackish marsh within this unit is predicted to experience a 1.4 ppt salinity increase due to the project, causing a loss of 2 acres (-1 AAHU) (Table 4).

The eastern two-thirds of this unit was historically a mixture of fresh and intermediate marsh with the west classified as brackish marsh. 1968 and 1978 vegetation type maps showed a trend toward more brackish conditions. In 1988, the majority of the unit was brackish marsh, with a small area of intermediate marsh located in the southeastern corner. In 1990, the unit consisted of approximately 7 percent intermediate marsh (2,500 acres) and 52 percent brackish marsh (18,960 acres), with the remaining 41 percent consisting of open water and upland habitats (15,010 acres).

Black Bayou (Project HU LA3) --- This 39,853-acre unit is the project area's largest and consists of primarily intermediate marsh. The Black Bayou unit is bordered on the west by the Sabine River and Sabine Lake, Pines Ridge to the south, the GIWW to the north, and the Gum Cove Ridge, Bancroft Canal, Black Bayou and Right Prong Canal to the east. The predicted 1.1 ppt salinity increase in the intermediate marsh extrapolates to a predicted net loss of 130 marsh acres (-509 AAHU's). The modeled brackish increase of 0.8 ppt will cause 4 acres of loss (-1 AAHU) (Table 4). The total predicted losses for the unit equal 134 acres and 510 AAHUs.

There has been a shift to more brackish marsh from 1949 to the present. In 1949, the distribution of marsh types was 50 percent fresh, 20 percent intermediate, and 25 percent brackish. By 1968, there was an increase of 15 percent in brackish marsh and 10 percent in intermediate marsh, and a 30 percent decrease in fresh marsh habitat. This increase in more saline marsh types may have been caused by saltwater intrusion via the Sabine-Neches and Calcasieu Ship channels. The unit currently consists of approximately 23 percent intermediate marsh (9,480 acres), 34 percent brackish marsh (13,750 acres), nominal fresh marsh (600 acres), and 33 percent open water (13,410 acres), with some swamp, upland, forest, and developed land (Louisiana Coastal Wetlands Conservation and Restoration Task Force and the Wetlands Conservation and Restoration Authority 1999).

West Johnson's Bayou (Project HU LA4) --- This unit lies just south of Sabine NWR and is bordered by Sabine Lake to the west, Buck Ridge to the south, Deep Bayou to the east, and Gray's Ditch to the north. Johnson's Bayou flows from the southeast to the northwest through the unit. The unit consists primarily of intermediate marsh (10,031 acres), with 14 percent (1,837 acres) brackish marsh. The predicted 1.2 ppt salinity increase is expected to cause an additional loss of 142 acres (-269 AAHU's) of intermediate marsh and a 0.7 ppt salinity increase would lead to the loss of 64 acres (-1 AAHU) of brackish marsh (Table 4).

In 1949, the unit was composed of 85 percent brackish marsh, and 5 percent each of saline marsh, intermediate marsh, and beach habitats. Little change in marsh type has taken place from 1949 to the present. In 1968, the area contained 75 percent brackish marsh, and 25 percent intermediate marsh (Louisiana Coastal Wetlands Conservation and Restoration Task Force and the Wetlands Conservation and Restoration Authority 1999).

Sabine Lake Ridges (Project HU LA5) --- This 33,472-acre unit is the most southerly of the Louisiana project hydrologic units and lies immediately north of the Gulf of Mexico and east of southern Sabine Lake and Sabine Pass. Subjected to higher salinities than the more northerly units, it is composed of 10 percent (3,198 acres) saline marsh, 44 percent (14,673 acres) brackish marsh, and 24 percent (8,232) intermediate marsh. Access for marine organisms is via Greens and Lighthouse Bayous. The 1.4 ppt maximum predicted salinity increase at the bayou's mouth would cause losses of 10 acres (-35 AAHU's) to saline marsh. A predicted salinity increase of 0.6 ppt would cause losses of 43 acres (-14 AAHU's) of brackish marsh and 93 acres (-218 AAHU's) of intermediate marsh (Table 4).

Sabine Lake Ridges Unit marsh types have recently shifted toward fresher marshes. In 1949, the area was 70 percent brackish marsh, 10 percent saline marsh, and 20 percent beach or Chenier. By 1968, 20 percent of the previous beach habitat had converted to intermediate marsh. Currently, the habitats in the unit consist of 11 percent saline marsh (3,800 acres), 35 percent brackish marsh (12,100 acres), 24 percent intermediate marsh (8,300 acres), 5 percent fresh marsh (1,810 acres), and 5 percent open water (1,713 acres), with the remaining 19 percent consisting of upland, swamp, forest, or developed land (6,545 acres) (Louisiana Coastal Wetlands Conservation and Restoration Task Force and the Wetlands Conservation and Restoration Authority 1999).

Johnson's Bayou Ridge (Project HU LA6) --- This small (4,089-acre) unit is bounded on the south by the Gulf of Mexico and on the north by Hackberry Ridge. Johnson Bayou Ridge habitats consist of brackish (2,744 acres) and saline (370 acres) marsh with Chenier forested uplands along Hackberry Ridge (975 acres). The 0.7 ppt predicted salinity increase would lead to a loss of 22 acres (-6 AAHU) of brackish marsh. A predicted salinity increase of 1.8 ppt would cause a loss of 5 acres (-2 AAHUs) of saline marsh over the project life (Table 4).

Forty percent of this unit consisted of saline marsh, with 5 percent brackish and intermediate marsh and the rest being Chenier ridge habitat in 1968. Since 1968, approximately 25 percent of the saline marsh has shifted to brackish (Louisiana Coastal Wetlands Conservation and Restoration Task Force and the Wetlands Conservation and Restoration Authority 1999).

Southeast Sabine (Project HU LA7) --- The 8,034-acre Southeast Sabine unit is bordered by a series of manmade canals bisecting the Sabine NWR. The western portion of this unit is bordered by the Starks Central Canal on the north, the Burton-Sutton Canal on the west, an unnamed canal to the east, and the Starks South Canal on the south. The work group determined that only the western portion of the unit would be affected by SNWW salinity increases. The unit contains 4,925 acres of intermediate marsh and 2,023 acres of fresh marsh. Predicted maximum salinity increases of 0.5 ppt would result in losses of 0 acres (-11 AAHUs) of fresh marsh. A predicted salinity increase of 0.2 ppt would cause a loss of 1 acre (-0 AAHUs) of intermediate marsh (Table 4).

From 1949 through 1988, the unit was classified as intermediate marsh, with 10-20 percent brackish marsh. The unit contains 58 percent intermediate marsh (12,430 acres), 31 percent brackish marsh (6,590 acres), nominal fresh marsh (10 acres), and 11 percent open water and other habitats (2,249 acres) (Louisiana Coastal Wetlands Conservation and Restoration Task Force and the Wetlands Conservation and Restoration Authority 1999).

Southwest Gum Cove (Project HU LA8) --- This is an interior marshland unit bounded by Gum Cove Ridge to the north, Starks North Canal on the south, and on the west by Right Prong and Black Bayous. Its 11,386 acres contain 3,615 acres of fresh marsh and 6,605 acres of intermediate marsh. Predicted salinity increases of 0.9 ppt would result in the loss of 8 acres (-14 AAHUs) of fresh marsh and a loss of 15 acres (-4 AAHU's) of intermediate marsh over the project life (Table 4).

The unit's habitats shifted to more brackish marshes from 1949-1968 when 15 percent of the fresh to intermediate marshes converted to brackish marsh. Habitats include approximately 38 percent fresh marsh, 23 percent intermediate marsh, 7 percent brackish marsh, and 17 percent open water. The remaining 14 percent incorporates upland, swamp, forest, or developed land (Louisiana Coastal Wetlands Conservation and Restoration Task Force and the Wetlands Conservation and Restoration Authority 1999).

East Johnson's Bayou (Project HU LA9) --- This 26,719-acre unit is composed primarily of intermediate marsh (26,138 acres) plus a small amount of uplands along Buck Ridge, which forms its southern boundary. It is bordered on the north by Sabine NWR. Salinity increases of 1 ppt are predicted to cause additional losses of 46 acres (-190 AAHUs) of intermediate marsh over current marsh loss (Table 4).

The East Johnson's Bayou Unit was divided evenly between intermediate and brackish marsh in 1949. By 1968, the unit was comprised of 70 percent intermediate marsh and 30 percent brackish marshes, which is indicative of a salinity decrease (Louisiana Coastal Wetlands Conservation and Restoration Task Force and the Wetlands Conservation and Restoration Authority 1999).

Louisiana portions of shared HU's (Project HU's LA/TX 1, 2) --- LA/TX 1 and 2 are predicted to have 0.1 ppt salinity increases, causing insignificant actual habitat losses and loss of 0 AAHU's to the cypress-tupelo community. The ICT Environmental Work Group biologists thought that such small predicted salinity increases would not significantly percolate into adjacent, higher elevation bottomland areas since bottomland flooding is almost always accompanied by increased freshwater events. Adjacent cypress-tupelo swamps would likewise be buffered from any slight channel salinity increases by large volumes of surface fresh water.

Habitat Trade-offs, Mitigation, and Beneficial Use (BU) Plan

On August 31, 2009, the Corps' Directorate of Civil Works – Planning Community issued implementation guidance for Section 2036(a) of the Water Resources Development Act of 2007. This guidance requires that the preferred alternative contain a mitigation plan for the fish and wildlife resources that are lost as a result of the unavoidable impacts caused by the project. These impacts must be compensated to the extent justified and the preferred alternative must have adequate mitigation that will ensure the channel improvement project will not have any measurable adverse impact to the significant resources in the area. The Corps also recognizes that the wetland resources outlined in this document are significant and could suffer long term impacts due to the preferred alternative.

The ICT met on several occasions and identified a preferred mitigation plan for Louisiana and Texas. All of the unavoidable impacts from the preferred alternative will occur in Louisiana. All of the project impacts in Texas will be offset by BU features.

The Work Group developed mitigation and BU goals, as follows:

- 1) No net loss of wetland acres,
- 2) Replace lost AAHU's 1:1,
- 3) Replace AAHU's in-kind,
- 4) Losses to be mitigated in the state in which they occur, and
- 6) Dredged material from Sabine Pass is to be shared equally between each state.

Following are explanations of proposed BU and mitigation features.

Texas

As previously discussed, land subsidence, salinity intrusion from original SNWW construction, small channel (largely oil field access) construction, levees, oil field brine runoff, and secondary salinity intrusion have all contributed to the conversion of over 9,500 acres of wetlands in the lower Neches River basin into tidally-influenced open water areas. Once converted, these areas are difficult to re-vegetate and return to their original productivity without raising lost elevations using massive amounts of dredged or otherwise imported material. Therefore, it was decided early in the interagency project planning process that new-work channel dredged material and subsequent maintenance material should be utilized to repair these distressed aquatic systems.

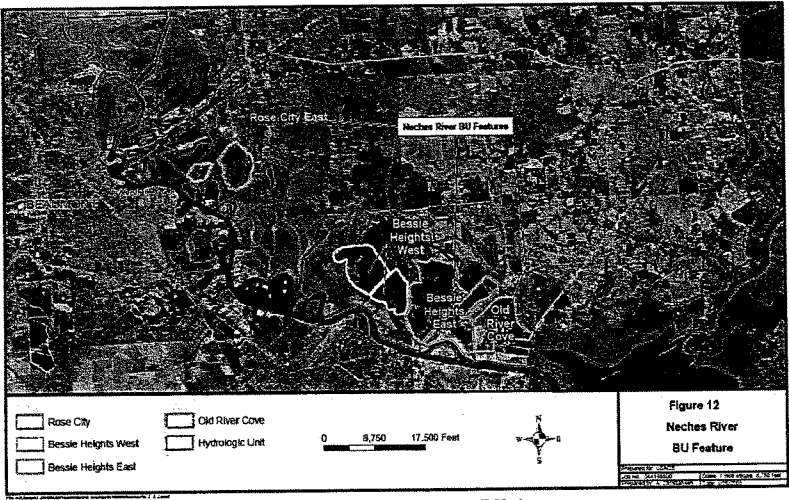

Figure 6 Texas Neches River BU sites

11

Figure 7 Texas shared BU beach nourishment

Figure 8 Louisiana BU beach nourishment

Rose City Marsh BU— This formerly productive freshwater system includes most of hydrologic unit TX3, a 5,805-acre area composed primarily of cypress-tupelo swamp and freshwater marsh prior to the early 1900s. A total of 225 acres of emergent fresh marsh-elevation substrate would be constructed (and planted) using new work material by project year 15 and 120 more acres would be added using maintenance material from the first maintenance dredging cycle following construction. The placement of dredge material is expected to restore 18 inches of top soil over eroded mud flats and open water, thereby creating 345 acres of emergent fresh marsh, improving 72 acres of shallow water habitat and nourishing an additional 151 acres during the two events. This would result in construction of approximately 568 acres of restored marsh, marsh edge, channels, and potential swamp forest ridges (Tables 6 and 7). **The Service recommends that the post-authorization project work group pursue plans for the restoration of cypress-tupelo forest vegetation on suitable, higher-elevation ridges within the restored marsh area.** Formerly, this was the predominant vegetation type at this location, and cypress-tupelo swamp forest has been shown to support high native wildlife populations in this region and to be in decline on a nationwide basis.

12

The existing low salinities (0.25 ppt) show little improvement from the BU. In fact, the model shows a slight (0.3 ppt) (Table 3) salinity increase under low flow conditions with the project. However, since this projected increase is slight, the Service does not consider it biologically significant and to be compensated by the magnitude of habitat creation. Under actual field conditions, it is likely that many areas protected from direct connection by the newly constructed marshes and pumped terraces would frequently retain pockets of freshwater runoff from the surrounding watershed. We consider acreage losses and gains, through habitat creation, to be more realistic than small model-predicted salinity changes. Also, we consider it doubtful that

model output is sensitive enough to predict very small benefits to salinity levels at individual habitat features within shallow areas far removed from main channels.

Bessie Heights Marsh BU--- The most extensive losses of interior coastal wetlands in Texas have occurred in the lower Neches River delta. Of the estimated 13,800 acres of marshes formerly in this sector, 12,632 acres have been lost to open water (White et al. 1987, Sutherland 1996). Primary causes were land subsidence and resultant salinity intrusion. Shallow water area (< 1 ft.) would be doubled within the sub-unit, and existing, currently stressed, marsh would be nourished by spillover from adjacent marsh creation. New work material to be used in this reach ranges in sand/clay ratios from 1:2 to 1:5. The marsh fans (splays) will be created by frequent movement of dredge pipes.

In the Bessie Heights East unit (Project HU 5), 1,190 acres of emergent intermediate marsh and 679 acres of emergent brackish marsh would be constructed using finer grained maintenance material. The DMMP features a total restoration of 1,869 acres in this unit, with improvement to 660 acres of shallow water habitat and the nourishing of an additional 615 acres of existing fringe marsh (Table 6). The inner marshes will have channels constructed to allow for drainage through reconstructed stream channels to the Neches River. This will provide flushing to the system and will maintain moderate soil salinities, while providing ingress and egress for marine dependent species.

Old River Cove Marsh BU---The Old River Cove (Project HU 6) will have a total of 639 acres of emergent brackish marsh restored, 139 acres of shallow water habitat improved and will re-nourish an additional 432 acres of existing fringe marsh at project inception (Table 6). Channels will be created to allow circulation throughout the created areas as well as to provide ingress and egress for marine dependent organisms. Conditions for submerged aquatic vegetation are expected to improve as still water areas are created and there is an increase in shallow water habitat. Table 6 summarizes the acreage to be improved from BU.

Table 6 Neches River BU Summary

Components of Neches River BU Feature	Restored Emergent Marsh	Improved Shallow Water Habitat	Nourished Existing Marsh	Total Influence Area
Rose City East	345	72	151	568
Bessie Heights East	1,869	660	615	3,180
Old River Cove	639	139	432	1,210
Total	2,853	871	1,198	4,958

13

The Service considers the marsh creation measures in the lower Neches delta, the salinity reductions within the created marsh areas and their basins, and the potential slight salinity reductions in the upper Neches River portion of the study area to be beneficial habitat measures and to compensate for the slight salinity-related habitat stress in lower project reaches. However, experience in other large-scale estuarine channel enlargement projects involving placement of large volumes of dredged material has taught us that methods and construction techniques often require significant adjustments, interagency coordination, planning, monitoring, and on-site inspections. Success of BU features depends on sound planning, timely inspections, and the

ability to modify construction techniques on-site. Salinity levels should be monitored in areas where the model predicts changes following channel enlargement.

Therefore, the **Service recommends that an interagency coordination team be formed to include all State and Federal environmental agencies to meet regularly and provide inspection oversight and recommendations during post-authorization planning and construction. The Service will request yearly Fish and Wildlife Coordination Act transfer funds during the construction phase to provide inspection and design recommendations for habitat creation features.**

14

Colonial Waterbird Needs Analysis

The Service reviewed colonial waterbird datasets from Texas (TCWC 2006), and Louisiana (Michot et al. 2004). Waterbird colony sites in Jefferson and Orange Counties, Texas, and Cameron Parish, Louisiana known to be active since 2000 were mapped and yearly averages tabulated. Numbers of active colonies and breeding populations were compared to available wetland habitat to estimate whether additional waterbird breeding colony(s) could increase populations of this desirable and beneficial bird group. Colonial waterbirds are considered an important species group and an indicator of the health of large aquatic ecosystems due to their high visibility and source of tourism revenue, their role as top-level predators, their sensitivity to environmental factors such as contamination, and the availability of reliable population estimates.

Orange and Jefferson Counties, Texas, from 1996 thru 2005, hosted at least 28 nesting colonies containing a 10-yr. average of 2,550 nesting pairs. Due to year-to-year inconsistencies in counting effort, the 10-yr. maximum count of 5,039 nesting pairs might be closer to the average yearly nesting population. These nesting waterbirds belonged to 13 species, including seven wading bird species. Wading birds (herons, egrets, and spoonbills) normally nest in mature brush and trees.

Calcasieu and Cameron Parishes, Louisiana, hosted 11 small colonies, detected during Michot et al.'s 2004 Louisiana aerial survey. These 11 colonies had five species and 220 nesting pairs, mostly black-crowned night herons. The black-crowned night heron is often overlooked in the TCWC counts. This species tends to aggregate in small daytime, often non-nesting, colonies in isolated mainland brush thickets and does not represent a true colonial waterbird in many aspects. An average of 1,214 wading bird nesting pairs were observed in three southwest Louisiana colonies; one colony in Pool 3 of the Sabine National Wildlife Refuge, and two colonies in the Gum Cove region north of Pool 3 in the 2004-2005 Louisiana statewide wading bird and seabird surveys (Green et al. 2006).

Orange and Jefferson Counties in Texas combined cover 1,490 sq. mile, over 50 percent of which is urbanized or industrial. Cameron and Calcasieu Parishes, Louisiana combined covers 3,026 sq. mile; approximately 10 percent is urbanized or industrial. Yet, the Texas side of the project area (Orange and Jefferson Counties) host, on average, about 20 times more colonial nesting waterbirds and eight times more species richness than the Louisiana side.

This indicates that there may be a shortage of predator-free nesting habitat in the southwest Louisiana region, and may indicate that additional predator-free nesting island(s) in the Sabine

Lake system could increase colonial waterbird populations over vast areas of appropriate feeding habitat in Louisiana.

Sabine Lake Colonial Waterbird Nesting Island BU Opportunity --- Because of the proximity to one-time sources of firm clay building material, the shortage of waterbird nesting habitat within large areas of feeding habitat in southwestern Louisiana, and the past success in creating waterbird nesting habitat in bay systems, the Service **recommends using new-work dredged material to construct a waterbird nesting island in the most efficient location for placement of material and at least one mile from shore in the upper Sabine Lake area.** The island should be 4 to 12-acres in size and should be built to an elevation of at least 8 ft. mean high tide. Suggested location(s) are shown in Figure 1.

15

The Service made similar recommendations for the Houston-Galveston Navigation Channels (HCNC) Project. In 1999, using stiff new-work clays from HGNC deepening, the 10-acre Evia island was constructed approximately 3 miles east of the ship channel and 1.5 miles north of Bolivar Peninsula, in southern Galveston Bay. Colonial-nesting waterbirds nested on Evia Island during the first year post-construction, and in increasing numbers and diversity each year following. Nesting populations have increased from 1,050 pairs in 2001 to 6,800 pairs in 2006. The percentage of all Galveston Bay nesting pairs which nest on Evia Island and the three other HGNC beneficial use islands has increased from 3 percent (1,824 nesting pairs) in 2001 to 23 percent (8,419 nesting pairs) in 2005.

Native tree plantings have begun to provide habitat for the (declining) wading bird species. Predator control, often an expensive requirement of nesting island management, was largely avoided by proper tree placement and the Service would assist in developing plans for tree placement and construction. The Service would also assist in post-construction monitoring and management. Texas Audubon Society and Golden Triangle Audubon Society have expressed interest in providing assistance in protection and management (Kasner 2007).

Texas and Louisiana Point Gulf Beach Nourishment--- Maintenance material from the Sabine Pass SNWW channel reach will be placed alternately, every three years, on either the Texas or Louisiana Gulf beach for a distance of approximately three miles. In addition to halting the projected slight accelerated shoreline loss from increased ship wake waves due to channel enlargement, a cumulative 674 acres of new saline marsh would be constructed by the end of the 50-year project life at Texas and Louisiana Points.

Sabine Pass maintenance material has averaged approximately 51 percent silt, 31 percent clay, and 18 percent sand for maintenance dredging cycles since 1975. The maintenance material would be hydraulically pumped onto the the beach and nearshore zone. Some material is expected to flow over existing beach, marsh, and near shore waters. Vegetation would be planted on the inland portion of the dredged material to assist in its stabilization. A similar Corps' WRDA Section 204 Continuing Authorities Program project constructed at Texas Point in 2004 showed that the dredged material dissipated quickly during the placement event, with 60 percent remaining following initial disposal. It is estimated that 50 percent of the remaining material after each placement episode will erode away by the end of each 6-year cycle. New material added every 6 years would eventually create 674 acres of new saline marsh by the end of the project life at Louisiana and Texas Points (USACE 2009)

Existing Disposal Area Use and Management (DMMP) ---

- DA 1-4 --- Nearshore sites should be maximized in order to maximize benefits to demersal and benthic communities from creating bottom surface topography. Within EPA Green Book guidelines, nearshore offshore disposal sites should be moved as close to the Gulf beach as practicable, for fisheries habitat as well as beach nourishment purposes. 16
- DA 16A --- This 202-acre site is an existing high-quality intermediate marsh, containing several shallow, open water ponds, bayous and natural circulation channels (Figure 2). It is unleveed, except for the low natural river berm, and receives tidal circulation through these avenues leading into the manmade ditch running along its southwest border. The site is presently at natural elevations. Therefore, the Service objects to the use of this site for dredged material disposal, especially given the availability of other nearby disturbed sites. 17
- DA 14A (82 acres) --- This site is a relatively undisturbed *Spartina patens* wet meadow, containing one large (approximately 6 acres) and several small open-water ponds. As a high-quality wetland at natural elevations which would freely flood during spring tide and heavy rainfall events, it provides habitat for a diverse array of native wildlife species. The Service objects to the use of this site for dredged material disposal, given the availability of other nearby disturbed sites. 18
- DA 23A (269 acres) --- This area is a leveed, second-growth, scrub-shrub forest. Wetland areas are present, many formed by the backwater effect of the levees. Dominant species are black willow (*Salix nigra*), hackberry, and Chinese tallow, with the occasional red maple, water oak, and yaupon (*Ilex vomitoria*). The Service recommends that if this site is converted to an upland DA: 1) damages to wetlands ("scrub-shrub" bottomland forest) be calculated using WVA methodology for project mitigation, and 2) disposal area water regime protocol be developed, in conjunction with Service and TPWD biologists, to maximize wetland characteristics of the enclosed DA for wintering waterfowl habitat during between-disposal periods. 19
- DA 24A (187 acres) --- This site is composed of a marginal upland (possibly remnant bottomland hardwood) ridge and isolated wetlands. Wetlands contain small open-water pockets but are primarily densely vegetated with California bulrush (*Schoenoplectus californicus*), common reed (*Phragmites australis*), and *Spartina patens*. Edges and ditches have a more diverse assemblage of wetland plants, including black willow, rattlebox (*Sesbania drumondii*), wax myrtle (*Myrica sebfiferum*), smartweed (*Polygonum sp.*), and narrow-leaf cattail. Uplands and transitional areas are dominated by the invasive Chinese tallow, but contain occasional yaupon, deciduous holly (*Ilex verticillata*), common baldcypress, red maple, sweetgum, American holly, and greenbriar. Hydrology is restricted by levees and roads, but both wetland and upland areas have potential for restoration. Adjacent wetlands to the north and northeast are of higher quality and contain more natural hydrology and circulation patterns. 20

The Service recommends that, if the 187-acre portion of the site is converted to an upland disposal area: 1) disposal area levee alignments and discharge points be reviewed by Service and TPWD biologists before final site designation for input on minimizing impacts to adjacent high-quality habitats, 2) disposal area water regime protocol be developed, in conjunction with Service and TPWD biologists and Jefferson County Navigation District, to maximize wetland characteristics of the enclosed DAs during between-disposal periods for wintering waterfowl habitat.

DA 26 --- (192 acres) This leveed site, adjacent to the Neches River in an old oxbow bend, has previously been used for disposal of SNWW material. It is freshwater marsh dominated by Chinese tallow, with small pockets of *Phragmites* sp., leafy three-square, narrowleaf cattail, water hyssop, rice cutgrass, and wax myrtle, primarily along remnant borrow ditches. While the site does have some value as waterbird and native reptile and amphibian habitat associated with the few, small open-water areas, its value is limited. Therefore, the Service would not object to its use as a new-work dredged material disposal site. However, a disposal area water regime protocol should be developed, in conjunction with Service and TPWD biologists, to maximize wetland characteristics of the enclosed DA during between-disposal periods for wintering waterfowl habitat.

21

DA 27A (84 acres) --- This leveed site contains a “backwater”, isolated, early successional swamp forest created by previous levee construction. Species composition, limited species diversity, and high degree of disturbance make this habitat of fairly low value.

22

DA 27C (87 acres) --- The entire site has been leveed in the past and has received overland flow from past dredging activities. This site is a secondary upland forest. Common tree species (to 35 ft.) are water oak, sweet gum, arrowwood viburnum (*Viburnum dentatum*), Carolina buckthorn (*Frangula caroliniana*), wax myrtle, and loblolly pine (*Pinus taeda*). Most trees greater than 10 inch diameter at breast height (dbh) have been wind-thrown by recent storm events. The site has some value as wintering songbird and small mammal habitat. The Service recommends that a disposal area water regime protocol be developed, in conjunction with Service and TPWD biologists and Jefferson County Navigation District, to maximize wetland characteristics of the enclosed DA during between-disposal periods for wintering waterfowl habitat.

23

DA 27D (35 acres) --- This leveed area receives regular inflow from an adjacent industrial cooling facility which may contain some contaminants. The water table is kept artificially high year-round, supporting a dense vegetative community dominated by California bulrush and fringed by second-growth common baldcypress, Chinese tallow, and sweetgum. Small open-water areas and outlying roadside borrow ditches contain dense stands of invasive water hyacinth and *Salvinia minima*, with some native yellow pond-lily. Dense, weed-choked plant cover and the artificial water regime limit this site's wetland wildlife value, but it supports a wetland wildlife community typified by red-winged blackbird (*Aegialius phoeniceus*), common coot (*Fulica atra*), moorhen (*Gallinula chloropus*), sedge wren (*Cistothorus platensis*), and wood duck (*Aix sponsa*).

The Service recommends that if DA 27D is converted to an upland DA that a disposal area water regime protocol be developed to maximize wetland habitat potential during between-disposal intervals for wintering waterfowl use.

24

Table 7 SNWW Dredge Material Management Plan Restoration (BU) and Nourishment Features

Hydro unit	No.	Description	Size of Influence Area
Rose City	TX3-1 East	Restoring fresh marsh & shallow water habitat, & nourishing existing marsh in two construction events. New work material will be used to restore 225 ac marsh in 556 existing open water acres, construct hydraulic levees & construct three finger mounds & circular mound. Maintenance material from 1st cycle used to construct finger mounds & fill out northern margin, restoring an additional 120 acres of marsh. Material from Sec 18.	Influence area 568 ac; restoring 345 ac marsh in 556 open water acres
Bessie Heights	TX5-2	Restoration of intermediate & brackish marsh & shallow water habitat, and nourishment of existing marsh with maintenance material for 28 years. Assume 7 maintenance cycles - 267 acres marsh created per cycle. New work material used to build hydraulic containment levee at S end. Maintenance material used to restore 70-75% of the existing 2,546 ac of open water. Material comes from Neches River Channel Sect 13, 14, & 15.	Influence area - 3180 ac; 679 ac brackish marsh restored in 847 ac open water, and 1190 ac intermediate marsh restored in 1683 ac of open water.
Old River Cove	TX6-1	Restoration of brackish marsh & shallow water habitat, & nourishment of existing marsh with new work material. Area is semi-confined; new work material used to construct hydraulic containment levee along existing canals. New work material comes from Neches River Channel, Sections 13, 14, 15.	Influence area - 1,210 ac; restores 639 ac in 778 ac open water.
Keith Lake Marsh	TX9- 1	Marsh restoration in areas of breaking marsh north of Keith Lake, within the TPWD J.D. Murphree Wildlife Management Area. Degraded marsh areas will be filled with thin layers (6 to 24 inches) of maintenance material from Section 7 of the Port Arthur Canal in one maintenance cycle.	Influence area – 580 ac
Texas Point	TX 8-11	Nourish 0.5 to 3.5 miles from West Jetty using maintenance material from Section 5 over 50 yr project life. Unconfined placement of maintenance material along shoreline every 6 years for project life (8 placement episodes). Assume 50:50 split of material between Texas and Louisiana accomplished by alternating placement in TX and LA.	Affected shoreline 3.0 miles
Louisiana Point	LA5-6	Nourish 0.5 to 3.5 miles from East Jetty using maintenance material from Section 5. Unconfined placement of maintenance material along shoreline every 6 years for project life (8 placement episodes). Assume 50:50 split of material between Texas and Louisiana by alternating placement in TX and LA.	Affected shoreline 3.0 miles

(USACE 2009)

Table 8 Summary of DMMP Beneficial Use Feature Benefits (Units in AAHUs)

	Swamp	Bottomland Hardwood	Fresh Marsh	Intermediate Marsh	Brackish Marsh	Saline Marsh	Totals
Texas Impacts	-22	0	-206	-48	-131	-5	-412
TX 3 Rose City East			+178				+178
TX 5-2 Bessie Heights East				+305	+128		+433
TX 6-1 Old River Cove					+235		+235
TX 8-11 Texas Point Shoreline Nourishment						+222	+222
Texas BU Benefits							+1,068
Louisiana Impacts	0	0	-78	-1,571	-23	-37	-1,709
LA 5-2/6-2 Louisiana Point Shore Nourishment						+210	+210
Total Impacts							2,121
Total DMMP BU Benefits							1,278
Net Impacts over BU Benefits							-843

(USACE 2009)

The net Dredged Material Management Plan (DMMP) benefits (1,278 AAHUs) are not sufficient to totally offset project impacts of -2,121 AAHUs, thus a deficit of -843 AAHUs remain (Table 7). That deficit will be partially offset by the following proposed Louisiana mitigation. Louisiana impacts were minimized by Louisiana Point BU (+210 AAHUs), but 1,499 AAHUs of LA impacts remain to be mitigated. The benefits of the DMMP in Texas exceed Texas impacts by 656 AAHUs (+1,068 AAHUs from BU vs. -412 AAHUs impacts) (Table 8). Since the Coastal Zone Management Act does not apply to Federal lands, the Corps proposes to reduce the Louisiana mitigation needed by using excess Texas DMMP benefits to compensate for the project's impacts on the Sabine NWR. The total Sabine-Neches project impacts to the Sabine NWR (-340 AAHUs) will be offset by excess Texas DMMP benefits, leaving a surplus of +316 AAHUs and a compensatory mitigation target of 1,159 AAHUs in Louisiana (Table 9) (USACE 2009).

Table 9 Compensatory Mitigation Target for Louisiana (in AAHUs)

	Texas	Louisiana	Total Project Area
Net FWP Benefits/Impacts			
Total Impacts	-412	-1,709	-2,121
Total BU Benefits	1,068	210	1,278
Net FWP Benefits or Impacts	+656	-1,499	-843
Excess Texas Benefits Applied to Federal Land			
Excess Texas Benefits	+656		
Sabine NWR Impacts	-340		
Net Excess Texas Benefits	+316		
Compensatory Mitigation Target			
Net Impacts LA and Project		-1,499	-843
Federal Impacts Compensated By Texas Benefits		+340	
FWP Compensatory Mitigation Target		-1,159	-843 (-1,159 + 316)

(USACE 2009)

Louisiana SNWW Mitigation---

Sabine-Neches project impacts to Louisiana marshes are primarily related to salinity increases associated with the proposed channel deepening. Since no feasible salinity reducing mitigation measures could be found, the Habitat Workgroup evaluated various mitigation measures consisting of marsh restoration, terracing, shoreline protection and Gulf shoreline nourishment. Marsh restoration included different sources of dredged material - BU from the Channel to Orange maintenance dredging, to dedicated dredging in the GIWW and Sabine Lake. The Corps applied the CE/ICA in the certified version of the IWR-PLAN to identify mitigation features that provided the most cost effective environmental benefits to offset project impacts (USACE 2009).

Willow Bayou Unit Marsh Restoration - Sabine Lake Dedicated Dredging

Marsh restoration using material from dedicated dredging in Sabine Lake (Alternative B) or SNWW new work material (Alternative C) was proposed for the Willow Bayou hydrologic unit. Marsh restoration areas LA 2-16 through LA 2-19, and a fifth area (LA 2 ADD) located north of Willow Bayou Canal in Unit 5 of the Sabine SNWR were considered. LA 2-16 includes a 1,831-acre project area and would restore 822 acres of shallow open water with 2.6 million (M) cubic yards of dredged material. LA 2-17 includes a 2,297-acre mitigation area and would restore 1,035 acres of open water with 3.4 M cubic yards of material. LA 2-18 includes a 681-acre mitigation area and would restore 251 acres with an estimated 809,893 cubic yards of material.

Table 10 Summary of Benefits of Willow Bayou Marsh Restoration Measures Evaluated

Mitigation Measure	AAHUs	Project Influence Area (ac)	Existing Marsh Nourished (ac)	Open Water (ac)	Restored Emergent Marsh (ac)	Cubic Yds. (Mil cyds)	Cubic Yds./ Acre
LA 2-16B & C	445	1,831	803	1,028	822	2.6	3,163
LA 2-17B & C	492	2,297	1,003	1,294	1,035	3.4	3,285
*LA 2-18B & C	152	681	367	314	251	0.81	3,227
LA 2-19B & C	419	1,809	910	899	719	2.9	4,033
*LA 2-ADD B	214	1,285	745	540	436	1.5	3,440
Totals (considered)	1,722	7,903	3,828	4,075	3,263	11.21	3,435
Selected	366	3,775	1,112	854	687		

Note: * Selected Willow Bayou Mitigation Measures. (USACE 2009)

The increments were combined in the ICA according to the most cost effective pumping distances and costs. Marsh would be restored by unconfined flow of dredged material from a hydraulic pipeline from either Sabine Lake (Alternative B) or SNWW Section 10 new work (Alternative C). Pipeline relocation and elevation control would be necessary to obtain the appropriate intermediate marsh elevation. Channels (tidal creeks, trenasses) would be constructed after the material has settled to return the areas to natural hydrologic conditions allowing tidal action to affect the newly restored marsh and to facilitate estuarine fisheries organism access (USACE 2009).

Dedicated dredging Alternative B would take material from a Sabine Lake borrow area located approximately 1,000 ft from the Sabine NWR shoreline. That borrow area would average 1,030 ft wide by 1.8 to 7.8 miles long by 7.5 ft deep. The borrow area would be continuous and parallel with the present Sabine Lake long shore circulation patterns to prevent the development of hypoxic conditions detrimental to aquatic organisms. The area is expected to fill with Sabine Lake and River sediments post construction. An access channel may be needed for the hydraulic dredge to access the proposed borrow area.

The borrow site is located within a Sabine Lake oyster seed harvesting ground designated by the Louisiana Department of Wildlife and Fisheries (LDWF), but oysters are not present in the proposed borrow area due to reduced salinities. Sabine Lake oyster reefs are limited to higher salinity areas in the southern part of Sabine Lake adjacent to and south of Blue Buck Point. An oyster survey by T. Baker Smith, Inc. (2006) found no live oyster reefs in the vicinity of the proposed eastern Sabine Lake borrow area. Use of this borrow area to implement this marsh restoration mitigation requires a waiver of lake dredging mitigation requirements from LDWF (USACE 2009). **The Service recommends that the Sabine Lake borrow area be relocated at least 1,000 feet from the eastern Sabine Lake shoreline to reduce possible adverse effects to shoreline erosion.**

25

Marsh restoration Alternative C, using SNWW new work dredged material, would pump dredged material from the deepening of the navigation channel across Sabine Lake and into the

Willow Bayou Unit marshes on SNWR. The 11-mile pumping distance would require the use of several booster pumps. An access canal may be required for booster pumps to access the lake shoreline (USACE 2009).

Marsh restoration benefits (Tables 10, 11, and 12) were calculated based on restoring additional marsh acreage, and the restored marshes' affect on reducing salinities and shoreline erosion due to reduction in wind fetch. Restoration of marsh in open water areas would reduce wind fetch and promote the still water conditions favorable for the growth of submerged aquatic vegetation. Land loss rates are expected to be lower due to the production of a more stable, higher marsh elevation (USACE 2009).

The last two columns of Table 10 depict total volume and volume per acre restored for each Willow Bayou Unit mitigation measure. The mean volume per acre is 3,435 cubic yards. This amount is close to the 3,478 cubic yards per acre calculated for the Coastal Wetlands Planning Protection and Restoration Act (CWPPRA) Sabine Refuge Marsh Creation Cycle 3 project (230 acres; 800,000 cubic yards). However the Sabine Refuge Marsh Creation Cycle 1 project restored about 125 acres of marsh using approximately 6,400 cubic yards of material per acre for an average of 4,900 cubic yards per acre for the two confined BU marsh restoration sites. The proposed Sabine-Neches mitigation will be unconfined dredged material placement. If this comparison with area constructed beneficial use projects is valid, the volumes needed to restore the mitigation areas listed in Table 10 could be underestimated by as much as about 30%.

The Service questions whether the Corps would be able to achieve the degree of marsh restoration depicted in the mitigation with unconfined placement of dredged material (Tables 10, 11, and 12) and recommends that the Corps review their calculations for volume of dredged material needed to achieve the listed mitigation.

26

The ICT approved Willow Bayou increments LA 2-18 B and LA 2-ADD B above. Alternative C for each of the above, consisting of marsh restoration using dredged material from the Sabine-Neches channel was considered too costly due to the need to transport the SNWW new work at least 11 miles across Sabine Lake. **The Service recommends Alternative "C" in the event that Alternative "B", Sabine Lake dedicated dredging, is not viable for SNWW Sabine NWR marsh restoration mitigation.**

27

Black Bayou Marsh Restoration – Channel to Orange Maintenance Material

Marsh restoration using dredged material from maintenance dredging of the Channel to Orange, Texas was proposed at LA 3-10 west of Rusty Vincent Lake (Figure 9). Material would be pumped from the Sabine River Channel between East Pass and the GIWW in one increment (LA 3-10R). Intermediate marsh at LA 3-10R would be restored in 6 cycles between TY5 and TY30, adding 132 acres each 5-yr cycle for a total of 792 acres restored in 1,148 acres of open water within a 2,465-acre project area (Figure 9, Tables 11 and 12) (USACE 2009).

Table 11 Summary of Benefits of Selected Willow and Black Bayou Marsh Restoration Mitigation Measures; Channel to Orange Maintenance Material and GIWW Dedicated Dredging

Mitigation Measure	AAHU	Influence Area (ac)	Existing Marsh (ac)	Open Water (ac)	Restored Emergent Marsh (ac)

(USACE 2009)

28

Black Bayou Marsh Restoration - Dedicated Dredging of Lake Charles Deep Water Channel/GIWW

Marsh restoration using dedicated dredging of accumulated material in the Lake Charles Deep Water Channel/GIWW was proposed for three areas in the vicinity of the Black Bayou Cutoff Canal (Figure 9). The 30-foot-deep 24.9 mile-long Lake Charles Deep Water Channel, constructed by local interests, joins the GIWW between the Sabine River and Lake Charles. It was authorized as a federal channel by the River and Harbor Act of 1935. It provided a deep water channel from the Port of Lake Charles to the Gulf of Mexico via the Sabine-Neches Waterway and was last maintained in 1940 when the Calcasieu Ship Channel was deepened to 30 feet. The channel contains sediment that could be mined to restore marshes in the Black Bayou area (USACE 2009).

Material would be pumped from a 13-mile stretch of the GIWW in two increments (LA 3-15 and LA 3-18) with LA 3-15 located immediately south of the GIWW in the Black Bayou watershed (Figure 9, Table 11). LA 3-15 would be restored first then LA 3-18. LA 3-15B and LA 3-19B would fill 75 percent of existing open water area. Intermediate marshes would be constructed via hydraulic dredge and unconfined pipeline discharge, with tidal creeks constructed after dredged material settlement similar to that described for LA 3-10R above (USACE 2009).

