The seed yields per unit area for the R (Ryld) and S (Syld) phenotypes are calculated as follows:

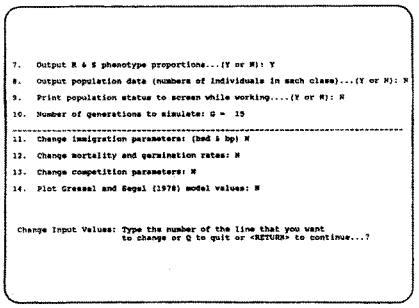

Figure 5. The second and third input screens for RSIM (the computer program version of the resistance simulation model) used for entering the initial conditions for starting a simulation and changing certain model parameter values.

$$Ryld_t = RY_t(TM_t) \quad [8.3]$$

$$Syld_t = SY_t(TM_t) \quad [8.4]$$

Ryld and Syld become the inputs to the seedbank in the next generation (t+1).

Simulations are conducted by inputting a set of initial conditions (Figure 5) and calculating in sequence equations 1.1 through 8.4. The computer program version of the resistance simulation model (RSIM) pro-

duces two types of output: a) Proportions of the R and S phenotype once per generation at the flowering stage before reproduction and b) numbers of individuals at each life-history stage for each generation.

MODEL BEHAVIOR ANALYSIS

Sensitivity and elasticity analysis (18, 20) on the complete simulation model identified two sets of life-history processes that are important for understanding and managing the dynamics of herbicide resistance: a) processes that influence fitness of the R phenotype relative to the S phenotype and crop species and b) processes that contribute to gene flow in space and time.

Fitness. Fitness describes the evolutionary advantage of a phenotype, which is based on its survival and reproductive success (2, 31). Relative fitness of R and S phenotypes has important consequences for the management of resistance. Reduced fitness in the R type (1, 14) infers that R plants will be replaced by S individuals over time after herbicide use is abandoned. Alternatively, if the fitness of the R type is not less than the S type (35), resistance should decline slowly, if at all. Fitness also will be influenced by the presence of other species. (i.e., crop or other weeds) in the system, especially if they are strong competitors. These premises have not been examined experimentally, although the alternatives lead to very different tactics for managing resistance (9).

Gene flow. Gene flow describes the processes that influence the maintenance of a particular genotype in a population. Gene flow processes directly alter the frequencies of R and S alleles in plant populations (16). Immigration of pollen and seed introduce genes into a population, while inbreeding and genetic drift result from limited gene flow. Seed dormancy conserves genes within a plant population. Seed bank dynamics include these gene flow processes, as well as seed survivorship (a fitness process).

Pollen and seed from outside populations are involved in two important management scenarios: a) the spread of resistance over the landscape and b) the use of S-genotype sources (e.g., fence rows, untreated rows, fields, addition of seed) to prevent or slow the evolution of resistance. Attempts to manage herbicide resistance are dominated by tactics to use other herbicides to remove R plants from populations that have developed resistance. Our model simulations suggest that manipulation of S-type gene flow is an alternative for resistance management. Such tactics could be more cost effective than control measures that only reduce R-type plants in already resistant fields.

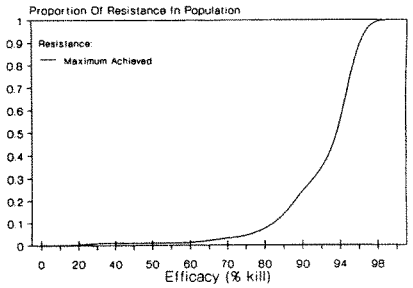

Figure 6. The influence of herbicide efficacy on the maximum level of resistance achieved in a weed population that had 5 continuous years of herbicide applications.

MANAGEMENT SCENARIOS

Simulations. The model was used to assess the influence of gene flow and fitness processes on the evolution of resistance in a weed population. Each of these assessments has management implications. In each analysis, all the parameters except for one were held constant. All the simulations were initiated with selected proportions of each genotype in the treated weed population and an adjacent (source for immigration) population of the same species. Herbicide application begins at Year 5 and is continued through Year 9 in the simulations. All references to the herbicide in the first three scenarios assume that there was a single herbicide in the system and that resistance to that herbicide is a single-gene, homozygous-recessive trait.

The relative fitness of the R and S phenotypes were arbitrarily set equal except in their relative competitive abilities with the crop (R = 1 = S = 1 and R = 0.7 that of the crop, S = 0.8 that of the crop) and their abilities to pollinate and fertilize (R = 0.9 that of S). The crop density was arbitrarily fixed at 200 plants m^{-2}. The following discussion illustrates four scenarios where model simulations were used to explore gene flow and fitness processes and their management implications.

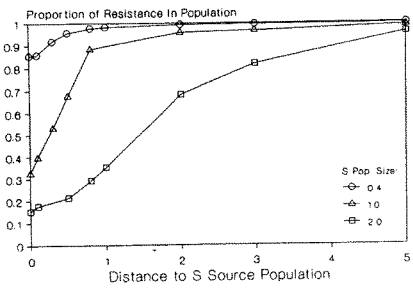

Figure 7. The influence of the size (relative to the treated population) and distance (in units of treated population diameter) to (edge of source to edge of treated) a 100% susceptible source population on the level of resistance achieved after 5 continuous years of herbicide applications.

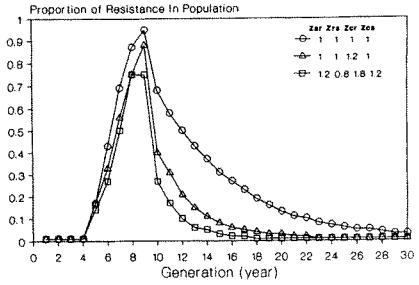

Figure 8. The influence of relative competitive abilities of resistant and susceptible phenotypes in the presence of the crop on evolution of and recovery from resistance (Equations 8.1 and 8.2).

Scenario 1. The influence of herbicide efficacy (h in Equation 4.2) on the evolution of resistance was explored (Figure 6). The simulations were initiated with no resistance in the treated populations, but resistance was introduced in each generation (year) by immigrant pollen from an adjacent (source) population. The model is designed to remove (kill) a proportion of the S individuals equivalent to the efficacy. The maximum level of resistance achieved in the treated population increased sharply when efficacy was about 80%.

The response to efficacy suggested from the simulations has important management implications. Reducing efficacy by intentionally leaving skips in the herbicide application would provide for enough healthy S individuals in the population to reduce the levels of resistance through fitness and gene flow processes. Susceptible individuals also may escape treatment naturally by following a different phenology. The potential for establishing an efficacy threshold to maintain a low proportion of resistance in a weed population is apparent. Competition and economic thresholds have been identified in many weed/crop systems (4) which indicate that high efficacy is often associated with "cosmetic" weed control rather than direct economic gain. Therefore, reducing efficacy to discourage the evolution of resistance may not reduce crop yields.

Scenario 2. This scenario examines the potential for immigrating S pollen and seed to decrease the role of evolution of resistance (Figure 7). The initial conditions for the simulations assumed 1% resistance already in the weed population followed by an increase to 90% resistance at the end of 5 continuous years of herbicide use. The influence of the size of a S source population (relative to the size of the treated population) and distance (in units of treated population diameter) to an outside S source of the weed was assessed for its ability to influence R levels in the treated population.

The simulations indicated that source areas equal to or larger than the treated population can decrease the maximum level of resistance (Figure 7). The management tactic implied by these simulations is to leave untreated adjacent rows or to maintain S populations of the weed dispersed through the treated population within a distance of one treated-population diameter.

Scenario 3. This scenario addresses the influence of competition on the evolution of and recovery from resistance (Figure 8). Competitive abilities of the R and S phenotypes relative to each other and the crop (Equations 8.1 and 8.2) were varied systematically in a set of simulations. Relative competitive ability had little influence on the rate of resistance evolution. The levels of resistance in the population over the first 3 yr of herbicide use did not differ in the simulations. However, the maximum level of resistance after 5 continuous years of herbicide use was highest (95%) when the R and S phenotypes and the crop were assumed to have equal competitive abilities. The maximum level of resistance was reduced to 85% when the R phenotype was assumed to be less competitive than both the crop and the S phenotype of the weed.

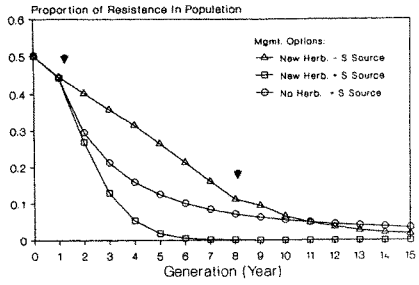

Figure 9. The use of a new herbicide (one that has 85% efficacy on both R and S individuals) and an S source population for managing recovery from herbicide resistance in a weed population. Arrows indicate the beginning and ending of continuous new herbicide applications.

The model simulations indicate that the most significant influence of relative competitive ability on resistance dynamics occurs in the recovery period following suspension of herbicide use (Figure 8). Three years after stopping herbicide use, 30% resistance remained in the population where competitive abilities were equal for the R and S phenotypes and the crop. The proportion of R plants was lower in the recovery period when the relative competitive ability of the R phenotype was decreased relative to the crop and the S phenotype.

The management tactic implied from manipulation of relative competitive abilities is to use or rotate to a crop with a greater competitive ability than the R phenotype. Manipulating competitive pressure by increasing the crop density is an equivalent management option. Changing crop densities had little influence on early evolution and maximum levels of resistance; however, critical crop densities were identified which maximized the rate of recovery to a susceptible weed population following the suspension of herbicide use.

Scenario 4. The model was used to assess management options for recovery after resistance is recognized in a weed population. The simulations were started with 50% resistance in the population. A new herbicide with 85% efficacy on R and S phenotypes was introduced at Year 1 and continued for 8 yr, then all herbicide application was suspended (Figure 9). The simulations indicated that the presence of an adjacent (source) population of S individuals decreased the time for recovery from resistance. Using a new herbicide without a source of immigrant S pollen or seed was not as effective at decreasing the level of R population as was an adjacent population without the use of a new herbicide.

The management implications suggested by these simulations further supports the potential of managing resistance by creating a source of the S phenotype to augment the effect of a new herbicide which will control both R and S weeds.

SUMMARY

The biological complexity and management implications of herbicide resistance can be explored with accurate simulation models that include pertinent biological processes. Gene flow and fitness were identified as important processes influencing resistance dynamics. These processes deserve further experiments to determine their potential for manipulation and management of resistance.

The potential management of resistance suggested by this model represents some alternative strategies and tactics with respect to other attempts to study herbicide resistance. These tactics include methods to decrease the R phenotype and to manipulate the S phenotype of the weed population. Each approach is reasonable, although greatest success should result from multiple integrated tactics for manipulating both R- and S-type weeds in a population.

Abstract

Field experiments were conducted in 11 states to evaluate broadleaf weed management programs in dicamba-resistant soybeans which involved the use of preemergence and postemergence dicamba. Preemergence (PRE) dicamba at 0.25 lb ae/acre provided less than 60% control of smooth pigweed, giant ragweed, velvetleaf, palmer amaranth, waterhemp, and morningglory spp., but 97% control of common lambsquarters and horseweed at 3 weeks after treatment (WAT). Preemergence flumioxazin plus chlorimuron or sulfentrazone plus cloransulam provided 66 to 100% control of these weeds. Use of dicamba postemergence (POST) improved uniformity of control of velvetleaf, smooth pigweed, morningglory, and glyphosate-susceptible waterhemp. However, combining dicamba at 0.25 lb/acre with glyphosate resulted in 30% to 65% greater control of glyphosate-resistant palmer amaranth, glyphosate-resistant common waterhemp, glyphosate-resistant horseweed, and glyphosate-resistant giant ragweed compared to sequentially applied glyphosate.

Introduction

Glyphosate-resistant soybean was commercialized in 1996 and as of 2007, 91% of soybean hectares in the United States were genetically engineered, herbicide-resistant varieties (9). Soybean producers have changed management practices during this time, relying more on conservation and no-tillage practices and use of glyphosate for weed control (10). Use of glyphosate in soybean production from 1995, the year prior to the introduction of glyphosate-resistant soybean when it was used as a burndown herbicide before planting, to 2006, the 10th year of use as a preplant or postemergence herbicide, in soybean increased by ten-fold in the United States (8) at the exclusion of other herbicide modes of action (10). As a result, several agronomically important broadleaf weeds have evolved resistance to glyphosate in the United States including: giant ragweed (*Ambrosia trifida*), common ragweed (*Ambrosia artemisiifolia*), waterhemp (*Amaranthus rudis*), palmer amaranth (*Amaranthus palmeri*), horseweed (*Conyza canadensis*) (4). Other species that are difficult to control with glyphosate include morningglory species (*Ipomoea* spp.), common

lambsquarters (*Chenopodium album*), and dandelion (*Taraxacum officinale*). The aforementioned weed species have been identified by growers in several recent surveys as being the most difficult to manage in current soybean production systems (3,5,6).

Although, glyphosate-resistant corn was introduced in 1997, many other herbicides in addition to glyphosate are used for postemergence weed control. Among those are plant growth regulators such as 2,4-D and dicamba. Dicamba has been used for broadleaf weed control in corn for several decades. Dicamba provides effective control of most of the common dicot weeds found in corn production (7) and to date, there are no weeds commonly found in corn production that have evolved resistance to dicamba (4). Dicamba-resistant soybean is currently being developed to assist farmers in controlling glyphosate-resistant and hard-to-control broadleaf weeds. The dicamba tolerance trait (2) will be stacked with glyphosate resistance and will provide the option of using dicamba preemergence or postemergence in soybean for weed control. There is little research published on dicamba use as a preplant burndown herbicide applied within 14 days of soybean planting, as a soil residual herbicide in soybean, or as a postemergence tankmix partner with glyphosate for control of problematic weed species often faced by farmers in the United States.

The objective of this research was to evaluate control of several problematic annual broadleaf weeds commonly found in soybean production in the United States with dicamba and dicamba + glyphosate weed control programs. Treatment programs consisted of preemergence or preplant application timings alone and followed by single or sequential postemergence applications.

Evaluating Weed Management Programs in Dicamba-Resistant Soybeans

Field experiments were conducted in Georgia, Kentucky, and Missouri in 2007 and in Georgia, Illinois, Indiana, Kansas, Kentucky, Missouri, Nebraska, North Carolina, Ohio, South Dakota, and Tennessee 2008 and 2009. Locations, soil types, and predominate broadleaf weeds at each site are shown in Table 1. Standard field research techniques were used to establish the experiments and apply preplant/preemergence and postemergence treatments. Treatments were applied with backpack sprayers at carrier volumes ranging from 15 to 20 gal/acre (GPA). Preemergence/preplant treatments were applied within 4 days before or after planting at 20 out of 23 site-years. Early postemergence (EPOST), postemergence, and late postemergence (LPOST) treatments were applied on weeds 3 to 5, 3 to 8, and 8 to 16 inches in height, respectively.

Two separate research trials were conducted. The first trial, hereafter referred to as the "non-glyphosate trial" was conducted in Indiana and Ohio in 2008 and 2009 (4 site years). Treatments evaluated in this protocol are listed in Table 2. The second trial, hereafter referred to as the "glyphosate trial," was conducted in all other states in 2007, 2008, and 2009 (19 site years) and treatments are shown in Table 3. The main difference between the treatments in the two trials is the fact that no glyphosate was applied postemergence with treatments 2 through 10 in the non-glyphosate trial. The preemergence residual herbicide used in the glyphosate trial was sulfentrazone plus cloransulam and the one used in the non-glyphosate trial was flumioxazin plus chlorimuron.

Table 1. Year, location, soil characteristics, tillage system, planting dates, and herbicide application dates for dicamba-resistant soybean field trials.

Year	Location	Soil class	Tillage	Planting date	Herbicide application dates				Weeds
					Preplant or pre-emergence (PRE)	Early post-emergence (EPOST) 3-5 inch weeds	Mid post-emergence (MPOST) 3-8 inch weeds	Late post-emergence (LPOST) 8-16 inch weeds

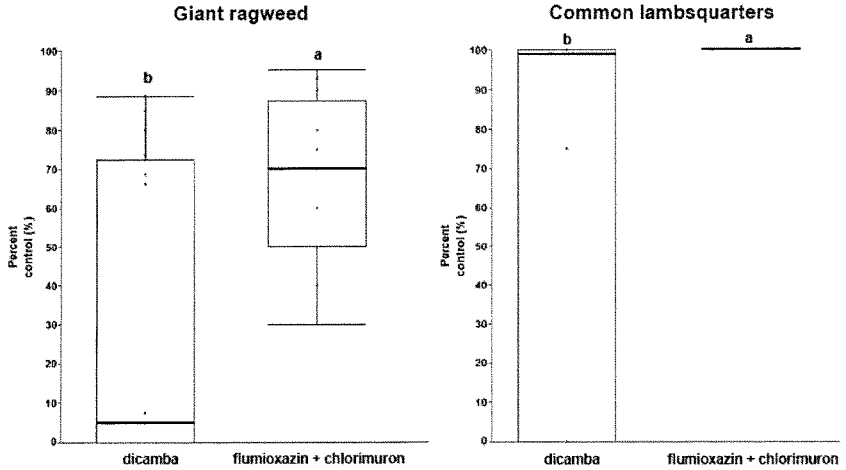
Visual evaluations of weed control were collected at 3 weeks after the PRE residual treatment and 3 to 5 weeks after the LPOST treatment on a 0 to 100 scale, with 0 = no control and 100 = control or death of all plants in the plot. Crop response and yield to the herbicide treatments were not collected for this research as the soybean cultivars used were not of commercial quality. Years were treated as a random variable and data were subject to analysis of variance using Proc Mixed in SAS. Data are presented as box and whisker plots and means are separated with Fisher's Protected LSD at the 0.05 level of significance.

Residual Control of Broadleaf Weeds with Soil-Applied Dicamba

Soil activity of dicamba at 0.25 lbs ae/acre was variable depending on the target weed species. In the non-glyphosate trial, flumioxazin + chlorimuron resulted in 70% control of giant ragweed compared to less than 10% with dicamba (Fig. 1). However, control of common lambsquarters was 98% with dicamba, compared to 100% control with flumioxazin + chlorimuron. In the glyphosate trials, common lambsquarters control with dicamba PRE was excellent and similar to sulfentrazone + chloransulam (Fig. 3). In addition, PRE activity of dicamba resulted in greater than 90% control of horseweed across numerous states (Fig. 3). However, for a majority of the troublesome broadleaf weeds in soybean, residual activity of dicamba compared to sulfentrazone + chloransulam was unacceptable. For velvetleaf, smooth pigweed, Palmer amaranth, common waterhemp, giant ragweed, and morningglory, dicamba activity was less than 60% control (Fig. 3). Comparatively, sulfentrazone + cloransulam controlled velvetleaf 94%, smooth pigweed 90%, palmer amaranth 85%, common waterhemp 82%, giant ragweed 95%, and morningglory spp. 80%. These results indicate that soil-applied dicamba at 0.25 lb ae/acre is effective in suppressing horseweed and common lambsquarters, but is much less effective than common industry standards at suppressing other widespread, problematic weeds evaluated in this research.



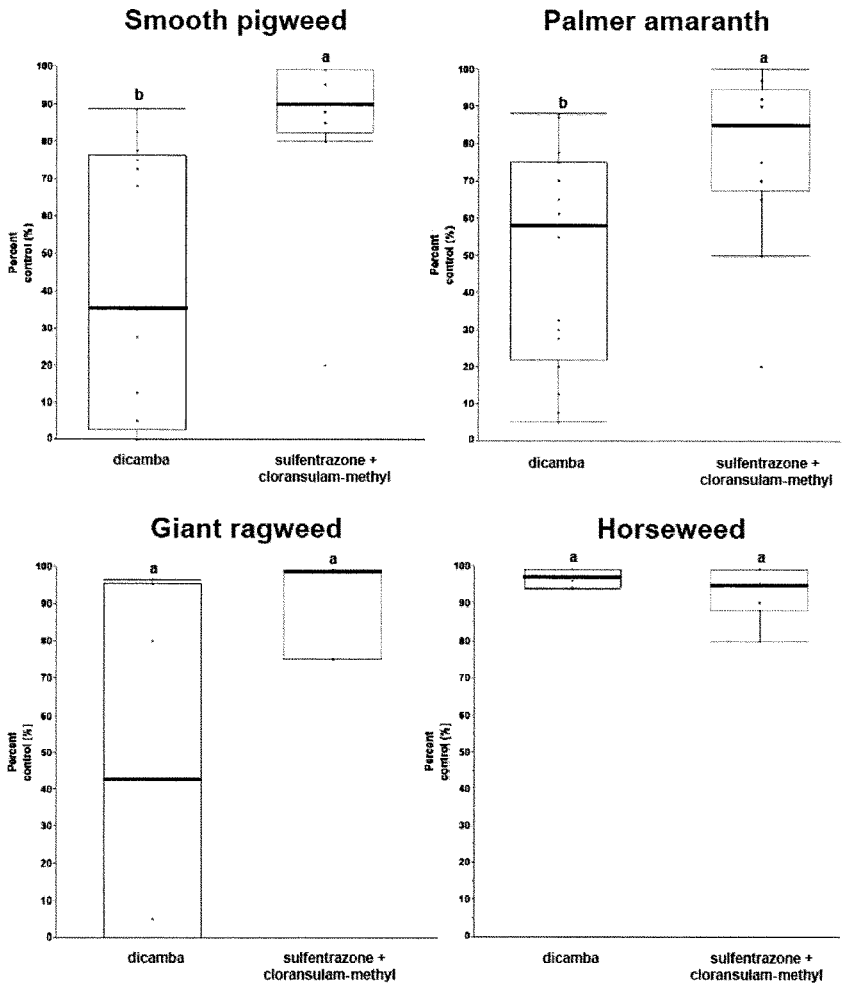


Fig. 1. Box and whisker plots of percent control with preplant dicamba (0.25 lb ae/acre) or flumioxazin (0.056 lb ai/acre) + chlorimuron (0.019 lb ai/acre) at 3 WAT in the non-glyphosate trial conducted in Indiana and Ohio. Horizontal line in the box denotes the mean value, upper edge (hinge) denotes 75th percentile, lower hinge denotes 25th percentile, vertical lines extend to the highest and lowest values. Means followed by the same letters are not different at $P = 0.05$.

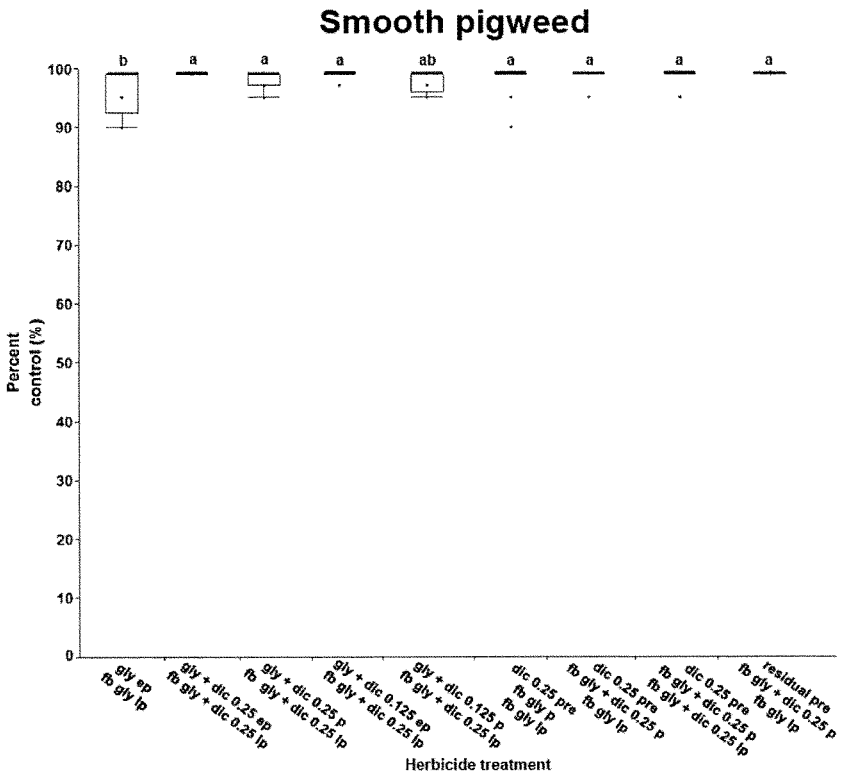
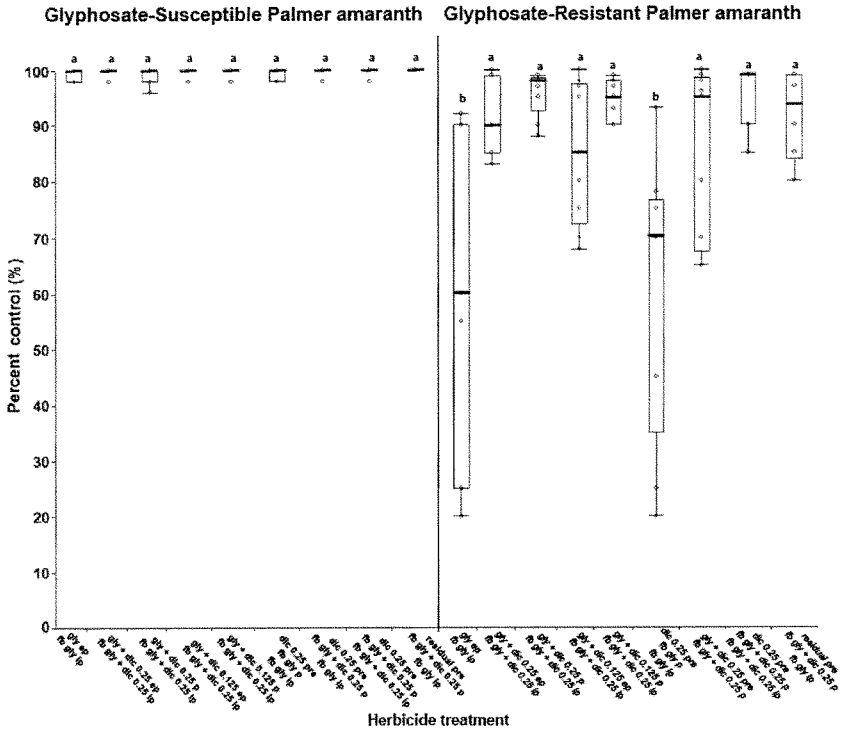
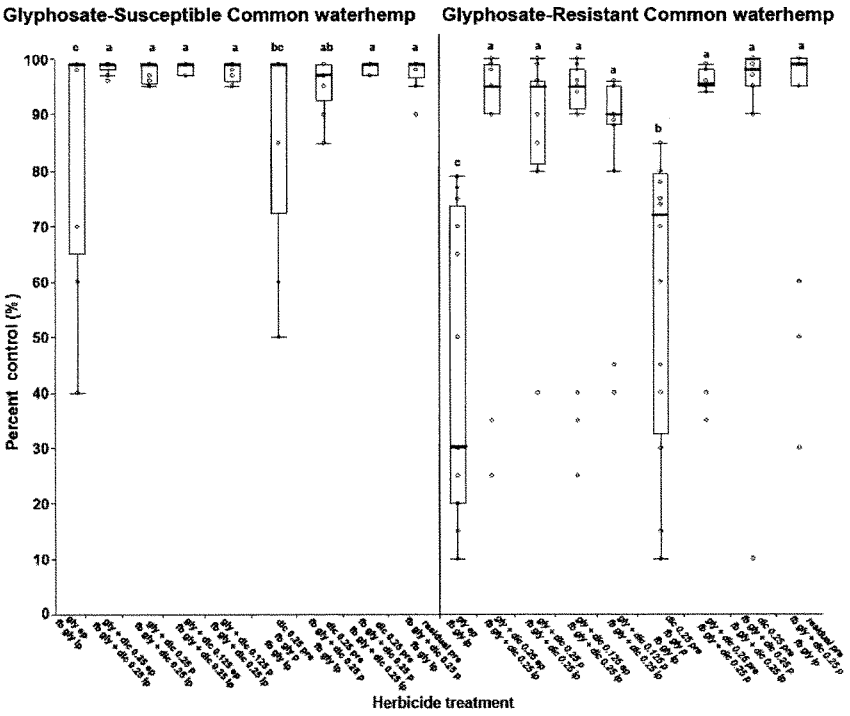
Means followed by the same letter are not different at $P = 0.05$.



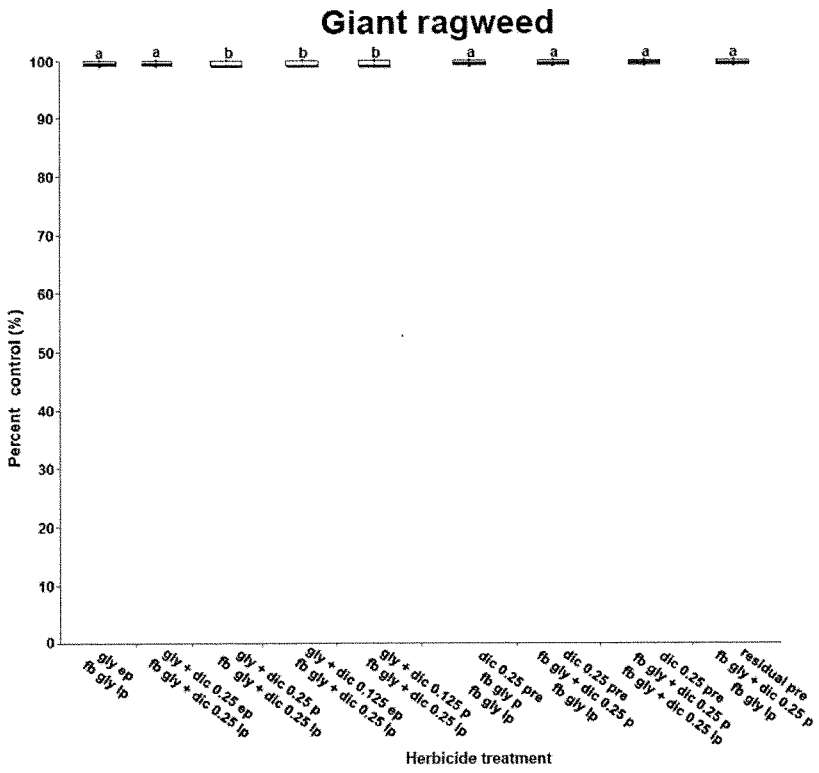
Control of Broadleaf Weeds with Postemergence Dicamba Alone Compared to Glyphosate Alone



In the non-glyphosate trial, control of velvetleaf with dicamba was rate dependent (Fig. 3). Treatments which included dicamba at 0.125 lb ae/acre resulted in up to 5% lower control than treatments which included 0.25 lb ae/acre in the initial postemergence treatment, and more velvetleaf plants survived with the lower POST rates of dicamba. Redroot pigweed and common lambsquarters control was not as rate dependent as velvetleaf, but control was timing dependent. EPOST followed by LPOST sequential treatments provided slightly greater control (5 to 10%) than POST followed by LPOST sequential treatments, irrespective of the dicamba rate. Control of glyphosate-resistant giant ragweed was only 70% with glyphosate alone compared to 92% control of the glyphosate-susceptible biotype (Fig. 3). Application of sequential treatments of dicamba POST, irregardless of rate or timing, resulted in complete control of both biotypes of giant ragweed.



Control of Broadleaf Weeds with Glyphosate + Dicamba vs. Glyphosate Alone



In the glyphosate trial, control of velvetleaf, smooth pigweed, glyphosate-susceptible Palmer amaranth and waterhemp, giant ragweed, and wild buckwheat was 95% or higher with all treatments (Fig. 4). Control of smooth pigweed was timing dependent and treatments which include EPOST application timings provided slightly less variable control than treatments which were applied POST or LPOST, and the addition of dicamba improved control over glyphosate alone. At sites with glyphosate-resistant plants, inclusion of dicamba in the POST treatment greatly improved weed control versus glyphosate alone. For Palmer amaranth, waterhemp, and horseweed, control increased from 60 to 100%, 30 to 95%, and 85 to 98%, respectively. Common waterhemp control was variable with glyphosate alone at both glyphosate-resistant and -susceptible sites. This would indicate that despite the absence of glyphosate-resistant waterhemp at many sites, dicamba improved the consistency of control. Treatments which included glyphosate applied postemergence without dicamba provided lower levels of weed control than treatments which included POST dicamba. Horseweed control was higher and less variable in treatments that included dicamba or flumioxazin, sulfentrazone, chlorimuron, or cloransulam applied preemergence than with treatments that included only postemergence glyphosate or glyphosate + dicamba. With morningglory, treatments which included glyphosate applied postemergence without dicamba resulted in 90 to 93% control. This increased to 98 to 99% control when dicamba was included POST.

Integration of new herbicide-tolerance traits such as dicamba results in the addition of novel modes of herbicide action and improves the consistency of POST broadleaf control programs versus glyphosate alone. Dicamba can also reduce the selection pressure for glyphosate-resistant weeds, preserving the technology of glyphosate-tolerant soybeans. In this research, residual activity of dicamba appears sufficient for early season control of horseweed and common lambsquarters. POST dicamba improved the control of the glyphosate-susceptible weeds evaluated, but improved control was most notable for the glyphosate-resistant weeds horseweed, giant ragweed, Palmer amaranth, and common waterhemp. Dicamba also improved the consistency of control of morningglory.

EVOLUTION IN ACTION: GLYPHOSATE-RESISTANT WEEDS THREATEN WORLD CROPS

Stephen B Powles, WA Herbicide Resistance Initiative, School of Plant Biology, University of Western Australia spowles@plants.uwa.edu.au – outlines the development of glyphosate resistant weeds and the weed control problems that are associated with it

Keywords: glyphosate, herbicide, resistance, GM crops, evolution, sustainability

Introduction

Glyphosate is by far the world's most widely used and important herbicide because it is efficacious, economical and environmentally benign (Dill *et al.*, 2008; Duke & Powles, 2008). Glyphosate dominates for non-selective weed control in agricultural ecosystems, especially to remove weeds between rows in established perennial tree, nut, vine crops and before seeding of annual crops. Globally, glyphosate is also the non-selective herbicide of choice in urban and industrial areas, national parks and other amenity areas. In these use patterns, there have been few instances of weeds evolving glyphosate resistance. While there are documented cases of glyphosate-resistant weed evolution in several countries (Table 1, reviewed by Powles, 2008) given the long term glyphosate usage, experience establishes that plants cannot easily evolve resistance to this herbicide.

The common factor in those examples (Table 1) where glyphosate-resistant weeds have evolved is very persistent glyphosate usage with little or no diversity in weed control practices. Unsurprisingly, glyphosate resistance has evolved most often in the resistance-prone genera *Conyza* and *Lolium*. It is important to recognise, however, that glyphosate continues to be effective globally in its traditional use patterns for non-selective weed control where there is sufficient diversity in control practices and not an extreme over-reliance on glyphosate. However, as discussed below, this situation has dramatically changed now that glyphosate has become a selective herbicide in transgenic crops.

Table 1. Global reports of evolved glyphosate-resistant weeds resulting from use of glyphosate as a non-selective herbicide (see Heap 2008, Powles 2008).

Species	Countries
Conyza spp.	Brazil, China, Spain, Israel, South Africa, USA
Lolium spp.	Australia, Brazil, Chile, France, South Africa, Spain, USA
Echinochloa colona	Australia
Eleusine indica	Malaysia, Taiwan
Parthenium hysterophorus	Colombia
Plantago lanceolata	South Africa

Glyphosate as a selective herbicide in transgenic glyphosate resistant crops

From 1996 onwards, a landmark development occurred with the commercialisation of transgenic (genetic modification obtained through gene manipulation using recombinant DNA technology) crops. By far the most important development has been crops endowed with a bacterial gene conferring resistance to glyphosate (Dill *et al.*, 2008). In transgenic glyphosate-resistant crops (hereinafter referred to as GR crops), glyphosate is used as a selective herbicide to remove weeds without crop damage, providing easy, economical, efficient weed control along with other agronomic advantages such as earlier seeding and reduced or zero tillage. GR crops are a spectacular commercial success (in those countries in which GM crops can be grown) with 95% of the more than 100 million hectares of currently grown transgenic crops being GR crops (Figure 1; James, 2006). In the Americas, the speed and extent of GR crop adoption has been phenomenal. GR soybean, cotton and maize dominate USA cropping. In 2006 GR soybean comprised 90%, cotton 91% and maize 60% of the entire USA plantings of these crops (Figure 2, Dill *et al.*, 2008). In southern USA cropping regions, GR soybean, cotton and maize are rotated on the same fields. In central and northern USA cropping regions, GR soybeans are almost universal and are often in rotation with GR maize.

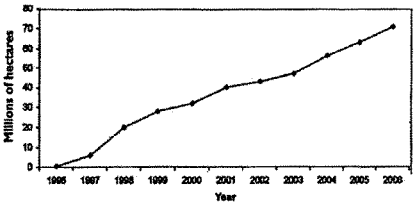

Figure 1: **Global glyphosate resistant crops.**

In Argentina, the adoption of GR crops is even more complete with almost the entire soybean crop being GR (Figure 3). GR crops are also being rapidly adopted in Brazil. The widespread adoption of GR crops and consequent high glyphosate usage (Figures 1-3) is understandable, as glyphosate is easy to use, economical and provides excellent weed control. GR crops all contribute to

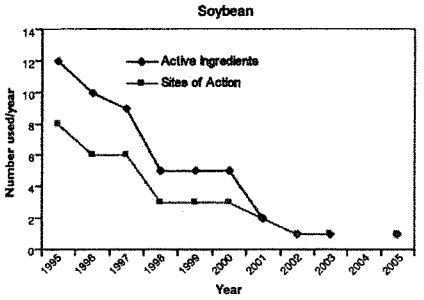

Figure 4: **Number of different herbicide active ingredients and herbicide sites of action used on at least 10% of hectares from 1995 to 2005 in soybean in the USA.**

widespread, high level adoption and therefore unprecedented, often exclusive, use of glyphosate over very large areas. While economically rational for growers and industry (Gianessi, 2005), from an evolutionary perspective the "glyphosate landscape" is an ideal environment in which any weedy plants that can survive glyphosate can thrive. This is especially so because the adoption of GR crops and intensive glyphosate usage often results in the cessation of use of alternative herbicides (Shaner, 2000) and/or tillage, and, therefore, there is no diversity in weed control practices. This further adds to the selection pressure for plants that can survive glyphosate. The adoption of GR soybean and glyphosate in the USA removed alternative herbicide diversity, resulting in almost complete reliance on glyphosate (Figure 4). This is also the case in Argentina and Brazil.

It must be emphasised that glyphosate used repeatedly and persistently post-emergent in GR crops across vast areas is a more intense evolutionary selection pressure for resistance than that which prevails for most traditional glyphosate uses (outlined in the Introduction). In a GR crop, any weed plants that survive glyphosate are likely to flower, pollinate and produce seed. Thus, in GR crops grown on the same fields for several years those weed species that have some level of natural tolerance to glyphosate can come to prominence in GR cropping systems (comprehensively reviewed by Owen, 2008). As well as these widely-occurring weed spectrum shifts, intense glyphosate use in GR crops grown persistently in the same fields/landscapes is a strong selection for resistance to evolve in previously glyphosate susceptible weed species (Powles, 2003). Evolved glyphosate-resistant weeds are a major risk for the continued success of GR crops.

Table 2. Evolved glyphosate-resistant weeds in transgenic glyphosate-resistant crops (see Heap 2008, Powles 2008)

Species	Country
Ambrosia artemisiifolia	USA
Ambrosia trifida	USA
Amaranthus palmeri	USA
Amaranthus tuberculatus	USA
Amaranthus rudis	USA
Conyza spp.	Brazil, USA
Lolium spp.	Brazil, USA
Sorghum halepense	Argentina, USA
Euphorbia heterophylla	Brazil

Table 2 lists the currently documented cases of evolved glyphosate-resistant weeds from usage of glyphosate as a selective herbicide in GR crops.

It is in GR crop areas in the USA and Argentina that glyphosate-resistant weed evolution is most threatening. Since the first report of glyphosate-resistant *Conyza canadensis* in a US GR soybean field in 2001, there are now at least three million hectares of USA GR crops infested with glyphosate-resistant *Conyza*. Even more worrisome are glyphosate-resistant populations of far more economically damaging weed species (Table 2). In some mid-western USA states there are now several known glyphosate-resistant populations of the very vigorous, highly competitive and economically damaging weeds *Ambrosia artemisiifolia* and *Ambrosia trifida*, as well as *Amaranthus rudis* and *Amaranthus tuberculatus*. In the southern cotton-growing states, there are many reports of glyphosate-resistant populations of *Amaranthus palmeri*, a very damaging weed of cotton crops. Evolution of glyphosate resistance in *Ambrosia* and *Amaranthus* populations is a looming threat to GR crop productivity and sustainability in the USA.

As in the USA, GR soybean has been massively adopted in Argentina. Almost the entire 16 million hectare Argentine soybean crop is GR, and nearly all of this is in no-till production systems with little diversity in weed control, and almost exclusive reliance on glyphosate. Additionally, GR maize is being adopted at a rapid rate. Therefore, the selection pressure is intense for evolution of glyphosate-resistant weeds. So far, the very damaging weed *Sorghum halepense* has evolved glyphosate resistance across a significant area of the GR soybean crop in the Salta province (Vila-Aiub *et al.*, 2008). Brazil did not commercialise GR crops until well after Argentina, the USA and Canada, with GR crop adoption occurring mainly since 2005. However, rapid adoption of GR soybean, maize and cotton is now underway. Thus far, glyphosate-resistant populations of *Conyza* and *Euphorbia heterophylla* have evolved in Brazilian GR soybean areas (Table 2). Paraguay and Uruguay are also adopting GR crops. Given the dominance of GR crops in soybean, cotton and maize agro-ecosystems in major cropping regions of North and South America, more species will inevitably evolve glyphosate resistance.

Canada: One example of sustainable use of a GR crop

It is instructive to contrast the situation in Canada with that in the USA and Argentina. In the western Canadian grainbelt provinces (Alberta, Manitoba, Saskatchewan), canola is the only GR crop present. In this agro-ecosystem, non-GR wheat and barley dominate, with canola as an important rotational crop. Additionally, not all the canola grown is GR: in 2007, of the six million hectares of canola in Canada, only 70% was GR. Canadian growers also have transgenic glufosinate-resistant canola, and mutagenesis-derived imidazolinone herbicide resistant canola. Therefore, there is the option for diversity in canola type and herbicide use. Also, it is important to recognise that as canola is a rotational crop, it is grown on a particular cropping field only every third or fourth year. As the rotational cereal and any other crops are not GR, it is thus likely that a GR crop is grown on a particular field only infrequently. Clearly, the glyphosate selection intensity on weed species in this Canadian canola-cereal cropping agro-ecosystem is much less than with GR crops in the USA or Argentina. Unsurprisingly, there are currently no known cases of evolved glyphosate-resistant weeds in Canada. This is undoubtedly due to the diversity (as it refers to herbicide use) evident in the Canadian cropping system, relative to that in the GR soybean-maize-cotton agro-ecosystems of the USA. Thus, GR canola should remain sustainable in Canada if this diversity is maintained. There are important lessons to be learnt for other parts of the world, from this sustainable use of a GR crop in Canada.

Conclusion

A major lesson evident from more than three decades of non-selective glyphosate use to control billions of plants worldwide is that where diversity in weed management systems is maintained, then weed control by glyphosate can be sustainable. Glyphosate is a remarkably robust herbicide from a resistance evolution viewpoint. However, as reviewed above, it is clear that where there is very intense glyphosate selection without diversity, glyphosate-resistant weed populations will evolve. Particularly, the evolution of glyphosate-resistant weed populations is a major threat in areas where transgenic glyphosate-resistant crops dominate the landscape, and in which glyphosate selection is intense and without diversity. As glyphosate usage continues to be intensive in these areas (Foresman & Glasgow, 2008), it is likely that glyphosate-resistant weeds will become a major problem. There is a strong likelihood that resistance evolution will eliminate glyphosate as a weed management option in these important crop regions. This being so, the re-introduction and/or maintenance of diversity in these agro-ecosystems is essential. What specifically constitutes "diversity" will vary according to region, ecosystem, enterprises, economics and many other factors. However, diversity will involve herbicide rotations/sequences, mixtures

of robust rates of herbicides with different modes of action, and use of non-herbicide weed control tools. Such diversity must be introduced now in the GR cropping areas of the USA, Argentina and Brazil. Mixtures of glyphosate with effective doses of different herbicides are already being adopted, and transgenic crops with additional herbicide-resistance genes are in development (Behrens *et al.*, 2007, Green *et al.*, 2008, Sammons *et al.*, 2007). Alternative herbicides and integration with non-herbicidal weed control tools will be required.

For those regions of the world that have not yet adopted GR crops and/or intensive glyphosate usage, there are lessons to be learnt from the GR crop experience in the Americas. By avoiding intense glyphosate reliance and through maintenance of diversity, the longevity of this precious herbicide resource and of excellent GR crop technologies can be sustained for future harvests. Glyphosate is essential for present and future world food production, and action to secure its sustainability should be a global imperative.

Herbicide-Resistant Crops: Utilities and Limitations for Herbicide-Resistant Weed Management†

JERRY M. GREEN*,§ AND MICHEAL D. K. OWEN#

§Stine-Haskell Research Center, Pioneer Hi-Bred International, Inc., Newark, Delaware 19714-0030, and #Department of Agronomy, Iowa State University, Ames, Iowa 50011-1011

Since 1996, genetically modified herbicide-resistant (HR) crops, particularly glyphosate-resistant (GR) crops, have transformed the tactics that corn, soybean, and cotton growers use to manage weeds. The use of GR crops continues to grow, but weeds are adapting to the common practice of using only glyphosate to control weeds. Growers using only a single mode of action to manage weeds need to change to a more diverse array of herbicidal, mechanical, and cultural practices to maintain the effectiveness of glyphosate. Unfortunately, the introduction of GR crops and the high initial efficacy of glyphosate often lead to a decline in the use of other herbicide options and less investment by industry to discover new herbicide active ingredients. With some exceptions, most growers can still manage their weed problems with currently available selective and HR crop-enabled herbicides. However, current crop management systems are in jeopardy given the pace at which weed populations are evolving glyphosate resistance. New HR crop technologies will expand the utility of currently available herbicides and enable new interim solutions for growers to manage HR weeds, but will not replace the long-term need to diversify weed management tactics and discover herbicides with new modes of action. This paper reviews the strengths and weaknesses of anticipated weed management options and the best management practices that growers need to implement in HR crops to maximize the long-term benefits of current technologies and reduce weed shifts to difficult-to-control and HR weeds.

KEYWORDS: Corn; *Zea mays*; cotton; *Gossypium hirsutum*; soybean; *Glycine max*; crop; herbicide; resistance; tolerance; weed management

INTRODUCTION

Herbicide-resistant (HR) crops, particularly glyphosate-resistant (GR) crops, have transformed the way many growers manage weeds. However, after three decades and billions of dollars invested in research, only a few transgenic herbicide traits are commercially available (*1*−*3*). Two transgenes code for a glyphosate-insensitive 5-enolpyruvylshikimate-3-phosphate synthase (EPSPS; EC 2.5.1.19), the *cp4 epsps* gene from *Agrobacterium tumefaciens* strain CP4 and the mutated *zm-2mepsps* from corn (*Zea mays* L.), and three transgenes code for metabolic inactivation. One gene from *Ochrobactrum anthropi* strain LBAA encodes for glyphosate oxidoreductase (GOX), and two homologous genes, *pat* and *bar* from *Streptomyces viridochromogenes* and *Streptomyces hygroscopicus*, respectively, encode *N*-acetyltransferases that inactivate glufosinate. Today, HR traits are used on >80% of the estimated 134 million hectares of transgenic crops grown annually in 25 countries (*3*, *4*) with a single trait, CP4 EPSPS, being by far the most utilized (*5*).

Growers rapidly adopted the first GR crops because the technology enabled a new weed control practice with glyphosate that was effective, easy-to-use, economical, safe, and novel. The novel attribute of the gene technology was essential to get patents that protected the large investment needed to develop the technology, whereas growers touted the simplicity and convenience of the glyphosate-based crop systems (*1*−*3*). Initially, glyphosate was exceedingly effective in GR crops, and many growers relied only on glyphosate to control weeds. Some academic weed scientists were concerned about the sustainability of this approach and predicted the evolution of resistance. However, no cases of GR weeds had evolved after more than two decades of broad use in noncrop situations (*6*), and some weed scientists and growers began to think that GR weeds would never be a problem. Then the paradigm changed in 1996 with the discovery of GR rigid ryegrass (*Lolium rigidum* Gaudin) in Australia (*7*, *8*).

Today, all accept the evolution of GR weeds is threatening the continued success of GR crops and the sustainability of glyphosate. Nineteen weeds have evolved resistance to glyphosate; about half evolved in GR crops (*9*). The basis for resistance has been attributed to altered EPSPS target site (*10*), reduced translocation or cellular transport to the plastid (*11*), sequestration in the vacuole (*12*), and gene amplification (*13*). GR weeds increase the cost of weed control and diminish the benefits of glyphosate-based weed management systems. In retrospect, it was inevitable that GR weeds would evolve. Glyphosate was a victim of its own

success. No matter how effective a herbicide is, weed management programs cannot rely so heavily on one tactic or weeds will ultimately adapt and survive in large numbers.

In essence, GR crops created the "perfect storm" for weeds to evolve resistance. Growers applied glyphosate alone over vast cropping areas to control genetically variable and prolific weeds year after year. Many of these weeds had already evolved resistance to other herbicide modes of action, so there was no good herbicide alternative when these weeds subsequently evolved resistance to glyphosate (*14*). Of particular note is the case of the highly competitive and prolific Palmer amaranth (*Amaranthus palmeri* S. Wats.). The explosion of GR Palmer amaranth populations in the southeastern United States became known as the "pigweed disaster" (*15*). These GR populations are forcing growers to change their production practices and increase the costs for weed control, even to the extent of hand-weeding. Because of these shortsighted use practices, glyphosate is not as effective as it used to be and growers must supplement glyphosate with other herbicides.

Growers now need to diversify the herbicides they use to mitigate the spread of GR weeds (*16*). Unfortunately, the chemical industry has not commercialized a herbicide with a new mode of action (MOA) for over two decades (*17*). This is partly because the number of chemicals that must be tested to discover a new herbicide has increased from fewer than 1000 in 1950 to more than 500,000 today and partly because companies are investing less money to discover new herbicides as the widespread use of GR crops has reduced the market opportunity. To address the GR weed problem, the industry is now developing new herbicide resistance traits that will expand the utility of currently available herbicides. However, it is critically important to recognize that these traits represent interim solutions for current weed problems and do not replace the long-term need to discover herbicides with new modes of action and to diversify weed management tactics.

UTILITIES AND LIMITATIONS OF CURRENT HERBICIDE TECHNOLOGIES

Current Herbicide Use Practices. GR crops came at a time of great socioeconomic change in agriculture. Farm size was increasing, and the number of growers was declining; thus, growers had to become more efficient. Furthermore, weeds were rapidly evolving resistance to various herbicides, and growers perceived weed management as taking too much time. Growers wanted new weed management tactics, and GR crops enabled an economical, efficient, and simple solution. Once growers started using glyphosate, they overused it. The average rate and number of applications of glyphosate increased as its price declined, and the use of other herbicides decreased (*18*, *19*). Competitors reacted by reducing the price of their herbicides, but those alternatives could not maintain their market presence (*20*).

In retrospect, GR crops could have helped to increase the diversity of herbicides that growers used (**Table 1**). GR crops did not require that growers use only glyphosate and the added diversity of glyphosate combined with other herbicides would have mitigated the evolution of HR weeds. However, the use of tank mixtures and sequential application of different herbicides declined. In one year, from 1997 to 1998, the use of glyphosate increased 81% in parallel with the increase of GR soybeans [*Glycine max* (L.) Merr.] from 13 to 36% (*21*). The number of herbicide active ingredients used on at least 10% of the U.S. soybean area declined from 11 in 1995 to only 1, glyphosate, in 2002 (*22*). Even though the chance of weeds evolving resistance to glyphosate in a particular location is still predicted to be lower than that with other herbicides, weeds ultimately did evolve glyphosate resistance as a direct result of the lack of weed management diversification on incredibly large areas of GR crops (*23*, *24*).

Interestingly, HR weeds often do not decrease the amount of herbicide used because growers make herbicide decisions based on weed complexes, not individual species or biotypes. If a weed evolves resistance to a herbicide, that herbicide has not lost all of its value as it still controls other weeds, and growers often continue to use the herbicide in a program with another herbicide to control the resistant weed. Furthermore, growers do not "recognize" the potential for weeds to evolve resistance to glyphosate until the biotypes appear in their fields (*25*). Unfortunately, this can lead to the practice of sequentially using herbicides until they are no longer effective, which is the fastest way to evolve multiple HR weeds (*16*). A combination of herbicides, cultural, and mechanical tactics provides the greatest protection from HR weeds.

Some weed species are particularly troublesome to control and in their propensity to evolve resistance (**Table 2**). Problematic weeds in glyphosate-based production systems that have evolved genetic mutations that confer glyphosate resistance include Palmer amaranth and waterhemp [*Amaranthus tuberculatus* (Moq.) Sauer]. Other weeds such as velvetleaf [*Abutilon theophrasti* (L.) Medik.], morningglories (*Ipomoea* spp.), Asiatic dayflower (*Commelina communis* L.), tropical spiderwort (*Commelina benghalensis* L.), and field bindweed (*Convolvulus arvensis* L.) often survive because of naturally higher tolerance. Populations of tolerant weed species increase when growers use less than full-labeled rates (*26*). Currently, at least seven GR weed species have evolved resistance to multiple herbicide MOAs, with one population of waterhemp in Illinois being resistant to four (*27*). The rapid expansion of multiple HR weed populations threatens the sustainability of current crop production systems (*16*).

The best weed management strategy is to control weeds prior to the loss of crop yield potential and proactively delay the evolution of weed resistance. Fortunately, most fields do not have GR weeds yet, and there is still time for many growers to implement diverse and proactive weed management practices (**Table 3**) (*28*).

Table 2. Summary of Key Row Crop Weeds and Herbicide Efficacy

weed species[a]		control rating (0–10) and resistance status[b,c]

[a] Weed selection determined by a market research survey of U.S. corn, soybean, and cotton growers by Gfk Kynetec, Inc., St. Louis, MO (used with permission). [b] Weed control ratings are summarized from U.S. extension guides with 0 being the lowest and 10 being the highest level of control. A rating of ≥7 indicates effective herbicide control. Weed ratings represent the highest observed for any active in that class. [c] An R next to herbicide efficacy rating indicates that this weed has developed resistance to herbicide mode of action (Heap 2010). [d] ACCase resistance has been confirmed but not listed at Heap 2010. [e] ACCase trait currently under development and anticipated to be an issue in feral corn after commercialization.

Generally, the basic management tactics are the same for both the prevention and control of HR weeds, that is, diversification of tactics to reduce selection pressure imposed by specific herbicides. The challenge is to implement these practices under prevailing economic constraints when growers are not convinced resistance management tactics will be effective or they believe industry will continue to deliver new solutions to manage weeds (*29*). Many growers are reluctant to diversify weed management because they perceive alternative tactics as being less cost-effective despite growing evidence that such tactics can improve profitability as well as mitigate resistant weed issues (*30*). More education will help overcome this perception as will the explosion of multiple HR weeds that emphatically persuades growers to diversify their weed management practices now or face serious long-term consequences.

Current Herbicide Technologies. Besides glyphosate, most current herbicides used for weed management in corn, soybean, and cotton are selective and typically used in mixtures to control a broad spectrum of weed species. The following section provides an overview of the utilities and limitations for various herbicide MOAs that have potential utility in HR crops.

Glyphosate. Glyphosate is a nonselective, broad-spectrum foliar herbicide with no soil residual activity that has been used for >30 years to manage annual, perennial, and biennial herbaceous grass, sedge, and broadleaf weeds as well as unwanted woody brush and trees. Glyphosate is labeled to control over 300 weed species. Many glyphosate formulations and salts are commercially available; the most common salts are the monopotassium and isopropylamine. The type and amount of adjuvant included in the various formulations differ greatly and strongly influence weed control. Glyphosate strongly competes with the substrate phosphoenolpyruvate (PEP) at the EPSPS enzyme-binding site in the chloroplast, resulting in the inhibition of the shikimate pathway. Products of the shikimate pathway include the essential aromatic amino acids tryptophan, tyrosine, and phenylalanine and other important plant metabolic products (*31*). The relatively slow MOA and physicochemical characteristics result in glyphosate translocation throughout the plant and accumulation at the vital growing points before phytotoxicity occurs.

Favorable physicochemical characteristics, low cost, tight soil sorption, application flexibility, low mammalian toxicity, and availability of GR crops have helped make glyphosate the most widely used herbicide in the world (*32*). A key advantage for glyphosate has been the consistent control of weeds almost without regard to size. However, the flexibility in glyphosate application timing and lack of soil residual have often resulted in growers delaying applications to help ensure that all of the weeds have emerged. Unfortunately, such delay in application means that the weeds have begun to compete with the crop and thus reduced potential yield. The increased use of mixtures with herbicides that have soil residual activity will encourage growers to make earlier glyphosate applications and increase the likelihood that a single application gives season-long control. Other commonly noted weaknesses with glyphosate are higher rates needed to control the more tolerant broadleaf weeds, antagonism by hard water and tank mixture partners, slow speed of action, and poor rainfastness.

Table 3. Assessment of Commonly Used Tactics for Herbicide-Resistant Weed Management (Adapted from Reference *28*)

tactic	benefits	risks	potential impact
herbicide rotation	reduced selection pressure, control HR weeds	lack of different MOAs, phytotoxicity, cost, limited weed spectrum of alternatives	excellent
herbicide mixtures	reduced selection pressure, improved control, broader weed spectrum	poor activity on HR weed species, increased cost; potential phytotoxicity	excellent
variable application rate and timing	better control of HR species, more efficient herbicide use	lack of herbicide residual activity, timing may be too late to protect yield potential, more applications	good to excellent
adjusted herbicide rates	better control of target species	increased target-site selection pressure with higher rates, increased nontarget site with lower rates (polygenic resistance)	poor to fair
precision herbicide application	decreased herbicide use, reduced selection pressure	increased cost of application, unavailability of weed population maps; poor understanding of weed seedbank dynamics; increased variability of control	poor
primary tillage	decreased selection pressure, consistent efficacy; depletion of weed seedbank	increased time required, increased soil erosion, increased costs, additional tactics needed	good to excellent
mechanical weed control strategies	decreases selection pressure; consistent efficacy, relatively inexpensive	increased time required, high level of management skill needed, additional tactics needed, potential for crop injury	poor to fair
crop selection/ rotation	changes agro-ecosystem, allows different herbicide tactics, reduced selection pressure	economic risk of alternative rotation crop, lack of adapted rotation crop, rotation crops similar and thus minimal impact on the weed community, herbicides, required, lack of research base, inconsistent impact on HR weed populations	fair to good
adjusted time of planting	potential improved efficacy on target weeds, reduced selection pressure	requires alternative strategies (tillage or herbicide), potential for yield loss, need for increased rotation diversity	poor to fair
adjusted seeding rate	reduced selection pressure, improved competitive ability for the crop	increased seed cost, potentially increased pest problems, increased intraspecific competition, reduced potential yields	fair
planting configuration	improved competitive ability for the crop, reduced selection pressure	unavailability of mechanical strategies, emphasis on herbicides, equipment limitations	good
cover crops, mulches, intercrop systems	improved competitive ability, reduced selection pressure, improved systems diversity, allelopathy	inconsistent effect on HR weeds, lack of understanding about systems, limited research base, potential crop yield loss, need for herbicide to manage the cover crop, lack of good cover crops	poor
seedbank management	reduced HR weed pressure, reduced selection pressure	lack of understanding about seedbank dynamics, requires aggressive tillage, emphasis on late herbicide applications, high level of management skill needed	fair to good
adjustment of nutrient use	improved competitive ability for the crop, efficient use of nutrient	lack of research base, inconsistent results, potential crop yield loss	poor

Glufosinate. Glufosinate is a nonselective, broad-spectrum foliar herbicide with no soil residual soil activity that inhibits glutamine synthetase [GS; EC 6.3.1.2], an enzyme that catalyzes the conversion of glutamate plus ammonium to glutamine as part of nitrogen metabolism (*31*). Glufosinate is faster acting and controls key broadleaf weeds such as morninglories (*Ipomoea* spp.), hemp sesbania (*Sesbania herbacea* (P. Mill.) McVaugh), Pennsylvania smartweed (*Polygonum pensylvanicum* L.), and yellow nutsedge (*Cyperus esculentus* L.) better than glyphosate. However, glufosinate is used at higher rates and has historically been more expensive than glyphosate. Cost and more restrictive application timing relative to weed size are probably its greatest disadvantages compared to glyphosate. Because glufosinate behaves as a contact herbicide, it must be applied to smaller plants than glyphosate and is not as effective on perennials that require significant translocation for complete control. Still, glufosinate is labeled to control >120 broadleaf weeds and grasses including key GR weeds. No weeds have been formally reported as glufosinate-resistant yet (*9*).

Synthetic Auxins. Synthetic auxin herbicides act as auxin agonists by mimicking the plant growth hormone indole-3-acetic

acid (IAA), disrupting growth and development processes, and eventually causing plant death, particularly in broadleaf species (*31*). Growers have used auxin herbicides widely for over 60 years as selective herbicides in monocotyledonous crops. Auxins control a broad spectrum of broadleaf weeds, including key weeds that have evolved resistance to glyphosate. Some synthetic auxins such as dicamba have fair soil residual activity with a half-life from 7 to 21 days. Relatively few weeds have evolved resistance to auxin herbicides, which is noteworthy considering their long-term and widespread use. For example, only six weed species have evolved resistance to dicamba after 50 years of widespread use in cereal and noncrop environments (*9*).

The increased use of dicamba and other auxin herbicides in auxin-resistant crops has the potential of injuring other broadleaf crops and reducing biodiversity in field edges and nearby noncrop habitat if unmanaged (*33*). Off-target movement of auxin herbicides can occur via spray particle and vapor drift. Particle drift is more problematic than vapor drift, but growers can manage with modified application techniques, drift control adjuvants, and correct decisions as to when, where, and how to apply. Particularly troublesome for auxin herbicides would be any movement onto highly sensitive crops such as soybeans, cotton (*Gossypium hirsutum* L.), or grapes (*Vitis vinifera* L.). Interestingly, 2,4-D is safer than dicamba on soybeans and dicamba is safer than 2,4-D on cotton (*34*). As little as 0.01% of the labeled rate of dicamba can injure soybeans (*35*), and 0.001% of the labeled rate of 2,4-D butyl ester formulation can injure tomatoes (*Lycopersicon esculentum* Mill.) and lettuce (*Lactuca sativa* L.) (*36*).

Some forms of dicamba and 2,4-D are highly volatile, especially at high temperatures. For example, the acid form of dicamba is more volatile than amine salt formulations, and some amine salts are more volatile than others. Considerable research is underway to minimize volatilization with new salts and formulations. The manufacturer can also reduce potential off-target movement with application restrictions based on temperature, droplet size, humidity, and wind speed. Because of their volatility and the sensitivity of nontarget crops, growers will probably not use auxin herbicides on vast areas during warm weather as is currently done with glyphosate.

HPPD Inhibitors. The enzyme 4-hydroxyphenyl pyruvate dioxygenase [HPPD; EC 1.13.11.27] converts 4-hydroxyphenyl pyruvate to homogentisate, a key step in plastoquinone biosynthesis. This is the most recently discovered herbicide MOA, and active analogue testing continues to generate new products (*37*). Inhibition of HPPD causes bleaching symptoms on new growth by indirectly inhibiting carotenoid synthesis due to the requirement of plastoquinone as cofactor of phytoene desaturase [PDS; EC 1.14.99] (*38*). Visible injury depends on carotenoid turnover and thus is slower to appear on older tissues than young leaves (*31*). HPPD-inhibiting herbicides control a number of important weed species and may have soil residual activity, and no weeds have been formally reported to be resistant to this MOA yet. Corn is naturally tolerant to key HPPD herbicides, but soybeans and cotton are generally sensitive.

ALS Inhibitors. Herbicides that inhibit acetolactate synthase (ALS; EC 2.2.1.6), also known as acetohydroxyacid synthase (AHAS), were discovered in the mid-1970s and are still widely used (*39*, *40*). The ALS enzyme is a key step in the biosynthesis of the essential branched-chain amino acids valine, leucine, and isoleucine. ALS is a nuclear encoded enzyme that moves to the chloroplast via a transit peptide. More than 50 different ALS-inhibiting herbicides from five different chemical classes (sulfonylureas, imidazolinones, triazolopyrimidines, pyrimidinylthiobenzoates, and sulfonylamino-carbonyl-triazolinones) are commercially available. The characteristics of ALS herbicides vary in their soil residual properties, crop response, and types of weeds that are effectively controlled. ALS herbicides can provide foliar and soil residual activity on important grass and broadleaf weeds at low application rates. The tendency of weeds to evolve resistance to ALS herbicides limits their utility (*9*), and their use is now mainly in mixtures with other types of herbicides.

PPO Inhibitors. Protoporphyrinogen oxidase (PPO; EC 1.3.3.4) is an essential enzyme that catalyzes the last common step in the biosynthesis of heme and ultimately chlorophyll by the oxidation of protoporphyrinogen IX to protoporphyrin IX. PPO-inhibiting herbicides cause the accumulation of protoporphyrinogen IX, which is photoactive, and exposure to light causes the formation of singlet oxygen and other oxidative chemicals that cause rapid burning and desiccation of leaf tissue. The soil residual and fast action characteristics of PPO herbicides complement the lack of soil residual and the slow activity of glyphosate.

PPO enzyme mutations tend to reduce the enzymatic activity, which helps explain the relatively slow evolution of resistant weeds to this 40-year-old herbicide class (*41*). Companies continue to synthesize analogues and commercialize new PPO-inhibiting herbicides. For example, saflufenacil was introduced in 2010 and is labeled for use in a wide variety of crops, including corn, soybeans, and cotton (*42*). Its label describes burndown and residual control of 70 broadleaf weeds including key troublesome weeds in glyphosate-based systems such as common lambsquarters (*Chenopodium album* L.), horseweed [*Conyza canadensis* (L.) Cronq.], waterhemp, and common (*Ambrosia artemisiifolia* L.) and giant (*Ambrosia trifida* L.) ragweeds.

ACCase Inhibitors. Acetyl coenzyme A carboxylase [ACCase; EC 6.4.1.2] is the first step of fatty acid synthesis and catalyzes the adenosine triphosphate (ATP)-dependent carboxylation of malonyl-CoA to form acetyl-CoA in the cytoplasm, chloroplasts, mitochondria, and peroxisomes of cells (*43*). ACCase-inhibiting herbicides generally inhibit the ACCase activity of monocot species and not dicots. The three chemical classes of ACCase inhibitors are cyclohexanediones (DIMs) (e.g., sethoxydim), aryloxyphenoxypropionates (FOPs) (e.g., quizalofop), and phenylpyrazolines (DENs) (e.g., pinoxaden). The ability to use ACCase herbicides selectively in corn would be useful, but the tendency of weeds to evolve resistance to this herbicide class would limit its utility to being part of a weed management system (*9*).

Other Herbicide Types. Currently used selective and burndown herbicides will continue to play important roles in weed management in HR crop systems (**Table 1**). In addition to the herbicide types already discussed, photosystem II (PSII) inhibitors such as triazine and urea herbicides, lipid synthesis inhibitors such as *S*-metolachlor, and phytoene desaturase (PDS) inhibitors such as clomazone will continue to be used as crop-selective herbicides to provide soil residual activity on key weeds. Paraquat is a photosystem I (PSI) inhibiting herbicide typically used in conservation and no-tillage production systems for nonselective burndown control of emerged weeds or as a directed spray with specialized application equipment in crop. Paraquat controls a broad spectrum of weeds, and the lack of soil residual allows rotational crop flexibility similar to glyphosate and glufosinate. Paraquat rapidly desiccates leaf tissue and thus does not translocate well enough to control perennial weeds. Paraquat is relatively inexpensive, but its high mammalian toxicity imposes significant use and handling restrictions.

UTILITIES AND LIMITATIONS OF CURRENT AND FUTURE HERBICIDE-RESISTANT CROP TECHNOLOGIES

Current HR Crop Technologies. A large number of transgenic and nontransgenic HR crops have been commercialized (**Table 4**).

Table 4. Summary of Commercial Herbicide-Resistant Crops in North America (Adapted from Reference *44*)

herbicide type		crop	year available
bromoxynil		cotton	1995
		canola	2000
ACCase inhibitor	- sethoxydim	corn	1996
	- quizalofop-P	sorghum	2011
glufosinate		canola	1995
		corn	1997
		cotton	2004
glyphosate		soybean	1996
		canola	1996
		cotton	1997
		corn	1998
		alfalfa	2005
		sugar beets	2005
imidazolinones		corn	1993
		canola	1997
		wheat	2002
		rice	2002
		sunflower	2003
specific sulfonylureas		soybean	1994
		sunflower	2006
		sorghum	2011
triazines		canola	1984

These HR crops generally eliminated all crop injury concerns and allowed the grower to select new herbicide options with improved weed activity and environmental safety. Before the advent of GR crops, most thought that the utility of HR crops would be limited to complementing selective herbicides (*45*−*47*). The full impact of HR crops really started in 1996 with the sales of GR soybeans. Since then, the speed at which growers adopted GR crops has been unprecedented in corn, soybeans, and cotton (*4*). Success came despite an unpopular "grower contract" and strong objections by biotechnology opponents to potential unknown effects on the environment and human health and the ethical question of interfering with the natural order.

Nontransgenic HR Crops. With the exception of Canada, nontransgenic HR traits are essentially unregulated. Scientists have used a wide range of nontransgenic techniques to create crops with resistance to a number of herbicide MOAs (**Table 5**). For example, the first commercial ACCase-resistant crop was a sethoxydim-resistant (SR) corn with an altered ACCase created using tissue culture selection (*49*). A second ACCase trait is in the final stages of commercialization for use in sorghum. This trait was transferred with traditional breeding methods from feral sorghum (shattercane, *Sorghum bicolor* L. Moench) that had evolved ACCase herbicide resistance because of agronomic practices (*50*).

Creating HR crops for ALS-inhibiting herbicides has been quite successful using tissue culture selection, pollen mutagenesis, microspore selection, seed mutagenesis, and gene transfer from close weedy relatives that had evolved herbicide resistance because of agronomic practices (*50*−*52*). Today, at least seven different ALS-resistant crops are commercially available (*53*). In all cases, resistance is due to an ALS mutation with three general crop phenotypes: broad resistance to ALS herbicides; resistance only to imidazolinone and pyrimidinylthiobenzoate herbicides; and resistance only to sulfonylurea and triazolopyrimidine herbicides (*54*, *55*).

Table 5. Summary of Nontransgenic Herbicide-Resistant Crops (Adapted from Reference *48*)

selection method	herbicide type	crop
whole plant	triazine	canola
seed mutagenesis	terbutryne	wheat
	sulfonylurea	soybean
	imidazolinone	wheat
		rice
tissue culture	sulfonylurea	canola
	atrazine	soybean
	imidazolinone	corn
	sethoxydim	corn
cell selection	imidazolinone	sugar beet
pollen mutagenesis	imidazolinone	corn
microspore selection	imidazolinone	canola
transfer from weedy relative	ALS inhibitor	sunflower
		sorghum
	ACCase inhibitor	sorghum

Table 6. Summary of Currently Available Transgenic Herbicide-Resistant Corn, Soybeans, and Cotton

crop	resistance trait	trait gene	trait designation	first sales
cotton	glyphosate	*cp4 epsps*	MON1445	1996

	glufosinate	*pat*	A2704-12	2009

Glyphosate-Resistant Crops. Nontransgenic HR crops were only modestly successful; the big success with HR crops began with transgenic GR soybeans in 1996 (**Table 6**). Growers perceived glyphosate resistance as the ideal herbicide trait because glyphosate controls over 300 annual and perennial weeds, has flexible application timings, and does not have any rotational crop restrictions (*56*). GR crops allowed growers to use glyphosate as an in-crop selective herbicide and replace more expensive, selective herbicides that controlled a narrower weed spectrum and had other issues (e.g., crop tolerance).

Within a decade after glyphosate became commercially available, the search began to find crop resistance to glyphosate. Nontransgenic approaches were not successful, and transgenic approaches were difficult and not initially successful (*57*). Initial attempts to find any natural enzymes in crops that could metabolically inactivate or were insensitive at the target site failed. Eventually, a gene for a glyphosate insensitive EPSPS with enzymatic characteristics similar to plant EPSPS was isolated from a common soil bacterium, *Agrobacterium tumefaciens* strain CP4, which was surviving in a glyphosate manufacturing waste stream in Luling, LA (*57*). This *cp4 epsps* gene has been used to develop GR soybeans, cotton, corn, canola, alfalfa (*Medicago sativa* L.), bentgrass (*Agrostis stolonifera* L.), and sugar beet (*Beta vulgaris* L.) (*5*).

Glyphosate resistance became the most rapidly adopted technology in the history of agriculture (*5*), but the first GR crops were not perfect. The timing, rate, and number of glyphosate

Table 7. Publicly Disclosed Non-glyphosate Transgenic Herbicide-Resistant Traits with Significant Utility in Corn, Soybeans, and Cotton (Adapted from Reference *48*)

herbicide/herbicide class	characteristics	reference
2,4-D	microbial degradation enzyme	*60*
ALS inhibitors	resistant ALS from many sources	*61*

multiple herbicide classes	glutathione *S*-transferase, *Escherichia coli*	*64*
	P450, *Zea mays*	*65*

applications had to be restricted to ensure crop resistance (*5*), and there were reports of a "yield drag" (*58*). A new generation of herbicide traits currently in development will be combined with current and new glyphosate traits to help continue to improve this technology and extend the transgenic weed management revolution.

Glufosinate-Resistant Crops. Glufosinate-resistant crops have been commercially available as long as GR crops (**Table 6**), but have not been as successful for a number of reasons, particularly because of the higher cost of glufosinate and its more restrictive application timings. Glufosinate resistance is widely available, not only because of its utility as a herbicide trait but also because it has been often used as a marker for other traits, particularly insect resistance traits. Resistance to glufosinate is due to metabolic inactivation of the parent molecule by either of two homologous enzymes, phosphinothricin *N*-acetyltransferase (PAT) or basta *N*-acetyltransferase (BAR), that catalyze the acetylation of glufosinate (*59*). Both genes were isolated from soil microorganisms, *pat* from *Streptomyces viridochromogenes* and *bar* from *Streptomyces hygroscopicus*. Cotton and soybean growers who are troubled by difficult to control GR weeds such as Palmer amaranth and waterhemp may rapidly adopt glufosinate-resistant crops and the use of glufosinate. "Dual stack" crop cultivars that include resistance to both glufosinate and glyphosate are now commercially available in cotton, soybeans, and corn and provide growers a choice between two broad-spectrum herbicides as well as an array of naturally selective herbicides to diversify their weed management practices.

Future HR Crop Technologies. Whereas GR crops have been very successful, the evolution of GR weeds was faster and more widespread than many expected. This rapid evolution of GR weeds and the lack of any new selective herbicides with novel MOAs is encouraging HR crop technology to evolve again. The next wave of technologies will combine resistance to glyphosate and other herbicides to provide growers with more herbicide options with different MOAs as well as the possibility of using herbicides with both foliar and soil residual activity. Scientists have discovered a plethora of herbicide traits that can be combined with glyphosate resistance to make multiple HR crops (**Table 7**). If used correctly, multiple HR crops with these traits can sustain the usefulness of glyphosate.

Resistance to Synthetic Auxin Herbicides. Corn is relatively tolerant to most synthetic auxin herbicides, but soybeans and cotton are sensitive, and scientists have long sought a transgene to give these crops resistance and allow the use of auxin herbicides (*66*). Auxin herbicides control a broad spectrum of broadleaf weeds, including most known GR broadleaf weeds. Because auxin herbicides act rapidly at multiple receptors and compete with an essential plant hormone pathway, making crops resistant by modifying the site of auxin action is difficult. In addition, these receptors respond differently to different auxin herbicide classes, for example, phenoxyacetates (e.g., 2,4-D), pyridinyloxyacetates (e.g., fluoroxypyr), benzoates (e.g., dicamba), picolinates (e.g., picloram), and quinolinecarboxylates (e.g., quinclorac) (*67*). So far, metabolic inactivation has proven to be a more successful strategy.

A gene encoding for dicamba monooxygenase (DMO), an enzyme that deactivates dicamba, was cloned from a soil bacterium, *Stenotrophomonas maltophilla*, and used to make dicamba-resistant soybeans (*63*, *68*). The DMO enzyme encodes a Rieske nonheme monooxygenase that metabolizes dicamba to 3,6-dichlorosalicylic acid (DCSA). The complete bacterial dicamba *O*-demethylase complex consists of the monooxygenase, a reductase, and a ferredoxin. Electrons are shuttled from reduced nicotinamide adenine dinucleotide (NADH) through the reductase to the ferredoxin and finally to the terminal component DMO. Researchers can successfully express DMO in the cell nucleus with or without a transit peptide as well as in the chloroplasts where the monooxygenase would have a source of electrons produced by photosynthesis and where transgenic proteins can often be expressed at higher levels. Commercialization of dicamba-resistant soybean and cotton is anticipated mid-decade.

A family of *aad* genes that code for aryloxyalkanoate dioxygenase provides resistance to certain auxin herbicide (*69*, *70*). The *aad-12* gene was isolated from *Delftia acidovorans* and codes for a 2-ketoglutarate-dependent dioxygenase that inactivates phenoxyacetate auxins (e.g., 2,4-D) and pyridinyloxyacetate auxins (e.g., triclopyr and fluoroxypyr) (*62*). This trait, DHT2, is being developed in soybeans. A second gene known as *aad-1* was isolated from *Sphingomonas herbicideovarans* and inactivates auxins and ACCase-inhibiting herbicides in the class known as FOPs (e.g., fluazifop) (*62*). This trait, DHT1, is being developed in corn. Both traits are reported to provide resistance to high rates of 2,4-D with no adverse agronomic effects.

The 2,4-D and dicamba resistance traits will always be used in stacks with at least one other herbicide-resistance trait (*62*, *71*). The expected increased use of auxin herbicides will increase the potential for off-target movement and injury to sensitive broadleaf plants. Due to this potential environmental problem, the herbicide and trait providers will likely introduce improved herbicide formulations with better use directions before the traits are commercialized mid-decade (*33*, *72*). Ironically, this risk of off-target movement could drive more rapid adoption of auxin traits because growers will want to protect their soybean and cotton crops from nearby applications of auxin herbicides.

Resistance to HPPD Inhibitors. In some ways, HPPD-inhibiting herbicides are ideal to complement glyphosate. Many HPPD herbicides have soil residual activity and control key broadleaf weeds that have already evolved resistance to glyphosate. Increased resistance mechanisms for HPPD herbicides include a less sensitive target site, overexpression of the enzyme, alternate pathway, increasing flux in the pathway, and metabolic inactivation (*38*, *48*). Crops resistant to HPPD herbicides have been in field development tests since 1999, but there have been no technical disclosures of HPPD resistance traits under developments thus far. Bayer CropScience in collaboration with Mertec LLC (Adel, IA) and M.S. Technologies LLC (West Point, IA) and Syngenta (Basel, Switzerland) have independently announced plans to develop HPPD-resistant crops. Bayer CropScience recently disclosed that they were developing soybeans resistant to three herbicide types: glyphosate, glufosinate, and HPPD herbicides (e.g., isoxaflutole) (*17*). Isoxaflutole can provide preemergence (PRE) and postemergence (POST) control of a relatively

broad spectrum of annual weeds with soil residual activity. The "triple stack" offers the advantage of enabling the use of two herbicide MOAs to which weeds have not yet evolved resistance.

Resistance to Other Herbicide Types. Resistance to other herbicide types could also have significant utility. For example, transgenic crops resistant to PPO-inhibiting herbicides have been developed, and the technology even received the trade name Acuron (*41*). The first PPO-resistant corn used a double-mutant PPO, PPO-1, from *A. thaliana*. Similarly, PPO-resistant rice used overexpression of the naturally resistant *Bacillus subtilis* PPO gene to confer resistance. Other approaches including increasing gene copy number and tissue culture to select for overexpression of wild type PPO genes have also been successful (*41*). The broad-spectrum weed control and soil residual activity of PPO herbicides could be useful in corn, soybeans, and cotton, but the existing widespread resistance to this class among some *Amaranthus* species limits the value of the technology.

A transgenic DHT1 trait also gives resistance to ACCase-inhibiting herbicides by degrading the alkanoate side chains to a hydroxyl of the FOP class of ACCase herbicides (e.g., quizalofop) (*62*). DHT1 corn reportedly tolerates postemergence applications of quizalofop of up to 184 g/ha with no adverse agronomic effects. This trait has utility in corn where commercial ACCase herbicides are not naturally selective. In addition, the specificity of its inactivation could allow the use of other ACCase herbicide types for HR volunteer corn management in rotational crops.

Most herbicide traits only give resistance to herbicides with one MOA. Metabolic inactivation systems based on cytochrome P450 monooxygenases (P450) and glutathione transferase (GST) have the potential to inactivate a wide range of herbicide types (**Table 7**). For example, native P450 enzymes can metabolically inactivate acetanilides, bentazon, dicamba, some ALS-inhibiting herbicides, isoxazoles, and urea herbicides (*65, 73*). The chemical specificity of this metabolic system may offer the unique potential to allow growers to use herbicides in the same MOA to control weeds in one season and still manage any feral volunteers with a herbicide in the same MOA in the next year.

Multiple HR Crops. No single herbicide resistance trait will be sustainable if the grower uses only the single herbicide type that the trait enables recurrently. The weed problems and their technological resolution must evolve together. Multiple HR crops will help by allowing the use of new herbicide mixtures with multiple modes of action, but agriculture must manage this technology objectively and pragmatically, balancing short-term and long-term interests, so as not to create a "transgenic treadmill" (*18*).

The lack of soil residual activity has encouraged multiple in-crop applications glyphosate, as many as four or more applications per growing season. Some of the new, multiple HR crop technologies will enable herbicide applications with soil residual activity and thus help growers to reduce selection pressure on the weed community by glyphosate (*74*). For example, the glyphosate and ALS trait stack that has recently been deregulated in the United States can allow the use of ALS-inhibiting herbicides with soil residual that are too phytotoxic to use on conventional crop cultivars (*75*). This stack consists of a metabolic system to inactivate glyphosate based on an enhanced glyphosate acetyltransferase enzyme from the soil bacterium *Bacillus licheniformis* (Weigmann) Chester (*76*) and a highly resistant ALS allele (HRA) with two mutations, tryp574leu and pro197ala (*75*).

A wide array of other combinations of current and new herbicide resistance traits is expected within the next decade. If used correctly, these multiple HR crops will provide new uses for existing herbicides to help growers better manage weeds and help sustain the utility of glyphosate and glyphosate resistance traits.

PATH FORWARD

Weed management dramatically changed with the widespread adoption of GR crops. Using glyphosate in GR crops made weed management too simple and convenient. Importantly, the high initial efficacy of glyphosate declined with repeated use, and current glyphosate-based weed management systems are in jeopardy as evidenced by the speed at which weed populations are evolving resistance. Still, glyphosate has not lost all utility; it controls more weeds more effectively than other herbicides, but it can no longer be applied alone anytime on any weed anywhere. Most growers still do not have any GR weeds in their fields and have time to implement proactive HR weed management practices to help sustain glyphosate. However, growers need to act now to diversify the herbicides and tactics they use, the crops they plant, their cultural practices, and field hygiene measures. The flexibility and range of alternative weed management practices will be narrow and require integration to replace glyphosate. These management practices will work better for the prevention rather than the control of GR weeds. Once present, GR weeds can be managed but are difficult if not impossible to eradicate.

Growers need new weed management options now. Current corn, soybean, and cotton cropping systems are based on a heavy reliance on glyphosate. Given the changes in weed populations that are being reported, it is of paramount importance that other weed management alternatives be identified and implemented quickly (*25, 77*). It is likely that no new herbicide or trait technology will match the impact of glyphosate and the first GR crops on agriculture. Growers will use these new technologies in combinations to fill in efficacy gaps and diversify weed management practices. Initially, it may look like an attempt to make glyphosate look "as good as it used to be". Some traits such as glufosinate resistance will enable a broad-spectrum alternative to glyphosate. Others will enable options with soil residual activity or new MOAs to control key GR weeds. Some HR crop technologies may benefit from incremental improvements in efficacy and properties of herbicides within long-standing herbicide MOAs that companies are still commercializing (*37, 42*).

Growers must diversify their weed management practices now (*78*). The more growers diversify, the less the risk that weeds will evolve herbicide resistance. Diversification may make weed management more complex, but growers must not use new HR crop systems in the same way that some used initial GR crops, as a means to rely only on one herbicide until it is no longer effective and then switch herbicides. If growers use the new HR crops and the herbicides that they enable properly, HR crops will expand the utility of currently available herbicides and provide long-term solutions to manage GR weeds.

HR crops will not replace the need for technical innovations, particularly the discovery of herbicides with new MOAs. Diversification will be much easier if growers can chose from among multiple effective and economical weed management options. In areas of the world that have not yet adopted GR crops, growers can learn from the experiences in North and South America. Growers must not wait, but implement best management practices as soon as new trait and herbicide technologies are available. By using diverse weed management practices, growers will preserve the utility of herbicide resistance traits and herbicide technologies and help maintain profitable and environmentally sustainable crop production systems for future generations.

Modelling the Effectiveness of Herbicide Rotations and Mixtures as Strategies to Delay or Preclude Resistance[1]

JONATHAN GRESSEL and LEE A. SEGEL[2]

Abstract. Herbicide-resistant populations have evolved only in monoculture and/or monoherbicide conditions at predictable rates for each compound and weed. No populations of triazine-resistant weeds have appeared in corn where rotations of crops and herbicides or herbicide mixtures were used. This is due to the greatly reduced competitive fitness of the resistant individuals, which could be expressed only during rotational cycles, and also to the greater sensitivity of resistant individuals to other herbicides, pests, and control practices ("negative cross-resistance"). The model presented here describes how an understanding of all of these factors can provide strategies to decrease the frequency of the resistant individuals during rotation. Rotations or mixtures may not delay the rate of appearance of resistance to inhibitors of acetolactate synthase (ALS), where the fitness of resistant biotypes is claimed to be near normal. The best way to delay resistance to ALS inhibitors is to use those compounds with less persistence so that the selection pressure will be lowered. Too little is known about the frequency of resistance to other herbicides with target-site resistance–to dinitroanilines, to acetyl CoA carboxylase inhibitors, or to those situations where a single enzyme system confers resistance to a broad spectrum of seemingly unrelated herbicides. **Nomenclature:** Corn, *Zea mays* L.

Additional index words: Herbicide resistance, fitness, selection pressure, seedbank dynamics, triazine resistance, metabolic cross resistance.

INTRODUCTION

Weeds are evolving resistance to different herbicides at different rates. Resistance can be avoided by understanding and analyzing the interacting factors involved in changing a sensitive weed population into a resistant one. These factors, described below, are inserted into models so that the quantitative importance of each factor can be evaluated. The model predictions favorably compare with the case histories of resistance. Newer models are described so that the effectiveness of different weed control strategies can be predicted better.

Weeds in North America have evolved resistant populations to herbicides only where there was monoculture with a single family of herbicides. The only exceptions until recently have been where different herbicides having the same site of action were used (e.g., a rotation of photosystem-II inhibiting herbicides) (17). Resistant-weed populations have evolved in wheat (*Triticum aestivum* L.) monoculture in England and Australia, where high selection pressure herbicides with different sites of action but the same putative mode of degradation are rotated (17, 19, 37, 41). Such metabolic cross resistances likely will evolve elsewhere.

The appearance of resistance in monoculture and/or mono-herbicide usage was described by a simple population model (22, 23) that integrated the following: a) the selection-pressure of the herbicide (based on the rate used, its effectivity with particular weeds, and its persistence); b) the germination dynamics of the weeds (over the season and from the soil seedbank); c) the initial frequency of resistant individuals deriving from natural mutations in the susceptible population; d) the fitness of the evolved resistant biotypes in competition with the wild type under field conditions; and e) the number of generations (seasons) the herbicide was used. This model helps to understand why resistance evolved in monoculture to the high selection pressure *s*-triazines in corn but not to herbicides exerting lower selection pressure, such as the thiocarbamates, chloroacetamides, and phenoxy herbicides, in similar weeds growing in this crop (22, 23).

It is consistent with the model that populations of weeds did not evolve that resist 2,4-D [(2,4-dichlorophenoxy)acetic acid] and MCPA [(4-chloro-2-methylphenoxy)acetic acid] in wheat. The model predicts the inevitably rapid appearance of weed biotypes resistant to the high residual activity sulfonylureas, as well as to chlorotoluron [*N*′-(3-chloro-4-methylphenyl)-*N*′*N*-di-

[1]Received for publication July 24, 1989, and in revised form Dec. 15, 1989.

methylurea], diclofop-methyl {methyl ester of (±)-2-[4-(2,4-dichlorophenoxy)phenoxyl]propanoic acid}, and mecoprop [(±)-2-(4-chloro-2-methylphenoxy)propanoic acid)] in weeds of wheat.

Resistant biotypes evolved first in those weeds where the herbicides exert the highest selection pressure. For example, diclofop exerts a higher selection pressure on ryegrass (*Lolium* spp.) species than on wild oat (*Avena* spp.) species. In agronomic terms, this herbicide is more effective on ryegrasses, and ryegrasses indeed have evolved resistance with greater rapidity (41).

Because of a lack of field ecology data, our early model inaccurately predicted evolution of resistance where herbicide mixtures and rotations were used. Vast areas of corn have received herbicide rotations including *s*-triazines for 30 yr, and resistant populations have not appeared. Our early model did not adequately consider the then unknown effects of the extreme lack of fitness in many resistant biotypes in the seasons that triazines were not used. The previous model (22, 23) correctly predicted that mixtures could delay considerably the evolution of resistance, but the lack of field data on selection pressure of mixtures left it to the reader to insert the correct parameters into the equations and the accompanying figures.

A new model (24) considers what happens during the "off" years when a given herbicide is not used and predicts that some high selection pressure herbicides can be used sparingly in rotation, possibly even after resistance has appeared. The data show the urgent need for further research concerning the physiological ecology of resistant weed populations.

MODELS

The original monoculture model described different possible rates of enrichment of resistant individuals in populations, until the populations were predominantly resistant (22, 23). Different constant proportions of susceptible and resistant plants germinated and survived to the end of the season, and susceptible and resistant individuals had (different) constant seed yields. Resistant individuals initially formed an exceedingly small fraction of the population, certainly a well-warranted assumption during the years of resistance enrichment, until there were sufficient numbers of individuals for resistance to be evident.

Various factors involved in evolution were found (after certain simplifications) to satisfy a simple algebraic equation giving our early model (22, 23). Solving this equation gives the frequency of resistant individuals after n years of treatment.

$$N_n^{(R)} = N_o^{(R)} \left[1 + \frac{f\alpha}{n}\right]^n \quad [1]$$

The factors included in the original monoculture monoherbicide model equation are the following:

$N_o^{(R)}$ is the very low frequency of resistant individuals in the population before it is exposed to the herbicide. Resistance is sustained in the population in the absence of herbicide by a balance between new mutations to resistance and depletion of a proportion of resistant individuals by their lesser fitness in the absence of selection. This results in a resistance fraction somewhat lower than the mutation frequency. Mutants conferring more fitness than the wild type become the wild type. Mutant fitness can be near neutrality, and the mutants would be found in different proportions at various geographical areas due to genetic "drift." $N_n^{(R)}$ is the proportion of resistance in the population after n seasons of treatments.

f, the competitive reproductive fitness, measures the compounded relative robustness of resistants in competition with susceptibles during germination, establishment, growth, pollination, seed production, and survival. By definition, fitness always is measured with resistant and susceptible plants in competition with each other in the absence of herbicide. When they are grown separately, the resistant individuals are often less "productive," but the competitive fitness differential is usually greater (Table 1)[3].

α, the selection pressure, is the ratio of the fraction of resistants that abound in the population after a herbicide application during that season to the corresponding fraction of susceptibles. Thus, early or late-germinating susceptible individuals that produce seeds are considered in this "effective-kill", in contrast with the initial weed control usually measured by weed scientists. For example, if the herbicide kills 90% of the susceptibles and none of the resistants, then $\alpha = 10$; if 99% of the susceptibles are controlled and none of the resistants, then $\alpha = 100$. The susceptible individuals would in-

[3]Letters following the symbol # are a WSSA-approved computer code from Composite List of Weeds, Revised 1989. Available from WSSA, 309 W. Clark St., Champaign, IL 61820.

Table 1. Lower productivity and competitive fitness of *s*-triazine-resistant biotypes[a].

Species[b]	Productivity	Competitive fitness (1:1)[c]	Reference
	(Resistant ÷ Susceptible)		
Smooth pigweed	0.90	0.18	1
Common groundsel	0.47	0.43	28
Common lambsquarters	0.75	0.08	52
Lateflowering goosefoot	1.00	1.78	52
Rapeseed	0.76	0.28	21

[a]Productivity is measured by growing resistant and susceptible biotypes separately; competitive fitness is measured by growing them in a mixture. In both cases, seed yield was measured, where "seed" may include fruit or whole flower depending on study cited.

[b]Smooth pigweed (*Amaranthus hybridus* L. # AMACH); common groundsel (*Senecio vulgaris* L. # SENVU); common lambsquarters (*Chenopodium album* # CHEAL); lateflowering goosefoot [*Chenopodium strictum* Roth. var. *glaucophyllum* (Aellen) H. A. Wahl. # CHESG]; rapeseed (*Brassica napus* L.)

[c]Fitness of 1:1 mixture.

clude those missed by sprays (in refuges) and "immigrants" due to seed and pollen influx.

The gene flow due to seeds and pollen usually is minimal, in the range of meters per years when actually measured (2, 30, 43). Immigration of resistant seed can be a problem when there is strong selection pressure in a field. One "pioneer" seed can form a large colony. Immigrating susceptible seed will have little numerical impact because of the larger reservoir of susceptible seed already in the field during the first cycles of selection for resistance.

$\bar{n}$ is the average number of years that a seed remains viable in the seed bank.

The predicted rates of enrichment of resistance are plotted from Equation [1] with different scenarios of selection pressure, seedbank dynamics, fitness, and initial frequency in Figure 1. These various measures of resistance change by a constant factor each year, giving rise to an exponential increase in resistant individuals (Figure 1). Estimated parameter values (that should have come from experimentation) were inserted into the equation to generate the scenarios. They were based on a limited data base, mostly from corollary systems, such as heavy metal tolerance. Research groups have begun to accurately measure weed-herbicide interactions for more precise estimates.

The frequency of resistance in the population starts at a low value and increases by a constant factor each year. In spite of the exponential increase, detecting resistant individuals in a field will be hard until resistance is at a level of 10 to 30% of the population.

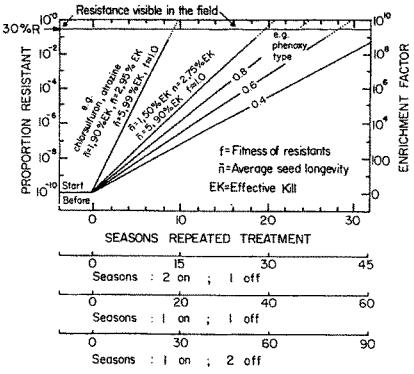

Figure 1. Presumed effects of herbicide rotations using the original model. Overall average effect of scenarios with different selection pressures [$\alpha = 10 =$ 90% effective kill (EK); $\alpha = 100 = 99\%$ EK; $\alpha = 2.0 = 50\%$ EK], seed bank dynamics ($\bar{n}$), the average seed duration in the soil, and *f* differential fitness. The different scales give the different rotational scenarios from monoherbicide to one treatment in three seasons. Calculated from equations in (22, 23). Modified from (24).

Messages from the model. *a) The importance of selection pressure.* Selection pressure is the most influential agronomic variable, with the largest effect on the evolution of resistance (Figure 1). For example, the atrazine [6 -chloro -*N*' -(1 -methylethyl) -1,3,5 -triazine-2,4 -diamine] and chlorsulfuron {2-chloro-*N*-[[(4-methoxy-6-methyl -1,3,5 -triazin -2 -yl)amino]carbonyl]benzenesulfonamide} levels required to kill different weeds vary over more than an order of magnitude. The selection pressure of both herbicides is greatest on annual broadleaf species requiring the lowest rates for weed control. The selection pressure is least for those weeds requiring the highest herbicide levels, i.e., usually the grasses. At a given herbicide rate, both herbicides control broadleaf species better, i.e., selection pressure is lower on grasses.

The first weeds to evolve atrazine-resistant populations were common groundsel, pigweed species, and lambsquarters species. The last to evolve resistance were the grasses, as the model predicted. Various broadleaf weeds already have evolved chlorsulfuron resistance in the field, at the level of the target enzyme. This occurred under repeated selection pressure of this

recently introduced and highly persistent herbicide. It was also easy to select for resistance to this herbicide in the laboratory (7, 26). If these two preferentially broadleaf controlling herbicides were used in conjunction with selective grass-controlling herbicides, their use rates could be decreased and the selection pressure on broadleaf weeds lowered.

Single annual use of herbicides with the greatest persistence always will exert the highest selection pressure (Figure 1). The triazines, dinitroanilines, and sulfonylureas meet this criterion of persistence with season-long control, and resistance has evolved to all these groups (16). 2,4-D and other phenoxy herbicides and thiocarbamates have short biological persistence in the soil, and resistance has not evolved to them. Resistance need not have evolved so rapidly. There are less persistent triazines than atrazine (such as cyanazine) {2-[[4-chloro-6-(ethylamino)-1,3,5-triazin-2-yl]amino]-2-methylpropane-nitrile] and far less persistent sulfonylureas for wheat than chlorsulfuron and metsulfuron {2-[[[[(4-methoxy-6-methyl-1,3,5-triazin-2-yl)-amino]carbonyl]amino]sulfonyl]benzoic acid} (5). If these less persistent analogs had been used, the selection pressure should have been lowered and the evolution of resistant populations delayed.

Paraquat (1,1′-dimethyl-4,4′-bipyridinium ion) resistance has evolved and may seem to contradict the theory's emphasis on persistence, as paraquat immediately loses biological activity upon reacting with soil colloids. The lack of residual persistence was balanced by farmer persistence. Paraquat resistance occurred where this herbicide was used 5 to 10 times during each season in monoherbicide usage.

b) Seedbank dynamics. The longer the life in the seedbank, the greater the buffering effect of susceptible seed from previous years, decreasing the rate of evolution of resistance. Common groundsel has evolved triazine resistance in orchards, nurseries, and roadsides where there was no mechanical cultivation but not in cultivated corn fields. The groundsel seed is incorporated into the soil seedbank in such corn fields, where it is viable for many years (54). All groundsel seed falling on undisturbed soil on roadsides or orchards either germinates or dies during the following season (42). Resistance thus evolved where there was the lowest average seed bank life time $\bar{n}$ as predicted. Such information must be considered in formulating strategies for resistance management. Many other species do not have a seedbank under specific agronomic situations, i.e., in minimum-till agriculture where $\bar{n} = 1$.

c) f, fitness of resistant individuals. The lack of fitness of resistant individuals can have a strong dampening effect on the evolution of resistance but only when it can be expressed, i.e., when the herbicide is not present. Thus, in monoherbicide culture, the lack of fitness can have little influence with persistent herbicides but could be effective with the less persistent herbicides. This is another reason to avoid persistent compounds, especially in monoculture.

Resistance to herbicides with the same site of action. The original model predicted that rotation or mixing of herbicides with the same site of action (and thus similar mode of resistance) will have the same effect as using a single herbicide. This was expected on biochemical grounds as well; plants resistant to atrazine had target-site cross resistance to all triazines, some phenylureas, uracils, etc., all at the same site in Photosystem II. The use of corn/soybean [*Glycine max* (L.)Merr.] or atrazine/metribuzin [4-amino-6-(1,1-dimethylethyl)-3-(methylthio)-1,2,4-triazin-5-(4*H*)-one] or sulfonylurea/imidazolinone rotations with various crops thus should be contraindicated if the various herbicides are effective on the same spectrum of weeds (17, 18, 23). For the same reason, the genetic engineering of atrazine-resistant soybean for use in monoherbicide culture would be misdirected unless the atrazine usage in corn were to be replaced by other herbicides.

Cross resistances to herbicides due to degradation. Metabolic cross resistances to insecticides and drugs having vastly different modes of action are common and are documented to the level of molecular biology (16). Such cross resistances to herbicides with different modes of action are a recent occurrence (17, 18, 27, 37, 41). Rigid ryegrass (*Lolium rigidum* L.), frequently called annual ryegrass, that evolved resistance to diclofop had cross resistance to chlorsulfuron as well as to all other wheat-selective herbicides (27). Blackgrass (*Alopecurus myosuroides* Huds. # ALOMY) that evolved resistance to chlorotoluron was cross resistant to chlorsulfuron, pendimethalin [*N*-(1-ethylpropyl)-3,4-dimethyl-2,6-dinitrobenzenamine], and diclofop (37).

Similar metabolic cross resistances to insecticides and drugs often were traced to the evolution of higher levels of nonspecific esterases, hydrolases, or monooxygenases. The resistances in blackgrass and rigid ryegrass can be abolished by adding specific monooxygenase inhibitors along with the herbicide (19, 20, 32, 41). Genetically engineering new modes of herbicide

resistance into wheat also could alleviate the problem (18, 19). Such data, along with the knowledge that wheat seems to have selective resistance to herbicides by mono-oxidations, suggest that these weeds may have evolved a biochemical mimicry, i.e., they have evolved a system similar to wheat to degrade wheat-selective herbicides (17, 18, 19).

MODELLING ROTATION

The model as shown in Figure 1 does not adequately account for events in the "off years" during rotations if the competitive fitness of the resistant biotype is low. Resistance is shown (Figure 1) to evolve at a fixed rate as a function of the number of generations or seasons a weed was treated with a particular herbicide. This means that if it would take 6 yr for resistance to occur in monoculture corn with atrazine as the sole herbicide, it either would take 9 yr in a corn/corn/wheat (or soybean) rotation where atrazine is used for control 2 of every 3 yr; or 12 yr in a corn/wheat (or soybean) rotation where atrazine is used every other year, or 18 yr in a corn/wheat/soybean rotation where atrazine is used once in 3 yr.

When the model was formulated a decade ago, triazine resistance appeared in areas of the cornbelt where such rotations were used, as there had been 6 to 10 yr of atrazine usage since it was introduced. Yet, resistant populations only appeared in monoculture, monoherbicide corn.

Mixtures. Few farmers in the center of the cornbelt grow monoculture corn, unlike areas to the east of the cornbelt where triazine resistance appeared in corn. Cornbelt farmers use rotations and/or mixtures of triazines with chloroacetamide herbicides, which allow the use of less atrazine and thus lower the selection pressure. The chloroacetamides also kill pigweeds (*Amaranthus* spp.) and lambsquarters (*Chenopodium* spp.) as well as grass weeds. Mixtures substantially delay resistance, both according to the model (22) and from field data, although the magnitude of this effect is yet unclear.

The reason for the efficacy of mixtures to delay resistance can be manyfold. The frequency of resistance is lowered to the compounded frequency for each component. If the frequency of resistance to one component is 10^{-7} and the other 10^{-8}, the compounded frequency is 10^{-15}. The lower rates of each component used decreases the selection pressure for each, adding to the delay in resistance. The fitness to each component is also compounded, which should give low fitness for the individual resistant to both compounds in a mixture. Simulations of this are illustrated in (22, 23). Certain mixtures are not "mixtures" in the sense of delaying resistance: those that act at the same site (e.g., two photosystem II inhibitors) and those that are degraded by the same enzyme system (e.g., possibly all the herbicides used in wheat that are degraded by monooxygenases).

The models for mixtures are described in greater detail, with figures showing scenarios, in (23). Herbicide rotation may be the only strategy remaining to delay the evolution of triazine resistance in corn as the chloroacetamide herbicides used in mixtures for corn are under attack for environmental reasons, and their use is restricted in many areas and forbidden in others.

We have incorporated better data into an updated model, to show how rotation has been a better strategy than previously predicted. The newer data and model emphasize the highly reduced fitnesses of the resistant biotypes, which are of greater magnitude and importance than had initially been expected.

Lack of fitness of resistant weeds – a major consideration. The initial model used an average fitness differential for all generations treated (Figure 1). The fitness differential between resistant and susceptible individuals essentially never can become apparent with herbicides such as triazines that give season-long control, as there is no time when the herbicide is not present for this differential to be expressed. Only the resistant biotypes can survive when the herbicide is present. Thus, the fitness differential is unimportant with triazines in monoherbicide culture but seems to be an important factor in delaying resistance to other herbicides with more ephemeral action.

The fitness differential is important when herbicide usage is stopped for a season or more. Resistant biotypes are often more susceptible to some of the herbicides and cultivation procedures used in the rotational years (negative cross resistance). We have modified the model to consider what happens to resistant individuals in the "off" years when the herbicide in question is not used (24).

The resistant individuals, initially present at very low frequencies in the field, must compete with the crop and with resistant members of other weed species. When the herbicide is not present, they must compete with susceptible members of the same and other species

that germinate throughout the year. During the evolution of resistant populations, only intraspecific competition has been considered, except for one study (53). More data are needed from the agro-ecologists on the important of interspecific competition, including that with crops and weeds.

The first studies on competitive fitness were performed by pregerminating seedlings of resistant and susceptible individuals, interplanting them at fixed distances, and allowing them to grow to maturity (9). The yields of the resistant and susceptible biotypes were measured. In almost all cases where this was done, the susceptible individuals outyielded the resistant ones (Table 1).

Most competition experiments have not been made with material that has nuclear isogenicity where resistant and susceptible alleles are in otherwise identical nuclear backgrounds. Nuclear isogenicity is easy to achieve by using reciprocal hybrids when dealing with cytoplasmically inherited triazine resistance. An otherwise identical plastome in such crosses cannot be guaranteed. This eventually may change when plastomes are engineered by site-directed mutagenesis. Repeatedly backcrossed material also provides near-nuclear isogenicity with a large differential in competitive fitness (21) (Table 1). There seems to be no fitness difference between resistant and susceptible individuals of lateflowering goosefoot (53). Lateflowering goosefoot is a slow-growing species, and photosynthetic electron transport probably does not limit its growth.

A few triazine-resistant grasses have been reported to be more productive and competitively fit than the wild type (56), but this must be checked under more rigorous conditions. In general, one must be wary of reports of evolved fitnesses that are better than the wild type. Considering the long periods that species have evolved, the wild type in any given location should have evolved to optimal fitness. Spurious reports of high fitness may result form various interrelated functions: a) fitness was not measured from germination on; b) density dependent functions were not considered; c) reactions to environmental conditions may have differed; d) germination characters and seed bank dormancies may have differed; and e) fitness was not measured under field conditions.

Some mutations to resistance may engender larger losses of fitness than others. Triazine resistance may lead to an extreme case of fitness loss that could be due to many other linked mutations in the chloroplast genome. Triazine resistance may evolve in populations containing a plastome-mutator gene (3). This could explain some of the unfitness of triazine-resistant plants as well as the variabilities of plastid fitness. Any plant with triazine-resistant plastids should have other mutations in its plastids. Deleterious nuclear mutations can be bred or selected out of populations because of chromosomal segregation along with somatic and meiotic recombination (crossing over). This is not as easy with chloroplasts, where recombinations are negligible. Thus, the unfitness in atrazine-resistant plants may not be due to the *psb*A gene mutation, as has been argued on biophysical grounds (31, 34, 47, 49).

Target site mutations or gene amplifications in enzymes present in low quantities may not exert such strong effects on resistance as was found with triazine resistance. Fitness measurements must be performed carefully with resistant weeds as soon as resistant populations appear.

The measurement of fitness. As we consider fitness a major factor in delaying resistance, the measurement of fitness is described in detail below.

a) Measurement from germination. Weeds produce hundreds to thousands of seeds to replace one plant. Most perish before maturity, many during overwintering, early germination, and establishment. The competition before establishment is probably the fiercest. Competitive fitness studies should be measured at this stage, but this usually has not been done. The simplest way to do this is to plant mixtures of resistant and susceptible seed and to ascertain which plants are resistant and susceptible by a nondestructive test or by using leaf pieces. The seeding should be done at various depths and densities and preferably under field conditions to best mimic the natural environment. As seeds from resistant plants are often smaller than those from sensitive plants, there surely should be a definite competitive disadvantage to resistance when the selecting herbicide is not present.

b) Density dependence of fitness. Density dependence of fitness has not been measured adequately. For example, it is not clear why annual bluegrass (*Poa annua* L. # POAAN) biotypes resistant to triazines evolved only in genotypes that were prostrate and not in those that are erect (10). The lack of competition in triazine-treated fields possibly allowed the prostrate types to spread. There are variations in the density dependence of diclofop-resistant rigid ryegrass (27). The resistant plants were more fit than the sensitive ones under

sparse than under dense spacing. The fitness also varies at different ratios of resistant to susceptible individuals in competition. Only the data from a 1:1 mixture are given in Table 1. The original data show that the resistant biotypes are even less fit than the 1:1 mixture when they are in a lower proportion in the populations. The data suggest that fitness should be measured at various densities and ratios of sensitive to resistant individuals, especially those that more closely approximate the initial low frequencies of resistant individuals in the field.

c) Environment and fitness. A lowered optimal temperature for growth and photosynthesis for resistant biotypes is one of the common (12) but not universal (51) pleiotropic effects found with triazine resistance. Interpretation of these findings can be complicated. The earlier germination and "head start" can be highly advantageous under many greenhouse conditions; but in the field, it can be devastating. A late frost will decimate the earlier germinating resistant population and leave the later germinating susceptible population. This demonstrates why fitness must be measured under field conditions to indicate what happens in the field.

d) Changing seedbank dynamics. Repeated and strong selection for resistant weeds under monoculture easily can abolish the "spaced out" germination typical of weeds during the season and over many seasons. This higher immediate germination of resistant individuals versus the susceptible in many fitness tests (e.g., 36) may give real but misleading results that do not approximate fitness properties under field conditions.

e) Narrow genetic base. Isozyme electrophoresis studies of resistant populations always have shown that resistant biotypes at least initially possess a much narrower genetic base than adjacent susceptible populations (10, 11, 14, 53). This is due to the "founder effect" of mutants in diverse populations measured soon after evolution. In genetic evolutionary terms, this suggests that under certain narrow conditions the resistant populations may be more fit than the wild type; but under broad and varying environmental conditions they will be less fit.

In many cases, this might mean that the fitness will increase slowly due to "nuclear compensation" from repeated crossing with the wild type susceptible population. The fundamental biochemical lesion caused by triazine resistance probably will prevent fitness from improving in that case. One can increase the yield of triazine-resistant species by intercrossing. Still the reciprocal intercrosses with the sensitive biotype as female parent always outyielded the resistant offspring in such crosses (4). The effect of interbreeding on increasing fitness will have to be checked with other types of herbicide resistance.

The importance of negative cross resistance. Resistant pests often are controlled more effectively than the wild type by a variety of agents. This phenomenon, known as "negative cross resistance," has been reported with antibiotic-resistant bacteria in medicine and in fungicide-resistant pathogens and insecticide-resistant arthropods (16).

Similar data can be found for weeds (Table 2), which indicates that the phenomenon should be explored as a part of resistance management procedures. Triazine-resistant individuals were often less fit under the agronomic procedures used during the "off" years when triazines were not used and procedures with negative cross resistance were used. We have no accurate counts of the decay of resistance in populations when triazine usage was stopped due to high resistance levels.

Negative cross resistance has been found with many weed control and biological factors:

a) Standard mechanical cultivations of mixed resistant and sensitive common groundsel populations reduced the resistant individuals more than the susceptible ones (54).

b) The differential lack of fitness often can be due to other biotic factors. It was found that triazine-resistant rutabagas (*Brassica napobrassica* L.), which nominally produced yields as high as the near iso-nuclear susceptible biotype, were totally and selectively decimated by a viral infection[4]. Triazine-resistant smooth pigweed was selectively eaten by beetle larvae, and triazine-resistant common lambsquarters was more susceptible to fungal disease than the wild types[5].

c) Many herbicides are more toxic to resistant individuals than to susceptible ones (Table 2). Table 2 only contains data for negative cross resistances, but these are not the preponderant cases and are not universal. Still, they can be elucidated and incorporated into strategies for managing resistant weeds, both before and after populations become preponderantly resistant.

The negative cross resistances in atrazine-resistant weeds include herbicides that act at or near the same

[a]Species not defined previously: horseweed [*Conyza canadensis* (L.)Cronq. # ERICA]; kochia [*Kochia scoparia* (L.)Schrad. # KCHSC]; american willowherb (*Epilobium ciliatum* Rafin. = *E. adenocaulon* Hausskn # EPIAC); goosegrass [*Eleusine indica* (L.)Gaertn. # ELEIN]; common chickweed [*Stellaria media* (L.)Vill. # STEME]; common cocklebur (*Xanthium strumarium* L. # XANST); jimsonweed (*Datura innoxia* Mill. # DATIN).

[b]Chemicals not defined previously: dinoseb [2-(1-methylpropyl)-4,6-dinitrophenol]; fluometuron [*N,N*-dimethyl-*N'*-[3-(trifluoromethyl)phenyl]urea]; DNOC (4,6-dinitro-*o*-cresol); oxyfluorfen [2-chloro-1-(3-ethoxy-4-nitrophenoxy)-4-(trifluoromethyl)benzene]; pyridate [*O*-(6-chloro-3-phenyl-4-pyridazinyl)-*S*-octyl carbonothioate]; chlorpropham (1-methylethyl-3-chlorophenylcarbamate); benazolin (4-chloro-2-oxo-3(2*H*)-benzothiazole-acetic acid); bentazon [3-(1-methylethyl)-(1*H*)-(2,1,3-benzothiadiazin-4-(3*H*-one 2,2-dioxide]; imazaquin [2-[4,5-dihydro-4-methyl-4-(1-methylethyl)-5-oxo-1*H*-imidazol-2-yl]-3-quinolinecarboxylic acid]; glufosinate [ammonium (3-amino-3-carboxypropyl)methylphosphinate]; MSMA (monosodium salt of methylarsonic acid); DMSA (disodium salt of methylarsonic acid).

[c]FW = fresh weight; PS = photosynthetic CO_2 fixation; thylakoids = photosystem II activity of isolated thylakoids.

[d]The I_{50} is the concentration lowering the parameter measured by 50%; R = resistant; S = susceptible. Where no I_{50} R/S ratio is given, there was a large degree of negative cross resistance at a single herbicidal rate.

site in photosystem II (DNOC and dinoseb) as well as herbicides acting on other photosystems (paraquat) or at totally different sites. There was negative cross resistance to other tubulin-binding herbicides in dinitroaniline-resistant goosegrass (Table 2) but not to six commercial herbicides on this weed (38). The negative cross resistance to imazaquin (Table 2) occurred in only one of 21 chlorsulfuron-resistant mutants. The other mutants had varying levels of co-resistance to imazaquin.

Resistant biotypes sometimes grow better in the presence of the herbicide than without the herbicide. For instance, Lipecki[6] found that a triazine-resistant biotype of smooth pigweed grown with 5 kg ha^{-1} simazine (6-chloro-*N,N'*-diethyl-1,3,5-triazine-2,4-diamine) had double the dry weight per plant than without the herbicide. This lower resistant-biotype productivity when the herbicide is not present results in a stronger lack of competitive fitness in the "off" years.

MODIFIED MODEL FOR ROTATIONS

The long-term effect of rotational strategies is easier to calculate by deriving new equations that better consider the rotational perturbations. We have modified Equation [1] to give a new basic equation

$$H_{p,q} = [1 + \delta\ (\alpha f_{on} - 1)^p\ [1 - \delta(1 - f_{off})]^q \quad [2]$$

where:

H is the overall enrichment factor giving the increase in resistance following a period of p "on" seasons of herbicide application and q "off" seasons without herbicide;

δ, the fraction of seeds leaving the seedbank each year, replaces $\bar{n}$, the average residence time as the factor describing seed bank characters.

The derivation of Equation [2] and the simplifications, approximations, and assumptions involved are detailed elsewhere (24). Equation [2] can be rearranged to solve for various parameters to predict the effects of different agricultural scenarios. The p "on" years and the q "off" years can occur in any order during the $p + q$ year period that is under study.

There is little added effect of a small "off" fitness (e.g., $f_{off} < 0.3$), as there is a significant loss of resistant seeds during the off years due to the decimation of these seeds in the seedbank by natural causes (rotting, insects, etc.). This loss will not be replaced by the small addition that emanates from less fit resistant seeds. Note that the "off" factor is simply f_{off} in the absence of a seedbank ($\delta = 1$), as the only factor affecting seed number will be seed deposition, however small. If $\delta = 1$, then a strong influence of f_{off} can be expected.

[6]Lipecki, J. 1988. Personal communication. Adademii Rolniczej W. Lublinie, St.-Leszczynskiego 7, Lublin, Poland.

Various applications of this newer model are plotted in Figures 2 to 5, showing examples of how this model can be used to predict what might happen in real field situations, when different herbicide treatments are used in various rotations.

The effects of various rotations on the rate of evolution of resistance are plotted using Equation [2] to show the effects of fitness during the season when the herbicide was used and a different (constant) fitness for seasons when not used (Figure 2). There is hardly any real added delay due to rotation on resistance when the resistant individuals have near-normal fitness (Figures 2 D to F). Actually, Figure 1 and Figures 2 D to F do not differ agronomically if the lines in Figure 2 are smoothed. This high fitness may be the situation with the weeds having resistance at the level of acetolactate synthase (based on productivity, not competition experiments). Thus, in such cases, with high fitness, the model states that rotation is of little assistance in truly delaying resistance. The only delay will be for the number of generations the particular herbicide is not used. In such cases, only lowering the selection pressure will delay resistance. Obviously, the model must be validated by agro-ecological experimentation.

When there is a large fitness differential between resistant and susceptible individuals (as with triazine-resistant weeds), there will be a delaying effect due to fitness (Figures 2 A to C), and the effect is greatest when selection pressure is lowest. The plots describe the reduction of the proportion of resistant individuals in the off years. There are even some situations at low selection pressure where resistant individuals disappear in "off" years more rapidly than they are enriched for in "on" years. Thus, rotation can be advantageous. When there is negative cross resistance, the fitness differential is even greater, and the results can be considered by using the effects of a lower fitness value f for this period.

Scenarios with a slow rate of overall enrichment, showing that it will take many years for resistant populations to become a major problem, are summarized in Table 3. The (log) factor of enrichments at the end of 9- and 15-yr periods are given. When this factor is compared with the initial frequency of resistance (N_o), it can be estimated whether resistant populations should have evolved. If N_o is 10^{-20} (a guess for the N_o of triazine resistance), fitness is 0.3 or less, and selection pressure is low, i.e., the effective kill is less than 95%, then we see that resistant populations will not evolve

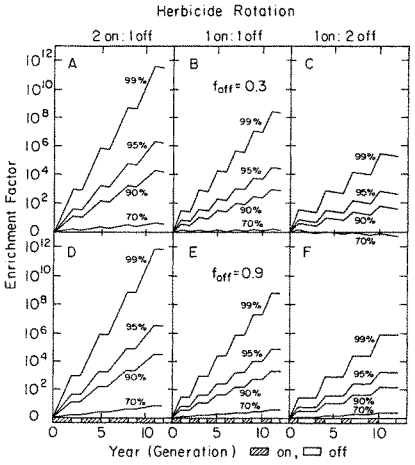

Figure 2. The effect of herbicide rotation on the rate of resistance enrichment. Three rotational scenarios are shown for herbicides with different selection pressures expressed as effective kill. "On" refers to the year the herbicide in question is used and "off" the year it is not used. The two fitnesses are those thought to represent triazine resistance (Table 1) (A to C; f = 0.3) and those thought to represent sulfonylurea/ALS resistance (7) (D to F; f = 0.9). The f_{on} = 1. The weed seeds in the seedbank are presumed to have a 2-yr residence time. Calculated from equations in (24).

under any of these scenarios. Triazine resistance would only appear in 15 yr in monoherbicide culture where the effective kill is 99% (Log H = 22.3, which makes up for the resistance frequency of 10^{-20}).

With chlorsulfuron, N_o should be 10^{-6} to 10^{-8} (7, 26, 45, 48) versus the estimates of 10^{-20} for triazine resistance. This high initial frequency explains why chlorsulfuron resistance evolved so rapidly. It is not clear that one need actually consider whether mutations to resistance are dominant or recessive; there may be only a small frequency difference between the two types in diploid organisms (55). This is because recombination (crossing over) can increase homozygous recessive frequencies in populations considerably. The selection pressure of 2,4-D is so low that no resistant populations occurred in 35 yr of monoculture wheat (29) as would be expected from Table 3.

The important predictive uses of this model are twofold:

Table 3. (Log) Enrichment of resistant individuals in weed populations over 9- and 15-yr periods under different herbicide rotations[a].

Rotation strategy	Effective kill[b]	9-yr period			15-yr period		
		Fitness in "off" years			Fitness in "off" years		
		0.9	0.5	0.3	0.9	0.5	0.3
	(%)	[Log 10 of enrichment factor (Log H)]					
No rotation	50	1.0	1.0	1.0	1.7	1.7	1.7
	90	5.1	5.1	5.1	8.5	8.5	8.5
	95	7.4	7.4	7.4	12.4	12.4	12.4

	99	4.4	4.0	3.8	7.3	6.7	6.4

[a]The table is best used to compare expected mutation frequencies for resistance and to see whether resistance would be expected with different management regimes. Examples of such frequencies would be *ca* 10^{-6} for a dominant monogenic trait, *ca* 10^{-12} for recessive monogenic mutants if unproven theory is accepted, or *ca* 10^{-7} if experimental data from another biological system (55) is accepted. A minus sign indicates a negative enrichment for resistance. It is presumed that the fitness of triazine-resistant weeds 0.3 to 0.5 and the fitness of ALS level sulfonylurea resistance is *ca.* 0.9. Calculated from equations in (24).

[b]The effective kill (the percent control over the whole season) of 50, 90, 95, and 99% are equivalent to $\alpha = 2, 10, 20, 100$, respectively in Equations [1] and [2]. A seed bank release of $\delta = 0.3$ (half-life in seedbank of 2 yr) and f_{on} of 1.0 were assumed.

a) to design rotational and mixture scenarios to delay resistance as much as possible yet still to obtain cost-effective weed control using herbicides such as chlorsulfuron and atrazine, which are among the least expensive and most active selective herbicides for wheat and corn, respectively;

b) once resistance has occurred, to design strategies whereby herbicide usage is stopped for a number of years, until the level of resistance is below a certain proportion, and then resume limited use, during a certain proportion of the rotation cycle. Such strategies have been designed for insecticides where there already are predominantly resistant populations. These populations become diluted because of fitness and the migration of susceptible individuals into the area (16). The treatment strategies are designed so the maximum proportion of resistant individuals does not exceed a certain limit percentage.

With this newer model, a kill percentage can be calculated that will give any (within reason) desired degree of resistance enrichment after p "on" years and q "off" years. This was done to calculate various types of enrichment for both minimum tillage and other situations where the seed bank can be negligible. It also can be used for tillage and other seed bank situations under conditions where various acceptable levels of enrichment were allowed or to stasis where no net increase in the frequency of resistance occurs. To achieve such stasis would be nirvana. There are theoretical situations, perhaps even field situations, where stasis might be achieved. Different treatment regimes with low selection pressures giving stasis without a seedbank are shown in Figure 3. Given this information, weed control of strategies can be designed where resistant individuals will not be enriched. One cannot obtain stasis with continuous use of a herbicide under conditions giving adequate weed control. One still can ensure that the rate of enrichment is low.

The model is plotted so selection pressures that provide resistance stasis as a function of the duration of seed remaining in the seedbank are shown in Figure 4 for various fitnesses. Three possible rotation strategies are examined. Some cases can have no enrichment at all for resistance. If the effective kill by 2,4-D in wheat is only 50 to 60% due to late weed germination, then under low fitness and a 1:1 rotation there is no enrichment. Stasis can even be obtained with selection pressures above 90% if there is a 2- or more yr interval between the treatments with the herbicide. Stasis is impossible with high selection pressure herbicides in

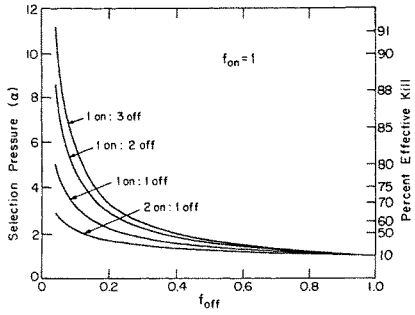

Figure 3. Resistance stasis for situations where there is no seedbank buffering as actually occurs in minimum-till agriculture. Values of selection pressure (α) and fitness (f) in "off" years that will allow no enrichment for resistance (stasis), when f_{on} = 1 (24). The effective kills are based upon total lack of herbicidal effect on the resistant individuals. Calculated from equations in (24).

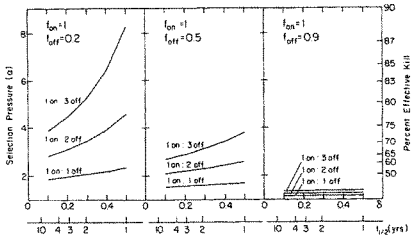

Figure 4. Conditions leading to a resistance stasis under various selection pressures (α), and with different rotation strategies or with different weed seed dynamics in the seedbank. The selection pressure also is shown as "effective kill" (the percent reduction in sensitive propagules over a whole season) with the assumption that the rare resistant individuals are totally unaffected by the herbicide. Here f_{on} = 1 while f_{off} takes a relatively low value in (A) and a higher value in (B) and (C). The f_{off} of 0.2 and 0.5 in A and B approximate those found with triazine resistance, and the f_{off} of 0.9 in (C) approximates the target site resistant mutants to acetolactate synthase inhibitors. The seedbank dynamics are given as δ, the fraction remaining in the soil at the end of a season, and $t_{0.5}$, the half-life of seeds in the seedbank. Calculated from equations in (24).

usual rotational sequences. Long duration of resistant seed in the seedbank is a deterrent to stasis, as resistant seeds act as a buffer for longer periods.

While stasis may be hard to achieve, a doubling of the frequency of resistant individuals every 3 yr would be acceptable. Selection pressures are depicted in Figure 5 that will just double the frequency of resistant individuals in the population in 3 yr with the "1-on: 2-off" strategy. At an intermediate duration of seed residence in the seed bank, the doubling of resistance occurs at the lowest selection pressures. This means that if the frequency of resistance is 10^{-6}, then it will take almost 60 yr for resistant populations to predominate.

CONCLUDING REMARKS

The model depicted from Equation [2] in Table 3 and Figures 2 to 5 describes the enrichment for resistant individuals in the population but only when they are still a minuscule proportion of the total population and not when a population actually nears resistance. As the resistant population becomes large, some of the simplifications that are valid only at lower resistant frequencies cannot be used. The complex equations from which Equation [2] was derived (24) must be used. These cast light on the new considerations that are needed for resistance management once there is a preponderance of resistant individuals. The consideration of the lower fitness in the "off" years can be refined further when actual data are available on fitness in different field situations with different species as well as more information on the dimunition of resistant populations under various agronomic and herbicide treatments.

Information on fitness also will be needed for many types of herbicide resistance to allow more accurate design of management strategies. What is clear is that all resistances so far have occurred in monoherbicide/monoculture or in equivalent situations that have the same effect. Weed species either receiving the same number of treatments, as in monoculture but over a longer period in rotational situations, or receiving mixtures that control the species have not evolved resistant populations.

Many resistant individuals are less fit (Table 1) because of the nature of the target site mutation conferring resistance or due to the high levels of gene products required to detoxify the herbicide. In other cases, resistant individuals may not be too unfit; or because of their nuclear inherited nature, many of the deleterious co-mutations may be lost. Chlorsulfuron-resistant mutants may not have lower productivity (7), but the competitive fitness of these plants has not been mea-

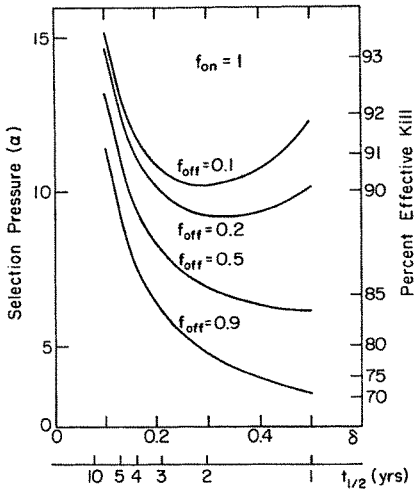

Figure 5. Selection pressures that cause a doubling of the proportion of resistant individuals in the population every 3 yr. The data are given for a 1 on: 2 off rotational strategy, with different fitness in the off years (f_{on} = 1) and different seed bank dynamics. The seedbank dynamics are given as δ, the fraction remaining in the soil at the end of a season, and $t_{.5}$, the half-life of seeds in the seedbank. Calculated from equations in (24).

sured. There are theoretical reasons, based on the site of the mutation on the gene, to assume that these sulfonylurea-mutants need not be very unfit (46). Thus, rotating chlorsulfuron with other herbicides may not delay resistance beyond the number of "off" years, as it has with atrazine and trifluralin [2,6-dinitro-*N*,*N*-dipropyl-4-(trifluoromethyl)benzenamine]. The added value of rotation will be only where the fitness is low in the off season.

Both the models and the limited field data suggest that the best tactics to prevent or to delay the appearance of resistant populations are:

a) to use herbicide treatments with the minimum selection pressure giving cost-effective weed control. Such treatments will not give near total weed control but leave behind enough susceptible seeds each year to dilute out resistant seeds;

b) to use herbicide mixtures of compounds acting at different sites of action and having different modes of degradation, preferably with herbicides having strong negative cross resistances;

c) to use rotations of herbicides having different sites of action and different modes of degradation, preferably where the weeds have negative cross resistance to the herbicides; and

d) to employ mechanical cultivations in the rotations, especially if they preferentially control unfit resistant biotypes.

These criteria are hard to meet with some monocultures, especially wheat. Wheat probably has only a single mode of degradation (19). In such situations, it is necessary either a) to rotate crops to allow herbicide rotation; b) to rotate with herbicides having a placement selectivity (e.g. 15) that is not related to herbicide metabolism in wheat; (c) to find synergists that preferentially inhibit herbicide degrading enzymes in the weeds of wheat (20).

Those high-selection-pressure herbicides having resistant mutants that are fit will be problems. The only alternative is to replace these with less persistent herbicides of the same group having less selection pressure and thus partially offsetting the lack of fitness.

Review/Analysis

Are Herbicide Mixtures Useful For Delaying the Rapid Evolution of Resistance? A Case Study[1]

ROGER P. WRUBEL and JONATHAN GRESSEL[2]

Abstract. Mixtures of herbicides have been proposed as strategies to prevent or delay the evolution of resistance to the resistance-prone sulfonylurea and imidazolinone herbicides that inhibit acetolactate synthase. These herbicides have become or are becoming widely used in soybean, wheat, rice, and other major crops. For a mixture to be efficacious in preventing resistance, the less resistance-prone component(s) should have the following traits compared to the vulnerable herbicide: a) control the same spectra of weeds; b) have the same persistence; c) have a different target site; d) be degraded in a different manner; and e) preferably exert negative cross-resistance. We compared the proposed mixing partners for use with several widely used acetolactate synthase inhibiting herbicides to these criteria and found that: a) all have somewhat different weed spectra; e.g. none control common cocklebur as well as imazaquin or imazethapyr in soybean, or kochia as well as chlorsulfuron in winter wheat; b) all are far less persistent than these vulnerable herbicides. Less persistent sulfonylureas are now on the market but are in limited use. Late in the season, the mixing partner is not present while the vulnerable herbicide remains active; c) most have different target sites; d) in soybean most mixing partners are degraded differently than vulnerable herbicides. In wheat virtually all herbicides used without safeners are degraded by monooxygenases, thus it is impossible to meet this criterion in this crop; e) none of the mixing partners exert negative cross-resistance. The present mixtures may have superior or more cost-effective weed control properties than the acetolactate synthase inhibitors used alone, but they do not meet all the criteria for resistance management. Not meeting the key criteria of identical control spectra and equal persistence aggravates future resistance problems, as has happened with insecticides. **Nomenclature:** Chlorsulfuron, 2-chloro-*N*-[[(4-methoxy-6-methyl-1,3,5-triazin-2-yl)amino]carbonyl]benzenesulfonamide; imazaquin, 2-[4,5-dihydro-4-methyl-4-(1-methylethyl)-5-oxo-1*H*-imidazol-2-yl]-3-quinolinecarboxylic acid; imazethapyr, 2-[4,5-dihydro-4-methyl-4-(1-methylethyl)-5-oxo-1*H*-imidazol-2-yl]-5-ethyl-3-pyridinecarboxylic acid; cocklebur, *Xanthium strumarium* L. #[3] XANST; kochia, *Kochia scoparia* (L.) Schrad. # KCHSC; corn, *Zea mays* L.; rice, *Oryza sativa* L.; soybean, *Glycine max* (L.) Merr.; winter wheat, *Triticum aestivum* L.

Additional index words: Imidazolinone resistance, sulfonylurea resistance; ALS-inhibitor resistance.

INTRODUCTION

The extensive and continuous use of herbicides over the last four decades has resulted in the evolution of weeds resistant to normally phytotoxic chemicals. Since the first reports of triazine-resistant weeds in the mid-1960s (19, 36), well over 100 weed species have been identified that have evolved biotypes with resistance to at least one and occasionally more than one herbicide type (46, 47, 53, 54, 55). Reports of evolution of newly resistant biotypes continue to increase steadily (46, 47), although many cases probably go unreported. Several disturbing trends have been recognized. Herbicide resistance seems to be appearing after fewer years of exposure to newer herbicides than to the older inhibitors of photosystem II; many weeds have shown a capacity to evolve resistance; and some of the resistant biotypes may have similar reproductive fitness to that of susceptible biotypes (1, 2, 45, 53, 55, 58). These trends indicate that resistance problems are accelerating and that management of weeds could become more difficult in the future due to herbicide resistance.

Several strategies have been proposed to prevent or

delay the evolution of resistant weed populations. Among them are rotation of crops, rotation of herbicides with different modes of action, use of combinations of herbicides with different modes of action, and conservation of susceptible weeds (37, 38, 39, 47, 59, 69, 70). These strategies aim to reduce the selection pressure favoring weed biotypes that have evolved herbicide negating mechanisms.

Groups of structurally dissimilar herbicides inhibiting acetolactate synthase (ALS)[4], including sulfonylureas, imidazolinones, and triazolopyrimidines, are especially prone to losing efficacy due to the rapid evolution of resistant weeds (55). While some weeds have evolved resistance to single chemical groups, other populations of the same species have evolved target site cross-resistance to ALS inhibitors of other chemical groups, even though they were subjected to only one (29, 41, 65, 72, 73, 75, 83).

Herbicide manufacturers acknowledge that there is serious potential for ALS-inhibitor resistance problems in weeds (4, 6, 13, 61) and have founded the ALS/AHAS[4] Inhibitor Resistance Working Group within their Herbicide Resistance Action Committee. Member companies of the working group have devised strategies that they believe will prevent or severely delay evolution of resistance in weeds. The core of the strategies is to use mixtures of herbicides with different modes of action to combat resistance. Their approaches also involve recommendations to growers to use weed surveys and weed thresholds to determine the actual need for herbicide use before spraying, to combine cultivation with herbicide treatment, and to rotate crops (13). The producers of the ALS inhibiting herbicides are promoting these strategies based on the continued use of their herbicides in combination with herbicides having different modes of action (4, 6, 61).[5,6,7] The continued use of imidazolinone herbicides in combination with other herbicides is even recommended to treat fields where imidazolinone-resistant weeds have been identified.[5] Still, the ALS/AHAS Resistance Working Group formed by industry has provided only general recommendations and no binding specific recommendations, due in part to the different economic interests of its member companies.

The primary objective of this paper is to examine the herbicide mixtures being recommended to determine if they can be potentially effective resistance management tools. We first discuss the characteristics of the herbicides of interest and then the theoretical considerations related to using herbicide mixtures for managing herbicide resistance. We then describe the characteristics required of a competent mixing partner. Finally, we analyze the likelihood of present recommendations for use of herbicide mixtures with imidazolinones in corn/soybean and with sulfonylureas in wheat cropping systems to meet the criteria delineated for effective herbicide resistance management.

CHARACTERISTICS OF ALS-INHIBITING HERBICIDES

The ALS inhibitors are relatively new classes of herbicides. The imidazolinones were developed and first marketed by the American Cyanamid Company in 1986. The sulfonylureas originally developed by E. I. Du Pont de Nemours and Company were first introduced in 1982 and are now manufactured by several companies. The triazolopyrimidines were developed by Dow-Elanco Corporation and are just now appearing on the market. These three chemistries of herbicides all inhibit acetolactate synthase, the first enzyme in the synthesis pathway leading to branched-chain amino acids (31, 52, 66, 71, 79, 80). In sensitive plants, the synthesis of valine, leucine, and isoleucine is curtailed. Most naturally resistant crops rapidly metabolize these herbicides and render them ineffective (73). The ALS inhibitors have a number of favorable characteristics from weed control and environmental perspectives. Most of these herbicides are highly efficacious for control of a broad spectrum of dicot weeds, and to a lesser extent monocots, as well as many perennials (Table 1). They are applied at relatively low rates, have very low mammalian toxicity, and are not mutagenic in the Ames test (86). Unfortunately, the ALS inhibitors are among the herbicides considered to be at highest risk for the evolution of resistance in weeds because they have a single target site, are effective against a wide spectrum of weeds, and many are relatively persistent, often providing season-long control of germinating weed seeds (55). Also, the various sites of mutations for resistance are not near the active site of the enzyme and thus there is no fitness loss due to a lower affinity for the normal substrates (77).

The incidence of herbicide resistance to ALS inhibitors,

[4]Abbreviations: ALS, acetolactate synthase (AHAS, acetohydroxyacid synthase is an often used synonym).

particularly sulfonylureas, is increasing. Since the first discovery of prickly lettuce (*Lactuca serriola* L. # LACSE) resistant to the sulfonylurea herbicide chlorsulfuron, in 1987 (57), 13 other weed species with ALS-resistant populations have been confirmed with expanding geographic areas being affected (73). Cross-resistance of weed biotypes to other ALS-inhibitors augments the potential problem. Patterns of cross-resistance of weeds to ALS-inhibitor herbicides within and among the chemical families are highly variable and unpredictable. Weed biotypes resistant to one ALS-inhibitor herbicide exhibit varying levels of cross-resistance to other ALS inhibitors (24, 29, 30, 41, 57, 65, 72, 75, 76, 78, 81).

CRITERIA FOR EFFECTIVE MIXTURES FOR RESISTANCE MANAGEMENT

Herbicide mixtures have been discussed and modeled as a means of preventing or delaying the evolution of resistance in weeds (33, 38, 39, 59). There is also extensive theoretical and experimental literature on the use of insecticide and fungicide mixtures (26, 28, 49, 50, 56, 70, 74, 82). We know of no field studies specifically designed to examine the effectiveness of herbicide mixtures compared to other methods of weed resistance management, but there are "epidemiological" data. Extensive areas of monoculture corn have been treated continuously with triazine/chloroacetamide mixtures over 20 yr. Two broadleaf weed groups (*Chenopodium* spp. and *Amaranthus* spp.) that have often evolved triazine resistance when triazines were used alone, have never been reported to evolve resistance where these mixtures were used. The chloroacetamides have some limited activity on these two genera.

It has been posited that the use of herbicide mixtures combining different modes of action will substantially delay or preclude evolution of resistance to the more vulnerable or at-risk herbicides (4, 6, 61).[5,6,7] This is because weeds resistant to the vulnerable herbicide will be destroyed by the mixing partner, or at least be rendered relatively unfit compared to the wild type. For our discussion we will assume that two herbicides are used in mixture although more are possible. We refer to "mixtures" as only those combinations of herbicides where the partners both affect the same target weed (Table 2, sp. A). Often mixtures are used where each member affects different weed spectra, e.g., mixtures of grass and broadleaf herbicides (spp. B and C in Table 2). These latter mixtures, which increase weed control benefits, have no influence in delaying evolution of resistance in weeds they do not affect. They might even exacerbate resistance by controlling competing weeds, creating a more open niche for resistant biotypes. It is hard to assess, without experimentation, what the effect on the rate of evolution will be when the mixing partner has a moderate effect on a species excellently controlled by the vulnerable herbicide (Table 2, sp. D).

Evolution of target-site resistance to both the vulnerable and the partner herbicides is possible when mixtures are used, but should be much delayed compared to the appearance of resistant biotypes where each herbicide is used separately. The following reasoning, based on a compounded resistance frequency model, has been used to theoretically support this supposition: If the frequency of individuals resistant to each component of a pesticide in a mixture is independent in the susceptible species, then the joint probability of evolution of co-resistance to both herbicides in one individual equals the product of the

Table 2. Possible effects of mixtures on different species.

	Species			
Control by	A	B	C	D
	level of control[a]			
Vulnerable herbicide	++	++	0	++
Mixing partner	++	0	++	+

[a]0 = no control; + = partial control; ++ = control.

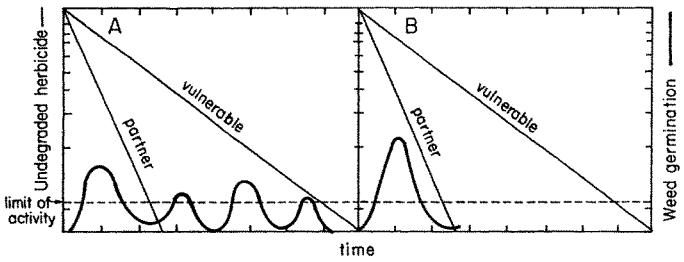

Figure 1. The persistence of herbicides in mixtures as related to germination flushes of weeds. The dissipation of herbicides is usually linear when herbicide remaining is plotted exponentially. The horizontal dashed line denotes when the herbicide is no longer biologically active. A. A situation where a weed species germinates throughout the growing season and many flushes are affected by only one component of a mixture. B. A situation where the weed species germinates in a single flush and is affected by both components of the mixtures.

probabilities of resistance for each partner [(28) for insecticides, (38) for herbicides]. For example: A weed has a natural mutation frequency of 10^{-5} for resistance to the vulnerable herbicide and 10^{-10} to a mixing partner having a different target site. The genes for resistance are inherited independently of each other (i.e., are not linked). Then, the joint probability of resistance to both pesticides in a mixture is $10^{-5} \times 10^{-10} = 10^{-15}$, which is very rare and is a smaller number. Thus, it would be expected that the simultaneous co-resistance to both herbicides, the only type that could appear, would evolve relatively slowly due to the minuscule initial frequency of doubly resistant individuals. Not only is the mutation frequency to joint resistance a compounded number, but any lack of fitness due to each mutation would also be compounded such that a weed with dual resistance may be far less fit and less competitive than wild type susceptible individuals (37, 38). However, the combination of herbicides can significantly increase the overall selection pressure on weeds by eliminating all susceptible genotypes due to use of full rates of both partners. In this case resistance to both herbicides may be delayed less than predicted by a compound model (38).

One major assumption of the compounded frequency of the resistance model described above is that the use of herbicides with different modes of action will not result in selection for weed biotypes possessing a single mechanism that detoxifies both partners. The evolution of generalized detoxification systems such as the monoxygenases common in wheat have been suggested to explain broad cross-resistance (33, 34) in blackgrass (*Alopecurus myosuroides* Huds. # ALOMY) (62) and rigid ryegrass (*Lolium rigidum* Gaudin # LOLRI) (64). There is some preliminary evidence (25, 27, 51) to support this idea of biochemical mimicry (33, 34) which is not universally accepted. (See the section below, "Evolution of metabolic resistance," for further discussion)

Characteristics of effective mixing partners for resistance management. It is possible that there will be cases of enhanced weed control by a mixture, but that such a mixture will be contraindicated vis-à-vis resistance management. Simply combining pesticides with different modes of action will not delay resistance if the efficacy and temporal activity of the mixed pesticides do not match (70). The mixing partner must effectively kill or severely weaken the weeds most sensitive to the vulnerable herbicide, because these weeds are the most likely to evolve resistance (38, 59). Both components should do so with nearly the same effectiveness; it may not be helpful if at the rate used, the mixing partner kills 75% of the weeds and the vulnerable kills 95%, unless the 20% remaining are severely inhibited such that they have a lesser reproductive capacity than the wild type. Otherwise, resistance could quickly evolve in the remaining 20% of weeds.

Both components of the mixture need to have similar persistence when weeds germinate throughout the cropping season. Otherwise, there will be a period when only the vulnerable one is present and effectively the target weed will not be exposed to a mixture at all (Figure 1A). Unlike crops, which have been selected to germinate uniformly and shortly after planting, seeds of many weed

species have many flushes of germination during a cropping season (20). If a susceptible weed has multiple flushes during the season, and the vulnerable herbicide has a longer period of activity than the mixing partner, then the vulnerable herbicide selects for individuals resistant only to it after the mixing partner has dissipated (Figure 1A). Thus, if the vulnerable herbicide has season-long activity (i.e., is selecting for resistant biotypes season-long, even when weed populations are below the economic threshold), it is critical that the mixing partner have the same persistence. This problem is accentuated when there is a long growing season and there can be more flushes of weeds producing viable seed in late season. Thus, a mixture may be more efficacious in northern, short season soybean areas than in southern areas with very long growing seasons.

A mixture that is not well matched for persistence can still be effective if the weeds germinate in a "single flush," without further germination, and both herbicides outlast the flush with equal efficacy (Figure 1B). Most cropping systems have many different weed species, so this circumstance can hold for some species but may often be irrelevant for the agroecosystem as a whole.

Methods could be devised for using a short-persistence mixing partner along with a long-persistence vulnerable herbicide. The short persistence mixing partner could be applied based on observations of weed germination or a farmer could repeatedly spray this herbicide throughout the season without such observations (not a recommended practice). The farmer might have to treat with the mixing partner late in the season (if registered) when application might confer no economic gain. It is also conceivable that a contact herbicide mixing partner, used late in the season, would not effectively eliminate all resistant weeds under the crop canopy. Unless there is very close overlap in the duration of efficacy between the two herbicides, a resistance management strategy based on their mixture is problematic and operationally complex.

The ideal mixing partner should have three other properties in addition to those just mentioned: Firstly, the mixing partner should have a different target site of action from the vulnerable herbicide. Thus, use of a triazine and a uracil or phenylurea can be contraindicated as mixtures, as they act on the same protein in photosystem II. The situation for ALS-inhibitors is slightly more complex because of the differential pattern of cross-resistance among weed species to ALS-inhibitor herbicides (30, 42, 73, 76). This pattern probably results in part from different or overlapping active sites for the herbicides on the ALS molecule (77). All weed biotypes resistant to one ALS-inhibitor are cross-resistant to at least some other ALS-inhibitors (73), and it is now impossible to predict the pattern of cross-resistance. Additionally, whereas one biotype of a species may have limited cross-resistance to other ALS-inhibitors, other biotypes of the same species may have broader overlapping spectra, i.e. the genes are present for broad spectrum ALS resistance. Thus, two ALS-inhibitors cannot be considered mixing partners for resistance management.

Secondly, the mixing partner should not be degraded in the same manner as the vulnerable herbicide. For example, if the vulnerable herbicide is degraded in the crop by a glutathione-transferase, the mixing partner should have no chemical site that can be attacked by that enzyme. This criterion could be a problem in wheat where all biochemically-selective herbicides seem to be degraded by monooxygenases in the crop (34). Herbicide mixtures for wheat would be subject to evolution of resistance in weeds capable of evolving increased levels of monooxygenase detoxification systems. This can come about by the evolution of higher levels of specific monooxygenases, by mutations coding for enhanced substrate (herbicide) specificity of one monooxygenase, or by mutations enhancing higher constitutive levels of all or many monoxygenases.

Thirdly, another useful attribute in a mixing partner would be to possess negative cross-resistance; i.e. where individuals resistant to the vulnerable herbicide are more susceptible than the wild type to the mixing partner. This would actually reduce the frequency of resistant alleles in the weed population. This strategy was first proposed for herbicides on the basis of laboratory data (40), and information on the existence of negative cross-resistance at the whole plant level has been published recently (18).

USE PATTERNS OF ALS-INHIBITING HERBICIDES, EVOLUTION OF RESISTANCE, AND HERBICIDE MIXTURES

Resistance in soybean. ALS-inhibiting herbicides were found to be highly efficacious in controlling weeds inadequately controlled throughout the season by other herbicides and thus came into rapid use (e.g., Table 3). Imidazolinone-resistant populations of common cocklebur were discovered in 1991 and 1992 in soybean fields in eight apparently independent locations along the Mississippi River valley.[5] In each case the fields were continuously planted to soybean and treated for several years with

imazaquin. At one site in Mississippi resistant biotypes were identified in 1991 after only three consecutive years of banded applications of imazaquin with cultivation between the rows (78).[8] This rapid evolution is especially worrisome, as it means that susceptible cocklebur could have grown in the areas between the rows. These susceptible biotypes should have diluted the number of resistant individuals in the seed bank and delayed the appearance of resistant populations. In Mississippi, cocklebur biotypes that evolved resistance due to exposure to imazaquin are cross-resistant to imazethapyr.[8] However, ALS extracted from these imazaquin-resistant cocklebur were sensitive to ALS-inhibitors of other chemical groups (78). An imazaquin-resistant biotype of cocklebur collected in Missouri was cross-resistant to other imidazolinones and sulfonyureas.[9] Because of the number of apparently unrelated resistant populations that have been detected so far, after just a few years of exposure, it is logical to conclude that cocklebur has the capacity to readily evolve resistance to the imidazolinones and possibly other ALS inhibitors.

Use of ALS-inhibitors in soybean and corn. The use of imidazolinone herbicides has been increasing dramatically in the U.S. The soybean area treated with either imazaquin or imazethapyr in Illinois, the largest soybean producing state, more than doubled from 20% in 1990 to 43% in 1992 (Table 3A). In Iowa, the soybean area treated with imidazolinones increased from 33% in 1990 to 52% in 1992. Across all major U.S. soybean producing states imidazolinone use increased from 27% of area treated in 1990, to 39% in 1991, to 47% in 1992 (Table 3B). Even without considering additional use of imidazolinones in soybean, the exposure of weeds to these herbicides will be increasing in the coming years because of their use in other rotational crops such as corn.

Commercial sale of imidazolinone-resistant corn was initiated in 1993 by four seed companies (Pioneer Hi-Bred, Zeneca Seeds, Ciba Seeds, and Cenex/Land O'Lakes), mostly in the northern corn belt. About a half million hectares of imidazolinone-resistant seed were available for planting in the 1993 season with the prospect of increased availability in future years as well as development of additional imidazolinone-resistant hybrid varieties (87).[10,11,12]

Extending the use of imidazolinones to corn presents several potential problems in terms of weeds evolving

resistance. A substantial part of the soybean area in the northern corn belt is rotated with corn. Fifty-seven percent of the area planted to either soybean or corn in 1989 in the northern corn belt was used to grow the alternate crop in 1988 (32). In 1991–1992 corn and soybean were rotated on 54% of the crop area (17). Thus, a farmer who formerly rotated herbicides along with soybean-corn crop rotations now has the option to continuously use imidazolinones. Some of the area planted to continuous corn or corn rotated with crops other than soybeans, which formerly never encountered imidazolinones, now will be exposed. Corn and soybean have similar growing seasons and across most of the northern corn belt they have essentially the same spectrum of summer annual weeds. Species such as foxtails (*Setaria* spp.), velvetleaf (*Abutilon theophrasti* Medicus # ABUTH), cocklebur, pigweeds (*Amaranthus* spp.), common lambsquarters (*Chenopodium album* L. # CHEAL), and smartweeds (*Polygonum* spp.) are problem weeds of both crops. Thus, if imidazolinones are used extensively in corn-soybean rotations, the same populations of weeds will be exposed to the same herbicide chemistry year after year, increasing the probability of the evolution of herbicide-resistant weed biotypes. The situation is further exacerbated by the availability of sulfonylurea herbicides in soybean and corn. Chlorimuron {2-[[[[(4-chloro-6-methoxy-2-pyrimidinyl)amino]carbonyl]amino]sulfonyl]benzoic acid} was applied to 17% (Table 3B) and thifensulfuron {3-[[[[(4-methoxy-6-methyl-1,3,5-triazin-2-yl)amino]carbonyl]amino]sulfonyl]-2-thiophenecarboxylic acid} to 7% of soybean crop area in 1992 (14). Two recently released sulfonylurea herbicides, nicosulfuron {2-[[[[4,6-dimethoxy-2-pyrimidinyl)amino]carbonyl]amino]sulfonyl]-*N,N*-dimethyl-3-pyridinecarboxamide} and primisulfuron {2-[[[[[4,6-bis(difluoromethoxy)-2-pyrimidinyl]amino]carbonyl]-amino]sulfonyl]benzoic acid}, were used to treat 8% of the corn area in 1992 (14).

Research is also underway to develop varieties of wheat, oilseed rape (*Brassica napus* L.) and tomato (*Lycopersicon esculentum* Mill.) resistant to ALS inhibitors (43, 48, 60, 63, 84). Already in many agricultural areas there are crops naturally resistant to at least one ALS inhibitor. With the prospect of increasing use of ALS-inhibiting herbicides we should expect the more extensive evolution of resistant weeds to follow quickly.

[13]Owen, M.D.K. 1993. Personal communication. Agronomy Dep., Iowa State Univ., Ames, IA 50011.

Analysis of herbicide mixtures recommended for imidazolinones in soybean/corn cropping. At present, imidazolinones are primarily used in soybean and are being extended into corn. Thus, we have analyzed the mixtures proposed for those two crops. As sulfonylurea and other ALS inhibitor use becomes more widespread, their mixtures should be evaluated using the same criteria. As imidazolinone-resistant cocklebur has been discovered in several locations, we have chosen to analyze the usefulness of the herbicide mixtures recommended by the manufacturer for lessening the likelihood of evolution of resistant populations of this weed. We posed the following rhetorical question: which, if any, of these mixtures might have prevented the evolution of imidazolinone-resistant populations of cocklebur? Cocklebur is an annual broadleaf weed commonly found in cultivated lands, pastures, along streams and rivers, and in waste places (44). Cocklebur is considered the most competitive weed of soybean in the southeastern U.S. (10). Each burr on the plant produces two heteromorphic seeds, with lower seeds having less dormancy than upper seeds (20, 44). Some seeds germinate promptly while others remain dormant and germinate months or years after maturity and dispersal (44). Cocklebur typically appears in fields throughout the growing season. Small plants can flower and set seed in the photoperiods of the early and late growing season.[8,13]

Cocklebur presents a difficult case for herbicide mixtures aimed at managing resistance for imazaquin and imazethapyr. Firstly, cocklebur is very sensitive to the imidazolinone herbicides used in soybean. Thus, these herbicides apply strong selection pressure for resistance. The recommended application rate for imazaquin in soybean is 140 g ai/ha (10). One-eighth that amount, 17 g/ha, is sufficient for control of cocklebur.[8] Imazethapyr controls cocklebur when applied to soil (65 to 75% control) or leaves (85 to 95% control) (11). Secondly, both imazaquin and imazethapyr are sufficiently active in the soil to provide season-long control of cocklebur (as well as other weeds). The manufacturer recommends waiting 11 mo before rotating corn, barley (*Hordeum vulgare* L.), peanut (*Arachis hypogaea* L.), or oat (*Avena sativa* L.) with soybean treated with imazaquin (12). For imazethapyr the recommended waiting periods are 9.5 mo for corn and peanut and 18 mo for most other crops (12). This suggests that these herbicides have residual lifetimes sufficient to remain effective against particularly susceptible crops and weeds for long durations. Cocklebur can germinate, flower, and set seed throughout the growing season, and

Table 4. Manufacturer's recommendations for broadleaf herbicide mixtures with imidazolinones to reduce the risk of weed resistance in soybean[a].

Imidazolinone	Recommended mixing partner(s)	Characteristics of mixing partner(s) for control of cocklebur
Imazethapyr	acifluorfen, lactofen, fomesafen	These herbicides only have activity for very small cocklebur (3 to 4 leaf stage), and efficacy is less than imidazolinones. All are short residual, contact herbicides requiring multiple applications for season-long cocklebur control.
Imazethapyr	metribuzin	Metribuzin provides only partial control of cocklebur
Imazethapyr	linuron	Linuron provides only partial control of cocklebur
Imazethapyr and imazaquin	glyphosate, paraquat	Glyphosate and paraquat are non-selective, short residual, post weed emergence herbicides. They effectively control cocklebur but multiple applications would be required for season-long control.
Imazaquin	clomazone	Clomazone is primarily a grass herbicide with only partial control of cocklebur.

[a]Mixing partner recommendations from (7).

after the crop has been harvested. By remaining active throughout and beyond the growing season, the imidazolinones can select for resistant, newly emerging cocklebur biotypes for many months after application. Thus, an effective mixing partner for the imidazolinones must provide equally effective season-long control of cocklebur.

Recommended mixing partners for soybean. Several of the herbicide mixing partners recommended by the manufacturer provide only partial control of cocklebur and would only delay resistant populations from evolving if they severely inhibit cocklebur and if they have the same duration of residual activity as the imidazolinone (Table 4). These include metribuzin [4-amino-6-(1,1-dimethyl(ethyl)-3-(methylthio)-1,2,4-triazin-5(4*H*)-one], linuron [*N'*-(3,4-dichlorophenyl)-*N*-methoxy-*N*-methylurea], and clomazone {2-[(2-chlorophenyl)methyl]-4,4-dimethyl-3-isoxazolidinone}. All three have shorter effective persistence either due to shorter actual half-life compared to the imidazolinones, or because they do not inhibit cocklebur as much as the imidazolinones. Thus, cocklebur germinating mid and late season are effectively controlled only in contact with the ALS inhibitor. Acifluorfen {5-[2-chloro-4-(trifluoromethyl)phenoxy]-2-nitrobenzoic acid}, lactofen {(±)-2-ethoxy-1-methyl-2-oxoethyl-5-[2-chloro-4-(trifluoromethyl)phenoxy]-2-nitrobenzoate}, and fomesafen {5-[2-chloro-4-(trifluoromethyl)phenoxy-*N*-(methylsulfonyl)-2-nitrobenzamide} are contact herbicides of relatively short persistence and do not control cocklebur as well as the imidazolinones. They are effective only for very small cocklebur (3- to 4-leaf stage). Glyphosate [*N*-(phosphonomethyl)glycine] and paraquat (1,1'-dimethyl-4,4'-bipyridinium ion) are non-selective herbicides requiring special application methods to protect crops from damage. Both herbicides are strongly and rapidly adsorbed to soil, rendering them biologically inactive. While glyphosate and paraquat control cocklebur, their inclusion in a cocklebur resistance prevention program requires that they be applied whenever the weed is observed in the field. As cocklebur has staggered and extended germination patterns, this becomes impractical. Thus, it appears that none of the mixing partners presently promoted for use with imazaquin and imazethapyr in soybean can effectively prevent resistant biotypes of cocklebur from evolving and spreading.

The manufacturer of the imidazolinones is now recommending late-season use of bentazon [3-(1-methylethyl)-(1*H*)-2,1,3-benzothiadiazin-4(3*H*)-one 2,2-dioxide], the major herbicide replaced by the ALS-inhibitor, to control cocklebur in the southern, long season soybean areas.[5] This strategy, if adopted quickly by farmers might both contain and set back resistance so that the imidazolinones could remain effective for a longer period. This will be effective only if bentazon can penetrate the soybean canopy to eliminate all late season germinators. Otherwise, resistant individuals will be left behind.

Recommended mixing partners for corn. Various mixing partners recommended by the manufacturer for use in imidazolinone-resistant corn are presented in Table 5. Bromoxynil (3,5-dibromo-4-hydroxybenzonitrile), 2,4-D [(2,4-dichlorophenoxy)acetic acid], and dicamba (3,6-dichloro-2-methoxybenzoic acid), when used at low rates in most environments, are effective for control of cocklebur but are short-persistence herbicides. Only atrazine [6-chloro-*N*-ethyl-*N'*-(1-methylethyl)-1,3,5-triazine-2,4-diamine] matches the efficacy and persistence characteristics (when used at full field rates) of imazethapyr and could

Table 5. Manufacturer's recommendations for broadleaf herbicide mixtures with imazethapyr to reduce the risk of weed resistance in imidazolinone resistant corn[a].

Recommended mixing partner	Characteristics of mixing partner for control of cocklebur
Atrazine	Has similar persistence and efficacy as imazethapyr for cocklebur, but at recommended rate of application (555 g ai/ha) would have little persistence.
Bromoxynil	A contact herbicide that degrades rapidly. It effectively controls cocklebur but multiple applications would be required for season-long control.
Dicamba	A systemic herbicide with limited persistence, that effectively controls cocklebur. Multiple applications would be required for season-long control.
2,4-D	A postemergence, short residual, systemic herbicide, that provides effective control of cocklebur. Multiple applications would be required for season-long control.

[a]Mixing partner recommendations from (7, 12).

delay the evolution of resistant populations. However, at the recommended application rate (555 g ai/ha) with imazethapyr, atrazine would have shorter-lived field activity than the normally used rate, which is two to four times higher. Thus, atrazine might not control cocklebur germinating late in the season.

Analysis of mixtures proposed for sulfonylureas in winter wheat. Much of the wheat cultivated around the world is grown in areas where few other crops can be grown, leading to extensive monocultures. Increases in yields have been largely due to breeding shorter, high harvest index wheats that respond to increased fertilization, and/or growing long season winter wheats that continue growing in the field for ca. 10 mo. Cultivating such wheats requires herbicides to suppress weeds, as weeds compete with the newer, shorter, wheat cultivars, or come up and compete in spring in the winter wheats. For over 40 yr, 2,4-D controlled many broadleaf weeds, with a variety of herbicides providing a modicum of grass control. Postemergence application of 2,4-D has short soil persistence and often allowed a flush of susceptible weeds to go to seed either before application, or after the herbicide dissipated. By letting susceptible weed seed persist in the seed bank, selection pressure for resistance has remained low. With the exception of a recent minor case (85), this low selection pressure may explain in part why no major outbreaks of 2,4-D resistant weeds have been reported.

The advent of highly persistent sulfonylurea herbicides such as chlorsulfuron and the slightly less persistent metsulfuron {2-[[[[(4-methoxy-6-methyl-1,3,5-triazin-2-yl)amino]carbonyl]amino]sulfonyl]benzoic acid} provided high levels of control for a broad spectrum of weeds, including some grasses. The users realized superior weed control (though not always higher yields) and competitive pricing brought about rapid acceptance of chlorsulfuron. Soon after registration on wheat in 1982, chlorsulfuron replaced about 40% of the 2,4-D previously used in U.S. winter wheat (3). By 1988 18.5% of the total area of the U.S. winter wheat crop was treated with chlorsulfuron (slightly more than 2 million ha) compared to 9.2% for 2,4-D (5). Target site resistance to chlorsulfuron rapidly evolved after 4 or 5 yr of continuous use in biotypes of prickly lettuce, kochia, and Russian thistle (*Salsola iberica* Sennen & Pau # SASKR) (73). The manufacturer of chlorsulfuron quickly came up with a series of resistance management strategies for affected areas (4, 61). The strategies included: a) no preemergence, only postemergence use; b) application no more than once in 4 yr; c) fallow use was proscribed; and d) use at lower rates in tank mixes with other herbicides. Recommendations a–c and use at lower rates all decrease selection pressure for evolution of target-site resistance and their utility is self-evident. The question we address here is whether mixing less vulnerable herbicides with chlorsulfuron and other ALS inhibitors will affect the rate of evolution of resistance.

Two types of resistance to chlorsulfuron have appeared in wheat; a) target site resistance with a modified ALS (24, 71, 72), and b) metabolic resistance characterized by a greatly enhanced rate of degradation of the herbicide (24, 25, 27). Both types have even evolved in different biotypes of the same weed (22).

All of the mixture partners proposed for chlorsulfuron have much lower biological persistence than chlorsulfuron (Table 6). They are dissipated within 4 to 6 wk of application whereas chlorsulfuron provides season long control, often lasting into following seasons, depending mainly on soil pH (21). Thus, none of the proposed partners meets the equal persistence criterion (except for weeds germinating in a single flush). The persistence problem has partially been met by the recent introduction of sulfonylureas with much shorter persistence. Some may persist longer than some of the mixing partners. Data are not available to compare rates of degradation in the same soil under the same conditions. In any case, the short-residual ALS-inhibitors introduced for winter wheat have not gained wide acceptance and are applied on only 3 to 6% of planted area (14).

Other sulfonylureas have been proposed as mixing part-

Table 6. Manufacturer's recommendations of herbicide mixtures with chlorsulfuron for resistance management in winter wheat[a].

