equal to the takeoff distance. If the takeoff distance includes a clearway—
(1) The takeoff run on a dry runway is the greater of—
   (i) The horizontal distance along the takeoff path from the start of the takeoff to a point equidistant between the point at which \( V_{LOF} \) is reached and the point at which the airplane is 35 feet above the takeoff surface, as determined under §25.111 for a dry runway; or
   (ii) 115 percent of the horizontal distance along the takeoff path, with all engines operating, from the start of the takeoff to a point equidistant between the point at which \( V_{LOF} \) is reached and the point at which the airplane is 35 feet above the takeoff surface, determined by a procedure consistent with §25.111.
(2) The takeoff run on a wet runway is the greater of—
   (i) The horizontal distance along the takeoff path from the start of the takeoff to the point at which the airplane is 15 feet above the takeoff surface, achieved in a manner consistent with the achievement of \( V_2 \) before reaching 35 feet above the takeoff surface, as determined under §25.111 for a wet runway; or
   (ii) 115 percent of the horizontal distance along the takeoff path, with all engines operating, from the start of the takeoff to a point equidistant between the point at which \( V_{LOF} \) is reached and the point at which the airplane is 35 feet above the takeoff surface, determined by a procedure consistent with §25.111.

§25.115 Takeoff flight path.
(a) The takeoff flight path shall be considered to begin 35 feet above the takeoff surface at the end of the takeoff distance determined in accordance with §25.113(a) or (b), as appropriate for the runway surface condition.
(b) The net takeoff flight path data must be determined so that they represent the actual takeoff flight paths (determined in accordance with §25.111 and with paragraph (a) of this section) reduced at each point by a gradient of climb equal to—
   (1) 0.8 percent for two-engine airplanes;
   (2) 0.9 percent for three-engine airplanes; and
   (3) 1.0 percent for four-engine airplanes.
(c) The prescribed reduction in climb gradient may be applied as an equivalent reduction in acceleration along that part of the takeoff flight path at which the airplane is accelerated in level flight.

§25.117 Climb: general.
Compliance with the requirements of §§25.119 and 25.121 must be shown at each weight, altitude, and ambient temperature within the operational limits established for the airplane and with the most unfavorable center of gravity for each configuration.

§25.119 Landing climb: All-engines-operating.
In the landing configuration, the steady gradient of climb may not be less than 3.2 percent, with the engines at the power or thrust that is available 8 seconds after initiation of movement of the power or thrust controls from the minimum flight idle to the go-around power or thrust setting—
(a) In non-icing conditions, with a climb speed of \( V_{REF} \) determined in accordance with §25.125(b)(2)(i); and
(b) In icing conditions with the landing ice accretion defined in appendix C, and with a climb speed of \( V_{REF} \) determined in accordance with §25.125(b)(2)(ii).

§25.121 Climb: One-engine-inoperative.
(a) Takeoff; landing gear extended. In the critical takeoff configuration existing along the flight path (between the points at which the airplane reaches \( V_{LOF} \) and at which the landing gear is fully retracted) and in the configuration used in §25.111 but without ground effect, the steady gradient of climb must be positive for two-engine airplanes, and not less than 0.3 percent for three-engine airplanes or 0.5 percent
§ 25.121 14 CFR Ch. I (1–1–13 Edition)

for four-engine airplanes, at $V_{LOF}$ and with—

(1) The critical engine inoperative and the remaining engines at the power or thrust available when retraction of the landing gear is begun in accordance with §25.111 unless there is a more critical power operating condition existing later along the flight path but before the point at which the landing gear is fully retracted; and

(2) The weight equal to the weight existing when retraction of the landing gear is begun, determined under §25.111.

(b) Takeoff; landing gear retracted. In the takeoff configuration existing at the point of the flight path at which the landing gear is fully retracted, and in the configuration used in §25.111 but without ground effect:

(1) The steady gradient of climb may not be less than 2.4 percent for two-engine airplanes, 2.7 percent for three-engine airplanes, and 3.0 percent for four-engine airplanes, at $V_{2}$ with:

(i) The critical engine inoperative, the remaining engines at the takeoff power or thrust available at the time the landing gear is fully retracted, determined under §25.111, unless there is a more critical power operating condition existing later along the flight path but before the point where the airplane reaches a height of 400 feet above the takeoff surface; and

(ii) The weight equal to the weight existing when the airplane’s landing gear is fully retracted, determined under §25.111.

(2) The requirements of paragraph (b)(1) of this section must be met:

(i) In non-icing conditions; and

(ii) In icing conditions with the final takeoff ice accretion defined in appendix C, if in the configuration of §25.121(b) with the takeoff ice accretion:

(A) The stall speed at maximum takeoff weight exceeds that in non-icing conditions by more than the greater of 3 knots CAS or 3 percent of $V_{SR}$; or

(B) The degradation of the gradient of climb determined in accordance with §25.121(b) is greater than one-half of the applicable actual-to-net takeoff flight path gradient reduction defined in §25.115(b).

(c) Final takeoff. In the en route configuration at the end of the takeoff path determined in accordance with §25.111:

(1) The steady gradient of climb may not be less than 1.2 percent for two-engine airplanes, 1.5 percent for three-engine airplanes, and 1.7 percent for four-engine airplanes, at $V_{FGO}$ with—

(i) The critical engine inoperative and the remaining engines at the available maximum continuous power or thrust; and

(ii) The weight equal to the weight existing at the end of the takeoff path, determined under §25.111.