Marsh restoration benefits (Tables 11 and 12) are derived from the restoration of marsh acreage, as well as the restored marshes' effect in reducing salinities and wind fetch. Reduction in wind fetch would reduce shoreline erosion and turbidity and stimulate the production of submerged aquatic vegetation (SAV). An estimated 75 percent of the open water would be restored to intermediate marsh, and existing fringe marsh would be nourished by winnowing fine-grained suspended solids during material placement. Land loss rates are expected to remain the same because the area currently has a low land loss rate with the construction of the Black Bayou Hydrologic Restoration CWPPRA Project (CS-27). Dedicated dredging in the GIWW is not

predicted to establish a hydrologic connection to the deeper navigation channels in the Sabine and Calcasieu Rivers, and is not predicted to provide a channel for salinity wedges from those channels to enter the GIWW (USACE 2009).

The Service concurs with unconfined placement of material and recommends the construction of tidal creek channels (or trenasses) at least ten feet wide and two feet deep in the restored marsh, six months to a year, after disposal in order to return the area to natural hydrology for tidal movement and estuarine aquatic organism access to the restored marshes. The dredged material pipeline for marsh restoration (i.e., Willow Bayou and Black Bayou Units mitigation) should be placed in existing canals and waterways to the greatest extent practicable.

Selected Mitigation Plan

The selected mitigation plan compensates for the National Economic Development Plan (NED) salinity increase and associated losses in marsh acreage and biological productivity by restoring 2,783 acres of intermediate marsh in Louisiana to compensate for a projected 691 acres of marsh losses due to SNWW project salinity impacts. These mitigation measures produce 1,181 AAHUs that provide full compensation for the remaining (after DMMP BU) 1,159 AAHUs of impacts while meeting original mitigation goals for a balance of +22 AAHUs (Table 12).

The Service concurs that the Louisiana mitigation measures below (Table 12), along with the above BU measures compensate for SNWW project impacts in Texas and Louisiana.

29

The Corps should acquire a refuge Special Use Permit from the Sabine NWR (Terry Delaine, manager, Sabine NWR, 337-558-5574; or Don Voros of the Southwest Louisiana Refuges Complex, 1428 Hwy 27, Bell City, LA 70630; 337-598-2216) to coordinate the final planning for the dedicated dredging marsh restoration mitigation on Sabine NWR.

30

Table 12 Recommended Louisiana mitigation measures, SNWW NED Plan

Selected Mitigation Measures	MFWP AAHU	Restored Emergent Marsh (acres)
Willow Bayou		
LA2-18 B Marsh Restoration (Sabine Lake dredging)	152	251
LA2 ADD B Marsh Restoration (Sabine Lake dredging)	214	436
Black Bayou		
LA3-10R Marsh Restoration (Channel to Orange maintenance material)	198	792
LA3-15B Marsh Restoration (GIWW dredging)	307	683
LA3-18B Marsh Restoration (GIWW dredging)	310	621
Total Mitigation Compensation	1,181	2,783
Total Remaining Impacts (after BU)	-1,159	-843
Net After Compensation	+22	+1,940

(USACE 2009)

31

Table 13 summarizes SNWW total impacts (- 938 acres and - 2,121 AAHUs) and DMMP BU (3,527 acres, 1,278 AAHUs) and mitigation (2,783 acres, 1,181 AAHUs) benefits. The balance of impacts vs. benefits project-wide is + 5,372 acres and + 338 AAHUs (Table 13). Impacts and benefits by habitat type are depicted in Table 14. In Louisiana, 92 percent (-1,571 AAHUs) of the impacts were to intermediate marshes, followed by 5 percent (-78 AAHUs) in fresh, 2 percent (-37 AAHUs) in saline, and 1 percent (-23 AAHUs) in brackish marshes. In Texas, 50 percent (-206 AAHUs) of the impacts were in fresh marsh, followed by 32 percent (-131 AAHUs) and 12 percent (-48 AAHUs) in brackish and intermediate marshes, respectively, and 5 percent (-22 AAHUs) in swamp habitats (Table 14). DMMP BU benefits of +1,068 AAHUs totally compensate for Texas impacts (-412 AAHUs). The mitigation (+1,181 AAHUs), Gulf shoreline DMMP BU benefits, and excess Texas DMMP benefits fully compensate for SNWW impacts to Louisiana marshes by providing an excess of +2,429 acres and + 22 AAHUs (Table 13).

Table 13 SNWW mitigation totals, by acres and AAHUs

Project Impacts (Acres/AAHUs)	FWP Impacts (Acres/AAHUs)	*Dredged Material Management Plan (DMMP) Benefits (Acres/AAHUs)	Net After DMMP (Acres/AAHUs)	Mitigation Benefits (MFWP) (Acres/AAHUs)	Difference (Acres/AAHUs)

(Units are in AAHUs)

Monitoring

BU monitoring in the Neches River sites

Success criteria at the Neches River sites will be the same as for the Louisiana sites. Texas has experienced colonization of some invasive species. The success criterion will include measures to limit the establishment of invasive plant species colonization at the BU sites. The Corps will assume management responsibilities for the first 10 years and then the Sabine Neches Navigation District (SNND) will assume responsibility for the remainder of the life of the project. Aerial photography will be used to monitor the progression of invasive species and will be flown in conjunction with the other data acquisition flights. Marsh elevation will be assessed one year after placement. The ICT will evaluate the data and determine if additional material is needed or if further action is necessary to allow for tidal exchange in the marsh. Marsh vegetation in this area has historically colonized on its own with little assistance. However, the ICT will evaluate the vegetation coverage in the mitigation sites and determine whether additional planting would be appropriate by using aerial photography beginning at year five after the material placement. If the vegetation coverage is not progressing, the ICT will make recommendations that will increase the likelihood of achieving the success criteria to include plantings. Invasive species will be monitored and the ICT will determine if further action is necessary to achieve the monitoring success criteria.

Table 15 Ecological success criteria for Texas mitigation sites

Monitoring the Neches River Beneficial Use Feature for the Sabine-Neches Waterway Channel Improvement Project			
	Fosse City East	Bossie Heights East	Old River Cove
Ecological Success Criteria			
Placed material will be 60-80% vegetated with native, typical, emergent marsh 5 yrs after placement of material.	158 ac vegetated emergent marsh after one dredging cycle.	1,308 ac vegetated emergent marsh after 28 yrs and seven maintenance dredging cycles.	447 ac vegetated emergent marsh.
Marsh remains intact and 60-80% vegetated with native, typical, emergent marsh at end of project, 50 yrs.	158 ac vegetated emergent marsh.	1,308 ac vegetated emergent marsh.	447 ac vegetated emergent marsh.
Invasive, noxious, and/or exotic plants comprise less than 4% of marsh cover.	Less than 6 ac with undesirable plants.	Less than 52 ac with undesirable plants.	Less than 18 ac with undesirable plants.
Placed material elevation.	Maximum optimal elevation (as determined by pre-construction surveys in consultation with ICT) 1 year after placement of material.		
Monitoring Organization	USACE for 1st 10 yrs. SNND for monitoring after Yr 10 through 50-year period of analysis.		

(Corps 2009b)

Louisiana

Mitigation success criteria for all five sites in Louisiana will be the same due to proximity and similarity in ecological processes at each of the sites. The success criteria will consist of 60 to 80 percent emergent marsh, 20-40 percent open water and adequate elevation of the placed dredge material to support the colonization of the marsh vegetation. Service personnel believe that the marsh elevations at these mitigation sites range from 1.1 to 1.2 ft. Each of the mitigation sites will be constructed to the highest elevations (with instruction from the ICT and pre-construction surveys) that will support marsh vegetation. This target elevation is assumed to reach approximately 1.6 to 1.7 ft NAVD88 after settlement. This target elevation will allow for the projected sea level rise. Over the 50 year life of the project, an ecological success criterion of 60-80 percent emergent marsh is expected to be sustained. However, adaptive management will

be utilized to ensure that the success criteria are met on all levels. The USACE and the project sponsor, the SNND will manage the monitoring of the sites. Invasive species are believed to not be a problem in Louisiana. However, a success criterion is included to protect the marshes and prevent the spread of invasive plants to the mitigation sites. In addition, aerial photography will be collected and used to assess the success of the sites eight times over the life of the project. Table 16 depicts the acreage to be created.

Table 16 Mitigation monitoring for Louisiana

Mitigation Monitoring in Louisiana for the Sabine-Neches Waterway Channel Improvement Project					
	Willow Bayou		Black Bayou West	Black Bayou East	
	LA 2-18B	LA 2-ADD B	LA 3-10R	LA 3-15B	LA 3-18B
Ecological Success Criteria					
Placed material will be 60-80% vegetated with native, typical, emergent marsh 5 yrs after placement of material.	176 ac vegetated emergent marsh	305 ac vegetated emergent marsh	92 ac marsh after 1st maintenance dredging, 185 ac marsh after 2nd maintenance dredging, 277 ac marsh after 3rd maintenance dredging, 378 ac marsh after 4th dredging cycle, 462 ac marsh after 5th dredging cycle, and 554 ac marsh after 6th dredging cycle	478 ac vegetated emergent marsh	435 ac vegetated emergent marsh
• Marsh remains intact and 60-80% vegetated with native, typical, emergent marsh at end of project, 50 yrs.	176 ac vegetated emergent marsh	305 ac vegetated emergent marsh	554 ac vegetated emergent marsh	478 ac vegetated emergent marsh	435 ac vegetated emergent marsh
Invasive, noxious, and/or exotic plants comprise less than 4% of marsh cover	Less than 7 ac with undesirable plants	Less than 12 ac with undesirable plants	Less than 22 ac with undesirable plants	Less than 19 ac with undesirable plants	Less than 17 ac with undesirable plants
Placed material elevation	Maximum optimal elevation (as determined by preconstruction surveys in consultation with ICT) 1 year after placement of material				
Monitoring Organization	U.S. Army Corps of Engineers and Sabine-Neches Navigation District				

(Corps 2009b)

Monitoring of the BU placement on the Gulf Shore

Dredge material from the project is to be placed alternately on the Texas and Louisiana shores near the top of Gulf beaches at Texas Point and Louisiana Point. Dredged material would nourish existing marshes and the near-shore shallow water. The expectation is that some of the material will remain and assist with the severe erosion that continues to plague these two shorelines. It is hoped that some of the material may wash up on the beaches due to high tides and storm events and may nourish the marshes behind the dunes. Monitoring efforts will be initiated every three years beginning with the first placement and will continue for two full 6-year cycles at each point to year 13. The focus of this objective is to monitor and evaluate the success of on-shore and near-shore disposal to achieve a reduced rate of shoreline erosion and possible accretion. Texas Point shoreline erosion rate average should be less than 44 ft/yr while the Louisiana shoreline should exhibit accretion rate averages of more than 1.2 ft/yr (USACE 2009b). The shoreline erosion or accretion will be calculated by using Year 1 baseline aerial photograph and photography from Years 4, 7, 10 and 13. An annual report completed by the District Engineer will summarize the results of the achieved successes, failures, disposal activities and recommendations for obtaining the goals set forth by the ICT. This report will be available to all ICT members and other cooperating agencies. Five years following the disposal, the ICT will meet to assess the results and status of the emergent marsh. At this time, the ICT will evaluate whether there is need for additional data collection and if not, the ICT can recommend other corrective actions such as plantings, discharge pipe placement, and contouring of the marsh. Monitoring activities are set to stop when it has been determined that placement of dredge material is achieving the goal of reduced shoreline erosion and marsh re-nourishment behind the Gulf beaches. By using adaptive management, the ICT can evaluate and make

modifications/recommendations on dredge material disposal at either of these sites during the monitoring period.

Summary of Service Conclusions and Recommendations

- 1.) Construct a 2 to 12-acre, + 8 ft. colonial waterbird nesting island at least one mile offshore in Sabine Lake using project-dredged material. The island should include a sloping sand beach, preferably protected by a rock breakwater similar to the design of Evia Island in Galveston Bay. The Service can assist in final design, location, and management. 32
- 2.) Create an interagency work group during post-authorization planning, and continue the work group through planning and construction phases. The work group would execute important design, inspection, and monitoring functions for habitat creation features. These include: a) the 345-acre freshwater marsh (potentially some swamp acreage) and 183-acre freshwater lake creation at Rose City, b) the 1,190-acre intermediate marsh and 679-acre brackish marsh and 1,090-acre shallow freshwater habitat creation at Bessie Heights, c) the 639-acre brackish marsh and 139-acre shallow water habitat at Old River Cove, d) the 687-acre intermediate marsh creation from Sabine Lake dredging at Willow Bayou on Sabine NWW and e) the 2,096-acre intermediate marsh creation from the GIWW and Channel to Orange-dedicated dredging of accumulated maintenance material in the LA Black Bayou Unit. Experience at ongoing Federal navigation projects in Galveston Bay, Corpus Christi Bay, Atchafalaya Bay, and elsewhere have shown us that large-scale habitat creation using dredged material requires ongoing feedback and modification during and following construction in order to successfully turn conceptual plans into successful habitat creation features. 33
- 3.) Include as part of the interagency work group tasks, the monitoring and guidance for aquatic habitat (wintering waterfowl) management within DMMP upland disposal sites 23A, 24A, 27A, 27C, and 27D. 34
- 4.) Replace on a 1:1 basis on suitable bottoms within Sabine Pass or in the southern portion of Sabine Lake, any estimated oyster reef losses caused by project features. Oyster habitat mitigation should be accomplished concurrently with channel construction, should consist of at least a 1-ft thick layer of shell or suitable cultch material such as graded limestone or fly-ash rock, and should be followed up at one year post-construction with bottom profiling survey and grab sampling to insure adequate relief (minimum average 0.5 ft above bay and pass bottom) and oyster spat coverage. This mitigation is not needed if no Sabine Lake or Pass oyster habitat is disturbed by project features. 35
- 5.) The Service concurs with Willow Bayou Unit Alternative "B", restoring marsh on the Sabine NWR through dedicated dredging of material from Sabine Lake and placing that material in open water areas on that refuge north of the Willow Bayou Canal. However, if Alternative "B" should not prove viable, the Service recommends that Alternative "C", beneficial use of new work material from the SNWW, be used to restore marsh on Sabine NWR, or the rock breakwater shoreline stabilization measures, or Sabine NWR terracing measures be implemented as long as the acres protected/restored and AAHUs gained fully compensate for projected impacts. 36
- 6.) The Service recommends that the Corps review their calculations for volume of dredged material needed to achieve the listed mitigation in Louisiana and questions whether the Corps 37

would be able to achieve the degree of marsh restoration depicted in the recommended mitigation with unconfined placement of dredged material (Tables 11 and 12).

- 7.) The Service recommends the construction of tidal creek channels (or trenasses) at least ten feet wide and two feet deep in the restored marsh, six months to a year, if necessary, after disposal in order to return the area to natural hydrology for tidal movement and estuarine aquatic organism access to the restored marshes. The tidal creeks could be constructed by tracking marsh buggy track-hoes, or similar equipment, over proposed creek channel routes. The dredged material pipeline for marsh restoration (i.e., Willow Bayou and Black Bayou Units mitigation) should be placed in existing canals and waterways to the greatest extent practicable to minimize marsh damage. 38
- 8.) The Service recommends that the Sabine Lake borrow area be relocated at least 1,000 ft from the eastern Sabine Lake shoreline to minimize borrow area shoreline impacts. 39
- 9.) The Corps should acquire a refuge Special Use Permit from the Sabine NWR (Terry Delaine, manager, Sabine NWR, 337-558-5574; or Don Voros of the Southwest Louisiana Refuges Complex, 1428 Hwy 27, Bell City, LA 70630; 337-598-2216) to coordinate the final planning for the dedicated dredging marsh restoration mitigation on Sabine NWR. 40
- 10.) The Service recommends that the Corps construct the Sabine-Neches project mitigation at the same time as waterway enlargement construction is performed. 41
- 11.) The Service recommends that the Corps require protective easements on privately owned lands where Sabine-Neches mitigation is to be performed to ensure that the mitigation is not compromised by future development activities. 42
- 12.) The Service recommends that the Corps implement a DMMP BU and mitigation monitoring program to consist of aerial photography interpretation, elevation, and vegetation surveys to be conducted periodically during the project life to ensure that the BU and mitigation is successful at offsetting project impacts during the project life. 43
- 13.) The Service recommends that if DA 27D is converted to an upland DA, a disposal area water regime protocol be developed to maximize wetland habitat potential during between-disposal intervals for wintering waterfowl use. 44
- 14.) Develop an exotic and invasive species plan that will be used to control exotic and invasive species at the mitigation sites based on the success criteria used in the monitoring plan. 45

RESPONSE TO COMMENTS

Comment No.	Response
1	The figure included in the Coordination Act Report (CAR) report is incorrect. It includes Neches River Beneficial Use (BU) components that have been dropped from the Preferred Alternative. Please see Final Environmental Impact Statement (FEIS) Figure 1.1-2 for the correct figure.
2	U.S. Army Corps of Engineers (USACE) notes that the CAR description of the Preferred Alternative (Recommended Plan in the Draft Feasibility Report [DFR]) is incorrect. The Recommended Plan is the Locally Preferred Plan (48-foot [ft] authorized depth), not the National Economic Development (NED) Plan (49 ft authorized depth). Also the description of the Recommended Plan in the CAR is incomplete. The Recommended Plan includes deepening and widening of the Taylor Bayou Channels and Basins and the addition of Neches River Turning/Anchorage Basins 1, 4 and 8 (see FEIS Section 2.3.2).
3	The figure included in the CAR report is incorrect. It includes Neches River BU components that have been dropped from the Preferred Alternative. Please see FEIS Figure 2.1-1 for the correct figure.
4	There are significant differences between U.S. Fish and Wildlife (USFWS) estimates of individual wetland types, as shown in CAR Table 1, and wetland type subtotals used in the Wetland Value Assessment (WVA) modeling of wetland impacts (FEIS Appendix C, Table 1). USACE notes that the Interagency Coordination Team (ICT) approved the wetland type acreages applied in the WVA modeling, and the impact results. Furthermore, USFWS in the CAR (pages 17-20) concurs with the USACE impact analysis. Therefore, the differences between these two estimates are assumed to be immaterial to the impact evaluation.
5	The total number of existing Placement Areas (PA) along the entire exiting Sabine-Neches Waterway (SNWW) is 20: 16 upland PAs and 4 Ocean Dredged Material Disposal Site (ODMDS) (see FEIS Section 2.4.2.1), not 13 as presented by the CAR.
6	PA 16A is discussed in FEIS Section 2.5.3.4.1: Areas Considered for PA Expansion. It is not an existing PA as implied by the CAR. As noted in the FEIS, this area was dropped from further consideration as a PA.
7	Table 4 reflects an error in FWP Net Change Average Annualized Habitat Units (AAHUs) presented in Draft EIS (DEIS) Table 4.1-3 for LA 8, Southwest Gum Cove, fresh marsh. The DEIS incorrectly shows a loss of 14 AAHUs for the net change to LA8 fresh marsh. The net change should be a loss 2 AAHUs (rather than a loss of 14 AAHUs as shown in the DEIS) and the total Louisiana change in AAHUs should therefore be a loss of 1,709 AAHUs.
8	USACE concurs with the restatement of losses by habitat type in this paragraph, with the exception of Louisiana losses in cypress-tupelo swamps. No loss (0 AAHUs) is predicted for Louisiana swamps (see FEIS Table 2.5-5). Also, USACE notes that the impacts listed in Table 4 would occur without the BU plan, which would fully offset impacts in Texas and partially offset impacts in Louisiana with BU benefits.
9	Error noted for comment 3 above is also reflected in this table. LA AAHUs for fresh marsh should be a loss of 78 rather than the loss of 90 shown in the table.
10	Comment noted. The Keith Lake Section 1135 CAP study was begun in 2003, well before impacts of the SNWW Channel Improvement Project (CIP) had been determined or potential mitigation measures defined. Since at that time it seemed likely that the CAP study and project construction would be completed before the SNWW CIP could be authorized and constructed, the Keith Lake Section 1135 study was considered separable from the SNWW CIP. It was assumed that a water control structure at the Fish Pass would be part of the future without-project condition for the SNWW CIP.

	Incremental impacts of the SNWW CIP will be calculated for the Salt Bayou unit of the SNWW study area when WVA modeling is completed for the Keith Lake Section 1135 study. It is possible that the excess Dredged Material Management Plan (DMMP) benefits (316 AAHUs) of the SNWW CIP will cover all incremental project impacts. However, if it is determined that additional mitigation is needed, then USACE and the non-Federal sponsor of the SNWW CIP will initiate consultation with resource agencies, identify and incrementally justify additional compensatory mitigation for the Salt Bayou unit, and prepare a supplemental environmental impact statement.
11	The figure included in the CAR report is incorrect. It includes Neches River BU components that have been dropped from the Preferred Alternative. Please see FEIS Figure 2.5-1 for the correct figure.
12	The proposed Rose City Marsh BU was developed in consultation with the ICT (which includes the USFWS) and benefits of the BU feature reflect marsh restoration, only. The ICT-approved BU plan for this area does not include plans for cypress-tupelo forest revegetation. USACE will not add this as a formal BU feature at this time. Although historically, cypress-tupelo swamp vegetation was the predominant vegetation at this location, the salinity regime in this area is changing due to climate change and relative sea level rise, and in the long term it is unlikely that this area would be able to sustain substantial cypress-tupelo forest vegetation.
13	USACE notes a typographical error in the acres of Nourished Existing Marsh for Bessie Heights East. The acres should be 651 (rather than 615), and the total should be 1,234 rather than 1,198. Further, USACE notes that the textual descriptions, and in general, the acreage descriptions in this table, reflect the revised BU plan presented in the FEIS. It is only the figures (described in Comment responses 1, 3, and 11 that convey a previous version of the BU plan.
14	USACE has committed to continuing the ICT through the preconstruction, engineering and design (PED) and project construction phases to provide input during the development of plans and specifications for BU features and mitigation measures, and on best management practices as described in response 6 above. The ICT would continue into the operations phase to ensure that the BU and mitigation measures have been constructed as specified in the DEIS and that the goals of the compensatory mitigation plan have been fully achieved. See FEIS Appendix J for a description of the mitigation monitoring and contingency plan, which describes the role and responsibilities of the non-Federal sponsor, the Sabine Neches Navigation District (SNND). USACE notes the USFWS stated intent to request the annual transfer funds under the FWCA during the construction phase. USACE will consider such requests for years in which significant SNWW CIP construction activities are scheduled and funds are available.
15	The construction of a bird island in Sabine Lake using new work material from the SNWW was evaluated during screening of potential BU features as described in FEIS Section 2.5.3.1. The ICT (including USFWS) participated in this screening and approved the results. Construction of a bird island using new work material was found to be feasible, but the costs would exceed placement in available upland PAs. This feature was eliminated because incremental costs were higher than upland placement and no cost-share partner could be identified.
16	USACE notes that the 4 closest ODMDS sites were designated by the U.S. Environmental Protection Agency (EPA) for the continued placement of dredged material removed from the SNWW Entrance Channel (Federal Register Vol. 52, No. 175, September 10, 1987, page 34218; FEIS, 1983 [EPA, 1983a]). The siting and impacts of the existing ODMDS were evaluated by the FEIS for the maintenance dredging of the SNWW Entrance Channel (the authorized 40-ft Project (USACE, 1975). The selected sites were located as close to the shoreline as practicable.
17	PA 16A is discussed in FEIS Section 2.5.3.4.1: Areas Considered for PA Expansion. As noted in the FEIS, this area was dropped from further consideration as a PA because the existing vegetation community and hydrologic connectivity to adjacent wetlands makes this a high quality native marsh providing important habitat for native fish and wildlife. USACE concurs with the USFWS assessment of the value of this area, and therefore did not include it in the FEIS Preferred Alternative (DFR Recommended Plan).
18	PA 14A is discussed in FEIS Section 2.5.3.4.1: Areas Considered for PA Expansion. As noted in the FEIS, this area was dropped from further consideration as a PA because it provides habitat for native wildlife species, is covered by a valuable intermediate wetland, and is intermittently hydrologically connected to the riparian corridor. USACE concurs with the USFWS assessment of the value of this area, and therefore did not include it in the FEIS Preferred Alternative (DFR Recommended Plan).

19	<p>PA 23A is discussed in FEIS Section 2.5.3.4: Existing Inactive PAs. Recommendation 1: As noted in the FEIS, existing PA23A is a leveed upland area covered by secondary growth of tallow and black willow forest. It has been extensively modified by past placement activities and levee systems that have artificially altered the hydrology. Surrounding levees hold water and isolate the area from adjacent waterbodies, preventing contributions to the function of adjacent wetlands and the riparian corridor. It contains degraded habitat with low habitat value, primarily roosting habitat and some wildlife cover. USACE maintains that WVA modeling of this isolated, non-wetland habitat is not warranted and that renewed use of this area would not constitute a significant adverse impact. Recommendation 2: The DMMP (FEIS Appendix D) estimates that this PA would be used every 6 years for the placement of maintenance material. The PA must be drained between maintenance cycles to allow the sediment to settle, consolidate and dry out sufficiently for it to be used for levee maintenance and to provide PA capacity for the next cycle. USACE cannot accommodate this recommendation because it must manage the PA to provide future capacity for maintenance material from the proposed SNWW CIP.</p>
20	<p>PA 24A is discussed in FEIS Section 2.5.3.4.1: Areas Considered for PA Expansion. Recommendation 1: Impacts to low quality wetlands in the proposed PA have been assessed by the WVA model and included in the impacts evaluation for the proposed SNWW CIP. In order to minimize impacts, USACE redrew the proposed boundary to exclude 144 acres of higher value marsh, reducing the proposed PA from 331 to 187 acres. The boundaries of the proposed PA are set, and the locations of the levees are constrained by the proposed PA boundaries. USACE will design discharge points to minimize impacts to adjacent high quality habitat. Recommendation 2: The DMMP (FEIS Appendix D) estimates that this PA would be used once and filled with new work material from construction of the proposed SNWW CIP. There would be no ongoing opportunities to maximize wetland characteristics as recommended.</p>
21	<p>PA 26 is discussed in FEIS Section 2.5.3.4: Existing Inactive PAs. Recommendation: The DMMP (FEIS Appendix D) estimates that this PA would be used every 6 years for the placement of maintenance material. The PA must be drained between maintenance cycles to allow the sediment to settle, consolidate and dry out sufficiently for it to be used for levee maintenance and to provide PA capacity for the next cycle. USACE cannot accommodate this recommendation because it must manage the PA to provide future capacity for maintenance material from the proposed SNWW CIP.</p>
22	<p>PA 27A is one of the active PAs discussed in FEIS Section 2.5.3.3.1: Existing Active PAs. USACE notes that USFWS does not object to its use and does not make any recommendations.</p>
23	<p>PA 27C is discussed in FEIS Section 2.5.3.4: Existing Inactive PAs. Recommendation: The DMMP (FEIS Appendix D) estimates that this PA would be used every 6 years for the placement of maintenance material. The PA must be drained between maintenance cycles to allow the sediment to settle, consolidate and dry out sufficiently for it to be used for levee maintenance and to provide PA capacity for the next cycle. USACE cannot accommodate this recommendation because it must manage the PA to provide future capacity for maintenance material from the proposed SNWW CIP.</p>
24	<p>PA 27D is discussed in FEIS Section 2.5.3.4: Existing Inactive PAs. Recommendation: The DMMP (FEIS Appendix D) estimates that this PA would be used every 6 years for the placement of maintenance material. The PA must be drained between maintenance cycles to allow the sediment to settle, consolidate and dry out sufficiently for it to be used for levee maintenance and to provide PA capacity for the next cycle. USACE cannot accommodate this recommendation because it must manage the PA to provide future capacity for maintenance material from the proposed SNWW CIP.</p>
25	<p>FEIS Section 5.5.1 states that the borrow trench would be located at least 1000 feet from the Sabine National Wildlife Refuge (SNWR) shoreline, and that the exact location of the trench would be determined in consultation with the ICT (which includes USFWS) during PED.</p>
26	<p>As recommended, USACE has reviewed calculations for the volume of dredged material needed to construct the proposed mitigation areas. USACE believes that the estimate is sufficiently accurate for feasibility planning, and notes that the estimated cost of the mitigation area includes a 30 percent contingency.</p>
27	<p>If any part of the recommended mitigation plan is found to be not viable after project approval, USACE and the non-Federal sponsor of the SNWW CIP would initiate consultation with the ICT, identify and incrementally justify alternative compensatory mitigation, and prepare a supplemental environmental impact statement.</p>

28	USACE notes that the recommended Willow Bayou Mitigation Measure LA 2-18 B does not include the alternative "C" as indicated in the USFWS table.
29	USFWS concurrence with the USACE mitigation and BU plans for the proposed SNWW CIP is noted.
30	As noted in FEIS Section 7.9 USACE has requested a compatibility determination from the SNWR for the proposed Willow Bayou mitigation area.
31	USACE notes that the Louisiana mitigation measures apply to the SNWW LPP, not the NED plan. Also, the table incorrectly compares and adds restored emergent marsh acres for Total Mitigation Compensation (2,783 acres) to the net SNWW CIP project impacts as measured in AAHUs (a loss of 843 AAHUs). The estimated total loss of acres as a result of the SNWW CIP is 691 acres (FEIS Table 2.4-16).
32	See USACE response to Comment 15.
33	See USACE response to Comment 14.
34	See USACE responses to Comments 19, 20, 21, 23, and 24.
35	FEIS Section 4.11.2.1.2 evaluates the potential for impacts to oyster reef by the proposed SNWW CIP. No impacts to oyster reef are anticipated in Sabine Pass because the channel is not being widened and no slumping is expected at the top of cut. No impacts to oyster reef in Sabine Lake are anticipated because salinities are generally too low to support spat growth, as confirmed by recent survey. Furthermore, as stated in FEIS Section ES.5 and Section 5.5.1, USACE has proposed that a water bottom survey of the borrow and access channel areas in Sabine Lake be conducted during the PED phase of the project. In the unlikely event that oyster reef is encountered, plans will be revised to avoid impacts.
36	See USACE response to Comment 27.
37	See USACE response to Comment 26.
38	FEIS Sections 5.5.1 and 5.5.2 describes the proposed Willow Bayou and Black Bayou mitigation measures. The descriptions include the construction of tidal creek channels. USACE will develop construction methods and plans in consultation with the ICT (which includes USFWS) during PED.
39	See USACE response to Comment 25.
40	See USACE response to Comment 30.
41	USACE plans to construct the proposed Willow Bayou, Black Bayou East and first phase of Black Bayou West concurrently with proposed channel deepening. The remaining 5 phases of the Black Bayou West mitigation measure would be completed over approximately the next 30 years in conjunction with maintenance dredging of the Sabine River Channel.
42	The Black Bayou East and West mitigation measures are located on private property. USACE has determined that conservation easements are not required because all restored areas would remain jurisdictional wetlands and would continue to be subject to the navigational servitude (Final FR Section VIII.E).
43	FEIS Appendix J contains a mitigation and beneficial use monitoring plan that was developed in consultation with USFWS and reviewed by the ICT. USACE received one comment on the draft plan, asking that we ensure ICT involvement in the monitoring. The plan contains periodic aerial photography interpretation and vegetation surveys. Construction contracts for mitigation and BU sites would incorporate an adaptive management approach to ensure that the initial construction contracts attain the appropriate elevation over the acreage specified for emergent marsh within each mitigation site.
44	See USACE response to Comment 24.
45	FEIS Appendix J contains a mitigation and beneficial use monitoring plan that was developed in consultation with USFWS and reviewed by the ICT. If the percentage coverage of exotic and invasive species exceeds the success criteria, the ICT will develop plans to remove and manage those species.

Mr. Don Klima
Advisory Council on Historic Preservation
Office of Federal Agency Programs
Old Post Office Building
1100 Pennsylvania Avenue, NW, Suite 803
Washington, DC 20004

Dear Advisory Council on Historic Preservation (Council):

The US Army Corps of Engineers, Galveston District (USACE), proposes to initiate a Programmatic Agreement (PA) to avoid and mitigate, if necessary, impacts to historic properties that may occur during construction and operation of the Sabine-Neches Waterway Channel Improvement Project (SNWW CIP). The SNWW CIP includes improvements to the existing navigation channel, a Dredged Material Management Plan (DMMP) and an ecological impacts mitigation plan. A full description and maps of the proposed channel improvements can be found in the enclosed Background Report (Enclosure).

The USACE proposes negotiation of a four-party PA which outlines procedures to be followed for Section 106 compliance as per 36 CFR 800.6 (c) to address potential impacts to historic properties identified in the Background Report for the SNWW CIP project area (Enclosure). The four parties include the USACE, the Jefferson County Waterways and Navigation District (JCWND) and the Texas and Louisiana State Historic Preservation Officers (SHPOs). The draft PA will also be coordinated with interested Native American Indian tribes in accordance with 36 CFR 800.3 (f)(2). Included in the Enclosure is a draft PA prepared by the USACE that has been informally coordinated with the JCWND. The intent of the PA is to avoid or mitigate impacts to historic properties in areas directly affected by new dredging and channel construction, construction staging and access areas, extensions of existing placement areas, ecological mitigation features, areas affected by the beneficial uses of dredged material, and ongoing maintenance dredging and placement activities related to the SNWW CIP.

We are notifying the Council of our intent to negotiate the PA for the SNWW CIP and inviting your participation pursuant 36 CFR 800.6 (a)(1)(i)(C). If you have any questions, please do not hesitate to call Ms. Nicole Minnichbach at 409-766-3878.

1619

Sincerely,

A handwritten signature in black ink, appearing to read 'Carolyn Murphy', written over the word 'Sincerely,'.

P. O. Box 44247
Baton Rouge, Louisiana 70804

Dear Dr. Eubanks:

The US Army Corps of Engineers, Galveston District (USACE), proposes to initiate a Programmatic Agreement (PA) to avoid and mitigate, if necessary, impacts to historic properties that may occur during construction and operation of the Sabine-Neches Waterway Channel Improvement Project (SNWW CIP). A full description of the proposed channel improvements can be found in the enclosed Background Report (Enclosure). The SNWW CIP includes improvements to the existing navigation channel, a Dredged Material Management Plan (DMMP) and an ecological impacts mitigation plan.

The USACE proposes negotiation of a four-party PA which outlines procedures to be followed for Section 106 compliance as per 36 CFR 800.6 (c) to address potential impacts to historic properties identified in the Background Report for the SNWW CIP project area (Enclosure). Included in the Enclosure is a draft PA prepared by the USACE that has been informally coordinated with the Jefferson County Waterways and Navigation District (JCWND). The intent of the PA is to avoid or mitigate impacts to historic properties in areas directly affected by new dredging and channel construction, construction staging and access areas, new or extensions of existing placement areas, ecological mitigation features, areas affected by the beneficial uses of dredged material, and ongoing maintenance dredging activities relate to the SNWW CIP.

In summary, Galveston District requests your review of the enclosed PA. Upon receipt of your comments and finalization of the draft PA in consultation with JCWND, the USACE will coordinate a final draft PA with interested Native American Indian tribes in accordance with 36 CFR 800.3 (f)(2). Public coordination required by 800.3 (a) will be accomplished by inclusion of the final draft PA in the Draft Environmental Impact Statement, which will be made available for public review and comment. If you have any questions, please don't hesitate to call Ms. Nicole Minnichbach at 409-766-3878.

Sincerely,

A handwritten signature in black ink, appearing to read 'Carolyn Murphy', written over the word 'Sincerely,'.

REF: Proposed Programmatic Agreement for Sabine-Neches Waterway Channel Improvement Project

Dear Ms. Murphy:

On February 9, 2007, the ACHP received your notification and on February 19 the supporting documentation regarding potential adverse effects to historic properties associated with the construction and operation of the Sabine-Neches Waterway Channel. Based upon the information you have provided, we have concluded that Appendix A, *Criteria for Council Involvement in Reviewing Individual Section 106 Cases* of our regulations "Protection of Historic Properties (36 CFR Part 800) does not apply to this undertaking. Accordingly, we do not believe that our participation in consultation to resolve adverse effects is needed. However, if we receive a request for participation from a State Historic Preservation Officer (SHPO), Tribal Historic Preservation Officer (THPO) or other consulting party, we may reconsider this decision. Additionally, should circumstances change and you determine that our participation is required, please notify us.

Pursuant to 36 CFR 800.6(b)(1)(iv), you will need to file the final Programmatic Agreement (PA) developed in consultation with the Texas and Louisiana SHPO and any other consulting parties, and related documentation with the ACHP at the conclusion of the consultation process. The filing of the PA and documentation with the ACHP is required in order to complete the requirements of Section 106 of the National Historic Preservation Act.

Thank you for providing us with the notification of adverse effect. If you have any questions, please call me at 202-606-8554.

Sincerely,

Tom McCulloch, Ph.D., R.P.A.

Sabine-Neches Waterway Channel
Improvement Project (SNWW CIP)
Cameron Parish, Louisiana

Dear Ms. Murphy:

Receipt is acknowledged of your letter dated February 7, 2007, transmitting a copy of the draft Programmatic Agreement (PA) for the proposed Sabine-Neches Waterway Channel Improvement Project (SNWW CIP).

We have completed our review of the document and have enclosed a marked-up copy with our comments. Please address our comments as appropriate and transmit a fully executed copy of the PA for our files.

Should you have any questions concerning our comments, do not hesitate to contact Duke Rivet in the Division of Archaeology at (225) 342-8170.

Sincerely,

Pam Breau

BILLING CODE 3710-08-M

DEPARTMENT OF DEFENSE

Department of the Army; Corps of Engineers

Intent To Prepare a Draft Environmental Impact Statement for Improvements to the Sabine-Neches Ship Channel Near Beaumont and Port Arthur, Texas as Published in a Resolution of the Senate Committee on Environment and Public Works, dated June 5, 1997, 105th Congress, 2nd Session

AGENCY: Department of the Army, U.S. Army Corps of Engineers, DoD.

ACTION: Notice of intent.

SUMMARY: The proposed action to be addressed in the Draft Environmental Impact Statement (DEIS) is to evaluate several widening and deepening alternatives to improve a deep-draft navigation channel that connects harbor facilities in the Beaumont and Port Arthur area with the Gulf of Mexico. The study will focus on circulation and salinity changes associated with an improved channel and develop dredged material disposal options that will include an evaluation of beneficial uses of dredged material. The project is being maintained at its authorized depth of 40 feet and includes about 56 nautical miles of deep-draft channel. The Beaumont/Port Arthur area is located about 90 miles northeast of Houston, Texas. The local sponsor for the project is the Jefferson County Waterway and Navigation District.

FOR FURTHER INFORMATION CONTACT: Questions about the proposed action and DEIS can be answered by: Ms. Lizette Richardson, (409) 766-3123, Project Manager, Project Management Branch, or Ms. Janelle Stokes, (409) 766-3039, Environmental Lead, Environmental Section, Planning Branch, Planning Environmental and Regulatory Division, P.O. Box 1229, Galveston, Texas 77553-1229.

SUPPLEMENTARY INFORMATION:

(1) *Background.* The study began in 1997 when Congress directed the Secretary of the Army to study the feasibility of modifying the channels serving the Ports of Beaumont, Port Arthur, and Orange, Texas in the interests of commercial navigation. A

reconnaissance study evaluated a deepening and widening plan to establish a Federal Interest in the project. The study concluded that there was a Federal Interest in continuing studies in 1998. The feasibility study began in March 2000 and will determine the most cost-effective alternative for improving the channel while protecting the Nation's environment.

(2) a. *Alternatives.* The construction alternatives that will be evaluated in the feasibility phase are: (1) Deepening the channel to 45 ft from offshore to the Beaumont turning basin; (2) deepening the channel to 48 ft from offshore to the Beaumont turning basin; (3) deepening the channel to 50 ft from offshore to the Beaumont turning basin; (4) various combinations of selective widening and turning basins; 5) various combinations of selective widening and turning basins with each one of the above depths.

b. *No Action.* A "No Action" alternative will be evaluated and presented for comparison purposes in evaluating the various construction alternatives.

(3) *Scoping.* The scoping process will involve Federal, State and local agencies, and other interested persons and organizations. Scoping meetings are scheduled for May 28 and 29, 2002 in Lake Charles, Louisiana, and Beaumont, Texas. The time and place of these meetings will be announced in local newspapers and mailings. Issues to be discussed at these meetings include, but are not limited to, changes in salinity and circulation, changes in fresh and saltwater marshes, water and sediment quality, erosion along the channel, threatened and endangered species impacts, opportunities for ecosystem restoration, and the beneficial use of dredged material. Any person or organization wishing to provide information on issues or concerns should contact the Corps of Engineers at the above address.

4. *Coordination.* Further coordination with environmental agencies will be conducted under the National Environmental Policy Act, the Fish and Wildlife Coordination Act, the Endangered Species Act, the Clean Water Act, the Clean Air Act, the National Historic Preservation Act, the Magnuson-Stevens Fishery Conservation and Management Act (Essential Fish Habitat), and the Coastal Zone Management Act under the Texas Coastal Management Program and the Louisiana Coastal Resources Program. An Interagency Coordination Team (ICT) has been formed to provide guidance and counsel on matters relating to the evaluation of environmental impacts of this project.

The ICT is composed of representatives from 4 Federal agencies, 7 regulatory agencies from the States of Texas and Louisiana, the local sponsor, and the U.S. Army Corps of Engineers.

5. *DEIS Preparation.* It is estimated that the DEIS will be available to the public for review and comment in January 2004.

Carolyn E. Murphy,

Chief, Environmental Section.

BILLING CODE 3710-52-P

DEPARTMENT OF ENERGY

Federal Energy Regulatory Commission

[Docket No. ER02-517-002, et al.]

UtiliGroup, Inc., et al.; Electric Rate and Corporate Regulation Filings

May 14, 2002.

The following filings have been made with the Commission. The filings are listed in ascending order within each docket classification.