Recommended mixing partner(s)[b]	Characteristics of mixing partner(s) for resistance management of chlorsulfuron[c]
2,4-D	A short residual systemic herbicide. Timing of application important for effective control of kochia but generally not as effective as chlorsulfuron, especially throughout the season.
Metribuzin	A short residual postemergence herbicide. Can provide good control for kochia but not throughout the season, and prickly lettuce but not in all areas throughout the season. Only partially controls Russian thistle.
MCPA	A short residual contact herbicide. Does not control Russian thistle, kochia, or prickly lettuce as well as chlorsulfuron and not throughout the season.
Bromoxynil	A short residual contact herbicide. At some locations can give excellent control of kochia, although not throughout the season. At other locations it is rated not nearly as effective as chlorsulfuron. Control of Russian thistle only fair.
Bromoxynil + MCPA	Both are short residual contact herbicides. Will not control kochia, Russian thistle, or prickly lettuce as well as chlorsulfuron throughout the season.
Dicamba	A short residual, contact herbicide. Not as effective as chlorsulfuron for control of kochia throughout the season. Only fair control of Russian thistle.
2,4-D + clopyralid	Both are postemergence systemic herbicides that dissipate more rapidly than chlorsulfuron. Clopyralid provides only partial control of kochia and Russian thistle. Mixture does not add to effectiveness of 2,4-D for target weeds.
Diuron	Diuron has a much narrower weed spectrum compared to chlorsulfuron. Kochia, prickly lettuce, and Russian thistle are not as effectively controlled as with chlorsulfuron.

ners but this does not meet the "different target" criterion, while some mixture partners (2,4-D, MCPA [(4-chloro-2-methylphenoxy)acetic acid], dicamba, bromoxynil) meet it. None of the mixing partners with different modes of action have the same spectrum of weeds controlled over the whole season (Table 6). Thus, weeds such as kochia, prickly lettuce, and Russian thistle would often be biologically "unaware" of a mixture partner, so that major weeds known to evolve resistance will continue to do so despite the mixture. Still, the rate of evolution may be somewhat dampened due to early season control by the vulnerable herbicide.

[14]J. Gressel, L. Segel, and M. Mangel, manuscript in preparation.

Evolution of metabolic resistance in weeds. The above strategies for wheat and soybean/corn almost solely address the evolution of target site resistance. There is a possibility that mixtures would not preclude the evolution of metabolic resistance. This could be prevented in corn or soybean by using a partner that cannot be degraded by the same enzyme type as degrades the ALS inhibitors. This is not the case in wheat, where in all documented cases herbicides are degraded by monooxygenases (34), unless another metabolic degradation system is activated by a protectant (68). If broadleaf weeds can evolve enhanced degradation by monooxygenases as have grass weeds (25, 27, 51), then there is reason to believe that the proposed mixtures will be subject to evolution of a similar resistance.

Reducing application rates of herbicides in mixtures lowers selection pressure for the evolution of target site resistance and has probably enhanced the rate of evolution of metabolic resistance, as has happened with insecticides (35).[14] Resistance derived from multiple genes or by gene amplification can evolve quickly only if low rates are used, which selects for incrementally added gene doses. Insects and fungi have evolved metabolic pesticide resistances under either polygenic control or due to gene amplification (cf. 23, 67). Similarly, mammalian cancer cells have evolved drug resistances that are also due to gene amplification. Thus, the lower rates usable in mixtures of herbicides can be expected to decrease the rate of evolution of target site resistance and enhance the rate of metabolic weed resistance (35).

Compliance with recommendations to use mixtures. Assuming there were mixtures available that could manage resistance, there is nothing that now requires a farmer to use them. Although the manufacturer of imazethapyr is strongly advocating mixtures for resistance management, 72% of the soybean farmers surveyed following the 1992 season indicated that they applied this herbicide alone and not in mixture (Figure 2A). Twenty-three percent applied imazethapyr with a grass herbicide as a complementary mixing partner to increase the spectrum of weeds controlled, rather than to control the weeds most likely to evolve resistance. Only 5% of the farmers surveyed used a broadleaf mixing partner that might have some delaying effect on the evolution of resistance in a weed like cocklebur.

In 1992, 29% of soybean farmers surveyed in Iowa and Illinois (the two largest soybean producing states) reported using imazaquin or imazethapyr alone or in combination with other ALS inhibitors (Figure 2B). Thirty-nine percent of farmers using the imidazolinones tank-mixed them with

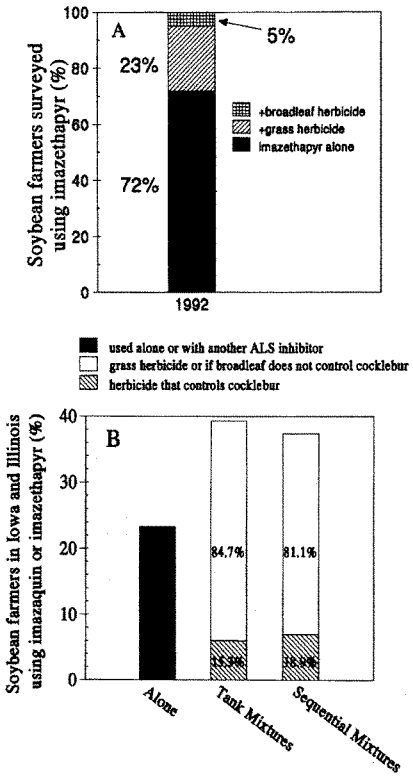

Figure 2. Usage of mixtures in soybean. A. The percentage of U.S. soybean farmers, surveyed following the 1992 season, using imazethapyr alone, with a grass herbicide, or with a broadleaf herbicide. Percentages are based on 1069 soybean farmers that reported using imazethapyr out of 7073 soybean farmers surveyed. Source: (15). B. The percentage of soybean farmers in Iowa and Illinois, surveyed following the 1992 season, using imazaquin or imazethapyr either alone, in tank-mix, or sequentially with other herbicides. Of the 1639 farmers surveyed in Iowa and Illinois, 481 (29.3%) used imazaquin or imazethapyr. Source: (15).

a non-ALS inhibitor, while 37% used a sequential treatment with a non-ALS inhibitor. Over 80% of farmers tank mixing or sequentially mixing chose mixing partners that can not control cocklebur (Figure 2B). The specific herbicides used with the imidazolinones were similar whether farmers used a tank mix or sequential applications. Seventy-five percent of farmers using tank-mixes choose dinitroaniline herbicides as the partner, while 61% of farmers used these herbicides in sequence with the imidazolinones. The dinitroanilines primarily control grass weeds and have minimal activity on cocklebur. In only 15% of the cases using tank-mixes and 19% of the sequential applications were herbicides used that have high activity for cocklebur (Figure 2B). These were all short residual herbicides, with glyphosate being the most popular. In summary, very few soybean farmers using imidazolinone herbicides are following the herbicide-resistance weed management mixture recommendations of the manufacturers.

In winter wheat, chlorsulfuron has been removed from market areas with the most severe resistance problems. In areas where chlorsulfuron continues to be sold, many farmers prefer it because of the weed free fields that result. In 1992, 14% of total U.S. winter wheat area, or 42% of the winter wheat area treated with herbicides, was treated with chlorsulfuron. This accounted for slightly over 2 million ha, an area equal to that treated with 2,4-D (14). An additional 7% of total winter wheat area was treated with another long residual sulfonylurea, metsulfuron, while two short residual sulfonylureas, thifensulfuron and tribenuron {2-[[[[(4-methoxy-6-methyl-1,3,5-triazin-2-yl)methylamino]carbonyl]amino]sulfonyl]benzoic acid}, were applied to 3 to 6% of planted area (14). Over 60% of winter wheat growers surveyed after the 1992 season that used herbicides applied at least one sulfonylurea herbicide (15). Label requirements in wheat for mixing more highly persistent sulfonylureas are often ignored, which has probably led to additional cases of resistance. Forty-six percent of the farmers surveyed applying chlorsulfuron to winter wheat in 1992 used this herbicide alone or in tank mix with metsulfuron, a sulfonylurea with only slightly less persistence (Figure 3). There are also reports that many farmers from areas where chlorosulfuron is proscribed purchase the herbicide elsewhere.

Thus, it appears that companies believing that their herbicides should be used in mixture for resistance management are having a difficult time convincing farmers to adopt this strategy. Based on present use patterns among growers, manufacturers would have to market resistance-prone herbicides only as premixes, to obtain compliance, assuming satisfactory mixture partners for resistance management were identified.

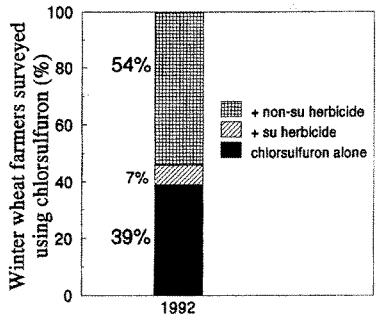

Figure 3. The percentage of winter wheat farmers surveyed following the 1992 season using chlorsulfuron alone, with another sulfonylurea herbicide, or with a non-sulfonylurea herbicide. Percentages are based on 205 winter wheat farmers who reported using chlorsulfuron out of 617 farmers surveyed who applied a herbicide. Source: (15).

CONCLUDING REMARKS

While the proposed mixing strategies may have some value for general weed control, the ones discussed do not meet the criteria for resistance management in preventing further evolution of resistant cocklebur or kochia as well as other weeds with similar properties. Mixtures have already broken down in Europe. Atrazine-resistant weeds appeared when fenuron (*N,N*-dimethyl-*N'*-phenylurea), a short residual herbicide, was used together with atrazine. Initially, only half the populations were resistant due to replenishment of susceptible plants from the seed bank. Repeated use of the atrazine-fenuron mixture enriched the resistant population to near 100%.[15]

Mixtures may theoretically be constructive tools for managing resistance when they meet the criteria listed. Still, it is questionable whether the problems of finding partners with the proper efficacy and persistence along with convincing farmers to use mixtures that increase costs without immediate weed control benefits can be overcome. If tenable mixtures could be found, they might have to be marketed only as premixes, as is done with some vulnerable fungicides. The herbicide mixtures presently recommended do not seem to have the properties to prevent or in some cases significantly delay the evolution of resistant weeds.

The possible lack of a major fitness difference between ALS level resistant and susceptible biotypes also argues for caution in use of these chemicals. We find it troubling that herbicide mixtures are being represented by some as a primary means to avoid or drastically delay ALS-inhibitor resistance problems. We believe that the marketing strategies leading to increased use of ALS-inhibiting herbicides, the development of imidazolinone-resistant corn cultivars and the development of other crop cultivars with resistance at the level of ALS are together ill-founded. This will likely result in even more widespread ALS-inhibitor resistance in weeds, requiring drastic steps to remediate the problem. The expansion of use of these herbicides, in the long-term serves neither the interests of the chemical industry nor of the agricultural community, which depends on industry. One must think beyond herbicides and short-term economics to retain excellent but resistance-prone chemistries such as the ALS inhibitors.

Now that ALS-resistant weeds have evolved in these cropping systems, mixtures containing a few percent of resistant and susceptible weed seeds can be used in controlled experiments in the field to rapidly evaluate the efficacy of various herbicide mixing strategies alongside other management strategies. Such experiments can be carried out in normally used cropping systems. This would provide some real data to evaluate mixtures under field conditions rather than relying too much on theoretical considerations.

Herbicide-Resistant Weeds: Management Tactics and Practices[1]

HUGH J. BECKIE[2]

Abstract: In input-intensive cropping systems around the world, farmers rarely proactively manage weeds to prevent or delay the selection for herbicide resistance. Farmers usually increase the adoption of integrated weed management practices only after herbicide resistance has evolved, although herbicides continue to be the dominant method of weed control. Intergroup herbicide resistance in various weed species has been the main impetus for changes in management practices and adoption of cropping systems that reduce selection for resistance. The effectiveness and adoption of herbicide and nonherbicide tactics and practices for the proactive and reactive management of herbicide-resistant (HR) weeds are reviewed. Herbicide tactics include sequences and rotations, mixtures, application rates, site-specific application, and use of HR crops. Nonherbicide weed-management practices or nonselective herbicides applied preplant or in crop, integrated with less-frequent selective herbicide use in diversified cropping systems, have mitigated the evolution, spread, and economic impact of HR weeds.

Additional index words: Herbicide resistance, integrated weed management.

Abbreviations: ACCase, acetyl-CoA carboxylase; ALS, acetolactate synthase; APP, aryloxyphenoxypropionate; CHD, cyclohexanedione; DSS, decision-support system; EPSPS, enolpyruvylshikimate-3-phosphate synthase; HR, herbicide resistant; HS, herbicide susceptible; IWM, integrated weed management.

INTRODUCTION

The main risk factors for the evolution of HR weeds are: (a) recurrent application of highly efficacious herbicides with the same site of action; (b) annual weed species that occur at high population densities, are widely distributed, genetically variable, prolific seed producers, and have efficient gene (seed or pollen) dissemination; and (c) simple cropping systems that favor a few dominant weed species (Owen 2001a; Thill and Lemerle 2001). Globally, the most economically important HR weeds include rigid (annual) ryegrass (*Lolium rigidum* Gaudin), wild oat (*Avena fatua* L.), *Amaranthus* spp. (redroot pigweed, *A. retroflexus* L.; smooth pigweed, *A. hybridus* L.; common waterhemp, *A. rudis* Sauer; and tall waterhemp, *A. tuberculatus* (Moq.) J.D. Sauer), common lambsquarters (*Chenopodium album* L.), green foxtail [*Setaria viridis* (L.) Beauv.], barnyardgrass [*Echinochloa crus-galli* (L.) Beauv.], goosegrass [*Eleusine indica* (L.) Gaertn.], kochia [*Kochia scoparia* (L.) Schrad.], horseweed [*Conzya canadensis* (L.) Cronq.], and blackgrass (*Alopecurus myosuroides* Huds.) (Heap 2005). For the majority of HR weed biotypes, herbicide resistance is target-site based, conferred by a single, major (i.e., large phenotypic effect) gene with a high degree of dominance (Powles et al. 1997). This mode of inheritance favors the rapid evolution of weed resistance to herbicides applied at registered rates.

In high-input cropping systems around the world, farmers are reluctant to proactively manage weeds to prevent or delay the selection for herbicide resistance. The cost and effort of preventing/delaying resistance to many herbicides are widely perceived or estimated to be the same as that of managing HR weeds, and therefore farmers often do not change their weed management program until resistance has occurred. The lack of proactive management of the evolution of HR weed populations may be due to farmers' primary interest in optimizing short-term economic returns, or inability to assess the economic risks associated with HR weeds (Rotteveel et al. 1997).

Low adoption of resistance–avoidance tactics may also be due to the lack of alternative herbicide groups (defined by site of action) to control the target weeds, or

Table 1. Use of integrated weed management practices by Western Australian grain farmers in 2000 (n = 132) (adapted from Llewellyn et al. 2004).

Practice[a]	Farmer adoption			Expected efficacy[c]
	HR[b]	no HR	All	
	%			
Stubble burning	85	66	76	47 ± 19
Weed seed catching	10	2	7	57 ± 15
Tillage	49	49	46	39 ± 22/49 ± 21
Autumn tickle (preplant tillage)	57	26	44	
Delayed planting	53	35	46	55 ± 23
Double knock	62	49	57	64 ± 21
Crop topping	44	11	30	62 ± 17
Green manuring	21	11	17	74 ± 19
Crop cut for hay	31	49	39	
Spray topping	95	94	94	
High wheat seeding rate	57	54	56	28 ± 17/35 ± 19
Trifluralin[d]				67 ± 14

[a] Double knock, crop topping, and spray topping are the use of a nonselective herbicide applied: preplant (followed by another nonselective herbicide or tillage), to annual legumes at postanthesis weed growth stage, and to pastures, respectively, to reduce weed seed production.

[b] HR: farmers with herbicide resistance (n = 77) vs. no resistance (n = 55).

[c] Efficacy expected by farmers for rigid ryegrass (*Lolium rigidum* Gaudin) control ± standard deviation; tillage, high seeding rate: difference among nonusers and users, respectively.

[d] Included for comparison.

unrealistic expectations that new herbicide technology will continually be forthcoming (Llewellyn et al. 2002). However, herbicides should be viewed as a nonrenewable resource. With the cost of discovering, developing, and marketing a novel herbicide at approximately United States (U.S.) $150 to $180 million in 2005 (D. Porter, personal communication), farmers cannot expect many compounds with novel sites of action to be commercialized in the near future.

Additionally, a lack of information on the impact of management tactics and practices on selection of herbicide resistance may limit a farmer's ability to delay resistance. How long herbicide resistance can be delayed by implementing a comprehensive integrated weed-management (IWM) program is uncertain. Moreover, recommendations to farmers to delay or prevent herbicide resistance are often similar to those recommended for managing resistance, thus discouraging the adoption of prevention tactics. Socioeconomic factors in developed countries, such as farmer demographics, increasing size of farms with concomitant limited labor and time availability, high percentage of leased land by renters with a general lack of awareness of previous herbicide history or reduced motivation for long-term stewardship, and preference for annual cropping systems based on lifestyle choice and cash flow, reinforces a heavy reliance on herbicides as the dominant method of weed control (Friesen et al. 2000).

Farmers usually increase the adoption of IWM practices only after herbicide resistance has evolved (Beckie and Gill, 2006). Populations of a number of HR grass weed biotypes threaten cereal grain production in different areas of the world. Cross-resistance (a single resistance mechanism conferred by one or more genes) and multiple resistance (two or more resistance mechanisms) in weed species have often been the main impetus for the utilization of a greater number of IWM practices in cropping systems (Powles et al. 1997, 2000). For example, farmers in Western Australia with infestations of HR rigid ryegrass practice weed seed catching at harvest more frequently than those with no resistance (Table 1). Farmers with resistance used an average of 8.4 IWM practices, significantly more than farmers with no resistance (mean of 6.6) (Llewellyn et al. 2004).

Prevention can cost significantly less than dealing with resistance once it fully develops, where intergroup herbicide resistance occurs, or where few alternative herbicides are available (Orson 1999). The greatest direct cost of herbicide resistance to the farmer can occur during the first year of poor weed control and consequent yield loss (Peterson 1999). Populations of weeds with high fecundity potential, such as rigid ryegrass, can increase rapidly after control failures caused by resistance. To manage resistance, farmers first use alternative herbicides (i.e., addition of a tank-mix partner or rotating to a herbicide with a different site of action). In some situations, herbicides that selected for resistance may continue to be used because of their cost-effective (i.e., economical) control of non-HR weed species (e.g., triazines or glyphosate applied to land with triazine- or glyphosate-HR biotypes, respectively). The addition of a herbicide to control the HR weed biotype, however, will

increase costs to the farmer (Peterson 1999). The short-term cost of resistance is minimal if alternative herbicides are available, such as those for control of many biotypes resistant to phenoxy or photosystem I-disrupting herbicides (Beckie et al. 2001b). In contrast, there may be a limited number of herbicide options for control of some intergroup-HR biotypes, and those that are available usually increase costs. For example, most or all alternative herbicides to control intergroup-HR biotypes of wild oat or green foxtail in the northern Great Plains increase costs to farmers (Beckie et al. 1999b, 1999c). Management of glyphosate-HR horseweed in conservation-tillage systems in the North Delta region of the United States requires a phenoxy herbicide and one or two residual herbicides. As a consequence of this additional herbicide cost (U.S. $16 to $62/ha), conservation tillage has dropped by about 50% in cotton (*Gossypium hirsutum* L.) and 30% overall (Steckel et al. 2005).

The prime strategy for managing herbicide resistance in weeds is to reduce the selection pressure for resistance evolution by any one selecting agent, while maintaining adequate weed control. Selection pressure has the greatest impact on herbicide-resistance evolution and is a factor that farmers can control. Selection pressure imposed by a herbicide is the product of selection intensity (efficacy) and selection duration (persistence in soil) (Putwain 1982). Herbicides applied in crop generally result in the greatest selection pressure compared with other application timings. Selection pressure against a weed population over time, resulting in increasing frequency of HR individuals that collectively possess one or more resistance mechanisms, is a function of frequency of application. Mathematically, the relative selection pressure of a herbicide on a target weed species in a population has been defined as the proportion of HR plants divided by the proportion of herbicide-susceptible (HS) plants that remain after exposure to the herbicide (Gressel and Segel 1982). These proportions are equal to one minus the effective kill, defined by seed yield reduction (Beckie and Morrison 1993; Gressel and Segel 1982). For example, if seed production of HR and HS biotypes is reduced by 42 and 99%, respectively, relative selection pressure is estimated to be $(1 - 0.42)/(1 - 0.99) = (0.58)/(0.01) = 58$. By definition, the selection pressure can only be reduced by lowering the effective kill of HS plants or increasing the effective kill of HR plants. No selection pressure is exerted when HS and HR genotypes are controlled equally. Diversification of selection pressures on weed populations, such as varying the type and timing of herbicide application (e.g., selective or nonselective herbicides applied preplant, in crop, preharvest, or postharvest), integrating cultural or mechanical weed management practices with reduced herbicide use, and diversifying the cropping system as a whole, is required to reduce the selection pressure of any one selecting agent (Boerboom 1999).

In this review, tactics and practices to effectively delay or manage HR weeds in input-intensive cropping systems worldwide are summarized. Herbicide-based tactics are emphasized, because herbicides will continue to be the dominant weed-control tool in these cropping systems during the forseeable future. Nonherbicide tactics and practices that have been proven effective in managing HR weeds are outlined. Examples are provided to illustrate the impact of herbicide and nonherbicide tactics on the successful proactive and reactive management of HR weeds.

HERBICIDE TACTICS

A herbicide sequence is defined as two or more applications of herbicides with different sites of action within one crop, whereas herbicide rotation is the application of herbicides with different sites of action to multiple crops over multiple growing seasons in a field. Herbicide sequences, rotations, or mixtures generally have the greatest effect in delaying resistance when the mechanism conferring resistance is target-site based, the target weed species are highly self-pollinated, and seed spread is restricted (Beckie et al. 2001b; Wrubel and Gressel 1994). Multiple resistance can evolve within a weed population through a change in selection history (usually sequential selection), through selection of multiple mechanisms by a single herbicide, or through outcrossing among individuals containing different resistance mechanisms (Hall et al. 1994; Preston and Mallory-Smith 2001). Based on a compounded resistance frequency model, the probability of HR mutants with multiple mechanisms of resistance (target-site based) in an unselected population is the product of the probabilities of resistance to each affected herbicide site of action and thus is rare (Wrubel and Gressel 1994). However, frequent use of herbicides in a field over time can enrich HR populations with different resistance mechanisms. Outcrossing among plants, such as *Lolium* spp. or blackgrass, in close proximity that possess different HR mechanisms can result in multiple-HR progeny. Spreading HR seed within and among fields can also aid this process.

Herbicide Sequences and Rotations. *Adoption.* Performance and cost of herbicides usually rank higher than site of action when farmers select a herbicide. The lack of suitable herbicide options associated with crop rotation can be an impediment to herbicide group rotation (Bourgeois et al. 1997b; Légère et al. 2000). The level of adoption of herbicide group rotation for resistance management has increased markedly during the past decade in Canada and Australia. There is little information on the adoption of this tactic in other countries. In western Canada in 1998, fewer than 50% of farmers practiced herbicide group rotation, even though awareness was high (Beckie et al. 1999a). By 2003, 70 (Saskatchewan) to 90% (Manitoba) of farmers claimed to rotate herbicides by site of action (H. Beckie, unpublished data). In 2005, over half of the herbicide products sold in Canada had resistance management labeling, which includes group identification symbols on the label and guidelines for resistance management tactics in the use directions (N. Malik, personal communication). The guidelines were a joint effort between the Pest Management Regulatory Agency (PMRA 1999) in Canada and the U.S. Environmental Protection Agency (2001). By 1998 in Australia, the adoption rate of herbicide group rotation was 85%, attributed largely to site-of-action labeling on herbicide containers (Shaner et al. 1999). It is the most common herbicide resistance management tactic cited by farmers in survey questionnaires conducted in Australia (Shaner et al. 1999) and Canada (H. Beckie, unpublished data). A prerequisite for herbicide group rotation is keeping field records of herbicides used each year. Software packages of crop and herbicide rotation planners are available in many jurisdictions, which facilitate record keeping and can flag high-risk herbicide practices, such as repeated use of herbicides with the same site of action.

Mitigating herbicide resistance risk. Evolution of target-site resistance in weed biotypes is attributed to frequent use of herbicides of the same site of action and their propensity to select for HR biotypes (Beckie et al. 2001a; LeBaron and McFarland 1990). Knowledge of resistance risk could be an incentive for farmers to practice herbicide sequences or rotations to delay the rate of evolution of resistance. The ease of selection for HR biotypes is governed by several factors. As described previously, the selection pressure (efficacy and persistence) imposed on the target weed species by a herbicide is the most important factor affecting the rate of evolution of resistance. The slow evolution of resistance in weed biotypes to phenoxy herbicides, first introduced in 1946, has been partially attributed to relatively low selection pressure (Coupland 1994). Similarly, relatively low efficacy of trifluralin, a dinitroaniline herbicide, on rigid ryegrass has been cited as one reason for relatively slow evolution of resistance (Table 1). In a 1998 Western Australian field survey of rigid ryegrass, population densities were unrelated to herbicide resistance, suggesting the availability of alternative herbicides, particularly trifluralin, to control HR rigid ryegrass (Llewellyn and Powles 2001).

Nonpersistent herbicides generally exert less selection pressure than those that control successive flushes of germinating weeds throughout the growing season. The contribution of persistence to selection pressure, however, depends on timing of herbicide application and the germination characteristics of the target species in a geographic region. The soil residual activity of herbicides did not strongly influence selection pressure on wild oat in a competitive crop (canola, *Brassica napus* L.) in western Canada (Beckie and Holm 2002). The selection pressure exerted on wild oat by residual herbicides was the same as or lower than that of nonresidual herbicides. In the relatively short growing season in the northern Great Plains, few wild oat plants may emerge after postemergence application of a nonresidual herbicide and produce viable seeds in a competitive crop. In other agroecoregions, herbicide persistence in soil can have a much greater effect on selection pressure.

Whereas a single mutation can confer resistance to single site-of-action herbicides, multiple mutations within a plant are often needed to confer resistance to herbicides with more than one site of action, such as chloracetamide herbicides (Foes et al. 1998). As indicated previously, individuals in an unselected population with multiple mutations for resistance generally would be rare (Preston and Mallory-Smith 2001; Wrubel and Gressel 1994). The frequency of HR alleles in unselected populations defines the starting point for resistance evolution, and thus impacts the length of time for resistance to evolve to noticeable levels. An unusually low rate of mutation of the locus conferring resistance, or alternatively few fit mutations, are speculated to contribute to the slow evolution of resistance to phenoxys and other herbicides, such as glyphosate (Gressel 1999; Jasieniuk et al. 1995). Fit mutations are more probable for noncompetitive inhibitors of target-site enzymes such as acetyl-CoA carboxylase (ACCase, EC 6.4.1.2) and acetolactate synthase (ALS, EC 4.1.3.18), where the herbicide binding site is different from the active site. The probability of finding an initial HR mutant in an unselected population increases with an increase in the number of

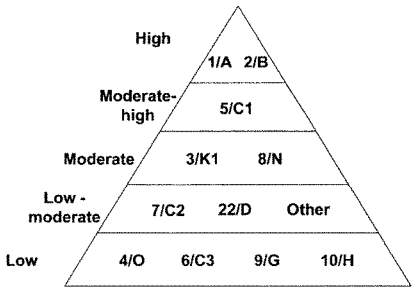

Figure 1. Classification of herbicide site of action by risk of selection for target-site resistance (high ≤ 10; moderate = 11–20; low >20 applications (H. Beckie and L. Hall, unpublished data); "Other": insufficient information to definitively categorize as low or moderate risk. Numerical (Weed Science Society of America) and alphabetical (Herbicide Resistance Action Committee) herbicide groups are described in Mallory-Smith and Retzinger (2003) or Heap (2005).

types of functional mutations (Murray et al. 1996). There are at least five different point mutations in each of the ACCase and ALS target sites in HR weed biotypes, each conferring a different cross-resistance pattern and level of resistance (Délye and Michel 2005; Gressel 2002). Indeed, the frequency of target-site–based ALS inhibitor-HR individuals in untreated populations of rigid ryegrass was found to be relatively high, ranging from 10^{-5} to 10^{-4} (Preston and Powles 2002a). In contrast, most mutations conferring resistance to glyphosate, a competitive inhibitor of enolpyruvylshikimate-3-phosphate synthase (EPSPS, EC 2.5.1.19), and glufosinate, a competitive inhibitor of glutamine synthetase (EC 2.7.7.42), are believed to be lethal.

The risk of target-site resistance, defined by the mean number of applications before resistance is detected, varies by herbicide group (Figure 1). This approach of risk assessment assumes that a particular herbicide site of action is effective for a set number of applications before the onset of target-site resistance. The use of herbicide "shots" is appropriate in economic models and farm-management decision aids (Diggle and Neve 2001). Anecdotal information, namely, field histories of herbicide use, usually is used for assessing the risk of selecting for resistance based on an herbicide's site of action. Only one long-term experiment has examined the effect of frequency of herbicide use on the evolution of resistance. In a large-plot field experiment conducted from 1979 to 1998, resistance in wild oat to triallate occurred after 18 yr where the herbicide was applied annually in continuous spring wheat (*Triticum aestivum* L.), but not where it was applied 10 times in a wheat–fallow rotation over the same period (Beckie and Jana 2000).

It is widely agreed that ACCase and ALS inhibitor herbicides pose a high risk for selecting HR biotypes relative to herbicides from other groups (Dellow et al. 1997; Gressel 1997; Heap 1999; LeBaron and McFarland 1990; Monjardino et al. 2003). High-risk herbicides should be applied less often in sequences or rotations than lower-risk herbicides. At a minimum, use of high-risk herbicides in consecutive years in a field should be avoided. In sequences, lower-risk, nonselective herbicides, such as photosystem-I electron diverters (paraquat, diquat) or EPSPS inhibitor (glyphosate) should be used preplant to reduce the number of weeds selected with in-crop herbicides that pose a higher risk. Ideally, high-risk herbicides should not be used in fields with high weed densities, because the number of HR mutants is proportional to population size (Jasieniuk et al. 1996).

Nonselective herbicides, such as paraquat, are commonly applied at the postanthesis stage of rigid ryegrass in annual legume (pulse) crops in Australia, referred to as "crop topping." In Western Australia, four times as many farmers with HR rigid ryegrass practice crop topping than those with no resistance (Table 1). This practice can markedly reduce weed seed production (Gill and Holmes 1997). In Australia, there has been wide adoption of herbicide techniques to reduce seed production to manage resistance in rigid ryegrass in both annual legume crops and pastures ("spray topping") (Table 1). The Australian National Glyphosate Sustainability Working Group (2005) recommends reducing the risk of glyphosate resistance by rotating glyphosate with paraquat for preplant weed control, or using a "double knock" (or "double knockdown") technique by following in sequence a preplant glyphosate application with tillage or a paraquat-based product (Weersink et al. 2005) (Table 1).

Trends discerned in the cross-resistance patterns of weed species resistant to herbicides of the same site of action may be used as a guide for strategic herbicide use. Patterns of cross-resistance, however, cannot be accurately predicted based on field histories of herbicide use. Incidence of aryloxyphenoxypropionate (APP) resistance in HR *Avena* spp. biotypes tends to be greater than that of cyclohexanedione (CHD) resistance in many countries (Beckie et al. 1999b, 1999c, 2002; Cocker et al. 2000; Mansooji et al. 1992; Seefeldt et al. 1994). Thus, as a short-term tactic to manage ACCase target-

site resistance in populations of this species, CHDs may have a higher probability of success. An apparently widespread point mutation in the ACCase gene resulting in an amino-acid change from isoleucine to leucine at position 1781 confers resistance to some APP and CHD herbicides in several grass weed species (Délye et al. 2003; Kaundun and Windass 2004). In various grass weed species, clethodim has often controlled ACCase inhibitor–HR biotypes in dicot crops (Bradley and Hagood 2001). Apparently, the point mutation(s) that confer(s) resistance to this herbicide occurs relatively infrequently.

Individuals in a population exposed to the same selection pressure can exhibit different patterns of cross-resistance, however, highlighting the probable short-term success of this approach. Wild oat patches with different cross-resistance patterns have been documented within a field (Andrews et al. 1998; Bourgeois et al. 1997a). ALS inhibitor resistance in a population of prostrate pigweed (*Amaranthus blitoides* S. Wats.) in a field in Israel is endowed by two point mutations, each conferring a different cross-resistance pattern (Sibony and Rubin 2003). Allele-specific assays can detect different point mutations (Délye et al. 2002; Kaundun and Windass 2004; Siminszky et al. 2005). Such assays are being commercialized to determine cross-resistance patterns rapidly in HR weed populations where resistance is target-site based, providing farmers with the option of applying an effective herbicide within the same growing season as weed tissue samples are collected for testing.

Herbicide resistance is often attributed to a lack of herbicide group rotation, that is, frequent or repeated use of herbicides of the same site of action. However, there is direct epidemiological evidence for the utility of herbicide group rotations in delaying the evolution of target-site resistance. Examples where herbicide group rotation has been credited in preventing or delaying resistance in weeds include triazine-HR weeds in North America (Stephenson et al. 1990), isoproturon-HR littleseed canarygrass (*Phalaris minor* Retz.) in India (Singh et al. 1999), ACCase inhibitor–HR wild oat in Canada (Légère et al. 2000) and rigid ryegrass in Australia (Gill 1995), and ALS inhibitor-HR common cocklebur (*Xanthium strumarium* L.) in the southern U.S. (Schmidt et al. 2004), wild radish (*Raphanus raphanistrum* L.) in Australia (Hashem et al. 2001a), paddy weed (*Lindernia micrantha* D.) in Japan (Itoh et al. 1999), and weeds in field crops in Europe (Hartmann et al. 2000).

Intergroup herbicide resistance can be conferred by a non-target-site mechanism, which commonly is enhanced metabolism (De Prado and Franco 2004). Metabolic resistance has been reported much more frequently in grass than broadleaf weeds (Werck-Reichhart et al. 2000). Cases of weed resistance due to metabolic detoxification are more frequent than those attributed to target-site mutation in U.K. populations of blackgrass, *Avena* spp., and Italian ryegrass (*Lolium multiflorum* Lam.) resistant to ACCase inhibitors or other herbicides; in European populations of blackgrass resistant to ACCase inhibitors, ALS inhibitors, or chlortoluron; and in European populations of grass species resistant to ALS inhibitors (Claude et al. 2004; Marshall and Moss 2004; Moss et al. 2003). Metabolism-based resistance to herbicides of different sites of action will clearly limit the effectiveness of herbicide group rotation as a tool to delay the evolution of herbicide resistance. Testing populations to determine herbicide resistance patterns is even more important where intergroup resistance is suspected and will help identify remaining herbicide options for farmers (Beckie et al. 2000).

Herbicides that are not readily metabolized in weeds are less likely to select for metabolism-based resistance. For example, the low incidence of dinitroaniline (e.g., trifluralin) resistance may be due to the paucity of detoxification mechanisms in target plants (Holt et al. 1993). Sulfometuron and imazapyr are slowly metabolized in plants and have been used to discriminate between target-site and metabolic resistance in rigid ryegrass (Boutsalis and Powles 1995; Preston and Powles 2002b). Two major enyzme systems have been implicated in herbicide resistance due to increased detoxification—cytochrome P450 monooxygenases and glutathione *S*-transferases (Table 2). These detoxification systems are expressed both constitutively and induced (upregulated) in response to herbicide safeners. Studies of the inheritance of cytochrome P450 monooxygenase-dependent resistance in weeds have shown that a single gene can endow cross-resistance to herbicides of different sites of action applied at registered rates (Letouzé and Gasquez 2001; Preston 2004). Cross-resistance can frequently occur between ACCase and ALS inhibitors, or between photosystem-II inhibitors and ACCase inhibitors (Preston 2004). However, different patterns of cross-resistance can occur in different species (Preston and Mallory-Smith 2001).

Herbicides used in sequences or rotations that are detoxified via pathways different from these two enzyme systems, or that are slowly or not metabolized (e.g., glyphosate, glufosinate, paraquat), will reduce the risk of selecting for metabolism-based, intergroup-HR weed

Table 2. Herbicides metabolized by cytochrome P450 monooxygenases (P450s) or glutathione *S*-transferases (GSTs) in herbicide-resistant weed biotypes.

[a] Abbreviations: APP, aryloxyphenoxypropionate; IMI, imidazolinone; PTB, pyrimidinylthiobenzoate; SCT, sulfonylamino-carbonyltriazolinone; SU, sulfonylurea.

[b] Proposed name. Chemical name: methyl 2({[4-methyl-5-oxo-3-propoxy-4,5-dihydro-1*H*-1,2,4-triazol-1-yl]carbonyl}amino}sulfonyl)benzoate sodium salt.

biotypes. Most cases of cross-resistance across herbicide sites of action have occurred through the use of wheat-selective herbicides (Hidayat and Preston 2001). Thus, herbicides not selective in wheat, such as sethoxydim or clethodim, and nonselective herbicides used in HR crops, such as glyphosate or glufosinate, will be important tools for managing metabolic resistance in grass weed biotypes in the future.

Herbicide-Resistant Crops: A Double-Edged Sword. Adoption of HR crops is driven primarily by easier and improved weed control or higher net returns (Burnside 1992; Devine and Buth 2001). Cultivation of such crops will increasingly influence future herbicide-use patterns. Globally, resistance to nonselective herbicides (i.e., glyphosate, glufosinate) is the dominant type of transgenic crop (72%, stacked traits excluded), and cultivated area has continued to expand since 1995 (Table 3). HR soybean [*Glycine max* (L.) Merr.] comprises the largest area at 48.4 million ha or 60% of the area planted to transgenic crops. Other important transgenic-HR crops include corn (*Zea mays* L.) (10% by area), cotton (about 6%), and canola (6%). Worldwide, 56% of soybean, 19% of canola, 15% of cotton, and 6% of corn planted in 2004 were transgenic-HR cultivars.

The judicious use of HR crops can slow the selection of HR weeds by increasing herbicide rotation options, such as the substitution of high-risk herbicides with lower-risk products. Nonselective herbicides used in HR crops in North America have been a powerful tool to proactively and reactively manage HR weeds, such as those resistant to high-risk herbicides, including ACCase and ALS inhibitors (Beckie et al. 2006). As a result, the potential economic impact of these HR weeds has been diminished. However, frequent use of HR crops in cropping systems, resulting in recurrent application of herbicides of the same site of action, may select for new HR weed biotypes or augment the selection that has occurred previously. Evolved weed resistance through selection pressure in HR crops generally poses a greater risk than evolved resistance in related weed species through gene flow because frequency of interspecific hybridization and subsequent introgression is often low (Beckie et al. 2001c; Warwick et al. 1999, 2004). Notable exceptions may include gene flow from HR canola to bird's rape/field mustard (*Brassica rapa* L.) in eastern

Canada (Warwick et al. 2003), HR wheat to jointed goatgrass (*Aegilops cylindrica* Host) in the western United States (Hanson et al. 2005; Seefeldt et al. 1998; Zemetra et al. 1998), and HR rice (*Oryza sativa* L.) to red rice (*O. sativa* L.) in the Americas (Gealy et al. 2003).

Potential impact of HR crops on selection for weed resistance is largely dependent on the size and intensity of the cropped area in an agricultural region and the herbicide site of action. Occurrence of glufosinate-HR weeds has not been reported. There are relatively few reports of weeds resistant to photosynthesis inhibitors at photosystem II (benzonitriles) (Heap 2005). The largest class of HR weeds worldwide are those resistant to ALS inhibitors. The use of ALS inhibitor herbicides in imidazolinone-HR crops will continue the selection for ALS inhibitor-HR broadleaf and grass weeds. Unless imidazolinone-HR crops and ALS inhibitor herbicides are used wisely, their commercial success will be limited.

Since the introduction of glyphosate-HR crops in the mid-1990s, several weed species resistant to the herbicide have been reported (Heap 2005). The majority of glyphosate-HR biotypes were not a consequence of glyphosate selection pressure in HR field crop production systems, but in orchards and vineyards, roadsides, or non-HR crops (e.g., preplant, preharvest, or postharvest).

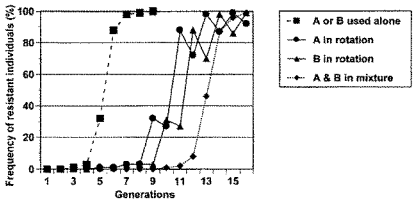

Figure 2. Predicted evolution of herbicide resistance (dominant inheritance) in an outcrossing weed species following repeated selection with herbicides A and B used alone, in a rotation, or in a mixture (adapted from Powles et al. 1997).

To date since 2000, however, evolution of three glyphosate-HR biotypes has been linked to glyphosate-HR cropping systems in the United States. In various regions of the United States, sequential in-season applications combined with near glyphosate-HR soybean monoculture (or glyphosate-HR cotton) have contributed to the evolution of glyphosate-HR horseweed across a large area in more than 10 states, glyphosate-HR common ragweed (*Ambrosia artemisiifolia* L.) in Missouri, and glyphosate-HR Palmer amaranth (*Amaranthus palmeri* S. Wats.) in Georgia (Heap 2005). Such practices create an intense selection pressure for weed resistance and jeopardize the future utility of this important herbicide. Given the importance of glyphosate in reduced-tillage cropping, monoculture glyphosate-HR crops and multiple in-crop glyphosate applications should be dissuaded. The inexpensive cost of glyphosate relative to total variable costs and its lack of soil residual activity are disincentives for a reduction in herbicide-use intensity. Nevertheless, greater implementation of IWM practices in glyphosate-HR crops, such as an intermediate (e.g., 38 cm) rather than a wide (e.g., 76 cm) row spacing in soybean (Chandler et al. 2001), can reduce weed populations and thus help reduce the real or perceived need for sequential in-crop glyphosate applications.

Herbicide Mixtures. Based on the compounded resistance frequency model, herbicide mixtures are predicted to delay resistance longer than rotations (Diggle et al. 2003; Powles et al. 1997) (Figure 2). Field experiments are being conducted to verify model predictions (H. Beckie, unpublished data). Acceptance by farmers of herbicide mixtures for resistance avoidance has been aided by cost-incentive programs from industry, formulated mixtures (e.g., phenoxy plus an ALS inhibitor), and the rapid evolution of resistance in specific cases. The herbicide combinations may be applied at lower individual

herbicide rates (Little and Tardif 2005), especially when interacting synergistically (Gressel 1990). A survey of 1,800 farmers in western Canada from 2001 to 2003 indicated that a majority of them tank-mix herbicides to delay or manage ALS inhibitor-HR broadleaf weeds (H. Beckie, unpublished data).

If mixing partners of different sites of action do not meet the criteria of similar efficacy and persistence, plus different propensity for selecting for resistance in target species, the effectiveness of mixtures for delaying target-site resistance will be reduced. For example, a mixture of an ALS inhibitor, chlorimuron, and metribuzin for ALS inhibitor resistance management of common waterhemp in the mid-western United States is not effective because chlorimuron is more persistent than metribuzin and common waterhemp has uneven and season-long emergence (Sprague et al. 1997). Imazaquin applied with pendimethalin did not delay imazaquin resistance in smooth pigweed because pendimethalin did not adequately control the species (Manley et al. 1998). Mixtures can inadvertently accelerate the evolution of multiple resistance if they fail to meet basic criteria for resistance management and are applied repeatedly (Rubin 1991). A biotype of rigid ryegrass became resistant to a mixture of amitrole and atrazine after 10 yr of widespread and repeated use (Burnet et al. 1991). To effectively delay metabolic resistance, the mixing partners must be degraded via different biochemical pathways (Wrubel and Gressel 1994). However, information on the mode of degradation of herbicides in plants is not known by farmers. Furthermore, mixtures to prevent or delay metabolic resistance in grass weeds, where this mechanism is most prevalent, may be cost-prohibitive unless graminicide partners interact synergistically and can be applied at lower rates.

Challenges to farmer adoption of mixtures for herbicide resistance management include increased cost and availability of suitable mixing partners that meet the criteria outlined above. The inherent limitation of mixtures in delaying target-site resistance is illustrated by the following example. The ALS inhibitor herbicide, thifensulfuron plus tribenuron (formulated mixture), is popular for controlling broadleaf weeds in cereal crops in the northern Great Plains. The phenoxy herbicide, MCPA, is registered as a tank mixture with this ALS inhibitor (Anonymous 2005). Eleven weed species are controlled by both mixing partners, including ball mustard [*Neslia paniculata* (L.) Desv.], kochia, redroot pigweed, Russian thistle (*Salsola iberica* Sennen & Pau), field pennycress (*Thlaspi arvense* L.), and wild mustard (*Sinapis arvensis* L.). This mixture should markedly delay ALS inhibitor target-site resistance in these species, particularly those that are highly self-pollinated, such as field pennycress. MCPA poses a low risk for selecting for resistance (Figure 1), both mixing partners have short soil residual activity, and MCPA is inexpensive. However, the rate of MCPA used in the mixture may result in reduced efficacy on some species, such as redroot pigweed and Russian thistle, compared with that of the ALS inhibitor herbicide. Moreover, common chickweed [*Stellaria media* (L.) Vill.] and common hempnettle (*Galeopsis tetrahit* L.) are only controlled by the sulfonylurea herbicide. Numerous ALS inhibitor-HR populations of these two species have been reported.

There is limited anecdotal evidence of the usefulness of mixtures in herbicide-resistance management. Mixtures with ALS inhibitors have successfully delayed ALS inhibitor resistance in weeds in rice in Japan and in field crops in Europe (Gressel 1997; Itoh et al. 1999). Farmers who included mixtures of herbicides with different sites of action coupled with various cultural practices were less likely to select ALS inhibitor–HR weed populations (Shaner et al. 1997). *Chenopodium* and *Amaranthus* spp., which often have evolved triazine resistance when triazines were used alone, rarely have been reported to evolve resistance where atrazine plus chloracetamide mixtures were used for over 20 yr in monoculture corn in North America (Wrubel and Gressel 1994). Atrazine is applied at a lower rate in this mixture, thus reducing selection pressure. Pendimethalin is an effective mixing partner (or when used in sequence) for propanil to delay or manage propanil resistance in junglerice [*Echinochloa colona* (L.) Link] in rice in Central America (Riches et al. 1997; Valverde 1996).

Effective resistance management is realized by herbicide mixtures that result in synergistic effects. Some carbamates and organophosphates competitively inhibit aryl acylamidase (EC 3.1.1.a), the enzyme responsible for catalyzing propanil metabolism in rice and propanil-HR junglerice. This inhibition can result in synergistic effects. A formulation of propanil and piperophos, a phosphoric herbicide, was first marketed in 1995 in Costa Rica and cost-effectively controls propanil-HR junglerice while achieving selectivity in rice (Valverde 1996; Valverde et al. 1999). Mixtures comprising a reduced rate of propanil and piperophos or anilofos are now widely used in Costa Rica and Columbia (Valverde et al. 2000). Similarly, mixtures of anilofos or piperophos with propanil at various rate combinations synergistically control propanil-HR barnyardgrass in rice in

the southern United States with little or no crop injury (Daou and Talbert 1999; Norsworthy et al. 1999a, 1999b; Talbert et al. 2000) (Table 4).

Can herbicide rotations or mixtures exploit reduced fitness of herbicide-resistant weeds and negative cross-resistance? Reduced fitness of triazine-HR plants compared with HS plants, documented frequently in the 1970s, resulted in optimistic predictions that this "cost of resistance" would also be prevalent in biotypes resistant to herbicides of other sites of action (Gressel and Segel 1982). The target-site mutations conferring most cases of triazine resistance reduce photosynthetic efficiency, which is often manifested by decreased plant productivity and competitiveness (i.e., reduced fitness). Upon discontinuation of triazine herbicides, reduced fitness of HR compared with HS biotypes was predicted to reverse the evolution of resistance at a rate dependent on the fitness differential between biotypes. Unfortunately, reduced fitness of biotypes resistant to herbicides of other sites of action has generally been minimal or not detectable (Holt and Thill 1994). Lack of measurably reduced fitness in HR biotypes has been inferred from little decline in the proportion of HR:HS individuals measured in fields over time after use of the selecting herbicide was discontinued (Andrews and Morrison 1997). For noncompetitive inhibitors of target-site enzymes, such as ACCase or ALS, the various sites of mutations for resistance are not near the active site of the enzyme and thus there is little fitness loss detectable due to lower affinity for the normal substrates (Gressel 1999; Wrubel and Gressel 1994).

Negative cross resistance, that is, HR plants are more sensitive to a herbicide than HS plants, has been documented in several triazine-HR weed biotypes (Dabaan and Garbutt 1997; Gadamski et al. 2000; Jordon et al. 1999; Parks et al. 1996). Some herbicides that inhibit photosystem II bind more efficiently to the mutant triazine binding domain than to the wild (HS) type. Triazine-HR weeds frequently show negative cross resistance to other photosystem-II inhibitors, such as bentazon and pyridate; triazine-HR weeds can also exhibit negative cross resistance to herbicides that do not affect photosystem II (Gadamski et al. 2000). Explanations for this phenomenon depend on the specific herbicide, but are largely speculative. The potential combined value of negative cross-resistance and general lack of fitness of triazine-HR biotypes in managing triazine resistance in weeds worldwide has yet to be realized (Gadamski et al. 2000). Nevertheless, pyridate is now mixed with triazine herbicides and applied on millions of hectares annually, especially in Europe, to control triazine-HR biotypes and preserve the cost-effectiveness of this class of herbicides (Gressel 2002). Negative cross resistance has also been observed in non-triazine–HR biotypes. For example, an imidazolinone-HR smooth pigweed biotype was 10-fold more sensitive to cloransulam, another ALS inhibitor, compared with an HS biotype (Poston et al. 2001).

Herbicide Rates. Many herbicides are commonly applied at less-than-registered rates to reduce costs. For example, in-crop herbicides are applied at reduced rates to 28% of cropped land annually in western Canada (Leeson et al. 2004, 2006; Thomas et al. 2003). When farmers apply herbicides at below-registered rates, it is based primarily on their experience with a product's performance as affected by weed growth stage or environmental conditions. They expect good weed control, although they are aware of the increased risk of suboptimal control. However, herbicide rate reduction without a corresponding reduction in efficacy will have no effect on selection for resistance. Model simulations have suggested that it is not profitable to reduce herbicide rates to reduce selection pressure (efficacy or persistence) for resistance, unless accompanied by a compensating increase in nonherbicidal weed control (Diggle and Neve 2001). The resulting increase in the abundance of HS weed populations would reduce crop yield and quality and increase weed seed return to the seed bank (Gorddard et al. 1996; Morrison and Friesen 1996).

Beckie and Kirkland (2003) examined the implication

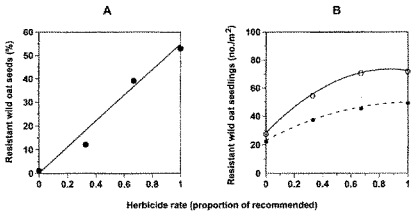

Figure 3. Implication of reduced herbicide rates on target-site resistance enrichment in wild oat: percentage of ACCase inhibitor–resistant individuals in seeds harvested after 4 yr of herbicide application at varying rates (A), and resistant seedlings recruited from the seed bank after 4 yr for the recommended (open circles) and high crop seeding rate (solid circles) treatments (B) [reproduced from Beckie and Kirkland (2003) by permission of the Weed Science Society of America].

of reduced rates of ACCase inhibitors in a 4-yr diverse crop rotation in conjunction with variable crop seeding rates on the enrichment of HR (target-site based) wild oat. As simulation models predict, reduced herbicide efficacy decreased the proportion of HR individuals in the population after 4 yr (Figure 3A). The high crop seeding rate compensated for a one-third reduction in herbicide rate by limiting total (HR plus HS) wild oat seed production and by reducing the number of HR seedlings recruited from the seed bank (Figure 3B). The study concluded that the level of resistance in the seed bank can be reduced without increasing the total seed bank population by manipulating agronomic practices to increase crop competitiveness against wild oat when ACCase inhibitor rates are reduced.

Herbicides applied at registered rates can clearly select for major gene (e.g., target-site) resistance, whereas initially, suboptimal herbicide rates may select for both major and minor gene (i.e. quantitative) resistance. Evolution of quantitative resistance relies on outcrossing among plants, resulting in incremental accumulation in their progeny of minor genes with additive or multiplicative effects (Jaseniuk et al. 1996). Therefore, such herbicide resistance is most probable and would evolve most rapidly in species such as blackgrass, rigid ryegrass, and kochia. Quantitative resistance has been documented or postulated in HR weed populations such as chlortoluron-HR blackgrass in the United Kingdom (Cavan et al. 1999; Chauvel and Gasquez 1994; Hall et al. 1994; Willis et al. 1997), diclofop-HR rigid ryegrass in Australia (Gressel 1997; Neve and Powles 2005a, 2005b; Preston and Powles 2002b), dicamba-HR kochia in North America (Belles et al. 2005; Cranston et al. 2001; Dyer et al. 2000; Westra et al. 2000), and isoproturon-HR littleseed canarygrass in India (Kulshrestha et al. 1999; Malik and Singh 1995; Singh et al. 1998, 1999). Less-than-recommended rates have been implicated or speculated as the causal factor in herbicide resistance in these biotypes. These species have a significantly or highly outcrossing mating system, except littleseed canarygrass (Malik et al. 1998).

Table 5. Incremental increase in the level of resistance (resistance factor, R/S), as measured by the dose required to kill 50% of the population (LD_{50}) or reduce biomass by 50% (GR_{50}), of rigid ryegrass biotype VLR1 after two or three cycles of selection with diclofop applied at sublethal doses (0.1 to 2 times the 1× rate of 375 g ai/ha) under greenhouse conditions (adapted from Neve and Powles 2005a).

Diclofop selection regime (proportion of 1× rate)	R/S based on LD_{50}	R/S based on GR_{50}
Nontreated control		
0.1, 0.2	7.4	6.7
0.1, 0.2, 0.5	11.8	16.3
0.1, 0.2, 1	55.8	49.3
0.1, 0.5	10.9	6.4
0.1, 0.5, 2	40.1	20.4

A population of rigid ryegrass evolved resistance to diclofop at the field-recommended rate when it was exposed to two or three cycles of sublethal rates in the greenhouse (Table 5). Similar results were found in a greenhouse study of the effect of sublethal rates of diclofop on 31 previously nontreated populations of rigid ryegrass (Neve and Powles 2005b). These results were consistent with those of a previous epidemiological study where levels of diclofop resistance in rigid ryegrass populations were positively correlated with the total amount of the herbicide applied over time and where low rates relative to those applied in other countries were typically used (Gressel 1997; Heap and Knight 1982). Maxwell and Mortimer (1994) and Gressel (1997) suggest that soil-residual herbicides may select for quantitative resistance because late-emerging weeds are exposed to lower herbicide doses that may allow accumulation of HR alleles. However, the mechanism of resistance to soil residual herbicides, such as triazines and sulfonylureas, is often target-site (i.e., major gene) mutation.

Gressel (1995) and Gardner et al. (1998) advocated a tactic of revolving herbicide doses to delay the evolution of major monogene (target site) and quantitative resistance. Routine reduced-rate application that lowers efficacy is not a good weed- or weed-resistance–management tactic (Morrison and Friesen 1996). If suboptimal rates are applied, nonherbicide methods to suppress weed seed production should be employed. Clearly, herbicides should not be repeatedly applied at suboptimal

rates to significantly or highly outcrossing target weeds, such as *Lolium* spp., blackgrass, and kochia, particularly when they occur in large populations (Gressel 2002; Jasieniuk et al. 1996).

Are there opportunities, however, to reduce rates without significantly lowering herbicide efficacy? In the past, registered rates were frequently based on the amount needed to control the least-sensitive weed, whereas other weeds on the product registration may be sensitive at much lower rates. Thus, the selection pressure on these very sensitive species can be extremely high. For example, reduced but effective ALS inhibitor herbicide rates used to control common chickweed in Europe compared with those used in North America doubled the time for resistance evolution by reducing the time those herbicides remain active in the soil (Beckie et al. 2001a; Kudsk et al. 1995). Recent trends in herbicide regulation and registration include more detailed information provided to users to adjust rates according to prevailing environment conditions and herbicide sensitivity, growth stage, or population densities of the target species; a primary regulatory objective in many countries is to promote the application of products at minimum effective doses (N. Malik, personal communication).

Site-Specific Herbicide Application. Site-specific management with the use of a global positioning system can be useful in monitoring and managing HR weed patches at early stages of development in a field over time. Unfortunately, most farmers in the northern Great Plains fail to detect small HR patches (H. Beckie, unpublished data). Comprehensive field scouting and HR weed patch management after in-crop herbicide application are usually not performed because of either a lack of awareness of the benefit of this practice or inconvenience due to large farm size. A study conducted at a 64-ha no-till site in western Canada assessed how preventing seed shed from HR wild oat affected patch expansion over a 6-yr period (Beckie et al. 2005). Area of treated patches increased by 35%, whereas nontreated patches increased by 330% (Figure 4). Patch expansion was attributed mainly to natural seed dispersal (nontreated) or seed movement by equipment at time of planting (nontreated and treated). Extensive (94 to 99%) seed shed from plants in nontreated patches before harvest or control of HR plants by alternative herbicides minimized seed movement by the combine harvester. Although both treated and nontreated patches were relatively stable over time, this study demonstrated that preventing seed production and shed in HR wild oat patches can markedly slow the rate of patch expansion. Consequently, herbicide effectiveness in a field is extended in space and time.

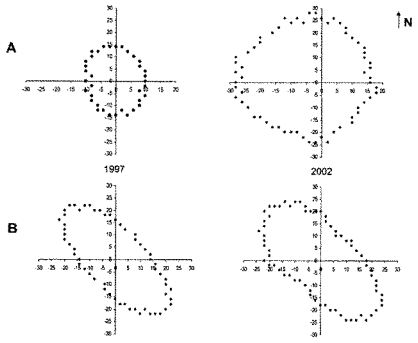

Figure 4. Patch management of herbicide-resistant wild oat in a 6-yr experiment in the northern Great Plains: a nontreated patch in 1997 and 2002 (A) vs. seed shed prevented in a patch from 1997 to 2002 (B) (*x* and *y* axis in meters, adapted from Beckie et al. 2005).

Site-specific herbicide application, utilizing weed abundance as a basis for delineating application areas in a field, would allow some reduction in the overall selection pressure. Costs of acquiring reliable weed-abundance distribution maps and herbicide application have limited its adoption by dry-land farmers growing relatively low cash-value crops. The effect of precision herbicide application on the rate of evolution of resistance would depend on the frequency of herbicide application to specific areas of a field over time and the proportion of the field treated each year. If application frequency of herbicides to specific areas of a field (e.g., lower-slope areas) is similar to conventional herbicide application, HR gene (seed, pollen) flow from these field areas to those treated less frequently may negate any potential benefits of the technology. Furthermore, if these treated areas contain the majority of the weed population present in the field, then this tactic may still result in a selection pressure similar to that of a blanket application.

Analogous to the refugia tactic in crops possessing the *Bacillus thuringiensis* trait to mitigate insect resistance, HS weed refuges has been proposed as a tactic to delay the evolution of herbicide resistance. However, leaving refugia of HS individuals to dilute the proportion of HR alleles in a population by gene flow will not be effective because the recessive control of resistance in outcrossing weed species is rare (Jasieniuk et al. 1996). Additionally, in cases of triazine resistance conferred by chloroplast

gene mutation, genetic recombination among plants does not occur (Stankiewicz et al. 2001). The only documented case of recessive inheritance of major monogene resistance in an outcrossing species was that of a picloram-HR yellow starthistle (*Centaurea solstitialis* L.) biotype found in the state of Washington (Sabba et al. 2003; Sterling et al. 2002).

INTEGRATING NONHERBICIDE TACTICS WITH HERBICIDES

Minimizing weed seed production is central to both HR and non-HR weed management programs. Cultural or mechanical practices affect weed population densities and seed production, and thus can delay the evolution of herbicide resistance by reducing the number of HR alleles in a population. Where high levels of HR alleles are believed to be present in unselected populations, such as ALS inhibitor resistance in common waterhemp and Palmer amaranth in North America (Peterson 1999) or *Lolium* spp. in Europe and Australia (Dinelli et al. 2000; Matthews and Powles 1992; Maxwell and Mortimer 1994; Preston and Powles 2002a), it is important to maintain low population densities via nonchemical methods or by using herbicides with a relatively low likelihood to select for these HR alleles. This tactic is also useful in fields where the high-risk ACCase and ALS inhibitors have been used frequently for over 20 yr. Many of these fields are likely well advanced along the herbicide-resistance evolution curve.

Cultural or mechanical practices will only halt or reverse the rate of enrichment for herbicide resistance in a weed population by eliminating selection pressure (controlling HS and HR plants equally in the absence of herbicide selection pressure) or controlling HR plants more than HS plants, respectively. Nonherbicide practices may increase the effective kill of HR plants relative to that of HS plants in situations where differences exist in the population dynamics of HR and HS biotypes. Seeds of triallate-HR wild oat are generally less dormant than those of HS populations (O'Donovan et al. 1999). Greater and more rapid emergence of HR individuals compared with HS individuals, analogous to that of ALS inhibitor-HR kochia biotypes (Dyer et al. 1993), may be potentially exploited for selective HR biotype control by tillage or nonselective herbicides before delayed planting. Similarly, triazine-HR black nightshade (*Solanum nigrum* L.) in The Netherlands emerges earlier than HS plants because of germination at lower soil temperatures (Kremer and Lotz 1998). In contrast, early planting of winter wheat in the Pacific northwest region of the United States can potentially reduce the competitive ability of HR Italian ryegrass, which emerges later than HS individuals (Radosevich et al. 1997). Tillage to bury seeds of an HR biotype of rigid ryegrass inhibited seedling recruitment compared with that of an HS biotype (Vila-Aiub et al. 2005).

The issues of economic risk, labor availability, and time management impact the adoption of some cultural or mechanical practices for HR weed management. Moreover, some practices such as stubble burning or intensive tillage are contrary to recommendations to improve soil or air quality or conserve soil, water, and energy, and thus their use is discouraged. Evolution of herbicide resistance in weed populations often has not resulted in less herbicide use or a marked increase in nonchemical control methods, except in some cases such as intergroup resistance in weeds (Powles et al. 1997; Preston and Mallory-Smith 2001) or glyphosate-HR horseweed (Steckel et al. 2005). Used singly, the effectiveness of nonherbicide practices is lower and less consistent than that of many herbicides, and may be highly dependent on environmental conditions; when used in combination, however, nonherbicide practices can manage weeds effectively (Blackshaw et al. 2004; Gill and Holmes 1997; Matthews 1994) (Table 6). Some nonherbicide tactics and practices that have proven effective in managing HR weeds are summarized below.

Cropping Systems and Practices. Crop rotations are dictated primarily by profit potential and not the management of HR weeds. Crop rotation, however, is frequently cited as one of the most influential factors in delaying or managing HR weeds (Bourgeois et al. 1997b; Carey et al. 1995; Chauvel et al. 2001; Gill and Holmes 1997; Hartmann et al. 2000; Powles et al. 1997; Ritter and Menbere 1997; Shaner et al. 1999; Singh et al. 1999; Stephenson et al. 1990). Diversity in sequences of crop types and phenologies in a rotation (i.e., dicots vs. monocots; winter- vs. spring-planted; cool vs. warm season; annual vs. perennial) may directly or indirectly reduce weed populations. Crop rotations can facilitate herbicide rotation or reduction (Beckie and Gill 2006). A field study in the northern Great Plains linked ACCase and ALS inhibitor resistance in wild oat to a lack of crop rotation diversity (Beckie et al. 2004). Inclusion of fall-planted and perennial forage crops in annual spring crop-based rotations effectively slowed the evolution of herbicide resistance in this weed species (Figure 5). A field survey documented the ability of 3- to 6-yr alfalfa (*Medicago sativa* L.) stands to reduce wild oat populations in cropping systems through crop competition and cutting

Table 6. Effect of cropping system on density of ACCase inhibitor-resistant blackgrass in the final year of an experiment in Burgundy, France (adapted from Chauvel et al. 2001).

Crop rotation[a]	Tillage[b]	Planting date[c]	Herbicide use[d]	Density

regime of the crop for hay (Ominski et al. 1999). The survey found that wild oat population densities were reduced by 96% in cereal fields that followed alfalfa versus a cereal crop.

Traditionally, Australian agriculture was based on crop–pasture rotation systems. A 3-yr pasture phase was shown to be a low-economic-risk option (Gill and Holmes 1997; Pearce and Holmes 1976). Rigid ryegrass population density was reduced 88 to 96% in wheat following pasture grazed in the spring during the flowering and reproduction stages of the weed (Pearce and Holmes 1976). The combination of grazing and nonselective herbicides (spray topping) reduces rigid ryegrass seed production, resulting in a rapid and marked decline in weed abundance (Gill and Holmes 1997). Preference for continuous annual cropping systems and poor economic returns, however, have led to a decline in the widespread inclusion of pastures in rotations (Monjardino et al. 2004).

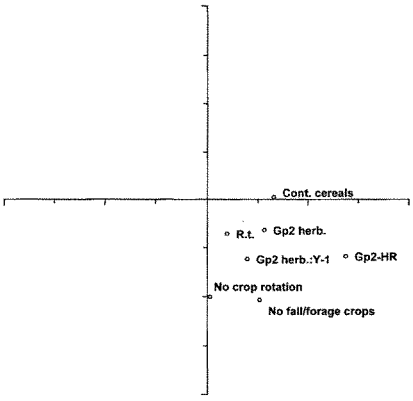

Figure 5. Significant associations between ALS inhibitor–resistant wild oat (Gp2-HR) and management practices in the northern Great Plains as determined from multiple correspondence analysis (Cont. cereals, continuous cereals; R.t., reduced tillage; Gp2 herb., ALS inhibitor used in current year; Gp2 herb.:Y-1, ALS inhibitor used 1 yr before; No crop rotation, crop rotation not used; No fall/forage crops, fall-planted or forage crops not used) (adapted from Beckie et al. 2004).

The potential value of crop rotation to delay or manage HR weeds will not be realized unless accompanied by diversification or reduction in herbicide use. Repeated use of herbicides with the same site of action will negate the weed-suppression benefits associated with crop rotation. Crop rotations had little influence on occurrence of ACCase inhibitor–HR wild oat in the northern Great Plains because farmers frequently applied these herbicides to cereal, oilseed, and annual legume crops that dominate cropping systems (Légère et al. 2000). Occurrence of resistance in wild oat was the lowest in rotations where frequency of fallow was the highest because of the reduced frequency of herbicide use. Similarly, despite diversity in crop rotations in Western Australia, repeated triazine use in different crops selected for triazine resistance in wild radish (Hashem et al. 2001b).

Inclusion of competitive crops and competitive cultivars of a crop in rotations is viewed by farmers as being important in HR weed management (Bourgeois et al. 1997b; Shaner et al. 1999). Quantitative trait loci for traits in wheat associated with weed competitiveness have been identified. These markers can be used by crop breeders to select for weed-competitive genotypes (Coleman et al. 2001). However, crop competitiveness can also be enhanced by increasing seeding rates. With the widespread appearance of HR rigid ryegrass, many Australian farmers are routinely increasing crop seeding rates by 20 to 40%, resulting in greater plant densities,

to improve competitiveness (Table 1) (Gill and Holmes 1997; Medd et al. 1987; Powles 1997). This practice is most cost effective for cereals. In the northern Great Plains, increased crop seeding rate is the most consistent cultural practice for managing weeds and maintaining crop yields (Beckie and Kirkland 2003; Blackshaw et al. 2004).

Delayed planting is often promoted for the control of some HR grass weed species in Europe, such as winter wild oat (*Avena ludoviciana* Durieu), hood canarygrass (*Phalaris paradoxa* L.), and blackgrass (Table 6, Chauvel et al. 2001; Orson 1999; Sattin et al. 2001), by depleting the seed bank before crop planting. Delayed rice planting in Central America is commonly used to reduce HR junglerice population densities (Valverde et al. 2000, 2001). In Australia, delayed crop planting has been integrated with other control tactics to manage HR rigid ryegrass (Table 1) (Gill and Holmes 1997; Powles and Matthews 1996).

Tillage Systems. Owen (2001b) reviewed the impact of tillage and mechanical practices in managing HR weed populations. The judicious use of timely tillage has been cited often as an important practice to delay or manage HR weeds (Bourgeous et al. 1997b; Chauvel et al. 2001; Orson and Livingston 1987; Peterson 1999; Stephenson et al. 1990). Tillage may substitute for herbicide use or influence seed bank dynamics. For example, plowing to bury weed seeds of blackgrass to reduce germination and emergence has been proven highly effective for management of HR populations in Europe (Moss 1997; Orson and Livingston 1987). Timely tillage can also stimulate weed germination before crop planting, such as "autumn tickle" (Table 1) (Boutsalis and Powles 1998; Gill and Holmes 1997).

Anecdotal field observations have frequently linked herbicide resistance in weeds to conservation-tillage systems, particularly no-till, which are increasingly being adopted by farmers because of cost and time efficiencies. Ratification of the Kyoto Protocol on greenhouse gas emissions will further encourage farmers to adopt reduced-tillage systems through economic incentives to increase carbon sequestration in soil. In a field study by Beckie et al. (2004), ALS inhibitor–HR wild oat was associated with such systems (Figure 5). Reduced tillage substitutes herbicide use for tillage to varying degrees. Reduced-tillage cropping can increase the abundance of specific weed species and consequently, result in greater herbicide use. However, an analysis of multiple studies found little evidence that reduced tillage increases herbicide use (Nazarko et al. 2005; Zhang et al. 2000). In the absence of tillage, weed seedlings may be derived largely from seeds shed in the previous crop and concentrated near the soil surface. Consequently, there will be little buffering against resistance evolution from old seeds, which may have greater percentage susceptibility (Moss 2002).

Limiting Herbicide-Resistance Gene Spread. Gene flow through pollen or seed movement from HR weed populations can provide a source of HR alleles in previously HS populations. Because rates of gene flow are generally higher than rates of mutation, the time required to reach a high level of herbicide resistance in such situations is greatly reduced (Jaseniuk et al. 1996). It is difficult to control the spread of herbicide resistance via pollen flow, especially when resistance is often endowed by a single, dominant or semidominant gene (Letouzé and Gasquez 1999; Richter and Powles 1993; Smeda et al. 2000). For example, pollen of ALS inhibitor–HR kochia can move more than 30 m in a cropped field (Mallory-Smith et al. 1993), and ACCase inhibitor–HR alleles in rigid ryegrass pollen can move more than 10 m in cropped or noncropped conditions (Hawthorn-Jackson et al. 2003). Seed movement is probably responsible for the majority of gene flow in weed populations (Diggle and Neve 2001). Seed movement has the potential to influence HR gene spread on a much larger scale than pollen flow.

HR weed seed spread within and among fields has been documented (Andrews et al. 1998; Hidayat et al. 2004; Li et al. 2000; Ritter and Menbere 1997; Stephenson et al. 1990; Tsuji et al. 2003). Fields within farms are more likely to have HR weeds than randomly picked fields, indicating movement of HR seed between fields via equipment (Anderson et al. 1996) or similar selection pressure among fields within a farm. Sharing of equipment among farmers has also been implicated in herbicide resistance (Debreuil et al. 1996). Weed seed spread by machinery, noncomposted manure, silage, or contaminated commercial seed stocks or feed (Ritter and Menbere 1997; Stephenson et al. 1990) is generally greater than natural seed dispersal. For example, wild oat seeds can spread more than 150 m by a combine harvester (Shirtliffe and Entz 2005). Spread of herbicide resistance among wild oat (*Avena* spp.) patches within 350 m of each other has been documented in the United Kingdom (Cavan et al. 1998). Wind dispersal of weed species having lightweight seeds, such as prickly lettuce (*Lactuca serriola* L.) (Rieger et al. 2001) and horseweed (Dauer and Mortensen 2005; VanGessel 2001), can also spread herbicide resistance rapidly. Wind can efficiently trans-

Table 7. RIM (resistance and integrated management) model scenarios: Economically optimal frequency of integrated weed management (IWM) practices when selective herbicide use is restricted over a 10-year period,[a] and resulting plant density of mature rigid ryegrass in a lupin–wheat rotation (adapted from Pannell et al. 2004).

Selective herbicide applications	Optimal frequency of IWM practices[b]				Total usage of nonselective treatments	Mature weed density[d]

[d] 10-yr mean.

port kochia and Russian thistle tumbleweeds for long distances (Mallory-Smith et al. 1993). As the incidence of herbicide resistance increases in a region, pollen and seed movement in addition to selection will increasingly influence such occurrences.

Management practices that limit the spread of HR seed can slow the occurrence of herbicide resistance. In western Canada, farmers who reported practicing weed sanitation (e.g., cleaning harvesting and tillage equipment when moving between fields, covering the grain truck box, mowing or spraying ditches or uncontrolled weed patches, applying composted versus fresh manure) were less likely to have HR wild oat than those who were less careful (Légère et al. 2000). Cleaning equipment when moving among fields, and mowing weed patches, ditches, and headlands ranked fourth and fifth, respectively, in importance among herbicide-resistance-management practices cited by farmers in western Canada (Bourgeois et al. 1997b). If the HR population covers a wide area across the field, management should focus on reducing seed return and spread by using low-risk herbicides in conjunction with cultural practices, such as cutting the crop (hay, silage, or green manure) before or soon after flowering of the HR weed species, growing competitive annual crops such as barley (*Hordeum vulgare* L.) or perennial crops, or collecting weed seeds at harvest. Weed populations can decline rapidly within one to two growing seasons for species having a relatively short-lived seed bank, such as rigid ryegrass.

Capture of weed seeds during the harvest operation is a technique used primarily by farmers dealing with herbicide resistance (Table 1). Some weed species, such as rigid ryegrass, do not shed seeds until well after maturity and therefore allow farmers the opportunity to collect seeds during harvest. In Western Australia, Gill (1996) reported a 60 to 80% removal of rigid ryegrass seeds, which reduced weed infestation in the subsequent crop by 73%. Although weed seed catching/removal at harvest is effective in managing HR weeds (Gill 1997; Gill and Holmes 1997; Matthews 1994), farmer adoption is low (Powles 1997; Shaner et al. 1999; Thill et al. 1994) (Table 1). In contrast, weeds such as wild oat may shed most seeds by cereal crop harvest in the northern Great Plains. Therefore, harvesting after extensive seed shed can reduce HR wild oat seed spread by equipment (Beckie et al. 2005).

Decision-Support Systems. Use of a decision-support system (DSS) can help farmers choose the best combination of IWM practices to delay or manage HR weeds on their farm. The most advanced DSS to date is the RIM (resistance and integrated management) model developed for IWM of single or multiple species in Australia (Monjardino et al. 2003; Pannell et al. 2004). It allows farmers to quickly assess the agronomic and economic performance of numerous combinations of management options over varying time frames (Table 7). Such a DSS, when continually maintained and updated, can be a useful tool for farmers to combat herbicide resistance in weeds.

CONCLUSIONS

Proactive or reactive management for herbicide resistance in weeds (a) must consider the relative risks of herbicides of different sites of action to select for target-site resistance and the differing propensity of herbicides to be metabolized in HR biotypes when sequencing or rotating herbicides; (b) must meet basic criteria for effective herbicide mixtures; and (c) should incorporate

agronomic practices in cropping systems that help reduce weed seed production and spread. Use of low-risk, nonselective herbicides applied preplant or in HR crops has improved HR weed management. However, frequent use of HR crops such as those resistant to imidazolinones or glyphosate may maintain conditions that lead to resistance, namely, simplified cropping systems favoring a few dominant weed species and frequent use of single site-of-action herbicides.

The extent to which farmers alter their current farming systems to manage herbicide resistance depends on the nature and magnitude of infestation of an HR biotype. In many cases, simply switching to an alternative herbicide will cost-effectively control the HR population. For serious herbicide resistance problems, for example, heavy infestations of intergroup-HR weed species, a longer-term cropping systems approach may be required. Approaches to IWM differ, depending on agroecological conditions, biology, and ecology of the weed species with evolved resistance, and agronomic and socioeconomic considerations by farmers. Although herbicides remain the dominant weed-control tool, diversification in cropping systems and practices can result in less herbicide used and thus a reduction in selection pressure for resistance. Even serious weed-resistance problems can be managed successfully if farmers are receptive to changes in their cropping systems. The increasing incidence and complexity of herbicide resistance in weeds will inevitably require farming systems with a reduced dependence on herbicides.

The Honorable Jim Jones
Deputy Assistant Administrator
Office of Chemical Safety and Pollution Prevention
U.S. Environmental Protection Agency
1200 Pennsylvania Ave., N.W.
Washington, D.C. 20460

Dear Mr. Jones:

In connection with the September 30, 2010 hearing of the Domestic Policy Subcommittee, entitled, "Are "Superweeds" an Outgrowth of USDA Biotech Policy? (Part II)", I hereby request that you provide answers in writing to the following questions for the hearing record.

1. Has USDA asked EPA to share its expertise on preventing pesticide resistance in the context of USDA's preparation of an environmental impact statement for Roundup Ready Alfalfa?
2. How many discussions or communications between USDA and EPA have specifically concerned 1) how USDA might mitigate or prevent the spread of Roundup resistance in weeds; and/or 2) how USDA might create a process whereby the agency would develop ways of mitigating or preventing the spread of Roundup resistance in weeds?
3. Does EPA believe that the Roundup Ready Alfalfa EIS now reflects adequately EPA's concern about pest resistance?

Ranking member Jordan submits the following additional questions:

1. Are there new technologies currently under review by USDA and EPA that would offer multiple modes of action to address weed resistance? Given the urgency expressed by the entire panel to address the issue of herbicide-resistant weeds, are there plans to expedite regulatory approval process to facilitate availability of these new technologies?

2. Is it true that development and registration of a new pesticide active ingredient takes 8 to 10 years, costs hundreds of millions of dollars, and requires more than 100 scientific studies conducted at the manufacturer's expense? After approval, does EPA continues to monitor use of the pesticide in the marketplace?
3. Had farmers experienced problems with herbicide-resistant weeds prior to the introduction of biotech crops?
4. Is there any reason to slow, delay or discourage the development and approval of new herbicide-resistant crops?
5. Will the introduction of new agricultural products such as herbicide-resistant crops benefit U.S. farmers?
6. Is the approval of such products a priority for EPA?
7. What steps is EPA taking to ensure such products are available to farmers?

The Oversight and Government Reform Committee is the principal oversight committee in the House of Representatives and has broad oversight jurisdiction as set forth in House Rule X.

We request that you provide written answers to these questions as soon as possible, but in no case later than **5:00 p.m. on October 30, 2010**.

If you have any questions regarding this request, please contact Jaron Bourke, Staff Director at (202) 225-6427.

Sincerely,

Dennis J. Kucinich
Chairman
Domestic Policy Subcommittee

cc: Jim Jordan
Ranking Minority Member

Questions for the Record
Committee on Oversight and Government Reform
Subcommittee on Domestic Policy
Hearing on "Are 'Superweeds' an Outgrowth of USDA Biotech Policy? (Part II)"
September 30, 2010

1. **Has USDA asked EPA to share its expertise on preventing pesticide resistance in the context of USDA's preparation of an environmental impact statement for Roundup Ready Alfalfa?**

The EPA and USDA/APHIS/BRS have discussed resistance management plans for herbicide resistant crops in general. USDA also asked EPA for input on the Roundup Ready alfalfa EIS, and we provided comments on that EIS describing how resistant weeds might develop in response to widespread planting of Roundup Ready alfalfa.

2. **How many discussions or communications between USDA and EPA have specifically concerned 1) how USDA might mitigate or prevent the spread of Roundup resistance in weeds; and/or 2) how USDA might create a process whereby the agency would develop ways of mitigating or preventing the spread of Roundup resistance in weeds?**

EPA has had approximately seven discussions with USDA/APHIS/BRS concerning herbicide resistant crops and the methods that could be used to manage resistance, including Roundup resistance. Several of these discussions concerned a project with the Weed Science Society of America (WSSA) to develop a comprehensive literature review to better understand the scope of herbicide resistance in genetically-engineered and non-genetically-engineered crops. The project was undertaken because controlling resistance is extremely complex and there is limited information on the most effective methods to manage resistance in the field. It is hoped that the results of the WSSA project will help EPA and USDA develop more effective methods to promote resistance management among pesticide users.

3. **Does EPA believe that the Roundup Ready Alfalfa EIS now reflects adequately EPA's concern about pest resistance?**

Upon review of the draft EIS, EPA expressed concerns to USDA regarding the development of herbicide resistant weeds. It is our understanding that USDA will incorporate EPA's comments concerning resistance into the final EIS. EPA plans to review the final EIS to determine whether EPA's concerns are addressed.

Ranking member Jordan submits the following additional questions:

1. **Are there new technologies currently under review by USDA and EPA that would offer multiple modes of action to address weed resistance? Given the urgency expressed by the entire panel to address the issue of herbicide-resistant weeds, are there plans to expedite regulatory approval process to facilitate availabilities of these new technologies?**

EPA does not regulate directly the herbicide-tolerant plant construct and cannot speak to whether the regulatory approval process will be expedited. EPA does, however, register pesticides that are used on herbicide-tolerant plants and ensures that the necessary conditions of use are adequate to protect human health and the environment. EPA is working with USDA and professional societies, including the Weed Science Society of America (WSSA), to increase understanding and use of the best practices and strategies to manage pest resistance, including resistant weeds found in herbicide-tolerant crops. EPA is also working with the American Phytopathological Society and the Entomological Society of America to identify the best practices to manage pest resistance to fungicides and insecticides. One important component of resistance management is for pesticide users to use products that have different modes of action. To facilitate this, EPA is updating its Pesticide Registration Notice which provides guidance to pesticide registrants on resistance management labeling. This work is being coordinated with Canada and Mexico through NAFTA. Additionally, EPA believes that herbicide-tolerant plants that are resistant to more than one herbicide, allowing for rotation of herbicides with differing modes of action, may be a useful tool in a comprehensive resistance management strategy.

2. Is it true that development and registration of a new pesticide active ingredient takes 8 to 10 years, costs hundreds of millions of dollars, and requires more than 100 scientific studies conducted at the manufacturer's expense? After approval, does EPA continues to monitor use of the pesticide in the marketplace?

Developing a new pesticide product can be a lengthy process. It takes time to identify new pesticidal active ingredients, determine their potential efficacy, develop the data necessary for registration, and complete the registration process. But, completing the registration process takes just a fraction of the total time needed to develop and bring a product to market. For example, the time period allowed under the Pesticide Registration Improvement Renewal Act (PRIA 2) for EPA to render a registration decision for genetically modified plant incorporated protectant (PIP) products varies from 12 to 18 months.

As to the number of scientific studies required for the registration process, and their associated costs, these are variable because the data requirements are tiered. Applicants and registrants do not share with EPA information regarding the cost of product development, therefore, EPA cannot speak to product research and development costs Additional costs may be incurred if the studies initially submitted to the Agency are deficient and do not permit us to make the necessary findings under the statute. The number of scientific studies submitted in association with a new pesticide will fluctuate depending upon the different circumstances described above.

After registration, EPA uses federal, state and private market surveys on pesticide use to understand pesticide use in the marketplace.

3. Had farmers experienced problems with herbicide-resistant weeds prior to the introduction of biotech crops?

The first herbicide resistant weed was reported in 1957 with the use of 2,4-D on sugar cane in Hawaii. There are currently 194 herbicide resistant weed species according to the

International Survey of Herbicide Resistant Weeds. The vast majority are not related to the introduction of herbicide resistant crops.

4. Is there any reason to slow, delay or discourage the development and approval of new herbicide-resistant crops?

EPA does not currently regulate directly herbicide-tolerant plant constructs. Pursuant to its authority under the Plant Protection Act, USDA regulates genetically engineered plants to ensure that these plants are not plant pests. Therefore, we cannot speak to whether there are actual bases grounded in specific regulatory scenarios to slow, delay, or discourage the approval of any particular herbicide-tolerant crop product.

5. Will the introduction of new agricultural products such as herbicide-resistant crops benefit U.S. farmers?

As a general matter, it can be stated that the introduction of new agricultural products typically provide benefits to U.S. farmers. New agricultural products can simplify weed control by allowing the use of broad spectrum herbicides on crops that would not normally tolerate these chemistries; promote no-till farming; control difficult to manage weeds; and allow growers more control over application timing. Herbicide-tolerant crops have been used in the U.S. agricultural system for over 10 years. The use of these crops has resulted in demonstrable economic and environmental benefits. Increases in herbicide resistant weeds, however, have been a concern for many farmers.

6. Is the approval of such products a priority for EPA?

As noted above, EPA does not currently regulate directly herbicide-tolerant plant constructs. EPA registers and imposes necessary conditions on use of the herbicide intended to be used in conjunction with herbicide-tolerant crops. As we do not currently regulate directly herbicide-tolerant plant constructs, we are not in a position to make approval of such products a priority. With respect to the herbicides intended to be used in conjunction with such crops, EPA approves the registration and use conditions of such herbicides according to the schedule established by the Pesticide Registration Improvement Amendments Act (PRIA 2).

7. What steps is EPA taking to ensure such products are available to farmers?

EPA collaborates with USDA/APHIS/BRS as necessary on its regulatory approvals. Moreover, EPA is working with UDSA/APHIS/BRS on improving understanding of the evolution of herbicide resistance and steps that can be taken to manage resistance.

The Honorable Ann Wright
Deputy Undersecretary for Marketing and Regulatory Programs
U.S. Department of Agriculture
1400 Independence Ave., SW
Washington, D.C. 20250

Dear Undersecretary Wright:

In connection with the September 30, 2010 hearing of the Domestic Policy Subcommittee, entitled, "Are "Superweeds" an Outgrowth of USDA Biotech Policy? (Part II)", I hereby request that you provide answers in writing to the following questions for the hearing record.

1. You say in your written testimony that "there must be a plant pest risk to deny a full deregulation, and herbicide resistance does not constitute a plant pest risk." That is a reference to Section 411 of the Plant Protection Act. But the very next section of the Act, Section 412, covers your authority to prevent the spread of "noxious weeds." Section 412 gives the Secretary authority to "prohibit or restrict…the movement…of any plant…if the Secretary determines that the prohibition or restriction is necessary to prevent…the dissemination of a…noxious weed within the United States." Can you point us to any provision of the Plant Protection Act that limits USDA to acting exclusively under Section 411's authority and denies USDA the ability to use the authority given to it by Section 412?
2. The Act defines noxious weeds (at 7 U.S.C. § 7702) as "any plant or plant product that can directly or indirectly injure or cause damage to crops … or other interest of agriculture… or the environment" (emphasis added). Is there any limitation in the statute's definition of "noxious weeds" that prevents its application to herbicide resistant weeds?
3. A plain reading of Section 412 in the context of the Act gives the Secretary broad authority to restrict the use of Roundup-resistant crops if sound science determines that those restrictions are necessary to prevent the spread of Roundup-resistant noxious weeds. Yet the Department has not used this authority to mitigate or prevent the

spread of existing or the development of new species of herbicide-resistant weeds. Why not? Please provide all documents discussing what the scope of the Secretary's exercise of authority under Sections 411 and 412 should be, including any legal memoranda prepared since the time of the Act's enactment.

4. You say in your testimony that "industry came to us and asked us to look at partial deregulation as one way to allow the planting of a GE crop." Will you provide the Subcommittee with copies of all such petitions for partial deregulation, as well as any related documentation or materials provided by the industry?
5. You have stated in court that any partial deregulation would be subject to analysis under the National Environmental Policy Act (NEPA) and would not, therefore, qualify as a categorical exclusion from those analytical requirements. *See* Fourth Declaration of Cindy Smith, Center for Food Safety v. Vilsack, No. 3:08-cv-00484-JSW (N.D. Cal., July 15, 2010). In view of recent litigation experience in which the Department has been rebuked by separate federal courts for failing to comply with NEPA requirements, will you explain in detail what the standard(s) for a Finding of No Significant Impact would be in the case of this partial deregulation?

Ranking member Jordan submits the following additional questions:

1. Will the introduction of new agricultural products such as herbicide-resistant crops benefit U.S. farmers?
2. Is the approval of such products a priority for USDA?
3. What steps is USDA taking to ensure such products are available to farmers?

The Oversight and Government Reform Committee is the principal oversight committee in the House of Representatives and has broad oversight jurisdiction as set forth in House Rule X.

We request that you provide written answers to these questions as soon as possible, but in no case later than **5:00 p.m. on October 30, 2010.**

If you have any questions regarding this request, please contact Jaron Bourke, Staff Director at (202) 225-6427.

Sincerely,

Dennis J. Kucinich
Chairman
Domestic Policy Subcommittee

cc: Jim Jordan
Ranking Minority Member

Questions for the Record—U.S. Department of Agriculture Response
Subcommittee on Domestic Policy Hearing
"Are Superweeds an Outgrowth of USDA Biotech Policy?"
September 30, 2010

Chairman Kucinich

1. You say in your written testimony that "there must be a plant pest risk to deny a full deregulation, and herbicide resistance does not constitute a plant pest risk." That is a reference to Section 411 of the Plant Protection Act. But the very next section of the Act, Section 412, covers your authority to prevent the spread of "noxious weeds." Section 412 gives the Secretary authority to "prohibit or restrict...the movement...of any plant...if the Secretary determines that the prohibition or restriction is necessary to prevent...the dissemination of a...noxious weed within the United States." Can you point us to any provision of the Plant Protection Act that limits USDA to acting exclusively under Section 411's authority and denies USDA the ability to use the authority given to it by Section 412?

Response:

There is no provision of the Plant Protection Act (PPA) that limits the U.S. Department of Agriculture (USDA) to only using its authorities under Section 411 of the Act, and not Section 412. In fact, USDA's Animal and Plant Health Inspection Service (APHIS) uses authorities under both sections of the PPA and currently plays a significant role in protecting American agriculture from both plant pests and noxious weeds.

To clarify, Section 412 of the PPA refers to noxious weeds, and the APHIS Plant Protection and Quarantine program has always defined a noxious weed as being either invasive or spreading at an uncontrolled rate, and also as harmful in some way to agriculture or the environment. The fact that a genetically engineered (GE) plant has a resistance to an herbicide does not make that plant any more invasive, destructive, or harmful than its non-GE form. Section 412 is only relevant to the discussion of herbicide resistance if the plant itself is a noxious weed before it is genetically altered or becomes a noxious weed with herbicide resistance after it is genetically altered.

The preamble to a recent proposed rule ("Importation, Interstate Movement, and Release Into the Environment of Certain Genetically Engineered Organisms; Proposed Rule," 73 Federal Register 197 (9 October 2008), pp 60007-60048.), discusses the standard APHIS uses for 'noxious' weeds:

> "The distinction between a weed and a noxious weed warrants emphasis. "Weeds," in the broadest sense of the word, could include any plant growing where and/or when it is unwanted; even plants that are desirable in some settings may be considered weeds in others. In a narrower sense, weeds are invasive, often non-native, plants which impact natural and managed ecosystems, often with significant negative consequences due to lost yields, changes in management practices, altered herbicide use, etc. Only a fraction of these problematic weeds are considered to be so invasive, so harmful, and so difficult to

control that Federal regulatory intervention to prevent their introduction or dissemination is justified, and these are the focus of the regulatory controls placed on them by APHIS. However, any weed, and virtually any plant or plant product, can be evaluated by APHIS to determine whether its characteristics and potential impacts warrant its listing as a noxious weed."

2. The Act defines noxious weeds (at 7 U.S.C. § 7702) as "any plant or plant product that can directly or indirectly injure or cause damage to crops...or other interest of agriculture...or the environment" (emphasis added). Is there any limitation in the statute's definition of "noxious weeds" that prevents its application to herbicide resistant weeds?

Response:

There is no provision in the Act that limits that statute's definition of "noxious weeds" to prevent the definition from applying to herbicide resistant weeds. I would like to clarify that APHIS does in fact consider resistance to herbicides as one of a number of factors when the Agency determines whether a plant should be considered a Federally-listed noxious weed. The primary consideration is stated in Section 412 of the PPA which refers to noxious weeds as either being invasive or spreading at an uncontrolled rate. Further, they must be harmful to agriculture or the environment. However, no plant has been determined to be a noxious weed solely because of resistance to a single herbicide.

3. A plain reading of Section 412 in the context of the Act gives the Secretary broad authority to restrict the use of Roundup-resistant crops if sound science determines that those restrictions are necessary to prevent the spread of Roundup-resistant noxious weeds. Yet the Department has not used this authority to mitigate or prevent the spread of existing or the development of new species of herbicide-resistant weeds. Why not? Please provide all documents discussing what the scope of the Secretary's exercise of authority under Sections 411 and 412 should be, including any legal memoranda prepared since the time of the Act's enactment.

Response:

The evolution of pests to become resistance to herbicides, insecticides, and other pesticides has been an issue for farmers for decades, and is not solely caused by the use of GE herbicide tolerant crops. As exemplified by the Australian experience, it is frequently the repeated use of a single herbicide mode of action that leads to the appearance of herbicide resistant weeds. The Act does not provide authority to the Secretary of Agriculture to regulate the use of herbicides.

To halt the spread of herbicide resistant weeds, and to prevent further development of more herbicide resistant weeds, a more fundamental, scientific approach is needed to determine how herbicides result in the appearance and spread of herbicide resistant plants and how to effectively use herbicides to minimize the risk of herbicide resistant weeds. The U.S. Environmental Protection Agency (EPA), which has the authority to regulate pesticides—including herbicides—has used its pesticide registration authority to mitigate the development of insect resistance to insecticide produced by genetically engineered crops. EPA achieves this by regulating the amount of insecticide present in the environment and by imposing resistance

management plans on plant incorporated protectants that make pesticidal claims. The regulation of the insecticide and use of refuges was based on scientific research on how insect resistance develops in targeted pests, and the best strategies available, in terms of deployment of insecticides, that will minimize the development of resistance in these insects.

USDA will continue to actively support research and extension as we work to determine how plants evolve resistance to herbicides, and what mitigation measures will minimize or halt the herbicide resistance in plants. Strong science is needed to support regulation, and the USDA is committed to providing resources and expertise to help those farmers that use herbicides in their farming practices.

We are providing to you all of the documents you requested with the exception of documents that would fall under the attorney/client privilege. We would be happy to discuss access to these documents with you; however, we are unable to provide you with copies of these documents. The requested documents are included in Appendix A. They include:

Syngenta Seeds, Inc.; Availability of Petition and Environmental Assessment for Determination of Nonregulated Status for Corn Genetically Engineered To Produce an Enzyme That Facilitates Ethanol Production, 74 Federal Register 106, (4 June 2009), pp 26832-26835.

Issue Paper 2: Incorporation of the Plant Protection Act Noxious Weed Provisions, U.S. Department of Agriculture, Animal and Plant Health Inspection Service, Biotechnology Regulatory Services, April 28, 2009. *Note: Provided during public meetings on revisions to APHIS' biotechnology regulations

Importation, Interstate Movement, and Release Into the Environment of Certain Genetically Engineered Organisms; Proposed Rule. 73 Federal Register 197, October 9, 2008, pp 60008-60048.

Plant Pests, Introduction of Genetically Engineered Organisms or Products, Final Rule, Federal Register, 52 Federal Register 115, June 16, 1987, pp 22892-22915.

4. You say in your testimony that "industry came to us and asked us to look at partial deregulation as one way to allow the planting of a GE crop." Will you provide the Subcommittee with copies of all such petitions for partial deregulation, as well as any related documentation or materials provided by the industry?

Response:

Yes. The requested documents are included in Appendix B. They include:

Forest Genetics International Letter to USDA Requesting Partial Deregulation of Roundup Ready Alfalfa Events J101/J163, August 6, 2010.

Environmental report, Partial Deregulation Measures for Cultivation of Roundup Ready® Alfalfa Events J101/J163, Forest Genetics International, August 5, 2010

Monsanto and KWS Letter to USDA Requesting Partial Deregulation of Roundup Ready Sugarbeet Event H7-1, July 29, 2010.

Environmental Report, Interim Measures for Cultivation of Roundup Ready Sugar Beet Event H7-1, Monsanto, July 30, 2010.

5. You have stated in court that any partial deregulation would be subject to analysis under the National Environmental Policy Act (NEPA) and would not, therefore, qualify as a categorical exclusion from those analytical requirements. *See* Fourth Declaration of Cindy Smith, Center for Food Safety v. Vilsack, No.3 :08-cv-00484-JSW (N.D. Cal., July 15,2010). In view of recent litigation experience in which the Department has been rebuked by separate federal courts for failing to comply with NEPA requirements, will you explain in detail what the standard(s) for a Finding of No Significant Impact would be in the case of this partial deregulation?

Response:

USDA is committed to performing thorough environmental reviews and seeking the views of the public on issues before the Department, including the regulation of GE organisms. In considering a request for a partial deregulation, APHIS would follow Agency and Council on Environmental Quality (CEQ) NEPA implementing procedures to indentify the appropriate level of NEPA analysis and documentation required, prior to taking any regulatory action. APHIS would carefully consider the possible environmental impacts of each regulatory action to ensure the appropriate level of science-based analysis required for a decision is adequate and sufficient.

APHIS will conduct an analysis on each of the issues regarding a partial deregulation, and then make a determination based on the context and intensity factors from the CEQ NEPA regulations that define how an issue may "significantly" impact the human environment, found in 40 CFR § 1508.27. This includes analyzing the significance of an action in several contexts and considering both short- and long-term effects, the degree to which the proposed action affects public health or safety, and the degree to which an action may impact endangered or threatened species, among other considerations listed under the regulations.

Ranking member Jordan

1. Will the introduction of new agricultural products such as herbicide-resistant crops benefit U.S. farmers?

Response:

Yes. The use of herbicide-resistant crops has had a significant, positive impact on the agricultural community. Benefits include:

- Increased profitability and efficiency for U.S. farmers—farmers can produce higher yields on less land;
- Use of safer herbicides;
- Decreased soil erosion due to increased no-till farming.

As the world's population increases, the demand for food is growing and the land available to farm is shrinking. To ensure the United States can meet these demands and yet protect and conserve our valuable farmland, USDA is pursuing policies that promote the coexistence of biotechnology-derived, conventional, and organic methods. Biotechnology is poised to be a critical tool in addressing important global issues, including food security, sustainability, and climate change. At USDA, we advocate the safe and appropriate use of this technology to help meet the agricultural challenges and consumer needs of the 21st century.

2. Is the approval of such products a priority for USDA?

Response:

Regulating the products of biotechnology is a critical role for USDA. We are committed to a strong, science-based biotechnology regulatory program because we view it as essential to the development of a sustainable agricultural system.

I can assure you that we take the biotechnology regulatory process very seriously, and that we strive for thorough and complete reviews, which can take a significant amount of time. While we have been challenged in recent years to respond to an increasing number of petitions for deregulation, we are constantly looking for ways to improve the process. For example, we have undertaken a reorganization of our biotechnology staff, and have hired additional scientists to improve performance and efficiency. We have also awarded contracts to assist with the preparation of technical documents, and to help us evaluate the many thousands of public comments received through the NEPA process. To further strengthen our program, USDA requested an increase of nearly $5.8 million in FY 2011 for our biotechnology program. If enacted, we would hire additional staff and improve the program's responsiveness without sacrificing its thoroughness.

3. What steps is USDA taking to ensure such products are available to farmers?

Response:

From a regulatory standpoint, our goal is to have a rigorous, science-based program in place to ensure that GE products, including herbicide resistant crops, are thoroughly vetted through our process, examined under NEPA, and determined safe before use by U.S. producers. We believe that our system achieves that goal, and has enabled producers to have access to innovative technologies that contribute to our larger agricultural economy, food security, and sustainability.

It is important to point out that we've made thousands of regulatory decisions without legal challenge, and none of our plant pest determinations have been overturned in court—though we do remain concerned about the court rulings on our NEPA documentation process. However, we continue to learn from those rulings and improve our processes, leading to higher quality environmental reports and reviews.

Issue Paper 2: Incorporation of the Plant Protection Act Noxious Weed Provisions

I. Objective of the Proposal

The goal of incorporating the noxious weed authority of the Plant Protection Act of 2000 (PPA) into the proposed revisions to the 340 regulations is to recognize and utilize both the plant pest and the noxious weed authorities provided by the Statute. The PPA grants the Secretary of Agriculture authority to develop regulations in order to detect, control, eradicate, suppress, prevent, or retard the spread of plant pests or noxious weeds. The PPA combines the authorities of several previous related acts, including the Plant Quarantine Act of 1912 (PQA), the Federal Plant Pest Act of 1957 (FPPA), and the Noxious Weed Act of 1974 (NWA).

APHIS' current Part 340 biotechnology regulations were first promulgated in 1987 using the FPPA and PQA, which provided USDA authority to regulate the importation and interstate movement of articles that are likely to result in the introduction or dissemination of *plant pests*. APHIS is proposing to revise the Part 340 regulations to also include its PPA noxious weed authority to regulate certain GE organisms. The proposal seeks to:

- Prevent potential gaps in APHIS' Part 340 regulatory oversight, namely for GE organisms which are unlikely to pose a plant pest risk but could pose a noxious weed risk.

- Have the regulatory authority to consider a broader range of potential harm from GE plants i.e., not just their potential for being a plant pest, but also their potential to be a noxious weed.

- Improve clarity of risk assessments, by evaluating GE plants that could be considered potential noxious weeds, in addition to evaluating their potential to be plant pests.

- Be able to regulate non-living material derived from a GE plant, if APHIS concludes that such material is likely to pose a noxious weed risk (e.g., create a noxious weed harm as enumerated in the PPA by injuring the interests of agriculture, the environment, or public health).

II. Description of Significant Comments Received to date.

Commenters focused on both the issue of incorporating the noxious weed authority into the scope of the rule as well as the issue of exactly *how* the noxious weed authority would be utilized or applied.

Many commenters focused on the very broad range of significantly harmful impacts encompassed in the noxious weed definition in the PPA. In general, industry and trade groups raised concerns that APHIS should narrowly limit its interpretation of the noxious weed definition, so that it was clear, for example, that economic or aesthetic impacts alone in the

absence of any significant physical damage did not make any plant a noxious weed. On the other hand, several public interest groups and numerous individuals wanted APHIS to interpret the definition as inclusively as possible, especially with regard to impacts on the environment, public health, and marketing or product quality impacts such as indirect impacts on organic agriculture.

Some commenters felt that the proposed rule "set the bar too low" for GE plants. If the impacts of GE plants are compared against impacts of "real" noxious weeds, as proposed, then few GE plants could ever rise to that level of harm and most GE plants might be quickly evaluated by APHIS to not be under its PPA jurisdiction and thus not subject to the Part 340 regulations. That is, only those plants that are noxious weeds (or are likely to be noxious weeds) to begin with would actually be within the scope of the Part 340 regulations.

III. APHIS Current Thinking

APHIS considers that it is preferable to revise its regulations to incorporate the noxious weed authority of the PPA. Doing so would allow regulatory oversight of GE organisms that do not fall within the jurisdiction of the current regulation's plant pest authority. APHIS also considers that the proposed revisions could also improve the clarity and transparency of APHIS' biotech risk assessments and enable APHIS to consider a broader range of factors (e.g., interests of agriculture, public health, the environment) that could potentially be injured by the GE plant if it were determined to be a noxious weed. The specifics of *how* APHIS will evaluate the noxious weed risk of GE plants may require some additional development and clarification. APHIS must consistently apply its PPA noxious weed authority and thus its noxious weed assessment of GE plants under the proposed regulations must be similar to and consistent with the way that APHIS has in the past and continues to evaluate the noxious weed risk of non-GE plants. It is not justifiable either from a regulatory or a scientific perspective to hold GE plants to a different standard than non-GE plants for risks regulated under the same statutory authority by the very same agency. However, APHIS will need to develop clear criteria and decision-making standards in order to better inform the public of how it intends to apply its PPA noxious weed authority to GE plants. Those criteria and standards will likely need to be incorporated into the regulation.

IV. Issues for Further Discussion

Comments related to incorporation of the PPA noxious weed authority into the proposed regulations raised a number of issues that APHIS will have to carefully consider:

- How can APHIS apply its PPA noxious weed authority to GE plants in a way that is consistent with and similar to its past and current noxious weed regulation of non-GE plants?

- What criteria or standards for evaluating GE plants as noxious weeds could APHIS develop that are consistent with the PPA definition of noxious weeds and APHIS application of its noxious weed authority to non-GE plants?

- How can APHIS develop noxious weed criteria applicable to GE plants and relate those criteria to the various impacts included in the PPA noxious weed definition—such as impacts on "other interests of agriculture" and "public health"— that are consistent with its past and current non-GE noxious weed assessments?

7 CFR Part 340

Importation, Interstate Movement, and Release Into the Environment of Certain Genetically Engineered Organisms; Proposed Rule

DEPARTMENT OF AGRICULTURE

Animal and Plant Health Inspection Service

7 CFR Part 340

[Docket No. APHIS–2008–0023]

RIN 0579–AC31

Importation, Interstate Movement, and Release Into the Environment of Certain Genetically Engineered Organisms

AGENCY: Animal and Plant Health Inspection Service, USDA.

ACTION: Proposed rule; notice of public forums.

SUMMARY: We propose to revise our regulations regarding the importation, interstate movement, and environmental release of certain genetically engineered organisms in order to bring the regulations into alignment with provisions of the Plant Protection Act. The revisions would also update the regulations in response to advances in genetic science and technology and our accumulated experience in implementing the current regulations. This is the first comprehensive review and revision of the regulations since they were established in 1987. This rule would affect persons involved in the importation, interstate movement, or release into the environment of genetically engineered plants and certain other genetically engineered organisms.

DATES: We will consider all comments that we receive on or before November 24, 2008. We will also consider comments made at public forums to be held in Davis, CA; Kansas City, MO; and Riverdale, MD.

ADDRESSES: You may submit comments by any of the following methods:

- *Federal eRulemaking Portal:* Go to *http://www.regulations.gov/fdmspublic/component/main?main=DocketDetail&d=APHIS-2008-0023* to submit or view comments and to view supporting and related materials available electronically.
- *Postal Mail/Commercial Delivery:* Please send two copies of your comment to Docket No. APHIS–2008–0023, Regulatory Analysis and Development, PPD, APHIS, Station 3A–03.8, 4700 River Road Unit 118, Riverdale, MD 20737–1238. Please state that your comment refers to Docket No. APHIS–2008–0023.
- *Public Forums.* Written and oral comment will be accepted at three public forums held during the comment period. See *Public Forums* below.

Reading Room: You may read any comments that we receive on this docket in our reading room. The reading room is located in room 1141 of the USDA South Building, 14th Street and Independence Avenue, SW., Washington, DC. Normal reading room hours are 8 a.m. to 4:30 p.m., Monday through Friday, except holidays. To be sure someone is there to help you, please call (202) 690–2817 before coming.

Other Information: Additional information about APHIS and its programs is available on the Internet at *http://www.aphis.usda.gov.*

FOR FURTHER INFORMATION CONTACT: Biotechnology Regulatory Services, APHIS, 4700 River Road Unit 147, Riverdale, MD 20737–1236; (301) 734–5710.

For information about the public forums, contact: Dr. T. Clint Nesbitt, BRS, APHIS, 4700 River Road Unit 147, Riverdale, MD 20737–1238; (301) 734–5673.

SUPPLEMENTARY INFORMATION:

Public Forums

In order to provide additional opportunities for the public to comment on the proposed rule, APHIS will hold public forums in three locations: Davis, CA; Kansas City, MO; and Riverdale, MD (see *Meeting Locations* below). These informal forums are designed to engage interested individuals from the public and elicit comments related to the proposed rule. The format will consist of informational posters and comment stations. Attendees will be able walk through the forum during the open hours and interact with other attendees and APHIS personnel. Short welcoming remarks will be given by APHIS personnel at 4:30 p.m. and again at 6 p.m. (local time), but there is no set schedule for each poster station, so the public may come and go at any time during the forum period. Participants will have the opportunity, if desired, to record brief oral comments with a court reporter or to submit comments in writing, following directions provided at the comment stations. A transcript of the oral comments and a copy of any written comments submitted at the public forums will be placed in the rulemaking record and will be available for public inspection.

The purpose of these public forums is to allow the public a venue in which to interact with APHIS representatives and to allow APHIS to solicit further information from the public. Comments received at these public forums will be added to this Docket.

Dates: The public forums will be held in Davis, CA, on October 28, 2008; in Kansas City, MO, on October 30, 2008; and Riverdale, MD, on November 13, 2008. Each public forum will be held from 4 p.m. to 7 p.m., local time.

Meeting Locations: The public forums will be held at the following locations:

USDA Riverside, Oklahoma City Memorial Conference Rooms B, C, and D, 4700 River Road, Riverdale, MD, 20737. For directions or facilities information, call (301) 734–8010.

Walter A. Buehler Alumni & Visitors Center, Alpha Gamma Rho Hall, University of California, Davis, CA, 95616. For directions or facilities information, call (530) 754–9195 or visit *http://www.alumnicenter.ucdavis.edu/.*

Hilton Kansas City Airport, Shawnee Room A, 8801 NW 112th Street, Kansas City, MO, 64153. For directions or facilities information, call (816) 891–8900 or visit *http://www.hiltonkci.com/.*

I. Introduction

The U.S. Department of Agriculture's (USDA) Animal and Plant Health Inspection Service (APHIS) regulates the safe introduction (environmental release, interstate movement, and importation) of certain genetically engineered (GE) organisms under its regulations in 7 CFR part 340. The regulations govern the introduction of GE organisms that might be plant pests. APHIS has amended the regulations several times in an effort to respond to the need for streamlined procedures and has established clear procedures to remove GE organisms that do not pose a plant pest risk from obligations under the regulation.

The APHIS regulations have been used most frequently for permits and notifications for importation, interstate movement, or environmental releases of GE plants, although a smaller number of permits have been issued for GE microorganisms and insects. To date, APHIS has authorized more than 13,000 environmental releases of GE plants, most of which have been part of the development of improved crop varieties for agriculture. These controlled environmental releases are sometimes referred to as field tests or field trials, in recognition of their relationship to field tests done in the traditional development of plant varieties, and in this document the terms field test or field trial should be understood to mean environmental release. In addition to permits and notifications, APHIS has completed reviews in response to petitions requesting nonregulated status under these regulations. To date, APHIS has granted 74 determinations of nonregulated status, and all of these have been for GE plants (more information about these is posted at *http://www.aphis.usda.gov/brs/not_reg.html*). Many of these plants have since been used to develop plant varieties that have become part of the options that growers have for agricultural production in the United States and other countries. The APHIS determinations of nonregulated status have been for the GE plant(s) and their progeny. The GE plant with nonregulated status can be used subsequently in plant breeding programs or in agriculture just like other plant lines. A GE plant that has received nonregulated status can be bred with another GE plant with nonregulated status, and the resulting progeny which could contain multiple GE traits still retains nonregulated status.

The bulk of APHIS-authorized introductions have been crop plants bearing genes which confer resistance to certain insects or tolerance to certain herbicides. Although the current program has been effective in ensuring the safe environmental release, interstate movement, and importation of certain genetically engineered organisms, technological advances have led to new uses and questions about how the current regulations and APHIS authorities will be used to maintain appropriate oversight. Advances in technology have created possibilities for new and different traits, such as those that would produce a compound for pharmaceutical or industrial use. In addition, researchers have been producing organisms that may not fall under the scope of our current regulations and are also beginning to focus more on perennial plants, such as grasses or trees, which may be capable of establishing and persisting outside the site of introduction.

APHIS is proposing to revise its regulations in order to respond to emerging trends in biotechnology, to address the current and future needs of the agency, to continue to ensure a high level of environmental protection, to improve regulatory processes so that they are more transparent to stakeholders and the public, to more efficiently use agency resources and to eliminate unnecessary regulatory burdens.

Given the diversity of U.S. agriculture, the USDA Advisory Committee on Biotechnology and 21st Century Agriculture recently in its March 2008 consensus report encouraged the continuing support of coexistence among various agricultural production systems in U.S. agriculture. APHIS concludes that the changes it is proposing will continue to support coexistence in U.S. agriculture.

In addition, APHIS is proposing changes to the regulations to reflect provisions of the 2008 Farm Bill recently enacted. Section 10204 of Title X of the Food, Conservation, and Energy Act of 2008 (Farm Bill) requires the Secretary of Agriculture to take action on each issue identified in the document entitled "Lessons Learned and Revisions under Consideration for APHIS' Biotechnology Framework," and where appropriate, promulgate regulations. APHIS is proposing certain regulatory changes concerning permit application information requirements, permit conditions, records, and reports that address many of the considerations outlined in Section 10204.

APHIS is also aligning this proposed rule with recommendations arising from the 2005 audit of the USDA Office of Inspector General entitled "Controls Over Issuance of Genetically Engineered Release Permits."

II. Background

A. APHIS Role in Federal Regulation of Genetically Engineered Organisms

Under the Coordinated Federal Framework for Regulation of Biotechnology,[1] USDA works with the Food and Drug Administration (FDA) and the Environmental Protection Agency (EPA) to ensure that the development and testing of biotechnology products occur in a manner that is safe for plant and animal health, human health, and the environment. USDA and EPA are the agencies responsible for protecting U.S. agriculture and the environment. EPA is responsible for the human health, animal health, and environmental safety issues raised by any pesticidal substance produced in genetically engineered (GE) organisms. FDA has authority over the safety of the whole food product other than the pesticidal components regulated by EPA.

B. Current Regulations in 7 CFR Part 340

APHIS administers regulations in 7 CFR part 340, "Introduction of Organisms and Products Altered or Produced Through Genetic Engineering Which are Plant Pests or Which There is Reason to Believe are Plant Pests" (referred to below as the regulations). The current regulations govern the introduction (importation, interstate movement, or release into the environment) of certain GE organisms termed "regulated articles." Regulated articles are essentially GE organisms which might pose a risk as a plant pest.

APHIS first promulgated these regulations in 1987 under the authority of the Federal Plant Pest Act of 1957 (FPPA) and the Plant Quarantine Act of 1912 (PQA), two acts that were subsumed into the Plant Protection Act (PPA, 7 U.S.C. 7701 *et seq.*) in 2000, along with other provisions.

Under the current regulations, a GE organism is a regulated article if it is a plant pest or if the Administrator has reason to believe it is a plant pest; more specifically:

[1] The Coordinated Framework is described in a notice published in the **Federal Register** on June 26, 1986 (51 FR 23302). The notice may be viewed at *http://www.aphis.usda.gov/brs/fedregister/coordinated_framework.pdf.*

"if the donor organism, recipient organism, or vector or vector agent belongs to any genera or taxa designated in § 340.2 and meets the definition of plant pest, or is an unclassified organism and/or an organism whose classification is unknown, or any product which contains such an organism, or any other organism or product altered or produced through genetic engineering which the Administrator determines is a plant pest or has reason to believe is a plant pest." (Definition of *regulated article*, § 340.1)

In other words, APHIS regulates the introduction (importation, interstate movement, and environmental release) of GE organisms if (1) any of the recipient, genetic donor, or vector organisms are plant pests or of unknown classification or (2) the Administrator has determined or has reason to believe the GE organism is a plant pest. As constructed the regulations apply to GE microorganisms, insects, and other traditional types of plant pests and to any GE plants if plant pest organisms (bacterial and viral plant pathogens) are the donor organisms and vector agents used in the creation of these GE plants.

Taxa containing "known plant pests" are those listed in current § 340.2. Current regulations also include a petition procedure (§ 340.5) which allows petitioners to ask APHIS to add or subtract taxa from the list in § 340.2. That list has not been amended since it was established in 1987.

As defined under the current regulations and the PPA, most plants are not plant pests, with the exception of a few parasitic plant species, such as striga, witchweed, and dodder.

The primary procedure for regulation under the PPA is the issuance of a permit, which is an authorization by the Secretary to move plants, plant products, biological control organisms, plant pests, noxious weeds, or articles under conditions prescribed by the Secretary. The PPA also authorizes the Secretary to determine which classes of the above articles must have a permit to be moved. Conditions associated with those permits can be tailored to achieve the appropriate level of regulatory control to make it unlikely that actions under the permit would result in the introduction or dissemination of a plant pest or noxious weed.

APHIS currently uses a permit and notification system to authorize importation, interstate movement and release into the environment (currently referred to as "introductions") of certain GE organisms. Under the current regulations, all regulated articles are eligible for the permitting procedure, but only certain plants are eligible for the notification procedure. Currently, most regulated GE plants are introduced under notification, which is a streamlined procedure. Examples of GE plants introduced under the notification procedure are those GE plants altered to be resistant to certain insects or herbicides. GE plants that do not meet the notification eligibility criteria and all other GE organisms, such as microbes and insects, must be introduced under the permit procedure in current § 340.4. In recent years, APHIS has processed most notifications and permits through its electronic, e-permitting system that is accessible by the internet at *http://www.aphis.usda.gov/permits/learn_epermits.shtml.*

In making a regulatory determination for a permit or notification for a GE organism subject to the part 340 regulations, APHIS makes such a determination on whether the actions under notification or permit are unlikely to result in the introduction or dissemination of a plant pest. This determination takes into account various risk factors, including, among other things, a low risk that the GE organism or its progeny can persist, reproduce, and establish without human assistance. Other risk factors that would support an "unlikely" determination would be minimal availability of suitable hosts or habitats for the organism and low risk that the organism may cause damage to plants and plant products.

Regarding the risk of introduction or dissemination of the GE organism as a plant pest, an "unlikely" determination takes into consideration both the nature of the organism (i.e., low risk that the organism or its progeny can persist, reproduce, establish, and spread without human assistance) *and* any additional mitigations that are placed upon the organism that restrict its movement and make its unauthorized introduction or dissemination unlikely.

The notification procedure was first added to the regulations in 1993, and then amended in 1997 to allow a broader range of plant species to be eligible for the procedure. The notification procedure was designed to be a streamlined procedure with the eligibility criteria and performance standards already built into the regulations. Over the past decade, APHIS has typically authorized 700–1200 notifications per year.

As part of the notification procedure, applicants must adhere to performance standards set forth by APHIS for proper confinement of the GE plants. The goal of proper confinement is to ensure that the GE plants do not persist in the environment. Under the notification procedure applicants provide information about the introduction sufficient for APHIS to evaluate eligibility for the procedure and impacts on the environment. This information includes information on the plant species, introduced gene(s), location(s), and anticipated time frame for the introduction.

For notifications, the eligibility criteria and the performance standards stated in the regulations must be met, but APHIS does not prescribe how the performance standards must be met. For example, one of the performance standards in § 340.3(c)(5) requires that "The field trial must be conducted such that (i) The regulated article will not persist in the environment, and (ii) No offspring can be produced that could persist in the environment." The responsible person might meet this standard in a field trial by isolating the regulated GE plants at a sufficient distance to preclude gene flow from the GE plant to sexually compatible plants in the vicinity. Another design protocol might meet the same performance standard by planting the GE plant at a time in the growing season when surrounding plants of the same species would not be biologically capable of being fertilized by pollen from the GE plant (temporal isolation).

The regulations in current § 340.3(e) specify that the APHIS notification procedure must be completed within 30 days for environmental release and importations and within 10 days for the interstate movement of a regulated article. If APHIS completes the review process and finds that all regulatory requirements have been met, the notification is authorized in a process termed "acknowledgement," and the applicant can proceed with the introduction under the terms of the notification. Notifications are valid for one year from the date of introduction.

Approximately 10% of APHIS authorizations are done under the permitting procedure. The permitting procedure, found in § 340.4 of the current regulation, describes the types of permits, information required for permit application, the standard permit conditions, and administrative information (e.g., time frames, appeal procedure, etc.). Permits include specific conditions that must be followed by the permit holder. Standard permit conditions are listed in the regulation, and APHIS can supplement these with additional conditions as necessary. The current regulations specify the amount of time that APHIS is allotted for review of complete permit applications: 60 days for permits for importation and interstate movement; 120 days for environmental release.

Some regulated articles are conditionally exempt from the requirement for permits when moved interstate under the conditions stipulated in the regulation. Conditional exemptions currently exist in the regulations for the interstate movement of certain GE bacteria (*Escherichia coli, Bacillus subtilis*), fungi (*Saccharomyces cerevisiae*), as well as the plant species *Arabidopsis thaliana*. APHIS established these conditional exemptions from interstate movement permit by amending the regulations in 1988 and 1990.

APHIS forwards the applications for all permits, and notifications, with any confidential business information redacted, to State regulators in the States to which regulated articles will be moved and/or in which environmental release is planned. This is done to notify States of the requested action and to allow States to review and comment on proposed releases or importations or movements.

The current regulations also include various provisions and prescribed standards for containers, marking, and identity that apply to shipments of regulated articles. For example, there are instructions regarding how to label containers of imported regulated articles with the nature of the contents, origin and destination, and other information, and detailed instructions on what materials (plastic, metal, etc.) and dimensions may be used for containers of regulated articles.

Under the current regulations, APHIS may also grant "nonregulated status" to a GE organism in accordance with the procedure described in § 340.6. A determination of nonregulated status means that the organism is no longer subject to the part 340 regulations, and therefore there is no longer any requirement for APHIS authorization under part 340 for a permit or notification when the GE organism is imported, moved interstate, or released into the environment.

C. Plant Protection Act Authority to Regulate Plant Pests, Noxious Weeds, and Biological Control Organisms

Under the provisions of the PPA, Congress has granted the Secretary of Agriculture authority to develop regulations in order to detect, control, eradicate, suppress, prevent, or retard the spread of plant pests or noxious weeds. The PPA grants the Secretary authority to regulate the movement into and through the United States of any plant, plant pest, plant product, biological control organism, noxious weed, article, or means of conveyance, in order to prevent the introduction or dissemination of *plant pests* and *noxious weeds*.

The current regulations were promulgated under former statutes, i.e., the FPPA and PQA, which provide USDA authority to regulate articles that present a risk of *plant pest* introduction or dissemination. In addition to the provisions of the FPPA and PQA, the PPA incorporates authority that previously was under the Noxious Weed Act of 1974. In order to best evaluate the risks associated with these GE organisms and regulate them when necessary, APHIS needs to exercise its authorities regarding noxious weeds and biological control organisms, in addition to its authority regarding plant pests.

The definition of plant pest in the PPA is broad and includes living organisms that could directly or indirectly injure, damage, or cause disease in any plant or plant product (7 U.S.C. § 7702(14)). Under the PPA, organisms which could be plant pests include:

- Protozoans
- Non-human animals
- Parasitic plants
- Bacteria
- Fungi
- Viruses or viroids
- Infectious agents or other pathogens
- Any article similar to or allied with any of the above articles.

The definition of noxious weed in the PPA includes:

> * * * any plant or plant product that can directly or indirectly injure or cause damage to crops (including nursery stock or plant products), livestock, poultry, or other interests of agriculture, irrigation, navigation, the natural resources of the United States, the public health, or the environment. (PPA § 7702(10))

An important distinction between noxious weeds and plant pests is that noxious weeds under the PPA are always plants or plant products. Plant pests are usually not plants (with the exception of certain parasitic plants such as dodder, striga, and witchweed), but are other types of organisms that harm plants.

III. Proposed Rule

A. Proposed Regulatory Scope (§ 340.0 Scope and general restrictions)

We propose to better align the regulations with the PPA authorities in order to ensure that the environmental release, importation, or interstate movement of GE organisms does not pose a risk of introducing or disseminating plant pests or noxious weeds. Although the current program has been effective in ensuring the safe environmental release, interstate movement, and importation of genetically engineered organisms, technological advances have led to the possibility of developing GE organisms that do not fit within the plant pest definition, but may cause environmental or other types of physical harm or damage covered by the definition of noxious weed in the PPA. Therefore, we consider that it is appropriate to align the regulations with both the plant pest and noxious weed authorities of the PPA.

1. Genetically Engineered Organisms Subject to 7 CFR part 340

We are proposing to revise the scope of the regulations in § 340.0 to make it clear that decisions regarding which organisms are regulated remain science-based and take both plant pest and noxious weed risks into account. The proposed scope of the regulations states that genetically engineered organisms whose importation, interstate movement, or release into the environment would be subject to the regulations are:

Genetically engineered plants if:

(i) The unmodified parent plant from which the GE plant was derived is a plant pest or noxious weed, or

(ii) The trait introduced by genetic engineering could increase the potential for the GE plant to be a plant pest or noxious weed, or

(iii) The risk that the GE plant poses as a plant pest or noxious weed is unknown, or

(iv) The Administrator determines that the GE plant poses a plant pest or noxious weed risk.

Genetically engineered non-plant, non-vertebrate organisms if:

(i) The recipient organism can directly or indirectly injure, cause damage to, or cause disease in plants or plant products; or

(ii) The GE organism has been engineered in such a way that it may increase the potential for it to be a plant pest; or

(iii) The risk that the GE organism poses as a plant pest is unknown, or

(iv) The Administrator determines that the GE organism poses a plant pest risk.

Under the current regulations, there is no explicit statement of the relative responsibilities of the Administrator and regulated parties in determining whether an organism met the definition for *regulated article* and therefore would be subject to the regulations. Under the proposed regulations, the responsible person for a GE organism could correctly apply the criteria in § 340.0 to determine whether the GE organism is subject to the regulations. Alternatively,

the Administrator could determine any GE organism to be regulated after determining that the GE plant poses a plant pest or noxious weed risk.

In many cases, it will be very straightforward for a responsible person to apply these criteria and determine that a GE organism is subject to the regulations. For example, the GE organism would clearly be subject to the regulations if the recipient organism were a plant pest or noxious weed. A GE organism would also clearly be subject to the regulations if there was little data or previous experience available concerning the recipient organism's plant pest or noxious weed potential, or the type of modification, with the result that it is difficult to do a reliable evaluation of the risks that the GE organism may be a plant pest or noxious weed.

In other cases, it may not be readily apparent to the responsible person for a GE organism whether or not the organism falls within the scope of § 340.0 and is regulated. For this reason, persons who are not sure about whether a GE organism falls within the regulations or who maintain that a particular GE organism is not subject to the regulations based on their belief that it is not an organism within the scope of § 340.0 may consult with APHIS.

A GE organism may be within the scope of the regulations based on the information available at the time of the determination, which is usually less information than is available when the Administrator evaluates, for example, whether a regulated GE organism should be considered for an exemption from the requirement for a permit, or should be considered for a determination of nonregulated status (see discussion of § 340.6 below regarding nonregulated status). In other words, this scope determination has one purpose (to determine whether regulation is necessary at all) and is based on one level of knowledge about a GE organism, while determinations regarding such things as necessary permit conditions or exemptions or nonregulated status have a different purpose and are based on a different level of knowledge about a GE organism.

It is important to note that while a GE organism may be within the scope of the regulations due to certain identified plant pest or noxious weed risks, it may also be within the scope of the regulations if there is not enough information about the GE organism's potential plant pest or noxious weed risks to make a decision regarding those risks. At the early stages of developing a GE organism, there may not be sufficient information available about the organism to clearly determine the potential associated plant pest or noxious weed risks. Unknown risks might lead to a determination by the Administrator that a GE organism should be subjected to regulatory oversight if APHIS lacks familiarity with the non-transformed recipient organism or the introduced trait.

The proposed scope makes it clear that the mere act of genetic engineering does not trigger regulatory oversight or mean that a GE organism will pose risks as a plant pest or noxious weed. Instead, it clarifies that APHIS would subject a GE organism to regulatory oversight based upon known plant pest and noxious weed risks of the parent organisms, or based upon the traits of the GE organism, or based upon the possibility of unknown risks as a plant pest or noxious weed when insufficient information is available.

Consultation With APHIS Regarding the Scope of These Regulations

The criteria described in the scope should help developers form a reasonable expectation as to whether their GE organism is within the scope of the regulations, based on the nature of the parent organisms, the engineered traits, and the amount of information available regarding the organism and similar organisms.

APHIS anticipates that initially the range of GE organisms that the Administrator may determine to be covered by the proposed regulatory scope will be broad. This will be due to both an initial measured implementation of the revised regulatory oversight as well as to the application of the scope criteria to the transformed organisms and recipient traits. Over time, the range of GE organisms subject to oversight is expected to decrease as APHIS becomes more familiar with these organisms and receives information from which it can reach a conclusion that these GE organisms or groups of organisms do not present increased or unfamiliar plant pest or noxious weed risks. Because the Administrator may make such a determination at any time the Administrator receives information that a GE organism is within the scope, APHIS expects that developers will seek early consultation with APHIS on whether the regulatory scope covers their GE organism. Since it is generally necessary for research or business plans to include, as early as possible, elements addressing regulatory processing, approval, and compliance, it will be in the interest of the developers to determine the regulatory status of their GE organism prior to contemplating its movement or environmental release. Therefore, APHIS will offer to consult with a developer of a GE organism regarding whether the GE organism is within the scope of the proposed regulations.

After consultation and review of available information, the Administrator will respond in writing as to whether the Administrator has determined that the GE organism is within the scope of the regulations. APHIS plans to make information publicly available by posting and maintaining information on its Web site about the determinations it makes pursuant to this consultation process to help the public and regulated entities understand which organisms are subject to the regulations.

We welcome suggestions from the public on the most appropriate ways to provide administrative guidance to the public on the issue of which GE organisms are within the scope of the regulations. The Agency is especially interested in ways which will balance transparency with the efficient use of Agency resources in conducting consultations and communicating information to the public regarding which GE organisms are within the scope of the regulations.

Organisms Specifically Excluded From the Scope of the Regulations

Specifically excluded from the proposed regulatory scope are GE microorganisms that are regulated as biological control organisms by the EPA under provisions of the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA). APHIS concludes that there is no need for such GE organisms to be evaluated by both agencies. EPA is already evaluating the environmental safety of such organisms with respect to their impact on the entire environment, including plants. We also propose to retain an exclusion from the current regulations for GE microorganisms where the recipient microorganism is not a plant pest and which have resulted from the addition of genetic material from a donor organism where the material is well characterized and contains only non-coding regulatory regions.

Effect of Noxious Weed Authority on the Scope of the Proposed Regulations

The definition of noxious weed encompasses plants that pose risks akin to plant pests, because it includes "any plant or plant product" that can "injure or cause damage to crops * * * other interests of agriculture * * * or the environment", but also includes plants that can pose harm to non-plant organisms, such as humans. Therefore

evaluation of noxious weed risk expands what we can consider, while still including those risks examined under the plant pest approach. When considering risks associated with a GE plant, we would continue to consider whether it can harm plants, as well as whether it can cause the other types of physical harm or damage described in the definition for noxious weed.

The first consideration in determining if a plant is a noxious weed is identifying what direct injury or damage (physical harm) the plant causes. If direct harm or damage is established, the next consideration is to evaluate any indirect damage the plant may cause to interests of agriculture, irrigation, navigation, the natural resources of the United States, the public health, or the environment. In general, federally listed noxious weeds are plants that are likely to be aggressively invasive, have significant negative impacts, and are extremely difficult to manage or control once established.

The distinction between a weed and a noxious weed warrants emphasis. "Weeds," in the broadest sense of the word, could include any plant growing where and/or when it is unwanted; even plants that are desirable in some settings may be considered weeds in others. In a narrower sense, weeds are invasive, often non-native, plants which impact natural and managed ecosystems, often with significant negative consequences due to lost yields, changes in management practices, altered herbicide use, etc. Only a fraction of these problematic weeds are considered to be so invasive, so harmful, and so difficult to control that Federal regulatory intervention to prevent their introduction or dissemination is justified, and these are the focus of the regulatory controls placed on them by APHIS. However, any weed, and virtually any plant or plant product, can be evaluated by APHIS to determine whether its characteristics and potential impacts warrant its listing as a noxious weed.

APHIS currently lists 98 aquatic, terrestrial, or parasitic plant taxa as noxious weeds. The species included in the list illustrate the kinds of plants APHIS considers to be sufficiently invasive, damaging, and difficult to control to be deemed noxious weeds. Table 1 describes some specific examples from the Federal noxious weed list and the kinds of impacts noxious weeds can have, to illustrate the types of effects APHIS will be looking for when evaluating whether GE plants reviewed under part 340 have any potential noxious weed traits. The experience and precedents developed by the APHIS–PPQ noxious weed program provide a guide for the regulation of plants that may be noxious weeds, and we intend to apply it to the consideration of GE plants in the same way.

TABLE 1—EXAMPLES OF IMPACTS CAUSED BY FEDERALLY LISTED NOXIOUS WEEDS

Impact	Description of impact	Example species
Lost productivity of crop fields.	Noxious weeds may directly compete with crop plants for limited resources, dramatically reducing yields.	Cogongrass (*Imperata cylindrica*) infests over 20 crop species; it releases chemicals into the soil that suppress crop growth and causes damaging puncture wounds to plant roots, bulbs, and tubers. Other examples include Benghal dayflower (*Commelina benghalensis*), red rice (*Oryza* spp.), and kikuyugrass (*Pennisetum clandestinum*).
Parasitic damage to crops.	Parasitic plants can cause significant reductions in yield by attaching themselves to a host plant, removing nutrients and ultimately killing it.	Federally listed noxious parasitic plants include the dodders (*Cuscuta* spp.)—with common names like strangleweed, devil's-guts, hellbine, and witch's hair—and witchweed (*Striga* spp.), which causes devastating losses in corn, sorghum, and rice.
Reduced productivity of pasture.	Grazing animals may avoid noxious weeds and consume the more favorable pasture species, resulting in increased noxious weed populations at the expense of more favorable species. Noxious weeds may also outcompete desirable pasture species.	Serrated tussock (*Nassella trichotoma*) has heavily infested large areas, leaving them completely incapable of supporting livestock.
Injury to humans or livestock.	Many noxious weeds are toxic, harming humans or livestock either when consumed or by direct contact.	Cape tulip (*Homeria* spp.) contains a cardiac glycoside, which can be fatal to livestock. Contact with giant hogweed (*Heracleum mantegazzianum*) causes painful skin blisters. Three-cornered jack (*Emex australis*) and devil's thorn (*Emex spinosa*) both bear spiny fruits that can cripple or cause injury to livestock or other animals.
Unchecked overgrowth.	Noxious weeds may be capable of completely dominating the landscape and preventing the use of cultivated or pasture lands for agriculture.	Mile-a-minute vines (*Mikania cordata* and *M. micrantha*) can entirely smother fields and forests in a dense, tangled mass of vines. A single plant of the aquatic weed giant salvinia (*Salvinia* spp.) can blanket 40 square miles in 3 months, and produce an underwater mat 3 feet thick.
Physical obstructions.	Growth rate and habit of some noxious weeds may physically hamper the movement of livestock and humans, or interfere with navigation of waterways.	Certain mesquites (*Prosopis* spp.), jointed prickly pear (*Opuntia aurantiaca*), and African boxthorn (*Lycium ferocissimum*) form impenetrable thickets filled with thorns or needles, blocking the movement of grazing animals, injuring them or preventing access to food and water.
Disruption of water flow.	Aquatic noxious weeds may disrupt water flow, adversely affecting irrigation, drainage and flood control canals, city water intakes, and recreational water use.	Notable examples include hydrilla (*Hydrilla verticillata*), giant salvinia (*Salvinia* spp.), and Chinese waterspinach (*Ipomoea aquatica*). Dense mats of oxygen weed (*Lagarosiphon major*) can completely shut down operation of hydroelectric plants.

TABLE 1—EXAMPLES OF IMPACTS CAUSED BY FEDERALLY LISTED NOXIOUS WEEDS—Continued

Impact	Description of impact	Example species
Habitat alteration	Noxious weeds may severely alter water quality by changing oxygen and nutrient content, may dramatically lower local water tables, or could so significantly outcompete or overgrow other vegetation resulting in a complete ecological shift of the habitat.	Infestation of lakes and ponds with hydrilla (*Hydrilla verticillata*) can alter aquatic ecosystems so drastically that native plants are entirely eliminated, rendering the habitat unsuitable for fish and other wildlife.

As discussed above, APHIS' determination that a plant is a noxious weed is based on notable physical harm or injury caused by the plant. The elements of the noxious weed definition include a number of interests that might be damaged by noxious weeds including not only plants but irrigation, navigation, the natural resources of the United States, the public health, the environment and interests of agriculture. Often APHIS quantifies the physical harm or injury in terms of economic losses. Loss in commodity value due to the presence of noxious weeds in seeds, for example, is a consequence of the anticipated physical damage that would be caused if the seed containing a noxious weed were distributed and planted; the economic loss is never simply the result of market preference to have commodities free of certain noxious weed seeds in and of itself, in the absence of any potential physical damage or harm. APHIS does not consider significant economic effects alone that are not linked to physical damage to be sufficient to determine a plant is a noxious weed.

Certainly, some noxious weeds can cause physical harm to the health of humans or livestock and other animals. In general, these impacts occur when individuals come into direct contact with the noxious plants or plant parts, which may cause physical injury or are toxic or otherwise harmful when consumed. Conceivably, noxious weeds growing in crop fields could potentially threaten public health, for example, if toxic parts of the noxious weeds are harvested and inadvertently enter the food supply. If such toxic or otherwise harmful noxious weed parts were found in food and caused the food to be "adulterated" within the meaning of the FFDCA, FDA could take regulatory action against the food.

Whereas APHIS has no direct role in evaluating the safety of foods, the agency plays an important supporting role in safeguarding the food supply by protecting the health of plants and animals at the farm level. When evaluating whether a particular GE plant may be a noxious weed because it poses a public health risk when growing in the environment, APHIS considers toxicity and other food safety information, including the type reviewed by EPA and FDA. In the case of GE plants, APHIS would not assess the safety of the GE plant for human or animal consumption, but would consider available information about toxicity and other food safety information in assessing noxious weed risk posed by the plants growing in the environment.

It should be noted, moreover, that most GE plants that APHIS has been regulating in the past, such as varieties of GE corn and soybeans modified with common agronomic traits, do not qualify as "noxious weeds". But with the increasing diversity of both agronomic and non-agronomic traits being engineered into plants it is appropriate to place regulatory controls upon GE plants proportionate to the likelihood that they may present a noxious weed risk until the potential risk can be appropriately evaluated.

How Non-Plant, Non-Vertebrate GE Organisms Fall Within the Scope of the Regulations

The proposed revision of the regulations retains control for potential plant pest risks posed by non-plant, non-vertebrate GE organisms. We would continue to explicitly use the plant pest provisions of the PPA for regulating non-plant, non-vertebrate GE organisms which align with the taxa listed in the PPA definition of plant pest. In its reviews of GE non-plant and non-vertebrate species, APHIS will continue to assess GE insects, fungi, bacteria, and other non-plant, non-vertebrate organisms for their potential to pose risks as plant pests.

The scope of the regulations as defined above makes it clear that it is the Administrator, and not the public, who determines whether a non-plant organism is within or outside the proposed scope of the Part 340 regulations. APHIS welcomes public comment on the proposed concise criteria that the Administrator would consider when concluding that a GE organism is not a plant pest. We envision providing additional information on the Administrator's interpretation on such criteria at the time of the final rule or in subsequent administrative guidance.

GE Vertebrate Animals Do Not Fall Within the Scope of the Regulations

Although the PPA definition of plant pest includes the potential for a nonhuman, vertebrate animal to be considered a plant pest, APHIS decided at this time that there are no demonstrated risks or pending GE animal developments indicating that it is necessary for the proposed regulations to evaluate vertebrate GE animals as potential plant pests. Because other statutory authorities exist for addressing GE animals, APHIS could guard against any plant pest risks that might be presented by GE vertebrate animals without directly regulating them under the regulations in part 340. On the other hand, we propose to regulate GE invertebrate animals under part 340 because many classes of invertebrates include known plant pests (e.g., insects, arachnids, nematodes, gastropods, etc.).

How GE Biological Control Organisms (BCOs) Fall Within the Scope of the Regulations

The PPA defines biological control organism (BCO) as "any enemy, antagonist, or competitor used to control a plant pest or noxious weed" (7 U.S.C. 7702(2)). The PPA gives the authority to regulate plant pests and noxious weeds, not specifically biocontrol organisms. APHIS recognizes that BCOs may have the potential to affect populations of noxious weeds or plant pests, or become plant pests themselves. To fall within the scope of the proposed regulations, the GE BCO would have to pose a threat as a plant pest or noxious weed. There are relatively few examples today of GE BCOs, but these may become more common in the future. For example, some researchers are developing GE biological control pink bollworms that

are sterile, which achieve their controlling effect by reducing the ability of fertile, non-GE pink bollworms to produce offspring. Such GE pink bollworm BCOs would fall within the scope of the proposed regulation, because they are plant pests. Although there are currently no examples of using GE plants as BCOs, such a GE plant would be evaluated under the proposed regulations to evaluate whether it is a noxious weed or a plant pest.

Currently, the federal regulation of microbial BCOs is regulated by EPA under FIFRA, and this covers GE as well as non-GE microorganisms used to mitigate the effect of pests. Unlike the PPA, which limits the definition of BCO only to organisms used to control plant pests and noxious weeds, FIFRA covers microorganisms used as biological control for any pest. APHIS considers it duplicative to have these regulations include GE microbial BCOs under its scope since FIFRA already adequately covers them, so APHIS is proposing that the regulatory scope language in § 340.0(d) would explicitly exclude GE microorganisms if they are already being regulated as BCOs by EPA under FIFRA. We are proposing to only regulate GE BCO macro-organisms that fall under the proposed regulatory scope (APHIS–PPQ currently regulates the macro-organism non-GE BCOs used to control plant pests and noxious weeds pursuant to other regulations). APHIS welcomes public comment on this aspect of its proposal.

Intrastate Movements of GE Organisms Between Contained Facilities and Activities in Contained Facilities Do Not Fall Within the Scope of the Regulations

Under the current regulations, certain GE organisms are only regulated by APHIS if they are imported, moved interstate, or released into the environment. The regulations do not govern intrastate movements between contained facilities such as laboratories, nor do they govern such activities as creating GE organism in a contained research laboratory. The proposed revision does not change this aspect of the regulations.

2. Deleting the List of Organisms Which Are or Contain Plant Pests

In § 340.2 of the current regulations, there is a list of taxa that are considered to be plant pests. Under the proposed scope, this list is not needed because we would not use taxonomic classification of donor and recipient organisms to determine if a GE organism is regulated. When in the course of evaluating a GE organism APHIS considers whether a donor or recipient species is likely to be a plant pest or noxious weed, we would consider the most up-to-date pest information maintained by PPQ. This information is more specific than the information in the list of plant pest taxa in the current regulations, and should be more useful and reliable than static lists of taxa. APHIS welcomes public comment on deletion of the taxa list and preferred sources of plant pest and noxious weed information for use under the proposed regulations.

With deletion of this list from the regulations, there is also no longer a need for the procedure currently described in § 340.5 for amending this list.

3. Regulating Whole Organisms, Parts, and Nonliving Products

APHIS proposes to clarify the regulated status of nonliving plant products in the regulations. First, the PPA defines a plant pest only as any *living* stage of any of the articles specifically named in the plant pest definition that can directly or indirectly injure, cause damage to, or cause disease in any plant or plant product. Moreover, APHIS does not consider most GE organisms or parts of GE organisms which cannot reproduce to present a risk as plant pests or noxious weeds.

Conversely, we would regulate importation, interstate movement and release into the environment of GE seedlings, seeds, tubers, cuttings, bulbs, spores, etc., because there is a reasonable, albeit small, possibility of reproduction, establishment, and spread if these were deliberately or accidentally released into the environment without authorization.

Viable pollen from GE plants imported, moved interstate, or released into the environment would be subject to the regulations because such movements of pollen can reasonably lead to genomes becoming established in the environment. Similarly, in circumstances where an article incidentally contains viable pollen, during movement, APHIS would consider the movement regulated. There are many cases, however, when pollen may be present but is no longer capable of producing offspring, e.g., nonviable or immature pollen. In such cases, APHIS would not require permits under this part. The commercial distribution of cut flowers is one pollen movement situation that APHIS has considered in light of the regulations, especially in cases where the flowers are grown in other countries then imported only as cut flowers. APHIS considers these circumstances to pose little, if any risk, and therefore would not require permits for these activities.

The PPA defines a noxious weed as encompassing both plants and plant products. A plant product is defined as "any flower, fruit, vegetable, root, bulb, seed, or other plant part that is not included in the definition of plant; or any manufactured or processed plant or plant part." APHIS has regulated GE organisms under part 340 for over 20 years, and there is no strong evidence to suggest the need to regulate nonliving (nonviable) plant products in most cases. However, if in a specific case the importation, interstate movement, or environmental release of nonliving products of a GE plant may pose noxious weed risks, APHIS has clear authority to address those risks by imposing permit conditions on the handling of such nonliving products of the GE organism in the permit issued for the associated living GE organism. The proposed regulations state clearly in § 340.3(b) that the Administrator may also assign permit conditions addressing nonliving plant materials associated with or derived from GE organisms when such conditions are needed to make it unlikely that the nonliving materials would pose a noxious weed risk. APHIS invites consultation from any person considering a movement or release of nonliving materials derived from a GE organism who is uncertain as to whether it would be regulated.

B. Permits for Authorizing Importation, Interstate Movement and Release Into the Environment of Certain GE Organisms

1. Elimination of the Notification Procedure

APHIS first added the notification procedure to the regulations in 1993 as an administratively streamlined procedure for certain GE plants that met the eligibility criteria described in the regulation. Rather than using customized requirements, like the permit conditions used for the permitting procedure, the notification procedure uses generalized performance standards that are described in the regulation itself. The use of the performance standards that do not vary from one notification to the next is one of the ways that the more rapid administrative turnaround was achieved. In some ways, the term "notification" has been misleading to the public, since they do not realize that sending a notification does not mean automatic authorization by APHIS.

APHIS reviews notifications to verify that the GE plant meets the eligibility criteria, and also evaluates whether the

proposed importation, interstate movement or environmental release can be done in a manner that meets the performance standards described in the regulation. In many ways, these APHIS evaluations for notifications are very similar to those done for permit applications, but the notification procedure relies on applicants agreeing to meet the performance standards described in the regulation rather than submitting an application for APHIS review describing the specific measures they will employ for the activity (as is the case for permits). With permits, but not with notifications, APHIS can accept the proposed measures or add to them and the result is a set of binding customized permit conditions.

Because the notification procedure uses only the performance standards in the regulations, it is more administratively streamlined, but the general nature of the standards has made it difficult for APHIS inspectors to determine if a notification holder is in compliance and can also make enforcement more difficult. For example, under the current regulations, one of the performance standards for notifications relevant to environmental releases states that: "The field trial must be conducted such that (1) the regulated article will not persist in the environment, and (2) no offspring can be produced that could persist in the environment." Conversely, specific conditions which APHIS places on permits are unambiguous, easy to verify at inspection, and easier to enforce. A specific permit condition that could be used to address just part of the performance standard described above might read: "After final harvest of the GE corn plants covered under this environmental release permit, the site will be monitored every 4 weeks for the emergence of volunteer corn seedlings for one year, and any emerging volunteer plants will be devitalized before they produce pollen. Records of the monitoring and management of volunteers must be maintained by the permit holder and made available to APHIS upon request."

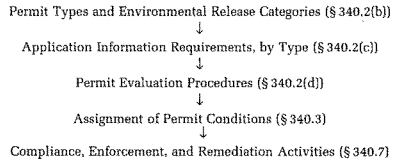
APHIS employs performance standards in many of its regulations, where appropriate. For example, we propose to employ a performance standard in another part of this proposal, container requirements for shipments of GE organisms. In that case, it is possible to employ a straightforward standard that the container must not break or leak when subjected to ordinary handling in transportation. The use of performance standards under the notification procedure has some benefits, such as providing the responsible person with flexibility in how the standard is met, e.g., allowing for appropriate change in protocols used during the growing season. However, there are some disadvantages in not specifically enumerating the specific measures that constitute compliance with the regulations. The permitting procedure does not have this disadvantage, because the permit conditions specify which actions need to be taken by the responsible person to be in compliance.

APHIS considered revising the performance standards and retaining the notification procedure, but this would not have remedied its shortcomings, especially the lack of specificity that is a necessity of using broadly applicable, performance standards in the regulations.

Under the proposed regulations where all authorizations will be done under a permitting procedure, the permit conditions will provide more specific information about what procedures the permit holder must follow in order to be in compliance. In the proposed rule, we are describing in detail the types of core permit conditions that will be imposed, plus the additional permit conditions that the Administrator can place upon the permit holder in order to make it unlikely that actions under the permit would result in the introduction or dissemination of a plant pest or noxious weed.

In view of the above discussion, APHIS has determined that it would have more flexible, risk-appropriate oversight, better regulatory enforcement and improved transparency if all regulated importations, interstate movements, and releases into the environment are authorized under the permitting procedure. The use of the permitting procedure in lieu of notifications is also necessary for APHIS to address some of the recommendations arising from the OIG Report and the provisions of the 2008 Farm Bill. For example, the OIG recommendations have led to proposed provisions in the regulations that will enable APHIS to add permit conditions to require additional reports during the course of an environmental release, the submission of notices to APHIS if the permit holder decides not to conduct the environmental release, and 7-day, pre-plant notices in the case of GE plants engineered to produce pharmaceutical or industrial substances. The last recommendation is already being implemented as a permit condition, because all of these authorizations are done under the permitting procedure. The OIG recommendations cannot be implemented under the notification procedure, because under the current regulations APHIS does not have the ability to attach conditions to notifications. This provides additional justification for APHIS to propose the elimination of the notification procedure. The APHIS proposal to eliminate the notification procedure is an effective way to address several of the provisions of the Farm Bill, such as the changes to the requirements for recordkeeping and reporting.

2. Revisions to Permit Procedures



APHIS proposes to reorganize the regulations to improve the clarity of the permit application and evaluation procedures. The proposed change is more a reorganization than substantive change, and should enhance the transparency of the regulations to the public. The permitting procedure will continue to identify and obtain information relevant to evaluating the risks associated with a proposed importation, interstate movement, or release into the environment, and determine and document whether, and under what conditions, the activity should be allowed. The proposed regulations related to the issuance of permits are divided into two sections. The first is proposed § 340.2, *Procedure for permits*, which describes permit types, the procedure for permit application (including information requirements), and the Agency's administrative actions for permits. The second is proposed § 340.3, *Permit conditions*, which describes the general types of conditions that APHIS may add to a permit, and the obligations of the responsible person after permit issuance.

APHIS is proposing explicit procedures for amendment, transfer of responsibility, and revocation of permits in order to establish clear regulatory procedures that can increase efficiency yet maintain adequate safety. Currently the APHIS administrative practices to amend, transfer, and revoke permits have not been explicit in the regulation, and this addition will provide increased transparency and efficiency.

The proposed changes organize the regulations to more clearly reflect the procedural steps in the application, evaluation, and issuance of a permit (see Figure 1). First, the different types of permits (importation, interstate movement, and environmental release) are described in § 340.2(b), as are new subcategories of environmental release permits. Second, the types of information that must be submitted with a permit application are described in § 340.2(c). The permit type, as well as

the nature of the environmental release (if the permit is for a release), affect the application information requirements. Third, § 340.2(d) outlines the procedural and administrative steps of issuing a permit. Finally, the attachment of conditions to permits, which is also dependent upon permit type and release category, is described in § 340.3. Each of these permit-related sections of the proposed regulations is discussed below.

Figure 1. Schematic of activities associated with issuance and enforcement of permits, showing associated sections of the proposed regulation.

3. Permit Types and Environmental Release Categories (§ 340.2(b))

As discussed above in the background section, APHIS currently uses two procedures—notification and permits—to authorize the importation, interstate movement and release into the environment of GE organisms considered to be regulated articles under this part. The permitting procedure can be used for all regulated articles, but the notification procedure can be used only for certain GE plants that meet the eligibility criteria described in the regulations. Whereas permits are issued with explicit permit conditions which must be met by the permit holder, notifications have generalized "performance standards" described in the regulation and therefore do not vary from one notification to the next. Currently, approximately 90% of APHIS authorizations are done under the notification procedure.

Under the proposed system, which would eliminate notifications, APHIS would continue to issue three types of permits—interstate movement, importation, and environmental release. The procedures for the first two types of permits are relatively straightforward, and the conditions usually required for these permits address risks that are very similar from one shipment to another. We propose only minor adjustments to the procedures for interstate movement and import permits. In general, deliberate release of GE organisms into the environment presents a greater risk of introducing or disseminating plant pests and noxious weeds, and thus requires more careful oversight, than shipments of GE organisms into and across the country in secure containers. Of the three permit types, only environmental release permits would be differentiated into broad risk-related categories by the Administrator. This categorization would occur prior to the detailed and specific APHIS evaluation of an individual permit application. Table 2 summarizes the relationship of the three permit types and categories that pertain to environmental release permits.

TABLE 2—PROPOSED PERMIT TYPES AND CATEGORIES FOR ENVIRONMENTAL RELEASE PERMITS

Type		Use
Importation permit		For securely moving a GE organism into the United States.
Interstate Movement		For securely moving a GE organism from any State into or through any other State.
Environmental Release:*	Release Category A	For releases into the environment, outside the constraints of physical containment that are found in a laboratory, contained greenhouse, fermenter, other contained structure, or secure shipment.
	Release Category B	
	Release Category C	
	Release Category D	
	Release Category E (non-plants)	

*In some cases, an environmental release permit may also incorporate permits for importation or interstate movement when such movements are incidental to the environmental release.

The proposed sorting system for environmental release permits includes five categories: Four for releases of GE plants (Categories A–D) and one for releases of all other GE organisms (Category E). Releases of GE non-plant organisms (Category E) would be placed into a single category and reviewed on a case-by-case basis. APHIS considered the creation of smaller risk-related subcategories for non-plants, but APHIS has received too few permit applications to warrant the creation of these smaller groupings. Releases of plants would be grouped into four categories, as described below.

APHIS considered a tiered permitting system which would sort proposed environmental releases of plants into a number of risk-based categories. Lowest risk releases would be assigned to Tier 1, slightly higher risk releases in Tier 2, and so on. In such a system, tier assignment is analogous to a risk rating. In developing the specifics of implementing such a system in the regulations, however, APHIS found that it was challenging to pre-assign all conceivable releases into tiers representing discrete levels of risk. There are a large number of risk factors that contribute to the overall risk associated with any given release. These factors include reproductive biology and growth habit of the species, potential for gene flow to other species, phenotype engineered into the organism, familiarity with the genetic material used, safety of any expressed products, scale of the release, location, duration, experience, and compliance history of the applicant, proximity to threatened

and endangered species, and other factors.

Sorting proposed releases considering all relevant factors would lead to an unwieldy system with many risk-based categories, and would essentially require a full risk assessment prior to assigning a proposed release to the appropriate risk category. Consequently, it would be nearly impossible for applicants and the public to predict the risk tier to which a proposed release would be assigned.

APHIS proposes that the permitting system for environmental release permits would assign releases into administrative categories based upon two primary risk-related factors described below, so that the categories would identify the general types of releases of plants which share broadly similar risks and management issues. This initial administrative sorting would be followed by an evaluation that fully characterized the risk of the proposed release, which would then be the primary basis for adding necessary permit conditions. APHIS concludes that such a system could appropriately sort most releases into groupings that are alike enough that they could usually be treated similarly initially, in terms of application information requirements and evaluation of potential risks. In most cases the initial groupings would also result in a similar level of oversight of the release and conditions attached to the permit-but any final determination of the permit category, oversight and permit conditions would depend on the results of the APHIS evaluation.

Using this approach, there is no prior conclusion that every release within the same category poses the same level of risk. Likewise, releases in different categories do not necessarily pose greatly different risks. For this reason, APHIS would not refer to these groupings as "tiers," as this implies an incremental increase in risk from tier to tier, but would instead label them as "categories" which are lettered and not numbered.

APHIS developed the proposed sorting scheme by first examining the types of releases that typically are authorized under its current regulations. APHIS then modified the categories to make them more explicitly connected to plant pest and noxious weed risks.

The two primary factors APHIS identified as most relevant to define its sorting system for environmental release permits were the (1) ability of the unmodified recipient plant species to persist in the wild and (2) potential of the engineered trait to cause harm, injury, or damage, as described in the definitions of plant pest and noxious weed. Secondary factors, which in some instances may change the initial categorization, include: how the recipient plant is commonly used (e.g., as a food or feed crop); the impact of the engineered trait on the fitness of the GE plant; and, the degree of uncertainty associated with the trait and its possible impacts.

Regarding the persistence factor, APHIS proposes to group plant species according to the risk of persistence of the plant or its progeny in the environment without human intervention. Based upon the growth habit of the plant species and presence of wild relatives in the United States, APHIS proposes to sort all plants into four groups, listed in order of increasing persistence risk:

- *Low:* Populations of the recipient plant are unlikely to persist in the environment without human intervention, and the recipient plant has no interfertile wild relatives in the United States. Examples include corn, soybeans, and cotton (except in certain areas).
- *Moderate:* Populations of the recipient plant are known to be weakly persistent in the environment without human intervention, or the recipient plant has interfertile wild relatives in the United States. Examples include alfalfa, beets, canola, rice, and tomato.
- *High:* Populations of the recipient plant are known to be strongly persistent in the environment without human intervention, or the recipient plant has interfertile wild relatives in the United States which are aggressive colonizers. Examples include creeping bentgrass, poplar, sorghum, and sunflower.
- *Severe:* The recipient plant is a Federally-listed noxious weed or is known to be similarly aggressive in its ability to colonize and persist in the environment without human intervention. Examples include hydrilla and kudzu.

These aspects of plant biology and growth habit are broad indicators of the increasing likelihood that the plant or its progeny can reproduce and spread without human intervention. "Interfertile wild relatives" includes both wild relatives in the traditional sense, as well as feral populations of the same species persisting outside agroecosystems. The distinction between "weakly persistent" and "strongly persistent," is intended to mean survival without human intervention for one or very few generations (weakly persistent) versus several to many generations (strongly persistent). APHIS will clarify which species fall into each group by publishing lists in guidance.

Similarly, with regard to the factor for potential harm caused by introduced traits, APHIS proposes to group traits engineered into plants into four simple groupings based upon the definitions of plant pest and noxious weed. The groups are listed in order of increasing potential hazard of the engineered trait:

- *Low:*
  - Any new proteins or substances produced are unlikely to be toxic or otherwise cause serious harm to humans, vertebrate animals, or invertebrate organisms upon consumption of or contact with the plant or plant parts; and
  - No morphological changes which could cause mechanical injury or damage; and
  - Introduced sequences are known not to result in plant disease, and confers no or very low increased disease susceptibility.

An example would include expression of well characterized proteins known not to be toxic or harmful, such as a marker gene that does not pose a food or feed safety concern, or expression of viral genes where it is demonstrated that no protein is produced

- *Moderate:*
  - Any new proteins or substances produced are unlikely to be toxic or otherwise cause serious harm to humans or vertebrate animals upon consumption of or contact with the plant or plant parts ; or
  - Novel resistance to the application of an herbicide; or
  - Has novel ability to cause mechanical injury or damage; or
  - Produces proteins or substances that are associated with plant disease that are not prevalent or endemic in the area of release, or that confer an increased susceptibility to disease.

Examples include expression of new CRY proteins, ,mechanisms of herbicide tolerance (e.g., CP4–EPSPS, which confers glyphosate tolerance), and production of viral movement proteins.

- *High:*
  - Any new proteins or substances produced may be toxic or to otherwise cause serious harm to humans or vertebrate animals, upon consumption of or contact with the plant or plant parts; or
  - Produces an infectious entity which can cause disease in plants.

Examples include mercury hyper-accumulators or production of some pharmaceutical compounds.

- *Severe:*

Any new proteins or substances produced are known or likely to be

highly toxic or fatal to humans or vertebrate animals, upon consumption of or contact with the plant or plant parts.

These aspects of the engineered trait are related to harms or damages associated with plant pests or noxious weeds. This takes into consideration (1) the harmfulness of any substances produced, (2) the possibility of creating morphological changes that would cause physical injury, and (3) the likelihood of increasing plant disease, either due to risk of creating novel pests or increased inoculum source. Novel resistance to an herbicide is included in the "moderate" category due to the impacts the trait could have on the ability to manage the plant or its progeny.

The proposed use of plant growth habit and trait harm or injury as the two main factors for the initial sorting of environmental releases into categories uses the two factors to roughly approximate "exposure" and "hazard," respectively. Thus, using a combination of these two factors alone, we propose the following initial sorting of plant-trait combinations into release permit categories (see Table 3). Once environmental releases of GE plants have been sorted into the permit categories shown in Table 3, we will review and evaluate the information submitted by the applicant to determine oversight and permit conditions. The information requested from applicants will not be limited to these factors and is, in fact, designed to allow us to evaluate any of the risks associated with noxious weeds and plant pests. In some instances, our review may result in a change to the release category assignment of a GE plant.

TABLE 3—INITIAL SORTING INTO ADMINISTRATIVE PERMIT CATEGORIES (A, B, C, AND D) FOR ENVIRONMENTAL RELEASES OF GE PLANTS, BASED UPON PERSISTENCE RISK OF THE RECIPIENT PLANT SPECIES AND POTENTIAL HARM OR DAMAGE OF THE ENGINEERED TRAIT

Persistence*	Potential harm or damage of engineered trait			
	Low	Moderate	High	Severe
Low	A	A	C	D
Moderate	A	B	C	D
High	B	B	C	D
Severe	D	D	D	D

*Persistence risk of the recipient plant species.

The sorting system above presumes that there is sufficient scientific information available about the GE plant to support the categorization. For example, the phenotype conferred by inserted sequences and the growth habit of the plant species in the U.S. must be well-characterized and based upon direct empirical observation of the genetic construct in the recipient plant species. In cases where less (or nothing) is known about phenotype of the engineered trait in the recipient plant species-such as inference based upon sequence similarity, protein structure modeling, or observation of the genetic construct in other species-the release category may be changed (from A to B or B to C) as a result of this uncertainty. Similarly, lack of familiarity with the plant species' behavior in the U.S. or the techniques needed to mitigate the likelihood of its persistence could also change the release category.

APHIS considered whether to adjust the categories table to acknowledge that an engineered trait could affect (enhance or detract from) the other factor axis, namely the persistence risk of the nonmodified recipient plant. Engineered traits such as resistance to biotic or abiotic stresses could theoretically increase the fitness of the plant, and thereby increase the likelihood that it will persist in the environment without human assistance. Considering the range of persistence risks posed by all of the different plant species sorted into any one of the proposed groupings, however, APHIS has concluded that in most instances the engineered trait would not alter the likelihood of persistence enough to warrant a change in initial release category. However, in cases where the engineered trait significantly alters plant growth habit, metabolism, or reproduction to increase the likelihood of persistence in the environment, APHIS could change the release category accordingly. Examples of such changes might include converting an annual species to a perennial or converting a plant with C3 metabolism to crassulacean acid metabolism (CAM).

The proposed category system should provide a simple, transparent way for APHIS review information in applications to initially sort releases into broad, risk-related categories, which can then be more efficiently assessed for the actual risks posed by the release. However, it should be emphasized that the categories are intended only for initial sorting, and other factors are taken into account in the APHIS evaluation when determining the specific permit conditions.

APHIS intends that release Category A will be associated with a level of regulatory oversight similar to environmental release notifications under the current system, and Categories B and C with a level of regulatory oversight similar to various permits that have been issued under the current system. However, it will be much clearer to the public what types of oversight will be applied broadly within each category. As we discussed above, oversight and permit conditions with each category will be similar, though not necessarily identical, for any plant within the category. Category D was created to acknowledge the possibility that some proposed releases may pose a very high risk of introducing a highly persistent or harmful plant into the environment. To date, APHIS has never been requested to allow releases that would fall into this category. If an applicant were to propose a Category D release, APHIS would only authorize such releases after imposing extremely strict levels of oversight akin to high security quarantine far exceeding that of Category C that would ensure that the GE plants could not persist in the environment. The information requirements, permit conditions, and general levels of oversight associated with each release Category are discussed below.

This simple sorting system places GE plants into categories and provides a relatively clear, simple rationale for placement in a given category. What follows is a series of illustrations of common plant-trait combinations and the release categories to which they would be assigned:

- *Category A:*
  - Bt corn producing CRY1ab toxin. The plant is unlikely to persist in the

environment and the safety of the protein has been assessed by the EPA.

○ Soybeans engineered with glyphosate tolerance conferred by CP4–EPSPS. While herbicide tolerance poses a "moderate" hazard, soybean has no interfertile wild relatives in the U.S..

• *Category B:*

○ Corn producing a new CRY protein. The plant is unlikely to persist and the novel CRY protein is likely to be toxic to some species that live or feed on the plant (normally Category A), but its food/feed safety is only inferred from similarity to other CRY proteins.

○ Random "knock-out" or antisense libraries of soybean lines. While the lines may not likely produce novel proteins or substances (Category A), because of the uncertainty associated with the impacts of genetic engineering on these lines, they would be treated as Category B. Well-characterized lines taken from such libraries that do not produce new proteins would likely be treated as Category A.

○ Kentucky bluegrass engineered with glyphosate resistance conferred by CP4–EPSPS. Herbicide resistance is a "moderate" hazard and bluegrass has interfertile wild relatives in the U.S.

○ Pines producing an enzyme to enhance paper production. Pines are persistent and have interfertile wild relatives in the United States.

• *Category C:*

○ Poplar engineered to produce enzymes for heavy metal bioremediation.

• *Category D:*

○ Any Federally listed noxious weed that has been genetically engineered; any GE plant producing a vertebrate toxin.

Permits for Environmental Releases of Plants Making Pharmaceutical and Industrial (PMPI) Compounds

APHIS considered whether to continue to issue environmental release permits for GE plants engineered to produce pharmaceutical and industrial compounds if the GE plant species is the same as, or sexually compatible with, a species commonly used for food or feed. APHIS concludes that the proposed permitting procedure and the use of stringent permit conditions can continue to effectively minimize the risks that may be associated with the environmental release of such GE plants. APHIS will continue to impose permit conditions that take into account the issues related to the safety of proteins or other substances that these plants have been engineered to produce. Based upon APHIS experience to date, many releases of GE plants producing pharmaceutical or industrial substances would fall in Category C, and would carry the same level of oversight as current permits for PMPI.

4. Permit Application Information Requirements (§ 340.2(c))

In the proposed regulations, we provide greater detail about the basic application information requirements that need to be addressed in all permit applications, as well as additional basic information required for each permit type and the categories in the case of environmental release permits. Under the current regulation, certain areas where APHIS routinely needs information from the applicant do not become apparent until the applicant submits the permit application (and APHIS subsequently follows up for additional information). Some of the information requirements related to recordkeeping, reporting, and contractual arrangements among the permit holder and agents are new to the regulation and reflect, in part, certain provisions of the 2008 Farm Bill and also align with recommendations of USDA's OIG 2005 Report. For example, the OIG recommendations have led to provisions that will enable APHIS to require geographic coordinates for the locations of environmental releases.