(2) The requirements of paragraph (c)(1) of this section must be met:

(i) In non-icing conditions; and

(ii) In icing conditions with the final takeoff ice accretion defined in appendix C, if in the configuration of §25.121(b) with the takeoff ice accretion:

(A) The stall speed at maximum takeoff weight exceeds that in non-icing conditions by more than the greater of 3 knots CAS or 3 percent of $V_{SR}$; or

(B) The degradation of the gradient of climb determined in accordance with §25.121(b) is greater than one-half of the applicable actual-to-net takeoff flight path gradient reduction defined in §25.115(b).

(d) Approach. In a configuration corresponding to the normal all-engines-operating procedure in which $V_{SR}$ for this configuration does not exceed 110 percent of the $V_{SR}$ for the related all-engines-operating landing configuration:

(1) The steady gradient of climb may not be less than 2.1 percent for two-engine airplanes, 2.4 percent for three-engine airplanes, and 2.7 percent for four-engine airplanes, with—

(i) The critical engine inoperative, the remaining engines at the go-around power or thrust setting;

(ii) The maximum landing weight;

(iii) A climb speed established in connection with normal landing procedures, but not exceeding 1.4 $V_{SR}$; and

(iv) Landing gear retracted.

(2) The requirements of paragraph (d)(1) of this section must be met:

(i) In non-icing conditions; and
(ii) In icing conditions with the approach ice accretion defined in appendix C. The climb speed selected for non-icing conditions may be used if the climb speed for icing conditions, computed in accordance with paragraph (d)(1)(ii) of this section, does not exceed that for non-icing conditions by more than the greater of 3 knots CAS or 3 percent.

§ 25.123 En route flight paths.

(a) For the en route configuration, the flight paths prescribed in paragraph (b) and (c) of this section must be determined at each weight, altitude, and ambient temperature, within the operating limits established for the airplane. The variation of weight along the flight path, accounting for the progressive consumption of fuel and oil by the operating engines, may be included in the computation. The flight paths must be determined at a speed not less than \( V_{FTO} \), with—

1. The most unfavorable center of gravity;
2. The critical engines inoperative;
3. The remaining engines at the available maximum continuous power or thrust; and
4. The means for controlling the engine-cooling air supply in the position that provides adequate cooling in the hot-day condition.

(b) The one-engine-inoperative net flight path data must represent the actual climb performance diminished by a gradient of climb of 1.1 percent for two-engine airplanes, 1.4 percent for three-engine airplanes, and 1.6 percent for four-engine airplanes—

1. In non-icing conditions; and
2. In icing conditions with the en route ice accretion defined in appendix C if \( V_{REF} \) for icing conditions exceeds \( V_{REF} \) for non-icing conditions by more than 5 knots CAS at the maximum landing weight.

(b) In determining the distance in paragraph (a) of this section:

1. The airplane must be in the landing configuration.
2. A stabilized approach, with a calibrated airspeed of not less than \( V_{REF} \), must be maintained down to the 50-foot height.
   (i) In non-icing conditions, \( V_{REF} \) may not be less than:
   (A) \( 1.23 V_{SR0} \);
   (B) \( V_{MCL} \) established under § 25.149(f);
   and
   (C) A speed that provides the maneuvering capability specified in § 25.143(h).
   (ii) In icing conditions, \( V_{REF} \) may not be less than:
   (A) The speed determined in paragraph (b)(2)(i) of this section;
   (B) \( 1.23 V_{SR0} \) with the landing ice accretion defined in appendix C if that speed exceeds \( V_{REF} \) for non-icing conditions by more than 5 knots CAS; and
   (C) A speed that provides the maneuvering capability specified in § 25.143(h) with the landing ice accretion defined in appendix C.

§ 25.125 Landing.

(a) The horizontal distance necessary to land and to come to a complete stop (or to a speed of approximately 3 knots for water landings) from a point 50 feet above the landing surface must be determined (for standard temperatures, at each weight, altitude, and wind within the operational limits established by the applicant for the airplane):

1. In non-icing conditions; and
2. In icing conditions with the landing ice accretion defined in appendix C if \( V_{REF} \) for icing conditions exceeds \( V_{REF} \) for non-icing conditions by more than 5 knots CAS at the maximum landing weight.

(b) In determining the distance in paragraph (a) of this section:

1. The airplane must be in the landing configuration.
2. A stabilized approach, with a calibrated airspeed of not less than \( V_{REF} \), must be maintained down to the 50-foot height.
   (i) In non-icing conditions, \( V_{REF} \) may not be less than:
   (A) \( 1.23 V_{SR0} \);
   (B) \( V_{MCL} \) established under § 25.149(f);
   and
   (C) A speed that provides the maneuvering capability specified in § 25.143(h).
   (ii) In icing conditions, \( V_{REF} \) may not be less than:
   (A) The speed determined in paragraph (b)(2)(i) of this section;
   (B) \( 1.23 V_{SR0} \) with the landing ice accretion defined in appendix C if that speed exceeds \( V_{REF} \) for non-icing conditions by more than 5 knots CAS; and
   (C) A speed that provides the maneuvering capability specified in § 25.143(h) with the landing ice accretion defined in appendix C.