1. UtiliGroup, Inc.

[Docket No. ER02-517-002]

Take notice that on May 3, 2002, UtiliGroup, Inc. (UtiliGroup) tendered for filing with the Federal Energy Regulatory Commission (Commission) additional information to its original Petition for Acceptance of Initial Rate Schedule, Waivers and Blanket Authority filed December 10, 2001 and Amendment filed February 4, 2002.

Comment Date: May 24, 2002.

2. San Diego Gas & Electric Company

[Docket No. ER02-613-001]

Take notice that on April 30, 2002, San Diego Gas and Electric Company (SDG&E) tendered for filing with the Federal Energy Regulatory Commission (Commission) revised tariff sheets in Docket No. ER02-613-000, dated December 24, 2001, reflecting its proposed recovery of revenue requirements. Since making its filing, SDG&E determined that the revenue requirement submitted did not include recovery of franchise fees paid to the cities and counties in its service territory.

SDG&E is requesting the Commission to approve the revised revenue requirements and rates effective July 1, 2002 through December 31, 2002.

Comment Date: May 24, 2002.

Notice of Availability for the Draft Environmental Impact Statement for the Sabine-Neches Waterway Channel Improvement Project, Southeast Texas and Southwest Louisiana and the Environmental Impact Statement Sabine-Neches Waterway Channel Improvement Project, Texas Ocean Dredged Material Disposal Site Designation

AGENCY: Department of the Army, U.S. Army Corps of Engineers (USACE), Department of Defense; U.S. Environmental Protection Agency (EPA).

ACTION: Notice of Availability.

SUMMARY: The U.S. Army Corps of Engineers, Galveston District, announces the release of the Draft Feasibility Report (DFR) and the Draft Environmental Impact Statement (DEIS), the EIS for the Ocean Dredged Material Disposal Site Designation, the Draft General Conformity Determination, and the public comment period, for the Sabine Neches Navigation District's (SNND) proposed Sabine-Neches Waterway Channel Improvement Project (SNWW CIP).

DATES: The USACE, Galveston District, will be accepting written public comments on the DEIS through February 10, 2010. All comments must be postmarked by February 10, 2010.

ADDRESSES: You may send written comments to the USACE, Galveston District, Attn: Ms. Janelle Stokes, P.O. Box 1229, Galveston, TX 77553-1229, or by email to janelle.s.stokes@usace.army.mil.

FOR FURTHER INFORMATION CONTACT: Questions about the proposed action and the DEIS should be directed to Ms. Janelle Stokes, (409) 766-3039, or at the email address above.

SUPPLEMENTARY INFORMATION:

Authority: The lead agency for this proposed channel improvement action is the USACE with several cooperating agencies including EPA, the National Marine Fisheries Service (NMFS), U.S. Fish and Wildlife Service (USFWS), the Texas General Land Office,

and the Louisiana Department of Wildlife and Fisheries (LDWF). As authorized by the Senate Committee on Environment and Public Works Resolution, dated June 5, 1997, USACE has reviewed previous USACE reports on the SNWW and other pertinent reports to determine the feasibility of modifying the channels serving the ports of Beaumont, Port Arthur, and Orange, Texas, in the interest of commercial navigation.

The lead agency for the proposed action to designate four new Ocean Dredged Material Disposal Sites (ODMDS) to receive portions of new work and future maintenance material from the proposed CIP is EPA, under the authority of Section 102 of the Marine Protection, Research, and Sanctuaries Act (MPRSA) (33 U.S.C. 1412).

Background: The USACE has joined in an agreement with the SNND to prepare a DFR and a DEIS for proposed improvements to the SNWW. The proposed SNWW CIP is intended to improve the efficiency of the deep draft navigation system while protecting the area's coastal and estuarine resources. The lead agency for the DEIS is USACE. This DEIS was prepared as required by the National Environmental Policy Act (NEPA) to present an evaluation of potential impacts associated with the proposed CIP. The DEIS is now available for public review and comment.

Project Description: The SNND proposes to increase the authorized depth of the channel from 40 to 48 feet along the entire 64-mile-long existing channel and add a 13.2-mile extension to the offshore channels into the Gulf of Mexico. The offshore navigation channels, known collectively as the Entrance Channel, are divided into the Extension Channel, the Sabine Bank Channel, the Sabine Pass Outer Bar Channel, and the Sabine Pass Jetty Channel. They would be deepened from 42 to 50 feet. The inshore channels (the Sabine Pass Jetty Channel, Sabine Pass Channel, Port Arthur and Sabine-Neches canals, and the Neches River Channel) would be deepened from 40 feet to 48 feet. No modifications to the existing Sabine Pass Jetties are contemplated in conjunction with this project. Potential rehabilitation of the jetties is currently being studied, with the goal of preparing a long range plan of modification needed to ensure that the jetties continue to function appropriately to support the Federal navigation channel. Except for the one channel reach just beyond the jetties, the bottom width of the offshore Entrance Channel would be 700 feet wide. Since the existing Sabine Bank Channel is 800 feet wide, the bottom width of the deepened channel would be reduced to 700 feet wide. However, high currents passing around the mouth of the jetties require that the bottom width of the Sabine Pass Outer Bar Channel remain 800 feet wide, and therefore the deepened channel would be tapered to connect to the 700 foot Entrance Channel. With the exception of the Taylor Bayou basins and channels, the inshore channels would retain their existing 500 to 400 foot widths. The Taylor Bayou basins and channels would be widened to improve maneuverability for vessels using that facility. Neither the Sabine Neches Canal nor the Neches River Channel would be systematically widened, but navigation efficiency would be improved with bend easings in both reaches, and the addition or enlargement of turning and anchorage basins on the Neches River Channel.

Approximately 98 million cubic yards (mcy) of new-work dredged material would be generated from the proposed project. Maintenance dredging over the 50-year period of analysis is expected to yield approximately 650 mcy of dredged material. Dredged material will be placed in 16 existing upland placement area (PA) features and two new expansion cells at existing upland PAs. For the Entrance Channel, material will be placed in four existing and four proposed ODMDS features.

The proposed sites for the four new ODMDS are bounded by the following coordinates:

ODMDS "A"

29° 24' 47" N, 93° 43' 29" W; 29° 24' 47" N, 93° 41' 08" W
29° 22' 48" N, 93° 41' 09" W; 29° 22' 49" N, 93° 43' 29" W

ODMDS "B"

29° 21' 59" N, 93° 43' 29" W; 29° 21' 59" N, 93° 41' 08" W
29° 20' 00" N, 93° 41' 09" W; 29° 20' 00" N, 93° 43' 29" W

ODMDS "C"

29° 19' 11" N, 93° 43' 29" W; 29° 19' 11" N, 93° 41' 09" W
29° 17' 12" N, 93° 41' 09" W; 29° 17' 12" N, 93° 43' 29" W

ODMDS "D"

29° 16' 22" N, 93° 43' 29" W; 29° 16' 22" N, 93° 41' 10" W
29° 14' 24" N, 93° 44' 10" W; 29° 14' 24" N, 93° 43' 29" W

The water depth at the proposed four new ODMDS ranges from 39 to 46 feet. The bottom topography is flat, and proposed ODMDS "A", the most inshore proposed ODMDS, is approximately 19 miles from the coast at its closest point. A separate DEIS evaluating the proposed designation by EPA of the four new proposed ODMDSs accompanies the SNWW CIP DEIS as Appendix B. Beneficial uses of dredged material in the DMMP consist of the Neches River Beneficial Use (BU) Feature (Rose City East, Bessie Heights East, and Old River Cove), and the Gulf Shore BU Feature at Texas and Louisiana Points. Compensatory mitigation in the form of marsh restoration is proposed for all unavoidable environmental impacts in Louisiana.

Availability of Draft Environmental Impact Statement (DEIS): Pursuant to section 102(2)(c) of the NEPA of 1969, as amended and as implemented by the Council on Environmental Quality (40 CFR parts 1500-1508) a DEIS for the proposed SNWW CIP has been filed with the EPA and is being made available to Federal, State, and local agencies, and all interested parties. The DEIS can be viewed online at <http://www.swg.usace.army.mil/>. Copies of the DEIS can be requested from Ms. Janelle Stokes at the address above. In addition, copies of the DEIS are available for viewing at the following libraries:

- Beaumont Public Library, 801 Pearl, Beaumont, TX 77701.

- R.C. Miller Library, 1605 Dowlen, Beaumont, TX 77701.
- Elmo Willard Library, 3590 East Lucas, Beaumont, TX 77701.
- Theodore Johns Branch Library, 4255 Fannett, Beaumont, TX 77701.
- City of Orange Public Library, 220 N. 5th Street, Orange, TX 77630.
- Marion and Ed Hughes Public Library, 2712 Nederland Ave., Nederland, TX 77627.
- Port Arthur Public Library, 4615 9th Avenue (at Highway 73), Port Arthur, TX 77642.
- Bridge City Public Library, 101 Parkside Drive, Bridge City, TX 77611.
- Calcasieu Parish Public Library, 301 W. Claude Street, Lake Charles, LA 70605.

Water Quality Certification: The USACE is requesting §401 State Water Quality certification from Texas and Louisiana for this action. A Clean Water Act §404(b)(1) evaluation of the proposed action, provided in the DEIS (Appendix E), summarizes the results of water and sediment analyses and describes the effects of the proposed discharges. Short-term increases in turbidity may be caused by the unconfined flow of dredged material during construction of BU features and mitigation measures. Proposed channel improvements should decrease the number of vessel trips, thus decreasing the probability of a spill. All relevant sediment and water quality data for both new-work and maintenance dredging material were reviewed by a team of State and Federal resource agencies (the Contaminants Workgroup of the Interagency Coordination Team), including the Texas Commission on Environmental Quality (TCEQ) and Louisiana Department of Environmental Quality (LDEQ), and they found no cause for concern over water or sediment quality in any channel reach.

Draft General Conformity: As required by the Clean Air Act, the EPA has promulgated rules to ensure that Federal actions conform to the appropriate State Implementation Plan (SIP). The General Conformity Rule (40 CFR Part 51, Subpart W) applies to Federal actions, within maintenance or nonattainment areas. Pursuant to Section 176 of the Clean Air Act Amendments of 1990, the USACE has prepared a document entitled, "Draft General Conformity Determination, Sabine-Neches Channel Improvement Project" (Appendix F). This document will be noticed for public comment and will be submitted by the USACE to the TCEQ, EPA, and other air pollution control agencies, as appropriate, concurrently with this DEIS. As part of the General Conformity process, the USACE will make this document available to the public for review and comment for a period of 30 days. During this time, the USACE will consult with the TCEQ and the EPA seeking concurrence that emissions from the Preferred Alternative are conformant with the Texas SIP for the Beaumont-Port Arthur area. Once written confirmation is received from the TCEQ and the EPA, the USACE will prepare a Final General Conformity Determination for the proposed SNWW CIP.

Construction activities associated with the proposed CIP would result in emissions from combustion products from project dredging, support, and reuse/disposal equipment.

Pollutant emissions from construction and dredging activities may result in short-term impacts on air quality in the immediate vicinity of the project site. Emissions of volatile organic compounds for the activities subject to USACE responsibility are exempt from a General Conformity Determination because they are below the 100-ton-per-year (tpy) threshold. Estimated nitrogen oxide (NO_x) emissions for activities subject to USACE responsibility would exceed the conformity threshold of 100 tpy for all years of construction. Therefore, USACE has prepared a General Conformity Determination for NO_x emissions, which would be submitted to TCEQ, EPA, and other air pollution control agencies, as appropriate, to ensure conformity of this project with the SIP. It is expected that the Preferred Alternative would be found to conform to the Texas SIP for the Beaumont-Port Arthur non-attainment area.

Section 102 of the Marine Protection Research, and Sanctuaries Act (MPRSA): Section 102 of the MPRSA requires a determination that dredged material placement in the ocean would not reasonably degrade or endanger human health, welfare, or amenities or the marine environment, ecological systems, or economic potential (shellfish beds, fisheries, or recreational areas). Maintenance and construction dredged material proposed for placement at the existing and the proposed new ODMDSSs, designated by the EPA under MPRSA, is subject to evaluation using the ocean dumping environmental criteria. The proposed new ODMDSSs are outlined in Appendix B of the DEIS. The conclusion of the ODMDSS Designation DEIS (Appendix B) was that the Preferred ODMDSSs met all of the five general and 11 specific criteria listed in 40 CFR 228.5 and 228.6 and are, therefore, acceptable under the MPRSA. All material transported for ocean disposal would be evaluated pursuant to EPA Ocean Dumping Regulations and Criteria (MPRSA Section 102). Use of the ODMDSSs would be in accordance with an approved Site Monitoring and Management Plan (SMMP, Appendix B).

National Register of Historic Places: The staff archaeologist has reviewed the latest published version of the National Register of Historic Places, lists of properties determined eligible, and other sources of information. The following is current knowledge of the presence or absence of historic resources and the effects of the proposed project upon these properties: remote sensing surveys have been completed for the Outer Bar Channel, the Sabine Pass Jetty Channel, the Sabine Pass Channel, the Port Arthur Canal, the Sabine-Neches Canal, and the Neches River Channel in Jefferson and Orange counties, Texas, and Cameron Parish, Louisiana. No remote-sensing survey has been conducted for the Sabine Bank Channel, the proposed Extension Channel or the existing or proposed ODMDSSs. This project would not impact NRHP-listed properties or State Archeological Landmarks; however, it may potentially adversely impact terrestrial and marine historic properties eligible for listing in the NRHP. This DEIS has been coordinated with the Texas and Louisiana State Historic Preservation Officers. A Historic Properties Programmatic Agreement (Appendix H) has been executed among the Texas and Louisiana SHPOs, the SNND and USACE to address subsequent investigations, coordinate surveys of impact areas, test potentially eligible sites, and manage data recovery or avoidance measures as necessary. Tribal coordination, required by the NHPA, has been conducted. Tribes with

historical or cultural ties to the region were contacted early in the study to identify their interests and concerns. The draft Programmatic Agreement has also been coordinated with the Tribes. No Tribes have requested to become consulting parties, and no impacts to Tribal land or traditional cultural properties have been identified.

Threatened and Endangered Species: Indications are that the proposed project may affect a few Federally listed endangered or threatened species. The project is likely to adversely affect but is not likely to jeopardize the following species: loggerhead, Kemp's ridley, hawksbill, leatherback, and green sea turtles. The project, however, is not likely to adversely affect the piping plover or its Critical Habitat, or the brown pelican. Potential impacts to the wintering piping plover would be associated with implementation of the Gulf Shore BU Feature. The recurring placement of dredged material for shoreline nourishment would affect areas of designated Critical Habitat. A Biological Assessment (BA) was prepared and was presented to the USFWS and the NMFS in the DEIS. NMFS has reviewed the BA and has prepared a Biological Opinion outlining the measures to be taken to avoid and minimize potential sea turtle takes, particularly during hopper dredging activities. The USFWS provided concurrence with the determinations made in the BA for all species under their jurisdiction, including nesting sea turtles (Appendix G).

Essential Fish Habitat (EFH): Consultation for EFH of the Magnuson-Stevens Fishery Conservation and Management Act was initiated in May 2002 with the public scoping meeting. Letters were also sent to the NMFS in April 2006. Our initial determination is the proposed action would have temporary and local impact on EFH and Federally managed fisheries in the Gulf of Mexico. In the long-term, restored marsh and improved shallow-water habitat in the proposed mitigation and Neches River BU Feature will create and benefit EFH. Open water in marshes would be improved as EFH habitat by creating smaller, shallow-water pools and channels in which fetch and turbidity are reduced. In addition, existing, sediment starved marsh within the influence areas targeted for mitigation and BU would be nourished by the winnowing of fine-grained sediments during unconfined placement of the dredged material. The requirements of the act have been met (Appendix A3).

Other Agency Authorizations: Texas and Louisiana Coastal Zone consistency certification is required. USACE has stated that the project is consistent with the Texas and Louisiana Coastal Zone Management Programs' goals and policies and will be conducted in a manner consistent with said Programs. Additional information can be found in Appendix I of the DEIS. The DEIS and Texas Coastal Consistency Determination has been submitted to the Coastal Coordination Council for review, and the Louisiana Coastal Consistency Determination has been submitted to the Louisiana Department of Natural Resources for review.

Public Comment and Public Hearing: A Public Hearing on the proposed project is scheduled for the last week of January. The specific day for the Public Hearing has not yet been determined. However, for more information on the hearing date, meeting location,

and general information, please visit <http://www.swg.usace.army.mil/>. Poster presentations will be available for viewing and project team members will be present to discuss the DEIS at a Workshop that will precede the hearing. The Workshop will be conducted from 5 p.m. to 6:45 p.m. on the day of the formal Hearing, and the formal Hearing will commence at 7 p.m.

Public Interest Review Factors: The DEIS will be reviewed in accordance with CEQ NEPA regulations (40 CFR Part 1500-1508), and USACE's regulation ER 200-2-2 (*Environmental Quality: Policy and Procedures for Implementing NEPA*, 33 CFR 230), and other pertinent laws, regulations and executive orders. The decision whether to recommend construction of this project to Congress will be based on an evaluation of the probable impacts, including cumulative impacts, of the proposed activity in the public interest. That decision will reflect the national concern for both protection and utilization of important resources. The benefits, which reasonably may be expected to accrue from the project, must be balanced against reasonably foreseeable detriments associated with the project. All factors which may be relevant to the project will be considered. These include, but are not limited to: dredged material management, air quality, shoreline erosion, economics, general environmental concerns, historic resources, protected species, navigation, recreation, water and sediment quality, energy needs, safety, hazardous materials, and in general, the welfare of the people.

Solicitation of Comments: The USACE is soliciting comments from the public, Federal, State, and local agencies and officials, Indian tribes, and other interested parties in order to consider and evaluate the impacts of this proposed activity. Comments will be considered in the evaluation of impacts on endangered species, historic properties, water quality, general environmental effects, and other public interest factors listed above. Comments will be used in preparation of the Final EIS pursuant to NEPA. Comments are also used to determine the overall public interest of the proposed activity.

16 December 2009
Date

DAVID C. WESTON
COL, EN
Commanding

Comment Date: 5 p.m. Eastern Time on Monday, December 28, 2009.

Any person desiring to intervene or to protest in any of the above proceedings must file in accordance with Rules 211 and 214 of the Commission's Rules of Practice and Procedure (18 CFR 385.211 and 385.214) on or before 5 p.m. Eastern time on the specified comment date. It is not necessary to separately intervene again in a subdocket related to a compliance filing if you have previously intervened in the same docket. Protests will be considered by the Commission in determining the appropriate action to be taken, but will not serve to make protestants parties to the proceeding. Anyone filing a motion to intervene or protest must serve a copy of that document on the Applicant. In reference to filings initiating a new proceeding, interventions or protests submitted on or before the comment deadline need not be served on persons other than the Applicant.

The Commission encourages electronic submission of protests and interventions in lieu of paper, using the FERC Online links at <http://www.ferc.gov>. To facilitate electronic service, persons with Internet access who will eFile a document and/or be listed as a contact for an intervenor must create and validate an eRegistration account using the eRegistration link. Select the eFiling link to log on and submit the intervention or protests.

Persons unable to file electronically should submit an original and 14 copies of the intervention or protest to the Federal Energy Regulatory Commission, 888 First St., NE., Washington, DC 20426.

The filings in the above proceedings are accessible in the Commission's eLibrary system by clicking on the appropriate link in the above list. They are also available for review in the Commission's Public Reference Room in Washington, DC. There is an eSubscription link on the Web site that enables subscribers to receive e-mail notification when a document is added to a subscribed docket(s). For assistance with any FERC Online service, please e-mail FERCOnlineSupport@ferc.gov or call (866) 208-3676 (toll free). For TTY, call (202) 502-8659.

Nathaniel J. Davis, Sr.,

Deputy Secretary.

DEPARTMENT OF ENERGY

Federal Energy Regulatory Commission

Combined Notice of Filings No. 2

December 16, 2009.

Take notice that the Commission has received the following Natural Gas Pipeline Rate and Refund Report filings:

Docket Numbers: RP10-117-001.

Applicants: Algonquin Gas Transmission, LLC.

Description: Algonquin Gas Transmission, LLC submits First Revised Sheet 590 et al to FERC Gas Tariff, Fifth Revised Volume 1 effective 12/1/09.

Filed Date: 12/11/2009.

Accession Number: 20091214-0130.

Comment Date: 5 p.m. Eastern Time on Wednesday, December 23, 2009.

Docket Numbers: RP10-188-001.

Applicants: Arlington Storage Company, LLC.

Description: Arlington Storage Company submits First Revised Sheet No 4A to FERC Gas Tariff, First Revised Volume No. 1.

Filed Date: 12/09/2009.

Accession Number: 20091210-0133.

Comment Date: 5 p.m. Eastern Time on Monday, December 21, 2009.

Any person desiring to protest this filing must file in accordance with Rule 211 of the Commission's Rules of Practice and Procedure (18 CFR 385.211). Protests to this filing will be considered by the Commission in determining the appropriate action to be taken, but will not serve to make protestants parties to the proceeding. Such protests must be filed on or before 5 p.m. Eastern time on the specified comment date. Anyone filing a protest must serve a copy of that document on all the parties to the proceeding.

The Commission encourages electronic submission of protests in lieu of paper using the "eFiling" link at <http://www.ferc.gov>. Persons unable to file electronically should submit an original and 14 copies of the protest to the Federal Energy Regulatory Commission, 888 First Street, NE., Washington, DC 20426.

This filing is accessible on-line at <http://www.ferc.gov>, using the "eLibrary" link and is available for review in the Commission's Public Reference Room in Washington, DC. There is an "eSubscription" link on the Web site that enables subscribers to receive e-mail notification when a document is added to a subscribed docket(s). ENVIRONMENTAL PROTECTION AGENCY

[FER-RL-8986-8]

Environmental Impact Statements; Notice of Availability

Responsible Agency: Office of Federal Activities, General Information, (202) 564-1399 or <http://www.epa.gov/compliance/nepa/>.

Weekly Receipt of Environmental Impact Statements

Filed 12/14/2009 Through 12/18/2009 Pursuant to 40 CFR 1506.9

Notice: In accordance with Section 309(a) of the Clean Air Act, EPA is required to make its comments on EISs issued by other Federal agencies public. Historically, EPA has met this mandate by publishing weekly notices of availability of EPA comments, which includes a brief summary of EPA's comment letters, in the **Federal Register**. Since February 2008, EPA has been including its comment letters on EISs on its Web site at: <http://www.epa.gov/compliance/nepa/eisdata.html>. Including the entire EIS comment letters on the Web site satisfies the Section 309(a) requirement

to make EPA's comments on EISs available to the public. Accordingly, after March 31, 2010, EPA will discontinue the publication of this notice of availability of EPA comments in the **Federal Register**.

BILLING CODE 6960-50-P

FEDERAL MINE SAFETY AND HEALTH REVIEW COMMISSION

Sunshine Notice

December 17, 2009.

TIME AND DATE: 10 a.m., Thursday, January 7, 2010.

PLACE: The Richard V. Backley Hearing Room, 9th Floor, 601 New Jersey Avenue, NW., Washington, DC.

STATUS: Open.

MATTERS TO BE CONSIDERED: The Commission will consider and act upon the following in open session: *Secretary of Labor v. Cumberland Coal Resources, LP*, Docket Nos. PENN 2008-51-R, *et seq.* (Issues include whether an order issued to the operator under 30 CFR 75.363(a) (requiring that hazardous conditions be corrected or posted) should be amended to allege a violation of 30 CFR 75.360(b) (requiring that the person conducting a preshift examination identify hazardous conditions).)

Any person attending this meeting who requires special accessibility features and/or auxiliary aids, such as sign language interpreters, must inform the Commission in advance of those needs. Subject to 29 CFR 2706.150(a)(3) and 2706.160(d).

CONTACT PERSON FOR MORE INFO: Jean Ellen, (202) 434-9950/(202) 708-9300 for TDD Relay/1-800-877-8339 for toll free.

Jean H. Ellen,

Chief Docket Clerk.

FEDERAL TRADE COMMISSION

Agency Information Collection Activities; Proposed Collection; Comment Request

AGENCY: Federal Trade Commission ("FTC" or "Commission").

ACTION: Notice.

SUMMARY: The information collection requirements described below will be

www.regulations.gov, your e-mail address will be automatically captured and included as part of the comment that is placed in the public docket and made available on the Internet. If you submit an electronic comment, EPA recommends that you include your name and other contact information in the body of your comment and with any disk or CD-ROM you submit. If EPA cannot read your comment due to technical difficulties and cannot contact you for clarification, EPA may not be able to consider your comment. Electronic files should avoid the use of special characters and any form of encryption and be free of any defects or viruses. For additional information about EPA's public docket visit the EPA Docket Center homepage at <http://www.epa.gov/epahome/dockets.htm>.

Docket: All documents in the docket are listed in the <http://www.regulations.gov> index. Although listed in the index, some information is not publicly available, e.g., CBI or other information whose disclosure is restricted by statute. Certain other material, such as copyrighted material, will be publicly available only in hard copy. Publicly available docket materials are available either electronically in <http://www.regulations.gov> or in hard copy at the ODI Docket in the EPA Headquarters Docket Center.

Dated: February 12, 2010.

Rebecca Clark,
Director, National Center for Environmental Assessment.

ENVIRONMENTAL PROTECTION AGENCY

[ER-FRL-8988-2]

Environmental Impact Statements; Notice of Availability

Responsible Agency: Office of Federal Activities, General Information (202) 564-1399 or <http://www.epa.gov/compliance/nepa/>.

Weekly Receipt of Environmental Impact Statements

Filed 02/01/2010 through 02/12/2010. Pursuant to 40 CFR 1506.9.

Notice

In accordance with Section 309(a) of the Clean Air Act, EPA is required to make its comments on EISs issued by other Federal agencies public. Historically, EPA has met this mandate by publishing weekly notices of

availability of EPA comments, which includes a brief summary of EPA's comment letters, in the **Federal Register**. Since February 2008, EPA has been including its comment letters on EISs on its Web site at: <http://www.epa.gov/compliance/nepa/eisdata.html>. Including the entire EIS comment letters on the Web site satisfies the Section 309(a) requirement to make EPA's comments on EISs available to the public. Accordingly, after March 31, 2010, EPA will discontinue the publication of this notice of availability of EPA comments in the **Federal Register**.

Federal Offices in Washington, DC, were closed because of inclement weather from February 8–11, 2010. Accordingly the Notice of Availability for the Weekly Receipt of Environmental Impact Statements filed 02/01/2010 through 02/05/2010 was not published in the **Federal Register** on February 12, 2010.

EIS No. 20100033, Draft EIS, BLM, CA Chevron Energy Solutions Lucerne Valley Solar Project, Proposing To Develop a 45-megawatt (MW) Solar Photovoltaic (PV) Plant and Associated Facilities on 516 Acres of Federal Land Managed, California Desert Conservation Area Plan Amendment, San Bernardino County, CA, Comment Period Ends: 05/19/2010, Contact: Greg Thomsen 951-697-5237.

EIS No. 20100034, Final EIS, USFWS, CA, Hatchery and Stocking Program, Operation of 14 Trout Hatcheries and the Mad River Hatchery for the Anadromous Steelhead, Federal Funding, California Department of Fish and Game, CA, Wait Period Ends: 03/22/2010, Contact: Bart Prose 916-978-6152.

EIS No. 20100035, Draft EIS, USACE, TX, Lake Columbia Regional Water Supply Reservoir Project, Proposes to Construct, Operate and Maintain a Dam and Reservoir, Mud Creek, Angelina River, Cherokee and Smith Counties, TX, Comment Period Ends: 04/05/2010, Contact: Brent Jasper 817-886-1733.

FARM CREDIT ADMINISTRATION

Farm Credit Administration Board; Sunshine Act; Regular Meeting

AGENCY: Farm Credit Administration.

SUMMARY: Notice is hereby given, pursuant to the Government in the Sunshine Act (5 U.S.C. 552b(e)(3)), that the February 11, 2010 regular meeting (75 FR 6393, February 9, 2010) of the Farm Credit Administration Board (Board) has been rescheduled due to the recent inclement weather in the Washington DC metropolitan area.

DATE AND TIME: The regular meeting of the Board will now be held at the offices of the Farm Credit Administration in McLean, Virginia, on February 24, 2010, from 9 a.m. until such time as the Board concludes its business.

FOR FURTHER INFORMATION CONTACT:

Roland E. Smith, Secretary to the Farm Credit Administration Board, (703) 883-4009, TTY (703) 883-4056.

ADDRESSES: Farm Credit Administration, 1501 Farm Credit Drive, McLean, Virginia 22102-5090.

SUPPLEMENTARY INFORMATION: This meeting of the Board will be open to the public (limited space available). In order to increase the accessibility to Board meetings, persons requiring assistance

should make arrangements in advance. Two of the three agenda items have been removed for this rescheduled meeting. The matter to be considered at the meeting is:

Open Session

- *Approval of Minutes*

○ January 14, 2010

Dated: February 16, 2010.

Roland E. Smith,

Secretary, Farm Credit Administration Board.

BILLING CODE 6705-01-P

FEDERAL COMMUNICATIONS COMMISSION

[IB Docket No. 04-286; DA 10-245]

Fourth Meeting of the Advisory Committee for the 2012 World Radiocommunication Conference Rescheduled to March 2, 2010

AGENCY: Federal Communications Commission.

ACTION: Notice.

SUMMARY: In accordance with the Federal Advisory Committee Act, as amended, this notice advises interested persons that the fourth meeting of the WRC-12 Advisory Committee will be held at the Federal Communications Commission. The purpose of the meeting is to continue preparations for the 2012 World Radiocommunication Conference. The WRC-12 Advisory Committee will consider any preliminary views and draft proposals introduced by the WRC-12 Advisory Committee's Informal Working Groups. The meeting, originally scheduled for February 10, 2010 as published in the *Federal Register*, Vol. 75, No. 9 on January 14, 2010, was postponed due to the closure of the Federal Government because of inclement weather. Less than 15 calendar days notice of the rescheduled meeting is being provided due to the need to receive the WRC-12 Advisory Committee's recommendations to provide timely input to the meeting of the Inter-American Telecommunication Commission (CITEL).

DATES: March 2, 2010, 11 a.m. to 12 noon.

ADDRESSES: Federal Communications Commission, 445 12th Street, SW., Room TW-C305, Washington, DC 20554.

FOR FURTHER INFORMATION CONTACT:

Alexander Roytblat, Designated Federal Official, WRC-12 Advisory Committee, FCC International Bureau, Strategic

Analysis and Negotiations Division, at (202) 418-7501.

SUPPLEMENTARY INFORMATION: The Federal Communications Commission established the WRC-12 Advisory Committee to provide advice, technical support and recommendations relating to the preparation of United States proposals and positions for the 2012 World Radiocommunication Conference (WRC-12).

In accordance with the Federal Advisory Committee Act, Public Law 92-463, as amended, this notice advises interested persons of the fourth meeting of the WRC-12 Advisory Committee. The WRC-12 Advisory Committee has an open membership. All interested parties are invited to participate in the WRC-12 Advisory Committee and to attend its meetings. The proposed agenda for the fourth meeting is as follows:

Agenda

Fourth Meeting of the WRC-12 Advisory Committee, Federal Communications Commission, 445 12th Street, SW., Room TW-C305, Washington, DC 20554.

March 2, 2010, 11 a.m. to 12 noon

1. Opening Remarks
2. Approval of Agenda
3. Approval of the Minutes of the Third Meeting
4. Informal Working Group Reports and Documents Relating to Preliminary Views
5. New Guidelines for Federal Advisory Committee Membership
6. Future Meetings
7. Other Business

Federal Communications Commission.

Mindel De La Torre,

Chief, International Bureau.

Cable: BARWILBM

Mr. Frank Garcia,

I have just received the notice for the meeting concerning the Sabine-Neches Waterway, Texas Feasibility Study. I will not be able to attend the meeting, but would like to take this opportunity to give you my comments.

I am the Assistant Manager for Barwil Agencies (NA) Inc., a worldwide steamship agency with an office in Beaumont, Texas. In case you are not familiar with what we do, here is a brief description. We are the agents for foreign and U.S. Flag vessels that come into the ports of Port Arthur, Beaumont, and Orange, Texas. We attend the vessels on behalf of the owners and/or charters and assist in an efficient port stay and turn around.

With the current status of the Sabine-Neches Waterway, I feel that it is close to reaching its capacity for vessel traffic movement and without improvements our ports will not be competitive enough to attract new business or maintain the current level. If the information I have is correct, the combined ports of Port Arthur, Beaumont and Orange, Texas make the fourth busiest port in the Nation. With the multi-million dollar expansions at the Fina Refinery and the Clark Refinery and with the Exxon/Mobil merger this will only serve to increase the vessel traffic volume on our waterway. Approximately 75 to 80 percent and in some cases more, the crude oil used by the local refineries comes via the waterway by vessels.

Not only would waterway improvements help the refineries it would also be beneficial to the ports themselves and open up more opportunities for grain, bag products and forest products. Keeping in mind the environmental impact that deepening and widening the Sabine-Neches Waterway would have, I believe it is imperative that improvements be made. If this issue is not addressed in a timely manner, economic growth and individual jobs could be lost.

Thank you for your time and the opportunity to make comments.

Sincerely,

Andy Collins

Assistant Manager
Barwil Agencies (NA) Inc.

Re: Sabine-Neches Waterway
Texas Feasibility Study

Dear Mr. Tomlinson:

The Sabine-Neches Waterway Texas Feasibility Study should include the environmental concerns and potential impacts on the marshes east of Sabine Lake in Louisiana. The potential impacts of saltwater intrusion, increased tidal fluctuation, decreased freshwater retention and vegetative marsh loss are immense. The dredging of the channel from 1912 through 1962 and maintained through this year has been directly responsible for the loss of approximately 50,000 acres of vegetative marsh in Louisiana in the Sabine wetland basin. The environmental concerns for the vegetative wetland loss are of grave concern to myself as a landowner and other concerned citizens. Louisiana involvement as a stakeholder in this process needs to be emphasized in the feasibility study due to the fact that the majority of wetlands affected are located in Louisiana.

By this means we would suggest that the historical hydrology and the wetland diversity be re-established in the Sabine Lake system. The widening and deepening of the Sabine-Neches waterway will cause further marsh loss to an already stressed and fragile system. This feasibility study, through hydrologic modeling and other methods, will identify the problems in the Sabine ecosystem. We would suggest in the absence of a lock at the mouth of the Sabine Pass Channel, that there be at least a constriction at the causeway at its junction with Highway 82 and the separation of the Sabine Lake from the navigation channel along the northern boundary of Sabine Lake. Hydrologic protection should also include maintenance and construction of water control structures along inlets into

the wetlands east of Sabine Lake. There are many wildlife and wetland issues involved in these wetlands due to the historical diversity in this area. This project, as presently proposed with no environmental components, will have significant adverse impacts on my land in Cameron Parish. We emphasize the environmental, social, and economic concerns in our area and expect to be kept abreast of the study as it progresses.

Thank you for the opportunity to have input in the early stages of this feasibility study. We look forward to working with you very closely in the future.

Sincerely,

Re: Sabine-Neches Waterway
Texas Feasibility Study

Dear Mr. Tomlinson:

I am purchasing property in Cameron Parish Louisiana which has frontage on the lower Sabine River near its entrance into Sabine Lake and I am very concerned about the impact of the proposed Sabine-Neches Channel Improvement Project. I would be very much opposed to any project which would cause any environmental damage or ecological changes to this area such as saltwater intrusion, increased tidal fluctuation, decreased freshwater retention, or marsh loss. The State of Louisiana and the Federal Government are doing everything possible to stop coastal wetland loss and I would not want to see any project take place whose effect is antagonistic to these efforts. I would hope that every effort would be taken to take environmental concerns into consideration as related to this project.

Thank you for the opportunity to express my concerns. Please keep me informed as the project progresses.

Sincerely,

Randy Richard

Re: Sabine - Neches Waterway
Channel Improvements Project

Dear Mr. Tomlinson:

As a landowner of approximately 1,200 acres of marshland adjacent within 2 miles of the Sabine River and Sabine Lake, I would like to express my concern over the deepening and widening of the channels serving the ports of Beaumont and Orange. Because of channelization in the past, marshlands east of Sabine Lake in Louisiana have realized increased salt water intrusion and tidal fluctuations which have had a negative impact in regards to erosion and loss of vegetation essential for a healthy marine estuary.

It is our hopes that your agency will strongly consider implementing measures that will not only stop further destruction of these fragile wetlands, but will help return the Sabine River basin to its historical state.

As a landowner on the lower Calcasieu River Estuary I can forewarn you that the widening and deepening of this channel will only accelerate the destruction and loss of these wetlands. We are witnessing firsthand rapid erosion and loss of marshland because of the tidal fluctuations caused by the Calcasieu River Ship Channel.

RE: Sabine-Neches Waterway
Texas Feasibility Study

Dear Mr. Tomlinson:

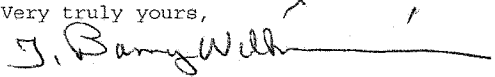

I was recently made aware of the Sabine-Neches Waterway channel improvement project planned with the U.S. Army Corps of Engineers. I understand that a feasibility study is going to be undertaken regarding this project. I represent the owners of wetlands and marshes lying east of the Sabine Lake in Louisiana. We have occupied this property in excess of thirty-three years. In that regard, we have already seen drastic changes in our marsh vegetation and salt water intrusion. The changes have been most pronounced in the last three to five years. However, the changes are for the worse and seem to be accelerating in the last year or two. It appears from the planned project that without due consideration and counter balancing measures that this project will further accelerate the negative impacts of salt water intrusion, increase tidal fluctuation, decreased fresh water retention and vegetative marsh loss. I realize that the project is probably a needed project from an economic standpoint. However, with the proper study and input I am certain that proper measures can be taken to lessen the negative impact of salt water intrusion, increased tidal fluctuation, decreased fresh water retention and vegetative marsh loss. It has been suggested that a lock at the mouth of the Sabine Pass Channel would help immensely in this regard. If this is too costly or not feasible then there should be at least some sort of constriction near the causeway at its junction with Highway 82 and the separation of the Sabine Lake from the navigation channel along the northern boundary of Sabine Lake. Other recommended measures are the maintenance and construction of water controlled structures along the numerous inlets into the wetlands east of Sabine Lake. Without these measures being taken I fear that there will eventually be a total destruction and loss of the wetlands and

Page 2

marshes as we have historically known them. Again, I must emphasize that without the implementation of the currently proposed project we are already having immense problems in this regard. Thank you for allowing me to provide some input in the early stages of this feasibility study. I would appreciate being kept notified of developments and the opportunity to further participate in this process.

If you have any questions, please contact me.

Very truly yours,

A handwritten signature in dark ink, appearing to read "T. Barry Wilkinson", with a long horizontal flourish extending to the right.

Re: Sabine-Neches Waterway, Texas Feasibility Study

Dear Major Turner:

The West Cameron Port Commission is concerned about the impact this navigation project would have on saltwater intrusion into the swamps and marshes of the Calcasieu-Sabine Basin east of Sabine River and Sabine Lake. These marshes have already suffered catastrophic losses due to hydrologic alterations. It is imperative that this feasibility study evaluate the potential impacts to the Louisiana and Texas coastal marsh ecosystem from these hydrologic alterations.

In essence, we the West Cameron Port Harbor & Terminal Commission stand in opposition to the widening and deepening of the channel.

Sincerely,

Clifton Cabell, President

Senator Mary Landrieu
United States Senate
Washington, DC 70510-1804

Dear Senator Landrieu:

The Cameron Preservation Alliance - Sabine Pass Lighthouse, Inc. request to be put on your mailing list to be notified of any correspondence, meetings or activities concerning the dredging, widening, and any other projects in which the Sabine Ship Channel is included.

We are very concerned about activities on-going in this area. The on-going Corp of Engineers project to dredge the Sabine River and dump the spoils on the banks of the river is very disturbing. There is a grove of 40 year old trees that will be destroyed. It is my understanding that the "Back to Nature" idea means that our government would take the lead in protecting and saving important areas such as this for future generations. This is a beautiful natural area with an abundance of migrating birds. This project is also interfering with the access to the Sabine Pass Lighthouse. The levees are butting up to the only access by vehicle to this National Treasure. The levee is several feet higher than the road, when it rains, the mud washes the road.

Should you need more information, please do not hesitate to contact me at 7226.

Sincerely,
Carolyn

Ms. Lizette Richardson
Galveston District
US Army Corps of Engineers
P O Box 1229
Galveston TX 77553-1229

Dear Ms. Richardson:

On behalf of the Coalition to Restore Coastal Louisiana, we would like to express our grave concern about the potential negative impacts on Louisiana's coastal wetlands should the proposed widening and/or deepening of the Sabine-Neches Waterway channel take place.

The proposed changes to the Sabine-Neches Waterway channel will increase shoreline erosion and saltwater intrusion in the Calcasieu-Sabine basin. Saltwater intrusion has contributed greatly to the loss of wetlands in the Calcasieu-Sabine basin over the past 50 years. This project would exacerbate the loss of additional wetlands and vital estuarine habitat.

Due to the potential for increased salinity and shoreline erosion, this proposed project appears to conflict with the restoration strategies outlined in *Coast 2050*. *Coast 2050* is a comprehensive strategic plan for restoring Louisiana's coastal wetlands and stabilizing the coastal zone to prevent further wetland loss. The plan has been approved by all 20 coastal parishes, as well as the state, and federal government agencies, including the US Army Corps of Engineers. This project as proposed could potentially thwart the implementation of *Coast 2050* and threaten Louisiana's ability to gain greater national support for coastal restoration.