The differences between the information required for an application under the current regulations versus the proposed regulations may be seen by comparing current § 340.4 to proposed § 340.2(c). Both the current and proposed application procedures require information characterizing the nature of the GE organism, including detailed molecular biology information about the expression of the introduced genetic material. They also both require information about the type of movement and/or release planned. The proposed rule requires more detail in some of these areas, and more description of the applicant's plans and methods to prevent unauthorized releases, and to respond to unauthorized releases if they occur. This information is used in part by APHIS to formulate the specific permit conditions. In cases where the permit is for environmental release, and would be in permit categories C or D according to the table in § 340.2(b)(3), a greater level of detail would be required for almost all aspects of the activity, including the recipient organism, the inserted gene(s), site location and management practices, and training and communication among the permit holder and agents involved in the activity covered under the permit. This information would also address the capability of the organism to persist or spread in the environment, or include details about how the engineered traits might be harmful.

5. Permit Conditions (§ 340.3)

Conditions are specific practices or requirements that an applicant must follow upon issuance of a permit. Under the current regulation, the permit conditions are described in the same section as the permit procedure itself. In the proposed revision, the permit conditions are enumerated in a separate section (§ 340.3) to accommodate the additional details to describe conditions for the three permit types as well as the categories of environmental release permits.

The use of permits and permit conditions gives APHIS and the responsible person a clearer understanding as to what actions must be taken for the permit holder to comply with the regulation. In the proposed regulation, APHIS has strived to provide as much transparency and predictability as possible about permit conditions while retaining sufficient flexibility so that the regulations will be adaptable in a broad range of cases.

Permits will be issued with the core permit conditions described in § 340.3(a), which are a minimum set of basic conditions for importation, interstate movement, and release. The Administrator may add to these conditions additional or expanded conditions when necessary to make it unlikely that actions under the permit would result in the introduction or dissemination of a plant pest or noxious weed.

The Administrator will assign the permit conditions in a manner that is commensurate with the risk of the individual proposed movement or release. Additional or expanded permit conditions may include, but are not limited to, specific requirements for: reproductive, cultural, spatial, temporal controls; monitoring; post-termination land use; site security or access restrictions; and management practices such as training of personnel involved in the release.

The proposed description of permit conditions elaborates on the "standard" permit conditions found in the current regulations, and the additional detail is designed to better communicate with potential applicants what the requirements are likely to be for their particular permit, and will better support administration of the program, including compliance and enforcement.

In the current regulation, only "standard" permit conditions are described, and APHIS has the authority to place other conditions upon the permit as deemed necessary by the

Administrator. The proposal for permit conditions will be more transparent to the public and this transparency will better facilitate planning by researchers, especially those who have not previously received permits from APHIS.

The proposed required core permit conditions consolidate six primary areas addressed in different parts of the current regulations to ensure compliance with the regulation and to make it unlikely that the permitted activity will result in the introduction and dissemination of a plant pest or noxious weed: Identity, shipment, unauthorized dissemination, communication and training, records, reports and notices. APHIS intends the list of specific condition areas we propose in § 340.3 to be used for all permits we issue as they apply to importation, interstate movement, and release into the environment. The required permit conditions listed in § 340.3 represent the permit conditions that we propose to apply for any type of permit. Listing them in the regulations should provide applicants with the ability to plan their activities with knowledge of the primary requirements for all activities that would have to be met to comply with the regulations.

For environmental release permits, proposed § 340.3(a)(4)(iii)(F) would also require the permit holder to notify APHIS seven days prior to initiation of the release if the release is Category C or D. For all Categories, permit holders are required to notify APHIS if they do not conduct the release.

The current regulations require environmental release permit holders to submit field test reports to APHIS within 6 months after termination of a field test. Under proposed § 340.3(a), the requirement simply states that the responsible person shall submit reports to APHIS at the times specified in the permit conditions and containing the information specified in the permit conditions.

APHIS is also proposing revision of the regulations to clarify the procedure it would use for amendment of permit conditions, transfer of a permit to a different responsible person, and revocation of an existing permit. Each of these additions to the regulations reflect current administrative practices and the incorporation of these into the regulations will make the overall system more transparent.

Currently, APHIS attaches conditions to permits at the moment the permit is issued to the applicant. Under the current regulations, the permitting procedure does not include a formal acknowledgement from the applicant prior to permit issuance that they are aware of and consent to the permit conditions. To verify that applicants are aware of and willing to abide by the conditions, APHIS proposes to add an additional administrative step in the permit procedure in § 340.2(d)(6) to support administration of the program. We are proposing to require that applicants agree prior to permit issuance that they will comply with all the permit conditions. Eventually, APHIS would build this feature into the existing ePermits system, and in the interim it would provide alternative mechanisms, such as e-mail communications, to implement this step of the permitting procedure.

APHIS is also proposing to clarify in § 340.2(h) of the regulations the procedure to be used when amendment of existing permit conditions is sought by the responsible person or required by APHIS, as well as the procedure for transfer of an existing permit to a different responsible person.

As with the current regulations, APHIS is retaining the flexibility to modify permit conditions as needed under individual circumstances. Proposed § 340.3 will increase transparency, yet still allow sufficient adaptability of the regulations for the full range of permit applications APHIS expects to receive today and in the future. APHIS recognizes that transparency and predictability for applicants must be balanced with maintaining Agency flexibility and adaptability for years to come under these regulations. APHIS encourages the public to comment on the choices we are proposing here, and we welcome suggestions for alternative approaches.

APHIS is proposing to revise the current sections of the regulations for container requirements for shipments of GE organisms (§ 340.8) and marking and identity requirements for imports of GE organisms (§ 340.7). Rather than the highly prescriptive approach in the current regulation, we will use an approach that is performance based and can be adapted to the activity that is being performed. This should provide greater efficiency for the public as well as APHIS, yet still achieve the necessary level of containment during shipments. We have reorganized this information in the regulations so that the requirements are associated with the related activity under the proposed regulation. For example, the shipping requirements for interstate movements under the conditional exemption have the requisite shipping conditions stipulated in the section for conditional exemptions. Likewise, the shipping conditions for import and interstate movement permits have been placed in the section for permit conditions, rather than retaining them in a separate section as in the current regulations. The performance-based standards we are proposing incorporates a simple performance standard in our proposed definition of secure shipment, discussed below: "Shipment of a package of sufficient strength and integrity to withstand leakage of contents, shocks, pressure changes, and other conditions incident to ordinary handling in transportation." APHIS is also proposing to require applicants to provide their proposed methods of secure shipment, and APHIS will specify the methods of secure shipment as a permit condition.

APHIS proposes to eliminate the marking and identity requirements for imports of GE organisms as a separate section of the regulations (current § 340.7). As with the container standard issue discussed above, appropriate labeling and related requirements would be highly individual depending on the organism, type of permit, and other conditions.

APHIS is proposing to include relevant tribal officials when it provides copies of permit applications to state regulatory officials. The current regulations state that APHIS provides this information to state regulatory officials.

6. Elimination of Courtesy Permits

APHIS is also proposing to eliminate the issuance of courtesy permits. Courtesy permits have been part of the regulations since their inception in 1987, but in an effort to better allocate APHIS resources, APHIS is proposing to remove this regulatory feature. The current regulations provide the ability for APHIS to issue "courtesy permits," in order to facilitate the movement of organisms which are outside the scope of these regulations, but whose movement might otherwise be hindered because of their similarity to organisms regulated under these regulations. The issuance of courtesy permits has generated confusion in the public and especially in the research community. The application form for courtesy permits is identical to the application for other types of permits, and the courtesy permit itself looks like other permits. This has led to the widespread misunderstanding by some researchers that courtesy permits are actually required for the movement of certain organisms, or that issuance of a courtesy permit removes the requirement for applicants to have other authorizations which may be required, under plant

pest regulations such as those found at 7 CFR part 330. APHIS commits significant resources to the issuance of these courtesy permits for the movement of organisms which are not subject to the provisions of part 340. APHIS will work with researchers and relevant government regulatory officials to facilitate the transition.

APHIS will also be available for consultation by persons who formerly used courtesy permits and other persons moving similar non-regulated articles, to discuss how to facilitate their movement. We also encourage the public to comment on the proposed elimination of courtesy permits and how APHIS should work with persons moving organisms for which we might formerly have issued courtesy permits.

C. Conditional Exemptions From Permit Requirement (§ 340.4)

The PPA allows the Secretary to create "exceptions" to the permit requirement when the Secretary deems that a permit is not necessary. That is, these regulated activities are allowed, under certain conditions, without seeking prior authorization via permit. The current APHIS regulations contain such PPA exceptions, but they are referred to as "exemptions" in the regulations. The current regulations include conditional exemptions from the requirement for interstate movement permits. These conditional exemptions were established in the regulations during the first few years after the regulations were first promulgated. The last conditional exemption was established in the regulations in 1990 for the interstate movement of GE plants of the species *Arabidopsis thaliana* as long as the conditions described in the regulations are met.

In its proposed revision to the regulations, APHIS is retaining the existing conditional exemptions from interstate movement. We are also proposing a new regulatory procedure that would enable APHIS to approve new conditional exemptions more efficiently than using the procedure of notice and comment rulemaking for each individual exemption. This can be a transparent and efficient way to provide regulatory relief. This new procedure for approving conditional exemptions is described in § 340.5, and it incorporates transparent steps including scientific review, public input, and adaptability when APHIS establishes the conditions relevant to the specific conditional exemption. Conditional exemptions, by their nature, will always include conditions and continued APHIS oversight to ensure that the conditions are met.

The current regulations provide for conditional exemptions from the requirement for permits for the interstate movement of certain GE strains of the microorganisms *Escherichia coli, Saccharomyces cerevisiae,* and *Bacillus subtilis,* and the plant *Arabidopsis thaliana* in § 340.2(b), and these conditional exemptions are being retained under the proposed regulations. Conditional exemptions from permit have been part of the regulations since the first exemption was established in 1988 (for the interstate movement of certain GE microorganisms), with the addition of another conditional exemption, through rulemaking, in 1990 for certain types of GE *Arabidopsis thaliana,* one of the most commonly used plants for scientific studies and which is frequently distributed among researchers. The essential conditions for each of these conditional exemptions address the following: (1) Species of the GE organism, (2) the types of genetic modifications that are allowed or prohibited for the GE organism, and (3) the manner in which the GE organism is shipped interstate. The existing conditional exemptions for the interstate movement of microorganisms were based on APHIS' conclusion that the exemption from the requirement for permits for interstate movement of these microorganisms would "not present a risk of the introduction or dissemination of a plant pest" (53 FR 12910, p.12910).

The existing conditional exemptions for *E. coli, Bacillus subtilis, Saccharomyces cerevisiae* and *Arabidopsis thaliana* are being retained in the proposed regulations. APHIS has no information that would indicate that such conditional exemption would be result in the introduction and dissemination of a plant pest or noxious weed. The text of the conditional exemption is being updated to place the shipping requirements with the other conditions associated with the exemption, instead of the current regulatory organization that has the shipping requirements in a separate section of the regulation.

In addition to the existing conditional exemptions, APHIS is proposing a transparent and efficient petition procedure in § 340.5 whereby the Administrator may approve additional conditional exemptions from permit without having to amend the regulations. This procedure would provide for a scientific review by APHIS as well as the opportunity for public review and comment on the scientific basis for the proposed exemption and the conditions associated with the exemption. The proposed procedure would provide an adaptable means of ensuring that the regulatory oversight is proportional to the risks posed by specific activities with GE organisms.

Proposed § 340.5 describes the procedure whereby a petitioner would seek a determination by the Administrator that the importation, interstate movement, and/or release into the environment of a GE organism is not subject to the requirement to have a permit under this part. We propose that the Administrator's decision to approve an exemption would be based upon a determination that the exemption from the requirement for a permit, when conducted with the associated conditions, is unlikely to result in the introduction or dissemination of a plant pest or noxious weed. APHIS anticipates that creating this new petition procedure to allow approval of additional conditional exemptions would enhance its ability to customize regulatory oversight to be proportional to any risks associated with importation, interstate movement, or release into the environment of a GE organism.

Under the proposed procedure, petitioners have the flexibility to propose various types of conditional exemptions from the requirement for a permit: The proposal can be for one or more permit types (importation, interstate movement, or release into the environment). In addition, the petitioner can propose the relevant conditions. The Administrator may approve the proposed conditional exemption as submitted in the petition, or the Administrator may impose alternatives to the requested exemption and conditions. The Administrator would review the scientific information and evaluate potential risks relevant to the proposal, then make the relevant documents (proposal and any supporting information) available to the public for review and comment prior to the Administrator's decision.

The information needed for a petition for conditional exemption would depend on the nature of the exemption requested and the proposed conditions for exemption. For example, conditional exemptions for the interstate movement of narrowly-defined groups of organisms with restrictive associated conditions might require considerably less information to justify than exemptions for broadly defined groups of organisms or less restrictive associated conditions. In making its determination, APHIS would consider all relevant information, including information in the scientific literature, copies of unpublished studies, and reviews by other regulatory agencies.

APHIS foresees many advantages to the proposed procedure, including scientific rigor, public involvement, and regulatory efficiency. APHIS would continue to provide to the public the relevant scientific information under consideration, its environmental analysis, and the rationale for its determination. The public would also retain its ability to provide comments to the agency prior to a decision approving a new exemption. APHIS decisions regarding these newly approved conditional exemptions would be published in the **Federal Register** and maintained on a list accessible to the public.

In evaluating whether to approve a new conditional exemption, APHIS would carefully consider issues related to enforceability of the conditional exemption when proposing to approve a conditional exemption. Unlike permit conditions, which are binding on the specific responsible person, the conditions associated with the exemption would apply to anyone who conducts the activity under the conditional exemption. Before granting such a conditional exemption, APHIS would take into consideration the likelihood that such conditions would be followed and the consequences if they are not.

Conditional exemptions could be used, for example, for the importation of certain GE commodities. A person could petition for an exemption from all permits for shipments of a particular GE commodity grain under the condition that the grain is not grown, but will only be moved for direct use as food, feed, or for processing. The proposed procedure to approve new exemptions would be sufficiently adaptable that it can consider approving exemptions for the shipment of certain GE commodities that would take into account any conditions necessary to make it unlikely to result in the introduction and dissemination of plant pests or noxious weeds.

APHIS considered proposing specific criteria in the regulations that the Agency would use when evaluating potential risks of imported GE commodities which are viable propagules such as grains like corn, wheat, etc. APHIS considered that such a criterion-based system in the regulations might allow APHIS to conduct expedited reviews of imports that met the specified criteria. APHIS considered criteria such as whether the GE plant had undergone a safety review in a foreign country, whether APHIS had granted nonregulated status to something similar, and the likelihood that the commodity could be propagated (seeds, fruit with seeds, nonviable products like flour, etc.).

However, at this time APHIS is not proposing such criteria in the regulation. APHIS does not rule out the possibility of developing such a criterion-based system in the future. We welcome comments from the public on this issue.

We are also proposing regulatory procedures whereby the Administrator may revoke any exemption under this part after it is approved. As proposed, the Administrator may revoke any exemption if the Administrator receives information subsequent to approving the exemption and makes a determination based upon this information that the circumstances have changed such that the exemption is likely to result in the introduction or dissemination of a plant pest or noxious weed. A revocation may not be appealed. However, any person may file a new petition in accordance with § 340.5 regarding the same or similar organisms covered by the exemption if new information relevant to the revocation becomes available.

In addition to this procedure for completely revoking an exemption so it would be unavailable for use by any person, we propose to add a provision in paragraph (e) of the conditional exemptions section, § 340.4, under which the Administrator may revoke the right of an individual person to use an exemption without revoking the exemption for other persons. The Administrator could revoke an individual's right to use an exemption after determining that the person or any agent of the person has failed to comply at any time with any provision of this part.

D. Petitions for Nonregulated Status (§ 340.5)

The current regulations include a procedure by which anyone may petition APHIS to grant "nonregulated status" to a GE organism, which means it would no longer be subject to the regulations in part 340. This nonregulated status is different from that of regulated articles that might be conditionally exempt from the requirement for a permit when moved interstate (following the conditions specified in the regulations).

Published APHIS decisions made under the current regulations have used different ways to express the basic standard "unlikely to pose a plant pest risk" in determining whether to grant nonregulated status to a specific GE organism. In its determinations, APHIS has conveyed the basic standard of "unlikely to pose a plant pest risk" by concluding that the GE organism "poses no more of a plant pest risk than its non-genetically engineered counterpart," "will not pose a plant pest risk"; or that there is "no plant pest risk," or "no direct or indirect plant pest effects." Regardless of the phrases used in its determination of nonregulated status to date, APHIS has applied the same basic evaluation criteria to each determination to conclude that the GE organism is unlikely to pose a plant pest risk and therefore is not subject to the part 340 regulations.

APHIS is proposing revisions to § 340.6 that will clarify the petition procedure, information requirements for petitions, and the standard upon which the Administrator will make a determination that a GE organism is approved for nonregulated status. Under the current regulations, the basic standard for a determination of nonregulated status of a GE organism has been related to plant pest risk. In § 340.6(b)(4) of this proposed rule, we are proposing to apply a similar basic standard derived from the proposed regulatory scope in § 340.0(a), namely, whether the GE organism is unlikely to be a plant pest or noxious weed.

The current regulations also have a provision at § 340.6 to extend a determination of nonregulated status and grant nonregulated status to a GE organism based on the similarity of the GE organism to an antecedent GE organism that has already granted nonregulated status (§ 340.6(e) "Extensions to determinations of nonregulated status"). This provision has been in the APHIS regulations since 1997 and has been used fifteen times to grant nonregulated status to additional GE plants based on similarity to their antecedents. This existing "extension procedure" was designed for APHIS to take into account the previous evaluation conducted by APHIS and thereby afford the potential for expedited evaluations of a petition for extension. The extension procedure has some administrative aspects which are streamlined but in practice the APHIS scientific reviews for extensions are similar to those of the antecedent organism.

Some members of the public have misunderstood the nature of the extension procedure, believing that APHIS has not conducted a thorough scientific review. Some members of the public have misconstrued the term "extension" to conclude that an extension would extend the duration of nonregulated status (nonregulated status is not granted with an expiration date).

For these reasons, APHIS is proposing to eliminate the extension procedure in

the regulation. APHIS sees no advantage to retaining the distinction in the regulations between reviews for antecedents and reviews for subsequent petitions for extensions. Because the proposed revisions for petition for nonregulated status provide a high degree of flexibility, a separate extension procedure is not needed in the regulation. Review of petitions under the proposed regulations will rely on previous evaluations of similar GE organisms when they exist. APHIS foresees that some evaluations for nonregulated status may require less time if previous evaluations have addressed the issues relevant to a new petition for nonregulated status.

In § 340.6 we propose some revisions to the information that the Administrator may require a petitioner to submit in consideration of the particular petition. In the current regulation, the information needs are described largely with respect to evaluating GE plants, but APHIS foresees that other GE organisms may also be suitable candidates. This provision may become more important as new commercial applications of biotechnology emerge and new types of information are needed to properly assess the risks associated with new types of GE organisms. In all of the nonregulated status requests processed to date, the subject organisms and the alterations involved did not present unanticipated or completely novel approaches and APHIS was able to make a determination based on information in the petitions. When needed, APHIS obtained additional information from petitioners, in a consultation process similar to the one proposed.

We are also proposing a regulatory procedure whereby the Administrator may revoke a previous approval of nonregulated status. This is consistent with the existing regulations and policies that the Administrator may place a deregulated GE organism back under the regulations if the Administrator concludes that the GE organism poses a plant pest risk. As proposed, the Administrator may revoke any approval of nonregulated status if the Administrator receives information subsequent to approval that the GE organism is likely to be a plant pest or noxious weed. If the Administrator revokes an approval for nonregulated status, the Administrator may approve for the same GE organism an exemption from the requirement for permit in accordance with § 340.5. The revocation, its effective date, and the reasons for it will be published in the **Federal Register**. A revocation may not be appealed. However, any person may file a new petition in accordance with § 340.5 or § 340.6 regarding the same or similar organisms covered by the revocation if new information relevant to the revocation becomes available.

Treatment of GE Organisms That Have Been Granted Nonregulated Status

Although the APHIS evaluations of GE plants that would be conducted under the proposed regulatory changes will evaluate some additional factors because of consideration of noxious weed risks, APHIS nonetheless considers this proposed revision to be sufficiently consistent with the criteria evaluated in making determinations of nonregulated status to date under the current regulations. For this reason, APHIS is proposing that all previous determinations of nonregulated status made since the early 1990s under the part 340 regulations will be automatically approved for nonregulated status under the revisions proposed here. The history of safe use of these nonregulated GE plants in agriculture in the United States and other countries gives APHIS confidence that it is appropriate to retain nonregulated status under the revised regulations for all those GE plants which have been granted nonregulated status under the existing regulations. Many of these GE plants have been incorporated into plant breeding programs and been used to develop hundreds of crop varieties that have been widely and safely used in agriculture around the world.

We also note that although the addition of the term "noxious weed" is new to the proposed regulation, previous evaluations for determinations of nonregulated status considered the concept of plant pest risk in a broad context that included consideration of potential weediness. The evaluations considered, *inter alia*, whether the unmodified plant was a weed, whether the GE plant was a weed, and whether the interbreeding of the GE plant with sexually compatible plant species would result in offspring that would be weeds. In each case in which APHIS granted nonregulated status to date, APHIS reached the conclusion that in each instance that the potential for weediness was unlikely to occur. In the case of some petitions for nonregulated status in which the GE plants were engineered with sequences derived from plant viruses, APHIS also considered in its reviews whether the genetic modification was unlikely to result in a new plant pest, in this case a plant virus (through mechanisms such as recombination or transencapsidation).

E. Compliance, Enforcement, and Remedial Action (§ 340.7)

1. Ensuring Compliance With Permits and Exemption Activities

In recent years, APHIS has strengthened its program in order to improve permit holders' compliance with the regulations, to augment the approaches used to prevent or remediate potential risks to plant health, and to utilize appropriate enforcement strategies. This proposal provides an opportunity to set forth the compliance and enforcement requirements and the tools and administrative practices APHIS may employ as part of an integrated approach to prevent the introduction or dissemination of plant pests and noxious weeds, and to support overall administration of the program. These matters are addressed in proposed § 340.7, "Compliance, enforcement, and remedial actions." These proposed regulatory changes also reflect certain provisions of the 2008 Farm Bill and align with recommendations of USDA's OIG.

APHIS seeks to clarify that it will use the full range of enforcement authorities and penalties granted under the PPA. As described above, APHIS issues permits with specific conditions or requirements placed upon the responsible person. Proposed § 340.7 clarifies the requirement for compliance with these conditions, as well as the approaches available to APHIS to verify compliance. Such conditions may include requirements for the responsible person to establish and maintain records related to the permit, as well as allowing APHIS to review those records. This section underscores APHIS' ability to conduct inspections and audit records related to the regulated activities.

In this proposed rule, the requirements for record retention are being increased. Records indicating that a GE organism that was imported or moved interstate reached its intended destination must be retained for at least 2 years after completion of importation or interstate movement, and all other records must be retained for at least 5 years after completion of all obligations required under a relevant permit or exemption. APHIS is also proposing changes to the nature of the records that are required, a topic discussed in greater detail in section E of this document, "E. Paperwork Reduction Act." Changes include a requirement to maintain records for activities done under a conditional exemption, as well as contracts and other information related to agreements between the responsible person and all agents that conduct activities subject to this part.

In a previous section of this proposal we discussed the types of records proposed as core permit conditions in § 340.3. We also propose to add certain recordkeeping requirements to § 340.7 that would apply not just to responsible persons exercising permits, but to all responsible persons and their agents engaged in the importation, interstate movement, or release into the environment of any GE organism that is subject to this part, including persons utilizing the conditional exemptions from permits.

In recent years, APHIS has accrued a great deal of experience in enforcing the regulations and investigating possible violations of them. This experience has helped us identify specific types of records that may not be required by the current regulations, but that are necessary for effective enforcement of the proposed regulations.[2] For example, in investigations of field trials we have found that we could not always obtain detailed maps for each planting area used during each season of the trial. This information is important for the efficient enforcement of the regulations. We also found that sometimes records of actual field trial operations over time were not sufficient to confirm that the procedures, equipment, and safeguards APHIS approved for a field trial were actually employed. That is, while existing records could generally confirm plans to use, for example, certain cleaning equipment or procedures at certain intervals, or to conduct plantings on certain dates, the records did not confirm that plans were actually carried out on the approved dates. We also found that records for some field trials did not identify which staff members or contractors were responsible for performing which duties, either during a field test or in the event of an unauthorized release that triggered the field test contingency plan. When responsibilities cannot be linked to specific individuals, it makes it very difficult to investigate possible violations. Another gap in necessary records we discovered through experience was the absence of clear written records of the responsibilities of different organizations, when several different entities were involved in a field trial. During investigations we may need to review not only any written contracts, but also any written agreements among researchers, developers, or other parties that are sharing performance of tasks required by the permit for a field trial.

The proposed regulations would allow APHIS to require these types of records. As APHIS considered the types of records needed to support the regulations it became apparent that regulations could not specify in a "one size fits all" fashion all record requirements that might be needed. Therefore, we propose to add those detailed record requirements of truly general applicability in § 340.3 and § 340.7. However, we also propose in § 340.3 that we would continue to impose any necessary additional record requirements appropriate to each permit situation as individual permit conditions.

Proposed § 340.7 also outlines the possible consequences of failure to comply with the regulations, including denial of future permits; revocation of current permits; destruction, treatment, and removal of GE organisms; issuance of penalties; and a means to settle alleged civil violations prior to the issuance of an administrative complaint.

Under this proposal, every person whose activities are within the scope of the regulations must comply with all the requirements of this part. Moreover, a responsible person can be held liable for the violation of any requirement of this part by any agent working for the responsible person (including persons contracted to conduct or carry out the environmental release on their own or on leased properties).

We propose to address remediation authority and procedures to a greater degree of detail than the current regulations. In proposed §§ 340.7(e) and (g) we explicitly state that the APHIS Administrator has the authority to take remedial actions in the event that an incident requires such actions. We also specify that the APHIS Administrator has the authority to order remedial action by others. These orders could take the form of an Administrative Order, Emergency Action Notification, or similar regulatory instrument. Additional information about these types of orders and related procedures are provided in administrative guidance on the APHIS Web site. The consequence for failure to abide by the orders of the Administrator is also described in proposed § 340.7, linking remediation to enforcement.

Finally, APHIS has clarified in the proposed regulations that in the event of a permit revocation, it may act or order action of the responsible person in the handling of the organisms, articles, or means of conveyances.

2. Low Level Presence of Regulated GE Plants in Seed or Grain

On March 29, 2007, APHIS published a **Federal Register** notice titled "Policy on Responding to the Low-Level Presence of Regulated Genetically Engineered Plant Materials" (72 FR 14649–14651; Docket No. APHIS–2006–0167. This notice described how APHIS responds when low levels of regulated GE plant materials occur in commercial seeds or grain that may be used for food or feed. This issue was also addressed in the DEIS in Issue 7. Both of these documents described how APHIS has addressed these occurrences in the past, and how the Agency intends to address them in the future. We are proposing to amend the current regulations to explicitly incorporate APHIS' low level presence policy.

As described in the DEIS, APHIS proposes to establish criteria under which the occurrence of a low level presence (LLP) of GE plant materials in seeds or grain may not be cause for agency remedial action. APHIS would still retain discretion to order corrective or remedial actions in situations that meet the non-actionable criteria, when the Administrator determines remedial action is needed to make the LLP unlikely to result in the introduction or dissemination of a plant pest or noxious weed. We propose to list criteria and describe possible enforcement actions in the regulations to improve transparency regarding how APHIS would respond to LLP in most instances. APHIS will not predetermine a specific level that is considered non-actionable as far as taking some remedial and/or enforcement action because this determination should always be made case-by-case. These criteria are intended to apply only to APHIS' decision to take or order remedial action in the event that LLP occurs. The proposed criteria are listed within the section describing the Administrator's ability to take or order remedial actions. Regardless of whether APHIS considers the LLP actionable with regard to remediation, any violations of the regulations or permit conditions could still result in any of the compliance and enforcement actions listed in the regulations, including imposing civil penalties.

APHIS is proposing a new provision in the regulations that would reflect the current policy cited above. The provision describes the criteria APHIS will use when determining that a LLP event would be non-actionable with regard to remediation, namely when the criteria support a conclusion that the

[2] Details of investigations that have led APHIS to propose expanded records requirements may be found in the "Lessons Learned" document cited above, and in investigation report documents on the APHIS Web site, e.g., "2007 Report of LibertyLink Rice Incidents" (*http://www.aphis.usda.gov/newsroom/content/2007/10/content/printable/RiceReport10-2007.pdf*) and "Transcript of Technical Briefing on Rice Investigation" (*http://www.usda.gov/wps/portal/!ut/p/_s.7_0_A/7_0_1OB?contentidonly=true&contentid=2007/10/0285.xml*).

LLP is unlikely to result in the introduction or dissemination of a plant pest or noxious weed. Because the criteria are safety-based, they will be used for incidents of low level presence originating domestically (e.g., from field testing) as well as any low level presence that might be detected in import shipments that may contain organisms subject to regulation.

APHIS also considered two additional criteria, which we have not adopted in the proposed rule. First, we considered a criterion that would require that the genetic material be introduced into the plant using a method that has been demonstrated to result in integration of the new sequences into the plant genome, as defined in § 340.1. We did not include this criterion in our proposal because its relevance in the LLP context is unclear. A second criterion considered was that the genetic material engineered into the GE plant does not encode substances with whose function APHIS is unfamiliar. APHIS did not adopt this criterion since it is redundant with the proposed criteria that will be used, i.e., that the function of the introduced genetic sequences is known and that key food safety issues have been addressed.

The DEIS, in Issue 7, Alternative 3, proposed that APHIS would also consider the LLP safety criteria when deciding whether to issue a permit for environmental release, and what type and severity of permit conditions to assign to the release permit. In its evaluation of permit applications, APHIS does plan to refer to the LLP criteria, as described above.

F. Administrative Changes

1. Confidential Business Information

APHIS is proposing a new § 340.8 to provide further guidance on the manner in which confidential business information (CBI) will be addressed in the implementation of these regulations. This change will support the overall administration of the program. The proposed § 340.8 cites the relevance of the Freedom of Information Act (FOIA) and exemptions from releasing information pursuant to FOIA, namely, 5 U.S.C. 552(b)(4), and states that APHIS may exempt from disclosure to the public trade secrets and commercial or financial information obtained from a person that are privileged or confidential. Proposed § 340.8 also states how persons wishing to protect confidential business information should communicate with APHIS in permit applications, petitions, or other submissions to APHIS.

2. Time Frames for APHIS Action on Permit Applications and Petitions

Current regulations specify time frames within which APHIS must take certain actions, such as issuing permits, acknowledging notifications or issuing decisions on petitions to grant nonregulated status. APHIS experience in the last several years has shown that the time required to complete these actions has increased beyond the time frames originally stipulated in the regulations in 1987 (permits) and 1993 (petitions for nonregulated status). As stated in the current regulation, APHIS is obligated to give its reply in the stipulated time, even if required procedures are not yet complete. Therefore, APHIS proposes to include in § 340.2(d) of the regulations a statement that APHIS will generally respond in the time frames indicated. APHIS believes it is important to continue to meet the indicated time frames whenever possible, but the most important thing is to communicate the actual status of reviews and procedures with applicants rather than be obligated to reach a decision in a certain number of days despite the complexities involved with a review. APHIS is particularly seeking comment on this proposed change from persons with experience under the current time frames.

3. Duration Period for Permits

Under the current regulations, notifications for environmental release and interstate movement are valid for one year, and the duration period for a permit issued for an environmental release is not specified. Currently interstate movement permits are only valid for one year from the date of issuance, and a new import permit must be obtained for each imported shipment.

APHIS will continue to retain the flexibility of the permitting procedure to authorize environmental release permits that can be effective for any appropriate time period. In some cases, it may be most efficient to authorize environmental release permits that are valid for more than a single year. In such cases, APHIS can retain adequate oversight by performing periodic inspections and requiring periodic reports. Experience has revealed situations where field tests lasting more than one year are essential. For example, some environmental releases of GE fruit trees may take several years to evaluate the fruit production that often does not begin for several years after planting.

In order to provide greater flexibility and efficiency, APHIS is also proposing to eliminate the current restrictions in the regulation on the duration of permits for interstate movement and importation. The proposed regulations will remove the requirements that interstate movement permits are only valid for one year from the date of issuance, and that importation permits must be obtained for each individual importation. These changes should give APHIS the flexibility to issue these permits with suitable durations to meet the individual circumstances.

G. Definitions and Miscellaneous Changes

APHIS proposes to change certain definitions in § 340.1 of the regulations, to add certain new definitions, and to remove definitions for terms that are defined in the PPA or that no longer appear in the regulations.

Revised Definitions

APHIS proposes to change the definitions of the following terms in § 340.1:

Release into the environment would read "Dispersal beyond the constraints of a contained facility or secure shipment. Synonymous with the term environmental release."

Secure shipment is a new term defined below. By adding reference to secure shipment in this definition, we clarify the distinction between environmental release and shipments for importation and interstate movement; any such movements which are not done by secure shipment constitute an environmental release.

Responsible person would read "The person who has control and will maintain control over a GE organism during its importation, interstate movement, or release into the environment and assures compliance with all conditions contained in any applicable permit or exemption as well as other requirements in this part. A responsible person shall be at least 18 years of age and be a legal resident of the United States or designate an agent who is at least 18 years of age and a legal resident of the United States." The change from the former definition is the addition of "at least 18 years of age," added to prevent possible enforcement difficulties.

New Definitions

APHIS proposes to add definitions of the following new terms:

Confidential business information, CBI would read "Information such as trade secrets or commercial or financial information that may be exempt from disclosure under Exemption 4 of the Freedom of Information Act (FOIA),

because disclosure could reasonably be expected to cause substantial competitive harm. USDA regulations on how the agency will handle CBI and how to determine what information may be exempt from disclosure under FOIA (5 U.S.C. 552) are found at 7 CFR § 1.12." We propose to add this definition because APHIS has often been asked to clarify what is and is not CBI, and how it is handled. The definition describes typical types of CBI, and the language in proposed § 340.8 describes how persons submitting documents to APHIS can request that identified information be treated as CBI. There is also additional guidance on CBI contained in administrative guidance on the APHIS Web site regarding document preparation for part 340 requests. However, it is important to realize that in actual situations where someone submits a FOIA request for particular information, the APHIS FOIA Officer makes the ultimate determination as to whether particular information shall be released, in accordance with the standards of FOIA, Executive Order 12600, and 7 CFR 1.12.

Contingency plan would read "A written plan stating how the responsible person will respond in the event of the unauthorized environmental release of GE organisms." We propose to define this new term to describe a document mentioned in both the permit application information requirements section (§ 340.2(c)) and the permit conditions section (§ 340.3).

Exempt, exempted, exemption would read "A determination by the Administrator that the importation, interstate movement, and/or release into the environment of an organism or class of organisms described in § 340.0(a) is not subject to the requirement to have a permit under this part. An exemption from one type of permit (e.g., interstate movement) does not remove remaining obligations to obtain other permits under this part." We propose to add this definition for the term *exemption* to refer to situations where a regulated movement is exempt from the requirement for a permit. The proposed definition is based on language in Sec. 411(b)(1) of the PPA (7 U.S.C. 7711(c)), titled "Exception to permit requirement," which authorizes the Secretary to issue regulations to allow the movement of specified plant pests without further restriction if the Secretary finds that a permit is not necessary.

Noxious weed would read "Any plant or plant product that can directly or indirectly injure or cause damage to crops (including nursery stock or plant products), livestock, poultry, or other interests of agriculture, irrigation, navigation, the natural resources of the United States, the public health, or the environment." This is the definition for noxious weed found in the PPA.

Recipient organism would read "The organism that will receive the genetic material from a donor organism in the process of genetic engineering (once the organism is engineered it is referred to as the genetically engineered (GE) organism)." This definition is needed to properly distinguish organisms and their traits in comparisons of GE organisms to the same organisms prior to transformation.

State or tribal regulatory official would read "State or tribal official with responsibilities for plant health, or any other duly designated State or tribal official, in the State or on the tribal lands where the importation, interstate movement, or release into the environment is to take place." This term is used in reference to consultations with States and tribes under the regulations.

Secure shipment would read "Shipment in a container or a means of conveyance of sufficient strength and integrity to withstand leakage of contents, shocks, pressure changes, and other conditions incident to ordinary handling in transportation."

We propose to add the following two definitions to make it clear that, when the Administrator authorizes it, a signature required under the regulations may be an electronic signature and a written document required under the regulations (e.g., a permit application) may be an electronic document.

Signature, signed would read "The discrete, verifiable symbol of an individual which, when affixed to a writing with the knowledge and consent of the individual, indicates a present intention to authenticate the writing. This includes electronic signatures when authorized by the Administrator."

Write, writing, written would read "Any document or communication required by this part to be in writing may also be provided by electronic communication when authorized by the Administrator."

Deletion of Definitions

We propose to remove the following definitions from the regulations: *courtesy permit, expression vector, introduce or introduction, regulated article, stably integrated, vector or vector agent,* and *well-characterized and contains only non-coding regulatory regions.*

These definitions would be removed because the terms would no longer be used in the regulations. We propose to eliminate the term *regulated article* partly because the use of the term "article" in current part 340 is not consistent with usage in the PPA, which uses the term article to mean "any material or tangible object that could harbor plant pests or noxious weeds"—that is, things like packing materials, shipping containers, commodities, etc.—and not a plant pest or noxious weed itself. Under the current regulation, however, *regulated article* refers exclusively to certain GE organisms. Furthermore, under both the PPA and part 340, "articles" are not regulated, but rather their importation, interstate movement or environmental release is regulated. For these reasons, the term "regulated article" in the current regulations is both inconsistent with the terminology of the PPA and difficult for the public to comprehend.

We also propose to remove the definition for introduction. APHIS currently uses the term in part 340 to denote certain kinds of activities that fall within the scope of the regulation, namely importation, interstate movement, and release into the environment. The PPA, however, does not specifically define the term introduction. Therefore, to avoid confusion, instead of using the term introduction to define the different types of regulated activities, APHIS will instead refer to these specific activities themselves in the regulations, namely, the importation, interstate movement and release into the environment.

Miscellaneous Changes

We also propose to make minor miscellaneous changes to the regulations to improve their clarity and remove redundancies. For example, in addition to adding the definition for CBI discussed above, we are consolidating requirements concerning CBI, formerly contained in several sections of the regulations, into proposed § 340.8.

IV. Required Analyses

A. National Environmental Policy Act

On January 23, 2004 (69 FR 3271), APHIS published a notice of intent to prepare a draft environmental impact statement (DEIS) in accordance with the National Environmental Policy Act in connection with the regulations at 7 CFR part 340 and potential changes to those regulations. This notice identified potential issues and alternatives to be studied and requested public comment to shape the scope of the DEIS.

On July 17, 2007, APHIS published the DEIS evaluating regulatory alternatives under consideration and solicited public comment on the DEIS

(72 FR 39021–39025). The Environmental Protection Agency published a separate notice on July 13, 2007, soliciting public comment on the DEIS (72 FR 38576–38577). The notices sought comments on the quality of our analysis of potential environmental effects of the alternatives under consideration, and also sought views on how each alternative would affect areas such as the overall effectiveness of our biotechnology program, its operational efficiency, industry compliance issues, or other issues that would be associated with the implementation of an alternative.

The major elements of this proposed rule were accurately described in the alternatives contained in the DEIS and their potential environmental effects were analyzed in the DEIS. Table 4 below provides a comparison between the proposed changes to part 340 and the DEIS. We received numerous comments on the DEIS, which will be discussed fully when we publish a final environmental impact statement (FEIS). The DEIS and the comments on it were used by APHIS to inform decision makers and aid the design of this proposal. Information from the DEIS comments, along with information from many other sources, including certain provisions of the 2008 Farm Bill and recommendations from USDA's OIG, was used to inform the drafters of this proposed rule about the issues perceived to be involved in and addressed by the rulemaking. We will respond to all DEIS comments in detail in the FEIS since the agency action (revising the regulations in part 340) is still subject to change based on comments and information received on this proposed rule, and thus we cannot provide definitive and final comment responses until we issue the FEIS and the final rule.

Consideration of the DEIS comments led APHIS to refine and reorganize some of the regulatory alternatives it considered. Therefore, the presentation and discussion of the alternatives proposed in this proposal do not exactly match those described in the DEIS. The differences are primarily a matter of reorganizing and realigning some material and their corresponding regulatory alternatives, using more descriptive terms in some criteria listed in the alternatives, and choosing between regulatory alternatives that fall within the analysis of the DEIS. Accordingly, the DEIS is still consistent and applicable as an analysis of the potential environmental effects of the proposed action. However, we are interested in receiving comments on whether any of the proposed regulatory alternatives in this document do not appear to have been adequately addressed within the DEIS.

TABLE 4—SUMMARY OF PROPOSED CHANGES TO THE REGULATIONS AND RELATIONSHIP TO DEIS

Summary of proposed substantive changes to the regulation	DEIS issue	DEIS alternative
Redescription of which GE organisms are subject to the regulations.	1	2 (DEIS preferred alternative) or 3.
Deletion of the list of plant pest taxa in the regulations and the petition procedure to amend the list.		
Clarification that APHIS has the authority to regulate nonliving materials through permit conditions in cases where such materials may pose a risk as a noxious weed.	5	2 (DEIS preferred alternative).
Revision of the application information requirements and permit conditions for all permit types.		
Elimination of the current notification procedure for importation, interstate movement, and release into the environment of certain types of GE plants (permitting procedure will be used instead).	2	4 (DEIS preferred alternative).
Revision of the permitting system for environmental releases:	2	4 (DEIS preferred alternative).
• Subdivision into 5 categories of permits for environmental releases (4 for GE plants, 1 for other GE organisms).	4	2 (DEIS preferred alternative).
• Continue strict permit conditions for environmental releases of GE plants engineered to produce compounds intended for pharmaceutical or industrial uses.	6	1 (No action alternative).
Continued use of permits with appropriate conditions for single or multiple year releases.		
Creation of new administrative procedures in permitting: (1) The explicit agreement of the responsible person to comply with regulatory requirements of the permit, (2) amendment of existing permit conditions, (3) transfer of permits to a different responsible person, and (4) revocation of a permit.		
Elimination of the prescribed shipping container provisions in favor of a performance based approach specified as permit conditions for importation and interstate movement.	10	2 (DEIS preferred alternative).
Revision of the existing conditional exemptions for interstate movement such that the shipping standard is part of the exemption. Addition of a recordkeeping requirement for persons using the existing conditional exemptions.		
Elimination of the option for APHIS to issue courtesy permits for importation, interstate movement, and environmental release of GE organisms which are not subject to the regulation.		
Creation of a petition procedure for the Administrator to approve additional conditional exemptions from the requirement for a permit. This also includes a description of administrative steps if Administrator revokes an exemption, amends the conditions of an exemption, or prohibits a person from using a conditional exemption.	3 8	2 (DEIS preferred alternative). 1 (DEIS No Action alternative).
Clarification and revision of the existing petition procedure for determining nonregulated status, including elimination of the procedure to extend a previous determination of nonregulated status, and a description of the administrative steps if Administrator revokes nonregulated status.		
Clarification of the actions the Administrator may take related to compliance, enforcement, and remediation.		
Clarification of APHIS approach to the low level presence of regulated GE plants in seed or grain.	7	3 (DEIS preferred alternative).
Definition of Confidential Business Information (CBI) and description of administrative practices for CBI.		

We received approximately 23,000 comments on the DEIS, of which more than 22,000 were variations of several form letters. There were also several lengthy and detailed evaluations of environmental, scientific, legal, cultural, and economic issues raised by the DEIS. APHIS took all comments related to regulatory changes under consideration as we developed the content of this proposed rule, and altered a number of preliminary ideas for the proposal based on comments. We will fully summarize and address the comments received on the DEIS in a Final Environmental Impact Statement to be prepared in conjunction with the publication of a final rule. In addition to specific DEIS issues that were discussed above in the Preamble, the following section summarizes and discusses those comments on the DEIS that were most directly related to the regulatory alternatives discussed in this proposed rule and the ways in which these comments affected development of the proposal.

Many DEIS commenters addressed how the regulations should use the PPA authorities regarding noxious weeds, plant pests, and biological control organisms. Most comments on the DEIS that addressed this issue stated that APHIS should expand the scope of its regulatory program beyond plant pests to include both noxious weeds and certain biological control organisms, consistent with all of the regulatory authorities of the PPA. The following opinions were expressed regarding PPA authority regarding noxious weeds and the meaning of the PPA definition of noxious weed.

Very few commenters suggested that APHIS biotechnology regulations should implement the PPA's noxious weed definition in its broadest possible sense. One commenter suggested that APHIS broadly interpret the phrase "other interests of agriculture," in the PPA definition of noxious weed such that APHIS would consider a plant to be a noxious weed if it poses solely economic harm, i.e., in the absence of physical harm. As explained previously in this proposal, such an interpretation is not consistent with the PPA, nor with the manner in which APHIS–PPQ has implemented the noxious weed program pursuant to the PPA. Many commenters suggested that APHIS needed clear regulations or policies to describe how it will be evaluating whether GE plants pose threats as noxious weeds. APHIS agrees and has framed this proposal to clarify the issue for the public.

Some commenters stated that APHIS should acknowledge limits to its consideration of potential damage to public health in APHIS regulations, and the noxious weed definition should not be interpreted so broadly as to provide APHIS with the legal responsibility or authority to determine the food safety of GE crops or to prevent GE crops from entering the food supply. The commenters stated that Congress clearly intended the FDA to be responsible in this area.

We agree, and this proposal acknowledges FDA authority in the food safety area. However, it is important that the regulatory procedures in each agency dovetail and support each other where agency mission areas come in contact. This proposal recognizes this need for mutual agency support. When a permit for environmental release, importation, or interstate movement of a new GE organism is submitted to APHIS, we would evaluate whether there are any signs that the environmental release, importation, or interstate movement of the organism could present risks to the public health. If APHIS is concerned that there may be food safety risks associated with the GE organism, we would contact FDA. The decision on whether or how to regulate food and feed from the GE organism to address food and feed safety risks would then be FDA's. On the other hand, it is also likely that existing food safety evaluations will prove to be useful and relevant to APHIS evaluations of a GE organism. Food safety concerns are one of several factors APHIS would take into account when considering, for example, what types of permit conditions are needed for the environmental release of a GE organism, or whether activities associated with the organism should qualify for an exemption from the permit requirement.

Several commenters stated that under the current regulations APHIS has always considered noxious weed risk, or at least "weediness." We agree that in practice, when APHIS assesses a GE plant it has always evaluated the potential weediness of the GE plant in relation to its plant pest potential. In the context of the PPA, "weediness" is more properly a noxious weed risk characteristic than a plant pest one, and the proposed revision of the regulations will more clearly align the regulations with the plant pest and noxious weed risk pursuant to the PPA. Current APHIS regulations and guidance directly address the importance of including weediness when evaluating risks associated with GE organisms. For example, when the petition procedure to grant nonregulated status was added to part 340 in 1993, the traits APHIS listed for evaluation explicitly included "weediness of the regulated article" (see current § 340.6(c)(4)).

Several DEIS commenters addressed what characteristics should trigger regulation of a GE organism, or put another way, how to set the scope of organisms subject to regulation. In the DEIS, APHIS explored many options including continuing to make its decisions primarily based upon the transformation event (also sometimes referred to as the individual transformed line, transgenic line or GE line). Some members of the public refer to this as an event-by-event approach. It is sometimes contrasted with a "trait-based" approach that focuses more on the resulting trait or phenotype of the GE organism. In a trait-based approach, a regulatory decision for an organism engineered for one phenotype would apply equally to other GE organisms if they had the same phenotype or trait, regardless of whether they were engineered with the same genes. APHIS invited comment on the relative merits of the event-by-event approach and the trait-based approach. The current regulations do not limit APHIS to one approach or the other. Many readers equated "event-by-event" with a "process-based" system and likewise equated "trait-based" regulation with a "product-based" system. Thus many comments focused on the relative merits of a product-based system versus a process-based system.

Some suggested that the trigger be "process-based", i.e., the process of modifying the organism by recombinant DNA techniques would be the determinant. Others suggested the trigger be "product-based", i.e., the nature of the resulting product (organism) would be the determinant for whether the organism would be subject to the regulation. Many of the comments were not actually related to the basis for the trigger, but rather to the focus of the risk assessment, with most stating that the risk assessments should be based on the biology of the organism (product-based), not the technique by which it was made (process-based). One commenter believes that the process of genetic engineering is a useful trigger, but once regulated, the characteristics of the GE organism should dominate APHIS considerations of safety.

Those supporting a process-based approach for identifying which organisms should be subject to regulation stated that each GE organism can have unintended as well as intended changes, and that these unintended changes to the organism would require that each individual resulting from genetic engineering must be assessed on a case-by-case basis.

Some commenters also suggested that this approach of APHIS assessment of each individual GE organism better protects the environment and human health than an approach that focuses primarily on the trait(s) of the GE organism.

Some commenters against process-based approach stated that this approach is illogical, on the one hand, to regulate a plant species with no known risks only because GE techniques were used to modify it, whereas on the other hand the same plant species modified by other techniques faces no additional regulatory requirements from APHIS.

Those supporting a product-based regulatory approach stated that it would be aligned with the preponderance of scientific opinion on the issue, that the characteristics of the organism should take precedence over the technique of genetic modification in the APHIS assessment of the organism. APHIS agrees that any evaluation of risk should be based on the biology of the product.

Several commenters suggested that the definition of *regulated article* would have to be reexamined and possibly redefined to reflect changes in the PPA. Commenters also stated that the term *regulated article* was problematic whether linked to specific taxa in § 340.2, under the current regulations, or linked to plants produced by particular technologies. These commenters emphasized that actions under the regulations usually amount to an investigation of whether an article (GE organism) needs to be regulated, and that predefining the subject of the investigation as a regulated article strongly implies that a decision has been made to require some regulatory oversight.

The proposed elimination of the term "regulated article" would facilitate a clearer understanding that it is not the GE organism that is regulated, but rather the importation, interstate movement, or release into the environment of the GE organism.

APHIS determined that eliminating "introduction" as a defined term would facilitate clearer understanding that the activities subject to the regulations are in fact importation, interstate movement, and release into the environment.

In the DEIS, APHIS discussed the need to regulate nonliving products of GE organisms. The preferred alternative was to have a procedure to regulate non-viable material only in certain rare circumstances when it might pose a risk. Most of the DEIS comments addressing this issue agreed that APHIS should regulate nonviable GE plant material only in certain circumstances, based on the risks posed. The few comments that provided greater detail identified toxicity risks and possible persistence in the environment of toxic nonviable plant parts or debris as the most significant risk associated with nonliving GE products. A few commenters also stated that adding a clear definition of "nonliving" or "nonviable" would aid the regulations.

APHIS has responded to these comments in this proposal by not usually regulating nonliving GE products, and by providing that when any control is needed over such a product that is associated with a living GE organism which is covered by a permit, due to toxicity or other risks, such controls would be included as permit conditions in permits issued for the associated living GE organism. We propose to provide for this by adding the following sentence to paragraph (b) of § 340.3, *Permit conditions:* "The Administrator may also assign permit conditions addressing nonliving materials associated with or derived from GE plants when such conditions are needed to make it unlikely that the nonliving materials would pose a noxious weed risk."

We received one DEIS comment directly addressing the issuance of courtesy permits. This comment supported retaining use of courtesy permits, and stated that courtesy permits facilitate the importation of GE *Drosophila melanogaster* strains by the research community and also ease the workload for APHIS. The continued issuance of courtesy permits diverts Agency resources unnecessarily from organisms that are within the scope of the regulations. We intend to help develop informational materials for the research community and other agencies that are aware of courtesy permits to clarify that such permits are not required, and to explain this to any persons who contact us requesting courtesy permits in the future.

Several DEIS comments addressed the notification procedure and supported eliminating it. Some comments suggested that the types of organisms formerly eligible for the notification process should instead be handled through a two-tiered permitting process, with experimental permits for field trials and commercial permits for GE crops that are to be sold in commerce. Other comments suggested that while some organisms might require permits with minimal conditions rather than notifications, others with even lower risks could be exempted from permit requirements. These latter comments also generally suggested that some of the criteria in the current regulations used to determine eligibility for the notification process could be preserved in the new regulations as criteria to identify organisms that should be exempted from the requirement for a permit. One commenter stated that since the current "notification" process involves acknowledgment by APHIS and conditions as well as notification, changing to a system of low risk permits would be a *de facto* acknowledgment of the current process. To address these issues, APHIS is proposing to eliminate notifications and to handle regulated GE organisms that previously would have been eligible for notifications through a permitting procedure.

We received a few comments on the DEIS generally related to procedures for reviewing permit applications. Comments stated that the role of States in reviewing or approving permit applications for GE crops has been very important and useful under the current regulations, and should continue in future regulations. Comments also stated the importance of scientific integrity in the review process, and emphasized the importance of coordinating with other agencies (particularly FDA and EPA review) when issues within their mission area arise during APHIS review of applications.

The proposed changes to the permit application procedure address these concerns. States would have a continuing role in application review that is very similar to their existing role, and we have been increasing interactions with the relevant tribal authorities in recent years.

Several comments were peripherally related to the DEIS issue of whether APHIS should establish standard or general permit conditions or what they should require. These comments emphasized that the purpose of permit conditions is to control risks not otherwise controlled, and that permit conditions must be developed in response to careful consideration of the risks presented by the particular permitted activity. One comment stated that APHIS should not require permit conditions that have the primary purpose of preventing crops from entering the food supply, because APHIS does not have the legal authority or scientific expertise to set them.

We have taken these views into account in designing this proposed rule. Proposed § 340.3 describes the core list of general conditions that APHIS would impose on all permits as well as additional conditions for specific types of permits. APHIS is also making it clear that APHIS may also add other specific

conditions to a permit upon its issuance. Conditions are specific practices or requirements that an applicant must follow upon issuance of a permit. Conditions are added as a consequence of the APHIS evaluation in order to make it unlikely that actions under the permit would result in the introduction or dissemination of a plant pest or noxious weed.

Several DEIS comments stressed that APHIS needs to do more to ensure that the permit conditions it sets are actually followed and enforced. The changes to permit procedures proposed for § 340.2 contribute to that goal by obtaining written agreement from the responsible person that he or she, and all of their agents, must comply with all of the permit conditions before issuance of the permit.

Almost all DEIS comments on containers or marking and identity for regulated articles supported performance standards for containers. Most of these commenters made the point that performance criteria are generally more adaptable and efficient than prescriptive criteria. Some stated that shipping research organisms interstate in enclosed containers is a low-risk activity that is very unlikely to result in release, establishment or harm.

Some commenters stated that the type of container indicated by performance standards must be appropriate to the level of risk in the tiered permit system for the shipped GE organism. One commenter requested that APHIS make its container standards consistent with the International Air Transporters Association (IATA) requirements for shipping.

The way this proposed rule deals with container standards is consistent with the above DEIS comments.

Most of the commenters addressing tiered or categorized permit systems supported APHIS establishing a tiered permitting system for plants based on criteria that included risk and other GE organism characteristics. However, commenters also stressed that risk categories should be based on a trait by species approach, not on the basis of individual transformed plant line (referred to as "event-by-event" in some of the comments). Some commenters advised against using limited broad based categories that include many different species with different biologies and different risk factors. Several stated the importance of evaluating permit applications on a case-by-case basis, to avoid the risk that categorizing permit types could result in approval of risky releases that were inadvertently seen as "routine categories."

Several commenters stated that a tiered permitting system should be flexible and allow consideration of any factors that seem relevant, or allow reclassification of a GE plant from one tier to another based on additional characterization information and agency familiarity with the GE plant. Some commenters opposed the development of a tiered risk-based permitting system because each transformation event can have unintended effects that must be assessed on a case-by-case basis, rather than through predefined categories. We have addressed these views in this proposed rule by changing the permit tier system described in the DEIS to a proposed permit application categorization system that is more flexible than the system described in the DEIS.

In the DEIS, APHIS considered whether to continue to issue environmental release permits for GE plants engineered to produce pharmaceutical and industrial compounds if the GE plant species is the same as, or sexually compatible with, a species commonly used for food or feed. APHIS concludes that the permitting procedure with its stringent permit conditions can continue to effectively minimize the risks that may be associated with the environmental release of such GE plants. APHIS will continue to impose appropriate permit conditions that take into account the issues related to the public safety of proteins or other substances that these plants have been engineered to produce.

Numerous commenters supported banning the outdoor production of pharmaceuticals and industrial substances in food and feed crops. Some stated that food crops should not be used for the production of pharmaceuticals and industrial substances.

Some commenters stated that GE plants used for the production of pharmaceuticals and industrial substances should be evaluated by criteria that are different from those used to evaluate crops intended for food. Other commenters stated that if such GE industrial plants were made from food crop species, or could spread genes to food crop species, they should be evaluated based on food safety risk, not the industrial product's function, and approved only if they pose no food safety risks. However, with regard to evaluating food safety, several commenters also stated that FDA should be the agency evaluating these risks.

We have not seen evidence suggesting that these types of organisms present unique or uncontrollable risks, or risks higher than those that may be associated with many other uses for GE plants. Our approach in this proposed rule addresses the other concerns cited by DEIS commenters.

Many commenters were concerned that the outdoor cultivation of GE plants producing pharmaceutical and industrial compounds could be a source of gene flow to nearby non-GE plants or result in the co-mingling of grain with related crop species intended for food or feed. Risks associated with this scenario may be abated by either of two means: (1) Preventing such gene flow or co-mingling from occurring, or (2) establishing that if such gene flow or co-mingling to other plants does occur, it does not present an unacceptable risk of introducing or disseminating a noxious weed.

Such gene flow can be minimized or substantially prevented through permit conditions developed for environmental releases of GE pharmaceutical or industrial plants. In many cases the genetic and phenotypic characteristics of the organism also serves to discourage survivability of the plant away from the intended site as well as gene flow to other plants. During the review prior to permit issuance, APHIS would also always consider the effects if the GE plant were likely to spread widely, or if large-scale gene flow to other plants occurred. A permit for an environmental release would not be approved if APHIS concluded there was a likelihood of such events causing any of the types of harm as described in the noxious weed definition.

One DEIS comment on the issue of multiple-year permits stated that compliance agreements should be used instead of actual multiple-year permits. Another suggested that multiple-year permits should be limited to trait/crop combinations not intended for feed or food use. In contrast, another comment stated that APHIS should consider allowing multi-year permits for any product, not just GE pharmaceutical or industrial plants.

Several commenters stated a risk-based opposition to multi-year permits and stated that crops engineered to produce pharmaceuticals or industrial compounds should always be regulated under an annually-reviewed permit system.

This proposed rule addresses the risk-based concerns cited by commenters in the proposed processes for issuing permits and granting exemptions, discussed elsewhere in this document. We propose to allow multi-year permits for any type of regulated activity, when we determine that appropriate risk-related conditions can be prescribed for those activities. We have not seen any

convincing evidence, in DEIS comments or elsewhere, that limiting use of multi-year permits to certain types of organisms would reduce risk or otherwise serve the purpose of the regulations.

Of the approximately 67 comments received by APHIS on the interstate movement exemptions discussion in the DEIS, 30 comments appear to support APHIS' preferred Alternative 2, under which APHIS would exempt from permit requirements for interstate movement a class of GE plants or organisms that are well-studied and present little or no environmental risk, as is currently done for *Arabidopsis*. However, many of these commenters suggested that APHIS choose an approach that combined this with one or more of the other Alternatives. Several commenters stated that the regulations should provide a procedure for APHIS to consider additional exemptions from interstate movement restrictions on a case-by-case basis.

APHIS has concluded that the most appropriate proposal for the regulations at this time is to provide a clear and adaptable procedure whereby it would use a case-by-case approach to consider the merits of new exemptions from the requirement for a permit. The procedure, described in proposed § 340.5, would allow for a transparent procedure in which APHIS would evaluate the proposed exemption, and the public would have an opportunity to review APHIS' evaluation and provide comments prior to APHIS decisions on individual cases. The proposed procedure should provide the benefit of transparency and scientific rigor while affording a more streamlined and cost-efficient procedure that would not require formal amendment of the regulations when each new exemption is approved.

Several DEIS comments addressed what criteria in the regulations the Agency could use to determine the level of risk assessment applied to imported GE commodities which are viable propagules. They fell into two general groups. Both groups stated that any expedited review or exemption for GE commodity imports needed to be granted based on a review of risk and a determination that the importation presented no significant risks. Beyond that, one group emphasized that commodity imports were in general inherently safe, and such an expedited system would be appropriate and would also greatly facilitate international trade. The other group was skeptical about inherent safety of GE commodities and suggested that exemptions should only be offered when there are procedures ensuring that the commodities are made non-viable or safeguards are in place to ensure that propagation will not occur. Some comments in this group also stated that such exemptions should not be granted for a GE commodity from any country until APHIS has confidence that the country has robust regulatory guidelines and assessment standards with strong, reliable science and trustworthy regulatory oversight, equivalent in effectiveness to the U.S. system.

One comment included a general statement that it was important that a petitioner for deregulation or exemption should work closely with APHIS to develop and evaluate the management plan under which the subject GE organism would be grown if deregulated or exempted. APHIS agrees that its regulatory approach should include working closely with petitioners on their proposals for exemption, especially if management plans are part of the requisite conditions. APHIS would retain some degree of oversight and could restrict movements of a GE organism such that the exemption and its conditions are unlikely to result in the introduction or dissemination of a plant pest or noxious weed. The proposed procedure to approve additional conditional exemptions is sufficiently adaptable even when the exemption is for all forms of movement (i.e., importation, interstate movement, and environmental release).

Very few DEIS comments directly addressed enforcement and compliance. A few comments stated that APHIS regulatory oversight and enforcement of its regulations in the past have been insufficient and have provided inadequate containment of GE crops. This proposed rule would strengthen enforcement and compliance and enhance the effectiveness of the regulations.

Comments on the discussion in the DEIS of low level presence ranged from suggestions that APHIS should completely prevent such incidents by banning all outdoor growth of GE plants to suggestions that LLP is a minor problem needing only minimal controls, and does not warrant an increased regulatory burden to control a minor risk. Some commenters stated that the preferred alternative in the DEIS accepted too high a level of risk. These commenters generally preferred DEIS alternative 4, which would impose very strict permit conditions on all environmental releases to reduce the likelihood of LLP events. Most commenters agreed that APHIS should adopt an LLP policy that recognizes the wide variety of risk levels associated with such incidents, and that beyond applying general criteria APHIS should investigate each unauthorized release individually and determine actions based on the facts surrounding each incident. Some commenters stated that any LLP policy should clearly state that even if an incident was found to be non-actionable (i.e., not requiring remedial action), persons involved would still be subject to enforcement actions such as civil penalties if violations of the regulations occurred.

APHIS has considered all these views in the development of this proposed rule and has attempted to find a reasonable balance. It is not warranted, or practical, to implement a "zero tolerance" LLP policy. Instead, we propose a policy that each LLP incident would be individually investigated, and APHIS would then make a decision on whether, or what kind of, remedial action is needed. In making this determination APHIS would use established criteria to rate the risks involved in the LLP incident. However, these criteria would not fully determine the APHIS response. In addition to considering the criteria, APHIS would evaluate any other relevant information regarding the LLP incident and order remedial action if it appears necessary.

Also, we propose to clearly state that regardless of whether APHIS considers the LLP actionable with regard to remediation, any violations of the regulations or permit conditions can still result in compliance and enforcement actions for failure to comply with the regulations.

One DEIS comment directly addressed timelines for APHIS to perform permit- and petition-related activities and urged APHIS to continue to define specific timelines for regulatory reviews to allow for a predictable regulatory review system. The comment stated that time frames are especially critical for field trial permitting activities since planting occurs during a narrow window each year and a delay of a month or two in a regulatory decision can result in a year delay due to the inability to timely plant a field trial.

We understand the concerns, and have decided to keep the time frames in the text of the regulations. However, as discussed above, APHIS will view them as performance goals and will generally respond in the time frames indicated, rather than be obligated to respond at those times. In recent years, there has been an increase in the time required for APHIS review due to the increasing complexity of issues related to environmental effects, new traits, and unfamiliar species. In addition to

retaining general time frames in the regulations, APHIS intends to discuss time frames with each applicant early in the application process, and to the extent possible give the applicant reliable time estimates based on the nature and complexity of the particular application and current APHIS activities and resources that are expected to affect the application review.

B. Executive Order 12866 and Regulatory Flexibility Act

This proposed rule has been reviewed under Executive Order 12866. The rule has been determined to be significant for the purposes of Executive Order 12866 and, therefore, has been reviewed by the Office of Management and Budget.

We have prepared an economic analysis for this proposed rule, which is summarized below. Copies of the full economic analysis are available by contacting the person listed under **FOR FURTHER INFORMATION CONTACT** or on the Regulations.gov Web site (see **ADDRESSES** above for instructions for accessing Regulations.gov). The analysis provides a cost-benefit analysis, as required by Executive Order 12866, and an analysis of the potential economic effects of this final rule on small entities, as required by the Regulatory Flexibility Act.

Background

The adoption of genetically engineered (GE) crops by farmers worldwide has become increasingly widespread. The United States, Argentina, Brazil, Canada, and China are the major GE crop adopters. In 2008, 92 percent of soybean, 80 percent of corn, and 86 percent of cotton acreages planted in the United States were genetically engineered (USDA NASS, 2008). In addition to the major field crops, GE varieties of papaya, yellow squash, and zucchini were available for commercial production in 2008.

Worldwide plantings of transgenic crops grew by 12 percent in 2007, reaching 282.4 million acres in 23 countries growing biotech crops in 2007, including 12 developing countries. Over the next decade, use of these "first-generation" GE crops, which carry traits such as insect resistance and herbicide tolerance, should continue to grow while a second generation of crops promises new applications and traits such as improved drought tolerance, biofuel-related enhancements, and quality and nutritional traits.[3]

[3] Global Status of Commercialized Biotech/GM Crops, ISAAA Briefs 37–2007, 35–2006, The International Service for the Acquisition of Agri-Biotech Applications, Cornell University.

The benefits associated with the use of some GE crops already in production include higher yields, lower pesticide costs, and overall savings in management time. There are also environmental benefits from reduced pesticide use. Attempts have been made to quantify the benefits that have occurred as a result of the adoption of GE crops and, according to a recent survey, farm-level net economic benefits worldwide from the adoption of GE crops were estimated to be $7 billion in 2006 (Brookes and Barfoot 2008). Total net benefits, 1996–2006, were estimated to be $34 billion. Of this total estimated net welfare gains, the United States experienced the largest benefit, with $15.8 billion; followed by Argentina, $6.6 billion; China, $5.8 billion; and Brazil, $1.9 billion (Brookes and Barfoot 2008). U.S. farmers' welfare gains from the adoption of biotechnology ranged from 29 to 42 percent of total net welfare gains (Price *et al.* 2005; Falck-Zepeda, Traxler, and Nelson 2000).

The high rate of GE crop adoption by farmers has been driven by an increase in consumption of product developed with the use of GE techniques. However, studies that quantify consumers' benefits from the use of biotechnology are limited, as most studies tend to focus on the direct adopters of biotechnology, i.e., the producers. Price *et al.* (2006) found consumers do benefit from the adoption of Bt cotton.

Overall, consumers' gains from the adoption of various GE crops have been estimated to range from 4 to 17 percent of total net welfare gains (Price *et al.* 2005; Falck-Zepeda, Traxler, and Nelson 2000).

Crop producers and consumers are not the only beneficiaries of recent advances in biotechnology. The providers of biotechnology have also benefited from the increased adoption of GE products. Intellectual property right laws have offered incentives for the private sector to invest in research and development of GE products, and as a result, plant breeding expenditures have largely shifted from the public to the private sector (Fuglie 2006). As private research spending has increased, so has the number of firms engaged in this type of research. However, consolidation and mergers during the 1990's resulted in an industry dominated by large companies. Currently, 80 percent of biotech traits that have been approved are owned or co-owned by four firms (Bayer Crop Science, DuPont, Monsanto, and Syngenta) or their subsidiaries (Kalaitzandonakes, Alston, and Bradford 2007).

With regard to the beneficial effects for the environment of GE plants in commercial production, their production has resulted since 1996 in decreases in the use of pesticides by 286 million kg and in the use of herbicides by 51 million kg (Brookes and Barfoot 2008). These declines represent 7.9 percent reductions. In terms of greenhouse gases, one study estimated cultivation using no-tillage systems associated with GE crops modified for herbicide tolerance to reduce fuel use by 32.52 liters/ha (89 percent) compared to conventional methods, and 14.7 liters/ha (76 percent) compared to reduced tillage methods (Jasa 2002). An American Soybean Association survey[4] showed significant reductions in tillage, and therefore in fuel use, by growers of glyphosate-tolerant soybeans. The fuel reductions were estimated as 1.26 gallons per acre, or, for the 56 million acres of glyphosate-tolerant soybeans planted in 2001, 70 million gallons of fuel saved and associated greenhouse gas emissions avoided. These fuel-use reductions translate into reductions of carbon dioxide emissions of 89.44 kg/ha and 40.43 kg/ha, respectively. Overall in 2006, the total carbon dioxide savings associated with the use of GE crops were 1.2 billion kg. This is equivalent to removing 540,000 cars from the streets for a year.

Benefits of the Proposed Rule

The proposed rule would provide benefits by establishing more efficient regulation of GE organisms and activities subject to part 340 and by continuing to provide a high level of protection against risks associated with these organisms and activities. Benefits would also include improved public understanding of and confidence in APHIS' biotechnology regulatory responsibilities, and improved clarity and transparency of the regulatory process. Several amendments of the proposed rule would improve the efficiency of APHIS' biotech regulatory process. Particular proposed changes that should improve the efficiency of the regulations include the elimination of courtesy permits and the establishment of a procedure to evaluate and grant requests for new exemptions from the requirement that GE organisms have a permit to be imported, moved interstate, or released into the environment.

Approving new exemptions could be done without amending the regulations, resulting in considerable time savings

[4] Cited in Fawcett, Richard and Towery, Dan. Conservation Tillage and Plant Biotechnology: How New Technologies Can Improve the Environment By Reducing the Need to Plow. Conservation Technology Information Center, West Lafayette, Indiana.

for regulated parties and reducing APHIS' rulemaking costs. Persons using an exemption would also avoid the costs and delays associated with obtaining a permit for each new planned movement or release of a GE organism covered by the exemption.

APHIS commits considerable resources to issuing courtesy permits not actually required by or needed to implement the part 340 regulations. These courtesy permits have been issued to facilitate the movement of GE organisms that are but whose movement may be hindered due to their similarity to organisms that are subject to part 340. By improving public awareness that such organisms do not need a permit and eliminating the courtesy permit process APHIS would improve efficiency and reduce its regulatory workload, and save time for regulated entities who would no longer make unnecessary courtesy permit requests.

The Agency currently issues environmental release permits, including permits that are used for production of pharmaceutical and industrial compounds sold in commerce. In general, permits for releases of plants producing pharmaceutical or industrial compounds have been limited to a one-year duration. However, the proposed regulations provide a more useful and efficient approach to setting appropriate risk-related conditions in multi-year environmental release permits. Under the proposed system, APHIS would likely increase issuance of multi-year environmental release permits, thereby reducing the time the regulated entities need to spend submitting applications as well as the time APHIS spends reviewing the permit applications.

APHIS' biotechnology operations would be aided by more clarity in terms of required data submissions and administrative procedures. More detail is provided regarding what applicant information is required for each permit application type, and how application information relates to the proposed new permit categories for environmental release permits. These changes, along with more clearly defined categories for the environmental release permits, would potentially reduce the time some entities, large or small, spend on an application or petition process. Increased efficiency benefits may be most helpful to smaller companies and public sector entities, where GE research is generally conducted on a much smaller scale than that of large agri-business enterprises.

The proposal includes provisions to require necessary recordkeeping and reporting but to fine-tune this burden through particularized permit conditions to require only what is needed to ensure regulatory compliance based on individual cases. This should contribute to greater efficiency.

The proposed rule's greater clarity and transparency is expected to enhance the general public's perception of APHIS regulation in this area, with associated benefits from increased support of and compliance with the regulations.

In addition to the information provided in the regulations, APHIS proposes to develop new guidance documents to assist in the preparation and submission of applications.

Costs of the Proposed Rule

There are several cost areas associated with the proposed rule. Costs associated with the proposed rule that regulated entities would incur include costs of learning and adapting procedures to changed requirements, providing more or different information in permit applications, and additional recordkeeping for some entities. The additional recordkeeping burden is discussed below in the Paperwork Reduction Act section. Annual costs resulting from the additional recordkeeping may be estimated as the salary and associated costs for 640 additional hours of recordkeeping divided among 160 respondents.

Many provisions of the proposed regulations are revisions of the current regulations, and it is not expected that familiarization costs would be substantial. However, estimates of these costs are not available and therefore APHIS invites public comment on the costs the regulated community may incur with respect to rule familiarization and changes to their application systems.

Costs to APHIS are currently incurred in the regulatory assessment and review of submitted materials. Because the new permit process is largely similar to the current process, it is expected that ongoing permit processing costs to APHIS would remain essentially unchanged. As a start-up cost to change the permit system to accommodate requirements of the proposed rule, APHIS may potentially incur a one-time additional cost of $500,000. However the current system is adaptable to the new regulations and it is not anticipated that there would be any efficiency loss during the transitional period. APHIS would also potentially incur incremental costs conducting outreach activities for the proposed rule, developing guidance documents to ensure that the regulated community is familiar with the requirements of the rule, and providing staff training that may be necessary. Because of the new definition of the scope of the regulations, APHIS may devote more resources to consultations with regulated parties if they request consultation to determine whether particular GE organisms are or are not subject to the regulations. Such consultation should decrease after the first year or two of implementation, as such determinations of regulated status accumulate and become the basis for guidance of general applicability.

Initial Regulatory Flexibility Analysis

In accordance with the Regulatory Flexibility Act of 1980 (Pub. L. 96–354), this analysis considers the economic impact of the proposed rule on small businesses, small organizations, and small governmental jurisdictions. Section 603 of the Act requires that the initial regulatory flexibility analysis (IRFA) be made available for public comments. This section addresses the IRFA requirements, as stated in Sections 603(b) and 603(c) of the Act.

Reasons Action Is Being Considered

APHIS is taking action to amend 7 CFR part 340, which was promulgated in 1987 under the authority of the Federal Plant Pest Act of 1957 and the Plant Quarantine Act of 1912. These acts were subsequently subsumed within the Plant Protection Act (PPA) of 2000, and the proposed revisions would bring part 340 in alignment with this Act. Advances in biotechnology and accumulation of oversight experience by APHIS have also made it necessary to revise and update the regulations, and in addition, the 2008 Farm Bill (The Food, Conservation, and Energy Act of 2008) enacted most recently contains provisions that need to be incorporated into the proposed rule. The proposed changes would improve the regulatory process by providing greater transparency, flexibility, and efficiency.

Objective and Legal Basis for the Rule

The objectives of this rule are to amend part 340 to provide consistency with the PPA authorities and to incorporate updates and improvements to provide a more efficient regulatory process while controlling potential risk to plant health and the environment. The PPA authorizes the Secretary of Agriculture to implement programs and policies designed to prevent the introduction and spread of plant pests and diseases. Specifically, the Secretary of Agriculture is given the authority under the PPA to prevent the importation or dissemination of plant pests and noxious weeds. To do so, the

Secretary may regulate the importation, interstate movement, and release into the environment of any plant, plant product, biological control organism, noxious weed, article, or means of conveyance that could potentially spread plant pests or noxious weeds.

Description and Estimate of the Number of Small Entities Regulated

The proposed rule may affect a wide range of public and private biotechnology research facilities, GE crop and seed production, food processors, grain processors, and paper producers that fall into various categories of the North American Industry Classification System (NAICS). For the purpose of this analysis and following the Small Business Administration (SBA) guidelines, the potentially affected entities are classified within the following sectors: Agriculture, Forestry, Fishing and Hunting (Sector 11), Manufacturing (Sectors 31–33), Wholesale Trade (Sector 42), Retail Trade (Sector 44 and 45), Transportation (Sectors 48 and 49), and Professional, Scientific and Technical Services (Sector 54).

For the Agriculture, Forestry, Fishing and Hunting sector, the subsectors of Crop Production, Animal Production, Forestry and Logging, and Support Activities for Agriculture and Forestry are potentially affected by this rule. The proposed rule may affect a wide range of establishments in the Crop Production category. Establishments in this category are considered small by SBA standards if annual sales are not more than $0.75 million. According to the 2002 Census of Agriculture, 97 percent of the farming businesses are considered small. Potentially affected crop-producing industries, with their NAICS codes in parentheses, are as follows: Soybean Farming (111110); Oilseed Farming (except soybean) (111120); Dry Pea and Bean Farming (111130); Wheat Farming (111140); Corn Farming (111150); Rice Farming (111160); Oilseed and Grain Combination Farming (111191); All Other Grain Farming (111199); Potato Farming (111211); Other Vegetable (except potato) and Melon Farming (111219); Orange Groves (111310); Citrus (except orange) Groves (111320); Apple Orchards (111331); Grape Vineyards (111332); Strawberry Farming (111333); Berry (except Strawberry) Farming (111334); Tree Nut Farming (111335); Fruit and Tree Nut Combination Farming (111336); Other Noncitrus Fruit Farming (111337); Mushroom Production (111411); Other Food Crops Grown Under Cover (111419); Nursery and Tree Production (111421); Floriculture Production (111422); Tobacco Farming (111910); Cotton Farming (111920); Sugarcane Farming (111930); Hay Farming (111940); Sugar Beet Farming (111950); Peanut Farming (111960); and All other Miscellaneous Crop Farming (111970).

Some aspects of animal production may be affected because some GE plants are used for animal feeds and may have enhanced nutritional value or other benefits. In terms of animal production, potentially affected entities include ones within the following industries: Beef Cattle Ranching and Farming (NAICS 112111); Cattle Feedlots (NAICS 112112); Hog and Pig Farming (NAICS 112210); Sheep Farming (NAICS 112410); Goat Farming (NAICS 112420); and Apiculture (NAICS 112910). Except for Cattle Feedlots, entities in all of these industries are considered small by SBA standards if annual sales are not more than $0.75 million. Cattle Feedlot establishments are considered small by SBA standards if annual sales are not more than $2 million. According to the 2002 Census of Agriculture, 93 percent of Cattle Feedlot businesses, 99 percent of Beef Cattle Ranching and Farming businesses, 81 percent of Hog and Pig Farming businesses, 99 percent of Sheep and Goat farming businesses, and 99 percent of Apiculture businesses are considered small.

For the Forestry and Logging subsector the potentially affected establishments are classified within Timber Tract Operations (NAICS 113110); Forest Nursery and Gathering of Forest Products (NAICS 113210); and Logging (NAICS 113310). Establishments in the category of Timber Tract Operations and Forest Nursery and Gathering of Forest Products are considered small by SBA standards if annual sales are not more than $6.5 million and establishments in the category of Logging are considered small if employment is not more than 500. According to the 2002 Survey of Business Owners, 99 percent of establishments in the Logging category are considered small. Neither the Census of Agriculture nor the Economic Census tracks revenue for establishments classified within Timber Tract Operations and Forest Nursery and Gathering of Forest Products.

In terms of Support Activities for Agriculture and Forestry, the potentially affected establishments are classified within Cotton Ginning (NAICS 11511); Soil Preparation, Planting, and Cultivating (NAICS 115112); Crop Harvesting (NAICS 115113); Postharvest Crop Activities (NAICS 115114); Farm Management Services (115116) Support Activities for Animal Production (NAICS 115210); and Support Activities for Forestry (NAICS 115310). Establishments in these categories are considered small by SBA standards if annual sales are not more than $6.5 million. However, neither the Census of Agriculture nor the Economic Census reports revenue for these establishments.

Entities that may be directly affected by the proposed rule in the Manufacturing Sector are classified within Ethyl Alcohol Manufacturing (NAICS 325193); Pesticide and Other Agricultural Chemical Manufacturing (NAICS 325320); Pharmaceutical Preparation Manufacturing (NAICS 325412); and Medicinal and Botanical Manufacturing (NAICS 325411). Establishments in the Ethyl Alcohol Manufacturing category are considered small if they employ not more than 1,000 persons and those in the category of Pesticide and Other Agricultural Chemical Manufacturing (NAICS 325320) are considered small if they employ not more than 500 persons. For both the Pharmaceutical Preparation Manufacturing (NAICS 325412); and Medicinal and Botanical Manufacturing (NAICS 325411) categories, establishments are considered small if they employ not more than 750 persons. According to the 2002 Economic Census, 98 percent of the establishments in the Chemical Manufacturing Sector had fewer than 500 employees and 99 percent had fewer than 1000. Therefore, businesses in the chemical manufacturing are predominantly small by SBA standards.

In terms of Wholesale Trade, entities that would be potentially affected may be found in the following categories: Fresh Fruit and Vegetable Merchant Wholesalers (NAICS 424480); Other Grocery and Related Products Merchant Wholesalers (NAICS 424490); Grain and Field Bean Merchant Wholesalers (NAICS 424510); Other Farm Product Raw Material Merchant Wholesalers (NAICS 424590); Farm Supplies and Merchant Wholesalers (NAICS 424910); and Flower, Nursery Stock, and Florists' Supplies Merchant Wholesalers (NAICS 424930). Establishments in the above categories are considered small by SBA standards if they employ not more than 100 persons. According to the 2002 Survey of Business Owners, 97 percent of the establishments in this category employed fewer than 100 people and are considered small by SBA standards.

Retail Trade, establishments that would be affected by the rules are in the following categories: Nursery and Garden Centers (NAICS 444220); Supermarkets and Other Grocery Stores (NAICS 445110); Fruit and Vegetable

Markets (NAICS 445230); All Other Specialty Food Stores (NAICS 445299); Food (Health) Supplement Stores (NAICS 446191); Warehouse Clubs and Superstores (NAICS 452910); and Florist (NAICS 453110). Establishments in the Nursery and Garden Center, Fruit and Vegetable Markets, All other Specialty Food Stores, Food (Health) Supplement Stores; and Florist categories are considered small by SBA standards if annual sales are not more than $6.5 million. Supermarkets and Other Grocery Stores are considered small by SBA standards if annual sales are not more than $25 million. While the Economic Census reports total annual sales, the Census does not provide a breakdown of these establishments by revenue categories.

In terms of the Transportation sector, the potentially affected entities are in the category Farm Product Warehousing and Storage (NAICS 493130). Establishments in this category are considered small by SBA standards if annual sales are not more than $23.5 million. However, the Economic Census reports only total revenue for all establishments in this category.

In terms of Professional, Scientific and Technical Services, establishments in the category of Research and Development in the Physical, Engineering, and Life Sciences (NAICS 54170) may be affected. Establishments in this category are considered small by SBA standards if they employ not more than 500 persons. According to 2002 Economic Census, 82 percent of the establishments in this category are considered small.

Although information was not available on the business sizes for all potentially affected establishments, based on the foregoing information we can assume that the majority of the entities that may be affected by the proposed rule are small by SBA standards.

Given the aforementioned, a review of entities that have made application requests to APHIS shows that of the 420 applicants for the last 6 years, 263 were universities and colleges and public and private research institutions. The remainder of the applicants fall under various NAICS classification codes specified above but given time constraints their business size could not be readily determined. We were able to ascertain that the 263 institutions (63 percent) are large by SBA standards as they fall under NAICS code 54170 Research and Development in Physical Science. Establishments in this category are considered small by SBA standards if they employ not more than 500 persons. Even though the 2002 Economic Census suggests that 82 percent of the establishments in this category are considered small, the majority of applicants to APHIS are large by SBA standards.[5]

Description and Estimate of Compliance Requirement

The proposed rule would require additional and modified information collections through recordkeeping, reporting, and notifications to APHIS when certain events occur. The proposed application process requires certain new information. The current and proposed rules both require submission of reports following an environmental release or field test, but the proposed requirement is more specific about the contents of such reports. Both the current and proposed rules require APHIS to be notified if an unauthorized release occurs or if during release the GE organism is found to have characteristics substantially different from those anticipated by the permit. The proposed rule is more specific about the types of records that must be kept for importations, interstate movements, and environmental releases, where the current regulations left more of these details to be specified only in permit conditions. In terms of record retention requirements, the proposed rule spells out a 2-year retention for records indicating that a GE organism imported or moved interstate reached its intended destination, and a 5-year retention for all other required records. By providing more specific information on what records are required, the proposed rule should alleviate some current burden that may result from persons keeping unnecessary records. In addition, APHIS has established the Biotechnology Quality Management System (BQMS), which is a voluntary compliance assistance unit within USDA APHIS. BQMS would facilitate the regulatory efforts of USDA APHIS by conducting outreach activities and providing compliance assistance to the regulated community. This would lessen any burden of the proposed rule to the regulated community.

Duplication, Overlap, and Conflict With Existing Rules and Regulations

APHIS has identified areas where the proposed rule will need to be closely coordinated with other Federal rules and statutory authorities. Coordination has been an important aspect of the daily implementation of the current regulation, and APHIS foresees additional areas for coordination under the proposed rule. In particular, APHIS will coordinate with the Food and Drug Administration (FDA) and the Environmental Protection Agency (EPA). FDA regulates GE organisms under the authority of the Federal Food, Drug and Cosmetic Act and the Public Health Service Act (42 U.S.C. 262 *et seq.*), as appropriate. The EPA regulates plant-incorporated protectants under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) and certain biological control organisms under the Toxic Substances Control Act (TSCA). As examples of areas that need coordination, some of the plant-incorporated protectants regulated by EPA are also subject to APHIS requirements under the PPA. Also, FDA is the primary U.S. agency responsible for ensuring the safety of commercial food and food additives, and FDA authority extends to any nonpesticidal substance that may be introduced into a new GE plant and that is expected to become a component of food. The proposed regulations would clarify the regulatory scope and procedures used by APHIS relative to these other agencies and improve the coordination process.

Significant Alternatives to the Rule

APHIS considered several significant alternatives during development of this proposed rule. We have compared the selected alternatives to others that were not selected to evaluate their feasibility and to consider whether any alternatives provide ways to minimize significant economic impacts on small entities. We have not identified any selected alternative that imposes disproportionate costs on small businesses, or any non-selected alternative that would both achieve the regulatory purposes and reduce costs for small businesses.

The selected alternative regarding the scope of the regulatory oversight was to add considerations of noxious weed risk in addition to evaluating plant pest risks, and to use genetic transformation, coupled with a determination by the Administrator as to whether a GE organism met certain risk-based criteria, as the trigger for regulation. Other alternatives considered included continuing to base the scope of regulation only on plant pest risks, or trying to develop a set of solely trait-based criteria that could be used to predict what articles would be regulated without the need for determinations by the Administrator. The first of these alternatives could have resulted in costs from damages caused by a GE plant with

[5] The size determination was made using public information about these entities. This information was primarily obtained from the entities' Web sites.

noxious weed aspects that was not regulated under the plant pest risks standard. The second alternative was not considered technically feasible, and could also have resulted in costs for persons who erroneously decide their GE plant is not within the scope of the regulations, but are overruled by a later determination by the Administrator that the GE plant is regulated.

The selected alternative for providing transparency and predictability to the permitting system was to establish permit categories for environmental releases of plants based on newly devised criteria. We also considered evaluating all requests for environmental release permits on a case-by-case basis, without categories. This alternative would have resulted in less predictability for applicants, and likely would have increased their costs for information collection because applications known to be in a particular category can contain less information about non-relevant areas.

The selected alternative regarding the duration period for permits was to make multi-year permits for interstate movement and importation more feasible by removing the one-year limit for interstate movement permits and the requirement to obtain a new importation permit for each imported shipment. We also considered alternatives to maintain either the current or alternative specific time limits for such permits. These alternatives would have resulted in additional costs for applicants who would have to reapply for permits, rather than having the original permit issued with an appropriate duration.

C. Executive Order 12372

This program/activity is listed in the Catalog of Federal Domestic Assistance under No. 10.025 and is subject to Executive Order 12372, which requires intergovernmental consultation with State and local officials. (See 7 CFR part 3015, subpart V.)

D. Executive Order 12988

This proposed rule has been reviewed under Executive Order 12988, Civil Justice Reform. If this proposed rule is adopted: (1) No State or local laws or regulations would be preempted by this rule; (2) no retroactive effect will be given to this rule; and (3) administrative proceedings will not be required before parties may file suit in court challenging this rule.

E. Paperwork Reduction Act

In accordance with section 3507(d) of the Paperwork Reduction Act of 1995 (44 U.S.C. 3501 *et seq.*), the information collection or recordkeeping requirements included in this proposed rule have been submitted for approval to the Office of Management and Budget (OMB). The information collection or recordkeeping requirements in current 7 CFR part 340 have been approved under OMB Control No. 0579–0085. Please send written comments to the Office of Information and Regulatory Affairs, OMB, Attention: Desk Officer for APHIS, Washington, DC 20503. Please state that your comments refer to Docket No. APHIS–2008–0023. Please send a copy of your comments to: (1) Docket No. APHIS–2008–0023, Regulatory Analysis and Development, PPD, APHIS, Station 3A–03.8, 4700 River Road Unit 118, Riverdale, MD 20737–1238, and (2) Clearance Officer, OCIO, USDA, room 404–W, 14th Street and Independence Avenue SW., Washington, DC 20250. A comment to OMB is best assured of having its full effect if OMB receives it within 30 days of publication of this proposed rule.

This proposed rule contains certain information collection and recordkeeping requirements that would apply to persons and their agents engaged in the importation, interstate movement, or release into the environment of any GE organism that is subject to the regulations. The majority of the requirements would apply to persons moving GE organisms under a permit issued by APHIS, but some requirements also apply to persons engaged in regulatory activities with GE organisms even when no permit is required, e.g., when they are exempted from the interstate movement permit requirement.

The proposed information and recordkeeping requirements are found in § 340.3, *Permit conditions*, and in § 340.7, *Compliance, enforcement, and remedial action*. Permit conditions for individual permits issued under the regulations may also require that certain records relevant to the particular movement must be kept.

The proposed permit conditions for shipments imported or moved interstate include maintaining records of the same types of information that the current regulations require to be on the package labeling of such shipments (nature and quantity, sender, destination, permit number, etc.) We believe that most persons shipping or importing GE organisms already maintain such records as part of normal business practices.

The proposed permit conditions for environmental releases include keeping records of all protocols or guidelines used to direct any environmental release. The current regulations already require persons conducting an environmental release under permit or notification to create and submit to APHIS a field test report, and in many cases the protocol or guidelines would normally be included in these field reports. This proposed change would require that the protocols or guidelines be kept in all cases as distinctly identifiable records, which may cause some increase in recordkeeping burden.

In some particular environmental release cases where higher risk levels make it necessary, the proposed rule would allow APHIS to add a special permit condition requiring the permit holder to maintain and make available to APHIS written manuals or protocols describing how specified permit conditions will be met, such as management practices used for the environmental release, training, communications, and identity preservation systems. This would be used in cases where it is deemed necessary to provide specific guidance in addition to the proposed general condition for all permits (i.e., that the holder must keep records related to permitted activities of sufficient quality and completeness to demonstrate compliance with all permit conditions and requirements under this part). Another proposed permit condition would require permit holders to develop and keep a written contingency plan to respond to any unauthorized environmental release. Both of these recordkeeping requirements would be added because some researchers or developers were found to be unclear about what management and communications practices were needed to prevent unauthorized releases, and also about their responsibilities and the measures they must take in the event of an unauthorized release.

The proposed procedure to apply for an environmental release permit requires applicants to submit a great deal of information characterizing the nature of the GE organism, the type of movement and release planned, plans and methods used to prevent unauthorized releases, and other matters. Most of the same information is obtained through the current application process, which allows the Administrator to require an applicant to submit any additional information that is needed for adequate evaluation of the application. The proposed application procedure is more specific in describing what information is required, and may result in a slight increase in the amount of information submitted with the average application.

The reporting burden for permit holders under the proposed rule would be similar to the burden under the

current regulations. In both cases they must submit reports of all field tests to APHIS, report any unauthorized releases, and submit any additional reports required as individual permit conditions in their permits.

The current regulations do not specify record retention periods, although some permits APHIS issued included specific retention requirements as permit conditions. This proposal would require that records associated with an importation or interstate shipment must be retained for at least 2 years after completion of the movement, and all other records (e.g., regarding environmental releases) must be retained for at least 5 years after completion of all obligations required under a relevant permit or exemption.

We are soliciting comments from the public (as well as affected agencies) concerning our proposed information collection and recordkeeping requirements. These comments will help us:

(1) Evaluate whether the proposed information collection is necessary for the proper performance of our agency's functions, including whether the information will have practical utility;

(2) Evaluate the accuracy of our estimate of the burden of the proposed information collection, including the validity of the methodology and assumptions used;

(3) Enhance the quality, utility, and clarity of the information to be collected; and

(4) Minimize the burden of the information collection on those who are to respond (such as through the use of appropriate automated, electronic, mechanical, or other technological collection techniques or other forms of information technology; e.g., permitting electronic submission of responses).

Estimate of burden: Public reporting burden for this collection of information is estimated to average 2 hours per response.

Respondents: Public and private biotechnology research facilities, GE crop and seed producers, food processors, grain processors, and paper producers that fall into various categories of the North American Industry Classification System.

Estimated annual number of respondents: 160.

Estimated annual number of responses per respondent: 2.

Estimated annual number of responses: 320.

Estimated total annual burden on respondents: 640 hours.

Copies of this information collection can be obtained from Celeste Sickles, the Agency Information Management Specialist, at (301) 851–2908.

F. E-Government Act Compliance

The Animal and Plant Health Inspection Service is committed to compliance with the E-Government Act to promote the use of the Internet and other information technologies, to provide increased opportunities for citizen access to Government information and services, and for other purposes. For information pertinent to E-Government Act compliance related to this proposed rule, please contact Mrs. Celeste Sickles, the Agency Information Management Specialist, at (301) 851–2908.

List of Subjects in 7 CFR Part 340

Administrative practice and procedure, Biotechnology, Genetic engineering, Imports, Packaging and containers, Permits, Plant diseases and pests, Noxious weeds, Transportation.

Accordingly, we propose to revise 7 CFR part 340 to read as follows:

PART 340—IMPORTATION, INTERSTATE MOVEMENT, AND RELEASE INTO THE ENVIRONMENT OF CERTAIN GENETICALLY ENGINEERED ORGANISMS

Sec.

340.0 Scope and general restrictions.
340.1 Definitions.
340.2 Procedure for permits.
340.3 Permit conditions.
340.4 Conditional exemptions from the requirement for a permit for interstate movement.
340.5 Petition for new conditional exemptions from the requirement for a permit.
340.6 Petition for nonregulated status.
340.7 Compliance, enforcement, and remedial action.
340.8 Confidential business information.
340.9 Costs and charges.

Authority: 7 U.S.C. 7701–7772 and 7781–7786; 31 U.S.C. 9701; 7 CFR 2.22, 2.80, and 371.3.

§ 340.0 Scope and general restrictions.

(a) In order to prevent the unauthorized introduction or dissemination of a plant pest or noxious weed, no person shall import, move interstate, or release into the environment genetically engineered organisms described in paragraph (b) of this section, unless the importation, interstate movement, or release into the environment:

(1) Is authorized under a permit issued by the Administrator in accordance with § 340.2, or

(2) Is exempt from the requirements for a permit in accordance with § 340.4 or § 340.5, or

(3) Is approved for nonregulated status in accordance with § 340.6 or has previously been approved for nonregulated status pursuant to former regulations under this part, or

(4) Is excluded in accordance with paragraph (d) of this section.

(b) Genetically engineered organisms whose importation, interstate movement, or release into the environment is subject to the regulations in this part are:

(1) Genetically engineered plants if:

(i) The unmodified parent plant from which the GE plant was derived is a plant pest or noxious weed, or

(ii) The trait introduced by genetic engineering could increase the potential for the GE plant to be a plant pest or noxious weed, or

(iii) The risk that the GE plant poses as a plant pest or noxious weed is unknown, or

(iv) The Administrator determines that the GE plant poses a plant pest or noxious weed risk.

(2) Genetically engineered non-plant, non-vertebrate organisms if:

(i) The recipient organism can directly or indirectly injure, cause damage to, or cause disease in plants or plant products; or

(ii) The GE organism has been engineered in such a way that it may increase the potential for it to be a plant pest: or

(iii) The risk that the GE organism poses as a plant pest is unknown, or

(iv) The Administrator determines that the GE organism poses a plant pest risk.

(3) *Opportunity to consult APHIS.* Any person may contact APHIS to discuss how the criteria of this paragraph apply in the case of a particular GE organism or group of organisms.

(c) The Administrator may issue permits for the importation, interstate movement, or release into the environment of certain genetically engineered organisms described in paragraph (a) of this section. These permits may include such requirements or conditions as the Administrator deems necessary to prevent the unauthorized introduction or dissemination of a plant pest or noxious weed. The Administrator may also designate certain exemptions from the requirement to obtain permits. The Administrator may also approve for nonregulated status a genetically engineered organism described in paragraph (a) of this section for which a determination has been made by the Administrator that the organism is unlikely to be a plant pest or noxious weed.

(d) Genetically engineered microorganisms that are regulated as biological control organisms under the Federal Insecticide, Fungicide, and Rodenticide Act are not subject to the regulations in this part. Genetically engineered microorganisms where the recipient microorganism is not a plant pest and which has resulted from the addition of genetic material from a donor organism where the material is well characterized and contains only non-coding regulatory regions are not subject to the regulations in this part.

§ 340.1 Definitions.

Terms used in the singular form in this part shall be construed as the plural, and vice versa, as the case may demand. The following terms, when used in this part, shall be construed, respectively, to mean:

Administrator. The Administrator of the Animal and Plant Health Inspection Service (APHIS) or any other employee of APHIS to whom authority has been, or may be, delegated to act in the Administrator's stead.

Animal and Plant Health Inspection Service (APHIS). An agency of the United States Department of Agriculture.

Confidential business information, CBI. Information such as trade secrets or commercial or financial information that may be exempt from disclosure under Exemption 4 of the Freedom of Information Act (FOIA), because disclosure could reasonably be expected to cause substantial competitive harm. USDA regulations on how the agency will handle CBI and how to determine what information may be exempt from disclosure under FOIA (5 U.S.C. 552) are found at 7 CFR 1.12.

Contained facility, contained structure. A physical structure designed to minimize release into the outdoor environment. Examples of contained structures include, but are not limited to, laboratories, containment greenhouses, bioreactors, and fermenters.

Contingency plan. A written plan stating how the responsible person will respond in the event of the unauthorized environmental release of GE organisms.

Donor organism. The organism from which genetic material is obtained for transfer to the recipient organism in the process of genetic engineering.

Environmental release. See definition of *Release into the environment.*

Exempt, exempted, exemption from permit. A determination by the Administrator that the importation, interstate movement, and/or release into the environment of an organism or class of organisms described in § 340.0(a) is not subject to the requirement to have a permit under this part. An exemption from one type of permit (e.g., interstate movement) does not remove remaining obligations to obtain other permits under this part.

Genetic engineering. The genetic modification of organisms by recombinant DNA techniques.

Genetically engineered, GE. A term applied to organisms that have been produced by genetic engineering, e.g., GE organisms, GE plants.

Import and importation. To move into, or the act of movement into, the territorial limits of the United States.

Inspector. Any employee of the Animal and Plant Health Inspection Service, U.S. Department of Agriculture, or other person, authorized by the Administrator, in accordance with law to enforce the provisions of this part.

Interstate movement. Movement from any State into or through any other State.

Means of conveyance. Any personal property used for, or intended for use for, the movement of any other personal property. This specifically includes, but is not limited to, automobiles, trucks, railway cars, aircraft, boats, freight containers, and other means of transportation.

Nonregulated status. A determination by the Administrator that an organism described in § 340.0(a) is not subject to any of the regulatory requirements of this part.

Noxious weed. Any plant or plant product that can directly or indirectly injure or cause damage to crops (including nursery stock or plant products), livestock, poultry, or other interests of agriculture, irrigation, navigation, the natural resources of the United States, the public health, or the environment.

Organism. Any active, infective, or dormant stage or life form of an entity characterized as living, including vertebrate and invertebrate animals, plants, bacteria, fungi, mycoplasmas, mycoplasma-like organisms, as well as entities such as viroids, viruses, or any entity characterized as living, related to the foregoing.

Permit. A written authorization by the Administrator for the importation, interstate movement, and/or release into the environment of a GE organism under this part.

Person. Any individual, partnership, corporation, company, joint venture, society, association, or other legal entity.

Plant. Any plant (including any plant part) for or capable of propagation, including trees, tissue cultures, plantlet cultures, pollen, shrubs, vines, cuttings, grafts, scions, buds, bulbs, roots, and seeds.

Plant pest. Any living stage of any of the following that can directly or indirectly injure, cause damage to, or cause disease in any plant or plant product: A protozoan, a nonhuman animal, a parasitic plant, a bacterium, a fungus, a virus or viroid, an infectious agent or other pathogen, or any other living stage similar to or allied with any of these organisms.

Plant product. Any flower, fruit, vegetable, root, bulb, seed, or other plant part that is not included in the definition of plant; or any manufactured or processed plant or plant part.

Recipient organism. The organism that will receive the genetic material from a donor organism in the process of genetic engineering (once the organism is engineered it is referred to as the genetically engineered (GE) organism).

Release into the environment. Dispersal beyond the constraints of a contained facility or secure shipment. Synonymous with the term environmental release.

Responsible person. The person who has control and will maintain control over a GE organism during its importation, interstate movement, or release into the environment and assures compliance with all conditions contained in any applicable permit or exemption as well as other requirements in this part. A responsible person shall be at least 18 years of age and be a legal resident of the United States or designate an agent who is at least 18 years of age and a legal resident of the United States.

Secure shipment. Shipment in a container or a means of conveyance of sufficient strength and integrity to withstand leakage of contents, shocks, pressure changes, and other conditions incident to ordinary handling in transportation.

Signature, signed. The discrete, verifiable symbol of an individual which, when affixed to a writing with the knowledge and consent of the individual, indicates a present intention to authenticate the writing. This includes electronic signatures when authorized by the Administrator.

State. Any State of the United States, the District of Columbia, American Samoa, Guam, Northern Mariana Islands, Puerto Rico, the Virgin Islands of the United States, and any other Territories, Possessions, or Districts of the United States.

State or tribal regulatory official. State or tribal official with responsibilities for plant health, or any other duly designated State or tribal official, in the

State or on the tribal lands where the importation, interstate movement, or release into the environment is to take place.

United States. All of the States.

Write, writing, written. Any document or communication required by this part to be in writing may also be provided by electronic communication when authorized by the Administrator.

§ 340.2 Procedure for permits.

(a) *General.* A permit is required for the importation, interstate movement, or release into the environment of any GE organism that is subject to this part, as described in § 340.0, The responsible person seeking a permit for the importation, interstate movement, or release into the environment of such organisms shall submit a written application for a permit to APHIS in accordance with paragraph (c) of this section and obtain the permit prior to the importation, interstate movement, or release into the environment.

(b) *Types of permits.* The Administrator may issue the following three types of permits under this part.

(1) *Import permit.* Import permits are for secure shipment via any means of conveyance from outside the United States into contained facilities within the United States.

(2) *Interstate movement permit.* Interstate movement permits are for secure shipment via any means of conveyance from a contained facility in any State into or through any other State to another contained facility.

(3) *Environmental release permit.* Environmental release permits are for the environmental release of GE organisms. In cases in which importation and interstate movements will occur incidental to an environmental release, the importation and interstate movements will also be authorized under the environmental release permit.

(c) *Permit application information requirements.* Applicants must submit to APHIS sufficient information about the specific nature of the GE organism and the particular proposed permit conditions, so that the Administrator is able to consider whether the proposed importation, interstate movement, or release into the environment is likely to result in the introduction or dissemination of a plant pest or noxious weed. The basic information required in permit applications is described in this paragraph. The type and level of detail needed for the Administrator to issue a permit may vary by type of permit. For environmental releases, application information will be used to sort proposed releases of GE organisms into administrative categories described in paragraph (d) of this section. Applicants should consult with APHIS prior to applying for permits in order to obtain further guidance as to what additional information the Administrator may require to be submitted with the application.

(1) *Information required in all permit applications.* Each application must include all of the following information, and any other information specified for individual types of permits as described in this paragraph:

(i) The name, title, and contact information (e.g., mailing address, e-mail, telephone and fax numbers) of the responsible person;

(ii) The type of permit sought (importation, interstate movement, or environmental release, and if the permit is for environmental release, which category);

(iii) Information necessary to identify and characterize the GE organism(s) for which a permit is sought, including:

(A) The scientific names of all donor and recipient species plus any designations used for the GE organism(s) (e.g., strain, line, variety);

(B) The form of the GE organism (e.g., seeds, rootstocks, tubers, spores, larvae, eggs) and the amount (e.g., numbers, total weight or volume); and a description of any biological material accompanying the GE organism under permit (e.g., culture medium, or host organisms, etc.);

(C) The anticipated phenotype of the GE organism and the nature of the inserted sequences or other genetic modification intended to confer the phenotype;

(D) Intended uses of the GE organism after the termination of the importation, interstate movement, or environmental release (e.g., contained research in laboratories or containment greenhouses, culturing, propagation, breeding, processing for analysis or manufacture, sale and distribution for consumption); and

(E) Description of how the GE organism will be marked, labeled, or otherwise identified during the importation, interstate movement, or environmental release;

(iv) The proposed time frame (estimated start and duration) within which the importation(s), interstate movement(s) or environmental release(s) will occur;

(v) Description of how permit requirements will be communicated to persons having contact with the GE organism under permit;

(vi) Description of any training given to persons having contact with the GE organism under permit, including but not limited to detailed information on how this training will facilitate compliance with conditions imposed under the permit and any other regulatory requirements under this part; and

(vii) A certification statement signed by the responsible person that certifies that the application information is correct.

(2) *Additional information required in all applications for importation permits, interstate movement permits, and all environmental release permits that include importation or interstate movement.*

(i) The location(s) of the origin(s) and destination(s), including information on the addresses, and contact details of the sender(s) and recipient(s), if different from the responsible person.

(ii) A description of the method of secure shipment.

(iii) A description of the manner in which packaging material, shipping containers, and any other material accompanying the GE organism will be disposed.

(3) *Additional information required in all environmental release permit applications.* Information should address the persistence risk and potential harm of the GE organism in the environment, including but not limited to:

(i) A description of how the phenotype of the GE organism differs from the phenotype of the recipient organism, particularly with respect to potential interactions with and its likelihood of persistence in the environment.

(ii) The location and size of all proposed release sites, including area, geographic coordinates, addresses, and contact information of a person at each release site, if different from the responsible person. Include information about the ecology and agronomy of each site, including but not limited to:

(A) Presence of any wild or cultivated species that are sexually compatible with the GE organism;

(B) Presence of any Federally-listed threatened or endangered species that could interact with the GE organism during the release;

(C) Presence of any designated critical habitat, or habitat proposed for designation, in the area of the release site; and

(D) Land use history of the site and adjacent areas.

(iii) A description of the site management practices and control procedures designed to make it unlikely that there will be unauthorized introduction or dissemination of the GE organism beyond the proposed area and

the permit time frame of release. Each of the descriptions shall include:

(A) Description of the methods and stages of transport of the GE organism from a contained facility to the environmental release site, and any storage methods used at the site;

(B) Description of methods of planting, inoculation, or release; any reproductive or cultural controls; methods of treatment and harvest used for the GE organism; and a proposed plan for monitoring the site for pests, diseases, and effects on other organisms during the time the GE organism is released;

(C) Description of the methods and stages of transport of the GE organism from release site back into contained facilities, or methods of devitalization at the site(s) of the environmental release;

(D) Description of the cleaning, disinfection, or other methods used to make it unlikely that unauthorized dissemination of the GE organism into the environment could occur via means of conveyance and other articles (e.g., planters, harvesters, containers);

(E) Description of any post-release land use practices, including any monitoring plans to ensure that the GE organism or its progeny are unlikely to reproduce and disseminate in the environment after the termination of the release (e.g., managing volunteer plants); and

(F) Description of the contingency plans associated with the release.

(d) *Administrator action on permit applications.* An initial review should generally be completed by APHIS within 15 days of the receipt of the application for importation or interstate movement permits, and within 30 days for environmental release permits. An application will be considered complete when the Administrator determines that it includes all information required by this section and any additional information that the Administrator determines is needed for review. If necessary after its initial evaluation of an application, APHIS will notify the applicant in writing if the submitted application information is incomplete, and the applicant will be provided the opportunity, without prejudice, to revise the application information to meet the needs for administrative processing and scientific review. Once the Administrator has determined that an application is complete, the Administrator will commence review. The APHIS review should generally be completed within 60 days after it is determined to be complete for importation and interstate movement permits, and within 120 days after it is determined to be complete for environmental release permits.

(1) *Administrative categories for environmental releases.* The Administrator will use the following categories to efficiently administer the program and tailor regulatory oversight in a manner that is commensurate with risk. Environmental releases of GE plants are assigned to one of four categories (A–D), using the factors described in (i–iv). A fifth category (E) is for environmental releases of all non-plant organisms; applications in this category will be reviewed on a case-by-case basis.

(i) *Initial sorting into categories.* The Administrator will use the following factors to initially sort environmental releases into administrative categories.

(A) Persistence of the nonmodified plant, ranked as follows:

(*1*) *Low:* Populations of the recipient plant are unlikely to persist in the environment without human intervention, and the recipient plant has no interfertile wild relatives in the United States.

(*2*) *Moderate:* Populations of the recipient plant are known to be weakly persistent in the environment without human intervention, or the recipient plant has interfertile wild relatives in the United States.

(*3*) *High:* Populations of the recipient plant are known to be strongly persistent in the environment without human intervention, or the recipient plant has interfertile wild relatives in the United States which are aggressive colonizers.

(*4*) *Severe:* The recipient plant is a Federally-listed noxious weed or is known to be similarly aggressive in its ability to colonize and persist in the environment without human intervention.

(B) Potential harm or damage of the engineered traits, ranked as follows:

(*1*) *Low:* Any new proteins or substances produced are unlikely to be toxic or otherwise cause serious harm to humans, vertebrate animals, or invertebrate organisms upon consumption of or contact with the plant or plant parts; and

(*i*) No morphological changes which could cause mechanical injury or damage; and

(*ii*) Introduced sequences are known not to result in plant disease, and confers no or very low increased disease susceptibility.

(*2*) *Moderate:* Any new proteins or substances produced are unlikely to be toxic or otherwise cause serious harm to humans or vertebrate animals upon consumption of or contact with the plant or plant; or

(*i*) Novel resistance to the application of an herbicide; or

(*ii*) Novel ability to cause mechanical injury or damage; or

(*iii*) Produces proteins or substances that are associated with plant disease that are not prevalent or endemic in the area of release, or that confer an increased susceptibility to disease.

(*3*) *High:* Any new proteins or substances produced may be toxic or to otherwise cause serious harm to humans or vertebrate animals, upon consumption of or contact with the plant or plant parts; or

(*i*) Produces an infectious entity which can cause disease in plants.

(*4*) *Severe:* Any new proteins or substances produced are known or likely to be highly toxic or fatal to humans or vertebrate animals, upon consumption of or contact with the plant or plant parts.

(C) Environmental releases will be initially sorted into administrative categories A–D as shown in Table 1, based upon the persistence risk and potential harm described in paragraphs (d)(1)(i)(A) and (B) of this section.

TABLE 1 TO § 340.2(d)(1)—INITIAL SORTING INTO PERMIT ADMINISTRATIVE CATEGORIES (A, B, C, AND D) FOR ENVIRONMENTAL RELEASES OF GE PLANTS, BASED UPON PERSISTENCE RISK OF THE RECIPIENT PLANT SPECIES AND POTENTIAL HARM OR DAMAGE OF THE ENGINEERED TRAIT

Persistence*	Potential harm or damage of engineered trait			
	Low	Moderate	High	Severe
Low	A	A	C	D
Moderate	A	B	C	D
High	B	B	C	D

TABLE 1 TO § 340.2(d)(1)—INITIAL SORTING INTO PERMIT ADMINISTRATIVE CATEGORIES (A, B, C, AND D) FOR ENVIRONMENTAL RELEASES OF GE PLANTS, BASED UPON PERSISTENCE RISK OF THE RECIPIENT PLANT SPECIES AND POTENTIAL HARM OR DAMAGE OF THE ENGINEERED TRAIT—Continued

Persistence*	Potential harm or damage of engineered trait			
	Low	Moderate	High	Severe
Severe	D	D	D	D

*Persistence risk of the recipient plant species.

(2) *Modification of initial sorting based upon additional considerations.* Following initial sorting using the factors described in paragraph (1)(i) of this section, the Administrator may reassign the environmental release to a different category based upon one or more of the following factors:

(i) How the recipient plant is used;

(ii) Whether the added trait significantly alters the persistence risk of the GE plant;

(iii) Whether the gene function is known and based upon empirical observation of the added trait in the same species; and

(iv) Any other information the Administrator deems relevant to the risk of introduction or dissemination of a plant pest or noxious weed.

(3) *APHIS review and assignment of permit conditions.* The Administrator will conduct a review and assign appropriate permit conditions so that the proposed activity will be conducted in a manner that makes it unlikely to result in the introduction and dissemination of a plant pest or noxious weed.

(4) *State or tribal review and comment.* The Administrator will submit for notice and review a copy of the permit application and any permit conditions to the appropriate state or tribal regulatory official. Comments received from the state or tribal regulatory official may be considered by the Administrator prior to permit issuance.

(5) *Site inspection.* Prior to and after permit issuance, an inspector may inspect the sites or the means of conveyance associated with the proposed importation, interstate movement, or release into the environment. The responsible person must allow any such inspections.

(6) *Issuance of a permit.* The Administrator may issue a permit if the Administrator concludes that the actions allowed under the permit are unlikely to result in the introduction or dissemination of a plant pest or noxious weed.

(i) Prior to the issuance of a permit, the responsible person must agree in writing, in a manner prescribed by the Administrator, that the responsible person and all agents of the responsible person will comply with the permit conditions. The Administrator will deny the permit application if the responsible person does not agree that both the responsible person and all of his or her agents will comply with all of the permit conditions.

(ii) If a permit is issued, the permit will include specific permit conditions required by the Administrator in accordance with § 340.3. If a permit is denied, within a reasonable time thereafter the applicant will be informed in writing of the reasons why the permit was denied and will be given the opportunity to appeal the denial in accordance with the provisions of paragraph (g) of this section.

(e) *Denial or revocation of a permit.* Permits may be denied or revoked in accordance with this paragraph.

(1) *Denial.* The Administrator may deny an application for a permit if:

(i) The Administrator cannot conclude based on the application that the actions proposed under the permit are unlikely to result in introduction or dissemination of a plant pest or noxious weed; or

(ii) The Administrator receives information apart from the application that precludes a conclusion by the Administrator that the actions proposed under the permit would be unlikely to result in the introduction or dissemination of a plant pest or noxious weed; or

(iii) The Administrator determines that the responsible person or any agent of the responsible person has failed to comply at any time with any provision of this part. This would include failure to comply with the conditions of any permit issued.

(2) *Revocation.* The Administrator may revoke a permit if:

(i) The Administrator receives information subsequent to issuing a permit and makes a determination based upon this information that the circumstances have changed such that actions under the permit would be likely to result in the introduction or dissemination of a plant pest or noxious weed; or

(ii) The Administrator determines that the responsible person or any agent of the responsible person has failed to comply at any time with any provision of this part. This would include failure to comply with the conditions of any permit issued.

(f) *Notice of revocation.* The Administrator may revoke, either orally or in writing, any permit which has been issued. If the revocation is oral, the Administrator will communicate the revocation and the reasons for it in writing as promptly as circumstances allow.

(g) *Appeal of denial or revocation of permit.* Any person who has been denied a permit or had a permit revoked may appeal the decision in writing to the Administrator within ten days after receiving the written notification of the revocation or denial. The appeal shall state all of the facts and reasons upon which the person relies to assert that the permit was wrongfully revoked or denied. The Administrator will grant or deny the appeal, in writing, stating the reasons for the decision as promptly as circumstances allow. Upon request of the applicant, a hearing may be held to resolve any conflict as to any material fact. Rules of practice concerning such a hearing will be adopted by the Administrator. This administrative remedy must be exhausted before a person can file suit in court challenging the denial or revocation of a permit.

(h) *Amendment or transfer of permits.* Permits issued under this part may only be amended or transferred in accordance with this section.

(1) *Amendment at responsible person's request.* Where circumstances have changed so that a responsible person desires to have the permit amended, such responsible person must submit a written justification and provide supporting information to APHIS. The Administrator will review the amendment request, and may amend the permit. Prior to issuance of an amended permit, the responsible person must agree in writing that he or she and all of his or her agents will comply with the amended permit and conditions.

(2) *Amendment initiated by APHIS.* The Administrator may amend any

permit and its conditions at any time, upon determining that the amendment is needed to make it unlikely that actions under the permit would result in the introduction or dissemination of a plant pest or noxious weed, or to ensure that the permit is in compliance with all of the requirements of this part. As soon as circumstances allow, the Administrator will notify the responsible person in writing of the amendment to the permit and the reason(s) for it. The responsible person must agree in writing to comply with the permit and conditions as amended before the Administrator will issue the amended permit. If the responsible person does not agree in writing to comply with the amended permit and conditions, the existing permit will be revoked.

(3) *Transfer of permits.* Permits issued through this part may only be transferred by the Administrator in response to a request by both the responsible person and the proposed transferee, or in the case of a deceased responsible person, the deceased responsible person's legal representative and the proposed transferee. Such transfer may occur if the Administrator determines that:

(i) The proposed transferee meets all of the qualifications of a responsible person under this part;

(ii) The proposed transferee has provided adequate written assurances to the Administrator that the proposed transferee and all of his or her agents will meet the terms and conditions of the permit, including any outstanding mitigation requirements or commitments under this part, and that the proposed transferee agrees to assume all responsibility and liability associated with permit activities and responsibilities; and

(iii) The proposed transferee has provided such other information as the Administrator determines is necessary to the processing of the request for transfer of permit.

§ 340.3 Permit conditions.

(a) *Core permit conditions.* Permits will be issued with the permit conditions below, which are a minimum set of basic conditions. The Administrator may add additional or expanded conditions when necessary to make it unlikely that actions under the permit would result in the introduction or dissemination of a plant pest or noxious weed.

(1) *Permit conditions for all permit types.*

(i) *Identity.* The identity of the GE organism shall be maintained at all times, in order to maintain control of the GE organism, keep it distinct from other organisms, and minimize unintended mixing of the GE organism with other organisms. Conditions for maintaining the identity of the GE organism include, but are not limited to:

(A) Marking, labeling, or otherwise identifying all GE organisms during the course of the permit; and

(B) Having the ability to account for all GE materials associated with the permit.

(ii) *Communication and training.* The responsible person shall effectively communicate any and all conditions, activities, actions, and contingency plans associated with the permit to all his or her agents and any other persons participating in permit-related activities, in order to ensure all persons comply with all requirements under this part. Conditions for communicating and training include, but are not limited to:

(A) Establishing, implementing, and maintaining the means to effectively communicate to all his or her agents and any other persons participating in permit-related activities;

(B) Providing a copy of the permit and conditions to all agents involved in a permit; and

(C) Training all agents and any other persons participating in permit-related activities to effectively conduct tasks required under the permit.

(iii) *Records.* In addition to any other records required by this section or § 340.7(b), records, related to permitted activities of sufficient quality and completeness to demonstrate compliance with all permit conditions and requirements under this part, must be maintained.

(iv) *Notice.* The responsible person shall notify APHIS orally within 24 hours of discovery, and subsequently in writing within 5 business days of discovery, in the event of an unauthorized importation, interstate movement, or release into the environment of a GE organism regulated under this part.

(2) Additional permit conditions for interstate movement permits, importation permits, and environmental release permits which include either an interstate movement or importation.

(i) *Shipment.* The GE organism must be transported in such a way as to minimize the likelihood of the unauthorized release of the GE organism. Conditions include, but are not limited to:

(A) Ensuring that the GE organism is transported in such a way that it is a secure shipment, as defined in § 340.1; and

(B) Treating or disposing of all packaging material, shipping containers, and any other material accompanying the GE organism in such a manner as to make it unlikely to result in the organism's unauthorized importation, interstate movement, or release into the environment.

(ii) *Records.* In addition to any other records required by this section or § 340.7(b), the following records shall be maintained:

(A) Information identifying the general nature and quantity of the organism being shipped;

(B) Name and address of sender, owner, or person shipping the organism;

(C) Name, address, and telephone number of recipient;

(D) Any invoices, packing lists, or bills of lading used for the shipment;

(E) The shipper's name and identifying shipper's mark and number; and

(F) A description of any containers that were used to transport the GE organisms, and a copy of any label used on these containers during transport.

(3) *Additional permit conditions for import permits, and environmental release permits which include importation.*

(i) *Port(s) of Entry.* The GE organism shall be presented for entry only at a port(s) specified in the permit.

(ii) *Records.* In addition to any other records required by this section or § 340.7(b), the responsible person shall maintain records that identify the country and locality where the GE organism was collected, developed, manufactured, reared, cultivated or cultured.

(4) *Additional permit conditions for environmental release permits.*

(i) *Environmental release controls.* Sufficient controls shall be applied during the environmental release of the GE organism to make it unlikely to result in the unauthorized release of the GE organism into the environment. Conditions include, but are not limited to:

(A) Taking adequate precautions as described in the permit to ensure that the GE organism is not inadvertently released in transit between contained facilities and the location of environmental release;

(B) Developing and being prepared to implement a written contingency plan to respond to any unauthorized environmental release;

(C) Following any and all required reproductive, cultural, spatial, and temporal controls, such as isolation distances, buffer zones, and flower removal, as described in the permit, and monitor to ensure that the controls are maintained throughout the duration of the release;

(D) Cleaning equipment used in the environmental release in order to remove or devitalize any viable GE organism the equipment may carry, as described in the permit;

(E) Devitalizing or moving into a contained facility any viable GE material remaining at the termination of the environmental release, when applicable, as described in the permit; and

(F) Managing and monitoring the area of release after the termination of the environmental release and removing or devitalizing any GE organisms which persist after the release, as required in the permit.

(ii) *Records.* In addition to any other records required by this section or § 340.7(b), the following records shall be maintained for each release:

(A) All protocols or guidelines used to direct any environmental release of the GE organism; and

(B) All environmental release reports for the organism. At a minimum such reports must include the APHIS reference number for the environmental release, methods of observation used during the environmental release, resulting information, and analysis regarding all deleterious effects on plants, nontarget organisms, or the environment, and any notices sent to APHIS of any unusual occurrence during the environmental release.

(iii) *Reports and Notices.* In order for the Administrator to monitor the progress of the environmental release, and to evaluate compliance with required permit conditions, permit conditions will include, but are not limited to:

(A) The responsible person shall submit periodic reports and notices to APHIS at the times specified in the permit and containing the information specified within the permit; and

(B) The responsible person shall notify APHIS orally within 24 hours of discovery, and subsequently in writing within 5 business days of discovery, in the event that the GE organism is found to have characteristics substantially different from those listed in the permit or if any circumstances occur which may increase the risk of disseminating a plant pest or noxious weed.

(C) The responsible person shall notify APHIS in writing if the authorized release will not be conducted.

(D) Within 28 days after the initiation of the release, the responsible person shall report to APHIS in writing the final release site coordinates; number of GE organisms actually released; any information related to the expected date(s) and quantities of GE organisms for subsequent planned releases to be done under this permit.

(E) The responsible person shall provide APHIS with a final report that includes information related to any occurrences during the release that might result in the dissemination of a plant pest or noxious weed.

(F) For categories C and D, permit holders shall provide APHIS with written notice no less than seven days prior to the planned initiation of the release.

(G) For categories C and D, permit holders shall provide APHIS with a report no less than 21 days prior to release termination (e.g., harvest of GE plants) that describes the anticipated date(s) of termination.

(b) *Standard for additional permit conditions assigned by Administrator.* The Administrator will assign the permit conditions described above in a manner that is commensurate with the risk of the individual proposed release. Additional or expanded permit conditions may include, but are not limited to specific requirements for: Reproductive, cultural, spatial, temporal controls; monitoring; post-termination land use; site security or access restrictions; and management practices such as training of personnel involved in the release. The Administrator may also assign permit conditions addressing nonliving materials associated with or derived from GE plants when such conditions are needed to make it unlikely that the nonliving materials would pose a noxious weed risk.

§ 340.4 Conditional exemptions from the requirement for a permit for interstate movement.

(a) *General.* Certain GE organisms described in paragraph (b) of this section may be moved interstate without a permit under this part, if they meet the shipping conditions enumerated in paragraph (c).

(b) *Conditional exemptions from the requirement for a permit for interstate movement of certain organisms.* A permit for interstate movement will not be required for the following genetically engineered organisms provided that they meet the requirements of this paragraph and paragraph (c).

(1) *Escherichia coli* genotype K–12 (strain K–12 and its derivatives), sterile strains of *Saccharomyces cerevisiae*, or asporogenic strains of *Bacillus subtilis*, provided that the introduced genetic sequences:

(i) Are maintained on a nonconjugation proficient plasmid, and the organism does not contain other conjugation proficient plasmids or generalized transducing phages;

(ii) Do not cause the production of an infectious entity;

(iii) Are not carried on an expression vector if the cloned genes code for:

(*A*) A toxin to plants or plant products, or a toxin to organisms beneficial to plants; or

(*B*) Other factors directly involved in eliciting plant disease (e.g., cell wall degrading enzymes; or

(*C*) Substances acting as, or inhibitory to, plant growth regulators.

(2) *Arabidopsis thaliana* provided that the introduced genetic sequences:

(i) Do not cause the production of an infectious entity;

(*ii*) Are not derived from an animal or human pathogen;

(*iii*) Do not encode products that are toxic to vertebrates;

(*iv*) Do not encode products known to or likely to be causal agents of disease in vertebrates; and

(*v*) Do not encode products intended for pharmaceutical or industrial use.

(c) *Shipping conditions.* Organisms that meet the criteria described in paragraph (b) of this section must be shipped as follows:

(i) The container and means of conveyance must provide secure shipment to make it unlikely that the introduction or dissemination of the organisms will occur while in transit.

(ii) The container must contain a document which includes the following written information:

(A) Names and contact details for the sender and recipient, and

(B) A statement that the contents are genetically engineered and are eligible for interstate movement without permit under this part, but are not exempt from permit requirements under this part if the organism is imported or released into the environment;

(iii) The responsible person shall notify APHIS orally within 24 hours of discovery, and subsequently in writing within 5 business days of discovery, in the event of an unauthorized release into the environment of a GE organism regulated under this part.

(d) *Revocation of an exemption from requirement for permit.* The Administrator may revoke any existing conditional exemption. The Administrator may revoke a conditional exemption if the Administrator receives information subsequent to approving the conditional exemption and makes a determination based upon this information that the circumstances have changed such that the conditional exemption is likely to result in the introduction or dissemination of a plant pest or noxious weed. The revocation, its effective date, and the reasons for it will be published in the **Federal**

Register. A revocation may not be appealed. However, any person may file a new petition in accordance with § 340.5 regarding the same or similar organisms covered by the revocation if new information relevant to the revocation becomes available.

(e) *Revocation of a person's use of a conditional exemption from requirement for permit.* The Administrator may revoke the right of any person to use a conditional exemption from the requirement for a permit under this part after determining that the person or any agent of the person has failed to comply at any time with any provision of this part. This would include failure to comply with the conditions of any permit or exemption.

(1) *Appeal of revocation of a person's use of a conditional exemption.* Any person who has had the right to use a conditional exemption revoked may appeal the decision in writing to the Administrator within ten days after receiving the written notification of the revocation. The appeal shall state all of the facts and reasons upon which the person relies to assert that the use of the conditional exemption was wrongfully revoked. The Administrator will grant or deny the appeal, in writing, stating the reasons for the decision as promptly as circumstances allow. Upon request of the applicant, a hearing may be held to resolve any conflict as to any material fact. Rules of practice concerning such a hearing will be adopted by the Administrator. This administrative remedy must be exhausted before a person can file suit in court challenging the revocation.

§ 340.5 Petition for new conditional exemptions from the requirement for a permit.

(a) *General.* Any person may petition to initiate the procedure for establishing a new conditional exemption from the requirement for a permit under § 340.0(b)(1) of this part. The Administrator may initiate the procedure without filing a petition. All petitions and all actions by the Administrator to establish a new conditional exemption will be evaluated according to the standards for petition approval or denial contained in paragraph (b)(4) of this section.

(b) *Petition submission and evaluation procedure.* To petition for a new conditional exemption from the requirement for a permit under this part, a petitioner must submit a written petition to the Administrator.

(1) The petition must contain information that supports a conclusion that use of the conditional exemption is unlikely to result in the introduction or dissemination of a plant pest or noxious weed. The information shall include the following:

(i) Description of the biology of the organism prior to genetic engineering.

(ii) Detailed description of the genetic changes made to the organism.

(iii) Detailed description of the phenotype of the GE organism, including known and potential differences from the recipient organism that could change the likelihood that the GE organism will pose a risk as a plant pest or noxious weed. Examples of relevant information include, but are not limited to:

(A) Growth habit and reproduction of the GE organism;

(B) Potential host range or geographic area of distribution;

(C) Potential for other organisms to pose risks as plant pests or noxious weeds if they acquire the trait from the GE organism (e.g. via sexual reproduction, horizontal gene transfer);

(D) Susceptibility of the GE organism to disease or damage by pests;

(E) Pathogenicity of the GE organism and/or ability of the GE organism to cause damage or injury to plants or plant parts;

(F) Toxicity, allergenicity, and/or ability of the GE organism to damage or injure other organisms;

(iv) A detailed description of proposed condition(s) to be associated with the exemption and how the conditions would make the exemption unlikely to result in the introduction or dissemination of a plant pest or noxious weed.

(v) Any relevant experimental information, published references, or scientific information which support the conclusions of the petition;

(vi) All reports required under § 340.3;

(vi) Any information known to the petitioner that the GE organism may pose a risk as a plant pest or noxious weed;

(vii) Any other information that the Administrator believes to be relevant to a determination that the proposed conditional exemption from the requirement for a permit for the importation, interstate movement, or release into the environment of the GE organism is unlikely to result in the introduction or dissemination of a plant pest or noxious weed.

(viii) A signed certification by the petitioner that, to the best knowledge and belief of the petitioner, the petition includes all information on which to base a determination, and that it includes all information known to the petitioner which is unfavorable to the petition.

(2) *Insufficient information.* If, upon initial review of the petition, the Administrator concludes that there is insufficient information upon which to make a determination on the petition, the petitioner will be sent a written notice indicating what additional information may be required.

(3) *Public notice.* The Administrator should generally complete the review of the complete petition within 180 days, then publish a notice in the **Federal Register** of the availability of documents related to APHIS' assessment of the proposed conditional exemption. This notice will specify that comments will be accepted from the public on the proposal.

(4) *Petition approval or denial standard.* The Administrator will assess the GE organism and the conditions of the requested exemption to determine whether the requested exemption from a permit for importation, interstate movement, or release into the environment would be unlikely to result in the introduction or dissemination of a plant pest or noxious weed. The Administrator will also consider whether any conditions not contained in the petition would be needed to ensure that the requested exemption would be unlikely to result in the introduction or dissemination of a plant pest or noxious weed. After completing review of the available information and any public comments received on it, the Administrator will furnish to the petitioner and publish in the **Federal Register** one of the following responses:

(i) *Approve a conditional exemption from requirement for a permit.* The approval of a conditional exemption from the requirement for a permit will state which GE organism(s) may be imported, moved interstate, and/or environmentally released without a permit under this part, as well as the conditions relevant to the exemption. The Administrator may also add additional conditions not proposed in the petition, if the Administrator concludes that additional conditions are needed to ensure that the conditional exemption would be unlikely to result in the introduction or dissemination of a plant pest or noxious weed.

(ii) *Deny a conditional exemption from requirement for a permit.* The Administrator will deny a petition if the Administrator cannot conclude that the proposed exemption would be unlikely to result in the introduction or dissemination of a plant pest or noxious weed. The Administrator's written decision will set forth the reason for the denial.

(c) *Appeal of decision.* Any person whose petition under § 340.5 has been denied may appeal the decision in writing to the Administrator within ten days after receiving the written notification of the decision. The appeal shall state all of the facts and reasons upon which the person relies to show that the decision should be changed. The Administrator will grant or deny the appeal, in writing, stating the reasons for the decision as promptly as circumstances allow. Upon request of the applicant, a hearing may be held to resolve any conflict as to any material fact. Rules of practice concerning such a hearing will be adopted by the Administrator. This administrative remedy must be exhausted before a person can file suit in court challenging the decision.

(d) *Amending an exemption after approval.* The Administrator may amend conditions to any conditional exemption approved under this section. The Administrator may amend a conditional exemption if the Administrator determines based on information received subsequent to the approval of the exemption that the exemption needs to be amended to ensure that the exemption would be unlikely to result in the introduction or dissemination of a plant pest or noxious weed, and that additional conditions can successfully mitigate that risk. The Administrator may also amend a conditional exemption if needed to ensure that the exemption is in compliance with all of the requirements of this part. The amended conditional exemption and the reasons for it will be published in the **Federal Register**. The addition of conditions may not be appealed. However, any person may file a new petition in accordance with paragraph (a) of this section regarding the same or similar organisms covered by the amended exemption if new information relevant to the amended exemption becomes available.

(e) *Revocation of an exemption from requirement for permit.* The Administrator may revoke any conditional exemption under this section. The Administrator may revoke a conditional exemption if the Administrator receives information subsequent to approving the exemption and makes a determination based upon this information that the circumstances have changed such that the conditional exemption is likely to result in the introduction or dissemination of a plant pest or noxious weed. The revocation, its effective date, and the reasons for it will be published in the **Federal Register**. A revocation may not be appealed. However, any person may file a new petition in accordance with this section regarding the same or similar organisms covered by the revocation if new information relevant to the revocation becomes available.

(f) *Revocation of a person's use of a conditional exemption from requirement for permit.* The Administrator may revoke the right of any person to use a conditional exemption from the requirement for a permit under this part after determining that the person or any agent of the person has failed to comply at any time with any provision of this part. This would include failure to comply with the conditions of any permit or exemption.

(1) *Appeal of revocation of a person's use of a conditional exemption.* Any person who has had the right to use a conditional exemption revoked may appeal the decision in writing to the Administrator within ten days after receiving the written notification of the revocation. The appeal shall state all of the facts and reasons upon which the person relies to assert that the use of the exemption was wrongfully revoked. The Administrator will grant or deny the appeal, in writing, stating the reasons for the decision as promptly as circumstances allow. Upon request of the applicant, a hearing may be held to resolve any conflict as to any material fact. Rules of practice concerning such a hearing will be adopted by the Administrator. This administrative remedy must be exhausted before a person can file suit in court challenging the revocation.

(2) [Reserved]

§ 340.6 Petition for nonregulated status.

(a) *General.* Any person may petition to initiate the procedure for approving nonregulated status under this part for a GE organism. The Administrator may initiate the procedure without filing a petition. All petitions and all actions by the Administrator to initiate the procedure for approving nonregulated status will be evaluated according to the standards for petition approval or denial contained in paragraph (b)(4) of this section.

(b) *Petition submission and evaluation procedure.* To petition for approval of nonregulated status, a petitioner must submit a written petition to the Administrator.

(1) The petition must contain information that supports a conclusion that the GE organism is unlikely to be a plant pest or noxious weed. The information shall include the following:

(i) Description of the biology of the organism prior to genetic engineering.

(ii) Detailed description of the genetic changes made to the organism.

(iii) Detailed description of the phenotype of the GE organism, including known and potential differences from the recipient organism that could change the likelihood that the GE organism is unlikely to be a plant pest or noxious weed. Examples of relevant information include, but are not limited to:

(A) Growth habit and reproduction of the GE organism;

(B) Potential host range or geographic area of distribution;

(C) Potential for other organisms to pose risks as plant pests or noxious weeds if they acquire the trait from the GE organism (e.g. via sexual reproduction, horizontal gene transfer);

(D) Susceptibility of the GE organism to disease or damage by pests;

(E) Pathogenicity of the GE organism and/or ability of the GE organism to cause damage or injury to plants or plant parts;

(F) Toxicity, allergenicity, and/or ability of the GE organism to damage or injure other organisms;

(iv) Any relevant experimental information, published references, or scientific information which support the conclusions of the petition;

(v) All reports required under § 340.3;

(vi) Any information known to the petitioner that the GE organism may pose risk as a plant pest or noxious weed;

(vii) Any other information that the Administrator believes to be relevant to a determination that the GE organism is unlikely to be a plant pest or noxious weed.

(viii) A signed certification by the petitioner that, to the best knowledge and belief of the petitioner, the petition includes all information on which to base a determination, and that it includes all information known to the petitioner which is unfavorable to the petition.

(2) *Insufficient information.* If, upon initial review of the petition, the Administrator concludes that there is insufficient information upon which to make a determination on the petition, the petitioner will be sent a written notice indicating what additional information may be required.

(3) *Public notice.* The Administrator should generally complete the review of the complete petition within 180 days, then publish a notice in the **Federal Register** of the availability of documents related to APHIS' assessment of the proposal for nonregulated status. This notice will specify that comments will be accepted from the public on the proposal.

(4) *Petition approval or denial standard.* The Administrator will assess the GE organism to determine whether the GE organism is unlikely to be a plant pest or noxious weed. After completing review of the available information and any public comments received on it, the Administrator will furnish to the petitioner and publish in the **Federal Register** one of the following responses:

(i) *Approve nonregulated status.* The approval of nonregulated status will state which GE organism(s) have been determined to have nonregulated status.

(ii) *Deny nonregulated status.* The Administrator will deny a petition if the Administrator cannot conclude that the GE organism is unlikely to be a plant pest or noxious weed. The Administrator's written decision will set forth the reason for the denial.

(c) *Appeal of decision.* Any person whose petition under § 340.6 has been denied may appeal the decision in writing to the Administrator within ten days after receiving the written notification of the decision. The appeal shall state all of the facts and reasons upon which the person relies to show that the decision should be changed. The Administrator will grant or deny the appeal, in writing, stating the reasons for the decision as promptly as circumstances allow. Upon request of the applicant, a hearing may be held to resolve any conflict as to any material fact. Rules of practice concerning such a hearing will be adopted by the Administrator. This administrative remedy must be exhausted before a person can file suit in court challenging the decision.

(d) *Revocation of nonregulated status.* The Administrator may revoke any approval of nonregulated status of a GE organism. The Administrator may revoke an approval of nonregulated status if the Administrator receives information subsequent to approving the nonregulated status and makes a determination based upon this information that the circumstances have changed such that the GE organism is likely to be a plant pest or noxious weed. If the Administrator revokes an approval for nonregulated status, the Administrator may approve for the same GE organism an exemption from the requirement for permit in accordance with § 340.5. The revocation, its effective date, and the reasons for it will be published in the **Federal Register**. A revocation may not be appealed. However, any person may file a new petition in accordance with this section regarding the same or similar organisms covered by the revocation if new information relevant to the revocation becomes available.

§ 340.7 Compliance, enforcement, and remedial action.

(a) *Access for inspection.* Inspectors shall have access to inspect any relevant premises, facility, location, storage area, waypoint, materials, equipment, means of conveyance, and other articles related to importation, interstate movement, and environmental releases of GE organisms regulated under this part.

(b) *Access to audit and review records.* Inspectors shall have access to audit and review all records required to be maintained under this part.

(c) *Required records.* Responsible persons and their agents engaged in the importation, interstate movement, or release into the environment of a GE organism subject to the regulations of this part are required to establish and keep the following records.

(1) All records required as a condition of a permit or a conditional exemption approved under the procedure described in § 340.5.

(2) Address and any other information needed to identify all contained facilities where the GE organism was stored or utilized, and all locations where the GE organism was released into the environment;

(3) A record identifying which APHIS permit, if any, authorized the importation, interstate movement, or release into the environment;

(4) A record identifying which exemption under this part, if any, authorized the importation, interstate movement, or release into the environment; and

(5) Copies of contracts between the responsible person and all agents that conduct activities subject to this part for the responsible person, and copies of other records (e.g., e-mails, telephone records) for such agreements made without a written contract.

(d) *Record retention.* Records indicating that such a GE organism that was imported or moved interstate reached its intended destination must be retained for at least 2 years after completion of importation or interstate movement, and all other records must be retained for at least 5 years after completion of all obligations required under a relevant permit or exemption.

(e) *Enforcement.* (1) Failure of any person to comply with any of the requirements of this part may result in any or all of the following:

(i) Denial of a permit request by that person;

(ii) After the issuance of a permit, revocation of a permit and destruction, treatment, or removal of the GE organism, or other measures as deemed appropriate or necessary by the Administrator;

(iii) Criminal and/or civil penalties, and

(iv) Remedial or other measures as determined appropriate and necessary by the Administrator.

(2) The Administrator may seek a civil penalty as well as impose and require corrective action plans, remedial measures or other measures as determined appropriate and necessary by the Administrator.

(3) Prior to the issuance of a complaint seeking a civil penalty, the Administrator may enter into a stipulation in which the responsible person agrees to take certain remedial actions or other measures in addition to or in lieu of a stipulated civil penalty, in accordance with 7 CFR § 380.10.

(f) *Liability for acts of an agent.* For purposes of enforcing this part, the act, omission, or failure of any agent for a responsible person as defined in § 340.1 of this part may be deemed also to be the act, omission, or failure of the responsible person.

(g) *Remedial action.* The Administrator may hold, seize, quarantine, treat, apply other remedial measures to, destroy, or otherwise dispose of any GE organisms subject to this part, in order to ensure the GE organisms are unlikely to result in the dissemination of a plant pest or noxious weed. Accordingly, the Administrator may order the responsible person for an active or revoked permit or any other person, through an Emergency Action Notification or other administrative order, to apply remedial measures to a GE organism or means of conveyance carrying a GE organism subject to regulation by this part. The Administrator's determination of whether or not to require or order corrective and/or remedial action in a given situation does not affect, influence, restrict, or in any other way limit the Administrator's determination on whether or not to seek criminal or civil penalties or order other compliance or enforcement requirements as deemed necessary or appropriate by the Administrator to the given situation.

(1) Failure of a person to comply with the Administrator's order for corrective and/or remedial action authorizes the Administrator to take corrective and/or remedial action and recover from the person the costs of any care, handling, application of remedial measures, devitalization, or disposal incurred by APHIS in connection with the corrective and/or remedial actions taken.

(2) *Low level presence (LLP) remedial action.* The Administrator may order remedial action for any unauthorized release into the environment of GE

organisms, including situations involving a low-level mixing of GE plants and materials subject to regulation [1] under this part with commercial seed and grain. In some LLP situations the Administrator may determine not to order remedial action, if the Administrator determines that the low-level mixing is unlikely to result in the introduction or dissemination of a plant pest or noxious weed. These determinations will be made in the same way, based on the same factors, regardless of whether the LLP originates domestically or is found in import shipments that may contain organisms subject to regulation. The factors the Administrator will consider that would support a decision not to order LLP remedial action include, but are not limited to, determinations that:

(i) A GE plant of the same species expressing nearly identical proteins or substances has already been approved for nonregulated status under this part; or

(ii) All of the following statements are true with regard to the GE plant or plants subject to the regulations under this part.

(A) The function of the introduced genetic sequences is known and its expression in the GE plant is unlikely to pose plant pest or noxious weed risk;

(B) Introduced genetic sequences do not cause the production of an infectious entity;

(C) Any genetic sequences derived from plant viruses are non-coding regulatory sequences of known function; or, if sense or antisense genetic sequences, they are derived from viruses prevalent and endemic in the United States that infect plants of the same host species and do not encode a functional noncapsid gene product responsible for cell-to-cell movement of the virus.

(D) The GE plant is not expected to establish outside of a managed ecosystem, and has no sexually-compatible, wild relatives in the United States;

(E) The GE plant does not produce new substances that are known or likely to be toxic to non-target organisms, does not contain genetic sequences from animal or human pathogens, and does not encode products known or likely to be causal agents of disease in animals or humans.

(F) If the GE plant is a food or feed crop, then at least one of the following must be true:

(*1*) The U.S. Environmental Protection Agency has established a tolerance or an exemption from tolerance for any plant-incorporated protectant expressed by the GE plant, or

(*2*) Key food safety issues of the new protein or other substance have been addressed, or,

(*3*) No new protein or substance is produced.

§ 340.8 Confidential business information.

In accordance with the Freedom of Information Act (FOIA) and exemptions from releasing information pursuant to FOIA, namely, 5 U.S.C. 552(b)(4), APHIS may exempt from disclosure to the public trade secrets and commercial or financial information obtained from a person that are privileged or confidential. Persons wishing to protect confidential business information in permit applications, petitions, or other submissions to APHIS under this part should do so in the following manner. If there are portions of a document deemed to contain trade secret or confidential business information, each page containing such information must be marked "CBI Copy." A second copy of each such document must be submitted with all such CBI deleted and marked on each page where the CBI was deleted: "CBI Deleted." In addition, those portions of the document which are deemed "CBI" must be identified in an attachment to the document, which also must justify how each piece of information requested to be treated as CBI is a trade secret or is commercial or financial information and are privileged or confidential.

§ 340.9 Costs and charges.

The services of the inspector related to carrying out this part and provided during regularly assigned hours of duty and at the usual places of duty will be furnished without cost.[2] The U.S. Department of Agriculture will not be responsible for any costs or charges incident to inspections or compliance with the provisions of this part, other than for the services of the inspector.

Done in Washington, DC, this 1st day of October 2008.

Charles D. Lambert,

Acting Under Secretary for Marketing and Regulatory Programs.

[FR Doc. E8–23584 Filed 10–6–08; 9:30 am]

BILLING CODE 3410–34–P

[1] "Subject to regulation" may include situations where a GE organism granted nonregulated status subsequently had that status revoked in accordance with § 340.6(d).

[2] The Department's provisions relating to overtime charges for an inspector's services are set forth in 7 CFR part 354.0.

Regulatory Analysis and Development, PPD, APHIS, Station 3A–03.8, 4700 River Road Unit 118, Riverdale, MD 20737–1238. Please state that your comment refers to Docket No. APHIS–2008–0098.

Reading Room: You may read any comments that we receive on this docket in our reading room. The reading room is located in room 1141 of the USDA South Building, 14th Street and Independence Avenue SW., Washington, DC. Normal reading room hours are 8 a.m. to 4:30 p.m., Monday through Friday, except holidays. To be sure someone is there to help you, please call (202) 690–2817 before coming.

SUPPLEMENTARY INFORMATION:

Background

The U.S. Department of Agriculture's (USDA) Animal and Plant Health Inspection Service (APHIS) regulates the introduction—meaning the importation, interstate movement, and environmental release—of genetically engineered (GE) organisms that are, or may be, plant pests. Such GE organisms and products are considered "regulated articles." Applicants that are issued permits or received acknowledgment of notifications to introduce GE organisms are required to comply with all APHIS regulations.

To enhance improvements in compliance, APHIS initiated development of a voluntary, audit-based compliance assistance program known as the Biotechnology Quality Management System (BQMS). On September 20, 2007, APHIS issued a press release announcing plans to establish a BQMS Pilot Development Project.

APHIS selected five volunteer participants for the pilot program after soliciting letters of interest through a notice published in the **Federal Register** on September 2, 2008 (73 FR 51266–51267, Docket No. APHIS–2008–0098). The main component of the BQMS pilot project is the draft audit standard, which provides criteria used for the objective evaluation of quality management systems to determine if a system will be certified as an APHIS Biotechnology Quality Management System during the audit portion of the pilot program. The regulatory requirements of 7 CFR part 340 for performance standards and permit conditions are the foundation for the draft audit standard.

The draft audit standard is used by pilot participants to develop sound management practices to enhance compliance with the regulatory requirements of 7 CFR part 340 for environmental releases, importations, and interstate movements of regulated articles. Participants have applied the draft audit standard to their organization's regulated biotechnology program to plan, implement, document, and examine the efficacy of quality assurance and quality control measures related to introductions of regulated articles.

APHIS is soliciting comments for a period of 60 days on the draft audit standard currently used in the BQMS pilot project. Within the draft audit standard, Requirement 7 specifies that participants address critical control points for the introduction of regulated articles by developing containment procedures for regulated articles; developing measures for the identification of regulated articles in storage, being moved, imported, or transferred, and in field locations; developing procedures for planning and monitoring environmental releases of regulated articles; developing methods for post-harvest handling activities and methods to maintain the identity of regulated material; developing procedures for the devitalization and disposition of regulated articles; as well as developing procedures for the submission of regulatory compliance incidents to the appropriate regulatory authorities. APHIS is soliciting comments on the draft audit standard as a whole, and Requirement 7 in particular.

1. Do the critical control points in Requirement 7 of the draft audit standard identify all areas and elements that organizations should focus on in order to maintain compliance with the regulatory requirements under 7 CFR part 340?

2. Is the draft audit standard consistent with current best practices used by the regulated community?

3. Can the public identify incentives USDA might employ to encourage participation in the voluntary program by commercial industry as well as academic institutions?

4. The BQMS is designed to be flexible according to the size of the participating organization. Is this flexibility apparent in the draft audit standard?

Upon conclusion of the BQMS pilot project, APHIS will consider all comments received during the comment period to revise the draft audit standard to improve the efficacy of this project. This feedback, as well as comments from the participants on the pilot BQMS project, will be used to inform the development of a BQMS audit standard and any future BQMS initiative. The BQMS draft audit standard is available for public review as indicated under the **ADDRESSES** and **FOR FURTHER INFORMATION CONTACT** sections of this notice.

Done in Washington, DC, this 29th day of May 2009.

Kevin Shea,

Acting Administrator, Animal and Plant Health Inspection Service.

BILLING CODE 3410–34–P

DEPARTMENT OF AGRICULTURE

Animal and Plant Health Inspection Service

[Docket No. APHIS–2007–0016]

Syngenta Seeds, Inc.; Availability of Petition and Environmental Assessment for Determination of Nonregulated Status for Corn Genetically Engineered To Produce an Enzyme That Facilitates Ethanol Production

AGENCY: Animal and Plant Health Inspection Service, USDA.

ACTION: Notice; reopening of comment period.

SUMMARY: We are reopening the comment period for a petition submitted by Syngenta Seeds, Inc., seeking a determination of nonregulated status for corn designated as transformation event 3272 and its associated environmental assessment prepared by the Animal and Plant Health Inspection Service under our regulations found at 7 CFR part 340. This action will allow interested persons additional time to prepare and submit comments on the petition, environmental assessment, and the revised plant pest risk assessment.

DATES: We will consider all comments that we receive on or before July 6, 2009.

ADDRESSES: You may submit comments by either of the following methods:

- *Federal eRulemaking Portal:* Go to *http://www.regulations.gov/fdmspublic/component/main?main=DocketDetail&d=APHIS-2007-0016* to submit or view comments and to view supporting and related materials available electronically.
- *Postal Mail/Commercial Delivery:* Please send two copies of your comment to Docket No. APHIS-2007-0016, Regulatory Analysis and Development, PPD, APHIS, Station 3A03.8, 4700 River Road Unit 118, Riverdale, MD 20737-1238. Please state that your comment refers to Docket No. APHIS-2007-0016.

Reading Room: You may read any comments that we receive on this docket in our reading room. The reading room is located in room 1141 of the USDA South Building, 14th Street and Independence Avenue SW., Washington, DC. Normal reading room hours are 8 a.m. to 4:30 p.m., Monday through Friday, except holidays. To be sure someone is there to help you, please call (202) 690-2817 before coming.

Other Information: Additional information about APHIS and its programs is available on the Internet at *http://www.aphis.usda.gov.*

FOR FURTHER INFORMATION CONTACT: Dr. Andrea Huberty, Biotechnology Regulatory Services, APHIS, 4700 River Road Unit 146, Riverdale, MD 20737-1236; (301) 734-0485, e-mail: *andrea.f.huberty@aphis.usda.gov.* To obtain copies of the petition, the draft environmental assessment, or the plant pest risk assessment, contact Ms. Cindy Eck at (301) 734-0667, e-mail: *cynthia.a.eck@aphis.usda.gov.* The petition, draft environmental assessment, and plant pest risk assessment are also available on the Internet at *http://www.aphis.usda.gov/brs/aphisdocs/05_28001p.pdf, http://www.aphis.usda.gov/brs/aphisdocs/05_28001p_ea.pdf,* and *http://www.aphis.usda.gov/brs/aphisdocs/05_28001p_ra.pdf.*

SUPPLEMENTARY INFORMATION: The regulations in 7 CFR part 340, "Introduction of Organisms and Products Altered or Produced Through Genetic Engineering Which Are Plant Pests or Which There Is Reason to Believe Are Plant Pests," regulate, among other things, the introduction (importation, interstate movement, or release into the environment) of organisms and products altered or produced through genetic engineering that are plant pests or that there is reason to believe may be plant pests. Such genetically engineered (GE) organisms and products are considered "regulated articles."

On October 7, 2005, APHIS received a petition seeking a determination of nonregulated status (APHIS Petition No. 05-280-01p) from Syngenta Seeds, Inc., of Research Triangle Park, NC (Syngenta), for corn (*Zea mays* L.) designated as transformation event 3272, which has been genetically engineered to produce a microbial enzyme that facilitates ethanol production. The petition stated that Event 3272 corn is unlikely to pose a plant pest risk and, therefore, should not be a regulated article under APHIS' regulations in 7 CFR part 340.

In a notice[1] published in the **Federal Register** on November 19, 2008 (73 FR 69602-69604, Docket No. APHIS-2007-0016), APHIS announced the availability of the Syngenta petition and a draft environmental assessment (EA) for public comment. APHIS solicited comments on the petition, whether the subject corn is likely to pose a plant pest risk, and on the draft EA. APHIS received over 13,000 comments on the petition, the draft EA, and the plant pest risk assessment by the close of the 60-day comment period, which ended on January 20, 2009.

There were 40 comments from organizations or individuals that supported the deregulation of the Event 3272 corn. Over 13,000 comments opposed to the deregulation were submitted. The vast majority of the approximately 13,000 comments opposing the deregulation were from letters conveying essentially identical points compiled by organizations generally opposed to any genetic engineering of plants. Several individuals and organizations also submitted documents, many popular press articles or documents published by those opposed to genetic engineering of plants in general, which they assert are relevant to this regulatory decision for Event 3272 corn.

Most of the comments supporting nonregulated status for Event 3272 corn came from organizations representing corn farmers and ethanol production interests. These comments include statewide corn growers' and agribusiness associations from at least 12 different States where most of the nation's corn is grown. Several national organizations also voiced their support for the deregulation. The principal reasons given by these groups are the benefits anticipated for farmers and the ethanol production industry, as well as the ability to meet biofuel production mandates and to promote international trading interests. While APHIS does not determine nonregulated status for GE organisms pursuant to its biotech regulations (Part 340) based on economic or marketing factors, the support from farmers of corn does suggest that individuals with a substantial interest in the health of the national corn crop do not perceive that either plant pest risks or economic/marketing risks will arise if Event 3272 corn is granted nonregulated status.

Several of the comments provided scientific support for the deregulation of Event 3272 corn. Many of these supportive statements were based on scientific studies included in the petition (such as evidence of decreased water use in ethanol production, reduced greenhouse gas emissions, other reduced inputs in ethanol production). There were several comments that also provided additional studies that would support deregulation of Event 3272 corn on the basis of diminished environmental impacts compared to current ethanol production practices. These studies supported the findings of lowered greenhouse gas emissions and reduced inputs, and also suggest that there will be no impacts on wet distilled grains and improved dried distilled grains, and that the Event 3272 corn is equivalent to currently grown corn lines in other agronomic and nutritional qualities, demonstrated through field and feed studies.

Many of the comments that opposed deregulation were based on general opposition to the development and use of GE plants, without citing or addressing any specific environmental issues in the EA or the pest risk assessment for the petition for Event 3272 corn. Many of these comments simply assert that APHIS should prepare an Environmental Impact Statement to fully address all the potential issues associated with a decision to grant nonregulated status to Event 3272 corn without specifically explaining what they perceive to be the inadequacies of the draft EA's environmental analysis. There were many general comments expressing generic, nonspecific concerns over possible gene flow, disruption to organic farming practices, and concerns of food and environmental safety.

Another common comment that APHIS received regarding the determination of nonregulated status for Event 3272 corn is the general "energy" concern related to the effectiveness and value of producing ethanol from corn. Many comments suggested that

[1] To view the notice, petition, draft EA, the plant pest risk assessment and the comments we received, go to *http://www.regulations.gov/fdmspublic/component/main?main=DocketDetail&d=APHIS-2007-0016.*

producing ethanol from corn is not an efficient method for achieving energy needs or meeting any alternative energy mandates for the United States. However, in determining the nonregulated status for a genetically engineered plant pursuant to its Part 340 biotechnology regulations, APHIS does not have authority to consider the economic, marketing, or commercial usefulness of the plant, or issues such as the feasibility of meeting energy needs through any particular crop and its related harvesting and processing aspects.

APHIS did receive some comments that raised specific issues of concern if Event 3272 corn was granted nonregulated status. These issues included specific food safety concerns such as the potential for Event 3272 corn to be allergenic, as well as concerns surrounding the potential economic and manufacturing issues if Event 3272 corn were to become present in corn wet-milling processes.

APHIS does believe it is appropriate to address in this notice certain comments submitted that questioned the conclusion that Event 3272 corn is not a plant pest, and that there is no basis for regulatory control of this GE plant under our statutory authorities and Part 340 biotechnology regulations. These comments argue that the alpha-amylase enzyme engineered into Event 3272 corn may cause damage (degradation of corn starch products) to manufactured or processed plant products if Event 3272 corn is included in the manufacturing and processing of corn starch products. The comments claim that this type of damage comes within the definition of a plant pest. One of these comments [2] claims that "a plant pest consists of any living stage of an article similar to or allied with a bacterium or any article similar to or allied with a bacterium that can cause direct damage to a processed plant product. The 'article' in this application (petition) is the thermo-stable alpha-amylase enzyme expressed in Event 3272, which has the potential for injury to plant products if misdirected to corn wet milling facilities.

APHIS' statutory authority to regulate genetically engineered organisms under the Plant Protection Act (PPA) (7 U.S.C. 7701 *et seq.*) and its Part 340 biotechnology regulations is limited to those GE organisms that are plant pests as defined in Section 403, Subsection 14 of the PPA:

> Plant Pest—The term "plant pest" means any living stage of any of the following that can directly or indirectly injure, cause damage to, or cause disease in any plant or plant product:
> (A) A protozoan.
> (B) A nonhuman animal.
> (C) A parasitic plant.
> (D) A bacterium.
> (E) A fungus.
> (F) A virus or viroid.
> (G) An infectious agent or other pathogen.
> (H) Any article similar to or allied with any of the articles specified in the preceding subparagraphs.

Thus, in regulating GE organisms under 7 CFR part 340, APHIS takes a "safeguarding" approach and examines the plant pest risk for genetically engineered plants by looking at all regulated genetically engineered plants for their potential to be plant pests (See plant pest risk assessment, pg. 1). However, under its PPA statutory authorities APHIS cannot regulate GE plants that are outside the PPA's plant pest definition in 7 U.S.C. 7702(14). This statutory definition provides specifically that only a parasitic plant can be a plant pest.

One of the central purposes of the PPA is to prevent the introduction into or dissemination of plant pests within the United States. The PPA at 7 U.S.C. 7702(14) provides that a plant pest must be a living stage of one of a specific list of organisms ("articles") that cause injury, damage, or disease in plants or plant products, or an article similar to or allied with such an organism (article). An "article" is defined in the PPA (7 U.S.C. 7702(1) as follows:

> Article—The term 'article' means any material or tangible object that could harbor plant pests or noxious weeds.

As mentioned above, there were some comments that questioned the conclusion that Event 3272 corn is not a plant pest. These comments argue that the alpha-amylase enzyme in Event 3272 corn is a plant pest because it may interfere with corn starch processing and thus directly or indirectly damage plants or plant products. The developer of Event 3272 corn submitted a document after the close of the document [3] period that argues that Event 3272 corn does not meet the PPA statutory definition of a plant pest. In this document, the commenter provided its analysis of APHIS' regulatory authority under the PPA, and among other things, suggests that separate constituent parts of an organism (in this case, an enzyme expressed by Event 3272 corn) are excluded from the definition of plant pest in the PPA because the enzyme "cannot be regarded as 'living'."

APHIS agrees that enzymes such as alpha-amylase are proteins that catalyze chemical reactions. Enzymes are not "living." Thus, enzymes cannot be plant pests because they are not living and cannot be a "living stage" of any of the organisms ("articles") listed in the PPA's definition of a plant pest in subparagraphs (A) through (G) of 7 U.S.C. 7702(14). Likewise, the Event 3272 corn alpha-amylase enzyme also cannot be a living stage of any article similar to or allied with any of the articles specified in subparagraphs (A) through (G), and thus does not fall within the statutory definition of a plant pest as listed in subparagraph (H) of the PPA's plant pest definition (*i.e.*, "Any article similar to or allied with any of the articles specified in the preceding subparagraphs"). APHIS has determined that the alpha-amylase enzyme engineered into Event 3272 corn is not a plant pest because the alpha-amylase enzyme in Event 3272 corn is not living and thus cannot itself be a living stage of any organism listed in the PPA's plant pest definition.

Moreover, Event 3272 corn itself is not a plant pest since it is clearly not a living stage of any of the organisms (articles) listed in subparagraphs (A) through (G) of 7 U.S.C. 7702(14). Nor is Event 3272 corn itself the living stage of any article (organism) similar to or allied with any of the articles specified in subparagraphs (A) through (G) as required by subparagraph (H) of 7 U.S.C. 7702(14). Thus, APHIS has likewise determined that Event 3272 corn itself is not a plant pest as defined by the PPA. Nevertheless, APHIS evaluated the ability of Event 3272 corn to harbor plant pests in the Plant Pest Risk Assessment and determined that Event 3272 corn does not harbor any living stage of any of the organisms (articles) that are defined as potential plant pests in subparagraphs (A) through (G). First, APHIS described the genetic material that was inserted into Event 3272 corn, which included sequences from plant pests, and included an assessment analyzing the plant disease risk posed by the genetic sequences. Second, APHIS also analyzed the risk that Event 3272 corn would disseminate plant pests (*i.e.* act as an 'article'). APHIS concluded that the inserted genetic material in Event 3272 corn does not cause plant disease and Event 3272 corn does not increase susceptibility to plant disease or insect pests, and therefore does not harbor plant pests. (The comments received on the docket

[2] *See http://www.regulations.gov/fdmspublic/component/main?main=DocumentDetail&d=APHIS-2007-0016-0175.1.*

[3] *See http://www.regulations.gov/fdmspublic/component/main?main=DocumentDetail&d=APHIS-2007-0016-0222.1.*

during the initial comment period did not dispute or comment on these particular issues related to APHIS' plant pest risk assessment.)

For the reasons explained above, APHIS has determined that neither Event 3272 corn itself, nor the alpha-amylase enzyme in Event 3272 corn, is a plant pest. To make clear APHIS' above determination that neither Event 3272 corn, nor the alpha-amylase enzyme in Event 3272 corn, is a "living stage" of any of the organisms (articles) listed in subparagraphs (A) through (H) of the PPA's plant pest definition, APHIS has revised the plant pest risk assessment for Event 3272 corn to include the PPA's definition of a plant pest. The revised assessment also concludes that neither Event 3272 corn nor the alpha-amylase enzyme in Event 3272 corn is a plant pest because neither Event 3272 corn nor the alpha-amylase enzyme meets the PPA's definition of a plant pest. These revisions to the plant pest risk assessment are for clarity and further explanation, but do not change the overall conclusions made in the draft plant pest risk assessment that Event 3272 corn is unlikely to pose a plant pest risk.

APHIS welcomes additional comment on the issues raised during this process. APHIS is also requesting comment on the revised plant pest risk assessment, and APHIS' conclusion, as explained above, that Event 3272 corn and the alpha-amylase enzyme in Event 3272 corn are not plant pests. APHIS will carefully evaluate all additional comments received during this process, and any other relevant information. All comments received regarding the petition, draft EA, and plant pest risk assessment will be available for public review on the Regulations.gov Web site (see footnote 1 for a link). After reviewing and evaluating the comments on the petition, draft EA, plant pest risk assessment, and other relevant information, APHIS will make its determination, either approving or denying the petition. APHIS will then publish a notice in the **Federal Register** announcing the regulatory status of Event 3272 corn and the availability of APHIS' written regulatory and environmental decision.

Accordingly, we are reopening the comment period on Docket No. APHIS–2007–0016 for an additional 30 days. This action will allow interested persons additional time to prepare and submit comments. We will also consider all comments received between January 21, 2009 (the day after the close of the original comment period), and the date of this notice.

Authority: 7 U.S.C. 7701–7772 and 7781–7786; 31 U.S.C. 9701; 7 CFR 2.22, 2.80, and 371.3.

Done in Washington, DC, this 29th day of May 2009.

Kevin Shea,

Acting Administrator, Animal and Plant Health Inspection Service.

Rural Utilities Service

PowerSouth Energy Cooperative; Notice of Finding of No Significant Impact

AGENCY: Rural Utilities Service, USDA.

ACTION: Notice of finding of no significant impact.

SUMMARY: Notice is hereby given that the Rural Utilities Service (RUS), an agency delivering the United States Department of Agriculture (USDA) Rural Development Utilities Programs, has made a Finding of No Significant Impact (FONSI) with respect to a request from PowerSouth Electric Cooperative (PowerSouth) for assistance to finance the construction and operation of a new 360 megawatt peak-load natural gas-fired generation facility at PowerSouth's existing McIntosh Power Plant in Washington County, Alabama.

