§ 1066.250 Base inertia verification.

(a) Overview. This section describes how to verify the dynamometer’s base inertia.

(b) Scope and frequency. Perform this verification upon initial installation and after major maintenance.

(c) Procedure. Verify the base inertia using the following procedure:

(1) Warm up the dynamometer according to the dynamometer manufacturer’s instructions. Set the dynamometer’s road-load inertia to zero and motor the rolls to 5 mph. Apply a constant force to accelerate the roll at a nominal rate of 1 mph/s. Measure the elapsed time to accelerate from 10 to 40 mph, noting the corresponding speed and time points to the nearest 0.01 mph and 0.01 s. Also determine average force over the measurement interval.

(2) Starting from a steady roll speed of 45 mph, apply a constant force to the roll to decelerate the roll at a nominal rate of 1 mph/s. Measure the elapsed time to decelerate from 40 to 10 mph, noting the corresponding speed and time points to the nearest 0.01 mph and 0.01 s. Also determine average force over the measurement interval.

(3) Repeat the steps in paragraphs (c)(1) and (2) of this section for a total of five sets of results at the nominal acceleration rate and the nominal deceleration rate.
(4) Use good engineering judgment to select two additional acceleration and deceleration rates that cover the middle and upper rates expected during testing. Repeat the steps in paragraphs (c)(1) through (3) of this section at each of these additional acceleration and deceleration rates.

(5) Determine the base inertia, \( I_b \), for each measurement interval using the following equation:

\[
I_b = \frac{F}{\frac{S_{\text{final}} - S_{\text{initial}}}{\Delta t}}
\]

Eq. 1066.250-1

Where:
- \( F \) = average dynamometer force over the measurement interval as measured by the dynamometer, in ft·lbm/s².
- \( S_{\text{final}} \) = roll surface speed at the end of the measurement interval to the nearest 0.01 mph.
- \( S_{\text{initial}} \) = roll surface speed at the start of the measurement interval to the nearest 0.01 mph.
- \( \Delta t \) = elapsed time during the measurement interval to the nearest 0.01 s.

Example:
- \( F = 1.500 \text{ lbf} = 48.26 \text{ ft·lbm/s}^2 \)
- \( S_{\text{final}} = 40.00 \text{ mph} = 58.67 \text{ ft/s} \)
- \( S_{\text{initial}} = 10.00 \text{ mph} = 14.67 \text{ ft/s} \)
- \( \Delta t = 30.00 \text{ s} \)

\[
I_b = \frac{48.26}{\frac{58.67 - 14.67}{30.00}} = 32.90 \text{ lbm}
\]

(6) Determine the arithmetic mean value of base inertia from the five measurements at each acceleration and deceleration rate. Calculate these six mean values as described in 40 CFR 1065.602(b).

(7) Calculate the base inertia error, \( I_{\text{error}} \), for each measured base inertia, \( I_b \), by comparing it to the manufacturer’s stated base inertia, \( I_{\text{ref}} \), using the following equation:

\[
I_{\text{error}} = \frac{I_{\text{bac}} - I_{\text{ref}}}{I_{\text{ref}}} \times 100 \%
\]

Eq. 1066.250-2

Example:
- \( I_{\text{ref}} = 32.96 \text{ lbm} \)
- \( I_{\text{bac}} = 33.01 \text{ lbm} \)
I_{\text{error}} = -0.15\%

(8) Calculate the inertia error for each mean value of base inertia from paragraph (c)(6) of this section. Use Equation 1066.265-2, substituting the mean base inertias associated with each acceleration and deceleration rate for the individual base inertias.

(d) Performance evaluation. The dynamometer must meet the following specifications to be used for testing under this part:

(1) The base inertia error determined under paragraph (c)(7) of this section may not exceed ±0.50% relative to any individual value.

(2) The base inertia error determined under paragraph (c)(8) of this section may not exceed ±0.20% relative to any mean value.

§ 1066.255 Parasitic loss verification.

(a) Overview. Verify and correct the dynamometer’s parasitic loss. This procedure determines the dynamometer’s internal losses that it must overcome to simulate road load. These losses are characterized in a parasitic loss curve that the dynamometer uses to apply compensating forces to maintain the desired road-load force at the roll surface.

(b) Scope and frequency. Perform this verification upon initial installation, within 7 days before testing, and after major maintenance. Note that this procedure relies on proper verification or calibration of speed and torque, as described in §§1066.235 and1066.240. You must also first verify the dynamometer’s parasitic loss curve as specified in §1066.255.

(c) Procedure. Use the following procedure to verify the accuracy of the dynamometer’s parasitic loss curve as specified in §1066.255:

(1) Warm up the dynamometer as specified by the dynamometer manufacturer.

(2) Perform a torque verification as specified by the dynamometer manufacturer. For torque verifications relying on shunt procedures, if the results do not conform to specifications, recalibrate the dynamometer using NIST-traceable standards as appropriate until the dynamometer passes the torque verification. Do not change the dynamometer’s base inertia to pass the torque verification.

(3) Set the dynamometer inertia to the base inertia with the road-load coefficients A, B, and C set to 0. Set the dynamometer to speed-control mode with a target speed of 10 mph or a higher speed recommended by the dynamometer manufacturer. Once the speed stabilizes at the target speed, switch the dynamometer from speed control