Also, the Coastal Wetlands Planning, Protection and Restoration Act (CWPPRA) requires that all US Army Corps of Engineers' navigation and flood control projects be consistent with coastal restoration plans developed under the CWPPRA statute. We have seen no evidence to date that this has been done with respect to this project.

Irrespective of this legal requirement for consistency, any proposed project that will contribute to the destruction of wetlands while state and federal government programs spend millions of dollars to restore those same wetlands is inconceivably wasteful and ill-planned.

We will submit a letter outlining our concerns in greater detail by June 28.

Sincerely,

Mark S. Davis
Executive Director

Our Coast ... Our Future

COMMENT FORM

**PUBLIC SCOPING MEETING
SABINE-NECHES WATERWAY FEASIBILITY STUDY & EIS
LAKE CHARLES, LA. – MAY 28TH, 2002
BEAUMONT, TX. – MAY 29TH, 2002**

This form is provided for your comments on the Sabine-Neches Waterway Feasibility Study and Environmental Impact Study. We appreciate your interest and comments on this project.

Comments:

It has recently been brought to the attention of Jefferson County Drainage District
No. 7 that a Feasibility Study is under way relative to the modification of the
Sabine-Neches Waterway. As you are probably aware, the District operates and
maintains a Hurricane Flood Protection System consisting of a combination of Pump
Stations, Canals and the Levee. This system was designed and built by the U.S.C.O.E.
with the District serving as the local sponsor. The District is concerned about the
impact that deepening and widening the channel may have relative to the integrity of
the hurricane levee. In the past few years, settlement of the blanket stone along
the waterway has been observed and is presently being monitored by the District.
This problem has also been expressed to the Corp. At this time, the District is
requesting to be brought into the discussion group so as to address any issues that
may adversely effect the levee system.

PUBLIC SCOPING MEETING
SABINE-NECHES WATERWAY FEASIBILITY STUDY & EIS
LAKE CHARLES, LA. - MAY 28TH, 2002
BEAUMONT, TX. - MAY 29TH, 2002

This form is provided for your comments on the Sabine-Neches Waterway Feasibility Study and Environmental Impact Study. We appreciate your interest and comments on this project.

Comments:

After attending the meeting in Beaumont on 5/29/02, I discussed the issues presented with one of my clients, Jefferson County Drainage District No. 7 (DD7). The staff at DD7 has expressed some concerns and have raised some valid issues which need to be considered. DD7 along with the U.S.C.O.E. constructed the Hurricane Flood Protection Levee (HFPL) around Pt. Arthur in the 70's and 80's. DD7 would like to know what impacts to the HFPL and the associated gate and pumping structures will be caused by the proposed upgrade to the Sabine-Neches Waterway. DD7 is additionally disturbed by the fact that they have not been contacted by any member of the project team to discuss any issues they might have in addition to those stated above.

Dear Ms. Stokes & Ms. Richardson,

I am sorry I cannot be at the public scoping meeting for the Draft Environmental Impact Statement (DEIS) for the Sabine-Neches Waterway Feasibility Study. Please forgive this hand written letter.

My computer has malfunctioned and is not working.

Please send me a copy of any materials available or handed out at the scoping meetings about this proposal.

"When we try to pick out anything by itself, we find it hitched to everything else in the universe." John Muir

We have a number of concerns we want to bring to your attention.

First, the cumulative impacts of this project and all past, present, and future foreseeable actions must be addressed fully in a comprehensive DEIS. For instance, some of the actions that should be analyzed, assessed, & evaluated include the environmental impacts of the present, past, or future Neches River Channel, the Port Arthur East and West Turning Basins, the Beaumont Turning Basin, the East and West Sabine Pass Jetties, all dredge disposal areas, Taylors Bayou Turning Basin, the Gulf Intercoastal Waterway, the Sabine-Neches Canal, Highway 87, the Orange Turning Basin, the Cow Bayou Channel, the Adams Bayou Channel, the Sabine River Channel, the Channel Around Harbor Island, the Orange Municipal Slip, the Channel to Echo, the Sabine Pass Anchorage Basin, the Sabine Pass Jetty Channel, the Sabine Pass Outer Bar, the Sabine Bank, the Port Arthur Canal,

③

The Neches River Saltwater Barrier, the Steinhagen Dam & expansion, the Sam Rayburn Dam and expansion, Toledo Bend Reservoir, Rockland Reservoir, Fastrill Dam (weches), Lake Palestine, Lake Striker, Lake Easter, Lake Jacksonville, Lake Athens, Lake Cherokee, Martin Lake, Lake Murrant, Lake Tyler, Lake Tyler East, Big Cow Creek Dam, Bon Weir Dam, Ponta Dam, Socoozee Dam, Stateline Dam, State Highway 322 Stages I & II, Rabbit Creek Dam, Carthage Dam, Kilgore Dam, various wastewater treatment plants, water pipelines or canals, and other water projects in the Sabine & Neches Rivers. Also any major ports/other developments and highways.

All of these past, present, and foreseeable future actions have or will have impacts on the Sabine & Neches Rivers. In toto all must be comprehensively assessed in a DEIS that analyzes all cumulative impacts.

For instance, we are very concerned that the existing channels in the Sabine and Neches and any proposals to deepen those channels will increase saltwater intrusion and impact the Big Thicket National Preserve ^(BTNP), including the Beaumont and Pine Island / Little Pine Island Bayous Corridor. This will result in diminished biodiversity and vegetation killing.

We are very concerned about so-called beneficial ⁽⁴⁾ uses of dredged materials. At present we do not favor the creation of spoil islands in any marine or brackish environments.

These islands will simply serve as another way to re-deposit the dredge material while giving the appearance of being environmentally green. Storms will overtop & re-deposit sediments into prime nursery areas for finfish, coahs, shrimps and other marine or aquatic life.

We are concerned that deepening channels to 45-50 feet will increase salinity in brackish water areas & destroy their nursery area function.

The full cost of the proposal must have full mitigation provided. This means full land acquisition to mitigate for destroyed or degraded habitats. Only then will a true benefit/cost be determined & project feasibility can then be assessed.

The full impacts of this proposal on the development of the floodplains of the Neches & Sabine Rivers must be determined.

(5)

The full impacts on Blue Elbow Swamp must be determined.

The full impacts on this proposal driving development in a hurricane and storm prone area must be determined.

The full impacts on the Texas Point and McFadden National Wildlife Refuges must be determined.

The full impacts on the J. D. Murphree Wildlife Management Area and Sabine Rim state Park must be determined.

The full impacts of dredge disposal on the beach paralleling State Hwy 81 must be determined & the linkages fully assessed including impacts.

We urge the Corps not to rush into this project. Already Corps personnel are stating the project looks like it has a positive benefit when public review & input and full assessment, analysis, & evaluation have not been done (See enclosed articles). This appears to make the Corp biased in favor of the proposal before it has even

(6)

been assessed. This biasing is illegal under the National Environmental Policy Act (NEPA) and the Council on Environmental Quality's (CEQ) NEPA implementing regulations.

We appreciate the opportunity to comment and request we be placed on the mailing list and be sent all information about this proposal including a hard copy of the DEIS.

Thank you.

Sincerely,

Brandt Mannchen

Engineers weigh ship channel deepening

Sabine-Neches passage could be dredged to 50 feet

By **DAN WALLACH**
THE ENTERPRISE

BEAUMONT — A preliminary decision to deepen the Sabine-Neches Ship Channel to 50 feet from its existing 40 feet could be ready by July.

An engineer conducting a study for the U.S. Army Corps of Engineers said the depth range under consideration is anywhere from 45 to 55 feet.

"The draft work we've been

doing so far looks like it's in the 50-foot range," said Richard Tomlinson, the project manager. "We don't officially know ourselves, so we can't say for sure."

"To recommend the project, the corps must show an economic benefit in the national interest."

A local waterway official said that benefit already is proved with the corps recently increasing the waterway's ranking for foreign-trade tonnage from fifth to third.

The trend in U.S. ports is to cut

deeper channels to accommodate larger ships, particularly those that serve oil and petrochemical refining plants.

Tomlinson said the estimated cost of digging the Sabine-Neches channel 10 feet deeper is about \$400 million.

The local sponsors would have to pay 25 percent of the cost, he said.

The local sponsors also would have to provide some additional assets, such as real estate for

placement of dredged material.

However, current law requires local sponsors to pay 50 percent of the total cost if the channel depth goes past 45 feet, said Tom Jackson, general manager of the Jefferson County Waterway and Navigation District.

Also, if the depth goes past 45 feet, the local sponsor assumes maintenance costs, Jackson said.

"There is a proposal to nullify that penalty, but as it stands today, there is a penalty for

STUDY, next page

FROM THE BUSINESS COVER

STUDY: Benefits would exceed upgrade costs

Continued from page 1D

depths past 45 feet," Jackson said.

"If it changes, we could go to 50 feet," he said.

Another wild card is the cost of relocating pipelines that cross the channel, he said.

A federal judge in Houston this week wrote an opinion involving the Port of Houston that places the cost of pipeline relocation on the port.

The corps already approved cutting the Houston Ship Channel to 45 feet from 40 feet, and construction there is under way.

The port is appealing the judge's decision.

In July 1991, U.S. District Judge Howell Cobb in Beaumont dealt with a similar problem in which a pipeline company wanted Drainage

District 6 to pay for line relocations in the Taylor Bayou flood control project.

Cobb ruled against the pipeline company, saying its position "not only was not good law, but not good sense."

The Fifth Circuit Court of Appeals in 1993 upheld Cobb's ruling that the pipeline company was responsible for the relocation.

Jackson said at least 65 pipelines cross the Sabine-Neches ship channel.

The corps' recommendation for deepening is based on a cost-benefit ratio averaged during a 50-year span for the project, Tomlinson said.

In the case of the Sabine-Neches channel, the cost-to-benefit ratio is 1-to-2, he said.

If the cost is measured at about \$400 million, the benefit is expected to yield about \$800 million, he said.

"All depths are in that (cost-benefit) ballpark," he said.

The greatest net benefit results from a depth of 50 feet for the channel, he said.

The corps also is studying whether to deepen the channel serving Corpus Christi to as deep as 52 feet from its current 45 feet.

Tomlinson said the corps will determine its recommendation in July and prepare its environmental impact study for public review by December 2003.

A final version of the plan should be ready by April 2004, he said.

Business reporter Dan Wellach may be reached at dwellach@beaumontenterprise.com or call (409) 833-3311, ext. 450.

Dredge project would produce huge amounts of silt, sludge

By **GEORGE ZARAZUA**
THE ENTERPRISE

WEATHER

Today: Scattered showers

Update, page 2A

<http://www.SoutheastTexasLive.com>

By **GEORGE ZARAZUA** The Enterprise

I

BEAUMONT — Sorry kids, this is bigger than mud pies.

We're talking about millions of tons of silt, or dredged sediment, that is expected to be pumped from the bottom of the Sabine-Neches Ship Channel if the federal government approves the deepening and widening of the waterway.

It's such a colossal amount of dirt that the U.S. Army Corps of Engineers has begun to consider what to do with it, even before the project is approved.

Deepening the ship channel to 45 feet will produce enough silt, commonly called spoil, to create a mountain 14,000 feet above sea level if dumped in one place, or fill the Astrodome three times.

Traditionally, the Corps has set the dredged sediment aside, dumping it either on land surrounding the river or out in the Gulf of Mexico, where ships don't travel.

But in an effort to be more environmentally friendly, not to mention there's little room in the county for a mountain-sized mud pile, the Corps has enlisted the aid of a Baton Rouge consulting firm to help come up with solutions.

Representatives with Gulf Engineers and Consultants Inc. have had public meetings across Southeast Texas and Southwest Louisiana, asking residents how more than 40 million cubic yards of dredged sediment can be used to help the environment.

The representatives recently posed the question to Jefferson County commissioners.

SILT, page 6A

SILT: Project not yet approved

Continued from page 1A

"We're not interested at this point whether the ideas are technically or economically feasible, the Corps is going to take all the suggestions that are made and sort them out," said Jacques Bagur, one of the consultants.

County Commissioners said they want the dredged sediment pumped out along the county's coast, forming barriers that would protect not only its beaches, but also Texas 87.

Richard Tomlinson, the Corps' project manager, said other suggestions include pumping the silt via pipelines to areas such as the Bessie Heights Marsh and the J.D. Murphee Wildlife Management Area to replenish their marshes.

"This is going to be some good stuff," Tomlinson said. "In fact, we anticipate there is going to be a demand for the material."

If all else fails, then the Corps could build its own island.

It's been done before with the dredged sediment from the deepening project at the Houston Ship Channel, said Marilyn Uhrich, a spokeswoman for the Corps in

Galveston.

It took the Corps about a month to create Evia Island, which has become a protected habitat for gulls, pelicans, sandpipers and a myriad of other birds.

Re: Public Scoping Meeting — Sabine Neches Waterway Feasibility Study and EIS

Dear Colonel Waterworth:

Stream Property Management, Inc. is a wholly owned subsidiary of the Estate of J.G. Gray located in Lake Charles, Louisiana. We own, manage and represent tens of thousands of acres that will be adversely impacted by the widening and/or deepening of the Sabine Neches Waterway. Huge areas of valuable coastal wetlands in the Sabine Basin in Louisiana have been adversely affected for the past century by the changes in hydrology through salt water intrusion and increased tidal fluctuation caused by the Sabine-Neches Waterway.

In this day and time of environmental awareness, our country and state have recognized the importance of coastal wetlands. Louisiana passed Act 6 (R.S. 49:213 et seq.) in 1989 creating the Coastal Wetlands Conservation and Restoration Authority as the initial step to restore Louisiana Coastal Wetlands. The Coastal Wetlands Planning, Protection, and Restoration Act (P.L. 646) was passed by the 101st U.S. Congress in 1990. These Acts have shown widespread public support and awareness in Louisiana and the United States for the preservation and restoration of our coastal wetlands. There have been huge mistakes made in the past allowing large quantities of salt water to intrude into traditional freshwater wetlands. The coastal marshes located in Calcasieu and Cameron Parishes were traditionally fresh and intermediate wetlands with a small border of brackish marsh along the shoreline. Since the channel construction and enlargements, beginning in the late 1800's, huge areas of these wetlands have been washed out to sea. Because of the fragile nature and organic composition of the soils, these soils have not been rebuilt, thus leaving vast open water expanses.

The deepening and widening of channels has been shown to not only increase salinities but to increase tidal fluctuations and storm surges. In low lying areas such as these wetlands surrounding Sabine Lake, an increased tidal amplitudes are devastating to these fragile marshes. The added danger in deepening and widening this channel is a further threat to the deterioration of our coastal wetlands, allowing increased hurricane and tropical storm surges to inundate these marshes.

As your staff can aptly demonstrate, the losses on both sides of Sabine Lake parallel the channel improvements on the Sabine Neches Channel. It is also evident at this point in time that freshwater is becoming a more valuable resource as witnessed by your latest project regarding the saltwater barrier in the Neches River. There is no such barrier in the Sabine River. There is no such barrier between the Sabine Basin and the Calcasieu Basin which was connected by a deep water channel by act of congress in 1912. The hydrology of this basin can not tolerate more changes and, in fact, needs to have the past century of adverse impacts addressed as soon as possible.

Coast 2050 is a comprehensive plan endorsed by five departments of the U.S. Government and the State of Louisiana. This plan outlines many restoration efforts, along with the white paper published in 1994, the Calcasieu-Sabine Basin plan submitted by NRCS in 1989 and many other plans that have addressed these problems and outlined solutions. The solutions identify a salinity control measure at Sabine Pass, along with perimeter control projects, one of which has been recently approved by the Coastal Wetlands Planning, Protection and Restoration Act, the East Sabine Lake Project. This project outlines a perimeter control system to control salinity inside the interior marshes of the east side of Sabine Lake. This project has been developed by five federal agencies including the U.S. Army Corps of Engineers (New Orleans District) to protect this area. As pointed out in the scoping meeting in Lake Charles, we have seen no evidence of coordination between the Interagency Coordination Team (ICT) group for the Sabine Neches Waterway and the plans and construction projects being implemented in Louisiana. A representative from Coastal Management, Department of Natural Resources, has been attending these ICT meetings but coordination in regard to these larger projects has not been witnessed according to the minutes of the ICT.

Many meetings with user groups were held to ask for public input into eco-system planning and beneficial use of dredged spoil ideas. The 244 suggestions by user groups and landowners are added to the official record for the scoping meeting by this letter with Attachment "A". One of the issues that was brought up during these user group meetings was lack of public input, and lack of the ability to question the merits of the project, along with the lack of public and private participation. Private landowners that are being affected by this project have had an almost inconsequential voice in this process. This was evidenced in the scoping meeting that was held in Lake Charles on May 28th by allowing the public only three minutes per person to comment. The Corps of Engineers and Jefferson County Navigation District have had years to plan this project and have spent millions of dollars prior to these scoping meetings. The individuals from the public whose land was being affected were given a total time of three minutes to speak at the scoping meeting. This is hardly enough time for an individual to explain his

Page 3 of 3
Colonel Waterworth

interest in the project or how the project may affect him. Now, is it equitable that the government has spent millions in preparing for this project and allows the public, whose private land is being affected, a three minute time frame with the option to submit written comments as per this correspondence? I feel this was totally inadequate and totally unfair to the private landowners being affected by this channel.

By this means, we request that before any channel improvements are approved that the past wetland damages of this channel be restored to the satisfaction of the landowners affected by this channel improvement prior to the proposed channel improvement project moving forward.

Some spoil disposal sites are located on the east bank of the Sabine River in Louisiana from Sabine Pass to Sabine Lake. These areas of spoil deposition should no longer be used with the technology we have available today. This spoil should be placed for beneficial use in many areas around the lake that are not being utilized at this time. Spoil is also being placed in public water bottoms of Sabine Lake. This public resource does not deserve to be taken away for channel improvements and/or maintenance. The Keith Lake area on the west side of the Sabine Neches channel has also been severely deteriorated by the saltwater intrusion and excessive tidal fluctuation caused by this channel. Many opportunities for water control and beneficial use of dredged spoil are available in that area as evidenced by suggestions in Attachment "A".

I want to thank you for the ability to make these comments and would hope that further coordination with private landowners and individuals who will be adversely affected by the proposed channel improvements be consulted and kept abreast of every activity in the future. I regret that this type of government action is intended for the public good but seems to exclude the public from comment except for limited and controlled through "scoping" meetings.

Sincerely,

David Richard

RECOMMENDATIONS MASTER LIST

1. Deposit dredged materials in open water areas within the marshes (affected by subsidence, erosion, and saltwater intrusion) at Texas Point NWR.
2. Deposit dredged materials at Lafitte's Landing 1 and 2 (south end of Pleasure Island, lake side, along shoreline and by marina) to provide shoreline erosion control and wetland creation.
3. Deposit dredged materials at Pleasure Island Marina for shoreline erosion control and marsh creation.
4. Construct a salinity control structure at the Keith Lake Fish Pass/SNCC intersection to reduce saltwater intrusion while allowing for unhindered navigation and marine organism ingress/egress.
5. Construct a system (depending on hydrologic model) of berms or levees (terraces) north of Pleasure Island in the gap and restore the island along the Sabine-Neches Canal to protect the lake from higher salinities in the channels.
6. Restore the hydrologic connection (freshwater sheetflow) at Salt Bayou between the marshes north and south of the GIWW.
7. Construct a structure on the east part of Salt Bayou to restore freshwater flow to marshes south of the GIWW.
8. Deposit dredged materials, particularly those with higher sand content, linearly along the shoreline from Texas Point NWR westward through McFaddin NWR.
9. Deposit dredged materials, particularly those with higher sand content, linearly along the shoreline east of the entrance channel.
10. Create gaps in both entrance channel jetties to increase sediment transport to Gulf shorelines.
11. Stabilize the shoreline on the east edge of Texas Point NWR at gaps in the jetty north of pilot station and repair the jetty.
12. Construct a two to six acre bird island or islands, at least five feet high with a sheltered lagoon, in the north part of Sabine Lake near Sidney Island at least one mile offshore.
13. Establish salinity controls, including the restoration of historic flow volumes, in Texas Bayou and associated channels connecting to the SNWW on Texas Point NWR through such things as low-level rock weirs, plugging man-made channels, water control structures, and/or other channel modifications.

14. Deposit dredged materials in open water areas and degraded marshes in the east part of the Salt Bayou watershed north and south of Keith Lake.
15. Stabilize the shoreline in any reaches of the GIWW projected to have increased salinities as a result of the project.
16. Establish erosion control on the Taylor Bayou outfall canal shoreline, primarily on the south bank.
17. Stabilize the banks of the GIWW in Louisiana, particularly the south bank, because the north bank has been largely stabilized through two coastal restoration projects.
18. Protect the cypress swamp area south of the Neches River Saltwater Barrier from possible excessive salinities by installing structures, terraces, or other hydrologic components.
19. Use high sand content dredged materials from offshore, including existing disposal areas, for beach enhancement purposes.
20. Implement the East Sabine Lake Hydrologic Restoration Project to protect approximately 35,000 acres of brackish to intermediate marsh in the west part of the Sabine NWR and adjacent lands from elevated salinities by such things as water control structures at major bayous and canals and earthen terraces in existing shallow-water areas.
21. Construct a gate on the Sabine Pass Channel or a sill offshore to establish hydrologic control.
22. Restore the interior hydrology of Salt Bayou marshes south of the GIWW on TPWD land.
23. Construct a low-level rock weir or similar structure at the causeway to prevent excessive salinities from entering the lake.
24. Construct salinity controls in the brackish marsh regions east of the intersection of Lighthouse Bayou and the Sabine Pass Channel.
25. Deposit dredged materials from the SNWW in large, shallow, open-water areas in the west part of the Sabine NWR north and south of the Willow Bayou Canal and in the Greens Lake area.
26. Deposit dredged materials from the SNWW on the east shoreline of Sabine Lake at the Sabine NWR and adjacent lands.
27. Deposit dredged materials from the SNWW in the open-water areas of the Greens Lake area to create marshes.

28. Establish salinity control between the GIWW and the Sabine River to protect the Louisiana side.
29. Establish salinity control west of the Hwy. 87 bridge and the GIWW to protect the Texas side.
30. Use new work materials one-time offshore that would degrade to feeder berms.
31. Establish topographic relief offshore.
32. Establish nearshore feeder berms for shoreline protection.
33. Protect and stabilize the Middle Marsh Drain Ditch.
34. Restore the saltwater guard lock at the north end of Pleasure Island.
35. Establish salinity control at the mouth of Cow Bayou.
36. Establish salinity control at the mouth of Adams Bayou.
37. Establish salinity control on the Old Ferry Road Borrow Ditch.
38. Establish salinity control at Old River Bayou.
39. Create terraces in the Entergy Power Plant Marsh.
40. Isolate the Entergy outfall canal by recreating the historic canal berms.
41. Use dredged materials to create terraces and mounds and backfill canals in the Bessie Heights Marsh.
42. Restore the natural hydrology of the Bessie Heights Marsh by restoring the natural bayou and closing the two canals.
43. Divert some of the stormflow in Anderson Gully into the Bessie Heights Marsh.
44. Restore the cypress swamps in the Rose City Oilfield through hydrologic restoration, salinity control, and beneficial use of dredged materials.
45. Plug the Hwy. 87 borrow ditch to restore flows to Nig Bayou.
46. Protect the shoreline on the north side of Old River Cove.
47. Use dredged materials to create mounds and terraces in Old River Cove.
48. Use dredged materials in the Old River Unit of the Lower Neches River WMA.

49. Use dredged materials in the open-water areas of the Burton Canal Marsh east of the Sabine River and the Burton Canal.
50. Use dredged materials in the open-water areas of the marsh east of Phoenix Lake.
51. Protect and restore the north shore of Keith Lake.
52. Construct a structure in the Sabine River at Orange to protect the cypress-tupelo swamps upstream if Sabine Compact withdrawals are implemented.
53. Use dredged materials to create a bird island north of the causeway.
54. Use dredged materials to restore marsh elevations in the interior of the Salt Bayou Marsh south of the GIWW.
55. Divert the Neches River through the Bessie Heights Marsh into Sabine Lake by leveeing the channel.
56. Create a substrate for oysters in south Sabine Lake to restrict salinity and flow.
57. Construct a navigation lock at Sabine Pass, which would resolve many of the problems, particularly saltwater intrusion, in the Sabine Lake area.
58. Construct a low-level rock weir constriction at the mouth of Sabine Lake at the causeway to reduce saltwater intrusion.
59. Implement the East Sabine Lake Hydrologic Restoration Project (a CWPPRA project) to provide salinity control on the east shore of Sabine Lake.
60. Implement the NRCS Public Law 566 rock weirs along the length of Black Bayou.
61. Construct a salinity control structure at the mouth of Black Bayou.
62. Use dredged materials between Pleasure Island and Sabine Island to create an earthen barrier that would protect Sabine Lake from saltwater intrusion from the channels.
63. Use dredged materials to restore the marsh in the Old River Unit south of Bridge City.
64. Remove Placement Area 11 at the north end of Pleasure Island to restore the estuarine bottom and reestablish public access to state waterbodies.
65. Remove Placement Area 8 at the south end of Pleasure Island to restore the estuarine bottom and reestablish public access to state waterbodies.
66. Use dredged materials to restore the marshes north and south of Keith Lake.

67. Use dredged materials to restore the marshes in the Greens Bayou area.
68. Use dredged materials to restore the marshes in the Willow Bayou area.
69. Establish an earthen barrier with water control structures along the entire east edge of Sabine Lake to protect the marshes from salinity intrusion and wave action.
70. Use dredged materials to restore the marshes north of Lighthouse Bayou.
71. Construct a structure at the mouth of Lighthouse Bayou to reduce salinity intrusion.
72. Use dredged materials to restore the marshes south of Perry Ridge.
73. Provide greater opportunities for fishing (for example, piers) to compensate for the decline of boater access to Sabine Lake from Louisiana that has been brought about by hydrologic restoration projects.
74. Stabilize the shoreline on the east side of Sabine Lake using boudin bags (geotextile tubes filled with dredged materials).
75. Use dredged materials to restore the marshes northwest of the Black Bayou Oil and Gas Field.
76. Maintain Sabine River freshwater flows into Sabine Lake in keeping with the Coast 2050 strategy.
77. Establish a navigation lock on the GIWW at Gum Cove Ridge to reduce saltwater intrusion to the east.
78. Use dredged materials to enhance the existing marsh strip and refurbish the deteriorated rock barriers on the south side of the GIWW in the Gum Cove Unit 13 area.
79. Use dredged materials to restore the marshes and establish a bird island south of the GIWW in the Gum Cove Unit 13 area.
80. Provide shoreline protection and hydrologic restoration for the fresh marsh east of the Sabine River and between the GIWW on the south and the Sabine Island WMA on the north.
81. Create terraces and use dredged materials to restore marshes between Perry Ridge and the Sabine River.
82. Protect the marshes between the Sabine NWR and Sabine Pass by protecting the shoreline of Sabine Lake and establishing salinity controls on Madame Johnsons Bayou,

Forge Bayou, Greens Bayou, and Johnsons Bayou in keeping with the East Sabine Lake Hydrologic Restoration Project.

83. Use dredged materials to restore marsh in all open-water areas east of Sabine Lake where it is feasible to pump them, and construct terraces to restore marsh in all open-water areas east of Sabine Lake where it is not feasible to pump dredged materials (note: not location specific).
84. Use dredged materials and construct terraces in the open-water areas of the Black Bayou Cutoff Canal area.
85. Restore the hydrology and prevent saltwater intrusion at the oil field ditch and lateral ditches running west from the Black Bayou Cutoff Canal.
86. Establish a state park in the area east of Lighthouse Bayou and south of Hwy. 82 (contingent on private property donation and not necessarily including the lighthouse).
87. Use dredged materials to restore eroded beaches in the vicinity of the 15-mile marker from the Louisiana line (that is, in the Dunn Beach and Martin Beach areas).
88. Construct an earthen barrier on the east bank of the Sabine River from the GIWW to Sabine Island to eliminate saltwater intrusion.
89. Use dredged materials to restore the marshes in the area north of the GIWW and west of the Gray and Vinton drainage canals.
90. Use one-time placement of dredged materials in various areas to create coastal forest and chenier habitat (note: not location specific).
91. Use dredged materials to create cheniers on the high marsh from Louisiana Point to Holly Beach.
92. Use dredged materials to restore marshes in the Bessie Heights Marsh area.
93. Provide erosion control along the channel on the north portion of Pleasure Island.
94. Provide erosion control along the channel on the extreme south portion of Pleasure Island.
95. Use dredged materials to restore the north end of Pleasure Island where Sabine Lake is breaking through.
96. Use dredged materials to restore the southern tip of the peninsula north of the northern tip of Pleasure Island.

97. Provide erosion control using concrete revetment on the west side of the Port Arthur Canal across from Placement Area 11 in the vicinity of the vessel repair facility.
98. Use dredged materials to close the gap between the channel and Sabine Lake north of Pleasure Island.
99. Use dredged materials to close the gaps between the islands at the north end of Sabine Lake.
100. Elevate Hwy. 87 with dredged materials near Sabine Pass.
101. Provide erosion control along the channel on the south portion of Pleasure Island in the vicinity of Placement Area 8.
102. Use dredged materials to restore the marsh on the south end of Humble Island.
103. Use dredged materials to restore the marsh on the south side of the GIWW below Taylor Bayou.
104. Use dredged materials to restore the marshes north of the GIWW in Louisiana.
105. Restore access to the Sabine Lighthouse and stop erosion in the immediate area.
106. Use dredged materials to build developable land on the north side of the Neches River from Beaumont downstream.
107. Use dredged materials to build up the area near Hwy. 82 and the causeway so that a bridge can be built over the channel directly linking Hwy. 82 and Hwy. 87.
108. Use dredged materials to restore the eroding beach in the vicinity of Peveto Beach.
109. Breach the levees and use dredged materials to restore the manmade lakes within Sabine NWR to their original marsh condition.
110. Use dredged materials to fill in oilfield service canals wherever they are contributing to salinity intrusion into Louisiana's marshes (note: not location specific).
111. Use dredged materials to build islands offshore on both sides of the channel for migratory birds that would simulate the function of a natural delta.
112. Use dredged materials to build islands for migratory birds in Sabine Lake far enough from shore to protect from predators.
113. Use dredged materials to construct cheniers in Louisiana and Texas, planting them with oaks and other vegetation that occur on natural cheniers.

114. Use dredged materials to restore cheniers in Louisiana and Texas (perhaps by removing the existing top layer of sand and shell, depositing dredged materials, and they relaying the sand and shell on top), with easements to protect them for bird use.
115. Use dredged materials to buffer cheniers in Louisiana and Texas that are in danger of disappearing.
116. After placing dredged materials in new placement areas, shape and contour the areas so that they appear natural, and plant native vegetation to support wildlife (note: not location specific).
117. Shape and contour existing dredged material placement areas so that they appear natural, and plant native vegetation to support wildlife (note: not location specific).
118. Construct recreational amenities, particularly primitive campgrounds, on cheniers and on placement areas that have been filled (note: not location specific).
119. Construct a lock at Sabine Pass to prevent saltwater intrusion into Sabine Lake.
120. Construct a bulkhead on the channel side of Pleasure Island from the intersection of the SNWW and the GIWW to the north end of the island.
121. Mine dredged materials from Placement Area 8 to build up the 43 acres at the south end of Pleasure Island owned by the port and then replace with new dredged materials.
122. Preserve the productive shallow-water areas of the two placement areas on Pleasure Island by depositing dredged materials on top of the existing levees, particularly near the channel, and develop the land for recreational use.
123. Use dredged materials to build up the land on the southern portion of Pleasure Island from Placement Area 8 to the south end of the island on the lake side and bulkhead the channel side.
124. Provide erosion control for all of Pleasure Island on the channel side.
125. Use dredged materials to rebuild the approximately one-quarter mile of land at the north end of Pleasure Island that has completely eroded away and protect it with erosion control structures.
126. Use dredged materials to build up the land on Pleasure Island directly across from the Taft Avenue Extension to preserve its potential as a location for a second bridge to the island.
127. Construct a new salinity control structure on the north side of the GIWW at the point where Salt Bayou intersects the GIWW.

128. Use dredged materials to restore the beach and create dunes south of McFaddin NWR between Sea Rim State Park and High Island.
129. Use dredged materials to rebuild the island at the McFadden Bend Cutoff (Reserve Fleet area across from Sun Terminal) that was lost to erosion.
130. Use dredged materials to restore Bessie Heights Marsh and construct salinity control structures to protect the marsh.
131. Construct a salinity control structure on the Keith Lake Fish Pass.
132. Limit salinity intrusion into Keith Lake by using dredged materials to fill in the cuts that have been made into the lake on its north side.
133. Build vegetated dunes and institute ongoing erosion control and beach nourishment for the eroded beach in the vicinity of McFaddin NWR.
134. Construct a structure at the channel end of the Pilot Station Cut to limit saltwater intrusion.
135. Construct a structure at the channel end of the Texas Bayou Cut to limit saltwater intrusion.
136. Construct a structure at Keith Lake Fish Pass to limit saltwater intrusion.
137. Investigate the potential for mining existing placement areas for high-quality dredged materials that can be used in various restoration projects (note: not location specific).
138. Use maintenance dredging materials from the GIWW to restore the eroded beach in the vicinity of McFaddin NWR.
139. Use dredged materials from the lower portion of Taylor Bayou for marsh restoration and beach nourishment.
140. Mine the high-quality sediments from behind the dam at Steinhagen Lake (outside of the study area) for use in marsh restoration and beach nourishment projects in the study area.
141. Modify the jetty system to restore the longshore current and deposition of materials along the beach west of the channel.
142. Use the high-quality materials from offshore channel dredging to restore the eroded beach in the vicinity of McFaddin NWR.
143. The beach in the vicinity of McFaddin NWR is being eroded because the longshore current is deflected outward by the jetties and then turns back sharply toward the beach.

- Build a longshore parallel jetty system to minimize the assault on the beach by the inwardly turning longshore current.
144. Because it is of higher quality, use dredged materials from the GIWW for beach restoration west of the channel rather than for other purposes.
 145. Reinforce the shoreline all along the channel to reduce erosion and the need for maintenance dredging.
 146. Implement the Drainage District 6 proposed Taylors Bayou Diversion Channel project west of the present diversion channel and from Taylors Bayou to the GIWW to alleviate flooding.
 147. Use dredged materials to restore the eroding beach south of McFaddin NWR to protect Hwy. 87.
 148. Pump sand from offshore to restore the eroding beach south of McFaddin NWR to protect Hwy. 87.
 149. Restore the Rose City Marsh in keeping with the plan of action submitted by TNRCC, which involves breaking the open-water areas into cells with levees and restoring one cell at a time with dredged materials.
 150. Preserve the oxbow above the Rose City Marsh, with possible donation or easement and recreation link with mainland.
 151. Close the breaks into the marsh on the southeast bank of Keith Lake that are contributing to saltwater intrusion.
 152. Resolve the problem of too much fresh water in the Blind Lake area where the TPWD levee and the GIWW are interrupting sheetflow, perhaps by constructing a drainage canal to the GIWW.
 153. Reduce saltwater intrusion into Bessie Heights Marsh by separating the marsh from the Neches River by building a levee along the river bank and rebuilding the levee on the GSU canal.
 154. Reduce saltwater intrusion by building a levee across the old dredged material placement area to Bird Island Bayou.
 155. Restore the Mires Bayou area by building levees to close the oxbow at both ends, which would limit saltwater intrusion.
 156. Protect the Texas Point marshes by constructing a longshore rock jetty and placing dredged materials along the beach behind the jetty.

157. Use dredged materials to restore marshes throughout the study area that have been converted to open-water areas, as seen by comparing historic to contemporary maps (note: not location specific).
158. Constrict the channel to about 250 feet at Sabine Pass to reduce saltwater intrusion into Sabine Lake.
159. Construct a lock at Sabine Pass to eliminate saltwater intrusion into Sabine Lake.
160. Deposit dredged materials southeast of the lighthouse to create a raised area or dunes that would protect the lighthouse from storm surges and assist in erosion control.
161. Place dredged materials southeast of the lighthouse along the mudflats and slightly inshore at an elevation of about three feet to protect the lighthouse.
162. Control coastal erosion west of Johnsons Bayou by the placement of materials from offshore channel dredging.
163. Use every opportunity presented by the present and proposed projects to preserve the lighthouse for future generations (note: not site or recommendation specific).
164. Construct a saltwater barrier at the mouth of Lighthouse Bayou to limit saltwater intrusion into the marsh.
165. Construct an emergent or submerged rock barrier north of the causeway to limit saltwater intrusion into Sabine Lake.
166. Build a levee or separate salinity control structures from Blue Buck Point east to limit saltwater intrusion into the marshes through the numerous small ditches and oilfield canals.
167. Construct an erosion control structure and rebuild the land with dredged materials in the eroding cove on the east side of the lake and north of the causeway.
168. Construct an erosion control structure and rebuild the land with dredged materials in the eroding cove on the east side of the lake and south of the causeway.
169. Construct a lock at the mouth of the channel to eliminate saltwater intrusion into Sabine Lake.
170. Build placement areas to a reasonable level, then move on to other areas, allowing the old placement areas to vegetate or be used for development (note: not location specific).
171. Use dredged materials to restore the eroding beaches from Texas Point to High Island.
172. Use dredged materials for dune restoration south of Hwy. 87 if it is ever rebuilt.

173. Use dredged materials for marsh restoration in the Bessie Heights Marsh.
174. Use dredged materials for marsh restoration in Keith Lake wherever open-water areas are emerging.
175. Use dredged materials for marsh restoration in the Salt Bayou watershed north and south of the GIWW.
176. Use dredged materials to build up low-lying land suitable for development that is not marsh land (note: not location specific).
177. Because most dredged materials contain pollutants, continue to put them in placement areas rather than using them for ostensibly beneficial purposes (note: not location specific).
178. Any beach-quality sand that is available should be used to restore the eroding beaches from Texas Point to High Island.
179. Use dredged materials to construct a road to the Sabine Lighthouse.
180. Use dredged materials to restore the beaches east of the channel.
181. Construct a lock at the mouth of the channel to eliminate saltwater intrusion into Sabine Lake.
182. Construct a revetment or levee and fill in back with dredged materials to restore the eroding cove at the mouth of Lighthouse Bayou.
183. Remove Point Hunt Island in the channel to allow a straight passage for vessels so that the land to the east is not subjected to collisions.
184. Use dredged materials to fill in the open-water areas in Sabine NWR.
185. Use dredged materials to further build up the potentially developable land on the east side of the channel, and investigate ways to modify present restrictions on development.
186. Constrict the channel at Sabine Pass to reduce saltwater intrusion into Sabine Lake.
187. Construct a weir in the vicinity of the causeway to reduce saltwater intrusion into Sabine Lake.
188. Construct a series of small islands between the north end of Pleasure Island and Sabine Island to reduce saltwater intrusion into Sabine Lake from the channel.

189. Use the higher-quality dredged materials obtained through offshore dredging for marsh and beach restoration.
190. Use dredged materials to restore the shoreline and Hwy. 87 between Texas Point and High Island.
191. Continue to insure freshwater inflow into Sabine Lake from the Neches and Sabine rivers (note: not location specific).
192. Construct a public boat launch on the Louisiana side of the causeway at the site of the present deteriorated boat ramp to provide access to Sabine Lake from Louisiana.
193. Rehabilitate the old boat launch at the burned out bridge on old Hwy. 90.
194. Rebuild the deteriorating islands between the north end of Pleasure Island and Sabine Island to reduce saltwater intrusion into Sabine Lake from the channel.
195. Construct substrates for oysters in Sabine Lake to renew oyster production.
196. Ensure that future restoration and beneficial use projects comply with Louisiana mandates and Louisiana's Coast 2050 plan (note: not location specific).
197. Stabilize the levees of the GIWW throughout its entire extent in the Louisiana portion of the study area.
198. Restore the levees on the Vinton Drainage Canal.
199. Use dredged materials to restore road access to the Sabine Lighthouse.
200. Construct a lock in Sabine Pass to eliminate saltwater intrusion into Sabine Lake.
201. Use dredged materials for erosion control on both sides of the channel from Sabine Pass to the north end of Pleasure Island.
202. Stabilize the shoreline of the entire Neches River channel.
203. Stabilize the lake shoreline and replenish adjacent marshes in the area from Blue Buck Point to Johnsons Bayou, leaving the bayous open.
204. Construct a structure within the causeway to slow tidal flows in and out of the south end of Sabine Lake.
205. Construct a lock at the mouth of the Sabine River to regulate freshwater flows into Sabine Lake from Toledo Bend Reservoir.
206. If the SNWW project is approved, develop a joint Louisiana-Texas plan to deal with any unforeseen problems that might occur (note: not location specific).

207. Use dredged materials for beach restoration from Texas Point to High Island.
208. Construct a fishing pier in connection with the improved boat launch on the Louisiana side of the causeway.
209. Construct a large parking area in connection with the improved boat launch on the Louisiana side of the causeway.
210. Construct a structure at the mouth of Lighthouse Bayou to limit saltwater intrusion.
211. Use dredged materials to restore the beach from Louisiana Point to Constance Beach.
212. Use dredged materials to reinforce the roadbed of Hwy. 82 along the Louisiana coast.
213. Use dredged materials to enhance the beach at Louisiana Point.
214. Use dredged materials to restore Fina Anchorage Island created by the cutoff in the Neches River.
215. Use dredged materials for chenier restoration in Louisiana, including planting of native vegetation to provide habitat for neotropical migratory songbirds.
216. Use dredged materials to restore deteriorating marshes in the chenier plain.
217. Use dredged materials to construct new cheniers in Louisiana.
218. Establish salinity control on the bayous and canals entering Sabine Lake from Louisiana.
219. Use dredged materials to restore cheniers on the Texas side of the channel.
220. Use dredged materials to restore beaches and dunes along the Louisiana coast to provide bird habitat.
221. Move Hwy. 87 one thousand feet inland from the beach from Texas Point to High Island, build a dune structure, and fill in the area with dredged materials to slow erosion.
222. Stockpile dredged materials and mine them for beneficial use when needed (note: not location specific).
223. Use dredged materials (sand and mud) to restore the coastline west of Texas Point.
224. Use dredged materials to restore the marshes north of Keith Lake.
225. Restore the marshes from Bessie Heights Marsh to Rose City Marsh as one marsh system.