ADDRESSES: The FONSI is available for public review at USDA Rural Utilities Service, 1400 Independence Avenue, SW., Stop 1571, Washington, DC 20250–1571; and at PowerSouth's headquarters office located at 2027 East Three Notch Street, Andalusia, Alabama 36420. To obtain copies of the FONSI or for further information, contact Stephanie Strength, Environmental Protection Specialist, USDA, Rural Utilities Service, 1400 Independence Avenue, SW., Stop 1571, Washington, DC 20250–1571; Telephone: (202) 720–0468 or e-mail: *stephanie.strength@wdc.usda.gov;* or PowerSouth's headquarters office located at 2027 East Three Notch Street, Andalusia, Alabama 36420.

SUPPLEMENTARY INFORMATION: PowerSouth is proposing to construct a new 360 megawatt peak-load natural gas-fired generation facility at PowerSouth's existing McIntosh Power Plant with an in-service date of late 2010. The proposed project would consist of two 180 megawatt combustion turbine units operated by natural gas. Burns and McDonnell Engineering Company, Inc., an environmental consulting firm, has prepared an Environmental Analysis (EA) for RUS. Rural Utilities Service has conducted an independent evaluation of the EA and believes that it accurately assesses the impacts of the proposal and has determined that no significant impacts would result from the construction and operation of the proposal.

Any final action by RUS related to the proposed project will be subject to, and contingent upon, compliance with all relevant Federal environmental laws and regulations and completion of environmental review procedures as prescribed by the 7 CFR part 1794, Environmental Policies and Procedures.

Dated: May 29, 2009.

James R. Newby,

Acting Administrator, Electric Program, Rural Utilities Service.

Plant Pests; Introduction of Genetically Engineered Organisms or Products; Final Rule

DEPARTMENT OF AGRICULTURE

Animal and Plant Health Inspection Service

7 CFR Parts 330 and 340

[Docket No. 87-021]

Introduction of Organisms and Products Altered or Produced Through Genetic Engineering Which Are Plant Pests or Which There is Reason To Believe Are Plant Pests

AGENCY: Animal and Plant Health Inspection Service, USDA.

ACTION: Final rule.

SUMMARY: This document establishes regulations for the introduction (importation, interstate movement, or release into the environment) of genetically engineered organisms and products which are plant pests or for which there is reason to believe are plant pests (regulated articles). The regulations set forth procedures for obtaining a permit for the release into the environment of a regulated article and for obtaining a limited permit for the importation or interstate movement of a regulated article. Such permits are required before a regulated article can be introduced in the United States. These regulations are necessary to prevent the entry into and dissemination and establishment of plant pests in the United States.

DATE: Effective date of final rule is July 16, 1987.

FOR FURTHER INFORMATION CONTACT: Terry L. Medley, Director, Biotechnology and Environmental Coordination Staff, Animal and Plant Health Inspection Service, U.S. Department of Agriculture, Room 408, Federal Building, 6505 Belcrest Road, Hyattsville, MD 20782, 301-436-7602.

SUPPLEMENTARY INFORMATION:

Background

On June 26, 1986, the Animal and Plant Health Inspection Service (APHIS) published a proposed rule entitled, "Introduction of Organisms and Products Altered or Produced Through Genetic Engineering Which Are Plant Pests or for Which There Is Reason to Believe Are Plant Pests" (51 FR 23352-23366 hereinafter referred to as the proposed regulations). The proposed regulations set forth procedures for obtaining a permit prior to the introduction (importation, interstate movement, or release into the environment) of genetically engineered organisms or products which are plant pests or for which there is reason to believe are plant pests (regulated articles).

The provisions that appeared in the proposed regulations and adpopted in this final rule concerning the ned to obtain a permit prior to introducing a regulated article are consistent with existing permit requirements in 7CFR Parts 300-399. Such requirements are imposed by APHIS in regulating the movement of non-genetically engineered organisms, products, and certain articles which are plant pests or could harbor plant pests. The final rule extends the regulation of certain organisms not genetically engineered to certain organisms that are genetically engineered.

Comments Received on Proposed Regulations

APHIS attempted to solicit as many comments as possible on its proposed regulations through public hearing held in Sacramento, California, on July 29, 1986, and in Washington, DC, on August 5, 1986, and through an extension of the comment period from August 25 to September 26, 1986 (51 FR 29401, August 15, 1986). Including the comments presented at the public hearings, APHIS received 184 comments on the proposed regulations. Commenters included academicians, businesses engaged in genetic engineering, trade associations, professional organizations, private individuals/consultants, State departments of agriculture, members of the U.S. House of Representatives, and a representative from a State legislature.

APHIS has carefully considered all the comments on the proposed rule.

Based on the rationale set forth in the proposed regulations and in this document, APHIS is promulgating a final rule which will become effective on July 16, 1987.

Under the final rule, a person has to obtain a permit to import, move interstate or release into the enviroment a genetically engineered organism or product only if:

(1) The organism has been altered or produced through genetic engineering from an organism (donor, vector, or recipient);

a. That is included in the list of genera and taxa in § 340.2 and such organism meets the definition of a plant pest; or

b. That is an unclassified organism and/or an organism whose classification is unknown; or

(2) The product contains such an organism (described in (1); or

(3) Any other organism or product (not included in (1) or (2) altered or produced through genetic engineering, which the Deputy Administrator determines is a plant pest or has reason to believe is a plant pest. Thus, this final rule regulates certain genetically engineered organisms and products that present plant pest risks, and, as explained in more detail below, does not regulate an article merely because of the process by which it was produced.

Many provisions, as noted below, have been changed in response to comments, which were generally constructive and often complex. Because numerous changes have been made to the regulations as originally proposed, a summary of those changes is presented at the outset of the preamble. The summary includes the number of the paragraph in which the rationale for the APHIS action is discussed. Following the summary is a detailed discussion of the relevant comments received, and APHIS' response to those comments. The preamble is organized to correspond with sections of the final rule.

SUMMARY OF CHANGES MADE IN THE FINAL RULE

Section	APHIS action	Paragraph No. of response
§ 340.1 Definitions:		
Certificate of exemption	Changed to courtesy permit	5
Classical genetics	Not adopted	6
Genetic engineering	Adopted new definition	7
Genetic manipulation	Not adopted	8
Mutagen	Not adopted	10
Organism	Amended by excluding prions and non-living components and parts	11, 21, 22
Pathogen	Not adopted	12
Plant	Amended by excluding bacteria, fungi, and prokaryotic algae	14
Regulated article	Adopted with revisions	16
§ 340.2 Groups of Organisms:		
Removed the following taxa		20, 21

SUMMARY OF CHANGES MADE IN THE FINAL RULE—Continued

Section	APHIS action	Paragraph No. of response
Prions.		
Rickettsial-like organisms associated with plant disease		
Added the following taxa or groups of organisms:		
Gram-negative xylem-limited bacteria associated with plant diseases		
Gram-negative phloem-limited bacteria associated with plant diseases		
Added petition procedure in § 340.4 to amend list of organisms.		42
§ 340.3 Permits:		
§ 340.3(a)	Added provisions for designation of confidential business information (CBI) material	24, 25
§ 340.3(b)	Added permit for environmental release with provisions for State notification and review; APHIS review to be completed in 120 days.	29, 31
§ 340.3(c)	Added limited permit for interstate movement or importation with provisions for State notification and review; APHIS review to be completed in 60 days.	30, 31, 32, 34
§ 340.3(d)	Added provisions for premises inspection prior to permit issuance	28
§ 340.3(f)	Did not adopt requirement to report death of a regulated article; substituted reporting of unanticipated characteristics or unusual occurrence (excessive mortality or morbidity or unanticipated effects).	39
§ 340.4 Certification of exemption	Did not adopt; substituted provision for courtesy permit in § 340.3(h); Section redesignated as "petition to amend the list of organisms."	34, 42
§ 340.5 Marking and identity	None	
§ 340.6 Container requirements:		
§ 340.6(c)	Added new section to allow variance from container requirements	43
§ 340.7 Costs and charges	None	

Comments on APHIS'Authority to Restrict the Introduction of a Regulated Article

1. Approximately thirty-one commenters prefaced their remarks with general statements supporting APHIS' approach in Part 340. The comments included backing for APHIS as "lead agency" and support of APHIS' authority pursuant to the Federal Plant Pest Act (FPPA) and Plant Quarantine Act (PQA) to regulate genetically engineered organisms as set forth in its proposed regulations. Seven commenters, however, alleged that APHIS lacks the authority under the provisions of the FPPA and PQA for the proposed rule. Specifically, the commenters indicated that the FPPA does not authorize APHIS to regulate "release into the environment," but only importation and interstate movement; and that the FPPA and Federal Noxious Weed Act (FNWA) and the Act of 1903 have no "beforehand testing" or pre-release review requirements to determine if new organisms might be pests, noxious weeds or contagious agents.

APHIS disagrees with the commenters who challenged APHIS' authority for the proposed rule. Is should be noted that APHIS never cited the Federal Noxious Weed Act (7 U.S.C. 2801 *et seq.*) or the Act of 1903 (21 U.S.C. 111 *et seq.*) as authority for promulgating a final rule under Part 340. Rather, APHIS cites as authority the Plant Quarantine Act (7 U.S.C. 151 *et seq.*) and the Federal Plant Pest Act (7 U.S.C. 150aa *et seq.*).

It is the Department's position that the provisions of the rule requiring a permit prior to the release into the environment of certain genetically engineered organisms or products containing such organisms is consistent with the legislative intent of the FPPA and is a reasonable construction of the Department's statutory responsibilities under the FPPA.

The FPPA was enacted to fill gaps in the Department's authority to protect American agriculture against invasion by foreign plant pests and diseases. It confers very broad authority on the Secretary of Agriculture to prevent the dissemination into the United States or interstate of plant pests.

The legislative history of the FPPA indicates that in addition to providing authority to regulate organisms that "can injure" plants or plants products, the FPPA provides authority to regulate organisms that might later be found to be injurious to cultivated crops. (See the Department's legal opinion concerning this issue, attached as Appendix G of "Issues in the Federal Regulation of Biotechnology: From Research to Release", a report prepared by the Subcommittee on Investigations and Oversight of the Committee on Science and Technology of the House of Representatives, 99th Cong., 2nd Session, December 1986).

2. One commenter who expressed the view that separate regulation of genetically engineered organisms is not authorized by the FPPA suggested that APHIS should amend its existing regulations rather than promulgate new regulations.

APHIS disagrees with this commenter and has determined that separate regulations for certain genetically engineered organisms are needed. Under the FPPA, APHIS can regulate plant pests whether they are naturally occurring or genetically engineered. APHIS' regulations in 7 CFR 330.200 are applicable to persons seeking to import, or move interstate plant pests which are naturally occurring and have not resulted from genetic engineering. APHIS believes that the regulations in 7 CFR 330.200 are not adequate to regulate the introduction (importation, interstate movement, or release into the environment) of genetically engineered organisms and products for two reasons. The regulations as presently written provide no way for the public to determine whether or not a genetically engineered organism or product would be deemed a "regulated article." Secondly, the data that is called for in a permit application under 7 CFR 330.200 would not provide APHIS with sufficient information to make a determination on the plant pest status of certain genetically engineered organisms or products. In short, APHIS determined that its existing regulations could not be readily amended to include the data elements that are needed to adequately regulate the introduction of genetically engineered organisms, and that separate regulations for genetically engineered organisms are required.

APHIS is not treating genetically engineered organisms and products which are plant pests or for which there is reason to believe are plant pests differently than so-called "established" plant pests or naturally occurring organisms which there is reason to believe are plant pests. In both cases, a permit must be obtained from APHIS prior to importation and interstate movement. In the case of certain genetically engineered organisms, APHIS has determined that the release

into the environment of certain genetically engineered organisms is tantamount to the introduction of a new organism. Further, living organisms do not acknowledge State lines. Therefore, a permit must be obtained from APHIS prior to release into the environment.

Comments on the Scope of the Proposed Regulations

3. Some commenters expressing support for APHIS' approach also expressed concern that the proposed rule was too broad and inclusive and needed modification to be practicable. Some commenters indicated that the proposed regulations would cause APHIS to be overwhelmed with applications for permits. Many commenters expressed the view that APHIS should have the ability to exclude certain products or classes of products from the regulations as experience indicates certain exemptions are justified.

APHIS agrees with commenters expressing the view that the proposed regulations were too broad and inclusive and has made several revisions to narrow the scope of the regulations.

As a means of eliminating the need for a "responsible person" to submit a new application for a limited permit for the interstate movement of a regulated article between contained facilities each time the person seeks to move the article interstate, APHIS has added provisions in § 340.3(c)(1) that would allow such movement to be made under the provisions of a single limited permit, which would be valid for one year. Such a permit could be renewed thereafter, if appropriate. This change should significantly eliminate the number of applications APHIS will have to process, and significantly reduce the number of applications that would have to be submitted. (See paragraph 32.) Further, as discussed in more detail in paragraphs 11, 16, and 19, APHIS has amended the definitions of "organism", and "regulated article", as well as the list of organisms in § 340.2. These changes narrow the scope of the final rule.

In addition, in order to facilitate the addition or removal of certain genera, species, or subspecies of organisms on the list in § 340.2, APHIS has included provisions in §340.4 of the final rule for a person to submit a petition to amend the list of organisms. (See paragraph 42.)

Comments Requesting that APHIS Not Regulate Research

4. Sixty-eight comments were received from academic researchers and/or institutions expressing opposition to APHIS' regulation of the introduction (importation, interstate movement, or release into the environment) of regulated articles. The majority of the commenters argued that this amounts to the regulation of research and that biotechnology research can be regulated by the research community itself using institutional biosafety committees and the USDA Guidelines that were set forth in the Advanced Notice of Proposed USDA Guidelines for Biotechnology Research. (See 51 FR 23387–23393) These commenters argued that a clear distinction exists between research and product development, and that APHIS should regulate only when a product is involved.

APHIS disagrees with those commenters that believe that the agency is regulating research. APHIS believes that the regulation of the introduction of certain genetically engineered organisms does not amount to regulation of research, but rather regulation of movement and release into the environment of a regulated article. The final rule does not attempt to prescribe what a person can or cannot do in a laboratory or contained greenhouse, but rather, under what conditions a regulated article can be moved or released. It should be noted that a person does not become subject to these regulations until the person seeks to *introduce* genetically engineered organisms. Thus, APHIS does not believe that the final rule is an attempt to regulate research.

APHIS also disagrees with the comments that argued that APHIS should only become involved when a "product" is involved; there is no statutory limitation in the FPPA or PQA for APHIS to regulate in such a manner. APHIS' statutory responsibility is to take those measures necessary to prevent the introduction into the United States of "plant pests."

Comments on Definitions (§ 340.1)

The definitions of key words in proposed Part 340 collectively generated the largest number of comments on a single section. Comments on the individual definitions and APHIS' response are presented in alphabetical order.

Certificate of Exemption

5. No change has been made in this definition, but the name has been changed to "courtesy permit." For a discussion of the comments and explanation of the rationale for the change see paragraph 34.

Classical Genetics

6. The six comments on this definition generally indicated that it should have included such processes as protoplast, cell, and embryo fusion, and mutagenesis, because such processes have traditionally been associated with classical genetics techniques. APHIS agrees with this assessment, and has revised the definition of "genetic engineering" to exclude reference to classical genetics as well as protoplast, cell, and embryo fusion, and mutagenesis. An examination of the literature describing the techniques used in genetics prior to the introduction of recombinant DNA technology finds that many techniques other than interspecific crosses have been in common use. The transfer of genetic traits by methods such as protoplast, cell, and embryo fusion, and mutagenesis has been an accepted part of genetics for some years prior to the development of various recombinant DNA technologies for the movement of genes. It would thus seem that the techniques in question should properly be included as a part of classical genetics, and excluded from the definition of "genetic engineering."

As a result of the change in the definition of "genetic engineering" to exclude reference to classical genetics, the definition of "classical genetics" has been deleted.

Genetic Engineering

7. The twenty-three comments on this definition generally expressed the view that such techniques as protoplast, cell, and embryo fusion, and mutagenesis encompass classical genetic processes.

For the reasons stated in paragraph 6 above on classical genetics, APHIS agrees with the comments that specific techniques such as protoplast, cell and embryo fusion, and mutagenesis should not be included in "genetic engineering." A new definition has been provided, as follows: "The genetic modification of organisms by recombinant DNA techniques." It should be noted that if a new organism or product was produced using classical genetic techniques, and the new organism was a plant pest, it would be regulated pursuant to a similar permit system found in 7 CFR 330.200.

Genetic Manipulation

8. Because the definition of genetic engineering has been modified and the term genetic manipulation is not used in the current definition of that term, APHIS has deleted the definition of genetic manipulation.

Introduce

9. Two comments were received on the definition of introduce. One commenter suggested that the definition be expanded to include "creation of a new organism or genotype" in addition to importation, interstate movement, and release into the environment. The commenter argued that the regulation of genetic engineering should begin with the development of the organism in the laboratory.

As previously stated, the final rule does not regulate laboratory research conducted at contained facilities. The responsibility at USDA for the oversight of biotechnology research is delegated to the Assistant Secretary for Science and Education. APHIS believes that if the laboratory is a contained facility, such regulation by APHIS would be unnecessary from the standpoint of preventing the introduction of genetically engineered organisms which are plant pests or which there is reason to believe are plant pests, and would, therefore, be beyond APHIS' statutory authority.

Another commenter expressed the view that the term introduce or introduction is somewhat redundant in that it overlaps with the definition of release into the environment, and that the term "release into the environment" should be dropped from the definition of introduce.

APHIS disagrees with the commenter that inclusion of the phrase "release into the environment" is redundant. Inclusion of the phrase "release into the environment" in the definition of introduce is meant to advise persons that APHIS is regulating the release into the environment of a regulated article, in addition to regulating interstate movement and importation. According to § 340.0(a) of the final rule, no person shall *introduce* (release into the environment) a regulated article unless the introduction is authorized by a permit and the introduction is in conformance with all of the applicable restrictions in this part.

Mutagen

10. Because the definition of genetic engineering has been modified and the term mutagen (mutagenesis) is not used in the current definition, APHIS is deleting the definition of mutagen.

Organism

11. The twelve comments on the definition as proposed expressed the view that it was too broad and should not include portions of organisms. APHIS agrees with these comments, and has deleted the language "and any part, copy, or analog thereof, including DNA, RNA, which is infectious."

The original definition of organism included these constituent parts, which are not included in any currently accepted concept of the nature of an organism. APHIS has reviewed this question, and determined that the separate constituent parts of an organism can not be regarded as "living", and do not present the same plant pest risk that the complete or intact organism may pose. This is not to deny that some components, such as DNA sequences, or organisms, which are plant pests may not present some risk if they are incorporated into other organisms. However, it has been determined that it is possible to regulate the risk associated with these cell components without restoring to the inclusion of these non-living constituents as organisms. This is because a genetically engineered organism which contains these components from an organism listed in § 340.2 would be deemed a regulated article.

Prions have also been deleted from this definition, and from the list of organisms in § 340.2. The reasons for the deletion are explained in the discussion of the comments on § 340.2.

An amended definition has been adopted, as follows: "Any active, infective, or dormant stage of life form of an entity characterized as living, including vertebrate and invertebrate are animals, plants, bacteria, fungi, mycoplasmas, mycoplasma-like organisms, as well as entities such as viroids and viruses, or any entity characterized as living, related to the foregoing."

Pathogen

12. Because the definition of regulated article has been modified and the term pathogen (pathogenic) is not used in the current definition, APHIS is deleting the definition of pathogen.

Person, Responsible Person

13. One commenter noted that the proposed regulations contained definitions of the terms "person" and "responsible person." The commenter asked, "who is responsible, the individual or the individual and his corporation?

The final rule aplies to either a single person when acting alone when there is no corporation or other legal entity, or the person designated by the corporation or other legal entity to be the responsible person and the corporation or other legal entity, when the responsible person is acting within the scope of his or her employment of the corporation.

Plant

14. The majority of the seventeen commenters on this definition pointed out that it was not consistent with the classification of organisms in § 340.2 of the proposed regulations. These comments noted that the definition of plant included bacteria, but that bacteria was not listed under the Kingdom Plantae; bacteria had been listed under the Kingdom Monera. The commenters argued that bacteria should not be included in the definition of plant

Other commenters objected to the inclusion of fungi and prokaryotic algae in the plant kingdom. One commenter noted that the inclusion of such organisms in the plant kingdom fails to consider the results of twenty-five years and more of comparative biochemistry concerned with the structure and function of cells.

APHIS agrees with these comments, and has accordingly deleted bacteria, fungi, and prokaryotic algae from the definition.

An amended definition has been adopted, as follows: Any living stage or form of any member of the plant kingdom including, but not limited to eukaryotic algae, mosses, club mosses, ferns, horsetails, liverworts, angiosperms, gymnosperms, and lichens (which contain algae) including any parts (e.g., pollen, seeds, cells, tubers, stems) thereof, and any cellular components (e.g., plasmids, ribosomes, etc.) thereof.

Plant Pest

15. Nine comments were received on the definition of plant pest. The commenters indicated that the definition was very broad and overly inclusive, that it included numerous examples of nonpathogenic organisms, and that it failed to adequately notify applicants of the characteristics or criteria to enable a determination of non-pest status.

APHIS acknowledges that the definition of plant pest is very broad. However, APHIS disagrees that the definition is overly inclusive, and the definition has been adopted as proposed. The definition of plant pest comes from the definition of plant pest found in the FPPA (7 U.S.C. 150aa *et seq.*). As discussed in response to paragraph 1, the definition of plant pest was deliberately made broad by Congress to include those organisms that might *later* be found to be injurious to plants. APHIS has determined that all of the types of organisms included in the definition of plant pest have been

known to directly or indirectly injure or cause either disease or damage in plants, or in plant parts, or in processed, manufactured, or other products of plants. APHIS believes that the definition of plant pest indicates to a person that an organism that does not have plant pest status would be one that does not directly or indirectly injure or cause disease or damage in any plants, or plant parts, or any processed, manufactured, or other products of plants.

Regulated Article

16. Thirty-four comments were received on the definition of regulated article. Fifteen of these comments expressed the opinion that the proposed definition of regulated article was too broad. Some commenters stated that as defined "regulated article" could be interpreted in a way that would include many organisms that the commenters did not consider to be plant pests. In many cases commenters identified specific organisms that they stated were not plant pests, and thus should not be subject to regulation. Other commenters stated that the inclusion of non-living components of plant pest organisms should not be included as a regulated article.

APHIS agrees with these comments, and has modified the final rule in several respects to narrow the scope of regulated article.

First, the list of organisms in § 304.2, which would cause a genetically engineered organism or product to be deemed a "regulated article," has been modified, by deleting certain organisms and by clearly stating how the list is to be utilized. Secondly, the definition of organism has been modified to exclude non-living components or parts of organisms listed in § 340.2. Lastly, APHIS has modified the definition of regulated article to indicate that an organism which belongs to any genera or taxa designated in § 340.2 must meet the definition of "plant pest" or be an unclassified organism and/or an organism whose classification is unknown, or contain such an organism, or any other organism which the Deputy Administrator determines is a plant pest or has reason to believe is a plant pest. The change is significant since it would affect whether the genetically modified organism is deemed a regulated article.

The following new definition has been adopted: "Any organism which has been altered or produced through genetic engineering if the donor organism(s), recipient organism(s), or vector or vector agent(s) belongs to a genera or taxa designated in § 340.2 of this part and meets the definition of plant pest, or is an unclassified organism and/or an organism whose classification is unknown, or any product which contains such an organism, or any other organism or product altered or produced through genetic engineering which the Deputy Administrator determines is a plant pest or has reason to believe is a plant pest. Excluded are recipient microorganisms which are not plant pests and which have resulted from the addition of genetic material from a donor organism where the material is well characterized and contains only non-coding regulatory regions." (The rationale for the exclusion for certain microorganisms is discussed in paragraph 18).

Several commenters suggested that APHIS add procedures which would provide for the exclusion of organisms altered by recombinant methods, which are not plant pests.

APHIS agrees with the commenters and believes that the petition procedure discussed in paragraph 42 is responsive to the commenters' concerns.

Several commenters suggested that the delegation of authority to the Deputy Administrator to designate an organism as a "regulated article" based upon "reason to believe" was a standardless delegation of authority.

APHIS disagrees with these comments. The provision for the Deputy Administrator to designate an organism as a regulated article based upon "reason to believe" has been retained.

Section 105 of the FPPA grants the emergency authority to regulate an organism, where there is reason to believe it is a plant pest or in order to prevent the dissemination into the United States of a plant pest. With regard to conventional plant pests, the Deputy Administrator of APHIS has used this authority when it was necessary to regulate an organism that was likely to be a plant pest and was not otherwise specified because of plant pest risk as a regulated article. "Reason to believe" is based on scientific information, such as taxonomic association and biological data. This standard is an objective, not subjective one.

An example of the use of "reason to believe" occurred in 1982 when a previously undescribed disease was observed on lime trees in Southwestern Mexico. APHIS regulations prohibit entry of citrus fruit from countries where citrus canker is present. Initially it proved difficult to make a specific identification of the pathogen associated with this disease. Because the pathogen belonged to the bacterial genus *Xanthomonas*, and because the disease caused lesions on citrus leaves, it was determined that there was reason to believe that the disease in Mexico was citrus canker, and that the organism associated with the disease was a plant pest. This resulted in various actions being taken to prevent the introduction of the disease into the United States. Subsequent research conducted in the United States and Mexico confirmed that the organism causing the disease in Mexico was *Xanthomonas campestris* pv. *citri*, a regulated plant pest.

The decision by APHIS to designate an organism as a regulated article based upon the "reason to believe" provision will be an objective, informed decision made after review of substantive information regarding demonstrated plant pest risks. It will not be an arbitrary one.

Release into the Environment

17. Of the eighteen comments on this definition, the largest number concerned the fact that the proposed definition relied only on physical containment, and ignored biological containment. Other commenters requested a definition of contained greenhouse, expressed approval of the definition, or suggested various approaches to the evaluation of containment.

One commenter indicated that a general understanding of this term has been that release occurs if an experiment does not take place within the confines of a laboratory where the organism can be physically contained and remedial measures taken in the event of an accident. APHIS agrees with the commenter and believes that the concept of release should be based on the concept of a release from the confines of physical containment. One commenter suggested regulating release only if there is a deleterious alteration of the environment. APHIS believes that what is "deleterious" to the environment is too subjective a standard. USDA believes that a release from physical confinement is more understandable and a practical standard.

APHIS has adopted the definition of "release into the environment" as originally proposed. APHIS believes biological and greenhouse containment are key issues in discussions concerning this definition. While the definition of release into the environment does not formally include the concept of biological containment (i.e. the inability of the regulated article to survive outside specific environmental or host conditions) APHIS believes that biological containment is one important factor in determining the prescribed level of physical containment. Since greater scrutiny is needed to judge the

efficacy of biological containment than physical containment. APHIS does not believe a claim of biological containment is sufficient to exempt a party from the requirement of having to obtain a permit for the release of a regulated article into the environment. In APHIS' review of permit applications, determinations of the adequacy of biological containment will vary according to the subject organism and quality of scientific evidence, and will be made on a case-by-case basis. In its review process, APHIS will allow biological containment in lieu of physical containment if it determines this will prevent the dissemination and establishment of plant pests in the United States.

APHIS does not believe it is practical to try to define what is a "contained greenhouse", since what is considered adequate physical containment will vary according to the subject organism, and that such determination must be made on a case-by-case basis. For example, physical containment will depend upon combinations of laboratory practices, containment equipment, and special laboratory design. APHIS will review the data submitted in a permit application concerning the description of a "contained facility" in determining whether the contained facility is adequate to prevent the release into the environment of the genetically engineered organism. A person should consult the NIH Guidelines at 51 FR 16958, "Appendix G—Physical Containment", for guidance on what are appropriate methods of physical containment.

APHIS acknowledges that the Biotechnology Science Coordinating Committee, the National Institutes of Health, and the Environmental Protection Agency are all attempting to define what constitutes release into the environment. If a uniform definition is adopted by these groups APHIS shall consider proposing to amend the final rule to incorporate such a definition.

Well-Characterized and Contains Only Non-Coding Regulatory Regions; Exclusion for Certain Microorganisms

18. A total of nineteen comments were received on this exclusion from the definition of regulated article. It was proposed to exclude microorganisms that are "non-pathogenic, non-infectious, and otherwise not plant pests that have resulted from the addition of genetic material that is well characterized and contains only non-coding regulatory regions."

The comments on this provision ranged from doubt about the scientific soundness of such an exclusion to requests that the exclusion be retained and expanded to include other non-coding regions.

Based upon a review of these comments and the scientific literature, it was determined that there is no evidence that the addition of well-characterized non-coding regulatory genes from a prokaryote or eukaryote to a prokaryote has resulted in the *de novo* appearance of a gene product which did not exist prior to the acquisition of the new genetic material. The scientific literature indicates that regulatory, transcriptional or translational ambiguities are not found in the transfer of well characterized genetic material between prokaryotes, or from eurkaryote to prokaryote, but do occur in prokaryote to eukaryote transfers.

One commenter indicated that some pathogens have the capacity to increase in virulence or change in host range in response to a single gene mutation and that some avirulent derivatives of pathogens have the potential to regain pathogenicity by mutation. The commenter stated that such microorganisms need to be examined before release to the environment. However, the commenter noted that a distinction must be made between a derivative of a pathogen, potentially harmful, and a nonpathogenic organism bearing an introduced gene from a pathogen.

APHIS agrees with the commenter that if the recipient microorganism is not a pathogen or a plant pest the microorganism after the addition of genetic material which is well characterized and contains only non-coding regulatory regions, will also not be a pathogen or a plant pest. Therefore, as adopted in the final rule, recipient microorganisms which are not plant pests and which have resulted from the addition of genetic material from a donor organism which is "well characterized and contains only non-coding regulatory regions" are not regulated articles. However, if the recipient microorganism was a plant pest, the addition of such genetic material would not lessen the fact that the recipient microorganisms presents a plant pest risk, and as such, would be a regulated article.

One commenter suggested that other non-coding regions such as ribosomal RNAs, tRNAs, and RNAs as required for replication also be exempted from review because these do not encode proteins.

APHIS disagrees with the commenter. The reason that the exclusion cannot be currently extended to other specific non-coding, non-regulatory regions such as ribosomal RNAs, tRNAs, and RNAs required for replication is that most of these aforementioned genes are part of a complex interdependent system of operons. These operons generally contain a very wide array of disconnected functions which interact with other related and unrelated operons to poroduce critical non-structural proteins which are needed in equimolar amounts. Therefore, the consequences of the genetic transfer of this level of genetic complexity, even between bacteria, are not well understood, and could have unforeseen results. APHIS believes there may be significant potential plant pest problems present in this type of gene transfer if the exclusion were more extensive.

Commenters argued that "knowing the exact nucleotide base sequence of a regulatory element or the transfer of non-coding regulatory sequences" does not allow one to predict the biological role of this element when placed in another organism.

APHIS disagrees with the commenters. In the case of [the transfer between prokaryotes or eukaryotes to prokaryotes] "well-characterized non-coding regulatory genes," there is absolute predictability of the biological role of these genetic elements, and it can only execute its original predetermined regulatory function.

One commenter argued that it did not make sense to exempt only non-coding sequences. The commenter indicated that almost all "coding" sequences should be given exempt status such as cloned sequences. Another commenter noted that there are many well-characterized *coding* regions, which have no known or expected hazard to health or the environment, which should also be excluded.

APHIS disagrees with the commenters who believe that microorganisms which have resulted from the addition of genetic material which contains coding regions should also be exempt.

With the exclusion for microorganisms as modified in the final rule, it is impossible for the benign recipient to acquire new structural genes or gene products. The exclusion of well-characterized *coding* genes could result in the acquisition of deleterious new or novel gene products in a benign recipient. Therefore, the commenter's suggestion has not been accepted.

One commenter suggested modifying the definition of well-characterized and contains only non-coding regulatory regions. The commenter suggested modifying the definition by eliminating section (c) of the definition because it is redundant to sections (a) and (b) and by revising section (c) to indicate that the

transferred genetic material must be non-coding in the new host microorganism.

The modification of the definition as suggested by the commenter is unnecessary. There is no evidence to support the commenter's suggestions that a non-coding gene from a donor microorganism could be a coding gene in a recipient microorganism.

One commenter noted that the precision in molecular biological experiments must not be confused with precision in predicting their ecological consequences. The commenter indicated that this alteration of the organism as a whole or its relationship to other organisms in the environment would be unknown, and that such regulatory changes in the organism can create "novel" organisms which are eminently suited to disrupt ecological niches.

APHIS disagrees with the commenter's assertion that a novel or new organism would be created as a result of the addition of genetic material that contains only well-characterized non-coding regulatory regions. APHIS believes that in this specific case, the absolute understanding of the underlying molecular genetic mechanism is the sole determinant in being able to predict the plant pest characteristics of the modified microorganism. It is APHIS' position that when donor genetic material from an organism which is well characterized and contains only non-coding regulatory regions is placed into a benign receipient microorganism, the recipient will not acquire plant pest traits or become a plant pest.

Furthermore, APHIS believes that the genetic manipulations which create such a microorganism would be similar to the same type of genetic manipulations which occur in nature through mutation and natural selection (the higher or lower production of a pre-existing structural gene) or through classical breeding techniques which man has been using for the past 10,000 years. In short, such a modified microorganism would be so close to ones produced by natural mutational events or selective breeding programs (classical techniques) that there is no reason to believe that such a microorganism would be a plant pest. Furthermore, APHIS believes that the possibility of harmful ecological consequences would not be considered significant.

Comments Concerning the List of Organisms in (§ 340.2)

19. Fifty-two comments were received on the list of organisms in § 340.2, which are or may contain known plant pests or for which the Department has reason to believe are plant pests. The commenters generally expressed the view that the list was overly broad and inclusive, and that only organisms known to be plant pests should be included. Other comments were received which objected to the inclusion of various taxa or groups of organisms which commenters argued were not plant pests.

APHIS agrees with those commenters that believe that the list was overly broad and inclusive, and agrees that only organisms from any genera or taxa listed in § 340.2 and that meet the definition of "plant pest" should be regulated. APHIS has made several revisions in the final rule to implement this change.

APHIS has revised the prefatory language in § 340.2 of the rule, which explains how to determine if an organism classified in an unlisted taxa which comes under a higher listed taxa would be deemed to be a plant pest. Further, APHIS has amended the definition of "regulated article" to indicate that an organism which belongs to any genera or taxa designated in § 340.2 must meet the definition of plant pest before it is deemed a regulated article. In addition, APHIS has added the following new footnote 4 to § 340.2 which explains the conditions that must be met before an organism is deemed a plant pest.

An organism belonging to any taxa contained within any listed genera or taxa is only considered a plant pest if the organism "can directly or indirectly injure, cause disease, or damage in any plants or parts thereof, or any processed, manufactured, or other products of plants." Thus, a particular unlisted species within a listed genus would be deemed a plant pest for purposes of § 340.2 if the scientific literature refers to the organism as a cause of direct or indirect injury, disease, or damage to any plants, plant parts, or products of plants. [If there is any question concerning the plant pest status of an organism belonging to any listed genera or taxa, the person proposing to introduce the organism in question should consult with APHIS to determine if the organism is subject to regulation.]

As the language in the footnote indicates, an organism is not necessarily considered to be a plant pest, and thus subject to regulation, simply because the organism is a member of any listed genera or taxa. The list of genera or taxa in § 340.2 is presented as a list of all taxa which may contain plant pests. Within any listed genus or taxon, the organisms subject to regulation as plant pests are only those organisms that meet the statutory definition of plant pest (i.e., causes injury, disease, or damage in plants, plant parts, or products of plants). In most cases, organisms that are known to be plant pests will be referred to or discussed in the scientific literature. APHIS' reveiew of the scientific literature involves a search of the relevant agricultural data bases which include, but are not limited to Agricola, Biosis Previews, Cab Astracts, Agris International, Life Sciences Collection, and Supertech.

In addition to all those species for which the plant pest status can be determined by reference to the scientific literature, there will be certain other species or organisms for which the plant pest status will be unclear, due to such things as problems with taxonomic designation. If there is any question concerning the plant pest status of any species or organism belonging to any listed genera or taxa, the person proposing to introduce the organism in question should consult with APHIS to determine if the organism is subject to regulation.

This procedure for determining if an organism is subject to regulation under Part 340 is the same type of determination that must be made when a person proposes to import or move interstate non-genetically engineered organisms that may be subject to regulations promulgated under the FPPA and PQA and found in 7 CFR 330.200.

Lastly, for the reasons discussed in the proposed regulations of June 26, 1986, published in the **Federal Register** at 51 FR 23355, unclassified organisms and/or organisms whose classification is unknown are also included in § 340.2.

20. Many comments contained statements that various groups of organisms listed in § 340.2 should be removed from the list because these organisms are not plant pests. The groups of organisms most frequently mentioned in these comments were the bacterial genera *Rhizobium* and *Bradyrhizobium*, and various groups of mycorrhizal fungi.

However, those commenters did not present sufficient data to justify excluding *Rhizobium*, *Bradyrhizobium*, and various groups of mycorrhizal fungi from the list of organisms in § 340.2.

These taxa or groups of organisms contain organisms that are able to infect plants and survive at the expense of the host plant. The interaction between the infecting organism and the host plant is usually regarded as a symbiotic one, with the plant benefiting from the increased availability of essential nutrients. However, because the groups of organisms in question contain species that are well adapted to infecting and surviving in their plant hosts, it was determined necessary to retain these groups on the list in § 340.2. It should be noted that new § 340.4 provides the

procedures for amending the list of organisms in § 340.2.

The list in § 340.2 is composed of all those genera or taxa which may contain organisms that are plant pests. Within any taxonomic series, the lowest unit of classification actually listed is the group which is composed of, or includes, organisms that are regulated. Organisms belonging to all lower taxa contained within the group that is listed are included as organisms which are or may contain plant pests, if they otherwise meet the definition of plant pest as explained above. For example, when the lowest unit listed of a particular series is an order, then members of all families, genera, and species belonging to that order are meant to be included as organisms which are or may contain plant pests, if such organisms meet the statutory criteria for being a plant pest.

In a second example, if an order is included on the list, but is followed by a listing of one or more of the families belonging to that order, then only the members (all genera and species) of those families listed that meet the definition of plant pest are intended to be regulated. Members of any other families within that order that are not listed are not regulated.

It is crucial to note that an organism of any genera or taxa listed in § 340.2 is significant only when the organism meets the definition of a plant pest and two additional conditions are met. The organism must have been modified in some way through the process of genetic engineering (as defined in § 340.1), and there must be the intention to import the organism, to move the organism interstate, or to release the organism in the environment. If an organism is listed in § 340.2 but does not meet both the condition of movement or release to the environment, and of being modified by a process of genetic engineering, it is not regulated under Part 340.

Finally, it should be noted that all other regulations which affect the importation or movement of an organism which is a plant pest or could harbor a plant pest remain in effect regardless of the status of the organism under Part 340. To remind persons of this fact the following language has been added to footnote 1.

Under regulations promulgated in 7 CFR "Subpart-Nursery Stock" a permit is required for the importation of certain classes of nursery stock whether genetically engineered or not. Thus, a person should consult those regulations prior to the importation of any nursery stock.

21. Several comments were received which contained statements that the list of organisms in § 340.2 includes groups which have an incorrect taxonomic designation or that the list is incomplete with regard to the Kingdom Monera. In response to these comments, APHIS scientists reviewed the list of organisms and determined that certain changes were appropriate.

Taxonomy is a dynamic branch of the biological sciences, and is particularly so when the organisms being classified are in taxa or genera that have only recently been identified. After consulting the current literature, the following changes are made in the list of organisms in § 340.2.

Prions have been removed from the list of organisms which are or contain plant pests in § 340.2. There is no evidence at the present time that any prion is associated with a plant pest. All of the prions identified to date have been associated with diseases in animals. If in the future a prion should be found to be associated with a plant pest or suspected of causing a plant disease that organism could be added to the list.

The group of organisms previously referred to as Rickettsial-like organisms associated with plant disease are correctly described as gram-negative xylem-limited bacteria associated with plant diseases. Examples of diseases associated with these pathogens are Pierce's disease of grape and phony disease of peach.

Some organisms previously thought to be mycoplasma-like organisms (MLO) are in fact true bacteria and should be correctly listed as gram-negative phloem-limited bacteria associated with plant diseases. Examples of organisms in this group are the bacteria which are associated with citrus greening disease and clover club leaf disease.

Concerning those comments that the list is incomplete, APHIS is conducting a further examination of the plant pest status of members of various taxa in the Kingdom Monera to determine if additional taxa should be added to the list or if a more specific and exact listing can be proposed for members of some of the genera listed. If APHIS' research indicates additional taxa should be included in § 340.2 or if the list should be made more specific, a document shall be published in the Federal Register proposing to add such taxa or otherwise to revise the list.

Items Exempt From Regulation and Procedures for Removing Organisms From the List

22. Thirty-nine comments contained statements objecting to the inclusion of various organisms or portions or constituents of organisms as plant pests. Many comments contained statements that various portions (plasmids, DNA fragments, etc.) of plant pests be exempted from regulation if these components are "non-pathogenic." Some comments contained the suggestion that "disabled" pathogens not be regulated as plant pests.

In response to these comments, APHIS has modified the definition of organism so that this definition as amended now excludes parts or components of organisms listed in § 340.2. As previously stated, the definition proposed by APHIS for organism has been revised, and now excludes non-living components of living organisms. The reasons for this change have been previously explained in paragraph 11. Any organism containing these parts or components would be regulated if the parts or components were incorporated into the organism through the process of genetic engineering (as defined in § 340.1).

The movement of killed organisms that are included in the list of organisms in § 340.2 is not regulated. The movement of non-living components (including, but not limited to, DNA, RNA, and plasmids) of organisms included on the list of organisms in 340.2 is not regulated. However, if certain components of regulated plant pest organisms, including DNA and RNA sequences, organelles, and plasmids retain their identity and are incorporated as part of an organism, then the introduction of this organism would be regulated under Part 340. It was not APHIS' intent to imply that all species, biotypes, lines, or races of the taxa listed in proposed § 340.2 were plant pests. For example, *Erwinia caritovora* is a bacterial plant pathogen causing soft rot diseases. All members of the genus *Erwinia* are included in the list of organisms in § 340.2. If this organism is modified by the process of genetic engineering, the modified bacteria are subject to regulation under Part 340. If genetically engineered bacteria of this species are killed, then the killed cells and/or any parts or components (including DNA and RNA sequences) that might be extracted from them are not subject to regulation. Should any genetic material from these killed bacteria, including DNA and RNA or other component as noted at the beginning of § 340.2, be introduced into any living organism by the process of genetic engineering, then that organism would be subject to regulation under Part 340.

23. Many comments expressed concern about the inclusion of certain organisms as plant pests. In many cases these organisms are members of a group containing many plant pests, such as the

bacterial genera *Pseudomonas, Xanthomonas,* and *Erwinia.* Commenters frequently requested that specific organisms belonging to these groups which were believed not to be plant pests be removed from the list. These requests were based on conclusions and opinions, rather than any complete submission of factual material.

Organisms or groups of organisms are considered to be on the list of organisms in § 340.2 if they meet the statutory definition of plant pest. To determine if a particular species is a plant pest, a person should consult the scientific literature or APHIS to determine if the species has plant pest characteristics, as discussed in footnote 4 above.

APHIS recognizes that there may be instances when it may be appropriate to remove specific organisms from the list because they do not appear to be plant pests. Provisions for submitting a petition to remove a specific organism or group of organisms from the list are discussed in § 340.4. Any person may submit a petition to remove an organism or group of organisms from the list in § 340.2. The petition should include full and factual information supporting the request for removal.

Comments on Permits for the Introduction of a Regulated Article (§ 340.3)

Numerous comments were received on § 340.3 of the regulations pertaining to the issuance of a permit for the introduction of a regulated article. The comments pertained to: The need for additional provisions to protect confidential business information; the 180 day review period for processing permit applications; data required in applications; the need for state involvement in the review process; certificate of exemption/courtesy permits; the need for additional safeguards to be added to the final rule; and the standard permit conditions.

Confidential Business Information

24. One commenter suggested that it would be beneficial if the regulations contained specific instructions to an applicant in order to identify and protect confidential business information (CBI).

APHIS agrees with the commenter, and has revised § 340.3(a) of the final rule to include provisions advising applicants how CBI should be designated and submitted. Under § 340.3(a) the responsible person should submit two copies of a permit application. If there is CBI information contained in the application, then each page of the application containing such information should be marked "CBI Copy." In addition, those portions of the application deemed CBI should be so designated. The second copy of the application should have all such CBI deleted and should be marked on each page of the application where CBI was deleted "CBI Deleted." If an application does not contain CBI, then the first page of both copies of the application should be marked "No CBI."

APHIS believes that such procedures will readily identify those applications which contain CBI and will specifically designate those portions which the applicant feels must be protected. In addition, by requiring that an applicant submit a second copy of an application with CBI deleted, this will provide APHIS with a copy of the application which can be routinely sent to the State departments of agriculture for their notification, and review of the application and to requesting public interest groups without concern that CBI data might not be properly safeguarded.

25. Other comments acknowledged that the APHIS policy statement on CBI (See 50 FR 38561–38563, September 23, 1985) was an important element in USDA's regulatory program, but that it is important that these same procedures apply equally to any individual outside of APHIS, at other USDA agencies, that handle CBI in connection with an APHIS action.

APHIS agrees with these commenters. It should be noted that if CBI is made available to other government employees at other USDA agencies, such employees are prohibited under the Trade Secrets Act (18 U.S.C. 1905 *et seq.*) from disclosing such information. The Trade Secrets Act imposes serious criminal penalties for violating its provisions, and those government employees handling CBI are aware of the need to safeguard CBI. In addition, the USDA is drafting CBI materials specifically for the Office of Agricultural Biotechnology (OAB) which is the office which coordinates biotechnology research for the Science and Education Administration. These CBI materials will include a "Guide for the Control of Confidential Business Information Relating to Proposals for Approval of Biotechnology Research," and a "Commitment to Protect Confidential Business Information Form," to be signed by any person who receives CBI in an official capacity through the OAB.

180 Day Review Period for Processing Permit Applications

26. Fifty-three comments were received on the proposed provisions of the regulations which provided for a 180 day period for the review of permit applications.

The comments ranged from the observation that 180 days was "too long" to more strongly worded statements that such a delay was "unreasonable, unacceptable, and untenable." Approximately half the commenters (25) on the 180 day review period suggested a shorter review period and/or structured review procedures.

One commenter suggested that the review period should be no longer than 60 days. Other commenters expressed the view that applications should be reviewed for their completeness within 45 days, with a final decision being made in 90 days. The commenters suggested that for complicated applications, there could be a provision for an extended review of up to 120 days if the applicant and APHIS so agreed.

Most commenters suggested that a 90 day review period would be reasonable and in accord with the processing time for a pre-manufacturing notification (PMN) submitted to EPA under the Toxic Substances Control Act.

Nearly a quarter of the comments on this issue objected to the fact that in the proposed review period, APHIS did not distinguish between the different types of permits people would be requesting. These comments expressed the view that release into the environment and interstate movement or importation were separate activities and should be treated as such. One commenter suggested that 14 days would be a more appropriate period for the issuance of a movement permit.

APHIS agrees with the commenters that believe the proposed 180-day review period should be reduced and that the review period should vary according to the type of permit being issued.

APHIS has adopted a 120-day period, rather than a 60-day or 90-day time period time to review an application for release into the environment for two reasons. First, before APHIS issues a permit for release, a thorough and comprehensive environmental assessment must be prepared. Because of the doctrine of "Functional Equivalency," the EPA, which by statute must review a PMN within 90 days from receipt of a complete PMN, does not have to prepare an environmental assessment during the review period. APHIS has determined it necessary to prepare environmental assessments pursuant to the National Environmental Policy Act (NEPA) prior to issuance of a permit for release into the environment. Therefore, APHIS believes that it needs 120 days to review a permit application for environmental release. In the event an environmental impact statement

(EIS) has to be prepared, the review period would be extended. Secondly, the final rule, as revised, provides that before APHIS issues a permit for environmental release it shall submit a copy of the application for State notification and review. Because of the necessity to coordinate and consult with the State where release shall occur, APHIS believes it's advisable to allow for more than a 60-day review period.

It should be noted that 120 days would be the *maximum* time APHIS would need to review a complete application for environmental release that does not involve the preparation of an EIS, and is the period an applicant should use for planning purposes. APHIS shall make every attempt to complete its final review in less than 120 days. One hundred and twenty days will also allow APHIS to schedule an inspection of the site where the release is to occur prior to the issuance of a permit, as provided for in new § 340.3(d). It should be further noted that § 340.3(b) of the final rule is being revised to indicate that APHIS will complete its initial review within 30 days of receipt and shall advise the responsible individual if any additional information is needed within 30 days of receipt of the application.

APHIS disagrees with the commenter who suggested that a 14-day review period would be a sufficient period to process an application for a permit for interstate movement. As explained in more detail below, because of the need to consult with State officials and possibly to conduct an inspection of the contained facility where the regulated article is to be stored, APHIS has amended the final rule in § 340.3(b) to provide for a 60-day review period. For the review of applications for interstate movement or importation into a contained facility, APHIS will, however, complete its initial review within 15 days of receipt and advise the responsible individual if additional information is required. It should also be noted that 60 days is the *maximum* time USDA will take to review a complete permit application for interstate movement or importation to a contained facility and is the period an applicant should use for planning purposes. In all possible cases, APHIS will try to complete its final review in less than 60 days.

Data Required in an Application

27. One commenter noted that a significant amount of genetic information is required in advance of approval of experimentation. The commenter noted that the level of documentation required by these regulations is usually generated as a result of the research.

As revised, the final rule calls for less data in an application for a limited permit for interstate movement or importation than must be submitted in an application for environmental release. APHIS believes that the data that is required for an application for environmental release should have been obtained before release is requested, and can be obtained from the scientific literature and/or by doing research within a contained facility.

28. One commenter indicated that there is no need for APHIS to require extensive documentation on proposed experiments after the work has been approved elsewhere. The commenter suggested that documentation of other approvals, a brief description of the materials, and a statement of the level of containment should be enough to quickly be granted a permit to receive cultures that are to be used in a contained facility.

APHIS believes that the provisions of the final rule which provide for the issuance of a limited permit for interstate movement of a regulated article into a contained facility address many of the concerns raised by the commenter. As revised, APHIS will issue limited permits for interstate movement in less time by requiring less data than a permit for release into the environment.

Other commenters argued that the proposed regulations were too restrictive as they pertained to the interstate movement of low risk genetically engineered organisms. One commenter indicated that prior approval should not have to be obtained for the interstate movement of organisms shipped between laboratories which comply with NIH containment guidelines. The commenter argued that in such situations a simple notification to USDA pertaining to the movement of such organisms would suffice. These commenters did not present specific examples of the types of organisms and under what conditions certain organisms would not pose a risk of plant pest dissemination.

It appears that there are circumstances under which certain genetically engineered organisms such as those employed as "libraries" or biological containers can be moved interstate between contained facilities under conditions which would not present a risk of plant pest dissemination, and for which no permit would be required. It appears that such organisms are *E. coli* K-12 or other bacterial strains with similar characteristics, containing genetic material from any plant pest, except when such genetic material contains genes which code for: substances toxic to plants and organisms in the agro-ecosystem; or substances influencing plant growth; or genes for disease susceptability; or substances or characteristics associated with resistance to pesticides.

Likewise, a unique synthetic nucleotide sequence added as a "marker" for identification of a specific microorganism, when constructed to not constitute an open reading frame in any register, also poses no risk and is completely benign.

In accordance with notice provisions of the Administrative Procedure Act, APHIS intends to publish a proposed rule in the Federal Register within the next 30 days which would amend Part 340 to include these exclusions.

The fact that APHIS intends to publish a document which would propose to make certain changes to the final rule, shortly after its publication, reflects APHIS' belief that the regulations should be malleable and keep pace with the scientific "state of the art." It is anticipated that the APHIS regulations will parallel the NIH Guidelines in the sense that these regulations will continue to evolve and be updated as experience is gained and more information becomes available on the plant pest risk presented by the introduction of genetically engineered organisms. In short, APHIS believes that when it can be shown that the interstate movement between contained facilities of certain organisms does not present a risk of plant pest introduction or dissemination, then the regulations should be amended to exclude such movement from the permit requirements.

Lastly, to facilitate receipt of current data relative to the plant pest status of certain organisms from outside sources, APHIS has included the petition process in § 340.4 of the final rule.

Permit Processing Procedures

29. Section 340.3(b) of the final rule is a new section and is entitled, "Permit for release into the environment." If an application for environmental release is complete when received, APHIS shall notify the responsible individual of the date of receipt of the application for purposes of advising the applicant when the 120 day review period commenced. If an application is not complete, APHIS will advise the responsible individual what additional information must be submitted and shall commence the 120 day review period upon the receipt of the additional information, assuming the

additional data requested is adequate. When it is determined that an application is complete, APHIS shall submit to the State department of agriculture where the release is planned, a copy of its initial review and a copy of the application marked "CBI Deleted" or "No CBI" for State notification and review. Pursuant to APHIS' CBI Policy Statement of September 23, 1985 (50 FR 38561–38563), the requirements of Section VIII(b) must be complied with by a State prior to disclosure by APHIS to the State of CBI material. This section requires that the request be for an official purpose; that the requester have security procedures equivalent to those of APHIS; and that the person submitting the material determined by APHIS to be CBI be notified of the request prior to any disclosure.

An application for release into the environment must include the information required by § 340.3(b)(1)–(14). These are the same 14 data elements that appeared in the proposed regulations under § 340.3(a).

30. Section 340.3(c) of the final rule is a new section and is entitled, "Limited permits for the interstate movement or importation of a regulated article." This section provides for a 60 day review period with an initial review being performed by APHIS within 15 days of receipt of an application. Like an application for release into the environment, if an application is incomplete and additional information must be requested, APHIS will commence the 60 day review period upon receipt of the additional information. Section 340.3(c) of the final rule also provides that when APHIS determines that an application is complete, APHIS shall submit a copy of its initial review and the "CBI Deleted" or "No CBI" copy of the application to the State department of agriculture located in the State of destination of the regulated article, for State notification and review of the application.

State Involvement in the Review Process

31. Several comments were received from State departments of agriculture concerning the need for State involvement and participation when APHIS is deciding whether to issue a permit for release into the environment. A comment from the State of New Mexico indicated that notification of the State where release will be accomplished is necessary to minimize last minute complications. The State of California indicated that it has regulations that mandate certain review procedures prior to the release of certain genetically engineered organisms into the environment, and that APHIS' permit application for the introduction of genetically engineered organisms contains no provisions for State recommendations on the application. The State of North Carolina further indicated that the State where a person intends to release a regulated article should be given an opportunity to review the application, and that the State should be notified of any exemptions that may be granted, or if a permit is withdrawn.

APHIS agrees with these commenters that State notification and review of an application for the introduction of a regulated article is essential. To ensure that the affected State has been notified and has an opportunity to review a permit application for release or interstate movement or importation, APHIS has modified §§ 340.3(b) and (c) to include provisions that call for State notification and review of a permit application. These provisions which ensure State involvement and participation in the permitting process for genetically engineered organisms is totally consistent with existing procedures for the issuance of a permit for the movement of plant pests under 7 CFR 330.200. It is envisioned that State regulatory officials will play a significant role in providing site specific and other environmental and ecological data on the location where a genetically engineered organism is to be released, and otherwise assist in the enforcement of the Federal regulations, on a cooperative basis.

Provisions for the Issuance of a Single Permit for Multiple Interstate Movements

32. New § 340.3(c)(1) provides that the responsible person may apply for a single limited permit that would be valid for the interstate movement of multiple regulated articles moving between contained facilities in lieu of having to submit an application for each individual interstate movement. Such a limited permit for interstate movement would be valid for one year from the date of issuance. The purpose of this provision is to eliminate the need for a person to have to go to APHIS for approval each time the person proposes to ship a regulated article, when this information can be made available to APHIS in advance of the shipments, all at one time. APHIS has added provisions allowing for multiple shipments to multiple locations under a single limited permit in response to comments that it would be too burdensome to require a person to submit a new application for each new shipment. New § 340.3(c)(1) further provides that a limited permit for interstate movement of a regulated article shall only be valid for the movement of those regulated articles moving between those locations specified in the application. If a person seeks to move regulated articles other than those specified in the application or to locations other than those specified in the application, a supplemental application must be submitted to APHIS.

Section 340.3(c)(1) of the final rule further provides that the responsible person shipping a regulated article interstate shall keep records for one year demonstrating that the regulated article reached its intended destination. The purpose of this requirement is for the shipper of the regulated article and APHIS to be able to verify that the regulated article, in fact, reached its intended destination, and to provide the capacity to trace a regulated article in the event it is delivered to the wrong location. This provision can be satisfied when using the mail by sending a regulated article, "certified mail, return receipt requested," or by using a carrier that requires the consignee sign for the delivery. If a person does not use the mail or a carrier to deliver a regulated article, then the consignee should keep a log of when the regulated article is received, and a duplicate copy of the log should be maintained by the responsible individual. This section also requires that no person move a regulated article interstate unless the number of the limited permit appears on the outside of the shipping container.

A person must submit data required by §§340.3(b) (1), (2), (4), (8), (7), (9), and (11–14) in an application for a permit for multiple interstate movements. This is the same information that would have to be submitted in an application for a limited permit for a single interstate movement. This data would provide APHIS with necessary information about the nature of the regulated article(s), the method of movement, and how it shall be contained during movement and at the article's destination(s). Such information will enable APHIS to decide whether or not a permit can be issued. If a permit is issued, such data will be used in determining what conditions, if any, should be imposed as part of the permit to eliminate or reduce the possibility of dissemination of a plant pest.

Limited Permits for Importation

33. New § 340.3(c)(2) of the final rule provides that the responsible person seeking a permit for the importation of a regulated article to a contained facility must submit an application for a permit

at least 60 days prior to the importation of *each shipment* of regulated articles.

Unlike a limited permit for interstate movement, APHIS is requiring that a person submit a separate application for each importation of regulated articles rather than issuing a "single" permit for importation that would be valid for multiple importations for a specified period.

APHIS has traditionally allowed persons moving regulated articles interstate to do so repeatedly under the provisions of a single limited permit, for movement to specified destinations for utilization or processing. Such a system would not be practicable for the importation of regulated articles because the entry status of many imported articles frequently changes depending on the plant pest status of the article's country of origin. Because the entry status of a regulated article is subject to change, APHIS needs to review each permit application for importation prior to importation so that a decision whether to allow importation can be made on a case-by-case basis.

APHIS anticipates that in many cases, a request for the renewal of a limited permit for importation can be processed in less than 60 days. APHIS has added the following new footnote 7 to § 340.3 (c)(2) to reflect this fact.

Renewals may receive shorter review. In the case of a renewal for a limited permit for importation that was issued less than one year earlier, APHIS will notify the responsible person within 15 days that either: (1) The renewal permit is approved or (2) that a 60 day review period is necessary because the conditions of the original permit have changed.

APHIS is also requiring that the responsible person importing a regulated article keep records for one year that demonstrate that the regulated article arrived at its intended destination. The one year recordkeeping requirement is consistent with the recordkeeping requirement for limited permits for interstate movement. A person must submit data required by §§ 340.3(b)(1),(2),(4),(6),(7),(9), and (11)–(14) in an application for a limited permit for importation. This is the same data that must be submitted in an application for a limited permit to move a regulated article interstate. APHIS believes that such data will enable it to properly evaluate the risk of allowing the regulated article to be imported. This data will provide APHIS with necessary information about the country of origin of the regulated article, the nature of the regulated article, the method of movement, and how it shall be contained during movement and at its final destination. As with limited permits for interstate movement, because the regulated article is moving under containment into a contained facility, APHIS is requiring that the same data be submitted in an application to import the regulated article as is required in an application for interstate movement.

Certificate of Exemption/Courtesy Permits

34. Six comments were received on § 340.4 of the proposed regulation entitled, "Certificate of Exemption." Several commenters suggested that the term "exemption" is not appropriate because it implies that APHIS is exempting the introduction of a regulated organisms from the provisions of the regulation, rather than providing an indication that the organism was never subject to the regulation to begin with. These commenters suggested that the appropriate name for such a document should be a "courtesy permit," as found in 7 CFR 330.208. One commenter suggested that a certificate of exemption be issued in situations where a regulated article is biologically contained.

APHIS agrees with commenters that argued the name "certificate of exemption" is a misnomer, and has changed the name of the document that will be issued to "courtesy permit." APHIS will issue a courtesy permit under the same circumstances that were proposed for the issuance of a "certificate of exemption," i.e., the organism was never subject to regulation under Part 340, but is similar to other organisms regulated under Part 340.

APHIS also added new § 340.3(h)(3) which indicates that a courtesy permit will be issued within 60 days from the receipt of a complete application, or the applicant will be advised that a permit is required under § 340.3(b) or (c). APHIS will conduct its initial review of a courtesy permit application within 15 days of receipt of a complete application and advise the applicant within this period if any additional information is required. It should be noted that 60 days is the maximum time it will take for the issuance of a courtesy permit, and that every effort will be made to issue such permits in less than 60 days.

Since courtesy permits are issued for organisms which are not regulated articles, the issue of containment, whether biological or physical, is not material.

35. One commenter believed that a person would be required to obtain a "certificate of exemption" (now courtesy permit) when organisms are produced through classical genetics.

APHIS wishes to stress that a courtesy permit is an *option* that an applicant may seek if it believes that such a permit would facilitate the movement of an organism through a USDA port of entry, because the movement might otherwise be impeded because of its similarity to a regulated article.

Lastly, one commenter suggested that a certificate of exemption should be extended to those genetically engineered organisms otherwise subject to regulation under Part 340, that can be documented not to be plant pests.

In such cases, APHIS would issue a permit without conditions (restrictions) for the introduction of the regulated article.

The preceding discussion on APHIS permits can be summarized as follows:

APHIS PERMITS FOR THE INTRODUCTION OF A REGULATED ARTICLE[1]

Type of permit	Application elements	USDA review period	USDA action	State notification and review required
Environmental release	§ 340.3(b)(1)–(14)	120 days (maximum time from receipt of complete application;[1] initial review within 30 days).	Issue permit with conditions; request additional data; or deny permit with reasons.	Yes.
Limited Permit for Interstate Movement or Importation into a Contained Facility.	§ 340.3(b) (1), (2), (4), (6), (7), (9), (11)–(14).	60 days (maximum time from receipt of complete application; initial review within 15 days).	Same as above	Yes.

APHIS PERMITS FOR THE INTRODUCTION OF A REGULATED ARTICLE[1]—Continued

Type of permit	Application elements	USDA review period	USDA action	State notification and review required
Courtesy Permit[1] (not required; may be sought at the option of an applicant; organism not a regulated article).	§340.3(b) (1), (2), (5), (7) and statement why not a regulated article.	60 days with initial review within 15 days.	Issue courtesy permit; request additional data; or advise applicant that another permit is required.	No (if courtesy permit issued). Yes (if another permit issued).

[1] The 120 day review period would be extended if preparation of an environmental impact statement was required.

Need for Additional Safeguards

38. Three comments were received on the need for additional safeguards to be added to the rule. One commenter indicated that the proposed regulations did not contain the safeguards already present in 7 CFR 330.202(b) applicable to the movement of plant pests. The commenter noted such provisions allows USDA to inspect at its discretion, any site or premises prior to the issuance of a permit, to determine the adequacy of the site or premises for purposes of containment.

APHIS agrees with the commenter and believes that the final rule should contain provisions giving APHIS the option to conduct a site or premises inspection prior to the issuance of a permit. Accordingly, APHIS has added new § 340.3(d) entitled, "Premises inspection," which is consistent with 7 CFR 330.202(b) of its existing plant pest regulations. Section 340.3(d) provides that an inspector may inspect the site or facility where regulated articles are proposed to be released or contained under permit.

This section further provides that failure to allow the inspection of a premises prior to the issuance of an environmental release or limited permit shall be grounded for the denial of the permit.

37. Other commenters suggested that USDA publish guidelines for academic investigators that would be useful in determining what constitutes a pathogenic or environmental hazard, and recommendations for commensurate containment levels. One commenter further suggested that APHIS publish a laboratory safety monograph which addresses feasible greenhouse containment, and construction and utilization of growth chambers. Another commenter suggested that USDA include in its regulations minimal safety precautions for biotechnology research. The commenter further noted that not all personnel have the desirable training in anti-contamination and containment techniques.

APHIS believes that it would be beyond the scope of the regulations to include minimal safety precautions for biotechnology research. These comments pertain to worker safety and do not address the issue of plant pest dissemination and establishment. APHIS believes that such information should be made available by other Federal agencies whose responsibility is to regulate Federally funded research or worker safety, e.g., the National Institutes of Health, the Science and Education Administration of USDA, or the Occupational Safety and Health Administration (OSHA).

For reasons discussed in paragraph 17, APHIS does not believe the issuance of a monograph for greenhouse containment is appropriate because of the need to make such determinations on a case-by-case basis.

Standard Permit Conditions

38. Several commenters objected to the wording of some of the standard permit conditions. These commenters argued that the phrase "as determined necessary by the Deputy Administrator" is vague and open-ended.

In an attempt to provide more specificity to the standard permit conditions, APHIS has moved the phrase "as determined necessary by the Deputy Administrator" from the conditions in §§ 340.3(f) (1) and (2) and has inserted the phrase, "in a manner so as to prevent the establishment and dissemination of plant pests." APHIS believes this change makes these conditions more specific.

Sections 340.3(f) (7) and (8) still retain the phrase, "as determined necessary by the Deputy Administrator." The language in § 340.3(7) gives APHIS the authority to specify in a permit any special conditions that might be deemed necessary to ensure the regulated article will not be accidentally released or that there will not be an unauthorized release. APHIS believes that such determinations can only be made on a case-by-case basis, and that retention of this phrase gives APHIS the flexibility need to ensure against an accidental or unauthorized released of the regulated article.

Section 340.3(f)(8) provides that a regulated article shall be subject to the application of remedial measures (including disposal) determined by the Deputy Administrator to be necessary to prevent the spread of plant pests. Such authority would only be exercised in the event of an accidental release of the regulated article, and gives APHIS the necessary authority to prevent the dissemination of plant pests. Such emergency authority is found in 7 U.S.C. 150dd of the FPPA.

APHIS has revised § 340.3(f)(9) to now read, "a person who has been issued a permit shall submit to Plant Protection and Quarantine monitoring reports on the performance characteristics of the regulated article in accordance with any monitoring reporting requirements that may be specified in a permit. This condition previously specified that such reports would have to be submitted, "as deemed necessary by the Deputy Administrator." The decision to require the submission of monitoring reports will be made on a case-by-case basis, and will depend on the nature of the regulated article. Monitoring reports will not be required of all permittees.

39. Six commenters objected to the time periods for reporting specified events to APHIS (i.e., unauthorized release (24 hours)), characteristics substantially different from those in an application (5 working days), and death of the regulated article (5 working days). Several commenters also objected to having to report the death of the regulated article, believing that death is not an unusual occurrence. One commenter objected to the fact that oral notification was required immediately, and, in every case, followed by the submission of written notification. In response to these comments, APHIS has made the following changes to the reporting requirements in § 340.3(f)(10).

Oral reporting to APHIS is now only required in the event of any accidental or unauthorized release. Because of the potential consequences of such an event, APHIS believes that such

occurrence must be orally reported, immediately upon discovery, and in writing within 24 hours. If immediate oral notification is impossible, then reporting should occur on the first working day after discovery of the release. APHIS has eliminated the requirement of oral notification for all reportable events other than unauthorized or accidental release.

40. One commenter suggested that the rule should vary the time within which an accidental or unauthorized release must be reported, depending on the nature of the regulated article.

While not all regulated articles present the same risk of plant pest dissemination, APHIS believes that in the event of an unauthorized or accidental release, it needs to know about such events as quickly as possible and that reporting times should be uniform (24 hours) regardless of the nature of the regulated article.

41. In response to several comments, APHIS has eliminated the requirement of having to report the death of a regulated article in proposed § 340.3(c)(10)(iii). Under § 340.3(f)(10)(ii) of the final rule, a person need only report in writing, as soon as possible, but not later than 5 working days, if the regulated article or associated host organism is found to have characteristics substantially different from those listed in the permit application or suffers any unusual occurrence (excessive mortality or morbidity or an unanticipated effect on non-target organisms). APHIS believes that the death of a regulated article, as discussed above, should not be a reportable event.

APHIS believes that, as modified, having to report excessive mortality or morbidity or an unanticipated effect on a non-target organism as soon as possible but not later than 5 working days, is a reasonable requirement. APHIS believes that this requirement will advise the Agency of any disease or pest that may be of significance.

It should be noted that APHIS has added the phrase "as soon as possible" to clarify the agency's intent that the reporting should be prompt. However, APHIS has not changed the requirement which appeared in the proposed regulations that the reporting must not occur later than 5 working days from the observance of such events.

Denial of a Permit

APHIS, to fully inform permittees of their appeal rights, has included provisions in §§ 340.3(e) and (g) which provide appeal provisions in the event a permit is denied.

Petition To Amend the List of Organisms (§ 340.4)

42. Several commenters suggested that USDA should include a mechanism which would allow persons to petition for the "delisting" or removal of organisms from the list of organisms in § 340.2 of the final rule, if it could be demonstrated that such organisms are not plant pests. Other commenters indicated that USDA should include a mechanism that would allow a person to seek the addition of organisms to the list, if it could be shown that such organisms were plant pests.

USDA agrees with the commenters and has added a new § 340.4 to the final rule, entitled "Petition to Amend the List of Organisms." USDA believes that the petition mechanism will afford interested persons the opportunity to readily bring information to USDA's attention, as new information becomes available about existing or newly discovered organisms. The petition process in § 340.4 is in accord with section 4(e) of the Administrative Procedure Act (5 U.S.C. 553(e)) for the issuance, amendment, or repeal of a rule and with USDA's Departmental Proceedings in 7 CFR 1.28.

Under § 340.4(a) of the final rule, any person may submit a petition to the Deputy Administrator of Plant Protection and Quarantine to amend the list or organisms in § 340.2 by adding or removing any genus, species, or subspecies. Section 340.4(a) further provides that a petitioner may supplement, amend, or withdraw a petition, in writing, without prior approval of the Deputy Administrator and without prejudice to resubmission at any time, until the Deputy Administrator rules on the petition.

Section 340.4(b) specifies the submission procedures and format of a petition. This section requires that a petitioner provide two copies of a petition to the Deputy Administrator in care of the Director of the Biotechnology and Environmental Coordination Staff.

Section 340.4(b) also specifies what must be included in the "Statement of Grounds" of the petition. A person must include a full statement explaining the factual grounds why the genus, species, or subspecies to be added to § 340.2 is a plant pest or why there is reason to believe the genus, species, or subspecies is a plant pest. In the case of a petition to remove a genus, species, or subspecies from the list, a person must include a full statement explaining why the genus, species, or subspecies is not a plant pest or why there is no reason to believe the genus, species, or subspecies is not a plant pest. The petition should include copies of scientific literature which the petition is relying upon, copies of unpublished studies, or date from tests performed. Because the petition and any accompanying data will be made available for public inspection, the petition should not include trade secret or confidential business information.

A person must also include in the "Statement of Grounds" representative information known to the petitioner which would be unfavorable to a petition to add or remove organisms. Section 340.4(b) also requires that a petitioner sign a short certification that must be included as part of the petition.

Section 340.4(c) specifies the administrative action that will be taken on a petition. Under § 340.4(c), a petition which appears to be complete will be filed by the Director of the Biotechnology and Environmental Coordination Staff, stamped with the date of filing, and assigned a docket number. The Director of the Biotechnology and Environmental Coordination Staff will notify the petitioner in writing of the filing and the docket number of the petition. If a petition is incomplete, the petitioner shall be sent a notice indicating how the petition is deficient.

After a complete petition is filed, USDA shall publish a proposal in the **Federal Register** to amend § 340.2 and soliciting comments thereon from the public. Any written comments submitted shall become part of the docket file. The Deputy Administrator shall furnish a written response to each petitioner within 180 days of the receipt of the petition. The decision shall be placed in the public docket file in the offices of the Biotechnology and Environmental Coordination Staff.

The response will either: (1) Approve the petition in whole or in part, in which case the Deputy Administrator shall concurrently take appropriate action (publication of a document in the **Federal Register** amending § 340.2 of this part); or (2) deny the petition in whole or in part.

APHIS has chosen 180 days as the time period in which to respond to a petition for the following reasons: (1) A 180 day review period would provide APHIS reviewers sufficient time to perform thorough and comprehensive research on the material presented in a petition and to consult with other scientists at other institutions both domestically and internationally; (2) a 180 day review period provides APHIS with sufficient time to schedule public hearings during the petition process should that be necessary, and (3) a 180

day review period is consistent with the petition procedures utilized by other Federal agencies, namely, the Food and Drug Administration in their regulations in 21 CFR 10.30.

Container Requirements (§ 340.6)

43. Eight comments were received on the proposed container requirements in § 340.6 of the regulations. The commenters generally expressed the view that the container requirements were overly stringent and too restrictive, or in other cases inappropriate.

One commenter indicated that to assume that an organism is dangerous simply because it has been genetically modified is not justified. Another commenter indicated that in certain instances one may wish to carry plant seedlings a short distance across a State line in an open flat in a car. The commenter further indicated that in such an instance, there would be essentially no chance of dispersal of the plant since it would be devoid of any reproductive parts, and presumably all plant parts could be collected and accounted for in case of an accident.

USDA disagrees with the comment that a presumption exists that an organism is dangerous because it has been genetically modified. Consistent with stated USDA policy, the final rule does not regulate an organism because of the process by which it is modified. USDA believes that if a person is seeking to introduce an organism that is engineered from organisms which are known plant pests, then certain precautions are necessary. One precaution that must be taken is that until the plant pest status of the organism is established, special container requirements are required. The container requirements set forth in the final rule are no more stringent than what would be required for the movement of plant pests under permit in 7 CFR 330.200. However, USDA agrees with the commenter that argued that for certain organisms and in certain instances the container requirements may be inappropriate due to unique circumstances (the volume, nature, or life stage of the regulated article).

In order to remedy this situation on a case-by-case basis, APHIS has included a procedure whereby a person seeking to move a regulated article may seek a variance from the container requirements if the responsible individual believes the container requirements are inappropriate.

Section 340.6(b) of the final rule entitled, "Request for a variance from container requirements" provides that a person may submit a short statement describing why the applicable container requirements are inappropriate for the regulated article to be moved and what the individual would use in lieu thereof. USDA shall advise the responsible individual in writing at the time a permit is granted on the individual's request for a variance.

Cost of Preparing a Permit Application

Twenty comments were received on the APHIS analysis made pursuant to E.O. 12291 on the economic impact of the regulations. APHIS stated that it anticipated the cost of preparing a permit application to be not greater than $5,000 per application. Many of these commenters erroneously interpreted the statement to mean the APHIS would charge applicants not more than $5,000 as the fee for processing permit applications.

APHIS wishes to explain the $5,000 represented the maximum *in-house cost* to an applicant of submitting an application for a permit to APHIS. The $5,000 estimated cost was based on the salary of a Ph.D. researcher earning $60,000 per year. It was estimated that it would take approximately two weeks to prepare an application. The $5,000 figure also includes the cost of clerical support and reproduction costs. With the exception of reproduction and postage or handling costs, these costs are ordinary salary costs that must be paid regardless of whether a person is submitting a permit application to APHIS. Five thousand dollars for the most part represents the upper limit of the in-house costs. APHIS believes that in many cases, the cost will be significantly less than $5,000. It should be noted that one producer of genetically engineered organisms indicated that the $5,000 figure was accurate based on the cost of submitting an application for the field testing of a genetically engineered organism.

It should be further noted that under the final rule the $5,000 figure is only applicable to the cost of preparing an application for a permit for release into the environment. An application for a limited permit for the interstate movement or importation of a regulated article into a contained facility requires the submission of less data, and the time and cost required to prepare such an application should be less than $5,000.

Comments Concerning Joint Jurisdiction

Several comments were received on the issue of overlapping jurisdiction between USDA and EPA. Dual or redundant reviews of the same organism or product were mentioned as an unwelcome possibility.

During the months since the "Coordinated Framework" was first published as a proposed policy by the OSTP and Federal agencies in December 1984 (49 FR 50856–50907) the components of EPA and USDA that have jurisdiction in the same area have been in communication on a regular basis. USDA through its Biotechnology and Environmental Coordination Staff and EPA through its Office of Toxic Substances and Office of Pesticide Programs have identified principal liaisons who have the responsibility to share information, coordinate data requests, and keep one another informed of communications with submitters. These individuals will ensure that data requests are not duplicated.

Compliance With the National Environmental Policy Act

APHIS indicated in its proposed regulations at 51 FR 23359 on June 26, 1986, that the issuance of all permits for the introduction of a genetically engineered organism would be in accordance with National Environmental Policy Act (NEPA), USDA regulations, and APHIS Guidelines implementing NEPA.

APHIS shall prepare environmental assessments and, where necessary, environmental impact statements prior to issuing a permit for the release into the environment of a regulated article. The D.C. Circuit's decision in *FET v. Heckler*, stated that "NEPA requires an agency to evaluate the environmental effects of its action at the point of commitment." 756 F.2d 143 (D.C. Cir. 1985) With regard to this final rule, APHIS has concluded that the "point of commitment" occurs when the agency takes action on each individual application to issue a permit for the release into the environment of a genetically engineered organism.

The final rule does not irrevocably commit APHIS to any decision concerning issuance of any permits for release. APHIS retains the authority to grant or deny a permit for release on a case by case basis. However, APHIS has prepared a special environmental assessment on the effect of these regulations.

The special environmental assessment for the final rule discusses alternatives that were considered in lieu of promulgation of this rule and is available from the person listed under "FOR FURTHER INFORMATION CONTACT."

Editorial Changes

APHIS has also made minor editorial changes, where necessary.

Executive Order 12291 and Regulatory Flexibility Act

This final rule is issued in conformance with Executive Order 12291 and has been determined to be not a "major rule." Based on information compiled by the Department, it has been determined that the proposed rule will not have a significant effect on the economy; will not cause a major increase in costs or prices for consumers, individual industries, Federal, State, or local government agencies, or geographic regions; and would not have a significant adverse effect on competition, employment, investment, productivity, innovation, or on the ability of United States-based enterprises to compete with foreign-based enterprises in domestic or export markets.

As explained above, regulations regulate the introduction (importation, interstate movement, and release into the environment) of organisms and products altered or produced through genetic engineering which are plant pests or which there is reason to believe are plant pests. Such organisms and products are deemed regulated articles for which either a limited or environmental release permit would have to be obtained prior to its introduction.

It is anticipated that the cost of preparing a permit application for the release into the environment of a regulated article will be no more than $5.00 per application. The cost of preparing an application for a limited permit which requires less data than an environmental release permit should be less than $5,000. The required information about the organism, and the way it was altered or produced should be available from documents pertaining to the research and development of the regulated article. Thus, a person seeking to obtain a permit should not have to generate any new data, but rather submit to APHIS, what should be, existing data. The $5,000 estimated cost is based on the salaries of a Ph.D. researcher and the necessary clerical staff working for approximately 2 weeks in preparing an application for a permit for environmental release. During the first year, the Department does not expect to receive more than 50 applications for release into the environment. Most other costs associated with complying with the regulations, e.g., container requirements, are merely incidental to a person complying with sound laboratory and research practices. The only other costs associated with complying with the regulations would arise if a supplemental report were required, e.g., an accidental or unauthorized release of a regulated article, the regulated article is found to have substantially different characteristics than those listed in the application, or if APHIS otherwise believes monitoring reports are required. It is anticipated that the cost of such reports in most instances would be minimal.

APHIS is requiring that an application for a permit be submitted 120 days prior to the time a person seeks to release a regulated article into the environment. APHIS believes that the 120 day time period required to process a permit application will not be an unreasonable delay in the marketing of organisms or products subject to regulations under Part 340. It is anticipated that if USDA receives only 50 applications the first year for the release into the environment, the average time to process any application will be considerably less than the maximum processing periods of 120 days. APHIS does not believe that the applications will come all at once. In the short term, we anticipate receiving 50 applications the first year, growing to perhaps 3,000 by 1989. The experience gained during the first year should help expedite the review of future applications. As more applications are processed, shorter review times could be achieved through the use of data previously submitted.

Since the timing of when to submit an application to USDA is left to an applicant, USDA believes that both large and small business entities will be able to incorporate the review period into their planning process so as not to disrupt the marketing of organisms or products that are subject to regulation.

Under the circumstances referred to above, the Administrator of the Animal and Plant Health Inspection Service has determined that this action would not have a significant economic impact on a substantial number of small entities.

Paperwork Reduction Act

Information collection requirements contained in this document have been approved by the Office of Management and Budget (OMB) under the provisions of the Paperwork Reduction Act (44 U.S.C. 3501 et seq.) and have been assigned OMB control number 0579-0085.

Executive Order 12372

This program/activity is listed in the Catalog of Federal Domestic Assistance under No. 10.025 and is subject to the provisions of Executive Order 12372 which requires intergovernmental consultation with State and local officials. (See 7 CFR Part 3015, Subpart V.)

List of Subjects

7 CFR Part 330

Customs duties and inspection, Garbage, Imports, Plant diseases, Plant pests, Plants (Agriculture), Quarantine, Soil, Stone and quarry products, Transportation.

7 CFR Part 340

Agricultural commodities, Biotechnology, Genetic engineering, Plant diseases, Plant pests, Plants (Agriculture), Quarantine, Transportation.

PART 330—FEDERAL PLANT PEST REGULATIONS; GENERAL; PLANT PESTS; SOIL, STONE AND QUARRY PRODUCTS; GARBAGE

Accordingly, 7 CFR Part 330 is amended to read as follows:

1. The authority citation for 7 CFR Part 330 is revised to read as follows:

Authority: 7 U.S.C. 147a, 150bb, 150dd-150ff, 161, 162, 450, 2260; 19 U.S.C. 1306; 21 U.S.C. 111, 114a; 31 U.S.C. 9701; 7 CFR 2.17, 2.51, and 371.2(c).

2. Paragraph (h) § 330.100 is revised to read as follows:

§ 330.100 Definitions.

* * * * *

(h)(1) *Plant pest.* Except for §§ 330.200 through 330.212, "Plant Pest" means any living stage of any insects, mites, nematodes, slugs, snails, protozoa, or other invertebrate animals, bacteria, fungi, other parasitic plants or reproductive parts thereof, viruses, or any organisms similar to or allied with any of the foregoing, or any infectious substances which can directly or indirectly injure or cause disease or damage in any plants or parts thereof, or any processed, manufactured, or other products of plants.

(2) *Plant pest.* For purposes of §§ 330.200 through 330.212, "Plant Pest" means any living stage of insects, mites, nematodes, slugs, snails, protozoa, or other invertebrate animals, bacteria, fungi, other parasitic plants or reproductive parts thereof, viruses, or any organisms similar to or allied with any of the foregoing, or any infectious substances of the aforementioned which are not genetically engineered as defined in 7 CFR 340.1 which can directly or indirectly injure or cause disease or damage in any plants or parts thereof, or any processed, manufactured, or other products of plants.

* * * * *

Accordingly, 7 CFR, Chapter III, is amended by adding Part 340 to read as follows:

PART 340—INTRODUCTION OF ORGANISMS AND PRODUCTS ALTERED OR PRODUCED THROUGH GENETIC ENGINEERING WHICH ARE PLANT PESTS OR WHICH THERE IS REASON TO BELIEVE ARE PLANT PESTS

Sec.

340.0 Restrictions on the introduction of regulated articles.
340.1 Definitions.
340.2 Groups of organisms which are or contain plant pests.
340.3 Permits for the introduction of a regulated article.
340.4 Petition to amend the list of organisms.
340.5 Marking and identity.
340.6 Container requirements for the movement of regulated articles.
340.7 Cost and charges.

Authority: 7 U.S.C. 150aa–150jj, 151–167, 1622n; 31 U.S.C. 9701; 7 CFR 2.17, 2.51, and 371.2(c).

§ 340.0 Restrictions on the introduction of regulated articles.

(a) No person shall introduce any regulated article unless: (1) Such introduction is authorized by a permit; and (2) such introduction is in conformity with all of the other applicable restrictions in this part.[1]

(b) Any regulated article introduced not in compliance with the requirements of this part shall be subject to the immediate application of such remedial measures or safeguards as an inspector determines necessary to prevent the introduction of such plant pests.[2]

[1] Part 340 regulates the introduction of organisms altered or produced through genetic engineering and their products which are plant pests or which there is reason to believe are plant pests. The introduction into the United States of such articles may be subject to other regulations promulgated under the Federal Plant Pest Act (7 U.S.C. 150aa *et seq.*), the Plant Quarantine Act (7 U.S.C. 151 *et seq.*), and the Federal Noxious Weed Act (7 U.S.C. 2801 *et seq.*) and found in 7 CFR Parts 319, 321, 330, and 360. For example under regulations promulgated in 7 CFR "Subpart-Nursery Stock" (7 CFR 319.37) a permit is required for the importation of certain classes of nursery stock whether genetically engineered or not. Thus, a person should consult those regulations prior to the importation of any nursery stock.

[2] Pursuant to section 106 of the Federal Plant Pest Act (7 U.S.C. 150dd) the Secretary of Agriculture is authorized to order prompt removal from the United States or to seize, quarantine, treat, apply other remedial measures to, destroy, or otherwise dispose of, in such manner as the Secretary deems appropriate, certain regulated articles which are believed to be infested or infected by or contain a plant pest.

§ 340.1 Definitions.

Terms used in the singular form in this part shall be construed as the plural, and vice versa, as the case may demand. The following terms, when used in this part, shall be construed, respectively, to mean:

Courtesy permit. A written permit issued by the Deputy Administrator in accordance with § 340.3(h) of this part.

Deputy Administrator. The Deputy Administrator for Plant Protection and Quarantine, Animal and Plant Health Inspection Service, U.S. Department of Agriculture, or any other officer or employee of the Department to whom authority to act in his/her stead has been or may hereafter be delegated.

Donor organism. The organism from which genetic material is obtained for transfer to the recipient organism.

Environment. All the land, air, and water; and all living organisms in association with land, air and water.

Genetic engineering. The genetic modification of organisms by recombinant DNA techniques.

Inspector. Any employee of Plant Protection and Quarantine, Animal and Plant Health Inspection Service, U.S. Department of Agriculture, or other person, authorized by the Deputy Administrator in accordance with law to enforce the provisions of this part.

Interstate. From any State into or through any other State.

Introduce or introduction. To move into or through the United States, to release into the environment, to move interstate, or any attempt thereat.

Move (moving, movement). To ship, offer for shipment, offer for entry, import, receive for transportation, carry, or otherwise transport or move, or allow to be moved into, through, or within the United States.

Organism. Any active, infective, or dormant stage or life form of an entity characterized as living, including vertebrate and invertebrate animals, plants, bacteria, fungi, mycoplasmas, mycoplasma-like organisms, as well as entities such as viroids, viruses, or any entity characterized as living, related to the foregoing.

Permit. A written permit issued by the Deputy Administrator for the introduction of a regulated article under conditions determined by the Deputy Administrator not to present a risk of plant pest introduction.

Person. Any individual, partnership, corporation, company, society, association, or other organized group.

Plant. Any living stage or form of any member of the plant kingdom [3] including, but not limited to, eukaryotic algae, mosses, club mosses, ferns, angiosperms, gymnosperms, and lichens (which contain algae) including any parts (e.g. pollen, seeds, cells, tubers, stems) thereof, and any cellular components (e.g. plasmids, ribosomes, etc.) thereof.

Plant pest. Any living stage (including active and dormant forms) of insects, mites, nematodes, slugs, snails, protozoa, or other invertebrate animals, bacteria, fungi, other parasitic plants or reproductive parts thereof; viruses; or any organisms similar to or allied with any of the foregoing; or any infectious agents or substances, which can directly or indirectly injure or cause disease or damage in or to any plants or parts thereof, or any processed, manufactured, or other products of plants.

Plant Protection and Quarantine. The organizational unit within the Animal and Plant Health Inspection Service, U.S. Department of Agriculture, delegated responsibility for enforcing provisions of the Plant Quarantine Act, the Federal Plant Pest Act, and related legislation, and quarantine and regulations promulgated thereunder.

Product. Anything made by or from, or derived from an organism, living or dead.

Recipient organism. The organism which receives genetic material from a donor organism.

Regulated article. Any organism which has been altered or produced through genetic engineering, if the donor organism, recipient organism, or vector or vector agent belongs to any genera or taxa designated in § 340.2 of this part and meets the definition of plant pest, or is an unclassified organism and/or an organism whose classification is unknown, or any product which contains such as organism, or any other organism or product altered or produced through genetic engineering which the Deputy Administrator determines is a plant pest or has reason to believe is a plant pest. Excluded are recipient microorganisms which are not plant pests and which have resulted from the addition of genetic material from a donor organism where the material is well characterized and contains only non-coding regulatory regions.

Release into the environment. The use of a regulated article outside the constraints of physical confinement that are found in a laboratory, contained

[3] The taxonomic scheme for the plant kingdom is that found in Synopsis and Classification of Living Organisms by S.P. Parker, McGraw Hill (1984).

greenhouse, or a fermenter or other contained structure.

Responsible person. The person who has control and will maintain control over the introduction of the regulated article and assure that all conditions contained in the permit and requirements in this part are complied with. A responsible person shall be a resident of the United States or designate an agent who is a resident of the United States.

Secretary. The Secretary of Agriculture, or any other officer or employee of the Department of Agriculture to whom authority to act in his/her stead has been or may hereafter be delegated.

State. Any State, the District of Columbia, American Samoa, Guam, Northern Mariana Islands, Puerto Rico, the Virgin Islands of the United States, and any other Territories or Districts of the United States.

United States. All of the States.

Vector or vector agent. Organisms or objects used to transfer genetic material from the donor organism to the recipient organism.

Well-characterized and contains only non-coding regulatory regions (e.g. operators, promoters, origins of replication, terminators, and ribosome binding regions). The genetic material added to a microorganism in which the following can be documented about such genetic material: (a) The exact nucleotide base sequence of the regulatory region and any inserted flanking nucleotides; (b) The regulatory region and any inserted flanking nucleotides do not code for protein or peptide; and (c) The regulatory region solely controls the activity of other sequences that code for protein or peptide molecules or act as recognition sites for the initiation of nucleic acid or protein synthesis.

§ 340.2 Groups of organisms which are or contain plant pests.

The organisms that are or contain plant pests are included in the taxa or group of organisms contained in the following list. Within any taxonomic series included on the list, the lowest unit of classification actually listed is the taxon or group which may contain organisms which are regulated. Organisms belonging to all lower taxa contained within the group listed are included as organisms that may be or may contain plant pests, and are regulated *if they meet the definition of plant pest in § 340.1*[4]

[4] Any organism belonging to any taxa contained within any listed genera or taxa is only considered to be a plant pest if the organism "can directly or indirectly injure, or cause disease, or damage in any plants or parts thereof, or any processed, manufactured, or other products of plants." Thus a particular unlisted species within a listed genus would be deemed a plant pest for purposes of § 340.2, if the scientific literature refers to the organism as a cause of direct or indirect injury, disease, or damage to any plants, plant parts or products of plants. (If there is any question concerning the plant pest status of an organism belonging to any listed genera or taxa, the person proposing to introduce the organism in question should consult with APHIS to determine if the organism is subject to regulation.)

Note.—Any genetically engineered organism composed of DNA or RNA sequences, organelles, plasmids, parts, copies, and/or analogs, of or from any of the groups of organisms listed below shall be deemed a regulated article if it also meets the definition of plant pest in § 340.1.

§ 340.3 Permits for the introduction of a regulated article.

(a) *Application for permit.* Two copies of a written application for a permit to introduce a regulated article shall be submitted by the responsible person on an application form obtained from Plant Protection and Quarantine, to the Biological Assessment Support Staff (Biotech Unit), Plant Protection and Quarantine, Animal and Plant Health Inspection Service, U.S. Department of Agriculture, Federal Building, 6505 Belcrest Road, Hyattsville, Maryland 20782. If there are portions of the application deemed to contain trade secret or confidential business information (CBI), each page of the application containing such information should be marked "CBI Copy". In addition, those portions of the application which are deemed "CBI" shall be so designated. The second copy shall have all such CBI deleted and shall be marked on each page of the application where CBI was deleted, "CBI Deleted". If an application does not contain CBI then the first page of both copies shall be marked "No CBI".

(b) *Permit for release into the environment.* An application for the release into the environment of a regulated article shall be submitted at least 120 days in advance of the proposed release into the environment. An initial review shall be completed by Plant Protection and Quarantine within 30 days of the receipt of the application. If the application is complete, the responsible individual shall be notified of the date of receipt of the application for purposes of advising the applicant when the 120 day review period commenced.[5] If the application is not complete, the responsible individual will be advised what additional information must be submitted. Plant Protection and Quarantine shall commence the 120 day review period upon receipt of the additional information, assuming the additional information submitted is adequate. When it is determined that an application is complete, Plant Protection and Quarantine shall submit to the State department of agriculture of the State where the release is planned, a copy of the initial review and a copy of the application marked, "CBI Deleted", or "No CBI" for State notification and review. The application shall include the following information: [6]

(1) Name, title, address, telephone number, signature of the responsible person and type of permit requested (for importation, interstate movement, or release into the environment);

(2) All scientific, common, and trade names, and all designations necessary to identify the: Donor organism(s); recipient organism(s); vector or vector agent(s); constituent of each regulated article which is a product; and, regulated article;

(3) Names, addresses, and telephone numbers of the persons who developed and/or supplied the regulated article;

(4) A description of the means of movement (e.g., mail, common carrier, baggage, or handcarried (and by whom));

(5) A description of the anticipated or actual expression of the altered genetic material in the regulated article and how that expression differs from the expression in the non-modified parental organism (e.g., morphological or structural characteristics, physiological activities and processes, number of copies of inserted genetic material and the physical state of this material inside the recipient organism (integrated or extrachromosomal), products and secretions, growth characteristics);

(6) A detailed description of the molecular biology of the system (e.g., donor-recipient-vector) which is or will be used to produce the regulated article;

(7) Country and locality where the donor organism, recipient organism, vector or vector agent, and regulated article were collected, developed, and produced;

(8) A detailed description of the purpose for the introduction of the regulated article including a detailed description of the proposed experimental and/or production design;

(9) The quantity of the regulated article to be introduced and proposed schedule and number of introductions;

(10) A detailed description of the processes, procedures, and safeguards which have been used or will be used in the country of origin and in the United States to prevent contamination, release, and dissemination in the production of the: Donor organism; recipient organism; vector or vector agent; constituent of each regulated article which is a product; and regulated article;

(11) A detailed description of the intended destination (including final and all intermediate destinations), uses, and/or distribution of the regulated article (e.g., greenhouses, laboratory, or growth chamber location; field trial location; pilot project location; production, propagation, and manufacture location; proposed sale and distribution location);

(12) A detailed description of the proposed procedures, processes, and safeguards which will be used to prevent escape and dissemination of the regulated article at each of the intended destinations;

(13) A detailed description of any biological material (e.g., culture medium, or host material) accompanying the regulated article during movement; and

(14) A detailed description of the proposed method of final disposition of the regulated article.

(c) *Limited permits for interstate movement or importation of a regulated article.* An application for the interstate movement or importation of a regulated article shall be submitted at least 60 days in advance of the first proposed interstate movement and at least 60 days prior to each importation. An initial review shall be completed by Plant Protection and Quarantine within 15 days of the receipt of the application. If the application is complete, the responsible person shall be notified of the date of receipt of the application for purposes of advising the applicant when the 60 day review period commenced. If the application is not complete, the responsible person will be advised what additional information must be submitted. Plant Protection and Quarantine shall commence the 60 day review period upon receipt of the additional information, assuming the additional information submitted is adequate. When it is determined that an application is complete, Plant Protection and Quarantine shall submit to the State department of agriculture of the State of destination of the regulated article a copy of the initial review and the application marked, "CBI Deleted", or "No CBI" for State notification and review.

(1) *Limited permit for interstate movement.* The responsible person may apply for a single limited permit for the interstate movement of multiple regulated articles in lieu of submitting an application for each individual interstate movement. Each limited permit issued shall be numbered and shall be valid for one year from the date

[5] The 120 day review period would be extended if preparation of an environmental impact statement in addition to an environmental assessment was necessary.

[6] Application forms are available without charge from the Biological Assessment Support Staff, Plant Protection and Quarantine, Animal and Plant Health Inspection Service, U.S. Department of Agriculture, Federal Building, 6505 Belcrest Road, Hyattsville, Maryland 20782, or from local offices which are listed in telephone directories. A person should specify in requesting the application that the permit is for the introduction of a regulated article subject to regulation under Part 340.

of issuance. If a permit is sought for multiple interstate movements between contained facilities the responsible individual shall specify in the permit application all the regulated articles to be moved interstate: the origins and destinations of all proposed shipments: a detailed description of all the contained facilities where regulated articles will be utilized at destination: and a description of the containers that will be used to transport the regulated articles. A limited permit for interstate movement of a regulated article shall only be valid for the movement of those regulated articles moving between those locations specified in the application. If a person seeks to move regulated articles other than those specified in the application, or to a location other than those listed in the application, a supplemental application shall be submitted to Plant Protection and Quarantine. No person shall move a regulated article interstate unless the number of the limited permit appears on the outside of the shipping container. The responsible person shipping a regulated article interstate shall keep records for one year demonstrating that the regulated article arrived at its intended destination. The responsible person seeking a limited permit for interstate movement shall submit on an application form obtained from Plant Protection and Quarantine the data required by § 340.3(b)(1), (2), (4), (6), (7), (9), and (11)–(14).

(2) *Limited permit for importation.* The responsible person seeking a permit for the importation of a regulated article shall submit an application for a permit prior to the importation of *each* shipment of regulated articles. The responsible person importing a regulated article shall keep records for one year demonstrating that the regulated article arrived at its intended destination. The responsible person seeking a limited permit for importation shall submit on an application form obtained from Plant Protection and Quarantine data required by § 340.3(b)(1), (2), (4), (6), (7), (9), and (11)–(14).[1]

(d) *Premises inspection.* An inspector may inspect the site or facility where regulated articles are proposed, pursuant to a permit, to be released into the environment or contained after their interstate movement or importation. Failure to allow the inspection of a premises prior to the issuance of a permit or limited permit shall be grounds for the denial of the permit.

(e) *Administrative action on applications.* After receipt and review by Plant Protection and Quarantine of the application and the data submitted pursuant to paragraph (a) of this section, including any additional information requested by Plant Protection and Quarantine, a permit shall be granted or denied. If a permit is denied, the applicant shall be promptly informed of the reasons why the permit was denied and given the opportunity to appeal the denial in accordance with the provisions of paragraph (g) of this section. If a permit is granted, the permit will specify the applicable conditions for introduction of the regulated article under this part.

(f) *Permit conditions.* A person who is issued a permit and his/her employees or agents shall comply with the following conditions, and any supplemental conditions which shall be listed on the permit, as deemed by the Deputy Administrator to be necessary to prevent the dissemination and establishment of plant pests:

(1) The regulated article shall be maintained and disposed of (when necessary) in a manner so as to prevent the dissemination and establishment of plant pests.

(2) All packing material, shipping containers, and any other material accompanying the regulated article shall be treated or disposed of in such a manner so as to prevent the dissemination and establishment of plant pests.

(3) The regulated article shall be kept separate from other organisms, except as specifically allowed in the permit:

(4) The regulated article shall be maintained only in areas and premises specified in the permit:

(5) An inspector shall be allowed access, during regular business hours, to the place where the regulated article is located and to any records relating to the introduction of a regulated article:

(6) The regulated article shall, when possible, be kept identified with a label showing the name of the regulated article, and the date of importation:

(7) The regulated article shall be subject to the application of measures determined by the Deputy Administrator to be necessary to prevent the accidental or unauthorized release of the regulated article;

(8) The regulated article shall be subject to the application of remedial measures (including disposal) determined by the Deputy Administrator to be necessary to prevent the spread of plant pests:

(9) A person who has been issued a permit shall submit to Plant Protection and Quarantine monitoring reports on the performance characteristics of the regulated article, in accordance with any monitoring reporting requirements that may be specified in a permit:

(10) Plant Protection and Quarantine shall be notified within the time periods and manner specified below, in the event of the following occurrences:

(i) Orally notified immediately upon discovery and notify in writing within 24 hours in the event of any accidental or unauthorized release of the regulated article:

(ii) In writing as soon as possible but not later than within 5 working days if the regulated article or associated host organism is found to have characteristics substantially different from those listed in the application for a permit or suffers any unusual occurrence (excessive mortality or morbidity, or unanticipated effect on non-target organisms);

(11) A permittee or his/her agent and any person who seeks to import a regulated article into the United States shall:

(i) Import or offer the regulated article for entry only at a port of entry which is designated by an asterisk in 7 CFR 319.37–14(b);

(ii) Notify Plant Protection and Quarantine promptly upon arrival of any regulated article at a port of entry, of its arrival by such means as a manifest, customs entry document, commercial invoice, waybill, a broker's document, or a notice form provided for such purpose; and

(iii) Mark and identify the regulated article in accordance with § 340.5 of this part.

(g) *Withdrawal or denial of a permit.* Any permit which has been issued may be withdrawn by an inspector or the Deputy Administrator if he/she determines that the holder thereof has not complied with one or more of the conditions listed on the permit. APHIS will confirm the reasons for the withdrawal of the permit in writing within ten (10) days. Any person whose permit has been withdrawn or any person who has been denied a permit may appeal the decision in writing to the Deputy Administrator within ten (10) days after receiving the written notification of the withdrawal or denial. The appeal shall state all of the facts and reasons upon which the person relies to show that the permit was wrongfully withdrawn or denied. The Deputy Administrator shall grant or

[1] Renewals may receive shorter review. In the case of a renewal for a limited permit for importation that has been issued less than one year earlier, APHIS will notify the responsible person within 15 days that either: (1) The renewal permit is approved or (2) that a 90 day review period is necessary because the conditions of the original permit have changed.

deny the appeal, in writing, stating the reasons for the decision as promptly as circumstances allow. If there is a conflict as to any material fact, a hearing shall be held to resolve such conflict. Rules of practice concerning such a hearing will be adopted by the Administrator.

(h) *Courtesy permit—(1) Issuance.* The Deputy Administrator may issue a courtesy permit for the introduction of organisms modified through genetic engineering which are not subject to regulation under this part to facilitate movement when the movement might otherwise be impeded because of the similarity of the organism to other organisms regulated under this part.

(2) *Application.* A person seeking a courtesy permit shall submit on an application form obtained from Plant Protection and Quarantine data required by §§ 340.3(b)(1), (2), and (5) of this part and shall indicate such data is being submitted as a request for a courtesy permit. A person should also include a statement explaining why he or she believes the organism or product does not come within the definition of a regulated article. The application shall be submitted at least 60 days prior to the time the courtesy permit is sought.

(3) *Administrative action.* Plant Protection and Quarantine shall complete an initial review within 15 days of the date of receipt of the application. If the application is complete, the responsible individual shall be notified of the date of receipt of the application for purposes of advising the applicant when the 60 day review period commenced. If the application is not complete, the responsible individual will be advised what additional information must be submitted, and shall commence the 60 day review period upon receipt of the additional information, assuming the additional information submitted is adequate. Within 60 days from the date of receipt of a complete application, Plant Protection and Quarantine will either issue a courtesy permit or advise the responsible individual that a permit is required under § 340.3(b) or (c).

§ 340.4 Petition to amend the list of organisms.

(a) *General.* Any person may submit to the Deputy Administrator a petition to amend the list of organisms in § 340.2 of this part by adding or deleting any genus, species, or subspecies. A petitioner may supplement, amend, or withdraw a petition in writing without prior approval of the Deputy Administrator and without prejudice to resubmission at any time until the Deputy Administrator rules on the petition. A petition to amend the list of organisms shall be submitted in accordance with the procedures and format specified by this section.

(b) *Submission procedures and format.* A person shall submit two copies of a petition to the Deputy Administrator of Plant Protection and Quarantine, in care of the Director of the Biotechnology and Environmental Coordination Staff, Animal and Plant Health Inspection Service, U.S. Department of Agriculture, 6505 Belcrest Road, Room 406, Federal Building, Hyattsville, Maryland 20782. The petition should be dated, and structured as follows:

Petition To Amend 7 CFR 340.2

The undersigned submits this petition under 7 CFR 340.4 to request the Deputy Administrator of Plant Protection and Quarantine, to [add the following genus, species, or subspecies to the list of organisms in 7 CFR 340.2] or [to remove the following genus, species, or subspecies from the list of organisms in § 340.2].

A. Statement of Grounds

[A person must present a full statement explaining the factual grounds why the genus, species, or subspecies to be added to § 340.2 of this part is a plant pest or why there is reason to believe the genus, species, or subspecies is a plant pest or why the genus, species, or subspecies sought to be removed is not a plant pest or why there is reason to believe the genus, species, or subspecies is not a plant pest. The petition should include copies of scientific literature which the petitioner is relying upon, copies of unpublished studies, or data from tests performed. *The petition should not include trade secret or confidential business information.*

A person should also include representative information known to the petitioner which would be unfavorable to a petition for listing or delisting. [If a person is not aware of any unfavorable information the petition should state, Unfavorable information: NONE].

B. Certification

The undersigned certifies, that to the best knowledge and belief of the undersigned, this petition includes all information and views on which the petitioner relies, and that it includes representative data and information known to the petitioner which are unfavorable to the petition.

(Signature) _____
(Name of petitioner) _____
(Mailing address) _____
(Telephone number) _____

(c) *Administrative action on a petition.* (1) A petition to amend the list of organisms which meets the requirements of paragraph (b) of this section will be filed by the Director of the Biotechnology and Environmental Coordination Staff, stamped with the date of filing, and assigned a docket number. The docket number shall identify the file established for all submissions relating to the petition. The Biotechnology and Environmental Coordination Staff, will promptly notify the petitioner in writing of the filing and docket number of a petition. If a petition does not meet the requirements of paragraph (b) of this section, the petitioner shall be sent a notice indicating how the petition is deficient.

(2) After the filing of a petition to amend the list or organisms USDA shall publish a proposal in the **Federal Register** to amend § 340.2 and solicit comments thereon from the public. An interested person may submit written comments to the Director of the Biotechnology and Environmental Coordination Staff on a filed petition, which shall become part of the docket file.

(3) The Deputy Administrator shall furnish a response to each petitioner within 180 days of receipt of the petition. The response will either: (i) Approve the petition in whole or in part in which case the Deputy Administrator shall concurrently take appropriate action (publication of a document in the **Federal Register** amending § 340.2 of this part; or (ii) deny the petition in whole or in part. The petitioner shall be notified in writing of the Deputy Administrator's decision. The decision shall be placed in the public docket file in the offices of the Biotechnology and Environmental Coordination Staff, and in the form of a notice published in the **Federal Register.**

§ 340.5 Marking and identity.

(a) Any regulated article to be imported other than by mail, shall, at the time of importation into the United States, plainly and correctly bear on the outer container the following information:

(1) General nature and quantity of the contents;

(2) Country and locality where collected, developed, manufactured, reared, cultivated or cultured;

(3) Name and address of shipper, owner, or person shipping or forwarding the organism;

(4) Name, address, and telephone number of consignee;

(5) Identifying shipper's mark and number; and

(6) Number of written permit authorizing the importation.

(b) Any regulated article imported by mail, shall be plainly and correctly addressed and mailed to Plant Protection Quarantine at a port of entry designated by an asterisk in 7 CFR 319.37-14(b) and shall be accompanied

by a separate sheet of paper within the package plainly and correctly bearing the name, address, and telephone number of the intended recipient, and shall plainly and correctly bear on the outer container the following information:

(1) General nature and quantity of the contents;

(2) Country and locality where collected, developed, manufactured, reared, cultivated, or cured;

(3) Name and address of shipper, owner, or person shipping or forwarding the regulated article; and

(4) Number of permit authorizing the importation;

(c) Any regulated article imported into the United States by mail or otherwise shall, at the time of importation or offer for importation into the United States, be accompanied by an invoice or packing list indicating the contents of the shipment.

§ 340.6 Container requirements for the movement of regulated articles.

(a) *General requirements.* A regulated article shall not be moved unless it complies with the provisions of paragraph (b) of this section, unless a variance has been granted in accordance with the provisions of paragraph (c) of this section. [8]

(b) *Container requirements*—(1) *Plants and plant parts.* All plants or plant parts, except seeds, cells, and subcellular elements, shall be packed in a sealed plastic bag of at least 5 mil thickness, inside a sturdy, sealed, leak-proof, outer shipping container constructed of corrugated fiberboard, corrogated cardboard, wood, or other material of equivalent strength.

(2) *Seeds.* All seeds shall be transported in a sealed plastic bag of at least 5 mil thickness, inside a sealed metal container, which shall be placed inside a second sealed metal container. Shock absorbing cushioning material shall be placed between the inner and outer metal containers. Each metal container shall be independently capable of protecting the seeds and preventing spillage or escape. Each set of metal containers shall then be enclosed in a sturdy outer shipping container constructed of corrugated fiberboard, corrugated cardboard, wood, or other material of equivalent strength.

(3) *Live microorganisms and/or etiologic agents, cells, or subcellular elements.* All regulated articles which are live (non-inactivated) microorganisms, or etiologic agents, cells, or subcellular elements shall be packed as specified below:

(i) *Volume not exceeding 50 ml.* Regulated articles not exceeding 50 ml shall be placed in a securely closed, watertight container (primary container, test tube, vial, etc.) which shall be enclosed in a second, durable watertight container (secondary container). Several primary containers may be enclosed in a single secondary container, if the total volume of all the primary containers so enclosed does not exceed 50 ml. The space at the top, bottom, and sides between the primary and secondary containers shall contain sufficient nonparticulate absorbent material (e.g., paper towel) to absorb the entire contents of the primary container(s) in case of breakage or leakage. Each set of primary and secondary containers shall then be enclosed in an outer shipping container constructed of corrugated fiberboard, corrugated cardboard, wood, or other material of equivalent strength.

(ii) *Volume greater than 50 ml.* Regulated articles which exceed a volume of 50 ml, shall comply with requirements specified in paragraph (b)(3)(i) of this section. In addition, a shock absorbing material, in volume at least equal to that of the absorbent material between the primary and secondary containers, shall be placed at the top, bottom, and sides between the secondary container and the outer shipping container. single primary containers shall not contain more than 1,000 ml. of material. However, two or more primary containers whose combined volumes do not exceed 1,000 ml. may be placed in a single, secondary container. The maximum amount of microorganisms or etiologic agents, cells, or subcellular elements which may be enclosed within a single outer shipping container shall not exceed 4,000 ml.

(iii) *Dry ice.* If dry ice is used as a refrigerant, it shall be placed outside the secondary container(s). If dry ice is used between the secondary container and the outer shipping container, the shock absorbing material shall be placed so that the secondary container does not become loose inside the outer shipping container as the dry ice sublimates.

(4) *Insects, mites, and related organisms.* Insects, mites, and other small arthropods shall be packed for shipment as specified in this paragraph or in paragraph (b)(3) of this section. Insects (any life stage) shall be placed in an escape-proof primary shipping container (insulated vacuum container, glass, metal, plastic, etc.) and sealed to prevent escape. Such primary container shall be placed securely within a secondary shipping container of crushproof styrofoam or other material of equivalent strength; one or more rigid ice packs may also be placed within the secondary shipping container; and sufficient packing material shall be added around the primary container to prevent movement of the primary shipping container. The secondary (styrofoam or other) container shall be placed securely within an outer shipping container constructed of corrugated fiberboard, corrugated cardboard, wood, or other material of equivalent strength.

(5) *Other macroscopic organisms.* Other macroscopic organisms not covered in paragraphs (b) (1), (2), and (4) of this section which do not require continuous access to atmospheric oxygen shall be packaged as specified in paragraph (b) (3) or (4) of this section. All macroscopic organisms which are not plants and which require continuous access to atmospheric oxygen shall be placed in primary shipping containers constructed of a sturdy, crush-proof frame of wood, metal, or equivalent strength material, surrounded by escape-proof mesh or netting of a strength and mesh size sufficient to prevent the escape of the smallest organism in the shipment, with edges and seams of the mesh or netting sealed to prevent escape or organisms. Each primary shipping container shall be securely placed within a larger secondary shipping container constructed of wood, metal, or equivalent strength material. The primary and secondary shipping containers shall then be placed securely within an outer shipping container constructed of corrugated fiberboard, corrugated cardboard, wood, or other material of equivalent strength, which outer container may have air holes or spaces in the sides and/or ends of the container, provided that the outer shipping container must retain sufficient strength to prevent crushing of the primary and secondary shipping containers.

(c) *Request for a variance from container requirements.* A responsible person who believes the container requirements normally applicable to the movement of the person's regulated article(s) are inappropriate due to unique circumstances (such as the nature, volume, or life stage of the regulated article) may submit in an application for a permit, a request for a variance from the container requirements. The request for a variance under this section shall consist of a short statement describing why the

[8] The requirements of this section are in addition to and not in lieu of any other packing requirements such as those for the transportation of etiologic agents prescribed by the Department of Transportation in Title 49 of the Code of Federal Regulations or any other agency of the Federal government.

normally applicable container requirements are inappropriate for the regulated article which the person proposes to move and what container requirements the person would use in lieu of the normally prescribed container requirements. USDA shall advise the responsible person in writing at the time a permit is granted on the person's request for a variance.

§ 340.7 Cost and charges.

The services of the inspector during regularly assigned hours of duty and at the usual places of duty shall be furnished without cost.[9] The U.S. Department of Agriculture will not be responsible for any costs or charges incident to inspections or compliance with the provisions of this part, other than for the services of the inspector.

[9] The Department's provisions relating to overtime charges for an inspector's services are set forth in 7 CFR Part 354.

Done at Washington, DC, this 10th day of June, 1987.

D. Husnik,

Acting Deputy Administrator, Plant Protection and Quarantine, Animal and Plant Health Inspection Service.

Re: Environmental Report - Partial Deregulation Measures for Cultivation of Roundup Ready® Alfalfa Events J101/J163

Dear Mr. Gregoire:

Forage Genetics International, LLC ("FGI"), a wholly owned subsidiary of Land O'Lakes, Inc. ("Land O'Lakes"), is an alfalfa breeding and seed production company and one of the original petitioners who sought a determination of non-regulated status for glyphosate-tolerant alfalfa in Docket No. APHIS-2007-0044. On behalf of the cooperative members of Land O'Lakes and our customers, we are writing to request that the Animal and Plant Health Inspection Service ("APHIS") grant a temporary "partial deregulation" or implement other administrative interim measures to mitigate the harm to the interests of those members and farmers resulting from delays in commercial planting of glyphosate-tolerant alfalfa. We request that such measures be implemented until such time as APHIS concludes its review of the petition for non-regulated status and its new decision on the petition takes effect. The proposed interim measures are consistent with the type of partial deregulation discussed recently by the U.S. Supreme Court in the *Geertson* case.

Land O'Lakes

Land O'Lakes is a farmer-owned food and agricultural cooperative representing the interests and needs of more than 300,000 direct and indirect members across America.

Land O'Lakes was organized in 1921 with the goals of enabling a stronger presence in the marketplace and of giving farmer-members a stronger voice in their own economic destinies. As a farmer-owned cooperative, Land O'Lakes proved to be an idea, and an organization, that worked for its producer-members. In the late 1920s, members asked us

to take that cooperative idea into the agricultural inputs marketplace, and we entered the farm supply business. Our goal at that time was to provide farmer-members a secure, competitively priced supply of high-quality inputs. It was from those beginnings that our current Feed, Seed and Crop Protection Products businesses were born. Innovation is a hallmark of Land O'Lakes' performance in both agricultural inputs and the food side of our business.

Our structure as a cooperative continues to benefit members in a variety of ways: generating market access (and capturing value from the market) for our farmer-members; providing a secure source of high-quality agricultural inputs; enabling members to participate in the profits/losses generated by our businesses; and developing and delivering new products and services tailored to member needs. And, through their representation on our board of directors, our farmer-members exercise control over the strategic direction of the cooperative. Ultimately, a key element in determining that strategic direction is our stated Mission of "optimizing the value of our members' dairy, crop and livestock production."

A Leader in Agricultural Technology

FGI is a vertically integrated alfalfa seed company involved in basic R&D, plant breeding/product development, seed production, sales and marketing of alfalfa seed. Our research efforts include the development of biotechnology traits and conventional breeding. The seed products we develop are sold in both the U.S. and export markets, and to both conventional and organic alfalfa producers.

We see significant grower value for biotechnology traits, but understand that there are sectors of the U.S. and global markets that will choose not to plant alfalfa with these traits. The continued success of our business depends on our ability to serve all of these markets – biotechnology, conventional and organic – and includes a commitment to stewardship practices that enable market and environmental coexistence. Again, this dedication to sound science and producer choice is an important part of our company culture.

Biotechnology can play a significant role in the future of alfalfa, which is the fourth largest crop grown in the U.S. and is a key component of the diet of dairy cows. Alfalfa acres have been declining over the past 20 years, due in part to weed and quality issues. Additionally, growers have reduced the amount of alfalfa planted in part because the availability of biotechnology in other crops provides growers a better opportunity to manage production risks compared to growing conventional alfalfa. As acres of alfalfa decline, so too do the benefits that alfalfa provides as a key contributor to sustainable agriculture, including:

- Nitrogen fixation/crop rotation benefits
- Reduced soil erosion compared with row crops
- Deep, extensive root systems that improve soil tilth and sequester carbon

- Key source of digestible fiber and protein that can be produced right on the farm for the diet of dairy cows.

In order to address the problems in alfalfa caused by weed and quality issues, FGI has worked with Monsanto Company ("Monsanto") to develop glyphosate-tolerant alfalfa known as Roundup Ready® alfalfa ("RRA"). Under an exclusive license from Monsanto, FGI has been the developer, a seed producer, and seller of RRA. FGI's alfalfa breeding program developed all of the initial RRA cultivars and, along with one other seed company licensed by FGI, has contracted the production of all of the RRA seed sold prior to March 2007. All seed harvested thereafter was placed in controlled storage subject to Court Order and APHIS Administrative Rule. Though it is FGI's intent to license other alfalfa breeding companies to develop RRA varieties in the future, FGI is currently the sole source of seed available for RRA varieties for planting. The RRA seed is to be sold by seed companies that are licensed by Monsanto to sell the product to licensed forage growers.

History of RRA

RRA was deregulated in June 2005 by APHIS following preparation of an Environmental Assessment (which included public comment) and the issuance of a Finding of No Significant Impact – a process consistent with 78 prior or more recent deregulation decisions issued by the agency.

In February of 2007, Judge Charles Breyer of the United States District Court for the Northern District of California held that APHIS had not taken a sufficiently "hard look" in its Environmental Assessment of RRA at certain specific issues in support of the agency's decision to deregulate RRA. Judge Breyer's determination focused principally on the potential for gene flow from RRA to conventional or organic alfalfa seed fields, noting that alfalfa seed production has traditionally occurred in certain fairly concentrated areas of certain Western states. Although Judge Breyer also expressed concern regarding a possibility of flowering by alfalfa forage crops, APHIS' experts, along with multiple academic experts, concluded that the possibility for gene flow from one forage field to another was highly remote. The evidence submitted in the case also indicated that RRA growers would suffer significant harm in excess of $200 million from a halt in their ability to plant and use RRA for forage production for crop years 2007, 2008 and spring 2009.

Judge Breyer issued a preliminary injunction in March 2007 preventing any new planting of RRA beginning March 30, 2007, and subsequently issued a permanent injunction in May 2007 that enjoined further planting and sale of RRA pending completion of an Environmental Impact Statement ("EIS"). The injunction allowed the continued harvest of hay and seed production fields established prior to March 30, 2007, subject to certain conditions imposed by the court. Finally, the court enjoined APHIS from granting the RRA deregulation petition "even in part" before preparation of an EIS.

® Roundup Ready is a registered trademark of Monsanto Technology LLC.

During the remedy phase in Judge Breyer's court, APHIS representatives testified that they believed the agency would conduct an EIS within two years of the court order. Based largely on APHIS' estimated timeline, FGI elected to honor its seed production contracts with individual seed growers rather than pay to terminate these contracts. FGI purchased seed from the seed growers of RRA varieties produced in 2007, 2008 and 2009. All RRA seed purchased by FGI during these years was produced under multi-year grower contracts in place prior to the injunction. FGI also recalled from its seed company customers, who in turn recalled from their customer-growers, RRA seed produced and shipped but not planted prior to March 30, 2007. Thus, millions of pounds of RRA seed are in controlled storage.

Preparation of the EIS has taken APHIS longer than anticipated. Next spring will mark the fourth anniversary of the injunction and the EIS has not been completed.

Impacts of *Geertson* Litigation – The Risk of Further Delay

Although all RRA seed is now in storage conditions designed to optimize medium-term seed viability, seed quality is beginning to deteriorate. Based on our tracking of changes in germination percentages over the last 12 months, and our experience with typical patterns in seed quality decline, we believe that missing the spring 2011 commercial planting opportunity would place a significant volume of seed stocks at risk of deteriorating below current Certified Seed quality standards.

Any further delay in commercial planting opportunity would greatly increase potential losses. The RRA inventory described above, and the risk associated with this inventory, is owned by FGI, and passed on to our parent company and, ultimately, its farmer-members.

Prior to Judge Breyer's injunction, approximately 5,500 growers planted about 250,000 acres of RRA in the fall 2005, spring 2006, fall 2006, and/or truncated spring 2007 planting seasons. In a survey of a random sampling of these 5,500 RRA growers, farmers self-report a yield advantage of 0.9 tons/per acre/per year for RRA, when compared to conventional hay production on their farms. Based on average current hay prices, that translates into a $110 per acre/per year farm-gate advantage. Based on expected potential sales in the spring of 2011, typical planting rates and an average four-year rotation, the aggregated incremental value of RRA associated with spring 2011 planting alone is approximately $160 million.

A missed opportunity to plant RRA in spring 2011 is lost income for alfalfa growers, particularly important during the recent period of lower hay prices and a difficult dairy economy.

Request for Temporary Partial Deregulation or Other Interim Measures

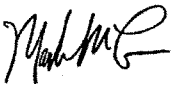
The District Court's injunction on planting of RRA was ultimately appealed to the U.S. Supreme Court. In its decision of June 21, 2010, the Court overturned Judge Breyer's

injunction and specifically anticipated the ability of APHIS to take interim measures by partially deregulating RRA with appropriate mitigation conditions during the continued preparation of the EIS. In the Supreme Court's own words, "a partial deregulation need not cause respondents any injury at all, much less irreparable injury; if the scope of the partial deregulation is sufficiently limited, the risk of gene flow to their crops could be virtually nonexistent." The Supreme Court remanded the *Geertson* case for further proceedings consistent with its June 21 opinion.

In the interest of our farmer member/owners and alfalfa growers in general, we are requesting that APHIS grant such an interim partial deregulation of RRA. Our co-petitioner, Monsanto, concurs in this request. Enclosed for your reference is an Environmental Report which discusses a set of proposed interim measures, consistent with the measures discussed recently by the Supreme Court, along with the potential environmental impact of those measures. We set forth these proposed measures and conditions of use in the context of the ongoing RRA litigation. Although there has been no evidence of any actual harm to the environment from multiple years of RRA seed and forage crop cultivation to date, these measures are nevertheless crafted to further minimize (if not eliminate) any perceived risks previously identified in the litigation context. In short:

- For RRA seed production, only eight pre-authorized seed grower consortia at physically isolated locations would be allowed during this interim period. The seed growers at these specific pre-authorized locations have requested the opportunity to produce RRA seed and would be required to follow the best management practices of the National Alfalfa and Forage Alliance ("NAFA"). These best practices have been adopted by the industry as standards for any future RRA seed production as part of an overall stewardship program designed to ensure coexistence of various alfalfa hay and seed markets. In addition, certain minimum isolation requirements for RRA seed fields would be increased during this interim period.

- For production of RRA forage (i.e., hay or haylage), our request includes a number of interim measures, including seed identification requirements, field tracking and geographic restrictions that would locate the very large majority of these RRA forage production acres in areas with no alfalfa seed production at all. It is important to note that over 99% of the alfalfa planted in the United States is planted for harvest as forage.



Conclusion

In sum, we propose that APHIS grant our request for limited interim measures designed to mitigate harm to thousands of growers until APHIS' final decision on the petition for non-regulated status takes effect. By granting our request for partial deregulation of RRA, APHIS would protect the interests of agriculture and consumers and, at the same time, address potential environmental impacts cognizable under the National

Environmental Policy Act by providing for a negligible risk of gene flow from RRA plantings.

FGI, Land O'Lakes and our farmer member/owners appreciate the efforts APHIS has made to address the challenges that have been raised to the commercialization of RRA and pledge our continued support and cooperation as we face the challenges that lie ahead. Your prompt consideration of this request for interim administrative action will be greatly appreciated. Please contact me with any questions concerning this request.

Sincerely,

Mark McCaslin, PhD
President

Enclosure

SECTION 1.0 INTRODUCTION

This Environmental Report (ER) examines the environmental impacts of cultivation of Roundup Ready® alfalfa (RRA) lines J101 and J163 (J101/J163)[1] for a temporary period subject to a range of measures, including geographic restrictions, stewardship requirements and other limitations. This ER is provided in connection with the petitioners' supplemental request for non-regulated status *in part* (commonly known as "partial deregulation") for RRA. This document is intended to provide information that may be utilized by the United States Department of Agriculture's (USDA) Animal and Plant Health Inspection Service (APHIS) in complying with the National Environmental Policy Act (NEPA)[2] and its applicable regulations[3] either in connection with partial deregulation of RRA or for any other regulatory or administrative action adopting the measures addressed herein. A partial deregulation or other administrative action adopting the measures may be superseded at a later date after APHIS completes the Environmental Impact Statement (EIS) and makes its determination regarding the pending petition for complete deregulation of RRA.

Alfalfa (*Medicago sativa* L.) was planted on approximately 21 million acres in the U.S. in 2009. Overall crop value was $7.9 billion in the 2009-2010 crop year. Over 99 percent of the alfalfa planted in the U.S. is planted for harvest as forage, with less than one percent harvested for seed. RRA, which has been genetically engineered to be tolerant to the herbicide glyphosate, is currently cultivated on approximately 200,000 acres or less, (USDA NASS, 2010b; USDA APHIS, 2009), pursuant to permit or court order.

1.1 PURPOSE OF THIS ER

1.1.1 Background

In April 2004, under the requirements of the Plant Protection Act (PPA)[4] and its implementing regulations,[5] Monsanto Company (Monsanto) and Forage Genetics International (FGI) submitted a petition to APHIS for a determination of non-regulated status for RRA (Rogan and Fitzpatrick, 2004). Monsanto is an agricultural company involved in the development and marketing of biotechnology-derived agricultural products. FGI is an alfalfa seed company and a

[1] The terms RRA and glyphosate tolerant alfalfa,or GT alfalfa are used interchangeably throughout this document.
[2] NEPA of 1969, as amended; Title 42 of the U.S. Code (42 U.S.C.) §§4321-4347.
[3] Council on Environmental Quality (CEQ) regulations implement NEPA and are found in Title 40 of the Code of Federal Regulations (40 C.F.R.), Parts 1500 through 1508. The U.S. Department of Agriculture has implemented NEPA regulations, which are found at 7 C.F.R. part 1b, as has APHIS, and those are found at 7 C.F.R. part 372.
[4] 7 U.S.C. §§7701-7786.
[5] 7 C.F.R. Part 340.

wholly-owned subsidiary of Land O'Lakes, Inc., a farmer-owned food and agricultural cooperative representing the interests and needs of more than 300,000 direct and indirect members across the U.S. APHIS, through its Biotechnology Regulatory Service (BRS), is one of three federal agencies responsible for regulating biotechnology in the U.S. under the Coordinated Framework described in Section 1.4. APHIS regulates genetically engineered (GE) organisms that may be plant pests, the Environmental Protection Agency (EPA) regulates plant incorporated protectants and herbicides used with herbicide-tolerant crops, and the U.S. Department of Health and Human Services' Food and Drug Administration (FDA) regulates food and animal feed. The FDA completed its consultation process for RRA in 2004 (Tarantino, 2004). EPA approved the use of glyphosate over the top of RRA on June 15, 2005. The use of glyphosate over the top of RRA did not require an increase in the existing glyphosate residue tolerance of 400 ppm in the animal feed, non-grass crop group. EPA issued a new glyphosate tolerance for alfalfa seed of 0.5 ppm on February 16, 2005.[6]

NEPA requires federal agencies to evaluate the potential impact of proposed major federal actions and consider such impacts during the decision-making process. After agency review for safety, including an evaluation of relevant scientific data and all public comments relating to potential plant pest risks and related environmental impacts, APHIS issued an Environmental Assessment (EA) pursuant to NEPA in 2005 (USDA APHIS, 2005). Based on that EA, APHIS reached a finding of no significant impact (FONSI) on the environment from the unconfined cultivation and agricultural use of RRA and its progeny (USDA APHIS, 2005). Accordingly, in June 2005, APHIS granted non-regulated status to RRA (USDA APHIS, 2005).

After RRA was deregulated, the seeds were sold and planted. During the growing season of 2005 and 2006, approximately 200,000 acres were planted in 1,552 counties in 48 states (Alaska and Hawaii were not included). Approximately nine months after APHIS granted non-regulated status to RRA, two alfalfa seed growers and seven associations filed a lawsuit against the USDA over its decision to deregulate RRA, claiming that APHIS' EA failed to adequately consider certain environmental and economic impacts as required by NEPA. In February 2007, the court granted the plaintiffs' motion for summary judgment, finding that APHIS is required to prepare an EIS before approving its deregulation of RRA, and vacated APHIS' 2005 decision to deregulate RRA (U.S. District Court (USDC), 2007a). On March 12, 2007, the Court issued a preliminary injunction order in the case (USDC, 2007b). The order prohibited all sales of RRA seeds, effective on the date of the order, pending the Court's issuance of permanent injunctive

[6] 40 C.F.R. §180.364; 70 Fed. Reg. 7864 (Feb. 16, 2005).

relief; and prohibited all future planting, beginning March 30, 2007. The Court also vacated APHIS's deregulation determination. On March 23, 2007, APHIS published a notice in the Federal Register describing the Court's decision that RRA was once again a regulated article.[7] On May 3, 2007, the Court issued a permanent injunction regarding the control of the RRA that had been planted, and requiring APHIS to issue an administrative order specifying mandatory production practices that must be implemented by RRA growers (USDC, 2007c). The Court issued an amended judgment on July 23, 2007, further clarifying the mandatory production practices (USDC, 2007d). APHIS issued its administrative order on July 12, 2007 (USDA APHIS, 2007a). In August and September 2007, USDA, Monsanto, FGI and others filed an appeal, arguing that the injunction was improper. After the Ninth Circuit Court of Appeals affirmed the district court decision, the U.S. Supreme Court decided to hear the case. In June 2010, in *Monsanto Co. et al. v. Geerston Seed Farms et al.*, the Supreme Court overturned the lower court ruling, striking down the injunction.

Following issuance of the district court's amended judgment in July 2007, APHIS commenced work on the EIS for complete deregulation. The Notice of Intent was published in the Federal Register on January 7, 2008.[8] The notice of availability for the draft EIS was published in the Federal Register on December 18, 2009.[9] In the draft EIS, APHIS preliminarily concluded that there is no significant impact on the human environment due to granting nonregulated status to RRA (USDA APHIS, 2009). The comment period for the draft EIS, following an extension granted by APHIS, concluded on March 3, 2010. Approximately, 145,000 comments were submitted. APHIS is now preparing the final EIS.

1.1.2 Purpose of and need for action

This ER has been prepared to support an anticipated EA to be prepared by APHIS with respect to a partial deregulation of RRA. The ER examines the environmental impacts of implementing the proposed measures laid out below, either through a partial deregulation of RRA or other administrative means. The proposed measures would allow commercialization and deregulation of RRA in limited areas and under specific cultivation conditions explained more fully below in Section 1.1.3. If APHIS concludes that an EA supports a FONSI for the proposed measures, APHIS could decide to implement such measures through "partial deregulation".

[7] 72 Fed. Reg. 13735 (Mar. 23, 2007).
[8] 73 Fed. Reg. 1198 (Jan. 7, 2008).
[9] 74 Fed. Reg. 67205 (Dec. 18, 2009).

1.1.3 The proposed measures

Monsanto/FGI have proposed the following measures to be implemented through partial deregulation or other administrative means. The companies state that these measures would allow a subset of alfalfa farmers to obtain the substantial benefits of RRA pending complete deregulation. For example, they expect RRA to (i) offer growers a wide-spectrum weed control option that will enhance stand establishment and increase alfalfa forage; (ii) increase flexibility to treat weeds on an as-needed basis; (iii) allow alfalfa production on marginal land with severe weed infestations; and (iv) provide growers with a weed control system that has a reduced risk profile for the environment. The proposed measures include a separate set of restrictions for RRA forage production and RRA seed production. These restrictions are described in the sections below.

FORAGE PRODUCTION RESTRICTIONS

1) **Grower Requirements**: Each grower is required to abide by the terms specified in their Monsanto Technology / Stewardship Use Agreement (MT/SA) and accompanying Technology Use Guide (TUG), which contractually obligates growers to comply with stewardship requirements related to growing RRA for forage. A copy of the MT/SA and TUG are included in Appendix A.
2) **RRA Seed Licensing Requirements**: All RRA seed is sold through a network of licensed seed companies and their retailers and dealers/distributors. Each seed company is required to have a current Genuity® Roundup Ready® Alfalfa Commercial License Agreement to sell RRA seed. This agreement specifies the limited rights of the seed companies to market the product, including stewardship requirements associated with RRA.
3) **Seed Identification**: RRA seed bag labeling and a unique purple seed colorant will be required product identity mechanisms to notify all RRA forage growers of the presence of the RRA trait and the geographic limitations for product use.[10]
4) **Crop Harvest (Forage only)**: RRA fields, except as noted under "Seed Production Restrictions" Section below, may be harvested for forage only. All growers shall adhere to limitations as outlined in the MT/SA and TUG (Monsanto TUG, attached as Appendix A).[11]

[10] Similar labeling and use agreements are typically used for the sale and stewardship of other GE crops, so growers are currently familiar with such contractual obligations.

[11] Forage growers who have previously used RRA are familiar with this crop use limitation. See Appendix A.

5) **Geographic Restrictions for Forage Planting based on Cropping Practices**:
Geographic restrictions will be placed on forage planting by state and county based on the amount of alfalfa seed produced (see Appendix B). Data on the amount of seed produced is from the 2007 Census of Agriculture, as summarized in Figure 1-1 (for additional details see Table 1-1 and Appendix B). Geographic restrictions for alfalfa forage plantings will be defined in three categories (Tiers I, II, and III) based on the amount of alfalfa seed production reported in each state. (See Appendix B for maps).

   a. Tier I: States with no reported alfalfa seed production (2007); 27 States and all counties within each.

      i. New RRA forage production plantings are allowed in accordance with the requirements established by the TUG and Genuity® Roundup Ready® Alfalfa Commercial License Agreement.

      ii. Forage growing is the only reported crop practice for alfalfa. No commercial alfalfa seed growth was reported in Tier I states in 2007. However, if conventional seed production fields are now present, then RRA forage grown near these new conventional seed production fields are subject to the requirement provided in Restriction Enhancement A (see Tier II.ii below).

   b. Tier II: States with <100,000 lbs annual seed production (2007); 12 States and all counties within each.
   Commercial alfalfa seed production occurs in these states; however, the number of seed growers, seed acres and cumulative pounds are limited and widely dispersed. Only 0.51 percent of the U.S. alfalfa seed crop is produced in these states (2007).

      i. New RRA forage production plantings are allowed in accordance with the requirements established by the TUG and Genuity® Roundup Ready® Alfalfa Commercial License Agreement.

      ii. Restriction Enhancement A applies if the RRA forage field is located within 165 ft of a commercial, conventional alfalfa seed production field. Under Restriction Enhancement A, the RRA grower must harvest forage before 10 percent bloom.

1. *Rationale for Restriction Enhancement A*: In grower locations where an individual RRA forage field is within 165 ft of a conventional seed production field, the TUG requires the RRA grower to mitigate RRA flowering by harvesting not later than 10 percent bloom stage to mitigate pollen production. RRA forage grower compliance with the TUG's 10 percent bloom stage harvest has been high and rarely was it delayed by weather or other factors. (See Appendix J). This restriction will address mitigations at or near geographic (county, state and federal) borders. The 165 ft distance is the science and market-based, industry recognized isolation distance for certified alfalfa seed crops (see Association of Official Seed Certifying Agencies (AOSCA), 2009); and, the potential extent of gene flow of 10 percent bloom hay to nearby seed crops is de minimis at 165 ft (Teuber and Fitzpatrick, 2007; Van Deynze et al., 2008).

c. Tier III: States each having >100,000 lbs annual seed production (2007); 11 States. Enhanced restrictions to be applied based on predominant county cropping practices. In the eleven states with greater than 100,000 acres of annual alfalfa seed production, additional by-county geographic restrictions will apply. In many cases, within each state, seed acreage is geographically concentrated and typically localized to a few specific counties where climate is suitable for seed growing. (See geographic maps for each of these states in Appendix B.) In these states, alfalfa seed is typically grown by professional growers under seed company contracts and official seed certification inspection programs are widely used by growers and the contracting seed companies. Alfalfa forage production is also a major enterprise in these states and in many cases it is geographically separate from seed crop acres.

    i. By-County criterion used to determine eligibility for new RRA forage plantings.

        1. Counties without seed production reported (Appendix B).

a. New RRA forage production is allowed in accordance with the requirements established by the TUG and Genuity® Roundup Ready® Alfalfa Commercial License Agreement.

b. Restriction Enhancement A: If RRA forage field is located within 165 ft of a conventional alfalfa seed field, RRA grower must harvest forage at or before 10 percent bloom.

c. Restriction Enhancement B: All RRA forage growers are required to report GPS coordinates of all RRA forage field locations. GPS field location information is available for monitoring and enforcing the planting restrictions applicable to RRA forage fields.

d. Forage production is the only reported crop practice in these counties. Commercial alfalfa seed growing is not reported.

2. Counties with seed production reported (Appendix B).

a. Restriction Enhancement C: New RRA forage plantings are not allowed in counties with commercial alfalfa seed production.

b. Commercial alfalfa seed growing is a predominant activity in these counties

c. 99.5 percent of U.S. alfalfa seed production is in these counties.

6) **Summary of Allowed Forage Production Scope:**

a. Nationwide, the counties excluded from new RRA forage production under the requested partial deregulation represent 99.5 percent and 21.84 percent of the alfalfa seed production pounds (lbs) and forage production acres, respectively (See Appendix B).

b. Nationwide, the counties where new RRA forage plantings are allowed (with various restrictions) include 0.5 percent and 78.16 percent of the alfalfa seed production (lbs) and forage production acres, respectively.

7) **Monitoring and Enforcement of Forage Crop Restrictions**

Support and enforcement of the partial deregulation of RRA for forage production would be accomplished by the following mechanisms.

a. **Education and Communication**: Education and communication activities would be conducted with hay growers, seed dealers/sellers and seed companies. Examples of these activities include training and information sessions for dealers and sellers, detailing the requirements for selling RRA, sales meetings, periodic visits with growers and sellers, and computer based training modules that can be tailored to specific areas of focus related to the product and requirements.

i. **Training**: Online training would be required for each seed company staff member handling RRA as well as the appropriate personnel at Monsanto/FGI.

ii. **The MT/SA and accompanying Monsanto TUG**: The MT/SA and accompanying TUG, a legal agreement between growers who utilize Monsanto technologies and Monsanto, would be updated to include direct reference to the partial deregulation conditions, including the limitations pertaining to where RRA forage can be grown and hay and forage management practices.

iii. **Packaging Updates**: In addition to being clearly labeled as RRA seed, all bags of finished product would have an additional prominent tag that lists the states and counties in which the product could not be planted. In addition the seed would have a unique coating color (purple) that identifies it as being RRA seed.

iv. **Dealer Requirements**: All dealers selling RRA would sign a dealer agreement legally binding them to adhere to the partial deregulation requirements.

v. **Industry Communications**: Alfalfa industry-specific groups would be utilized to support communication of the partial deregulation requirements in communications to their members. These include National Alfalfa and Forage Alliance (NAFA), American Seed Trade Association (ASTA), etc.

vi. **RRA Information Line**: A toll free number will be available for growers or other individuals to clarify information or answer questions regarding the partial deregulation.

b. **Assessment and Verification**: Multiple assessment and verification tools will be utilized to monitor and verify adherence to the partial deregulation request.

i. **Reconciliation of Sales Data**: All sales to hay growers will be reconciled with remaining RRA seed inventory at the end of the planting season (twice per year). This reconciliation will be part of a legal commercial requirement of the seed companies and dealers selling RRA.

ii. **GPS coordinates**: GPS coordinates will be collected on all sales in the eleven (11) Tier III states. The GPS coordinates will be collected on all fields planted with RRA. Information will be validated at time of receipt; questionable data will be reviewed.

iii. **Hotline**: A toll-free hotline will be available for individuals to report violations to the partial deregulation ruling.

c. **Proactive Sampling, Testing and Review, inclusion of third parties**: Various internal and/or third parties will be utilized to randomly review plantings and to determine grower compliance with the conditions of the partial deregulation.

d. **Enforcement**: Violations of the partial deregulation decision will have the following impacts:

i. **Grower**: Takeout of the alfalfa field in violation would be required. Grower has the potential to lose access to RRA.

ii. **Dealer**: Any dealer incentive payments would be at risk. In addition, dealers would also risk losing their ability to sell RRA in the future.

iii. **Seed Company**: Any seed company incentive payments would be at risk. In addition, seed companies would also risk losing their ability to sell RRA in the future.

e. **Ongoing Measurement**: An annual report would be prepared by FGI for the USDA summarizing activities in all areas identified above. Additional data would be provided upon request.

f. **Any potential additional investigation or action** would be conducted in accordance with all federal, state and local laws concerning individual property rights, inspections and sampling activities. Monsanto has demonstrated that it does not exercise its patent rights where trace amounts of patented seeds or traits are present in a farmer's fields as a result of inadvertent means.

Table 3-9. State Production of Alfalfa Seed (2007 Census of Agriculture).

State	Farms	Seed Acres Harvested	Pounds of Seed Harvested
California	114	36,625	19,083,458

RRA SEED PRODUCTION RESTRICTIONS

The National Alfalfa and Forage Alliance (NAFA) used current science and extensive stakeholder input to design the "Best Management Practices (BMP) for Roundup Ready Seed Production" (See Appendix C in this ER for additional details on BMPs for Roundup Ready® Alfalfa Seed Production). These BMP have been adopted by the industry as standards for any future RRA seed production as part of an overall stewardship program designed to ensure coexistence of various alfalfa hay and seed markets. All RRA seed grower contracts require full adherence to the NAFA BMP, a type of identity preserved process-based seed stewardship, which includes but is not limited to the following measures:

- RRA seed field location reporting to official seed certification agencies
- Field and isolation zone inspection by official seed certification agencies
- Equipment cleaning prior to and after use
- Segregated and uniquely identified seed handling and storage
- Planting stockseed labeling
- FGI RRA seed grower education and contracting
- Field termination reporting
- Seed company monitoring of compliance
- Annual third-party review of efficacy of BMP
- Other

FGI has individual seed-producer farmer partners who have asked for the opportunity to produce RRA seed crops.

Partial deregulation of RRA would include seed production that is restricted to eight defined seed grower consortia (Table 1-2). FGI has determined that each of these individual consortia could meet or exceed the National Alfalfa & Forage Alliance BMP for RRA Seed Production (NAFA, 2008a) parameters and the proposed partial deregulation enhancements to isolation distance described below (See Appendix C and Table 1-2).

1) **Seed Identification**: Stockseed container to be clearly labeled as containing RRA trait seed. Grower seed contracts and official field reporting will notify each seed grower regarding the measures imposed for seed growing.

2) **Implement all NAFA BMP with Isolation Enhancement**

   a. All BMP measures will be followed, documented, monitored and enforced for compliance by FGI or its representatives. In addition, each field will be inspected annually by the local seed certification agency, confirming minimum isolation standards for that production year.

   b. Measures will set the enhanced, minimum, isolation requirements for RRA seed fields as follows. The minimum required isolation from conventional, commercial seed fields will be 4 miles and 1 mile, when honeybees or leafcutter bees are the managed pollinating species, respectively.

   c. The potential for gene flow at NAFA BMP isolation is de minimis (Van Deynze et al. 2008) and this measure's proposed enhancement of isolation distance would further ensure de minimis gene flow potential into conventional seed crops should they be present.

3) **Geographic Restrictions**:

   a. Only eight pre-authorized, physically-isolated locations for RRA seed production will be allowed. Each location of proposed seed growing is composed of one to three large seed growers who will act together to manage isolation control within a local, informal RRA seed grower consortium.

Table 1-2 Eight Seed Grower Consortia

Grower Consortium	Counties and State	Number of requesting growers	Approximate number of initial acres (2010-2011)	Managed pollinator bee species	Seed harvest equipment status, ownership	Current isolation distance to conventional seed	NAFA Best Practices minimum isolation distance	Partial Deregulation Isolation, minimum distance
A. Northern California	Lassen, CA	1	300	leafcutter	On-Farm	>5mi	900 ft	1 mi
B. Central California	Kings, Kern, Fresno, CA	2	2,000	Honeybee +leafcutter	On-farm	4 mi	3 mi	4 mi

D. Eastern Idaho	Oneida, Manidoka, Twin Falls, ID		500	leafcutter	On-farm	1 mi	900 ft	1 mi
E. Western Idaho	Ada, Canyon, Payette, ID	3	2,000	leafcutter	On-farm	1 mi	900 ft	1 mi
F. Nevada	Humbolt, Pershing, NV	2	600	leafcutter	On-farm	2 mi	900 ft	1 mi
G. Texas	Carson, Castro, Donley, Gray, Lamb, Ochiltree, Roberts, Swisher, TX	1	500	leafcutter	On-farm	>10 mi	900 ft	1 mi
H. Utah	Box Elder, Cache, Millard, Weaver, UT	3	500	leafcutter	On-farm	5 mi	900 ft	1 mi

873

1.2 RATIONALE FOR CREATION OF RRA

Alfalfa is a small seeded perennial forage crop that competes with annual weeds during establishment and with annual and perennial weeds in established stands. With irrigated alfalfa stands, weed seeds in irrigation water can reinfest the stand with weed seeds with every irrigation event. Weed infestation increases the risk of successful establishment and weeds generally compete with alfalfa for light, water, and nutrients. Weeds can have an adverse affect on the quality of harvested forage and effectively shorten the productive life of the alfalfa stand. RRA offers alfalfa growers a simpler, more effective, more flexible, and less expensive herbicide alternative for weed control. Current weed control programs in alfalfa production have serious limitations because certain weed species are difficult to control. Certain of these difficult to control weeds are poisonous and/or toxic to livestock. Glyphosate applications to RRA will offer flexibility in timing of weed control, including preplant, preemergence and/or postemergence applications. In contrast to most other commonly used alfalfa herbicides, glyphosate can safely be applied at virtually any stage of GT alfalfa development. The use of GT alfalfa can help increase alfalfa forage yield and forage quality through better weed control (Rogan and Fitzpatrick, 2004, pp. 20-21; Medlin and Siegelin, 2001).

Glyphosate is not used for in-crop weed control in conventional alfalfa (those without glyphosate tolerance) because it damages the plants. With GT alfalfa, growers have another option for weed control.

1.3 SCOPE OF ENVIRONMENTAL ISSUES ADDRESSED

During the lawsuit discussed above, certain specific issues were identified by the court as requiring additional NEPA analysis by APHIS (USDC, 2007). These primary issues are described below and are addressed in the Affected Environment and Environmental Consequences sections of this ER. Other issues identified by APHIS in the draft EIS are also addressed to the extent they are relevant to the proposal for partial deregulation to ensure full disclosure and analysis of any potential impacts associated with partial deregulation of RRA under the proposed measures. Many of the citations herein are to the draft EIS discussions of the basic facts regarding alfalfa, its weed threats and cultivation.

1.3.1 Gene transmission to non-genetically engineered alfalfa

Alfalfa is a perennial crop and is typically replanted every three to six years. The crop is typically harvested for forage three to eight times per year, depending on location and seasonal climate. Most alfalfa in the U.S. is harvested in the late vegetative stage (pre-bloom) to optimize

yield and nutritional quality. Forage quality begins to drop dramatically in hay harvested after the flowering stage, and continues to deteriorate as the crop further matures toward pod/seed set (USDA APHIS, 2009, p. 40). Hay harvested after 10 percent bloom is generally of poor quality for feed and has low market value (USDA APHIS, 2009, p. G-6). This leaves little opportunity for pollination among forage crops. Alfalfa is exclusively pollinated by bees which normally pollinate other alfalfa plants growing in close proximity. However, pollinations at greater distances can occur (e.g, less than 1 to greater than 3 miles depending upon the bee species).

In contrast, growers promote flowering and seed ripening in commercial seed fields. In most fields, flower buds begin to form on stems approximately 4 to 6 weeks after field mowing during long-day photoperiods and warm weather. Once alfalfa begins flowering, it flowers indeterminately, and its duration depends on moisture, temperature, and other factors (Rogan and Fitzpatrick, 2004). Ripe seed, viable for germination, is formed 5 to 6 weeks after pollination (i.e., 9 to 12 weeks total after mowing). Seed harvested before this stage is not viable.

Cross-pollination between RRA and conventional or organic alfalfa crops could potentially result in the inadvertent presence of GE material in conventional or organic alfalfa hay intended for a market with specific or zero tolerance for the presence of GE material. Putnam (2006) estimated that the GE sensitive hay market is approximately 3 to 5 percent of the total market. He estimated that the majority of the market (95 to 97 percent) is composed of growers that may either adopt RRA varieties and/or are not likely to be GE sensitive in their buying decisions.

Detailed analysis of the potential for gene transmission from RRA has been conducted. Potential impacts from both hay and seed production on organic and conventional hay and seed production, other Medicago crops, and feral populations of alfalfa are analyzed in Sections 3.3 through 3.8 of this ER. A study of the topic was separately published (Van Deynze et al., 2008).

1.3.2 Socioeconomic impacts

The court found that APHIS failed to analyze in its initial EA the socio-economic impacts of deregulating RRA on organic and conventional farmers. Therefore, further analysis was conducted and is discussed in Sections 3.15 of this ER.

1.3.3 Consumer's choice to consume non-GE food

The court found that APHIS failed to analyze the possibility that deregulation of RRA would degrade the human environment by eliminating a consumer's choice to consume, or a grower's

choice to grow, non-GE food. Therefore, further analysis was conducted and is discussed in Section 3.10 of this ER.

1.3.4 Potential for development of glyphosate-resistant (GR) weeds

As the adoption of GT crops has grown, the use of glyphosate has increased (National Research Council [NRC], 2010, Figures S-1, S-2, and S-3; Young, 2006). Concerns have been expressed that increased use of glyphosate may lead to development of GR weeds. Further analysis was conducted and is discussed in Sections 2.4 and 3.11 of this ER.

1.3.5 Cumulative effects of increased use of glyphosate

Further analysis of cumulative impacts from increased use of glyphosate was conducted and is discussed in Section 4 of this ER.

1.4 FEDERAL REGULATORY AUTHORITY – COORDINATED FRAMEWORK

Interagency coordination in scientific and technical matters is the responsibility of the federal Office of Science and Technology Policy (OSTP), which was established by law in 1976. A large part of the OSTP's mission is "to ensure that the policies of the Executive Branch are informed by sound science" and to "ensure that the scientific and technical work of the Executive Branch is properly coordinated so as to provide the greatest benefit to society" (OSTP, undated).

In 1986, the OSTP published a "comprehensive federal regulatory policy for ensuring the safety of biotechnology research and products", the *Coordinated Framework for the Regulation of Biotechnology* (Coordinated Framework) (OSTP, 1986). The OSTP concluded that the goal of ensuring biotechnology safety could be achieved within existing laws (OSTP, 1986).

The Coordinated Framework specifies three federal agencies responsible for regulating biotechnology in the U.S.: USDA's APHIS, the EPA, and the FDA. APHIS regulates GE organisms under the PPA of 2000. EPA regulates plant-incorporated protectants and herbicides used with herbicide-tolerant crops under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) and Federal Food, Drug, and Cosmetic Act (FFDCA). FDA regulates food (including animal feed, but not including meat and poultry, which is regulated by USDA), including food and feed produced through biotechnology, under the authority of the FFDCA. Products are regulated according to their intended use and some products are regulated by more than one agency. Together, these agencies ensure that the products of modern biotechnology are safe to grow, safe to eat, and safe for the environment. USDA, EPA, and

FDA enforce agency-specific regulations to products of biotechnology that are based on the specific nature of each GE organism.

In 2001, in a joint Council on Environmental Quality (CEQ)/OSTP assessment of federal environmental regulations pertaining to agricultural biotechnology, the CEQ and OSTP found that "no significant negative environmental impacts have been associated with the use of any previously approved biotechnology product" (CEQ/OSTP, 2001, p. 1).

For RRA, the plant is reviewed by USDA and FDA, whereas EPA is responsible for registering the use of the glyphosate herbicide and establishing a tolerance for allowable glyphosate residues.[12] As indicated herein, although certain issues such as weed resistance and impacts of glyphosate on animals or plants are addressed by EPA (not APHIS), this ER nevertheless addresses those issues.

1.4.1 USDA regulatory authority

The APHIS BRS mission is to protect U.S. agriculture and the environment using a dynamic and science-based regulatory framework that allows for the safe development and use of GE organisms. Under its authority from the PPA, APHIS regulates the introduction (importation, interstate movement, or release into the environment) of certain GE organisms and products.[13] A GE organism is presumed to be a regulated article if the donor organism, recipient organism, vector, or vector agent used in engineering the organism belongs to one of the taxa listed in the regulation[14] and is also presumed to be a plant pest. APHIS also has authority under these rules to regulate a GE organism if it has reason to believe that the GE organism may be a plant pest or APHIS does not have sufficient information to determine that the GE organism is unlikely to pose a plant pest risk.[15]

Under APHIS' regulations a person may petition APHIS to evaluate submitted data and determine that a particular regulated article is unlikely to pose a plant pest risk, and, therefore, should no longer be regulated.[16] The petitioner is required to provide information related to plant pest risk that the agency may use to determine whether the regulated article is unlikely to

[12] Under the FFDCA and associated regulations, EPA sets a tolerance, or maximum residue limit, for pesticide treated food and feed items. A tolerance is the amount of pesticide residue allowed to remain in or on each treated food commodity. The tolerance is the residue level that triggers enforcement actions. That is, if residues are found above that level, the commodity will be subject to seizure by the government.

present a greater plant pest risk than the unmodified organism.[17] If the agency determines that the regulated article is unlikely to pose a plant pest risk, the GE organism will be granted non-regulated status. In such a case, APHIS authorizations (i.e. permits and notifications) would no longer be required for environmental release, importation, or interstate movement of the non-regulated article or its progeny.

It was under these regulations that Monsanto/FGI submitted the petition for a determination of non-regulated status for event J101/J163 (Rogan and Fitzpatrick, 2004). J101/J163 alfalfa were considered regulated because they contain non-coding deoxyribonucleic acid (DNA) segments derived from plant pathogens and the vector agent used to deliver the transforming DNA is a plant pathogen (See Section 3.1 for a discussion of these concepts) (USDA APHIS, 2005, p. 5).

1.4.2 EPA regulatory authority

EPA is responsible for regulation of pesticides (including herbicides such as glyphosate) under the FIFRA.[18] FIFRA requires that all pesticides be registered before distribution, sale, and use, unless exempted by EPA regulation. Before a product is registered as a pesticide under FIFRA, it must be shown that when used in accordance with the label, it will not result in unreasonable adverse effects on the environment.

Under the FFDCA, as amended,[19] pesticides added to (or contained in) raw agricultural commodities generally are considered to be unsafe unless a tolerance or exemption from tolerance has been established. EPA establishes residue tolerances for pesticides under the authority of the FFDCA. EPA is required, before establishing a pesticide tolerance to reach a safety determination based on a finding of reasonable certainty of no harm under the FFDCA, as amended by the Food Quality Protection Act of 1996 (FQPA). The FDA enforces the tolerances set by the EPA. EPA approved the use of glyphosate over the top of RRA on June 15, 2005. The use of glyphosate over the top of RRA did not require an increase in the existing glyphosate residue tolerance of 400 ppm in the animal feed, non-grass crop group; this tolerance supports the feeding of alfalfa forage that has been treated with glyphosate to livestock. EPA issued a new glyphosate tolerance for alfalfa seed of 0.5 ppm on February 16, 2005.[20]

[20] 40 C.F.R. §180.364; 70 Fed. Reg. 7861 (Feb. 16, 2005).

1.4.3 FDA regulatory authority

FDA, which has primary regulatory authority over food and feed safety, has published a policy statement in the Federal Register concerning regulation of products derived from new plant varieties, including those genetically engineered (FDA, 1992). Under this policy, FDA uses a consultation process to ensure that human food and animal feed safety issues or other regulatory issues (e.g. labeling) are resolved prior to commercial distribution of a bioengineered food. Monsanto/FGI submitted a food and feed safety and nutritional assessment summary for RRA to FDA in October 2003. FDA completed its consultation process in 2004 (Tarantino, 2004; Hendrickson and Price, 2004). FDA's analysis and related impacts are discussed in Section 3.10.

1.5 THE NATIONAL ORGANIC PROGRAM AND BIOTECHNOLOGY

Congress passed The Organic Foods Production Act (OFPA) of 1990 to avoid the confusion and misrepresentation then taking place in the "organic" marketplace.[21] The OFPA required the USDA to establish a National Organic Program (NOP) to develop uniform standards and a certification process for those producing and handling food products offered for sale as "organically produced."[22] The OFPA requires certification under the NOP, which was finalized in 2000, to be process-based.[23] "The certification process does not guarantee particular attributes of the end product; rather it specifies and audits the methods and procedures by which the product is produced" (Ronald and Fouche, 2006). The NOP defines certain "excluded methods" of breeding that cannot be used in organic production, describing them as "means that are not possible under natural conditions or processes."[24] Along with genetic engineering, three other modern breeding techniques are specified as "excluded methods" in the regulations.[25] Thus, a certified organic grower cannot intentionally plant seeds that were developed by these specific excluded methods. However, because "organic" is based on process and not product, the mere presence of plant materials produced through excluded methods in a crop will not jeopardize the integrity of products labeled as organic, as long as the grower follows the required organic production protocol. Also, other modern breeding methods -

[21] 7 U.S.C. § 6501 et seq.
[22] 7 C.F.R. Part 205, announced at 65 Fed. Reg. 80548 (Dec. 21, 2000).
[23] 7 U.S.C. §6503(a).
[24] 7 C.F.R. §205.2.
[25] *Id.*

for example, induced radiation or chemical mutagenesis - are not specified as excluded methods by the NOP (discussed in Section 3.1.1).

All organic growers' production plans must be approved by an organic certifying agent before the farm can be certified as "organic."[26] Such plans must include, among other things, steps the organic grower is taking to avoid what the NOP refers to as "genetic drift" from any neighboring crops using excluded methods.[27] Certification must include on-site inspections of the farm to verify the procedures set forth in the organic production plan.[28]

Thus, the NOP recognizes the coexistence of organic growers with neighboring growers who may choose to grow products developed using certain methods of biotechnology. So long as an organic grower follows an approved organic method of production that seeks to avoid contact with these specific biotechnology-derived crops, if some residue of the biotechnology-derived plant material is later found in the organic crop (or food produced from it), neither the crop (or food) nor the organic farm is in danger of losing its organic status. According to the standards established by the NOP, no grower or seed producer should lose organic certification due to inadvertent transmission of genetic material from a genetically engineered crop.

In the context of the genetic drift discussion, in the preamble of the NOP regulations, USDA emphasized that it is the use of excluded methods as a production method that is prohibited, not the mere presence of a product of excluded method:

> It is particularly important to remember that organic standards are process based. Certifying agents attest to the ability of organic operations to follow a set of production standards and practices that meet the requirements of the Act and the regulations. This regulation prohibits the use of excluded methods in organic operations. The presence of a detectable residue of a product of excluded methods alone does not necessarily constitute a violation of this regulation. As long as an organic operation has not used excluded methods and takes reasonable steps to avoid contact with the products of excluded methods as detailed in their approved organic system plan, the unintentional presence of the products of excluded methods should not affect the status of an organic product or operation.[29]

The NOP calls for testing only if there is "reason to believe" that a grower has used excluded methods.[30] The preamble states that a "reason to believe" may be triggered by situations such

---

[26] *See* 7 C.F.R. Part 205, Subpt. E.
[27] *See id.* at 205.201; 65 Fed. Reg. 80547, 80556 (Dec. 21, 2000) (discussing "genetic drift").
[28] 7 C.F.R. §205.403.
[29] 65 Fed. Reg. 80547, 80556 (Dec. 21, 2000).
[30] 7 C.F.R. §205.670(b).

as a formal, written complaint to the certifying agent regarding the practices of a certified organic operation; the proximity of a certified organic operation to a potential source of drift; or the product from a certified organic operation being unaffected when neighboring fields or crops are infested with pests.[31]

This testing provision does not establish a zero tolerance standard for the presence of products of excluded methods in organically labeled food. Rather, it serves as a warning that excluded methods may have been used: "Any detectable residues of. . . a product produced using excluded methods found in or on samples during analysis will serve as a warning indicator to the certifying agent."[32]

> [T]hese regulations do not establish a "zero tolerance" standard. . . [A] positive detection of a product of excluded methods would trigger an investigation by the certifying agent to determine if a violation of organic production or handling standards occurred. The presence of a detectable residue alone does not necessarily indicate use of a product of excluded methods that would constitute a violation of the standards."[33]

Only if the organic producer intentionally used excluded methods of crop production will that producer be subject to suspension or revocation of organic certification.

Indeed, since the time GE crops were introduced in the U.S. in the mid-1990s, organic markets have grown and expanded (Smith, 2010b, p. 10).

1.5.1 Non-GMO Project working standard

The Non-GMO[34] Project is a non-profit organization created by leading members of the organic industry to "offer consumers a consistent non-GMO choice for organic and natural products that are produced without genetic engineering or recombinant DNA technologies" (Non-GMO Project, 2010a). The Non-GMO Project has created a working standard to implement its goal. The standard sets action thresholds for "GMO" (GE) adventitious presence for certain products. If these action thresholds are exceeded, the participant must investigate the cause of the exceedance and take corrective action (Non-GMO Project, 2010, p. 13). The standard sets a threshold of 0.25 percent for GE material for the presence of GE traits in non-GE seeds (p. 28), and a 0.9 percent threshold for non-GE food or feed (p.14).

[32] *Id.* at 80628.
[33] *Id.* at 80632.
[34] GMO stands for genetically modified organism.

1.5.2 Growth in organic and GE farming

Expansion of organic farming has succeeded at the same time as the growth of GE crops. Consumer demand for organically produced goods "has shown double-digit growth for well over a decade" and organic products "are now available in nearly 20,000 natural food stores and three of four conventional grocery stores." Organic products "have shifted from being a lifestyle choice for a small share of consumers to being consumed at least occasionally by a majority of Americans" (USDA Economic Research Service [ERS], 2009c).

1.6 COEXISTENCE IN U.S. AGRICULTURE

1.6.1 Coexistence and biotechnology

Coexistence of different varieties of sexually compatible crops has long been a part of agriculture, especially in seed production, where large investments are made in developing new varieties and high seed purity levels are required by the Federal Seed Act's implementing regulations.[35] The aspect of coexistence most relevant to this document is that related to specific methods of crop production. In this context, coexistence refers to the "concurrent cultivation of conventional, organic, and genetically engineered (GE) crops consistent with underlying consumer preferences and choices" (USDA Advisory Committee, 2008). The differences among these crops that are particularly relevant to coexistence in this ER are in the types of breeding methods (sometimes referred to as "genetic modifications") that are associated with each of these three types of crop production.

"**Genetic engineering**" is defined by APHIS regulations as "the genetic modification of organisms by recombinant DNA techniques."[36] Recombinant DNA (rDNA) techniques are discussed in Section 3.1.1 of this ER. While there are many ways to genetically modify a crop, the APHIS definition of GE crops applies only to those developed using rDNA techniques, which are among the more modern breeding methods.

Organic crops are those produced in accordance with the requirements of the NOP, discussed in Section 1.5.

Conventional crops are simply those that are neither GE nor organic. They may be commodity crops (mass produced), or they may be identity preserved, with some characteristic tailored for a specific end user. Identity-preserved usually refers to a "specialty, high-value, premium or niche market" (Massey, 2002). One type of identity preserved product that has

[35] 7 C.F.R. § 201
[36] 7 C.F.R. §340.1

been produced since the introduction of GE crops is "non-GE"; however, there are no mandatory standards governing the use and/or marketing of "non-GE" products. (USDA Advisory Committee, 2008).

Farmers who want to maximize their profitability must decide whether the higher prices (premiums) they may receive for organic or identity-preserved crops are sufficient to offset the added managerial costs of producing these crops. As researchers have noted, "Although yields on organic farms are sometimes less than those of conventional systems, price premiums make it an attractive option for growers looking for specialized markets and a higher-value product" (Ronald and Fouche, 2006).

1.6.2 USDA position on coexistence and biotechnology

It is USDA's position that all three methods of agricultural production described above can provide benefits to the environment, consumers, and the agricultural economy (Smith, 2010b).

1.6.3 Coexistence in U.S. agriculture

The USDA Advisory Committee on Biotechnology and 21st Century Agriculture who reported that "coexistence among the three categories of crops is a distinguishing characteristic of U.S. agriculture, and makes it different from some other parts of the world," expressed its belief that U.S. agriculture supports coexistence, and recommended continued government support of coexistence (USDA Advisory Committee, 2008). Among the Committee's findings:

- The U.S. is the largest producer of GE crops in the world.
- The U.S. is one of the largest producers of organic crops in the world.
- The U.S. is one of the largest exporters of conventionally-grown, identity preserved, non-GE crops in the world.
- Some U.S. farmers currently are producing a combination of organic, conventional, and GE crops on the same farm.

Among the coexistence-enabling factors the Committee identified is the existing "legal and regulatory framework that has enabled different markets to develop" without foreclosing the ability of "participants in the food and feed supply chain to establish standards and procedures (e.g., not setting specific mandatory adventitious presence (AP) thresholds and having process-based rather than product-based organic standards)." At the same time, development of practices and testing methods that allow for voluntary thresholds has also enabled coexistence (USDA Advisory Committee, 2008).

As APHIS has previously observed, "studies of coexistence of major GE and non-GE crops in North America and the European Union (E.U.) demonstrated that there has been no significant gene flow from GE crops and that GE and non-GE crops are coexisting with minimal adverse economic effects" (Smith, 2010b, pp. 11-12) (citing Gealy et al., 2007; Brookes and Barfoot, 2003; Brookes and Barfoot, 2004(a) and (b), and Walz 2004). In addition, "the agricultural markets and local entities have addressed coexistence through contractual arrangements, management measures, and marketing arrangements. This market-based approach to coexistence has created economic opportunities for all kinds of producers of agricultural products." (*Id.* p. 9). RRA is one of fifteen GT events previously deregulated by USDA. See APHIS, EPA, Petitions of Non-Regulated Status Granted or Pending by APHIS as of February 2, 2010, http://www.aphis.usda.gov/brs/not_reg.html).

1.7 ROLE OF THE NATIONAL ACADEMIES IN AGRICULTURAL BIOTECHNOLOGY

The analyses in this ER are based on published, peer-reviewed scientific papers; federal government assessments; assessments from international agencies; information from specialists from many universities; data collected by Monsanto/FGI under controlled conditions; and information from other relevant sources. One resource used for this ER is the National Academies (NA), a private, non-profit institution that advises the nation on scientific and technical matters. It consists of the National Academy of Sciences (NAS), the National Academy of Engineering, the Institute of Medicine (IM) and the National Research Council (NRC) (NA, 2010). Scientists, engineers and health professionals are elected by their peers to the academy and serve *pro bono*. Reports are prepared by committees of members with specialized expertise and reviewed by outside anonymous experts (Alberts, 1999). NA reports, as well as the scientific studies used in those reports, are used as applicable throughout this document.

The NA has been active in studies related to agricultural biotechnology since the 1970s and works cooperatively with federal agencies, and its reports have provided guidance and recommendations for process improvement to regulatory agencies (Alberts, 1999). The NRC 1989 guidelines for field testing of genetically engineered organisms were used as the basis for agency procedures for field trials (Alberts, 1999; NRC, 1989). In studies in 1987 and 2000 the NRC emphasized that the characteristics of the modified organism should be the object of a risk assessment, and not the methods by which the modifications were accomplished; and that the risks associated with recombinant DNA techniques are the same in kind as risks from other types of genetic modification (NRC, 1987; NRC, 2000). This position was re-iterated in a 2004

study prepared jointly by the IM and the NRC. Whether such compositional changes result in unintended health effects is dependent on the nature of the substances altered and the biological consequences of the compounds. To date, "no adverse health effects attributed to genetic engineering have been documented in the human population" (Institute of Medicine and National Research Council [IM/NRC], 2004, p. 8). In a 2002 report, the NRC "found that the current standards used by the federal government to assure environmental safety of transgenic plants were higher than the standards used in assuring safety of other agricultural practices and technologies" (NRC, 2002). The NRC reports that, while biotechnology is not without risk, since the first commercial introduction of transgenic plants, "biotechnology has provided enormous benefits to agricultural crop production" (NRC, 2008). NRC's latest report on biotechnology in agriculture evaluates the impact of genetically engineered crops on farm sustainability (NRC, 2010). The authors concluded that an understanding of impacts on all farmers will help ensure that GE technology contributes to sustainability and that commercialized GE traits to date, when used properly, "have been effective at reducing pest problems with economic and environmental benefit to farmers" (NRC, 2010).

1.8 ALTERNATIVES

In addition to the alternative of implementing the partial deregulation measures (Alternative 2), this ER considers the alternative of full regulation (Alternative 1).

1.8.1 Alternative 1 – No Action

In conducting NEPA review, agencies consider a no action alternative, which provides a baseline against which action alternatives can be evaluated. This ER identifies the no action alternative as a return to full regulation – or the *status quo* when the petition for deregulation of RRA was initially submitted. Under this alternative, the introduction of RRA would be fully regulated and would require permits issued or notifications acknowledged by APHIS until APHIS completes its EIS and issues a Record of Decision (ROD) regarding whether to deregulate RRA. For purposes of this analysis, we assume that Alternative 1 would not involve widespread RRA cultivation, and instead would contemplate a return to conventional alfalfa crops or to crops other than alfalfa.[37]

[37] This ER does not address the acres of RRA planted prior to March 30, 2007, and cultivated pursuant to conditions required by the district court and implemented by APHIS by administrative order. These acres are reaching the end of their productive lives and will be removed within the next few years under either Alternative. Because their acreage and expected lifespan is so small, and because their impacts would be identical under either Alternative, the analysis of these limited impacts would not be meaningful within the scope of this ER.

1.8.2 Alternative 2 – Partial Deregulation

Under this alternative APHIS would implement the proposed measures described in Section 1.1.3.

SECTION 2.0 AFFECTED ENVIRONMENT

2.1 ALFALFA CHARACTERISTICS

Alfalfa (*Medicago sativa* L.) is a deep-rooted and short-lived perennial plant considered to be the "Queen of Forages" due to its high nutritional content for cattle, sheep and horses (USDA APHIS, 2009, p. 18).

2.1.1 Growth

Alfalfa is recognized as a widely adapted crop, growing in all continental States, as well as Alaska and Hawaii. Alfalfa initially grows from seed, but after each harvest or winter it will re-grow from buds arising from the perennial crown/root structure. As alfalfa grows, yield (i.e. above ground biomass) increases until alfalfa yield peaks at full bloom. However, juvenile vegetative alfalfa vegetative alfalfa plants have the highest nutritional value and that nutritional value decreases as the plant approaches full flower. The vegetative growth interval during most of the year is 22 to 40 days. The crop is typically harvested for forage three to eight times per year, depending on location and seasonal climate. The alfalfa plant grows until stopped by a hard freeze. Fields grown for forage production are typically maintained for 3 to 6 years or longer in some areas (USDA APHIS, 2009, p. 18-19).

2.1.2 Pollination

Alfalfa is predominantly cross-pollinated and the flowers depend entirely on bees for cross-pollination. Alfalfa requires bees to physically "trip" flowers to release pollen for egg fertilization and seed production (refer to Section 2.2.3) (USDA APHIS, 2009, p. 19).

Alfalfa is exclusively insect pollinated (Mallory-Smith and Zapiola, 2008). The flowers depend on bees for cross-pollination. Alfalfa seed farmers must stock bees to ensure pollination because most regions that cultivate alfalfa seed do not have naturally occurring populations of effective alfalfa pollinators. Forage farmers do not stock bees, however, because they do not want or need pollination of their fields (USDA APHIS, 2009, p. 94; Rogan and Fitzpatrick, 2004). Leafcutter bees (Megachile rotundata F.) are typically used to pollinate alfalfa seed production fields in the cooler Pacific Northwest (PNW), and honey bees (Apis mellifera) are primarily used in the Desert Southwest. However, a few growers in niche regions like southern Washington use alkali bees (Nomia melanderi) due to their unique geography and climate (USDA APHIS, 2009, p. 19). Alfalfa pollen is not carried by the wind; it is not wind-pollinated. Severe environmental conditions such as, heavy winds in combination with drought, may sometimes

cause flowers to trip and self-pollinate. Although rare, self-pollinated seeds have inferior vigor and germination due to genetic inbreeding depression in alfalfa (Teuber, 2007).

Pollen-mediated gene flow decreases exponentially as the distance from the pollen source increases (Mallory-Smith and Zapiola, 2008). However, the type of pollinator determines the extent. All bees have a limited range over which they will search to efficiently collect pollen; most nectar or pollen foraging occurs close to the nest when flowers are present. The maximum foraging radius for each of the three commercially available bee species (honey bees, leafcutter bees, and alkali bees) depends heavily on the abundance of nectar and pollen resources. Leafcutter bees have the shortest routine foraging radius of less than a 1/4 mile. The honey bee and alkali bee having a forging range of 1 to 3 miles (Arnett, 2003; Gathmann and Tscharntke, 2002; Hammon et al., 2006; Teuber et al., 2005). Honey bees may infrequently transport alfalfa pollen and effect pollination up to 3 miles from the source (St. Amand et al., 2000; Teuber et al., 2004; Hammon et al. 2006). Honey bees are predominantly nectar collectors and as such they tend to avoid the tiny alfalfa flowers when other sources of nectar flowers are available. When visiting alfalfa flowers, honey bees are known as inefficient pollinators because they predominantly "side-feed" solely for nectar, i.e., they leave the flower closed (un-tripped) and un-pollinated. Feral honey bees and native bees including *Bombus* spp., *Osmia* spp., *Agapostomen* spp. and *Megachile* spp. can also be found visiting alfalfa flowers in varying numbers. These species may sometimes pollinate alfalfa flowers but their importance in alfalfa pollination is minor (USDA APHIS, 2009, p. O-5; Hammon et al., 2006; Arnett, 2002).

2.2 ALFALFA PRODUCTION

2.2.1 Forage production, general

Alfalfa is among the most important forage crops in the U.S., with more than 21 million acres in cultivation. Recognized as the oldest plant grown solely for forage, alfalfa has been used as livestock feed because of its high protein and low fiber content. Alfalfa is ranked fourth on the list of most widely grown U.S. crops by acreage and is ranked third among agricultural crops in terms of value (USDA APHIS, 2009, p. 17). The harvested acreage of alfalfa harvested for forage (dry hay) was approximately 21 million acres in 2009, which generated 71 million tons of hay at an average yield of 3.35 tons per acre (USDA ERS, 2010a and 2010b). Over the last 60 years (since 1951), harvested alfalfa hay acreage in the U.S. has ranged between 20.7 acres (2010) and 29.8 million (1957) (USDA ERS, 2010a). From 1951 to 2009 (latest year available), total U.S. production (dry) has ranged between 46.8 million tons (1951) and 91.9 million tons

(1986) (USDA ERS, 2010b). Since 1950, yields generally increased until about the mid-1980s; since then yields in most years have been around 3.3 tons per acre. The total acreage of harvested alfalfa has generally been declining since the mid-1980s, with 2010 the lowest year since 1950 (USDA ERS, 2010a). The production decreases are due to alfalfa's use in crop rotation declining in the U.S., and the increased use of corn silage as a source of forage in dairy diets coupled with the decline in dairy (milk) prices paid to farmers. Alfalfa requires different management, equipment, and labor schedules than other major cropping systems such as corn and soybeans. Transportation of bulky alfalfa hay or haylage to distant markets may be prohibitively expensive (USDA APHIS, 2009, p. 34). In the 2009/2010 season (May 2009 to April 2010), the average price farmers received for alfalfa hay was $115/ton, compared to $101/ton for other hay (USDA ERS, 2010c).

Alfalfa is grown for forage in almost every U.S. state. U.S. production of hay/haylage and seed harvested for the 2006 season is shown in Table 2-1. Haylage is alfalfa that is chopped at higher moisture content than hay, and stored in silos, bunkers or plastic bags to enable controlled fermentation to preserve the nutritional content. The major U.S. alfalfa producing regions include the Southwest, PNW, Inter-Mountain, Plains, North Central, and East-Central. The North-Central and the East-Central regions are the highest acreage hay and haylage regions in the U.S.; whereas, the Southwest and PNW regions produce the most seed in the U.S. (USDA NASS, 2010b).

Cultural practices

Seeding and planting. The objectives of seedbed preparation are to manage crop residue (the leftover vegetative matter from the previous crop), minimize erosion, improve soil structure, and eliminate early season weeds. Alfalfa requires a good establishment for a long-lived productive

stand. Results from seed failure include poor seedbed preparation, seeding too deep or too shallow, low moisture availability, freezing, diseases, insects, damage from herbicides, and excess competition for light and nutrients from a companion crop or from weeds. Slight differences in seeding may be in the equipment used, such as, drills, broadcasting, or aerial broadcasting. Seeding time during the year varies from region to region. Northern areas will generally seed in spring to avoid major freezing damage of young seedling plants whereas all other areas will seed in the fall. Recommended seeding times are based on the previous crop, soil water availability throughout the year, and the time of year. The recommended soil preparations are similar in all regions unless no-till planting is used and no-till planting can be used in all regions (USDA APHIS, 2009, p. 84). No-till productions systems do not have any associated tillage where weed control is entirely through chemical means.

Fertilizing. The only differences in fertilizing among alfalfa growers occur in the composition of the fertilizer used because of the different soil types in different regions. All regions generally recommend good availability of phosphorus and potassium. Nitrogen fertilizer is generally not recommended unless considerable refuse from the previous crop exists (USDA APHIS, 2009, p. 84).

Harvesting. Alfalfa grown for forage can be used for grazing or harvested as greenchop, haylage/silage or hay. The only major difference for harvesting in different regions is the total number of harvests per year. The northern regions typically have up to two or three harvests per year due to shorter growing seasons. Southern regions can have six or more harvests per year. The major differences are in the adaptation of different varieties to the different climates of the U.S. and differing levels of various pests (weeds, disease, and insects) (USDA APHIS, 2009, p. 84).

Harvesting. Alfalfa grown for forage can be used for grazing or harvested as greenchop, haylage/silage or hay. The only major difference for harvesting in different regions is the total number of harvests per year. The northern regions typically have up to two or three harvests per year due to shorter growing seasons. Southern regions can have six or more harvests per year. The major differences are in the adaptation of different varieties to the different climates of the U.S. and differing levels of various pests (weeds, disease, and insects) (USDA APHIS, 2009, p. 84).

Crop rotations. Crop rotations can help maintain soil fertility, reduce soil erosion, avoid pathogen and pest buildup, adapt to weather changes, avoid allelopathic effects (effects to reduce the growth of one plant due to chemical releases by another) and increase profits.

Weeds can be a problem in alfalfa, but once alfalfa is established, it acts as a suppressor of weeds and is commonly used in rotations for weed reduction. Alfalfa is also used in crop rotations because it provides nitrogen to the soil, which decreases fertilizer inputs in other rotations. Rotating perennials, such as alfalfa, with annuals also helps control weeds and improves soil tilth. Using other crops to rotate with alfalfa is likewise advisable because mature alfalfa is autotoxic to seedling alfalfa. (USDA APHIS, 2009, p. 73 and 75).

2.2.2 Organic alfalfa hay production

Between 2000 and 2005, the number of acres in certified organic alfalfa hay production fluctuated slightly, but overall showed an increasing trend. The percentage of total alfalfa hay acres certified as organic per year was between 0.51 to 0.92 percent nationally during this time period (see Table 2-2). During 2005 (the most recent year for which certified organic alfalfa acres are reported), there were 204,380 acres in certified organic production, which was approximately 0.92 percent of the U.S. alfalfa dry hay total (USDA APHIS, 2009, p. 48).

Table 2-2 Organic Alfalfa Hay Harvested Acreage.

Acreage	2000	2001	2002	2003	2004	2005
Total	113,157	116,608	155,437	135,717	175,260	204,380
Share of Total U.S. Acreage	0.51%	0.49%	0.67%	0.58%	0.81%	0.92%

Source: USDA-ERS, 2005; USDA-NASS, 2007; USDA APHIS, 2009, p. 48

Organic alfalfa hay production is similarly distributed geographically to conventional hay. However, production of organic alfalfa hay is a more significant proportion of total alfalfa hay production in some States. In 2005, for example, more than 4 percent of all alfalfa hay acreage in Idaho was organic, compared to just 0.92 percent nationally. Organic alfalfa, like organic dairy, also seems to occur in pockets, with 72 percent of organic acreage located in just 6 States—Idaho, Wisconsin, Minnesota, North Dakota, South Dakota, and California. These 6 States account for about 41 percent of total U.S. alfalfa acreage (USDA APHIS, 2009, p. 48).

The increased price per ton of hay received by organic growers is partially offset by a reduction in forage quality (due to increased weeds in the hay) and an approximately 12.5 percent reduction of alfalfa yield per acre (Long et al., 2007). The 2005 national average yield per acre for all alfalfa hay production was 3.39 tons. Based on differences in organic and conventional alfalfa yield from Long et al. (2007), the total estimated U.S. organic hay production in 2005 was about 606,242 tons; the total U.S. production of alfalfa hay in 2005 was approximately 76,149,000 tons. The resulting eaverage organic alfalfa yield per acre, in 2005, was 2.97 tons. This estimate is approximate, however, and is only presented here for illustrative purposes (USDA APHIS, 2009, p. 48).

2.2.3 Seed production

Maintaining seed purity, identity and quality

The Federal Seed Act and its implementing regulations[38] establish basic standards for certification of seed, which are carried out by state seed certifying agencies. A state seed certifying agency is created by state law, has authority to certify seed, and has standards and procedures approved by USDA "to assure the genetic purity and identity of the seed certified." Seed certifying agencies' standards and procedures must meet or exceed those specified in the

[38] 7 C.F.R. §201.

USDA regulations.[39] Federal law also allows for international seed certification. Through the certification process, the certifying agency "gives official recognition to seeds produced of a cultivar or named variety under a limited generation system which ensures genetic purity, identity, and a given minimum level of quality" (USDA, 2009a). In the case of alfalfa, State Crop Improvement Associations (or sometimes Seed Grower Associations) provide certifications that seed production followed minimum standards, such as isolation between different alfalfa varieties, absence of prohibited noxious weeds in the field, inspection of conditioning (separation) facilities, maintaining traceability of seed lots, and seed testing (USDA APHIS, 2009).

The most common levels of certification that would normally be available for consumer purchase would be "registered seed" or "certified seed." Breeder seed is controlled by the seed developer and is the source for the production of the other classes of certified seed, and foundation seed is normally used to establish new production fields (USDA, 2009a and 7 C.F.R. § 201.2). Standards are highest for Breeder/Foundation seed, next highest for Registered; while "Certified" has the least stringent requirements of the certified categories. In all cases, the party seeking the certification is responsible for ensuring the requirements are met.

Certified seed must have a label indicating, among other things, the percent of pure seed, inert matter, other crop, and weed seed. Seed purity standards vary between states but remain high, particularly for foundation seed stock. At least 99 percent of each seed harvest must contain the pure seed variety (i.e. < 1 percent genetic off-types), and there are strict limits on the allowable amounts of other crops, weeds and inert matter. After seed crops have been evaluated by seed labs, they are tagged with seed labels in accordance with law. The Association of Official Seed Certifying Agencies (AOSCA) requires that a representative sample from each submitted crop undergo multiple tests at a seed lab. All types of seed crops must be accurately labeled. The Foundation and Certified seeds are identified by a special tag that includes variety, kind, origin, net weight, percent pure seed, percent other materials, amount of noxious seed and weeds, and identification of the seed lab performing the analysis (USDA APHIS, 2009).

California, the leading producer of alfalfa seed, provides an example of typical rules for field eligibility (past use and spatial isolation) and seed purity standards. These rules are followed by most states. For cultivating Foundation seed (seed of the highest purity), alfalfa must not have grown on the land in the previous four years. For Certified seed, alfalfa must not have been grown on the land in the previous one to two years. These past use requirements may vary

[39] 7 U.S.C. §1551(a)(25); 7 C.F.R. §201.67.

depending on the intervening crops. The boundaries of the field must be clearly set and all noxious weeds and volunteer plants must be eradicated before planting. Foundation seed fields must be isolated from alfalfa of different varieties by 900 feet (ft). Certified fields must be isolated by 165 ft However, a "10 percent rule" provides some flexibility for Certified fields. Under this rule, if 10 percent or less of the Certified field is in the 165 foot isolation zone, then the entire field is considered Certified. However, if more than 10 percent is in the isolation zone, then that part of the field must be separated and not harvested as Certified seed (USDA APHIS, 2009).

Summary of practices for alfalfa seed production

Unlike alfalfa hay production, alfalfa seed production is largely concentrated both geographically and in the number of producers. Seed production occurs primarily in niche areas of the western U.S. on approximately 100 to 120 thousand acres under intensive management and irrigated field conditions (see Figure 1-1). It requires a long growing season with a very warm temperature, very low humidity during seed ripening, and specialized equipment. Most professional seed producers use cultured bees and specialized equipment associated with bee culture (USDA APHIS, 2009, p. 68).

Based on the 2007 Census of Agriculture, the top three seed producing states, accounting for over 60 percent of production, were California with 31 percent of produced seed, Washington with 17 percent, and Idaho with 15 percent. The remaining seed production was highly concentrated in the western states of Nevada, Oregon, Wyoming, Montana, and Utah (USDA APHIS, 2009).

As shown in Table 3-9 of the draft EIS (included as Figure 1-1 of this ER), within the seed producing states seed production is localized to certain counties. In the most recent USDA-NASS Census of Agriculture (2007), during 2002 and 2007, 1,234 and 806 farmers grew alfalfa seed on 110.6 and 120 thousand acres, respectively. This is a small number of growers in comparison to those growing alfalfa for forage (i.e., 344,000 and 290,000 alfalfa hay growers in 2002 and 2007, respectively). During 2007, 90 percent of the U.S. seed crop tonnage was grown by 304 seed growers operating farms with at least 100 acres of alfalfa seed (USDA-NASS, 2009). Therefore, most of the alfalfa seed production is managed by a relatively small number of large professional seed producers. Nearly all large growers have at least one proprietary seed production contract with one of the four national alfalfa seed production companies (USDA APHIS, 2009, p. 68-69).

Cultural practices used to produce seed are distinct from those used to produce forage. Professional seed growers usually grow seed under terms of a two or three year term seed company contract, by variety name. The contracting seed company supplies the stock seed (e.g., foundation seed) to the seed producer and the genetic source variety of the seed is documented. In contrast, seed companies purchasing or growing "common seed" or "catch crop" seed typically use lower management and inputs, the genetic identity of the stock seed is often unspecified/unknown and the resultant product quality is highly variable and cannot be certified as to cultivar or variety identity (USDA APHIS, 2009, p. 69).

Typically, seed fields are planted in the fall and clipped back in late spring so that bloom within the field is uniform, synchronous and optimally timed for the warm dry season and optimal pollinator activity. Weed and in-crop volunteer controls (herbicides and cultivation) are applied mainly prior to the start of pollination or after seed harvest. Flowering begins in approximately mid-June. Insecticides (primarily for *Lygus* control) and other pesticides are applied prior to bee release to avoid insecticide damage to the bees. At approximately 50 percent flower (early to mid-July), cultured bees are gradually moved into the seed field for pollination with their domicile or hive for local shelter. The field is actively pollinated for approximately one month, allowed to ripen seed for approximately 4 weeks more, and then, chemically desiccated or swathed several days prior to combining the seed. At the end of the pollination period and just prior to desiccation, the pollinating generation of bees is either at the end of their lifecycle (i.e., leafcutter or alkali bees), or are transported by the honeybee keeper to a different location to forage on fall-flowering plant species. Seed is harvested in mid August to late September depending on geography. In long-growing season regions, the cool-season alfalfa forage growth between seed crops is sometimes mechanically harvested or grazed (USDA APHIS, 2009, p. 69).

Stands of alfalfa grown for seed production only are usually maintained for an average of three production seasons. The length of the seed stand is generally predetermined by the seed production contracts and AOSCA variety certification standards. In contrast to forage stands, most alfalfa seed planted for seed production purposes is planted at a low density in widely spaced rows and not cut monthly. Consequently, weeds in the seed fields have more open area and time to proliferate and compete with the alfalfa. Therefore, weeds, insects, and pests are intensively managed in seed production systems. Weed seeds and weed debris in grower seed lots directly reduce the purity and yield of alfalfa seed and drive up growers' costs to remove them (USDA APHIS, 2009, p. 69-70).

RRA seed production since 2005

In 2006-2007, RRA seed was produced in the U.S. on a widespread basis for the first time since deregulation in 2005. This presented an opportunity for FGI to implement an internal seed quality program to monitor the efficacy of the FGI Best Practices for RR Stewardship during Seed Production ("FGI Best Practices"). Conventional alfalfa seed lots grown and/or processed in proximity to RR seed in 2006 and 2007 were tested for the adventitious presence (AP) of the RR trait. The data showed that the AP of the RR trait in FGI conventional seed lots occurred infrequently and, in all cases if detected, was at a very low level—0.004 to 0.180 percent. This was well within the FGI's goal of <0.5 percent AP. This large-scale commercial validation of FGI Best Practices supports research-based isolation standards and demonstrates the effective implementation of quality control programs at both the grower and processor level. FGI believes that this, and more recent industry reviews together demonstrate that reasonable tools are available and are being used by seed producers to allow successful coexistence of diverse alfalfa seed market sectors and preserve conventional seed and hay market choices (USDA APHIS, 2009). In late 2007, following the Court's Decision, the FGI Best Practices were extensively reviewed by the Steering Committee of the National Alfalfa & Forage Alliance Peaceful Coexistence Workshop (October 10, 2007). The steering committee was composed of a broad array of alfalfa industry stakeholders. In January, 2008, NAFA's Board of Directors and all genetic suppliers of NAFA adopted the NAFA BMP (Appendix C) as requirements for RRA seed producers. A third-party panel of State Seed Certification Agencies has reviewed 2008 and 2009 conventional alfalfa seed crop year data and has stated that the NAFA BMP appear to be working to achieve coexistence, i.e., conventional and RRA varieties have been produced successfully during the period following widespread cultivation of RRA.

All alfalfa seed production since 2005

The latest information of total alfalfa seed production is from the 2007 Census of Agriculture, when 121,467 acres of alfalfa seed were harvested producing approximately 62 million pounds of seeds at an average productivity of approximately 510 lbs/acre.

Alfalfa seed acreage and production increased between 2002 and 2007, reversing the trend of decreases in alfalfa seed production over the preceding few years. Economic, social and competitive challenges face both U.S. alfalfa seed and forage growers. These challenges include: changes in global seed demand and production, economics, environmental constraints, regulatory issues, and insect control and weeds. The presence of weeds can have a greater impact on costs in alfalfa seed production than alfalfa forage production. Post-harvest

separation of weed seed from the alfalfa seed is costly; therefore, the control of weeds in the field is a more desirable method of seed quality control. No primary or secondary noxious weeds are allowed for certified seed (USDA APHIS, 2009, p. 43-44).

Seed availability

All four of the major U.S. seed genetic suppliers and seed production companies (FGI, Pioneer Hi-Bred, Dairyland Seeds and Cal/West Seeds) sell conventional and/or organic seed products. Prior to the federal court injunction, these varieties were sold alongside of one or more RRA varieties. RRA was sold by more than 20 seed brands all of which continued to offer conventional cultivar products (USDA APHIS, 2009).

During the 2005-2007 period of deregulation of RRA, approximately 200,000 and 18,000 acres of RRA hay and seed, respectively, were grown with no substantiated disruption of the market for conventional alfalfa hay or seed (USDAS APHIS, 2009; McCaslin, 2007).

Organically certified and conventionally grown seed lots are routinely marketed to U.S. organic forage producers for the establishment of organic alfalfa forage fields. Although a small amount of organic alfalfa seeds used in the U.S. are purchased from U.S. seed distributors, little or none of the organic alfalfa seeds appear to have been originally grown in the U.S. (McCaslin, 2007). There is little information available to indicate if there are any certified organic alfalfa seed producers in the U.S. (USDA APHIS, 2009). Organic alfalfa seed sold in the U.S. by U.S. seed companies is therefore most likely to have been wholly or largely imported from organic producers in Canada or elsewhere, where insect pests in alfalfa seed production are less catastrophic and base production costs for seed are much lower (McCaslin, 2007).

2.3 GENE FLOW

This section provides background information on gene flow, which is relevant to the impacts analysis provided in Section 3 of this ER.

Gene flow has been defined as the "incorporation of genes into the gene pool of one population from one or more populations" (Futuyma, 1998). Gene flow is a basic biological process in plant evolution and in plant breeding, and in itself does not pose a risk (Bartsch et al., 2003; Ellstrand, 2006, p. 116).

There are several factors that influence the probability of gene flow between alfalfa fields. The following is a list of factors adapted from Putnam, 2006 (USDA APHIS, 2009, p. 100):

- Probability of synchronous flowering (e.g., the percentage of days where several plants flower simultaneously);
- Relative availability and abundance of pollen from various sources (e.g., the percentage of bloom during each day of synchronous flowering);
- Presence of pollinators and pollinator types
- Pollinator activity on days of synchronous flowering and placement of bee hives (e.g., influenced by timed bee release and weather);
- Distance between fields (alfalfa populations);
- Probability of seed maturation; and
- Probability of seed germination.

2.3.1 Hybridization

In plant biology, when gene flow occurs between individuals from genetically distinct populations and a new plant is formed, the new plant is called a hybrid (Ellstrand, 2003, p. 10). Hybridization is usually thought of as the breeding of closely related species or subspecies resulting in the creation of a plant that has characteristics different from either parent. Usually this occurs through deliberate human efforts; however, it can also occur indirectly from human intervention, or in nature. For example, when plants are moved to a new environment (with or without human intervention), they may hybridize with plants of a closely related species or subspecies in that new location.

For natural hybridization to occur between two distinct populations, the plants from the two populations must flower at the same time, they must be close enough so that the pollen can be carried from the male parent to the female parent, fertilization must occur, and the resulting embryo must be able to develop into a viable seed that can germinate and form a new plant (Ellstrand, 2003, pp. 11-13).

Characteristics that favor natural hybridization between two populations when the above requirements are met include (Mallory-Smith and Zapiola, 2008, p. 429):

- Presence of feral populations (domestic populations gone wild) and uncontrolled volunteers
- Presence of a high number of highly compatible relatives
- Self-incompatibility

- Large pollen source
- Large amounts of pollen produced
- Lightweight pollen
- Large insect populations (insect pollinated)
- Long pollen viability

Feral populations are discussed in Section 2.6. **Volunteers** are plants from a previous crop that are found in a later crop and are also discussed in Section 2.6.

There are **no sexually compatible** wild relatives of alfalfa present in the U.S. (Mallory-Smith and Zapiola, 2008; Van Deynze et al., 2008, p. 7). Therefore, movement of the CP4 EPSPS gene found in RRA varieties can only occur within or among cultivated or feral alfalfa populations (USDA APHIS, 2009, p. 94).

Alfalfa (*Medicago sativa* L.) is predominantly **self-incompatible**; that is, fertilization does not occur between the male and female parts on the same plant. Self-incompatible plants must be cross-pollinated (also known as "out-crossed") to form viable seed: that is, for fertilization to occur, the female part of the flower (the stigma) must successfully receive pollen from the male part of a second plant (the anther). The majority of cross-pollination in alfalfa is effected by bees visiting plants growing in very close proximity (i.e., within four meters) (St. Amand et al., 2000).

As discussed in Section 2.1.2, alfalfa is exclusively **insect-pollinated**, and, in seed production areas, farmers must stock bees to ensure economic levels of seed production.

Gene flow via seed mixtures

Nearly all alfalfa forage producers purchase seeds for planting, largely because grower-produced grower-saved-seed is only possible in the niche seed-growing geographies. Commercially produced seed is generally produced under a contract from a seed company: the foundation stock seed is provided to the contract grower by the seed company and seed lots are harvested, transported and conditioned by variety name and lot code. Such contracts and the typical use of official seed certification schemes maintain field and seed lot segregation, identity and varietal purity. Seed certification standards set limits on the percentage of other variety off-types that are allowed. Therefore, seed growers and seed producers are aware of the importance of routine cleaning of field equipment, seed transportation containers and seed processing equipment as means to mitigate off-types and weed seed presence to very low

levels. Regardless of stringent management, commercial agricultural seeds are not and cannot be 100 percent pure. Therefore, it is widely recognized that some seed admixtures may still inadvertently occur, and that, in all but exceptional cases they are likely to pose no safety, economic or regulatory issues.

2.3.2 Seed-to-seed gene flow studies

FGI performed gene flow studies in Idaho from 2000 to 2002 using leafcutter bees for pollination, however, the presence of feral and native bees were also noted. These studies showed a mean gene flow of 1.39 percent at 500 ft and 0.0000 percent at ¾ of a mile (Fitzpatrick et al., 2002). Table 2-3 and Figure 2-1 below summarize the findings of these field studies.

Table 2-3. Summary of FGI Idaho Gene Flow Studies (Fitzpatrick et al., 2002)

Isolation distance	Year 2000	Year 2001 [a]	Year 2002 [a,b]	2000-2002 Overall Mean Observed gene flow (99.9% C.I. upper bound)
0 ft (Source Plot)	*Source* (1.0 A)	*Source* (1.6 A)	*Source* (1 A)	
500 ft	Reps 1-4: 0.03 A, N [c]	-	-	1.39% (1.72%)
900 ft	-	Rep 1: 0.7 A, N. Rep 2: 1.6 A, N.E.	-	0.28% (0.34%)
1000 ft	Reps 1-4: 0.03 A, N [c]	-	-	0.32% (0.45%)
1500 ft	Reps 1-4: 0.03 A, N [c]	Rep 1: 1.6 A, W. Rep 2: 1.6 A, N.W.	Rep 1: 1 A, S.W. Rep 2: 1 A, S.E.	0.08% (0.13%)
2000 ft	Rep 1: 2.0 A, N.W. [c]	-	-	0.00% (0.05%)
2640 ft (1/2 mi)	-	-	Rep 1: 1 A, S.W. Rep 2: 1 A., S.E.	0.003% (0.02%)
3960 ft (3/4 mi)	-	-	Rep 1: 1 A, S.W. Rep 2: 1 A, S.E.	0.0000% (0.01%)
5280 ft (1 mi)	-	-	Rep 1: 1 A, N.W. Rep 2: 1 A, S.E.	0.0000% (0.01%)
Mean no. seed tested per trap distance	14,750	41,250	60,000	

Notes: Isolation distance between trap and source, number of replicates per distance, replicate plot size (acres), trap plot cardinal direction from source and, interplot land cover a,b,c, the mean observed gene flow and the upper bound of true gene flow (i.e., the 99.9 percent confidence interval upper limit) are given. Interplot land cover:a various crop species typical for the area (e.g., onions, corn, wheat, etc.); b roadways, or c fallow. "-" indicates distance not tested.

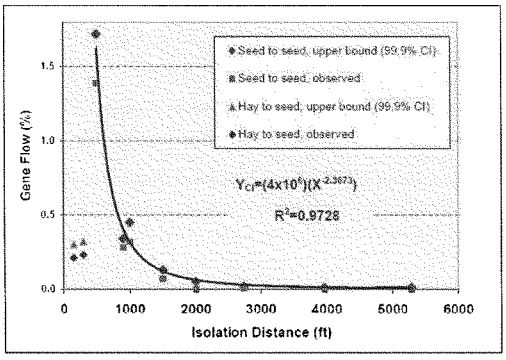

Figure 2-1 – Gene Flow

UC—Davis, Monsanto/FGI performed a gene flow study during the 2003 growing season using honey bees. The pollen-mediated gene flow at isolation distances of 900 ft, 5,000 ft, and 2.53 miles were 1.49 percent, 0.2 percent, and ≤0.06 percent, respectively (Teuber et al., 2007).

A mixed honey bee and leafcutter bee gene flow study was performed in the San Joaquin Valley of California in 2006 and 2007 (Teuber et al., 2007; Van Deynze et al., 2008). Summary data from those studies are presented in the Table 2-4 below.

Table 2-4 Seed to Seed Gene Flow (Teuber et al., 2007)

Distance	Gene Flow (% adventitious presence)
165 ft.	2.3
900 ft.	0.9
4,000 ft.	0.6
1 mile	0.2
3 miles	0.03
5 miles	Not detected

FGI conducted a gene flow study subsequent to the 2006 growing season which validated the FGI Best Practices (FGI, 2007). The observed gene flow ranged from 0.09 percent at an isolation distance of one mile to 0.01 percent at an isolation distance of three miles. At distances of 5 miles or greater, the gene flow was not detected.

To summarize, data collected under actual seed production conditions found gene flow ranging from 0.00 to 0.18 percent when FGI Best Practices were used. This is well below the FGI Company's domestic market goal of less than 0.5 percent adventitious presence. As required by the NAFA BMP (2008a), a third-party review panel has annually conducted a review of conventional seed crop gene flow data. In each of the two annual reviews, the panel has validated that NAFA BMP are working on a commercial scale to enable coexistence among conventional and RRA seed producers (NAFA, 2009; Fitzpatrick and Lowry, 2010).

2.3.3 Gene flow potential

This ER addresses potential gene flow pathways as follows:

- Potential for gene flow from RRA forage crops to conventional and organic forage crops (Section 3.3)
- Potential for gene flow from RRA forage crops to native alfalfa (Section 3.4)
- Potential for gene flow due to feral alfalfa populations (Section 3.5)
- Potential for gene flow from RRA forage crops to rangeland alfalfa (Section 3.6)
- Potential for gene flow from RRA forage crops to conventional or organic alfalfa seed production areas (Section 3.7)
- Potential for gene flow from RRA to any of the above receptors, in alfalfa seed production (Section 3.8)

2.4 ALFALFA WEED MANAGEMENT

2.4.1 Weed characteristics and concerns

While a weed can be defined as any unwanted plant, problem weeds are those that are competitive and persistent. Healthy, productive stands of alfalfa require attention to manage pests (including weeds), fertilizer inputs, irrigation (if applicable), and harvest timing. Weeds can be a problem in alfalfa particularly at establishment of a new stand and after the stand has started to thin toward the end of its life. Once a dense stand of alfalfa has been established, the competition of the alfalfa plants with weeds and the fact that alfalfa is cut at regular intervals during the production season act as suppressors of weeds. Weed control at establishment is a particularly important time since good weed control at this time leads to the establishment of a dense, healthy stand for the life of the crop.

Several years after sowing alfalfa when plants weaken and stands become thin weeds become more competitive with alfalfa and can contribute to a significant decline in alfalfa yield and forage value. Certain weed species found in alfalfa stands are particularly difficult to control, are poisonous to livestock, negatively affect palatably or livestock performance, impart off flavors to milk products, and may be noxious regulated species (USDA APHIS, 2009, p. 73).

Competition for light, water and nutrients. A grower tries to capture the plant resources on his land - primarily light, water, and nutrients - for his crop; however, competitive weeds often secure some of these resources for their growth, at the expense of the crop. Some common characteristics of competitive weeds are rapid seedling establishment, high growth rates, prolific root systems and large leaf areas.

Weed persistence. Persistent weeds are able to survive year after year on a given piece of ground, in spite of a farmer's efforts to control them. Some plants are both competitive and persistent through the production of large numbers of seeds. The bushy wild proso millet, for example, shatters upon contact when mature, and can produce 400 to 12,000 seeds per square foot. While high reproductive rates also contribute to a weed's persistence, seed dormancy is also an important trait in persistence. Cultivated soils typically contain thousands of seeds per square meter, waiting for the opportunity to germinate. Some seeds, for example, velvetleaf, can remain viable in the soil for up to 50 years. Many perennial weed species have the ability to reproduce from root fragments. Canada thistle, for example, has a deep, spreading root system that can continue to send up shoots after the surface plant has been removed multiple times. Some weeds have the ability to alter their characteristic in response to stress; for example, some weeds respond to drought by flowering and going to seed early (Tranel, 2003; McDonald et al., 2003, pp. 9-12).

Weeds are controlled in conventional alfalfa and RRA with chemicals (herbicides), cultural methods (rotation, mowing, companion crops, monitoring), and mechanical methods (tillage). The cultural and mechanical methods are permitted for organic farmers. RRA systems allow for the use of one additional herbicide, glyphosate.

2.4.2 Problem weeds in alfalfa production

The following weeds have been identified as problem weeds in alfalfa that prevent production of maximum yields: Barnyardgrass, Bermudagrass, Bluegrass (annual), Bromes, Buckhorn plantain, Bulbous bluegrass, Burning nettle, Canarygrass, Chesseweed, Chickweed (common), Coastal fiddleneck, Cupgrass, Dandelion (common), Dodder, Filarees, Field bindweed,

Flixweed, Foxtail (green), Foxtail (yellow), Foxtail barley, Goosegrass, Groudsel (common), Hare barley, Johnsongrass, Junglerice, Knotweed, Lambsquarter (common), London rocket, Miner's lettuce, Mustards, Nettleleaf, Nightshade, Nutsedges, Palmer Amaranth, Pepperweeds, Prickly lettuce, Quackgrass, Redmaids, Russian thistle, Ryegrass, Shepardspurse, Sowthistle, tinkgrass, Wild oats, Wild Radish, Witchgrass, and Yellow starthistle (UC IPM, 2006) . These weeds are summarized in Table 2-5. Most of these weeds, and others, are present throughout all the alfalfa growing regions. Certain weeds are classified as annual, biennial or perennial. An annual or biennial is a plant that completes its life cycle to produce seed in one or two years (or less), respectively. Perennials are plants that live for more than two years. They may reproduce by seeds, rhizomes (underground creeping stems) or other underground parts. Weeds are further classified as broadleaf (dicots) or grasses (monocots).

1 – Glyphosate resistant weed
Note: Refer to Table G-8 in the draft EIS for Glyphosate resistant weed infestations by state
Source: (UC IPM. 2006), (USDA APHIS, 2009, Tables G-3 and G-7), and (USDA, 2010b)

2.4.3 Use of herbicides to control weeds

Herbicides are used at three different phases in conventional alfalfa farming, which include stand establishment (to prepare the ground), established stands (to control weeds), and during stand removal (to kill alfalfa). The 17 EPA-registered herbicides that are used for stand removal or to control volunteer alfalfa include:

Herbicide	Mode of Action
2,4-DB (Butyrac, Butoxone)	- Synthetic Auxin; Growth regulator
Benfluralin (Balan)	- Dinitroanalines; Microtubule assembly inhibition
Bromoxynil (Buctril) -	- Nitriles; Photosystem II inhibitors
Clethodim (Prism, Select)	- Acetyl-CoA carboxylase (ACCase) inhibitors
Diuron (Karmex, Direx)	- Ureas, Amides; Photosystem II inihitors
EPTC (Eptam)	- Thiocarbamates; Seed growth inhibitors (shoot)
Hexazinone (Velpar)	- Photosystem II inhibitors
Imazamox (Raptor)	- Acetolactate synthase (ALS) inhibitors
Imazethapyr (Pursuit)	- ALS inhibitors
Metribuzin (Sencor)	- Photosystem II Inhibitors
Norfluzaon (Solicam)	- Carotenoid biosynthesis inhibitors
Paraquat (Gramoxone Inteon)	- Bipyridiliams; Cell membrane disruptor

Pronamide (Kerb)	- Dinitroanilines; Microtubule assembly inhibition
Sethoxydim (Poast)	- ACCase Inibitors
Terbacil (Sinbar)	- Photosytem II Inhibitors
Trifluralin (Treflan/TR-10)	- Dinitroanilines; Microtubule assembly inhibition

Source: (USDA APHIS, 2009, Table G-1) and (Heap, 2010)

Table 2-6 summarizes the effectiveness of the herbicides on broadleaf weeds in seedling alfalfa, Table 2-7 summarizes the effectiveness of the herbicides on grass weeds in seedling alfalfa, and Table 2-8 summarizes the effectiveness of herbicide combination control on weeds in seeding alfalfa.

Alfalfa stands are usually thinning and vulnerable to weeds after 2 to 8 years. Alfalfa stands are typically removed by killing the alfalfa by either tillage, herbicide application, or both. RRA cannot be removed using glyphosate; therefore, just like conventional alfalfa, RRA can be removed using tillage and/or labeled, non-glyphosate herbicides.

2.4.4 Non-herbicide weed management practices

Weeds can also be controlled through cultural and mechanical methods. Weed management options include:

- Rotation of crops
- Winter crops in rotation
- Mowing or flash grazing
- Companion crops/co-cultivation/interseeding/nurse crop
- Cover crops (smother crops) (prior to planting alfalfa)

- Field scouting for early detection
- Monitor for weed species and population shifts
- Mechanical removal
- Adjusting harvest frequency
- Burning
- Tillage cultivation (seed production only)

Forage harvest removes weed biomass and developing weed seedlings. Regular forage harvest at late vegetative/mid bud stage combined with healthy competitive stands, effectively manage many key weed species, especially during the middle stages of a specific stand. Crop rotations can help maintain soil fertility, reduce soil erosion, avoid pathogen and pest buildup, adapt to weather changes, avoid the effects to reduce growth of one plant due to chemicals released by another, and increase profits. Alfalfa is also used in crop rotation because it provides nitrogen to the soil, which decreases fertilizer inputs in other rotations. Perennials and annuals promote and restrict different weeds, so rotating perennial and annual crops helps control weeds in general. Rotating alfalfa is also advised because mature alfalfa is autotoxic to seedling alfalfa (USDA APHIS, 2009, p. 74-75).

2.5 HERBICIDE RESISTANCE

Herbicide resistance is "the inherited ability of a plant to survive and reproduce following exposure to a dose of herbicide normally lethal to the wild type" (WSSA, 1998).

Herbicide resistance is a result of natural selection. Plants within a population of a given species are not all identical; they are made up of "biotypes" with various genetic traits. Biotypes possess certain traits or characteristics not common to the entire population. Herbicides, that suppress or kill weeds, can exert selection pressure on weed populations. When a herbicide is applied, the plants with genes that can confer resistance to it, which had no special survival qualities before the herbicide was introduced, become the survivors who are then able to reproduce and pass on their genes. With repeated application of the same herbicide and no other herbicide or weed control practice, the resistant biotype becomes the dominant biotype in that weed community. In the mid-1950s, Harper (1957) theorized that annual, repeated use of any herbicide could lead to shifts in weed species composition within a crop-weed community. Similarly, Bandeen et al. (1982) suggested that a normal variability in response to herbicides exists among plant species and tolerance can increase with repeated use of an herbicide.

Indeed, as of June 27, 2010, 341 herbicide resistant weed biotypes have been reported to be resistant to 19 different herbicide modes of action (Heap, 2010). Glyphosate-resistant weeds account for 5 percent of the herbicide resistant biotypes (as documented on the www.weedscience.org website) while weeds resistant to herbicides that inhibit acetolactate synthase (ALS), such as Raptor and Pursuit, account for 31 percent of the herbicide resistant biotypes (Wilson, 2010a, p. 6).

Figure 2-2 shows the increase in herbicide resistant biotypes with time. Among the herbicides commonly used in conventional alfalfa, Prism, Poast and Select are ACCase inhibitors; Raptor and Pursuit are ALS inhibitors; Butyrac and Butoxone are growth regulators, and Karmex and Direx are in the category of photosynthesis inhibitors. Figure 2-2 shows only the number of confirmed resistant biotypes. The total extent and distribution of resistant biotype varies widely. Details of herbicide resistant weed in alfalfa are discussed in Section 3.11.

For as long as herbicide resistance has been a known phenomenon, public sector weed scientists, private sector weed scientist and growers have been identifying methods to address the problem. For instance, when a farmer uses multiple weed control tools, each effective on a particular species, herbicide resistance biotypes will be controlled and the resistance biotype generally will not become the dominant biotype within a population (Gunsolus, 2002; Cole, 2010a, p. 4). By contrast, weed resistance is known to occur most rapidly in areas where there is a sole reliance

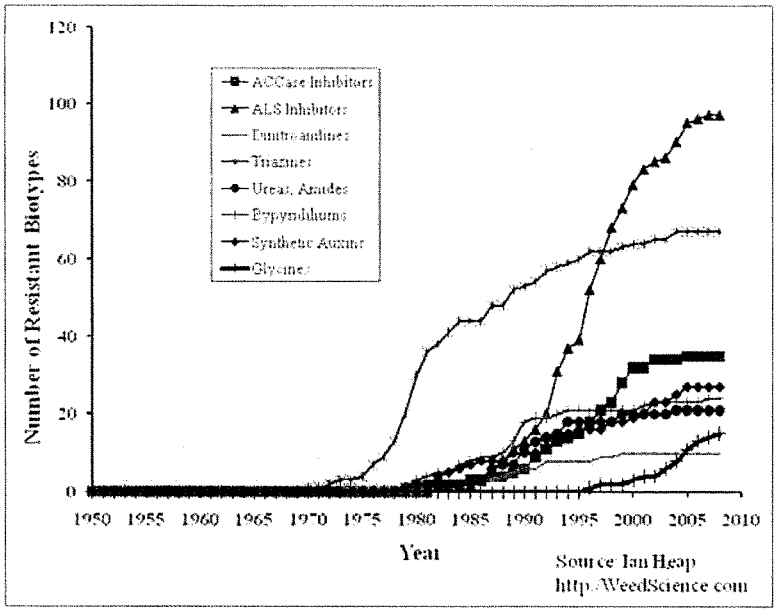

Figure 2-2. Herbicide resistance worldwide

on a single herbicide used repeatedly over multiple crop generations for the management of a specific weed spectrum.

When a grower encounters a biotype that is resistant to an herbicide he is using, the grower must use an alternate method of weed control. Management practices that can be used to retard the development of resistance, such as those routinely used by alfalfa growers, include herbicide mixtures, herbicide rotation, mowing, and crop rotation.. The WSSA reports: "Weed scientists know that the best defense against weed resistance is to proactively use a combination of agronomic practices, including the judicious use of herbicides with alternative modes of action either concurrently or sequentially" (WSSA, 2010b).

2.6 SEXUALLY COMPATIBLE RELATIVES INCLUDING CONSPECIFIC FERAL AND VOLUNTEER ALFALFA

2.6.1 Native sexually compatible relatives

There are no sexually compatible native relatives of alfalfa present in the U.S. (Mallory-Smith and Zapiola, 2008; Van Deynze et al., 2008, p. 7). No native members of the genus Medicago are found in North America (USDA APHIS, 2009, p. 20).

2.6.2 Feral and volunteer alfalfa

Feral crops are those that have become de-domesticated. Based on available data, de-domestication has occurred in only a few crops. These feral crops are of minor importance compared with other weeds (Gressel, 2005). In North America, the feral plants that cause much of the economic damage are imported horticultural plants; for example, Japanese privet, Japanese honeysuckle and kudzu (Gressel, 2005).

For purposes of this ER, unmanaged alfalfa planted for pasture, grazing or road-side reclamation (and similar uses) is also considered feral as, once established, they receive no or minimal agronomic inputs (e.g., clipping). Cultivated and feral alfalfa populations source to the same *Medicago sativa* L. germplasms that were repeatedly introduced to North America over a 400 year period.

Rogan and Fitzpatrick (2004) summarize the extent of feral populations in six major alfalfa-producing States—California, Washington, Idaho, Wyoming, Nevada, and Montana—confirming that minor feral populations do exist in areas where alfalfa seed or forage is produced (USDA APHIS, 2009, p. 22). Compared to cultivated alfalfa, feral alfalfa occurs at a relatively low density and scale. Kendrick et al. (2005) performed a biogeographic survey of five states (California, Idaho, Pennsylvania, South Dakota, and Wisconsin) in 2001 and 2002 and found that feral plants were not present or were sparse in most agricultural areas. Approximately 22 percent of the surveyed sites had dispersed or patches of feral alfalfa within 1.25 miles of cultivated alfalfa (Kendrick et al. 2005; Van Deynze et al., 2008). Relative to the geographies in which only forage is grown, areas with seed production fields were found to have fewer feral alfalfa plants growing in roadsides. Using herbicides or mechanical means, feral alfalfa can be and is controlled by certified alfalfa seed growers as a standard method to help assure isolation from other sources of pollen during varietal seed production (AOSCA, 2009).

Feral, or naturalized, alfalfa populations can escape agricultural fields and multiply by natural regeneration throughout the U.S. Feral alfalfa can be found at air fields, canals, cemeteries,

ditch banks, fence rows, highways, irrigation ditches, pipelines, railroads, rangeland, right-of-ways, roadsides, and wastelands. Alfalfa plants that are not part of cropping systems generally have no regular external inputs like irrigation, herbicides, insecticides, and fertilizers. All feral alfalfa in the U.S., like alfalfa under cultivation, originated from introduced varieties.

In general, survival without management inputs requires feral plant populations to have traits that may differ from those of cultivated plants. The most common traits include:

- variety of pollinators,
- continuous seed production,
- considerable seed output,
- seeds produced in several habitats,
- seed dispersal over short and long distances,
- seed dormancy (ability to form a seedbank),
- broad germination requirements,
- discontinuous germination,
- rapid vegetative growth,
- ability to withstand competition,
- tolerance to unfavorable biotic and abiotic conditions, and
- rapid flowering

A portion of alfalfa seeds may be temporarily impervious to water; these are "hard" seeds. The hard seeds may decay in soil or lay un-germinated (dormant) for a period of time (e.g., a few weeks to several years). Gradually, the hard seed coat ages and the seed will germinate or decay. Alfalfa develops small fragile seedlings that if successfully established may become volunteers in subsequent crops or in unmanaged areas. Hard seed likely contribute few volunteer plants after one year, as, alfalfa seeds generally do not persist for more than one year in field soil (Albrecht et al., 2008). Data for persistence of hard seed in seed production fields is given and discussed in Van Deynze et al. (2008), this confirms Albrecht et al. where studies were done in forage plantings in the Midwest. To guard against hard seed carryover, seed growers take steps to eliminate residual alfalfa volunteers prior to planting (Putnam and Undersander, 2009, attached as Appendix I). AOSCA varietal purity standards (2009) require

land history of 2 or 4 years without alfalfa cultivation, for the Certified and Foundation alfalfa seed generations, respectively. Little to no secondary seeds are formed on hay crop stems because they are harvested in their juvenile stage (weeks before any new, viable seed is formed). A mature alfalfa stand is highly competitive and highly autotoxic to fragile, emerging secondary seedlings. Therefore, secondary seedlings are a very unlikely avenue for effective gene flow into existing solid-seeded alfalfa plantings. The autotoxic reaction and inter-plant competition severely limit germination and seedling vigor of alfalfa sown or dropped into existing or newly terminated alfalfa stands. Solid-seeded cultivated alfalfa fields do not successfully self-seed. Attempts to thicken existing alfalfa stands by deliberately inter-planting new seed into them typically fail, which is why most agronomists do not recommend the practice (Canevari et al., 2000; USDA APHIS, 2009, p. 18-19, 100).

Several scientists have reported that volunteer GT plants could become a problem in rotational crops when both rotational crops are GT, however none provided specific information or data (e.g., Cerdeira and Duke, 2006; Owen and Zelaya, 2005; York et al, 2004; NRC, 2010). RRA volunteers would be expected to be more of concern in crops grown for seed, such as corn and soybeans. Volunteer alfalfa plants—whether conventional or RRA—are controlled by use of mechanical means (e.g., tillage) or by application of several registered non-glyphosate broad-leaf herbicides. Feral alfalfa can also be controlled using these practices, or with glyphosate.

2.7 FOOD, FEED AND OTHER ALFALFA USES

Both food (sprouts, dietary supplements, and herbal or homeopathic medicine) and animal feed (hay, haylage, or silage) are derived from alfalfa.

Alfalfa forage, primarily harvested as hay or haylage, is used as a source of fiber and protein in animal diets. Most alfalfa forage is fed to dairy or beef cattle, but can also be an important part of the diet for horses, sheep and goats.

A small fraction of alfalfa seeds are used to produce sprouts for human consumption. Any alfalfa seed for sprouts must be certified as having been produced to food-grade specifications and therefore food-grade seed is grown and distributed in an entirely separate channel from that for general use, non-food-grade planting seeds. Food-grade seeds for sprouts are produced throughout the world, but the major suppliers are Canada, Italy, U.S. and Australia. Sprouts are cultivated from clean raw (non-coated, untreated) seeds in controlled environment sprouting chambers for approximately 5 to 10 days before sale to consumers.

FDA and equivalent regulatory bodies in Japan, Korea, Canada, Australia/New Zealand, etc., have granted full approval for the use of RRA as a food (see Section 3.11). Monsanto and FGI have developed the RRA varieties for field planting purposes (only), and as such the companies do not intend nor allow (give license to) any seed growers or seed purchasers to use RRA varieties for food-grade sprout production (Hubbard, 2008; USDA APHIS, 2009, p. 18).

2.8 PHYSICAL AND BIOLOGICAL ISSUES

The affected environment for land use, air quality, water quality, ecology, threatened and endangered species, and other sensitive wildlife is the alfalfa producing areas and the seed producing regions. The affected environment for climate is global, as impacts on climate change are a global issue.

2.9 SOCIOECONOMICS AND HEALTH

The affected environment for socioeconomic issues includes those individuals who could potentially be economically impacted if their food or agricultural products are adversely affected by RRA, and those who could be economically impacted if RRA becomes a deregulated article. Potential impacts to the first group are discussed primarily in Section 3.10 and impacts to the second group are discussed in Section 3.15. The potential for health impacts to individuals who may come into contact with RRA or alfalfa seeds or other products derived from RRA is discussed in Sections 3.10 and 3.14. Health effects of potential exposure to herbicides are discussed in Section 3.14.

SECTION 3.0 ENVIRONMENTAL CONSEQUENCES

3.1 PLANT PATHOGENIC PROPERTIES AND UNINTENDED EFFECTS

APHIS previously determined, based on scientific analysis and in accordance with its obligations under the PPA, that RRA does not exhibit plant pathogenic properties (USDA APHIS, 2009).

APHIS considered the potential for the transformation process, the introduced DNA sequences, or their expression products to cause or aggravate plant disease symptoms in RRA and its progeny or in other plants.

APHIS also considered whether data indicate that unintended effects would arise from the genetic engineering of these plants. APHIS considered information from the scientific literature as well as data provided by Monsanto/FGI in their petition that was developed from their field trials (USDA APHIS, 2009).

Based on the analysis summarized below, there are no impacts resulting from plant pathogenic properties, introduced or aggravated disease symptoms, or unintended effects under any of the alternatives. Details of the Monsanto/FGI studies are included in the petition (Rogan and Fitzpatrick, 2004).

3.1.1 Background

Plant genetic modification

Plant genetic modification by humans ranges from the simple approach of directed selection – where seeds of plants with desired traits are saved and replanted – to complex methods such as the use of rDNA (see definitions on next page). APHIS regulations define genetic engineering as genetic modification through the use of rDNA technology.[40] Crossing (and then recrossing) two sexually compatible plants by taking the pollen from one plant and brushing it onto the pistil of another remains the mainstay of modern plant breeding (IM/NRC, 2004). Both more traditional, "conventional breeding" and rDNA methods can involve changes in the frequency, sequence, order, and regulation of genes in a plant and can use many of the same enzymes. However, with conventional breeding all the tens of thousands of genes in the plant are involved, and with the rDNA method only a few genes are involved. In classical breeding, crosses can be accomplished only between closely related species, and therefore only traits that are already present in those species can be targeted. In contrast, the rDNA approach can

[40] 7 C.F.R. § 340.1.

use genes from any living organism, thus opening the door to vast potential in trait development (Lemaux, 2008, p. 774; AMA, 2000).

Other examples of plant genetic modification include cell fusion (the protective cell wall is stripped and cells are fused by some external force) and induced mutagenesis (inducing mutations in seeds by ionizing radiation or carcinogenic chemicals) (Ronald and Adamchak p. 88). Mutagenic techniques, which have been in use since the late 1920s, create random mutations and are limited by their inability to target a desired trait (FDA, 1992; Lundqvist, 2009, p. 39).

Agrobacterium

Agrobacterium tumefaciens (*Agrobacterium*) is a soil microbe that has been called "nature's own genetic engineer" because of its ability to transfer a fragment of its own DNA into a host plant (AMA, 2000). (See definitions at right.) The transferred DNA is stably integrated into the plant DNA, and the plant incorporates and expresses the transferred genes. The transferred DNA (T-DNA) reprograms the host plant cells to grow into callus tissue and produce certain amino acid derivatives that are a food source for the *Agrobacterium.* On a macro scale, the callus tissue growth is called crown gall disease. In the early 1980s scientists developed strains of *Agrobacterium* with T-DNA that lacked the disease-carrying genes ("disarmed" *Agrobacterium*). *Agrobacterium* transformation system has been utilized in the development of a large number of genetically engineered plants in commercial production (IM/NRC, 2004, pp. 28-29). The method uses a DNA molecule called a **vector** that serves as a carrier to insert T-DNA that contains specific genetic elements. These genetic elements are organized into a **gene cassette**, which consists of a gene encoding for a single biological function plus other genetic elements necessary for the expression of that gene when introduced into the plant. Other elements in the gene cassette include a **promoter**, which can be thought of as the "on switch" for the gene encoding for the desired trait; and a targeting sequence, which makes sure the gene product, typically a protein, ends up in the right location within the cell (such as the chloroplast).

Unintended effects from breeding

Most crops naturally produce allergens, toxins or other antinutritional substances; these often serve the plant as natural defense compounds against pests or pathogens (FDA, 1992). Plant breeders may monitor the levels of antinutritional substances relevant to their crop. For

example, lignin is an indigestible cell wall component that limits forage digestibility. Alfalfa breeders typically monitor lignin content of plants in their breeding programs.

Scientists from the Institute of Medicine (IM) and the National Research Council (NRC) ranked breeding methods according to their relative likelihood of producing unintended effects, which they hypothesized would correspond to the degree of genetic disruption associated with the method. Selection from a homogeneous population was ranked at one end of the spectrum (less likely to produce unintended effects) and induced mutagenesis (from chemicals or radiation) was ranked at the other end (more likely). *Agrobacterium* transfer of rDNA was among the methods ranked in between (IM/NRC, 2004, Figure ES-1). Recent studies in Europe comparing transgenic and conventional barley suggest that conventional breeding may cause more unintended effects than rDNA methods, likely because of the very large number of genes that are affected in conventional breeding techniques (Sonnewald, 2010).

Glyphosate tolerance

As discussed in Section 2, glyphosate acts by inhibiting the action of the enzyme EPSPS, in plants. EPSPS is a catalyst for a reaction necessary for the production of certain amino acids essential for plant growth. When plants are treated with glyphosate the EPSPS enzyme is inhibited, they cannot produce the amino acids needed for continued growth and eventually die. The EPSPS protein and the reaction it catalyzes are present in all plants and microbes. There are variations in the amino acid sequence of EPSPS among different plants and bacteria. GT is achieved by introducing an EPSPS enzyme, termed CP4 EPSPS, that is not inhibited in the presence of glyphosate. An *Agrobacterium* strain (designated CP4) was the source of the CPR EPSPS gene that encodes for the CP4 EPSPS enzyme (Rogan and Fitzgerald, 2004). The CP4 EPSPS enzyme carries out the same enzymatic reaction in the plant as the native EPSPS; however, when plants that contain the CP4 EPSPS are sprayed with glyphosate, they are able to continue to produce the essential amino acids needed for plant growth. The objective of the genetic modification in RRA was to simplify and improve weed management practices in alfalfa by the addition of the CP4 EPSPS enzyme to confer tolerance to glyphosate (USDA APHIS, 2005).

Transformation system

RRA was developed using a disarmed Agrobacterium-mediated transformation system of sterile alfalfa leaflets. Post-transformation, the Agrobacterium were eliminated from tissues by a 7-week culture on antibiotic-containing medium. Glyphosate was used to select for transformed

tissues containing the EPSPS gene construct. This technique of using a disarmed Agrobacterium strains followed by selection has a 20-year history of safe use and has been used for transformation of a variety of plant species and tissues. The plant material used for development of RRA was FGI proprietary alfalfa clone R2336 from a high yielding, fall dormant breeding population. The initial plants, selected for tolerance to glyphosate, were designated J101/J163, and various populations were developed from these events to provide the data presented in the petition (USDA APHIS, 2005).

DNA sequences inserted into RRA

Data supplied in the petition and reviewed by APHIS indicate that the CP4 EPSPS expression cassette inserted into alfalfa events RRA contains the CP4 EPSPS coding sequence under the regulation of the 35S promoter, a heat shock protein intron (HSP70), a chloroplast transit peptide (CTP2) sequence and a E9 3' polyadenylation sequence. The CTP2 CP4 EPSPS coding region used to produce events J101/J163 is the same as that employed in several other RR crops such as soybean, which have been previously reviewed and granted non-regulated status by the USDA. The CP4 EPSPS gene does not cause disease and has a history of safe use in a number of GE plants (e.g., corn, cotton, and soybean varieties).

3.1.2 Evaluation of intended effects

Analysis of inheritance

Data were provided by Monsanto/FGI and reviewed by APHIS that demonstrate stable integration and inheritance of the EPSPS gene cassette over several breeding generations. Statistical analyses show that GT is inherited as a dominant trait in a typical Mendelian manner (M).

Analysis of gene expression

Monsanto/FGI collected data on EPSPS protein concentrations from field trials conducted at several locations. The companies determined EPSPS protein concentrations using standard laboratory techniques. EPSPS concentrations on a fresh weight basis averaged 257 micrograms (µg)/gram in plants with event J101, 270 µg/gram in plants with event J163, and 252 µg/gram in plants from the population containing both events J101/J163. EPSPS is ubiquitous in plants and microorganisms and has not been associated with hazards from consumption or to the environment. Crops that contain this protein and have been granted non-regulated status have included corn, soybean, cotton, rapeseed, and sugar beet (USDA APHIS, 2010a). In 2009, significant acreages of corn (59 million acres or 68 percent of the total), upland

cotton (6.3 million acres or 71 percent of the total) and soybean (70.5 million acres or 91 percent of the total) grown in the U.S. were planted with herbicide tolerant varieties (USDA NASS, 2010c). Although these acreages include all herbicide tolerant varieties, GT ones (containing CP4 EPSPS) predominate. All have also undergone FDA review (FDA, 2010).

Analysis of the intended trait

Monsanto/FGI conducted numerous field trials to evaluate RRA in different environments. Standard field trials evaluated (1) agronomic performance, (2) disease and pest resistance performance, and (3) seed multiplication. Agronomic practices used to prepare and maintain each field trial were characteristic of each representative region. Where the glyphosate herbicide Roundup® was used in trials, no negative impacts from application were noted (Rogan and Fitzpatrick, 2004).

3.1.3 Evaluation of possible unintended effects

Disease and pest susceptibility

On the basis of pest and disease susceptibility data reviewed by APHIS, RRA populations were no different from control or conventional alfalfa populations in the prevalence of or response to diseases or pests. Since the deregulation of RRA in 2005, there have been no reports of any change in disease or pest interactions in RRA compared to conventional alfalfa (USDA APHIS 2009).

During field trials from 1999 to 2003 and after deregulation of RRA in 2005, RRA has been grown over a broad geographic distribution of sites in the U.S. This has exposed RRA to a wide range of naturally occurring diseases. The principal alfalfa diseases in the U.S. affect the foliar, crown, root, vascular, and seedling health of alfalfa plants. Fungi are the primary pathogen type involved in most alfalfa diseases. Nematodes, bacteria, viruses, and other microbes can also reduce alfalfa production. The major economic diseases that occurred during field trials included: seedling damping-off (fungal genera such as *Pythium*, *Phytophthora*, *Aphanomyces*); foliar diseases (fungal genera such as *Leptosphaerulina*, *Colletotrichum*, *Peronospora*, *Phoma*, *Stemphylium*, *Cercospora*, and stem nematodes like *Ditylenchus*); and root rots, vascular wilts and crown diseases (fungal genera such as *Phytophthora*, *Aphanomyces*, *Verticillium*, *Fusarium*, *Phoma*, and bacterial wilt caused by *Clavibacter*) (USDA APHIS, 2009).

The major insect pest species affecting alfalfa vary between regions in the U.S. During field trials and after deregulation of RRA in 2005, RRA has been exposed to a wide range of naturally occurring insect pests. The principal economic insects included: potato leafhoppers

(*Empoasca fabae*), aphids [pea (*Acyrthosiphon pisum*), blue (A. kondoi) and spotted alfalfa aphids (*Therioaphis maculata*)], alfalfa weevil (*Hypera postica*), lygus bugs (*Lygus* species), other plant bug species (family *Miridae*) and alfalfa caterpillars (various Lepidopteran species). The disease and pest susceptibility observations for the field trials were provided to APHIS. These observations consistently showed no significant differences in the disease and insect susceptibility between events J101/J163 (or synthetic populations developed using both events) and the conventional control lines or commercial reference varieties. Although occasional differences were noted at some field sites, there were no concurrent trends of differences across field sites or years. This suggests that these differences were likely due to random variation. Additional disease ratings taken as part of the phenotypic comparative studies also indicate that diseases and pest incidence are unchanged in RRA compared to the control and that RRA is not more or less susceptible to pests or diseases than conventional alfalfa. Commercial experience and additional research conducted since the 2005 deregulation decision are consistent with the findings from field trials during the regulated period (USDA APHIS, 2009).

Gene silencing

In evolutionary biology, a homologous trait is one derived from a common ancestor that appears in multiple species. Homology may be manifested on a macro scale, for example, in the similarity in mammal forelimbs, and on a genetic scale, in DNA sequences. Al-Kaff et al. (1998) have noted gene silencing effects when transgenic plants have been infected by a virus with DNA sequence homology to a portion of the introduced genes. The only virus-derived DNA in the introduced gene cassette is the promoter, which is from the figwort mosaic virus. None of the viral diseases of alfalfa is related to figwort mosaic virus (Whitney and Duffus, 1986), so silencing of the EPSPS gene would not be expected and has not been observed.

Compositional changes

The composition of forage produced by RRA plants containing either event J101, J163, or the paired events J101 X J163 was measured and compared to the composition of control and conventional alfalfa forage (Rogan and Fitzpatrick, 2004). Monsanto/FGI analyzed alfalfa for compositional changes as part of their submission to FDA in the consultation process. While FDA uses these data as indicators of possible nutritional changes, APHIS views them as general indicators of possible unintended changes.

Compositional analyses evaluating carbohydrates, protein, ash, minerals, fiber, lignin, fat, and 18 amino acids (a total of 35 different components) identified three statistically different values compared with the control population for J101, seven statistically different values for J163, and 11 statistically different values for the paired J101 X J163 population. However, all analyses fell within the 99 percent tolerance interval developed from the conventional varieties grown in the same locations, providing additional evidence that J101, J163 and the paired J101 X J163 populations do not exhibit unexpected or unintended effects (USDA APHIS, 2005).

3.2 WEEDINESS PROPERTIES AND FERAL CROPS

This section addresses two questions:

1. What are the weediness properties of alfalfa?
2. Is RRA any more likely to become a weed than conventional alfalfa?

For information on feral alfalfa or volunteer alfalfa, refer to Section 2.6.2.

3.2.1 Weediness properties of alfalfa

Alfalfa (*Medicago sativa* L.) is not listed as a serious weed in *A Geographical Atlas of World Weeds* (Holms et al., 1991) or as a weed in *World Weeds: Natural Histories and Distribution* (Holms et al., 1997), *Weeds of the North Central States* (http://www.aces.uiuc.edu/vista/html_pubs/WEEDS/list.html), *Weeds of the Northeast* (Uva et al.,1997), or *Weeds of the West* (Whitson et al., 1992). Alfalfa is not listed as a noxious weed species by the U.S. Federal Government (7 C.F.R. Part 360) and is not listed as a weed in the major weed references (Crockett, 1977; Holm, Pancho et al., 1979; Muenscher, 1980) (USDA APHIS, 2009).

Although feral (free-living) populations of alfalfa are fairly common and volunteers may occur among succeeding crops, alfalfa is not considered a serious weed, a noxious weed, or an invasive species[41] in the U.S. The Interactive Encyclopedia of North American Weeds, Version 3.0, includes alfalfa (NCWSS, 2005). But this reference does not indicate why alfalfa is considered a weed. It may be included based on its potential occurrence as an unwanted volunteer in agricultural settings (USDA APHIS, 2009 p. H-13).

[41] A species that is not native to a particular ecosystem and whose introduction does or is likely to cause economic damage or environmental harm or harm to human health. Executive Order 13112 – Invasive Species (1999); USDA National Agricultural Library, 2010.

3.2.2 RRA and weediness

Some scientists, for example, Ellstrand (2006), have raised the question of "unintended crop descendents from transgenic [GE] crops." Ellstrand states (p. 116): "The possibility of unintended reproduction by transgenic crops has raised questions about whether their descendents might cause problems. These problems have fallen into two broad categories: first, the direct feral descendents of the crops may prove to be new weeds or invasives, and second, that unintended hybrids between transgenic crops and other plants could lead to certain problems." This section discusses the weediness properties of RRA, and addresses the concern of direct descendents of the crop that "may prove to be new weeds or invasives." Hybridization is addressed in several later sections.

Alfalfa does not naturally hybridize with any wild relatives in North America. Having established that there are no related, sexually compatible wild relatives in the U.S., movement of the CP4 EPSPS gene can only occur to cultivated or feral alfalfa populations through pollination by bees, dropped seeds or seed admixtures.

RRA events J101/J163 were field tested in North America from 1999 to 2003 and planted commercially after deregulation in 2005. APHIS reviewed data on characteristics that might relate to or have an effect on increased weediness. These included seed dormancy, seed germination, seedling emergence, seedling vigor, spring stand, spring vigor, seed yield, vegetative growth or plant vigor, plant dormancy, growth habit, flowering properties, and effect on symbiotic organisms (USDA APHIS, 2009). No unusual characteristics were noted that would suggest increased weediness of J101/J163 plants relative to the control populations.

In a separate evaluation, the Canadian Food Inspection Agency (CFIA), whose responsibilities include regulation of the introduction of animal food and plants (including crops) to Canada, reached the same conclusion about the weediness potential of events J101/J163 compared with non-transgenic alfalfa. In 2005, the CFIA authorized the "unconfined release into the environment and livestock feed use of alfalfa events J101/J163" (CFIA, 2005). In its evaluation of events J101/J163, CFIA "determined that stand establishment, enhanced growth, vigour or stand longevity; changes in susceptibility to plant pests and diseases common to alfalfa; increases in forage and seed yield and increases in seed dormancy were within the normal range of expression of these traits currently displayed by commercial alfalfa varieties" (CFIA, 2005). The CFIA reached the following conclusions (CFIA, 2005):

> No competitive advantage was conferred to these plants, other than that conferred by tolerance to glyphosate herbicide. Tolerance to Roundup®

agricultural herbicides will not, in itself, render alfalfa weedy or invasive of natural habitats since none of the reproductive or growth characteristics were modified.

The above considerations, together with the fact that the novel traits have no intended effects on alfalfa weediness or invasiveness, led the CFIA to conclude that alfalfa events J101/J163 have no altered weed or invasiveness potential compared to currently commercialized alfalfa.

3.2.3 Impacts

Alternative 1: No Action

Under Alternative 1, there would be no impacts from RRA on weediness properties of alfalfa or feral alfalfa because new RRA would not be grown commercially.

Alternative 2: Partial Deregulation of RRA

APHIS has concluded that alfalfa does not exhibit weediness properties, and that RRA does not exhibit any altered weediness properties when compared with conventional alfalfa. Therefore, Alternative 2 would not impact the weediness characteristics of alfalfa.

Feral, non-RRA exists throughout the U.S. RRA does not exhibit any increased feral growth potential when compared to conventional alfalfa. Therefore, Alternative 2 would not affect the feral growth potential of alfalfa.

Under Alternative 2, RRA volunteers in crop production would be controlled by mechanical means (e.g., tillage) or by application of one of several registered non-glyphosate herbicides.

3.3 IMPACTS OF RRA FORAGE CROPS ON CONVENTIONAL AND ORGANIC FORAGE CROPS

This section considers the possibility of impacts from RRA forage crops on conventional and organic forage crops through gene flow (refer to Section 2.3 for a general discussion of gene flow), or by mixing in harvesting or transportation.

3.3.1 Pollen sources in forage production fields

As discussed in Section 2.3, alfalfa is a short-lived perennial crop plant that peaks in forage yield during the second and third year. In the hay production fields, alfalfa is grown for its high nutritional value for cattle and horses. The nutritional value is at its highest during the plant's young vegetative state. As the plant approaches full flower, its nutritional value decreases. Therefore, alfalfa grown for hay is managed to limit growth to the juvenile state. Most alfalfa hay in the U.S. is harvested before 10 percent of the stems have one or more open flowers. Thus, most forage fields are cut before most plants have produced any pollen and prior to when they

could be pollinated. This practice is widely recommended so that hay production and nutritional quality of the hay are optimized to maximize the farmer's economic productivity (USDA APHIS, 2009, p. 18-19, 100).

3.3.2 Potential for gene flow in forage production fields

Cross-pollination, if it occurred could potentially result in adventitious (inadvertent) production of embryos with the GT gene in a conventional or organic hay production field. Because alfalfa forage is typically managed for high quality and harvested before 10 percent bloom, and RRA forage producers are concerned with high quality, there is little potential for cross-pollination because the availability of pollen is minimized as a consequence of normal harvest activities. Furthermore, as mentioned in Section 3.3, in all but exceptional cases, native populations of bees are insufficient to effect economic levels of alfalfa seed pollination so they are augmented using cultured bee colonies. Unlike seed farmers, forage producers do not stock bees to produce the forage crop because they do not want or need pollination of their fields (USDA APHIS, 2009, p. 94; Rogan and Fitzpatrick, 2004).[42]

Nonetheless, if cross-pollination occurs in forage fields, the inadvertently pollinated plants are without gene flow consequence because they are almost always harvested before developing embryos mature to become viable seed. For effective gene flow from a RRA hay field to a conventional/organic hay field, each of the following must occur: (1) cross pollination between RRA and conventional plants; (2) delayed harvest allowing mature seed to form in the conventional/organic field; (3) mature RRA seed shattering and falling to the ground rather than being removed in forage harvest; (4) successful establishment of the new RRA seedling in the established conventional/organic alfalfa stand. Each of these requirements are unlikely and the combination of all of them happening is remote (Putnam, 2006; Van Deynze et al., 2008). Even in instances where weather or equipment failures delay harvesting of GT or non-RRA hay fields, there is little risk of unwanted GT gene flow into alfalfa production (Van Deynze et al., 2008). Alfalfa hay normally is harvested at or before first flower, 6 to 9 weeks before the ripe seed stage (Putnam, 2006; USDA APHIS, 2009 p.100). Regardless of proximity and management of a potential neighboring RRA hay field, a conventional/organic hay producer can eliminate any risk of potential pollen-mitigated RRA gene flow by simply harvesting prior to ripe seed stage.

[42] An exception to the foregoing are an unknown number of conventional alfalfa forage producers who inadvertently or by agreement allow a honeybee keeper to forage bees on the alfalfa field to produce a honey crop or brood. (See USDA, 2009 at Appendix O.) This would be unlikely for RRA forage producers because producers generally cut before blooms are useful for honey production. Honeybees would be unlikely to forage on RRA forage fields because bloom would be managed to maintain high quality forage.

3.3.3 Potential consequences of gene flow in forage production fields

As discussed above, because alfalfa hay is harvested well before ripe seed is produced, gene flow into or between RRA and conventional forage crops is expected to be de minimis.

3.3.4 Growing and marketing alfalfa

Dairy farmers would be the most likely users of RRA hay because they often depend on pure alfalfa stands that are free of weeds and grasses, whereas, beef cattle producers and horse owners typically feed their animals a mix of alfalfa-grass hay (Putnam, 2005; USDA APHIS, 2009, p. 17).

The dairy industry has widely accepted biotechnology-derived products, including recombinant bovine somatotropin (rBST) used to increase a cow's milk production, and GT crops such as corn, soybean, canola, and cottonseed meal used in feed. However, organic dairy producers have rejected GT crops and require hay from organically grown (non-RRA) crops. Although organic milk production has grown considerably, it is still less than one percent of the total U.S. production (Miller, 2005; Putnam, 2006). Additionally, some horse owners may prefer using non-RRA feed. However, because many horses are sickened or die from poisonous weeds in hay, many horse owners may choose RRA. Like organic milk production, organic beef production will require non-RRA alfalfa. However, organic beef production is less than one percent of the total beef production industry, and the non-organic beef industry is not expected to be sensitive to RRA (NCBA, 2005; Putnam, 2006).

Less than two percent of U.S. alfalfa hay production is exported (NAFA, 2008b). The export of alfalfa hay is of particular economic interest in the Columbia Basin of Washington and the Imperial Valley of California, where local exporters, supported by local hay producers, have developed this market. Seven states in the western U.S. export approximately 4-5 percent of their production (NAFA, 2008b). The largest importers of U.S. produced alfalfa hay are Japan, South Korea, and Taiwan. RRA has been approved for import into these three countries, and to Canada and Mexico. These five countries together represent over 90 percent of total U.S. hay exports (USDA APHIS, 2009, Table 3-15, p. 55). Although there are no regulatory barriers for the vast majority of this market, customer preference may demand testing for adventitious presence (AP) of the RRA trait in conventional hay sold for export. Protein-based test strips and testing protocol have been developed to test hay destined for AP sensitive markets (Woodward et al., 2006). These low-cost testing methods have been widely adopted by the export industry

to service the market segment requiring such tests, successfully avoiding any disruption of this important hay industry segment. (See USDA APHIS, 2009, p. Q-19).

3.3.5 Potential for and consequences of mechanical mixing

Alfalfa has small seeds that are planted, harvested, transported and processed for sale using large equipment designed especially for alfalfa seed crop handling. Seed growers and seed processing companies utilize lot segregation and equipment cleaning routines to remove seeds from equipment. Effective lot identification, segregation and equipment cleaning are practices required for the production of certified quality seeds. Vacuums, compressed air, sweeping, partial or complete disassembly, washing with water, etc. are effective means used to clean planting, harvesting, transportation, seed conditioning and seed treatment/coating equipment before or after use. These widely-adopted sanitation routines have been successful helping to assure negligible content of off-types, weed seeds, inert and non-crop mixtures (AOSCA, 2009).

As in all other agricultural production practices, there is possibility for mixtures between seed crops due to residual seeds in equipment, seed spillage, planting or lot blending mistakes or other human errors, however, the potential for impact is highly managed and therefore limited. Conventional seed crop handling practices vary widely and depend on the producer's end product quality targets (e.g., common seed to certified seed markets). Historically (i.e., 20-50 years ago), conventional alfalfa seed has sometimes been transported in trucks or trailers and seed escapes along transportation routes were commonplace. In contrast, first, all RRA seed growers are uniformly obligated under their FGI seed grower contracts to observe certified seed standards for seed identification, segregation and handling (AOSCA, 2009). Second, RRA seed producers are obligated to following the NAFA BMP requirements for contained transportation of seeds, equipment sanitation, and obvious seed lot labeling, etc. (see below). FGI provides training and the secure, labeled seed bins to each RRA grower and monitors compliance to the contract requirements. The NAFA BMP stipulates the following sanitation, identification and segregation requirements that must be followed for all RRA seed production:

> Sanitation requirements. Manage equipment to minimize seed mixture potential between different varieties and or variety types. Growers shall use dedicated equipment for planting and harvesting RRA seed production, when possible. Zero tolerance for seed admixture is not feasible under commercial production conditions; however, grower must take reasonable steps to assure that equipment is clean prior to and after use in the Roundup Ready seed field. *Examples*: Planter inspection, clean-down before and after use; Combine inspection, clean-down thoroughly before and after use; RRA seed bins may only be used for RRA seed; maintain physical separation of varieties in storage; inspect bins before use; Handle all like-trait varieties together; plan for harvest

> sequence of fields to maintain best separation of varieties by trait type; Clean all seed handling equipment to avoid mixing RRA and conventional seed; Return unused, unopened stock seed to the contracting seed company for credit; maintain in clean storage areas; When a contract harvester is used for RRA seed harvest, Growers must notify the contract harvester, in advance, that the field to be harvested is RRA (NAFA, 2008a).

Mechanical mixtures between lots in forage harvesting are possible, but mixing is limited in extent by the following common alfalfa forage practices (NAFA, 2008b): (1) Most hay (>75 percent) is harvested and fed on the same farm of production, therefore, growers know the type of variety planted in each field and fields are harvested separately. Fields lots are typically harvested separately and because each field may have a different feed quality level, the harvests are typically placed into separate storage areas for feeding. (2) Hay is not fungible during marketing, that is typically, each hay lot is identified, segregated and traceable to the field of origin during transportation, brokerage and sale. This is especially the case for organically certified crop products which must remain segregated from non-organically produced crops throughout all handling steps. (3) Some GE-sensitive hay marketers or feed processing facilities (meal, cubes, pellets) use commercial testing kits to test for the presence of the RRA trait in hay, thereby, offering a post harvest means to assure RRA hay segregation from non-RRA hay.

3.3.6 Impacts

Alternative 1: No Action

Under Alternative 1, there would be no impacts to growers of organic or conventional hay because RRA hay would not be grown commercially.

Alternative 2: Partial Deregulation of RRA

Based on the above discussions, RRA hay production under Alternative 2 would be expected to result in minimal impact for the following reasons:

- The reproductive biology of the alfalfa plant combined with normal harvest management for alfalfa forage provide for a de minimis likelihood of gene flow from one forage production field to another.
- Hay fields would be cut before seed is produced.
- A combination of geographic restrictions and gene flow mitigation measures (e.g harvest management requirements) significantly reduce the forage-to–seed gene flow interface. Gene flow mitigation measures (MT/SA and Technology Use Guide) are contractually

required for all RRA hay producers. These mitigation measures are practicable, contract-enforced, science-based, and market-driven. They have been designed to enable coexistence by mitigating all or nearly all unwanted gene flow between dissimilar crops and to aid in protecting non-GT, export, and organic hay and seed alfalfa crops. There have been negligible impacts since commercial seed production began in 2005 due to the efficacy of these BMP.

- Low-cost testing procedures are readily available to meet the needs of market requiring such tests.
- The conservative measures associated with this alternative include additional conservative forage/hay production restrictions that will ensure an extremely low likelihood and extent of gene flow from one production field to another.
- The biology, cultivation and marketing practices typically used in conventional alfalfa hay production limit the potential for physical and handling mixture to very low levels. The likelihood and extent of RRA and non-RRA mixtures are highly constrained by RRA seed grower practices stipulated and enforced under RRA seed grower contracts.
- RRA seed bag labeling and a unique purple seed colorant will be required for all RRA seed, which will notify RRA forage growers of the presence of the RRA trait and the limitations for product use. The colorant and bag labeling will reduce the likelihood of inadvertent planting by any organic or non-GE producer.
- As discussed in Section 3.8.1, conventional and organic alfalfa seed will continue to be available.

3.4 IMPACTS FROM RRA FORAGE CROPS ON NATIVE ALFALFA

As discussed in Section 2.6.1, no native members of the genus *Medicago* are found in North America. Therefore, there would be no impacts to native alfalfa under either alternative, because none exists.

3.4.1 Impacts

Because there are no native alfalfa populations in the U.S., there would be no impact with either alternative.

3.5 IMPACTS FROM RRA FORAGE CROPS ON FERAL ALFALFA POPULATIONS

The *M. sativa* species has naturalized populations in all 50 States (USDA APHIS, 2009, p. 23). Synchronous flowering of hay or seed production fields neighboring feral alfalfa will likely lead to cross-pollination. Feral alfalfa has the potential to act as a bridge for gene flow from GT alfalfa crops to non-GT alfalfa crops. First, the RRA hay or seed production field could serve as a pollen donor to the feral non-RRA. The subsequent feral GT offspring could then serve as the pollen donor to the non-GT hay or seed production field. Feral alfalfa near hay and seed fields should be controlled to avoid gene flow to the feral population (USDA APHIS, 2009, p. 101). Feral alfalfa in roadsides, ditchbanks and pastures is commonly controlled by mowing, disking, cultivation or the use of herbicides. Biogeographic survey data documents that, although climate and cropping practices are favorable for seed propagation, feral alfalfa is actually less abundant in seed producing geographies than other regions (Rogan and Fitzpatrick, 2004; Kendrick et al., 2005). Possible explanations for this observation are that, as seed producers follow seed certification standards requiring isolation, they routinely practice effective mitigations to control or prevent feral alfalfa populations (mowing, herbicides, cultivation). Also, alfalfa would not be intentionally planted in species mixtures in roadsides, pastures or rangelands where professional seed production occurs.

The barriers to gene flow into conventional/organic hay fields described in Section 3.3 also apply to pollen-mediated gene flow from RRA forage to feral alfalfa plants. These barriers also apply to pollen-mediated gene flow from feral alfalfa plants to conventional or organic alfalfa forage and will limit potential feral-to-hay gene flow to extremely low levels. Additionally, feral alfalfa will have low seed production plus damage from lygus bug and infection from seed-borne fungi when seed develops under damp conditions. (Putnam and Undersander, 2009 attached as Appendix I). The primary limitations to feral-to-seed gene flow is the relative paucity/abundance of pollen and proximity of pollinators in the field optimally managed for seed production, compared with a low density of feral plants growing some distance away and without the benefit of water, nutrient or pest control inputs (Van Deynze et al., 2008). A further mitigating factor is that Certified seed production requires a minimum 165 ft isolation between the seed production field and any feral alfalfa allowed to flower. Many seed growers have historically produced Certified seed.

3.5.1 Impacts

Alternative 1: No Action

Under Alternative 1, there would be no impacts regarding feral alfalfa because no RRA hay or seed would be produced commercially.

Alternative 2: Partial Deregulation of RRA

Based on the above discussions, Alternative 2 would be expected to result in minimal impact to feral alfalfa for the following reasons:

- The reproductive biology of the alfalfa plant combined with normal harvest management for alfalfa forage provide for a de minimis likelihood of gene flow from an RRA forage production fields to feral alfalfa and from feral alfalfa to conventional or organic forage production fields.
- The proposed limitations on the scope of allowed RRA seed production will be defined and stringently controlled as a means to mitigate the likelihood and possible extent of gene flow to non-RRA crops. The proposed restrictions have been designed to enable coexistence by mitigating all or nearly all unwanted gene flow between dissimilar crops and to aid in protecting non-GT, export, and organic hay and seed alfalfa crops. The restrictions include but are not limited to the following: isolation distance, seed field reporting, labeling, segregation and all other contractually required components of the NAFA BMP. All RRA seed acres will be grown under FGI contracts that require each field to be grown and inspected to meet State Seed Certification requirements including the requirement to isolate the field from other alfalfa within 165 ft.; this, therefore, includes control of feral alfalfa. These mitigation measures are practicable, contract-enforced, science-based, and market-driven. There have been negligible impacts since commercial seed production of RRA began in 2005 in large part due to the demonstrated efficacy of these BMP (NAFA, 2009; Fitzpatrick and Lowry, 2010 attached as Appendix K).
- The conservative measures associated with this alternative include additional conservative seed production and forage/hay production restrictions that will ensure an extremely low likelihood and extent of gene flow from one production field to feral alfalfa from feral alfalfa to conventional or organic forage production fields.

3.6 IMPACTS FROM RRA FORAGE CROPS TO RANGELAND ALFALFA CROPS

Commercially cultivated alfalfa and feral alfalfa populations properly belong to the *M. sativa* complex, a group of closely related subspecies that are reproductively compatible. The most commonly cultivated alfalfa in the world is *M. sativa* subsp. *sativa*, but subspecies *falcata* is also cultivated on a limited basis, primarily under rangeland conditions and in colder regions (USDA APHIS, 2009, p. 30).

Rangeland alfalfa populations might increase if certain ranchers intentionally seed alfalfa to increase hay quality and soil nitrogen (Waggener, 2007; High Plains Midwest Ag Journal, 2008). As has historically been the case, seed producers will remain aware of seeding practices in neighboring rangelands, ditchbanks, pastures, roadsides, or other minimally-managed areas.

Both subspecies *M. sativa* subsp. *sativa* and M. s. subsp. *falcata*, have been historically used to derive alfalfa cultivars in North America. In addition to *M. s.* subsp. *sativa* (purple flowered alfalfa), *M. s.* subsp. *falcata* has been used as a winterhardy germplasm source by alfalfa breeders since at least the early 1950s. Therefore, the potential for natural gene flow between subspecies *sativa* and *falcata* is well documented and well understood (Monsanto-FGI comment to the DEIS Appendix 1 p. 14). It is reasonable to predict that hybridization between rangeland *falcata* subspecies and RRA varieties with mostly *sativa* parentage would occur, but they would present no novel or unstudied risk. The limited number of acres of falcata and the barriers for gene outflow from cultivated hay field sources (Putnam, 2006; Van Deynze et al., 2008) will limit the likelihood and extent of effective gene flow from RRA forage production to any synchronous alfalfa plants naturalized in the rangeland. Additionally, gene flow from a naturalized *falcata x sativa* plant to neighboring conventional or organic forage or production fields would be limited by the expected very low frequency of RRA varieties in rangeland usage and the array of gene flow barriers described in Van Deynze et al. (2008).

3.6.1 Impacts

Alternative 1: No Action

Under Alternative 1, there would be no impacts to rangeland alfalfa because no RRA hay or seed would be produced commercially.

Alternative 2: Partial Deregulation of RRA

Based on the above discussions, Alternative 2 would be expected to result in minimal impact to rangeland alfalfa for the following reasons:

- The reproductive biology of the alfalfa plant combined with normal harvest management for alfalfa forage provide for a de minimis likelihood of gene flow from one forage production field to another.
- Gene flow mitigation measures (MT/SA, FGI Stewardship Program, and NAFA BMP for RRA Seed Production) are contractually required for all RRA seed producers. These mitigation measures are practicable, contract-enforced, science-based, and market-driven. They have been designed to enable coexistence by mitigating all or nearly all unwanted gene flow between dissimilar crops and to aid in protecting non-GT, export, and organic hay and seed alfalfa crops. There have been negligible impacts since commercial seed production began in 2005 due to the efficacy of these BMP (NAFA, 2009; Fitzpatrick and Lowry, 2010).
- Glyphosate is minimally used in rangeland situations, and therefore there would be no selective advantage for RRA plants in the rangeland. (USDA APHIS, 2009, p. 98-99).
- The conservative measures associated with this alternative include additional conservative seed production and forage/hay production restrictions that will ensure an extremely low likelihood and extent of gene flow from one production field to another.
- As discussed in Section 3.8.1, conventional and organic alfalfa seed will continue to be available.

3.7 IMPACTS FROM RRA FORAGE CROPS TO CONVENTIONAL OR ORGANIC ALFALFA SEED PRODUCTION AREAS

There is potential for cross-pollination due to synchronous flowering in a RRA forage crops and adjacent non-RRA seed crops. As seed producers follow AOSCA isolation distances for seed certification, gene flow will be minimized because gene flow decreases exponentially with distance from crop (Van Deynze et al., 2008) (see also discussion in Section 2.3). Research from Teuber et al. (2007) showed that hay-to-seed gene flow is low if the AOSCA certified seed isolation distance of 165 ft from sexually compatible crops is observed. In that study, at a distance of 165 ft, the extent of gene flow to nearby seed fields was less than 0.5 percent even when neighboring alfalfa hay fields were harvested at 20 or 50 percent bloom. (Hay fields are typically harvested before 10 percent bloom.) When the isolation distance from the edge of the seed crop to neighboring alfalfa forage fields was increased to 350-600 ft, the gene flow decreased to a mean of 0.01 percent (Van Deynze et al., 2008).

3.7.1 Impacts

Alternative 1: No Action

Under Alternative 1, there would be no impacts from RRA forage crops to conventional or organic seed production crops because no RRA hay or seed would be produced commercially.

Alternative 2: Partial Deregulation of RRA

Based on the above discussions, Alternative 2 would be expected to result in minimal impact from RRA forage crops to conventional and organic seed production areas the following reasons:

- Alfalfa forage production fields are generally cut prior to 10 percent bloom and before seed is allowed to set.
- Gene flow mitigation measures (MT/SA and Technology Use Guide) are contractually required for all RRA hay producers. These mitigation measures are practicable, contract-enforced, science-based and market-driven. They have been designed to enable coexistence by mitigating all or nearly all unwanted gene flow between dissimilar crops and to aid in protecting non-GT, export, and organic hay and seed alfalfa crops. There have been negligible impacts since commercial seed production began in 2005 due to the efficacy of these BMP.
- Under Restriction Enhancement A of the proposed measures, in states where alfalfa seed production fields were historically (2007) or are currently present, if the RRA forage field is located within 165 ft of a commercial, conventional, seed production field, the RRA grower must harvest forage before 10 percent bloom. This restriction is the science- and market-based, industry recognized isolation distance for certified alfalfa seed crops, and the potential and extent of gene flow of 10 percent bloom hay to nearby seed crops is de minimis at a distance of 165 ft (Teuber and Fitzpatrick, 2007; Van Deynze et al., 2008).
- Additionally, in states where there is more than 100,000 lbs. of annual alfalfa seed production, additional restrictions apply by county to further reduce the potential for gene flow. In counties without seed production, RRA forage growers must report the GPS location of all RRA fields. Under Restriction Enhancement C, in counties with seed production, no new RRA forage plantings are allowed.

- As discussed in Section 3.8.1, conventional and organic alfalfa seed will continue to be available.

3.8 IMPACTS FROM RRA SEED PRODUCTION

3.8.1 Cross-pollination

The greatest potential for cross-pollination and mixing among crop species occurs in seed production because that is where pollination is intended to, and does, occur (see description in Section 2.1.2). The relationships between isolation distance, pollinator species and pollen-mediated gene flow in alfalfa seed production has been studied extensively (Van Deynze et al, 2008). This science informed the current industry standards for isolation in NAFA Best Practices for RRA Seed Production (www.alfalfa.org) and was validated in 2008 and 2009 in large scale surveys of adventitious presence of the RRA trait in conventional seed (Fitzpatrick and Lowry, 2010). Physical mixing of seeds can occur during harvesting, seed cleaning, packaging, and transport. These activities are also governed by NAFA Best Practices for RRA Seed Production, and are components of adventitious presence evaluated in the annual third party audit/validation conducted on commercial seed lots.

The production of non-RRA alfalfa seed and forage both rely on continued availability of non-RRA parent seed, with non-detectable levels of the RRA trait. There is a clear consensus in the industry that there will always be a market (domestic and international) for non-RRA varieties developed and produced in the U.S. There is no reason to believe that industry and/or university alfalfa breeders will not continue to develop varieties for these markets. The production of Breeder seed generation (Syn1) alfalfa seedstock is often done in a screen cage to exclude incoming pollinators, so there should be no new incremental effort required to avoid low level gene flow from neighboring RRA seed or hay production. The production of Foundation (Syn2) alfalfa seedstock requires adherence to AOSCA standards, which include extraordinary isolation from all neighboring alfalfa (seed, hay or uncultivated sources). The standard Foundation seed required isolation of 900 ft is often sufficient to eliminate gene flow from neighboring RRA alfalfa seed or hay production, but occasionally very low levels of adventitious presence are found. When a non-detect standard for Foundation seed is adopted by the breeder, use of an additional isolation distance would decrease the risk of low level gene flow. As a general practice of stringent quality control, Breeder and Foundation seed is routinely evaluated for trueness-to-type, including a lack of off-types. In the event of a low incidence of an off-type, such as presence of the RRA trait in conventional alfalfa, breeders routinely cull the off-type plants and repeat the variety seed increase (APHIS, 2009, Appendix V). Adherence to

AOSCA standards for certified seed production and attention to detail in quality control of seedstocks has been a successful strategy for high quality U.S. seed production by American seed companies (Monsanto/FGI Comments to draft EIS at p. 6-7). Additionally, in cooperation with several U.S. alfalfa seed companies, AOSCA (2010) has developed a new seed production protocol for the production of alfalfa seed. The new protocol is tailored to meet the needs of seeds destined for export, organic and other sensitive market channels where biotechnology traits are expressly excluded. Meeting the specific and incremental requirements of this "special" AOSCA certification program allows the seed producer to label the seed with a statement certifying adherence to the AOSCA program (Monsanto/FGI Comments to draft EIS at p. 5; NAFA, 2008b; NAFA, 2008c; NAFA, 2008d).

3.8.2 Seed Mixing

The biology, cultivation and marketing practices typically used in conventional alfalfa seed and hay production limit the potential for physical and or handling mixtures to very low levels. The likelihood and extent of RRA and non-RRA mixtures are negligible and highly constrained by RRA seed grower practices stipulated and enforced under RRA seed grower contracts. Organic or other GE sensitive hay producers will opt to plant non-GE seeds and will follow their routines for maintaining segregation between hay lots. The impacts to non-RRA markets are expected to be negligible, especially because all RRA seed and hay growers must manage their crop according to their obligations under contracts, licensing, seed certification standards and or segregation standards for organic crops.

RRA is compositionally similar to seed and forage from conventional alfalfa. Therefore, from a food and or feed safety perspective, the impact of mixtures between RRA and non-RRA seeds or forage is negligible. However, as discussed elsewhere in this document (Sections 3.3.4, 3.3.5, 3.15 and 4.10) and extensively throughout the DEIS (USDA APHIS, 2009), there is a segment of consumers and markets that due to their rejection of GE crops or traces thereof, may experience socio-economic concerns and nominal (and voluntary) GE mitigation/avoidence costs (e.g., testing costs).

3.8.3 Impacts

Alternative 1: No Action

Under Alternative 1, there would be no impact from RRA seed production on organic or conventional alfalfa seed production because no RRA hay or seed would be produced commercially.

Alternative 2: Partial Deregulation of RRA

Under the partial deregulation alternative, there would be no or negligible impacts to growers of organic or conventional alfalfa seed for the following reasons:

- Gene flow mitigation measures (FGI Stewardship Program, and NAFA BMP for RRA Seed Production) are contractually required for all RRA seed producers. The isolation distances and other mitigation measures required by the NAFA BMP are practicable, contract-enforced, science-based and market-driven. They have been designed to enable coexistence by mitigating all or nearly all unwanted gene flow between dissimilar crops and to aid in protecting non-GT, export, and organic hay and seed alfalfa crops. There have been negligible impacts since commercial seed production began in 2005 due to the efficacy of these BMP. The eight RRA seed grower consortia authorized to plant under partial deregulation would meet or exceed the NAFA BMP parameters with enhanced additional isolation requirements. The minimum required isolation from conventional, commercial seed fields will be 4 miles and 1 mile when honeybees or leafcutter bees are the managed pollinating species, respectively. The potential for gene flow at the NAFA BMP isolation is de minimis (Van Deynze et al., 2008), and the proposed increase to the isolation requirement would further ensure de minimis gene flow potential from RRA seed fields to conventional seed crops should they be present.
- The biology, cultivation and marketing practices typically used in conventional alfalfa seed production limit the potential for physical and handling mixture to very low levels. The likelihood and extent of RRA and non-RRA mixtures are highly constrained by RRA seed grower practices stipulated and enforced under RRA seed grower contracts.
- Conventional and organic alfalfa seed will continue to be readily available to growers.

3.9 LIVESTOCK PRODUCTION SYSTEMS

RRA alfalfa will be used in livestock production systems as feed for livestock. Therefore, its only potential impacts to livestock production systems would be related to animal feed, which is discussed in Section 3.10.

3.10 FOOD AND FEED

Both food (sprouts, dietary supplements, and herbal or homeopathic medicine) and animal feed (hay, haylage, or silage) are derived from alfalfa. In this section we summarize the large body of scientific evidence that has been developed that supports the conclusion that food and feed

derived from RRA are as safe and healthy as food and feed derived from conventional alfalfa. While the evidence has largely been developed by Monsanto and/or FGI, it has been evaluated and peer reviewed by FDA and by panels of government scientists from Canada, Japan, Australia, New Zealand, Mexico, Korea, and the Philippines, all of whom have approved, or recommended for approval, the use of products from RRA in their countries.

We begin with a summary of FDA's authority and policy under the FFDCA with regard to ensuring the safety of food and feed derived from genetic engineering, documenting each element FDA evaluated in its consultation process. We then summarize the evaluations and conclusions of several other international scientific oversight groups.

3.10.1 FDA authority and policy

FDA policy statement. In 1992, the FDA issued a policy statement clarifying its interpretation of the FFDCA regarding foods (including animal feed) derived from new plant varieties, including plants developed by genetic engineering. The purpose of the policy is "to ensure that relevant scientific, safety, and regulatory issues are resolved prior to the introduction of such products into the marketplace" (FDA, 1992). FDA is the "primary federal agency responsible for ensuring the safety of commercial food and food additives, except meat and poultry products" and "FDA has ample authority under the FFDCA safety provisions to regulate and ensure the safety of foods derived from new plant varieties, including plants developed by new techniques. This includes authority to require, where necessary, a premarket safety review by FDA prior to marketing of the food" (FDA, 1992). Under section 402(a)(1) of the FFDCA, a food is adulterated and thus unlawful "if it bears or contains an added poisonous or deleterious substance that may render the food injurious to health or a naturally occurring substance that is ordinarily injurious" (FDA, 1992).

FDA has the authority to ensure safety of new foods. FDA considers its existing statutory authority under the FFDCA and its implementing regulations "to be fully adequate to ensure the safety of new food ingredients and foods derived from new varieties of plants, regardless of the process by which such foods and ingredients are produced" (FDA, 1992). "The existing tools provide this assurance because they impose a clear legal duty on producers to assure the safety of foods they offer to consumers; this legal duty is backed up by strong enforcement powers; and FDA has authority to require premarket review and approval in cases where such review is required to protect public health" (FDA, 1992).

Developers have the responsibility to evaluate the safety of new foods. "It is the responsibility of the producer of a new food to evaluate the safety of the food and assure that the safety requirement of section 402(a)(1) of the act is met. FDA provides guidance to the industry regarding prudent, scientific approaches to evaluating the safety of foods derived from new plant varieties, including the safety of the added substances that are subject to section 402(a)(1) of the act. FDA encourages informal consultation between producers and FDA scientists to ensure that safety concerns are resolved" (FDA, 1992).

Foods developed by new methods do not present greater safety concerns. "FDA believes that the new techniques are extensions at the molecular level of traditional methods and will be used to achieve the same goals as pursued with traditional plant breeding. The agency is not aware of any information showing that foods derived by these new methods differ from other foods in any meaningful or uniform way, or that, as a class, foods developed by the new techniques present any different or greater safety concern than foods developed by traditional plant breeding" (FDA, 1992).

FDA's goal is to ensure the safety of all food and feed. "The goal of the FDA's evaluation of information on new plant varieties provided by developers during the consultation process is to ensure that human food and animal feed safety issues or other regulatory issues (e.g. labeling) are resolved prior to commercial distribution" (FDA, 1997).

3.10.2 FDA biotechnology consultation note to the file BNF 000084

FDA makes the contents of its biotechnology notification files (BNFs) available on the internet (see reference FDA, 2004; RRA is BNF 000084). FDA documented its RRA consultation with Monsanto/FGI in a note to the file dated December 8, 2004 (FDA, 2004). That information is summarized below.

Characterization, inheritance, and stability of the introduced DNA

Using standard analytical techniques, Monsanto/FGI verified that events J101/J163 contained a single copy of the CP4 EPSPS cassette, and that all components were intact (FDA, 2004; Rogan and Fitzpatrick, 2004).

Monsanto/FGI conducted crosses using conventional breeding techniques. These studies indicate that the introduced trait (glyphosate tolerance) was stably inherited as a dominant trait (FDA, 2004; Rogan and Fitzpatrick, 2004).

Using standard analytical techniques, Monsanto/FGI demonstrated the stable integration of the T-DNA over five generations (Rogan and Fitzpatrick, 2004).

Introduced substance – CP4 EPSPS enzyme

As discussed in Section 3.1.1, EPSPS is a catalyst for a reaction necessary for the production of certain aromatic amino acids essential for plant growth and has a similar function in bacteria and fungi (for example, baker's yeast). While EPSPS is present in plants, bacteria and fungi, it is not present in animals; animals do not make their own aromatic amino acids, but rather obtain them from the foods they consume. Thus, EPSPS is normally present in food and feeds derived from plant and microbial sources (Harrison et al., 1996). There are variations in the genetic makeup (amino acid sequences) of EPSPS among different plants and bacteria. The EPSPS used in Agrobacterium sp. strain CP4 is just one variant of EPSPS. A unique characteristic of CP4 EPSPS is that, unlike EPSPS commonly found in plants, it retains its catalytic activity in the presence of glyphosate (FDA, 2004; Rogan and Fitzpatrick, 2004).

Concentrations in alfalfa. CP4 EPSPS protein levels in sample extracts were measured using standard methods, with the resulting average concentration of approximately 0.02 to 0.03 percent (192 to 317 parts per million) (Rogan and Fitzpatrick, 2004).

Toxicity of CP4 EPSPS. The FDA concluded that "the CP4 EPSPS protein produced by RRA lines J101/J163 was biochemically and functionally equivalent to CP4 EPSPSs produced by other RR crops, and to the family of EPSPS proteins that naturally occur in crops and microbiologically-based processing agents that have a long history of safe consumption by humans and animals" (Hendrickson and Price, 2004). This similarity of the CP4 EPSPS protein to EPSPS's in a variety of foods supports the lack of health concerns and extensive human and animal consumption of the family of EPSPS proteins (Rogan and Fitzpatrick, 2004).

Studies were conducted on mice, using CP4 EPSPS doses of 400, 100, and 40 milligrams (mg) of CP4 EPSPS per kilogram (kg) of body weight per day (mg/kg body wt –d). For a typical 0.03-kg mouse, the 400 mg/kg body wt –d dose equated to 12 mg per mouse per day. The study was designed to reflect a 1,000-fold factor of safety on the highest possible human exposure to CP4 EPSPS, based on assumed exposures to soybean, potato, tomato, and corn at the time the study was done (Harrison et al., 1996). The daily CP4 EPSPS content in the maximum mouse exposure was equivalent to the amount in approximately 160 pounds of RRA. No treatment-related adverse effects were observed, and there were no significant difference in any

measured endpoints between the CP4 EPSPS treated mice and the control group (Harrison et al., 1996, p. 735).

Monsanto/FGI also compared the amino acid sequence of CP4 EPSPS to protein sequences in the public domain ALLPEPTIDES database using the FASTA algorithm, and reported no biologically relevant sequence similarities between CP4 EPSPS protein and known toxins were observed (Bonnette, 2004). A peptide is a molecule consisting of several linked amino acids (GMO Safety, 2010a).

Allergenicity. Allergens can be derived from many sources: in animal hair, pollen, insect bites, dust mites, plants, pharmaceuticals, and food. Approximately 20,000 allergens have been identified. Most allergens in food are high molecular weight proteins and are rather resistant to gastric acid and digestive enzymes (GMO Safety, 2010a).

Monsanto searched a comprehensive database of allergens (Hileman et al., 2002) containing sequences of known allergens, for amino acid homology to the CP4 EPSPS protein, and concluded that there was no immunologically significant amino acid sequence homology between the CP4 EPSPS protein and amino acid sequences of allergens in the database (Bonnette, 2004).

At least two studies have been conducted on the mammalian digestibility of CP4 EPSPS. In the first study, the CP4 EPSPS protein was exposed to simulated gastric (stomach) and intestinal fluids that were prepared according to the U.S. Pharmacopoeia (1990). The half-life of the CP4 EPSPS protein was reported to be less than 15 seconds in the gastric fluid, greatly minimizing any potential for the protein to be absorbed in the intestine. The half-life was less than ten minutes in the intestinal fluid (Harrison et al., 1996, p 738). The second study reported similar results (Bonnette, 2004). Specifically, FDA (2004) noted the following from the Monsanto/FGI submmittal: the soil bacterium used to create RRA is not a known allergen or pathogen (does not cause allergic reactions or diseases); the CP4 EPSPS gene and protein lack structural similarities to any allergen (it does not have the same structure as anything that causes allergic reactions).

Food and feed uses of alfalfa

Alfalfa has a long history as a feed source for animals. Greater than 95 percent of alfalfa is used as animal feed.

Human food uses of alfalfa are minor and it is consumed as compressed leaf material for dietary supplements and herbal teas or as fresh sprouts. The seeds germinated for sprouts are

produced and marketed in a distinct, food-grade channel from those for field (non-food) purposes (Section 2.7). A small fraction of alfalfa seeds are used to produce sprouts for human consumption. Any alfalfa seed for sprouts must be certified as having been produced to food-grade specifications and therefore food-grade seed is grown and distributed in an entirely separate channel from that for general use, non-food-grade planting seeds. Food-grade seeds for sprouts are produced throughout the world, but the major suppliers are Canada, Italy, U.S. and Australia. Sprouts are cultivated from clean raw (non-coated, untreated) seeds in controlled environment sprouting chambers for approximately 5 to 10 days before sale to consumers.

FDA and equivalent regulatory bodies in Japan, Korea, Canada, Australia/New Zealand, etc., have granted full approval for the use of RRA as a food (see Section 3.11). Monsanto and FGI have developed the RRA varieties for field planting purposes (only), and as such the companies do not intend nor allow (give license to) any seed growers or seed purchasers to use RRA varieties for food-grade sprout production (Hubbard, 2008; USDA APHIS, 2009, p. 18). The FGI mandated purple seed coating for all commercial RRA seed helps mitigate unintended use of RRA seed for sprouts.

Alfalfa is the principal forage for cattle and horses because of its high nutritional content. The nutritional content of alfalfa is highest in young vegetative alfalfa plants and decreases as plants approach full flower. Dairy cows are generally fed the highest quality alfalfa hay (vegetative to bud stage). Beef cattle, horses, heifers, and non-lactating dairy cows are fed hay that is higher in fiber and lower in protein. Forms of storage include hay, haylage, and silage. Grazing is sometimes used as an alternative to harvesting alfalfa. However, grazing presents a risk of animal loss due to bloating and difficulties in alfalfa stand maintenance if grazing is continuous (Rogan and Fitzpatrick, 2004).

Honey bee hives commonly use alfalfa and clover as nectar sources. Therefore, managed and wild bee hives are often associated with alfalfa fields (FDA, 2004; USDA, 2009 draft EIS Appendix O).

Compositional analysis

To assess whether alfalfa events J101/J163 are as safe and nutritious as conventional alfalfa varieties, the composition of forage produced by Roundup Ready alfalfa plants containing either event J101, J163, or the paired events J101 X J163 was measured and compared to the composition of control and conventional alfalfa forage. This study was conducted under USDA

Notification Number 01-029-12n. Forage was harvested from plants grown in field trials and analyzed using standard methods or other suitable methods (Monsanto, 2004).

Forage samples were collected from all plots and analyzed for 35 different nutritional components. Compositional analyses of the forage samples included proximates (protein, fat, ash and moisture), acid detergent fiber (ADF), neutral detergent fiber (NDF), lignin, amino acids, and minerals (calcium, copper, iron, magnesium, manganese, phosphorous, potassium, sodium and zinc), as well as carbohydrates by calculation. In all, 35 different components were analyzed to assess the composition of Roundup Ready alfalfa (Rogan and Fitzpatrick, 2004).

Statistical analyses were performed on the compositional data for the RRA containing events J101/J163. As expected, statistically significant differences were observed for the concentration of some of the analytes in comparison to the control. Where values were different, the mean was within the 99 percent tolerance interval developed for the analyte using conventional alfalfa reference varieties. Therefore, it is unlikely that these differences are biologically meaningful. These data are consistent with the conclusion that forage produced by alfalfa plants containing event J101 or J163 is comparable to forage produced by control or conventional alfalfa varieties. These compositional data support the conclusions derived from other phenotypic studies indicating that no biologically meaningful changes were associated with alfalfa populations containing event J101 or event J163 (Monsanto, 2004).

Conclusion

Based on the data submitted, the FDA considered the consultation process to be complete and acknowledged this in Biotechnology Consultation Note to the File BNF No. 000084 (FDA, 2004).

3.10.3 Health Canada approval 2005

Health Canada's Food Directorate has legislated responsibility for premarket assessment of "novel foods." Under Canadian regulations, foods derived from alfalfa lines containing events J101/J163 are considered novel foods because they are derived from a plant that has been GM to exhibit characteristics that were not previously observed in the plant (Health Canada, 2005).

Health Canada conducted a comprehensive assessment of GT alfalfa lines containing events J101/J163 according to its "Guidelines for the Safety Assessment of Novel Foods," reviewing the same information Monsanto/FGI provided to FDA in its consultation, and made the following conclusion (Health Canada, 2005):

> "Health Canada's review of the information presented in support of the food use of glyphosate tolerant alfalfa lines containing events J101/J163 concluded that

the food use of alfalfa lines containing this event does not raise concerns related to safety. Health Canada is of the opinion that alfalfa lines containing events J101/J163 are as safe and nutritious as current commercial alfalfa varieties."

3.10.4 CFIA approval 2005

The CFIA evaluated GT alfalfa events J101/J163 for use as livestock feed and approved their use in 2005. Based on its evaluation of data provided by Monsanto/FGI, and as summarized in its Decision Document DD2005-53, the CFIA "determined that these plants with a novel trait (PNT) do not present altered environmental risk nor, as a novel feed, do they present livestock feed safety concerns when compared to currently commercialized alfalfa varieties in Canada" (CFIA, 2005).

3.10.5 Japan approval

Japan approved the food use RRA in 2005 and the feed use in 2006. Environmental approval was also granted in Japan in 2006 (Japan Biosafety Clearinghouse, 2010; Center for Environmental Risk Assessment, 2010).

3.10.6 Australia – New Zealand approval

Food Standards Australia New Zealand (FSANZ) is a bi-national government agency with responsibility to develop and administer the Australia New Zealand Food Standards Code. FSANZ approved the food use of RRA in 2006 (FSANZ, 2006). FSANZ found "no public health and safety concerns. On the basis of the available evidence, including detailed studies provided by the Applicant, food derived from GT lucerne J101/J163 is considered as safe and wholesome as food derived from other commercial lucerne varieties." (FSANZ, 2006, p. ii).

3.10.7 Other approvals

RRA was also approved for use as food and/or feed in Mexico in 2005 (Ministry of Health), in the Philippines in 2006 (Department of Agriculture Bureau of Plant Industry), and in Korea in October 2007 (Center for Environmental Risk Assessment, 2010). Environmental approval was granted in Korea in January 2008 (Rural Development Administration).

3.10.8 Impacts

Alternative 1: No Action

Under Alternative 1, there would be no impact from RRA on feed or food, or on consumer choice.

Alternative 2: Partial Deregulation of RRA

Health effects of consumption of RRA. Alfalfa is consumed as both animal feed (hay/haylage) and human food (e.g., alfalfa sprouts). Based on the scientific evidence summarized in this section, health impacts from consuming RRA food or feed are not expected from RRA. Feed derived from RRA is equivalent to feed derived from conventional alfalfa. Although RRA has been found to be equivalent to conventional alfalfa by several international scientific agencies, Monsanto/FGI have determined that RRA will not be licensed for use for any human food purposes.

Health and consumer choice effects of consumption of food or feed derived from RRA. Beef and dairy products may be derived from cattle/cows that have consumed RRA. The Food and Agricultural Organization of the United Nations (FAO), the World Health Organization (WHO), and the Organization for Economic Cooperation and Development (OECD) have made statements regarding the potential for the protein encoded by the transgene (the CP4 EPSPS protein) to transfer to animal-derived products intended for human consumption (FAO/WHO 1991; FDA 1992; OECD 2003). These reports, as well as the studies summarized above in this section have concluded that the CP4 EPSPS protein is equivalent to other forms of the EPSPS protein, and that food and feed containing the CP4 EPSPS protein is as safe and nutritious as the conventional counterparts. As discussed in Section 3.10.1, the half-life of the CP4 EPSPS protein in the digestive system is only a few minutes; no detectable amounts of the CP4 EPSPS protein are expected to be found in beef or dairy products from animals fed RR alfalfa. Although uncommon, fragments of transgenes have been found in dairy and animal products (Flachowsky and others, 2005). If very low levels of transgenic fragments could be infrequently found in dairy products and beef from cattle/cows consuming RRA, presumably they would also be present in the same products, from the use of corn as cattle feed, as most corn grown in the U.S. is genetically engineered. Honey from bees is mostly fructose and glucose; however, possibly it could have minute fragments of transgenic DNA from pollen from RRA. The presence of DNA fragments, GE or otherwise, is not a health issue (on the safety of DNA (FDA, 1992); however, depending on how "non-GE food" is defined, it could affect a consumer's choice to consume non-GE food. The minute levels that might potentially be found in honey, beef or dairy products would, for example, be far below the threshold standards for non-GE food proposed by the Non-GMO Project (Section 1.5). A consumer with "zero tolerance" for beef or dairy derived from GE products or that might contain minute fragments of transgenes would have the choice of consuming organic honey, beef and dairy products. Presumably that

consumer would already be consuming organic beef and dairy products because of the use of GE corn as cattle feed. Market demand will ensure that conventional and organic alfalfa will still be available to the dairy or cattle farmer who wishes to avoid RRA.

Summary. Based on the above analysis, Alternative 2 would be expected to have no or negligible impacts on food or feed, or consumer choices regarding food or feed.

3.11 WEED CONTROL AND GR

3.11.1 Weed control with conventional alfalfa

Weed management is an important aspect of alfalfa production. Some of the negative effects of weeds in alfalfa crops include the following:

- competition with weeds can reduce yield and cause thinning in the stand;
- weeds can lower the nutritional quality of alfalfa hay because many weeds are lower in protein (50 percent less protein than alfalfa) and higher in fiber compared to alfalfa;
- poisonous weeds containing toxic alkaloids (a type of chemical) (e.g., common groundsel, fiddleneck, yellow starthistle, and poison hemlock) can make alfalfa hay unmarketable;
- under some conditions weeds can accumulate toxic nitrate concentrations (e.g., lambsquarters, kochia, and pigweed);
- some weeds with a spiny texture can cause mouth and throat ulcerations in livestock (e.g., foxtail, wild barley, cheatgrass, and bristlegrass);
- weeds that are unpalatable to livestock result in less feeding and, therefore, less productivity (of either beef or milk);
- some weeds can contribute to off flavors in milk (e.g., wild celery, Mexican tea, creeping swinegrass, and mustards); and
- weeds that contain higher moisture content than alfalfa (e.g., dandelion) can cause bale problems such as mold, off-color hay, and high bale temperatures, which are a fire hazard.

(Canevari et al., 2007; Canevari et al., 2006; Van Deynze et al., 2004; Loux et al., 2007; Miller et al., 2006; Orloff et al., 1997; Orloff et al., 2009, attached as Appendix D; USDA APHIS, 2009 pp. 105-06).

Without weeds, alfalfa can grow at a density of about 12 plants per square foot. Heavily weed-infested stands can have less than one alfalfa plant per square foot (Canevari et al., 2007). In California, if weeds are not effectively controlled, they can represent up to 76 percent of the first cutting yields (USDA APHIS, 2009, p. 106).

3.11.2 Weed control with RRA

The following discussion of RRA and weed management was based largely on the technical report, *Effects of Glyphosate-Resistant Weeds in Agricultural Systems* (USDA APHIS 2009, Appendix G, attached as Appendix E of this ER).

RRA can be used by farmers for weed management in alfalfa crops. Its unique characteristics allow for effective weed control throughout the growing season of an alfalfa crop, and, alfalfa and alfalfa farming practices per se have characteristics that will complement the weed control provided by glyphosate and, as such, will aid in the suppression of the development of GR weeds. The ability for alfalfa to fix nitrogen encourages the decision to follow alfalfa in the rotation with a crop that requires additional nitrogen, such as the annual grasses of corn and various cereal crops. These subsequently rotated crops can tolerate a spectrum of herbicides substantially different from the herbicides used in alfalfa. This encourages rotation of crops and herbicides, both of which are highly recommended for reducing the probability of developing herbicide resistant weeds (Orloff et al., 2009; USDA APHIS, 2009, p. 109).

Alfalfa produced for forage purposes (e.g., hay and silage in GE, conventional, or organic production systems) is mowed regularly at a recommended cutting height of 3 inches. This removes all plant material higher than 3 inches including weeds (Orloff et al., 1997), which may not have had time to produce flowers, pollen or seed. This regular removal of all plant mass above 3 in. of the soil surface, including all vegetative weed material, greatly suppresses or eliminates seed production in weed species, and is especially effective in controlling annual weeds (USDA APHIS, 2009, p. 109).

In a RRA farming system for forage, the combination of broad spectrum weed control from glyphosate (which should lead to more vigorous alfalfa competition), and regular mowing, which reduces the likelihood that any GR weeds in the RRA field have had time to produce pollen or set seed, greatly decreases the probability of the development of GR weeds. In some parts of the western U.S., alfalfa produced with irrigation requires multiple herbicide applications to control repeated influx of weed seed introduced with irrigation water. In most cases the use of one or more non-glyphosate herbicides with increased residual activity will be required to

provide effective weed control (Orloff et al., 2009, attached as Appendix D). In seed production, although an early spring or late fall mowing sometimes occurs, in-season mowing only occurs once, as one seed crop is removed each year; thus, there is a potential for greater weed seed production compared to alfalfa forage production. However, in order to maximize yield for a seed crop and minimize weed seed content, alfalfa seed production (including RRA seed production) currently receives significantly higher cultural and herbicide inputs (beyond glyphosate only) to reduce weed cover than in alfalfa forage production. Glyphosate can only be applied in alfalfa seed production when plants are in the vegetative state. Other herbicides will be used to control weeds during the longest part of the growing season. These additional herbicides with other modes of action will also work to reduce weed seed production and minimize glyphosate-resistant weeds in the seedbank of fields where RRA is grown for seed (USDA APHIS, 2009, p. 109).

3.11.3 Herbicide-resistant weeds

A number of genetic, biological/ecological, and operational factors are involved in determining if a weed species will evolve a resistance to any herbicide (Georghiou and Taylor, 1986; Neve, 2008). Genetic factors include the frequency of genes in a weed species that promotes resistance to a particular herbicide, the ability and rate of changes to genes to cause resistance, the way genes for resistance are passed down to offspring, and the fitness of the plant (and these genes) in the presence and absence of an herbicide. Biological and ecological factors include how the weed species reproduces (selfing or outcrossing), seed production capacity, seed bank turnover, and amount of gene flow within and between populations (Maxwell and Mortimer, 1994; Jasieniuk et al., 1996; Neve, 2008). The genetic factors and biological/ecological factors involved highlight that different species may present different risks of resistance, depending on the genetics of the weed and the biology of the plant. Operational factors involved in the evolution of weed resistance include the type of chemistry and how the herbicide kills plants (e.g. mode-of-action), the frequency with which the herbicide is applied, and the dose and pattern of herbicide application.

Alfalfa weed management, including major weeds in alfalfa, herbicides used, herbicide mode of action, and herbicide resistance, was discussed in Sections 2.5. Measures to reduce herbicide resistance were also discussed in Section 2.5.

3.11.4 GR weeds

As discussed in Section 2, herbicide resistance is not a unique or new phenomenon. The development of weeds resistant to a particular herbicide mode of action is an issue that growers have faced for decades. As with other herbicide modes of action, not all weeds respond the same to glyphosate, and some species naturally vary in their tolerance to the herbicide.

Because of the nature of glyphosate and its history of use, generally speaking, there is a reduced potential that there will be a selection for weed resistance, compared to other herbicides. Glyphosate is a nonselective, foliar-applied, broad spectrum, post-emergent herbicide compared to many other herbicide groups. It operates by binding to a specific enzyme in plants thereby interfering with the plant's required metabolic process. Glyphosate is the only herbicide that binds with this enzyme, and therefore it is highly specific (Cole, 2010, p. 5; Orloff, 2009, p. 6, attached as Appendix D).

Accordingly, while glyphosate has been used extensively for over three decades, there have been relatively few cases of resistance development, as compared to many other herbicides and when considering the substantial glyphosate-treated acreage worldwide (approximately 1 billion acres) and the total number of weeds that the herbicide can control. In the U.S., there are ten weed species where GR biotypes are known to exist in certain areas of the country (19 weeds have been reported to have developed GR at some location worldwide). These resistant weeds represent a relatively small minority of the overall weed population. For example, in 2009, approximately 135 million of the 173 acres of corn, soybeans and cotton in the U.S. were planted with a herbicide tolerant variety, with the most common tolerance trait being glyphosate tolerance (USDA NASS, 2009a). At the same time, only about 6 percent of the total planted corn, soybean and cotton acres in the U.S. are estimated to have some level of presence of weeds resistant to glyphosate (Ian Heap as reported by WSSA, 2010b). As discussed above, the characteristics of glyphosate itself reduce the potential for the development of herbicide resistance as compared to other herbicide families. As such, certain herbicide families have been classified according to their risk of resistant weed development. Beckie (2006) lists ALS and ACCase inhibiting herbicides as "High" risk for resistance development, while glyphosate is considered a "Low" risk herbicide for the development of herbicide resistant weeds. ALS and ACCase inhibiting herbicides are commonly used in conventional alfalfa production, and weeds resistant to these two herbicide groups are widely distributed across alfalfa growing regions of the U.S. RRA can help delay resistance to these herbicides by adding to the diversity of herbicide modes of action in alfalfa production.

Use of herbicides with different modes of action, either concurrently or sequentially, is an important defense against weed resistance (WSSA, 2010b). "Use of a single product or mode of action for weed management is not sustainable. Some of the best and most sustainable approaches to prevent resistance include diversified weed management practices, rotation of modes of action and especially the use of multiple product ingredients with differing modes of action" (WSSA, 2010b). In addition, cultural practices such as cultivation or mowing are effective weed resistance management operations.

The WSSA reports higher levels of awareness among growers regarding the need to minimize the potential for development of GR: "In a market research study that surveyed 350 growers in 2005 and again in 2009, in response to the question, 'are you doing anything to proactively minimize the potential for resistance to glyphosate to develop,' 67 percent said yes in 2005 and 87 percent said yes in 2009" (David Shaw, as reported in WSSA, 2010). "In a 2007 survey of 400 corn, soybean and cotton growers, resistance management programs were often or always used by 70 percent or more of all three grower groups" (Frisvold and Hurley as reported by WSSA, 2010b). There is widespread information available from universities and other sources regarding GR. Public universities (i.e. University of California, North Dakota State University, University of Minnesota), herbicide manufacturers (i.e. www.weedresistancemanagement.com, www.resistancefighter.com) and crop commodity groups (i.e. National Corn Growers Association, American Soybean Association) have internet web sites with information on prevention and management of herbicide resistance. Monsanto's TUG (attached to this document as Appendix A) provides specific management practices for the prevention of glyphosate resistant weeds. Additionally, the UC's Integrated Pest Management website (http://www.ipm.ucdavis.edu/PGM/weeds_common.html) and at the UC Weed Research and Information Website (http://wric.ucdavis.edu/information/information.html) provide information on weed identification and specific weed management practices (Orloff et al., 2009; attached as Appendix D).

Alfalfa growers have strong financial and practical interests in managing weeds effectively and preemptively to reduce the development of herbicide resistance in order to maximize yield potential. The development of GR weeds harms the economic return per acre for the individual farmer and the entire alfalfa industry (Orloff et al., 2009, attached as Appendix D).

As such, strategies and recommendations to delay the development of GR weeds have been developed for alfalfa (Orloff et al., 2009, attached as Appendix D; TUG, attached as Appendix A). In general, weed scientists recommend the following to mitigate the risk of herbicide

resistance in alfalfa: (1) Apply integrated weed management practices. Use multiple herbicide modes-of-action with overlapping weed spectrums in rotation, sequences, or mixtures; (2) Use full recommended rate and proper application timing for the hardest to control weed species present in the field; (3) Scout fields after herbicide application to ensure control has been achieved; (4) Avoid allowing weeds to reproduce by seed or to proliferate vegetatively; (5) Monitor site and clean equipment between sites; (6) Start with a clean field and control weeds early by using a burndown treatment or tillage in combination with a preemergence residual herbicide as appropriate; (7) Use cultural practices such a cultivation and crop rotation, where appropriate; and (7) Use good agronomic principles that enhance crop competitiveness. (HRAC, 2009). Similarly, the TUG recommends scouting for weeds; starting with a clean field using a burndown herbicide application or tillage; controlling weeds when they are small; crop rotation with opportunities for other modes of action; crop rotation; and "the right herbicide product at the right rate and at the right time." (TUG, p. 10, attached as Appendix A). All RR technology users, including alfalfa growers, are contractually obligated through the MT/SA to follow the TUG. RRA seed growers are also required by the NAFA BMP to "[m]anage weeds and volunteers using integrated weed control strategies (e.g., conventional practices supplemented with Roundup agricultural herbicide formulations applied according to the label for alfalfa seed production)" (NAFA, 2008).

Table 2-5 in Section 2.4.2 lists weeds known to be found in alfalfa and the biotypes known to be glyphosate resistant. Since 1998, 14 new GR weeds have been found globally. Nine of these have glyphosate resistant biotypes in the U.S. Of these nine, four species are known to be common in alfalfa fields.

3.11.5 Impacts

Alternative 1: No Action

Under Alternative 1, there would be virtually no effect on the potential for weeds to develop resistance to glyphosate, given that glyphosate use is minimal with conventional alfalfa. However, under Alternative 1, the impact of weeds resistant to other herbicides is likely to continue to increase as growers would continue to use conventional weed control methods, including other herbicide modes of action.

As discussed above, glyphosate use in alfalfa can be an effective tool against weeds resistant to non-glyphosate herbicides, such as ALS-inhibitors and ACCase-inhibitors. Weed resistance

to glyphosate is not as common as resistance to many other herbicides (Orloff et al., 2009, p. 6, attached as Appendix D).

Alternative 2: Partial Deregulation of RRA

Under Alternative 2, impacts, if any, with respect to the development of GR weeds due to increased use of glyphosate associated with RRA crop production are expected to be very small. First, as discussed above, the nature of glyphosate itself makes it less likely that new GR weed populations will develop in alfalfa as a result of the use of glyphosate in RRA. Specifically, there is a relatively low rate of resistance in weeds to glyphosate relate to the widespread use of this chemical. (Orloff et al., 2009, p. 6; attached as Appendix D). Because of this differential in weed resistance between glyphosate and other herbicides, the introduction of this additional mode of weed control may have a net positive effect on weed resistance in alfalfa production. Second, there is a high level of awareness about the potential for GR weeds and many readily available resources to assist growers with management strategies (e.g., Orloff et al., 2009). Third, because herbicide resistance is a heritable trait, it takes multiple growing seasons for herbicide tolerant weeds to emerge and become the predominant biotype in a specific area (Cole, 2010a, p. 4). Researchers have concluded that even if growers completely relied on only one herbicide, it is likely to take at least five years for an herbicide-resistant weed population to develop (Kniss, 2010a, p. 4; Beckie, 2006, Neve, 2008; Werth et al., 2008). This is a reason why crop monitoring and follow up by weed scientists in cases of suspected resistance are important parts of all herbicide resistance stewardship programs. Fourth, RRA growers are required to abide by the following requirements, which will operate to mitigate the risk of glyphosate weed resistance in RRA:

- Read and follow all herbicide use directions and recommendations;
- Follow all stewardship practices outlined in Monsanto's TUG (Appendix A) which includes weed resistance management practices; and
- • Follow the Weed Resistance Management Guidelines to minimize the risk of resistance development (see Monsanto's TUG, p. 4; http://www.weedresistancemanagement.com/guidelines.html).

3.12 PHYSICAL

The assessment of impact to land use in the sections below considers the impacts to land use or current cultivation practices under the no action alternative and the proposed partial deregulation alternative.

3.12.1 Land Use

Alternative 1: No Action

Under Alternative 1, there would be no impact to land use or current cultivation practices. There would be no new planting of RRA for commercial purposes. It is anticipated that existing alfalfa acres would continue to be planted with non-RRA or non-alfalfa crops.

Alternative 2: Partial Deregulation of RRA

Under Alternative 2, it is expected that RRA would be planted on existing alfalfa acreage for hay or seed production provided that the proposed partial deregulation measures discussed in Section 1.1.3 above are followed. Appendix G charts the anticipated adoption of RRA under Alternative 2. However, the impact of this alternative on the overall amount of land devoted to alfalfa cultivation is expected to be minimal, as under this alternative, land currently used for alfalfa seed or hay production would continue to be used in the same manner. Alfalfa production is largely a market-driven decision rather than a technology-driven decision. (USDA-APHIS, 2009, p. 157). The availability of a new weed control option is not expected to impact current land use management. However, since glyphosate controls a broad range of weeds, farmers may choose to plant RRA on fields with greater weed potential. If the life span of RRA can be extended longer than current alfalfa stand lifespans, this might impact land use decisions regarding crop rotation practices, but is not expected to change the nature of land use into or out of agricultural production.

3.12.2 Air Quality and Climate

The assessment of impacts to air quality and climate in the sections below considers impacts to air quality and climate practices under the no action alternative and the proposed partial deregulation alternative. Under Alternative 1, existing alfalfa acreage will continue to be planted with non-RRA or non-alfalfa crops.

Alternative 1: No Action

The no action alternative would result in an adverse impact to air quality and climate. The continued regulation of RRA would result in continued planting of conventional and/or organic alfalfa. Non-RRA requires greater tillage for weed control than does RRA. Weed control in non-RRA is usually primarily accomplished by pre-plant tillage to prepare a weed-free seed bed, and/or by clipping targeted to stop weed growth and competition (with or without crop harvest). As glyphosate is a crop-safe, broad spectrum herbicide, it is possible that additional alfalfa

acres, like other herbicide tolerant crops, would be established using no-till methods. Comparatively, the tillage associated with non-RRA establishment requires greater use of farm machinery which results in greater greenhouse gas emissions.

Alternative 2: Partial Deregulation of RRA

As previously stated, the partial deregulation of RRA is expected to result in an increase in the total acreage of RRA crops. This would be accompanied by increased glyphosate application and decreased tillage of alfalfa fields. Because glyphosate is non-volatile (i.e., does not evaporate readily) at normal temperatures and is not considered an atmospheric contaminant (EPA, 1993), the increased application of glyphosate is not expected to result in adverse impacts to air quality. If glyphosate is applied aerially, any potential drift-related impacts can be minimized by utilizing recognized practices for managing the potential for off target movement (i.e., using of specific nozzle types, limiting applications to conditions less favorable for drift). The overall impacts from aerial application are expected to be minimal because only around two percent of glyphosate is applied aerially in the U.S. (USDA APHIS, 2009). The decreased tillage of alfalfa fields under this alternative would have a net positive effect on air quality and climate by reducing the operation of farm machinery and the associated greenhouse gas emissions. Emissions related to global warming, ozone depletion, summer smog and carcinogenicity, among others, were found to be lower in GT crop systems than conventional systems (Bennett et al., 2004).

3.12.3 Water Quality

The assessment of impacts to water quality in the sections below considers impacts on surface water quality and groundwater. Under Alternative 1, alfalfa acres will continue to be planted with non-RRA or non-alfalfa crops.

Alternative 1: No Action

Surface water. Alternative 1 would have an adverse impact on surface water quality. Under this alternative, growers would continue to plant conventional and organic alfalfa, resulting in the continued reliance on tilling and/or multiple herbicides for weed control. The adverse impact would be due to the continued generation of runoff containing: 1) herbicides with greater environmental impact than glyphosate; and/or 2) particulate matter derived from increased tillage and soil erosion. Tillage causes widespread soil disturbance resulting in erosion and topsoil loss, with a corresponding increase in sedimentation and turbidity in streams. This

erosion can also transport herbicides used on the fields into the surface waters. The usage of a GT cropping system such as RRA allows for cultivation with reduced tillage.

Groundwater. Alternative 1 would result in an adverse impact to groundwater. Adverse impacts would result from the continued use of multiple herbicides to control weeds. The vast majority of growers would continue to plant conventional alfalfa, resulting in the use of multiple herbicides for weed control. Several non-glyphosate herbicides have a higher potential to leach into groundwater, which results in groundwater contamination.

Alternative 2: Partial Deregulation of RRA

Surface water. Partial deregulation would result in increased planting (increased acreage) of RRA. The associated increase in application of glyphosate for weed control would reduce the impact on surface water quality by facilitating the adoption of conservation tillage methods and reducing the use of other herbicides with greater potential for adverse impact. Conservation tillage reduces disturbance of the soil and associated soil erosion from wind and water, and is facilitated by use of a GT cropping system such as RRA. The net effect would be lower amounts of herbicide and suspended sediment in runoff, which would improve water quality in streams and lakes (Wiebe and Gollehon, 2006).

Groundwater. The increased application of glyphosate under Alternative 2 would have a positive effect on groundwater quality by reducing the use of other herbicides that more readily leach into groundwater.

3.13 BIOLOGICAL

Potential environmental effects of pesticide use are carefully considered as a part of the FIFRA pesticide registration process. Prior to the approval of a new pesticide or a new use of that pesticide (including a change in pesticide application rates and/or timing) and before reregistering an existing pesticide, EPA must consider the potential for environmental effects and make a determination that no unreasonable adverse effects to the environment will be caused by the new pesticide, new use or continued use.

To make this determination, EPA requires a comprehensive set of environmental fate and ecotoxicological data on the pesticide's active ingredient (40 C.F.R. Part 158). EPA uses these data to assess the pesticide's potential environmental risk (exposure/hazard). The required data include both short- and long-term hazard data on representative organisms that are used to predict hazards to terrestrial animals (birds, nontarget insects, and mammals), aquatic

animals (freshwater fish and invertebrates, estuarine and marine organisms), and nontarget plants (terrestrial and aquatic).

Information regarding the impacts of glyphosate on the biological environment is summarized below. Additional information on this topic is also being considered in the USDA APHIS Draft Environmental Impact Statement (DEIS) on the Deregulation of Glyphosate Tolerant Alfalfa (Docket No. APHIS-2007-0044) (USDA APHIS, 2009).

3.13.1 Animal and plant exposure to glyphosate

Glyphosate is a non-selective herbicide with post-emergence activity on essentially all annual and perennial plants. As discussed in Section 3.1.1, this activity is due to inhibition of EPSPS, an enzyme involved in aromatic amino acid synthesis. As with any herbicide, a risk exists that spray drift could pose issues for plants on the borders of the target field. However, EPA takes the potential for spray drift into account when conducting the risk assessment it uses to establish pesticide application rates and direction for use, which are designed to minimize spray drift risks. Glyphosate binds tightly to agricultural soils and is not likely to move offsite dissolved in water. Moreover, glyphosate is not readily taken up from agricultural soil by plants. This limits the impact of glyphosate use on non-target plants, including aquatic plants.

Alternative 1: No Action

Plants. Under the no action alternative, RRA would remain regulated, and growers of conventional alfalfa would continue to use multiple herbicides for weed control. Many of the non-glyphosate herbicides are selective herbicides that kill only particular groups of plants such as annual grasses, perennial grasses, or broadleaf weed species. Therefore, growers of conventional alfalfa use more than one herbicide to achieve satisfactory weed control. In addition, some of the other herbicides are applied at greater volumes compared to glyphosate.

The continued use of other herbicides would result in potential adverse impacts to non-target plants. The herbicides used in conventional alfalfa production have been found, in general, to have more significant environmental impacts than glyphosate (USDA APHIS, 2009). This is consistent with the EPA decision to grant reduced risk status for glyphosate use in RRA. Comparison of results from terrestrial and aquatic plant studies with predicted exposure from herbicide use suggests that most of the herbicides used in conventional alfalfa systems may have greater adverse effects than glyphosate on aquatic or terrestrial plant species.

Animals. Under this alternative RRA would remain regulated, and growers of conventional alfalfa would continue to use an array of herbicides for weed control. Many of the herbicides

used in conventional alfalfa production have been found to have higher toxicity to certain animal species than glyphosate. Animal species within and adjacent to fields of conventional alfalfa would continue to be exposed to these more toxic herbicides. The amphibian habitat in watersheds where conventional and organic alfalfa are grown would continue to be impacted by higher levels of tillage, soil erosion, sedimentation in runoff, and turbidity in ponds, lakes, and rivers than would otherwise be the case if RRA were grown.

Under this alternative, alfalfa growers will continue to have difficulty controlling certain weed species that sicken, poison or reduce growth of horses, cattle and other livestock. Livestock illness and suffering related specifically to consumption of toxic weeds in alfalfa forage would remain unchanged. Economic losses associated with veterinary service costs and livestock productivity losses would remain unchanged.

Alternative 2: Partial Deregulation of RRA

Plants. With partial deregulation, the acreage of RRA and the associated use of glyphosate would increase. The increased glyphosate use would be accompanied by a corresponding decrease in the use of other herbicides that have a higher potential to impact non-target plant life. So this alternative would have an overall positive effect on terrestrial and aquatic plants. The EPA has concluded that glyphosate use on RRA poses reduced risk compared to the use of other herbicides for weed control.[43] As is the case with aerial application of any herbicide, terrestrial and aquatic plants in the vicinity of alfalfa fields may be incidentally exposed to glyphosate by spray drift. However, if aerial applications are minimized and/or appropriate spray drift reduction practices are utilized, this risk to non-target plants would be reduced; recall that EPA has determined that no unreasonable adverse effects occur from spray drift of glyphosate when applied according to label directions. Each year there are millions of acres of GT crops that are treated with glyphosate with minimal impact to adjacent non-target terrestrial plants including crops, when appropriate drift minimization measures are practiced.

Because glyphosate binds strongly to soil particles and has no herbicidal activity after binding to soil, no effects on aquatic plants will result from surface water runoff from glyphosate use on RRA. Conservation tillage and no tillage practices have the potential to mitigate impacts to aquatic plants through decreasing soil-laden runoff.

[43] A reduced risk decision is made at the use level based on a comparison between the proposed use of the pesticide and existing alternatives currently registered on that use site. A list of decisions regarding Reduced Risk Status can be found at: http://www.epa.gov/opprd001/workplan/reducedrisk.html

Animals. With partial deregulation, the acreage of RRA and the associated use of glyphosate would increase. The increased glyphosate use would be accompanied by a corresponding decrease in the use of other herbicides that have a higher potential to impact animals.

Based on the data available on glyphosate usage, chemical fate, and toxicity, glyphosate is not expected to pose an acute or chronic risk to the following categories of wildlife (EPA, 1993):

- Birds;
- Mammals;
- Terrestrial Invertebrates;
- Aquatic Invertebrates;
- Fish; and
- Soil Microorganisms.

Glyphosate is practically non-toxic to slightly toxic to birds, freshwater fish, marine and estuarine species, aquatic invertebrates and mammals and practically non-toxic to honey bees (which are used to assess effects on non-target insects in general) (EPA, 1993). Glyphosate has a low octanol-water partition coefficient, indicating that it has a tendency to remain in the water phase rather than move from the water phase into fatty substances. Therefore, it is not expected to accumulate in fish or other animal tissues.

As a part of the reregistration evaluation under FIFRA, EPA conducted an ecological assessment for glyphosate. This assessment compared the results from toxicity tests with glyphosate conducted with various plant and animal species to a conservative estimate of glyphosate exposure in the environment (Estimated Environmental Concentration (EEC)). In the Reregistration Eligibility Decision (RED) for glyphosate (EPA, 1993), the exposure estimates were determined assuming an application rate of 5.0625 lb active ingredient per acre (ai/A), which exceeds 3.75 lb a.e./A, the maximum EPA labelled use rate for a single application for agricultural purposes. When the EECs were calculated for aquatic plants and animals, the direct application of this rate (5.0625 lb a.e./A) to water was assumed. Based on this assessment, EPA concluded that effects to birds, mammals, fish and invertebrates are minimal based on available data (EPA, 1993).

The glyphosate end-use products used in agriculture contain a surfactant to facilitate the uptake of glyphosate into the plant (Ashton and Crafts, 1981). Depending on the surfactant used, the toxicity of the end-use product may range from practically nontoxic to moderately toxic to fish

and aquatic invertebrates (EPA, 1993). For this reason, the 1993 Glyphosate RED stated that some formulated end-use products of glyphosate needed to be labeled as "Toxic to fish" if they were labeled for direct application to water bodies. Due to the associated hazard to fish and other aquatic organisms, glyphosate end-use products that are labeled for applications to water bodies generally do not contain surfactant, or contain a surfactant approved for direct application to water bodies.

Possible adverse impacts to amphibians resulting from the deregulation of RRA may be offset by the shift from other herbicides used in alfalfa cultivation, which are considered to have higher environmental impacts in general. Additionally, amphibian habitat in watersheds where RRA is produced could be improved through conservation tillage, resulting in decreased soil erosion, decreased sedimentation in runoff, and decreased turbidity in ponds, lakes, and rivers fed by surface waters.

Glyphosate can theoretically be toxic to microorganisms because it inhibits the production of aromatic amino acids through the shikimate pathway. However, field studies show that glyphosate has little effect on soil microorganisms, and, in some cases, field studies have shown an increase in microbial activity due to the presence of glyphosate (USDA FS, 2003).

Glyphosate itself is slightly toxic to amphibians; however, amphibians exhibited greater sensitivity to Roundup® formulations than to glyphosate tested as an acid or isopropylamine (IPA) salt. This could be due to the surfactant (POEA) used in agricultural formulations, which has been found to be more toxic to amphibians and other aquatic animals than the herbicide itself (Lajmanovich et al., 2003). Some researchers have suggested that, in combination with POEA, Roundup® could cause extremely high rates of mortality to amphibians that could lead to eventual population declines (Relyea, 2005). However, the testing methods of the Relyea (2005) study have been called into question due to the high exposure doses, which exceed application rates of glyphosate (regulated by FIFRA), as well as the fact that this Roundup® product is not approved for use in an aquatic setting (USDA APHIS, 2009). Considering the potential for aquatic exposure to glyphosate formulations from terrestrial uses, EPA recently evaluated the effect of glyphosate and its formulations on another amphibian species, the California red-legged frog, and concluded that aquatic exposure to glyhphosate or its formulations posed no risk to this threatened species (EPA, 2008). Because EPA considered a wide range of application rates in their evaluation for the red-legged frog, this conclusion can also be applied to amphibians exposed to glyphosate from applications on GT alfalfa.

3.13.2 Threatened and endangered species

Alternative 1: No Action

Under this alternative RRA would remain regulated, and growers of conventional alfalfa would continue to use a multitude of herbicides for weed control. Many of the herbicides used in conventional alfalfa production have been found to have higher toxicity to certain animal species than glyphosate. Threatened and endangered species within and adjacent to fields of conventional alfalfa would continue to be exposed to these more toxic herbicides. The amphibian habitat in watersheds where conventional and organic alfalfa are grown would continue to be impacted by higher levels of tillage, soil erosion, sedimentation in runoff, and turbidity in ponds, lakes, and rivers than would otherwise be the case if RRA were grown.

Alternative 2: Partial Deregulation of RRA

Under partial deregulation, the acreage of RRA would likely increase with a concomitant increase of glyphosate use for weed control. Based on the information presented below, there is no expected impact based on the ecological safety assessment conducted for glyphosate discussed below (Mortensen et al., 2008) and growers implementation of glyphosate application practices required by Monsanto that are designed to protect threatened or endangered species.

Monsanto recently performed an updated assessment of the impact to threatened and endangered species of glyphosate application to GT crops. The results of this assessment were submitted to USDA as Monsanto Report No. RPN-2007-227 (Mortensen et al., 2008). Monsanto also prepared an endangered species assessment for terrestrial plants that was submitted to USDA (Honegger et al., 2008). The findings of these assessments are as follows:

- Threatened or endangered terrestrial or semi-aquatic plant species are not at risk from ground applications of glyphosate at rates less than 3.5 lb active ingredient per acre (ai/A). Since the maximum single application rate before or after crop emergence in GT alfalfa is 1.55 lb ai/A, no listed plant species are predicted to be at risk from ground application of glyphosate to RRA.
- • Threatened or endangered terrestrial or semi-aquatic plant species are not at risk from aerial applications of glyphosate at rates less than 0.70 lb ai/A. Since rates above 0.7 lb ai/A are needed to control a number of weed species, buffers for aerial application have been proposed by Monsanto (using an EPA-accepted drift model) to permit aerial application at rates up to 1.55 lb ai/acre while still predicting no impact on plant growth at the edge of the buffer. Monsanto has developed a web site, www.Pre-Serve.org, to

provide growers a means to determine if threatened or endangered plant species are potentially at risk from glyphosate applications that they are planning on GT crops. The requirement for growers to consult this web site has been incorporated into the Monsanto Technology/Stewardship Agreement and Technology Use Guide, an agreement that growers sign when purchasing any Monsanto GT seed. Through the implementation of the Pre-Serve web site and its mandated use by growers, threatened and endangered plant species are protected from potential effects from glyphosate use on RRA.

- Other taxa (including birds, mammals, insects, fish, amphibians, aquatic invertebrates, and aquatic plants) are not at risk from the use of glyphosate herbicides in alfalfa production. In addition, other taxa are not at risk from indirect effects resulting from habitat alteration from the use of glyphosate.

Amphibians use a wide range of aquatic habitats for their breeding sites and could be exposed to glyphosate in surface water. Considering the potential for aquatic exposure to glyphosate formulations from terrestrial uses, EPA recently evaluated the effect of glyphosate and its formulations on the California red-legged frog (CRLF). EPA concluded that aquatic exposure to glyphosate and its formulations posed no risk to this threatened species (EPA, 2008). As a part of the endangered species effects assessment for the California red-legged frog, EPA evaluated the effect of glyphosate at application rates up to 7.95 lb ai/A. Based on this assessment, the application of glyphosate at the maximum, single, in-crop application rate specified on the EPA-approved label for RRA (1.55 lb ai/A) would have no effects on threatened and endangered species of fish, amphibians, birds, or mammals.

Although not specifically discussed in the assessment, it can also be determined that there would be no effects of glyphosate or its formulations on threatened or endangered vascular aquatic plants and aquatic invertebrates (EPA, 2008). For terrestrial invertebrates, it was determined that there were no effects on non-endangered species. Although not specifically stated in the CRLF assessment, exposure levels from spray drift to threatened or endangered invertebrates adjacent to RR alfalfa fields are below the level[44] that would result in a conclusion of risk. Additional information has been provided to EPA to also support a conclusion of no risk for small terrestrial invertebrates that might be present in the field at the time of glyphosate application. For terrestrial plants, the potential for effects on non-endangered species was assessed, and using the endpoints and EECs provided, it could be determined that there would

[44] Screening level drift assumptions are one percent for ground applications and five percent for aerial applications.

be no effects on terrestrial plants from ground applications at the maximum single in-crop application rate for RRA.

3.13.3 Potential impact of exposure to RRA

APHIS analyzed the potential impacts to threatened and endangered species from directly contacting, consuming, or hybridizing with RRA and/or their progeny. This analysis considered the effect of production of RRA on designated critical habitat or habitat proposed for designation. The results are as follows:

- RRA is not expected to become more invasive in natural environments or have any difference in effect on critical habitat than their parental non-GT line in the absence of glyphosate selection.
- Analysis of forage samples from several locations demonstrates that RRA is compositionally and nutritionally equivalent to other alfalfa varieties currently on the market. It is not expected to have adverse nutritional effects on any threatened and endangered species that feeds upon it. The RRA CP4 EPSPS protein does not have toxic or pathogenic effects that would affect threatened and endangered species or their critical habitat.
- RRA is not expected to form hybrids with any state or federally listed threatened or endangered species of plant or any plant species proposed for federal listing.

Based on this assessment, APHIS could not identify any difference between the impacts from exposure to RRA and the impacts from exposure to other alfalfa varieties (conventional and organic varieties). Consequently, there would be little or no differences between Alternatives 1 and 2 in terms of the exposure of threatened and endangered species to RRA.

3.14 HUMAN HEALTH AND SAFETY

3.14.1 Consumer health and safety

Because RRA is compositionally and nutritionally identical to non-RRA and because alfalfa forage and seed are not directly consumed by humans, the main issue regarding consumer health and safety is potential dietary exposure to glyphosate herbicide residues. The general public may be exposed to herbicides used on RRA if they consume animal commodities arising from livestock fed on the treated alfalfa. For the reasons described below, this risk is very small, and there would be little or no differences between Alternatives 1 and 2 in terms of the impact of regulation or partial deregulation of RRA on consumer health and safety.

Consumption of adjacent crops impacted by spray drift is a theoretically possible route of exposure, but is not a normal part of dietary risk assessment (EPA, 2000). The predominant route of potential dietary glyphosate exposure to consumers linked to RRA is via consumption of meat / milk from livestock fed on the treated alfalfa. EPA's procedures to estimate dietary exposure fully account for these processes (EPA, 2000; EPA, 1993). EPA has determined that there is a reasonable certainty that no harm will result from aggregate exposure to glyphosate residues (71 Fed. Reg. 76180 (Dec. 20, 2006)). According to the RED (EPA, 1993), glyphosate has relatively low oral and dermal acute toxicity and has been placed in Toxicity Category III for these effects (Toxicity Category I indicates the highest degree of acute toxicity, and Category IV the lowest). The acute inhalation toxicity study was waived because glyphosate is nonvolatile and because adequate inhalation studies with end-use products exist and show low toxicity.

Glyphosate is already used for weed control with conventional alfalfa and other GT crops, including GT corn, GT soybeans, and GT cotton. In addition, it is registered for use in weed control with several fruits and vegetables, and tolerances are established in the consumable commodities of these crops. The current upper estimates of exposure risk for glyphosate are based on highly conservative fruit and vegetable intake rates with an assumed high estimated amount of glyphosate residue. The current aggregate dietary risk assessment completed by EPA concludes there is no concern for any subpopulation regarding exposure to glyphosate, including the use on many fruits and vegetables (71 Fed. Reg. 76180 (Dec. 20, 2006)). Moreover, the potential exists for decreases in the applications and subsequent residues of more toxic herbicides if RRA is partially deregulated.

The use of glyphosate does not result in adverse effects on development at non-maternally toxic doses, reproduction, or endocrine systems in humans and other mammals (EPA, 1993; WHO, 2004; ECETOC, 2009). Under present and expected conditions of use, glyphosate does not pose a health risk to humans (EPA, 1993). Additionally, the nature of glyphosate residue in plants and animals is adequately understood, and studies with a variety of plants indicate that uptake of glyphosate from soil is limited. The material that is taken up is readily translocated throughout the plant. In animals, most ingested or absorbed glyphosate is eliminated in urine and feces. As discussed in Section 3.10, no impacts from consumption of food or feed containing the CP4 EPSPS protein would be expected.

3.14.2 Hazard identification and exposure assessment for field workers

The main issue regarding the health and safety of field workers and RRA is potential worker exposure to glyphosate used for weed control. For the reasons described below, the health risk

from field worker exposure to glyphosate is small when used in accordance with labeling. There would be little or no differences between Alternatives 1 and 2 in terms of the impact of regulation or partial deregulation of RRA on field worker health and safety.

Glyphosate is already used for weed control with conventional alfalfa and other GT crops, including GT corn, GT soybeans, and GT cotton. In addition, it is registered for use in weed control with several fruits and vegetables. So the potential for field worker exposure to glyphosate will continue to exist whether RRA is regulated or deregulated.

With regard to subchronic and chronic toxicity, one of the more consistent effects of exposure to glyphosate at high doses is reduced body weight gain compared to controls. Body weight loss is not seen in multiple subchronic studies, but has at times been noted in some chronic studies at excessively high doses ≥ 20,000 ppm in diet (WHO, 2004). Other general and non-specific signs of toxicity from subchronic and chronic exposure to glyphosate include changes in liver weight, blood chemistry (may suggest mild liver toxicity), and liver pathology (USDA FS, 2003). Glyphosate is not considered a carcinogen; it has been classified by EPA as a "Group E carcinogen", which means that it shows evidence of non-carcinogenicity for humans (EPA, 1993).

EPA's human health analysis considers both the applicator and bystander as having the potential for exposure to glyphosate. Based on the toxicity of glyphosate and its registered uses, including use on GT crops, EPA has concluded that occupational exposures (short-term dermal and inhalation) to glyphosate are not of concern because no short-term dermal or inhalation toxicity endpoints have been identified for glyphosate (71 Fed. Reg. 76180 (Dec. 20, 2006)).

Additional evidence to support the EPA conclusion can be found in the *Farm Family Exposure Study*, a biomonitoring study of pesticide applicators conducted by independent investigators (Acquavella et al., 2004). This biomonitoring study determined that the highest estimated bodily adsorption of glyphosate as the result of routine labeled applications of registered glyphosate-based agricultural herbicides to crops, including GT crops, was approximately 400 times lower than the reference dose (RfD) established for glyphosate. Furthermore, investigators determined that 40 percent of field workers (applicators) did not have detectable exposure on the day of application, and 54 percent of the field workers had an estimated bodily adsorption of glyphosate more than 1000 times lower than the RfD (Acquavella et al., 2004). Use patterns and rates for RRA are typical of most glyphosate agronomic practices. Therefore, the partial deregulation of RRA would not significantly increase the exposure risk to pesticide applicators.

Finally, the biomonitoring study also found little evidence of detectable exposure to individuals on the farm who were not actively involved with or located in the immediate vicinity of application of glyphosate-based herbicides to crops. Considering the similarity of the use pattern and application rates of the glyphosate products in this study compared to those registered for use on RRA and GT crops in general, bystander exposure attributed to the use of glyphosate on GT crops is expected to be negligible.

Based on the above information, the use of currently registered herbicide products containing glyphosate in accordance with the EPA labeling requirements will not pose unreasonable risks or adverse effects to field workers or bystanders. In general, the herbicidal activity of glyphosate is due primarily to a metabolic pathway that does not occur in humans or other animals, and, thus, this mechanism of action is not directly relevant to the human health risk assessment. EPA considers glyphosate to be of low acute and chronic toxicity by the dermal route of exposure. Glyphosate is considered a Category IV dermal toxicant and is expected to cause only slight skin irritation (USDA APHIS, 2009).

3.15 SOCIAL AND ECONOMIC IMPACTS OF THE PROPOSED PARTIAL DEREGULATION

APHIS has studied the potential socioeconomic impacts of fully deregulating RRA (USDA APHIS, 2009, pp. 125-145 & Appendix S). Although the types of potential socioeconomic impacts discussed in the draft EIS under full deregulation would remain the same as under this proposed partial deregulation, the scale (extent and scope) of each impact would be significantly more limited. The proposal restricts (excludes) forage planting of RRA within county-level proximity to 99.5 percent of the U.S. alfalfa seed crop production areas and it would place highly stringent isolation conditions and other requirements on a small, pre-defined group of RRA seed producers.

Simply stated, protection of conventional and organic seed purity has been identified as an important component for the coexistence of GE, conventional and organic agricultural crops, including alfalfa. As it is primarily a geographically-structured approach parsed to the county level by seed vs. forage crop production criteria, the partial deregulation is intended to preclude the possibility for socio-economic impacts (favorable or unfavorable) specifically inter-related with gene flow into >99.5 percent of the U.S. alfalfa seed crop. The remaining approximately 0.5 percent of the seed crop is also unlikely to be impacted because when and if grown in local proximity to a RRA forage crop (<165 ft), the RRA forage producers would be required to

mitigate the amount of available RRA pollen by cutting the RRA hay crop prior to 10 percent bloom.

USDA has clearly endorsed coexistence of GE, conventional and organic growers, crops and markets. During the period in which USDA/APHIS finalizes a court-ordered EIS and prepares a record of decision on the deregulation of RRA, the terms of the proposed Partial Deregulation cautiously parse out the areas of primary "gene flow interface" between RRA and conventional alfalfa, enabling immediate RRA grower benefits without interfering with conventional and organic crops and markets. The proposed partial deregulation conditions will enable, without restriction, the continued supply of conventional variety seeds and basic generation seeds for export, organic or domestic use. It would also allow producers to choose to use or not use RRA on approximately seventy-eight percent (78%) of U.S. forage production acres and enable a nominal number of RRA seed growers on seed production acres where extraordinary isolation exists. The actual adoption of the technology by forage growers is anticipated to be some fraction of the eligible (allowed) alfalfa acreage total in each region of the U.S. (Appendix G). Those most likely to adopt the technology are those producers serving dairy herd forage needs. However, pending completion of an EIS and a final deregulation decision, this partial deregulation would not uniformly enable all forage or seed growers the choice to participate in the socio-economic benefits of the technology, and moreover, in future years, it is possible that RRA seed supplies could fall short of RRA seed demand or that forage market inequities might develop between competing geographies with and without the technology.

It is likely that through improvements to weed management, the widespread adoption of the RRA technology by growers could result in economic benefits related to the quantity and improved forage quality of U.S. hay supplies (see below). Forage producers and dairy producers may most directly benefit from more abundant supplies of dairy quality forage with fewer weeds. Organic forage, dairy, and other food producers would also be likely to economically benefit from increased market share related to the newly-heightened market differentiation between organic and non-organic dairy and forage production strategies, e.g., the organic dairy food customer base may increase if a proportion of conventional consumers begin to purchase organic foods due to a negative perception of GE alfalfa. Since the RRA crops were first grown (2005-2007) the organic dairy sector has experienced market growth. According to several independent analyses (Putnam and Undersander, 2009, attached as Appendix I; Van Deynze et al., 2008; NAFA, 2008d; Putnam, 2006; Putnam, 2007), organic forage supplies and organic farming practices are unlikely to be at economic risk, adversely

impacted, or materially affected by the deregulation or growing of RRA. Simple, minimal/no-cost effective methods are available to organic and conventional forage producers wishing to avoid RRA irrespective of their neighbor's choice to grow RRA seed or hay crops. Specifically, organic or non-GE forage producers need only to cut their hay before seed ripens, purchase non-GE planting seeds qualified for organic use and maintain organic hay lot segregation; i.e., follow current routine farm plans required by the NOP. Organic dairy or livestock producers will continue to grow and/or purchase only organically qualified (identity-preserved, segregated) feedstuffs; i.e., follow current routine farm plans required by the NOP. A minority, approximately 3 to 5 percent, of total alfalfa production may be sensitive to GE traits (Putnam, 2007). Therefore, it may be reasoned that a similar percentage of U.S. alfalfa forage growers would opt to take these nominal steps to avoid RRA trait presence in their conventional hay crops.

Forage production. Benefits to farm socio-economics include improvements to grower profitability, consistent and abundant on-farm forage supply, and, the ease and flexibility of weed control.