226. Fill manmade ditches within the Texas marshes (Sea Rim Pintail Flats Marsh, Lower Neches Marsh, Bessie Heights Marsh, Texas Point Marsh, McFaddin Marsh, Meyers Bayou Marsh, etc.) to restore the historic hydrology and salinity (note: not location specific).
227. Construct a saltwater barrier at Sabine Pass.
228. Construct water control structures at the mouth of every canal and bayou in Texas that connects with the channel (Pilot Station, Texas Bayou, Keith Lake Fish Pass, Bessie Heights, Lower Neches, etc.) to restore the historic hydrology, and use dredged materials to fill the canals after water control is accomplished (note: not location specific).
229. Use dredged materials to raise Hwy. 87 from the GIWW bridge south to Sabine Pass.
230. Reconstruct Hwy. 87 from the GIWW bridge south to Sabine Pass to allow sheetflow under the road.
231. Use dredged materials to build up eroding areas on Pleasure Island while avoiding any damages to the lake.
232. Develop a comprehensive study of the best possible restoration of the marsh system from Bessie Heights Marsh to Rose City Marsh.
233. Transport dredged materials outside of the study area so that they can be more widely used, for example at Rollover Pass (note: not location specific).
234. Use dredged materials to create vegetated dunes and restore the beaches from Texas Point to High Island.
235. Mine existing placement areas for materials to build dunes and restore beaches along the Texas coast (note: not location specific).
236. Use dredged materials to build a barrier island from Texas Point to Rollover Pass.
237. After historic hydrology and salinity have been reestablished (as per 226 and 228) in Texas' degraded marshes (Sea Rim Pintail Flats Marsh, Lower Neches Marsh, Bessie Heights Marsh, Texas Point Marsh, McFadin Marsh, Meyers Bayou Marsh, etc.), build land masses and islands, with coarse dredged sand used to establish bird grit sites (note: not location specific).
238. Use dredged materials to construct a bird island in Sabine Lake.
239. Use the higher-quality materials from offshore dredging for beach restoration.

240. Construct water control structures at the mouth of every canal and bayou in Texas that connects with the channel (Pilot Station, Texas Bayou, Keith Lake Fish Pass, Bessie Heights, Lower Neches, etc.) to restore the historic hydrology, and use dredged materials to fill the canals after water control is accomplished (note: not location specific).
241. Use dredged materials to create vegetated dunes and restore the beaches from Texas Point to High Island.
242. Use dredged materials from the SNWW and from Entergy's canal dredging to restore the declining marshes on Entergy property.
243. Use dredged materials to levee Entergy's outflow canal to keep sediment out of the canal and to keep the flow of water from eroding the marsh.
244. Use dredged materials in any fashion that would keep saltwater from intruding into the marshes on Entergy property.

Re: Scoping Comments Sabine-Neches Waterway

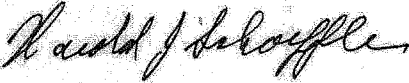

The following concerns are listed in the hopes that these issues will be thoroughly investigated and addressed in the environmental impact study.

1. Any dredging project threatens aquifers, and a geologic study of the entire site is necessary to make sure that vitally needed groundwater sources are not contaminated.
2. Mitigate the loss of productive water bottoms, wetlands and farmlands related to spoil disposal and channel enlargement.
3. Limit through the building of a lock system the loss of fresh water during flood, salt water intrusion during low water droughts and minimize hurricane storm surges.
4. Maintain the estuarine nature of the Sabine lake and marsh system.
5. Allow for the escapement of species such as eels and channel bass that depend on free movement from fresh water to salt water.
6. Protect entire area from long term loss of wetlands and marshes.
7. Consider as an alternative the piping of products to an offshore terminal such as an offshore super port.
8. Determine impact on neo-tropicals, wading birds, water fowl, terns, skimmers, brown pelicans and sandpipers.
9. Determine the impacts of a worse case collision such as two tankers, and determine the need for a port traffic control system over the entire project area.
10. Determine impacts on water quality during initial and maintenance dredging.
11. Determine shoreline impacts on riparian zones related to vessel wave impacts and initial and maintenance dredging.
12. Determine impacts on 404B1 guideline areas such as wildlife reserves and management areas, rookeries, wetlands, oyster reefs, mud flats, sandbars and beaches.
13. Determine socio-economic impacts on sport commercial fisheries, hunting, crabbing, shrimping, tourism, oystering and other recreational losses associated with the project.
14. Endangered sea turtles are attracted to tidal passes such as the Sabine and could be taken by dredges. Determine the risk and take all precautions to protect endangered sea turtles.

p. 2

15. Determine the impacts on flora and fauna in the project area. Look at placing top soil, grading, leveling and planting of spoil areas above sea level with a goal of creating wildlife habitat.
16. Make spoil areas subject to the public servitude.
17. Test sediments for toxic materials before dredging over entire length of project.
18. Determine impacts of increased shipping and marine traffic.
19. Determine gulf shoreline impacts due to possible changes in near shore currents and wave patterns.

Sincerely,

Harold J. Schoeffler

Ms. Lizette Richardson
Galveston District
US Army Corps of Engineers
P O Box 1229
Galveston TX 77553-1229

Dear Ms. Richardson:

On behalf of the Coalition to Restore Coastal Louisiana, we would like to express our grave concern about the potential negative impacts on Louisiana's coastal wetlands should the proposed widening and/or deepening of the Sabine-Neches Waterway channel take place.

The proposed changes to the Sabine-Neches Waterway channel will increase shoreline erosion and saltwater intrusion in the Calcasieu-Sabine basin. Saltwater intrusion has contributed greatly to the loss of wetlands in the Calcasieu-Sabine basin over the past 50 years. This project would exacerbate the loss of additional wetlands and vital estuarine habitat.

Due to the potential for increased salinity and shoreline erosion, this proposed project appears to conflict with the restoration strategies outlined in *Coast 2050*. *Coast 2050* is a comprehensive strategic plan for restoring Louisiana's coastal wetlands and stabilizing the coastal zone to prevent further wetland loss. The plan has been approved by all 20 coastal parishes, the state, and federal government agencies, including the US Army Corps of Engineers. This project, as proposed, could potentially thwart the implementation of *Coast 2050* and threaten Louisiana's ability to gain greater national support for coastal restoration.

Also, the Coastal Wetlands Planning, Protection and Restoration Act (CWPPRA) requires that all US Army Corps of Engineers' navigation and flood control projects be consistent with coastal restoration plans developed under the CWPPRA statute. We have seen no evidence to date that this has been done with respect to this project.

Specific ecological impacts include, but are not limited to increased salt-water intrusion, plant community changes, loss of wetlands as a result of plant community changes due to salt-water intrusion, increased introduction of exotic species due to ballast water discharge, loss of oyster reefs in Sabine Lake due to increased salinity levels, contaminants in dredged sediments entering the food web, increased scour of some channel areas, and potential impacts to sensitive fin fish species such as paddle fish. Overwhelmingly, the increase in salinity levels to the estuary, including surrounding wetlands, will have the broadest and longest lasting effects. Three dimensional models by Dr. Ehab Meselhe of the University of Louisiana-Lafayette indicate that a large volume (wedge) of salt-water can potentially move well into the channel, with its proposed dimensions, as well as into Sabine Lake. Experience has taught us that

Ms. Lizette Richardson
 June 28, 2002
 Page 2

increasing channel depth and width directly allows more salt laden water to enter the ecosystem. Both the existing Sabine-Neches Water Way (SNWW) and the nearby Calcasieu Ship Channel are examples of these impacts. Wetland deterioration connected with salt-water intrusion is well documented. Marshes near the Calcasieu Ship Channel underwent almost immediate changes after dredging to deepen the channel was conducted in the mid 1950's, resulting in the loss of nearly all fresh and oligohaline marshes within 20 years (USFWS data). Some of these exist as salt marshes today, but thousands of acres of land were converted to open water. Currently, intense efforts funded by CWPRA and in accordance with *Coast 2050* are being conducted to restore these ecosystems to healthy and productive habitat.

Along the Sabine Lake eastern shoreline, healthy coastal marsh in Sabine National Wildlife Refuge will undoubtedly be impacted. This area is one of the healthiest areas of marsh in southwestern Louisiana. Loss or deterioration of this habitat will allow greater intrusion into the interior of the refuge. To the north of the refuge, Gray Stream Property Management Company owns much of the wetland between the north refuge boundary and the Gulf Intercoastal Water Way (GIWW). These wetlands are already in a state of advanced deterioration. Additional stresses due to increased salt-water effects could potentially result in the loss of these lands.

Potential impacts to fauna in the estuary include detrimental effects upon paddle fish, Kemp's Ridley Sea Turtle and oyster reefs. Within the Sabine River Drainage Basin, the Western Sand Darter and the Western Hill Splitter Mussel reside, both on the endangered species list of the state of Texas, and therefore species of concern in the state of Louisiana (LA DWF). The paddle fish is a long-lived, migratory, and environmentally sensitive species, typically not reaching breeding maturity until after 3 years of age or longer. If environmental conditions are not right, breeding will not occur. Impacts due to salt-water intrusion and due to increased suspended sediments in the water column as a result of dredging could adversely affect the reproduction of this species. Populations of paddle fish have decreased steadily over the past few decades, resulting in this species being placed on the protected species list of the state of Louisiana. In addition, larval paddle fish drift to the south end of Sabine Lake which is the nursery area for the species. Most people agree that salt-water concentrations will increase at the south end of the lake, thus further endangering this estuarine species.

Kemp's Ridley Sea Turtle populations occupy nearshore waters near Sabine Pass. Dredging operations could have direct impacts upon the turtles. Oyster reefs are common in the lower half of Sabine Lake. Altering the isohaline will result in the loss of some of these reefs. Payouts by the state of Louisiana to owners of oyster reefs must be considered in cost-benefit ratio analyses. Also, increased sediment loads in the water column will adversely affect these oyster beds, covering them at least in part and lowering productivity or possibly killing them outright.

Ms. Lizette Richardson
 June 28, 2002
 Page 3

Little has been said about the beneficial use of dredged materials. These materials should be used to restore and/or enhance degraded marshes. However, since these materials come from a heavily traveled ship channel which is connected to a city with heavy industry, the potential for contaminants in the sediments is large. Virtually no work has been done on the concentrations of contaminants in dredged materials used beneficially for wetland restoration. There is no record as to whether or not contaminants, such as heavy metals, are entering the food web and possibly bioaccumulating as they move up the line. The only research project addressing this question is being conducted at McNeese State University, in Lake Charles Louisiana and no data has been produced yet for public use. In another project, on the Anacostia River, large concentrations of contaminants have been found in sediments which were dredged from the river and then used to restore degraded marsh. Therefore, this issue should be of major concern.

The potential for the introduction of exotic species will increase with increased ship traffic from foreign ports. Since ballast water exchange at sea is not mandated in the United States, organisms from foreign waters will be released when the ballast is dumped from these ships. Either requiring ballast exchange at sea, or requiring the quarantining of ships until port authorities can ascertain that no non-native species exist within the ballast, must be enforced to reduce this threat. Introduced species is already a major problem in US waters.

The question of hurricane and storm surge impacts has arisen. Some feel that these impacts will be minimal since hurricanes are infrequent. This is inadequate reasoning. Given the low elevation of the Louisiana coast, even many miles inland, coastal flooding due to storm surge and other weather related events is a fairly common occurrence. A tropical system, such as a hurricane can be low enough in intensity as to not cause widespread structural damage to buildings but can still produce significant tidal surges. Along the Gulf of Mexico coast in Louisiana, as sustained southern wind can produce tidal surges several feet above normal. Tropical storms and low lever hurricanes can produce surges sufficient enough to flood much of the landscape. These don't even need to directly hit the area of the proposed project to cause flooding. As long as the winds are from the southwest to the southeast, tidal surges of unusual height will occur. Therefore, the premises, as well as the logic used to present the argument that hurricanes will have a negligible effect are flawed. These wetlands are our best defense against tidal surges. To compromise their integrity and structure will certainly lead to increased flooding problems and associated costs.

In general, this project seems to be designed to benefit just a few people, namely those of Beaumont, Texas, while the negative impacts and costs will be the burden of many, mostly the people of Louisiana. Ecological impacts of increased salt concentrations will affect both flora and fauna and result in wetland loss. We have seen this cause-and-effect many times. Therefore, the cost of restoration of Louisiana wetlands must be considered. Also, since this project will most likely have negative impacts on Louisiana wetlands, then it violates the CWPRA requirement that all US Army Corps of Engineers' navigation and flood control

Ms. Lizette Richardson

June 28, 2002

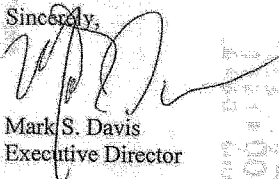

Page 4

projects be consistent with coastal restoration plans developed under the CWPPRA statute. Additional costs will be felt in the loss of commercial oyster fishing and potential lawsuits, loss of tourism in declining sport fishing, loss of tourism due to loss of wetlands (unless these are restored), an increase in the decline of protected, threatened and endangered aquatic species, and increased National Security costs as shipping traffic increases to the Port of Beaumont.

Finally, we were dismayed at the effort put forth at the EIS Scoping meeting in Lake Charles on May 28, 2002. In opening remarks, the US Army Corps of Engineers stated it wished to assemble all concerns relative to this project. However, only three minutes per person was allowed which, given the complexity of the issues and the range of concerned parties, was grossly inadequate. This constraint seemed to fulfill the legal obligation of the Corps to solicit comments, but did not provide enough time for the presentation of all issues and concerns of the public in attendance. The purpose of public meetings and public comment is to learn from the public's experience and to better understand the concerns they have. It is not to learn what can be learned in three minutes. The perfunctory nature of this meeting defeated the very purpose of the meeting to a large extent and we would hope that future efforts to build the record as required by the National Environmental Policy Act and common courtesy will be better handled.

In closing, we feel that any proposed project that will contribute to the destruction of wetlands while state and federal government programs spend millions of dollars to restore those same wetlands is inconceivably wasteful and ill-planned.

Sincerely,

Mark S. Davis

Dear Colonel Buechler:

I have been contacted by Mr. Norris East of Hackbay, Louisiana, regarding the proposed widening and/or deepening of the Sabine-Neches Waterway channel.

Please give the views and concerns of Mr. East every appropriate consideration within federal guidelines. Also, please investigate the enclosed correspondence sent to me and provide me with any information you might have which responds to the issues raised in his letter. Your reply may be forwarded to the attention of Noelle Zeringue.

Thank you for your attention and assistance.

Sincerely,

JOHN BREAUX

ANSWER TO YOUR LETTER
4-17-02

DEAR SIRS

02 JUL 25 AM 9:19

I WOULD LIKE TO KNOW WHY YOU
HAD TO PUT THE SALT WATER BARRIER
AT LAKE CHARLES IF SALT WATER
DOES NO DAMAGE TO CALCASIEU
RIVER

I WOULD ASSUME THAT YOU HAVE NEVER
BEEN THERE HAVE SEEN LOT OF DAMAGE
TO THE TREES CROSS BANK ERIEON.

IN YOUR LETTER YOU STATED THAT
ACAP AT CAMERON WOULD BE A
HAZARD TO SHIPPING

WELL WHAT WOULD YOU SAY ABOUT
ALL THE LOCKS ON THE INTRIA
POSTAL CANAL I SUPPOSE THAT
IS NO HAZARD WELL FRIEND I HAPPEN
TO BE A TUG BOAT CAPTAIN

SO I KNOW FROM FIRST HAND
WE DO NOT HAVE THE POWER OF
THE SHIP'S TO CONTROL THE BARGES
IF A SHIP CAPTAIN CANNOT PASS
THRU A STRAIT CHANNEL HE BETTER
GO BACK TO SCHOOL.

YOU STATED THAT WE ASSUMED THAT
400 FT CHANNEL WOULD DO NO DAMAGE

I RECENTLY TOOK A TRIP TO WASHINGTON DC. I MET PRES BUSH. I WILL WRITE HIM ABOUT THIS SINCE TIME LIMIT WITH HIM COULD NOT EXPLAIN ALL DETAILS. MAKE I AM ON THE SUBJECT ABOUT THE CHANNEL DAM OPPOSED TO PUT SPOIL IN CALCASIEU LAKE UNTIL YOU FILL UP LAKE CHARLES - PREIN LAKE - MOSS LAKE THE RIVER IN PREIN LAKE WOULD HOLD A LOT OF SPOIL SENT THE BEST OUT THE CHANNEL TO GULF LIKE THE WATER GOES TO CONTS HEAD IT DOES NOT FILTER ALONG THE BEACHES LIKE IT USE TO THE STATE OF LA SPENTS MILLIONS TO KEEP THE BEACHES FROM WASHING AWAY BECAUSE OF THE SHIP CHANNEL. YOU SAY AT THE TIME FED. STUDIES ESTIMATED SHORT TERM SALINITIES WERE 2 CENTS THIS WAS 1968 WE ARE NOW IN 2002 NEED I SAY MORE.

Re: EA for Proposed Enlargement of Sabine-Neches Navigation Channel.

Dear Ms. Richardson:

Please address my comments in the final EA for the above proposal.

The first consideration must be the safety of the people of Beaumont, Port Arthur, Bridge City and the entire project area. The second must be the protection of the commercial and residential property in these cities and elsewhere in the project area.

We cannot afford a repeat, at public expense, of the Mississippi River Gulf Outlet Canal, which was built by the Corps of Engineers (COE) over the objections of farsighted people, who correctly warned of the eminent possibility of hurricane surge damage. Now COE has realized its mistake and is calling for the canal to be closed.

No benefit/cost ration on this project can be considered complete or legal, unless it takes into consideration the very real possibility of loss of both human life and property from this project.

The Cost of Anticipated Hurricane Damage

Can COE provide assurance no loss of life and property will occur from hurricanes or other storms because of this project?

If not, then the cost of both accident and property insurance must be considered as a project cost.

Also mandatory, is an accurate and realistic appraisal of transportation benefits, not inflated projections, which, for waterways like the Red River, Ouachita-Black and Tennessee-Tombigbee, have materialized.

At the same time, the proposal demands, under NEPA, the very best possible projection of all potential wildlife losses (dealt with separately later in these comments). Prior to construction of the

Sabine-Neches Waterway EA

2

Tenn-Tom in northeast Mississippi, the Tombigbee had 52 species of freshwater mussels, the largest and most diverse mussel population in the state, including 16 species found nowhere else in Mississippi.

Today, out of 10 federally listed species in the project area, 5 have been extirpated from the state.

At one time the Neches River was habitat for many of the numerous mussels which can still be found in the Calcasieu River basin in Louisiana. COE has a legal responsibility to the people of this country to make certain what happened on the Tombigbee doesn't occur on the Neches and other American rivers.

Benefits/Costs

To comply with the NEPA requirement to inform the public sufficiently that informed and reasonable choices can be made, the EA must convincingly demonstrate why the economic benefits to a few interests will outweigh the losses to the American public at large, in terms of safety, health, recreational opportunities, and the use and enjoyment of the resources of this area.

Here in Louisiana, we have been the recipients of the Ouachita-Black and Red River Navigation projects and numerous projects in the coastal swamps and marshes and the only tangible benefit I can see is that we are losing 50 square miles annually in one of the most productive marshes anywhere. And right here in my backyard we almost lost one of the 10 most important wetlands in North America, Catahoula Lake, courtesy of COE.

Another area of significance is, how much is enough? I've heard the original channel is 125-ft wide by 10-ft deep and now COE proposes to enlarge it to 400-ft wide by 50-ft deep. How long will it be before new technology in the shipping industry demands an even deeper, wider and more dangerous channel?

When do we reach the point where the benefits of one more deep water port fail to outweigh the benefits from conserving our natural resources? And who gets to decide, the people who will foot the bill, or COE, which will benefit the most?

Since this project borders on Louisiana, I believe the Corps has a responsibility to assess the cumulative impact of its projects in Louisiana ~~and~~ from the Pearl River all the way across the state to the Sabine.

From a legal standpoint, the need to do this is covered by Article 9, Section 1 of the Louisiana Constitution.

The project will almost certainly increase the potential for destructive surges from the Gulf, will require dredging on a regular basis and will increase the possibility of stirring up toxic materials in Sabine Lake, etc. All of this must be discussed in the EA.

Mercury potential

Before any spoil is dredged, it must be tested for mercury and other contaminants, and plans must be formulated for handling it in a manner that won't pose health risks to humans or wildlife.

Spoil taken from 50-feet deep in the channel may not be suitable for creating wetlands or depositing in wetlands. The ability of this spoil to grow vegetation must be determined first.

A projection is needed on how often the channel will require dredging. In the event the material removed from the channel is contaminated by any of several materials, the periodic redistribution of these materials is a critical factor.

To avoid likely legal challenges, water quality testing for a 401 Water Quality Certification should be done by EPA, not some "captive" state agency.

Here in Louisiana, establishment of TMDLs has been taken out of the hands of LDEQ and this agency has been successfully sued on, what appears to be, a very similar COE project on Little Lake and the Pearl River.

Wetlands

Any wetlands destroyed or degraded in the Sabine NWR or Texas Point NWR should be replaced adjacent to these refuges and the plans for all wetland mitigation under 404 of the Clean Water Act should be in place before the project is started. Under no circumstances should this mitigation be the pie in the sky by and by we've seen for the Red River Navigation Project, where after 30 years all the mitigation land has not been acquired.

In addition, mitigation must be included for all project induced damages, including, but not confined to:

1. The impact of wave action or salt water intrusion damage to:
 - A. The western boundary of the Sabine NWR.

Sabine-Neches Waterway

4

- B. The eastern boundry of the Texas Point NWR
 - C. Privately owned wetlands anywhere on Sabine Lake.
 - D. The lighthouse(s) or other historic sites at Sabine Pass or elsewhere.
 - E. Damage to hways 73, 82 and 87.
 - F. Sabine Island WMA.
 - G. Salt water intrusion into the coastal aquifer.
2. Damage to the Gulf ecosystem from dredging a channel 20-miles out from shore.
 3. Damage if the channel induces the summer dead water from the Gulf to come inland.
 4. Adverse impact on the terrestrial, avian and aquatic wildlife associated with the project area, including Sabine Lake, Sabine Pass, associated marshes and estuaries and the Gulf:
 - A. Sea turtles, crabs, shrimp, oysters, fish, sharks
 - B. Waterfowl, sea birds, shorebirds,
 - C. Neo-tropical migratory birds,
 - D. Raptors,
 - E. Whales, manatee, dolphins,
 - F. Plankton.
- All the species in all the above categories must be studied for population numbers, and mitigation measures taken for any projected decline in their numbers as a result of the project.
5. In addition, COE has a legal responsibility under the provisions of the Endangered Species Act to consult with the U.S. Fish & Wildlife Service on the following federally listed species and include any correspondence or Memorandums of Understanding in the EA:

Sea Turtles:

Green, Hawksbill, Kemp's Ridley, Leatherback and Loggerhead.

Sabine-Neches Waterway

5

Whales:

Blue, Sei, Sperm and Finback.

Manatee:

West Indies Manatee

Water birds:

Brown Pelican

Shore birds:

Piping plover.

Raptors:

Bald eagle, peregrine falcon

In addition to the several federally listed species, numerous other species are listed as endangered by the state of Texas.

While I am not knowledgeable about the laws of Texas, any of species which occur on the Louisiana side of the project are protected under article 9, section one of the Louisiana constitution.

These species listed by Texas include:

Whales:

Gervais beaked, goose beaked, pigmy sperm, dwarf sperm, killer whale or orca, false-killer, short-finned pilot, pigmy killer, and black right.

Dolphin:

Atlantic spotted and rough toothed

Water birds:

Reddish egret, white-faced ibis, wood stork.

Raptors:

Swallow tailed hawk, common black hawk, northern aplomado falcon, gray hawk, zone-tailed hawk

Shorebirds

Sooty tern

Sabine-Neches Waterway

River fish

Paddlefish, shovelnose sturgeon.

Please respond to my comments in the EA and provide me with a copy of this document.

Sincerely,

Richard W. Bryan, Jr.

Enclosure

November 9, 2002

U. S. Senator John Breaux
705 Jefferson St., Room 103
Lafayette, LA. 70501

02 DEC 16 PM 6:37

Dear Senator Breaux,

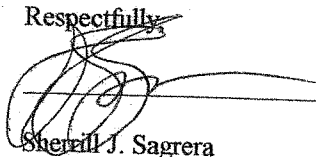

The State, Federal and local Governments along with participation of the public has developed a comprehensive restoration plan (Coast 2050). All projects must be consistent with this plan.

The U. S. Army Corp of Engineers' New Orleans district has participated and signed off on the plan. All projects of navigation, shoreline protection, hydrologic restoration, river diversions and the like consider impact to their neighbors. It seems that the Corps is the Corps. Why is the Corps' Galveston district supporting the Sabine/Neches Channel, which is detrimental to the efforts that we, the New Orleans district and Coast 2050, are trying to achieve? Co-ordination between these two districts should be achieved. Some kind of consensus should be reached so we can save the coast/wetlands of Louisiana.

Funding is a critical issue. Funds that benefit one area should not be detrimental to the ongoing efforts of neighboring areas.

I don't want to stand in the way of economic progress. But economic progress should not be at the expense of the wetlands and the environment.

Respectfully,

Sherrill J. Sagrera

RESPONSE TO COMMENTS

Comment No.	Response
1	Thank you for providing this information.

January 10, 2010

USACE
Corps of Engineers
Galveston District
P O Box 1229
Galveston, TX 77553-1229

RE: Public Comments D.E.I.S.

Dear Ms. Stokes:

I would like to address some of my concerns with the dredge containment compartments used for dredging in the deepening and widening of waterways. My observations over the last 32 years of the containment areas on Pleasure Island have caused me to have concerns regarding the large impact on the marine life in the spoil areas. I have witnessed many fish and shrimp kills over the years and I am concerned that the original design of these compartments is not being adhered to. Below are my concerns.

TPWD Designation – TPWD has classified spoil area #10 & #11 as nursery areas for marine life. If this is indeed a nursery area how can spoil be placed in the compartments and destroy the nursery? 1

Effluent Ditches – The effluent ditches were designed to release the overflow of water from the spoil areas back out to the environment. Marine life travels through these ditches into and out of the spoil areas. The spoil placement in the dredge areas is not being monitored and the ditches are filled up with silt. In the case of spoil area #10 the ditch there is so filled with silt that the water is coming out over the road on the North effluent ditch. This has happened on the last two dredging operations. Apparently the dredging companies are not doing their jobs properly. If compartment #11 is monitored properly for silt placement, the two effluent ditches have the potential to be used for development of a marina and fishing area in the future. 2

Marine Life & Bird Sanctuary – All dredge areas contain marine life that enter into the spoil areas due to high tides and storms. Then they become trapped and end up dying because of the climate changes. No one has ever spoken up about the impact on the marine life that is lost due to these sites. Bird life is impacted by the completion of these sites as well. Pleasure Island is a bird sanctuary and many avid bird watchers visit the Island every year. 3

Public Notice – After all construction is done and spoil area 10 and 11 is done and before any dredging starts I would ask the Corps of Engineers put into public record that all citizens can use these levee roads for fishing and bird watching. The Corps maintain the grassy areas adjacent to the roads. Over the years no one has wanted responsibility for the grass cutting. Without proper maintenance of the grassy areas access on the levee roads become impaired. 4

From 1977 through 1982 my brother and I had spoil area #11 leased for the research of aquaculture farming. With a grant from Texas A&M and Lamar University, the possibilities were very positive and the sites have great potential for the development of aquaculture. Under controlled conditions the marine life could be raised and returned to the environment. After 32 years observation we have witnessed the overall picture of the use of these dredge sites by the Corps of Engineers.

RESPONSE TO COMMENTS

Comment No.	Response
1	The primary purpose of the two large placement areas on Pleasure Island (Placement Areas [PA] 8 and 11) is to store dredged material removed from the Sabine-Neches Waterway (SNWW). However, in 1997-1998, changes were made to PA 11 that allows it to serve as a nursery area for marine organisms while the area slowly fills with dredged material. Two drop-outlet structures in PA 11 were relocated to allow decanted water to exit into Sabine Lake during dredged material discharge operations. The relocation allows free tidal exchange and is providing a temporary increase in forage and nursery areas for sport and commercial fishery species. PA 11 will eventually be filled with sediments, slowly decreasing the size of the temporary forage and nursery areas. At that time, future management options, including effluent discharge locations, will be evaluated. No changes were made to outlet structures at PA 8 (referred to as PA 10 in the comment).
2	In the past at PA 8 (referred to as PA 10 in the comment), effluent did cover the road at times during dredging contracts. A construction contract underway at this time will rectify this situation by raising the elevation of the roadway. The roadway around PA 11 does not flood because the drop outlet structures drain the effluent, keeping it from overtopping the road.
3	The drop outlet structures are left open to facilitate marine life access, and therefore provide an escape route after high tides and storms. We must emphasize that the primary purpose of the PAs is the containment of dredged material. Wildlife utilizes the areas between placement episodes.
4	The roads are open to the public the majority of the time. Access is restricted during levee repair or construction contracts because it is not safe for the public to use the roads at those times. The U.S. Army Corps of Engineers (USACE) Port Arthur Area Office does not routinely maintain the grassy areas adjacent to the roads. The levee roads are public roadways in the City of Port Arthur.
5	Thank you for your comments.

Stokes, Janelle S SWG

Subject: Economic Impact on Coastal Low Income Communities

Ms. Janelle Stokes

This Project will be or has been (per study) funded with Federal Dollars.
There needs to be consider and Added , what will be the Economic Affect on these Coastal Communities which are Black , 1
Hispanic and large levels of unemployment and poverty.

I am Elected Official (commissioner) of Port Of Port Arthur , elected in 1987.

COMMENTS

I am quite certain that the comment is really not going to make any difference but placing maintenance dredge spoil on the "beaches" just on the other side of the jetties in both Texas and Louisiana is simply a matter of convenience. If there is a true concern about the erosion that is taking place, then place something substantial such as Chenier LNG did. All of the shell from their spoil is still in place - even after Ike. Jerry Mambretti, TP&W, Dr. Harrel and Dr. Whittle all agree that placing spoil with only 25% sand (according to you) does more damage than good.

It is my recommendation that it would be wiser to place this spoil farther off the beach and put something substantial along the shore. I'm obviously aware of the serious costs associated with all of this - but we learned from the last time this was done that the muck simply carries downshore and ruins SeaRim and McFaddin beaches.

Please make additional comments on the back.

RESPONSE TO COMMENTS

Comment No.	Response
1	FEIS section 2.5.3.2.2 (Gulf Shore Beneficial Use [BU] Feature) contains an in-depth evaluation of the anticipated effects of regular shoreline nourishment at Texas and Louisiana points using maintenance material from Sabine Pass. The proposed beneficial use was evaluated and approved by the Interagency Coordination Team (ICT). It is acknowledged that most of the material will be composed of fine-grained sediments, and that some of the material will be rapidly lost from the vicinity of the shoreline. The mobile material within the surf zone should generally migrate to the west at both Texas and Louisiana points. There, the additional fine-grained sediments could lower erosion rates through mudflat accretion and wave attenuation.
2	USACE assumes that "something more substantial" refers to dense clays that originate from channel or mooring basin deepening. The use of heavier clays from the deepening of the Sabine Pass Channel was evaluated and determined to be more costly than upland placement (FEIS section 5.4.1.2). A cost-share sponsor would be needed to adopt and implement this as a beneficial use measure, and no non-federal sponsor has been identified at this time. Use of heavier clays from the deepening was also evaluated as a potential mitigation measure (FEIS Section 5.4.2), but was not adopted because of high incremental costs.

COMMENTS

The environmental research on impact of the project was conducted by the U.S. Army Corps of Engineers. This concludes me to believe the research false and biased. A nonaffiliated research team should be implemented. The cost of over 7 billion will be pushed onto the tax-payers while the oil companies will benefit primarily. Overall, I do not believe this project should be implemented due to the biased study on Environmental impact.

Please make additional comments on the back.

RESPONSE TO COMMENTS

Comment No.	Response
1	Extensive studies were conducted by USACE in compliance with Council on Environmental Quality (CEQ) National Environmental Policy Act (NEPA) regulations and in coordination with the ICT. These studies utilized the best available scientific information and reached objective, scientifically-based conclusions. The FEIS was also reviewed by a team of independent external peer reviewers, and revisions to the analyses were made based on their recommendations.
2	Direct and indirect economic benefits of the proposed deepening will accrue to all users of the SNWW, and to the regional and national economy. The economic analysis presented in Feasibility Report (FR) Section V.F establishes that there would be a net economic benefit to the nation from the proposed project.

 phone: 713.375.6000
 fax: 713.375.6000

Cheniere and its Sabine Pass LNG Terminal strongly supports the proposed deepening and widening project of the Sabine-Neches Waterway. We wish to see our waterway remain highly competitive with other ports and waterways by being able to ~~safely~~ accommodate the larger ships that now carry so much of the world's trade. *with a higher degree of safety.*

Of course, for our part, we are most interested in promoting the capability of the Sabine-Neches waterway to safely handle the world's largest existing LNG carriers. These ships are nearly 1,150 feet in length and 180 feet in breadth. These very large LNG carriers, like other large ships trading to our area, are presently limited to a forty feet fresh water draft when entering the Sabine-Neches. Many such vessels would come in deeper if the Waterway's channels were deeper and wider. 1

Any deepening or widening will make our waterway more competitive for business that uses the larger ships and automatically adds additional safety margins for the existing shipping already present. Cheniere supports this project and the U.S. Army Corps of Engineers and hopes the deepening and widening work will proceed without delay. 2

**Texas Energy Coalition – Comments Regarding
Proposed Sabine Neches Waterway Channel Improvement Project**

USACE Public Meeting – January 26 and 27, 2010

Good evening. My name is David Corban. I am a lawyer with Fulbright & Jaworski L.L.P, and I am authorized to make the following comments on behalf of Shell Pipeline, Explorer Pipeline, Enterprise Products, Kinder Morgan, and the other members of the Texas Energy Coalition. The Texas Energy Coalition was founded in 1995, and its membership is made up of pipeline transmission companies that work together on issues of common interest.

Prior to the release of the Sabine Neches Waterway draft feasibility report (DFR) on December 24, 2009, there was no prior communication by the sponsors of the proposed project with the pipeline industry regarding pipeline relocation issues. This was the case despite repeated requests to the Corps of Engineers for information about the proposed project's potential impact on the pipeline industry.

The DFR that was made available for the first time in late December describes a large number of pipeline relocations that the project will require. The replacement of pipelines that transport essential commodities such as natural gas is not only costly, it also requires years of advance planning and coordination, and it creates operational and engineering burdens for an industry that has strategic significance for the American economy. Yet the DFR provides little detail about the project's impact on pipeline operations, which pipelines will need to be relocated, where those pipelines are located, or how costs were estimated for pipeline relocations.

Given these circumstances, we believe it is unrealistic to expect that our members could provide any meaningful comments on the DFR by February 10, 2010. We believe that a more realistic comment period would allow at least 120 days, and we therefore respectfully request that the comment period be extended to at least April 26, 2010. In making this request, we assume that the Corps will promptly and definitively identify the pipelines that will need to be moved, the owner of each such pipeline, and sufficient information to understand and respond to the Corps' estimate of the costs for moving each such pipeline.

Based upon the DFR, we do understand the Corps of Engineers to have acknowledged that this project, as proposed, would be a deep-draft project for cost sharing purposes, and further, as required by the deep-draft cost-sharing provision of the Water Resources and Development Act of 1986, that the Corps will recommend that half of the pipeline relocation costs for this deep-draft project be borne by the pipeline owner and the other half by the local sponsor of the project.

Thank you for the opportunity to comment on the proposed project.

Mr. David Corban
Fulbright & Jaworski, LLP-Texas Energy Coalition

Houston, TX 77057

RESPONSE TO COMMENTS

Comment No.	Response
1	Owners of pipelines crossing the SNWW were contacted by U.S. Army Corps of Engineers (USACE) in 2002. USACE requested that they provide the most current "as-built" drawings and the location of SNWW crossings to enable our assessment of potential project impacts. The project's non-Federal sponsor has made numerous presentations to industry trade groups and community organizations throughout the study period, providing updates of the study and project descriptions.
2	The DFR provides sufficient information for feasibility-level planning. A list of potentially affected pipelines was provided to pipeline companies during the Draft EIS (DEIS) public comment period. The USACE list of potentially affected pipelines should not be considered definitive. This list will be refined based on information submitted to USACE during the public comment period and subsequent to the USACE/Pipeline Owner information meeting on January 25, 2011. The individual circumstances of each pipeline will be evaluated by USACE in consultation with the non-Federal sponsor and the pipeline owner during the preconstruction, engineering, and design (PED) and Construction phases, and decisions regarding necessary actions will be made individually for each pipeline at that time. There will be sufficient time for pipeline companies to make necessary preparations after the project is approved.
3	The comment period was extended an additional 30 days to March 12, 2010.
4	Please see Section 2.4.1.12 of this Final EIS for a discussion of the allocation of pipeline relocation costs.

Stokes, Janelle S SWG

From: Jerry Norris [sabinecaptain@sabinelakefishing.com]
Sent: Thursday, January 28, 2010 11:47 AM
To: Stokes, Janelle S SWG
Subject: Sabine waterway dredge material placement

Importance: High

Ms. Stokes, I have reviewed the proposed project. I have comments on the placement of spoil near the Sabine Jetties. The rate of land loss on the Texas side of the Jetty along the beach front is documented at a loss that should be addressed with all of the spoil from the project near the beach front on the west side of the jetty. The Louisiana side of the jetty has minimal loss. This should be addressed on not a half and half basis as suggested by the current plan. The Texas side of the jetty is losing 95% more land per year than the Louisiana side. I was a party to the placement of the spoil during the process with Cheniere. 1

As noted in the findings a large majority of the spoil was washed through the cut on the east side of the jetty and lost due to the sediment type and currents. placing spoil on the Louisiana side of the jetty is not sound science and not in the best interest of addressing erosion along the Texas Point. Please reconsider and place all of the spoil on the Texas side each and every time the channel is dredged in that area. I am available for any questions or help that I can give on this matter. 2

Thank you Capt. Jerry Norris

RESPONSE TO COMMENTS

Comment No.	Response
1	The dredged material that would be used for the Gulf Shore BU Feature originates from the Sabine Pass Channel. The state boundary between Texas and Louisiana follows this channel. Since the material comes from both states, the BU feature is designed to benefit both states and comply with Coastal Zone Management Act regulations promulgated by each state.
2	FEIS section 2.5.3.2.2 (Gulf Shore BU Feature) contains an in-depth evaluation of the anticipated effects of regular shoreline nourishment at Texas and Louisiana points using maintenance material from Sabine Pass. The proposed beneficial use was evaluated and approved by the ICT. All of the material cannot be used in Texas for reasons presented in the USACE response to Comment 1.

Ms. Stokes, I have been reading the available on-line materials related to this project and I was wondering if the COE has a listing or map that identifies the locations and owners of the 42 pipelines that may have to relocated. I saw several references to the relocation issue but no where did I see those pipelines identified. Thank you for your assistance. 1

5 February 2010

Attn: Janelle Stokes

Ref.: Sabine-Neches Waterway Channel Improvement Project (SNWW CIP)

Dear Ms. Stokes:

This letter is in response to the invitation for written comments in the U.S. Army Corps of Engineers cover letters of 16 December 2009 and 18 December 2009. The cover letters accompanied a CD which contained several documents relating to the Sabine-Neches Waterway Channel Improvement Project (SNWW CIP). Air Products owns and operates and 10 inch diameter hydrogen pipeline that crosses the Neches River Channel (near 292+00). Based on the information contained in the provided documents, Air Products has the following comments:

- 1) In the Draft Feasibility Report for Sabine-Neches Waterway Channel Improvement Project Southeast Texas and Southwest Louisiana Volume I, Section VI: Description of Tentatively Recommended Plan, Deep-draft Utility Relocations and Removals, it is noted that the proposed channel improvements would require the relocation of 42 deep-draft utilities. **Air Products requests the list of the 42 deep-draft utilities designated for relocation.** 1
- 2) In the Draft Feasibility Report for Sabine-Neches Waterway Channel Improvement Project Southeast Texas and Southwest Louisiana Volume I, Appendix 1(Engineering Plats), cross sections of the Neches River at several stations are depicted on Drawing No. C-15. **Air Products requests a cross section for the location where the Air Products 10" diameter hydrogen pipeline crosses the Neches River (near 292+00). Additionally, Air Products requests the GPS coordinates of both the existing Neches River centerline and the proposed Neches River centerline at that location (near 292+00).** 2
- 3) In the Draft Environmental Impact Statement for Sabine-Neches Waterway Channel Improvement Project Southeast Texas and Southwest Louisiana, Volume IV, Appendix E: Clean Water Act section 404(b)(1) Evaluation, Section e: Description of the Proposed Discharge, Item (4): Time and Duration of Discharge, it is noted that contracts 6-12 would be constructed with hydraulic pipeline dredges. **Air Products requests further description of the hydraulic pipeline dredge process.** 3

Your feedback is greatly appreciated. The requested information will allow Air Products to gain a more complete understanding of the proposed Sabine-Neches Waterway Channel Improvement Project (SNWW CIP). If you have any questions regarding these comments, please feel free to contact me via any of the provided means.