As indicated above, in the defined geographies where RRA forage production would be allowed with restrictions for new plantings (Table 1-1 and Appendix B of this ER), forage producers would have a new tool available for weed management throughout the life of the stand. Forage producers (n=201) who have previously commercially used the RRA technology report an average increase in productivity of 0.9 total acres per year (T/A/yr) which translates to approximately $100 acre per year (A/year) incremental crop value at an average hay price of $110 total (T) (RRA Satisfaction Study, Market Probe, 2008, attached as Appendix H). Over the life of the stand (e.g., 3 to 5 years), the approximate incremental value of RRA forage production is $300 to $500 per acre (A).

Like growers of other GE crops, many growers of RRA also report experiencing intangible social benefits (see examples of Public Comments to draft EIS included in Appendix F). Specifically, growers report that the RRA technology improves their farming experience in that weed control is easier, simpler, more reliable (less risk of failure), herbicide timing is more flexible and crop injury (stress) is lessened. They also acknowledge the lessened risk to water sheds and to herbicide applicators (self, family and employees) compared to several other herbicide choices. Relative to their economic benefits and risks, currently available weed management strategies may not be implemented at all because they can be expensive, ineffective on target weeds, restricted in use due to environmental or worker safety issues, difficult to apply at the correct time for good control, and some measures reduce alfalfa crop yield or stand longevity more than

the weeds (e.g., early clipping, companion and cover crops). RRA growers note that the RRA technology is especially beneficial for weed control during the early seedling establishment period when the new planting can be at risk of failure (complete loss) due to unchecked weed competition. Although there are many reasons why alfalfa plantings fail in the first year, growers who adopt RRA would likely have less exposure to economic risk and intangible uncertainty associated with the possibility of losing their valuable planting inputs, meanwhile ensuring a more consistent supply of nutritious forage for livestock than the alfalfa growers not adopting the technology.

Seed Production. Socio-economic benefits related to RRA seed production include: improved profitability for RRA seed growers; the benefits described above associated with improved weed control; and a seed supply of new RRA varieties targeting new production niches, thus enabling the forage benefits described herein.

The seed producer consortia outlined in Table 1-2 have several things in common. These growers all produced RRA seed in 2006, 2007, 2008 and/or 2009. They will receive FGI training on RRA Seed Production Best Practices and will be monitored by FGI for compliance as required by the NAFA BMP and the proposed conditions for partial deregulation. These growers also all produce seed in a setting that allows substantial isolation from conventional alfalfa seed production. Table 1-2 shows the existing isolation, and the minimum required isolation required in future years under the terms of this partial deregulation. In all cases the required isolation exceeds the NAFA RRA Seed Production Best Practices.

Pollen-mediated gene flow is inversely proportional to isolation distance, and varies by introduced pollinator species. Any new RRA seed production with the growers and production areas outlined in Table 1-2 will have a minimal impact on conventional or organic seed production targeted for either U.S. or export markets.

SECTION 4.0 CUMULATIVE IMPACTS

This section discusses the cumulative impacts that may be associated with Alternative 2, when combined with other recent past, present, and reasonably foreseeable future actions within the affected environment. Cumulative impacts that will occur are expected to be negligible.

Cumulative impacts occur when the effects of an action are added to the effects of other actions occurring in a specific geographic area and timeframe. The cumulative impact analysis follows CEQ's guidance: Considering Cumulative Effects Under the National Environmental Policy Act (CEQ, 1997). The steps associated with the analysis include:

- Specify the class of actions for which effects are to be analyzed.
- Designate the appropriate time and space domain in which the relevant actions occur.
- Identify and characterize the set of receptors to be assessed.
- Determine the magnitude of effects on the receptors and whether those effects are accumulating.

4.1 CLASS OF ACTIONS TO BE ANALYZED

This analysis addresses regional and national actions that may have impacts that may accumulate with those of the proposed partial deregulation measures.

4.2 GEOGRAPHIC AND TEMPORAL BOUNDARIES FOR THE ANALYSIS

As described in Section 2, over the past 60 years, the number of alfalfa hay acres harvested annually in the U.S. has ranged between 20.7 million acres (2010) and 29.8 million acres (1957), with peak tonnage of hay production in the mid-1980s (USDA ERS, 2010a). In 2006, 20.9 million acres of alfalfa was harvested for forage. (In contrast, 122.1 acres of alfalfa was harvested for seed.) Alfalfa is grown for forage throughout the U.S. Based on 2008 production data by county, the four major U.S. alfalfa producing regions include the north-central, west, northeast, and south, with the north-central and the west regions being the highest producing regions in the U.S.

Under this proposal, we anticipate that any future alfalfa planting under partial deregulation will conform to the geographic use restrictions described herein, with the exception of a minimal number of acres (e.g. less than 100 acres) that may be produced under APHIS permit. In the event this proposal is granted, the small and declining number of RRA acres planted under APHIS permit will not have incremental cumulative impact on any of the resource areas.

Activities relevant to the cumulative impacts analysis have been identified from reviews of information available from government agencies, such as NEPA documents, land-use and natural resource management plans, and from private organizations. Not all actions identified in this analysis would have cumulative impacts on all resource areas.

4.3 RESOURCES ANALYZED

Issues evaluated in this cumulative impacts analysis include some of the resource areas discussed in Sections 2 and 3 including land use, air quality and climate, water quality, biological, and human health and safety. In addition, specific topics analyzed include: cumulative impacts related to any possibility of development of glyphosate resistant weeds, and cumulative impacts of potential increased glyphosate usage with the cultivation of GT crops.

4.4 CUMULATIVE IMPACTS RELATED TO THE DEVELOPMENT OF GLYPHOSATE RESISTANT WEEDS

Glyphosate offers many benefits to the grower as a weed control product. Glyphosate controls a broad spectrum of grass and broadleaf weed species present in U.S. production fields, has flexible use timings, and when used in GT crops, has a very high level of crop safety. As the adoption of GT crops has grown, the use of glyphosate has increased over the past several years. As discussed in Section 3, with the increased use of glyphosate, there is also the potential for increased selection pressure for the development of new glyphosate-resistant weed populations and/or new glyphosate-resistant weed species.

As discussed in Section 2.4, there is a low probability for the development of new glyphosate-resistant weed populations and/or development of new resistance weed species from the use of glyphosate herbicides in conjunction with plantings of RR alfalfa. The expected use pattern of herbicides, including glyphosate, in alfalfa and the alfalfa production practices (e.g. frequent mowing) provides a basis for retarding the development of new resistance. It also provides a basis for managing resistance that may be present from movement of a resistant weed seed into an alfalfa field or cross-pollination from a resistant weed to a sexually compatible weed within an alfalfa field.

As discussed in Section 3.11.14, market research studies indicate that growers of glyphosate-tolerant crops are increasingly taking measures to minimize the potential for development of glyphosate resistance. Based on the adoption of these measures by growers of other GT crops such as GT corn, GT soybeans, and GT cotton (Frisvold et al., 2009), similar adoption of these measures by GT alfalfa growers is anticipated. In all three of these other GT crops, growers are

adopting best management practices, in particular the more frequent use of complementary herbicides in a glyphosate-based weed management programs in corn (Givens et al., 2009; Frisvold et al., 2009). The key best management practices recommended by industry and academics to control against weed resistance are as follows : a) identifying weeds and monitoring for escapes to determine if current practices need to be modified to achieve acceptable levels of weed control, b) using proper herbicide rates and timing, c) using crop rotation to facilitate use of different modes of action over time, d) using agronomic management practices to supplement herbicide weed control, e) alternating herbicides with different modes of action, and e) tank mixing herbicides of different modes of action (HRAC, 2009; Orloff et al., 2009; Monsanto, 2010a).

Increased glyphosate use is not expected in the major GT crops (corn, soybeans and cotton), as GT usage in these crops is high and likely not to increase beyond current levels. As discussed above and in Section 3.11, there is a high level of awareness among growers of these crops of the need to minimize the potential for development of glyphosate resistance, and evidence that growers are implementing management practices to prevent the development of glyphosate resistant weeds.

These management practices for all glyphosate-tolerant crops, combined with the specific alfalfa weed management practices discussed in Section 2.4, will together help minimize the cumulative potential for development of glyphosate resistant weeds under Alternative 2. Thus, Alternative 2 is not expected to contribute to cumulative adverse impacts on the development of glyphosate-resistant weeds.

4.5 CUMULATIVE IMPACTS OF POTENTIAL INCREASED GLYPHOSATE USAGE

The increase in glyphosate used under the proposed interim measures described in this ER (Alternative 2), would be minimal. Assuming a 50 percent market share, the amount of glyphosate applied to RRA would be 1,627,500 lb a.e (0.5 x 21 million total alfalfa acres X 1.55 lb a.e./A). Calculating from Table N-3 on page N-16 in the draft EIS, total use of glyphosate on corn, cotton, soybean, and wheat is equal to 126,308,000 lbs. Therefore, even if glyphosate is used on 50 percent of total alfalfa acres, the glyphosate use on alfalfa would be 1.3 percent of the glyphosate used on these four major crops.

According to the USDA ERS (2009), U.S. farmers have adopted genetically engineered crops widely since their introduction in 1996. Soybeans and cotton genetically engineered with herbicide-tolerant traits have been the most widely and rapidly adopted GE crops in the U.S.,

followed by insect-resistant cotton and corn. Figure 4-1 shows the percentage of acres of genetically engineered crops in the U.S. between 1996 and 2009. Appendix G charts data from Monsanto/FGI of the anticipated adoption of RRA under Alternative 2 over a 10 year period.

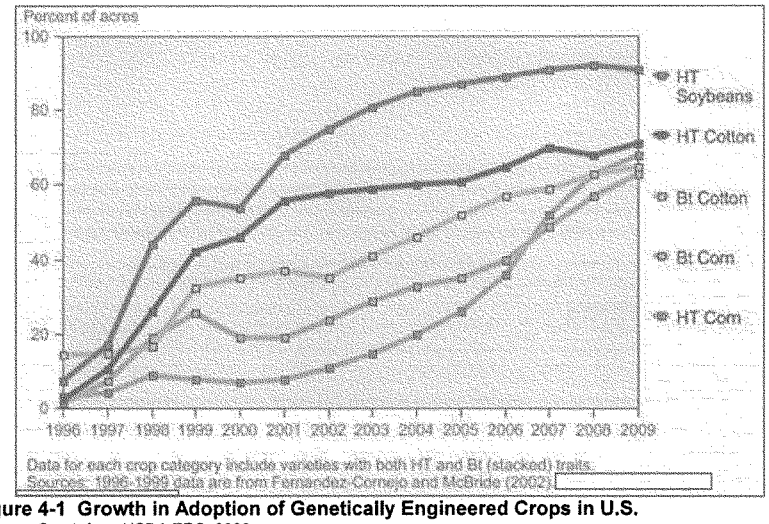

Figure 4-1 Growth in Adoption of Genetically Engineered Crops in U.S.
Source: Graph from USDA ERS, 2009

Herbicide-tolerant crops, which are engineered to survive application of specific herbicides that previously would have damaged the crop, provide farmers with a broader variety of options for effective weed control. Based on USDA survey data, herbicide tolerant soybeans went from 17 percent of U.S. soybean acreage in 1997, to 68 percent in 2001 and 91 percent in 2009. Plantings of herbicide tolerant cotton expanded from approximately 10 percent of U.S. acreage in 1997 to 56 percent in 2001 and 71 percent in 2009. The adoption of herbicide tolerant corn was slower in previous years, but has reached 68 percent of U.S. corn acreage in 2009 (USDA ERS, 2009).

Corn growers use the largest volume of herbicides. Approximately 96 percent of the 62.2 million acres used for growing corn in the 10 major corn-producing States were treated with more than 164 million pounds of herbicides in 1997 (USDA ERS, 2009). Soybean production in the U.S. also uses a large amount of herbicides. Approximately 97 percent of the 66.2 million soybean acres in the 19 major soybean-producing States were treated with more than 78 million pounds of herbicides in 1997 (USDA ERS, 2009). Cotton production relies heavily on

herbicides to control weeds, often requiring applications of two or more herbicides at planting and postemergence herbicides later in the season (Culpepper and York, 1998). Close to 28 million pounds of herbicides were applied to 97 percent of the 13 million acres devoted to upland cotton production in the 12 major cotton-producing States in 1997 (USDA ERS, 2009).

Pesticide use on corn and soybeans has declined since the introduction of GE corn and soybeans in 1996. Several studies have analyzed the agronomic, environmental, and economic effects of adopting GE crops, including actual pesticide use changes associated with growing GE crops (McBride and Brooks, 2000; Fernandez-Cornejo, Klotz-Ingram, and Jans, 1999, 2002; Giannessi and Carpenter, 1999; Culpepper and York, 1998; Marra et al., 1998; Falck-Zepeda and Traxler, 1998; Fernandez-Cornejo and Klotz-Ingram, 1998; Gibson et al., 1997; ReJesus et al., 1997; Stark, 1997). Many of these studies have concluded that herbicide use is reduced with herbicide-tolerant varieties (USDA ERS, 2009).

Studies conducted by the USDA shows an overall reduction in pesticide use related to the increased adoption of GE crops. Based on the adoption of GE crops between 1997 and 1998 (except for herbicide-tolerant corn, which is modeled for 1996-97), the decline in pesticide use was estimated to be 19.1 million acre-treatments, 6.2 percent of total treatments (USDA ERS, 2009). Most of the decline in pesticide acre treatments was from less herbicide used on soybeans, which accounts for more than 80 percent of the reduction (16 million acre-treatments) (USDA ERS, 2009).

The adoption of herbicide-tolerant crops such as RRA, GT soybeans, and GT corn results in the substitution of glyphosate for previously used herbicides. The GT crops allow farmers to limit and simplify herbicide treatments based around use of glyphosate, while a conventional weed control program can involve multiple applications of several herbicides. In addition, and more importantly, herbicide-tolerant crops often allow farmers to use more benign herbicides (USDA ERS, 2009).

There are known benefits associated with the use of glyphosate herbicides compared to herbicides currently used by alfalfa producers. Glyphosate has documented favorable characteristics with regard to risk to human health, non-target species, and the environment (Malik et al., 1989; Williams et al., 2000). Glyphosate is classified by the EPA as Group E (evidence of non-carcinogenicity for humans) (57 Fed. Reg. 8739 (Mar. 12, 1992)). In 1998, the EPA granted Reduced Risk status for an expedited review of the submitted residue data package supporting the use of glyphosate.

Petitions for non-regulated status are pending for additional events or lines of GT soybean, corn, sugar beets, and creeping bentgrass (USDA APHIS, 2010). If deregulated, the production of new GT crops would lead to increased glyphosate application, and in the instances that it is cultivated in or near the same geographic areas where RRA is produced, this could lead to a cumulative impact on non-target plants impacted by glyphosate. However, given that these acres are already being used for agricultural production (in the case of corn and soybeans, most likely through a RR cropping system), these plants are likely already exposed to glyphosate or other pesticides.

Studies of the relationship between genetically engineered crops and herbicide use has shown that an increase in GT crops can result in a decrease in mechanical tillage (Brimner et al., 2005; Fernandez-Cornejo, 2006; Gianessi and Reigner, 2006; Kleter et al., 2007; Sankula, 2006; Johnson et al., 2008). The potential cumulative impact from this reduction in mechanical tillage is discussed in the following sections.

4.6 CUMULATIVE IMPACTS ON LAND USE, AIR QUALITY AND CLIMATE

As discussed in Section 2, alfalfa acreage has fluctuated little for the past 60 years, although acreage has generally been declining since the mid-1980s. Acreage used for alfalfa would not be expected to be impacted by increased RRA plantings. Therefore, as discussed in Section 3, Alternative 2 is not expected to impact land use directly or indirectly, other than the anticipated shift of certain acreage from conventional or organic alfalfa production to RRA production as a result of a partial deregulation (See Appendix G charting anticipated adoption of RRA under Alternative 2), and no cumulative impacts on land use are anticipated from Alternative 2.

As discussed in Section 3, Alternative 2 is expected to have positive impacts on air quality and climate, primarily resulting from reduced tillage. Consequently, Alternative 2 is not expected to have any adverse cumulative impacts on air quality or climate.

4.7 CUMULATIVE IMPACTS ON WATER QUALITY

As discussed in Section 3, the advent of GT crops and the use of post-emergent herbicides that could be applied over a crop during the growing season have facilitated the use of conservation tillage farming practices, since weeds could be controlled after crop growth without tilling the soil (USDA ERS, 2009). The use of GT crops (particularly soybeans) has intensified that trend since it often allows a more effective and less costly weed control regime than using other post-emergent herbicides (USDA ERS, 2009; Carpenter and Gianessi, 1999).

The impact of conservation tillage (including no-till, ridge-till, and mulch-till) in controlling soil erosion and soil degradation is well documented (Edwards, 1995; Sandretto, 1997). By leaving substantial amounts of plant matter over the soil surface, conservation tillage 1) reduces soil erosion by wind; 2) reduces soil erosion by water; 3) increases water infiltration and moisture retention; 4) reduces surface sediment and water runoff; and 5) reduces chemical runoff (USDA ERS, 2009).

Glyphosate may potentially be found in surface water runoff when erosion conditions lead to the loss of surface particles. However, as discussed in Section 3, partial deregulation of GT crops typically leads to an increase in conservation tillage and no tillage systems, which results in less mechanical disturbance of the soil during alfalfa cultivation and thereby decrease the loss of surface soil. Consequently, given that glyphosate binds strongly to soil particles and has no herbicidal activity after binding to soil, no-tillage and conservation tillage are expected to further reduce the likelihood of any impact of surface water runoff (Wiebe and Gollehon, 2006). Therefore, no cumulative adverse impacts to surface water or groundwater are anticipated.

4.8 CUMULATIVE BIOLOGICAL IMPACTS

For non-target terrestrial species, available ecological assessments in EPA RED (EPA, 2003) documents or registration review summary documents provide the support that the use of glyphosate represents reductions in chronic risk to birds compared to benfluralin, norflurazon, paraquat, sethoxydim, and trifluralin, and in acute risk to small mammals in comparison to bromoxynil, EPTC, and paraquat. For other alfalfa herbicide products, as well as glyphosate, no significant risks to birds or other non-target terrestrial species were indicated in the available information.

For non-target aquatic species, Tables 4-1, 4-2, and 4-3 provide summaries of the estimated exposure and hazard information for the traditional herbicides used in conventional alfalfa production, and present quantitative comparisons of the derived Risk Quotients. Exposure, defined as the EEC, was calculated for all products using the assumptions (assuming aerial application) of 5 percent drift of spray applied to a one-acre field onto water and 5 percent runoff from 10 treated acres into a one-acre pond six feet in depth. Herbicide treatments were based on the maximum single application rate for alfalfa taken from product labels. Hazard information (LC50 or EC50) for each active ingredient was taken from the EPA Ecotoxicology One-Liner Database (if available) or other EPA source documents and summarized in Tables 4-1, 4-2, and 4-3 as the upper and lower values from the range of values reported. Hazard information for the end-use formulated products is generally not readily available; thus, this analysis is a

comparison based solely on the active ingredients. Any label warnings and other available hazard and/or risk descriptions for non-target aquatic species are also included. The Risk Quotient is determined for each active ingredient by dividing the EEC by the hazard (LC50 or EC50) value.

Plants potentially at risk from the use of glyphosate are potentially at risk from the use of any herbicide. Like most herbicides, plants are highly sensitive to glyphosate. Monsanto has developed a program named Pre-Serve to address the use of glyphosate, including aerial spraying, in areas where threatened plants may be located. Following use instructions on the EPA-approved label and use limitations described in Pre-Serve would address any such risk of exposure. Federal law requires pesticides to be used in accordance with the label. Conservation tillage and no tillage practices provide additional assurance that the impact to aquatic plants is reduced by decreasing soil-laden runoff.

The EPA-approved labels for products containing 2,4-DB, celthodim, sethoxydim, and trifluralin include warnings of toxicity or adverse effects to fish, and/or aquatic invertebrates and/or aquatic plants. Risk Quotients that exceed the Trigger Value of 0.5 for aquatic animals and 1.0 for aquatic plants are highlighted in bold text in Tables 4-1, 4-2, and 4-3 as exceeding a Level of Concern, based on EPA Ecological Effects Rejection Analysis and Deterministic Risk Characterization Approach. Current alfalfa herbicide products containing benfluralin, bromoxynil, diuron, hexazinone, metribuzin, norflurazon, paraquat, terbacil, and trifluralin are shown to exceed these Levels of Concern. As supported by the EPA designation of reduced risk for application of glyphosate to alfalfa, glyphosate is a more environmentally preferred herbicide compared to other herbicides currently used in alfalfa production since glyphosate is generally less toxic and has favorable degradation properties.

Table 4-1. Comparison of Potential Effects of Glyphosate and Alfalfa Herbicides on Freshwater Fish

Active Ingredient	Max. lb/acre (single appl.)	EEC[1] (ppm)	Fish LC_{50} (a.i.)[2] Range (ppm)		Fish Risk Quotient[3] Range		Classification / Label Warnings

4.9 CUMULATIVE IMPACTS ON HUMAN HEALTH AND SAFETY

Where pesticides may be used on food or feed crops, EPA sets tolerances (maximum pesticide residue levels) for the amount of the pesticide residues that can legally remain in or on foods. EPA undertakes this analysis under the authority of the Federal Food, Drug, and Cosmetic Act (FFDCA). Under the FFDCA, EPA must find that such tolerances will be safe, meaning that there is a reasonable certainty that no harm will result from aggregate exposure to the pesticide chemical residue. This finding must be made and the appropriate tolerance established before a pesticide can be registered for use on the particular food or feed crop in question (USDA APHIS, 2009).

Another potential impact of the use of glyphosate on human health is pesticide applicator exposure related to the increased glyphosate usage. Biomonitoring of pesticide applicators conducted by independent investigators has shown that bodily adsorption of glyphosate as the result of routine, labeled applications of registered glyphosate-based agricultural herbicides to crops, including to RRA, was thousands of times less than the allowable daily intake level established for glyphosate (Acquavella et al., 2004). Given similarity in use pattern and rates, the commercialization of RRA will not significantly increase the exposure risk to pesticide applicators. Furthermore, EPA, the European Commission, the WHO, and independent scientists have concluded that glyphosate is not mutagenic or carcinogenic, not a teratogen nor a reproductive toxicant, and that there is no evidence of neurotoxicity associated with glyphosate (EPA, 1993; EC, 2002; WHO, 2004; Williams et al., 2000).

Bystander exposure to glyphosate as a result of pesticide application to RRA would be negligible, since such applications would occur in an agricultural setting in relatively rural alfalfa fields, not in an urban setting. A biomonitoring study found little evidence of detectable exposure to individuals on the farm who were not actively involved with or located in the immediate vicinity of application of glyphosate-based herbicides to crops (Acquavella et al., 2004) Considering the similarity of the use pattern and application rates of the glyphosate products in this study compared to those registered for use on RRA and GT crops in general, bystander exposure attributed to the use of glyphosate on GT crops is expected to be negligible.

4.10 CUMULATIVE SOCIAL AND ECONOMIC IMPACTS

As discussed above in Sec. 3.15, the potential for gene flow from RRA seed acreage to conventional or organic alfalfa could have an adverse economic impact on conventional or organic growers who expect to receive a premium for their crops in markets that demand non-

RRA products. The partial deregulation measures proposed in Alternative 2, including isolation distances associated with seed production, are specifically designed to render the risk of any such impacts de minimis. Moreover, the reproductive biology of the alfalfa plant combined with normal harvest management for alfalfa forage provide for a de minimis likelihood of gene flow from one forage production field to another. Those producing organic or non-GE hay are likely required to maintain cultivation standards required by the NOP or identity preservation contracts that provide additional assurances against gene flow. While some of these growers may enter into contractual agreements that require testing for the presence of GE plant material, those tests are simple and inexpensive. Hay failing to meet contractual standards may still be sold as commodity hay.

It is anticipated that growers who plant RRA under Alternative 2 will experience economic benefits related to the quantity and improved forage quality of U.S. hay supplies. Growers have reported other socio-economic benefits, including greater flexibility, safety, ease and simplicity of weed control. APHIS has studied the potential socioeconomic impacts of fully deregulating RRA (USDA APHIS, 2009, pp. 125-145 & Appendix S).

4.11 SUMMARY OF POTENTIAL CUMULATIVE IMPACTS

When considering the impact that the use of glyphosate could have on the human environment in conjunction with other GT crops already being cultivated in the same affected environments, the facts suggest that increased use of glyphosate on acreage that shifts from conventional or organic alfalfa production to RRA production will have little, if any, additive effect. Alternatively, this new use of glyphosate has the potential to reduce risks to the affected environment from the use of other, more harmful, herbicides on these limited acreages. This is supported by the assessment of the hazards associated with glyphosate when compared to other available herbicides used for weed control in alfalfa production. Subsequently, there is no reasonably anticipated adverse cumulative impact on human health or the environment from the use of glyphosate associated specifically with Alternative 2.

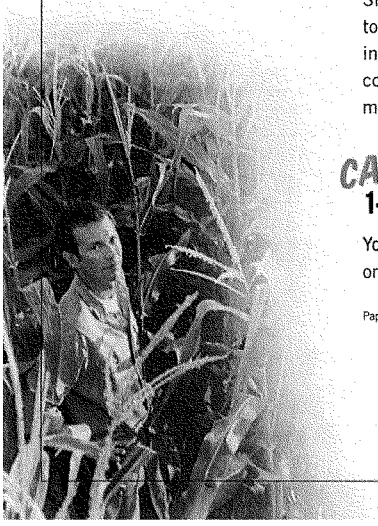
*Pesticides registered by the U.S. EPA will not cause unreasonable adverse effects to man or the environment when used in accordance with label directions.



RE:NEW

YOUR ABILITY TO ENHANCE YOUR CROPS TODAY!

It's time to ReNEW your license

If you haven't renewed your Monsanto Technology/Stewardship Agreement (MTSA) in the past nine months, **take care of it today!**

Signing the MTSA ensures you'll have access to current and next-wave technologies. These innovations will enhance plant drought tolerance, cold tolerance, nitrogen use efficiency, yield and much more!

CALL

1-800-768-6387, Option 3

You'll then have the option to complete the process online or through conventional mail.

Paper MTSA's will continue to be accepted.

Introduction

This 2010 Technology Use Guide (TUG) provides a concise source of technical information about Monsanto's current portfolio of technology products and sets forth requirements and guidelines for the use of these products. As a user of Monsanto Technology, it is important that you are familiar with and follow certain management practices. Please read all of the information pertaining to the technology you will be using, including stewardship and related information. Growers must read the Insect Resistance Management (IRM)/Grower Guide prior to planting for important information on planting and IRM.

This technical guide is not a pesticide product label. It is intended to provide additional information and to highlight approved uses from the product labeling. Read and follow all precautions and use instructions in the label booklet and separately published supplemental labeling for the Roundup® agricultural herbicide product you are using.

Included in this guide is information on the following:

Stewardship Overview	4
Introducing Genuity™	6
Insect Resistance Management	8
Weed Management	10
Coexistence and Identity Preserved Production	12
Corn Technologies	15
YieldGard® and Genuity™ Corn Technologies Product Descriptions	
Roundup Ready® Technology in Corn	
Cotton Technologies	21
Genuity™ Bollgard II® and Bollgard® Cotton	
Roundup Ready Technologies in Cotton	
Genuity™ Roundup Ready 2 Yield® and Roundup Ready Soybeans	31
Genuity™ Roundup Ready® Alfalfa	35
Genuity™ Roundup Ready® Spring Canola	38
Genuity™ Roundup Ready® Winter Canola	39
Genuity™ Roundup Ready® Sugarbeets	40

If you have any questions, contact your Authorized Retailer or Monsanto at 1-800-768-6387.

A Message About Stewardship - SEED AND TRAITS

Monsanto Company is committed to enhancing farmer productivity and profitability through the introduction of new agricultural biotechnology traits. These new technologies bring enhanced value and benefits to farmers, and farmers assume new responsibilities for proper management of these traits. Farmers planting seed with biotech traits agree to implement good stewardship practices, including, but not limited to:

- Reading, signing and complying with the Monsanto Technology/Stewardship Agreement (MTSA) and reading all annual license terms updates before purchase or use of any seed containing a trait.
- Reading and following the directions for use on all product labels.
- Following applicable stewardship practices as outlined in this TUG.
- Reading and following the IRM/Grower Guide prior to planting.
- Observing regional planting restrictions mandated by the U.S. Environmental Protection Agency (EPA).
- Complying with any additional stewardship requirements, such as grain or feed use agreements or geographical planting restrictions, that Monsanto deems appropriate or necessary to implement for proper stewardship or regulatory compliance.
- Following the Weed Resistance Management Guidelines to minimize the risk of resistance development.
- Complying with the applicable IRM practices for specific biotech traits as *mandated* by the EPA and set forth in this TUG.
- Utilizing all seed with biotech traits only for planting a single crop.
- Selling crops or material containing biotech traits only to grain handlers that confirm their acceptance, or using those products on farm.
- Not moving material containing biotech traits across boundaries into nations where import is not permitted.
- Not selling, promoting and/or distributing within a state where the product is not yet registered.

CROP OR MATERIAL HANDLING STEWARDSHIP STATEMENT

Monsanto Company is a member of Excellence Through Stewardship® (ETS). Monsanto products are commercialized in accordance with ETS Product Launch Stewardship Guidance, and in compliance with Monsanto's Policy for Commercialization of Biotechnology-Derived Plant Products in Commodity Crops. This product has been approved for import into key export markets with functioning regulatory systems. Any crop or material produced from this product can only be exported to, or used, processed or sold in countries where all necessary regulatory approvals have been granted. It is a violation of national and international law to move material containing biotech traits across boundaries into nations where import is not permitted. Growers should talk to their grain handler or product purchaser to confirm their buying position for this product. Excellence Through Stewardship® is a registered trademark of Biotechnology Industry Organization.

WHY IS STEWARDSHIP IMPORTANT?

Each component of stewardship offers benefits to farmers:

- Signing the MTSA provides farmers access to Monsanto's biotech trait seed technology.
- Following IRM guidelines guards against insect resistance to *Bacillus thuringiensis (B.t.)* technology and therefore enables the long-term viability of this technology, and meets EPA requirements.
- Proper weed management maintains the long-term effectiveness of glyphosate-based weed control solutions.
- Utilizing biotech seed only for planting a single-commercial crop helps preserve the effectiveness of biotech traits, while allowing investment for future biotech innovations which further improves farming technology and productivity.

Practicing these stewardship activities will enable biotechnology's positive agricultural contributions to continue.

Farmers' attitudes and adoption of sound stewardship principles, coupled with biotechnology benefits, provide for the sustainability of our land resources, biotechnology and farming as a preferred way of life.

SEED PATENT INFRINGEMENT

If Monsanto reasonably believes that a farmer has planted saved seed containing a Monsanto biotech trait, Monsanto will request invoices and records to confirm that fields in question have been planted with newly purchased seed. If this information is not provided within 30 days, Monsanto may inspect and test all of the farmer's fields to determine if saved seed has been planted. Any inspections will be coordinated with the farmer and performed at a reasonable time to best accommodate the farmer's schedule.

If you have questions about seed stewardship or become aware of individuals utilizing biotech traits in a manner other than as noted above, please call 1-800-768-6387. Letters reporting unacceptable or unauthorized use of biotech traits may be sent to:

Monsanto Trait Stewardship
800 N. Lindbergh Boulevard NC3C
St. Louis, MO 63167

For more information on Monsanto's practices related to seed patent infringement, please visit: www.monsanto.com/seedpatentprotection.

Provide Anonymous or Confidential reports as follows:

"Anonymous" reporting results when a person reports information to Monsanto in such a way that the identity of the person reporting the information cannot be identified. This kind of reporting includes telephone calls requesting anonymity and unsigned letters.

"Confidential" reporting results when a person reports information to Monsanto in such a way that the reporting person's identity is known to Monsanto. Every effort will be made to protect a person's identity, but it is important to understand that a court may order Monsanto to reveal the identity of people who are "known" to have supplied relevant information.

The Beyond the Seed Program was launched by the American Seed Trade Association (ASTA) to raise awareness and understanding of the value that goes beyond the seed. The future success of U.S. agriculture depends upon quality seed delivered by an industry commitment to bring innovation and performance through continued investment. For more information about seed technology, visit ASTA's Beyond the Seed Program at www.beyondtheseed.org.

Genuity™ Unites the Best Traits*

As a purchaser of Monsanto biotech trait products, your investment helps fuel the research and development engine that leads to the discovery and delivery of new technologies for agriculture. Current and future Genuity™ traits are designed to deliver high yield potential, maximize return on seed investments and consistently deliver future trait innovations.

CORN

Higher yields come from quality grain. Genuity™ VT Triple PRO™ was the next generation of corn technology available for the 2009 growing season. Genuity™ VT Triple PRO™ provides dual modes of action against above-ground pests such as corn earworm, European and southwestern corn borers, sugarcane borer, southern cornstalk borer and fall armyworm. Reduced kernel damage from corn earworm means the potential for reduced Aflatoxin contamination. Genuity™ VT Triple PRO™ dual modes-of-action also allows for a reduction in refuge acres required in southern cotton-growing regions while providing long-term effectiveness and consistency.

GENUITY™ SMARTSTAX™

Scheduled for launch in 2010, Genuity™ SmartStax™ is the most-advanced, all-in-one corn trait system that controls the broadest spectrum of above- and below-ground insects and weeds. Genuity™ SmartStax™ provides control of corn earworm, European corn borer, southwestern corn borer, sugarcane borer, fall armyworm, western bean cutworm, black cutworm, western corn rootworm, northern corn rootworm and Mexican corn rootworm. Genuity™ SmartStax™ contains Roundup Ready® 2 Technology and LibertyLink® herbicide tolerance. Genuity™ SmartStax™ also allows for a reduction in refuge acres in the corn belt from 20% down to 5% for above- and below-ground refuge. Genuity™ SmartStax™ is also approved for a 20% refuge in the cotton belt.

SOYBEAN

Genuity™ Roundup Ready 2 Yield® soybeans are taking yield to a higher level. They were developed to provide farmers with the same simple, dependable and flexible weed control and crop safety they've come to rely on with the first-generation Roundup Ready® soybean system, but with higher yield potential. This is possible because of advanced insertion and selection technologies.

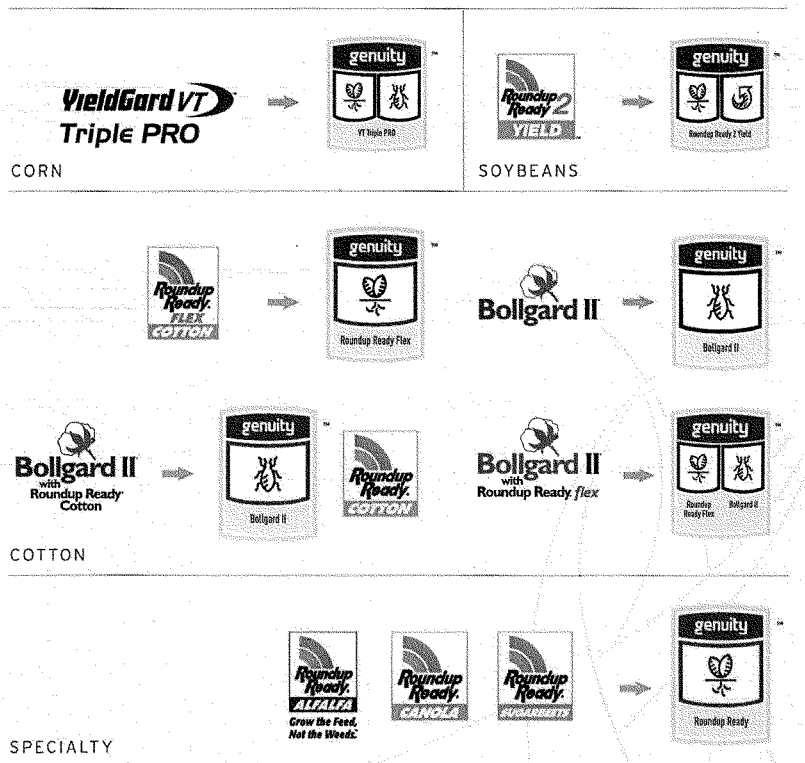
COTTON

Genuity™ Roundup Ready® Flex and Genuity™ Bollgard II® offer the ultimate combination of peace of mind and flexibility. They contain unrivaled built-in worm control to stop the most leaf- and boll-feeding worm species, including bollworms, budworms, armyworms, loopers, saltmarsh caterpillars and cotton leaf perforators. Protecting just one additional boll per plant can result in significantly higher lint yield. The convenience and savings from fewer or no sprays for worms can make a big difference when it comes to the bottom line.

SPECIALTY

Genuity™ Roundup Ready® alfalfa: Bred from an innovative germplasm pool, it offers outstanding weed control, excellent crop safety and preservation of forage quality potential.

Genuity™ Roundup Ready® canola: Offers excellent control of broadleaf weeds and grasses, even in tough weather conditions. Also features excellent crop safety and broad application flexibility.



Genuity™ Roundup Ready® sugarbeets: Excellent in-plant tolerance to over-the-top applications of labeled Roundup agricultural herbicides. Offers outstanding weed control, excellent crop safety and preservation of yield potential.

*See pages 16 and 17 for additional traits.

NOTE: Farmers must read the IRM/Grower Guide prior to planting for information on planting and Insect Resistance Management.

Monsanto's New Generation of Technologies

As Monsanto continues to develop new generations of technologies, several of our newer technologies are migrating to the Genuity™ brand. These products and their new logos are presented below.

INSECT RESISTANCE MANAGEMENT (IRM)

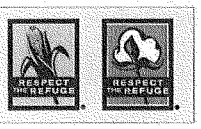
An **EFFECTIVE** IRM program is a vital part of responsible product stewardship for insect-protected biotech products. Monsanto is committed to implementing an effective IRM program for all of its insect-protected *B.t.* technologies in all countries where they are commercialized, including promoting farmer awareness of these IRM programs. Monsanto works to develop and implement IRM programs that strike a balance between available knowledge and practicality, with farmer acceptance and implementation of the plan as critical components.

The U.S. EPA requires that Monsanto implement, and farmers who purchase insect-protected products follow, an IRM plan.* IRM programs for *B.t.* traits are based upon an assessment of the biology of the major target pests, farmer needs and practices, and appropriate pest management practices. These **mandatory regulatory programs** have been developed and updated through broad cooperation with farmer and consultant organizations, including the National Corn Growers Association and the National Cotton Council, extension specialists, academic scientists, and regulatory agencies.

*In some areas, a natural refuge option is available for Bollgard II. See the current IRM/Grower Guide for details.

The IRM programs for planting seeds containing *B.t.* traits contain several important elements. One key component of an IRM plan is a refuge. A refuge is simply a portion of the relevant crop (corn or cotton) that does not contain a *B.t.* technology for the control of the insect pests which are controlled by the planted technology(ies). The lack of exposure to the *B.t.* proteins means that there will be susceptible insects nearby to mate with any rare resistant insects that may emerge from *B.t.* products. Susceptibility to *B.t.* products is then passed on to offspring, preserving the long-term effectiveness of the technology.

Farmers who purchase seeds containing *B.t.* traits must plant an appropriately designed refuge. Refuge size, configuration, and management is described in detail in the sections on those products in the 2010 IRM/Grower Guide.



Failure to follow IRM requirements and to plant a proper refuge may result in the loss of a farmer's access to Monsanto technologies. Monsanto is committed to the preservation of *B.t.* technologies. Please do your part to preserve *B.t.* technologies by implementing the correct IRM plan on your farm.

MONITORING PROGRAM

The U.S. EPA requires Monsanto to take corrective measures in response to a finding of IRM non-compliance. Monsanto or an approved agent of Monsanto must monitor refuge management practices. The MTSA signed by a farmer requires that upon request by Monsanto or its approved agent, a farmer must provide the location of all fields planted with Monsanto technologies and the locations of all associated refuge areas as **required**, to cooperate fully with any field inspections, and allow Monsanto to inspect all fields and refuge areas to ensure an approved insect resistance program has been followed. All inspections will be performed at a reasonable time and arranged in advance with the farmer so that the farmer can be present if desired.

IRM GUIDELINES

Farmers must read the current IRM/Grower Guide prior to planting for information on planting and IRM. If you do not have a copy of the current IRM/Grower Guide, you may downloaded it at www.monsanto.com, or you may call 1-800-768-6387 to request a copy by mail.

WEED MANAGEMENT

Monsanto considers product stewardship to be a fundamental component of customer service and responsible business practices. As leaders in the development and stewardship of Roundup® agricultural herbicides and other products, Monsanto invests significantly in research to continuously improve the proper uses and stewardship of our proprietary herbicide brands.

This research, done in conjunction with academic scientists, extension specialists and crop consultants, includes an evaluation of the factors that can contribute to the development of weed resistance and how to properly manage weeds to delay the selection for weed resistance. Visit **www.weedtool.com** for practical, best practices-based information on reducing the risk for development of glyphosate-resistant weeds. Developed in cooperation with academic experts, the website provides options for managing the risk on a field-by-field basis.

Glyphosate is a Group 9 herbicide based on the mode of action classification system of the Weed Science Society of America. Any weed population may contain plants naturally resistant to Group 9 herbicides. The following general recommendations help manage the risk of weed resistance occurring.

WEED RESISTANCE MANAGEMENT PRACTICES:

- Scout your fields before and after herbicide application
- Start with a clean field, using either a burndown herbicide application or tillage
- Control weeds early when they are small
- Add other herbicides (e.g. a selective in-crop and/or a residual herbicide) and cultural practices (e.g. tillage or crop rotation) as part of your Roundup Ready® cropping system where appropriate
- Rotation to other Roundup Ready crops will add opportunities for introduction of other modes of action
- Use the right herbicide product at the right rate and the right time
- Control weed escapes and prevent weeds from setting seeds
- Clean equipment before moving from field to field to minimize spread of weed seed
- Use new commercial seed that is as free from weed seed as possible

Monsanto is committed to the proper use and long-term effectiveness of its proprietary herbicide brands through a four-part stewardship program: developing appropriate weed control recommendations, continuing research to refine and update recommendations, education on the importance of good weed management practices and responding to repeated weed control inquiries through a product performance evaluation program.

GLYPHOSATE-RESISTANT WEEDS

Monsanto actively investigates and studies weed control complaints and claims of weed resistance. When glyphosate-resistant weed biotypes have been confirmed, Monsanto alerts farmers and develops and provides farmers with recommended control measures, which may include additional herbicides, tank-mixes or cultural practices. Monsanto actively communicates all of this information to farmers through multiple channels, including the herbicide label, **www.weedscience.org**, supplemental labeling, this TUG, media and written communications, Monsanto's website, **www.weedresistancemanagement.com**, and farmer meetings.

Farmers must be aware of, and proactively manage for, glyphosate-resistant weeds in planning their weed control program. When a weed is known to be resistant to glyphosate, then a resistant population of that weed is by definition no longer controlled with labeled rates of glyphosate. Roundup® agricultural herbicide warranties will not cover the failure to control glyphosate-resistant weed populations.

Report any incidence of repeated non-performance on a particular weed to your local Monsanto representative, retailer or county extension agent.

Note: Always read and follow all pesticide label requirements.

ROUNDUP BRAND AGRICULTURAL OVER-THE-TOP HERBICIDE PRODUCTS

Read and follow all product labeling before using Roundup agricultural herbicides over the top of products with Roundup Ready Technology.

You may use another glyphosate herbicide, but only if it has federally approved label instructions for use over that specific Roundup Ready crop, and the product and the use label for that Roundup Ready crop has been approved by your specific state. Contact the product manufacturers, the local retailers or the local extension agents for confirmation that the products carry EPA and state approved labeling for this use. **MONSANTO DOES NOT MAKE ANY REPRESENTATIONS, WARRANTIES OR RECOMMENDATIONS CONCERNING THE USE OF GLYPHOSATE PRODUCTS SUPPLIED BY OTHER COMPANIES WHICH ARE LABELED FOR USE OVER ROUNDUP READY CROPS. MONSANTO SPECIFICALLY DENIES ALL RESPONSIBILITY AND DISCLAIMS ANY LIABILITY FOR ANY DAMAGE FROM THE USE OF THESE PRODUCTS IN ROUNDUP READY CROPS. ALL QUESTIONS AND COMPLAINTS CAUSED BY THE USE OF GLYPHOSATE PRODUCTS SUPPLIED BY OTHER COMPANIES SHOULD BE DIRECTED TO THE SUPPLIER OF THE PRODUCT IN QUESTION.**

MONSANTO BRANDS OF SELECTIVE OVER-THE-TOP HERBICIDE PRODUCTS

Herbicide products sold by Monsanto for use over the top of Roundup Ready crops for the 2010 crop season are as follows:

Roundup WeatherMAX®

Roundup PowerMAX®

Read and follow all product labeling before using Roundup agricultural herbicides over the top of Roundup Ready traits. To learn more about applicable supplemental labels or fact sheets, call 1-800-768-6387.

Tank-mixtures of Roundup agricultural herbicides with insecticides, fungicides, micronutrients or foliar fertilizers are not recommended as they may result in reduced weed control, crop injury, reduced pest control or antagonism. Refer to the Roundup agricultural herbicide product label, supplemental labeling or fact sheets published separately by Monsanto for tank-mix recommendations.

Do not add additional surfactants and/or products containing surfactants to these Roundup agricultural herbicides unless otherwise directed by the label. Other glyphosate products labeled for use in Roundup Ready technologies may require the addition of surfactants, or other additives to optimize performance, that may increase the potential for crop injury. Monsanto will label and promote only fully tested brands that do not require surfactants and other additives for over-the-top applications to Roundup Ready Crops.

GLYPHOSATE ENDANGERED SPECIES INITIATIVE

Before making applications of glyphosate-based herbicide products, licensed farmers of crops containing Roundup Ready technology must access the website **www.pre-serve.org** to determine whether any mitigation requirements apply to the planned application to those crops, and must follow all applicable requirements. The mitigation measures described on the website are appropriate for all applications of glyphosate-based herbicides to all crop lands.

Farmers making only ground applications to crop land with a use rate of less than 3.5 lbs of glyphosate a.e./A are not required to access the website. If a farmer does not have web access, the seed dealer can access the website on behalf of the farmer to determine the applicable requirements, or the farmer can call 1-800-332-3111 for assistance.

RECOMMENDATIONS FOR MANAGING GLYPHOSATE-RESISTANT WEEDS IN ROUNDUP READY CROPS

In certain areas, populations of ryegrass, johnsongrass, marestail, common ragweed, giant ragweed, *Palmer Amaranth* and waterhemp are known to be resistant to glyphosate. For control recommendations for resistant biotypes of these weeds, refer to **www.weedresistancemanagement.com** or call 1-800-768-6387. When approved, supplemental labeling for specific herbicide products can also be viewed on **www.cdms.net** or **www.greenbook.net** or obtained by calling 1-800-768-6387.

COEXISTENCE AND IDENTITY PRESERVED PRODUCTION

Coexistence in agricultural production systems and supply chains is not new. Different agricultural systems have coexisted successfully for many years around the world. Standards and best practices were established decades ago and have continually evolved to deliver high purity seed and grain to support production, distribution and trade of products from different agricultural systems. For example, production of similar commodities such as field corn, sweet corn and popcorn has occurred successfully and in close proximity for many years. Another example is the successful coexistence of oilseed rape varieties with low erucic acid content for food use and high erucic acid content for industrial uses.

The introduction of biotech crops generated renewed discussion of coexistence focused on biotech production systems with conventional cropping systems and organic production. These discussions have primarily focused on the potential economic impact of the introduction of biotech products on other systems. The health and safety of biotech products are not an issue because their food, feed and environmental safety must be demonstrated before they enter the agricultural production system and supply chain.

The coexistence of conventional, organic and biotech crops has been the subject of several studies and reports. These reports conclude that coexistence among biotech and non-biotech crops is not only possible but is occurring. They recommend that coexistence strategies be developed on a case-by-case basis considering the diversity of products currently in the market and under development, the agronomic and biological differences in the crops themselves and variations in regional farming practices and infrastructures. Furthermore, coexistence strategies are driven by market needs and should be developed using current science-based industry standards and management practices. The strategies must be flexible, facilitating options and choice for the farmer and the food/feed supply chain, and must be capable of being modified as changes in markets and products warrant.

Successful coexistence of all agricultural systems is achievable and depends on cooperation, flexibility and mutual respect for each system. Agriculture has a history of innovation and change, and farmers have always adapted to new approaches or challenges by utilizing appropriate strategies, farm management practices and new technologies.

The responsibility for implementing practices to satisfy specific marketing standards or certification lies with that farmer who is growing a crop to satisfy a particular market. Only that farmer is instructed to employ the practices appropriate to assure the integrity of his/her crop. This is true whether the goal is high-oil corn, white/sweet corn or organically produced yellow corn for animal feed. In each case, the farmer is seeking to produce a crop that is supported by a market price and consequently that farmer assumes responsibility for satisfying reasonable market specifications. That said, the farmer needs to be aware of the planting intentions of his/her neighbor in order to gauge the need for management practices.

IDENTITY PRESERVED PRODUCTION

Some farmers may choose to preserve the identity of their crops to meet specific markets. Examples of Identity Preserved (I.P.) corn crops include production of seed corn, white, waxy or sweet corn, specialty oil or protein crops, food grade crops and any other crop that meets specialty needs, including organic and non-genetically enhanced specifications. Farmers of these crops assume the responsibility and receive the benefit for ensuring that their crop meets mutually agreed contract specifications.

Based on historical experience with a broad range of I.P. crops, the industry has developed generally accepted I.P. agricultural practices. These practices are intended to manage I.P. production to meet quality specifications, and are established for a broad range of I.P. needs. The accepted practice with I.P. crops is that each I.P. farmer has the responsibility to implement any necessary processes. These processes may include sourcing seed appropriate for I.P. specifications, field management practices such as adequate isolation distances, buffers between crops, border rows, planned differences in maturity between adjacent fields that might cross-pollinate and harvest and handling practices designed to prevent mixing and to maintain product quality. These extra steps associated with I.P. crop production are generally accompanied by incremental increases in cost of production and consequently of the goods sold.

General Instructions for Management of Pollen Flow and Mechanical Mixing

For all crop hybrids or varieties that they wish to identity preserve, or otherwise keep separated, farmers should take steps to prevent mechanical mixing. Farmers should make sure all seed storage areas, transportation vehicles and planter boxes are cleaned thoroughly both prior to and subsequent to the storage, transportation or planting of the crop. Farmers should also make sure all combines, harvesters and transportation vehicles used at harvest are cleaned thoroughly both prior to and subsequent to their use in connection with the harvest of the grain produced from the crop. Farmers should also make sure all harvested grain is stored in clean storage areas where the identity of the grain can be preserved.

Self-pollinated crops, such as soybeans, do not present a risk of mixing by cross-pollination. If the intent is to use or market the product of a self-pollinated crop separately from general commodity use, farmers should plant fields a sufficient distance away from other crops to prevent mechanical mixture.

Farmers planting cross-pollinated crops, such as corn or alfalfa, who desire to preserve the identity of these crops, or to minimize the potential for these crops to outcross with adjacent fields of the same crop kind, should use the same generally accepted practices to manage mixing that are used in any of the currently grown I.P. crops of similar crop kind.

It is generally recognized in the industry that a certain amount of incidental, trace level pollen movement occurs, and it is not possible to achieve 100% purity of seed or grain in any corn production system. A number of factors can influence the occurrence and extent of pollen movement. As stewards of technology, farmers are expected to consider these factors and talk with their neighbors about their cropping intentions.

Farmers should take into account the following factors that can affect the occurrence and extent of cross-pollination to or from other fields. Information that is more specific to the crop and region may be available from state extension offices.

- Cross-pollination is limited. Some plants, such as potatoes, are incapable of cross-pollinating, while others, like alfalfa, require cross-pollination to produce seed, importantly, cross-pollination only occurs within the same crop kind, like corn to corn.
- The amount of pollen produced within the field can vary. The pollen produced by the crop within a given field, known as pollen load, is typically high enough to pollinate all of the plants in the field. Therefore, most of the pollen that may enter from other fields falls on plants that have already been pollinated with pollen that originated from plants within the field. In crops such as alfalfa, the hay cutting management schedule significantly limits or eliminates bloom, and thereby restricts the potential for pollen and/or viable seed formation.
- The existence and/or degree of overlap in the pollination period of crops in adjacent fields varies. This will vary depending on the maturity of crops, planting dates and the weather. For corn, the typical pollen shed period lasts from 5 to 10 days for a particular field. Therefore, viable pollen from neighboring fields must be present when silks are receptive in the recipient field during this brief period to produce any grain with traits introduced by the out-of-field pollen.
- Distance between fields of different varieties or hybrids of the same crop: The greater the distance between fields the less likely their pollen will remain viable and have an opportunity to mix and produce an outcross. For wind-pollinated crops, most cross-pollination occurs within the outermost few rows of the field. In fact, many white and waxy corn production contracts ask the farmer to remove the outer 12 rows (30 ft.) of the field in order to remove most of the impurities that could result from cross-pollination with nearby yellow dent corn. Furthermore, research has also shown that as fields become further separated, the incidence of wind-modulated cross-pollination drops rapidly. Essentially, the in-field pollen has an advantage over the pollen coming from other fields for receptive silks because of its volume and proximity to silks.
- The distance pollen moves. How far pollen can travel depends on many environmental factors, including weather during pollination, especially wind direction and velocity, temperature and humidity. For bee-pollinated crops, the farmer's choice of pollinator species and apiary management practice may reduce field-to-field pollination potential. All these factors will vary from season to season, and some factors from day to day and from location to location.
- For wind-pollinated crops, the orientation and width of the adjacent field in relation to the dominant wind direction. Fields oriented upwind during pollination will show dramatically lower cross-pollination for wind-pollinated crops, like corn, compared to fields located downwind.

Advanced breeding and biotechnology have had a major impact on farming production. From 1971 to 1995, average corn yields were increasing at a rate of 1.5 bushels per acre, per year. Since the advent of biotech in 1996, corn yields have increased at a rate of 2.6 bushels per acre, per year, for a total increase of 32 bushels per acre.*

Excellence Through Stewardship

Monsanto Company is a member of Excellence Through Stewardship® (ETS). Monsanto products are commercialized in accordance with ETS Product Launch Stewardship Guidance, and in compliance with Monsanto's Policy for Commercialization of Biotechnology-Derived Plant Products in Commodity Crops. This product has been approved for import into key export markets with functioning regulatory systems. Any crop or material produced from this product can only be exported to, or used, processed or sold in countries where all necessary regulatory approvals have been granted. It is a violation of national and international law to move material containing biotech traits across boundaries into nations where import is not permitted. Growers should talk to their grain handler or product purchaser to confirm their buying position for this product. Excellence Through Stewardship® is a registered trademark of Biotechnology Industry Organization.

IRM GUIDELINES

For specific refuge requirements for *B.t.* corn and cotton, see the current IRM/Grower Guide, sent with this TUG. If you have not received a copy of this Guide, it can be downloaded at www.monsanto.com, or call 1-800-768-6387 to request a copy be mailed to you.

Before opening a bag of seed, be sure to read and understand the stewardship requirements, **including applicable refuge requirements for insect resistance management,** for the biotechnology traits expressed in the seed as set forth in the Monsanto Technology Agreement that you sign. By opening and using a bag of seed, you are reaffirming your obligation to comply with those stewardship requirements.

* USDA Yields were calculated using 3 year rolling averages (32 Yield is 2.6 bu/ac *12 years). 2008 Yield is from Doane Ag Services forecast in April 8, 2008 Quarterly Crop Outlook.

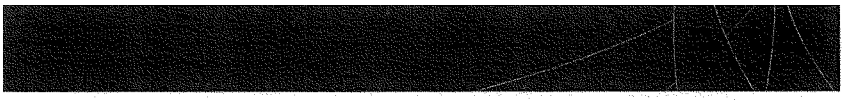
Genuity™ Trait Products and YieldGard® Corn Technologies Product Descriptions

GENUITY™ SMARTSTAX™

Scheduled to launch in 2010, Genuity™ SmartStax™ is the most advanced, all-in-one corn trait system that controls the broadest spectrum of above- and below-ground insects and weeds. Genuity™ SmartStax™ hybrids will contain *B.t.* proteins that represent three separate modes of action for control of lepidopteron, above-ground insect pests, as well as combined modes of action for control of coleopteran, below-ground insect pests. Providing multiple *B.t.* proteins for control will dramatically decrease the probability that insects will become resistant to the traits, resulting in enhanced durability of transgenic insect control via *B.t.* genes. Based on this multiple gene approach, Genuity™ SmartStax™ is approved for reduced refuge in the corn belt from 20% down to 5% for both above- and below-ground pests. The cotton belt refuge for Genuity SmartStax™ is also reduced, from 50% down to 20%.

GENUITY™ VT TRIPLE PRO™

(Formerly YieldGard VT Triple PRO™) — Genuity™ VT Triple PRO™ is available in selected southern corn- and cotton-growing areas. It includes broad-spectrum insect control against corn earworm, European and southwestern corn borers, sugarcane borer, southern cornstalk borer, fall armyworm, western corn rootworm, northern corn rootworm and Mexican corn rootworm. Its advanced control of ear pests can result in higher grain quality and higher-yielding crop potential. The dual mode-of-action of Genuity™ VT Triple PRO™ allows for lower corn borer refuge acres in southern cotton-growing areas compared to other registered *B.t.*-traited products. It includes the same Roundup Ready® 2 Technology as Monsanto's previous product, YieldGard VT Triple. Seed containing Genuity™ VT Triple PRO™ technology is treated with seed-applied insecticide.*



YIELDGARD VT TRIPLE®

YieldGard VT Triple technology combines YieldGard Corn Borer and YieldGard VT Rootworm/RR2® technology into a single plant. YieldGard VT Triple corn hybrids control European and southwestern corn borer, sugarcane borer, southern cornstalk borer, western corn rootworm, northern corn rootworm and Mexican corn rootworm. YieldGard VT Triple technology suppresses corn earworm, fall armyworm and stalk borer. By providing in-plant protection against the above insect pests, the genetic yield potential of YieldGard VT Triple corn hybrids is preserved. YieldGard VT Triple corn hybrids also include Roundup Ready 2 Technology. This trait allows a farmer to experience the benefits of utilizing Roundup agricultural herbicides in a weed control system that provides the broadest weed control spectrum available, better application flexibility, and superior crop safety. Seed containing YieldGard VT Triple technology is treated with seed-applied insecticide.*

GENUITY™ VT DOUBLE PRO™

Genuity™ VT Double PRO™ is a new corn technology scheduled for launch in 2010. It includes broad-spectrum insect control against corn earworm, European and southwestern corn borers, sugarcane borer, southern cornstalk borer and fall armyworm. The dual mode-of-action of Genuity™ VT Double PRO™ allows for lower corn borer refuge acres compared to other registered *B.t.*-traited products. Seed containing Genuity™ VT Double PRO™ technology is treated with seed-applied insecticide.*

*A seed-applied insecticide can protect seed, roots and seedlings from insects such as black cutworm, wireworm, white grubs, seed corn maggots, chinch bug and early flea beetles.

YieldGard VT Rootworm/RR2

YIELDGARD VT ROOTWORM/RR2®

YieldGard VT Rootworm/RR2 technology is the current YieldGard stacked-trait product for control of western corn rootworm, northern corn rootworm and Mexican corn rootworm. Protecting the root of the corn plant from feeding by corn rootworm larvae decreases lodging and protects the genetic yield potential of YieldGard VT Rootworm/RR2 corn hybrids. The Roundup Ready 2 Technology allows a farmer to experience the benefits of utilizing Roundup agricultural herbicides in a weed control system that provides the broadest weed control spectrum, better application flexibility and superior crop safety. Seed containing YieldGard VT Rootworm/RR2 technology is treated with seed-applied insecticide.*

YIELDGARD® CORN BORER

YieldGard Corn Borer corn hybrids contain an insecticidal protein from *B.t.* that protects corn plants from European corn borer, southwestern corn borer, sugarcane borer and southern cornstalk borer resulting in full yield potential.

YIELDGARD PLUS

YieldGard Plus corn technology combines YieldGard Corn Borer and YieldGard Rootworm technology into a single plan.

YIELDGARD ROOTWORM

YieldGard Rootworm corn hybrids contain an insecticidal protein from *B.t.* that protects corn roots from larval feeding by western, northern and Mexican corn rootworm.

YIELDGARD® CORN BORER WITH ROUNDUP READY® CORN 2

YieldGard Corn Borer with Roundup Ready Corn 2 offers farmers all the benefits of both traits combined in one crop. These hybrids exhibit the same insect protection qualities as YieldGard Corn Borer and, like Roundup Ready Corn 2, are tolerant to over-the-top applications of Roundup® agricultural herbicides.

YIELDGARD PLUS WITH ROUNDUP READY CORN 2

YieldGard Plus with Roundup Ready Corn 2 offers farmers all the benefits of all three traits combined in one crop. These hybrids exhibit the same insect protection qualities of YieldGard Corn Borer and YieldGard Rootworm and, like Roundup Ready Corn 2, are tolerant to over-the-top applications of Roundup® agricultural herbicides. Seed containing YieldGard Plus technology is treated with seed-applied insecticide.*

YIELDGARD ROOTWORM WITH ROUNDUP READY CORN 2

YieldGard Rootworm with Roundup Ready Corn 2 offers farmers all the same insect protection qualities as YieldGard Rootworm and, like Roundup Ready Corn 2, is tolerant to over-the-top applications of Roundup agricultural herbicides.

*A seed-applied insecticide can protect seed, roots and seedlings from insects such as black cutworm, wireworm, white grubs, seed corn maggots, chinch bug and early flea beetles.

ROUNDUP READY® Technology in Corn

WEED CONTROL RECOMMENDATIONS

Roundup Ready® Corn 2 (RR2) and corn with Roundup Ready® 2 Technology are equivalent in their tolerance to Roundup agricultural herbicides. Products with Roundup Ready Technology contain in-plant tolerance to Roundup agricultural herbicides.

The Roundup Ready® Technology system's flexibility, broad-spectrum weed control and proven crop safety offer farmers weed control programs that allow them to use the system in the way that provides the greatest benefit. Farmers can select the program that best fits the way they farm. Options include the use of a residual herbicide with a Roundup® agricultural herbicide, tank-mixing other herbicides with Roundup agricultural herbicides where appropriate and a total postemergence program.

AGRONOMIC PRINCIPLES

Corn yield is very sensitive to early-season weed competition. Weed control systems must provide farmers the opportunity to control weeds before they become competitive. The Roundup Ready Technology system provides a mechanism to control weeds at planting and once they emerge. Farmers are provided excellent crop safety and full yield potential, with applications made from planting through 48" of corn height. Drop nozzles must be used between 30" and 48" of corn height. Failure to control weeds with the right rate, at the right time and with the right product, can lead to increased weed competition, weed escapes and the potential for decreased yields. Use other approved herbicide products with Roundup agricultural herbicides if appropriate for the weed spectrum.

PROGRAM	INSTRUCTIONS AND USE RATES*	ADDITIONAL INFORMATION
For use where residual herbicides are typically used for early-season weed control: **Residual Herbicide Plus Roundup WeatherMAX®**	Use the proper Roundup Ready RATE™ of Bullet®, Degree®, Degree Xtra®, Harness®, Harness Xtra, Harness Xtra 5.6L, Micro-Tech™, or Lariat® (no post) as defined in the table below and the individual product labels, either pre or postemergence to the crop.** Follow with Roundup WeatherMAX at 16 to 22 oz/A post sequentially after preemergence application or tank-mixed in-crop with the residual. Applications should be made before weeds exceed 4" in height. **Roundup Ready RATEs***** Harness 1.5 Pints Degree 3.0 Pints Harness Xtra 1.2 Quarts Harness Xtra 5.6L 1.5 Quarts Degree Xtra 2.0 Quarts Micro-Tech 2.0 Quarts Lariat 2.0 Quarts Bullet 2.0 Quarts	Use full labeled rate of residual when application is 14 days or more prior to planting or when tough grasses are present, e.g., barnyardgrass, shattercane, seedling johnsongrass, sandbur. Use a minimum of 2.5 pt/A of Harness on woolly cupgrass and wild proso millet. Products containing atrazine will provide improved control of cocklebur, giant ragweed, *Palmer Amaranth* and morningglory. Tank-mix products such as 2,4-D, dicamba or Status® herbicide with Roundup WeatherMAX for control of glyphosate-resistant marestail (horseweed), *Palmer Amaranth* and other difficult-to-control weeds. Use 22 to 32 oz/A of Roundup WeatherMAX* when morningglory or perennial weeds are present or when broadleaf weeds are 4" in height or taller.
For use where total postemergence programs are effective and sustainable: **Roundup WeatherMAX Sequential**	Apply Roundup WeatherMAX at 16 to 22 oz/A before weeds exceed 4" in height and follow with a second application at 16 to 22 oz/A for an additional flush of weeds before they exceed 4" in height.	Use 22 to 32 oz/A of Roundup WeatherMAX when morningglory or perennial weeds are present. Tank-mix products such as 2,4-D, dicamba or Status herbicide with Roundup WeatherMAX for control of glyphosate-resistant marestail (horseweed), *Palmer Amaranth* and other difficult-to-control weeds.
Maximum Use Rates For Roundup WeatherMAX	**Products with Roundup Ready 2 Technology In-crop:** • 32 oz/A per single application • Total: 64 oz/A from emergence through 48" height of corn, drop nozzles must be used from 30" to 48" corn.	**Products with Roundup Ready 2 Technology Total Season:** The combined total of preplant, in-crop and preharvest applications of Roundup WeatherMAX can not exceed 5.3 qt/A. The combined total of in-crop and preharvest applications can not exceed 66 oz/A.

*If using another Roundup agricultural herbicide, you must refer to the label booklet or Roundup Ready Corn 2 Technology supplemental label for that brand to determine appropriate use rates. If using Roundup PowerMAX®, application rates are the same as for Roundup WeatherMAX. If using another residual herbicide, follow the labeled use rate instructions applicable to Roundup Ready Corn 2. Follow all pesticide label requirements.

**Atrazine may also be used as a residual herbicide in the Roundup Ready Corn 2 System.

***You may apply up to the full residual herbicide labeled rate for corn.

WEED RESISTANCE MANAGEMENT FOR CORN WITH ROUNDUP READY TECHNOLOGY

Follow all pesticide label requirements and the guidelines below to minimize the risk of developing glyphosate-resistant weed populations in a Roundup Ready Technology system.

- Start clean with a burndown herbicide or tillage. Early-season weed control is critical to yield.
- Apply pre-emergence residual herbicides such as Harness Xtra, Degree Xtra or other residual herbicides at the recommended rate.
- Or apply a pre-emergence residual herbicide at the recommended rate tank-mixed with Roundup WeatherMAX® at a minimum of 22 oz/A in-crop before weeds exceed 4" in height.
- Follow with a postemergence in-crop application of Roundup WeatherMAX at a minimum of 22 oz/A for additional weed flushes before they exceed 4" in height.
- Roundup WeatherMAX may be tank-mixed with other herbicides for postemergence weed control.
- Report repeated non-performance to Monsanto or your local retailer.

RECOMMENDATIONS FOR MANAGING GLYPHOSATE-RESISTANT WEEDS IN PRODUCTS WITH ROUNDUP READY TECHNOLOGY

WEEDS	INSTRUCTIONS AND USE RATES*
Glyphosate-Resistant Marestail (Horseweed)	Start clean with a burndown program or tillage. -Tank-mix Roundup agricultural herbicides with 2,4-D, or dicamba, according to the label directions. In-crop, tank-mix 22 ounces per acre of Roundup WeatherMAX with Clarity® (8 to 16 fluid ounces per acre) or 2,4-D (0.5 to 1.0 lb active ingredient per acre) from corn emergence to the 5-leaf stage of corn growth (approximately 8" tall). Or tank-mix 22 ounces per acre of Roundup WeatherMAX with 5 ounces per acre of Status® herbicide when the corn is 4" to 36" tall (V2 to V10). Marestail should not exceed 6" in height at the time of in-crop application.
Glyphosate-Resistant *Amaranthus* Species **- *Palmer Amaranth*** **- Waterhemp**	Start clean with a burndown program or tillage. Use a residual herbicide such as Harness Xtra, Harness Xtra 5.6L, Degree Xtra or other residual herbicide either preemergence or in-crop for control of *Amaranthus* species. In-crop, tank-mix Roundup WeatherMAX with other herbicides such as 2,4-D, dicamba (Clarity or Banvel®) or Status herbicide to control emerged weeds. Applications of Status herbicide should be made when the corn is between 4" and 36" tall (V2 to V10). Follow all label directions. *Amaranthus* species should not exceed 3" in height at the time of in-crop application.
Glyphosate-Resistant *Ambrosia* Species **- Giant Ragweed** **- Common Ragweed**	Start clean with a burndown program or tillage. Use a residual herbicide such as Harness Xtra, Harness Xtra 5.6L, Degree Xtra or other residual herbicide either preemergence or in-crop for control of *Ambrosia* species. In-crop, tank-mix Roundup WeatherMAX with other herbicides such as 2,4-D, dicamba (Clarity or Banvel) or Status herbicide to control emerged weeds. Applications of Status herbicide should be made when the corn is between 4" and 36" tall (V2 to V10). Follow all label directions. *Ambrosia* species should not exceed 3" in height at the time of in-crop application.
Glyphosate-Resistant Johnsongrass	Start clean with a burndown program or tillage. Use a residual herbicide such as Harness Xtra, Harness Xtra 5.6L, Degree Xtra or other residual herbicide containing atrazine preemergence to reduce the competition from seedling johnsongrass prior to the emergence of corn. In-crop, tank-mix Roundup WeatherMAX with a herbicide such as Accent®, Equip™ or Option® for control of emerged weeds including seedling and rhizome johnsongrass. Follow all label directions of tank-mix partners, especially those related to weed size.

In certain areas, Italian ryegrass is known to be resistant to glyphosate. For control recommendations, refer to **www.weedresistancemanagement.com** or call 1-800-768-6387. When approved, supplemental labeling for specific herbicide products can also be viewed on **www.cdms.net** or **www.greenbook.net.**

*Follow all pesticide label requirements.

Genuity™ Bollgard II® and Bollgard® Cotton Descriptions

GENUITY™ BOLLGARD II® COTTON

Genuity™ Bollgard II® cotton contains two distinct insecticidal proteins from *Bacillus thuringiensis (B.t.)* that increase the efficacy and spectrum of control and reduce the chance that resistance will develop to the *B.t.* insecticidal proteins, relative to Bollgard® cotton. Genuity™ Bollgard II® cotton normally provides excellent, season-long control of tobacco budworm, pink bollworm and cotton bollworm. Genuity™ Bollgard II® cotton provides good protection against fall armyworm, beet armyworm, cabbage and soybean loopers and other secondary leaf- or fruit-feeding caterpillar pests of cotton. Applications of insecticides to control these insects are substantially reduced with Genuity™ Bollgard II® cotton.

BOLLGARD® COTTON

Bollgard cotton contains a single insecticidal protein from *B.t.* that provides good control against three major lepidopteran insect pests of cotton. Specifically, Bollgard cotton provides excellent, season-long control of tobacco budworm and pink bollworm, and suppression of cotton bollworm. When the above-mentioned insect larvae feed on Bollgard cotton plants, the *B.t.* protein protects the plants from damage by reducing larval survival. Under high infestation, application of insecticides may be necessary to protect Bollgard cotton.

BOLLGARD PHASE OUT

The U.S. Environmental Protection Agency has mandated the following terms and conditions:*

- Bollgard® cotton may be sold through September 30, 2009. After that date, all sales of Bollgard cotton are prohibited.
- All Bollgard cotton seed must be planted by midnight of July 1, 2010 (the expiration date of the Bollgard cotton registration). After July 1, 2010, planting of Bollgard cotton seed is prohibited. Any Bollgard cotton seed not planted on or before July 1, 2010, must be returned to either the retailer or to Monsanto. No refunds are to be issued on Bollgard cotton seeds bought for planting in 2010 and returned by growers.
- An adequate amount of refuge seed must be purchased for planting an appropriate refuge for Bollgard cotton. Purchase of refuge seed with the Bollgard cotton seed is mandatory, and such seed must be purchased by growers in advance of their receipt of Bollgard cotton seed. Any seed purchased for use as a refuge is non-refundable, unless the proportional amount of Bollgard cotton seed that the refuge seed would have supported is returned at the same time.
- Any order for replacement or additional Bollgard cotton seed for the 2010 planting season, that does not conform to the requirements stated above must be filled with Genuity™ Bollgard II® cotton seed (or other products with current registrations).
- On-farm IRM assessments will be conducted during the planting season.
- In 2010, Bollgard cotton may only be planted in: Alabama, Arkansas, Florida (North of Florida Route 60), Georgia, Kentucky, Louisiana, Maryland, Missouri, Mississippi, North Carolina, South Carolina, Tennessee, Texas (excluding the ten prohibited Texas panhandle counties of: Dallam, Sherman, Hansford, Ochiltree, Lipscomb, Hartley, Moore, Hutchinson, Roberts, and Carson) and Virginia.

*It is a violation of federal law to sell or distribute an unregistered pesticide.

NOTE: Sale or commercial planting of Bollgard®cotton is prohibited in certain states, including: Arizona, California, Colorado, Kansas, New Mexico and Oklahoma.

Sale or planting of Bollgard is prohibited in the Texas counties of: Carson, Dallam, Hansford, Hartley, Hutchison, Lipscomb, Moore, Ochiltree, Roberts, and Sherman.

Sale or commercial planting of both Genuity™ Bollgard II® and Bollgard is prohibited in Hawaii, Puerto Rico, the U.S. Virgin Islands, and in Florida south of Route 60 (near Tampa).

The *B.t. delta endotoxin* protein expressed in this cotton targets certain cotton insect pests. Routine applications of insecticides to control certain insects are usually unnecessary when cotton containing the *B.t. delta endotoxin* protein is planted. However, if insecticide applications are necessary to control certain cotton insect pests, follow all label requirements.

Genuity™ Bollgard II® and Bollgard® Cotton

INSECT RESISTANCE MANAGEMENT (IRM)

Lepidopteran cotton pests have demonstrated the ability to develop resistance to many chemical insecticides. As a preemptive measure, Genuity™ Bollgard II® and Bollgard® cotton must be managed in ways that will retard insect resistance development. These practices are designed to ensure that some lepidopteran populations are not exposed to the *B.t.* proteins so they can maintain susceptibility in select populations. In order to achieve this, refuge cotton that does not contain *B.t.* proteins must be planted.

GENUITY™ BOLLGARD II - DUAL EFFECTIVE DOSE

Resistance management is critical to the long-term viability of our technology and the benefits realized by our farmer customers. 2010 is a transition year for Monsanto *B.t.* cotton products as we shift all U.S. cotton acres toward the two-gene insect control product, Genuity™ Bollgard II® cotton. The move to multiple-gene products, including Genuity™ Bollgard II®, offers dual effective modes of action against target insect pests, increasing the longevity of the technology.

INTEGRATED PEST MANAGEMENT (IPM)

Integrated Pest Management (IPM) is an effective and environmentally sensitive approach to pest management that relies on a combination of common-sense practices. IPM programs use current, comprehensive information on the life cycles of pests and their interaction with the environment. This information is used to manage pests in a manner that is least harmful to people, property and the environment.

Prevention

Using the best agronomic management practices in conjunction with the appropriate cotton varieties will yield the greatest benefits.

Use varieties, seeding rates and planting technologies appropriate for each specific geographical area. As much as possible, manage the crop to avoid plant stress.

- Employ appropriate scouting techniques and treatment decisions to preserve beneficial insects that can provide additional insect pest control.
- Manage for appropriate maturity and harvest schedules, destroy stalks immediately after harvest to avoid regrowth and minimize selection for resistance in late-season infestations.
- Use soil management practices that encourage destruction of over-wintering pupae.

Monitor and Identify

Fields should be carefully monitored for all pests, including cotton bollworms, to determine the need for remedial insecticide treatments. For target pests, scouting techniques and supplemental treatment decisions should take into account the fact that larvae must hatch and feed before they can be affected by the *B.t.* protein(s) in either Genuity™ Bollgard II® or Bollgard cotton. Fields should be scouted regularly, following periods of heavy or sustained egg lay, especially during bloom, to determine if significant larval survival has occurred. Scouting should include a modified whole-plant inspection, including terminals, squares, blooms, bloom tags and small bolls. Larvae larger than 1/4 inch (3- to 4-days old) are generally recognized as survivors that may not be controlled by Genuity™ Bollgard II® or Bollgard cotton.

Read the IRM/Grower Guide prior to planting for information on planting and Insect Resistance Management. If you do not have a copy of this Guide, you may download it at www.monsanto.com, or call 1-800-768-6387 to request a copy by mail.

Control

Monsanto recommends the use of appropriate remedial insecticide treatments to ensure desired levels of control if any cotton insect pest reaches locally established thresholds in Genuity™ Bollgard II® or Bollgard cotton.

Although Genuity™ Bollgard II® and Bollgard cotton will sustain less damage from some of the most troublesome lepidopteran pests, they will not provide protection against non-lepidopteran species. These insects should be monitored and treated with insecticides when necessary, using recommended thresholds. Whenever possible, select insecticides that are least harmful to beneficial insects.

NOTE: In 2010, sale or commercial planting of Bollgard® cotton is prohibited in the following states: Arizona, California, Colorado, Kansas, New Mexico and Oklahoma.

In 2010, sale or planting of Bollgard® is prohibited in the Texas counties of: Carson, Dallam, Hansford, Hartley, Hutchison, Lipscomb, Moore, Ochiltree, Roberts, and Sherman.

In 2010, sale or commercial planting of both Genuity™ Bollgard II® and Bollgard® is prohibited in Hawaii, Puerto Rico, and the U.S. Virgin Islands, or in Florida south of Route 60 (near Tampa).

Roundup Ready® Cotton, Genuity™ Bollgard II® with Roundup Ready® Cotton and Bollgard with Roundup Ready Cotton

ROUNDUP READY COTTON

Roundup Ready® cotton varieties contain in-plant tolerance to Roundup® agricultural herbicides, enabling farmers to make in-crop applications of Roundup WeatherMAX® or Roundup PowerMAX® according to label requirements.

GENUITY™ BOLLGARD II WITH ROUNDUP READY COTTON AND BOLLGARD WITH ROUNDUP READY COTTON

Genuity™ Bollgard II® with Roundup Ready® cotton and Bollgard with Roundup Ready varieties offer farmers the benefits of both insect protection and glyphosate tolerance combined in one crop. These varieties exhibit the same insect protection qualities as Genuity™ Bollgard II® and Bollgard cotton and enable farmers to make in-crop applications of Roundup WeatherMAX or Roundup PowerMAX according to label requirements.

MARKET OPTIONS

Gin by-products of cotton containing Monsanto's biotech traits, including cottonseed for feed uses, are fully approved for export to Canada, Japan, Mexico and South Korea. Cottonseed containing Monsanto traits may not be exported for the purpose of planting without a license from Monsanto.

It is a violation of national and international law to move material containing biotech traits across boundaries into nations where import is not permitted.

RECOMMENDED MANAGEMENT PRACTICES

Managing Roundup Ready cotton, Bollgard with Roundup Ready cotton and Genuity™ Bollgard II® with Roundup Ready® cotton requires that a farmer follow the recommended management practices associated with cotton containing each individual trait. Farmers of Bollgard with Roundup Ready cotton and Genuity™ Bollgard II® with Roundup Ready® cotton varieties must follow the same guidelines for establishing required refuge options, practicing IRM and managing target and non-target pests as described for Bollgard and Genuity™ Bollgard II® cotton in the IRM/Grower Guide.

APPLICATION OF ROUNDUP WEATHERMAX® AND ROUNDUP POWERMAX®

Roundup Ready cotton is genetically improved to provide tolerance to glyphosate, the active ingredient in Roundup agricultural herbicides. Roundup Ready cotton can receive over-the-top applications of Roundup agricultural herbicides only through the four-leaf stage. With the introduction of Genuity™ Roundup Ready® Flex cotton, there is the potential for both Roundup Ready cotton and Genuity™ Roundup Ready® Flex cotton to be used on a farmer's farm. This creates concern for the crop safety of Roundup Ready cotton. Monsanto recommends that farmers:

- Maintain accurate records of which technologies have been planted and where they have been planted.
- Communicate the field plan with other members of their work force to ensure proper applications for each technology.
- Clearly mark fields to indicate which technology has been planted.

WEED RESISTANCE MANAGEMENT GUIDELINES

Follow all pesticide label requirements and these guidelines to minimize the risk of developing glyphosate-resistant weed populations in a Roundup Ready cotton system:

- Scout fields before and after each burndown and in-crop application.
- Start clean with a burndown herbicide program or tillage.
- Use the right herbicide product at the right rate and right time.
- Add soil residual herbicide(s) and cultural practices as part of a Roundup Ready weed control program.
- In-crop, apply Roundup WeatherMAX at a minimum of 22 oz/A when weeds are less than 6" in height.
- Tank-mix other approved herbicides with Roundup WeatherMAX if necessary for postemergence weed control.
- Clean equipment before moving from field to field to minimize the spread of weed seed (as well as nematodes, insects and other cotton pests).
- Should repeated non-performance occur, report to Monsanto or your local retailer.

WEED CONTROL RECOMMENDATIONS

Weed control in cotton is essential to help maximize both fiber yield and quality potential. Cotton is very sensitive to early-season weed competition, which can result in unacceptable stands and/or reduced yield potential. The Roundup Ready® cotton system provides farmers with the right tools to control weeds before they become competitive.

PROGRAM	INSTRUCTIONS AND USE RATES*	ADDITIONAL INFORMATION
Preplant Burndown	Always start clean by planting into a weed-free field using either tillage or a burndown application. In no-till and reduced-till systems, apply a preplant burndown application of Roundup WeatherMAX®** at 22 to 44 oz/A in a tank-mix with dicamba or 2,4-D. See the dicamba and 2,4-D product label for rates and time intervals required between application and cotton planting. State restrictions may apply.	Early-season weed competition can result in unacceptable stands and/or reduced yield potential. This tank-mix is recommended for control and management of glyphosate-resistant marestail (*Conyza sp.*) or other tough-to-control weeds. Burndown application should be made far enough in advance of planting to control existing weeds.
Residual Herbicides	Apply residual herbicide(s) as part of a Roundup Ready cotton weed control program. Use the recommended label rate and timing of the residual herbicide applied. Refer to individual product labels for list of residual herbicides that may be used.	The residual herbicide(s) may be applied as either a preemergence (including preplant incorporated), postemergence, and/or layby application as allowed on the label of the specific product being used.
Over-The-Top through Fourth Leaf	Apply Roundup WeatherMAX over the top from crop emergence through the fourth true-leaf (node) stage (until the fifth true leaf reaches the size of a quarter). Two applications can be made during this period at a maximum rate of 22 oz/A per application. Refer to the "Annual Weeds Rate Table" in the Roundup WeatherMAX label for rate recommendations for specific annual weeds.	In-crop over-the-top applications must be at least 10 days apart and the cotton must have at least two nodes of incremental growth between applications. Care should be taken to record growth stage at first application. In situations where the potential for weed infestations is high (including perennial weeds), make the first application early enough to allow a second application before cotton exceeds the fourth true-leaf stage. Over-the-top applications after the fourth true-leaf stage can result in boll loss, delayed maturity, and/or yield loss.
Selective Equipment	After the fourth true-leaf stage through layby, Roundup WeatherMAX may be applied using precision post-directed or hooded sprayers which direct the spray to the base of the cotton plant. Two post-directed applications can be made during this period at a maximum rate of 22 oz/A per application.	Place nozzles in a low horizontal position to permit spray pattern to overlap in the row while contact of spray solution with cotton leaves should be avoided to the maximum extent possible. Excessive foliar contact can result in boll loss, delayed maturity, and/or yield loss. There must be two nodes of growth and at least 10 days between applications.
Preharvest Over-The-Top Applications	Before harvest and after cotton reaches 20% boll-crack, if needed, apply up to 44 oz/A of Roundup WeatherMAX. This treatment is effective in controlling late-season perennial weeds and can improve harvest efficiency.	Applications must be made at least 7 days prior to harvest. Roundup agricultural herbicides are not effective for preharvest cotton regrowth in Roundup Ready cotton. Do not apply Roundup agricultural herbicides preharvest to crops grown for seed under contract at an authorized cotton seed company.

Roundup Ready cotton has excellent vegetative tolerance to Roundup WeatherMAX allowing early-season over-the-top applications. Incomplete reproductive tolerance requires that applications after the 4-leaf (node) stage be properly post-directed.

ATTENTION: Use of Roundup agricultural herbicides in accordance with label directions is expected to result in normal growth of Roundup Ready cotton, however, various environmental conditions, agronomic practices, and other factors make it impossible to eliminate all risks associated with the product, even when applications are made in conformance with the label specifications. In some cases, these factors can result in boll loss, delayed maturity, and/or yield loss.

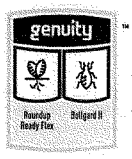
*Follow all pesticide label requirements.

**If using another Roundup agricultural herbicide, you must refer to the label booklet or Roundup Ready cotton supplemental label for that brand to determine appropriate use rates. If using Roundup PowerMAX®, application rates are the same as for Roundup WeatherMAX.

RECOMMENDATIONS FOR MANAGING GLYPHOSATE-RESISTANT WEEDS

WEEDS	INSTRUCTIONS AND USE RATES*
Glyphosate-Resistant Marestail (Horseweed)	Start clean with a burndown herbicide program or tillage. -Tank-mix Roundup agricultural herbicides with dicamba or 2,4-D (consult label for plant back timing). If you have dense stands of marestail, use a preplant residual herbicide at the recommended rate and timing, such as diuron (Direx®) or flumioxazin (Valor®). Use Roundup WeatherMAX in-crop, as needed, at a minimum of 22 oz/A to control other weeds. In-crop, if applying post-directed to glyphosate-resistant marestail, Roundup WeatherMAX can be tank-mixed with other herbicides, such as diuron or MSMA. Marestail should be less than 6" in height at the time of in-crop application.
Glyphosate-Resistant *Amaranthus* Species **- *Palmer Amaranth*** **- Waterhemp**	Start clean with a burndown herbicide program or tillage. Apply a preemergence residual herbicide such as pendimethalin (Prowl®) plus fluometuron or fomesafen (Reflex®) or flumioxazin (Valor) for control of *Amaranthus* species. In-crop, tank-mix Roundup WeatherMAX at 22 oz/A with metolachlor or other labeled chloracetamide herbicide before *Amaranthus* species emerges. Use Roundup WeatherMAX in-crop, as needed, at a minimum of 22 oz/A to control other weeds. A post-directed application of Roundup WeatherMAX tank-mixed with MSMA and a residual such as diuron (Direx) or flumioxazin (Valor) should be made to control *Amaranthus* species 3" or smaller in height and prevent additional flushes.
Glyphosate-Resistant *Ambrosia* Species **- Giant Ragweed** **- Common Ragweed**	Start clean with a burndown herbicide program or tillage. Apply a preemergence residual herbicide such as pendimethalin (Prowl) plus fluometuron or fomesafen (Reflex)for control of *Ambrosia* species. In-crop, tank-mix Roundup WeatherMAX at 22 oz/A with metolachlor before *Ambrosia* species emerges. Use Roundup WeatherMAX in-crop, as needed, at a minimum of 22 oz/A to control other weeds. A post-directed application of Roundup WeatherMAX tank-mixed with MSMA and a residual such as diuron (Direx) or flumioxazin (Valor) should be made to control *Ambrosia* species 3" or smaller in height and prevent additional flushes.
Glyphosate-Resistant Johnsongrass	Start clean with a burndown herbicide or tillage. Preplant incorporate a residual herbicide such as pendimethalin or trifluralin for control or suppression of seedling johnsongrass. Apply Roundup WeatherMAX in a tank-mix with herbicides such as SelectMAX®, Assure® II or Poast Plus for the control of emerged weeds including seedling and rhizome johnsongrass. Follow all label directions of tank-mix partners, especially those related to weed size.

In certain areas, Italian ryegrass is known to be resistant to glyphosate. For control recommendations, refer to **www.weedresistancemanagement.com** or call 1-800-768-6387. When approved, supplemental labeling for specific herbicide products can also be viewed on **www.cdms.net** or **www.greenbook.net.**



*Follow all pesticide label requirements.

Genuity™ Roundup Ready® Flex Cotton and Genuity™ Bollgard II® with Roundup Ready® Flex Cotton

GENUITY™ ROUNDUP READY® FLEX COTTON

Genuity™ Roundup Ready® Flex cotton varieties possess improved reproductive tolerance to Roundup® agricultural herbicides. This technology gives farmers the opportunity to make over-the-top broadcast applications of labeled Roundup agricultural herbicides from crop emergence up to seven (7) days prior to harvest.

GENUITY™ BOLLGARD II® WITH ROUNDUP READY® FLEX COTTON

Genuity™ Bollgard II® with Roundup Ready® Flex varieties offer farmers the benefits of both insect protection and glyphosate tolerance combined in one crop. These varieties exhibit the same insect protection qualities as Genuity™ Bollgard II® and are tolerant to over-the-top applications of Roundup WeatherMAX® and Roundup PowerMAX®.

MARKET OPTIONS

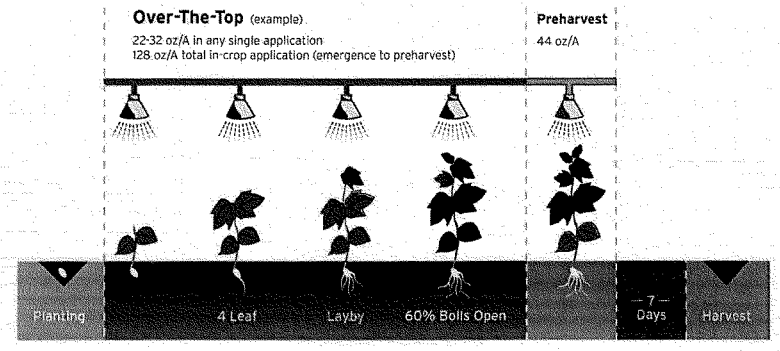
Genuity™ Roundup Ready® Flex cotton and Genuity™ Bollgard II® with Roundup Ready Flex cotton have regulatory clearance in the United States, but do not have import approval in all export markets. Processed fractions from these products, including linters, oil, meal, cottonseed and gin trash, must not be exported without all necessary approvals in the importing country. It is a violation of national and international law to move material containing biotech traits across boundaries into nations where import is not permitted.

RECOMMENDED MANAGEMENT PRACTICES

Managing Genuity™ Roundup Ready® Flex cotton and Genuity™ Bollgard II® with Roundup Ready® Flex cotton requires a farmer to follow the recommended management practices associated with cotton containing each individual trait. Farmers of Genuity™ Bollgard II® with Roundup Ready® Flex cotton must follow the same guidelines for establishing required refuge options, practicing IRM and managing target and non-target pests as described for Genuity™ Bollgard II® cotton in the IRM/Grower Guide.

WEED RESISTANCE MANAGEMENT GUIDELINES

Follow all label requirements and the guidelines below to minimize the risk of developing weed resistance in a Genuity™ Roundup Ready® Flex cotton system:



- Scout fields before and after each burndown and in-crop application.
- Start clean with a burndown herbicide program or tillage.
- Use the right herbicide product at the right rate and right time.
- Add soil residual herbicide(s) and cultural practices as part of a Genuity™ Roundup Ready® Flex cotton weed control program.
- In-crop, apply Roundup WeatherMAX at a minimum of 22 oz/A when weeds are 3" to 6" in height.
- Tank-mix other approved herbicides with Roundup WeatherMAX if necessary for postemergence weed control.
- Should repeated non-performance occur, report to Monsanto or your local retailer.
- Clean equipment before moving from field to field to minimize the spread of weed seed (as well as nematodes, insects and other cotton pests).

APPLICATION OF ROUNDUP WEATHERMAX® AND ROUNDUP POWERMAX®

- May be applied over-the-top and/or in-crop, from crop emergence up to 7 days prior to harvest.
- A maximum rate of 32 oz/A per application may be applied using ground application equipment while the maximum is 22 oz/A per application by air.
- There are no growth or timing restrictions for sequential applications.
- Four (4) quarts/A is the total in-crop volume allowed from emergence to 60% open bolls.
- A maximum total volume of 44 oz/A may be applied between layby and 60% open bolls.
- Post-directed equipment may be used to achieve more thorough spray coverage of weeds or if herbicides not labeled for over-the-top application will be tank-mixed with Roundup WeatherMAX or Roundup PowerMAX.

PREHARVEST APPLICATIONS

- Up to 44 oz/A may be applied after cotton reaches 60% open bolls and before harvest, if needed.
- Applications must be made at least 7 days prior to harvest.

CROP SAFETY OF OVER-THE-TOP GLYPHOSATE APPLICATIONS

Monsanto has determined that a combination of components in glyphosate formulations have the potential to cause leaf injury when applied during later stages of crop growth. Roundup WeatherMAX and Roundup PowerMAX are the only Roundup agricultural herbicides labeled and approved for new labeled uses over the top of Genuity™ Roundup Ready® Flex cotton.

Leaf injury may occur if the products are not used according to the product label, used at higher than recommended rates or if overlap of spray occurs in the field. **Farmers must confirm that any glyphosate formulation to be used on Genuity™ Roundup Ready® Flex cotton has been labeled for use on Genuity™ Roundup Ready® Flex cotton and should confirm that it has been tested to demonstrate crop safety.**

WEED CONTROL RECOMMENDATIONS

Weed control in cotton is essential to maximize both fiber yield and quality potential. Cotton is very sensitive to early-season weed competition, which can result in unacceptable stands and/or reduced yield potential. The Genuity™ Roundup Ready® Flex cotton system, with improved reproductive tolerance to Roundup® agricultural herbicides, provides farmers with the right tools to control weeds.

PROGRAM	INSTRUCTIONS AND USE RATES*	ADDITIONAL INFORMATION
Preplant Burndown	Always start clean by planting into a weed-free field using either tillage or a burndown application. In no-till and reduced-till systems, apply a preplant burndown application of Roundup WeatherMAX®** at 22 to 44 oz/A in a tank-mix with dicamba or 2,4-D. See the dicamba and 2,4-D product label for rates and time intervals required between application and cotton planting. State restrictions may apply.	Early-season weed competition can result in unacceptable stands and/or reduced yield potential. This tank-mix is recommended for control and management of glyphosate-resistant marestail (*Conyza sp.*) or other tough-to-control weeds. Burndown application should be made far enough in advance of planting to control existing weeds.
Residual Herbicides	Apply approved residual herbicide(s) as part of a Genuity™ Roundup Ready® Flex cotton weed control program. Use the recommended label rate and timing of the residual herbicide applied. Refer to individual product labels for list of residual herbicides that may be used.	The residual herbicide(s) may be applied as either a preemergence (including preplant incorporated), postemergence, and/or layby application as allowed on the label of the specific product being used.
In-Crop Weed Control	Target the first application of Roundup WeatherMAX on 1-2 leaf cotton when weeds are small. Apply a minimum of 22 oz/A of Roundup WeatherMAX in-crop. The need for sequential applications of Roundup WeatherMAX will depend upon the occurrence of subsequent weed flushes. Refer to the "Annual Weeds Rate Table" in the Roundup WeatherMAX label booklet for rate recommendations for specific annual weeds.	Early-season weed competition can reduce yield potential in cotton. Select timing of application based on the most difficult to control weed species in your field. Post-direct or hooded sprayers can be used to achieve more thorough spray coverage on weeds.
Preharvest Over-The-Top Applications	Before harvest and after cotton reaches 60% open bolls, if needed, apply up to 44 oz/A of Roundup WeatherMAX. This treatment is effective in controlling late-season perennial weeds.	Applications must be made at least 7 days prior to harvest. Roundup agricultural herbicides are not effective for preharvest cotton regrowth in Genuity™ Roundup Ready® Flex cotton.

*Follow all pesticide label requirements.

**The maximum volume of Roundup WeatherMAX and Roundup PowerMAX® that may be used in a single season is 5.3 quarts per acre.

RECOMMENDATIONS FOR MANAGING GLYPHOSATE-RESISTANT WEEDS

WEEDS	INSTRUCTIONS AND USE RATES*
Glyphosate-Resistant Marestail (Horseweed)	Start clean with a burndown herbicide program or tillage. -Tank-mix Roundup agricultural herbicides with dicamba or 2,4-D (consult label for plant back timing). If you have dense stands of marestail, use a preplant residual herbicide at the recommended rate and timing, such as diuron (Direx®) or flumioxazin (Valor®). Use Roundup WeatherMAX in-crop, as needed, at a minimum of 22 oz/A to control other weeds. In-crop, if applying post-directed to glyphosate-resistant marestail, Roundup WeatherMAX can be tank-mixed with other herbicides, such as diuron or MSMA. Marestail should not exceed 6" in height at the time of in-crop application.
Glyphosate-Resistant *Amaranthus* Species **- *Palmer Amaranth*** **- Waterhemp**	Start clean with a burndown herbicide program or tillage. Apply a preemergence residual herbicide such as pendimethalin (Prowl®) plus fluometuron or fomesafen (Reflex®) or flumioxazin (Valor) for control of *Amaranthus* species. In-crop, tank-mix Roundup WeatherMAX at 22 oz/A with metolachlor or other labeled chloracetamide herbicide before *Amaranthus* species emerges. Use Roundup WeatherMAX in-crop, as needed, at a minimum of 22 oz/A to control other weeds. A post-directed application of Roundup WeatherMAX tank-mixed with MSMA and a residual such as diuron (Direx) or flumioxazin (Valor) should be made to control *Amaranthus* species 3" or smaller in height and prevent additional flushes.
Glyphosate-Resistant *Ambrosia* Species **- Giant Ragweed** **- Common Ragweed**	Start clean with a burndown herbicide program or tillage. Apply a preemergence residual herbicide such as pendimethalin (Prowl) plus fluometuron or fomesafen (Reflex) for control of *Ambrosia* species. In-crop, tank-mix Roundup WeatherMAX at 22 oz/A with metolachlor before *Ambrosia* species emerges. Use Roundup WeatherMAX in-crop, as needed, at a minimum of 22 oz/A to control other weeds. A post-directed application of Roundup WeatherMAX tank-mixed with MSMA and a residual such as diuron (Direx) or flumioxazin (Valor) should be made to control *Ambrosia* species 3" or smaller in height and prevent additional flushes.
Glyphosate-Resistant Johnsongrass	Start clean with a burndown herbicide or tillage. Preplant incorporate a residual herbicide such as pendimethalin or trifluralin for control or suppression of seedling johnsongrass. **Apply Roundup WeatherMAX in a tank-mix with herbicides such as SelectMAX®, Assure® II or Poast Plus for the control of emerged weeds including seedling and rhizome johnsongrass. Follow all label directions of tank-mix partners, especially those related to weed size.**

In certain areas, Italian ryegrass is known to be resistant to glyphosate. For control recommendations, refer to **www.weedresistancemanagement.com** or call 1-800-768-6387. When approved, supplemental labeling for specific herbicide products can also be viewed on **www.cdms.net** or **www.greenbook.net.**

*Follow all pesticide label requirements.

GENUITY™ ROUNDUP READY 2 YIELD® AND ROUNDUP READY® SOYBEANS

Genuity™ Roundup Ready 2 Yield® and Roundup Ready® soybean varieties contain in-plant tolerance to Roundup® agricultural herbicides. This means you can spray Roundup agricultural herbicides in-crop from emergence through flowering.

Spray labeled Roundup agricultural herbicides over the top from emergence (cracking) through flowering (R2 stage soybeans) for unsurpassed weed control, proven crop safety and maximum yield potential. R2 stage soybeans end when a pod 5 millimeters (3/16") long at one of the four uppermost nodes appears on the main stem along with a fully developed leaf (R3 stage).

WEED CONTROL RECOMMENDATIONS

Starting clean with a weed-free field, and making timely post-emergence in-crop applications, is critical to obtaining excellent weed control and maximum yield potential. The Roundup Ready soybean system provides the flexibility to use the herbicide tools necessary to control weeds at planting and in-crop. Failure to control weeds with the right rate, at the right time and with the right product, can lead to increased weed competition and the potential for decreased yield.

PROGRAM	INSTRUCTIONS AND USE RATES*	ADDITIONAL INFORMATION
Preplant Burndown	To start clean in no-till systems, apply a burndown application of Roundup WeatherMAX®** at 22 to 44 oz/A before planting. See the label for appropriate rates by weed species. For control and management of glyphosate-resistant marestail (*Conyza sp.*) or other difficult-to-control weeds present at burndown, apply 22 oz/A of Roundup WeatherMAX in a tank-mix with 1 to 2 pt/A 2,4-D. Make applications 7 to 30 days before planting and before marestail reaches 6" in height.	Always start with a weed-free field. In no-till and reduced-till systems, apply a Roundup WeatherMAX® burndown application to control existing weeds before planting. Adding 2,4-D in the burndown can significantly reduce broadleaf weed pressure at post-emergence timing. Read the 2,4-D product label for time intervals required between application and soybean planting.
Residual Herbicide Plus Roundup WeatherMAX	Use the recommended label rate of a soil-applied residual herbicide applied preemergence to soybeans as defined in the individual product's labeling. The residual product may be tank-mixed with Roundup WeatherMAX at burndown. Refer to individual product labels for list of residual herbicides that may be used. Follow with 22 oz/A Roundup WeatherMAX in-crop when weeds are 2" to 8" tall. Refer to the "Annual Weeds Rate Table" in the Roundup WeatherMAX label for rate recommendations for specific annual weeds. Crop rotation following Genuity™ Roundup Ready 2 Yield® and Roundup Ready soybeans is strongly encouraged. Use of a residual herbicide is encouraged especially if the cropping system is a continuous Roundup Ready system.	A residual program is encouraged when agronomic conditions favor the practice. Reducing Roundup WeatherMAX rate when tank-mixing with a residual or use of premixes utilizing a reduced rate of glyphosate (such as Extreme®) is not recommended. If the in-crop application is delayed and weeds are larger, apply a higher rate of Roundup WeatherMAX.
Roundup WeatherMAX	Apply a minimum of 22 oz/A of Roundup WeatherMAX** in-crop when weeds are 2" to 8" tall. Refer to the "Annual Weeds Rate Table" in the Roundup WeatherMAX label for rate recommendations for specific annual weeds. Choose the rate to control the most difficult-to-control weed in your field. A sequential application of this product may be required to control new flushes of weeds in the Roundup Ready soybean crop. If a sequential application is necessary, apply 16 to 22 oz/A of Roundup WeatherMAX** when weeds are 3" to 6" tall.	In-crop application of Roundup WeatherMAX provides control of labeled weeds. For best results, apply 3 to 4 weeks after planting or when weeds are less than 8" tall. If initial application is delayed and weeds are larger, apply a higher labeled rate of Roundup WeatherMAX.

*Follow all pesticide label requirements.

**If using another Roundup agricultural herbicide, you must refer to the label booklet or Genuity™ Roundup Ready 2 Yield® soybean or Roundup Ready soybean supplemental label for that brand to determine appropriate use rates. If using Roundup PowerMAX, application rates are the same as for Roundup WeatherMAX.

GENUITY™ ROUNDUP READY 2 YIELD® AND ROUNDUP READY® SOYBEANS

PROGRAM	INSTRUCTIONS AND USE RATES*	ADDITIONAL INFORMATION
Glyphosate-Tolerant Volunteer Corn	Tank-mix Roundup WeatherMAX® with 6 to 12 oz/A of Select Max® and apply to 4" to 36" glyphosate-tolerant volunteer corn.	Choose your Roundup WeatherMAX rate based on the weed species and size listed in the "Annual Weeds Rate Table" of the Roundup WeatherMAX Label.
Maximum Use Rates for Roundup WeatherMAX	**In-Crop:** • 44 oz/A per single application • 44 oz/A during flowering • 64 oz/A emergence through flowering (R2 stage soybeans) **Preharvest:** • 22 oz/A application	**Total Season:** The combined total of preplant, in-crop and preharvest applications of Roundup WeatherMAX can not exceed 5.3 qt/A. The combined total of in-crop and preharvest applications can not exceed 64 oz/A.

*Follow all pesticide label requirements.

Herbicide products sold by Monsanto for use over the top of soybeans with Genuity™ Roundup Ready 2 Yield® Technology for the 2010 crop season are as follows:

- Roundup WeatherMAX
- Roundup PowerMAX

WEED CONTROL RECOMMENDATIONS

KEY WEEDS	INSTRUCTIONS AND USE RATES*	ADDITIONAL INFORMATION
Weeds that Tend to Have Multiple Emergence Events	Where dense stands of weed species such as common lambsquarters, tall and common waterhemp, *Palmer Amaranth*, redroot pigweed, common ragweed, and giant ragweed are expected, the following agronomic practices are recommended: • Start clean with tillage or burndown in no-till and reduced till systems. include 2,4-D in the burndown. • Plant soybeans in narrow rows (<20"). • Use a pre-plant residual herbicide. • Use the right rate of Roundup WeatherMAX at the right time (proper weed size).	Weeds such as lambsquarters, waterhemp, pigweed, and giant ragweed tend to emerge throughout the season. Sequential Roundup WeatherMAX applications or the addition of a soil residual herbicide may be required for control of subsequent weed flushes.
Difficult-to-Control Weeds	Black nightshade, velvetleaf, waterhemp, morningglory, lambsquarters, Florida pusley, giant ragweed, Pennsylvania smartweed, groundcherry, hemp sesbania and spurred anoda are difficult-to-control weeds. Please refer to the Roundup agricultural herbicide label for specific rates and weed sizes for control of these weeds.	These weed species require special attention be paid to Roundup WeatherMAX rate and application timing (proper weed size) to obtain excellent weed control. A sequential application may be required if a new weed flush occurs, especially in soybeans planted in wide rows (>20").
Perennial Weeds	An in-crop application of 22 to 44 oz/A of Roundup WeatherMAX** will provide suppression and/or control of nutsedge and perennial weeds like Canada thistle, field bindweed, hemp dogbane, horsenettle, johnsongrass, milkweed, quackgrass, etc.	For additional information on perennial weeds, see the "Perennial Weeds Rate Table" in the label booklet for Roundup WeatherMAX. For best control, allow perennials to achieve at least 6" or more of growth before spraying.

*Follow all pesticide label requirements.

**If using another Roundup agricultural herbicide, you must refer to the label booklet or Roundup Ready Soybean or Genuity™ Roundup Ready 2 Yield® Soybean supplemental label for that brand to determine appropriate use rates. If using Roundup PowerMAX, application rates are the same as for Roundup WeatherMAX.

WEED RESISTANCE MANAGEMENT GUIDELINES

Follow all pesticide label requirements and the guidelines below to minimize the risk of developing glyphosate-resistant weed populations in a Roundup Ready Soybean System:

- Crop rotation is strongly encouraged.
- Scout fields before and after each burndown and in-crop application.

- Start clean with a burndown herbicide or tillage.
  - Tank-mix with 2,4-D to control glyphosate-resistant marestail or other tough-to-control broadleaf weeds.
- Use the recommended label rate of a soil-applied residual herbicide such as INTRRO®, Valor®, Valor XLT® or Gangster®.
- In-crop, apply Roundup WeatherMAX at a minimum of 22 oz/A before weeds exceed 8" in height.
- If an additional flush of weeds occurs, a sequential application of Roundup WeatherMAX at 22 oz/A may be needed before weeds exceed 6" in height.
- Refer to individual product labels for a list of recommended tank-mix partners.
- Clean equipment before moving from field to field to minimize the spread of weed seed.
- Report repeated non-performance to Monsanto or your local retailer.

RECOMMENDATIONS FOR MANAGING GLYPHOSATE-RESISTANT WEEDS

WEEDS	INSTRUCTIONS AND USE RATES*
Glyphosate-Resistant Marestail (Horseweed)	**Preplant:** Apply a tank-mixture of 22 oz/A Roundup WeatherMAX® with 1 pt/A 2,4-D before marestail exceeds 6" in height. See the 2,4-D product label for time intervals required between application and planting. **In-crop:** It is strongly encouraged that marestail should be controlled prior to planting using recommended preplant burndown treatments. In-crop, apply a tank-mixture of 22 oz/A Roundup WeatherMAX with 0.3 oz/A FirstRate®. This treatment should be used as a salvage treatment only for a marestail infestation that was not controlled preplant. Application should be made between full emergence of the first trifoliate leaf and 50% flowering stage of soybeans. At the time of treatment, marestail should not exceed 6" in height.
Glyphosate-Resistant *Amaranthus* Species **- *Palmer Amaranth*** **- Waterhemp**	**Preplant:** Apply a tank-mix of 22 oz/A Roundup WeatherMAX with a preemergence residual herbicide such as alachlor (INTRRO®), flumioxazin (Valor®) or another residual herbicide for preemergence control of *Amaranthus* species. 2,4-D may be added to the tank-mix to help control emerged *Amaranthus* species and other broadleaf weeds preplant only. Follow label instructions regarding application timing relative to soybean planting. **In-crop:** It is strongly encouraged that a preemergence residual product be used to control *Amaranthus* species prior to emergence. If there is emerged *Amaranthus* in-crop, apply a tank-mixture of 22 oz/A Roundup WeatherMAX with a postemergence product with activity on *Amaranthus* such as lactofen (Cobra®), fomesafen (Flexstar®) or cloransulam (FirstRate). Applications should be made on emerged *Amaranthus* that does not exceed 3" in height. Read and follow all product label instructions. It is likely that visual soybean injury will occur with these tank-mixtures.
Glyphosate-Resistant *Ambrosia* Species **- Giant Ragweed** **- Common Ragweed**	**Preplant:** Apply a tank-mix of 22 oz/A Roundup WeatherMAX with a preemergence residual herbicide such as cloransulam (FirstRate) or cloransulam + flumioxazin (Ganster®) or another residual herbicide for preemergence control of *Ambrosia* species. 2,4-D may be added to the tank-mix to help control emerged *Ambrosia* species and other broadleaf weeds preplant only. Follow label instructions regarding application timing relative to soybean planting. **In-crop:** It is strongly encouraged that a preemergence residual product be used to control *Ambrosia* species prior to emergence. If there is emerged *Ambrosia* in-crop, apply a tank-mixture of 22 oz/A Roundup WeatherMAX with a postemergence product with activity on *Ambrosia* such as lactofen (Cobra) or fomesafen (Flexstar). Applications should be made on emerged *Ambrosia* that does not exceed 3" in height. Read and follow all product label instructions. It is likely that visual soybean injury will occur with these tank-mixtures.
Glyphosate-Resistant Johnsongrass	Start clean with a burndown herbicide or tillage. Preplant incorporate a residual herbicide such as pendimethalin or trifluralin for control or suppression of seedling johnsongrass. Apply Roundup WeatherMAX in a tank-mix with herbicides such as SelectMAX®, Assure® II or Poast Plus for the control of emerged weeds including seedling and rhizome johnsongrass. Follow all label directions of tank-mix partners, especially those related to weed size.

In certain areas, Italian ryegrass is known to be resistant to glyphosate. For control recommendations, refer to **www.weedresistancemanagement.com** or call 1-800-768-6387. When approved, supplemental labeling for specific herbicide products can also be viewed on **www.cdms.net** or **www.greenbook.net.**

*Follow all pesticide label requirements.

CANOLA
ALFALFA
SUGARBEET

GENUITY™ ROUNDUP READY® ALFALFA

ATTENTION: Pursuant to a Court Order issued on May 3, 2007, Genuity™ Roundup Ready® alfalfa seed **CAN NOT be commercially sold or planted** until further administrative regulatory actions are completed. For more information, and the latest updates on Genuity™ Roundup Ready® alfalfa, go to www.roundupreadyalfalfa.com.

Genuity™ Roundup Ready® alfalfa varieties have in-plant tolerance to Roundup® agricultural herbicides, enabling farmers to apply labeled Roundup agricultural herbicides up to 5 days before cutting for unsurpassed weed control, excellent crop safety and preservation of forage quality potential.

Hay and Forage Management Practices

Genuity™ Roundup Ready® alfalfa must be managed for high quality hay/forage production, including timely cutting to promote high forage quality (i.e. before 10% bloom) and to prevent seed development. In geographies where conventional alfalfa seed production is intermingled with forage production and the agronomic conditions (climate and water/irrigation availability) are such that forage alfalfa is allowed to stand and flower late in the season, Genuity™ Roundup Ready® alfalfa must be harvested at or before 10% bloom to minimize potential pollen flow from hay to common or conventional alfalfa seed production. Farmers who are unwilling to or who can not make this commitment to stewardship should not continue to grow Genuity™ Roundup Ready® alfalfa.

Genuity™ Roundup Ready® alfalfa varieties have excellent tolerance to over-the-top applications of labeled Roundup agricultural herbicides. An in-crop weed control program using Roundup WeatherMAX® or Roundup PowerMAX® will provide excellent weed control in most situations. A residual herbicide labeled for use in alfalfa may also be applied postemergence in alfalfa. Contact a Monsanto Representative, local crop advisor or extension specialist to determine the best option for your situation.

Stand Takeout and Volunteer Management

Crop rotations can be divided into two main groups, alfalfa rotated to: 1) grass crops (e.g. corn and cereal crops); and 2) broadleaf crops. More herbicide alternatives exist for management of volunteer alfalfa in grass crops. The recommended steps for controlling volunteer Genuity™ Roundup Ready® alfalfa are:

- Diligent Stand Takeout
- Start Clean
- Plan for Success
- Timely Execution

DILIGENT STAND TAKEOUT

Use appropriate, commercially available herbicide treatments alone for reduced tillage systems or in combination with tillage to terminate the Genuity™ Roundup Ready® alfalfa stand. Refer to your regional technical bulletin for specific stand takeout recommendations. **NOTE:** Roundup® agricultural herbicides are **not** effective for terminating Genuity™ Roundup Ready® alfalfa stands.

START CLEAN

If necessary, utilize tillage and/or additional herbicide application(s) after stand takeout, and before planting of the subsequent rotational crop to manage any newly emerged or surviving alfalfa.

PLAN FOR SUCCESS

Rotate the crops with known and available mechanical or herbicidal methods for managing volunteer alfalfa, keeping in mind that Roundup agricultural herbicides will not terminate Genuity™ Roundup Ready® alfalfa stands.

- Rotations to certain broadleaf crops are not advisable if the farmer is not willing to implement recommended stand termination practices.
- In the event that no known mechanical or herbicidal methods are available to manage volunteer alfalfa in the desired rotational crop, it is suggested that a crop with established volunteer alfalfa management practices be introduced into the rotation.

TIMELY EXECUTION

Implement in-crop mechanical or herbicide treatments for managing alfalfa volunteers in a timely manner; that is, before the volunteers become too large to control or begin to compete with the rotational crop.

Planting Requirements

Genuity™ Roundup Ready® alfalfa is not permitted to be planted in any wildlife feed plots.

Stewardship

All Genuity™ Roundup Ready® alfalfa farmers shall sign the Monsanto Technology/Stewardship Agreement (MTSA) limited-use license application which provides the terms and conditions for the authorized use of the product. Due to special circumstances, alfalfa farmers in the Imperial Valley of California will also sign an Imperial Valley Use Agreement (IVUA) with specific stewardship commitments. The MTSA or IVUA must be completed before purchase or use of seed.

Both the MTSA or IVUA explicitly prohibit all forms of commercial seed harvest on the stand. Every alfalfa farmer producing seed of Genuity™ Roundup Ready® alfalfa must possess an additional, separate and distinct seed farmer contract to produce Genuity™ Roundup Ready® alfalfa seed. Genuity™ Roundup Ready® alfalfa seed may not be planted outside of the United States, or for the production of seed or sprouts.

Any product produced from a Genuity™ Roundup Ready® alfalfa crop or seed, including hay and hay products, must be labeled and may only be used, exported to, processed or sold in countries where regulatory approvals have been granted. It is a violation of national and international laws to move material containing biotech traits across boundaries into nations where import is not permitted.

Pursuant to a Court Order issued on May 3, 2007, Genuity™ Roundup Ready® alfalfa farmers must adhere to the requirements set out in the December 18, 2007 USDA Administrative Order **(http://www.aphis.usda.gov/brs/pdf/RRA_AB_final.pdf)** until the USDA completes its regulatory process.

These requirements include, but are not limited to:

- Pollinators shall not be added to Genuity™ Roundup Ready® alfalfa fields grown only for hay production.
- Farm equipment used in Genuity™ Roundup Ready® alfalfa production shall be properly cleaned after use.
- Genuity™ Roundup Ready® alfalfa shall be handled and clearly identified to minimize commingling after harvest.

For additional information visit the USDA website: **http://www.aphis.usda.gov/biotechnology/alfalfa_history.shtml**

For more information and the latest updates on Genuity™ Roundup Ready® alfalfa, go to **http://www.roundupreadyalfalfa.com**

To meet sales reporting requirements, the seed supplier is required to identify and list all Genuity™ Roundup Ready® alfalfa field locations. Therefore, all farmers MUST PROVIDE their seed supplier with the GPS coordinates of all their Genuity™ Roundup Ready® alfalfa fields.

WEED RESISTANCE MANAGEMENT GUIDELINES

Follow all pesticide label requirements and the guidelines below to minimize the risk of developing glyphosate-resistant weed populations in a Genuity™ Roundup Ready® alfalfa system:

- Scout fields before and after each herbicide application.
- Use the right herbicide product at the right rate and at the right time.
- To control flushes of weeds in established alfalfa, make applications of Roundup WeatherMAX® or Roundup PowerMAX® herbicide at 22 to 44 oz/A before weeds exceed 6" in height, up to 5 days before cutting.
- Use other approved herbicide products tank-mixed or in sequence with Roundup agricultural herbicide if appropriate for the weed spectrum present as part of a Genuity™ Roundup Ready® alfalfa weed control program.
- Report repeated non-performance to Monsanto or your local retailer.

WEED CONTROL RECOMMENDATIONS

In established stands, to preserve the quality potential of forage and hay, applications should be made after weeds have emerged but before alfalfa re-growth interferes with application spray coverage of the target weeds.

PROGRAM	INSTRUCTIONS AND USE RATES*	ADDITIONAL INFORMATION
Established Stands	After the first harvest of a newly established stand, up to 44 oz/A of Roundup WeatherMAX®** herbicide per cutting may be applied up to 5 days before each subsequent cutting. The combined total per year for all in-crop applications in established stands must not exceed 132 oz/A (4.1 qt/A) of Roundup WeatherMAX.	Applications between cuttings may be applied as a single application or in multiple applications (e.g. 2 applications of 22 oz/A). Sequential applications should be at least 7 days apart.
Weeds Controlled	For specific application rates and instructions for control of various annual and perennial weeds, refer to the Roundup WeatherMAX®* herbicide label booklet. Some weeds with multiple germination times or suppressed (stunted) weeds may require a second application of Roundup WeatherMAX®* herbicide for complete control. For some perennial weeds, repeated applications may be required to eliminate crop competition throughout the growing season.	In addition to those weeds listed in the Roundup WeatherMAX® label booklets, this product will suppress or control the parasitic weed, dodder (*Cuscuta* spp.) in Genuity™ Roundup Ready® alfalfa. Repeat applications may be necessary for complete control. For tough-to-control weeds or weeds not controlled by Roundup® agricultural herbicides use labeled rates of other approved herbicides, alone or in tank-mixtures, with Roundup agricultural herbicides.
Maximum Use Rates	**In-Crop:** - 44 oz/A per single application. - Established Stand Total: 44 oz/A per cutting up to 5 days before harvest.	**Total Per Year:** The combined total per year for all in-crop applications in established stands must not exceed 132 oz/A (4.1 qt/A) of Roundup WeatherMAX.

*Follow all pesticide label requirements.

**If using another Roundup agricultural herbicide, you must refer to the label booklet or separately published Genuity™ Roundup Ready® alfalfa supplemental label for that brand to determine appropriate use rates. If using Roundup PowerMAX, application rates are the same as for Roundup WeatherMAX.

GENUITY™ ROUNDUP READY® SPRING CANOLA

Genuity™ Roundup Ready® spring canola hybrids contain in-plant tolerance to Roundup agricultural herbicides, enabling farmers to apply Roundup® agricultural herbicides over the top of Genuity™ Roundup Ready® spring canola anytime from emergence through the 6-leaf stage of development.

The introduction of the Roundup Ready® trait into leading spring canola hybrids and varieties gives farmers the opportunity for unsurpassed weed control, proven crop safety and maximum profit potential. With Genuity™ Roundup Ready® spring canola, farmers have the weed management tool necessary to improve spring canola profitability, while providing a viable rotational crop to help break pest and disease cycles in cereal-growing areas.

WEED RESISTANCE MANAGEMENT GUIDELINES

Follow all pesticide label requirements and the guidelines below to minimize the risk of developing glyphosate-resistant weed populations in a Genuity™ Roundup Ready® spring canola system:

- Scout fields before and after each burndown and in-crop application.
- Start clean with a burndown herbicide or tillage.
- In-crop, apply Roundup WeatherMAX® herbicide before weeds exceed 3" in height.
- A sequential application of Roundup WeatherMAX herbicide may be needed.
- Clean equipment before moving from field to field to minimize the spread of weed seed.
- Report repeated non-performance to Monsanto or your local retailer.

WEED CONTROL RECOMMENDATIONS (SPRING-SEEDED)

PROGRAM	INSTRUCTIONS AND USE RATES*	ADDITIONAL INFORMATION
Two-Pass Program– For Annual and Perennial Weed Control	For broad-spectrum control of annual and perennial weeds, use an initial application of 11 oz/A of Roundup WeatherMAX**, in 5 to 10 gal/A water volume. No surfactant is required. Make a second application of 11 oz/A of Roundup WeatherMAX** no less than 10 days after initial application up to the 6-leaf stage (prebolting). Do not exceed 11 oz/A per application.	Spray when canola is at the 0- to 6-leaf stage of growth. To maximize yield potential, spray Genuity™ Roundup Ready® spring canola at the 1- to 3-leaf stage to eliminate competing weeds. Short-term yellowing may occur with later applications, with little effect on crop growth, maturity, or yield. Wait a minimum of 10 days between applications. Two applications of Roundup WeatherMAX will: • Control late flushes of annual weeds such as foxtail, pigweed, and wild mustard. • Provide season-long suppression of Canada thistle, quackgrass, and perennial sow thistle. • Provide better yields by eliminating competition from both annuals and hard-to-control perennials.
Single Application– For Annual Weed Control	For broad-spectrum control of annual and easy-to-control perennial weeds, make a single application of 16 oz/A of Roundup WeatherMAX.**	For best results, spray Genuity™ Roundup Ready® spring canola at the 2- to 3-leaf stage. Can be applied up to 6-leaf stage; yellowing may occur with later application with little effect on crop growth, maturity, or yield. No additional over-the-top applications can be made.
Maximum Use Rate For Roundup WeatherMAX	Two over-the-top applications: Do not exceed 11 oz/A per application. Single over-the-top applications: Do not exceed 16 oz/A. No additional application can be made.	

*Follow all pesticide label requirements.

**If using another Roundup agricultural herbicide, you must refer to the label booklet or separately published Genuity™ Roundup Ready® canola supplemental label for that brand to determine appropriate use rates. If using Roundup PowerMAX, application rates are the same as for Roundup WeatherMAX.

GENUITY™ ROUNDUP READY™ WINTER CANOLA

Genuity™ Roundup Ready® winter canola varieties have been developed for seeding in the fall and harvesting the following spring/summer.

Genuity™ Roundup Ready® winter canola varieties contain in-plant tolerance to Roundup® agricultural herbicides, enabling farmers to apply Roundup agricultural herbicides over the top of Genuity™ Roundup Ready® winter canola from crop emergence to the pre-bolting stage. The introduction of the Roundup Ready trait into winter canola varieties gives farmers the opportunity of unsurpassed weed control, crop safety and maximum yield potential. Genuity™ Roundup Ready® winter canola offers farmers an important option as a rotational crop in traditional monoculture winter wheat production areas. Introducing crop rotation is an important factor in reducing pest cycles, including weed and disease problems.

WEED RESISTANCE MANAGEMENT GUIDELINES

Follow the same guidelines as stated for spring canola.

WEED CONTROL RECOMMENDATIONS (WINTER-SEEDED)

PROGRAM	INSTRUCTIONS AND USE RATES*	ADDITIONAL INFORMATION
Sequential Applications	The two-pass program gives the greatest flexibility in controlling late emerging weeds. For broad-spectrum weed control, apply 11 to 22 oz/A of Roundup WeatherMAX** herbicide to 2-leaf or larger Genuity™ Roundup Ready® winter canola in the fall. Use 5 to 10 gallons/A water volume. Do not add surfactants. **Apply a second application of Roundup WeatherMAX** at 11 to 22 oz/A at a minimum interval of 60 days after the first application and before bolting in the spring.** Do not exceed 22 oz/A per application.	Spray when Genuity™ Roundup Ready® winter canola is at the 2-3 leaf stage of growth. Early applications can eliminate competing weeds and improve yield potential. Two applications of Roundup WeatherMAX will provide control of early emerging annual weeds and winter emerging weeds such as downy brome, cheat and jointed goatgrass.
Single Application	For broad-spectrum control of annual and easy-to-control perennial weeds, make a single application of 16 to 22 oz/A of Roundup WeatherMAX**, preferably in the fall.	For best results, spray Genuity™ Roundup Ready® winter canola at the 2-3 leaf stage and when weeds are small and actively growing. Applications must be made prior to bolting. Use the higher rate in the range when weed densities are high, when weeds have over wintered or when weeds become large and well established.
Maximum Use Rate for Roundup WeatherMAX	Any single over-the-top application of Roundup WeatherMAX** should not exceed 22 oz/A. No more than two over-the-top applications may be made from crop emergence to canopy closure prior to bolting in the spring.	Applications of greater than 16 fluid ounces/A prior to the 6-leaf stage may result in temporary yellowing and/or growth reduction.

*Follow all pesticide label requirements.

**If using another Roundup brand herbicide, you must refer to the label booklet or Genuity™ Roundup Ready® winter canola supplemental label for that brand to determine appropriate use rates. If using Roundup PowerMAX, application rates are the same as for Roundup WeatherMAX.

GRAZING

It is recommended that Genuity™ Roundup Ready® winter canola not be grazed. While Genuity™ Roundup Ready® winter canola may provide farmers additional opportunity as a forage for grazing livestock, at the present time insufficient information exists to allow safe and proper grazing recommendations. Preliminary data suggest that excessive grazing can significantly reduce yield, and that careful nitrate management is critical in managing Genuity™ Roundup Ready® winter canola as a forage to limit the risk of livestock nitrate poisoning. State universities are assessing the potential and the instructions for grazing Genuity™ Roundup Ready® winter canola and they will provide grazing management guidelines when their research is completed.

GENUITY™ ROUNDUP READY® SUGARBEETS

Genuity™ Roundup Ready® sugarbeet varieties have in-plant tolerance to Roundup® agricultural herbicides, enabling farmers to apply labeled Roundup agricultural herbicides from planting through 30 days prior to harvest for unsurpassed weed control, excellent crop safety and preservation of yield potential.

MANAGEMENT PRACTICES

Sugarbeets are extremely sensitive to weed competition for light, nutrients and soil moisture. Research on sugarbeet weed control suggests that sugarbeets need to be kept weed-free for the first eight weeks of growth to protect yield potential. Therefore, weeds must be controlled when they are small and before they compete with Genuity™ Roundup Ready® sugarbeets (exceed crop height), that is from less than 2" up to 4" in height, to preserve sugarbeet yield potential. *More than one in-crop herbicide application will be required* to control weed infestations to protect yield potential as Roundup agricultural herbicides have no soil residual activity. Bolting sugarbeets must be rogued or topped in Genuity™ Roundup Ready® sugarbeet fields.

Genuity® Roundup Ready® sugarbeet varieties have excellent tolerance to over-the-top applications of labeled Roundup agricultural herbicides. A postemergence weed control program using Roundup WeatherMAX® or Roundup PowerMAX® will provide excellent weed control in most situations. A residual herbicide labeled for use in sugarbeets may also be applied preemergence, preplant or postemergence in Genuity™ Roundup Ready® sugarbeets. Contact a Monsanto Representative, local crop advisor or extension specialist to determine the best option for your situation.

WEED RESISTANCE MANAGEMENT FOR GENUITY™ ROUNDUP READY® SUGARBEETS

Follow all pesticide label requirements and the guidelines below to minimize the risk of developing glyphosate-resistant weed populations in a Genuity™ Roundup Ready® sugarbeet system:

- Start clean with tillage and follow-up with a burndown herbicide, such as Roundup WeatherMAX, if needed prior to planting.
- Early-season weed control is critical to protect sugarbeet yield potential. Apply the first in-crop application of Roundup WeatherMAX at a minimum of 22 oz/A while weeds are less than 2" in height.
- Follow with additional postemergence in-crop application of Roundup WeatherMAX at a minimum of 22 oz/A for additional weed flushes before weeds exceed 4" in height.
- Add spray grade ammonium sulfate at a rate of 17 lbs/100 gallons of spray solution with Roundup® agricultural herbicides to maximize product performance.
- Use mechanical weed control/cultivation and/or residual herbicides where appropriate in your Genuity™ Roundup Ready® sugarbeets.
- Use additional herbicide modes of action/residual herbicides and/or mechanical weed control in other Roundup Ready crops you rotate with Genuity™ Roundup Ready® sugarbeets.
- Report repeated non-performance of Roundup agricultural herbicides to Monsanto or your local retailer.

AGRONOMIC PRINCIPLES IN SUGARBEETS

Sugarbeets are very sensitive to early-season weed competition. It is important to select the appropriate herbicide product, application rate and timing to minimize weed competition to protect yields. The Genuity™ Roundup Ready® sugarbeet system provides a mechanism to control weeds at planting and once Genuity™ Roundup Ready® sugarbeets emerge. Failure to control weeds with the right rate, at the right time and with the right product, can lead to increased weed competition, weed escapes and the potential for decreased yields. Tank-mixtures of Roundup agricultural herbicides with fungicides, insecticides, micronutrients or foliar fertilizers are not recommended as they may result in crop injury and reduced pest control or antagonism.

PLANTING REQUIREMENTS

Genuity™ Roundup Ready® sugarbeets are not permitted to be planted in any wildlife feed plots.

STEWARDSHIP

All Genuity™ Roundup Ready® sugarbeet farmers shall sign the Monsanto Technology/Stewardship Agreement (MTSA) limited-use license application which provides the terms and conditions for the authorized use of the product. The MTSA must be signed and approved prior to purchase or use of seed.

WEED CONTROL RECOMMENDATIONS

PROGRAM	INSTRUCTIONS AND USE RATES*	ADDITIONAL INFORMATION
Preplant Burndown	After preplant tillage or bedding operations have been completed, a preplant burndown application of Roundup WeatherMAX®** at 22 to 44 oz/A may be applied to control weeds that have germinated after tillage and prior to planting. See the label for appropriate rates by weed species and weed size.	Always utilize tillage to start with a weed-free field.
Over-The-Top Applications up to eight-leaf Genuity® Roundup Ready® Sugarbeets	Up to two applications of Roundup agricultural herbicides may be made prior to the 8-leaf stage of Genuity® Roundup Ready® sugarbeets. The first application of 22 to 32 oz/A of Roundup WeatherMAX** should be made when weeds are less than 2" in height to protect yield potential. Make an additional application of 22 to 32 oz/A of Roundup WeatherMAX before weeds exceed 4" in height. Maximum in-crop Roundup WeatherMAX prior to 8-leaf stage must not exceed 56 oz/A.	Sugarbeets are sensitive to weed competition and can lose yield rapidly if weeds are not controlled early. More than one in-crop Roundup WeatherMAX application will be required to control weed infestations to protect yield potential as Roundup agricultural herbicides have no soil residual activity. Add ammonium sulfate at a rate of 17 lbs/100 gallons of spray solution with Roundup agricultural herbicides to maximize product performance. Tank-mixtures of Roundup agricultural herbicides with fungicides, insecticides, micronutrients or foliar fertilizers are not recommended. Sequential applications should be at least 10 days apart.
Over-The-Top Applications to greater than eight-leaf Genuity® Roundup Ready® Sugarbeets	Up to two additional applications of 22 oz/A of Roundup WeatherMAX can be made after the eight-leaf stage up to 30 days prior to harvest. Maximum in-crop Roundup WeatherMAX from 8-leaf stage up until 30 days prior to harvest must not exceed 44 oz/A.	Add ammonium sulfate at a rate of 17 lbs/100 gallons of spray solution with Roundup agricultural herbicides to maximize product performance. Tank-mixtures of Roundup agricultural herbicides with fungicides, insecticides, micronutrients or foliar fertilizers are not recommended. Sequential applications should be at least 10 days apart.
Maximum Use Rates	**In-Crop:** • Two applications of Roundup WeatherMAX prior to the 8-leaf stage of Genuity® Roundup Ready® sugarbeets - 32 oz/A per single application up to the 8-leaf stage. - Combined maximum of 56 oz/A in-crop prior to the 8-leaf stage • Two applications of Roundup WeatherMAX after the 8-leaf stage up to 30 days prior to harvest - 22 oz/A per single application after the 8-leaf stage. - Combined maximum of 44 oz/A in-crop after the 8-leaf stage until 30 days prior to harvest	**Total Per Year:** The combined total per year for all Roundup WeatherMAX applications including pre-plant must not exceed 5.3 qt/A. Total in-crop application must not exceed 3 qt/A. Add ammonium sulfate at a rate of 17 lbs/100 gallons of spray solution with Roundup agricultural herbicides to maximize product performance. Tank-mixtures of Roundup agricultural herbicides with fungicides, insecticides, micronutrients or foliar fertilizers are not recommended.

*Follow all pesticide label requirements.

**If using another Roundup agricultural herbicide, you must refer to the label booklet or separately published Genuity® Roundup Ready® sugarbeets supplemental label for that brand to determine appropriate use rates. If using Roundup PowerMAX, application rates are the same as for Roundup WeatherMAX.

This guide was printed using Utopia II XG Cover and Text which contains 30% post-consumer waste. Savings derived from using 30% post-consumer fiber in lieu of 100% virgin fibers:

- Saves the equivalent of 585 mature trees
- Reduces solid waste by 35,308 pounds
- Reduces waste water by 213,390 gallons
- Reduces greenhouse gas emissions by 199,989.75 pounds

Before opening a bag of seed, be sure to read, understand and accept the stewardship requirements, **including applicable refuge requirements for insect resistance management,** for the biotechnology traits expressed in the seed as set forth in the Monsanto Technology Agreement that you sign. By opening and using a bag of seed, you are reaffirming your obligation to comply with the most recent stewardship requirements.

Roundup Ready® Alfalfa seed is currently not for sale or distribution. The movement and use of Roundup Ready® Alfalfa forage is subject to a USDA administrative Order available at http://www.aphis.usda.gov/brs/pdf/RRA_A8_final.pdf.

This stewardship statement applies to all products listed herein except Genuity™ VT Double PRO™, Genuity™ VT Triple PRO™ and Genuity™ SmartStax™. See restrictions related to Genuity™ Double PRO™, Genuity™ VT Triple PRO™ and Genuity™ SmartStax™ below:

Monsanto Company is a member of Excellence Through Stewardship® (ETS). Monsanto products are commercialized in accordance with ETS Product Launch Stewardship Guidance, and in compliance with Monsanto's Policy for Commercialization of Biotechnology-Derived Plant Products in Commodity Crops. This product has been approved for import into key export markets with functioning regulatory systems. Any crop or material produced from this product can only be exported to, or used, processed or sold in countries where all necessary regulatory approvals have been granted. It is a violation of national and international law to move material containing biotech traits across boundaries into nations where import is not permitted. Growers should talk to their grain handler or product purchaser to confirm their buying position for this product. Excellence Through Stewardship® is a registered trademark of Biotechnology Industry Organization.

IMPORTANT: Grain Marketing and Seed Availability: Genuity™ VT Double PRO™ has received the necessary approvals in the United States, however, as of October 22, 2009, approvals have not been received in certain major corn export markets. **Genuity™ VT Double PRO™** will not be launched and seed will not be available until after import approvals are received in appropriate major corn export markets. ***B.t.* products, including Genuity™ VT Double PRO™** may not yet be registered in all states. Check with your Monsanto representative for the registration status in your state.

IMPORTANT: Grain Marketing and Seed Availability: Genuity™ VT Triple PRO™ has received the necessary approvals in the United States however, as of October 22, 2009, approval has not been received in all major corn export markets. Monsanto anticipates that all such approvals will be in place for the 2010 growing season. If all approvals are not in place, **Genuity™ VT Triple PRO™** seed will only be available as part of a commercial demonstration program that includes grain marketing stewardship requirements. It is a violation of national and international law to move material containing biotech traits across boundaries into nations where import is not permitted. Consult with your seed representative for current regulatory and stewardship information status.

IMPORTANT: Grain Marketing and Seed Availability: Genuity™ SmartStax™ has received the necessary approvals in the United States, however, as of October 22, 2009, approvals have not been received in certain major corn export markets. **Genuity™ SmartStax™** will not be launched and seed will not be available until after import approvals are received in appropriate major corn export markets. ***B.t.* products, including Genuity™ SmartStax™** may not yet be registered in all states. Check with your Monsanto representative for the registration status in your state.

Cottonseed containing Monsanto traits may not be exported for the purpose of planting without a license from Monsanto.

Individual results may vary, and performance may vary from location to location and from year to year. This result may not be an indicator of results you may obtain as local growing, soil and weather conditions may vary. Growers should evaluate data from multiple locations and years whenever possible.

Growers may utilize the natural refuge option for varieties containing the Bollgard II® trait in the following states: AL, AR, FL, GA, KS, KY, LA, MD, MS, MO, NC, OK, SC, TN, VA, and most of Texas (excluding the Texas counties of Brewster, Crane, Crockett, Culberson, El Paso, Hudspeth, Jeff Davis, Loving, Pecos, Presidio, Reeves, Terrell, Val Verde, Ward and Winkler). The natural refuge option does not apply to **Bollgard II** cotton grown in areas where pink bollworm is a pest, including CA, AZ, NM, and the above listed Texas counties. It also remains the case that **Bollgard®** and **Bollgard II** cotton cannot be planted south of Highway 60 in Florida, and that **Bollgard** cotton cannot be planted in certain other counties in the Texas panhandle. Refer to the Technology Use Guide and IRM/Grower Guide for additional information regarding Bollgard II, Bollgard, natural refuge and EPA-mandated geographical restrictions on the planting of *B.t.* cotton.

ALWAYS READ AND FOLLOW PESTICIDE LABEL DIRECTIONS. Roundup Ready® crops contain genes that confer tolerance to glyphosate, the active ingredient in Roundup® brand agricultural herbicides. Roundup® brand agricultural herbicides will kill crops that are not tolerant to glyphosate. Degree® and Harness® are not registered in all states. Degree® and Harness® may be subject to use restrictions in some states. Bullet®, Degree Xtra®, Harness®, INTRRO®, Lariat®, and Micro-Tech® are restricted use pesticides and are not registered in all states. The distribution, sale, or use of an unregistered pesticide is a violation of federal and/or state law and is strictly prohibited. Check with your local Monsanto dealer or representative for the product registration status in your state.

Tank mixtures: The applicable labeling for each product must be in the possession of the user at the time of application. Follow applicable use instructions, including application rates, precautions and restrictions of each product used in the tank mixture. Monsanto has not tested all tank mix product formulations for compatibility or performance other than specifically listed by brand name. Always predetermine the compatibility of tank mixtures by mixing small proportional quantities in advance.

National Alfalfa & Forage Alliance Best Management Practices for Roundup Ready® Alfalfa Seed Production

NAFA Coexistence Document — Adopted January 2008

Best Management Practices for Roundup Ready® Alfalfa Seed Production

Introduction

The genetic supplier members (hereinafter called the "Companies") of National Alfalfa & Forage Alliance (NAFA) have agreed to jointly adopt, as a minimum, the following Best Management Practices for Roundup Ready Alfalfa (RRA) Seed Production in the United States. Compliance is required under a separate and binding agreement of the Companies to each other in this commitment. Forage Genetics International (FGI) is the exclusive licensed seed producer of RRA and will require all RRA seed production sub-licensees (herein after called the "RRA Seed Contractor(s)") to become a party to this binding agreement. It is not the intent of this document to establish best management practices for the production of alfalfa seed for GE sensitive markets. Changes to this document will require a recommendation from the Companies and approval by the NAFA Board of Directors.

Roundup Ready Trait Stewardship in Seed Production

- This document establishes RRA commercial seed production policies that exceed industry standards for Certified alfalfa seed production.
- Specifically, RRA seed production practices will meet or exceed Association of Official Seed Certifying Agencies (AOSCA) standards for the seed production of Foundation Class alfalfa seed production.
- All RRA seed growers must complete RRA seed stewardship training and agree to follow the RRA seed production policies as described herein and as required by RRA seed production contracts.

RRA Seed Contractors' Responsibilities

Isolation. The RRA Seed Contractor will insure that the isolation distance between the new planting and any established conventional seed production meets the following pollinator-specific isolation requirements for RRA seed production. Note the pollinator designated applies to normal pollinating bees introduced or locally cultured for alfalfa seed production in the area. If more than one pollinator species is introduced or locally cultured, the longer minimum distance applies.

- Leaf cutter bee – 900 feet
- Alkali bee – 1 mile
- Honey bee – 3 miles

Every year the Companies will collectively sample conventional seed lots, test for adventitious presence of the Roundup Ready trait, and use isolation distance from RRA seed production to monitor the effectiveness of current isolation standards. The Companies, along with three AOSCA representatives of state crop improvement associations or their designees, will analyze the data and make recommendations for changes to required isolation distances, if appropriate.

Reporting. The RRA Seed Contractor shall report GPS coordinates of all established and planned RRA seed production fields to local state seed certification officials as early as possible, but no later than two weeks prior to planting. State officials will confirm minimum isolation and establish a state pinning map for RRA seed production. The RRA Seed Contractor must authorize state officials to report to any seed grower or seed company, on request, the isolation distance between a planned new conventional alfalfa seed field and the nearest RRA seed field. GM-trait sensitive conventional or organic alfalfa seed producers can then use this third party service to assist them in planning their field locations to meet their company's isolation or field crop history goals or the certification agent may use the data to certify a stated isolation distance. The RRA Seed Contractor shall also notify local state seed certification officials, and officials shall confirm when a RRA seed production field is terminated.

GE-free seed production zones. The RRA Seed Contractor will limit RRA seed production contracts to the following states: Arizona, California, Colorado, Idaho, Montana, Nevada, Oregon, Texas, Utah, Washington and Wyoming. The RRA Seed Contractor will also respect any GE-free alfalfa seed production zone designated as such by a consensus of local seed growers. Recognition and designation of such zones will be based on the requirements of each state. It is envisioned that the local state seed certification agency would play an active role in administering programs of this nature.

Cooperation. All seed companies are encouraged to communicate and work together individually to manage joint seed quality issues and concerns.

RRA seed grower training. The RRA Seed Contractor will require RRA stewardship training for all new RRA seed growers. The RRA seed grower will confirm having received a copy of the NAFA Best Management Practices for Roundup Ready Alfalfa Seed Production (see Appendix 2).

RRA seed grower contracts. The RRA Seed Contractor shall stipulate which bee species can be introduced for pollination and incorporate key grower stewardship requirements (as listed below) in RRA seed production contracts.

License. The RRA Seed Contractor will have an FGI license for RRA seed production, including reporting requirements for acreage planted and seed harvested, by variety.

RRA Seed Growers' Responsibilities

Monsanto Technology/Stewardship Agreement (MTA). RRA Seed Grower must sign an MTA and are bound by the terms outlined in the current Monsanto Technology Use Guide (TUG). The MTA is a limited-use license for Monsanto traits, and renews automatically each year. The TUG is updated annually.

Observe patent rights. All RRA stock seed and harvested seed contains patent-protected, Roundup Ready trait, therefore:

- All seed transfer/sale is exclusive between RRA Seed Grower and the RRA Seed Contractor; no seed may be sold by RRA Seed Grower to other parties.
- RRA Seed Grower may not save seed for any purpose as per MTA.

Observe all federal, state and local regulations. It is the RRA Seed Grower's responsibility to know and obey current federal, state and local regulations affecting their agricultural practices. Some examples are as follows:

Federal Laws and Regulations:

- Pesticide use labels and restrictions;
- U.S. Patent Rights;
- Plant Variety Protection; Federal Seed Act.
- Phytosanitary laws governing import or export of seeds and pollinators.

State Laws and Regulations:

- Noxious or prohibited weeds, pathogens or insects;
- Pesticide use labels and restrictions

Local Laws and Regulations:

- Pesticide use notifications (field posting);
- County restrictions or prohibitions on the use of biotechnology, as applicable.

Bees. RRA Seed Grower will manage pollinators to minimize pollen flow to conventional/other variety fields.

- Only contract-specified bee species can be introduced for pollination supporting RRA seed production.
- There shall be no bee domicile movement from RRA to conventional alfalfa seed fields until pollination is finished for the year.
  - Once bees are in RRA seed fields, they may only be moved among RRA fields. It is the RRA Seed Grower's responsibility to inform their pollinator contractors or bee keepers of this requirement.
- RRA Seed Grower will locate domiciles to maximize domicile distance to other varieties, to the extent reasonable and appropriate to each field.
- The main pollinator bee species will be stated on each RRA Seed Grower Contract. Isolation requirements are specific to the main pollinator species.
- If honeybees are not the contract-stipulated pollinator species, the RRA Seed Grower will discourage neighbors from keeping honeybee hives in proximity to RRA seed production. In cases where this cannot be avoided, RRA Seed Grower is required to report the incident to the RRA Seed Contractor.

Isolation. RRA Seed Grower will assist RRA Seed Contractor with field location planning prior to planting, isolation zone monitoring after planting and facilitate crop improvement inspections as requested.

- The pollinator species-specific isolation policy is as follows (minimum distance to preexisting conventional seed at planting of RRA):
  - Leaf cutter bee – 900 feet
  - Alkali bee – 1 mile
  - Honey bee – 3 miles
- Once the RRA seed field is planted, State Certification officials will visit to confirm minimum isolation distances are in place. RRA Seed Grower must cooperate with this verification process.
- If the RRA Seed Grower learns that new alfalfa seed field(s) are planned or planted in close proximity the RRA seed field, RRA Seed Grower will communicate this information to RRA Seed Contractor. Management strategies for maintaining RRA seed quality (varietal/ trait purity) can then be implemented by the RRA Seed Contractor.

Trait purity. RRA stock seed is guaranteed by the provider to have ≥90% RR plants; up to 10% non-RR plants, or "nulls", are normal and expected based on the breeding and genetics of the trait.

- Growers must apply sufficient Roundup® herbicide to kill the <10% nulls prior to 9 inches of growth in the establishment year.
- Apply only registered (labeled) Roundup brand herbicides to the field.

Weeds and in-crop volunteers. Manage weeds and volunteers using integrated weed control strategies (e.g., conventional practices supplemented with Roundup agricultural herbicide formulations applied according to the label for alfalfa seed production). Integrated weed control strategies:

- Minimize risk of weed shifts or development of tolerant weeds. Growers are required to use integrated weed control methods.
- Maintain variety true to type: RRA seed fields need non-Roundup practices to control in-crop Roundup Ready alfalfa volunteers sprouting from prior year

seed crop in carry-over fields. This is consistent with conventional alfalfa seed production practices for certified quality seeds.

Stand take-out.

- The RRA seed field must be destroyed at the expiration/termination of the seed contract. Take-out must be completed prior to first flower in the subsequent year so that seed certification inspectors can verify stand termination.
- Stand termination and volunteer management measures must be sufficient to allow seed certification inspectors to validate stand take-out and to render the alfalfa stand worthless for any unlicensed purpose or use (e.g., unlicensed seed, forage, hay or pasture production purpose).
- RRA stand take-out date and method must be reported to the RRA Seed Contractor and stand destruction verified by local crop improvement using the RRA stand take out form, or the equivalent, to report the information (see Appendix).
- Plan to use a subsequent crop that allows management of alfalfa and RRA alfalfa volunteers should they occur.

Sanitation requirements. Manage equipment to minimize seed mixture potential between different varieties and or variety types. Growers shall use dedicated equipment for planting and harvesting RRA seed production, when possible. Zero tolerance for seed admixture is not feasible under commercial production conditions; however, grower must take reasonable steps to assure that equipment is clean prior to and after use in the Roundup Ready seed field. *Examples:*

- Planter inspection, clean-down before and after use;
- Combine inspection, clean-down thoroughly before and after use;
- RRA seed bins may only be used for RRA seed; maintain physical separation of varieties in storage; inspect bins before use;
- Handle all like-trait varieties together; plan for harvest sequence of fields to maintain best separation of varieties by trait type;
- Clean all seed handling equipment to avoid mixing RRA and conventional seed;
- Return unused, unopened stock seed to the contracting seed company for credit; maintain in clean storage areas;
- When a contract harvester is used for RRA seed harvest, Growers must notify the contract harvester, in advance, that the field to be harvested is RRA.

Communication. Immediately communicate questions or concerns to the RRA Seed Contractor or to FGI.

Field records. RRA Seed Grower must record and communicate the following to RRA Seed Contractor:

- Planting date; actual acres planted; seed rate/acre; stock seed received/returned;
- Accurate field address with latitude/longitude (decimal degrees) and local field map;
- Roundup herbicide application date(s), rate(s), formulation used;
- Seed box/bin numbers used for harvest;
- Stand destruct date and methods used using the RRA stand take out form, or the equivalent, to report the information (see Appendix).

RRA Seed Contractors' Production Staff Responsibilities

- Working in close partnership with seed growers;
- Complying with binding agreements with local crop improvement organizations:
  - RRA Seed Contractor will report each field location, planting date and stand take-out date to local crop improvement organizations;
- Coating RRA stock seed purple for easy identification by seed growers;
- Recommending changes to this document, should the need arise.

APPENDIX 1

VERIFICATION OF STAND TAKE-OUT TO TERMINATE THE PRODUCTION OF ROUNDUP READY® ALFALFA SEED

The AGREEMENT: The Grower planted the RRA Proprietary stock seed described below on the acreage described below. In accordance with the terms of the Proprietary Seed Services Agreement for the Production of Roundup Ready Alfalfa Seed, upon expiration or termination of the agreement, the grower must take such actions as are necessary to prevent any future seed harvest or unlicensed use for hay, forage or grazing. Stand destruction must occur not later than first flower in subsequent year. Grower must notify Contracting Seed Company of each stand take-out date and method used to destroy the stand. The Contracting Seed Company must perform on-site verification that each field has been killed and Contracting Seed Company will notify local crop improvement organization of stand termination.

Use a separate form for each field or field group reported to crop improvement.

Avoiding Weed Shifts and Weed Resistance in Roundup Ready Alfalfa Systems

STEVE B. ORLOFF, University of California Cooperative Extension Farm Advisor, Siskiyou County; **DANIEL H. PUTNAM,** Extension Agronomist, Department of Plant Sciences, University of California, Davis; **MICK CANEVARI,** University of California Cooperative Extension Farm Advisor, San Joaquin County; and **W. THOMAS LANINI,** UC Cooperative Extension Weed Ecologist, Department of Plant Sciences, University of California, Davis

OVERVIEW

Weeds present a continual challenge for profitable alfalfa production. The Roundup Ready (RR) production system, using transgenic alfalfa, has the potential to simplify weed management by improving broad-spectrum control of both annual and difficult-to-control perennial weeds. The use of glyphosate, in combination with transgenic crops, has proven to be a reliable weed control strategy.

However, weed species shifts and the selection for glyphosate-resistant weeds can result from the increased use of this technology if the crop is not managed properly from the outset. Aspects of the alfalfa production system both favor and discourage the occurrence of weed shifts and the evolution of resistant weeds. Alfalfa is a competitive perennial crop that is cut multiple times per year, making it difficult for most weeds to become established. On the other hand, the RR alfalfa system may be vulnerable to weed shifts and resistant weeds for several reasons: tillage typically only occurs between crops, alfalfa is produced over a wide geographical area and in large fields with a great diversity of weeds, and there is potential for long-term repeated use of a single herbicide because it is a perennial crop. In this publication we recommend an integrated weed management system designed to prevent the proliferation of tolerant or resistant weeds. Elements include crop rotation, rotations with herbicides of different modes of action (preferably soil-residual herbicides), tank mixtures, and irrigation and harvest timing. Successful adaptation of these concepts into production systems would assure the long-term effectiveness and sustainability of the Roundup Ready system in alfalfa. A preemptive approach is warranted; these strategies should be employed before weed shifts and weed resistance occur.

IMPORTANCE OF WEED CONTROL IN ALFALFA

Alfalfa, the queen of forages, is the principal forage crop in the United States and frequently the third most important crop in value. It is a vital component of the feed ration for dairy cows and is a principal feed for horses, beef cattle, sheep, and other livestock. Because animal performance depends upon the palatability and nutritional value of alfalfa, livestock managers, especially those in the dairy and horse industry, expect high-quality hay. Although many factors influence quality, the presence of grassy and broadleaf weeds (of low forage quality) plays a significant role in reducing the feeding value of hay throughout the United States. Weeds that accumulate nitrates or are poisonous to livestock are also a major concern in alfalfa, since poisonous weeds sicken or kill animals every year (Puschner 2005). Most livestock producers demand weed-free alfalfa for optimum quality and maximum animal performance.

Weed-free alfalfa can be difficult to achieve, whether using nonchemical methods or conventional herbicides. Typically, no single herbicide controls all weeds present in a field, and some weeds—especially perennials—are not adequately controlled with any of the currently registered conventional herbicides. Cultural practices such as modifying harvest schedules, grazing, time of planting, and use of nurse crops such as oats (*Avena sativa* L.) help suppress weeds; however, these practices are almost never entirely effective and some of them suppress alfalfa seedling growth. In addition to being difficult to achieve, complete weed control in alfalfa is costly. Alfalfa growers continually seek ways to enhance the level of weed control while minimizing costs.

Roundup Ready technology was a major development in alfalfa weed control, providing growers with a useful weed management tool and a means to deal with some of the most difficult-to-control weed species.

THE ROUNDUP READY ALFALFA TECHNOLOGY

Glyphosate (Roundup) is generally considered the most effective broad-spectrum post-emergence herbicide available. The first commercially available glyphosate-resistant crops were soybean, canola, cotton, and corn, which were released in 1996, 1997, 1997, and 1998, respectively. Glyphosate-resistant or Roundup Ready alfalfa (RR alfalfa) was developed through biotechnology in late 1997 and became commercially available in the fall of 2005. This technology imparts genetic resistance to glyphosate by inserting a single gene from a soil bacterium into alfalfa. These biotechnology-derived alfalfa plants have an altered enzyme that allows them to tolerate a glyphosate application while susceptible weeds are killed. Glyphosate resistance is the first commercially available, genetically engineered (GE) trait in alfalfa.

This technology was a major development in alfalfa weed control, providing growers with a useful weed management tool and a means to deal with some of the most difficult-to-control weed species. Researchers have evaluated its effectiveness as a weed control strategy (Canevari et al. 2007; Sheaffer et al. 2007; Steckel et al. 2007, Van Deynze et al. 2004). The advantages and disadvantages of this technology have been reviewed (Van Deynze et al. 2004). Glyphosate was found to be especially effective for weed control in seeding alfalfa (Canevari et al. 2007). Glyphosate typically causes no perceptible crop injury, is much more flexible and less restrictive in application, and provides superior weed control across a range of weed species when compared with other currently used herbicides. One of the greatest advantages of this technology is that it provides a tool for suppressing perennial weeds such as dandelion (*Taraxacum officinale*), yellow nutsedge (*Cyperus esculentus* L.), bermudagrass (*Cynodon dactylon* (L.) Pers.), and quackgrass (*Elytrigia repens* (L.) Nevski) that have not been adequately controlled with conventional practices.

After deregulation of this trait in 2005, over 300,000 acres of RR alfalfa were planted in the United States, about 1.4 percent of U.S. acreage. (For equivalents between U.S. and metric systems of measurement, a conversion table is provided at the end of this publication.) However, in the spring of 2007, further plantings were suspended pending the outcome of a legal challenge and further environmental analysis by the U.S. Department of Agriculture's Animal and Plant Health Inspection Service (USDA-APHIS). There were two key issues in this process: the possibility of contamination of organic and conventional alfalfa through the adventitious presence of the gene, and the possibility of a greater level of weed resistance due to the adoption of the Roundup Ready technology in alfalfa (USDA 2008).

Grower experience in commercial fields following deregulation confirmed many of the benefits that early research had suggested in terms of the efficacy and safety of the RR system (Van Deynze et al. 2004). Growers have generally found that this technology is easy to use and provides superior weed

control and improved forage quality in many cases compared with conventional herbicides. However, no new technology is a panacea, and, like other weed control strategies, RR alfalfa has its limitations. An important limitation of this new weed-management system is the potential for weed shifts and weed resistance. This publication discusses techniques that are available to manage the possibility of weed shifts and weed resistance occurring in Roundup Ready alfalfa weed control systems.

WEED SHIFTS AND WEED RESISTANCE

Change in weed populations as a result of repeated use of a single herbicide is not a new phenomenon. Such changes result from shifts in the weeds present from susceptible to tolerant species, or conversion of a population within a species to resistant individuals, as a consequence of selection pressure (Holt and LeBaron 1990; Prather et al. 2000).

Weed Shift

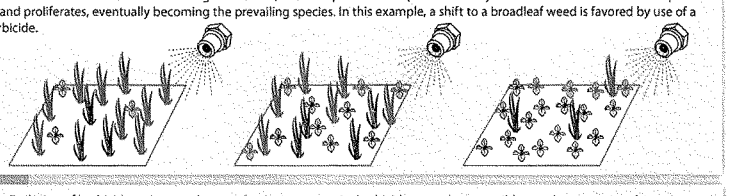
A weed shift refers to a change in the relative abundance or type of weeds as a result of a management practice (fig. 1). The management practice could be herbicide use or any other practice such as tillage, manure application, or harvest schedule that brings about a change in weed species composition.

In the case of chemical weed control, no single herbicide controls all weeds, as weeds differ in their susceptibility to an herbicide. Susceptible weeds are largely eliminated over time with continued use of the same herbicide. This allows inherently tolerant weed species to remain, which often thrive and proliferate with the reduced competition. As a result, there is a gradual shift to tolerant weed species when practices are continuously used that are not effective against those species. A weed shift does not necessarily have to be a shift to a different species. For example, with a foliar herbicide without residual activity like glyphosate, there could also be a shift within a weed species to a late-emerging biotype that emerges after application. In the case of weed shifts, the total population of weeds does not necessarily change as a result of an herbicide or an agronomic practice; these practices simply favor one species (or biotype) over another.

Weed Resistance

In contrast to a weed shift, weed resistance is a change in the population of weeds that were previously susceptible to an herbicide, turning them into a population of the same species that is no longer controlled by that herbicide (fig 2).

Figure 1. Weed shifts due to herbicide application. A weed species shift occurs when both susceptible and tolerant weed species are present in a field. After continued use of a single herbicide, the susceptible weed species is nearly eliminated. The tolerant weed species survives and proliferates, eventually becoming the prevailing species. In this example, a shift to a broadleaf weed is favored by use of a grass herbicide.



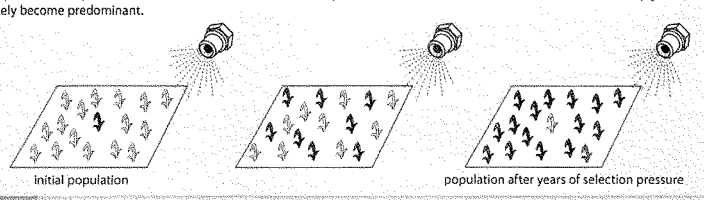


Figure 2. Evolution of herbicide resistance due to selection pressure. An herbicide controls susceptible weeds, preventing them from reproducing and leaving only those individuals carrying the genes for resistance. Typically an extremely small percentage of the weed population initially possesses the genes for resistance. These altered genes are thought to exist in weed populations at very low frequencies. As repeated use of an herbicide controls the susceptible individuals, the resistant weeds continue to multiply and ultimately become predominant.

While weed shifts can occur with any agronomic practice (crop rotation, tillage, frequent harvests, or use of particular herbicides), the evolution of weed resistance is only the result of continued herbicide application. The use of a single class of herbicides continually over time creates selection pressure so that resistant individuals of a species survive and reproduce, while susceptible ones are killed.

Which Is More Important, Weed Shifts or Weed Resistance?

A weed species shift is far more common than weed resistance, and ordinarily takes less time to develop. If an herbicide does not control all the weeds, the tendency is to quickly jump to the conclusion that resistance has occurred. However, a weed shift is a far more likely explanation for weed escapes following an application of glyphosate. See table 1 for a list of weeds sometimes found in alfalfa fields that are tolerant to or difficult to control with glyphosate.

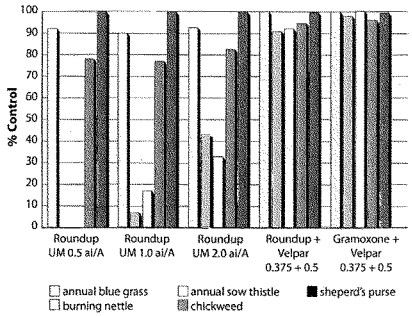
Table 1. Annual weeds encountered in alfalfa fields that are potential candidates for weed shifts in continuous glyphosate systems

Latin name	Common name
*Brassica nigra**	black mustard
Chenopodium album†	lambsquarters
Echinochloa colona†	junglerice
*Epilobium brachycarpum**	Willowherb, panicle willowherb, panicle
*Eragrostis**	lovegrass
Erodium spp.†	filaree
Lamium amplexicaule†	henbit
Lolium multiflorum†‡	ryegrass
*Malva parviflora**	malva (cheeseweed)
Polygonum convolvulus†	wild buckwheat
Polygonum spp.†	knotweeds
Portulaca oleracea†	purslane
Sonchus oleraceus†	annual sowthistle
*Trifolium spp.**	clover
*Urtica urens**	burning nettle

Note: This table includes weeds that are listed as susceptible on the label but are difficult to control and weeds which are not controlled by glyphosate.
*Glyphosate-tolerant weeds—not listed as controlled on product label.
†Difficult to control weeds.
‡Glyphosate-resistant biotype has been confirmed.

Are Weed Shifts or Weed Resistance Linked Only to Genetically Engineered Crops?

A common misconception is that weed resistance is intrinsically linked to genetically engineered (GE) crops. However, this is not correct. The occurrence of weed shifts and weed resistance is not unique to genetically engineered crops. Weed shifts and resistance are caused by the practices that may accompany a GE crop (for example, repeated use of a single herbicide), not the GE crop itself. Similarly, some people believe that herbicide resistance is transferred from the GE crop to weed species. However, unless a crop is genetically very closely related to a naturally-occurring weed, weed resistance cannot be transferred from crop to weed. In the case of alfalfa, there are no known wild plants that cross with alfalfa, so direct transfer of herbicide resistance through gene flow to weedy species will not occur. However, the glyphosate-tolerant genes from RR alfalfa can be transferred to feral (wild) alfalfa plants if cross pollination occurs.



Link to Management Practices

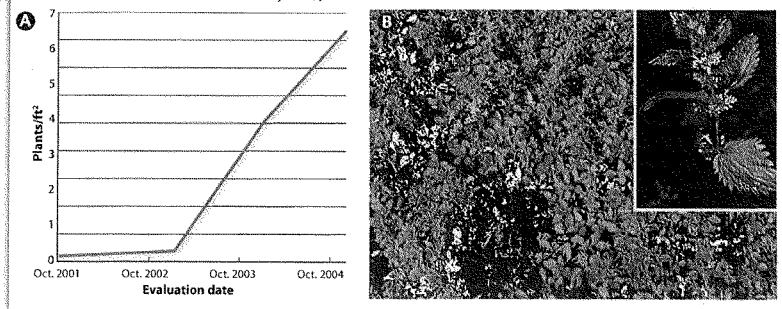
The development of weed shifts or the evolution of weed resistance in cropping systems is primarily a result of management practices, not the crop itself. Continued use of the same management practice, in this case the use of a single herbicide, increases the probability of a weed shift or the evolution of resistant weeds as a result of constant selection pressure. For example, if the herbicide diuron (Karmex) is used alone for several years in established alfalfa, susceptible weeds are controlled. However, there is likely to be an increase in tolerant weeds such as common groundsel (*Senecio vulgaris*), Persian speedwell (*Veronica persica*), and others. Similarly, if imazethapyr (Pursuit) is used repeatedly for several years without rotating with other herbicides, there is likely to be an increase in the population of prickly lettuce (*Lactuca serriola*), annual sowthistle (*Sonchus oleraceus*), and many grassy weeds that are not controlled by this herbicide. Rigid ryegrass (*Lolium rigidum*) and horseweed (*Conyza canadensis*) resistance to glyphosate was the outcome of repeated glyphosate applications in California orchards and noncrop settings, respectively. Weed shifts and weed resistance are not new; evolved resistance was first reported in the 1970s and now occurs with a range of herbicide classes (Holt and LeBaron 1990; Heap 1999; Heap 2008).

RR Crops Present a Challenge

Transgenic herbicide-resistant crops do, nonetheless, have greater potential to foster weed shifts and resistant weeds since a grower is more likely to use a single herbicide repeatedly in herbicide-resistant crops such as RR alfalfa. Additionally, the accumulation of acreage of different RR crops (corn, soybean, and cotton) could increase the potential for weed shifts or weed resistance in cropping systems utilizing RR crops. This is because the probability of repeated use of the

Figure 3. Weed control 69 days after treatment in an established stand of Roundup Ready alfalfa, San Joaquin County, California, 2004.

same herbicide is higher and the potential applied acreage (and therefore the size and genetic diversity of the weed population) is greater. Fortunately, there are simple methods available to prevent weed shifts and weed resistance from occurring.



In studies conducted in San Joaquin County, California, weeds shifts were found to occur during the first few years of use when glyphosate-tolerant weeds were present (Van Deynze et al. 2004). Annual bluegrass and shepherd's purse were adequately controlled with glyphosate, whereas chickweed control was about 80 percent and burning nettle and annual sowthistle were not adequately controlled with any of the glyphosate rates (fig. 3). During the 3 years of this field trial, when glyphosate was used repeatedly, there was a gradual weed species shift away from annual bluegrass and shepherd's purse to higher populations of burning nettle and annual sowthistle (figs. 4A and 4B). A tank mix of glyphosate and Velpar, or a rotation to Velpar and Gramoxone, was needed to adequately control all weed species at this location.

To our knowledge there have been no documented cases of weed resistance in alfalfa during the first 3 years of RR alfalfa production (2005 to 2008) in the United States.

WEED SHIFTS AND RESISTANCE WITH RR ALFALFA

The possibility of weed shifts and weed resistance is a concern with RR alfalfa. This is due to its perennial growth habit, its long stand life, and the potential for repeated use of a single herbicide over several years without crop rotation. Although some stands last 3 to 4 years, it is common in many areas of the United States to keep an alfalfa stand in production for 5 to 7 years or longer. If the rotation crop (e.g. a grain crop) is not treated with an herbicide, an even longer period of time without herbicide diversity could occur. In this instance, weed populations could slowly return to preglyphosate composition, but the new species or resistant biotypes would not disappear. In areas where alfalfa is rotated with transgenic RR corn, cotton, or soybean varieties, this

Figure 4. (A): Increase in burning nettle population in Roundup Ready alfalfa with repeated annual applications of glyphosate alone, San Joaquin County, California, 2006. **(B):** Plot overtaken with burning nettle after 3 years of continual glyphosate use. *Photos:* Mick Canevari; insert, J.M. DiTomaso, from DiTomaso and Healy 2007, p. 1565.

again could result in a prolonged time period where a single herbicide is used repeatedly.

There are aspects of the alfalfa production system that both favor and discourage the development of weed shifts and the evolution of resistant weeds.

Attributes of Alfalfa That Favor Weed Shifts and Resistance

First, crop rotation opportunities with a perennial crop like alfalfa are significantly reduced compared with annual cropping systems. Mechanical weed control, such as cultivation, is impractical in a solid-seeded perennial crop like alfalfa, and hand weeding is not economical. Alfalfa is grown over extensive acreage in the United States and fields can be large in size; therefore, the overall weed flora available for selection of resistant traits or for weed shifts is plentiful. Perennials like alfalfa, if sprayed repeatedly with the same herbicide, are likely candidates for weed shifts and weed resistance.

Attributes of Alfalfa That Discourage Weed Shifts and Resistance

On the other hand, many weeds do not flourish in an alfalfa field due to its perennial nature and the competitiveness of the crop after establishment. Alfalfa is an aggressive competitor with most weeds, which fail to establish in alfalfa fields due to the crop's vigorous growth and shading ability. In addition, many weed species do not tolerate the frequent cutting that occurs in alfalfa fields. The lack of soil disturbance once the alfalfa stand is established also reduces opportunities for germination of some weed species. Furthermore, the interval between alfalfa cuttings is short enough that seed production for many weeds is reduced compared with annual crops that allow completion of the weeds' life cycles.

Risk of Resistance Generally Lower with Glyphosate Than with Other Herbicides

Weed shifts or resistant weeds are unavoidable and will occur eventually with any herbicide used repeatedly, and the same is true with the use of glyphosate (Heap 1999). Fortunately, resistance to glyphosate is not as common as resistance to many other herbicides, such as acetolactate synthase (ALS) and acetyl-CoA carboxylase (ACCase) herbicides that have a single binding site and single target enzyme mechanisms of action (Heap 2008). The relatively low rate of resistance in weeds to glyphosate relative to the widespread use of this chemical has not been fully explained, but may be due to the number or frequency of mutations that may be required to confer resistance to glyphosate. Two resistance mechanisms, a weak target site mutation, and a reduced glyphosate translocation mechanism have been documented in weed species that have evolved resistance to this herbicide (Powles and Preston 2006).

Regardless of the mechanism, weed resistance to glyphosate is not as common as resistance to other herbicides. However, cases of weed resistance to glyphosate have been documented and are increasing. There is a range of species across the world with documented resistance to glyphosate (table 2). Fortunately, most of these species are not common in alfalfa fields. Two weed species in particular have evolved resistant populations in California: *Lolium* spp. (ryegrass) and *Conyza* sp. (marestail). The latter is not important in alfalfa, but ryegrass is frequently found in alfalfa fields. Glyphosate-resistant ryegrass is increasing in the Sacramento Valley and northern San Joaquin Valley of California and may become problematic during fall stand establishment of RR alfalfa.

Weed shifts and/or weed resistance have occurred with the other transgenic RR crops released before RR alfalfa (Duke and Powles 2008). Weed resistance is of greater concern than weed shifts and has occurred in RR soybean, cotton, and corn in less than a decade after their initial release (see table 2). Alfalfa growers can learn from experience with these crops and in noncrop areas as a preemptive measure to avoid, or at least minimize, the problems with weed shifts and weed resistance. These problems are sure to occur in alfalfa if proper weed management practices are not followed.

Alfalfa growers can learn from experience with other RR crops and in noncrop areas as a preemptive measure to avoid, or at least minimize, the problems with weed shifts and weed resistance.

WEED MANAGEMENT PRINCIPLES TO REDUCE WEED SHIFTS AND RESISTANCE IN ALFALFA

Glyphosate-resistant crops have provided growers with an easy-to-use, low-cost, and effective weed management tool. However, the effectiveness of weed control systems using RR crops can make growers complacent in their weed control practices. Even though this technology is highly effective, growers must follow sound weed management

principles to prevent short- or long-term weed shifts or weed resistance from occurring. This includes weed identification, crop rotation, attention to application rate, proper timing of application, herbicide rotation, and tank mixtures.

Weed Identification

Effective weed management practices begin with proper identification to assess the competiveness of the weeds present and to select the proper herbicide if one is needed. A weed management strategy to prevent weed shifts and weed resistance requires knowledge of the composition of weeds present. Identification of young seedlings is particularly important because seedling weeds are easier to control. Resources for weed identification can be found at the UC IPM Web site (http://www.ipm.ucdavis.edu/PMG/weeds_common.html) and at the UC Weed Research and Information Center Web site (http://wric.ucdavis.edu/information/information.html).

Table 2. Glyphosate-resistant weed populations

Resistant weed	Common name	Location of resistant populations	Situation(s)	Year first reported
UNITED STATES			(In the U.S.)	
Amaranthus palmeri	Palmer amaranth	Arkansas, Georgia, North Carolina, Mississippi, Tennessee	corn, cotton, soybean	2005
Amaranthus rudis	common waterhemp	Illinois, Kansas, Minnesota, Missouri	corn, soybean	2005
Ambrosia artemisiifolia	common ragweed	Arkansas, Kansas, Missouri	soybean	2004
Ambrosia trifida	giant ragweed	Arkansas, Indiana, Kansas, Minnesota, Ohio, Tennessee	cotton, soybean	2004
Conyza bonariensis	hairy fleabane	California	roadsides	2007
Conyza canadensis	horseweed (marestail)	17 states including California	cotton, nurseries, roadsides (in CA), soybean	2000
Lolium multiflorum	italian ryegrass	Mississippi , Oregon	cotton, orchards, soybean	2004
Lolium rigidum	rigid ryegrass	California	orchards	1998
Sorghum halepense	Johnsongrass	Arkansas	soybean	2007
WORLD			(In the world)	
Conyza bonariensis	hairy fleabane	Brazil, Colombia, South Africa, Spain	corn, orchards, soybean, vineyards, wheat	2003
Conyza canadensis	horseweed (marestail)	Brazil, China, Czech Republic, Spain	orchards, soybean, railways	2005
Digitaria insularis	sourgrass	Brazil , Paraguay	soybean	2006
Echinochloa colona	junglerice	Australia (New South Wales)	cropland	2007
Eleusine indica	goosegrass	Colombia , Malaysia	cropland , orchards	1997
Euphorbia heterophylla	wild poinsettia	Brazil	soybean	2006
Lolium multiflorum	Italian ryegrass	Argentina, Brazil, Chile, Spain	cropland orchards, soybean	2001
Lolium rigidum	rigid ryegrass	Australia, France, South Africa, Spain	asparagus, orchards, railways, sorghum, vineyards, wheat	1996
Plantago lanceolata	buckhorn plantain	South Africa	orchards, vineyards	2003
Sorghum halepense	Johnsongrass	Argentina	soybean	2005
Urochloa panicoides	liverseedgrass	Australia (New South Wales)	sorghum, wheat	2008

Frequent Monitoring for Escapes

It is difficult to detect an emerging weed shift or weed resistance problem if fields are not frequently monitored for weeds that escape current weed management practices. Identification and frequent monitoring can detect problem weeds early and guide management practices, including herbicide selection, rate, and timing.

Herbicide Rate and Timing

It is important to use the appropriate rate and timing for the weeds present. For example, some weeds that are considered somewhat tolerant to glyphosate (cheeseweed, filaree, and purslane) can be controlled effectively in seedling alfalfa with glyphosate, provided the proper rate is used and the application is made when the weeds are very small. Research in Nebraska over a 7-year period (Wilson 2004) demonstrated a rapid increase in lambsquarters when a low rate of glyphosate (0.5 lb ai/acre) was applied, but a higher rate (1.0 lb ai/acre) successfully controlled this weed. Just like with traditional weed management programs, the grower must be sure to use the recommended rate for the weed species present and treat at the appropriate time when the weeds are still small.

Crop Rotation

One of the most effective practices for preventing weed shifts and weed resistance is crop rotation, which allows growers to modify selection pressure imposed on weeds. Continuous (also called back-to-back) alfalfa is not recommended for other agronomic reasons, but especially would be ill advised when it comes to management of resistance and weed shifts. Crops differ in their ability to compete with weeds; some weeds are a problem in some crops, while they are less problematic in others. Rotation therefore would not favor any particular weed spectrum. Crop rotation also allows the use of different weed control practices, such as cultivation and application of herbicides with different sites of action. As a result, no single weed species or biotype should become dominant. The effectiveness of crop rotation to manage weed shifts and resistance is substantially reduced if another RR crop (such as corn or cotton) is planted in rotation with RR alfalfa, since the same herbicide and selection pressure would likely occur.

Using an effective herbicide with a different mode of action from the one to which the weeds are resistant controls both the susceptible and resistant biotypes, thus preventing reproduction and slowing the spread of the resistant biotype.

Agronomic Practices

In addition to crop rotation, several management practices may have an impact on the selection of problem weed populations. If problem weeds germinate at a specific time of year, crop seeding date can be shifted to avoid these weed populations, allowing a vigorous alfalfa crop to develop that is capable of outcompeting weeds. Delaying irrigation after alfalfa cutting can reduce germination of certain summer annual weeds. However, this practice only works on some soil types, and water stress in alfalfa can reduce yields. Harvest management can, in some cases, assist in eliminating or suppressing problem weed populations, but harvests must occur before weed seed production to prevent weed proliferation.

Rotation of Herbicides

Weed shifts occur because herbicides are not equally effective against all weed species and herbicides differ greatly in the weed spectrum they control. A weed species that is not controlled will survive and increase in density following repeated use of one herbicide. Therefore, rotating herbicides is recommended. Rotation of herbicides reduces weed shifts, provided the rotational herbicide is highly effective against the weed species that is not controlled with the primary herbicide. The grower should rotate to an herbicide with a complimentary spectrum of weed control, along with a different mechanism of action and therefore a different herbicide binding site. Weed susceptibility charts are useful to help develop an effective herbicide rotation scheme (Canevari et al. 2006). In addition, publications on herbicide chemical families are available to assist growers in choosing herbicides with different mechanisms of action (Retzinger and Mallory-Smith 1997).

Rotating herbicides is also an effective strategy for resistance management. Within a weed species there are different biotypes, each with its own genetic makeup, enabling some of them to survive a particular herbicide application. The susceptible weeds in a population are killed, while the resistant ones survive, set seed, and increase over time. Using an effective herbicide with a different mode of action from the one to which the weeds are resistant, however, controls both the susceptible and resistant biotypes. This prevents reproduction and slows the spread of the resistant biotype.

Herbicide Tank Mixtures

For the same reasons that rotating herbicides is effective, tank mixing herbicides is also recommended. The key is to select tank mix partners that have different target sites and that compliment each other so that, when combined, they provide complete or nearly complete weed control.

RECOMMENDED WEED MANAGEMENT PROGRAM FOR RR ALFALFA

The cost of RR alfalfa seed, including the technology fee, is generally twice or more than that of conventional alfalfa seed. Naturally, growers will want to recoup their investment as quickly as possible. Therefore, considerable economic incentive exists for the producer to rely solely on repeated glyphosate applications alone as a weed control program. Some producers may even be inclined to shave the rates to the minimum amount that would provide acceptable weed control. While relying solely on glyphosate and shaving rates may provide satisfactory results in the short term, it is a risky practice in the long run as it will accelerate weed species shifts and the evolution of resistant weeds. Sound weed management practices should be employed to maintain the effectiveness of the RR technology.

Roundup Ready alfalfa is still a relatively new technology, so there has been limited field experience with it to date. The following are some suggestions to consider based upon proven resistance management strategies, our understanding of alfalfa production practices, and our initial experience with RR alfalfa. Ultimately, growers and pest control advisors hold the key to avoiding weed shifts and resistance by reducing selection pressure, which is accomplished by developing a weed management program that does not rely solely on the continuous use of glyphosate. Any management practice that reduces the selection pressure (in this case, the selection pressure imposed by continual use of the same herbicide) will help avoid weed species shifts and resistance.

For Seedling Alfalfa, Use Glyphosate Alone or in a Tank Mix Combination

Seedling alfalfa is most vulnerable to weed competition because weeds are often more vigorous and competitive than young alfalfa. Additionally, complete weed control in seedling alfalfa is often difficult to achieve and frequently requires tank mixes of different herbicides to control the broad spectrum of weeds found in an individual field. Yield and stand loss from weed competition, and injury from conventional herbicides, are usually far greater in seedling than in established alfalfa. Numerous field trials throughout the United States have proven the effectiveness of RR alfalfa for stand establishment. Superior weed control with no perceptible alfalfa injury has occurred in most studies. Therefore, it is only logical to use glyphosate for weed control in RR seedling alfalfa for the cost savings, improved weed control, reduced crop injury, superior stand establishment, and the elimination of the small percentage of alfalfa seedlings (commonly called nulls) that do not carry the RR gene. Delayed removal of these nulls may cause weed control problems in the future by creating open spaces for weeds to grow.

Ordinarily, 1.0 pound per acre active ingredient of glyphosate is sufficient for weed control during the seedling period. However, a higher rate may be needed if the field contains some of the more tolerant weeds listed in table 1. A tank mix may be advised if especially-difficult-to-control weeds are present. For example, a tank mix of glyphosate with imazamox (Raptor) or imazethapyr (Pursuit) may be advised if burning nettle is present, or a tank mix with clethodim (Prism) will be necessary if the field or surrounding area is known to have glyphosate-resistant ryegrass.

Rotate or Tank Mix Herbicides at Least Once During the Life of an Alfalfa Stand

Alfalfa stand life varies considerably throughout the western United States depending on the production area, grower practice, and the existence of profitable rotation crop options. A stand life of 3 to 5 years is common in the Central Valley of California and other warm, long growing-season areas of the Southwest. A stand life of 5 to 7 years is common in much of the Northwest, and some alfalfa stands remain in production in excess of 10 years. As suggested by the principles outlined above, it is unwise to rely solely on glyphosate applications for weed control throughout the life of a transgenic alfalfa field. This practice would encourage weed shifts and resistance, and over time weed control would diminish in most cases. Once an herbicide is rendered ineffective as a result of resistant weeds, its usefulness as a weed control tool may be greatly diminished. After a resistant weed population has gained a foothold, it is practically impossible to eliminate it due to the presence of a weed seedbank.

Most alfalfa producers apply an herbicide to alfalfa during the dormant season to control winter annual weeds that infest the first cutting. It is strongly recommended that growers not rely solely on glyphosate for their winter weed control program for the duration of the stand. They should rotate to another herbicide or tank mix at least once in the middle of the life of a stand, and perhaps twice if the stand life is over 5 years (table 3).

Use an Herbicide with a Different Mode of Action

Fortunately, all of the herbicides currently registered in alfalfa—and there are several to choose from—have

Table 3. Comparison of weed management strategies for glyphosate-resistant alfalfa using continuous glyphosate applications versus a recommended approach where glyphosate is rotated with other herbicides during a 4-year alfalfa stand

Year	Objective	Season	Continuous glyphosate strategy	Rotational herbicide strategy
Seedling	control weeds that compete during stand establishment	fall	glyphosate	glyphosate
1	control late-emerging weeds during establishment	winter (late)	glyphosate	glyphosate*
	summer annual weed control may not be needed first year	spring		
		summer		
		fall		
2	control winter annual weeds and/or pre-emergence control of summer weeds	winter	glyphosate	soil residual herbicide or tank mix* of soil residual herbicide with glyphosate†
	summer annual weed control/dodder	spring		
		summer	glyphosate	
		fall		
3	control winter annual weeds and/or pre-emergence control of summer weeds	winter	glyphosate	soil residual herbicide or tank mix* of soil residual with glyphosate†
	control summer annual grassy weeds/ dodder	spring	glyphosate	
		summer (mid)	glyphosate	
		fall		
4	control winter annual weeds	winter	glyphosate	glyphosate
	control summer annual grassy weeds/ dodder	spring	glyphosate	
		summer (mid)	glyphosate	glyphosate
	(stand take-out)	fall (late)	tillage and/or 2,4-D + dicamba as necessary	tillage and/or 2,4-D + dicamba as necessary
(4 years)	**Total number of glyphosate applications**		10	4–6

Note: A combination of soil residual herbicides and different modes of action is recommended to prevent weed shifts and herbicide resistance. These are examples only—appropriate strategies should be modified for different regions and weed pressures.

*Tank mixing with another herbicide is advised if significant populations of glyphosate, tolerant weeds such as burning nettle are present.

†Soil residual herbicide (depending on location and weed spectrum, use hexazinone, diuron, or metribuzin) for pre-emergence control of winter annual weeds. An application of a dinitroaniline herbicide (pendimethalin or trifluralin) applied at this time will control summer annual grassy weeds.

a different target site of action than does glyphosate. The soil-residual herbicides applied during the dormant season to established alfalfa [such as hexazinone (Velpar), diuron (Karmex), metribuzin (Sencor), and pendimethalin (Prowl)] would be appropriate herbicides for a rotation or tank-mix partner. The rotation herbicide or tank-mix partner of choice depends on the weeds present in the field and their relative susceptibility to the herbicides. Paraquat (Gramoxone) is another candidate for rotation, but paraquat, like glyphosate, lacks residual activity and is applied late in the dormant season. By rotating paraquat with glyphosate, growers could potentially be selecting for early-emerging weeds that may be too large to control at the typical timing for these herbicides. In addition, they could be selecting for late emerging weeds that germinate after the application.

Rotate Herbicides Early in Stand Life So Glyphosate Remains Effective

Weed control during the last year of an alfalfa stand is often challenging because the stand is typically less dense and competitive and also there are fewer herbicide options from which to choose. There are significant plant-back restrictions associated with many of the soil-residual herbicides used in alfalfa, so glyphosate is a good choice for controlling weeds in the final year of RR alfalfa field. The preference to use glyphosate in the final year of an alfalfa stand underscores the importance of rotating herbicides earlier so that glyphosate will remain effective and continue to control the majority of the weeds.

Consider a Soil-Residual Herbicide for Summer Annual Weed Control

Summer annual grass weeds such as yellow and green foxtail (Setaria spp.), barnyardgrass (*Echinochloa crus-galli*), cupgrass (*Eriochloa* spp.), and jungle rice (*Echinochloa colona*), and less frequently, broadleaf weeds like pigweed (*Amaranthus* spp.) or lambsquarters (*Chenopodium album*), can be problematic in established alfalfa. These weeds emerge over an extended time period whenever soil temperatures and moisture are adequate, typically from late winter or early spring (as early as February in the Central Valley) throughout the summer. Weeds may emerge between alfalfa cuttings, so several applications may be necessary in California's Central Valley for a foliar herbicide without residual activity like glyphosate to provide season-long control.

Multiple applications of a single herbicide during a season is cited as promoting weed resistance. Therefore, growers should not rely solely on glyphosate for summer grass control for multiple seasons. It remains to be seen how many applications of glyphosate will be required for season-long summer grass control. In some of the long growing-season areas of California, as many as two to three applications per season may be needed in older, thinner stands. Rather than making multiple applications of glyphosate, a better approach may be to apply a pre-emergence soil-residual dinitroaniline herbicide like trifluralin (Treflan) or pendimethalin (Prowl), or possibly EPTC (Eptam), and follow up with glyphosate later in the season as needed for escapes. Not only is this approach more in line with management practices to avoid weed shifts and resistance, but it may be more economical as well, compared with multiple applications of glyphosate.

The practice of rotating herbicides or applying tank mixtures is recommended for both dormant applications aimed at winter annual weeds and for spring/summer applications intended to control summer annual weeds. For example, rotating to hexazinone (Velpar) for winter annual weed control for a year does nothing to prevent weed species shifts or the evolution of resistance in the summer annual weed spectrum. Herbicides for summer annual weed control should be rotated as well.

Frequency of Rotation Depends on Weed Species and Escapes

There is no definitive rule on how often herbicides should be rotated. Our suggestion to rotate or tank mix at least once in the middle years of the life of a stand (or more often for long-lived alfalfa stands) may need to be modified depending upon actual observations of evolving weed problems. The key point, which cannot be overemphasized, is the importance of diligent monitoring for weed escapes. Producers should stay alert to the appearance of weed species shifts and evolution of resistant weeds. If the relative frequency of occurrence of a weed species increases dramatically, chances are that it is tolerant to glyphosate and immediate rotation of herbicides or a tank mix is advised. If a few weeds survive among a weed species that is normally controlled easily with glyphosate, it could be an indication of weed resistance, assuming misapplication and other factors can be eliminated as possible causes. Weed resistance should be confirmed by controlled studies conducted by a weed scientist. However,

in these situations, it is imperative to prevent reproduction of a potentially resistant biotype. Treat weed escapes with an alternative herbicide or other effective control measure.

CONCLUSIONS

The Roundup Ready alfalfa production system has the potential to simplify weed management, while also improving the spectrum of weed control. However, growers should learn from the experience gained in other crops and stay alert to the occurrence of weed shifts and evolution of resistant weeds. The key is for growers to reduce selection pressure, not to rely on repeated applications of glyphosate year after year, application after application. Well-known management principles are available to manage weed shifts and weed resistance in RR alfalfa. Rotate crops, rotate herbicides, and utilize tank mixes as needed, depending on the weed species and weed escapes present. A grower should not wait for a problem to occur before he or she employs these practices; a preemptive approach is strongly encouraged.

METRIC CONVERSIONS

English	Conversion factor for English to metric	Conversion factor for metric to English	Metric
pound (lb)	0.454	2.205	kilogram (kg)
acre (ac)	0.4047	2.47	hectare (ha)
pound per acre (lb/ac)	1.12	0.89	kilogram per hectare (kg/ha)

WARNING ON THE USE OF CHEMICALS

Pesticides are poisonous. Always read and carefully follow all precautions and safety recommendations given on the container label. Store all chemicals in their original labeled containers in a locked cabinet or shed, away from foods or feeds, and out of the reach of children, unauthorized persons, pets, and livestock.

Recommendations are based on the best information currently available, and treatments based on them should not leave residues exceeding the tolerance established for any particular chemical. Confine chemicals to the area being treated. THE GROWER IS LEGALLY RESPONSIBLE for residues on the grower's crops as well as for problems caused by drift from the grower's property to other properties or crops.

Consult your county agricultural commissioner for correct methods of disposing of leftover spray materials and empty containers. Never burn pesticide containers.

PHYTOTOXICITY: Certain chemicals may cause plant injury if used at the wrong stage of plant development or when temperatures are too high. Injury may also result from excessive amounts or the wrong formulation or from mixing incompatible materials. Inert ingredients, such as wetters, spreaders, emulsifiers, diluents, and solvents, can cause plant injury. Since formulations are often changed by manufacturers, it is possible that plant injury may occur, even though no injury was noted in previous seasons.

Appendix E

Effects of Glyphosate-Resistant Weeds in Agricultural Systems (Appendix G from Draft EIS)

Appendix G. Effects of Glyphosate-Resisant Weeds in Agricultural Systems

1100

Effects of Glyphosate-Resisant Weeds in Agricultural Systems

Executive Summary

Alfalfa is grown for forage, grazing, seed production (forage and sprouts), human consumption, and honey production. The most acreage is for dry hay forage. In 2005, 22,439,000 acres of dry hay alfalfa was harvested and 204,380 (0.9%) of those acres were certified organic. In addition to mechanical and cultivation techniques, conventional farming allows the use of 16 different herbicides to control weeds in alfalfa. Organic farming does not allow synthetic pesticides or the use of crop varieties produced through genetic engineering. Glyphosate-tolerant (GT) alfalfa allows for the application of glyphosate directly onto growing plants, which provides increased options for weed control over conventional and organic systems. GT alfalfa allows for flexibility in timing of glyphosate application to control weeds. In the two years that GT alfalfa seed was on the market ~200,000 acres were planted in 1,552 counties in 48 states.

Alfalfa Growing Regions

The seven growing regions in the United States have varying optimal alfalfa varieties and farming practices, such as frequency of cutting, companion cropping, and irrigation. California, South Dakota, Idaho, Nebraska, Montana, and Wisconsin are the top six alfalfa hay producing states (in 2007). South Dakota, Montana, Wisconsin, and North Dakota, have the largest acreage of alfalfa hay. California's acreage is highly productive.

Crop Rotations

Crop rotation options may be different between conventional and GT farming systems. Many of the non-glyphosate herbicides have follow-up planting restrictions that limit crop rotation choices in conventional farming. Farmers using GT cropping systems are advised to include some years of non-GT crops in rotation, so there may be limitations in the use of other GT crops if GT alfalfa is used in a rotation plan.

Alfalfa Stand Removal

Glyphosate is the primary tool used to remove conventional alfalfa stands. Use of herbicides other than glyphosate for removal of GT alfalfa is a major difference between GT alfalfa and conventional alfalfa. Non-glyphosate herbicides and tillage are recommended for effective GT alfalfa stand removal.

Volunteer Alfalfa

Farmers are not able to use glyphosate to control volunteer GT alfalfa in other GT crops. However, 11 other herbicides and mixtures of those herbicides are available to control volunteer GT alfalfa. These are the same herbicides that are used to control non-GT alfalfa with the exception that glyphosate can be used to control non-GT alfalfa.

Weeds in Alfalfa

Weeds are controlled in conventional alfalfa with chemicals (herbicides), cultural methods (rotation, companion crops, monitoring), and mechanical methods (tillage). The cultural and mechanical methods are permitted for organic farmers. GT systems allow for the use of one additional herbicide, glyphosate. Weeds are undesirable because they compete with crops, leading to lower yields, can lower the nutritional value of crops, can be poisonous or unpalatable to livestock, can cause off flavors in milk, and can cause trouble with bailing. At least 129 different weed species are identified as minor or major problems in alfalfa. Out of 14 new glyphosate resistant weeds found since 1998, eight are known to be weeds in alfalfa. Out of at least 21 weeds that have natural resistance to glyphosate, ten are known to be a problem in alfalfa. These 18 weeds that are both resistant to glyphosate and traditionally listed as problems in alfalfa include: common ragweed, horseweed, Italian ryegrass, Johnsongrass, Palmer Amaranth, buckhorn plantain, goosegrass, junglerice, bermudagrass, burning nettle, cheeseweed, common lambsquarters, field bindweed, filaree, large crabgrass, morningglory, nutsedge, and purslane. Although the composition of weed shifts is based on the local seedbank, these 18 weeds are candidates for becoming more prevalent than glyphosate-resistant sensitive weeds in rotations that include GT alfalfa.

Glyphosate Resistant Weed Distribution

Nineteen states and over two million acres of cropland contain new glyphosate resistant weeds. The heaviest infestation is in the Southeast and Midwest. Overlap with the major alfalfa producing states in the Intermountain regions (Washington, Oregon, Idaho, Montana, Wyoming, Colorado, Utah, Nevada, and parts of California) seems to be minimal at this point. However, given that there is overlap between glyphosate resistant weed locations and alfalfa hay acreage there is potential for rapid shifts of glyphosate resistant weeds into GT alfalfa fields if GT alfalfa were to be widely adopted. California is a concern because glyphosate resistant weeds are present and alfalfa is a major crop in California.

1.0 Introduction

The scope of this report covers how glyphosate-tolerant (GT) alfalfa could impact weed dynamics in agricultural systems. Gene flow from GT alfalfa is covered in another technical report in this series (Appendix J). In this report, different types of alfalfa crops and cropping systems are described. Regional differences in alfalfa farming are summarized and discussed within the context of weed management. Glyphosate resistant weeds and the potential risks from volunteer GT alfalfa are also discussed. This report is limited to weed dynamics in agricultural systems. Potential effects of farming with GT alfalfa on ecosystems is discussed in other technical reports. This report is limited to practices involving weed management and does not include discussion of control of diseases, insects, nematodes, and vertebrate pests and management of field fertility and soil conservation.

Weed management is an important aspect of alfalfa production. Some of the negative effects of weeds include the following (Canevari et al., 2007; Canevari et al., 2006; Van Deynze et al., 2004; Loux et al., 2007; Miller et al., 2006; Orloff et al. 1997):

- Competition with weeds can reduce yield and cause thinning in the stand.
- Weeds can lower the nutritional quality of alfalfa hay because many weeds are lower in protein (50 percent less protein than alfalfa) and higher in fiber compared to alfalfa.
- Poisonous weeds containing toxic alkaloids (e.g., common groundsel, fiddleneck, yellow starthistle, and poison hemlock) can make alfalfa hay unmarketable.
- Under some conditions weeds can accumulate toxic nitrate concentrations (e.g., lambsquarters, kochia, and pigweed).
- Some weeds with a spiny texture can cause mouth and throat ulcerations in livestock (e.g., foxtail, wild barley, cheatgrass, and bristlegrass).
- Weeds that are unpalatable to livestock result in less feeding and, therefore, less productivity (either beef or milk).
- Some weeds can contribute to off flavors in milk (wild celery, Mexican tea, creeping swinegrass, and mustards).
- Weeds that contain higher moisture content than alfalfa (dandelion) can cause bail problems such as mold, off-color hay, and high bale temperatures, which are a fire hazard.

Without weeds, alfalfa can grow at a density of about 12 plants per square foot. Heavily infested stands can have less than one alfalfa plant per square foot (Canevari et al., 2007). In California, if weeds are not effectively controlled weeds can represent up to 76 percent of the first cutting yields (Gianessi et al, 2002). The limiting factor for weed control in alfalfa is that, by the time alfalfa reaches the stage of growth that is tolerant to herbicides, weeds are also beyond their susceptible stage (Gianessi et al., 2002). Glyphosate-tolerant alfalfa was developed so that the broad spectrum herbicide, glyphosate, could be applied directly to alfalfa fields to control weeds. The glyphosate-tolerant (GT) trait was introduced through genetic engineering. Although glyphosate-tolerance has arisen naturally in some plants due to decades of glyphosate use, so far, all crops with glyphosate-tolerance have had the trait introduced through genetic engineering.

1.1 Methodology

A literature search was designed to identify peer review articles and grey literature (e.g., government reports, State Agricultural Extension Office publications) on weeds in alfalfa (Appendix G-2 of this technical report). Several DIALOG databases were searched. Google, Google Scholar, Scirus, and Yahoo search engines supplemented the DIALOG search. Calculations for percentages of harvest were done with Microsoft Excel. Alfalfa harvest statistics were obtained from USDA's National Agricultural Statistics Service (http://www.nass.usda.gov/index.asp). In addition, USDA's Economics, Statistics and Market Information System (ESMIS), which is a collaborative project between Albert R. Mann Library at Cornell University and USDA, provided information on alfalfa harvesting (http://usda.mannlib.cornell.edu/MannUsda/homepage.do). USDA's Agricultural Marketing Service also provided information on harvests (http://www.ams.usda.gov). The common and scientific names for weeds (Appendix G-3 of this technical report) were found in the USDA Plants database (http://plants.usda.gov/java/invasiveOne).

2.0 Alfalfa Cropping Systems

This chapter discusses how alfalfa is used, the farming practices for growing alfalfa, and the alfalfa growing regions in the United States.

2.1 Alfalfa Uses

Alfalfa is grown for seed production, human food, honey, grazing, and forage. Forage comprises the largest acreage for alfalfa stands. In 2007, 72.5 million tons of dry hay alfalfa was produced from 21.6 million acres harvested (www.nass.usda.gov).

2.1.1 Forage

Alfalfa is considered the "Queen of Forages" because of its high nutritional content when fed to cattle and horse livestock (Putnam et al., 2001). Due to climate and other differences, farming practices differ regionally. However, some farming characteristics are shared among growing regions. Alfalfa stands have two growing phases, establishment of seedlings (first year) and established (two to eight years). Weed management differs for each phase (Orloff et al., 1997). During the seedling establishment phase, companion or nursery crops, such as oats, wheat, and barley can be used to help shelter the alfalfa seedlings, help prevent soil erosion, and suppress weeds because they germinate and grow faster than alfalfa (Canevari et al, 2007). Well established alfalfa that is not thinning has fewer issues with weeds because established alfalfa is a good competitor. Alfalfa can be harvested (mowed) every 30 to 50 days depending on growth conditions in the region, local weather patterns, and alfalfa variety. In most of the growing regions, alfalfa is only cut three to four times a year, but in the Southwestern U.S. growers can cut up to10 or 11 times per year (Putnam et al., 2001). To determine when to harvest, farmers balance yield and nutritional content. Yield increases as plants grow and peaks at 100% bloom, but nutritional content is highest in young vegetative plants and decreases until full flower. There is no optimal harvest schedule, because farmers make different decisions based on changing market demand. Farmers may choose to harvest between late bud stage and full bloom, however, alfalfa hay production experts recommend cutting alfalfa for hay at 10% bloom, as this stage provides the most valuable and nutritious forage (e.g., Sheaffer et al. 2000). . The highest quality hay (bud stage) is generally used for active dairy cows. Whereas hay that is lower in protein and higher in fiber, is fed to beef cattle, horses, heifers (too young to milk) and non-lactating dairy cows (Ball et al., no year). Alfalfa for livestock feed can be stored in a variety of forms:

- Hay - dry bailed at 18-20% moisture
- Haylage - round bale silage, baled at 50-60% moisture, wrapped in plastic
- Silage - chopped and blown into a silo or a truck

2.1.2 Grazing

Grazing is sometimes used as an alternative to harvesting alfalfa. Grazing allows for high nutritional gains per animal, but the risks include animal losses due to bloating and difficulties in alfalfa stand maintenance if continuous grazing is present. Farmers may choose grazing for dormant-season alfalfa stubble, a substitute for early or late season cutting, and rotational grazing during the growing season. It is strongly recommended that animals not graze before flowering begins. Alfalfa root carbohydrate reserves may not be sufficient if early grazing is permitted and the potential for bloat decreases with flowering (Orloff et al., 1997).

2.1.3 Seed Production (Hay and Sprouts)

Alfalfa is also consumed by humans (e.g., sprouts, dietary supplements, and herbal teas). Sprouts have been the source of several foodborne outbreaks due to bacterial contamination (FDA 1999). Epidemiological investigations suggest that seeds are the likely source in most, if not all, sprout-associated illness outbreaks. Seed grown for sprouts have more stringent restrictions for chemical applications during growing since the chemicals must be evaluated as food residues. Sources of animal waste in fields, such as grazing areas and irrigation water, must also be controlled to reduce the likelihood of pathogens from animal waste coming into to contact with seeds. For these reasons, sprout seed and hay seed are usually grown separately (FDA 1999).

FDA considers GT alfalfa not materially different from conventional alfalfa; therefore it is permitted for human consumption (FDA 2004). However, Monsanto does not allow GT alfalfa to be planted for sprouts (Hubbard 2008). If GT alfalfa was present in human food, it would not be considered adulterated and would not need to be removed from the market.

2.1.4 Honey

Alfalfa and clover are common nectar sources for honey bee hives. Although alfalfa is not specifically grown for bees, both managed and wild bee hives are often associated with alfalfa fields (Hammon et al., 2007).

2.2 Alfalfa Farming Practices

Alfalfa framing practices are broken into three categories, organic, conventional, and glyphosate-tolerant alfalfa. Only aspects of farming related to weed control are discussed. Practices for controlling disease, insects, nematodes, and vertebrate pests and management of field fertility and soil conservation are not discussed.

2.2.1 Organic Farming

For this report, organic production is only those cropping systems that fall under the USDA National Organic Program (NOP) definition of organic farming and are certified organic production systems. In organic systems, the use of synthetic pesticides, fertilizers, and genetically engineered crops is strictly limited. NOP publishes a list of approved substances for organic farming inputs (http://www.ams.usda.gov/AMSv1.0).

GT alfalfa is not approved for use in organic systems because it is genetically engineered and because glyphosate application is not permitted in organic systems.

In organic systems, where herbicides are not permitted, alfalfa is tilled and allowed to sit for seven to ten days. Two or more discing passes may be necessary if weed germination is observed. The field should also be treated with nutrients, such as compost and boron, and left for a week to check for further weed germination. Planting can occur once weed growth potential is minimized (Guerena and Sullivan 2003). Manure fertilizer should be composted to kill weed seeds (Canevari et al., 2007).

2.2.2 Conventional Farming

Conventional farming includes any farming system where synthetic pesticides or fertilizers are used. The definition of conventional farming usually includes the use of genetically engineered crops, but genetically engineered GT alfalfa is considered separately for this report (Harker et al., 2005). Conventional farming covers a broad scope of farming practices, ranging from farmers who only occasionally use synthetic pesticides to those farmers whose harvest depends on regular pesticide and fertilizer inputs. The 16 herbicides that may be used in conventional farming are summarized in table G-1 (based on OMAFRA 2008; Canevari et al., 2007; Rogan and Fitzpatrick 2004; Loux et al., 2007).

Table G-1. Herbicides Used in Conventional Alfalfa Farming

Herbicide (Brand)	Stand Stage	Weed	Notes
2,4-DB (Butyrac, Butoxone)	1-4 trifoliolate or established stands	Prickly lettuce Annual sowthistle Mustards Curly dock	• No harvesting or grazing allowed for 60 days following treatment
Benefin (Balan)	Before seeding	Annual grasses Broadleaf	• Not for use on soils high in organic matter
Bromoxynil (Buctril)	2-4 trifoliolate	Coastal fiddleneck Mustard0s Common groundsel Annual sowthistle	• Often tank mixed with other herbicides
Clethodim (Prism, Select)	2-4 trifoliolate or established stands	Summer grasses Yellow foxtail Green foxtail Barnyardgrass Bermudagrass Johnsongrass Goosegrass Volunteer cereals	• Well established perennials require multiple applications • Allow 15 days between application and grazing, feeding, or harvesting of alfalfa
Diuron (Karmex, Direx)	Established stands	Winter annuals Broadleaf Some grasses	• Persists in soil for one year, so cannot be used in last year of stand
EPTC (Eptam)	Established stands	Summer grasses Nutsedge	• Applied before germination • Controls for 30 to 45 days so repeated applications may be necessary

Hexazinone (Velpar)	6 inches of root growth in new stands or established stands	Broadleaf Grasses Common groundsel Chickweed miners Lettuce annual Bluegrass dandelion Buckhorn plantain Speedwell	• Many crops cannot be planted for 18 months without yield damage
Imazamox (Raptor)	2-4 trifoliolate or established stands	Winter annual Grasses Broadleaf	• Preharvest interval is 20 days
Imazethapyr (Pursuit)	2-4 trifoliolate or established stands	Winter annuals Mustards Shepherd's purse Creeping swinecress Chickweed	• Follow-up planting restrictions range from 4 to 40 months
Metribuzin (Sencor)	Established stands	Lamb's-quarters Wild mustard Redroot pigweed Common ragweed Shepherd's-purse Lady's-thumb Velvetleaf Jimsonweed Prostrate pigweed Russian thistle Yellow wood-sorrel Prickly mallow Chickweed Cocklebur Carpetweed Dandelion seedlings Barnyard grass Crab grass Foxtail Fall panicum Witch grass Johnson grass Cheat grass	• No grazing or harvesting allowed for 28 days following application
Norfluzaon (Solicam)	Established stands	Broadleaf Grasses Nutsedge	• Cannot be applied within 28 days of harvest • Does not control emerged weeds • 24 month rotation interval
Paraquat (Gramoxone Inteon)	3, 6, or 9 trifoliolate; established stands	Broad spectrum	• Rescue treatment when weeds form a canopy over alfalfa • No harvest or grazing until 60 days after application • Often used in the last year of the stand
Pronamide (Kerb)	First trifoliate leaf stage	Perennial grasses Quack grass Annual grasses Volunteer cereals Common chickweed	• No grazing or harvesting allowed for 120 days following application
Sethoxydim (Poast)	2-4 trifoliolate or established stands	Summer grasses Yellow foxtail Green foxtail Barnyardgrass Bermudagrass Johnsongrass Goosegrass	• Well established perennials require multiple applications
Terbacil (Sinbar)	Established stands	Barnyard grass Bluegrass Crab grass Foxtail Chickweed Cheat grass Perennial rye grass Wild barley Mustard Prickly lettuce Stinkweed Annual sow-thistle Henbit Lamb's-quarters Pigweed	• Can not plant any other crop for 2 years after Sinbar application

		Purslane Ragweed Partial control of: Quack grass Horsenettle Vetch Yellow nut sedge	
Trifluralin (Treflan/TR-10)	Established stands	Summer grasses	• Applied before germination • Rainfall or sprinkler irrigation is required within 3 days after irrigation to incorporate the herbicide • Controls dodder before germination

2.2.3 GT Farming

GT alfalfa can be integrated into conventional farming practices. Farming GT alfalfa is mostly the same as farming conventional alfalfa, with two important exceptions. Weeds can be controlled by the application of glyphosate directly on top of growing alfalfa and, when alfalfa stands reach the end of their life cycle (typically after 3-8 years depending on growing region), glyphosate cannot be used to kill the stand to prepare for another rotation (Miller et al., 2006). In GT alfalfa, herbicides other than glyphosate combined with tillage are required to obtain 100 percent removal. Several of the recommended GT alfalfa stand removal herbicides result in restrictions regarding what crops can be planted next, so careful crop rotation plans are necessary when using GT alfalfa. Stand removal is discussed in the technical report *Effects of Changes in Farming Practices on Water, Soil and Air Due to Use of Glyphosate-Tolerant Alfalfa* (appendix J).

Another important difference to some farmers is that non-GT crops cannot be used as companion crops for GT alfalfa. For farmers that plant pure alfalfa stands this difference does not matter. For farmers that traditionally use companion crops, this difference is important. Companion crops can increase overall forage yield but decrease hay quality (McCordick et al., 2008).

2.2.4 Crop Rotation in Alfalfa

For weed, insect, and disease management, it is recommended that alfalfa be used in rotation with other crops. It is also advised to rotate alfalfa because mature alfalfa produces medicarpin, which is auto toxic to seedling alfalfa (Guerena and Sullivan 2003). This autotoxicity is the primary problem for alfalfa seeded after alfalfa (Jennings, no year). Table G-2 presents rotation recommendations for control of several common alfalfa pests.

Table G-2. Recommended Rotations for Pest Reduction (Goodell 2006)

Pest	Recommended Rotation
Root knot nematode	1 year rotation with cotton
Stem nematode	3-4 year rotation with small grains, beans, cotton, corn, sorghum, lettuce, carrots, tomatoes, or forage grasses.*
Diseases: Bacterial wilt Anthracnose Spring blackstem Common leafspot Stagonospora	3-4 year rotation with small grains, beans, corn, sorghum, forage grasses.*
Winter weeds	A minimum of 1 year (preferably longer) in crops such as small grains, wheat, oats, winter forage grasses that allow the use of selective herbicides that are not registered in alfalfa.
Summer weeds	A minimum of 1 year (preferably longer) in crops such as small grains, beans, cotton, corn, sorghum, summer forage grasses that allow the use of selective herbicides that are not registered in alfalfa.
Dodder	At least 2 years with cotton or other nonhost crops such as small grains, beans, corn, sorghum, or forage grasses. Avoid rotations with crops such as tomatoes, onions, and carrots that also serve as a host for this weed.
Nutsedge	Two year rotation with corn or sorghum rotation that includes application of herbicide to control nutsedge.

* Three to four-year rotations give satisfactory results. A rotation for fewer years will provide minimal suppression.

Herbicides that can be used to remove GT alfalfa have rotation restrictions. For example, following clopyralid (Curtail® or Stinger®), pea, lentil, potato, and dry bean cannot be planted for 18 months. Picloram (Tordon®) can only be followed by grasses for the year after application. Sunflower, dry bean, and potato should not be planted for several years following picloram (Miller et al., 2006). Dicamba (Banvel®) should not be used prior to soybean and is also limited seasonally in California (Dillehay and Curran 2006). Because of these restrictions, alfalfa stand removal and rotation schedules should be closely coordinated. Non-glyphosate herbicides are available to manage alfalfa volunteers in wheat, oats, barley, sugar beet, and corn. Therefore rotations from GT alfalfa to those crops should be similar to rotations with non-GT alfalfa (Rogan and Fitzpatrick 2004).

Smother crops planted before alfalfa can suppress weeds. For example, sorghum-sudangrass hybrid or foxtail millet both suppressed weeds and enhanced subsequent alfalfa establishment (Forney et al., 1985).

No-till GT corn can be planted directly into alfalfa. In a study comparing no-till GT corn planted into cut or uncut alfalfa and various herbicide applications to control the alfalfa, corn yield was 13% higher following herbicide applications to uncut alfalfa. Application of glyphosate and dicamba at planting resulted in the greatest corn yield. Given that alfalfa is also a valuable crop, whether the corn yield gain is worth the loss of an alfalfa harvest should be weighed (Glenn and Meyers 2006).

2.3 Alfalfa Growing Regions

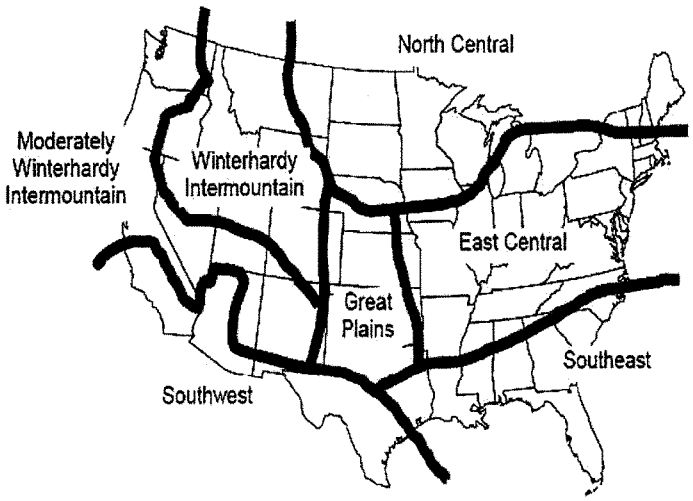

Figure G-1: Alfalfa growing regions (Rogan and Fitzpatrick 2004)

The Association of Official Seed Certifying Agencies, National Alfalfa and Miscellaneous Legumes Variety Review Board and USDA Plant Variety Protection Office recognizes seven growing regions in the United States, Moderately Winterhardy Intermountain, Winterhardy Intermountain, Southeast, Great Plains, North Central, East Central, and Southeast (figure G-1) (http://www.aosca.org/VarietyReviewBoards/Alfalfa.html). In addition, the Pacific Northwest, which includes Moderately Winterhardy Intermountain and Winterhardy Intermountain, is also sometimes recognized as a distinct growing region.

Table G-3 and table G-4 summarize the winter survival and fall dormancy ratings for alfalfa varieties. The National Alfalfa & Forage Alliance (NAFA) publishes a list of varieties and their winter survival ratings, fall dormancy ratings, and susceptibility to 17 different crop stresses (e.g., diseases, insects, grazing). The list is updated yearly and the 2007/2008 version lists 242 varieties of alfalfa (NAFA 2008). When selecting a variety, farmers consider yield, stand persistence, dormancy, pest and disease resistance, herbicide resistance, hay quality, price, seed certification, and other factors that may be specific to their farming situation (Orloff et al., 1997).

Table G-3. Winter Survival Ratings

Category	Check Variety	Score
Superior	ZG 9830	1
Very Good	5262	2
Good	WL325HQ	3
Moderate	G-2852	4

CUF 101	9
UC-1887	10
UC-1465	11

1 is very dormant, 11 is extremely non-dormant

Table G-5 presents the U.S. states in order of percentage of alfalfa harvest (in 2005). For each state, the growing region, the percentage of the total national harvest of all alfalfa are presented for 2002, 2005, and 2007; and the percentage of the national organic certified harvest are presented for 2002 and 2005. In 2005, the most recent USDA organic harvest report, 22,439,000 acres of dry hay alfalfa was harvested and 204,380 (0.9 percent) of those acres were certified organic. The number of acres harvested in a state does not indicate the quantity of the harvest. For example, as shown in table G-5, because of the growing season length, California ranks top in production (in 2007, ~11 percent of the national harvest and ~7 million pounds) and South Dakota ranks second (in 2007, ~6.8 percent of the national harvest and ~4 million pounds) even though South Dakota has ~2 million acres and California has less than 1 million acres of alfalfa.In addition, even though the Northeastern states rank low in the percentage of acres and quantity of harvest, alfalfa is the number one crop for several of those states (NAFA 2007).

Table G-5. Alfalfa Growing Regions and Percentage of Dry Hay Harvest by State

State	Growing Region	Percent of harvest acres			Percent of organic harvest	
		2002	2005	2007	2002	2005
South Dakota	North Central	10.57	10.70	9.86	8.58	6.82

ND = no data provided by USDA

Other differences in alfalfa farming are revealed by examining the number of farms that grow alfalfa and the number of farms that irrigate. Comparison of California and Wisconsin (table G-6) shows that in California ~97 percent of the farms irrigate, whereas in Wisconsin only 0.5 percent of the farms irrigate. In addition, the average farm size in California is much larger than in Wisconsin. It should be noted that the average farm size calculation is a bit misleading because in California mainly two farm sizes exist, small and very large (4,000 acres). In general, because farm size does not fit a normal distribution, the average farm size does not give a full picture of farm sizes. However average farm size does relay the general trend of farm size in a state. Like any census, these data may not include all alfalfa farms.

Table G-6. Alfalfa Dry Hay Harvest 2007 U.S. Agricultural Census

State	Number of Farms	Acres Harvested	Quantity (pounds) Harvested	Farms Irrigated	Acres Irrigated	% of Acres	% of Pounds	Avg. Acres per Farm

2.4 Summary of Findings

Alfalfa is grown for forage, grazing, seed production (forage and sprouts), human consumption, and honey production. The most acreage is for dry hay forage. Alfalfa is currently grown through conventional farming practices, organic farming, and in glyphosate-tolerant systems. In addition to mechanical and cultivation techniques, conventional farming allows the use of 16 different herbicides to control weeds in alfalfa. Organic farming does not allow synthetic pesticides or the use of crop varieties produced through genetic engineering. GT alfalfa allows for the application of glyphosate directly onto growing plants, which provides increased options for weed control over conventional and organic systems. In 2005, 22,439,000 acres of dry hay alfalfa was harvested and 204,380 of those acres were certified organic.

Crop rotation options may be different between conventional and GT systems. Many of the non-glyphosate herbicides have follow-up planting restrictions that limit crop rotation choices in conventional farming. Farmers using GT cropping systems are advised to include some years of non-GT crops in rotation, so there may be limitations in the use of other GT crops if GT alfalfa is used in a rotation plan.

The seven growing regions in the United States have varying optimal alfalfa varieties and farming practices, such as frequency of cutting, companion cropping, and irrigation. California, South Dakota, Idaho, Nebraska, Montana, and Wisconsin are the top six alfalfa hay producing states (in 2007). South Dakota, Montana, Wisconsin, and North Dakota, have the largest acreage of alfalfa hay. California's acreage is highly productive.

3.0 Glyphosate-Tolerant Alfalfa (Roundup Ready®)

Glyphosate-tolerant (GT)[23] alfalfa was deregulated in 2005 and by 2006, ~80,000 ha (~200,000 acres) were planted in the United States (Beckie and Owen 2007).[24] USDA APHIS lists all the counties in the United States where GT alfalfa has been planted (http://www.aosca.org/VarietyReviewBoards Alfalfa.html). GT alfalfa has been planted in 1,552 counties and 48 states. Alaska and Hawaii do not have GT alfalfa. In March of 2007 USDA published notice in the Federal Register that GT alfalfa is a regulated article and GT alfalfa seed sales and plantings were halted. GT alfalfa planted in the 2005 and 2006 growing seasons is still permitted to be harvested, but has court ordered stewardship practices to minimize risk of co-mingling GT and non-GT alfalfa (Hubbard 2008).

3.1 Using GT Alfalfa

Van Deynze et al., (2004) reported that in field trials when Roundup® (glyphosate) was applied during alfalfa stand establishment at the 3 to 4 trifoliolate stage, weeds were controlled and usually no second application was needed. Early applications allowed for late germination of weeds and later applications allowed weeds to compete with alfalfa. For example in the intermountain region applications at the unifoliolate to first trifoliolate stage resulted in invasion by prickly lettuces and henbit and required a second application. In the Southwest annual bluegrass and canarygrass germinated in early December and required a second application of glyphosate for control. The effectiveness of the first application during stand establishment is a function of which weed species are present and their germination period as well as how soon after application the alfalfa canopy covers the soil surface. In California there is period of time in the winter when alfalfa stands are dormant and rain causes winter weeds to germinate.

Recommended application of glyphosate to GT alfalfa is 0.75 to 1.5 pounds acid equivalent per acre (22 to 44 fluid ounces Roundup Weathermax 4.5S® per acre) at the three to five trifoliolate stage during stand establishment and up to five days before harvest in established stands (Dillehay and Curran, 2006). The maximum labeled rate for a single use of glyphosate on GT alfalfa is 1.55 pounds glyphosate acid equivalent per acre.

Alfalfa is polyploid (tetraploid), so small percentages (three to seven percent) of the seedlings do not have the GT trait. This is similar for other genetic traits. If glyphosate is sprayed early enough, plants containing the GT trait will fill in gaps left by dead weeds and non-GT alfalfa that was killed (Van Deynze et al., 2004). Up to six percent injury was observed after the first glyphosate application in a new stand, but was gone by the time of first harvest (McCordick et al., 2008). In GT alfalfa, crop injury from glyphosate application is much less than for other herbicides (Canevari et al, 2007).

GT alfalfa is an option for weed control; however it may not be appropriate in the following situations (Dillehay and Curran, 2006):

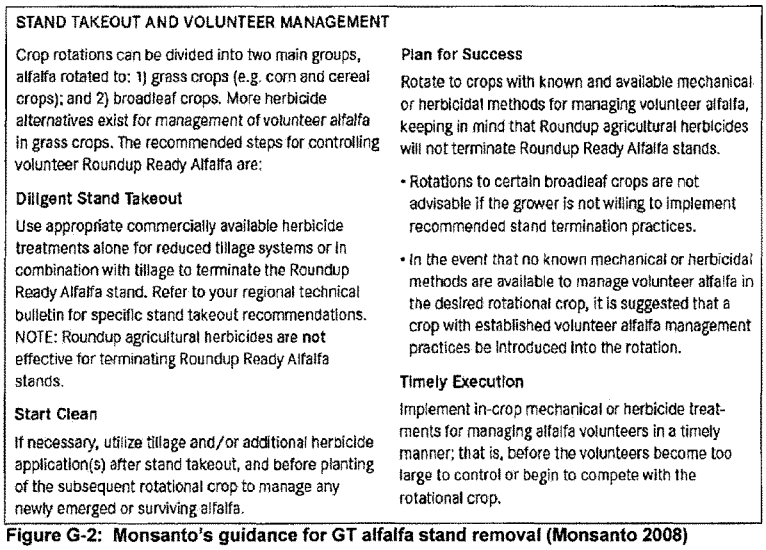
[23] "Resistance' and" tolerance" are usually synonyms and are often used interchangeably. In this report "tolerance" is used to indicate crop varieties that are intentionally engineered to withstand glyphosate application. "Resistance" is used to indicate weeds and weed biotypes that can withstand glyphosate application.
[24] 2.471 acres = 1 ha = 104 m²

- Alfalfa-grass mixtures and alfalfa seeded with companion/nursery crops
- Fields that have a history of low weed populations
- Fields that are rotated between alfalfa and other GT crop varieties (e.g. Roundup Ready® soybean)

McCordick et al. (2008) tested GT alfalfa in 2004 and 2005 growing seasons in field studies in Michigan. Two seeding regimes were used, clear seeded (only alfalfa seed) and oat companion crop. In both of these seeding regimes glyphosate, imazamox, and untreated conditions were tested. For the oat companion crop stands, clethodim was added to the imazamox treatment to increase control of oat. In the first year (stand establishment), temporary stunting was observed with glyphosate treatment, but it did not affect yield or stand density. Clear seeded alfalfa treated with glyphosate yielded the highest alfalfa dry matter in both years, even though combined forage yield was higher in the oat companion crop. When no herbicide was applied the oat companion crop had lower weed biomass than clear seeded alfalfa.

3.1.1 Stand Establishment

Forage alfalfa is planted in the spring and in the early fall in the Southwest and western regions. Currently trifluralin, EPTC, imazethapyr, imazamox, sethoxydim, clethodim, and bromoxynil herbicides are sometimes used during spring stand establishment and could be replaced with glyphosate if GT alfalfa is used. Use of GT alfalfa also allows weed control during late-summer and fall establishment (Rogan and Fitzpatrick 2004).



3.1.2 Stand Removal

One of the major differences between conventional alfalfa and GT alfalfa occurs during stand removal. Whereas glyphosate is often used to kill old stands of conventional alfalfa for crop rotations, GT alfalfa has to be removed through other mechanisms. Application of an herbicide (e.g., 2,4-D, dicamba (Banvel®), and clopyralid (Stinger®)) and tillage is effective. In no-till systems 2,4-D and dicamba can be applied together. However dicamba cannot be used before planting soybean (Dillehay and Curran, 2006).

Renz 2007 reported that dicamba and 2,4-D (WeedMaster®) applied at 2 pt/A achieved zero resprouting of alfalfa in the spring following herbicide application. Lower concentrations of WeedMaster resulted in 0.3 to 2.5 percent resprouting. The other herbicides applications (dicamba or 2,4-D only) resulted in 0.5 to 26.5 percent resprouting. In another study, picloram and 2,4-D was more effective than dicamba and 2,4-D (Miller et al., 2006). Combined with plowing, clopyralid, clopyralid plus 2,4-D, dicamba plus 2,4-D, picloram, and picloram plus 2,4-D all controlled alfalfa 100 percent. Plowing alone provided 75 percent control (Miller et al., 2006).

Potential effects of changes in tillage practices due to the use of GT alfalfa are discussed in the technical report *Effects of Changes in Farming Practices on Water, Soil and Air Due to Use of Glyphosate-Tolerant Alfalfa* (appendix K).

Figure G-2 shows Monsanto's guidance for GT alfalfa stand removal (Monsanto 2008).

STAND TAKEOUT AND VOLUNTEER MANAGEMENT

Crop rotations can be divided into two main groups, alfalfa rotated to: 1) grass crops (e.g. corn and cereal crops); and 2) broadleaf crops. More herbicide alternatives exist for management of volunteer alfalfa in grass crops. The recommended steps for controlling volunteer Roundup Ready Alfalfa are:

Diligent Stand Takeout

Use appropriate commercially available herbicide treatments alone for reduced tillage systems or in combination with tillage to terminate the Roundup Ready Alfalfa stand. Refer to your regional technical bulletin for specific stand takeout recommendations. NOTE: Roundup agricultural herbicides are **not** effective for terminating Roundup Ready Alfalfa stands.

Start Clean

If necessary, utilize tillage and/or additional herbicide application(s) after stand takeout, and before planting of the subsequent rotational crop to manage any newly emerged or surviving alfalfa.

Plan for Success

Rotate to crops with known and available mechanical or herbicidal methods for managing volunteer alfalfa, keeping in mind that Roundup agricultural herbicides will not terminate Roundup Ready Alfalfa stands.

- Rotations to certain broadleaf crops are not advisable if the grower is not willing to implement recommended stand termination practices.
- In the event that no known mechanical or herbicidal methods are available to manage volunteer alfalfa in the desired rotational crop, it is suggested that a crop with established volunteer alfalfa management practices be introduced into the rotation.

Timely Execution

Implement in-crop mechanical or herbicide treatments for managing alfalfa volunteers in a timely manner; that is, before the volunteers become too large to control or begin to compete with the rotational crop.

Figure G-2: Monsanto's guidance for GT alfalfa stand removal (Monsanto 2008)

3.2 Volunteer GT Alfalfa

Crop rotation is the practice of alternating crop species in the same field in different years. Crops are considered volunteer when they grow in a field during a year when they have not been planted intentionally. Volunteer crops are weeds because they compete with the current crop for resources and they may harbor insect and disease pests. For example, volunteer GT cotton in GT soybean can harbor boll weevil. Boll weevil is a serious cotton pest and is monitored aggressively in cotton for eradication. However boll weevil is not monitored in soybean (York, et al., 2004).

Volunteer GT crops have to be controlled through the use of other herbicides. For example GT wheat and canola is best controlled through paraquat and diuron (Rainbolt et al., 2004). Volunteer GT canola needs to be controlled before replanting canola because cultivars with different resistance genes can cross and result in multiple herbicide resistance (Rainbolt et al., 2004).

Herbicides that are used to control alfalfa, including GT alfalfa include (Rogan and Fitzpatrick 2004; Renz 2007; Dillehay and Curran, 2006; Miller et al., 2006):

- 2,4-D
- Clopyralid
- Dicamba
- Dicamba and diflufenzopyr
- Glufosinate
- Primsulfuron-methyl

- Mixtures of dicamba, 2,4-D, and clopyralid
- Picloram
- Picloram and 2,4-D
- Halsulfuron and dicamba
- Acetochlor
- Acetochlor and atrizine
- Acetochlor and atrizine and dicamba
- Atrizine and dicamba
- Clopyralid and flumetsulam

Monsanto demonstrated in their Deregulation Petition that the last five herbicides and mixes on the above list can control volunteer GT alfalfa in corn (Rogan and Fitzpatrick 2004). Clopyralid is effective at controlling volunteer alfalfa in broccoli (Tickes 2002). Clopyralid or 2,4-D provide control of volunteer alfalfa in 33 different crops. Exceptions include potatoes and popcorn (Rogan and Fitzpatrick 2004).

Feral alfalfa (alfalfa not in fields) is discussed in more depth in the technical report *Effects of Glyphosate-tolerant Weeds in Non-agricultural Ecosystems* (appendix H).

3.3 Summary of Findings

GT alfalfa allows for flexibility in timing of glyphosate application to control weeds. In the two years that GT alfalfa seed was on the market ~200,000 acres were planted in 1,552 counties in 48 states.

Glyphosate is the primary tool used to remove conventional alfalfa stands. Use of herbicides other than glyphosate for removal of GT alfalfa is a major difference between GT alfalfa and conventional alfalfa. Non-glyphosate herbicides and tillage are recommended for effective GT alfalfa stand removal.

Farmers are not able to use glyphosate to control volunteer GT alfalfa in other GT crops. However, eleven other herbicides and mixtures of those herbicides are available to control volunteer GT alfalfa. These are the same herbicides that are used to control non-GT alfalfa with the exception that glyphosate can be used to control non-GT alfalfa.

4.0 Weeds in Alfalfa

Although weeds can be a problem in alfalfa, once alfalfa is established, it acts as a suppressor of weeds and is commonly used in rotations for weed reduction. For example, prior rotation in alfalfa can reduce weed densities in sunflower to the same level as herbicide treatment and alfalfa in corn rotations also benefited corn yield and suppressed weeds (Clay and Aguilar 1998). Fields with a history of perennial weed infestation are not well suited for alfalfa (Canevari et al, 2007).

Wilson (1981) tested seven herbicides on dormant alfalfa in Nebraska and found good weed control that resulted in increased protein and total digestible nutrients (except for hexazinone application) compared to untreated control plots. Weeds that were successfully controlled included kochia, downy brome, tansymustard, Russian thistle, and prickly lettuce. Out of 48 weeds in alfalfa listed by the University of California Pest Management Guidelines, five weeds are not controlled by glyphosate: green foxtail, filed bindweed, yellow nutsedge, buckhorn plantain, and burning nettle. There was no data on pepperweeds. Three weeds stand out (field bindweed, yellow nutsedge, and buckhorn plantain) because they are not controlled well by glyphosate or any of the other 16 herbicides evaluated (table VII-3 in Rogan and Fitzpatrick 2004).

A list of 129 weeds that are known to infest alfalfa are in Appendix G-3 of this technical report, including the U.S. region where they are most prevalent as well as their scientific and common names.

General rules for managing weeds at establishment or in the seedling year include (Loux et al., 2007):

- Weeds that emerge with the crop are generally more destructive.
- Maintain the forage relatively weed-free for the first 60 days.
- Weeds that emerge beyond 60 days will not influence that year's forage yield.
- Later-emerging weeds may still influence forage quality.
- Winter annual weed competition in early spring is most damaging to forages.
- Broadleaved weeds are generally more competitive against legumes than grassy weeds.

4.1 Glyphosate Resistance in Weeds

Herbicide resistance can be defined as the inherited ability of a weed population to survive and reproduce following a herbicide application that is normally lethal to the vast majority of individuals of that species (lethal to the wild type) (Puricelli and Tuesca, 2005; Stoltenberg and Jeschke, no year). Farmers are concerned about glyphosate-tolerant weeds (Johnson and Gibson 2006). Figure G-3 represents the different weed populations in alfalfa. Since 1998, 14 new glyphosate resistant weeds have been found globally. Nine of these have glyphosate resistant biotypes in the United States. Eight of the new glyphosate resistant weeds known globally are also known to be weeds in alfalfa stands (see Appendix G-3 in this technical report for list of weeds in alfalfa). At least 21 weeds that have natural resistance to glyphosate exist. Ten of these naturally glyphosate resistant weeds are known to be a problem in alfalfa. Table G-7 lists

the weeds known to be glyphosate resistant in general or have glyphosate resistant biotypes. Figure G-4 summarizes the results of a recent farmer survey regarding their satisfaction with GT alfalfa and which weeds were controlled.

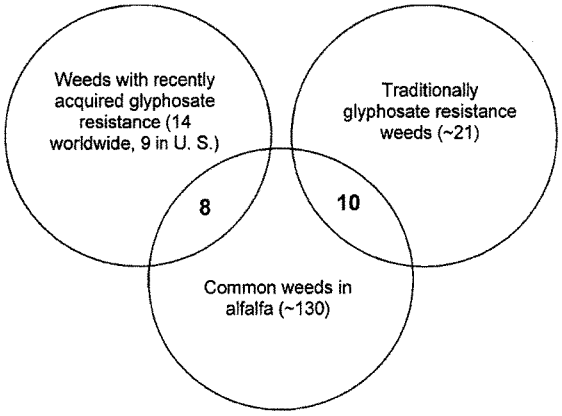


Figure G-7: Weeds in alfalfa

Table G-7. Glyphosate-resistant weeds

Common Name	Scientific Name	Resistant Biotype Reported in U.S.	Identified Problem in Alfalfa (Appendix G-3)	Listed on Roundup® Label	Source
Recently Evolved or Selected Resistant Biotypes					
Common Ragweed	*Ambrosia artemisiifolia*	Yes	Yes	Yes (with resistant biotype note)	Heap et al., 2008
Common Waterhemp	*Amaranthus rudis* and *Amaranthus tuberculatus*	Yes	No	Yes (with resistant biotype note)	Heap et al., 2008; Nandula et al., 2005
Giant Ragweed	*Ambrosia trifida*	Yes	No	Yes (with resistant biotype note)	Heap et al., 2008
Hairy Fleabane	*Conyza bonariensis*	Yes	No	Yes	Heap et al., 2008; Nandula et al., 2005
Horseweed	*Conyza canadensis*	Yes	Yes	Yes (with resistant biotype note)	Heap et al., 2008; Nandula et al., 2005

Italian Ryegrass	*Lolium multiflorum*	Yes	Yes	Yes (with resistant biotype note)	Heap et al., 2008; Nandula et al., 2005
Johnsongrass	*Sorghum halepense*	Yes	Yes	Yes (mixture also recommended)	Heap et al., 2008
Palmer Amaranth	*Amaranthus palmeri*	Yes	Yes	Yes (with resistant biotype note)	Heap et al., 2008
Rigid Ryegrass	*Lolium rigidum*	Yes	No	Yes (with resistant biotype note)	Heap et al., 2008; Nandula et al., 2005
Buckhorn Plantain*	*Plantago lanceolata*	No	Yes	No	Heap et al., 2008
Goosegrass	*Eleusine indica*	No	Yes	Yes	Heap et al., 2008; Nandula et al., 2005
Junglerice	*Echinochloa colona*	No	Yes	Yes (mixture also recommended)	Heap et al., 2008
Sourgrass	*Digitaria insularis*	No	No	No	Heap et al., 2008
Wild Poinsettia	*Euphorbia heterophylla*	No	No	No	Heap et al., 2008

Historically Naturally Resistant				
Asiatic dayflower	*Commelina communis*	No	No	Nandula et al., 2005
Birdsfoot trefoil	*Lotus corniculatus*	No	No	Nandula et al., 2005
Bermudagrass	*Cynodon dactylon*	Yes	Yes (partial control notes)	Cerdeira and Duke 2006
Burning nettle	*Urtica uren*	Yes	No (mixture recommended)	Van Deynze et al., 2004; Canevari et al., 2004
Cheeseweed	*Malva parviflora*	Yes	No (mixture recommended)	Van Deynze et al., 2004
Chinese foldwig	*Dicliptera chinensis*	No	No	Nandula et al., 2005
Common lambsquarters	*Chenopodium album*	Yes	Yes (mixture also recommended)	Nandula et al., 2005

Field bindweed*	*Convolvulus arvensis*	Yes	No (mixture recommended)	Nandula et al., 2005
Filaree	*Erodium* spp.	Yes	Yes (mixture also recommended)	Van Deynze et al., 2004
Florida pellitory	*Parietara debilis*	No	No	Cerdeira and Duke 2006
Hemp sesbania	*Sesbania exalta*	No	Yes	Cerdeira and Duke 2006
Large crabgrass	*Digitaria sanguinalis*	Yes	Yes (mixture also recommended)	Cerdeira and Duke 2006
Morning glory	*Ipomoea purpurea*	Yes	Yes (mixture also recommended)	Hilgenfeld et al. (2004; Cerdeira and Duke 2006
Nutsedge*	*Cyperus* spp.	Yes	Yes	Cerdeira and Duke 2006
Oval-leaf false buttonweed	*Spermacoce latifolia*	No	No	Cerdeira and Duke 2006
pillpod sandmat	*Chamaesyce hirta*	No	No	Cerdeira and Duke 2006
Purslane	*Portulaca oleracea*	Yes	Yes (mixture also recommended)	Van Deynze et al., 2004
Tropical Mexican clover	*Richardia brasiliensis*	No	No	Cerdeira and Duke 2006
Tropical spiderwort	*Commelina benghalensis*	No	No	Nandula et al., 2005
Velvet leaf	*Abutilon theophrasti*	No	Yes (mixture also recommended)	Nandula et al., 2005
Waterhemp	*Amarathus rudis and A. tuberculatus*	No	Yes (with resistant biotype note)	Cerdeira and Duke 2006

Cline 2004 reports that fleabane and henbit are also difficult to control with glyphosate. * These 3 weeds are not fully controlled by any of the 16 herbicides listed in the University of California Pest Management Guidelines (Rogan and Fitzpatrick 2004).

Survey of GT Alfalfa Farmers

Canevari (2007) reported survey results from interviews with alfalfa growers and industry representatives from California, Idaho, Nevada, Arizona, Washington, and New Mexico (43 respondents). The major weeds in alfalfa that were controlled by using a GT alfalfa system are listed below. Weeds that were cited as causing problems in alfalfa but were not mentioned by farmers as being controlled by glyphosate are highlighted in grey. A more comprehensive list of weeds in alfalfa is in appendix B.

Of the 24 growers surveyed all were satisfied with GT alfalfa. Advantages included less herbicide needed, yield increase, control of volunteer crops, excellent weed control, hay quality increase, better stand and water efficiency. Farmer concerns were that the seed is no longer available, the need for bale identification due to court order, and reluctance of the horse market. For the pest consultants, dealers, and researchers, concerns included export concerns, seed costs, weed resistance, weed shifts, market acceptance.

Bindweed	Dandelion	Knapweed	Morningglory
Bur clover	Dodder	Knotweed	Nutsedge
Canada thistle	Fiddleneck	Kochia	Pepperweed
Cocklebur	Foxtail	London rocket	Plantain
Common groundsel	Hoary cress	Lovegrass	Pigweed
Curly dock	Johnson grass	Mexican tea	Quackgrass
			Water grass

Figure G-4: Survey of GT alfalfa farmers

The 18 weed species (table G-7) that are both resistant to glyphosate and traditionally present problems in alfalfa likely pose the greatest threat for weed shifts in a GT cropping system. Eight weeds with newly identified resistance and ten weeds known to have some natural resistance to glyphosate are briefly described below.

4.1.1 New Glyphosate Resistant Weeds

Glyphosate resistant biotypes have recently been identified for the following eight weeds that are also common in alfalfa: common ragweed, horseweed, Italian ryegrass, Johnsongrass, Palmer Amaranth, buckhorn plantain, goosegrass, and junglerice. Each is briefly discussed below.

Common ragweed (*Ambrosia artemisiifolia*) germinates in May and early June, flowers in August to September, and sets seed in September. Each plant can release more than 30,000, three mm-long seeds, which can remain viable for more than 39 years buried. Seeds are dispersed by water and animals and can be blown across crusted snow in the winter. Common ragweed can thrive in soil containing high amounts of clay, gravel, or sand. It is found in cropland, abandoned fields, vacant lots, fence rows, waste areas, and along roadsides and railroads. Because it can accumulate large quantities of trace metals, it is very competitive and can cause nutritional deficiencies in crops. Not only does it taste bitter to livestock but it also causes nausea and mouth sores in livestock. It is very difficult to control as it can tolerate mowing, trampling, and grazing (Lanini, no year a). Common ragweed has a biotype that has multiple herbicide resistance to acetolactate synthase (ALS) inhibitors and PPO inhibitors (Heap et al., 2008).

Horseweed (*Conyza canadensis*) is a summer or winter annual that grows 1.5 to 6 feet tall (Loux et al., 2006). It produces a large number of seeds (200,000 per plant) that are wind-

dispersed. Seed dispersal in a corn field ranged from 12,500 seeds per square yard at 20 feet from the seed source, to more than 125 seeds per square yard at 400 feet from the seed source (Loux et al., 2006). Seeds can disperse a quarter mile when winds are only 10 miles per hour (Barnes et al., 2003). Seeds are able to germinate in no-till fields (undisturbed soil, includes non-crop sites) and tilled fields. Outcrossing among horseweed occurs at 1.2 to 14.5 percent which facilitates the spread of resistance traits (Stoltenberg and Jeschke, no year; Nandula et al., 2005; Loux et al., 2006). The known cases of glyphosate-resistant horseweed are characterized by frequent use of glyphosate, little or no use of alternative herbicides that control horseweed, and long-term no-tillage crop production practices (Loux et al., 2006). In addition to direct competition for light, water, and nutrients, horseweed can host the tarnished plant bug, an alfalfa pest, and the viral disease aster yellows, which is transmitted by aster leafhoppers to a wide variety of plants (Loux et al., 2006). Horseweed contains volatile oils, tannic acid and gallic acid that may cause mucosal and skin irritation in livestock (especially horses) and humans (Steckel, no year a). There are horseweed biotypes that are also resistant to ALS inhibitors. Several herbicides are effective at the rosette stage, but once horseweed is over six inches tall a three-way mixture of glyphosate, plus 2,4-D ester, plus chlorimuron or cloransulam, is recommended. Biotypes that are resistance to glyphosate and/or ALS inhibitors cannot be effectively controlled (Loux et al., 2006). In Ohio, a biotype that is resistant to both ALS inhibitors and glyphosate and a biotype in Michigan that is resistant to photosystem II inhibitors and ureas and amides have been identified (Heap et al., 2008). Over 500,000 acres in the Midwest are reported to be infested with glyphosate-resistant horseweed (Cline 2004). Others estimate that over two million acres in the U.S. are infested (Heap et al., 2008).

Italian Ryegrass (*Lolium multiflorum*) is an annual grass and is related to perennial ryegrass (*Lolium perenne*). Italian ryegrass can be intentionally cultivated with alfalfa as a companion crop and is good for grazing, hay, and silage (Hall 1992). However in cool, wet environments, it may outcompete alfalfa and, in very dry situations, it might not provide adequate ground cover (Schneider and Undersander 2008). Italian ryegrass is a weed in wheat because it stays green longer than wheat and causes cut wheat to heat and spoil (Peeper 2000). There are biotypes that exhibit multiple herbicide resistance to acetyl-CoA carboxylase (ACCase) inhibitors, ALS inhibitors, and Chloroacetamides (Heap et al., 2008). At least 5,000 acres in CA are reported to be infested with glyphosate resistant ryegrass (Cline 2004).

Johnsongrass (*Sorghum halapense*) is one of the ten most noxious weeds in the world. It is a fast-growing competitive perennial grass. Established Johnsongrass can be seven to nine feet tall and releases chemicals that inhibit surrounding plant growth. A plant produces 100 to 400 seeds that withstand silage and passage through livestock digestive systems. Seeds can germinate from 6 inches deep and are viable for three years. Stresses that interrupt normal growth, such as freezing, cutting, wilting, trampling, and herbicide exposure, can cause the release of toxic amounts of hydrocyanic acid which are poisonous to livestock. Johnsongrass is thought to be introduced from Egypt sometime after the Revolutionary War and was previously grown as forage in the south. If herbicides are not used it can be controlled by intense grazing and mowing for two years until the rhizomes are depleted. (CDFA, no year a; Lanini no year b). There are separate biotypes of Johnsongrass that have resistance to ACCase inhibitors, Dinitroanilines and ALS inhibitors (Heap et al., 2008).

Palmer amaranth (*Amaranthus palmeri*) is closely related to waterhemp and is the dominant pigweed in the Southwest. It is the most competitive and rapidly growing species of the weedy pigweeds and can reach a height of six feet (Steckel no year b). It is susceptible to herbicides when it is 4 to 6 inches tall (Scarpitti et al., 2007). Biotypes of Palmer amaranth have been identified with resistance to Dinitroanilines, photosystem II inhibitors, and ALS inhibitors (Heap et al., 2008).

Buckhorn Plantain (*Plantago lanceotata*) competes with crops for soil nutrients, water, and light and does well in droughts. It reproduces by seed and by tap root. Buckhorn plantain establishes slowly in alfalfa, but, once established, is difficult to control because of its extensive crown system (Wall and Whitesides, 2008). Glyphosate resistance is the only identified herbicide resistance in buckhorn plantain and has only been found in South Africa, so far (Heap et al., 2008).

Goosegrass (*Eleusine indica*) is an annual grass with an extensive root system that can produce 50,000 seeds per plant (Duble, no year). It is one of the five most troublesome weeds world-wide. It is found in agricultural fields, homeowner lawns, waste areas, roadsides, pastures, and golf courses. When it emerges with or shortly after a crop it can be a very competitive weed. Later in the growing season, it can produce enough biomass to hinder harvest (Steckel no year c). Some goosegrass biotypes exist that are known to be resistant to ACCase inhibitors, Bipyridiliums, Dinitroanilines, and ALS inhibitors. In Malaysia, a case of multiple resistance to ACCase inhibitors and glyphosate was found (Heap et al., 2008).

Junglerice (*Echinochloa colonum*) is a summer annual grass that is invasive in Tennessee, Hawaii, and Arizona (NPS 2007). It has little or no dormancy in tropical areas and germinates throughout the year. It can grow two to three feet high (Virginia Tech, no year). In Costa Rica, a biotype has been identified that has multiple resistance to ACCase inhibitors, ALS inhibitors, and ureas and amides. A glyphosate resistant biotype has been identified in Australia (Heap et al., 2008).

4.1.2 Traditionally Glyphosate Resistant Weeds

Ten weeds that are common in alfalfa and historically have some tolerance for glyphosate include bermudagrass, burning nettle, cheeseweed, common lambsquarters, field bindweed, filaree, large crabgrass, morningglory, nutsedge, and purslane. Each is briefly discussed below.

Bermudagrass (*Cynodon dactylon*) is a perennial grass that propagates through seed, root, or stem cuttings. If bermudagrass is cultivated, the soil should be dry because, if it is moist, the cut shoots will form new plants (Cudney and Elmore 2007). Bermudagrass is also grown as a forage crop (Undersander and Pinkerton 1988).

Burning nettle (*Urtica urens*) is a summer annual that flowers from June to November and is wind-pollinated. One plant can produce from 1,000 to 40,000 seeds. When left undisturbed in soil for six years, germination declined by 61 percent. However, 20 to 100 year-old seeds from excavations have been known to germinate. Seeds can also survive livestock digestive systems (Organic Garden 2007). Burning nettle stinging hairs contain histamine, formic acid, acetylcholine, acetic acid, butyric acid, leukotrienes, 5-hydroxytryptamine, and other irritants.

Dermal contact with the hairs leads to a mildly painful sting and itching or numbness for a period lasting from minutes to days (Thorne Research 2007). In Australia, a biotype resistant to photosystem II inhibitors has been identified (Heap et al., 2008).

Cheeseweed (*Malva neglecta*) is an annual or biennial dicot that reproduces from seeds. It is found on cultivated ground, new lawns, farmyards, and waste places (Mitich, no year). It is very competitive in alfalfa and, once established, is difficult to control. The fatty acids malvalic acid and sterculic acid may cause the plant to be toxic to horse, cattle, and sheep (Canevari 1997). Selenium or nitrate concentration has also been cited as the cause of toxicity (Hill 1993; USU, no year; Barnard, 1996).

Common lambsquarters (*Chenopodium album*) is a summer annual dicot that is adaptable to many environments. A plant can produce 100,000 seeds which can survive 30 to 40 years in soil (Lanini, no year c). Biotypes that are resistant to photosystem II inhibitors and ALS inhibitors have been identified in the United States (Heap et al., 2008). Glyphosate resistant lambsquarters has been reported in the Midwest and in a Madera, CA almond orchard (Cline 2004).

Field bindweed (*Convolvulus arvensis*) is a perennial dicot that reproduces by seed and vegetatively from deep-creeping roots and rhizomes. Young plants seldom produce seed in the first year, but one plant can produce 500 seeds. In fields, seeds can survive 20 years or more. Field binweed can harbor the viruses that cause potato X disease, tomato spotted wilt, and vaccinium false bottom. In addition, it contains tropane alkaloids and can cause intestinal problems in grazing horses (CDFA no year b).

Filaree (*Erodium cicutarium*) is a winter annual dicot that grows two to five inches high. It is adapted to a broad range of soil types and is found in oak woodlands, semi-desert grassland, desert shrublands, fields, lawns, and wasteplaces. Redstem filaree can be excellent forage for livestock and wildlife, but can cause bloating under heavy grazing (Pratt et al., 2002). It is competitive with crops and can cause yield reductions (Trainor and Bussan 2001).

Large crabgrass (*Digitaria sanguinalis*) is a summer annual that reproduces by seeds (Stritzke, no year). It is primarily a turfgrass weed, but can be founding thinning alfalfa stands (Elmore 2002). A biotype with multiple resistance to ACCase inhibitors and ALS inhibitors has been identified in Australia. Photosystem II inhibitor resistant biotypes have also been identified (Heap et al., 2008).

Morning glory (*Ipomoea purpurea*) is a perennial climbing vine that reproduces by seed (Pittwater Council, no year). It is a problem in crops because of competition. Morning glory seeds are toxic to humans (Filmer, no year). Morning glory foliage is toxic to livestock due to nitrates. Symptoms of acute nitrate poisoning are trembling, staggering, rapid breathing, and death. Chronic poisoning may result in poor growth, poor milk production and abortions. In cattle, there is evidence that vitamin A storage is affected (Robinson and Alex 1989).

Nutsedge (*Cyperus* spp.) is a hardy weed due to tubers that grow 8 to 14 inches below the ground and, when mature, can re-sprout 10 to 12 times after cutting before tuber resources are depleted. In addition, many herbicides are not translocated to tuber, and, therefore, do not

effectively control growth (Wilen et al., 2003). Alfalfa should not be planted in a field where nutsedge is a known problem (Canevari et al., 2003). In a study in California, nutsedge was reduced 96 to 98 percent using crop rotation and herbicides. The rotation was two years alfalfa with applications of EPTC herbicide, two years of barley double-cropped with corn and application of thiocarbamate herbicide, and two years of barley followed by fallow glyphosate applications (Canevari et al., 2007). Biotypes of *Cyperus difformis* that are resistant to ALS inhibitors have been found in California and globally (Heap et al., 2008).

Purslane (*Portulaca oleracea*) is a summer annual dicot that produces 240,000 seeds per plant and can survive five to 40 years. It can re-root after cultivation or hoeing, so it is difficult to control mechanically. It is a minor crop in the United States because it is edible and is used in ethnic cooking. In other crops, it is a weed because of competition (Cudney et al., 2007).

4.1.3 Mechanisms of Glyphosate-Tolerance

Glyphosate inhibits 5-enolpyruvylshikimate-3-phosphate (EPSP) synthase, which is a key enzyme in the shikimate pathway in plants and is required for plant growth. The effects of glyphosate can be stopped in several ways (Cerdeira and Duke, 2006; Stoltenberg and Jeschke, no year; Nandula et al., 2005):

Resistant EPSP synthase - A version of EPSP synthase that is not affected by glyphosate has been found in bacteria (*Agrobacterium*) and has been transferred into crop plant genomes. Also, the maize version of EPSP synthase has been modified by site directed mutagenesis to be resistant to glyphosate. A version of EPSP synthase with decreased binding to glyphosate has been found in the weed goosegrass (*Eleucine indica*).

Degrade glyphosate - A glyphosate-degrading enzyme has been found in bacteria (*Ochrobactrun anathropi*) and has been transferred into crop plant genomes.

Inactivate glyphosate - An enzyme found in bacteria (*Bacillus licheniformis*) has a weak ability to inactivate glyphosate through N-acetylation. The efficiency of this enzyme was increased by directed evolution in the lab and, when transferred to plants, confers resistance to glyphosate in field settings. A fungal gene encoding glyphosate decarboxylase has been discovered and patented for eventual use in crop plants.

Altered translocation of glyphosate – There is limited evidence that, in some glyphosate resistant ryegrass, glyphosate accumulates in mature leaf tissue rather than in the growing parts. Although the mechanism of resistance in horseweed is unknown, translocation experiments suggest that resistant biotypes do not translocate glyphosate to the growing parts of the plant (e.g., roots, young leaves, and crown).

Other – Resistant plants exist for which the mechanism of glyphosate resistance is not known. In addition, it is likely that there are mechanisms of resistance that have yet to evolve.

4.2 Weed Shifts in GT Alfalfa

Adopting new weed control strategies eventually leads to shifts in the weeds that are of greatest concern. Weed shifts can occur due to changes in tillage, irrigation, soil fertility, planting date, crop rotation, and herbicide use (Hilgenfeld et al., 2004). Changes to a no-till system results in a more diverse seedbank. Within weedy species variations in characteristics help weeds escape or tolerate weed management. These characteristics include seed dormancy, emergence patterns, growth plasticity, life cycle, life duration, shade tolerance, late-season competitive ability, seed dispersal mechanisms, and morphological and physiological variations (Hilgenfeld et al., 2004).

Because weed seedbanks in the soil can contain large reservoirs of dormant weed seed, short-term studies (a few years) might not detect the full potential shift in weed communities (Harker et al., 2005). However sometimes weeds shift can be observed within a few years. For example, in a field trial in an established GT alfalfa stand in the Southwest (San Joaquin Valley) burning nettle was not controlled and the population of burning nettle increased significantly over the three-year trail period (Canevari et al., 2004; Van Deynze et al., 2004). Tank mixtures with Velpar (hexazinone) or paraquat controlled burning nettle. Weeds that are difficult to control with glyphosate, such as dodder and cheeseweed, may need to be treated early and require a second application. Van Deynze et al (2004) recommend that the best way to prevent weed shifts is to avoid using the same herbicide year after year, rotate herbicides and crops, and include non-herbicide strategies to control weeds.

Puricelli and Tuesca (2005) found that continuous (once before planting, once at 40 days after planting, once in winter fallow in August) glyphosate application in field studies on three crop rotation sequences and two tillage systems lead to quantitative and qualitative changes in weed communities. They found that glyphosate application was a more important factor than crop sequence to explain weed community changes in summer crops. They also predicted that continual glyphosate application for longer than the five years in their study might lead to the development or higher increases in abundance of weeds tolerant to glyphosate. Weed species diversity in conventional versus no-tillage plots did not differ significantly.
Harker et al., (2005) reported that field studies of spring wheat-canola-spring wheat rotations of various combinations of GT and non-GT varieties under conventional tillage or low soil disturbance direct seeding systems indicate that weed community shifts are dependent on rotation pattern in a site-dependent manner. In the western Canada field locations, within 3 years, crop systems without GT varieties were associated (using canonical discriminant analysis) with green foxtail, redroot pigweed, sowthistle spp., wild buckwheat, and wild oat. The specific weeds associated with all GT variety systems included Canada thistle at the Brandon site, henbit at the Lacombe site, and volunteer wheat, volunteer canola, and round-leaved mallow at the Lethbridge site. One surprising finding was that high variability in wild buckwheat between the systems. Glyphosate is not very effective on wild buckwheat, so the authors propose that wild buckwheat seed production or viability may be restricted by glyphosate more than the wild buckwheat biomass. Therefore after glyphosate application the plant may appear visually robust, but its ability to reproduce has been effected, so in following years less wild buckwheat is observed (Harker et al., 2005).

It is plausible that the 18 weeds discussed in section 4.1 are the first candidates for weed shifts in GT alfalfa. However, as discussed in the studies summarized above, weed shifts are dependent on the composition of the weed seedbank in the soil and surrounding sources of weeds.

4.2.1 Weed Management Options

Weed management strategies in organic alfalfa systems, conventional alfalfa systems, and glyphosate-tolerant alfalfa systems differ. Management options for conventional systems include (Nandula et al., 2005; Guerena and Sullivan 2003):

- Chemical (See table G-6)
  - Alternating herbicides with different modes of action
  - Tank mixing herbicides
  - Sequences of herbicides
  - Application timing
- Cultural
  - Rotation between GT cultivars and non-GT cultivars
  - Winter crops in rotation
  - Companion crops/co-cultivation/interseeding/nurse crop)
  - Cover crops (smother crops) (prior to planting alfalfa)
  - Field scouting for early detection
  - Monitor for weed species and population shifts
- Mechanical
- Tillage cultivation

Organic alfalfa systems can use the cultural and mechanical strategies (except for use of GT cultivars). Nurse crops of peas or oats produce good hay for the horse market (Guerena and Sullivan 2003). GT alfalfa systems can use all of the strategies of conventional systems plus application of glyphosate directly on growing alfalfa. Options for rotating between GT cultivars and non-GT cultivars are reduced with GT alfalfa, since GT corn and GT soybean are popular rotation crops for alfalfa.

Cutting intervals affect weed infestation. For example, if alfalfa is cut too frequently (20 to 25 days) there is not enough time for root storage of carbohydrates so growth after cutting is not vigorous and weeds have a competitive advantage. However sometimes early harvest can rescue a heavily weed-infested new stand if the weeds are beyond the stage of optimum herbicide treatment (Canevari et al, 2007). Alternating long and short intervals between cuttings enables alfalfa to maintain root reserves so plants can recover from defoliation quickly and more vigorously compete with weeds (Canevari et al, 2007).

4.3 Distribution of Glyphosate Resistant Weeds

Table G-8 shows that currently 19 U.S. states are affected by glyphosate resistant weeds. The majority of new glyphosate resistant weeds are located in the Southeast and Midwest. The overlap with the major alfalfa producing states in the Intermountain regions seems to be minimal at this point (table G-6). However, given that there is overlap between glyphosate resistant weed locations and alfalfa hay acreage there is potential for rapid shifts of glyphosate resistant weeds

into GT alfalfa fields if GT alfalfa were to be widely adopted. California is a concern because glyphosate resistant weeds are present and alfalfa is a major crop in California. More detailed records of local weed infestations may be kept by state extension offices.

Table G-8. Glyphosate-Resistant Weed Infestations by State (Heap et al., 2008)

State	Weed species	~ Number of Sites in State Infested	~ Number of Acres in State Infested	Situation	Year Reported
Arkansas	***Conyza canadensis*** Horseweed	6-10 increasing	1,001-10,000 increasing	Cotton	2003
	Ambrosia artemisiifolia Common Ragweed	1	11-50	Soybean	2004
	Ambrosia trifida Giant Ragweed	6-10 increasing	101-500 increasing	Soybean	2005
	Amaranthus palmeri Palmer Amaranth	1 increasing	unknown	Soybean	2006
	Sorghum halepense Johnsongrass	1	unknown	Soybean	2007
California	***Lolium rigidum*** Rigid Ryegrass	11-50 increasing	1,001-10,000 increasing	Almonds	1998
	Conyza canadensis Horseweed	1	unknown	Roadside	2005
	Conyza bonariensis Hairy Fleabane	2-5	unknown	Roadside	2007
Delaware	***Conyza canadensis*** Horseweed	101-500	10,001-100,000	Soybean	2000
Georgia	***Amaranthus palmeri*** Palmer Amaranth	101-500 increasing	100,001-1,000,000 increasing	Cotton Soybean	2005
Illinois	***Conyza canadensis*** Horseweed	1,001-10,000 increasing	10,0001-1,000,000 increasing	Soybean	2005
	Amaranthus rudis Common Waterhemp***	1 increasing	51-100 increasing	Corn Soybean	2006
Indiana	***Conyza canadensis*** Horseweed	2-5 increasing	101-500 increasing	Soybean	2002
	Ambrosia trifida Giant Ragweed	1 increasing	11-50 increasing	Soybean	2005
Kansas	***Conyza canadensis*** Horseweed	51-100 increasing	10,001-100,000 increasing	Cotton Soybean	2005
	Ambrosia trifida Giant Ragweed	2-5 increasing	501-1,000 increasing	Soybean	2006
	Amaranthus rudis Common Waterhemp	2-5 increasing	101-500 increasing	Soybean	2006
	Ambrosia artemisiifolia Common Ragweed	1 increasing	11-50 increasing	Soybean	2007
Kentucky	***Conyza canadensis*** Horseweed	2-5 increasing	51-100 increasing	Soybean	2001
Maryland	***Conyza canadensis*** Horseweed	6-10 increasing	501-1,000 increasing	Soybean	2002
Michigan	***Conyza canadensis*** Horseweed	1 increasing	51-100 increasing	Nursery	2007

Minnesota	***Ambrosia trifida*** Giant Ragweed	2-5 increasing	101-500 increasing	Soybean	2006
	Amaranthus rudis Common Waterhemp	2-5 increasing	51-100 increasing	Soybean	2007
Mississippi	***Conyza canadensis*** Horseweed	101-500 increasing	1,001-10,000 increasing	corn, cotton, rice, and soybean	2003
	Lolium multiflorum Italian Ryegrass	unknown	1,001-10,000 increasing	Cotton Soybean	2005
Missouri	***Conyza canadensis*** Horseweed	101-500 increasing	10,001-100,000 increasing	Cotton	2002
	Ambrosia artemisiifolia Common Ragweed	1	11-50	Soybean	2004
	Amaranthus rudis Common Waterhemp**	1 increasing	1,001-10,000 increasing	Corn Soybean	2005
New Jersey	***Conyza canadensis*** Horseweed	6-10 increasing	101-500 increasing	Soybean	2002
North Carolina	***Conyza canadensis*** Horseweed	2-5 increasing	6-10 increasing	Cotton	2003
Ohio	***Conyza canadensis*** Horseweed	101-500 increasing	1,001-10,000 increasing	Soybean	2002
	Conyza canadensis Horseweed*	2-5 increasing	101-500 increasing	Soybean	2003
	Ambrosia trifida Giant Ragweed	2-5 increasing	101-500 increasing	Soybean	2004
Oregon	***Lolium multiflorum*** Italian Ryegrass	1 stable	1-5 stable	Orchards	2004
Pennsylvania	***Conyza canadensis*** Horseweed	2-5 increasing	101-500 increasing	Soybean	2003
Tennessee	***Conyza canadensis*** Horseweed	501-1,000 increasing	>2,000,000 increasing	Cotton Soybean	2001
	Amaranthus palmeri Palmer Amaranth	2-5 increasing	101-500 increasing	Cotton	2006
	Ambrosia trifida Giant Ragweed	101-500 increasing	1,001-10,000 increasing	Cotton Soybean	2007

* resistant to chlorimuron-ethyl, cloransulam-methyl, and glyphosate ** resistant to acifluorfen-Na, cloransulam-methyl, fomesafen, glyphosate, imazamox, imazethapyr, and lactofen *** resistant to chlorimuron-ethyl, glyphosate, and imazethapyr

Monsanto's guidance for weed resistance management in GT alfalfa is as follows (Monsanto 2008):

- Scout fields before and after each herbicide application.
- Use the right herbicide product at the right rate and at the right time.
- To control flushes of weeds in established alfalfa, make applications of Roundup WeatherMAX herbicide at 22 to 44 oz/A before weeds exceed 6", up to 5 days before cutting.
- Use other herbicide products tank-mixed or in sequence with Roundup agricultural herbicide if appropriate for the weed control program.
- Report repeated non-performance to Monsanto or your local retailer.

4.4 Summary of Findings

At least 129 different weed species are identified as minor or major problems in alfalfa. Out of 14 new glyphosate resistant weeds found since 1998, eight are known to be weeds in alfalfa. Out of at least 21 weeds that have natural resistance to glyphosate, ten are known to be a problem in alfalfa. These 18 weeds that are both resistant to glyphosate and traditionally listed as problems in alfalfa include: common ragweed, horseweed, Italian ryegrass, Johnsongrass, Palmer Amaranth, buckhorn plantain, goosegrass, junglerice, bermudagrass, burning nettle, cheeseweed, common lambsquarters, field bindweed, filaree, large crabgrass, morningglory, nutsedge, and purslane. Although the composition of weed shifts is based on the local seedbank, these 18 weeds are candidates for becoming more prevalent than GT sensitive weeds in rotations that include GT alfalfa.

Mechanisms of glyphosate resistance include resistant EPSP synthase, degradation of glyphosate, inactivation of glyphosate, and altered translocation of glyphosate.

Nineteen states and over two million acres of cropland are infested with new glyphosate resistant weeds. The heaviest infestation is in the Southeast and Midwest. Overlap with the major alfalfa producing states in the Intermountain regions seems to be minimal at this point. However, given that there is overlap between glyphosate resistant weed locations and alfalfa hay acreage there is potential for rapid shifts of glyphosate resistant weeds into GT alfalfa fields if GT alfalfa were to be widely adopted. California is a concern because glyphosate resistant weeds are present and alfalfa is a major crop in California.

Weeds are controlled in conventional alfalfa with chemicals (herbicides), cultural methods (rotation, companion crops, monitoring), and mechanical methods (tillage). The cultural and mechanical methods are permitted for organic farmers. GT systems allow for the use of one additional herbicide, glyphosate.

Appendix G-2. Literature Search

1.0 Literature Search Strategy

The following literature search was done for two of the technical reports:

Effects of Glyphosate-tolerant weeds in agricultural systems (former title: Increase in RR resistant weeds in crops)

Effects of Glyphosate-tolerant weeds in non-agricultural ecosystems (former title: Increase in RR resistant weeds in non-crop ecosystems)

1.1 Purpose

The purpose of this literature search is to locate references about the potential impacts of glyphosate-tolerant weeds in agricultural systems and in natural ecosystems.

The following DIALOG databases were included in the search:
- File 10:AGRICOLA 70-2008/Jun
- (c) format only 2008 Dialog
- File 156:ToxFile 1965-2008/Jun W2

1.2 Scope of Search

The search focused on any published references between 2000 and the present. A list of titles was screened followed by screening of abstracts for relevant titles. There were no limits on language for titles but only English language publications were retrieved for evaluation.

1.3 Keywords

A list of search parameters is listed below.

Synonyms of key topic
Glyphosate toleran*
Glyphosate resistan*
Roundup® Ready

Key words in combination with key topic Weed management Weed mitigation Weed control
Alfalfa
Medicago

Comparing *Roundup* *Ready* and Conventional Systems of *Alfalfa* Establishment

2007

URL: http://dx.doi.org/10.1094/FG-2007-0724-01-RS

Roundup *Ready* (RR) technology provides a new approach for *weed*

control during *alfalfa* (*Medicago* sativa L.) establishment. We determined the effect of RR and conventional establishment systems on*alfalfa* yield, *weed* yield, and forage quality when *alfalfa* was established using solo-seeding or oat mulch methods. A RR system was a RR*alfalfa* in combination with glyphosate (Roundup) and a conventional system was a non-RR variety with imazamox (Raptor). Non-RR and RR alfalfaswere also seeded with an oat companion crop. *Alfalfa* yields, plantpopulations, and forage quality were similar for the RR and conventionalsystems within solo-seeding and oat establishment methods in the seedingyear. Total seeding-year *alfalfa* yield was greater when solo-seeded usingan herbicide than when seeded with an oat companion crop harvested at boot.*Alfalfa* yield for the oat mulch and oat companion crop treatments werenot consistently different over...

Winter annual *weed* control with herbicides in *alfalfa*-orchardgrass mixtures
2008
4.0 ABSTRACT: *Alfalfa*-orchardgrass hay is popular in the Western UnitedStates because of an expanding horse-hay market. However, *weed* controlin mixed *alfalfa*-orchardgrass stands is problematic, as herbicides mustbe safe for both species. Most growers rely solely on the competitivenessof the crop for *weed* control, which is often insufficient, especiallyin older stands. Field experiments were established in northernCalifornia to determine the efficacy and crop safety of severalherbicides for winter annual *weed* control in established *alfalfa* -orchardgrass. Metribuzin at 560 or 840 g/ha and hexazinone at 420 g/ha applied...
...Paraquat at 560 g/ha applied shortly after crop green-up gave 50 to 82%*weed* control and caused significant injury to orchardgrass, which wasstill noticeable at first cutting....ORGANISMS: *Medicago* sativa {*alfalfa*} (Leguminosae)MISCELLANEOUS TERMS: *herbicide* *tolerance*

Selected Comments to Draft Environmental Impact Statement form Farmers Using Roundup Ready Alfalfa

APHIS-2007-0044-0320

Name: Daniel M. Luckwaldt
Address: Woodville, WI

Submitter's Representative: Daniel Luckwaldt
Organization: Luckwaldt Agriculture Inc.

I am a dairy farmer who planted 100 acres of round-up ready alfalfa when it was available. I seemed to work very good. Additionally it allowed me to plant my alfalfa in a no-till manner (which leaves a smaller carbon footprint) and not worry about weeds. Seemed like it was the best alfalfa I ever grew and was very easy/simple to manage.

APHIS-2007-0044-0516.1

Name: Gene Robben
Address: Dixon, CA

Organization: Robben Ranch

Robben Ranch is a large farming operation located near the town of Dixon, California. This farming operation normally raises approximately 4,000 acres of alfalfa each year. The hay that is produced on this ranch supplies several dairy and cattle operations in the southern part of the Sacramento valley and the northern part of the San Joaquin valley. Each fall this ranch tries to replace older stands of alfalfa and replaces fields of alfalfa that are of poor quality. These fall plantings can range from 800 to 1,000 acres. Fall planting of alfalfa has been the most successful for Robben Ranch.

Three years ago, Robben Ranch planted 600 acres of Roundup Ready Alfalfa to see how this new variety would produce and what type of quality it would have. This fall was the third year of production for the new Roundup Ready variety. It was found from production records that the Roundup Read Alfalfa equaled other varieties in production per acre, and had outstanding tests in T.D.N. (total digestible nutrients). The other factor that was a concern was how resistant was this alfalfa to Roundup Herbicide. After a few Roundup sprays, there was no apparent loss of plants or stands over the three year period.

Many farmers know that with our standard varieties of alfalfa, w can spend form $50 - $100 per acre annually for weed control. With Roundup Ready Alfalfa, expenses range from $10 - $30 per acre per year, which is a considerable savings over standard weed control. It was also noticeable that in the Roundup Ready Alfalfa fields almost 100% weed control was obtained.

Robben Ranch hopes the government will release Roundup Ready Alfalfa seed for the 2010 planting season. If so, this ranch will probable plant 1,000 acres of Roundup Ready Alfalfa this coming fall season. I feel that the government regulators fully analyze the benefit that Roundup Ready Alfalfa has for the American farmer and the environment they will release the seed for sale.

From an environmental standpoint, one can only hope that the regulators will find that with the release of Roundup Ready Alfalfa seed, several million pounds of current herbicides will be greatly decrease or eliminated. Velpar, Sincor, Direx, Gramoxone, and Treflan TR-10 granules

are just a few examples of these current herbicides being used. With the reduction of these herbicides, our streams and waterways will be much safer for our environment and us.

Document: APHIS-2007-0044-0813

Name: Kurt Robert Brink
Address: Richview, IL

Biotechnology-based breeding methods safely enhance and extend a crop's yield potential, feed value, adaptation, pest tolerance, environmental benefits, crop management and utilization options, as other biotech crops have demonstrated. The Roundup Ready alfalfa system provides dependable, cost-effective control of broadleaf and grassy weeds for the life of the alfalfa stand.
I have had a plot of RR Alfalfa now for at least 3 years and it has proven to be a major plus for our Dairy business in that we usually are able to maintain at least a RFV of 155 or better in each of 5 cuttings/year. With the ability to control weed growth, it is one of, if not the best stand I have among the 4 fields I do have in alfalfa.
It is imperative in these tough economic times that we are not deprived of whatever advantage we can glean from the seed technology this variety provides.Roundup Ready alfalfa can lead to more consistent, high-quality, weed-free hay, resulting in an increased supply of dairy-quality hay. The forage produced from Roundup Ready alfalfa is comparable in composition, nutritional value and safety to that produced from conventional alfalfa varieties, resulting in proven feed safety. Dairy farmers can benefit from increased milk production per ton of feed and fewer animals sickened by weeds in their feed.
I urge the USDA to consider biotechnology's long history of success and allow alfalfa growers to join other American farmers in the benefits and new opportunities offered by biotechnology.

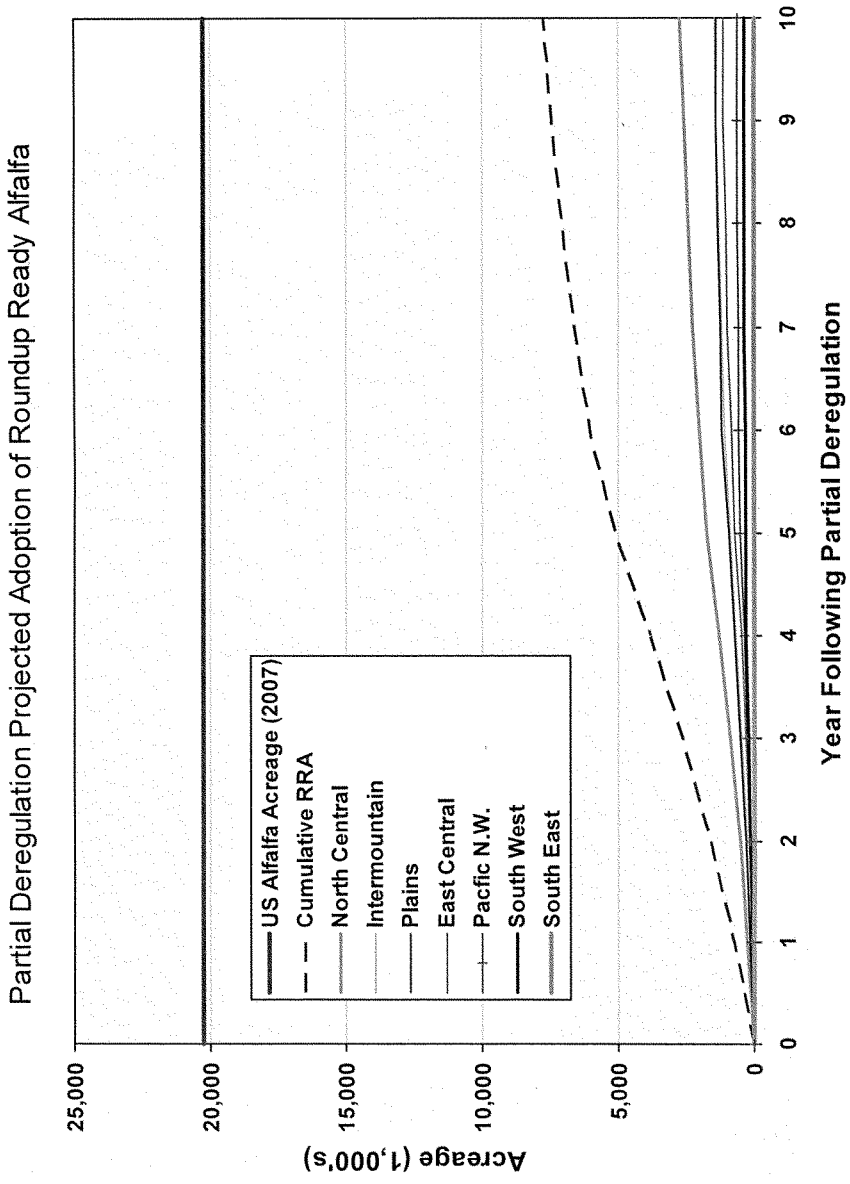
Document: APHIS-2007-0044-1094
Comment from John Maddox

Name: John Maddox
Address: Burrell, CA

I am a dairyman and alfalfa grower. I currently grow 2,400acs of conventional alfalfa and I would like to have the ability to purchase and grow Roundup Ready alfalfa. I did grow 40acs of Roundup Ready alfalfa when it was first avialable and was extremely satisfied with it.
The Roundup Ready system is extremely effective in controlling some of our toughest weeds that we have in our hay fields especially nutgrass which is a big problem for us to control with the currently avialable products that we have.
It eliminates summer grasses in the alfalfa which gives me greater flexibility in my winter spray applications.
I firmly believe that if I am able to grow Roundup Ready alfalfa, I am going to be able to better protect my workers because they will not have to be exposed to the more toxic herbicides that I currently have to use to control my weeds. This is a huge issue for us in California especially



with the many worker safety regulations that we put in place to provide a safe work environment for our employees.
For our dairy, it is of high importance to us to provide the highest quality feed that we can find for our milk cows so that we can maximize their production of high quality milk and butterfat. By growing Roundup Ready alfalfa, I found that my alfalfa was higher in quality and tonnage per acre due to the fact that it was much cleaner than my conventional fields. My 40acres of Roundup Ready alfalfa was the first field that ever produced 10 tons/acre for the year. We have never been able to do that with our conventional varities. This higher production per acre allows me to use less alfalfa acres to provide me the same amount of hay that I currently get from my conventional fields. This frees up some ground for me to rotate into other crops.

Third, because herbicide resistance is a heritable trait, it takes multiple growing seasons for herbicide tolerant weeds to emerge and become the predominant biotype in a specific area (Cole, 2010a, p. 4). Researchers have concluded that even if growers completely relied on only one herbicide, it is likely to take at least five years for an herbicide-resistant weed population to develop (Kniss, 2010a, p4; Beckie 2006, Neve, 2008; Werth et al., 2008). This is a reason why crop monitoring and follow up by University and industry weed scientists in cases of suspected resistance are important parts of all herbicide resistance stewardship programs.

The practice of repeated, in-season mowing combined with alfalfa's perennial nature reduce the likelihood of glyphosate-resistant weed development in >99 percent of the crop's acreage. The ability for alfalfa to fix nitrogen encourages the decision to follow alfalfa in the rotation with a crop that requires additional nitrogen, such as the annual grasses of corn and various cereal crops. These subsequently rotated crops can tolerate a spectrum of herbicides substantially different from the herbicides used in alfalfa. This encourages rotation of crops and herbicides, both of which are highly recommended for reducing the probability of developing herbicide resistant weeds (Orloff et al., 2009; USDA APHIS, 2009, P. 109).

Hay & Forage GROWER

January 1, 2009

Roundup Ready Reality?

by Fae Holin

Is emotion trumping science in debates over the release of Roundup Ready alfalfa? Two forage specialists think so. They've put together a paper debunking what they call misinformation presented at annual conferences around the country.

"We want to dispel some of those myths," says Dan Undersander, University of Wisconsin extension forage specialist. Undersander and his colleague at University of California-Davis, Dan Putnam, offer "a scientific perspective" for alfalfa growers and industry representatives as they evaluate Roundup Ready (RR) alfalfa.

RR alfalfa, legalized in 2005, lost that designation with a court injunction just about two years later. A USDA environmental impact statement, required by the court, is nearing completion with a public comment period expected in the next month. A decision on whether the transgenic crop should again be made available to growers is expected to follow several months later.

In the meantime, the forage specialists want to make sure the alfalfa industry is well-informed. They've offered *Hay & Forage Grower* a preview of their paper, which will be published in its entirety at hayandforage.com [http://hayandforage.com/understanding_roundup_ready_alfalfa_revised.pdf].

Here's a synopsis of their concerns:

1. Once you release this gene, you can't call it back.

Undersander and Putnam respond that the gene is already out - more than 300,000 acres of RR alfalfa have been planted for hay and a limited amount planted for seed. The real question, they write, is whether growers can continue to plant conventional seed. Their answer: Only non-RR alfalfa is being planted now and, if concerned about contamination, growers can test it for the RR gene.

2. Won't contamination from neighboring fields result in all seed being Roundup Ready eventually?

"No," they emphasize, citing that seed production methods and isolation distances will keep the presence of the gene "at a very low level for seed" and that "non-genetically enhanced (non-GE) seed will always be available."

3. Won't my neighbor's RR hayfields contaminate my non-GE alfalfa hay production through pollen and gene flow?

"No," they write. "There is an extremely low probability of gene flow among hayfields. For this to happen, fields must flower at the same time, pollinators must be present to move pollen (it does not blow in wind), plants must remain in fields four to six weeks after flowering for viable seed production, seed must shatter to fall to the ground and establish on the soil surface, seedlings must overcome autotoxicity to germinate and seedlings must overcome competition from existing plants."

Pollen can only be carried by pollinators such as bees, and honey bees don't like to pollinate alfalfa, they add. The specialists discuss the difficulties of the seed germinating, concluding that if growers take care to plant non-RR seed, it's unlikely their hayfields will become contaminated with the gene.

4. Will the seed companies be able to keep seed from being contaminated?

"Yes. The greatest real potential for pollen flow and contamination is during seed production," Undersander and Putnam write. They cite ways the seed industry has agreed to keep track of transgenic seed and reasons why it's in the companies' best interests to do so.

5. Won't feral alfalfa be a source of contamination?

"Feral (wild growing) alfalfa can act as a bridge for moving genes from one seed field to another, and thus should be controlled to prevent gene flow in any area where seed production occurs, whether GE or not. Feral alfalfa is primarily an issue in portions of Western states because little occurs elsewhere," write the forage specialists. They discuss reasons why feral seed would have low production and suggest that removing plants from ditches and roads is a good idea to prevent gene flow.

6. Won't hard seed be a source of contamination?

"Hard seed of alfalfa generally does not persist for more than one year in moist soils, much less after years of hay production," they respond. "To guard against hard seed carryover, seed growers take steps to eliminate residual alfalfa volunteers prior to planting. State seed certification standards already require that the alfalfa seed field's history include a two-year exclusion period before planting alfalfa for seed."

7. Much of the hay in my area is cut late with mature seed - we have good farmers but weather and equipment problems force late cuttings.

"This occasionally happens," Putnam and Undersander answer. "However, plants must remain in a field for four to six weeks after pollination of flowers for viable seed to form and longer for seed to shatter." Delayed cutting will cause little to no seed production in hayfields, and hay harvest should remove seed.

The last seven concerns have to do with **8)** growing organic hay; **9)** export markets; **10)** whether seed companies bias the research on RR alfalfa; **11)** possible effects it may have on insects, animals or the environment; **12)** whether farmers can or will follow stewardship protocols; **13)** weed resistance to Roundup and **14)** whether the risks of RR alfalfa outweigh the rewards.

"There is also a risk with NOT moving ahead with a technology," Under-sander and Putnam contend. RR alfalfa will control tough weeds, they write. "Further, if this breeding methodology is permanently banned, it would mean fewer genetic advancements for alfalfa in the future.

"It is important that alfalfa growers and the industry understand how to use this important new genetic tool, while at the same time, protecting those farmers who don't wish to adopt it."

January 2009

Understanding Roundup Ready Alfalfa

A number of concerns have been raised about the release of Roundup Ready (RR) alfalfa, the first biotech trait in alfalfa. Many of these concerns have been fueled by misinformation. In this article, we provide a scientific perspective on these concerns that we hope will inform.

Concern 1. Once you release this gene – you can't call it back.

Over 300,000 acres of RR alfalfa have been planted for hay over the past 2 to 3 years, with a limited amount planted for seed. The real question is whether you can continue to plant conventional alfalfa seed and the answer is a resounding 'yes' – all of the seed currently for sale is 'conventional' – and you only need to test it (or ask the seed company to test it) with inexpensive test strips to make sure it does not contain the gene if you don't want it. Conventional alfalfa seed will continue to be available after Roundup Ready alfalfa is released.

Concern 2. Won't contamination from neighboring fields result in all seed being Roundup Ready, eventually?

No. Seed production methods and isolation distances currently recommended by seed companies should keep adventitious presence at a very low level for seed. A gene will increase in a population only if the new gene gives the plant an advantage over other plants and the conditions creating the advantage are consistently present. Conversely, if plants are grown in an environment where the gene provides no advantage, the gene is more likely to remain in the population at very low levels or to be lost from the population. The formulas for computing these changes in gene frequency can be found in most books on population or quantitative genetics, such as Falconer and MacKay, 1996, Introduction to Quantitative Genetics, Longman Press. Thus non-GE seed will always be available.

Concern 3. Won't my neighbor's Roundup Ready hay fields contaminate my conventional or organic alfalfa hay production through pollen and gene flow?

No. There is almost zero probability of gene flow among hay fields. For this to happen all the following must occur:

- fields must flower at same time.
- pollinators must be present to move pollen (it does not blow in wind).
- plants must remain in field 4 to 6 weeks after flowering for viable seed production.
- seed must shatter, to fall to ground and establish on soil surface.
- seedlings must to overcome autotoxicity to germinate.
- seedlings must to overcome competition from existing plants.

Pollen moves among alfalfa plants only when carried by pollinators such as bees, and honey bees do not like to pollinate alfalfa. Alfalfa seed takes many weeks after flowering to mature sufficiently to germinate and longer to shatter and fall onto the ground. Alfalfa seed does not readily spread. Alfalfa does not germinate well on the soil surface. Germination will be further reduced by alfalfa autotoxicity from existing planting in the hay field (this is why interseeding alfalfa to thicken a stand generally fails). Germinating seeds must compete with established plants for water, nutrients and sunlight. Data has shown that interseeded plants generally die during the first growing season. Thus, if a grower takes care to plant conventional seed, it is very unlikely that the Roundup Ready gene will move to their hay fields. (See Gene Flow in Alfalfa: Biology, Mitigation, and Potential Impact on Production, Special Publication of the Council for Agricultural Science and Technology (CAST) at http://www.cast-science.org/displayProductDetails.asp?idProduct=157)

Concern 4. Will the seed companies be able to keep seed from being contaminated?

Yes, the greatest real potential for pollen flow and contamination is during seed production. The seed industry has agreed on a field tagging technique in areas where RR alfalfa seed will be grown so neighbors and other seed companies will know where RR seed is being produced. The bulk of non-GE alfalfa seed is produced for export by seed production companies and it is in their own best interest to control seed production to continue to produce the 30% or more of total production as non-biotech for export. This large volume of export seed production is much more significant economically than the less than 1% of total seed market for organic seed production. However, concerns and methodology for exported seed will allow organic seed production indefinitely, making non-biotech seed available to growers.

Concern 5. Won't feral alfalfa be a source of contamination?

Authors: Dan Putnam, University of California, and Dan Undersander, Univeristy of Wisconsin
January 2009

Feral (wild growing) alfalfa can act as a bridge for moving genes from one seed field to another, and thus should be controlled to prevent gene flow in any area where seed production occurs, whether biotech or not. Feral alfalfa is primarily an issue in portions of Western states because little occurs elsewhere. Feral alfalfa will have low seed production for the reasons described in #3 plus damage from lygus bug and infection from seed-borne fungi when seed develops under damp conditions. Seed from any feral plants will contribute to new plants only over a very short term, but removing feral alfalfa from ditches and roads is a good idea for organic and export growers to prevent gene flow. If feral alfalfa is deemed a problem in a specific area, then it must be controlled as off types of alfalfa and other problem weeds are currently controlled using cultural and other herbicide methods.

Concern 6. Won't hard seed be a source of contamination?

Hard seed of alfalfa generally does not persist for more than one year in moist soils (Albrecht et al. 2008 Forage and Grazinglands), much less after years of hay production. To guard against hard seed carryover, seed growers take steps to eliminate residual alfalfa volunteers prior to planting. State Seed Certification Standards already require that the alfalfa seed field's history include a 2-year exclusion period before planting alfalfa for seed.

Concern 7. Much of hay in my area is cut late with mature seed – we have good farmers but weather, equipment problems force late cuttings.

Although late cuttings occasionally happen viable seed development is unlikely. However, plants must remain in field for 4 to 6 weeks after pollination of flowers for viable seed to form and longer for seed to shatter. Delaying harvest 1 to 2 weeks due to weather, equipment problems and other issues will cause little to no seed production in hay fields (see item #3). Furthermore, hay harvest should remove this small amount of seed so that it doesn't become a problem.

Concern 8. Organic producers may have difficulty growing organic hay.

No – there is no reason that organic growers can't continue to successfully grow organic hay. In fact the presence of Roundup Ready alfalfa hay in the marketplace may increase the value of organic hay, for buyers who are sensitive to biotech traits. Current demand for organic hay has been high, in spite of the introduction of Roundup Ready alfalfa. There are a number of growers who currently grow both Roundup Ready alfalfa and organic hay on the same farm without difficulty. Organic growers should 1) select conventional seed that is tested for the trait if their customers have set a standard of no adventitious presence, 2) take simple steps to protect their crop from gene flow and 3) identify hay lots after harvest. Feedstuffs can be tested to ensure low biotech levels desired for these markets. Organic growers currently are certified to show that their crops are not grown with pesticides or non-organic fertilizers, and similar steps can be taken to show that they do not use genetically engineered crops.

Concern 9. Couldn't we lose our entire export market?

No. While export growers and buyers are sensitive to the presence of biotech traits in crops, they have developed market-assurance methods to demonstrate that they are marketing non-biotech alfalfa hay, including testing to assure buyers of the non-biotech status of hay. Japan, Taiwan, and Korea (main U.S. hay market) already use biotech corn and soybeans and have accepted some RR alfalfa hay. The European Union has approved use of certain biotech varieties of corn and soybeans in food and feedstuffs. While significant in some growing regions in the US, exported hay represents less than 1 % of total alfalfa hay production.

Concern 10. Isn't the research biased by the seed companies that stand to gain most?

RR technology at has been evaluated at many universities. This research is independent of the concerned commercial parties. The goal is to independently test a technology for its viability and environmental safety for farmers and for the general public. These studies must be well-designed, accurate and can only be published only after review by anonymous individuals from other institutions selected for impartiality.

Concern 11. Won't the Roundup Ready gene in alfalfa have a negative effect on insects, diseases, other biota, or the environment?

There is currently no evidence that this gene would have a negative effect on insects or animals, or the environment. The Roundup Ready gene has been thoroughly tested as other crops were released (corn, soybeans, cotton) and no impact on any other biota has been found. No toxicology issues have been identified with roundup ready alfalfa fed to animals. In the past ten years, billions of tons of corn, soybeans, cotton and alfalfa have been

Authors: Dan Putnam, University of California, and Dan Undersander, Univeristy of Wisconsin
January 2009

produced with this gene, and there has been no documented harm to animals, humans or wildlife. In fact the use of Roundup would replace some more toxic pesticides that have been used and found in ground water (e.g. Velpar).

Concern 12. Farmers can't/won't follow stewardship protocols.

All technology requires stewardship by farmers (e.g. fertilizer use, pesticide use, irrigation). Farmers must be educated about stewardship needed and required to use appropriate stewardship for any technology. The possibility of gene flow is no different in scope than controlling pesticide drift, fertilizer contamination from conventional farms, or for that matter, the influence of weeds from organic fields that may contaminate neighbor's fields. Good farmers know how to do this.

Concern 13. Won't there be weed resistance to Roundup from use of RR alfalfa?

Weed resistance and weed shifts are issues with all herbicides. New management programs have always resulted in shifts in weed pressure. For example, no-till crop production has resulted in different weed problems than when crops were grown with conventional tillage. Resistance to glyphosate has occurred in row crop situations. Inclusion of alfalfa might actually slow increase of resistant populations of weeds because an additional mechanical control (frequent hay harvest) is being added to the weed management program. Techniques are readily available to avoid weed shifts or weed resistance using the Roundup Ready system as detailed in a recent article (Orloff et al., 2008).

Concern 14. Risk far outweighs reward/Do we really need this? Are we willing to take this kind of gamble?

There is also a risk with NOT moving ahead with a technology that has clear potential benefits to farmers and the environment. Currently, many animals are killed or hurt each year by weedy alfalfa fields – something that Roundup Ready technology could help address. Also, some of the conventional herbicides have been found in well water – something not true with glyphosate. Additionally, Roundup Ready alfalfa would allow farmers to control tough weeds for which no other good method of control exists (e.g. winter annuals such as chickweed, wild garlic, wild onion, perennials such as dandelion. difficult weeds such as nutsedge and dodder, and poisonous weeds such as groundsel).

Further, if this breeding methodology is permanently banned, it would mean fewer genetic advancements for alfalfa in the future. Some traits currently under development, such as a low lignin gene that could mean higher forage yield and fewer cuttings for farmers, a leaf retention gene to retain leaves through harvesting process, genes which confer pest resistance, or genes to increase bypass protein, would never be available to farmers. It is not reasonable or fair to farmers to restrict a technology from use in alfalfa that is available in other crops.

A series of articles on biotech alfalfa and coexistence of GE and conventional alfalfa seed and hay production is available at http://www.alfalfa.org/CSCoexistenceDocs.html and http://alfalfa.ucdavis.edu/+producing/biotech.aspx.

In summary, it is essential that alfalfa growers and the industry understand how to use this important new genetic tool, while at the same time, protecting those farmers who don't wish to adapt it. Research has proceeded with great deliberation in the development of Roundup Ready alfalfa and shown it to be a good tool that will benefit many farmers. Like every other tool, it must be used with care and appropriate stewardship. It is important for the industry to manage for coexistence of biotech-adapting and non biotech-adapting farmers, since other important biotech traits are being developed which might be much greater benefit to farmers and society.

ROUNDUP READY ALFALFA HARVESTING STUDY

Study #3482

MONSANTO
imagine™

Prepared By:

Market Probe

St. Louis, Missouri

January 2010

METHODOLOGY

- To achieve the objectives set for this study, a total of 200 telephone interviews were completed with growers who had Roundup Ready alfalfa acres in production in 2009 and/or 2010. The interviews were distributed regionally:

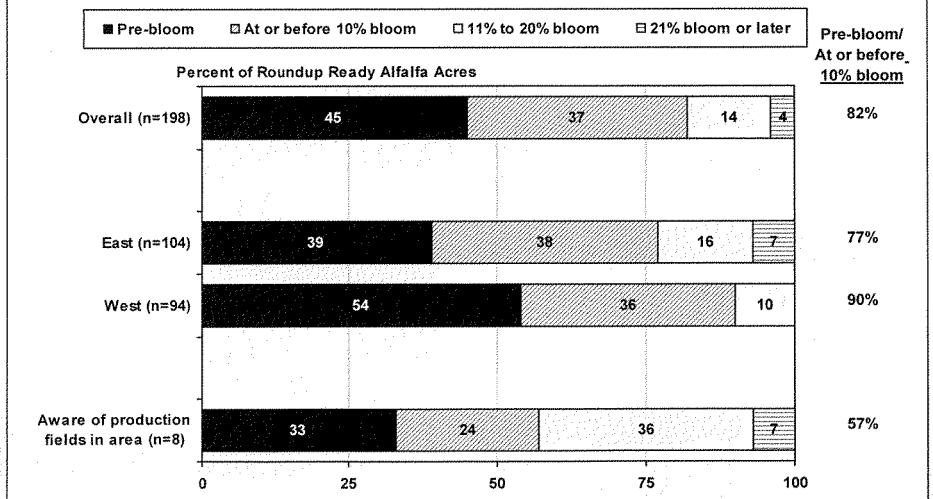
  West: WA/OR/ID/CA/NV/UT/AZ . . . . . N=95
  East: All other states, east of the Rockies . . . . . N=105

- Participants were screened on the following criteria:
  - Actively involved in farming
  - Primarily responsible for decisions concerning the management practices followed on alfalfa crop
  - Had 30+ acres of Roundup Ready alfalfa in production in 2009 or 2010
  - Not, nor anyone in household, working for a farm chemical manufacturer, distributor, or dealer
  - Not, nor anyone in household, working for a seed company, or as a farmer dealer
  - Not, nor anyone in household, raising alfalfa seed for a seed company

- A monetary honorarium was paid ($40-West and $20-East) to all participants. Interviews were conducted between January 18th and 25th, 2010.

2010 Roundup Ready Alfalfa Penetration

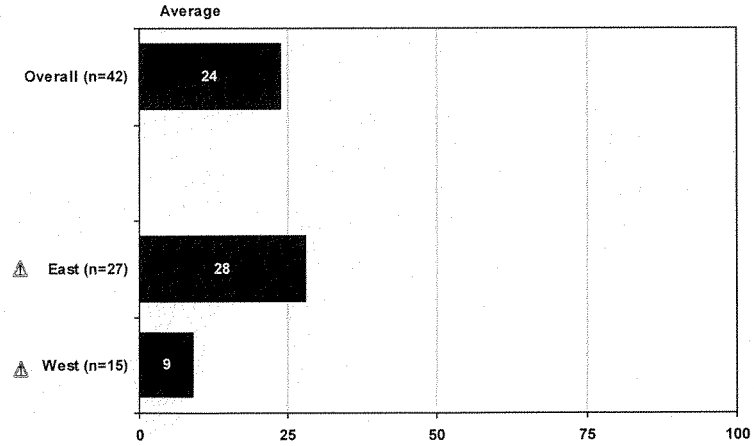
[Base=Respondents able to estimate]



To be included in this study, growers were required to have Roundup Ready alfalfa acres in 2009 and/or 2010

Q.D How many acres of alfalfa, including both established and newly seeded, will you have this year in 2010?
Q.E And, how many, if any, of these [Q.D] acres are Roundup Ready alfalfa, and how many are conventional alfalfa?

Percent Of Roundup Ready Alfalfa Harvested At Specific Stage In 2009



[Base=Respondents harvesting Roundup Ready alfalfa and able to estimate]

Q.3 In 2009, what percent of your total Roundup Ready alfalfa did you harvest:

Of the 18% of Occasions When Harvest Occurred After 10% Bloom, What Percent Were Due To Bad Weather?

[Base=Respondents harvesting at least some Roundup Ready alfalfa after 10% bloom, and able to estimate]

Q.4b What percent of the time was your decision to harvest Roundup Ready alfalfa after 10% bloom due to bad weather?

Alfalfa Seed Industry Innovations Enabling Coexistence

S. Fitzpatrick* and G. Lowry**

The alfalfa seed industry has recently implemented two complementary programs that together enable mutual coexistence between conventional and Roundup Ready alfalfa (RRA) seed producers. The 2010 Alfalfa Seed Stewardship Program (ASSP-2010) is an identity preserved process-based certificate offered by state seed certification agencies. It was developed by the Association of Official Seed Certifying Agencies (AOSCA) designed to serve GE-trait sensitive conventional seed producers (e.g., export). In 2008, the Best Management Practices for RRA Seed Production (BMPs) was adopted by the National Alfalfa & Forage Alliance. These BMPs are required coexistence protocols that apply only to RRA seed-producing companies (i.e., no new requirements are imposed upon external conventional seed producers). These market-driven, science-based programs were developed with the involvement of alfalfa industry stakeholders over a 5-year period (2005 to 2010) using all available market and gene flow data. An array of stakeholders were involved that represented diverse segments of the alfalfa seed and hay industries: scientists, seed certifiers, breeders, exporters, marketers, producers, growers and organic. These new programs are independent from and more stringent than AOSCA or OECD Seed Certification Programs. Forage Genetics and Pioneer Hi-Bred International (the only companies producing RRA seed), have collectively reported to inspectors that in 2009 greater than 97% of their conventional seed lots were produced without detection of the RRA trait (>500 lots tested with <0.00% RRA). If detected, AP was less than 0.5% (overall lot average <0.1%).

Seed Program	**No Program (e.g., common seed)**	**USDA National Organic Program Certification**	**Certified Seed**	**Roundup Ready Alfalfa (RRA) Seed**	**AOSCA AASP-2010 Identity Preserved, Certified Seed**
Market	U.S. domestic conventional (baseline)	Organic forage planting	U.S domestic conventional & RRA seed	U.S. domestic RRA seed	U.S. conventional seed for export
Purity Standard or Objective	n/a	No official purity standards; process-based requirements	≤1% off types	≤ 0.5% GE in *neighboring* conventional seed production	Non-detect GE
Spatial isolation from other seed field	n/a	Customized farm plan; not uniform mitigation standard	165 ft	900 ft to 3 mi at RRA seed field planting (pollinator specific)	≥5 miles
Program conforms to:	n/a	USDA-AMS National Organic Program	Federal Seed Act	Industry consensus and RRA seed co. contracts	AOSCA I. P. Program
Program monitored by:	n/a	Local Organic Certifying Agency	State Seed Certifying Agency	State Seed Certifying Agency	State Seed Certifying Agency
Program obligations fulfilled by:	n/a	Organic, conventional grower	Seed company and seed grower	RRA seed company and seed grower	GE-sensitive seed company and conventional seed grower
Growers using the program:	Conventional only	Conventional only	Both, conventional and RRA	All RRA, only	Conventional only

Re: Petition 03-323-01p for Non-Regulated Status, Roundup Ready® Sugarbeet -1; Event H7 Supplemental Request for "Partial Deregulation" or Similar Administrative Action

Dear Mr. Gregoire:

Monsanto Company ("Monsanto") and KWS SAAT AG ("KWS") jointly filed the petition for nonregulated status for Roundup Ready sugarbeet[1] Event H7-1 ("RRSB") which USDA's Animal and Plant Health Inspection Service ("APHIS") previously granted in March 2005. In light of recent developments in litigation, and with the support of thousands of sugarbeet growers nationwide and all sugarbeet cooperatives, processors and seed-producers, Monsanto and KWS jointly submit this supplemental request for "partial deregulation" or similar administrative action, as set forth below.

Background

On March 17, 2005, APHIS granted nonregulated status for RRSB following nearly 100 field trials, a 60-day comment period and issuance of an environmental assessment ("EA") concluding that the event presented "no significant impact on the human environment." In the years thereafter, a majority of our nation's sugarbeet growers adopted RRSB; wide-scale RRSB seed production began by 2006, and the multi-year process to develop appropriate RRSB varieties for growers in 10 states resulted in RRSB cultivation on roughly 95% of all U.S. sugarbeet acreage. The Government of Canada likewise approved RRSB for cultivation and human and animal consumption, and the European Union, Japan, Mexico, South Korea, Australia, New Zealand, China, Colombia, Russia, Singapore, and the Philippines each approved importation of sugar and other products derived from RRSB. Today, RRSB is processed into roughly half of our nation's domestic sugar supply.

[1] ® Roundup and Roundup Ready are registered trademarks of Monsanto Technology LLC.

On September 21, 2009, however, a Federal district court in San Francisco ruled that APHIS's 2005 EA for RRSB did not adequately evaluate potential cross-pollination from RRSB seed crops to other crops. The court held that APHIS "did not consider the effects of gene transmission on conventional farmers and consumers of sugar beet seed or of gene transmission to the related crops of red table beets and Swiss chard" and noted that such "seed production takes place primarily in the Willamette Valley of Oregon." *Center for Food Safety v. Vilsack ("CFS")*, No. 08-484, 2009 WL 3047227, *5, 13-14 (N.D. Cal. Sept. 21, 2009). That litigation is currently in the remedies phase, where the plaintiffs in the suit have sought a judicial order halting further planting of RRSB. Representatives of the thousands of sugarbeet growers nationwide along with sugarbeet cooperatives and processors, the seed companies who produce RRSB seed and Monsanto have intervened in this suit to urge the court not to halt ongoing or future RRSB cultivation. Specifically, the district court has been presented with evidence that an order immediately halting RRSB planting would have profound consequences for the nation's growers and many other parties, including that:

- Farming communities could suffer losses exceeding $2 billion;
- Approximately eight sugarbeet processing facilities would close (likely forever);
- More than 5,500 jobs would be lost; and
- The resulting domestic sugar shortages would, under USDA estimates, cost consumers $2.972 billion in 2011 alone.

Recently, the Supreme Court has addressed deregulation of a similar crop, Roundup Ready alfalfa, and provided significant guidance applicable here. *See Monsanto Co. v. Geertson Seed Farms*, No. 09-475, -- S. Ct. --, 2010 WL 2471057 (2010). The Supreme Court concluded that, even where a court has held that APHIS has violated NEPA with respect to a complete deregulation determination,"[a]t that point, it was for the agency [APHIS] to decide whether and to what extent it would pursue a *partial* deregulation." *Id.* at *13. "If ... a limited and temporary deregulation satisfied applicable statutory and regulatory requirements, it could proceed with such a deregulation even if it had not yet finished the onerous EIS required for complete deregulation." *Id.* The Supreme Court went on to identify a combination of geographic restrictions, isolation distances, and enforcement measures that could serve to eliminate any risk of "injury at all, much less irreparable injury." *Id.* at *15.

In light of this recent Supreme Court ruling, the Government has represented to the district court in San Francisco that, in the event the court vacates the existing RRSB deregulation, APHIS has authority to deregulate "in part" to "allow planting to occur under the conditions proposed by APHIS while the EIS is being prepared." As APHIS explained, it could take such action if "[i]ntervenors submitted a new petition or a supplement or amendment to a previous petition for a determination of nonregulated status of RRSB." Federal Defs.' Supp. Br. on Perm. Inj. Relief at 1, 13-14. The Government further explained that the Supreme Court's decision in "*Monsanto* clearly indicates that this type of interim administrative action would be permissible." *Id.* at 14; *see also Monsanto*, 2010 WL 2471057, at *15 (citing "representation from the Solicitor General" that APHIS has authority to do so). Separately, based on its expert analyses and review, APHIS has proposed to the district court a series of carefully tailored interim measures designed to address any potential risk of harm to other parties from continued cultivation of RRSB during the time period necessary for APHIS to reevaluate the RRSB petition for nonregulated status. Although there has been no record of any harm to any grower of any other crops in the multiple years of wide-scale RRSB production without these restrictions in place, the intervenors in this litigation have agreed that these additional interim requirements will reduce further an already negligible potential for any impact to other parties from RRSB.

Request for Interim Measures

With the support of each of the sugarbeet growers, cooperatives, processors and seed companies who have intervened in the pending RRSB litigation, Monsanto and KWS now jointly request that, in the event the court in the RRSB litigation vacates the existing deregulation determination, APHIS grant nonregulated status *in part* or take similar administrative action to authorize continued cultivation of the RRSB crop subject to the carefully tailored interim measures proposed by APHIS. Petitioners believe this request is appropriate in this context because:

(1) As APHIS explained its recent Supplemental Brief, the U.S. Supreme Court has clarified that APHIS has authority to implement interim measures through partial deregulation or similar means for this purpose;

(2) Sugarbeet growers nationwide, along with sugarbeet cooperatives, processors, seed companies and other interests, face significant harm from any halt in RRSB planting, cultivation, harvesting or processing; and

(3) Petitioners are requesting that APHIS implement measures that APHIS has already itself reviewed, analyzed and supported in the litigation context.

Attached to this letter is an Environmental Report, providing additional analysis of the proposed interim measures. The analysis in APHIS's original EA addressing Monsanto and KWS's petition, along with the 5000-page administrative record relating thereto and this Environmental Report all support petitioners' request for partial deregulation or similar administrative action.

Thank you very much for your attention to this matter.

Sincerely,

H. Keith Reding, Ph.D.
Regulatory Affairs Manager, Monsanto

Figure 4-1 Growth in adoption of genetically engineered crops in US

This Environmental Report (ER) examines the environmental impacts of continued cultivation of Roundup Ready® sugar beet event H7-1 (event H7-1) for a temporary period subject to a range of interim measures, including geographic restrictions, stewardship requirements and other limitations -- identified and analyzed by the US Department of Agriculture's (USDA) Animal and Plant Health Inspection Service (APHIS) in *Center for Food Safety v. Vilsack*, No. 08-484, N.D. Cal. This ER is provided in connection with the petitioners' supplemental request for non-regulated status *in part* (commonly known as "partial deregulation") for event H7-1. This document is intended to provide information that may be utilized by APHIS in complying with the National Environmental Policy Act (NEPA)[1] and its applicable regulations[2] either in connection with partial deregulation of event H7-1 or for any other regulatory or administrative action by APHIS adopting the interim measures addressed herein. The interim measures are intended to apply until APHIS completes its NEPA review of the petition for nonregulated status for event H7-1 and reaches a final determination regarding the petition.

The sugar produced from sugar beets, which were planted on approximately 1.2 million acres in the US in 2010, accounts for over half the US sugar production. Cash receipts for sugar beets were $1.3 billion in the 2007-2008 crop year. Event H7-1, which has been genetically engineered to be tolerant to the herbicide glyphosate, has been grown on a large scale in the US for multiple years and accounted for approximately 95 percent of the sugar beet planted in the US in the 2009/2010 crop year (USDA NASS, 2010b; USDA ERS, 2009a and 2009b).

1.1 PURPOSE OF THIS ER

1.1.1 Background

In 2003, under the requirements of the Plant Protection Act (PPA),[3] Monsanto Company and KWS SAAT AG (Monsanto/KWS) submitted a petition (Petition No. 03-323-01P) to APHIS for a determination of non-regulated status for event H7-1 and all progeny derived by conventional breeding from this event (Schneider, 2003). APHIS, through its Biotechnology Regulatory Service (BRS), is one of three federal agencies responsible for regulating biotechnology in the US under the Coordinated Framework described in Section 1.4. APHIS regulates genetically engineered (GE) organisms that may be plant pests, the Environmental Protection Agency

[1] NEPA of 1969, as amended; Title 42 of the US Code (42 USC) §§4321-4347
[2] Council on Environmental Quality (CEQ) regulations implement NEPA and are found in Title 40 of the Code of Federal Regulations (40 CFR), Parts 1500 through 1508. The U.S. Department of Agriculture has implemented NEPA regulations, which are found at 7 CFR Part 1b, as has APHIS, and those are found at 7 CFR part 372.
[3] 7 USC §§7701-7786

(EPA) regulates plant incorporated protectants and herbicides used with herbicide-tolerant crops, and the US Department of Health and Human Services' Food and Drug Administration (FDA) regulates food and animal feed. The FDA completed its consultation process for event H7-1 in 2004 and EPA agreed that its previous approval for glyphosate residue in sugar beet roots, tops and dried pulp was also applicable to event H7-1 ((Tarantino, 2004; Bonette, 2004; Schneider, 2003, p. 14). NEPA requires federal agencies to evaluate the potential impact of proposed major federal actions and consider such impacts during the decision-making process. After agency review for safety, including an evaluation of relevant scientific data and all public comments relating to potential plant pest risks and related environmental impacts, APHIS issued an EA pursuant to NEPA in 2005 (USDA APHIS, 2005). Based on that EA, APHIS reached a finding of no significant impact (FONSI) on the environment from the unconfined cultivation and agricultural use of event H7-1 and its progeny (USDA APHIS, 2005, p. 1). Accordingly, in March 2005, APHIS granted non-regulated status to event H7-1 (USDA APHIS, 2005, p. 26).

After event H7-1 was deregulated, the multi-year process of bringing it to commercial production began. Large scale commercial seed production began in 2006 to produce the seed crop used for planting root crops in 2008. Small scale root production occurred in 2006 and 2007. In January 2008, the Organic Seed Alliance, Sierra Club, High Mowing Organic Seeds, and the Center for Food Safety (CFS) filed a lawsuit against the USDA over its decision to deregulate event H7-1, claiming the USDA failed to take a "hard look" at the environmental effects of its decision to deregulate. The plaintiffs in the suit did not seek a preliminary injunction to halt planting. In September 2009, the court granted the plaintiffs' motion for summary judgment in the merits phase of the lawsuit, concluding that APHIS was required to prepare an environmental impact statement (EIS) before approving its deregulation of GE sugar beets. In December 2009, the court issued a schedule for the remedies phase of the lawsuit. At that point, representatives of thousands of family farms that were growing event H7-1 sugar beet root crops along with the four seed companies who produced seed and other interested parties were permitted to participate in the suit.

In May 2010, while the remedies phase of the lawsuit was proceeding, Cindy Smith, the APHIS Administrator, filed a declaration in the suit anticipating completion of the EIS in May 2012 (Smith, 2010b, pp. 7-8) and suggested that the court enter an order imposing certain interim measures that would allow continued cultivation of event H7-1. These interim measures would include geographic restrictions and a range of stewardship requirements, and would apply for a

temporary period pending completion of the EIS and the corresponding record of decision (ROD), and implementation of that decision. (Smith, 2010b, pp. 19-22). Alternatively, Administrator Smith proposed that the Court remand the case to APHIS with the intention that APHIS would take action to implement these interim measures administratively. On May 25, 2010, APHIS issued a notice of intent to prepare an EIS and a proposed scope of study (APHIS 2010).

On June 21, 2010, the U.S. Supreme Court ruled in litigation related to Roundup Ready® alfalfa, clarifying that a court in a NEPA case may not preemptively bar APHIS from issuing a "partial deregulation" or taking other administrative action to implement interim measures for cultivation of a genetically engineered crop while the agency completes an EIS evaluating complete deregulation. Monsanto Co. v. Geertson Seed Farms, No. 09-475, 561 U.S. (2010).

1.1.2 Purpose of and need for action.

The purpose of this ER, which has been prepared to support an anticipated EA, is to examine the environmental impacts of implementing interim measures, either through a partial deregulation of event H7-1 lines of glyphosate tolerant sugar beets or certain other administrative means. The interim measures have been identified to address concerns regarding potential impacts related to the planting and cultivation of event H7-1 while the EIS evaluating complete deregulation is being prepared. If APHIS concludes that an EA supports a FONSI for such interim measures, APHIS could decide to implement such measures through "partial deregulation" pending APHIS's determination on complete deregulation.

1.1.3 APHIS proposed interim measures/time frames for implementation

APHIS' proposed interim measures for Roundup Ready® sugar beets (RRSB), to be implemented either through a partial deregulation or other administrative means, are detailed below. These measures are the same as those proposed by Administrator Smith to the court (Smith, 2010b, pp. 19-22), along with time frames for implementation of those measures.

Interim measures Proposed by APHIS to the Court

Administrator Smith proposed the following interim measures in the lawsuit discussed above:

1) *Roundup Ready® Sugar Beet-Free Zone*

The planting of RRSB is prohibited in the entire State of California and in the State of Washington in the following counties west of the Cascades: Clallam, Jefferson, Grays Harbor, Island, Pacific, Mason, Thurston, Lewis, Cowlitz, Clark, Whatcom, Skagit, Snohomish, King,

Pierce, Skamania, San Juan, Kitsap, and Wahkiakum Counties. [These counties are shown in this ER in Figure 1-1].

2) *A Coexistence Zone for Beta Seed Crop Production in the Willamette Valley in Oregon*

   a. All parties to this action who grow *Beta* seed crops in the Willamette Valley must adhere to a four mile isolation distance between RRSB seed crops and other *Beta* seed crops.

   b. All parties to this action who grow *Beta* seed crops in the Willamette Valley must follow the Willamette Valley Specialty Seed Association (WVSSA) pinning procedures.

3) *Disclosure of Information Regarding Male Fertile RRSB Seed Crops.*

All growers of RRSB male fertile seed crops must provide locations with GPS coordinates to APHIS/BRS of any RRSB male fertile seed crops in the United States that exist at the time the Court's Order is issued or that are planted at any time during the interim period in which the EIS is being prepared. Information regarding existing plantings must be provided to APHIS within 30 days after issuance of the Order; information regarding future plantings during the interim period must be provided to APHIS within one week after the completion of planting of any RRSB male fertile seed crops. Within 60 days after issuance of the Order, APHIS/BRS shall set up a toll-free number that growers of non-GE *Beta* seed crops may use to request from APHIS/BRS the approximate distances from the nearest RRSB male fertile seed crop to their non-GE *Beta* seed crop.

Upon calling this number, the caller shall certify to APHIS/BRS that the caller is a grower of non-GE *Beta* seed crops or intends to grow non-GE *Beta* seed crops at an existing location in the United States. APHIS/BRS shall only provide to the caller the approximate distance from the nearest RRSB male fertile seed crop location to the caller's non-GE *Beta* seed crop.

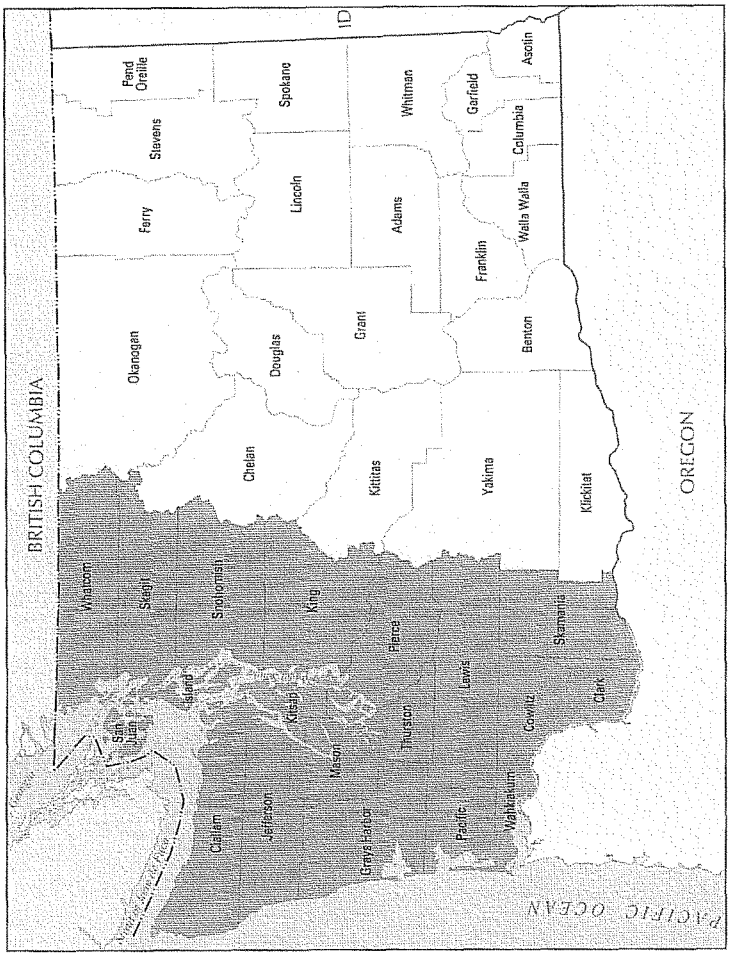

Figure 1-1. Roundup Ready® Sugar Beet-Free Zone
Sources: Smith, 2010b; National Atlas of the United States

4) *Measures to Prevent Mixing of Conventional Sugar Beet Seed and RRSB.*

RRSB seed producers shall follow protocols to ensure that mechanical mixing of material containing the RRSB trait and non-GE *Beta* seeds does not occur. Those protocols shall include:

a. A visual identification system for RRSB material (basic seed, stock seed, transplants (stecklings), and commercial seed) that accompanies seed material throughout the production system to delivery to ultimate purchaser;

b. A companion seed-lot based tracking and tracing system that is fully auditable;

c. Requirements for physical separation of RRSB material at all points in the seed production process from non-GE *Beta* material;

d. Requirements for monitoring, treating, and cleaning of all planting, cultivation and harvesting equipment to prevent RRSB seed, pollen or stecklings from being physically transferred out of production areas by inadvertent means;

e. Requirements for disposal of all unused RRSB stecklings by returning unused stecklings to the nursery field of origin and subsequent destruction through standard agricultural practices (physical destruction with tillage and chemical destruction in the subsequent crop););

f. Requirements for contained seed transport from field to cleaning facility, vehicle cleaning after transport of RRSB seed before use for other purposes, and devitalization of RRSB material derived from cleaning vehicles or processing facilities;

g. Prohibition on grower production of a RRSB seed and chard/red beet seed production on the same location/premises in the same year;

h. Prohibition on RRSB seed grower use or sharing of planting/cultivation equipment that might be used in a non-GE *Beta* seed production in the same growing year;

i. Prohibition on RRSB seed grower use of the same combine to harvest RRSB and non-GE *Beta* seed in the same year;

j. Provisions to force same-year sprouting of any RRSB seed left behind in production field for removal and destruction; plus 3-year monitoring of fields thereafter, along with removal and destruction of any beet plants;

k. Employee training in all aspects of a. through j. above;

l. No RRSB seed shall be cleaned or processed in any processing facility that also cleans and processes red beet or Swiss chard seed;

m. Recordkeeping to document compliance of a-l.

5) *Control of Any Bolters in the RRSB Root Crop Fields.*

All RRSB root crop growers must have contractual measures in place that require RRSB root crop growers to survey, identify, and eliminate any bolters in their root crop fields before they produce pollen or set seed.

6) *Control of Any Bolters in Harvested RRSB Root Crop in Outdoor Storage.*

All sugar beet processors or cooperatives that use RRSB must have measures in place to survey, identify, and eliminate any bolters in outdoor storage before they produce pollen or set seed.

7) *Third Party Audit for Compliance.*

APHIS will require third party audits to ensure that RRSB producers comply with requirements in paragraphs two and four above. APHIS expects that AMS [Agricultural Marketing Service], USDA, will be the third party auditor using its AMS-USDA Process Verified Program.

Time frame for Implementation

While certain interim measures could be implemented shortly after APHIS issues its interim order of partial deregulation or takes other administrative action regarding event H7-1 (e.g., Item 3), certain measures may require some additional time to fully implement. This ER makes the following assumptions as to when the various components of the interim measures would be implemented:

(1) *RRSB-free zone.* The sugar beet seed companies have represented that no RRSB sugar beet crops have been or would be planted in California or the subject counties in Washington State. Thus, these restrictions can be implemented immediately.

(2) *Willamette Valley coexistence zone*

While certain isolation distance and pinning requirements have already existed for years, the four-mile isolation distance and the pinning and audit requirements proposed in the interim measures will be implemented in full with the summer 2011 seed crop planting, which will occur in July and August of 2011 (Items 2 and 7). The current isolation distance provided by the Willamette Valley Specialty Seed Association pinning provisions is four miles between sugar beet seed crops on one hand and open-pollinated (OP) red beet or chard seed crops on the other. Most of these crops will have been pinned and planted by the end of August 2010.

3) *Disclosure of information regarding male fertile crops*

Time frames are included in the proposed interim measures, described above.

4) *Measures to prevent mixing of seed*

While these measures have already largely been implemented in the major seed production area, as discussed in Section 2.7.3 of this ER, we assume that full implementation will occur before the 2011 seed harvest.

5) *Control of bolters – root crop fields*

Contracts requiring control of bolters are in place currently for the 2011 spring planting.

6) *Control of bolters – root crop outdoor storage*

These measures will be in place before the 2011 harvest.

7) Third-party audits

Measures would be in place at the time of the partial deregulation or other administrative action imposing the interim measures.

1.2 RATIONALE FOR CREATION OF EVENT H7-1

Event H7-1 offers sugar beet growers a simpler, more flexible, and less expensive alternative for weed control relative to conventional weed control measures.

According to the World Agriculture Series volume *Sugar Beets*, "Weeds have been a major problem in sugar beet since the crop was first grown in the late 1700s" and "unlike insects, diseases and nematodes, weeds occur in all sugar beet fields every year, usually at populations that cause crop failure unless controlled" (May and Wilson, 2006, p. 359). Other researchers,

working before the introduction of event H7-1, have reported that "weed management is one of the main production costs with sugar beet" (Odero et al, 2008, p. 50).

As discussed in detail in Section 2.5, prior to widespread cultivation of event H7-1, sugar beet growers used a variety of means to control weeds, and herbicides are a key component. Herbicides are used by virtually all sugar beet growers; in 2000, approximately 98 percent of planted sugar beet acres received one or more herbicide applications (Ali, 2004, Table 4). In the 2000 growing season, 12 different active ingredients formulated as various herbicide products were commonly used in U.S. sugar beet production with a total of about 1.4 million pounds of herbicides applied (USDA APHIS, 2005, pp. 6-7). Typical conventional weed control consists of multiple applications of several different herbicides, often combined with hand or mechanical weeding (Odero et al, 2008).

Glyphosate is little-used for conventional sugar beets (those without glyphosate tolerance) because it damages the plants. With glyphosate-tolerant sugar beets, growers have an additional option for weed control.

1.3 COURT RULING AND ISSUES IDENTIFIED

During the lawsuit discussed above, the court identified certain specific issues as requiring additional analysis by APHIS (US District Court [USDC] 2008). These issues are described below and are addressed in the Affected Environment and Environmental Consequences sections of this ER. Additionally, this ER addresses issues that were not found to be problematic by the court in APHIS' initial EA. These issues are nevertheless addressed again here to ensure full disclosure and analysis of any potential impacts associated with partial deregulation of event H7-1 under the proposed interim measures.

1.3.1 Gene transmission from H7-1 sugar beets in production fields

Sugar beet is largely wind pollinated and has a biennial, two year life cycle when grown for seed; plants develop a large root the first year, then overwinter and flower, producing a seed stalk the second year. When grown to produce sugar, sugar beet roots are harvested during the first year while still in the vegetative (non-flowering) phase. Sugar beets grown for root crops rarely flower and thus rarely produce any pollen. However, certain conditions such as low temperatures after planting and longer day length can occasionally cause the sugar beet to "bolt" or produce a seed stalk (which can ultimately flower) during the first growing season (Bell 1946; Jaggard *et al.* 1983; Durrant and Jaggard 1988). Thus, further analysis to determine the

potential for gene transmission from event H7-1 being grown for root production to conventional sugar beets was conducted and is discussed in Section 3.3 of this ER.

1.3.2 Gene transmission to conventional sugar beets in seed production

Unlike sugar beet root production, seed production requires that the plants flower, become pollinated and develop seed. The court concluded that APHIS did not take a "hard look" at the potential for gene transmission in seed production in its initial EA in reference to the 2003 petition, and did not consider the fact that isolation distances set by the Oregon Seed Certification Standards are voluntary; whether the isolation distances were actually followed and are likely to be followed in the future; or if the isolation distances are sufficient to protect the non-GE crops that are inter-fertile with sugar beets. Therefore, further analysis to determine the potential for gene transmission from sugar beets being produced for seed production was conducted and is discussed in Section 3.9 of this ER.

1.3.3 Gene transmission to red table beets and Swiss chard

Cross-pollination between cultivated sugar beet and sexually compatible *Beta* species can occur when these plants grow close together and have overlapping flowering periods. The court found that because sugar beet pollen can travel large distances by wind, and because seed for sugar beets, Swiss chard, and table beets (which are all members of the same species and are all sexually compatible) are all grown in one valley in Oregon (albeit principally in different parts of the same valley), additional analysis is required to determine whether deregulation may significantly affect the environment as a result of any potential cross-pollination. Therefore, further analysis was conducted and is discussed in Sections 3.5 and 3.6 of this ER.

1.3.4 Socioeconomic impacts

The court found that APHIS failed to analyze in its initial EA the socio-economic impacts of deregulating event H7-1 on farmers and processors seeking to avoid GE sugar beets and derived products, stating,

> *Economic effects are relevant and must be addressed in the environmental review "when they are 'interrelated' with 'natural or physical environmental effects.'" Ashley Creek Phosphate Co. v. Norton, 420 F.3d 934, 944 (9th Cir. 2005) (emphasis in original) (quoting 40 C.F.R. 1508.14); see also Geertson Seed Farms v. Johanns, 2007 WL 518624, *7 (N.D. Cal. Feb. 13, 2007). In Geertson Seed Farms, the court found that "the economic effects on the organic and conventional farmers of the government's deregulation decision are interrelated with, and, indeed, a direct result of, the effect on*

*the physical environment; namely, the alteration of a plant specie[s]' DNA through the transmission of the genetically engineered gene to the organic and conventional [crop]." Id., 2007 WL 518624, *8 (emphasis added).*

The court held that APHIS was required to consider these effects in assessing whether the impact of its proposed action of deregulation was significant. Therefore, further analysis was conducted and is discussed in Section 3.17 of this ER.

1.3.5 Willingness of buyers to accept sugar derived from GE sugar beets

The court's ruling included a reference to a 2004 comment from Imperial Sugar, a company that at that time processed sugar beets (but no longer does) and currently produces and markets only cane sugar. Imperial Sugar raised a concern in response to the petition for deregulation that buyers of industrial and consumer sugars have expressed reluctance or opposition to receiving sugar derived from GE sugar beet. Imperial Sugar's opinion was that the industrial buyers' reluctance was caused by their belief that consumers would react negatively to products containing or derived from GE crops. Imperial Sugar was therefore concerned that industrial buyers would be unwilling to test the reaction of consumers by using sugar from event H7-1 in their branded products.

Currently, event H7-1 sugar beet is processed into a large percentage of our domestic sugar supply, and has been well accepted. Nevertheless, further analysis of this issue was conducted and is discussed in Section 3.11 of this ER.

1.3.6 Restrictions/labeling requirements by some countries on GE products

Imperial Sugar also commented that some countries will not allow GE products to be imported and that many nations require labeling of food products with GE content. However, less than two percent of the sugar produced in the US is exported (USDA FAS, 2010), and exports of products derived from event H7-1 sugar beets are expressly allowed in many foreign countries. Further information is available in Section 3.11 of this ER.

1.3.7 Potential for development of glyphosate-resistant weeds

As the adoption of glyphosate-tolerant crops has grown, the use of glyphosate has increased (National Research Council [NRC], 2010, Figures S-1, S-2, and S-3; Young, 2006). Concerns have been expressed that increased use of glyphosate may lead to development of glyphosate-resistant weeds. Further information is available in Sections 2.5 and 3.12 of this ER.

1.3.8 Cumulative effects of increased use of glyphosate

Further analysis of cumulative impacts from increased use of glyphosate was conducted and is discussed in Section 4 of this ER. However, since this ER is intended to address only the period of time until the EIS is completed, cumulative effects are considered for that time period.

1.4 FEDERAL REGULATORY AUTHORITY – COORDINATED FRAMEWORK

Interagency coordination in scientific and technical matters is the responsibility of the federal Office of Science and Technology Policy (OSTP), which was established by law in 1976. A large part of the OSTP's mission is "to ensure that the policies of the Executive Branch are informed by sound science" and to "ensure that the scientific and technical work of the Executive Branch is properly coordinated so as to provide the greatest benefit to society" (OSTP, undated).

In 1986, the OSTP published a "comprehensive federal regulatory policy for ensuring the safety of biotechnology research and products", the *Coordinated Framework for the Regulation of Biotechnology* (Coordinated Framework) (OSTP, 1986). The OSTP concluded that the goal of ensuring biotechnology safety could be achieved within existing laws (OSTP, 1986).

The Coordinated Framework specifies three federal agencies responsible for regulating biotechnology in the US: USDA's APHIS, the EPA, and the FDA. APHIS regulates GE organisms under the Plant Protection Act of 2000 (PPA). EPA regulates plant-incorporated protectants and herbicides used with herbicide-tolerant crops under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) and Federal Food, Drug, and Cosmetic Act (FFDCA). FDA regulates food (including animal feed, but not including meat and poultry, which is regulated by USDA), including food and feed produced through biotechnology, under the authority of the FFDCA. Products are regulated according to their intended use and some products are regulated by more than one agency. Together, these agencies ensure that the products of modern biotechnology are safe to grow, safe to eat, and safe for the environment. USDA, EPA, and FDA enforce agency-specific regulations to products of biotechnology that are based on the specific nature of each GE organism.

In 2001, in a joint CEQ/OSTP assessment of federal environmental regulations pertaining to agricultural biotechnology, the CEQ and OSTP found that "no significant negative environmental impacts have been associated with the use of any previously approved biotechnology product" (CEQ/OSP, 2001, p. 1).

For glyphosate-tolerant sugar beet event H7-1, the plant is reviewed by USDA and FDA, whereas EPA is responsible for registering the use of the glyphosate herbicide and establishing a tolerance for allowable glyphosate residues. As indicated herein, although certain issues such as weed resistance and impacts of glyphosate on animals or plants are addressed by EPA (not APHIS), this ER nevertheless addresses those issues.