Thank you,

Daniel Stahl

RESPONSE TO COMMENTS

Comment No.	Response
1	A list of potentially affected pipelines was provided to the Texas Energy Coalition and individual pipeline companies during the DEIS public comment period.
2	FR, Appendix I (Drawing # C-15) shows cross sections on the Neches River Channel in the vicinity of the Air Products pipeline. More detailed information on channel design will be developed and provided to all pipeline and utility companies during the PED phase.
3	USACE met with pipeline owners at an information meeting on January 25, 2011. More information on the hydraulic pipeline dredging process was provided at that time, and additional information will be provided during the PED phase. This is the same process that is used currently to maintain the existing SNWW channels.

TARGA

Targa Midstream Services Limited Partnership
 1000 Louisiana, Suite 4300
 Houston, Texas 77002
 713.584.1000

February 5, 2010

Ms. Janelle Stokes

 P.O. Box 1229
 Galveston, Texas 77563-1229
 e-mail: janelle.s.stokes@usace.army.mil

Re: Sabine-Neches Waterway Project and Study

Dear Ms. Stokes:

On behalf of Targa Midstream Services Limited Partnership ("Targa"), formerly known as Dynege Midstream Services Limited Partnership, I respectfully request an extension of the comment period currently to end on February 10, 2010, as set forth in the draft Feasibility Report (DFR) and the draft Environmental Impact Statement (DEIS) for the Sabine-Neches Waterway Improvement Project ("Project") that was received by Targa at the end of last year. Targa is requesting a minimum of sixty (60) days from that date to no earlier than April 10, 2010, to respond with our comments. 1

Prior to the release of the DFR, Targa was not provided any communication by the sponsor of the proposed Project regarding potential pipeline relocation issues. The DFR that was made available in December describes a large number of pipelines whose relocation or abandonment will be mandated by the Project. At least two of those pipelines are now owned by Targa. The limited time available since the release of the DFR has not provided Targa a sufficient opportunity for a complete analysis of the impact this significant undertaking will have on Targa. 2

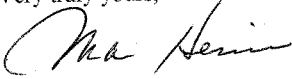

It can certainly be said that the relocation of pipelines that transport essential energy commodities through Texas and Louisiana will not only be prohibitively expensive, it will also require years of advanced planning and coordination. Clearly, the relocation of pipelines creates operational and engineering burdens for an industry that is facing greater regulation and competition. The DFR and DEIS provide little discussion of the actual costs to a pipeline owner such as Targa, the impact of pipeline relocation will have on other pipelines that interconnect with Targa, the number of producers whose wells will be affected should a shut-in occur, the impact on the nation as a whole as a result of the disruption to the natural gas and petrochemical industry, or the potential unintended environmental consequences this Project could have on the coastal wetlands. 3

Ms. Jannelle Stokes
February 5, 2010
Page 2

Therefore, Targa is respectfully requesting the comment period due date be no earlier than April 10, 2010.

We appreciate your consideration of this request.

Very truly yours,

A handwritten signature in black ink, appearing to read "Michael A. Heim". The signature is fluid and cursive, with the first name "Michael" and last name "Heim" clearly distinguishable.

RESPONSE TO COMMENTS

Comment No.	Response
1	The public comment period was extended an additional 30 days to March 12, 2010.
2	Owners of pipelines crossing the SNWW were contacted by USACE in 2002. USACE requested that they provide the most current "as-built" drawings and the location of SNWW crossings to enable an assessment of potential project impacts. The project's non-Federal sponsor has made numerous presentations to industry trade groups and community organizations throughout the study period, providing updates of the study and project descriptions. The individual circumstances of each pipeline will be evaluated by USACE in consultation with the non-Federal sponsor and the pipeline owner during the PED and Construction phases, and decisions regarding necessary actions will be made individually for each pipeline at that time. There will be sufficient time for pipeline companies to make necessary preparations after the project is approved.
3	FEIS Section 1.4.3 presents industry concerns about the costs of moving pipelines to accommodate a deeper channel. FEIS Section 2.4.1.12 presents a discussion of the allocation of pipeline relocation costs. Potential environmental impacts of pipeline relocation are assumed to be minimal. However, each pipeline relocation is case specific, and coordination with USACE-Galveston Regulatory Branch would be required in each case. However, relocations to place a pipeline deeper would not necessarily require a new permit. If a pipeline is being moved to a new location, then the impacts would be evaluated by the environmental assessment performed in conjunction with the Department of Army permit.

Resolution

STATE OF TEXAS

COMMISSIONERS' COURT

COUNTY OF JEFFERSON

OF JEFFERSON COUNTY, TEXAS

BE IT REMEMBERED at a meeting of Commissioners' Court of Jefferson County, Texas, held on the 8th day of February, 2010, on motion made by Everette D. Alfred, Commissioner of Precinct No. 4, and seconded by Mark L. Domingue, Commissioner of Precinct No. 2, the following Resolution was adopted:

Resolution Concerning the Sabine-Neches Waterway Channel Project

WHEREAS, the U.S. Army Corps of Engineers (USACE), in concert with Sabine-Neches Navigation District has proposed a project to widen and deepen the Sabine-Neches Waterway; and

WHEREAS, the USACE has prepared a study analyzing the feasibility and environmental impacts of proposed modifications to the portions of the Sabine-Neches Waterway that serves the ports of Beaumont and Port Arthur, Texas; and

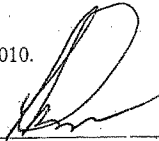

WHEREAS, the USACE study clearly demonstrates the necessity for these improvements to provide a safe waterway that will accommodate the current needs of our ports and industry; and

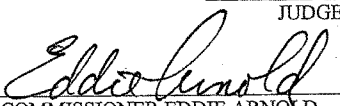

WHEREAS, the proposed improvements reasonably accommodate environmental concerns; and

WHEREAS, the proposed improvements are clearly cost effective and will provide a positive economic benefit and enable our ports to facilitate the handling of vital military cargo; and

NOW THEREFORE, be it resolved that the Commissioners' Court of Jefferson County, Texas Urges all elected officials and citizens to support this project and the adoption of the plan for these improvements as proposed.

SIGNED this 8th day of February, 2010.

JUDGE RONALD WALKER
County Judge

COMMISSIONER EDDIE ARNOLD
Precinct No. 1

COMMISSIONER MICHAEL S. SINEGAL
Precinct No. 3

COMMISSIONER MARK L. DOMINGUE
Precinct No. 2

COMMISSIONER EVERETTE D. ALFRED
Precinct No. 4

Mr. Fred Jackson

RE: Draft Environmental Impact Statement for Sabine-Neches Waterway (SNWW)
Channel Improvement Project Southeast Texas and Southwest Louisiana

Dear Ms. Stokes:

Doré Energy Corporation (DEC) strongly objects to the proposed improvements associated with the SNWW. DEC owns a large wetland tract in Cameron Parish, Louisiana, known locally as Cameron Meadows. The 18,611-acre tract is located north of Johnson's Bayou, south of, and adjacent to, the Sabine National Wildlife Refuge, and is within the SNWW Project and Study Area (study area). As a stakeholder, we respectfully submit the following comments and questions regarding the DEIS:

The project is economically driven by, and for, the State of Texas. It is understandable that Texas is willing to accept the projected detrimental environmental impacts as a tradeoff for the socioeconomic benefits that the improved ship channel is supposed to provide. Does the same hold true for the State of Louisiana? Would the DEIS authors identify, describe, and project all of the economic benefits, in terms of dollars, that the project would provide for Louisiana?

The DEIS states that the larger channel would cause greater tidal circulation and exchange, a minimal increase of water surface elevation, and marginally less fresh water retention. Increases in the tidal regime would have a very negative impact on the Cameron Meadows tract. The DEIS reports that 182,000 acres of intertidal marsh within the Louisiana portion of the study area would be indirectly, but adversely affected by "small increases in salinity levels". Projected impacts in Louisiana include a net loss of 1,499 Average Annual Habitat Units. Herein lies a major concern, these projections are based on salinity levels that are derived from modeling results, deemed likely by the DEIS preparers, and do not

USACE – Galveston District
ATTN: Ms. Janelle Stokes
Page 2

represent high-end values. What if the modeling effort is too low in its estimates of increases in salinity levels resulting from the SNWW channel improvements? What would the losses to intertidal marsh in Louisiana, including losses on the Cameron Meadows tract, be as the result of the modeling values exceeding those projected in the DEIS?

Specifically, the DEIS acknowledges that the amount of upstream salinity transport may at times be underestimated by modeling results. The DEIS also acknowledges two uncertainties of salinity variations with ecological Wetland Value Assessment modeling: (1) model quality and (2) performance and model predictions. With this understanding and apparent acceptance of the possible factor of error, the DEIS suggests that the net change in salinity in Louisiana in the future with the project to be within the range of a low of 0.0 to a high of 1.8 parts per thousand (ppt). The Gammill et al. report, entitled *Hydrologic Investigation of the Louisiana Chenier Plain* (2002), cites modeling, identified channel improvement to 50-ft, would result in a 2 to 3 ppt increase in salinities in the Calcasieu-Sabine Basin. This difference in modeling results may seem small to the casual observer, but it is rather significant. While *Hydrologic Investigation of the Louisiana Chenier Plain* is cited elsewhere, this conflicting salinity data is conspicuously absent in the DEIS. Do the DEIS authors believe there is something wrong with this data? Why was it left out of the DEIS? Does not the combination of acknowledged modeling error and conflicting salinity modeling results indicate adverse indirect impacts, resulting from increased salinity levels, could/would affect more than the stated 182,000 acres of intertidal marsh identified in Louisiana's portion of the project area? Moreover, as marsh is lost, it is replaced with more tidal water which continues to exacerbate the conversion of marsh to water. Did the DEIS authors identify and evaluate this process and consider the likelihood that it would occur as the result of the SNWW improvements?

5

The best buy mitigation alternative is troublesome. A number of structures were identified in the DEIS, some of which would help protect Cameron Meadows from high saline waters, but were summarily dismissed as not being cost effective when compared to the need to provide marine organism access. Should not the long-term preservation of existing emergent marsh be more important than creating conditions (e.g., increasing cross-section of SNWW) that will increase the frequency, duration, and adverse effects of spikes of high saline water in sensitive wetland areas for the sake of maintaining study area marine organism access?

6

Louisianans have long recognized the importance of the state's coastal wetlands and have long supported the state's coastal restoration efforts. The State of Louisiana and United States of America have spent hundreds of millions of dollars on coastal restoration in the

USACE – Galveston District
ATTN: Ms. Janelle Stokes
Page 3

past quarter of a century from funding through Coastal Wetlands Planning, Protection, and Restoration Act (CWPPRA) and other programs. In fact, a CWPPRA project, located on the Cameron Meadows tract, was nominated last month for 2011 CWPPRA funding. Is not the proposed SNWW project in direct conflict with federal and state restoration efforts in Louisiana? How can the SNWW be justified with its significant and bantered projection of unmitigated marsh impacts?

7

In summary, the DEIS fails to provide: (1) the project's economic value to the State of Louisiana; (2) resolution to conflicting modeling results and how much marsh could/would be lost or adversely affected by the project due to higher salinity levels than projected; (3) full mitigation plan or compensation for projected losses of intertidal marsh in most of the Louisiana portion of the study area including Cameron Meadows; and (4) resolution to the conflict between navigation needs in Texas, the project's acknowledged detrimental impacts to Louisiana marshes, and ongoing publicly supported and funded coastal restoration efforts in Louisiana.

8

9

DEC is not against economic prosperity in and for the State of Texas. We just do not want to lose our land in the process.

Thank you for the opportunity to make these comments.

Sincerely yours,

William Doré

RESPONSE TO COMMENTS

Comment No.	Response
1	Thank you for your comment.
2	The proposed SNWW CIP is a Federal Civil Works project, and as such, it would provide benefits to the Nation, not just one state. The economic analysis presented in FR section V.F establishes that there would be a net economic benefit to the United States from the proposed project. Direct and indirect economic benefits of the proposed deepening will accrue to all users of the SNWW, including the energy industries, and to the regional economy.
3	It appears that Cameron Meadows is located within LA-9, the East Johnsons Bayou hydro-unit. FEIS Chapter 4 fully evaluates potential impacts from the SNWW CIP to this unit. As noted in FEIS Section 4.6.2, the proposed project would result in a minimal increase in water surface elevation (averaging less than an inch), a slight increase the amount of tidal exchange, and a slight increase in the conveyance of inflows to the Gulf. All of these effects are minimal.
4	FEIS, Appendix C, Section 9.4 presents a sensitivity analysis of potential salinity impacts at the 95 percent confidence limit. Without the project, the hydrodynamic salinity (HS) and Wetland Value Assessment (WVA) models estimate that 4.0 percent of the marsh in the East Johnsons hydro-unit will be lost over 50 years. Potential land loss impacts from the proposed SNWW CIP range from 0 to 0.4 percent more than without the project. Proposed mitigation replaces estimated land loss with more than four times the amount of marsh projected to be lost, providing more than adequate mitigation for the full range of possible impacts.
5	USACE evaluated the modeling reported by Gammil et al. (2002) and decided not to use this model because of specific technical issues and non-coverage of the Texas portion of the study area. Hydrodynamic-salinity effects of channel deepening were modeled using the TABS-MDS code of ERDC-WES to compute hydrodynamics and salinity transport. This model has been used extensively over the last two decades in a variety of field investigations with excellent results. It has also has been certified for use by the USACE model certification program. The technical adequacy of the application of this model to the proposed project has been sustained by Agency Technical Review (ATR) and Independent External Peer Review (IEPR). The potential effect of higher salinity on land loss was evaluated by using the HS and WVA ecological model to estimate land loss due to the project.
6	USACE and the ICT made extensive efforts to identify effective mitigation measures that could minimize or eliminate the projected increase in salinity. The results of this effort are presented in FEIS Section 5.4.1.1. HS modeling and the WVA model were utilized to evaluate the effectiveness of salinity control structures. As described in FEIS Section 3.1.3, the WVA model was developed by a working group of state and federal agencies in Louisiana, and it is used extensively in Louisiana to prioritize Coastal Wetlands Planning, Protection and Restoration Act (CWPPRA). A projects for authorization. The value of marsh and open water habitats are both considered in this community model.
7	The relationship of the proposed SNWW CIP project to Louisiana coastal restoration and protection programs are described in FEIS Sections 7.26 through 7.30. The proposed project does not conflict with any of these plans. Impacts of the proposed project would be fully compensated by the Louisiana marsh mitigation measures.
8	Please refer to responses 1-7 above.
9	Thank you for your comment.

Stokes, Janelle S SWG

From: LEAten@aol.com

To: Stokes, Janelle S SWG
Subject: Note to Jan Stokes regarding the draft Sabine-Neches Waterway EIS:

Jan:

While many parts of my 1983 book (Indians of the Upper Texas Coast) are still relevant, the section on the Sabine Lake Area used in the draft EIS is quite out of date. And while the 2002 Aten and Bollich study (Late Holocene archeology of the Taylor Bayou Drainage Basin) is mentioned, none of its conclusions and recommendations have found their way into the summary of existing knowledge or the formulation of problems for a mitigation program in the draft EIS summary in Vol. II. Also, there is a new Aten and Bollich monograph now in press for publication in 2010 by TARL (this was mentioned in the December 2009 Friends of TARL Newsletter (pg. 14) on the subject of early ceramic sites in the Sabine Lake area. You may recall I sent an earlier version of this to you in 2007. 1

In addition to the sources (mostly surveys) mentioned in the draft EIS volume II section 3.13.1.1, I would recommend the following be reviewed and included:

Campbell, T. N., 1947, The Archaeology of the Texas Coast and its Relation to that of Mexico and the Lower Mississippi Valley. Unpublished Ph. D. dissertation, Harvard University. An early overall assessment that is still valuable in defining issues.

Stright, Melanie J., Eileen M. Lear, and James F. Bennett, 1999, Spatial Data Analysis of Artifacts Redeposited by Coastal Erosion: A Case Study of McFaddin Beach, Texas. Minerals Management Service, OCS Study MMS 99-0068, 2 volumes. A detailed study of mostly Paleo-Indian, Early and Middle Archaic lithic technology based, as you know, on the large collection from McFaddin Beach in the Sabine Area.

Aten and Bollich, 2002, Late Holocene Settlement in the Taylor Bayou Drainage Basin: Test Excavations at the Gaulding Site (41JF27), Jefferson County, Texas. Texas Archeological Society Special Publication No. 4, and Texas Archeological Research Laboratory Studies in Archeology 40. Although this study is mentioned in the draft EIS, its importance in defining research issues in the region doesn't seem to be appreciated. This monograph lays out the need for and approach to geoarcheology and culture history mainly for the Late Archaic in the project area.

Aten and Bollich, 2010, "Early Ceramic Sites of the Sabine Lake Area, Coastal Texas and Louisiana." This monograph is finished and is being published by Texas Archeological Research Lab (UT-Austin) this year. It begins more or less where the 2002 Taylor Bayou study ends; it continues identifying Sabine Area study needs from the Late Archaic into ceramics using cultures. If a copy is needed sooner than sometime this year I'm sure you could get a photocopy from Dr. Creel at TARL.

Aten, 2004, Archeological Reconnaissance at Black Hill Mound (41JF24), Jefferson County, Texas. Research in fulfillment of Texas Antiquities Committee Archeology Permit No. 2902. This report is being incorporated in the Aten and Bollich 2010 now in press. But if you need something sooner you should be able to get a copy of this report from the Texas Historical Commission. The Black Hill site appears to include a little Middle Archaic and a lot of Early Ceramic. It also deals with other geoarcheology issues not included in the 2002 Taylor Bayou monograph.

Data on the Late Ceramic and Historic periods still are very scarce and new studies "from scratch" are needed for them. 2

Taken together these studies lay a wider basis for formulating new research for Paleo-Indian through Early Ceramic in the Sabine than is indicated in the draft EIS. Although data and concepts for the Late Ceramic through Historic periods are still weak, the basic formulations for the earlier periods are now coming into focus. Thirty years ago I could say there was little known of Sabine prehistory. But not now. Thanks for giving me the opportunity to comment.

Jan, please call on me, and I am sure Charlie Bollich also, if we can be of further assistance on the SNWW project.

Best regards,

Larry

**Written Comments by Texas Energy Coalition Regarding
Proposed Sabine Neches Waterway Channel Improvement Project DFR**

February 9, 2010

U. S. Army Corps of Engineers
Galveston District
Attn: Ms. Janelle Stokes [janelle.s.stokes@usace.army.mil]
P. O. Box 1229
Galveston, Texas 77553-1229

Re: Request for extension of time to comment and interim comments regarding DFR/DEIS
for proposed Sabine Neches Waterway Channel Improvement Project

Dear Ms. Stokes:

We write on behalf of the Texas Energy Coalition, a group of pipeline transmission companies that collaborate on issues of common interest. By this letter, the Coalition (1) requests an enlargement of time in which to comment upon the DEIS and DFR and (2) offers certain interim comments regarding the DEIS and DFR.

In late December 2009, we received your correspondence inviting comments on the "Draft Environmental Impact Statement for the Sabine-Neches Waterway Channel Improvement Project, Southeast Texas and Southwest Louisiana and the Draft Environmental Impact Statement Sabine-Neches Waterway Channel Improvement Project, Texas Ocean Dredged Material Disposal Sites Designation" (referenced herein collectively as "DEIS"). We understand that as of yesterday, the deadline for comments on the DEIS has been extended from February 10, 2010, to March 12, 2010. Although your original letter and announcement were silent as to whether comments also were invited on the Draft Feasibility Report for the proposed Sabine Neches Waterway Channel Improvement Project (referenced herein as "DFR"), representatives of the Corps of Engineers subsequently advised that comments also were being accepted on the DFR and that the deadline for comments on the DFR was the same as for comments on the DEIS. We assume this deadline also will be extended to March 12, 2010, but would appreciate written confirmation of that decision.

The DFR and DEIS were made available to the public for the first time over the December holidays, at a time when many of our members' employees were on vacation. The practical and easily foreseeable effect of this timing, of course, was to delay the commencement of the review of the five volumes that comprise the DFR and DEIS. Furthermore, although the DFR and DEIS indicate that the proposed project will require a large number of pipeline relocations, there does not appear to have been any prior effort to coordinate the project's planning with pipeline owners and operators. This is the case even though it is common knowledge that pipelines lace the area impacted by the proposed project – a fact that is reflected in the DFR and DEIS as well (*see, e.g.*, DFR at pp. II-3, II-10, V-4-5, V-77, and VI-28).

The replacement of pipelines that transport essential commodities such as natural gas, natural gas liquids, crude petroleum and refined petroleum products is not only costly, it also requires years of advance planning and coordination, and it creates significant operational and engineering burdens for an industry that has strategic significance for the American economy. Particularly in congested areas such as the Sabine Neches Waterway, where there are multiple pipelines owned by multiple companies, the relocation of a significant number of pipelines must be preceded by a comprehensive and coordinated planning process regarding the relocation. Yet the DFR and DEIS provide little detail about the proposed project's impact on pipeline operations, which pipelines will need to be relocated, where those pipelines are located (other than the most general of descriptions), or how costs were estimated or projected for pipeline relocations. For example, the engineering narrative (located in chapter 13 of the DFR Appendix) indicates that "relocated lines were assumed to be directionally drilled, and bundled when possible," yet no detail is provided that would inform a reader which pipelines were assumed to be bundled, nor were other details provided that would permit our members to understand the logic – let alone the accuracy – of the Corps' feasibility and cost assumptions. There also appears to have been no consideration of the lead time requirements and additional expense that will be required for planning and coordination in the instance of multiple simultaneous pipeline relocations.

Besides relocations of existing pipelines, it also appears that the project may impact pipeline operations in other ways. Based upon one of the few references to particular pipelines in the entire DFR and DEIS (*see* Figure VII-3 of DFR), it appears that Placement Areas (both on-shore and off-shore) for the proposed project may impact a number of existing pipelines, appurtenances and their operations, yet there is no indication of whether those pipelines would be relocated or whether it is simply assumed that there would be no problems if additional overburden were to be added over those existing pipelines. For similar reasons, we need a better understanding of Beneficial Use Features. In other instances, it is unclear whether pipelines that operate near the Sabine Neches Waterway will be impacted by the project or whether the proposed project will require their relocation for other reasons.

On multiple occasions prior to the release of the DFR and DEIS, we have requested information from the Corps of Engineers (including through a series of requests under the Freedom of Information Act (FOIA) dating back to 2007) regarding the potential impact on pipeline operations of any project to deepen or widen the Sabine Neches Waterway. The Corps responded to each request by refusing to provide a single responsive document – that is, not until its production of a hard copy of the DFR and DEIS on December 24, 2009, in response to the Coalition's most recent FOIA request. Since then, the only document that the Corps has made available is a single spreadsheet with what appears to be a working list of pipelines that may be impacted by the project. This spreadsheet, which was not made available to the Coalition until January 12, 2010, has never previously been produced, even though it is dated September 30, 2005, and is clearly responsive to the Coalition's multiple FOIA requests to the Corps going back to 2007.

Under the circumstances, it is unrealistic to expect that the pipeline companies could provide any meaningful comments on the multi-volume DFR or DEIS by the original deadline of February 10, 2010, or even by the extended deadline of March 12, 2010. A more realistic comment period would allow at least 120 days from the date of issue (December 24, 2009), and we therefore respectfully request that the comment period be extended to at least April 26, 2010.

In making this request, we assume that the Corps will promptly and definitively identify the pipelines that will be impacted by the project, the owner of each such pipeline, and sufficient information to understand and respond to the Corps' estimate of the costs for removing or relocating each such pipeline. We also assume the Corps will promptly provide us with whatever additional documents are needed to understand the proposed project's impact on pipeline operations, including a projected timeline for when the relocations may actually be needed. Our members also believe that it is important for the Corps to meet with the Coalition and pipeline company representatives as soon as possible, in order to facilitate the information exchange.

9

Based upon the DFR, this project, as proposed, would be a deep-draft harbor project for cost sharing purposes under the Water Resources and Development Act of 1986. Under this law, half of the pipeline relocation costs for a deep-draft harbor project must be borne by the pipeline owner and the other half by the local sponsor of the project. Please confirm that this cost-sharing requirement will be part of any Chief's Report or other report or recommendation the Corps may make regarding the project.

10

Please advise the undersigned as soon as possible whether the comment period for the DFR and the DEIS will be extended, as requested above. We also ask that you contact Denis Calabrese (713-622-7388) or David Corban (713-651-5251) to coordinate the meeting requested above.

Very truly yours,

Denis Calabrese
Spokesperson

Mr. Denis Calabrese
Texas Energy Coalition

RESPONSE TO COMMENTS

Comment No.	Response
1	The comment period has been extended an additional 30 days to March 12, 2010. This information was placed on the USACE website at http://www.swg.usace.army.mil/pao/Docs/ExtensionofPublicCommentPeriodtoMarch12.pdf on February 8, 2010.
2	The release of the Draft FR and DEIS was established based on the schedule requirements needed to complete a Chief of Engineers report in Fiscal Year 2010.
3	Owners of pipelines crossing the SNWW were contacted by USACE in 2002. USACE requested that they provide the most current "as-built" drawings and the location of SNWW crossings to enable our assessment of potential project impacts. The project's non-Federal sponsor has made numerous presentations to industry trade groups and community organizations throughout the study period, providing updates of the study and project descriptions.
4	A list of potentially affected pipelines was provided to pipeline companies during the DEIS public comment period. The USACE list of potentially affected pipelines was developed for the purpose of feasibility level planning, and should not be considered definitive. This list will be refined based on information submitted to USACE during the public comment period and subsequent to the USACE/Pipeline Owner information meeting on January 25, 2011. The individual circumstances of each pipeline will be evaluated by USACE in consultation with the non-Federal sponsor and the pipeline owner during the PED and Construction phases, and decisions regarding necessary actions will be made individually for each pipeline at that time.
5	As noted, pipelines cross beneath existing PAs that are proposed for use with the SNWW CIP. USACE will coordinate with pipeline owners during PED and Construction phases to avoid impacts to these pipelines.
6	FEIS Section 2.4.1.12 discusses the potential for pipelines to be affected by BU and marsh mitigation areas. It is recognized that additional pipeline searches and coordination with pipeline owners will be required prior to construction. USACE will coordinate with pipeline owners during PED and Construction phases to avoid impacts to these pipelines.
7	As noted, a list of potentially affected pipelines was provided to pipeline companies during the DEIS public comment period.
8	The comment period was extended an additional 30 days to March 12, 2010.
9	The USACE feasibility study estimate of pipeline relocation costs was developed by USACE to estimate the fully funded cost allocation between USACE and the non-Federal sponsor. A preliminary construction schedule has been developed (Engineering Appendix Addendum 2009, chapter 14.0 Revised Schedules for Design and Construction) and is available upon request. However, the actual time table for project construction is uncertain at this time because it is dependent upon ASA and OMB approval of the Chief's Report, Congressional authorization and Congressional appropriation of funds. There will be sufficient time for pipeline companies to make necessary preparations after the project is approved. As requested, USACE met with pipeline owners at an information meeting on January 25, 2011.
10	Please see Section 2.4.1.12 of this FEIS for a discussion of the allocation of pipeline relocation costs.

Ms. Adams,

The Galveston District, Corps of Engineers, is extending the CEQ public comment period for the Sabine-Neches Waterway Channel Improvement Project, and Proposed Ocean Dredged Material Disposal Site Designation, Southeast Texas and Southwest Louisiana. The comment period was originally set to end on 2/10/2010, but it has been extended 30 days to 3/12/2010.

Re: Sabine-Neches Waterway Channel
Improvement Project

Dear Ms. Stokes:

The Texas Pipeline Association (TPA) is an organization of thirty-four member companies which gather, process, treat, transport, deliver and store natural gas and natural gas products to marketers, commercial and industrial end users and residential consumers in Texas and the United States.

The U.S. Corps of Engineers (Corps) has released the Draft Feasibility Report (DFR) and the Draft Environmental Impact Statement (DEIS) for the above referenced project and announced that it will accept written comments postmarked by February 10, 2010. The Texas Pipeline Association requests that the comment period be extended for an additional 60 days for the following reasons:

1. The material which must be reviewed is voluminous. The DEIS is over 1500 pages and the DFR is over 700 pages. 2
2. There are a number of issues which the TPA believes will require additional data to determine the magnitude of the impact of the project. It appears that there are approximately 50 pipelines which must be relocated or removed to accommodate the project. The process of relocating or removing pipelines is both expensive and complicated. The TPA believes the actual costs of the relocation and removal of numerous pipelines will turn out to be substantially higher than currently anticipated. 3
3. It is clear that much of the pipeline capacity that delivers oil, gas and products between the Gulf Coast of Texas and the Gulf Coast of Louisiana will be out of service for a 4

604 West 14th Street, Austin, Texas 78701
phone: (512) 478-2871 fax: (512) 473-8476 Email: texaspipelineassociation@yahoo.com

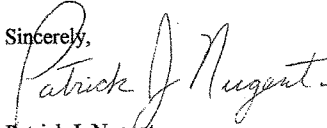

period of time to accommodate the project. It has not yet been determined how much of that capacity will not be put back into service due to the cost of relocation or removal. Moreover, there are safety and environmental risks of such operations which must be taken into consideration.

4. Neither the Corps nor the energy industry yet knows how much oil and gas production will have to be shut in or the period of time we can expect production to be interrupted by the relocation and removal projects. 5
5. Neither the Corps nor the public yet knows how much of the Gulf Coast's gasoline and diesel fuel supplies will be interrupted or for what time period that disruption will last. It also appears that delivery of products such as ethylene, butadiene, oxygen and ammonia will be interrupted to those industries which are major employers on the Gulf Coast. 6
6. We would note that the State of Louisiana, through its Department of Natural Resources, Office of Coastal Management (DNR) has stated its concerns about whether the deepening will increase damage done by storm surges as well as its concerns about many of the same issues raised by the TPA. The DNR has asked for an additional 90 days to evaluate the impact of the project. 7

Given the extensive nature of the project, the amount of existing data to be reviewed in the DFR and the DREIS, and especially the amount of data which needs to be collected regarding the impact on both the energy industry and its customers, the TPA asks that the comment period be extended at least 60 days so that a useful analysis of the project's impact can be done.

If you have any questions, please do not hesitate to contact me at texaspipelineassociation@yahoo.com or 512/478-2871 or 604 West 14 Street, Austin, Texas 78701.

Sincerely,

Patrick J. Nugent
Executive Director

RESPONSE TO COMMENTS

Comment No.	Response
1	The comment period was extended an additional 30 days to March 12, 2010.
2	The length of these documents is commensurate with the size and complexity of the proposed project.
3	The USACE feasibility study estimate of pipeline relocation costs was developed by USACE to estimate the fully funded cost allocation between USACE and the non-Federal sponsor. A list of potentially affected pipelines was provided to pipeline companies during the DEIS public comment period. The USACE list of potentially affected pipelines should not be considered definitive. This list will be refined based on information submitted to USACE during the public comment period and subsequent to the USACE/Pipeline Owner information meeting on January 25, 2011. The individual circumstances of each pipeline will be evaluated by USACE in consultation with the non-Federal sponsor and the pipeline owner during the PED and Construction phases, and decisions regarding necessary actions will be made individually for each pipeline at that time.
4	Channel deepening will be accomplished with numerous dredging contracts over many years, and associated pipeline relocations will similarly occur in increments, so no large disruptions in pipeline service are anticipated. USACE will ensure that channel construction contractors work with pipeline companies as needed to accommodate all parties for a safe and effective working plan.
5	See USACE response to Comment 4.
6	See USACE response to Comment 4.
7	A sensitivity analysis using the ADCIRC model was performed to determine what effect the proposed SNWW CIP might have on surge levels in the study area (Wamsley et al., 2010). The results of this analysis are presented in FR Chapter VIII, FEIS Section 4.1.5. The comment period was extended an additional 30 days to March 12, 2010.

TECHNICAL
CONSIDERATIONS FOR

Ms. Stokes,

I am with PB Energy Storage Services. I spoke with you recently on the phone in relation to the Draft Environmental Impact Study on the Sabine Neches Waterway. I am submitting a short technical evaluation on the impact of the project to PBESS's Pipeline Operation. We have looked at the deepening and widening of the channel as well as the location of the spoil areas in relation to our pipelines. Depending on where the centerline of the channel will be we do not see a big impact on our systems. We would like to point out that the spoil areas are directly over portions of both pipelines. As we do not know the finished depth of the spoil in these areas we are somewhat concerned. I have attached a letter as well as drawing that show the location of the pipelines, most recent profiles as well as Google Photos with GPS Coordinates. I also super imposed the drawing from your impact study with our pipelines.

Please feel free to contact me if you require more information or if we can help in any way.

Thanks

Chuck Fontenot

**Subject: PB ESS Technical Requirements for our Pipelines due to Sabine Neches,
Waterway Channel Improvement Project**

Date: February 2nd, 2010

To: Ms Janelle Stokes

PB Energy Storage Services is responsible for the operation of two pipelines crossing under the natural bottom of the Neches River as per attached drawings and pictures. One pipeline is 24" OD natural gas pipeline and the other is 6.625" OD ethane pipeline. The 24" OD Pipeline is required for the Gas Supply to Entergy's Bridge City Power Plant. The 6.625" OD pipeline is the ethane feedstock pipeline to Sasol NA's Westlake Power Plant. While we realize that this release is related to environmental impact particularly on the spoil areas, we wanted to make sure that the location of our pipelines related to both the spoil areas and river excavation were considered as soon as possible.

PB has reviewed the documents from Department of the ARMY, and applied standards and applicable specifications including DOT 195, DOT 192, ASME B31.4 (Liquids) and ASME B31.8 (Gas), to determinate the minimum necessary requirements for the proposed project.

The primary guidelines for this project to be considered are:

- All buried pipelines for river and stream crossings shall be installed below the normal level of bottom of river with a minimum cover not less than 48 inches, PBESS considers this to be adequate under the most perfect conditions of water movement, this depth should be increased as per calculations based on real conditions.
- Crossings of rivers, streams, lakes, and inland bodies of water are individual problems, and the designer shall investigate composition of bottom, variation in banks, velocity of water, scouring, and special seasonal problems. Where required,

detailed plans and specifications shall be prepared taking into account these and any special considerations or limitations imposed by the regulatory body involved.

- Underwater crossings modifications as this case, plans and specifications shall describe the position of the line, showing relationship of the pipeline to the natural bottom and the depth below mean low water level when applicable. To meet the conditions set out here, heavier wall thickness could be necessary. Approach and position of the line in the banks is important, as is the position of the line across the bottom. Special consideration shall be given to depth of cover and other means of protecting the pipeline in the surf zone. Special consideration shall be given to protective coating and the use of concrete jacketing or the application of river weights.
- Complete inspection shall be provided and all precautions shall be taken during construction to limit stress below the level that would produce buckling or collapse due to out-of-roundness of the complete pipeline.
- Plans and specifications shall describe alignment of the pipeline, depth below mean water level, and depth below bottom if ditched. Special considerations shall be given to use of weight coating(s), anchors, or other means of maintaining position of the pipeline under anticipated conditions of buoyancy and water motion. Complete constructions inspection and monitoring shall be provided. Precautions shall be taken during construction to limit stress below the level that would produce buckling or collapse due to out-of-roundness of the pipeline.
- Where pipelines and mains cross areas that are normally under water or subject to flooding (i.e., lakes, bays, or swamps), sufficient weight or anchorage shall be applied to the line to prevent flotation.
- Because submarine crossings may be subject to washouts due to the natural hazards of changes in the waterway bed, water velocities, deepening of the channel, or changing of the channel location in the waterway, design considerations shall be given to protecting the pipeline or main at such crossings. The depth of the line, location of the bends installed in the banks, wall thickness of the pipe, and the weighting of the line shall be selected on the characteristics of the waterway.

After analysis, PB ESS requirements:

4

- PB ESS has not in this case studied the soil conditions and water velocity for these crossings, due to the unpredictable conditions for this river, we want to keep the minimum depth as per drawings, which is 14.5' at TOP for both pipelines, unless than proper studies show than a shallower depth would not be a risk.
- If it becomes necessary that a minimum depth would be less than 14.5' and in the case that the pipeline could have the possibility of future exposure, the guidelines suggested above shall be considered and approved by PB ESS.

- If the width or depth of the river excavation makes the replacement of the pipeline necessary, then a new section of pipeline would be necessary and mainline block valves should be installed on the upstream side of major river crossings. Either a block or check valve shall be installed on the downstream side of major river crossing.
- PB ESS will require that a representative of our company be on-site at all times, during all excavation activities in the vicinity of these pipelines.
- Another issue that we have is regarding to the “Dredged Material Placement Areas”, because these are exactly above both pipelines. PB ESS will need maintenance access to the pipelines. If the depth of these spoil areas is significant then we may have issues with spoil placement. Attached to this document are pictures showing the approximate location of the pipelines. We are supplying the GPS coordinates in the Vicinity of the river. If possible we would like to avoid these areas above the pipelines.

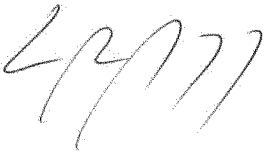

5

PB ESS is would be happy to review all information related to these pipelines with your engineers. We look forward to working with the Corp of Engineers in order to support this operation, with as little impact as possible to existing structures.

6

All technical questions should be directed to Mr. Masao Mayorga (mayorgam@pbworld.com) or Mr. Chuck Fontenot (fontenot@pbworld.com)

RESPONSE TO COMMENTS

Comment No.	Response
1	Thank you for providing this information.
2	Comment noted.
3	The USACE Galveston District guidance for DEEP DRAFT CHANNELS DISTRICT POLICIES AND PRACTICES can be found at http://www.swg.usace.army.mil/items/hgnc/#MEMO . The "primary guidelines" refer to the "normal level of bottom of river", "natural bottom" and this is not equivalent to the authorized depth of the federal channel.
4	Please refer to USACE response to Comment 3.
5	Maintenance access will be provided upon request. The individual circumstances of each pipeline will be evaluated by USACE in consultation with the non-Federal sponsor and the pipeline owner during the PED and Construction phases, and your concerns will be addressed at that time.
6	USACE met with pipeline owners at an information meeting on January 25, 2011. More information on project features that could affect pipelines will be provided as detailed plans are developed during PED and Construction phases.

RE: Draft Environmental Impact Statement (DEIS) for Sabine-Neches Waterway
Channel Improvement Project Southeast Texas and Southwest Louisiana
(SNWW)

Dear Ms. Stokes:

This letter of objection is written on behalf of Doré Energy Corporation (DEC), a landowner in Cameron Parish, LA. DEC owns an 18,611-ac tract, known as Cameron Meadows, which is comprised of coastal marsh that abuts the south side of the Sabine National Wildlife Refuge.

As we understand, the existing channel SNWW is currently 40-ft deep and the project calls for it to be extended into the gulf, widened, and deepened to 48 ft. A projected 98 M cu yds of material would be dredged during project construction with a maintenance requirement of 650 M cu yds that would be dredged over the following 50 years. The cited need for the project is attributed to current SNWW depth/channel configurations and ship congestion that impede shipments of crude oil in larger ships to existing oil refineries and petrochemical related facilities.

We believe that the SNWW is very comparable to the Mississippi River Gulf Outlet (MRGO), located in St. Bernard Parish, Louisiana. The MRGO has now been de-authorized by the U. S. Congress and a rock dam placed across the channel near its seaward end and a surge structure across its upper end at a cost in excess of one billion dollars. A Congressional authorized study is currently underway by the USACE, New Orleans District, to develop a plan for mitigation of environmental damages resulting from the MRGO. Estimates for implementing the environmental plan are between 1.5 and 2B dollars. Have similar costs been factored into the SNWW?

A report, prepared by the USACE, New Orleans District, entitled *Habitat Impacts of the Construction of the MRGO* (December, 1999), states that the 76-mile, waterway was dredged to its authorized 500-ft width and 35-ft depth by 1965. The USACE, New Orleans District, state on pg 1 of the report that “(c)onstruction of the MRGO and subsequent erosion has caused extensive loss of land in St. Bernard Parish”. Authors of the report calculated that thousands of wetland acres were lost as the result of the MRGO not only in St. Bernard Parish, but in *all* of the parishes that surround Lake Pontchartrain. Did the USACE, Galveston District, review and evaluate *Habitat Impacts of the Construction of the MRGO*? Does the USACE, Galveston District, know that navigation channels are a primary cause for coastal wetland loss and degradation in Louisiana? If so, why was a discussion on same not included in the DEIS?

The numbers of movements of ships in the DEIS are only provided by the SNWW percentage of nationwide totals. What is the numerical summary of the number of existing and projected shipments with and without the project? What is the numerical breakdown on types of vessels (including lengths, widths, drafts) documented as historically using the SNWW historically as well as the present time? What is the current frequency of marine movements by type of vessel? Where is the data that documents delays, accidents, near-misses, etc.? Where is data that identifies and documents specific areas of congestion along the SNWW that could be possibly "fixed" as a reasonable partial alternative to the preferred action? The need to bring crude oil shipments to refineries with 45-ft draft, vessels should be justified by a realistic and defensible projection of movements.

Several alternatives included the use of, or similarities to, the Louisiana Offshore Oil Port. The DEIS concludes that local interests along the existing SNWW do not want to invest their own resources into a solution that would not adversely affect Louisiana's wetland resources. Business interests would rather have the channel improved at the public and Louisiana's expense. Why would the USACE, Galveston District, not take a more in-depth look at the alternatives reviewed in the DEIS and attempt to identify new alternatives that would not adversely affect Louisiana? For instance, an authority or consortium of users could be formed that could investigate the feasibility of developing a partnered public and private funded offshore oil port or lightering system for large tankers.

The State of Texas would obviously benefit from the SNWW project; but how would the State of Louisiana benefit?

The DEIS states that the deepening and widening of the SNWW channel will increase the amplitude and salinities of incoming tides, shorten durations of freshwater retention, and increase overall water levels in the DEIS study area. These changes in environmental conditions will significantly affect wetlands and wetland productivity on the Cameron Meadows tract. The DEIS includes some breadcrumb mitigation offerings in Louisiana in the form of several relatively small wetland restoration projects at the Sabine National Wildlife Refuge and private lands, located north of the refuge. Why has no mitigation been proposed at Cameron Meadows? How does the USACE, Galveston District, plan to mitigate or compensate for the project's adverse, long-term cumulative impacts at Cameron Meadows and other wetland areas in Cameron Parish?

Thank you for the opportunity to make these comments.

Sincerely yours,

Sherwood M. Gagliano, Ph.D.
Chief Executive Officer

 Baton Rouge, LA 70802

RESPONSE TO COMMENTS

Comment No.	Response
1	Costs cited in the comment are specific to the Mississippi River-Gulf Outlet (MRGO) project and cannot be extrapolated directly to the proposed SNWW CIP. The cost to mitigate unavoidable environmental impacts have been included in the project cost estimate.
2	Galveston District is aware of the referenced document. The fact that navigation channels are one of the causes of coastal wetland loss in Louisiana is acknowledged in the FEIS (see Sections 1.4.2, 3.5, 3.9.4, 4.6 and 4.10) and this is reflected by the proposed mitigation plan for the project.
3	Requested information is presented in FR Chapter 5, and DFR Appendix 2. The DFR and DEIS are designed to complement one another, and both were provided for public review. The economic analysis presented in FR section V.F establishes that there would be a net economic benefit to the United States from the proposed project.
4	Non-structural alternatives, including new offshore ports like Louisiana Offshore Oil Port (LOOP) are thoroughly analyzed and presented in FR Chapter IV.D.
5	The proposed SNWW CIP is a Federal Civil Works project, and as such, it would provide benefits to the Nation, not just one state. The economic analysis presented in FR section V.F establishes that there would be a net economic benefit to the United States from the proposed project. Direct and indirect economic benefits of the proposed deepening will accrue to all users of the SNWW, including the energy industries, and to the regional economy.
6	It appears that Cameron Meadows is located within LA-9, the East Johnsons Bayou hydro-unit. FEIS Chapter 4 fully evaluates potential impacts from the SNWW CIP to this unit. As noted in FEIS Section 4.6.2, the proposed project would result in a minimal increase in water surface elevation (averaging less than an inch), a slight increase the amount of tidal exchange, and a slight increase in the conveyance of inflows to the Gulf. All of these effects are minimal.
7	The proposed mitigation replaces estimated land loss with more than four times the amount of marsh projected to be lost, providing more than adequate mitigation for the full range of possible impacts. The ICT, which includes several Louisiana resource agencies, selected all of the mitigation areas included in the mitigation screening. This screening process and the incremental cost analysis are described in FEIS Section 5.4. The proposed mitigation measures are located in the hydro-units with the highest predicted impacts.
8	As demonstrated in FEIS Section 4.16, the proposed SNWW CIP would not contribute to cumulative impacts in the study area because all impacts of the proposed SNWW CIP would be fully offset by compensatory mitigation measures, and the proposed project would have net beneficial effects on wetlands, water quality and SAV due to the extensive BU feature on the Neches River and the Gulf Shore BU feature.

RE: Comments to the Draft Environmental Impact Statement for the Sabine-Neches Waterway Channel Improvement Project

Dear Ms. Stokes:

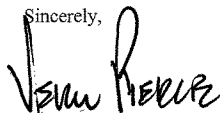

On behalf of Entergy Texas, Inc. ("ETI"), an investor-owned electric utility operating in Southeast Texas, I appreciate the opportunity to submit comments to the U.S. Army Corps of Engineers' Draft Environmental Impact Statement for the Sabine-Neches Waterway Channel Improvement Project ("Project").

After reviewing the information provided by the U.S. Army Corps of Engineers in its December 18, 2009 mailing, ETI became concerned that property owned by ETI had been identified as a "beneficial use" area and that dredge spoils could be deposited on this ETI-owned property. The property at issue is identified by the Corps as the Old River Cove area in the Corps' Figure VI-7, also noted as TX6-1a on Drawing No. C-25. Upon further review, ETI determined that most, if not all, of the Old River Cove area is owned by ETI and is subject to a public hunting license agreement between ETI (through its predecessor, Gulf States Utilities Company) and Texas Parks and Wildlife Department.

ETI has not yet fully investigated the potential impact that the placement of dredge spoils on this property may pose to ETI or the Texas Parks and Wildlife Department. However, with the close proximity of the Old River Cove area to ETI's Sabine Generating Plant (which lies immediately north of the Old River Cove area) and its associated intake and outfall canals, additional review and investigation as to the potential impact to the plant's operations must be evaluated. Due to the critical nature of Sabine Generating Plant's electric generation operations to the ETI system, any potential impact on the plant's operations must be reviewed and considered very carefully. ETI's concern exists irrespective of whether dredge spoils are placed on the ETI-owned property or placed on property not owned by ETI but within the vicinity of the ETI intake and outfall canals. Additionally, while not impacted by the proposed beneficial use of the Old River Cove area, ETI transmission facilities and gas pipeline facilities also may be impacted by the Project.

ETI appreciates being invited to participate in the comment process, and we look forward gathering more information as this Project progresses. If you have any questions or would like to discuss this matter further, please feel free to contact Kelly Cupero at (409) 981-2790 or Fred Manhart at (281) 297-3304.

Sincerely,

VP/th

Mr. Vernon Pierce
Director of Customer Service
Entergy Texas
P.O. Box 2951
Beaumont, TX 77704

RESPONSE TO COMMENTS

Comment No.	Response
1	Thank you for this information. Maps in the FR and FEIS will be revised to accurately reflect ownership of this tract. The tract in question is the location of a proposed BU feature (Old River Cove, TX 6-1).
2	USACE would work with Entergy during the PED and/or Construction phase to develop a detailed design plan that does not impact Entergy's intake and outfall canals, or impact plant operations during construction.
3	USACE would work with Entergy during the PED and/or Construction phase to develop a detailed design plan that does not impact Entergy's transmission facilities and gas pipelines.

Golden Triangle Audubon Society

Re: Sabine-Neches Waterway Channel Improvement Project

Dear Ms. Stokes:

Please find enclosed Golden Triangle Audubon Society's comments on the draft Environmental Impact Statement.

Yours sincerely,

John A. Whittle
Secretary

**Comments on the Draft EIS for the
Sabine Neches Waterway Channel Improvement**

March 9, 2010

These comments are submitted on behalf of Golden Triangle Audubon Society. Our territory covers Jefferson, Orange and Hardin counties in Texas and a few close-by communities.

Our major concern is that the coastal marshes and wetlands, Sabine Lake, and the wildlife that uses them be protected from the adverse effects of increased salinities and unnatural increased water flows from the Gulf under all conditions both normal and abnormal such as during major hurricanes. We fully understand the beneficial function of coastal marshes in attenuating the inflow of water from tropical storms and hurricanes, but equally understand that they will not do this if they are already degraded at the time of the event. This requires that salinity levels not be allowed to increase and existing channels not be exposed to increased exchange with Gulf salt water.

The first issue that we would raise is one of alternatives. The only alternatives to "No action" that are comprehensively addressed are those in which the only difference is in the depth to which it is proposed to dredge the channel. These are, in the larger picture, only relatively small changes in one major alternative. We believe that NEPA and common sense require a broader approach to the issues, so that an outcome that solves the problem and that is the best possible from an environmental perspective can be selected.

The first obvious alternative, briefly discussed in the draft document, involves an offshore oil terminal after the manner of the Louisiana Offshore Oil Port or LOOP. This has been successful, has involved only vanishingly small environmental impacts during construction and operation, and has survived two or three major hurricanes without environmental damage, being restored to full commercial operation in remarkably short times after such events. Such a port could be located so as to be capable of accommodating the Very Large Crude Carriers of today – LOOP is reported to be the only port in the nation so capable at present – while the proposed increase in the depth of the channels in the Sabine Neches Waterway System will only have a comparatively small effect on the capacity of tankers that can be accommodated. This alternative is dismissed in the draft document with minimal discussion, apparently in part because the proponents of such a port have not yet coalesced into a partnership with the resources and desire to pursue it in the immediate future in a Sabine-Neches related location. However, we do not believe this should prevent it from being a preferred alternative in a NEPA EIS. It is also indicated that such a port would not address the prime objective of increasing the "efficiency" the waterway system, because it would serve only one commodity, namely oil. Yet it is clear that the root cause of any current inefficiency is the number of oil tankers using the waterway system, and that there is no record of significant demonstrated need to use larger draft ships by other users of the waterway. If much of the tanker traffic is removed from the waterway system, the vessel traffic will be cut to a fraction of its current volume, and the "lack of efficiency" will be no more. The oil pipeline industry's environmental safety record is excellent, and we suggest is much better than the oil tanker industry record. Any spills that occur from pipelines are typically localized and do not affect large areas or numbers of people. This would make the "No action" alternative the logical preferred alternative from an environmental perspective in as far as the narrower scope of the current proposal is concerned, because such an oil port would not significantly impact the environment or add any additional risk to the coastal wetlands and communities except to the extent that pipeline construction does, and that would be a project under the jurisdiction of other agencies. An offshore oil port could provide more additional capacity than channel deepening, and would not leave an ongoing environmental impact when, at some time in the next generation, the world reduces its reliance on oil in favor of "renewable" energy sources.

One could also envisage other alternatives that would deepen the channel only as far north as Sabine Pass where tankers could be offloaded into a pipeline system for onward transportation and an alternative that would deepen the Channel only as far north as Port Arthur. Each of these would

We are concerned about what appears to us to be a lack of detailed consideration of the effects on wildlife. There are brief and rather vague descriptions of the birds in the areas to be impacted, taken it seems from broad-brush state and region-wide distribution data, albeit reliable in what it attempts to do. More site specific Christmas Bird Count data, which is available for the area of the proposed Gulf Shore Beneficial Use area, does not seem to have been used, nor is there any detailed discussion of the impacts in the short or long term or of cumulative impacts over time. We would note that, as yet, there is minimal documented input from the biological scientific staff of agencies with lands in the areas of potential impact. LDWF appears, even aside from its parochial concerns, not to be in support of the changes or the proposed mitigation, while US Fish and Wildlife Service appears yet to be heard from officially. We believe the professional opinions of the biologists in these agencies on likely effects on the marshes on either side of the channel near the coast should be solicited and fully considered.

We are concerned about the manner or placement of beneficial use dredge material along the Texas and Louisiana Coasts either side of the Channel from Texas Point westwards and Louisiana Point eastwards. If we understand correctly that the proposal is to deposit dredge material on shore along the current beaches at six year intervals, we believe the effect on wildlife could be very serious. The immediate beach area that is used by a number of wintering shorebird species including Piping Plovers, Whimbrel, Dunlins, and Black-bellied Plovers would be disrupted by the deposits, and would likely have just recovered fully when the next deposit was scheduled. The dredge material cannot be expected to immediately have the crustacean and invertebrate communities needed to provide shorebird food. On the Texas side, schemes that place the material near the jetty so that it is carried by the prevailing westerly currents along the shore in a more natural fashion over time should be planned. Alternatively, the material should be deposited a short distance offshore to be carried gradually on shore. There is also a need to monitor the dredge material to ensure that it does not contain any heavy metals or other contaminants.

There is an apparent absence of adequate consideration of potential storm and hurricane effects if the preferred alternative is implemented. This area remembers all too well the effects of recent hurricanes, Hurricane Ike in particular, and there is much evidence from the New Orleans area of the adverse consequences of the Mississippi River Gulf Outlet (MRGO) during Hurricane Katrina. It is worth comparing the MRGO with the current and proposed Sabine-Neches Waterway (SNWW) channels. The MRGO was 76 miles long (somewhat longer than the SNWW), only 36 feet deep (less than the current SNWW channels) and 500 feet wide (very roughly the same as the current average SNWW width). In response to local pressure and increasing evidence that the MRGO significantly contributed to the disaster in New Orleans during Hurricane Katrina, the MRGO was closed in July 2009. On November 18, 2009, the US District Court for the Eastern District of Louisiana found that the Corps was responsible for damages to many plaintiffs because, among other things, the original EIS was arbitrary and capricious, and because the Corps failed to protect the environment (mostly marsh) surrounding the MRGO. The most scientifically valid modeling suggests that the existence of the MRGO intensified the storm surge in Katrina by 20 percent, raised the wall of water 3 feet and increased the velocity of the surge from 3 ft/sec to 8 ft/sec. While that

modeling compared the existing MRGO versus no MRGO, and there are existing channels in the Sabine Neches system, there is no reason not to believe that increasing the depth of the channels would allow more wind driven storm surge into Sabine Lake and Bridge City and the Sabine River into Orange, and increased and possibly significant storm surge up the Neches through Port Neches to Beaumont and the salt water barrier, and up all the various bayous such as Taylor Bayou and Hillebrandt Bayou. The magnitude of such an increase will be difficult to predict accurately, but the effect will be there, and any increase in storm surge carries with it the inevitability of greater areas and areas further from the lakes, channels, rivers and bayous being impacted by waters driven by the storm surge. In a storm of the magnitude of Hurricane Ike, it is inevitable that near the coast, the storm surge will cover all the land. However, deeper channels reaching inland will be capable of carrying larger volumes of water for longer periods even before the storm surge has covered any land, and consequently, more water will be driven by the winds up these channels by the south winds on the east sides of storms. To conclude that such effects will be minimal is wishful thinking in the light of the MRGO experience in Katrina. In such a storm or hurricane event, some of the marshes adjacent to the Channel would receive a greater surge, would be able to absorb a lower fraction of the storm surge, would be damaged by salt water to a greater extent, and would therefore take much longer to recover. The cumulative effects of additional salt water exchanges would likely degrade more marsh, much as has happened south of New Orleans and all along the Louisiana coast. In short, the proposed increase in the channel depth will significantly increase the impact on the environment and the damage to communities in any future hurricane storm surge.

RESPONSE TO COMMENTS

Comment No.	Response
1	The FEIS thoroughly presents potential impacts associated with channel deepening (see particularly FEIS Sections 1.4.2, 3.5, 3.9.4, 4.6 and 4.10). A sensitivity analysis using the ADCIRC model was performed to determine what effect the proposed SNWW CIP might have on surge levels in the study area (Wamsley et al., 2010). The results of this analysis are presented in FR Chapter VIII, FEIS Section 4.1.5. All impacts of the proposed SNWW CIP would be fully offset by compensatory mitigation measures, and the proposed project would have net beneficial effects on wetlands, water quality and SAV due to the extensive BU feature on the Neches River and the Gulf Shore BU feature.
2	The No Action and 3 Non-Structural alternatives are thoroughly analyzed and presented in FEIS Section 2.2 and FR Chapter IV.D.
3	USACE disagrees with the assertion that and offshore oil port is dismissed with minimal discussion. FEIS Section 2.2.2.3 presents the results of an in-depth economic analysis in an extensive discussion of this alternative.
4	The DFR and DEIS are designed to complement one another, and both were provided for public review. The economic analysis presented in FR Chapter 5, and FR Appendix 2, describes significant benefits from the proposed channel deepening for refined petrochemical products, LNG, and dry bulk products, in addition to crude oil. The analysis acknowledges that an expansion of LOOP or construction of a similar facility in Texas would reduce the vessel traffic on the Neches River, and this would reduce (but not eliminate) the economic viability of the proposed SNWW CIP.
5	Past and present trends in infrastructure and fleet investments indicate that industry intends to continue using the Neches River Channel. An increase in the number of specially designed SNWW vessels was recently completed by one company, and another has invested in Neches River dock modifications for larger vessels. Significant facilities located on the Neches River Channel continue to be a focus of industry investment. Alternatives such as an unloading terminal along the Sabine Pass or Port Arthur Canal are discussed in FR Chapter IV (Non-Structural Alternatives-Alternative Mode of Commodity Transport) but would not address the needs of these users.
6	FEIS Sections 3.1.3 and 4.1.4 described the WVA community model, an ecological model that was used to assess and quantify impacts to fish and wildlife and their habitats. FEIS Appendix C, Section 2.6, describes all of the fish and wildlife species that were considered in developing the WVA model. Use of this model ensured appropriate consideration of the proposed project's effects on wildlife.
7	As demonstrated in FEIS Section 4.16 (Cumulative Impacts), the proposed SNWW CIP would not contribute to cumulative impacts in the study area because all impacts of the proposed SNWW CIP would be fully offset by compensatory mitigation, and the proposed project would have net beneficial effects on wetlands, water quality and SAV due to the extensive BU feature on the Neches River and the Gulf Shore BU feature.
8	FEIS Section 1.6 describes the ICT which is comprised of thirteen resource agencies from Texas, Louisiana and the Federal government. All of these agencies were involved throughout the study in determining what environmental studies needed to be done,

	reviewing study results, and screening and approving BU features and mitigation measures. The FEIS is explicit about the extensive involvement of all of these agencies in plan development. The resource agencies prepared their formal comments during the public comment period, and they are included in the FEIS, Appendix A. U.S. Fish and Wildlife Service (USFWS), which submitted its comments in the Coordination Act Report, agrees with the predicted project impacts, and proposed BU features and mitigation measures. U.S. Environmental Protection Agency (EPA), National Marine Fisheries Service (NMFS), and the Texas Parks and Wildlife Department (TPWD) have also expressed approval of impact assessments, and BU and mitigation measures.
9	Potential impacts to shorebirds and the wintering Piping plover are presented in FEIS Section 4.12.2, 4.13.2, 7.6, and Appendix G. The USFWS has concurred that the Gulf Shore BU feature is not likely to adversely affect the Piping plover or its critical habitat. Effects on other wading shorebirds are expected to be similar.
10	FEIS section 2.5.3.2.2 (Gulf Shore BU Feature) contains an in-depth evaluation of the anticipated effects of regular shoreline nourishment at Texas and Louisiana points using maintenance material from Sabine Pass. The mobile material within the surf zone should generally migrate to the west at both Texas and Louisiana points. The additional fine-grained sediments could lower erosion rates in Texas through mudflat accretion and wave attenuation. If material was placed closer to the west jetty, it would likely migrate to the east, contributing to the Sabine fillet, rather than being carried further westward.
11	FEIS Sections 3.3, 3.4, 4.4 and 4.5 summarize water and sediment quality in the study area. Sampling will be performed by USACE as part of its maintenance dredging program.
12	Information presented relative to the MRGO project cannot be extrapolated directly to the proposed SNWW CIP. USACE has performed a suite of studies and modeling specifically for this project area, the results of which support the environmental impacts and proposed mitigation presented in the FEIS. A sensitivity analysis using the ADCIRC model was performed to determine what effect the proposed SNWW CIP might have on surge levels in the study area (Wamsley et al., 2010). The results of this analysis are presented in FR Chapter VIII, FEIS Section 4.1.5. All impacts of the proposed SNWW CIP would be fully offset by compensatory mitigation measures, and the proposed project would have net beneficial effects on wetlands, water quality and SAV due to the extensive BU feature on the Neches River and the Gulf Shore BU feature.

COMMENTS ON THE DRAFT EIS FOR THE
SABINE NECHES WATERWAY IMPROVEMENT PROJECT

These comments are submitted on behalf of the Golden Triangle chapter of the Sierra Club. Our chapter includes members from Jefferson, Hardin, Orange and Chambers Counties.

We have four issues to raise with respect to the draft EIS for the Sabine-Neches Waterway channel Improvement project. These are:

- (1) Inadequate assessment of the potential for continued degradation of critical marshland in the vicinity of a further channelized Sabine Neches waterway. The subsequent impact on residential communities and industry from potential further loss of these wetlands is not fully addressed in the EIS. 1
- (2) Failure to consider the impact of dredge material disposal on wildlife and appropriateness of this material for beach replenishment to enhance desirability of local beaches for human use. 2
- (3) No assessment of alternative concepts to satisfy the needs of the current waterway users with respect to offloading oil, which appears to be the primary driver for a deeper channel. 3
- (4) Lack of documented input from USFWS and TPWD on impact of additional channelization on adjacent marshes, fishery nursery areas, and on wildlife in the several WMAs and NWRs located adjacent to the waterway and encompassed by the proposed project. 4

These issues are elaborated further in the following remarks.

- (1) Deepening the channel may well add significantly to the total volume of constricted water susceptible to being wind driven in a storm surge. It is now well understood what happens to a constricted waterway when a hurricane moves up a channel as was the case during Katrina in New Orleans. The Mississippi River Gulf Outlet, somewhat similar to the Sabine waterway, and built by the Corps, was found to contribute significantly to the New Orleans disaster. Indeed, the U.S. District Court for the Eastern District of Louisiana found that the Corps was responsible for much damage to plaintiffs because, in part, of an arbitrary and capricious EIS and a failure on the part of the Corps to protect the marshes in the vicinity of the river outlet.

The initial Sabine Waterway construction has contributed significantly to marsh degradation over most of the 20th century but in recent years through massive and costly efforts by state and local officials, stabilization of marshlands in the vicinity of the waterway has been somewhat achieved. Hurricane Ike demonstrated the need for adequate marsh lands to absorb storm surge.

In light of these recent disasters, the finding by the US. District court and coupled with knowledge of the impact of the Sabine waterway, as it currently

exists, on surrounding marshland leads us to conclude that a risk-benefits analysis of further channelization should be undertaken. Input from hurricane and disaster specialists, biologists, ecologists and community leaders are required before such a project is undertaken. We believe that such a study may well show that the risks to the larger community of proceeding with this project may far outweigh the perceived financial benefit to one small segment of the population.

- (2) Every dredging project requires spoils disposal and this project will generate significant spoils for disposal. The upper Texas coast has much experience with dredging for beach replenishment from dredging Rollover Bay for Bolivar beaches to offshore Galveston area dredging to replenish beaches to support a dynamic tourist trade on Galveston Island. Geologists and ecologists have learned that only certain types of dredge material will suffice for beach replenishment. There is no evidence whatsoever from the EIS that the dredge material from Sabine Neches is suitable for beach replenishment to sustain beach wildlife or to create an aesthetically pleasing environment for human use. In fact, the proposal to dump some of the spoils along the Texas and Louisiana beaches seems more along the lines of the mindset of the 19th century when the beach was the dumping ground for all manner of waste. We believe a careful scientific assessment of the material from such a dredge project should be undertaken with a view that all possibilities need be considered with respect to what to do with the dredge material. This might consist of construction of birding islands in Sabine Lake, such as those built in Galveston Bay following dredging of the Houston ship channel or other such uses as might be deemed appropriate. The arbitrary decision to dump spoils at Texas Point may well have disastrous impact of shore bird populations and the viability of the Texas Point National Wildlife Refuge.
- (3) The project goal is to increase the efficiency of the waterway yet alternatives to the proposed project have been only cursorily considered. For example, construction of an offshore oil port would remove most of the tanker traffic from the Sabine waterway and significantly improve its efficiency. This is a viable and proven alternative as has been demonstrated with the Louisiana Offshore Oil facility. It benefits from minimal environmental impact, is easy to expand as tankers increase in size and is done without cost to the taxpayer. Oil transport from the port via pipeline is safe and much more environmentally friendly than moving large tankers through narrow constricted waterways. The recent oil spill due to collision in the narrow Sabine waterway attests to this fact as a near environmental disaster akin to the Exxon –Valdez spill was only narrowly averted by the heroic actions of Coast Guard, state and local officials.
- (4) The upper Texas coast and the La coastal areas are among the richest fishing grounds in the world and supply nearly half of the seafood across the U.S. These fisheries are dependent on a healthy marsh system as nursery grounds. Increasing salinities endanger these fishing grounds and hence endanger a significant food supply across the U.S. We believe it is imperative that input from USFWS and TPWD be aggressively sought and considered before a project that could

substantially impact Texas and La commercial and recreational fishery is undertaken. Further, three federal NWR and three state WMA are encompassed by this project. These refuges were acquired at great public expense to protect and nurture wildlife. We find little or no comment in the EIS on the impact this project will have on these sensitive set-aside areas. Finally, we noted that the National Marine Fishery Agency has expressed grave concerns about the potential for damage to marsh, Sabine lake fishery nursery areas and indeed damage to the entire lower Sabine-Neches watershed . (page 698 of EIS draft under Public comments). We find their assessment most alarming.

Lastly, we have reviewed the many public comments appended to the EIS and find recommendations cited in three of these documents as particularly compelling for follow through. We believe each of the 244 recommendations proposed by the Stream Properties Management Group, Inc. (Lake Charles, La) in the public comments (pages 739-754) should be carefully evaluated and discussed individually in the EIS; we recommend the technical analysis proposed by TPWD (page 709) be implemented; and we concur with the recommendations proposed by the Louisiana Sierra Club (page 786).

We also request you elaborate further on the adverse environmental impact and unavoidable consequences of the dredge disposal plan documented by your consulting group on page 870 of the draft EIS.

RESPONSE TO COMMENTS

Comment No.	Response
1	Potential impacts of the proposed SNWW CIP to marsh in the study are thoroughly analyzed in the FEIS (see Sections 1.4.2, 3.5, 3.9.4, 4.6 and 4.10). All impacts of the proposed SNWW CIP would be fully offset by compensatory mitigation measures, and the proposed project would have net beneficial effects on wetlands, water quality and SAV due to the extensive BU feature on the Neches River and the Gulf Shore BU feature. USACE has performed a suite of studies and modeling specifically for this project area, the results of which support the environmental impacts and proposed mitigation presented in the FEIS. A sensitivity analysis using the ADCIRC model was performed to determine what effect the proposed SNWW CIP might have on surge levels in the study area (Wamsley et al., 2010). The results of this analysis are presented in FR Chapter VIII, FEIS Section 4.1.5.
2	FEIS section 2.5.3.2.2 (Gulf Shore BU Feature) contains an in-depth evaluation of the anticipated effects of regular shoreline nourishment at Texas and Louisiana points using maintenance material from Sabine Pass. Potential impacts to shorebirds and the wintering Piping plover are presented in FEIS Section 4.12.2, 4.13.2, 7.6, and Appendix G. The USFWS has concurred that the Gulf Shore BU feature is not likely to adversely affect the Piping plover or its critical habitat. The proposed Gulf Shore BU feature is supported by USFWS, NMFS, TPWD and the Texas Point National Wildlife Refuge.
3	The DFR and DEIS are designed to complement one another, and both were provided for public review. The economic analysis presented in FR Chapter 5, and FR Appendix 2, describes significant benefits from channel deepening for refined petrochemical products, LNG, and dry bulk products, in addition to crude oil. The analysis acknowledges that an expansion of LOOP or construction of a similar facility in Texas would reduce the vessel traffic on the Neches River, and this would reduce (but not eliminate) the economic viability of the proposed SNWW CIP.
4	FEIS Section 1.6 describes the ICT which is comprised of thirteen resource agencies from Texas, Louisiana and the Federal government and includes representatives from NWRs and WMAs in the study area. All of these agencies were involved throughout the study in determining what studies needed to be done, reviewing study results, and screening and approving BU features and mitigation measures. The FEIS is explicit about the extensive involvement of all of these agencies in plan development. The resource agencies prepared their formal comments during the public comment period, and they are included in the FEIS, Appendix A. USFWS, which submitted its comments in the Coordination Act Report, agrees with the predicted project impacts, and proposed BU features and mitigation measures. EPA, NMFS, and TPWD have also expressed approval of impact assessments, and BU and mitigation measures.

E-Mail: janelle.s.stokes@usace.army.mil

Re: Targa Resources, Inc.
Sabine-Neches Waterway Project and Study

Dear Ms. Stokes:

On behalf of Targa Midstream Services Limited Partnership, we are submitting comments concerning the Draft Feasibility Report (DFR) and the Draft Environmental Impact Statement (DEIS) concerning the above referenced project. Prior to the release of the DFR on December 24, 2009, there was no prior communication by the sponsor of the proposed project with Targa regarding potential pipeline relocation issues or the project in general. The DFR that was made available in December describes a large number of pipelines which carry a variety of products whose relocations will be required by the project. At least two of those pipelines identified in the project are owned by Targa Midstream Services Limited Partnership (successor to Dynegy Midstream Services Limited Partnership). Our review of the DFR and DEIS prompts Targa to submit the following comments for your consideration:

1. There appears to be inadequate evaluation of the costs associated with relocation of the pipelines at issue.

The DFR and DEIS indicate that 42 pipelines will require relocation and 6 abandoned pipelines will require removal. (Review of documents provided by the Corps suggests that number may be as high as 50 pipelines.) While there is a recognition in the DFR and DEIS that 50% of the costs would be borne by the non-federal sponsor, it is also suggested that the remaining 50% would be borne by pipeline owners. The DFR does not provide any confirmation by the sponsoring entity (Sabine Neches Navigation District) that it has the financial wherewithal to be responsible for the 50% stated by the Corps. More importantly, there is no detailed discussion within the DFR or DEIS which indicates the true anticipated costs of these proposed relocations. Targa's pipelines are in open water and many different considerations must be taken into account than for lines that are onshore. Not only is timing an important consideration as to when an offshore pipeline can be relocated or abandoned, plans to decommission and relocate/abandon a pipeline must also have other federal agency approval. As the Corps is aware, the Department of Interior – Mineral Management Services ("MMS") determines how pipelines in the Gulf are to be relocated or abandoned. Performing a relocation or removal of a

pipeline would require at the very least: retention of barge(s) to provide divers to survey the area and confirm the location and depth of Targa's line(s) in the Outer Continental Shelf; provision of protocols that ensure all applicable environmental standards and requirements are incorporated into the relocation/abandonment; shut in of gas from the producers on the pipeline; flushing and pigging the pipeline; exposing the line; 'jetting' the line to lower it; cutting and capping in order to remove a portion of the line for the required depth; installation of the required length of pipe once the fairway has been jetted to the required depth; covering of the line; hydrotesting and pigging the line for water removal; and purging and filling the line with gas prior to operation. It has been the experience of Targa that even simply capping and abandoning a pipeline can cost multiple millions of dollars. The above costs for such a forty year old line could range from \$5 to \$10 million or more.

Likewise, there is no discussion in the DFR or DEIS as to the mechanism by which the pipeline owners will be compelled to pay 50% of the costs. What is the Corps timetable for its recommendation of funding of the project by the Sabine Neches Navigation District (the "District")? It should be noted that a number of the pipelines were placed pursuant to permits which may not have included such requirements. Thus, the ultimate cost of relocation of those pipelines may be the subject of expropriation litigation; and there is no discussion in the DFR or the DEIS about the costs associated with that type of litigation and/or the results of same. Further, there is no discussion as to whether these potential costs would be included in the 50% reimbursable costs by the District.

2. There is no discussion in the DFR or DEIS concerning scheduling of the proposed relocations.

2

As noted by one previous commentator, the relocation of pipelines requires years of advance planning and coordination and generates significant operational and engineering burdens on the pipeline owners industry in general. Likewise, there are a limited number of pipeline construction companies with limited assets; and there is no discussion in the DFR or DEIS about the availability of equipment and engineering expertise to plan and coordinate the pipeline relocations and no discussion on the impact on the Nation as a whole of this massive disruption of current pipeline capacity.

3. There is no discussion in the DFR or DEIS regarding the impact on wells serviced by the pipelines or customers served by the pipelines.

3

There is no doubt that, when a pipeline is to be relocated, the wells serviced by that pipeline must be shut in and the lines purged. In such an instance, a number of those wells will not return to production; and there is no discussion in the DFR or DEIS regarding the number of such wells and the impact (both with regard to well owners and the American economy in general) resulting therefrom. In addition, there is no discussion as to the potential expropriation and/or damage litigation which may result from the loss of such wells. Further, as the Corps is aware, all production leases currently in the outer continental shelf are leased from the Mineral Management Services. There is no discussion as to how the interruption in production will impact on these individual producers and/or the MMS (for the benefit of the public) who has royalty interest in these wells. More importantly, there is no discussion as to the impact non-production of the wells will have on any termination provisions in these MMS leases.

In addition, the impacted pipelines provide a substantial portion of the energy supplies to both residential customers and industrial/power plant customers. The timing of the relocations and the coordination of such efforts is needed to reduce the impact on those customers of suddenly losing their supplies when the pipelines are taken out of service so that they can be relocated. Targa believes this issue has not been adequately addressed nor does there seem to be a plan in place to mitigate the harm

to customers, whether those are customers who depend on natural gas for household use or depend on the feedstock and fuel to keep industrial facilities and electric generation plants running.

4. There is no discussion in the DFR or DEIS regarding the potential environmental impacts associated with relocating 42 pipelines 4

As noted above, the relocation of a pipeline will require significant planning and creates an environmental risk of releases during relocation activities. The documents provided by the USACE indicate that the pipelines carry a variety of products including natural gas, ethylene, oxygen, nitrogen, butadiene, hydrogen, ethanes, and refined products; and there is no discussion in the DFR or DEIS regarding the potential environmental impacts associated with a release of such products during relocation activities. As to relocation of pipelines in the Outer Continental Shelf, there are regulations relating to searching for any possible obstructions, historic relics, environmental contaminants, etc., and there is no discussion regarding the magnitude of such potential hazards or the costs of avoiding same. In addition, the physical act of relocating pipelines causes disruptions to the seabed; and there is no discussion in the DFR or DEIS regarding potential environmental impacts associated with this significant amount of offshore construction.

5. There is no discussion in the DFR or DEIS regarding potential alternative channel extensions. 5

Neither the DRF or DEIS discusses alternative channel extension locations and there is no discussion whether any such alternatives would reduce the negative impacts discussed above. There does not appear to have been any analysis done as to alternative locations for the placement of spoil or different angles of approach for the channel extension. It would appear that changes in the angle and location of the spoil would eliminate the impact on at least some of the pipelines at issue.

6. There has been inadequate discussion of alternative methods to achieve economic growth in the area in question. 6

Several participants at various public meetings expressed serious concern about the environmental impacts associated with deepening the existing channel and creating a channel extension as discussed in the DFR and DEIS with particular concern to damage to Louisiana's wetlands estuaries and wildlife. Those commentators inquired as to whether comparable economic benefit could be obtained by the construction of an offshore port with a pipeline into the port at issue. Neither the DFR nor the DEIS discuss these comments or appear to consider this alternative.

7. There is no discussion in the DFR or DEIS regarding the potential environmental impacts associated with storm surges resulting from the deepening the channel in relationship to on-shore facilities. 7

While there has been some discussion (minimal at best) in the DFR and/or DEIS about the environmental impact of relocating or abandoning of lines, there is no discussion as to the impact on on-shore facilities from possible storm surges that could result from the deepening of the Sabine Pass, the Sabine Pass Jetty Channel, Sabine Pass Outer Bar Channel and the widening, deepening and extending of the Sabine Bank Channel. The Corps itself acknowledges that the only connection with the Gulf of Mexico is a long narrow pass called the Sabine Pass Benders from deep water in the Gulf through the Entrance Channel, which is divided into the Sabine Bank Channel and the Sabine Pass Outer Bar Channel. Targa has plants no more than twenty five miles from the mouth of the Sabine Pass. As the Corps is acutely aware, the deepening of the waterways in St. Bernard Parish was a cause

of most of the flooding that occurred in New Orleans during Hurricane Katrina in 2005. Indeed, a lawsuit against the Corps after Hurricane Katrina argued that the deepening of the St. Bernard waterway resulted in providing no protection to those persons and property on shore. The DFR and DEIS fail to address any flood protection system for those oil and gas facilities on shore should another Category 3 or greater hurricane come on shore at or near that part of Louisiana and Texas.

Targa believes that the real impact – and the real cost – of the project cannot be estimated with any accuracy until the issues identified have been addressed. Targa would, therefore, request that the Corps not recommend proceeding with requiring the relocation or abandonment of the affected pipelines until the impact, the cost and the reimbursement of costs have been fully addressed and costs obtained with reasonable certainty.

Targa appreciates being given the opportunity to provide these comments and stand ready to provide the Corps with any additional information it may request.

Respectfully submitted,

TARGA MIDSTREAM SERVICES
LIMITED PARTNERSHIP

RESPONSE TO COMMENTS

Comment No.	Response
1	The USACE feasibility study estimate of pipeline relocation costs was developed by USACE to estimate the fully funded cost allocation between USACE and the non-Federal sponsor. The individual circumstances of each pipeline will be evaluated by USACE in consultation with the non-Federal sponsor and the pipeline owner during the PED and Construction phases, and decisions regarding necessary actions will be made individually for each pipeline at that time. FEIS Section 2.4.1.12 presents a discussion of the allocation of pipeline relocation costs between the non-Federal sponsor and pipeline owners.
2	A preliminary construction schedule has been developed (Engineering Appendix Addendum 2009, chapter 14.0 REVISED SCHEDULES FOR DESIGN AND CONSTRUCTION) and is available upon request. However, the actual time table for project construction is uncertain at this time because it is dependent upon ASA and OMB approval of the Chief's Report, Congressional authorization and Congressional appropriation of funds.
3	USACE will provide estimated construction contract start and end dates as soon as they are available, so that owners can schedule their relocations as they see fit, ensuring completion of the relocation prior to the award of the contract for that portion of the channel. USACE will ensure that channel construction contractors work with pipeline companies as needed to accommodate all parties for a safe and effective working plan.
4	Potential environmental impacts of relocating pipelines to a deeper depth are assumed to be minimal. However, each pipeline relocation is case specific, and coordination with USACE-Galveston Regulatory Branch would be required in each case. Relocating a pipeline and placing it deeper would not necessarily require a new permit. If a pipeline is being moved to a new location, then the impacts would be evaluated by the environmental assessment performed in conjunction with the DOA permit.
5	Alternatives to the proposed channel extension are limited due to the bearing of the existing Sabine Bank Channel. Alternatives for offshore placement areas are thoroughly discussed in FEIS, Appendix B.
6	Non-structural alternatives, including new offshore ports like LOOP are thoroughly analyzed and presented in FR Chapter IV.D and FEIS Section 2.2.2.
7	A sensitivity analysis using the ADCIRC model was performed to determine what effect the proposed SNWW CIP might have on surge levels in the study area (Wamsley et al., 2010). The results of this analysis are presented in FR Chapter VIII, FEIS Section 4.1.5.
8	See USACE response to Comment 1. In addition, USACE recognizes that project costs may change as definitive plans for relocations (including utility relocations) are developed. FR Section XIII.D makes provisions for updating the economic evaluation to reflect additional associated costs identified during preparation of contract plans, and for notifying the affected pipeline owners.

COMMENT FORM

Sabine - Neches Waterway Channel Improvement Project

January 27, 2010

USACE - Galveston District

Attn: Ms. Janelle Stokes

P.O. Box 1229

Galveston, Texas 77553-1229

☐ I am a Public Official

Name and Mailing Address (Optional):

Name David Richard
Address P.O. Box 40, Lake Charles, LA 70602
Email Address drichard@streamcompany.com
Phone 337-433-1055 ext. 119

PLEASE CHECK THE APPROPRIATE ITEMS BELOW:

I am primarily interested in the project from the standpoint of a:

☐ Residential property owner or renter ☐ Business property owner or lessee
☐ Other (Please explain) Large Private Wetland Owner adjacent to Sabine Lake & GIWW
How did you learn about this meeting? Lake & GIWW
☐ Newspaper ☐ Notice in the Mail ☒ Email
☐ Other (Please explain) _____

COMMENTS: I do not feel the mitigation requirements meet the changes in hydrology caused by the channel improvements. No plans have been submitted to combat increases in tidal amplitude and salinity in Sabine Lake and the vast marshes that are influenced by these detrimental factors to mitigate the effects. The dredging of the GIWW is not acceptable as a source of dredged material for beneficial use applications as proposed. Erosion on the GIWW eventually is not addressed & the deepening of the GIWW will cause more land loss and endanger a hope pipeline corridor on the South Embankment. The Sabine River will need these beneficial use areas in the future so this option with no land rights is unacceptable.

Please make additional comments on the back.

These comment forms can be turned in tonight, mailed or emailed to the addressee below postmarked by February 10, 2010 to:

RESPONSE TO COMMENTS

Comment No.	Response
1	Given the fact that impacts of the proposed SNWW CIP are related primarily to salinity intrusion, extensive efforts have been made to identify effective mitigation measures that could minimize or eliminate the projected increase in salinity and tidal amplitude. The results of this effort are presented in FEIS Section 5.4.1.1. None of the salinity control structures were selected because the net effect of the structures was determined to be negative. Beneficial salinity effects were modest and could not overcome the adverse effects of restrictions to marine organism access.
2	Engineering design would minimize impacts to the Gulf Intracoastal Waterway (GIWW) shoreline to the greatest extent possible; instability of emergent shorelines is not anticipated because dredging would remove accumulated maintenance material only, as described in FEIS Section 5.5.2. In situ sediments beside and below the existing GIWW channel would not be disturbed. However, should analyses determine that stabilization of small areas is needed, USACE would propose stabilization plans at that time.

Re: Comments regarding DFR/DEIS for proposed Sabine Neches Waterway Channel Improvement Project

Dear Ms. Stokes:

Kinder Morgan affiliates include pipeline companies that have facilities located within the project area of the proposed Sabine Neches Waterway ("SNWW") Channel Improvement Project. Kinder Morgan is diligently performing a review of the proposed project. We have assembled a team comprised of land, legal, environmental, engineering, and operations representatives that is reviewing and analyzing the preliminary project plans and the limited information regarding existing pipeline river crossings in the DFR and DEIS.

By this letter, Kinder Morgan offers its comments on (1) the Draft Environmental Impact Statement for the Sabine-Neches Waterway Channel Improvement Project, Southeast Texas and Southwest Louisiana and the Draft Environmental Impact Statement Sabine-Neches Waterway Channel Improvement Project, Texas Ocean Dredged Material Disposal Sites Designation (collectively, the "DEIS") and (2) the Draft Feasibility Report for the proposed Sabine Neches Waterway Channel Improvement Project (the "DFR"). Your original letter and announcement were silent as to whether comments also were invited on the DFR, but representatives of the Corps of Engineers (the "Corps") subsequently advised that comments also were being accepted on the DFR.

The DFR and DEIS indicate that the proposed project will require a large number of pipeline relocations and removals, including at least six owned by Kinder Morgan affiliates, but Kinder Morgan is unaware of any prior effort to coordinate the project's planning with pipeline owners and operators, even though it is common knowledge that pipelines lace the area impacted by the proposed project. In fact, Kinder Morgan understands that the Corps declined to meet with representatives of the pipeline industry. Kinder Morgan's comments in this letter are intended to be as complete as possible given the lack of important details in the multi-volume DFR or DEIS and the Corps's refusal of the pipeline industry's request for additional

1

Ms. Stokes
 March 12, 2010
 Page 2 of 3

information and a more realistic comment period (120 days from the date of issue on December 24, 2009). Kinder Morgan reserves its rights to comment further upon receipt of additional information about the project.

The replacement of pipelines like Kinder Morgan's, that transport essential commodities such as natural gas and natural gas liquids, is not only costly, it also requires years of advance planning and coordination, and creates significant operational, engineering and environmental permitting burdens. Particularly in congested areas such as the Sabine Neches Waterway, where there are multiple pipelines owned by multiple companies, the relocation of a significant number of pipelines requires a comprehensive and coordinated planning process. Yet the DFR and DEIS provide little detail about the proposed project's impact on pipeline operations, which pipelines will need to be relocated, the depths and locations to which those pipelines will be relocated, how Corps permits for these pipeline relocations would be addressed, or how costs were estimated or projected for pipeline relocations. In fact, the DFR and DEIS appear to be based on a single spreadsheet, *dated September 30, 2005*, with what appears to be the Corps's working list of pipelines that may be impacted by the project. The engineering narrative (chapter 13 of the DFR Appendix) indicates that "relocated lines were assumed to be directionally drilled, and bundled when possible," but no detail is provided that would identify which pipelines were assumed to be bundled, or permit a reader to understand the logic – let alone the accuracy – of the Corps' feasibility and cost assumptions. Nor do the DFR and DEIS reflect any consideration of the lead time and expense required to obtain the permits required for the pipeline relocations, *e.g.*, environmental studies, environmental surveys, agency reviews and evaluations.

Finally, Kinder Morgan asks that the Corps reject the ongoing behind-the-scenes effort to circumvent the long-established federal law for 50/50 cost-sharing on pipeline relocations in deep-draft projects and declare its opposition to any change in the cost-sharing allocation. The SNWW project proposed by the Corps and the local sponsor has an authorized depth of 48 feet and so clearly constitutes a deep-draft project. Federal law (the Water Resources and Development Act of 1986, known as "WRDA 86") mandates that in all deep-draft projects, the costs of utility (pipelines) relocations must be DIVIDED EQUALLY between the pipeline owner and the local sponsor of the project. The Corps acknowledges this federal legal requirement in the "Cost Sharing" section of the DFR: "In accordance with Section 101(a)(4) of WRDA 86, 50 percent of deep-draft utility (pipeline) relocations would be borne by the utility owner and 50 percent would be borne by the non-Federal sponsor," *i.e.*, the Sabine Neches Navigation District (page XI-5). The campaign to sidestep WRDA 86 and shift costs to private industry ignores the fact that pipeline operations will not benefit from the project and will be forced, even under the 50/50 formula, to incur substantial out-of-pocket costs and relocation-related service interruptions.

Kinder Morgan respectfully requests that the Corps promptly:

1. definitively identify the Kinder Morgan pipelines that will be impacted by the project;
2. provide Kinder Morgan sufficient information to understand the Corps' estimate of the costs for removing or relocating each such pipeline;

Ms. Stokes
March 12, 2010
Page 3 of 3

3. provide Kinder Morgan with whatever additional documents or information are needed to understand the proposed project's impact on Kinder Morgan pipeline operations, including a projected timeline for when the relocations may actually be needed and how Corps permits would be addressed;
4. establish a working group or other appropriate method to bring the Corps and pipeline company representatives together to facilitate an information exchange; and
5. confirm that the cost-sharing requirement specified by WRDA 86 will be part of any Chief's Report or other report or recommendation the Corps makes regarding the project.

At your convenience, please contact me at the below telephone number.

Sincerely,

RESPONSE TO COMMENTS

Comment No.	Response
1	The comment period on the DFR and DEIS was extended an additional 30 days to March 12, 2010. USACE met with pipeline owners at an information meeting on January 25, 2011. More information on project features that could affect pipelines will be provided as detailed plans are developed during PED and Construction phases.
2	The FR provides sufficient information for feasibility-level planning. A list of potentially affected pipelines was provided to pipeline companies during the DEIS public comment period. The USACE list of potentially affected pipelines should not be considered definitive. The individual circumstances of each pipeline will be evaluated by USACE in consultation with the non-Federal sponsor and the pipeline owner during the PED and Construction phases, and decisions regarding necessary actions will be made individually for each pipeline at that time. There will be sufficient time for pipeline companies to make necessary preparations after the project is approved. Each pipeline relocation is case specific, and coordination with USACE-Galveston Regulatory Branch would be required in each case. Relocating a pipeline and placing it deeper would not necessarily require a new permit. If a pipeline is being moved to a new location, then the impacts would be evaluated by the environmental assessment performed in conjunction with the DOA permit.
3	Please see Section 2.4.1.12 of this FEIS for a discussion of the allocation of pipeline relocation costs.
4	Please refer to USACE responses 1-3 above.

Re: Comments regarding DFR/DEIS for proposed Sabine Neches Waterway Channel Improvement Project

Dear Ms. Stokes:

Enterprise Products Company ("EPC") is a pipeline company with facilities located within the project area of the proposed Sabine Neches Waterway ("SNWW") Channel Improvement Project (referenced herein as "SNWW Project").

The Enterprise family of companies is one of North America's largest midstream energy networks, providing services to producers and consumers of natural gas, natural gas liquids (NGLs), crude oil, refined products, liquefied petroleum gases (LPGs) and petrochemicals. The assets of the combined entities include more than 48,000 miles of onshore and offshore pipelines that gather and transport natural gas, NGLs, crude oil, petrochemicals, LPGs and refined products such as gasoline, diesel and jet fuel.

In late December 2009, EPC received correspondence inviting comments on the "Draft Environmental Impact Statement for the Sabine-Neches Waterway Channel Improvement Project, Southeast Texas and Southwest Louisiana and the Draft Environmental Impact Statement Sabine-Neches Waterway Channel Improvement Project, Texas Ocean Dredged Material Disposal Sites Designation" (referenced herein collectively as "DEIS") and the Draft Feasibility Report (referenced herein as "DFR"). The deadline for comments on these reports is Friday, March 12, 2010.

EPC is diligently performing a review of the SNWW Project, and the following summarizes the ongoing activities. We have assembled a SNWW Project team comprised of corporate management, land, legal, regulatory, engineering, and operations department representatives. The EPC team is reviewing and analyzing the preliminary project plans and the limited information regarding existing pipeline river crossings in the DFR and DEIS.

U.S. Army Corps of Engineers
 Sabine Neches Waterway Project
 March 12, 2010
 Page 2

The EPC team is also reviewing EPC pipeline asset records, and has identified pipeline facilities located in the SNWW Project area that may be effected by the proposed project. Approximately fifteen (15) EPC pipeline crossings ranging in size from 8-inch to 30-inch diameter have been identified as being located in the SNWW Project area. The Pipeline and Utility Table prepared by the U.S. Army Corps of Engineers ("COE") has tentatively identified six (6) EPC pipeline river crossings that may have to be relocated to accommodate the Project. Neches River pipeline crossing site visits and preliminary field survey reconnaissance operations have been conducted by EPC engineering and operations team representatives. Pipeline river crossing field survey and mapping operation plans are under development. A preliminary project composite base mapping system has been developed that is being utilized to composite and analyze EPC pipeline river crossing and SNWW Project information.

The purpose of this letter is to offer certain questions and comments regarding the DEIS and DFR.

1. Has a preliminary COE project schedule and project execution plan been developed? 1
2. Has a COE existing pipeline river crossing disposition evaluation plan and evaluation schedule been developed? 2
3. Has a COE existing pipeline river crossing relocation design and construction plan review and approval process been developed? 3
4. Since the project is designated in the DFR as a deep-draft harbor project, EPC requests a copy of the cost sharing and/or cost reimbursement plan that has been developed by the COE for pipeline relocation activities. Why hasn't the plan been made public as required by WRDA-86? 4
5. Has a pipeline relocation construction schedule and execution plan been developed? 5
6. Has COE developed any preliminary pipeline crossing relocation cost estimate information? 6
7. Have COE and other regulatory agency pipeline waterway crossing relocation permit requirements been determined and has the permit acquisition related time line been incorporated into the overall SNWW Project schedule? 7
8. Given the complexity of the relocations, has the COE factored into the time schedule the required logistics to coordinate multiple pipeline relocation construction operations between pipeline owners and operators? 8
9. Has the COE defined the location of all of the dredge disposal sites? The information provided for review is inadequate, and EPC requests more detailed information to determine effect on existing facilities. 9

Based upon the DFR, this project, as proposed, would be a deep-draft harbor project for cost sharing purposes under the Water Resources and Development Act of 1986. Under this law, half of the pipeline relocation costs for a deep-draft harbor project must be borne by the pipeline owner and the other half by the local sponsor of the project. Please confirm that this cost-sharing requirement will be part of any Chief's Report or other report or recommendation the Corps may make regarding the project.

10

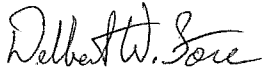

U.S. Army Corps of Engineers
Sabine Neches Waterway Project
March 12, 2010
Page 3

The replacement of pipelines that transport essential commodities that EPC handles is costly and requires years of advance planning and coordination. A project such as this creates substantial operational and engineering burdens for an industry that has strategic significance for the American economy. In congested areas such as the Sabine Neches Waterway, the relocation of a significant number of pipelines must be preceded by a comprehensive and coordinated planning process. The DFR and DEIS provide little detail about the proposed project's impact on pipeline operations, which pipelines will need to be relocated, where those pipelines are located, or how costs were estimated for pipeline relocations. There also appears to have been no consideration of the lead time requirements and additional expense that will be required for planning and coordination in the instance of multiple simultaneous pipeline relocations.

EPC believes that it is important for the COE to meet with EPC representatives and other pipeline company representatives in order to address the numerous questions detailed herein and facilitate an exchange of information. However, EPC understands that the COE is refusing such a meeting. We do not understand how a lack of communication helps anyone in dealing with issues as complicated as pipeline relocations in an area as congested with pipeline operations as the Sabine Neches Waterway, and we respectfully request that the COE reconsider its position and allow an adequate opportunity for dialogue and for meaningful comment.

At your convenience, please contact Lori Keeter, Senior Land Manager, at 713-803-2555.

Very truly yours,

A handwritten signature in dark ink, appearing to read "Delbert W. Fore". The signature is fluid and cursive, with the first name "Delbert" and last name "Fore" being the most prominent parts.

RESPONSE TO COMMENTS

Comment No.	Response
1	A preliminary construction schedule has been developed (Engineering Appendix Addendum 2009, chapter 14.0 REVISED SCHEDULES FOR DESIGN AND CONSTRUCTION) and is available upon request. However, the actual time table for project construction is uncertain at this time because it is dependent upon ASA and OMB approval of the Chief's Report, Congressional authorization and Congressional appropriation of funds.
2	USACE has developed a preliminary pipeline river crossing evaluation plan. More information on project features that could affect pipelines will be provided as detailed plans are developed during the PED and Construction phases.
3	The individual circumstances of each pipeline will be evaluated by USACE in consultation with the non-Federal sponsor and the pipeline owner during the PED or Construction phase, and decisions regarding relocations will be made individually for each pipeline at that time. For the feasibility study, it was assumed that existing pipelines would require, as a minimum, 5 feet of cover if the pipeline has been installed by directional drilling; or 8 feet of cover if it had been ditched/trenched and backfilled.
4	Please see Section 2.4.1.12 of this FEIS for a discussion of the allocation of pipeline relocation costs.
5	During the PED and Construction phases, USACE will provide estimated construction contract start and end dates to pipeline owners as soon as they are available, so that owners can schedule their relocations as they see fit, ensuring completion of the relocation prior to the award of the contract for that portion of the channel.
6	The USACE feasibility study estimate of pipeline relocation costs was developed by USACE to estimate the fully funded cost allocation between USACE and the non-Federal sponsor.
7	Potential environmental impacts of relocating the pipelines and replacing them at a deeper depth are assumed to be minimal. However, each pipeline relocation is case specific, and coordination with USACE-Galveston Regulatory Branch would be required in each case. Relocating a pipeline and placing it deeper would not necessarily require a new permit. If a pipeline is being moved to a new location, then the impacts would be evaluated by the environmental assessment performed in conjunction with the DOA permit.
8	USACE will ensure that channel construction contractors work with pipeline companies as needed to accommodate all parties for a safe and effective working plan.
9	Yes, all locations of the dredge material placement areas have been defined and described in the FR/FEIS (FR Chapter VI; FEIS Section 2.4).
10	Please see Section 2.4.1.12 of this FEIS for a discussion of the allocation of pipeline relocation costs.

Re: Comments regarding DFR/DEIS for proposed Sabine Neches Waterway Channel Improvement Project

Dear Ms. Stokes:

Chevron Pipe Line Company on its own behalf and on behalf of certain affiliated companies ("Chevron") operates pipeline assets that transport crude oil, petroleum products, liquefied petroleum gas, natural gas and chemicals within the United States and its territorial waters. Chevron has facilities located within the proposed Sabine Neches Waterway ("SNWW") Channel Improvement Project area, and to the extent possible has been diligently performing a review of the proposed project. We have assembled a team comprised of land, legal, environmental, engineering, and operations representatives that is reviewing the preliminary project plans and the limited information provided regarding impacts on existing pipeline river crossings.

With the time provided and limited pipeline specific data, Chevron is struggling to provide any meaningful comments by the specified deadline of March 12, 2010. A more realistic comment period would allow at least 120 days from the date of issue (December 24, 2009), and we therefore respectfully request that the comment period be extended to at least April 26, 2010. However, by receipt of this letter, Chevron offers initial comments on (1) the Draft Environmental Impact Statement for the Sabine-Neches Waterway Channel Improvement Project, Southeast Texas and Southwest Louisiana and the Draft Environmental Impact Statement Sabine-Neches Waterway Channel Improvement Project, Texas Ocean Dredged Material Disposal Sites Designation (collectively, the "DEIS") and (2) the Draft Feasibility Report for the proposed Sabine Neches Waterway Channel Improvement Project (the "DFR").

The DFR and DEIS indicate that the proposed project may require a large number of pipeline relocations and removals, possibly at least four operated by Chevron, but we are

unaware of any ongoing efforts by any governmental agencies to coordinate the project’s planning with pipeline owners and operators, even though it is common knowledge that pipelines significantly impact the proposed project area. The replacement of pipelines that transport essential commodities such as natural gas, natural gas liquids and chemicals is not only costly, it also requires years of advance planning and coordination, and creates significant operational, engineering and environmental permitting burdens. In congested areas such as the Sabine Neches Waterway, where there are multiple pipelines owned by multiple companies, the relocation of a significant number of pipelines requires a comprehensive and coordinated planning process.

The DFR and DEIS, however, provide little detail about the proposed project’s impact on (1) pipeline operations, (2) horizontal and vertical pipeline relocations, or (4) methodology for relocation cost estimates. In fact, the DFR and DEIS appear to be based on a single spreadsheet, *dated September 30, 2005*, with what appears to be the Corps’s working list of pipelines that may be impacted by the project. The engineering narrative (chapter 13 of the DFR Appendix) indicates that “relocated lines were assumed to be directionally drilled, and bundled when possible,” but no detail is provided that would identify which pipelines were assumed to be bundled, or permit a reader to understand the accuracy of the Corps’ feasibility and cost assumptions. The DFR and DEIS do not reflect any consideration for the lead time and expense required obtain the permits required for the pipeline relocations, *e.g.*, environmental studies, environmental surveys, agency reviews and evaluations.

Chevron respectfully requests that the Corps promptly:

- 1. definitively identify the Chevron pipelines that will be impacted by the project; 2
- 2. provide Chevron sufficient information to understand the Corps’ estimate of the costs for removing or relocating each such pipeline; 3
- 3. provide Chevron with whatever additional documents or information are needed to understand the proposed project’s impact on Chevron’s pipeline operations, including a projected timeline for when the relocations may actually be needed and how Corps permits would be addressed; 4
- 4. establish a working group or other appropriate method to bring the Corps and pipeline company representatives together to facilitate an information exchange; and 5
- 5. confirm that the cost-sharing requirement specified by WRDA 86 will be part of any Chief’s Report or other report or recommendation the Corps makes regarding the project. 6

At your convenience, please contact Rania Yacoub, at 713-432-3557.

Respectfully,

Dolores Barnhill

**Supplemental Written Comments by Texas Energy Coalition Regarding
Proposed Sabine-Neches Waterway Channel Improvement Project DFR**

March 12, 2010

U. S. Army Corps of Engineers
Galveston District
Attn: Ms. Janelle Stokes [janelle.s.stokes@usace.army.mil]
P. O. Box 1229
Galveston, Texas 77553-1229

Re: Supplemental comments regarding DFR/DEIS for proposed Sabine-Neches Waterway
Channel Improvement Project

Dear Ms. Stokes:

I am writing once again on behalf of the Texas Energy Coalition, a group of pipeline transmission companies that collaborate on issues of common interest. In my letter of February 9, 2010, the Coalition offered certain preliminary comments regarding the DEIS and DFR for the proposed Sabine-Neches Waterway Channel Improvement Project. The Coalition also posed a number of requests, which I will restate in summary fashion.

First, the Coalition requested an extension of time up to and through April 26, 2010, in which to make comments.

1

We have not received any response to that request.

Second, the Coalition requested that the Corps identify all pipelines that will be impacted by the project, provide sufficient information to understand and respond to the Corps' estimate of the costs for removing or relocating each such pipeline, and provide whatever additional documents are needed to understand the proposed project's impact on pipeline operations, including a projected timeline for when the relocations may actually be needed.

Again, the Corps has made no response to these requests.

2

Third, the Coalition also requested that the Corps meet with the Coalition and pipeline company representatives as soon as possible to facilitate the exchange of information and to confirm that the cost-sharing requirements for deep-draft relocations set forth in WRDA-86 will be part of any Chief's Report or other report or recommendation the Corps may make regarding the project.

Yet again, the Corps has made no response to these requests.

3

The Corps' refusal to provide sufficient information to make a reasoned response to the DFR and DEIS on a project estimated to cost more than \$1 billion is troubling. The Corps' persistent refusal to produce documents related to pipeline relocations on this project – coupled with its refusal even to meet with representatives of the pipeline industry regarding a project that is located in one of the nation's most concentrated areas of pipeline development – is even more troubling.

4

The Coalition sees no rational basis for the manner in which the DFR and DEIS for this project have been presented and objects to the lack of transparency in the process of seeking public input on the project.

The Coalition reserves the right to make additional comments if and when the Corps reconsiders its position on these issues. If you wish to discuss them, please contact Denis Calabrese (713-622-7388) or David Corban (713-651-5251).

Very truly yours,

A handwritten signature in black ink, appearing to read "Denis Calabrese". The signature is fluid and cursive, with the first name "Denis" and last name "Calabrese" clearly distinguishable.

Denis Calabrese
Spokesperson

RESPONSE TO COMMENTS

Comment No.	Response
1	USACE posted notice that the comment period was extended an additional 30 days to 3-12-2010 on the USACE website at http://www.swg.usace.army.mil/pao/Docs/ExtensionofPublicCommentPeriodtoMarch12.pdf on February 8, 2010.
2	A list of potentially affected pipelines was provided to pipeline companies during the DEIS public comment period. The USACE list of potentially affected pipelines should not be considered definitive. The individual circumstances of each pipeline will be evaluated by USACE in consultation with the non-Federal sponsor and the pipeline owner during the PED and Construction phases, and decisions regarding necessary actions will be made individually for each pipeline at that time. There will be sufficient time for pipeline companies to make all of the necessary preparations after the project is approved. The USACE feasibility study estimate of pipeline relocation costs was developed by USACE to estimate the fully funded cost allocation between USACE and the non-Federal sponsor.
3	USACE met with pipeline owners at an information meeting on January 25, 2011. Please see Section 2.4.1.12 of this FEIS for a discussion of the allocation of pipeline relocation costs.
4	See USACE responses to Comments 2 and 3 above.

Re: Comments regarding DFR/DEIS for proposed Sabine Neches Waterway Channel Improvement Project

Dear Ms. Stokes:

Colonial Pipeline Company has two pipelines within the project area of the proposed Sabine Neches Waterway ("SNWW") Channel Improvement Project. Each day, these two pipelines transport an average of 100 million gallons of gasoline, diesel fuels and national defense fuels to shipper terminals in 12 states and the District of Columbia.

I write today to comment on the Draft Environmental Impact Statement for the Sabine-Neches Waterway Channel Improvement Project, Southeast Texas and Southwest Louisiana and the Draft Environmental Impact Statement Sabine-Neches Waterway Channel Improvement Project, Texas Ocean Dredged Material Disposal Sites Designation (collectively, the "DEIS") and the Draft Feasibility Report for the proposed Sabine Neches Waterway Channel Improvement Project (the "DFR").

The DFR and DEIS indicate that the proposed project will require a large number of pipeline relocations and removals, possibly including the two owned by Colonial Pipeline Company. However, the documents outlined above offer very little information as to the impact to our pipelines, in terms of both operations and financial costs. As you are aware, the replacement of pipelines that transport essential commodities, such as refined petroleum products in Colonial's case, requires significant planning and coordination, and creates operational, engineering and environmental permitting burdens. In addition, the DFR nor DEIS reflect any consideration of the lead time and expense required to obtain the permits for the pipeline relocations.

At this time, it is difficult for Colonial to comment on the impact of the project. The DEIS and DFR are almost silent in respect to the impact of the project on energy infrastructure and

production facilities. This is despite more than 50 pipelines potentially being impacted. While we understand the basic project scope is to deepen and widen the Sabine Neches Waterway in order to accommodate larger ships, we do not have a clear understanding of the project scope and the impact of those plans on pipeline infrastructure because of the lack of detail in the Corps' documents.

We would hope the Corps would be willing to meet with representatives of Colonial, and the pipeline industry, to discuss important issues related to the project. This will help us determine the potential impact to our facilities and what steps need to be taken in order to plan and implement any facility relocations or removal of those facilities.

Further, we feel it is important to comment on the federal law that calls for the equal sharing of costs during projects of this nature. The Corps has also acknowledged this federal legal requirement in the "Cost Sharing" section of the DFR: "In accordance with Section 101(a)(4) of the Water Resources and Development Act of 1986, known as "WRDA 86", 50 percent of deep-draft utility (pipeline) relocations would be borne by the utility owner and 50 percent would be borne by the non-Federal sponsor," *i.e.*, the Sabine Neches Navigation District (page XI-5). It is our understanding that there has been some effort to circumvent this long-established federal law. We would formally request that the Corps declare its opposition to any change in the cost-sharing allocation.

Colonial Pipeline Company asks that you establish a working group or other appropriate method to bring the Corps and pipeline company representatives together to facilitate an information exchange; and confirm that the cost-sharing requirement specified by WRDA 86 will be part of any Chief's Report or other report or recommendation the Corps makes regarding the project.

Sincerely,

Sam Whitehead

RESPONSE TO COMMENTS

Comment No.	Response
1	The FR provides sufficient information for feasibility-level planning. A list of potentially affected pipelines was provided to pipeline companies during the DEIS public comment period. The USACE list of potentially affected pipelines should not be considered definitive. The individual circumstances of each pipeline will be evaluated by USACE in consultation with the non-Federal sponsor and the pipeline owner during the PED and Construction phases, and decisions regarding necessary actions will be made individually for each pipeline at that time. There will be sufficient time for pipeline companies to make necessary preparations after the project is approved. Each pipeline relocation is case specific, and coordination with USACE-Galveston Regulatory Branch would be required in each case. Relocating a pipeline and placing it deeper would not necessarily require a new permit. If a pipeline is being moved to a new location, then the impacts would be evaluated by the environmental assessment performed in conjunction with the DOA permit.
2	USACE met with pipeline owners at an information meeting on January 25, 2011. More information on project features that could affect pipelines will be provided as detailed plans are developed during PED and Construction phases.
3	Please see Section 2.4.1.12 of this FEIS for a discussion of the allocation of pipeline relocation costs.

April 7, 2003

Environmental Section

Mr. Earl Barbry, Sr., Chairman
Tunica-Biloxi Indian Tribe
P.O. Box 331
Marksville, Louisiana 71351

Dear Mr. Barbry:

The Corps of Engineers, Galveston District, in cooperation with the Jefferson County Waterway and Navigation District, is planning on making improvements to the Sabine/Neches Waterway in Jefferson and Orange Counties, Texas and Cameron Parish, Louisiana. These plans consist in widening and deepening the channel from the city of Beaumont to the end of the waterway in the Gulf of Mexico as shown on the attached map. All construction will be confined to the existing channel. Dredge material placement will occur, either in existing placement areas along the channel, the Gulf of Mexico or in Sabine Lake. As you will notice the study area marked on the enclosed map extends well outside the area of construction. This larger area marks places where the project team considered secondary effects such as saltwater intrusion into the coastal marshes.

As required under Section 106 of the National Historic Preservation Act 36CFR Part 800.3(f)(2) we are contacting you to determine if your tribe can assist us in identifying any historic properties or areas of religious and cultural interest in the project area. Your help in identifying such properties will be greatly appreciated.

Thank you for your cooperation in this matter. If you have any questions regarding this project, please contact Ms. Janelle Stokes, Galveston District Tribal Coordinator, at (409)766-3039.

Sincerely,

Carolyn Murphy
Chief, Environmental Section

FEBRUARY 7, 2007

Environmental Section

Mr. Earl J. Barbry, Sr., Chairman
Tunica-Biloxi Indian Tribe
P.O. Box 331
Marksville, LA 71351

Dear Mr. Barbry:

The US Army Corps of Engineers, Galveston District (USACE), proposes to initiate a Programmatic Agreement (PA) to avoid and mitigate, if necessary, impacts to historic properties that may occur during construction and operation of the Sabine-Neches Waterway Channel Improvement Project (SNWW CIP). The SNWW CIP includes improvements to the existing navigation channel, a Dredged Material Management Plan (DMMP) and an ecological impacts mitigation plan. A full description and maps of the proposed channel improvements can be found in the enclosed Background Report (Enclosure 1).

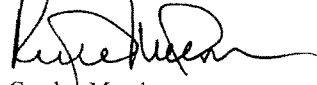

The USACE proposes negotiation of a four-party PA which outlines procedures to be followed for Section 106 compliance as per 36 CFR 800.6(c) to address potential impacts to historic properties identified in the Background Report for the SNWW CIP project area (Enclosure 1). The four parties include the USACE, the Jefferson County Waterways and Navigation District (JCWND) and the Texas and Louisiana State Historic Preservation Officers (SHPOs). The draft PA will also be coordinated with interested Native American Indian tribes in accordance with 36 CFR 800.3 (f)(2). Attached, as Enclosure 2, is a draft PA prepared by the USACE that has been informally coordinated with the JCWND. The intent of the PA is to avoid or mitigate impacts to historic properties in areas directly affected by new dredging and channel construction, construction staging and access areas, extensions of existing placement areas, ecological mitigation features, areas affected by the beneficial uses of dredged material, and ongoing maintenance dredging and placement activities related to the SNWW CIP.

As required under Section 106 of the National Historic Preservation Act 36 CFR Part 800.3(f)(2) we are contacting you to determine if your tribe can assist us in identifying any historic properties or areas of religious and cultural interest in the project area. Your help in identifying such properties will be greatly appreciated.

Thank you for your cooperation in this matter. If you have any questions regarding this project, please contact Ms. Nicole Cooper Minnichbach, Galveston District Archeologist, at (409)766-3878.

Stokes, Janelle S SWG

From: Bryant J. Celestine [celestine.bryant@actribe.org]
Sent: Friday, February 26, 2010 11:32 AM
To: Stokes, Janelle S SWG
Subject: Sabine-Neches Waterway DEIS

Dear Ms. Stokes:

On behalf of Mikko Oscola Clayton Sylestine and the Alabama-Coushatta Tribe, our appreciation is expressed on your efforts to consult us regarding the Draft Environmental Impact Statement for the Sabine-Neches Waterway Channel Improvement Project.

Our Tribe maintains ancestral associations throughout the state of Texas and Louisiana despite the absence of written documentation to completely identify Tribal activities, villages, trails, or religious sites. However, it is our objective to ensure significances of Native American ancestry, especially of the Alabama-Coushatta Tribe, are administered with the utmost considerations.

Upon review of the December 18, 2009 materials, no impacts to religious, cultural, or historical assets of the Alabama-Coushatta Tribe of Texas should occur in conjunction with this proposal. However, in the event of inadvertent discovery of human remains and/or archaeological resources, activity in proximity to the location must cease and appropriate authorities, including this office, notified without delay. 1

Should you require further assistance, please do not hesitate to contact us.

Sincerely,

Bryant J. Celestine
 Historic Preservation Officer
 Alabama-Coushatta Tribe of Texas

RESPONSE TO COMMENTS

Comment No.	Response
1	Thank you for reviewing the proposed Sabine-Neches Waterway Channel Improvement Project for potential impacts to tribal resources. The Alabama-Coushatta Tribe of Texas will be contacted in the event of an inadvertent discovery of human remains or archeological resources as required by Stipulations II and IV of the Historic Properties Programmatic Agreement (Final Environmental Impact Statement Appendix H).

1.0 PURPOSE AND NEED FOR THE ACTION

1.1 INTRODUCTION

The existing Federal project deep-draft channel (Figure 1-1), with a total length of roughly 65 miles, was first authorized to a depth of 25 feet in 1912 (Rivers and Harbor Act of July 25, 1912). It was deepened to 30 feet in 1922, 34 feet in 1935, 36 feet in 1946, and authorized to the present 40 feet in 1962 (Rivers and Harbor Act of October 23, 1962), although construction ran from 1965 to 1972. It extends from about a mile upstream of the Beaumont Turning Basin to the 42-foot contour in the Gulf of Mexico (Gulf). Bottom widths are 800 feet in the Entrance Channel, narrowing to 500 feet at the inland portion of the Jetty Channel, the Sabine Pass Channel, the Port Arthur Canal, the Sabine-Neches Canal, and 400 feet to the Beaumont Turning Basin.

As part of the National Environmental Policy Act (NEPA) process for the Sabine-Neches Waterway (SNWW) Channel Improvement Project (CIP), the U.S. Environmental Protection Agency (EPA), as a cooperating agency, is proposing to designate one or more Ocean Dredged Material Disposal Sites (ODMDSs) for placement of the construction and maintenance dredged material from an extension of the SNWW, roughly 13.2 miles farther into the Gulf. As part of the process, the existing ODMDSs will be examined for capacity and compatibility with the construction material and the greater quantity of maintenance material associated with the larger and deeper existing offshore channel. This ODMDS Designation Final Environmental Impact Statement (FEIS) was circulated for review with, and as part of, the FEIS for the SNWW CIP. Table 1-1 presents the quantities of dredged maintenance material from the existing and proposed channels and the construction (new work) material anticipated from the proposed SNWW CIP.

EPA's action for which this document was prepared is the designation of a site or sites for the ocean placement of new work (construction) material to be dredged from the SNWW Entrance Channel and Extension, and future maintenance material from the 13.2-mile SNWW Entrance Channel Extension. An FEIS for the maintenance dredging of the SNWW Entrance Channel (for the authorized 40-Foot Project [42 feet in the Entrance Channel]), was prepared by the U.S. Army Corps of Engineers (USACE, 1975). Four offshore sites are currently in use for the existing channel. These sites were designated by EPA for the continued placement of dredged material removed from the SNWW Entrance Channel (Federal Register [FR] Vol. 52, No. 175, September 10, 1987, page 34218; FEIS, 1983 [EPA, 1983a]). This Environmental Impact Statement (EIS) for the proposed new ODMDSs is included as an appendix to the Integrated Feasibility Report/EIS for the SNWW CIP. The purpose of EPA's action is to designate, based on 40 Code of Federal Regulations (CFR) 228, ocean disposal sites that would provide environmentally acceptable and economically and physically feasible areas for the placement of the construction material from the SNWW Entrance Channel and future maintenance material from the Entrance Channel Extension for the SNWW CIP.

Table 1-1
Existing and Proposed Entrance Channel Ocean Dredged Material Disposal Site Quantities

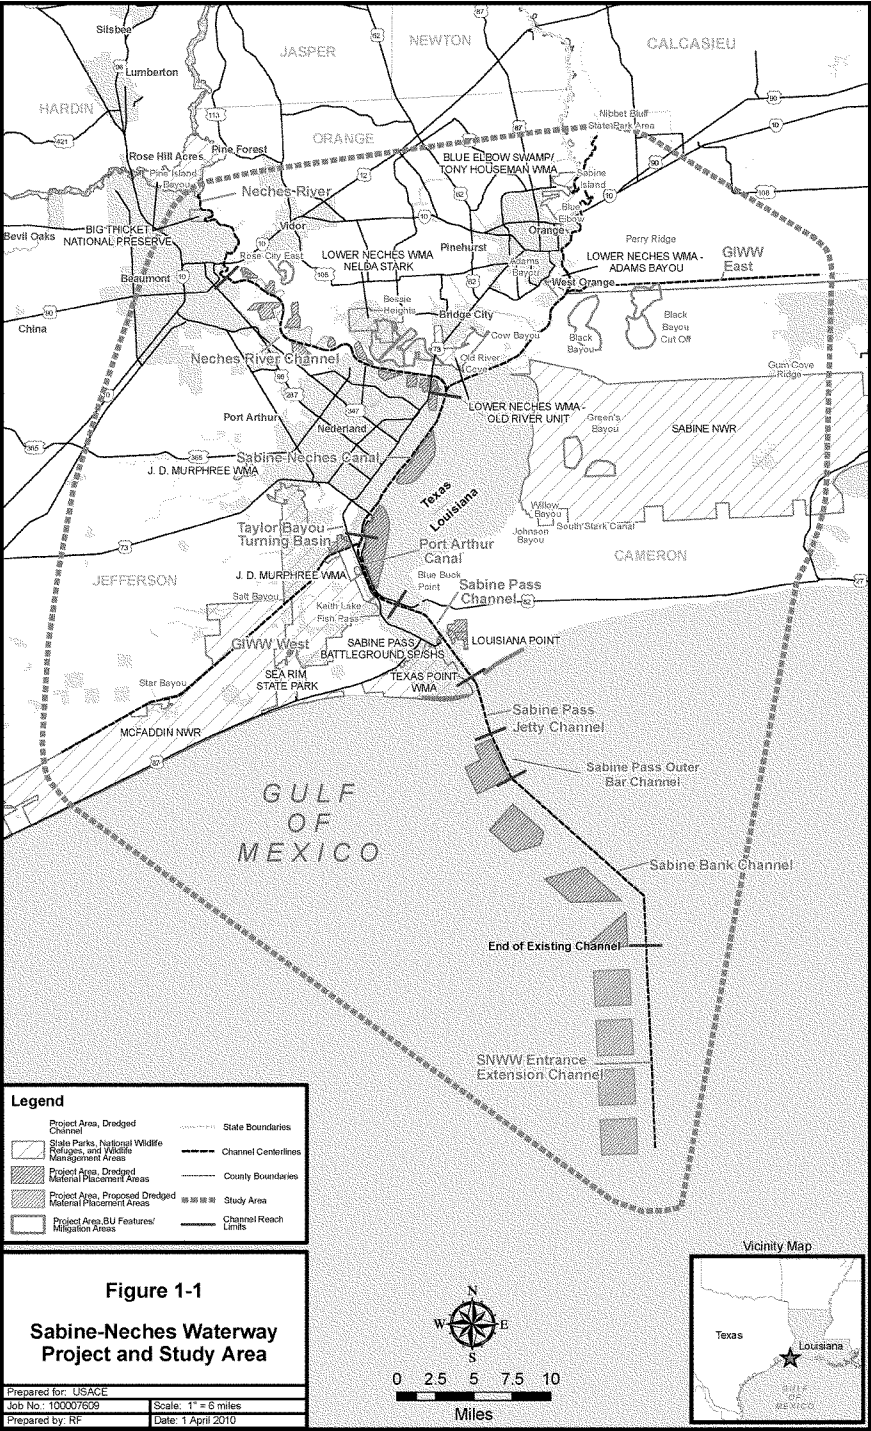

New Work Material		Existing Project		Proposed Project	
PA	Contributing Channel Channel Station	Quantity per year ² (cy)	Quantity per cycle (cy)	Quantity per year (cy)	Quantity ¹ (cy)
4	-214+88 0+00		Not Applicable		2,978,000
3	0+000 18+000		Not Applicable		5,923,000
2	18+000 53+000		Not Applicable		7,051,000
1	53+000 95+734		Not Applicable		8,307,000
					24,259,000 Total
A	95+734 114+000		Not Applicable		4,592,000
B	114+000 132+000		Not Applicable		5,296,000
C	132+000 150+500		Not Applicable		4,648,000
D	150+500 165+443		Not Applicable		4,201,000
					18,737,000 Total
Maintenance Material		Existing Project		Proposed Project	
PA	Contributing Channel Channel Station	Frequency (years)	Quantity per year ² (cy)	Quantity per year (cy)	Quantity per cycle ¹ (cy)
4	0+00 -214+88	5	227,700	1,138,500	270,540
3	0+00 18+000	1	1,993,700	1,993,700	1,352,700
2	18+000 53+000	4	430,600	1,722,400	4,473,000
1	53+000 95+734	4	628,200	2,512,800	4,473,000
			3,280,200	7,367,400	3,131,000
				6,686,040	1,508,000
					10,464,700 Totals
					334,302,000 Total per 50 years ³
A	95+734 114+000	4		Not Applicable	791,000
B	114+000 132+000	4		Not Applicable	194,750
C	132+000 150+500	4		Not Applicable	779,000
D	150+500 165+443	4		Not Applicable	200,250
					801,000
					161,750
					647,000
					754,500
					3,018,000 Totals
					37,725,000 Total per 50 years ³

¹ From USACE SNWW CIP Engineering Appendix

² Based on historic data for maintenance material going into PA 1, the farthest offshore of the existing ODMDSs.

³ These numbers are slightly larger than the 50-year Dredged Material Management Plan summary table because they include two additional years of material for reaches with 4-year cycles.

1.2 LEGISLATIVE BACKGROUND AND PROPOSED ACTION

Ocean disposal of dredged material was not specifically regulated in the United States until passage of the Marine Protection, Research and Sanctuaries Act of 1972 (MPRSA). Limited regulation was provided by the Supervisors' Act of 1888 and the Refuse Act of 1899. Under these acts, transportation and navigation factors, rather than environmental considerations, guided selection of placement locations by the USACE and the issuance of permits for ocean disposal.

Although the Fish and Wildlife Coordination Act of 1958 initially referred to inland tidal waters, it included consideration of the effects of dredged material on commercially important marine species. This act, together with subsequent judicial decisions, empowered the USACE to refuse permits if the dredging or filling of a bay or estuary would result in significant, unavoidable damage to the marine ecosystem.

MPRSA and the Federal Water Pollution Control Act (FWPCA), later amended by the Clean Water Act of 1977, both passed in 1972 and specifically addressed waste disposal in the aquatic and the marine environment. The FWPCA and the Water Quality Improvement Act of 1970 set up specific water quality criteria to be used as guidelines in controlling discharges into marine and aquatic environments. These water quality criteria applied to placement of dredged material only in cases where fixed pipelines were used to transport and discharge dredged material into the environment at discrete points. MPRSA, however, specifically regulates the transport and ultimate disposal of waste materials in the ocean. Under Title I of MPRSA, the primary regulatory vehicle of the act, a permit program for the disposal of dredged and nondredged materials was established that mandates determination of impacts and provides for enforcement of permit conditions.

The August 1975 London Convention on the Prevention of Marine Pollution by Dumping of Wastes and Other Matter (Convention) is the principal international agreement governing ocean dumping. The Convention specifies that contracting nations will regulate disposal in the marine environment within their jurisdiction, disallowing all disposal without permits. The nature and quantities of all waste material and the circumstances of disposal must be periodically reported to the International Maritime Organization (formerly the Inter-Governmental Maritime Consultative Organization), which administers the Convention.

In October 1973, the EPA issued the final Ocean Dumping Regulations and Criteria (the Regulations, or Ocean Dumping Regulations), revised in January 1977 (40 CFR Parts 220 to 229). These regulations established procedures and criteria for review of ocean disposal permit applications (Part 227), assessment of impacts of ocean disposal and alternative disposal methods, enforcement of permits, and designation and management of ocean disposal sites (Part 228). They also established procedures by which the EPA is authorized to designate ODMDs and times for ocean disposal of acceptable materials under Section 102(c) of the MPRSA and the criteria for site designation, including general and specific criteria for site selection.