1.4.1 USDA Regulatory Authority

The Animal and Plant Health Inspection Service (APHIS) Biotechnology Regulatory Service (BRS) mission is to protect US agriculture and the environment using a dynamic and science-based regulatory framework that allows for the safe development and use of GE organisms. Under its authority from the PPA, APHIS regulates the introduction (importation, interstate movement, or release into the environment) of certain GE organisms and products.[4] A GE organism is presumed to be a regulated article if the donor organism, recipient organism, vector, or vector agent used in engineering the organism belongs to one of the taxa listed in the regulation[5] and is also presumed to be a plant pest. APHIS also has authority under these rules to regulate a GE organism if it has reason to believe that the GE organism may be a plant pest or APHIS does not have sufficient information to determine that the GE organism is unlikely to pose a plant pest risk.[6]

Under APHIS' regulations a person may petition APHIS to evaluate submitted data and determine that a particular regulated article is unlikely to pose a plant pest risk, and, therefore, should no longer be regulated.[7] The petitioner is required to provide information related to plant pest risk that the agency may use to determine whether the regulated article is unlikely to present a greater plant pest risk than the unmodified organism.[8] If the agency determines that the regulated article is unlikely to pose a plant pest risk, the GE organism will be granted nonregulated status. In such a case, APHIS authorizations (i.e. permits and notifications) would no longer be required for environmental release, importation, or interstate movement of the non-regulated article or its progeny.

It was under these regulations that Monsanto/KWS submitted the petition for a determination of non-regulated status for event H7-1 (Schneider, 2003). Event H7-1 sugar beets were considered regulated because they contain non-coding DNA segments derived from plant

[4] 7 C.F.R. §.340

[8] *Id.* §340.6(c)(4)

pathogens and the vector agent used to deliver the transforming DNA is a plant pathogen (See Section 3.1 for a discussion of these concepts) (APHIS, 2005, p. 4).

1.4.2 EPA regulatory authority

EPA is responsible for regulation of pesticides (including herbicides such as glyphosate) under the FIFRA.[9] FIFRA requires that all pesticides be registered before distribution, sale, and use, unless exempted by EPA regulation. Before a product is registered as a pesticide under FIFRA, it must be shown that when used in accordance with the label, it will not result in unreasonable adverse effects on the environment. EPA granted the registration of glyphosate for use over the top of sugar beets on March 31, 1999.

Under the Federal Food, Drug, and Cosmetic Act (FFDCA), as amended,[10] pesticides added to (or contained in) raw agricultural commodities generally are considered to be unsafe unless a tolerance or exemption from tolerance has been established. EPA establishes residue tolerances for pesticides under the authority of the FFDCA. EPA is required, before establishing pesticide tolerance to reach a safety determination based on a finding of reasonable certainty of no harm under the FFDCA, as amended by the Food Quality Protection Act of 1996 (FQPA). The FDA enforces the tolerances set by the EPA. EPA established a tolerance for glyphosate residue found on beets, including sugar, roots, tops, and dried pulp on April 14, 1999 (64 Fed. Reg. 18360).

1.4.3 FDA regulatory authority

In 1992 FDA, which has primary regulatory authority over food and feed safety, published a policy statement in the Federal Register concerning regulation of products derived from new plant varieties, including those genetically engineered (FDA, 1992). Under this policy, FDA uses a consultation process to ensure that human food and animal feed safety issues or other regulatory issues (e.g. labeling) are resolved prior to commercial distribution of a bioengineered food. Monsanto/KWS submitted a food and feed safety and nutritional assessment summary for event H7-1 to FDA in April 2003. FDA completed its consultation process in August 2004 (Tarantino, 2004; Bonette, 2004).

[9] 7 USC §136 et seq.
[10] 21 U.S.C. § 301 et seq.

1.5 THE NATIONAL ORGANIC PROGRAM AND BIOTECHNOLOGY

Congress passed The Organic Foods Production Act of 1990 (OFPA) to avoid the confusion and misrepresentation then taking place in the "organic" marketplace.[11] The OFPA required the USDA to establish a National Organic Program (NOP) to develop uniform standards and a certification process for those producing and handling food products offered for sale as "organically produced."[12] The OFPA requires certification under the NOP, which was finalized in 2000, to be process-based.[13] "The certification process does not guarantee particular attributes of the end product; rather it specifies and audits the methods and procedures by which the product is produced" (Ronald and Fouche, 2006). The NOP defines certain "excluded methods" of breeding that cannot be used in organic production, describing them as "means that are not possible under natural conditions or processes."[14] Along with genetic engineering, three other modern breeding techniques are specified as "excluded methods" in the regulations.[15] Thus, a certified organic grower cannot intentionally plant seeds that were developed by these specific excluded methods. However, because "organic" is based on process and not product, the mere presence of plant materials produced through excluded methods in a crop will not jeopardize the integrity of products labeled as organic, as long as the grower follows the required organic production protocol. Also, other modern breeding methods - for example, induced radiation or chemical mutagenesis - are not specified as excluded methods by the NOP (discussed in Section 3.1.1).

All organic growers' production plans must be approved by an organic certifying agent before the farm can be certified as "organic."[16] Such plans must include, among other things, steps the organic grower is taking to avoid what the NOP refers to as "genetic drift" from any neighboring crops using excluded methods.[17] Certification must include on-site inspections of the farm to verify the procedures set forth in the organic production plan.[18]

Thus, the NOP recognizes the coexistence of organic growers with neighboring growers who may choose to grow products developed using certain methods of biotechnology. So long as an organic grower follows an approved organic method of production that seeks to avoid contact

[11] 7 USC § 6501 *et seq.*

[18] 7 C.F.R. § 205.403.

with these specific biotechnology-derived crops, if some residue of the biotechnology-derived plant material is later found in the organic crop (or food produced from it), neither the crop (or food) nor the organic farm is in danger of losing its organic status. No grower or seed producer has lost organic certification due to inadvertent transmission of genetic material from a genetically engineered crop.

In the context of the genetic drift discussion, in the preamble of the NOP regulations, USDA emphasized that it is the use of excluded methods as a production method that is prohibited, not the mere presence of a product of excluded method:

> It is particularly important to remember that organic standards are process based. Certifying agents attest to the ability of organic operations to follow a set of production standards and practices that meet the requirements of the Act and the regulations. This regulation prohibits the use of excluded methods in organic operations. The presence of a detectable residue of a product of excluded methods alone does not necessarily constitute a violation of this regulation. As long as an organic operation has not used excluded methods and takes reasonable steps to avoid contact with the products of excluded methods as detailed in their approved organic system plan, the unintentional presence of the products of excluded methods should not affect the status of an organic product or operation.[19]

The NOP calls for testing only if there is "reason to believe" that a grower has used excluded methods.[20] The preamble states that a "reason to believe" may be triggered by situations such as a formal, written complaint to the certifying agent regarding the practices of a certified organic operation; the proximity of a certified organic operation to a potential source of drift; or the product from a certified organic operation being unaffected when neighboring fields or crops are infested with pests.[21]

This testing provision does not establish a zero tolerance standard for the presence of products of excluded methods in organically labeled food. Rather, it serves as a warning that excluded methods may have been used: "Any detectable residues of . . . a product produced using excluded methods found in or on samples during analysis will serve as a warning indicator to the certifying agent."[22]

> [T]hese regulations do not establish a "zero tolerance" standard. . . [A] positive detection of a product of excluded methods would trigger an investigation by the certifying agent to determine if a violation of organic production or handling standards occurred. The presence of a detectable

> residue alone does not necessarily indicate use of a product of excluded methods that would constitute a violation of the standards."[23]

Only if the organic producer intentionally used excluded methods of crop production will that producer be subject to suspension or revocation of organic certification. There is no evidence that any organic grower has lost certification due to unintended presence of GE material.

1.5.1 Non-GMO Project Working Standard

The Non-GMO Project is a non-profit organization created by leading players in the organic industry to "offer consumers a consistent non-GMO choice for organic and natural products that are produced without genetic engineering or recombinant DNA technologies" (Non-GMO Project, 2010a). The Non-GMO Project has created a working standard to implement its goal. The standard sets action thresholds for "GMO" (GE) adventitious presence for certain products. If these action thresholds are exceeded, the participant must investigate the cause of the exceedance and take corrective action (Non-GMO Project, 2010, p. 13). The standard sets a threshold of 0.25% for GE material for the presence of GE traits in non-GE seeds (p. 28), and a 0.9% threshold for non-GE food or feed (p.14).

1.5.2 Growth in organic and GE farming

Expansion of organic farming has succeeded at the same time as the growth of GE crops. Consumer demand for organically produced goods "has shown double-digit growth for well over a decade" and organic products "are now available in nearly 20,000 natural food stores and three of four conventional grocery stores." Organic products "have shifted from being a lifestyle choice for a small share of consumers to being consumed at least occasionally by a majority of Americans" (USDA ERS, 2009c).

1.6 COEXISTENCE IN US AGRICULTURE

1.6.1 Coexistence and biotechnology

Coexistence of different varieties of sexually compatible crops has long been a part of agriculture, especially in seed production, where large investments are made in developing new varieties and high seed purity levels are required by the Federal Seed Act implementing regulations.[24] The aspect of coexistence most relevant to this document is that related to specific methods of crop production. In this context, coexistence refers to the "concurrent cultivation of conventional, organic, and genetically engineered (GE) crops consistent with

[23] *Id.* at 80632.
[24] 7 CFR § 201

underlying consumer preferences and choices" (USDA Advisory Committee, 2008). The differences among these crops that are particularly relevant to coexistence in this ER are in the types of breeding methods (sometimes referred to as "genetic modifications") that are associated with each of the three types of crops.

"**Genetic engineering**" is defined by APHIS regulations as "the genetic modification of organisms by recombinant DNA techniques."[25] Recombinant DNA (rDNA) techniques are discussed in Section 3.1.1 of this ER. While there are many ways to genetically modify a crop, the APHIS definition of GE crops applies only to those developed using rDNA techniques, which are among the more modern breeding methods.

Organic crops are those produced in accordance with the requirements of the NOP, discussed in Section 1.5.

Conventional crops are simply those that are neither GE nor organic. They may be commodity crops (mass produced), or they may be identity preserved, with some characteristic tailored for a specific end user. Identity-preserved usually refers to a "specialty, high-value, premium or niche market" (Massey, 2002). One type of identity preserved product that has been produced since the introduction of GE crops is "non-GE;" however, there are no mandatory standards governing the use and/or marketing of "non-GE" products (USDA Advisory Committee, 2008).

Farmers who want to maximize their profitability must decide whether the higher prices (premiums) they may receive for organic or identity-preserved crops are sufficient to offset the added managerial costs of producing these crops. As researchers have noted, "Although yields on organic farms are sometimes less than those of conventional systems, price premiums make it an attractive option for growers looking for specialized markets and a higher-value product" (Ronald and Fouche, 2006). There is such a niche market for organic red beets and organic Swiss chard. However, no premium or niche market exists for either conventional or organic sugar beets.

1.6.2 USDA position on coexistence and biotechnology

It is USDA's position that all three methods of agricultural production described above can provide benefits to the environment, consumers, and the agricultural economy (Smith, 2010b).

[25] 7 CFR §340.1

1.6.3 Coexistence in US crop production

Since the time GE crops were introduced in the US in the mid-1990s, organic markets have grown and expanded (Smith, 2010b, p. 10).

The USDA Advisory Committee on Biotechnology and 21st Century Agriculture who reported that "coexistence among the three categories of crops is a distinguishing characteristic of U.S. agriculture, and makes it different from some other parts of the world," expressed its belief that US agriculture supports coexistence, and recommended continued government support of coexistence (USDA Advisory Committee, 2008). Among the Committee's findings:

- The U.S. is the largest producer of GE crops in the world.
- The U.S. is one of the largest producers of organic crops in the world.
- The U.S. is one of the largest exporters of conventionally-grown, identity preserved, non-GE crops in the world.
- Some U.S. farmers currently are producing a combination of organic, conventional, and GE crops on the same farm.

Among the coexistence-enabling factors the Committee identified are the existing "legal and regulatory framework that has enabled different markets to develop" without foreclosing the ability of "participants in the food and feed supply chain to establish standards and procedures (e.g., not setting specific mandatory adventitious presence (AP) thresholds and having process-based rather than product-based organic standards)." At the same time, development of practices and testing methods that allow for voluntary thresholds has also enabled coexistence (USDA Advisory Committee, 2008).

As APHIS has previously observed, "studies of coexistence of major GE and non-GE crops in North America and the European Union (E.U.) demonstrated that there has been no significant gene flow from GE crops and that GE and non-GE crops are coexisting with minimal adverse economic effects" (Smith, 2010b, pp. 11-12) (citing Gealy et. al, 2007; Brookes and Barfoot, 2003; Brookes and Barfoot, 2004(a) and (b), and Walz 2004)). In addition, "the agricultural markets and local entities have addressed coexistence through contractual arrangements, management measures, and marketing arrangements. This market-based approach to coexistence has created economic opportunities for all kinds of producers of agricultural products." (*Id.* p. 9). RRSB is one of fifteen glyphosate-tolerant events previously deregulated by USDA. *See* APHIS, EPA, Petitions of Non-Regulated Status Granted or Pending by APHIS as of February 2, 2010, http://www.aphis.usda.gov/brs/not_reg.html.

1.7 ROLE OF THE NATIONAL ACADEMIES IN AGRICULTURAL BIOTECHNOLOGY

The analyses in this ER are based on published, peer-reviewed scientific papers; federal government assessments; assessments from international agencies; information from specialists from many universities; data collected by Monsanto/KWS under controlled conditions; and information from other relevant sources. One resource used for this ER is the National Academies (NA), a private, non-profit institution that advises the nation on scientific and technical matters. It consists of the National Academy of Sciences (NAS), the National Academy of Engineering, the Institute of Medicine (IM) and the National Research Council (NRC) (NA, 2010). Scientists, engineers and health professionals are elected by their peers to the academy and serve *pro bono.* Reports are prepared by committees of members with specialized expertise and reviewed by outside anonymous experts (Alberts, 1999).

The NA has been active in studies related to agricultural biotechnology since the 1970s, works cooperatively with federal agencies, and its reports have provided guidance and recommendations for process improvement to regulatory agencies (Alberts, 1999). The NRC 1989 guidelines for field testing of genetically engineered organisms were used as the basis for agency procedures for field trials (Alberts, 1999; NRC, 1989). In studies in 1987 and 2000 the NRC emphasized that the characteristics of the modified organism should be the object of a risk assessment, and not the methods by which the modifications were accomplished; and that the risks associated with recombinant DNA techniques are the same in kind as risks from other types of genetic modification (NRC, 1987; NRC, 2000). This position was re-iterated in a 2004 study prepared jointly by the IM and the NRC. Whether such compositional changes result in unintended health effects is dependent on the nature of the substances altered and the biological consequences of the compounds. To date, "no adverse health effects attributed to genetic engineering have been documented in the human population" (IM/NRC, 2004, p. 8). In a 2002 report, the NRC "found that the current standards used by the federal government to assure environmental safety of transgenic plants were higher than the standards used in assuring safety of other agricultural practices and technologies" (NRC, 2002). The NRC reports that, while biotechnology is not without risk, since the first commercial introduction of transgenic plants, "biotechnology has provided enormous benefits to agricultural crop production" (NRC, 2008). NRC's latest report on biotechnology in agriculture evaluates the impact of genetically engineered crops on farm sustainability. The authors concluded that an understanding of impacts on all farmers will help ensure that GE technology contributes to sustainability and that

commercialized GE traits to date, when used properly, "have been effective at reducing pest problems with economic and environmental benefit to farmers" (NRC, 2010).

1.8 ALTERNATIVES CONSIDERED

In addition to the alternative of partial deregulation or other administrative action implementing the interim conditions (Alternative 2), this ER considers the alternative of full regulation (Alternative 1).

1.8.1 Alternative 1 – No Action (full regulation)

In conducting NEPA review, agencies consider a No Action alternative, which provides a baseline against which action alternatives can be evaluated. This ER identifies the No Action alternative as a return to full regulation – or the *status quo* existing when the petition for deregulation of event H7-1 was initially submitted. Under this alternative, the introduction of event H7-1 lines of glyphosate tolerant sugar beets would be fully regulated and would require permits issued or notifications acknowledged by APHIS until APHIS completes its EIS and issues a Record of Decision (ROD) regarding whether to deregulate H7-1 lines of glyphosate tolerant sugar beets. For purposes of this analysis, we assume that Alternative 1 would not involve widespread event H7-1 sugar beet cultivation, and instead would contemplate a return to conventional sugar beet crops or to crops other than sugar beet. *Note*: As indicated above, the *status quo* is event H7-1 sugar beets comprising 95 percent of the U.S. sugar beet crop.

1.8.2 Alternative 2 – Partial Deregulation with Interim Conditions

Under this alternative, the introduction of event H7-1 lines of glyphosate tolerant sugar beets would be allowed under interim conditions until APHIS completes its EIS,, issues a Record of Decision, and that decision takes effect – currently anticipated for mid-2012 (Smith, 2010b, p. 8).

This section describes the affected environment and provides other contextual information for an understanding of the environmental consequences analyzed in Section 3.

2.1 SUGAR BEET CHARACTERISTICS AND USES

Sugar beet (*Beta vulgaris L.*) is a biennial plant that was developed in Europe in the 18th century from white fodder (animal feed) beets. Sugar reserves are stored in the sugar beet root during the first growing season for an energy source during overwintering. The roots are harvested for sugar at the end of the first growing season but plants that overwinter in a mild climate will produce flowering stems and seed during the following summer and fall. Sugar beet roots will not survive the winter in any of the growing regions except California (Cattanach et al, 1991).).

Pollination. The sugar beet is cross-pollinated (pollination occurs between plants rather than within single plant) by wind (Cattahach et al, 1991).

Climate. Sugar beets have adapted to a very wide range of climatic conditions. Sugar beets primarily are a temperate zone crop produced in the Northern Hemisphere at latitudes of 30 to 60°N. The sugar beet plant grows until harvested or growth is stopped by a hard freeze. Sugar beets primarily grow tops until the leaf canopy completely covers the soil surface in a field. This normally takes 70 to 90 days from planting. Optimal daytime temperatures are 60 to 80°F for the first 90 days of plant growth. Regions with long day length are most suitable for sugar beet growth. The most favorable environment for producing a sugar beet crop from 90 days after emergence to harvest is bright, sunny days with 65 to 80°F temperatures followed by nighttime temperatures of 40 to 50°F. These environmental conditions maximize yield and quality in a sugar beet crop. Sugar beets are successfully produced under irrigation in areas with very low rainfall and in regions relying on natural rainfall (Cattanach et al, 1991).

Products. Sugar beets contain from 13 to 22 percent sucrose. Sugar beet pulp and molasses are processing by-products used as feed supplements for livestock. These products provide required fiber in rations and increase the palatability of feeds. Molasses by-products from sugar beet processing are used in the alcohol, pharmaceuticals, and bakers' yeast industries (Cattanach et al, 1991).

2.2 ACCEPTANCE OF EVENT H7-1 SUGAR BEETS

Event H7-1 sugar beets were first available for commercial production in 2007 (Lilleboe, 2008). In the 2009/10 crop year, event H7-1 varieties accounted for about 95 percent of planted area, up from about 60 percent in 2008/09 (USDA ERS, 2009a). Since, as noted in Section 1, no event H7-1 sugar beets have been grown in California and California represents approximately 3 percent of US sugar beet production (Table 2-1), 98 percent of the planted 2009/2010 sugar beet crop in the remaining US sugar beet regions was event H7-1.

2.3 SUGAR BEET ROOT PRODUCTION

2.3.1 US Production by regions

The US is among the world's largest sugar producers. Unlike most other producing countries, the US has both large and well-developed sugarcane and sugar beet industries. Since the mid-1990s, sugarcane has accounted for about 45 percent of the total sugar produced in the US, and sugar beets for about 55 percent of production. Since 1961, planted sugar beet acreage has fluctuated within the range of 1.1 million (low in 1982) to 1.6 million (high in 1975) (USDA NASS 2010a). Annual cash receipts for sugar beets in the US in the past few years have ranged up to $1.5 billion (USDA ERS, 2009b).

Figure 2-1 shows the five major US sugar beet producing regions, along with 2008 production by county.

Great Lakes. Great Lakes sugar beet production, now entirely in Michigan, occurs in the flat area around Saginaw Bay. Sugar beets grown in the Great Lakes region do not require irrigation. The Great Lakes region also includes Ohio, where sugar beets were last produced in 2004.

Upper Midwest. The Upper Midwest is the largest sugar beet production region in the US, with the majority of this production in the Red River Valley. The Red River flows north into Canada and forms most of the North Dakota-Minnesota border. It flows through a broad, flat valley formed by an ancient glacial lake. The Minnesota River Valley, another broad, flat glacial valley that crosses southern Minnesota and is almost continuous with the Red River Valley, is also a large production area. Irrigation is uncommon in the Red River/Minnesota River Valleys (Ali, 2004). There is another, much smaller Upper Midwest production area along the Montana border of North Dakota, in the valley of the Yellowstone River and its tributaries.

Great Plains. The Northern Great Plains region includes production areas in northern Wyoming and southern Montana. The major sugar beet growing areas in the Northern Great Plains are the sandy loam soils along the Yellowstone River and its tributaries (Mikkelson and Petrof, 1999, p. 2). The Southern Great Plains subregion includes growing areas in western Nebraska, southeastern Wyoming and northeastern Colorado, primarily in the valley of the Platte River and its tributaries. All Great Plains sugar beet production requires irrigation (Thomas et al, 2000, p. 1; Mikkelson and Petrof, 1999, p. 3; McDonald et al, 2003, p. 2).

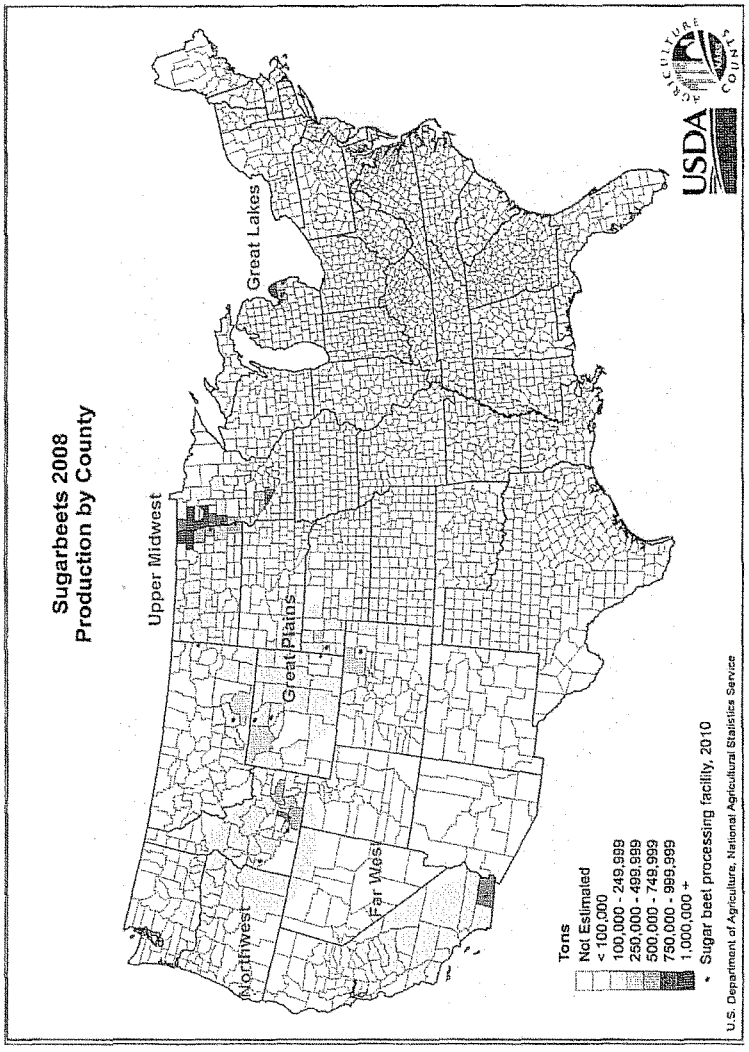

Figure 2-1. US sugar beet regions and 2008 county production.

The Great Plains region previously included New Mexico and Texas, where sugar beets were last harvested in 1997.

Northwest. Most production in the Northwest region is in the sandy loam soil of the Snake River Valley in Idaho. This area also requires irrigation (Traveller and Gallian, 2000, p. 1). In addition, production occurs in southeast Washington state, east of the Cascade mountains.

Far West (California). The only sugar producing area in California is in the Imperial Valley in the far southern end of the state, where the only remaining sugar processing plant in California exists. Production occurred in the Central Valley (near the middle of the state) through 2008; however, the last processing plant in this area closed in 2008. As recently as the 1990s, nearly 30 percent of sugar beet production was in the Central Valley; there were also small areas of production in coastal counties (but production in those regions no longer exist) (California Beet Growers Association, 1998, p.1).

US production for the 2009/2010 season (harvested in 2009 and processed in 2009/2010) is shown in Table 2-1. In 2010, sugar beet was planted on 1.2 million acres (USDA ERS, 2010a, Table 14). Sugar beet production by county from 2005 to 2008, including acres planted, acres harvested, yield per acre, total yield and sucrose percent, is tabulated in Appendix D.

The distribution of planted acreage by state is shown in Figure 2-2.

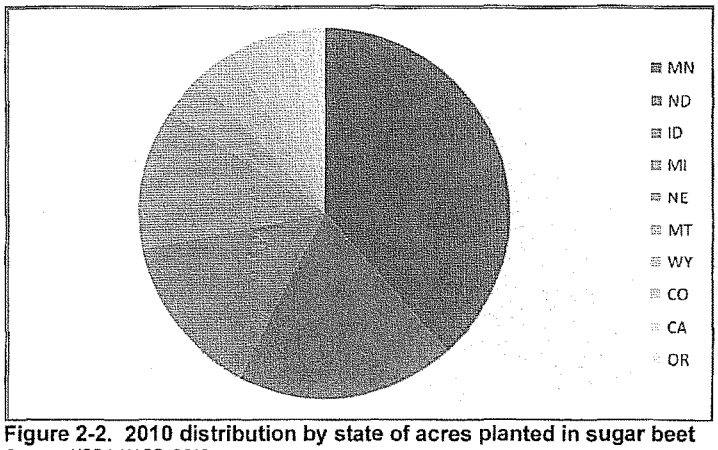

Figure 2-2. 2010 distribution by state of acres planted in sugar beet
Source: USDA NASS, 2010a

2.3.2 Grower-processor relationships

Sugar beet production, more than most crops, requires close coordination between the grower and the processor. The crop is of little value without a processor to extract the sugar, and a sugar processing facility cannot stay in business without a reliable supply of beets (Kaffka and Hills, 1994, p. 2). While a type of syrup can be made on a small scale, home garden production of sugar would be impractical; processing cannot be duplicated successfully in a home kitchen (California Beet Growers Association, 1998, p. 3). Sugar beets are 75 percent water and expensive to transport long distances (Michigan Sugar Company, 2010a). For economic reasons, sugar beets are typically grown within 60 miles of a processing facility, but may be grown up to 100 miles away (Western Sugar Cooperative, 2006a). Locations of the 22 processing facilities in operation in 2010 are shown in Figure 2-2. While existing facilities have been upgraded, no new currently operating processing facilities have been built in the US since 1975. An estimated cost for an average-sized new facility in 1991 was $100 million (Cattanach et al, 1991, p. 16). The cost would be substantially higher today due to inflation and other factors.

Sugar beet production and processing in the US is done almost entirely by grower-owned cooperatives. The cooperatives own the processing facilities and the sugar beet farmers are members of the cooperatives. The members own shares of stock that require them to grow a specified acreage of beets in proportion to their stock ownership in the cooperative and guarantee processing for their beets. US companies are summarized by regions below. Cooperatives are owned by growers who are principally family farmers. According to the 2007 US Census of Agriculture, over 4,000 farms grow sugar beets (USDA ERS 2009b).

Great Lakes. Michigan Sugar Company, the third-largest sugar beet processor in the US, processes all the sugar beets in the Great Lakes region, as well as beets from Ontario, Canada.. The cooperative has over 1,000 grower-shareholders who grow sugar beets on 150,000 acres each year. The sugar beets are processed into sugar at factories in Bay City, Sebewaing, Caro and Croswell. The cooperative employs 450 year-round and 1,200 seasonal employees, generates nearly $400 million in direct economic activity annually in the local communities in which it operate, and annually produces nearly one billion pounds of sugar (Michigan Sugar Company, 2010b).

Upper Midwest. Three cooperatives operate in the Upper Midwest. American Crystal Sugar Company, the largest sugar beet producer in the US, is owned by approximately 3,000

shareholders who raise 500,000 acres of sugar beets in the Red River Valley of Minnesota and North Dakota. The company operates five sugar processing facilities in the Red River Valley: three in Minnesota (Crookston, East Grand Forks and Moorhead) and two in North Dakota (Drayton and Hillsboro). American Crystal also operates a sugar beet processing facility in eastern Montana at Sidney, under the name Sidney Sugars Incorporated. American Crystal's fiscal year 2009 Red River Valley crop averaged 25.4 tons per acre with 17.6 percent sugar content.. In 2009, the company produced approximately 3 billion tons of sugar and 681,000 tons of agri-products (molasses and pulp) (American Crystal Sugar Company, 2009). Minn-Dak Farmers Cooperative, with 450 shareholders, operates a processing facility in Wahpeton, in the far southeast corner of North Dakota. Minn-Dak also operates a yeast factory, which uses molasses from sugar beet processing (Minn-Dak Farmers Cooperative, undated). The Southern Minnesota Beet Sugar Cooperative has approximately 600 shareholders who farm 120,000 acres, and operates a processing facility near Renville, Minnesota (Southern Minnesota Beet Sugar Cooperative, 2010).

Great Plains. The Western Sugar Cooperative, with 135,000 acres and five factories, processes most of the Great Plains sugar beet. Processing facilities are in Fort Morgan, Colorado; Billings, Montana; Scottsbluff, Nebraska; and Lovell and Torrington, Wyoming. Wyoming Sugar Beet Company, LLC is not a cooperative, but works through the Washakie Farmers Cooperative to acquire beets for its plant in Worland, Wyoming (Boland, 2003).

Northwest. The Amalgamated Sugar Company LLC processes all the sugar beet in the Northwest region. Amalgamated is owned by Snake River Sugar Company, a grower-owned cooperative, and is headquartered in Boise, Idaho with processing plants in Paul, Twin Falls, and Nampa, Idaho (Snake River Sugar Company, 2009).

Far West (California). Spreckels Sugar Company, a subsidiary of Southern Minnesota Beet Sugar Cooperative, operates a sugar beet processing facility in Brawley, California, in the Imperial Valley. Yields in the Imperial Valley are higher than anywhere else in the US, averaging approximately 40 tons per acre (Spreckels Sugar, 2009).

Tillage systems *are defined by the amount of crop residue remaining on the soil.*

Conventional tillage *systems leave less than 30 percent of crop residue remaining on the soil when planting another crop.*

Conservation tillage *leaves 30 percent or more of the previous crop residue covering the soil when planting another crop.*

Reduced tillage *leaves 15 to 30 percent of the previous crop residue covering the soil when planting another crop.*

Mulch tillage *disturbs the soil prior to planting. Tillage tools such as chisels, field cultivators, disks or blades are used. Weed control is accomplished with herbicides and/or cultivation.*

No Till *leaves the soil undisturbed.*

With ***strip tillage****, a specific type of conservation tillage, tillage is confined to narrow strips where seeds will be planted. Strip tillage is usually done in the fall. The loosened soil creates a ridge 3 to 4 inches high, which improves soil drainage and warming. By spring, it usually settles down to 1 or 2 inches high, and after planting the field is flat.*

Sources: Ali, 2004, p. 32;

2.3.3 Sugar beet cultivation practices

Seed bed preparation and tillage. The objectives of seedbed preparation are to manage crop residue (the leftover vegetative matter from the previous crop), minimize erosion, improve soil structure, and eliminate early season weeds. Tillage, which can be done in fall and spring, can help improve soil structure and eliminate early weeds, but tillage can also increase erosion. No-till, strip tillage in previous crop residues, and other conservation tillage systems (see definitions at left) require more planning and better management (Cattanach et al, 1991). In addition to the reduced tillage methods (noted at left), no-till productions systems do not have any associated tillage where weed control is entirely through chemical means. A survey conducted in 2000, before event H7-1 sugar beets were available, found that use of conventional tillage for sugar beet production varied by region from 64 percent of acreage in the Red River Valley in the Upper Midwest to 96 percent of acreage in the Northwest (California was not included because there was too little data). Growers in the Red River Valley reported using reduced tillage on 16 percent of sugar beet acres and mulch tillage on 20 percent (Ali, 2004). Because weeds can be effectively controlled with glyphosate applications, event H7-1 sugar beets may be grown with less tillage (NRC, 2010, p. 6; Duke and Cerdeira, 2007, p. 3; Wilson, 2009).

In the Idaho (Northwest), prior to glyphosate tolerant sugar beets conventional tillage was essential for weed control, minimizing soil erosion and improving soil structure (Ali, 2004; Traveller and Gallian, 2000, p. 1). Since the introduction of event H7-1, some farmers in the Northwest have switched to strip tillage and have reported reduced fuel and labor costs and

reduced wind erosion (Lilleboe, 2008). Researchers in Idaho found that while conventional tillage was necessary for weed control with conventional beets, the practice has little to no benefit with glyphosate-tolerant sugar beets (Miller and Miller, 2008).

In much of the Great Plains region, conventional sugar beets were cultivated using conservation tillage systems; however, deep tillage, which is used to improve drainage, was utilized to help reduce the risk of soil borne diseases (mainly the beet necrotic yellow vein virus causing rhizomania) (McDonald et al, 2003, p.2). Farmers in the Great Plains have reported that strip tilling and event H7-1 have "been a great marriage," with strip tilling resulting in reduced wind erosion, reduced irrigation requirements and fuel and time savings (Lilleboe, 2010).

Michigan Sugar Company recommends conservation tillage practices to help control erosion resulting from strong early spring wind in the Great Lakes region (Michigan Sugar Company, 2009, p. 2). However, since the introduction of the event H7-1 this growing region has the option of implementing varying methods of reduced tillage systems.

Recent studies by North Dakota State University have found that since the introduction of event H7-1, strip tillage is a viable option for sugar beet production that reduces fuel and fertilizer costs and susceptibility to wind erosion (Overstreet et al, 2009). A member of the Minn-Dak Farmers Cooperative, who farms about 1,100 acres of sugar beets annually, has found that instead of three post-emergence tillage trips across the fields, with event H7-1 he now needs "little to no tillage post-emergence" (Mauch, 2010, p. 3).

Planting and harvesting times. In all regions except the Far West (California), sugar beet root crops are planted in early spring (March through May, depending on latitude and location) and harvested in fall (September through November, also varying with regions) (McDonald et al, 2003; Mikkelson and Petrof, 1999, p 3; Michigan Sugar Company, 2010b).

In the Imperial Valley in California, sugar beets are planted in September and October and harvested from April to July (California Beet Growers Association, 1999, p. 1).

Crop rotations. Sugar beets tend to be grown with other crops in three- to five-year rotations, although sometimes two years is used. The rotation results in improved soil fertility, fewer problems with diseases, and improved yields and quality of beets. The impact of certain soil borne diseases, nematodes (parasitic, microscopic worms) and weeds are minimized through

crop rotations (Mikkelson and Petrof, 1999, p. 3; USDA ERS, 2009b, p. 2; Hirnyck et al, 2005, p. 13).

To assess the likelihood that the rotational crops planted after event H7-1 sugar beet would be another glyphosate-tolerant crop an analysis of rotations to other crops was conducted and included in the petition (Schneider, 2003, Table VII-13). This rotational crop table has been updated with crop information from the 2007 planting season and includes projected acreage for recently commercialized glyphosate-tolerant crops (Table 2-2).

2.3.4 Sugar beet bolters and volunteers

Bolting. Sugar beet, if left to grow in a temperate climate, is a biennial plant that produces an enlarged root the first year and flowers in the second year. Typically, the plant is induced to flower through a process called vernalization that occurs during prolonged exposure to cooler temperatures. Occasionally sugar beets will bolt (produce a seed stalk that may ultimately flower) in their first year of production; however, with breeding, bolting tendency has been reduced. Much effort has gone into producing sugar beets that resist bolting, and today's varieties show little bolting (OECD, 2001, p. 15). No difference in bolting characteristics would be expected between conventional and event H7-1 sugar beets, as the introduction of the glyphosate tolerant trait does not affect the bolting characteristics of the sugar beet. In the 2000-2001 variety field trials with lines containing event H7-1 reported in the petition, six of 12 event H7-1 sugar beet varieties had 0.00 percent bolters; for those varieties with bolters, the percentages were 0.03 percent for three; 0.06 percent for two, and 0.19 percent for one. All entries were established as six row plots forty feet in length with six replications at each location in 2000, and four replications at each location in 2001 (Schneider, 2003, Table VI-9). Darmency et al report bolting percents now as low as 0.01 percent (2009, p. 1090). While Darmency et al were referring to conventional sugar beets, event H7-1 would not affect bolting characteristics, and breeders continue to select for low rates of bolting.

For bolting to occur, the plants first require exposure to temperatures around 40 to 42 degrees F (others report 34 to 39 degrees F in the 4 to 5 leaf stage; conditions are variety-dependent), followed by exposure to increasing day length (12 hours or more). Varieties differ in their sensitivity to bolting, with easy bolting lines requiring only a few to 1000 hours of exposure to low temperatures, while bolting-resistant lines may require 2000 hours or more. Beets can de-vernalize when exposed to high temperatures (OECD, 2001, p. 15).

Bolting depletes the root of simple sugars, translocating this stored energy into the above-ground biomass, making the root woody and worthless as a source of sugar. Bolters are taller than the rest of the crop. Thus, bolters are effectively weeds within a sugar beet field. The woody roots that result from bolters can damage harvesting and processing equipment (Ellstrand, 2003, p. 5-7). For these reasons, growers remove bolters. A bolter is evident in a field weeks before the seed stalk would flower to produce pollen or seed. Thus, stewardship can be 100% successful in eliminating any small probability of flowering.

1244

In the Imperial Valley in California, sugar beets are planted in September, grow through the winter months, and are harvested the following April through June. Vernalization occurs more frequently in the Imperial Valley than in the other US regions, where sugar beet is planted in the spring and harvested in the fall. If the winter in the Imperial Valley is unusually cold and harvesting is delayed, some bolters can develop (California Beet Growers Association, 1998, pp. 3-5; Bartsch et al, 2003).

Sugar beet volunteers. Volunteers are plants from a previous crop that are found in subsequent crops. In most crops, volunteers grow from seeds. If sugar beet bolters are allowed to go to seed in certain more temperate climates, the seed may sprout and cause volunteers in later years, in other crops. Groundkeepers are a type of volunteer derived from vegetative tissue (small roots) left in the field after harvest, which can grow in the next season if not controlled.

In most parts of the US where sugar beets are grown, beet roots would not be expected to survive the winter, and therefore groundkeepers would be of little concern (Panella, 2003). Cattanach et al., who focused on production in the northern plains and upper Midwest (including North Dakota and Minnesota), reported that sugar beets could not survive the winter in these areas (1991).

Sugar beets are not good competitors with other crops. Any that survive can be reservoirs for beet diseases and good management practices dictate that they be removed (Kaffka, 1998).

2.4 GENE FLOW

Definition. Gene flow has been defined as the "incorporation of genes into the gene pool of one population from one or more populations" (Futuyma, 1998). Gene flow is a basic biological process in plant evolution and in plant breeding, and itself does not pose a risk (Bartsch et al, 2003; Ellstrand, 2006, p. 116).

How gene flow is addressed in this document. In this section we provide some background information on gene flow, which is included in several different discussions of impacts, as follows:

- Potential for gene flow from event H7-1 sugar beet crops to conventional sugar beet crops (Section 3.3)
- Potential for gene flow from event H7-1 sugar beet to crops to organic sugar beet crops (Section 3.4)
- Potential for gene flow from event H7-1 sugar beet crops to other *Beta* crops (Section 3.5)

- Potential for gene flow from event H7-1 sugar beet crops to other *Beta* seed production areas (Section 3.6)
- Potential for gene flow from event H7-1 sugar beet crops to native beets (Section 3.7)
- Potential for gene flow from event H7-1 sugar beets crops to weed beets (Section 3.8)
- Potential for gene flow from event H7-1 sugar beet to any of the above receptors, in sugar beet seed production (Section 3.9)

Hybridization. In plant biology, when gene flow occurs between individuals from genetically distinct populations and a new plant is formed, the new plant is called a hybrid (Ellstrand, 2003, p. 10). Hybridization is usually thought of as the breeding of closely related species resulting in the creation of a plant that has characteristics different from either parent. Usually this occurs through deliberate human efforts; however, it can also occur indirectly from human intervention, or in nature. For example, when plants are moved to a new environment (with or without human intervention), they may hybridize with plants of a closely related species or subspecies in that new location.

For natural hybridization to occur between two distinct populations, the plants from the two populations must flower at the same time, they must be close enough so that the pollen can be carried from the male parent to the female parent, fertilization must occur, and the resulting embryo must be able to develop into a viable seed that can germinate and form a new plant (Ellstrand, 2003, pp. 11-13).

Introgression. Hybridization may occur in one generation, but in most cases, does not continue on its own. If it does, and stable new populations result, the process is called introgression. For introgression to occur, hybridization of offspring back with the parent types (backcrossing) must occur several times. Because hybrids of distantly related species may not produce viable seed, introgression is much less common than hybridization. For example, in studies done with canola and a weedy relative, backcrossing from the hybrids to the weeds occurred at one-hundredth to one-thousandth the rate of the original hybridization (reported in Stewart, 2008, p. 2). Nevertheless, when weed species are introduced to new areas, there is the potential that those introduced plants may hybridize with other closely related species. Novel hybrids therefore may be created. In addition, novel hybrids may be created through back-crossing (i.e. introgression) with parent species which may change the native species with non-native genetic material. Invasive weeds can result from hybridization events, which mix genetic material potentially producing a wide array of genotypes. Some of these genotypes may exhibit increased invasive properties (USDA ARS, 2008).

Characteristics that favor natural hybridization between two populations when the above requirements are met include (Mallory-Smith and Zapiola, 2008, p. 429):

- Presence of feral populations (domestic populations gone wild) and uncontrolled volunteers
- Presence of a high number of highly compatible relatives
- Self-incompatibility
- Large pollen source
- Large amounts of pollen produced
- Lightweight pollen
- Strong winds (wind pollinated)
- Large insect populations (insect pollinated)
- Long pollen viability

Feral populations are discussed in Section 2.9.4. **Volunteers**, which are plants from a previous crop that are found in a later crop, are common in agriculture and were discussed in Section 3.2.3.

Highly compatible relatives of sugar beets present in the US include red table beets, spinach (or leaf) beets, and Swiss chard (discussed in Sections 3.5, 3.6 and 3.9); and weed beets of the same or closely related species (discussed in Section 3.8).

Sugar beets and other members of the species *B. vulgaris* are **self-incompatible**; that is, fertilization does not occur between the male and female parts on the same plant. Self-incompatible plants must outcross: for fertilization to occur, the pollen from the male part of one plant must be caught by the sticky stigma within the flower of the female part of another plant.

Sugar beets are largely pollinated by **wind** (Mallory-Smith and Zapiola, 2008, Table 1; OECD, 2001, p. 21). The potential for longer-distance gene flow increases with higher wind speeds (Mallory-Smith and Zapiola, 2008, p. 3). Depending on wind conditions, wind-borne sugar beet pollen can be distributed horizontally at least 4,500 meters (2.8 miles) (OECD, 2001, p. 22). However, as discussed in Section 3.9, the vast majority of the pollen does not travel these great distances, and the very small amount that does is unlikely to pollinate another plant.

Successful wind-pollinated flowering plants must produce **large amounts of pollen**: the chances of any single wind-blown pollen grain landing on and being held by the stigma of

another plant are very small. Pollen occurs in "clouds": scientists have estimated sugar beet pollen production at one billion pollen grains per plant (Schneider, 1942, as reported in OECD, 2001, p. 22). There is great competition within this cloud for the limited available ovules (only one each), and the stray pollen from another source has extremely limited opportunity for success. In a large, densely planted area such as a seed production field, pollination is much more likely from the pollen cloud within the field than from stray pollen from another field (Westgate, 2010, p. 3; Hoffman, 2010a, p. 8)).

While pollen can be maintained for longer periods under laboratory conditions, scientists report that sugar beet **pollen viability** under natural conditions is limited to 24 hours (OECD, 2001, p 22; Hoffman, 2010a, p. 8).

2.5 SUGAR BEET WEED MANAGEMENT

This section addresses weed management in sugar beets. Uncultivated wild beets, including feral beets and weed beets, are described in Section 2.9.

2.5.1 Weed characteristics and concerns

While a weed can be defined as any unwanted plant, problem weeds are those that are competitive and persistent within a given cropping system.

Competition for light, water and nutrients. A grower tries to capture the plant resources - primarily light, water, and plant essential nutrients; however, competitive weeds often secure some of these resources for their growth, at the expense of the crop. Some common characteristics of competitive weeds are rapid seedling establishment, high growth rates, prolific root systems and large leaf areas.

Competition for light is probably the most important weed consideration for sugar beets, particularly in irrigated fields, which promote improved growing conditions. Sugar beets ultimately convert solar energy into sucrose, and reduction in light can have a dramatic impact on yields. Thus, weeds that grow taller than sugar beets, especially those with broad leaves, compete with available sunlight that the sugar beet would have used to make sucrose. Barnyardgrass (*Echinochloa crus-galli)*, for example, has broad, flat leaves and can grow up to 5 ft tall, as can Canada thistle (*Cirsium arvense*). Common lambsquarter (*Chenopodium album)* and kochia (*Kochia scoparia)* are fast-growing weeds that can grow to six ft tall and quickly shade sugar beet seedlings. Wild oat (*Avena fatua)* and green foxtail (*Setaria viridis*) grow to heights ranging from approximately 26 to 41 inches. Sugar beet, by comparison, takes months

to reach its final height of approximately 22 inches (Tranel, 2003; McDonald et al, 2003, pp. 9-12; Mesbah et al, 1994, p. 1).

A plant's ability to compete for water is determined largely by the volume of soil the roots occupy. Weeds with large root systems are more likely to be detrimental to sugar beets during periods of water stress. Some perennial weeds can store a multi-year food supply in their roots (Tranel, 2003; McDonald et al, 2003, pp. -12; Mesbah et al, 1994, p. 1).

Plants that develop a root system early in the season have long roots relative to the part of the plant above ground and have high uptake potential can compete successfully for nutrients. Simply applying more fertilizer does not solve the problem and may exacerbate it by stimulating weed growth; weeds often absorb nutrients faster and in greater amounts than sugar beets (Mesbah et al, 1994, p. 1).

Weed persistence. Persistent weeds are able to survive year after year on a given piece of land, in spite of a farmer's efforts to control them. Some plants are both competitive and persistent through the production of large numbers of seeds. The bushy wild proso millet (*Panicum miliaceum*), for example, shatters upon contact when mature, and can produce 400 to 12,000 seeds per square foot. While high reproductive rates also contribute to a weed's persistence, dormancy is the most important trait in persistence. Cultivated soils typically contain thousands of seeds per square meter, waiting for the opportunity to germinate. Some weed seeds, for example, velvetleaf (*Abutilon theophrasti)*, can remain viable in the soil for up to 50 years (McDonald et al, 2003, p. 12). Many perennial weed species have the ability to reproduce from root fragments. Canada thistle, for example, has a deep, spreading root system that can continue to send up shoots after the surface plant has been removed multiple times. Some weeds have the ability to alter their characteristic in response to stress; for example, some weeds respond to drought by flowering and going to seed early (Tranel, 2003; McDonald et al, 2003, pp. 9-12).

2.5.2 Sugar beets and weeds

The sugar beet plant is a poor competitor against weeds, especially from emergence until the sugar beet leaves shade the ground. Emerging sugar beets are small, lack vigor, and take approximately two months to shade the ground. Thus, weeds have a long period to become established and compete. To avoid yield loss from weed competition, weeds need to be controlled within four weeks after sugar beet emergence and weed control needs to be

maintained throughout the season (Cattanach et al, 1991, p. 6; California Beet Growers Association, 1999, p. 25; McDonald et al, 2003, p. 13; Mikkelson and Petrof, 1999, p 19).

Uncontrolled weeds that emerge with the crop may cause from 30 to 100 percent yield losses (California Beet Growers Association, 1999; p. 25; Sprague, 2009). Increasing weed density causes increasing magnitude of yield loss, although the relationship is not linear: a few weeds may not affect yield, and at high weed populations the weeds begin competing with one another. While yield losses are the major concern, weeds create other problems. Late-season weeds can hinder harvesting operations. For example, infestations of wild mustard can cause loss of small beets during harvesting. Many weed species host pathogens (curly top virus), nematodes (sugar beet cyst nematode) and insects (aphids). High levels of weed control are essential for profitable sugar beet production (California Beet Growers Association, 1999; p. 25; Mikkelson and Petrof, 1999, p 19; Mesbah et al, 1994). Prior to adoption of event H7-1 sugar beets, growers regularly used multiple chemical herbicides to attempt to control weeds. (Cole, 2010a, pp. 12-13; Cole, 2010b, pp. 10-14; Kniss, 2010, p. 5; Wilson, 2010a, p. 9; Hoffman, 2010, p. 12).

2.5.3 Problem weeds in sugar beet production

The USDA Agricultural Research Service (ARS) has identified the following weeds as problem weeds in sugar beets that have previously prevented production of maximum yields to conventional crops: kochia (*Kochia scoparia)*, pigweed (*Amaranthus spp.)*, common lambsquarter (*Chenopodium album)*, nightshade (*Solanum spp.)*, common mallow (*Malva neglecta)*, cocklebur *(Xanthium strumarium),* barnyardgrass (*Enchinochloa crus-galli)*, foxtail (*Setaria)*, wild millet (*Panicum miliaceum)*, wild oats (*Avena fatua)*, sowthistle (*Sonchus L.)*, Canada thistle (*Cirsium arvense)*, nutsedge (*Cirsium arvense)*, and dodder (*Cuscuta L.)* (USDA ARS, 2008, p 61). Most of these weeds, and others, are present throughout all the sugar beet growing regions. Weeds are classified as annual or perennial. An annual is a plant that completes its life cycle in one year or less and reproduces only by seed. Annuals are further classified as broadleaf or grass. Perennials are plants that live for more than two years. They may reproduce by seeds, rhizomes (underground creeping stems) or other underground parts.

Kochia (*Kochia scoparia)*, an annual broadleaf plant, is a member of the Goosefoot family, the same family as sugar beet. Weeds in the same family as a crop often thrive in the same growing conditions.

Pigweed (*Amaranthus spp.)* is a broadleaf annual that is a weed problem in many crops. There are several species; redroot pigweed is most common (UC Integrated Pest Management [IPM] 2010).

Common lambsquarter (*Chenopodium album*)is an annual broadleaf in the same family as sugar beets. With its rapid growth and large size it quickly removes soil moisture (McDonald et al, 2003).

Nightshade (*Solanum spp.)* is a broadleaf annual that grows 6-24 inches tall (McDonald et al, 2003).

Common mallow (*Malva neglecta)* and **cocklebur** *(Xanthium strumarium)* are widespread broadleaf annuals.

Barnyardgrass (*Enchinochloa crus-galli*, **foxtail** (*Setaria)*, **wild millet** (*Panicum miliaceum)* and **wild oats** (*Avena fatua)* are annual grasses.

Sowthistle (*Sonchus L.)* is a perennial plant that reaches a height of 3 to 7 feet and reproduces by seed and underground roots.

Canada thistle (*Cirsium arvense)* is a perennial that reproduces by seeds and underground roots and grows 2 to 5 feet tall. The roots extend several feet deep and some distance horizontally. Canada thistle is the most prevalent and persistent non-grass weed in Minnesota, and is the no. 1 noxious weed in Colorado. It is a problem weed in all growing regions. (Durgan, 1998, p. 8; Colorado Department of Agriculture, undated; McDonald et al, 2003, p. 10).

Nutsedges (*Cyperus spp.)* are among the most problematic weeds of agriculture in temperate to tropical zones worldwide. They are difficult to control, often form dense colonies, and can greatly reduce crop yields. Nutsedges reproduce primarily by rhizomes (UC IPM 2010).

Dodder (*Cuscuta L.)* is an annual parasitic weed that grows only by penetrating tissues of host plants to obtain water and nutrients. Each plant produces thousands of seeds that can remain dormant in the soil for years (UC IPM, 2010).

Velvetleaf (*Abutilon theophrasti*) is a broadleaf annual that grows 2-7 feet tall (McDonald et al, p. 12; USDA 1999a, pp. 18-19).

Ragweed (*Ambrosia spp.*) are annual broadleaf weeds that can be very competitive with crops.

2.5.4 Other non-herbicide weed management practices

In addition to crop rotation and tillage, discussed above, sugar beet growers of conventional sugar beets have other non-herbicide means to manage weeds. Narrow row widths (22 – 24 inches) are commonly used by both conventional and sugar beet growers and those growing glyphosate-tolerant sugar beets, for quicker canopy closure (Cattanach et al, 1991; McDonald et al, 2003; Mikkelson and Petrof, 1999, p. 21). With respect to glyphosate-tolerant sugar beets in particular, because these crops do not require cultivation (i.e., in-crop tillage), sugar beet growers are switching to narrow-row production. With narrower rows, glyphoste-tolerant sugar beets can achieve canopy closure earlier in the growing season, which deprives weeds of sunlight and therefore retards late season weed growth (Wilson, 2010b, p. 4). Growers also use weed-free seed. Additionally, nearly all growers scout their fields for weeds (Ali, 2004).

2.5.5 Use of herbicides to control weeds

Herbicide use is regulated by EPA under FIFRA, rather than by APHIS, and EPA has granted glyphosate reduced risk status (Schneider, 2008, p. 4). Herbicides are used by virtually all sugar beet growers; in 2000 approximately 98 percent of planted acres received one or more herbicide applications (Ali, 2004, Table 4). Herbicides may be used before the crop emerges from the ground (pre-emergence) or after (post-emergence). Pre-plant incorporated (PPI) herbicides are mixed in with the soil before planting. The application method, whether PPI, pre-emergence or post-emergence, largely determines when the herbicide will contact plants and the portion of the plant contacted. In selecting a herbicide, a grower must consider, among other factors, the potential adverse effects on the crop, whether the herbicide is registered for use on the crop, residual effects that may limit crops that can be grown in rotation, effectiveness on expected weeds, and cost.

Herbicide mode of action. Herbicides are chemicals that move into a plant and disrupt a vital process. They are classified according to their mode of action, which is the overall manner in which the herbicide affects a plant at the tissue or cellular level. Most herbicides bind to, and thereby block the action of, a specific enzyme.[26]

2.5.6 Weed control with conventional sugar beets

Conventional sugar beet growers use the weed control measures discussed above, plus a variety of herbicides. There are hundreds of commercial herbicides; only a fraction of that total can be appropriate for use with conventional sugar beet (Table 2-3).

[26] An enzyme is a biological catalyst and is usually a protein. Enzymes are discussed in more detail in Section 3.1.1.

The Weed Science Society of America (WSSA) has classified herbicides by group number, based on their mode of action. As shown in Table 2-3, herbicides commonly used with sugar beet include group numbers 1, 2, 3, 4, 5, 8, and 9 (Tranel, 2008, Dexter et al, 1994; Ross and Childs, undated):

Group 1 herbicides inhibit the action of the enzyme ACCase

Group 2 herbicides inhibit the action of the enzyme ALS

Group 3 herbicides inhibit cell division (mitosis inhibitors)

Group 4 herbicides mimic the plant growth hormone auxin and cause uncontrolled cell growth (synthetic auxins)

Group 5 herbicides inhibit photosynthesis

Group 8 herbicides inhibit a single key enzyme involved in fatty acid synthesis

Group 9 herbicides inhibit the action of the enzyme ESPSP

Table 2-4 summarizes the effectiveness of the herbicides in Table 2-3 on the important sugar beet weeds identified by USDA ARS. As the table shows, no single herbicide is effective on all weeds. Some of these herbicides can be mixed together and applied at the same time (tank-mixed). For conventional sugar beets, glyphosate can be applied only pre-emergence. Blank cells indicate no data were available for that source.

Current practices for weed control in conventional sugar beets include tillage, pre-plant incorporation of grass and broadleaf herbicides, and in-crop use of grass and broadleaf herbicide tank mixtures (Dexter and Luecke, 2003; Dexter and Zollinger, 2003; WSSA, 1994). Each of these practices has limitations. Cultivation and pre-plant incorporation of herbicides are associated with narrow windows of application, which is based on a specific weed size or crop stage (Baker et al., 1982; Baker and Johnson, 1979; Campbell and Janzen, 1995; Fawcett, 1995). Additionally, herbicide performance and crop injury are influenced heavily by soil pH, target weed size, crop size, air temperature, and irrigation practices. Morever, many of the currently applied herbicides leave soil residues, whose persistence can impact crop rotation options in subsequent seasons (Dexter and Zollinger, 2003; WSSA, 1994)

1258

Conventional weed control options are complex due to the need for several applications of multiple tank-mixed herbicides to achieve long-term, broad-spectrum weed control. As an example, a common practice in sugar beet production is to use "micro-rates" of herbicides (Dexter and Zollinger, 2003). This is accomplished by tank mixing multiple herbicides at reduced rates in combination with an oil additive. The components of the tank mixture may include Betanex (desmedipham), Betamix (phenmedipham + desmedipham), Nortron (ethofumesate), Upbeet (triflusulfuron methyl), and Stinger (clopyralid); and Select (chlethodim), if grasses are present. A minimum of three applications is recommended, beginning at the cotyledon growth stage and followed by weekly applications of this herbicide mixture. The intent of the micro-rate program is to lower overall herbicide costs and reduce the potential for crop injury.

A member of the Minn-Dak Farmers Cooperative, who farms about 1,100 acres of sugar beets annually, described his conventional weed control system (Mauch, 2010, pp. 2-3):

> Prior to planting Roundup Ready® sugar beet, my herbicide regimen for conventional beet seed was very complicated and labor intensive. Pre-emergence, I used a combination of Eptam (which is very toxic to the sugar beet) and RoNeet (which is very expensive). Approximately two weeks after the beet plants emerge, I started spraying a mix of BetaMix, Betanex, UpBeet, Nortron and Stinger and adjunctives to make the herbicides stick better to the crops. This would be sprayed four times (approximately once a week). Even after spraying several times, there were still weeds and I then needed to hire manual labor to hoe and pull out the weeds.

This description of the complexity of conventional weed control is similar to that provided by researchers evaluating weed management in sugar beets (Odero et al, 2008). Odero et al evaluated 20 different weed treatment alternatives for conventional sugar beets and found that the following treatment yielded the highest net economic return: PPI treatment with Nortron (ethofumesate), followed by three micro-rate treatments of a tank mixture of Betamix (phenmedipham + desmedipham) and Nortron (ethofumesate), followed by Outlook (dimethenamid-P); with hand-hoeing following each herbicide application.

Other researchers have also found that a combination of herbicides plus hand hoeing is required to effectively control weeds in conventional sugar beets (Dexter and Luecke, 2003).

Hand-weeding is necessary in many situations; however, it is cost-prohibitive as a replacement for herbicides. USDA data shows that in 2000, conventional sugar beet growers spent an

average of $94.28/acre for all chemicals (insecticides, herbicides, fungicides, etc.) (Ali, 2004, p. 7). Five-year studies of the cost of hand-weeding sugar beet at the University of California – Davis, as reported by the California Beet Growers Association, found that the cost of hand weeding was between $260 to over $650 per acre (California Beet Growers Association, 1999, p. 29). Using the midyear of 1996 as the base year, this is equivalent to approximately $373 to $914 per acre in 2010 dollars, or approximately three to seven times what sugar beet growers spent on all chemicals. More recently, scientists in Wyoming have found that net returns for optimal herbicide application combined with hand weeding are more than twice the net returns for hand weeding alone (Odero et al, 2008, Table 4).

2.5.7 Weed control with event H7-1

In-crop applications of glyphosate can be made from crop emergence up to 30 days prior to harvest. This flexibility allows the grower a wider window of application, with the application timing based on weed pressure, not on crop stage. Typically only 2-3 post-emergence applications of glyphosate are applied with GE sugar beets (Mauch, 2010; Grant, 2010). The broad spectrum of weed control offered by glyphosate (Table 2-4) reduces the need for tank mixing with additional herbicides. However, the use of other herbicides in combination with or in sequence with glyphosate is recommended as needed under specific conditions to address select weed and/or weed resistance issues.

Monsanto's Technology Use Guide (TUG, 2010, Appendix E) provides specific weed control recommendations for event H7-1 sugar beet. The TUG recommends the use of "mechanical weed control/cultivation and/or residual herbicides" with event H7-1 sugar beets, where appropriate, and "additional herbicide modes of action/residual herbicides and/or mechanical weed control in other Roundup Ready® crops" rotated with event H7-1 (TUG, 2010, p. 40).

2.6 HERBICIDE RESISTANCE

Herbicide resistance is "the inherited ability of a plant to survive and reproduce following exposure to a dose of herbicide normally lethal to the wild type" (WSSA, 1998).

Herbicide resistance is a result of natural selection. Plants of a given species are not all identical; they are made up of "biotypes" with various genetic traits. Biotypes possess certain traits or characteristics not common to the entire population. Herbicides, that suppress or kill weeds, can exert selection pressure on weed populations. When a herbicide is applied, the plants with resistance to it, which had no special survival qualities before the herbicide was

introduced, become the survivors who are then able to reproduce and pass on their genes. With repeated application of the same herbicide and no other herbicide or weed control practice, the resistant biotype becomes the dominant biotype in that weed community. In the mid-1950s, Harper (1957) theorized that annual, repeated use of any herbicide could lead to shifts in weed species composition within a crop-weed community. Similarly, Bandeen et al. (1982) suggested that a normal variability in response to herbicides exists among plant species and tolerance can increase with repeated use of an herbicide. Indeed, as of June 27, 2010, 341 herbicide resistant weed biotypes have been reported to be resistant to 19 different herbicide modes of action (Heap, 2010). Glyphosate-resistant weeds account for 5 percent of the herbicide resistant biotypes while weeds resistant to herbicides that inhibit acetolactate synthase (ALS), such as Upbeet, account for 31 percent of the herbicide resistant biotypes. (Wilson, 2010a, p. 6).

Figure 2-3 shows the increase in herbicide resistant biotypes with time. Among the herbicides commonly used in conventional sugar beet, Assure II, Poast, and Select are ACCase inhibitors; Upbeet is an ALS inhibitor; Treflan HFP is a dinitroaniline; Stinger is a synthetic auxin, and glyphosate is a glycine. Figure 2-3 shows only the number of confirmed resistant biotypes. The total extent and distribution of resistant biotype varies widely. Details of herbicide resistant weed in sugar beets are discussed in Section 3.12.

For as long as herbicide resistance has been a known phenomenon, public sector weed scientist, private sector weed scientist and growers have been identifying methods to address the problem. For instance, when a farmer uses multiple weed control tools to achieve weed control, herbicide resistance biotypes will be controlled and the resistance biotype generally will not become the dominant biotype within a population (Gunsolus, 2002; Cole, 2010a, p. 4). By contrast, weed resistance is known to occur most rapidly in areas where there is a sole reliance on a single herbicide used repeatedly over multiple crop generations for the management of a specific weed spectrum.

When a grower encounters a biotype that is resistant to an herbicide he is using, the grower must use an alternate method of weed control. Management practices that can be used to retard the development of resistance, such as those routinely used by sugar beet growers, include herbicide mixtures, herbicide rotation, crop rotation, and increased cultivation.

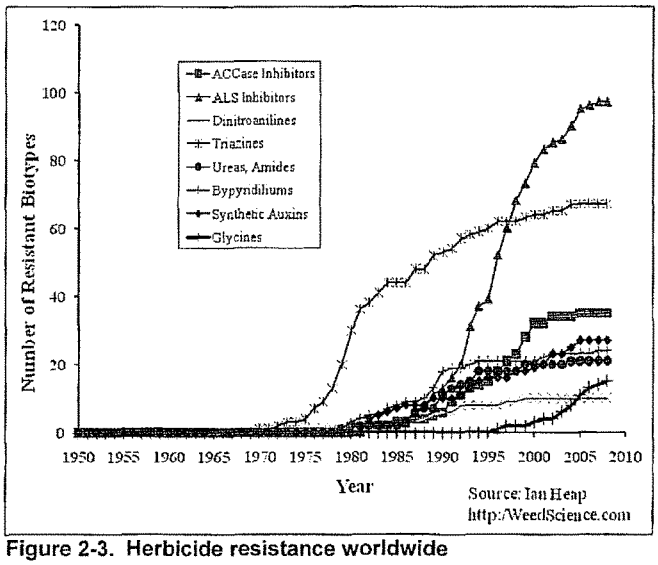

Figure 2-3. Herbicide resistance worldwide

Management practices that can be used to retard the development of resistance, such as those routinely used by sugar beet growers, include herbicide mixtures, herbicide rotation, crop rotation, and cultivation. The WSSA reports: "Weed scientists know that the best defense against weed resistance is to proactively use a combination of agronomic practices, including the judicious use of herbicides with alternative modes of action either concurrently or sequentially" (WSSA, 2010b).

2.7 SUGAR BEET SEED PRODUCTION

2.7.1 Variety development

When developing plant varieties for commercial release, plant breeders select individual plants with desirable characteristics, such as higher yields or pathogen resistance. This breeding involves transferring pollen from one source plant to fertilize another plant. Once plants with the desired traits have been selected, a population of those plants with similar characteristics are classified as varieties.

Commercial sugar beet variety development has been done exclusively by private sugar and seed companies in the US. Currently these are Crystal/ACH, Hilleshog (Syngenta), Seedex,

Betaseed (KWS) and SESVanderhave/Holly. As plant breeders continue to develop new germplasm, the identification of desirable traits (e.g., resistance to specific diseases, high sugar content, etc.) is incorporated into the development of new varieties. Due to geographic variability in weather, growing conditions, climate, insect and disease susceptibility vary from region to region, different varieties are developed for different regions. Sugar beet company selection committees in each region establish a list of approved varieties based on coded variety trials, which are designed to give an unbiased evaluation of the genetic potential of all sugar beet variety entries while other variables (stand, fertility, moisture levels, etc.) are kept constant. Growers may grow only those varieties that appear on the sugar beet company approved list for that region. Variety trials insure the use of the most productive varieties to maximize returns to the growers and sugar companies. Trials last 2 to 3 years and involve millions of plants each year.

2.7.2 Hybrids and cytoplasmic male sterility

To produce seed for commercial planting of the chosen variety, some crops, such as cotton and soybeans, rely on the same individual plant to serve as the female (pollen acceptor) and male (pollen donor) to produce seed. Other crops, such as corn and sugar beet, rely on two different varieties, called inbreds, to produce hybrid seed that carries traits from both parent lines. Hybrid varieties typically exhibit greater vigor than the parent lines on which they are based, resulting in plants with higher yields, better resistance to stress, and other desirable traits.

Once a biotech plant such as event H7-1 has been developed, researchers will use that plant to breed the biotech trait to other varieties. In breeding sugar beet varieties for future commercial production, the biotech trait could be maintained on either the male or female plants. For greater breeding flexibility and efficiency in producing new varieties, plant breeders may prefer to breed additional varieties by introducing the biotech trait on male pollinator population of plants and use those plants to fertilize the same male-sterile female plants (Skaracis and De Biaggi, 2005). If the biotech trait is only on the female (male sterile) plant with CMS, as discussed below, that trait cannot be transferred to other plants in order to breed new inbreds. In hybrid sugar beet seed production, although each plant flower contains both male (the anther) and female (the stigma) parts, individual plants can be made female-only, or male sterile. Male sterility results in the failure of plants to produce functional anther, pollen or male gametes (Hovland, 2010, p. 2). In order for seed multiplication of the male sterile or female plant to occur, plant breeders develop a partner line ("O-Type") which is genetically identical to its equivalent male sterile or female line with the exception of its ability to produce pollen. This

identical O-Type is then used as the pollinator (male plant) to pollinate the female plant, resulting in offspring that will again be male sterile and not produce pollen. This seed, after meeting quality criteria relative to any impurities, is then used as the male sterile or female basic seed in the commercial seed production fields. This system is known as Cytoplasmic Male Sterility (CMS). It is the system used in many other crops to develop male sterile or female basic seed lines that do not produce pollen. Using female-only plants in seed production ensures that the hybrid seed harvested from those plants will be a cross between the two parent lines. Male and female lines are planted in alternating strips in a sugar beet seed production field, typically with two to four times as many female rows as male rows to maximize the amount of seed collected (Hoffman, 2010a, p.5). Often stecklings (small transplants) are used for the male lines. After pollination occurs, the male plants are destroyed (Holly Hybrids, 2007). Only very rarely would a CMS fertile plant produce pollen and such plants can be identified and rogued.

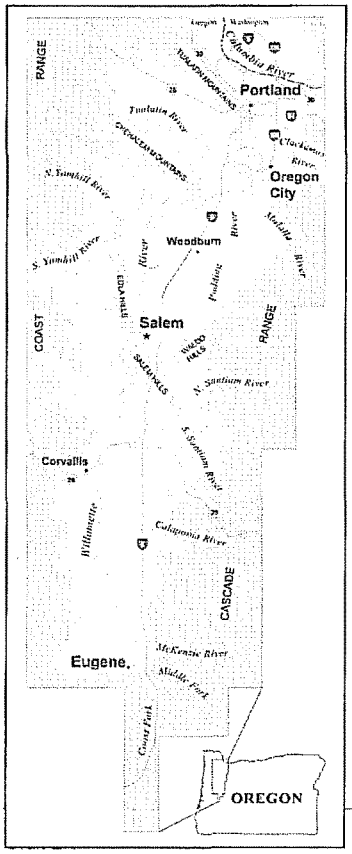

Figure 2-4. Willamette Valley
Source: Givler and Wells, 2001

One producer reports identifying only two pollen-producing plants within a crop of over eleven million total plants (Anfinrud deposition, 2010, 178).

In the Willamette Valley, 78.6% of the 2009-2010 seed crop were grown with the glyphosate-tolerant trait on the female inbred. These female inbreds are male sterile because of the CMS trait and thus are bred not to produce pollen. (Preliminary Injunction Hearing, March 5, 2010, pgs. 17-18; 25). Therefore, the risk of transferring the glyphosate-tolerant trait to other plants from these seed production fields is negligible or zero.

2.7.3 Commercial sugar beet seed production

Willamette Valley

At least ninety-five percent of the Oregon sugar beet seed production (equal to 70% or more of the total US

production), is in the Willamette Valley, located between the Coast Range and the Cascade Range (Figure 2-4 at left) (Stankiewicz Gabel, 2010, p. 7). The valley is over 100 miles long. The climate is cool enough for winter vernalization (prolonged exposure to a minimum cool temperature for a prolonged period of time that enables the plant to flower) but warm enough for the roots to live through the winter. Summers are very dry, producing ideal conditions for seed harvesting. While sugar beet is normally a biennial plant, conditions in the valley are such that seed can be produced in one year rather than two. Sugar beet seeds are planted in August or September and vernalize over the winter. The following spring, the plant produces a seed stalk (bolt). Seeds are harvested in late July to August. One seed company, Betaseed, grows the basic and commercial seed for its varieties at the southern and southeastern fringes of the Willamette Valley.. Syngenta develops its varieties elsewhere, and then ships the basic seed to West Coast Beet Seed Company (WCBS) for the commercial production. SESVanderHave develops its varieties both in the Willamette Valley and elsewhere, and ships basic seed produced elsewhere to West Coast Beet Seed Company (WCBS) for seed production. WCBS is jointly owned by a group of sugar beet seed and sugar companies.

With its unique growing conditions, the Willamette Valley is used for seed production for many different kinds of seeds. In addition to seeds, many vegetables are also grown in the valley. It is a major area for production of "most temperate vegetables, herbs and vegetable seeds" (Mansour, 1999). Because high quality and seed purity are important to many growers, and because the valley is the site of varied seed production, sugar beet seed production companies have worked cooperatively to develop and implement protocols to maintain seed purity and quality. Most seed companies, including both WCBS and Betaseed, belong to the Willamette Valley Specialty Seed Association (WVSSA) and follow the guidelines for isolation and minimum separation distances between fields (Appendix A).

WCBS and Betaseed have developed explicit standard operating procedures and grower guidelines that are intended to minimize and/or eliminate the possibility of inadvertent seed mixing (Appendix B).

Maintaining the integrity of seeds

Currently, the WVSSA implements pinning procedures and isolation guidelines for seed production within the Willamette Valley. Pinning procedures identify the geographic location of production fields by placing pins and flags on a map. This is used to establish isolation distances between seed production fields. Additionally, WCBS and Betaseed have instituted

protocols and management practices to further maintain the integrity of seed which are essentially the same as required by Item 4 of the interim measures (Section 1.1.3). Seed production and quality control are a significant cost, to seed companies, and these companies within the Willamette Valley and throughout seed production areas carefully control growing conditions and production practices to ensure that seed is pure and of high quality – despite the fact that quality control in seed production carries significant cost.

WCBS Seed Production. WCBS currently produces much of the sugar beet seed for some of the sugar beet seed companies.. WCBS obtains basic seed from these sugar beet companies to further increase these small seed volumes into larger commercial quantities. Management of these fields and planting locations is controlled utilizing a tracking and tracing system distinguishing seed lots from the moment of initial delivery of seed, designated for seed production, to WCBS throughout the subsequent planting and harvest. This management further continues until the delivery of the finished packaged seed to the customer. Some companies further incorporate various computerized and digital tracking systems designed to manage real-time seed batch movement and quality testing. Many of these companies have sealed packaging and specified color coding designations to further identify seed batches/lots. (Meier, 2010, p. 3). Similarly, other companies ship event H7-1 sugar beet seed in packages accompanied by a declarations document that states the event H7-1 status of the basic seed (Anfinrud, 2010, p. 2).

WCBS contracts to individual growers for seed production. WCBS prohibits production of a red beet or Swiss chard seed crop by any WCBS grower in a year in which that grower is producing sugar beet seed, whether genetically engineered (GE) or conventional. WCBS also prohibits the sharing of planting, cultivation and harvesting equipment for red beet/Swiss chard and sugar beet seed, whether they are producing GE or conventional sugar beet seed (Loberg, 2010, p. 2; also in Appendix B of this ER[27]). In addition, WCBS requires its growers, by contract, to adhere to minimum isolation distance within a three mile radius of any GT field (Appendix B).

WCBS maintains control of all material, whether GE or conventional, from point of origin to return of the seed to the seed company (Appendix B). This includes control of the disposal of any excess GE stecklings that are not used for seed production. When those stecklings are not used for seed production and remain in the nursery field, such stecklings are uprooted and

[27] These requirements are in the Appendix B WCBS protocol, under the heading "GM Grower Guidelines." While the title is "guidelines," the protocol is clear that these restrictions are included in WCBS contracts with growers.

mixed into the soil during tillage for soil preparation for the next crop. Destruction occurs with this tillage and is followed by chemical control in the subsequent crop. Stecklings that are removed from the nursery, but are not used, are destroyed or securely disposed. The prevailing method is returning unused stecklings to the nursery field of origin and subsequent destruction through standard agricultural practices (physical destruction with tillage and chemical destruction in the subsequent crop) (Loberg, 2010, p 2; and Appendix B of this ER).

Precleaning of seed at WCBS for shipment to the seed development company takes place in the dedicated WCBS facility. This process removes sticks, chaff, weeds and the like that may be contained in the seed when initially harvested. Because WCBS does not handle red beet or Swiss chard seed, its seed precleaning operations present no opportunity for mechanical mixing of sugar beet seed, whether conventional or GE, with red beet or Swiss chard seed. In years when WCBS produces both GE and conventional sugar beet seed, physical separation requirements and cleaning protocols protect against inadvertent mixing. In 2009, only two growers produced conventional seed for WCBS. All of this conventional seed was pre-cleaned at the end of the season, after completion of the pre-cleaning of the event H7-1 seed and after complete cleaning of the equipment.

After the pre-cleaning, WCBS returns the seeds to the seed development company in sealed containers with color-coded labeling and shipping documents, which are checked upon arrival at seed processing facilities. Syngenta, for example, marks each container with a computer-generated and tracked batch number (Meier, 2010). SESVanderHave labels its event H7-1 seed with an orange triangle. (Anfinrud, 2010, at p. 3).

Betaseed seed production. Betaseed performs its own basic seed production, and like WCBS, it contracts commercial seed production to individual growers. Betaseed has adopted standard operating procedures (SOPs) that require all materials to be adequately identified and tracked through a computerized, bar-coded system from basic seed production to commercial seed production to final processing and shipping. All Betaseed personnel involved in seed production are trained in the SOPs and required to sign an acknowledgement that they have read, understood, and will comply with the SOPs (Lehner, 2010, p. 10).

Betaseed supervises its commercial seed growers' practices for conformance with Betaseed's stewardship requirements. Betaseed's grower contracts provide for such supervision, as well as Betaseed's right to enter the grower's fields and take remedial action if the grower does not

comply with Betaseed's instructions. Betaseed pins all of its commercial seed fields in compliance with the WVSSA's pinning rules to ensure that isolation distance guidelines are followed. In addition, Betaseed requires its growers, by contract, to adhere to isolation distances of four miles from other crops that may cross-pollinate with sugar beets.. Betaseed also requires growers to clean their equipment before and after harvesting a sugar beet variety, and to monitor for and eliminate volunteer sugar beets. According to the SOPs, Betaseed personnel are present for the beginning of every harvest by a commercial grower. Betaseed provides bar-coded tote boxes into which the harvested seed is placed for transport to Betaseed's processing facility (Lehner, 2010, pp. 3-5).

Betaseed performs "grow-outs" each year in which it plants samples of its commercial seed lots to ensure that the seed produces the expected variety of plant. Betaseed's grow-out observation plot did not produce any off-types this year (Lehner, 2010, p. 3).

Syngenta seed processing. Syngenta processes sugar beet seed in its facility in Longmont, Colorado that is used only for sugar beet processing; a small percentage of the seed is processed by third party seed vendors in separate facilities dedicated to sugar beet processing (facilities where no red beets or Swiss chard seeds are processed). Processing of seed requires seven months and involves polishing, sorting by size, pelleting, treatment with fungicides and insecticides required by certain customers, coloring, packaging and shipping to growers in sealed packages. Syngenta maintains an extensive tracking and tracing system for every seed lot. This system includes a visual color identification of all RRSB material; a computerized, real-time record of seed batch movement, periodic germination and genetic identity testing; and extensive employee training. Syngenta also uses cleaning protocols to prevent any inadvertent mixing of RRSB and conventional sugar beet seed during processing. The cleaning process requires the removal of all RRSB seeds from the equipment and the plant floor. "Chase" seed is used to ensure that all GT seed has been removed from the equipment (Meier, 2010). with color-coded labels (Meier, 2010).

SESVanderHave seed processing, storage, treating, packaging, warehousing, transportation and distribution. Neither SESVanderHave, its growers nor its contractors are involved in any respect in chard or red beet breeding, production or processing. SESVanderHave's GE protocols require that conventional seed and event H7-1 seed are never handled or processed at the same time. For example, SESVanderHave does not allow its

processing contractors to process conventional seed at the same time that they are processing event H7-1 seed. (Anfinrud, 2010, p. 3).

SESVanderHave receiving/storage of unprocessed seed protocols. SESVanderHave has additional GE protocols that apply to unprocessed seed shipped from West Coast Beet Seed. All event H7-1 seed products are identified upon arrival at bulk storage facilities. Shipping documents from West Coast Beet Seed are used to double check the seeds that arrive in Sheridan, Wyoming facilities. Also, proper disposal of reject or spilled seed is established by variety, lot and size. Product is unloaded only after insuring that storage bins and label bins have appropriate markings (event H7-1 products are labeled with an orange triangle). (Anfinrud, 2010, p. 3).

SESVanderHave seed processing/storage protocols. Seed processed on behalf of SESVanderHave by third parties are subject to contractual arrangements that require compliance by processing contractors with SESVanderHave's GE protocols designed to prevent mixing of event H7-1 seed with other seeds during the various processing, treating, packaging, warehousing, transportation and distribution stages. Before dumping seed into the seed processing line, necessary equipment (conveyors, legs, distributors, storage bins) is cleaned. Product is unloaded only after insuring that storage bins have appropriate markings (event H7-1 products are labeled with an orange triangle). A key lock and appropriate label is placed on each bin discharge slide. Once product is in storage bins, the tops of bins are sealed by tinning pipe. If necessary, unloading equipment is cleaned and seed is disposed of in proper manner followed by a documented inspection. Bins with event H7-1 products are labeled with an orange triangle. Processed seed is placed into properly labeled storage totes and clean-down procedures are followed between seed lots. Rejected seed is disposed in a local landfill. All event H7-1 seed totes are labeled with an orange triangle. Totes are then transferred to the warehouse and put in inventory by variety, lot number, warehouse and slot. (Anfinrud, 2010, p. 3).

SESVanderHave treating and packaging protocols. Product to be primed, pelleted, treated and packaged is identified. When event H7-1 seed enters any facility under contract with SESVanderHave, the necessary equipment (legs, distributors, blending system, Delta screen, treater, conveyors, aspirators, and bagging scale) is thoroughly cleaned before the product is introduced. All processes require documentation of weights introduced and weights after contract processing is complete. All contractors have been audited by SESVanderHave

personnel to assure compliance with GE protocols. Final packaging of event H7-1 seed is done in approved packages with proper labels. Packaged seed is transferred to the warehouse and put on inventory by variety, lot, treatment, warehouse, and slot. When treating of event H7-1 seed is completed, if necessary, all treating/packaging equipment is cleaned following clean-down procedures. Reject seed is disposed of in an appropriate manner. (Anfinrud, 2010, p. 4).

SESVanderHave warehousing, transportation and distribution protocols. Seed to be shipped is identified by printing delivery orders that identify event H7-1 seed. Warehouse crews stage loads. Each pallet of event H7-1 seed is identified with a cover sheet. Any broken bags during transportation are recovered and returned to the originator for proper repair or disposal. Drivers are informed that event H7-1 seed is present on loads. Sales and marketing personnel confirm that event H7-1 seed shipments are to approved customer locations (Anfinrud, 2010, p. 4).

SESVanderHave Auditing of Compliance with GE Protocols. SESVanderHave audits its contractors' compliance with its GE protocols as well as its own compliance to assure that SESVanderHave's standards of stewardship are maintained. SESVanderHave employees as well as outside consultants have worked on the audits, which have covered production, storage, processing, priming, pelleting, coating, packaging, handling, shipping and distribution of event H7-1 sugar beet seed. (Anfinrud, 2010, p. 4).

Betaseed seed processing. Betaseed processes and packages its own seed for distribution. Betaseed does not produce or process seed of any *Beta* species other than sugar beets, so there is no potential for mixing of GE seed with seed of any other *Beta* species in Betaseed's processing facility (Peters, 2010, p. 2).

Betaseed employs a computerized tracking system to ensure that all of its varieties of seed are kept separate as they are processed. All processing steps are recorded and auditable. Every box of seed that is processed is accompanied by both a human readable label and a bar-code containing information about the seed, including whether it is GE or conventional. Seed cannot be loaded into Betaseed's processing equipment until the bar-code accompanying the seed has been scanned and the seed is determined to be of the intended variety. In the last two seasons, Betaseed has only processed one variety of conventional seed (and only a single lot of this variety in the last season). To avoid the possibility of any mixing of GE seed with the conventional variety, Betaseed processed its conventional seed before processing any of its GE seed. Betaseed thoroughly cleans its entire processing system before and after processing conventional seed (Peters, 2010, pp. 2-4).

Betaseed also conducts bioassay tests on each lot of seed at least twice as the seed is processed through its plant to ensure that lots of GM varieties are glyphosate resistant and that conventional varieties do not contain GM seeds (Peters, 2010, p. 4).

2.8 RED TABLE BEET, SWISS CHARD, AND SPINACH BEET PRODUCTION

2.8.1 Vegetable beet production

In the USDA database, "beets" include red table beets, Swiss chard, and spinach beets (grown for the leaves). In the following discussion, these products are referred to as "vegetable beets." In 2007, the most recent year for which published data are available, 8,412 acres of beets were harvested in the US, on 2,744 farms, for an average of three acres per farm. Approximately 63 percent of the acreage was for processed beets, and the rest for the fresh market (USDA NASS, 2010b). The total value of vegetable beet production in 1999, the most recent year for which USDA has data available, was approximately $7 million. Based on the most recent year for which USDA has both harvested acreage and production value data (1997), the average value of vegetable beet production per acre was approximately $720, which would be roughly $1,000 in 2010, adjusted for inflation (USDA NASS, 2010b).

There is little overlap between areas of major vegetable beet production and sugar beet root production. Over half the 2007 acreage of vegetable beets (59 percent) was in two states, New York and Wisconsin, where sugar beets are not grown. California harvested 979 acres of vegetable beets in 2007. All California counties with five or more harvested acres reported are coastal. [28] Sugar beets are grown only Imperial County in California. Oregon harvested 425 acres of vegetable beets, but no vegetable beet production was reported in the two Oregon counties with sugar beet root crops; however, some vegetable beet crops are grown in the Willamette Valley. One county in Colorado (Larimer), and one county in Michigan (Lapeer), reported both sugar beet and vegetable beet harvests. No more than 7 acres of vegetable beets were harvested in any single Minnesota county. Harvested vegetable beet acreage for all other sugar beet producing states in 2007 was ten acres or less each (Montana, Idaho, Nebraska, North Dakota, and Wyoming) (USDA NASS, 2010b). Although there is little overlap in major production areas, based on USDA FSA (Farm Service Agency) data, vegetable beet crops and sugar beet crops can sometimes be found growing in adjacent fields (Stankiewicz Gabel, 2010, p. 8).

[28] These results, which don't distinguish between organic and conventional, are not completely consistent with the State of California organic results discussed in Section 2.4.3, probably because of variations in the database of growers reporting.

2.8.2 Red table beet and Swiss chard seed production

The most comprehensive data currently available for red table beet and Swiss chard seed production is from the FSA, however, the FSA does not distinguish between organic and conventional. Also, FSA does not include leaf beet seed production, which is apparently minor. According to data from the USDA FSA, red table beet seed in 2009 was grown on approximately 1,130 acres, with 92% grown in Washington State, 7% in Oregon and 1% in California; and Swiss chard seed in 2009 was grown on approximately 166 acres, with 51% grown in Washington State and 49% in California. Based on FSA data, there are no counties where both Swiss chard and table beet seed are grown, and only one county, in the Willamette Valley, where both sugar beet seed and table beet seed are grown. In that county the FSA data lists only two table beet seed fields. The total FSA-reported red table beet seed production in Oregon is approximately 79 acres (Stankiewicz Gabel, 2010, p. 7). There is also minor Swiss chard seed production in Oregon.

Based on older USDA published data, ninety-five percent of US red table beet seed production (650 to 700 acres) occurs within the small-seeded vegetable seed production area of western Washington State that includes Skagit, Island and Snohomish counties (See Figure 2-1 for locations) (Foss, 2007). These data do not exactly match the FSA data because they are for different years, and planting practices change from year to year.

Neither sugar beet root crops nor sugar beet seed crops are grown in the part of western Washington where the majority of the US red table beet and Swiss chard seed production occurs. Very little sugar beet root crop is produced in Washington State; the nearest processing facility is far to the south, in southern Idaho. In 2008, only one county, Benton reported sugar beet production (1,600 acres) (USDA NASS, 2010b). Benton County is in the Columbia Basin on the east side of the Cascade Range. There is no reported production of *Beta* seeds other than minor sugar beet in the Columbia Basin.

Due the extreme distance of this sugar beet production area from the Idaho processing facility, it is very unlikely that anyone would consider growing west of the Cascade range, in the area of other *Beta* production. As set forth in Section 2.3.2, transportation costs and proximity to a processing facility are key limiting factors in where to grow sugar beets.

The locations of red table beet and Swiss chard seed production in California are not known, but sugar beet root crops are grown only in the Imperial Valley, and these are conventional sugar beets.

As discussed in Section 2.7.3, the majority of the US sugar beet seed production occurs in the Willamette Valley where seed production for the various beet products (sugar beet, table beet and chard) is divided along geographical lines. Sugar beet seed is grown in the southern and central portions of the valley, table beet seed is grown in the northern region, and Swiss chard seed is grown at the margins.[29] The total estimated red table beet and Swiss chard seed production in the Willamette Valley in 2010 is 100 to 120 acres (McReynolds, 2010). Based on the FSA data, this appears to be all or virtually all of red table beet and Swiss chard seed production in Oregon.

Commercial seed production for red table beet is similar to that for sugar beet. Seed companies retain ownership of the seed, the growing crop, and the harvested seed. Growers produce and harvest the crop, and are then paid the contract price if the resulting seed meets contract quality criteria, typically an 85 percent seed germination rate and 99 percent purity (Foss, 2007).

Typically, the red table beet crop is planted in seed beds in mid-June. Plants not displaying true varietal characteristics are removed by hand. In October, the beets are topped mechanically, dug, placed in windrows, and covered with about one foot of soil to protect the roots against freezing during the winter. In March or early April, the over-wintered roots (stecklings), are removed from the windrows and brought to Skagit County for transplanting into production fields. Exposure of the roots to the winter season in windrows, followed by transplanting into fields in the spring, vernalizes the stecklings. Seed harvest occurs in late summer and early fall (August to September). The crop is cut, placed in windrows, dried 10 to 14 days in the field, and then threshed mechanically to capture the seed (Foss, 2007).

No information for Swiss chard seed production practices was found.

[29] Morton, 2010, p. 149:24-150:20.

2.8.3 Organic Red Table Beet and Swiss Chard Production

California is the only state for which organic red table beet and Swiss chard production data are publicly available. In USDA's reports, red table beets and Swiss chard are included in the "other vegetable" organic category. California accounts for 76 percent of "other" organic vegetable production within the sugar-beet producing states, and there is very little or no organic production of red table beets, Swiss chard, or leaf beets in the four major sugar beet production states (MN, ND, MI and ID) (Figure 2-5) (USDA, 2010c). The 2007 acreage and dollar value of organic red table beets and Swiss chard in California are shown in Figures 2-6 through 2-9. No data were found for organic seed production of red table beets, Swiss chard or spinach beets.

2.9 NATIVE AND UNCULTIVATED NON-NATIVE BEETS

Plants that are native to a particular area or ecosystem are those that are not introduced by humans, but occur at those locations without human intervention.

Non-native beets fall into one of three categories: wild plants, weeds and feral beets. Non-native wild beets are those that that were never cultivated, and grow on their own outside of an agricultural/horticultural setting. Weeds, discussed in Section 2.5, included unwanted plants in an agricultural/horticultural setting. Feral beets are those that were originally domesticated, but have escaped cultivation and grow on their own.

2.9.1 Native beets

No native members of the genus *Beta* are found in North America (USDA, 2010a; Mansfeld, 1986, as reported in OECD, 2001, Table 3). Thus, all of the *Beta* species in North America, both cultivated and uncultivated, were introduced through human intervention from outside the continent.

2.9.2 Uncultivated wild beets in the US

Beta species in the US and potential for hybridization with sugar beet

The USDA reports two *Beta* species in the US: *Beta procumbens* and *Beta vulgaris*. Some researchers (e.g., Bartsch and Ellstrand, 1999; Bartsch et al, 2003) consider *Beta macrocarpa* as a separate species; however, USDA ARS reports that the designation was changed in 2000 to *B. vulgaris ssp. macrocarpa* (USDA/ARS, 2010a). *B. procumbens* can be artificially crossed with sugar beet (a *B. vulgaris* subspecies), but the plants usually die at the seedling stage (OECD, 2001, p. 25). In any case, *B. procumbus* in the US has been identified only in Pennsylvania, where sugar beet is not grown (USDA ARS, 2010a). Sugar beet hybridizes with all *B. vulgaris* subspecies, including *B. vulgaris ssp. macrocarpa*. The hybrids are all annuals, flowering in the first year and producing little or no root or sugar yield (Messéan et al, 2009, p. 49).

***B. macrocarpa* (or *B. vulgaris ssp. macrocarpa*).** There is some scientific disagreement about the compatibility of sugar beet and *B. vulgaris ssp. macrocarpa* (referred to hereafter as *B. macrocarpa*, the terminology in all sources except USDA/ARS 2010a). OECD reports that *B. vulgaris* and *B. macrocarpa* are fully compatible and the resulting hybrids are vigorous and fertile (OECD, 2001, p. 24). In contrast, Dr. R.T. Lewellen, a USDA, ARS geneticist who has worked with sugar beet at the USDA/ARS Salinas Research Station for many years has done

research on *B. macrocarpa* and has concluded that it does not outcross readily to sugar beet. This is because *B. macrocarpa* usually bolts and flowers too early to cause a risk of hybridization with sugar beet. Additionally, any hybrid of sugar beet and *B. macrocarpa* would possess several genetic factors that pose a challenge to the plants' survival in nature. For example, the hybrid would be mostly pollen sterile and would have disturbed genetic ratios and growth habit. Finally, because *B. macrocarpa* is self-fertile, a cross could only be made with sugar beet by using self-sterile or male sterile sugar beet plants – something which is unlikely to occur in nature (Panella, 2003).

Other researchers have also found that hybridization between *B. macrocarpa* and sugar beet is relatively rare because the flowering times usually do not overlap (Bartsch et al, 2003, p. 108; McFarlane, 1975 as reported in OECD, 2001, p. 24). In addition, based on genetic studies, Bartsch and Ellstrand (1999) report a "strong genetic differentiation between *B. vulgaris* and *B. macrocarpa*, which supports the notion that the latter is a separate species" and find it "remarkable" that hybridization between the two "is still possible" (pp. 1126 and 1129).

Sugar beets have been grown in the Imperial Valley since 1932 (Spreckels Sugar, 2009). As noted above, the earliest dated collected *Beta* specimen is from 1938; however, Bartch and Ellstrand reference observations of uncultivated wild beets in the Imperial Valley from 1928 (Bartsch and Ellstrand, 1999, p. 1126). When Bartsch and Ellstrand did their research in 1998 and found evidence of introgression between *B. macrocarpa* and *B. vulgaris* in two percent of the *B. macrocarpa* tested, sugar beets had been grown in the Imperial Valley for 66 years.

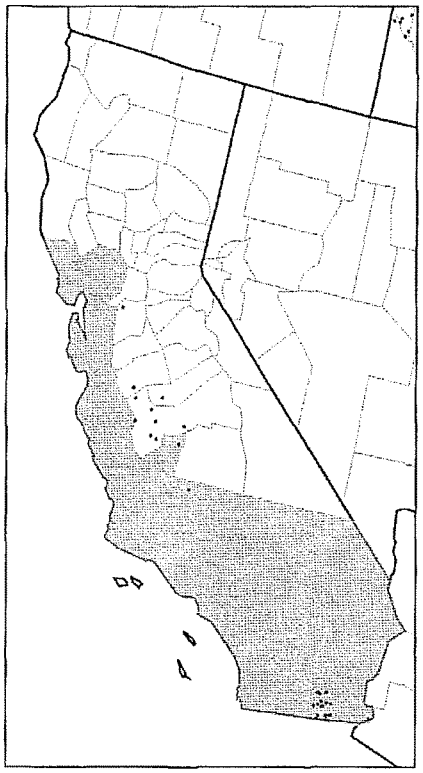

Figure 2-10. All CA counties with *beta* records
Source: Consortium of California Herbaria, 2008

Uncultivated wild beets in California

The USDA/ARS has 13 *B. vulgaris var. maritima*[30] and 7 *B. vulgaris ssp. macrocarpa* collected specimens in its National Plant Germoplasm System, all donated in 1985 by J.S. McFarlane of the USDA ARS Salinas, California office. The two *B. vulgaris ssp. macrocarpa* samples with collection information included were both from the Imperial Valley; one was collected from a sugar beet field in 1968; collection information for the other was not noted (USDA/ARS, 2010a). The Consortium of California, which keeps a database of 16 herbaria (collections of plant specimens) throughout the state, documents 172 *Beta* accessions from 15 counties, collected between 1896 and 2006 (counties show in Figure 2-10 at left) (Consortium of California Herbaria, 2008).

Forty of the specimens are designated *B. macrocarpa*, 19 as *B. vulgaris ssp. maritima*, one simply as *Beta*, and the rest are designated *B. vulgaris*. Seventeen of the accessions are from Imperial County: 14 of these are designated *B. macrocarpa*, one is designated *B. vulgaris*, and one was originally identified as *vulgaris* and later corrected to *macrocarpa*. Imperial County collection dates ranged from 1938 to 1998 (Consortium of California Herberia, 2008). Calflora's database includes herberbia records, plus other documented or recorded observations. California counties with records of *B. vulgaris* or *B. macrocarpa* are shown in Figure 2-12, along with sugar beet production areas (shown as blue dots).

[30] Specimens were originally identified as *Beta vulgaris ssp. maritima*

There have been a number of hypotheses regarding the origin of the California uncultivated wild beets, including that at least some of them are wild (feral) sugar beets (Johnson and Burtch, 1959, as referenced in Bartsch and Ellstrand, 1999, p. 1120). However, based on genetic analysis, Bartsch and Ellstrand (1999) concluded that the uncultivated wild beets in California have two independent and primary genetic origins, one from European *B. macrocarpa* (the uncultivated wild beets found in the Imperial Valley and on the Channel Islands) and one from European *B. vulgaris* (beets from all other areas in California where uncultivated wild beets are found). They found that what they termed the *B. macrocarpa* of the Imperial Valley and the Channel Islands were, with the exception of one population, "genetically identical with a Spanish *B. macrocarpa* from the Mediterranean area of Cartagena" (Bartsch and Ellstrand, 1999, p. 1126). The singe exception was a population in the Imperial Valley of *B. macrocarpa* that showed genetic similarities with *B. vulgaris*, which led them to conclude that the sugar beet (a subspecies of *B. vulgaris*) had introgressed with *B. macrocarpa* (Bartsch and Ellstrand, p. 1126). Bartsch and Ellstrand concluded that the other uncultivated wild beets in California are descended from cultivated Swiss chard and red table beets, European sea beets, and hybridized populations among these (Bartsch and Ellstrand, 1999, p. 1128).

Uncultivated beets in other sugar beet seed or root production regions

One record for uncultivated *B. vulgaris* was found for Oregon: a specimen collected in 1998 from Corvallis in Benton County, by Andrew A. Duncan (Rice, 2010). Two records for uncultivated *B. vulgaris* were found in Michigan, one of which was in Tuscola County, which is in the Great Lakes Region of sugar beet production (USDA 2010a). USDA shows five counties in western Montana with *B. vulgaris* records (Madison, Gallatin, Ravilli, Missoula, Pondera and Cascade), based on Booth and Wright's 1996 *Flora of Montana* (USDA 2010a). None of these counties are in that part of Montana included in the Great Plains Region of sugar beet production (Figure 2-2). In addition, Rice (2010), a more updated source, shows no *Beta* records for Montana (2010). While there is widespread information about uncultivated beets in California, no other information was found other than that summarized here for uncultivated beets in any other sugar beet seed or root production areas. Since these records indicate only "*B. vulgaris*" it is not possible to determine from the information whether these plants are sugar beets or some other subspecies.

In addition, USDA has previously concluded that *BetaB. vulgaris* only poses a weed issue for sugar beet crops in the Imperial Valley of California (USDA APHIS, 2005).

DEFINITIONS

Ecosystem *– the complex of a community of organisms and its environment.*

Species *– group of organisms all of which have a high degree of physical and genetic similarity, generally interbreed only among themselves, and show persistent differences from members of allied groups of organisms.*

Introduction *- intentional or unintentional escape, release, dissemination, or placement of a species into an ecosystem as a result of human activity.*

Native species *- with respect to a particular ecosystem, a species that, other than as a result of an introduction, historically occurred or occurs in that ecosystem.*

Alien species *– with respect to a particular ecosystem, any species, including its seeds, eggs, spores or other biological material capable of propagating that species, that is not native to that ecosystem.*

Invasive species *- alien species whose introduction does or is likely to cause economic damage or environmental harm or harm to human health.*

Invasive plants *– introduced species that can thrive in areas beyond their natural range of dispersal. These plants are characteristically adaptable, aggressive, and have a high reproductive capacity. Their vigor combined with a lack of natural enemies often leads to outbreak problems.*

Sources: Executive Order 13112 – Invasive Species (1999); USDA National Agricultural Library, 2010.

2.9.3 Weed beets

Beets (genus *Beta*) generally are not weeds: there are no *Beta* species included in the Weed Science Society of America's (WSSA) list of 3,488 weeds (2010a). No *Beta* species are included among the 1,553 weeds in the USDA database of invasive and noxious weeds (USDA, 2010b).

Weed beets in European sugar beet production

We discuss the problem of weed beets in European production fields because it is a concern in Europe and may raise questions about whether the same issues may occur in the US, and, if so, what impact the use of event H7-1 sugar beet would have. Weed beets have been a serious problem in European sugar beet production since the 1970s (May, 2001; Desplanque et al, 2002; Ellstrand, 2003). In 2000, some sugar beet fields in the EU were growing more weeds than beets (Ellstrand, 2003). Weeds of the same or closely related species as the crop can present special problems. Their seeds and young plants may be indistinguishable, and they will have very similar responses to herbicides. Unlike sugar beets, the weed beets flower in the first year, and produce many seeds. Because they are the same species, any herbicide that is effective on the weed beet will also damage or destroy the sugar beet. Thus, the weed beets must be manually removed, and the grower often does not find that the weed beets are not sugar beets until they bolt. The weed beets form a seed bank that can persist for years. While weed beets and native sea beets grow in many parts of Europe, the weed beets in the production fields apparently do not originate from weeds near the production fields. In the 1990s, the

problem was traced to hybridization of weed beets with the sugar beets grown in seed production areas (Ellstrand, 2003, p. 70-73). Sugar beet and sea beet (*B. vulgaris ssp. maritima*) hybridize freely and the resulting progeny are fully fertile. Sugar beet and sea beet also share a common flowering period. Sugar beets are grown in many parts of Europe, but seed production occurs mainly in the temperate climate regions of southwest France and northeast Italy, where weed beets are also present (Bartsch et al, 2003).

While the sugar beets and weed beets introgress with each other, and the weed beets and the native sea beets that grow along much of the Atlantic European and the Mediterranean also introgress with each other, in a century of sugar beet production, gene flow from sugar beets has not altered the genetic diversity of wild sea beets in the region, including in the seed production areas (Bartsch et al, 2003).

Weed beets in the Imperial Valley

In the US, the only reports of weed beets as a problem have been in sugar beet production in the Imperial Valley (Lewellen et al, 2003; Bartsch et al, 2003; Lilleboe, 2009). The weed beet situation in the Imperial Valley is very different from that in Europe. The weed beets in Europe originated from seed production fields, where the sugar beet plants and nearby wild beets all flower at the same time, and the resulting hybrids apparently contaminated the seed supply. Thus, the European weed beets in sugar beet root production fields originated from the inadvertent planting of the weed beet seeds along with the sugar beet seeds. In the Imperial Valley, the weed beets are *B. macrocarpa*, which were present in the Imperial Valley before the introduction of sugar beets, and have coexisted with sugar beets since 1938 with very little hybridization (Bartsch and Ellstrand, 1999; Bartsch et al, 2003).

2.9.4 Feral crops

Based on available data, de-domestication has occurred in only a few crops. These feral crops are of minor importance compared with other weeds (Gressel, 2005). In North America, the feral plants that cause much of the economic damage are imported horticultural plants; for example, Japanese privet (*Ligustrum japonicum*), Japanese honeysuckle (*Lonicera japonica*) and kudzu (*Pueraria lobata*) (Gressel, 2005).

Scientists from Oregon State University report that there are no feral sugar beet crops in the US (Mallory-Smith and Zapiola, 2008, Table 1). As discussed in Section 2.5.3, in California, the only sugar beet growing state with documented beet populations (as opposed to the isolated

reports from a few other locations), genetic assessment of uncultivated wild beets has not supported the conclusion that any of these beets are feral crops.

Based on this information, and the poor competitive characteristics of sugar beets, we have concluded that the existence of feral sugar beet crops in the US is unlikely, and any that might exist are negligible.

2.10 FOOD AND FEED USES OF SUGAR BEET

In addition to producing granulated sugar, sugar beet processing facilities produce a co-product known as dried beet pulp. Pulp is the dried fiber residue left after most of the sugar has been extracted from the sliced beets. Dried beet pulp is typically sold as either a shred (with or without molasses added) or in pellet form for animal feed. Beet molasses is produced in quantities ranging from 4 percent to 5 percent of the weight of the beets and contains about 50 percent sugar. Beet molasses is used for production of yeast, chemicals and pharmaceuticals, as well as in the production of mixed cattle feeds (Southern Minnesota Beet Sugar Cooperative, 2010a).

Multiple countries that regulate the importation of biotechnology-derived crops and derived products have granted regulatory approval to event H7-1 sugar beets for food and feed uses, including Japan, Canada, Mexico, European Union, South Korea, Australia, New Zealand, China, Colombia, Russian Federation, Singapore, and the Philippines (FSANZ, 2005; Monsanto/KWS 2007; Berg 2010). Canada and Japan have also approved event H7-1 sugar beets for cultivation in those countries (Sato, 2008; CFIA, 2005).

2.11 PHYSICAL AND BIOLOGICAL ISSUES

The affected environment for land use, air quality, water quality, ecology, threatened and endangered species, and other sensitive wildlife is the area in the sugar beet root producing areas (shown in Figure 2-1) and in the seed producing region in the Willamette Valley, the seed producing region (Figure 2-4). The affected environment for climate is global, as impacts on climate change are global issue.

2.12 SOCIOECONOMICS AND HEALTH

The affected environment for socioeconomic issues includes those individuals or groups who could be economically impacted if their food, feed, or agricultural products are adversely affected by event H7-1. It also includes those who would be economically impacted if event H7-

1 becomes a regulated article: growers of event H7-1 sugar beets, sugar processors, seed companies, and sugar marketers and sugar buyers. Potential impacts to the first group are discussed primarily in Section 3.11 and impacts to the second group are discussed in Section 3.16. The potential for health impacts to individuals who may come into contact with glyphosate-tolerant sugar beets or beet seeds, or sugar or other products derived from glyphosate-tolerant sugar beets is discussed in Sections 3.11 and 3.15. Health effects of potential exposure to herbicides are discussed in Section 3.15.

Section 3 of this ER examines the possible impacts of a partial deregulation of H7-1 or similar administrative action.

3.1 PLANT PEST PROPERTIES AND UNINTENDED EFFECTS

APHIS previously determined, based on scientific analysis and in accordance with its obligations under the Plant Protection Act, that sugar beet event H7-1 is not a plant pest and does not exhibit plant pathogenic properties (USDA APHIS, 2005).

APHIS considered the potential for the transformation process, the introduced DNA sequences, or their expression products to cause or aggravate disease symptoms in sugar beet event H7-1 and its progeny or in other plants. APHIS also addressed the potential for event H7-1 to become a weed or make other plants that it breeds with into weeds.

APHIS also considered whether data indicate that unintended effects would arise from engineering of these plants. APHIS considered information from the scientific literature as well as laboratory and field data collected during the trials with event H7-1 that was provided by Monsanto/KWS in its petition (included in Schneider, 2003).

Based on the analysis summarized below, there are no impacts resulting from plant pest properties, introduced or aggravated disease symptoms, or unintended effects under any of the alternatives. Details of the Monsanto/KWS studies are included in the petition (Schneider, 2003).

3.1.1 Background

Plant genetic modification

Plant genetic modification by humans ranges from the simple approach of selection – where seeds of plants with desired traits are saved and replanted – to complex methods such as the use of recombinant DNA (rDNA; see definitions on next page). Crossing (and then recrossing) two sexually compatible plants by taking the pollen from one plant and brushing it onto the pistil of another is still the mainstay of modern plant breeding (IM/NRC, 2004). Both conventional breeding and rDNA methods can involve changes in the sequence, order, and regulation of genes in a plant and can use many of the same enzymes. However, with conventional breeding all the tens of thousands of genes in the plant are involved, and with the rDNA method only a few genes are involved. In classical breeding, crosses can be accomplished only between closely related species, and therefore only traits that are already present in those species can

be targeted. In contrast, the rDNA approach can use genes from any living organism, thus opening the door to vast potential in trait development (Lemaux, 2008, p. 774; AMA, 2000).

Other examples of plant genetic modification include cell fusion (the protective cell wall is stripped and cells are fused by some external force) and induced mutagenesis (inducing mutations in seeds by ionizing radiation or carcinogenic chemicals) (Ronald and Adamchak p. 88). Mutagenic techniques, which have been in use since the late 1920s, create random mutations and are limited by their inability to target a desired trait (FDA, 1992; Lundqvist, 2009, p. 39).

Agrobacterium

Agrobacterium tumefaciens (*Agrobacterium*) is a soil microbe that has been called "nature's own genetic engineer" because of its ability to transfer a fragment of its own DNA into a host plant (AMA, 2000). (See definitions at right.) The transferred DNA is stably integrated into the plant DNA, and the plant incorporates and expresses the transferred genes. The transferred DNA (T-DNA) reprograms the host plant cells to grow into callus tissue and produce certain amino acid derivatives that are a food source for the *Agrobacterium*. On a macro scale, the callus tissue growth is called crown gall disease. In the early 1980s scientists developed strains of *Agrobacterium* with T-DNA that lacked the disease-carrying genes ("disarmed" *Agrobacterium*). *Agrobacterium* transformation system has been utilized in the development of a large number of genetically engineered plants in commercial production (IM/NRC, 2004, pp. 28-29). The method uses a DNA molecule called a **vector**

DEFINITIONS

Nucleotide *– basic building block of nucleic acids such as DNA. Each nucleotide is made up of a nitrogen-containing group, a sugar, and a phosphate group.*

Nucleic acid *– a chain of nucleotides.*

DNA *– deoxyribonucleic acid – a type of nucleic acid that acts as the genetic material in most living things.*

Chromosome *– a DNA molecule containing all or parts of the genome of an organism, which has the ability to replicate.*

Genome *– the complete set of genes in an organism.*

Gene *– the basic unit of heredity; it is a segment of DNA on a specific site on a chromosome.*

Amino acid *– one of 20 chemical building blocks for proteins; there are also nonprotein amino acids.*

Catalyst *– a chemical that speeds up a chemical reaction but is not changed by the chemical reaction.*

Enzyme *– a biological catalyst; usually a protein.*

Recombinant DNA (rDNA) techniques *– procedures used to join together DNA segments. Under appropriate conditions, a rDNA molecule can enter a cell and replicate there.*

Mutation *– any change in the base sequence of DNA.*

Diploid *– containing two sets of chromosomes (one from each parent0.*

that serves as a carrier to insert T-DNA that contains specific genetic elements. These genetic elements are organized into a **gene cassette,** which consists of a gene encoding for a single biological function plus other genetic elements necessary for the expression of that gene when introduced into the plant. Other elements in the gene cassette include a **promoter**, which can be thought of as the "on switch" for the gene encoding for the desired trait; and a targeting sequence, which makes sure the gene product, typically a protein, ends up in the right location within the cell (such as the chloroplast).

Unintended effects from breeding

Most crops naturally produce allergens, toxins or other antinutritional substances; these often serve the plant as natural defense compounds against pests or pathogens (FDA, 1992). Plant breeders typically monitor the levels of antinutritional substances relevant to their crop. For example, solanine is a naturally-occurring toxin produced by potatoes and is part of the plant's defense against insects and fungus. Potato breeders typically monitor solanine levels and reject lines that generate too much of it (IM/NRC, 2004).

Scientists from the Institute of Medicine (IM) and the National Research Council (NRC) ranked breeding methods according to their relative likelihood of producing unintended effects, which they hypothesized would correspond to the degree of genetic disruption associated with the method. Selection from a homogeneous population was ranked at one end of the spectrum (less likely to produce unintended effects) and induced mutagenesis (from chemicals or radiation) was ranked at the other end (more likely). *Agrobacterium* transfer of rDNA was among the methods ranked in between (IM/NRC, 2004, Figure ES-1). Recent studies in Europe comparing transgenic and conventional barley suggest that conventional breeding may cause more unintended effects than rDNA methods, likely because of the very large number of genes that are affected in conventional breeding techniques (Sonnewald, 2010). These results are consistent with those observed by APHIS with event H7-1 and many other plants produced through rDNA methods: except for the intended trait, the GE plant is found to be substantially equivalent to its non-GE counterpart.

Glyphosate tolerance

As discussed in Section 2, glyphosate acts by inhibiting the action of the enzyme 5-enolpyruvylshikimate-3-phosphate synthase, EPSPS, in plants. EPSPS is a catalyst for a reaction necessary for the production of certain amino acids essential for plant growth. When

plants are treated with glyphosate the EPSPS enzyme is inhibited, they cannot produce the amino acids needed for continued growth and eventually die. The EPSPS protein and the reaction it catalyzes are present in all plants and microbes. There are variations in the amino acid sequence of EPSPS among different plants and bacteria. Glyphosate tolerance is achieved by introducing an EPSPS enzyme, termed CP4 EPSPS, that is not inhibited in the presence of glyphosate. An *Agrobacterium* strain (designated CP4) was the source of the *cp4 epsps* gene that encodes for the CP4 EPSPS enzyme (Schneider, 2003). The CP4 EPSPS enzyme carries out the same enzymatic reaction in the plant as the native EPSPS; however, when plants that contain the CP4 EPSPS are sprayed with glyphosate, they are able to continue to produce the essential amino acids needed for plant growth. The objective of the genetic modification in event H7-1 was to simplify and improve weed management practices in sugar beet by conferring tolerance to glyphosate.

Transformation system

Event H7-1 was developed using a disarmed *Agrobacterium*-mediated transformation of a sugar beet variety used in plant breeding. Cotyledons (part of the seed embryo) derived from sterile seedlings of the diploid sugar beet line 3S0057 were used as the explant source. An explant is any portion of a plant that is to be used to initiate culture. These cotyledons were immersed in an *Agrobacterium* suspension and co-cultured for two to four days. The explants were then transferred to selective media containing 500 mg/l carbenicillin to eliminate the *Agrobacteria*. Glyphosate was used for selection of glyphosate-tolerant tissue, with tissue containing a genetic insertion to confer glyphosate tolerance assigned a unique number, such as event H7-1. After approximately seven weeks, the developed plantlets were transferred to rooting media and placed in a greenhouse. All subsequently developed event H7-1 sugar beet breeding lines and variety candidates were derived by traditional plant-breeding methods (Schneider, 2003, pp. 20-21).

DNA sequences inserted into sugar beet event H7-1

Data supplied in the petition and reviewed by APHIS (Section V.A., pp 29-44) support the conclusion that event H7-1 contains the following gene cassette:

1) a promoter from a modified figwort mosaic virus,

2) targeting sequence from the plant *Arabidopsis thaliana*,

3) the EPSPS gene from *Agrobacterium* sp. strain CP4, and

4) a portion of a gene from pea that directs genetic processing

This same gene cassette is present in other Roundup Ready® cotton and canola, which have previously been deregulated by USDA (Schneider, 2003, p. 24). The non-coding promoter is from the plant pathogen figwort mosaic virus. The promoter cannot cause plant disease and serves a purely regulatory function for the EPSPS gene. The CP4 EPSPS gene does not cause disease and has a history of safe use in a number of genetically engineered plants (e.g., corn, cotton and soybean varieties).

3.1.2 Evaluation of intended effects

Analysis of inheritance

Data was provided and reviewed by APHIS that demonstrates stable integration and inheritance of the EPSPS gene cassette over several breeding generations. Statistical analyses show that glyphosate tolerance is inherited as a dominant trait in a typical Mendelian manner (Schneider, 2003, Table V-2, pp. 45-46).

Analysis of gene expression

The level of CP4 EPSPS protein was determined from tissues collected from field trials with event H7-1 conducted at several locations. Using standard laboratory techniques, protein concentrations from H7-1 beet leaves and processed roots (brei) were determined (Schneider, 2003, Table V-3, p. 50). EPSPS proteins are ubiquitous in plants and microorganisms and have not been associated with hazards from consumption or to the environment. Crops that contain the CP4 EPSPS protein have been granted non-regulated status have included corn, soybean, cotton, rapeseed and sugar beet (USDA APHIS, 2010a). In 2009, significant acreages of corn (59 million acres or 68% of the total corn acres), upland cotton (6.3 million acres or 71% of the total cotton acres) and soybean (70.5 million acres or 91% of the total soybean acres) grown in the US were planted with herbicide tolerant varieties (USDA NASS, 2010c). Although the data include all herbicide tolerant varieties, glyphosate tolerant ones (containing CP4 EPSPS) predominate. All have also undergone FDA review (FDA, 2010).

Analysis of the intended trait

Numerous field trials were conducted in the US (Schneider, 2003, Tables VI-4 to VI-6) and in Europe (Schneider, 2003, Table VI-7) to evaluate event H7-1 in different genetic backgrounds

and in different environments. Standard field trials evaluated 1) agronomic performance, 2) disease and pest resistance performance, 3) steckling (seedling) production and 4) seed multiplication. Standard industry farming practices for the various locales was used in these trials. These practices would typically include control measures for weeds, diseases and insects. Where glyphosate was used in trials, no negative impacts from application glyphosate were noted.

3.1.3 Evaluation of possible unintended effects

Disease and pest susceptibility

In trials conducted from 1998 to 2002, qualitative and quantitative data addressing disease susceptibility and overall agronomic performance of event H7-1 were collected to assess possible effects from introduction of the CP4 EPSPS gene cassette. As summarized below, information collected from these trials indicate that event H7-1 does not alter sugar beet's susceptibility to diseases and pests. Experience in production fields since 2007 supports this conclusion.

Nursery trials in US. During the 2000 and 2001 growing seasons, quantitative data was collected from variety trials at Betaseed nurseries for comparison of varieties with event H7-1 to conventional varieties for relative resistance to four common sugar beet diseases: *Cercospora* leaf spot, *Aphanomyces* root rot, *Rhizoctonia* root rot, and curly top virus. In these trials, results of season-long testing for disease susceptibility from one to three varieties with the H7-1 event were compared with four conventional varieties. The results indicated that the disease susceptibility of the H7-1 varieties was within the range of the conventional varieties (Schneider, 2003, Section A.1).

Field trials in US. A total of 98 separate Monsanto/KWS field trials were conducted in the US from 1998 to 2002 included comparative evaluation of susceptibility to the four diseases evaluated in the nursery trials, plus several fungal seedling diseases and Rhizomania (Schneider, 2003, Section VI.A.2). Together, these are the major diseases of economic importance affecting sugar beet production in the US (Schneider, 2003, p. 60). At all but six trial locations there were no differences observed between the event H7-1 varieties and the conventional comparators. At one trial site increased susceptibility to powdery mildew was noted while at three other sites decreased susceptibility was noted. At two trial sites increased susceptibility to *Cercospora* leaf spot was also noted. Given the interactions between the environment, the genetic backgrounds of the cultivars used and some inherent genetic

variability within sugar beet varieties, these results are not unexpected and do not indicate an increased pest risk. A similar likely insignificant difference was noted in a greenhouse trial using different *Fusarium* fungus isolates. Other researchers have suggested that it may be difficult to predict field results from greenhouse/ laboratory experiments control lines or differences outside the range of conventional sugar beet norms.

Field trials in Europe. Additional field trials were conducted with event H7-1 in Europe in 1998 and 1999 and monitored for several diseases and nematode worms. No diseases or nematode symptoms were reported in any of the trials for either event H7-1 or conventional control sugar beets (Schneider, 2003, Section A.3).

Gene silencing

In evolutionary biology, a homologous trait is one derived from a common ancestor that appears in multiple species. Homology may be manifested on a macro scale, for example, in the similarity in mammal forelimbs, and on a genetic scale, in DNA sequences. Al-Kaff, et al.(1998) have noted gene silencing effects when transgenic plants have been infected by a virus with DNA sequence homology to a portion of the introduced genes. The only virus-derived DNA in the event H7-1 gene cassette is the promoter, which is from the figwort mosaic virus. None of the viral diseases of beet is related to figwort mosaic virus (Whitney and Duffus, 1986) so silencing of the EPSPS gene would not be expected, and has not been observed.

Compositional evaluation

Monsanto/KWS compared the composition of event H7-1 sugar beets with conventional sugar beets derived from the same parent line ("near isogenic control line"). To eliminate the influence of normal genetic variation between different hereditary lines and varieties, isogenic lines are usually used as a standard for comparison (GMO Safety, 2010a). The analysis of H7-1 sugar beets for compositional changes was included in Section VI.C of the petition (Schneider, 2003) and was also part of the Monsanto/KWS submission to FDA in the consultation process (See Section 3.11 for a discussion of the FDA consultation process and results). While FDA uses these data as indicators of possible nutritional changes, APHIS views them as a general indicator of possible unintended changes.

Compositional analyses evaluating carbohydrates, proteins, fiber, fat, sugars, the antinutrient saponin, and eighteen amino acids (a total of 55 statistical comparisons) in tops (leaves) and roots (brei) identified seven statistically different values compared with the near isogenic control line. All analyses fell within the range of values observed for both the near isogenic control line

and conventional sugar beet varieties, providing additional evidence that event H7-1 sugar beet does not exhibit unexpected or unintended effects (Schneider, 2003).

3.2 WEEDINESS PROPERTIES, VOLUNTEERS AND FERAL CROPS

This section addresses two questions:

1. What are the weediness properties of sugar beet?
2. Is the event H7-1 sugar beet more likely to become a weed than a conventional sugar beet?

3.2.1 Weediness properties of sugar beet

As discussed in Section 2.5, sugar beets (*B. vulgaris*) are poor competitors with both weeds and other crops (i.e., beet can compete only with members of their own species). This is discussed in Section 3.8.

3.2.2 Event H7-1 sugar beet and weediness

Some scientists, for example, Ellstrand, 2006, have raised the question of "unintended crop descendents from transgenic crops." Ellstrand states (p. 116): "The possibility of unintended reproduction by transgenic crops has raised questions about whether their descendents might cause problems. These problems have fallen into two broad categories: first, the direct feral descendents of the crops may prove to be new weeds or invasive plants, and second, that unintended hybrids between transgenic crops and other plants could lead to certain problems." This section discusses the weediness properties of H7-1 sugar beet, and addresses the concern of direct descendents of the crop that "may prove to be new weeds or invasive plants." Hybridization is addressed in several later sections.

Event H7-1 was field tested in North America from 1998 to 2003 and in Europe from 1998 to 1999. In these trials, no differences were observed between H7-1 lines and non-transgenic lines with respect to the plants' ability to persist or compete as a weed (Schneider, 2003; USDA APHIS, 2005). In these evaluations, APHIS considered data relating to plant vigor, bolting, seedling emergence, seed germination, seed dormancy and other characteristics (USDA APHIS, 2005).

In a separate evaluation, the Canadian Food Inspection Agency (CFIA), whose responsibilities include regulation of the introduction of animal food and plants (including crops) to Canada, reached the same conclusion about the weediness potential of event H7-1 compared with non-

transgenic sugar beet. In 2005, the CFIA authorized the "unconfined release into the environment and livestock feed use of the sugar beet event H7-1" (CFIA, 2005). In its evaluation of event H7-1, CFIA "determined that germination, flowering, root yield, susceptibility to plant pests and diseases typical to sugar beet and bolting percentage were within the normal range of expression of these traits currently displayed by commercial sugar beet hybrids" (CFIA, 2005). The CFIA reached the following conclusions (CFIA, 2005):

> No competitive advantage was conferred to these plants, other than that conferred by tolerance to glyphosate herbicide. Resistance to Roundup® agricultural herbicides will not, in itself, render sugar beet weedy or invasive of natural habitats since none of the reproductive or growth characteristics were modified.
>
> The above considerations, together with the fact that the novel traits have no intended effects on weediness or invasiveness, led the CFIA to conclude that the H7-1 sugar beet event has no altered weed or invasiveness potential compared to currently commercialized sugar beet.

Thus, the potential for event H7-1 to become a weed or invasive plant was determined to to be no greater than conventional sugar beets. Neither sugar beets or other beta species plants are considered a weed issue in any state other than California.

3.2.3 Sugar beet volunteers

Volunteers, which are plants from a previous crop that are found in a later crop, may result from bolters or groundkeepers. Refer to Section 2.3.4 for a detailed discussion.

Root production

While several scientists have reported that volunteer glyphosate tolerant plants could in theory become a problem in rotational crops when both rotational crops are glyphosate tolerant, none provided specific information or data relevant to sugar beets (e.g., Cerdeira and Duke, 2006; Owen and Zelaya, 2005; York et al, 204; NRC, 2010). Since sugar beet is grown for the vegetable and not the seed, volunteers in a root crop could occur only from the rare plant that has bolted, if it is allowed to go to seed. Groundkeepers are cold sensitive and only rarely survive winter conditions in most sugar beet production areas (Grant, 2010,p. 7; Cattanach et al, 1991; Panella, 2003).

As discussed in Section 2.3.4, bolters deplete the sugar content of the root and cause problems with harvesting. Thus, good management practices and the grower's own interest dictate removal of bolters. Sugar beet varieties are specifically bred to make bolters rare. Volunteers

are unlikely even if bolters are not removed because a series of unlikely events must each coincide to produce volunteers. If a bolter is not removed, it must be pollinated by another bolter, and be allowed to go to seed; the seed must then survive the winter freeze and germinate. And even if this does occur, the resulting volunteer would need to successfully compete with the next year's crop, and could be controlled by mechanical means or by several registered herbicides other than glyphosate that can be used on sugar beet volunteers (Meister, 2009). Depending on the rotation crops chosen to follow sugar beet (in the normal 3-4 year rotation), growers can use tillage and/or herbicides. Examples of some herbicides are methylsulfuron methyl, 2,4-dichlorophenoxyacetic acid (2,4 D) and 3,6-dichloro-o-anisic acid (dicamba) for the control of any volunteers prior to planting and after crop emergence.

Seed production

Control of volunteers is more of a concern with seed production, for both conventional and event H7-1 sugar beet, to maintain seed purity. As discussed in Section 2.7.3, WCBS and Betaseed control all seed production in the Willamette Valley. WCBS has detailed requirements in it protocol (in Appendix B of this ER) for post-harvest field management. After harvesting, the fields are shallow tilled and irrigated to promote sprouting of shattered seeds (unless sufficient rainfall to promote sprouting has occurred). Fall plowing is not allowed. After the seed is allowed to sprout, it is controlled by herbicides or other means. All equipment is cleaned according to WCBS procedures before it leave the fields. Fields used for growing event H7-1 are inspected by WCBS "for a minimum of five years or until no volunteers are noted (Appendix B). Betaseed has similar requirements.

3.2.4 Impact summary

Alternative 1

Under Alternative 1, there would be no impact from event H7-1 1 on weediness or volunteers.

Alternative 2

Weediness properties. Based on the information summarized in the subsection, APHIS has concluded that sugar beet does not exhibit weediness properties, and that event H7-1 does not exhibit any altered weediness properties when compared with conventional sugar beet. Therefore, Alternative 2 would not impact the weediness characteristics of sugar beet.

Feral crops. As explained in Section 2.9, the existence of feral sugar beet crops in the US is highly unlikely, and any population that may exist would be negligible. Because there are no

known or suspected feral crops of sugar beets in the US, Alternative 2 would not impact feral sugar beet crops.

Volunteers in root crop fields. Volunteers resulting from root crops are generally not a concern because the crop is harvested in the vegetative stage, bolters are generally rogued (removed), and the occasional volunteer would be unlikely to survive the winter freeze and could be controlled by other means than glyphosate. The interim measures further reduce the potential for any volunteers resulting from a root crop by requiring complete control of bolters. Under the proposed interim measures, all event H7-1 root crop growers will have measures in place that require them to survey, identify, and eliminate any bolters in their root crop fields before they produce pollen or set seed (Item 5). Therefore, no or negligible impacts from event H7-1 volunteers in root crop fields would be expected under Alternative 2.

Volunteers in seed production fields. Managing volunteers in seed production fields is an important part of seed growers' efforts to maintain seed purity. WCBS and Betaseed have protocols in place to force same-year sprouting of seed left behind in the production field, plus long-term monitoring (five years for WCBS) of production fields to identify and remove any volunteers. The interim measures contain a universal requirement to force same-year sprouting, of any event H7-1 seed left behind in the production field, and subsequent removal and destruction of plants (Item 4.j); 3-year monitoring of fields for volunteers along with removal and destruction (Item 4j); employee training (Item 4k); recordkeeping to document compliance (Item 4m); and third-party audits for compliance (Item 7). Given the existing industry standards coupled with the mandates of the interim measures to control volunteers, no or negligible impacts from event H7-1 volunteers in seed production fields would be expected under Alternative 2.

3.3 IMPACTS OF EVENT H7-1 SUGAR BEET ROOT CROPS ON CONVENTIONAL SUGAR BEET CROPS

This section considers the possibility of impacts from event H7-1 sugar beet crops on conventional sugar beet crops through gene flow (refer to Section 2.4 for a general discussion of gene flow), or by mixing in harvesting, transportation, stockpiling, or processing.

3.3.1 Pollen sources in production fields

As discussed throughout this document, in production fields sugar beets are grown for their roots and are harvested before they flower. The only sources of event H7-1 pollen in production

fields would be from uncontrolled bolters. Refer to Section 2.3.4 for a detailed discussion of bolting.

3.3.2 Potential for gene flow in root production fields

Because sugar beets are harvested in the vegetative stage, before they flower, there is little potential for cross-pollination between root production fields. Cross-pollination, if it occurred could potentially result in adventitious (inadvertent) presence of genetic material from the crop in one field into a nearby crop's field. Scientists from Oregon State University report that for sugar beet "gene flow via pollen or seed in root production fields is generally not an issue" (Mallory-Smith and Zapiola, 2008, p. 433). Messéan et al concur: "the potential for adventitious presence of GM material in non-GM sugar beet production is low through cross-pollination since the harvest is vegetative" (2009, p. 49). The European Commission (the executive body of the European Union [EU]) Scientific Committee on Plants (2001) also assessed the potential for adventitious presence of event H7-1 sugar beet at various stages of farm production. The Committee identified seed production as the major potential source of adventitious presence, with other sources, including planting, cultivation, cross-pollination, volunteers, harvesting and production all with no or minor potential contributions (p. 8).

Because pollen dispersal is a concern with sugar beet seed production, it is discussed in detail in the analysis of impacts in seed production (Section 3.9). The Section 3.9 discussion evaluates distances over which cross pollination may occur; this is an issue with little relevance to root production.

3.3.3 Potential for mixing of event H7-1 and conventional sugar beets

As discussed in Section 2.2, 95 percent of sugar beet seeds planted in the US in 2010 were glyphosate-tolerant. Except in California, where only conventional sugar beet has been grown to date, production, processing and marketing within the industry no longer distinguishes between event H7-1 and conventional sugar beet crops—they are processed and marketed together. The 22 sugar beet processing facilities in the US process a combination of event H7-1 and conventional sugar beets. As discussed in Section 2.3, no currently operating sugar beet processing facilities have been built in the US since 1975. Because a processing facility is required for sugar production, the 22 processing facilities account for all the beet sugar produced in the US. Markets have been available for the sugar, beet pulp, molasses and other products (Kaffka and Hills, 1994, p. 2; California Beet Growers Association, 1998; Western Sugar Cooperative, 2006a; Michigan Sugar Company, 2010b; American Crystal Sugar

Company, 2009; Minn-Dak Farmers Cooperative, undated; Snake River Sugar Company, 2009).

3.3.4 Consequences of gene flow in production fields

We have found no reports of cross-pollination between event H7-1 sugar beet root production fields and conventional sugar beet crops since event H7-1 sugar beets were first grown in production fields in limited quantities the US in 2006. As discussed above, because sugar beets are harvested in the vegetative stage, bolters are uncommon, and it is good management practice to remove bolters, pollen movement, or gene flow between event H7-1 and conventional crops is expected to be minimal.

If bolters occurred in two nearby fields, one with event H7-1 and one with conventional sugar beets, and the bolters were not controlled and were allowed to flower, a conventional plant could potentially become fertilized with event H7-1 pollen, and the resulting seeds may contain the event H7-1 trait. This occurrence would not affect the conventional sugar beet crop because it would be harvested before these new resulting seeds grew into sugar beet plants, if they did. If the seeds germinated and the resulting plants survived the winter, which is unlikely in most sugar beet production areas, the volunteer plants would appear in the conventional sugar beet farmer's next rotational crop, and (if they survived) would be treated as weeds, as described in Section 3.3, and would be eliminated.

There is evidence that growers pay close attention to bolters. All growers that submitted declarations in the sugar beet litigation declared that bolters are easy to spot in their fields and if seen they would destroy them. There is no evidence that we have seen to the contrary. Any conventional sugar beet grower concerned about this occurrence could prevent it by controlling bolters in his sugar beet crop, which is normally stewardship for any sugar beet crop.

3.3.5 Potential consequences from mechanical mixing

With the exception of the Imperial Valley where only conventional sugar beets have been grown, grown, commingling of harvested beets from H7-1 seed and conventional seed has occurred since 2007, with no consequences.

1300

3.3.6 Impact Summary

Alternative 1

Under Alternative 1, there would be no gene flow impact from event H7-1 root crop production to conventional sugar beet crops.

Alternative 2

Gene flow. Even without the interim measures, impacts from event H7-1 sugar beet root crops to conventional sugar beet root crops have not occurred and would not be expected because: 1) sugar beets are harvested in the vegetative stage, before they flower; 2) if bolting and cross-pollination occurred in nearby fields, the root crop would not be affected; 3) any conventional grower who wanted to be certain of preventing cross pollination could do so by controlling bolters in his own root production fields; 4) a volunteer event H7-1 hybrid appearing in a subsequent crop resulting from cross pollination in root production fields can be controlled using standard weed control practices and would not likely survive the winter in most growing areas in any event.

The interim measures further reduce the potential for gene flow from event H7-1 root crops to conventional root crops by requiring complete control of bolters. Under the proposed interim measures, commercial event H7-1 root crop growers will have measures in place that require them to survey, identify, and eliminate any bolters in their root crop fields before they produce pollen or set seed (Item 5). Item 6 of the interim measures requires event H7-1 processors or cooperatives to survey, identify, and eliminate any bolters in outdoor storage before they produce pollen or set seed. Therefore, no or negligible impacts from gene flow from event H7-1 sugar beet root crops to conventional sugar beet root crops would be expected under Alternative 2.

Mixing of harvested beets. Currently, by mutual agreement among growers, cooperatives, processors and marketers, event H7-1 sugar beets and conventional sugar beets are harvested, transported, stockpiled, processed and marketed without distinction in all areas except California, where event H7-1 sugar beet has not been grown. No impacts have occurred and none are expected. Through the interim measure (Item 1) prohibiting planting of event H7-1 in California, this status quo will be maintained. Therefore, under Alternative 2, no impacts are expected resulting from mechanical mixing of event H7-1 and conventional sugar beets.

3.4 IMPACTS OFOF EVENT H7-1 ROOT CROPS ON ORGANIC SUGAR BEET CROPS

Based on all available information, we have concluded that there is essentially no organic sugar beet production in the US. The only reference to organic sugar beet production we found was from the State of California, where 0.02 to 0.03 acre of sugar beet production in Los Angeles County was reported from 2002 to 2007, with most recent annual sales of five dollars (California Department of Food and Agriculture, 2010). California is by far the largest producer of organic commodities in the US, accounting for approximately one-third of sales in 2008 (USDA, 2010c, Table 1). USDA tracks production of a number of organic crops, but not organic sugar beets. Although no other information was found, similar production may be occurring in other states.

We have found no other information about organic sugar beet production in the US. As discussed in Section 2.3, all the commercial sugar beet grown in the US is processed into sugar at one of the 22 processing facilities, none of which process organic sugar beets.

3.4.1 Impact summary

Based on the above discussion, neither alternative would be expected to result in impacts to organic sugar beet production, because there is essentially zero organic sugar beet production in the US.

There is a substantial European organic sugar beet business, and American organic farmers may in the future decide to grow organic sugar beets. This would most likely be small-scale production, as no processing facility would be available. The presence of event H7-1 sugar beet would not inhibit the development of an organic sugar beet industry. As discussed in Section 3.4, a grower of organic sugar beets could ensure no cross-pollination from event H7-1 fields by controlling any bolters in his sugar beet crop. As discussed in Section 3.9, organic sugar beet seed is available from European suppliers. Therefore, Alternative 2 is not expected to result in impacts to organic farmers who may choose to grow sugar beets in the future.

3.5 IMPACTS OFOF EVENT H7-1 ROOT CROPS ON OTHER *BETA* (NON-SEED) CROPS

The cultivated forms of *B. vulgaris*, including sugar beet, red table beet, Swiss chard, and spinach (leaf) beets are all varietal members of the subspecies *vulgaris* (*B. vulgaris* ssp. *vulgaris*) (OECD, 2001, Table 2). They are all biennial and all are sexually compatible with sugar beets (OECD, 2001). Whether grown for leaves or roots, beet crops are all harvested in their first year before they produce seed. In addition, as discussed in Section 2.8.1, there is

virtually no overlap between sugar beet root production areas and major areas of production of other *Beta* crops.

Most growers purchase seed for their table beet crops; however, a few organic gardeners may allow part of their crop to vernalize then to go to seed and then save the seed for replanting. If a sugar beet production root crop was grown close to a table beet crop that was allowed to go to seed and the sugar beet crop had uncontrolled bolters that flowered at the same time as the other beet crop, there would be some very small potential for hybridization between the sugar beet and other beet. Based on the discussion in Section 3.3, this occurrence would be expected to be exceedingly rare and unlikely to occur. The situation would be no different for event H7-1 or conventional sugar beet. There is no indication that this has occurred since wide scale H7-1 beet root production began in 2008.

3.5.1 Impact summary

Alternative 1

Under Alternative 1, there would be no impacts from event H7-1 root crop production on other *Beta* crops.

Alternative 2

Assuming no interim measure provisions, impacts from event H7-1 sugar beet root crops to conventional sugar beet root crops have not occurred and would not be expected because: 1) sugar beets are harvested in the vegetative stage, before they flower; 2) if bolting and cross-pollination occurred between event H7-1 and other *Beta* vegetable crops, the harvested crop would not be affected; 3) any grower of *Beta* vegetable crops who wanted to be certain of preventing cross pollination could do so by controlling bolters in her own vegetable crop fields; 4) a volunteer event H7-1 hybrid appearing in a subsequent crop resulting from cross pollination can be controlled using standard weed control practices and 5) major production of sugar beet root crops and other *Beta* vegetable crops do not coincide. In addition, among the sugar beet production areas, organic *Beta* vegetable growers, who may sometimes save their own seed, are concentrated in California, where only conventional sugar beet is grown.

The interim measures further reduce the potential for gene flow from event H7-1 root crops to other *Beta* vegetable crops by requiring complete control of bolters. Under the proposed interim measures, all event H7-1 root crop growers will have measures in place that require them to survey, identify, and eliminate any bolters in their root crop fields before they produce pollen or

set seed (Item 5). Item 6 of the interim measures requires event H7-1 processors or cooperatives to survey, identify, and eliminate any bolters in outdoor storage before they produce pollen or set seed. Therefore, no or negligible impacts from gene flow from event H7-1 sugar beet root crops to other *Beta* vegetable crops would be expected under Alternative 2. The prohibition on growing event H7-1 in California (interim measure Item 1), where the majority of the organic *Beta* vegetable crops in sugar beet production areas is grown, will further reduce the potential for any impact.

In the multiple years of cultivation to date of GT sugar beet on a wide scale, there are no indications that gene flow has occurred.[31]

3.6 IMPACTS OF EVENT H7-1 SUGAR BEET ROOT CROPS ON OTHER *BETA* SEED PRODUCTION AREAS

As discussed in Section 2.8, nearly all red table beet and Swiss chard seed production occurs in western Washington State and in California, where event H7-1 sugar beet root crops are not grown. A small amount of red table beet and Swiss chard seed production occurs in the Willamette Valley, where sugar beet root crops are not grown. Spinach beet seed production, if it exists separately from red table beet and Swiss chard production, is apparently very small.

3.6.1 Impact summary

Alternative 1

Under Alternative 1, there would be no impacts from event H7-1 production on other *Beta* crops.

Alternative 2

Even without the interim measures, impacts from event H7-1 sugar beet root crops to seed production areas for red table beets and Swiss chard (other *Beta* seed crops) have not occurred and would not be expected because: 1) sugar beets are harvested in the vegetative stage, before they flower; 2) seed production for red table beets and Swiss chard does not occur in or near the same geographic areas as event H7-7 sugar beet root production.

Even if the unlikely event there were isolated areas of other *Beta* seed crops outside the main production areas (seed savers) and near sugar beet root crops, the interim measures further reduce the potential for gene flow from event H7-1 root crops to other *Beta* seed crops by requiring complete control of bolters. Under the proposed interim measures, all event H7-1 root

[31] Hofer Decl. (Dkt. #48) ¶ 14; Berg Decl. (Dkt. #39) ¶ 15; Grant Decl. (Dkt. #45) ¶ 18; Lehner Decl. (Dkt. #252) ¶ 6.

crop growers will have measures in place that require them to survey, identify, and eliminate any bolters in their root crop fields before they produce pollen or set seed (Item 5). Item 6 of the interim measures requires event H7-1 processors or cooperatives to survey, identify, and eliminate any bolters in outdoor storage before they produce pollen or set seed. Therefore, no or negligible impacts from gene flow from event H7-1 sugar beet root crops to other *Beta* seed crops would be expected under Alternative 2. The prohibition on growing event H7-1 in California and the Western Washington counties where the majority of the US red table beet and Swiss chard seed production occurs (interim measure Item 1), will further reduce the potential for any impact. In the multiple years of wide scale cultivation of H7-1 sugar beets, there have been no indications that that any gene flow has occurred [32]

3.7 IMPACTS OF EVENT H7-1 ROOT CROPS ON NATIVE BEETS

As discussed in Section 2.9, no native members of the genus *Beta* are found in North America. Therefore, gene flow to native beets will not occur under either alternative.

The absence of native *Beta* plants in North American is an important difference for sugar beet production concerns (both event H7-1 and conventional) from other regions of the world, in particular, the EU, where "[i]t is considered essential to preserve the diversity of sea beet [wild *B. vulgaris ssp. maritima*] for any long term plant breeding strategy, and for conservation and study in its own right" (Messéan et al, 2009, p. 40).

3.7.1 Impact summary

Because there are no native beet populations in the US, there would be no impact with either alternative.

3.8 IMPACTS OF EVENT H7-1 CROPS ON NON-NATIVE WILD AND WEEDBEETS

Non-native wild and weed beets are described in detail in Section 2.9. Except for isolated reports in Michigan and Oregon, all the known populations of non-native wild and weed beets in sugar beet root production states occur in California, where event H7-1 sugar beets are not grown. As discussed in Section 2.9, *B. macrocarpa* weed beets are a weed issue in the Imperial Valley, the only major sugar beet production area in California. Even so, research in 1998 found only minor introgression between the sugar beets and *B. macrocarpa* after 66 years of coexistence in the Imperial Valley (Bartsch and Ellstrand, 1999).

[32] Hofer Decl. . (Dkt. . #48) ¶ 14; Berg Decl. . (Dkt. . #39) ¶ 15; Grant Decl. . (Dkt. . #45) ¶ 18; Lehner Decl. . (Dkt. . #252) ¶ 6.

3.8.1 Impact summary

Alternative 1

Under Alternative 1, there would be no effect of gene flow from event H7-1 to non-native wild or weed beets.

Alternative 2

APHIS has previously concluded that there are no issues with weed beet populations in the U.S. outside California. Within the states where event H7-1 root crops are grown, there are reports of non-native wild beets from Montana, Oregon and Michigan. The reports from Montana are dated; more recent data do not indicate the presence of non-native wild or weed beets in Montana. Also, the report was from a part of Montana where sugar beets root crops are not grown. The single report from Oregon is from an area where sugar beet root crops are not grown. One of the Michigan reports was from a county where sugar beet crops are produced. No additional information was found, and weed beets are not reported as a weed problem in sugar beet root production in Michigan (Michigan Sugar Company, 2009). Based on the absence of any information about any uncultivated beet populations in Michigan (and the challenges in surviving winter) non-native wild or weed beet populations are expected to be nonexistent or minor. The only potential for impact from a sugar beet root crop would be by gene flow from an uncontrolled bolter, assuming any non-native wild or weed beet is close enough to the bolter and flowering at the same time, so that it might be pollinated. Based on this information, the potential for impact from sugar beet root production crops on non-native wild or weed beets appears to be negligible. It would be non-existent with the proposed interim measures. Under the proposed interim measures, all event H7-1 root crop growers will have measures in place that require them to survey, identify, and eliminate any bolters in their root crop fields before they produce pollen or set seed (Item 5). Item 6 of the interim measures requires event H7-1 processors or cooperatives to survey, identify, and eliminate any bolters in outdoor storage before they produce pollen or set seed In the multiple years of H7-1 cultivation to date, there have been no issues identified with wild or weed beets.

Non-native wild and weed beet populations exist in California. However, no event H7-1 commercial crops have been grown in California, and Item 1 of the interim measures prohibits growing event H7-1 crops in California.

Therefore, under Alternative 2, no impacts to non-native wild or weed beets would be expected.

3.9 IMPACTS OF EVENT H7-1 SEED PRODUCTION ON CONVENTIONAL SUGAR BEET AND OTHER *BETA* SEED CROPS

It is possible, without proper stewardship, for cross-pollination and gene flow between crop types during seed production, because that is where pollination happens. Also, absent appropriate stewardship measures, physical mixing of seeds is possible during harvesting, seed cleaning, packaging and transport.

3.9.1 Maintaining seed purity, identify and quality

The Federal Seed Act and its implementing regulations[33] establish basic standards for certification of seed, which are carried out by state seed certifying agencies. A state seed certifying agency is created by state law, has authority to certify seed, and has standards and procedures approved by USDA "to assure the genetic purity and identity of the seed certified." Seed certifying agencies' standards and procedures must meet or exceed those specified in the USDA regulations.[34]

However, sugar beet seed is generally not certified, and seed companies have established their own standards, as described in Section 2. There are certified wheat, soybean and corn seed growers who produce their seed to sell to farmers for planting their commercial crops. This issue is not relevant in sugar beets, because none of the sugar beet root growers harvest any sugar beet seed. All sugar beet seed producers sell all of their seed to seed companies to be sold to farmers. Even if sugar beet root growers could save some seed, they have no means for processing it (so it would work in a planter) and providing the appropriate seed treatments and would never take the risk of trying to plant it because of the uncertainty of what they have.

While sugar beet seed is generally not certified, the Oregon Seed Certification Service (OSCS) standards for certified seed and the corresponding isolation distances are reported here, as additional data points on what to expect in seed purity from a given isolation distance. The OSCS has set the following standards for those items for certified sugar beet seed (OSCS, 1993):

- Pure seed, minimum: 99.00%
- Other crops, maximum: 0.10%
- Inert matter, maximum: 1.00%

[33] 7 C.F.R. §CFR 201
[34] 7 U.S.C. §USC 1551(a)(25) and 7 C.F.R. §CFR 201.67

- Weed seed, maximum: 0.10%

Minimum isolation distances required for certified seed are as follows (OSCS, 1993):

- From sugar beet pollen of similar ploidy or between fields where male sterility is not used – 2,600 ft (0.49 mile)
- From other pollinator or genus *Beta* that is not a sugar beet – 8,000 ft (1.5 mile)

The maximum specified OSCS required isolation distance for sugar beet seed production is 10,200 ft (1.9 miles, from other, non-sugar beet *Beta* species) for "stock" seed which has a maximum allowable concentration of "other crop" seed of 0.00% (OSCS, 1993).

3.9.2 Summary of practices for sugar beet seed production

All of the sugar beet seed in the Willamette Valley is produced by either West Coast Beet Seed Company (WCBSC) or by Betaseed (see Section 2.7 of this ER). WCBSC has developed explicit standard operating procedures and grower guidelines that are intended to minimize and/or eliminate the possibility of pollen-flow between fields of related Beta species (See Section 2.7 and Appendix B). Both WCBS and Betaseed belong to the Willamette Valley Specialty Seed Association (WVSSA) and follow the guidelines for isolation and minimum separation distances between fields (Appendix A). The minimum isolation distance from event H7-1 ("GMO") sugar beet and all other open pollinated Beta crops, in both the WCBS protocol and the WVSSA guidelines is four miles. All growers of commercial specialty seed in the Willamette Valley are members of the WVSSA (Loberg, 2010). This includes all commercial companies raising Beta species. The isolation distances required by WVSSA between Event H7-1 sugar beets and other Beta species such as chard or table beets is 2.1 miles further than the maximum required OCCS isolation distance for stock seed discussed above.

Principles of quality assurance for sugar beet seed production have been set forth in an industry-endorsed Code of Conduct (Appendix C). The Sugar Beet Code of Conduct adopted by the beet group of the International Seed Federation (ISF) describes the measures the sugar beet seed industry has taken to deliver high quality varieties, including measures to minimize adventitious presence of transgenic sugar beet seed in non-transgenic Beta seed. The Code of Conduct document has been agreed on by Syngenta Seeds, SESVanderHave, Danisco Seed, Fr. Strube Saatzucht KG, A. Dieckmann-Heimburg, KWS (owns Betaseed), and affiliated companies.

3.9.3 Sugar beet seed production since 2007

Commercial H7-1 sugar beet seed has been produced since 2005, with the first major seed production year in 2006. The total acreage of H7-1 sugar beet in the Willamette Valley since 2008 has been between 4000 and 5000 acres (Gabel, 2010, p. 7; Pierson, 2010, p.10). Only one grower who sells organic beet or chard seed has been identified in the Willamette Valley. That grower produced chard seed on approximately 1-3 acres at the Western margin of the Willamette Valley. He has tested his organic chard seed using a PCR test capable of detecting 0.01% GE content during this period (Morton, 2010, 61:15-62:6). That seed has been tested each year since 2007 and to date has not detected the presence of any H7-1 sugar beet. (Hoffman, 2010a, p. 15; Morton, 2010, 36:8-17, 75:19-77:13, 99:6-21, 112:10-14; Stearns, 2010, 40:4-15, 49:6-16).

In May 2009, an incident was reported involving event H7-1 steckling disposal that raised questions regarding one sugar beet seed company's stewardship and disposal requirements for those materials (Roseboro, 2009). Stecklings are sugar beet roots that may be transplanted into hybrid sugar beet fields. In or around May 2009, the Pro Bark garden store in Corvalis, Oregon procured a quantity of peat moss from Betaseed. Betaseed had used the peat moss to transport a shipment of sugar beet stecklings, and after the shipment had been transplanted, some quantity of stecklings remained in the peat moss. After Pro Bark obtained the peat moss Pro Bark mixed it with potting soil and offered it for sale as a fertile soil mixture. Betaseed learned that the mix was being sold and that it contained some stecklings, and at that point, Pro Bark's records indicated that it had sold portions of the mixture to thirty customers located in the Corvalis and Albany area. Betaseed repossessed the portion of the mixture that had not been sold. Betaseed personnel visited twenty of the thirty customers who had purchased portions of the mixture and removed any stecklings or steckling fragments found in the mixture. The owner of Pro Bark contacted seven additional purchasers and requested that they inspect for and destroy any stecklings they had purchased (Lehner 2010, pp 7-10.)

Betaseed reported that the stecklings found in the mixture after repossessing it were not likely to survive and produce pollen. Most of the stecklings were fragmented, rotting or dead. Also, because a large percentage of Betaseed hybrid sugar beet fields in the Willamette Valley in 2009 had the event H7-1 gene only on the non-pollinating female plant (see Section 2.7), the shipment of stecklings that Betaseed had transported in the peat moss was composed of less than 5% H7-1 male pollinators. Therefore, according to Betaseed, the chances that any steckling in the peat moss was intact, alive and a male H7-1 pollinator were remote. In addition, given the time of year when the fertile mixture was sold, cross-pollination would have been very

unlikely even if the stecklings had been able to produce pollen, and there were no subsequent reports of any cross-pollination from the stecklings. Betaseed subsequently revised its Standard Operating Procedures to provide for proper disposal of the peat moss in which it transports stecklings (Lehner, 2010, pp. 7-10).

3.9.4 Measured sugar beet pollen dispersal

Many studies have been done to measure distances over which cross-pollination may occur in *Beta* species, with a range of results (e.g., Bartsch et al, 2003; Chamberlain, 1967; Darmency et al, 2009; Darmency et al, 2007; Fenart et al, 2007). Darmency et al (2009) summarized a literature review of studies on pollen flow in sugar beet (values reported in meters converted to feet):

Authors	Maximum dispersal
Alibert et al (2005)	2.1% at 700 ft
Archimowitsch (1949)	0.3% at 2,000 ft
Bateman (1947)	0.07% at 62 ft
Brants et al (1992)	8% at 250 ft
Dark (1971)	0.1% at 100 ft
Dark (1971)	3,900 ft max (using a pollen trap, not hybrid seed production)
Darmency et al (2007)	1.3% at 920 ft
Jensen and Bogh (1942)	2,600 ft max (using a pollen trap, not hybrid seed production)
Madsen (1994)	0.31% at 250 ft
Saeglitz et al (2000)	40% at 660 ft
Scott and Longden (1970)	26 ft max (using a pollen trap, not hybrid seed production)
Stewart and Cambell (1952)	10% at 50 ft
Vigouroux et al (1999)	1.2% at 50 ft

Note: The maximum dispersal was "the highest rate at the farthest distance to which pollen or hybrids were found in the study".

Darmency et al (2009, p. 1085) note that the experiments "were hardly comparable because the experimental design varied widely." The researchers also found that nearly all fertilization from pollen source occurs near the field (within about 0.3 miles). The summary table does not make distinction between mere pollen presence and actual hybridization, which, as discussed previously, can be very different. Darmency et al did not report how many, if any, of these studies used isolated bait plants rather than groups of receptor plants that would be producing their own pollen cloud, which, as discussed above, could make a substantial difference (i.e., the percentages of pollination by an outside source are much smaller with competition). Also, in their own experiments, even when the pollen reached the target plant and hybridization did

occur, Darmency et al found a large drop in germination rates in seeds produced by plants removed from the source, with approximately 40 percent at the source dropping to one percent at around 1,000 feet from the source (2009, p. 1087).

3.9.5 Modeled sugar beet pollen dispersal

Research scientists specializing in modeling pollen dispersal have modeled the sugar beet pollen dispersal for outcrossing to the organic *Beta* production field of a Plaintiff's declarant who believed his fields would be cross-pollinated by event H7-1. The nearest event H7-1 field was 6.9 miles distant. Using conservative assumptions and modeling conditions for the three days during the "pollen shed" period when wind conditions were most likely to result in cross-pollination (June 22, 23, and 27), the modelers obtained the following results for likelihood of outcrossing: June 22, 1 in 4.9 million; June 23, one in 1.1 billion; and June 27, 1 in 222 million. The risk of any successful pollination in these circumstances is highly remote.

3.9.6 Site-specific assessment of cross-pollination potential in the Willamette Valley

This discussion focuses on the Willamette Valley because it is the only known location where event H7-1 commercial seed production and commercial seed production of Swiss chard and red table beet coexist. At least three qualified scientists have evaluated the potential for gene flow from event H7-1 to other *Beta* seed crops in the Willamette Valley: Mark Westgate, PhD, whose results are summarized above; Neil Hoffman, Ph.D. and Leonard Panella, Ph.D. Westgate is a professor of crop production and physiology at Iowa State University, whose "scientific research focuses on understanding environmental factors that affect pollination and seed formation" (Westgate, 2010, p. 1). Hoffman is a plant physiologist who is currently an APHIS official. Among his previous positions were professor of plant biology at the Carnegie Institution and Stanford University (Hoffman 2010a, p. 1). Panella, a plant geneticist, is research leader of the sugar beet research unit at the USDA ARS Crop Research Laboratory in Fort Collins, Colorado (Panella, 2010, p. 1).

Westgate explains that most pollen falls within the "immediately surrounding" area of the source field. In addition, many other factors affect the possibility of cross pollination in two *Beta* seed production fields, including receptiveness of the female, wind and humidity conditions, viability of the pollen, and competition (see Section 2.4 for a general discussion of these factors). For example, Swiss chard and table beets that are grown for seed are primarily open pollinated (all plants produce pollen) rather than hybrids using male sterile females, as is used in the production of most sugar beet seed (discussed in Section 2.7). The pollen cloud in an open

pollinated field is "typically four times more dense than the local pollen cloud for a standard hybrid field" with "billions" of pollen grains per square meter making it much more difficult for a small amount of the stray pollen that might be carried on the wind from another field to compete in the open pollinated fields (Westgate, p. . 5). Westgate concludes, in general, "when all the principal factors affecting pollination are considered, the probability of pollination of table beet or chard fields by sugar beet pollen in the Willamette Valley is infinitesimally small" (Westgate, 2010, p. 6).

Hoffman indicates that nearly all fertilization from a pollen source (99.9%) occurs within the first 500 m (about 0.3 miles), and that any pollen that might reach another downwind field would have to compete with pollen from that field. Based on his assessment of conditions in the Willamette Valley, Hoffman concluded that the 4-mile isolation distance (as articulated in Interim measure No. 2) "to isolate unlike sexually compatible crops such as Swiss chard, table beets and sugar beets is more than 12 times the distance needed to reduce cross-pollination between RRSB and Swiss chard to 0.1% (1 seed in 1000) in a worst case scenario without competition from a local pollen source" (Hoffman, 2010a, p. 14). Hoffman expects the level of gene flow to be less than one seed in 10,000 (0.01%) with a four mile isolation distance. Panella concurred with Hoffman's analysis and conclusion (Panella, 2010, p. 5). Carol Mallory-Smith, PhD, professor in the Department of Agriculture at Oregon State University in the Willamette Valley, concluded that the "proposed restrictions [interim measure including a 4 mile isolation distance] will provide significant safeguards to protect Beta species seed producers while the EIS is being conducted" and that the risk of geneflow would be "extremely low." (Mallory-Smith, 2010, pp. 1-2).

3.9.7 Use of event H7-1 trait on male-sterile female

Seed production companies use a hybrid seed production system in which the event H7-1 trait is on the female (male sterile plants) in a large proportion of commercial seed production fields. In the Willamette Valley at least two seed companies use this system exclusively (Anfinrud, 2010, pp. 1-2; Lehner, 2010, pp. 5-6; Meier, 2010, p. 8). Essentially zero event H7-1 pollen is produced by these "female side" seed production fields. As a result of these methods, 78.6% of the currently growing GE sugar beet seed crop in the Willamette Valley is male-sterile female. Because these plants produce virtually zero pollen, they eliminate any realistic risk for unintentional spread of the GE trait.

3.9.8 Red table beet offtypes

Seed companies growing sugar beets in the Willamette Valley occasionally find a very small percentage of off-types from red table beet crops. Seed companies have indicated a very low level of off-types in sugar beet crops, and one seed company reports that its latest "observation plots did not produce any off-types" (Lehner, 2010, p. 3). Customers (i.e., growers of commercial sugar beet root crops) have likewise indicated that after inspecting the millions of plants grown in variety trials conducted over several years, "the number of chard or red beet off-types were so small as to be, for all intents and purposes, not quantifiable." (Grant, 2010, p.6; Berg, 2010, p. 5; Hofer, 2010, p.4). Seed companies regularly perform grow out tests to determine if there are any issues with off-types (Lehner, 2010, p.3; Hovland, 2010, pp. 2-3). Red table beet offtypes in sugar beet fields could occur due to nearby backyard gardeners growing red table beets, or might occur from open pollinated red table beet fields upwind from sugar beet fields. (Anfinrud, 2010, 109:13-17). In an open pollinated field, every plant sheds pollen (Stander, 2010, p. 2). Thus an acre of open pollinated red table beets would produce far more pollen than an acre of hybrid sugar beet fields, where the only one-fourth to one-third of the plants produce pollen (Westgate, 2010, p. 5). The Willamette Valley Specialty Seed Association pinning guidelines and isolation distances require 4 mile isolation distances between open pollinated red beet and sugar beet fields, in order to limit red beet off types in sugar beet fields (Stander, 2010, p. 2). The potential for sugar beet gene transmission to open pollinated red beet fields is very low, because as indicated, a greater volume of pollen per acre are shed by the open pollinated field (Westgate, 2010, p. 5) (indicating "billions" of pollen grains per square meter shed by an open pollinated red beet field).).

3.9.9 No sensitivity to event H7-1 by conventional sugar beet growers; Stewardship regarding mechanical mixing

There is no indication of sensitivity by customers for conventional sugar beet seed to the possibility of an inadvertent presence of event H7-1 genetic material in the conventional seed (Pierson, 2010, p. 17). First, there is currently no market in the U.S. for organic sugar beets (Pierson, 2010, p. 17). Second, in most areas where both event H7-1 and conventional sugar beets are grown, both types of beets would be combined and processed together, with no effort to differentiate between sugar from H7-1 and conventional beets (Pierson, 2010, pp. 16-17). The sugar from conventional beets does not differ chemically or in any other way from the sugar from H7-1 beets (Hoffman, 2010, p. 16).

As set forth in Section 2.7.3, each of the seed companies producing H7-1 seed utilizes detailed measures to address the possibility of mechanical mixing of H7-1 and conventional sugar beet

seed. These measures would be subject to audit under the interim measures to ensure that they continue to be utilized and are successful.

Because seed production for red beet and chard seed crops is completely separate from sugar beet seed production, there is virtually no risk of mechanical mixing. As discussed in Section 2.8, the two types of production employ different growers, different equipment and different facilties. Accordingly, there is no significant risk of mixing.

3.9.10 Question of zero tolerance

We have identified one organic seed producer who has chosen to produce organic chard seed (among several other organic crops) in the Willamette Valley. This organic producer has approximately one to three acres of production on the Western margin of the Valley. He has indicated that he faces a risk of genetic transfer from event H7-1 seed fields, and that he sells to customers for his organic chard with **zero tolerance** for any level of outcrossing with event H7-1. That producer has tested his chard seeds since 2007 with a PCR genetic test and found no indications of event H7-1 traits in his crops. To date, he has not lost sales due to a risk of cross pollination from Event H7-1. He reports that the costs of the PCR testing for multiple years since 2007 have totaled roughly $700, and that a positive test for event H7-1 for his crop could negatively affect the reputation that producer has with his customers. That seed producer has also indicated in public statements through the media that he is not concerned about a risk of cross-pollination from event H7-1 seed fields where the GE trait is on the female non-pollinator (Morton, 2009, 9:12-19). A seed retailer who buys from that producer has reported that he has multiple sources for chard seed outside the Willamette Valley, including in California, but continues to purchase from that producer nevertheless.

In addition, both that seed producer and the seed retailer have participated in the development of a consensus standard setting a threshold for the presence of GE traits in organic food products and in seed. The Non-GMO Project Working Standard, sponsored by leading players in the organic industry (including Whole Foods), specifically permits crops to be verified "non-GMO" despite the presence of a low level of biotech content—0.25% for GE sugar beet seed and other *Beta* seed crops (Non-GMO Project, 2010, pp. 25, 34) and 0.9% in organic food and feed. Section 2.4.3 of the Working Standard explains that its product content standards apply to the crops listed on Appendix B, plus "close relatives of these crops that are subject to cross pollination" (Non-GMO Project, 2010, p. 12). Appendix B specifically lists "sugar beets" as one of those crops "with GMO Risk" subject to the standard, and also expressly identifies "chard"

and "table beets" as close relatives for which cross-pollination is possible (Non-GMO Project, 2010, p. 34). Section 2.6 explains that "[t]he Non-GMO Project has established" a 0.1% GMO content threshold for "seed and other propagation materials" for all crops listed in Appendix B, but the standards include a specific variance of 0.25% for sugar beet seeds and other crops identified (Non-GMO Project, 2010, pp. 14, 34). This 0.25% level is thus the Working Standard's current threshold for "non-GMO" sugar beet seed and other *Beta* seed crops.

Other commercial producers of sugar beet, red beet or chard seed in the Willamette Valley have all consented to and abide by the Willamette Valley Specialty Seed Association standards, discussed in Section 2.7 and Appendix A.

3.9.11 Seed availability

As discussed in Section 2.7, sugar beet variety development is competitive, technological, and expensive multi-year activity. Seed companies develop varieties with traits they expect growers to want, and the sugar beet companies seed selection committees chose the varieties they wish to grow. It is a market-driven process, where the grower cooperatives themselves determine what is available for planting. Every year, each sugar beet company has a number of varieties that growers may choose from. As the popularity of event H7-1 sugar beet among growers has grown, there have been fewer available conventional varieties and more event H7-1 varieties; however, conventional varieties have been available. There is no organic sugar beet seed production in the sugar beet seed production areas.

Conventional and/or organic sugar beet seeds are available from some US seed suppliers (conventional), and from European seed companies (conventional and organic). (SESVaderHave, 2010; Millington Seed Company, 2010). KWS has some 250 varieties of sugar beet seeds available, including organic (KWS, Grain, 2008). Organic sugar beet is a noteworthy crop in the EU (Eurostat, 2010). Not all organic beets are processed into sugar; some are used to produce a syrup that is integrated into organic food preparations (Ceddia and Cerezo, 2008).

3.9.12 Impact Summary

Alternative 1

Under Alternative 1, there would be no gene flow impacts to growers of organic or conventional *Beta* seed from the production of event H7-1 sugar beet seed.

Alternative 2

Under Alternative 2, no or negligible impacts from event H7-1 seed production on growers of organic or conventional *Beta* seed are expected for the following reasons:

- The large majority of red beet and chard seed crops are grown in different geographic areas than are Event H7-1 sugarbeets.
- Even in the Willamette Valley (where most sugarbeet seed crops and a limited acreage of other beta species seed crops are grown), there have been no reported impacts since H7-1 commercial seed production began in 2006, and with the proposed interim measures, the potential for impacts would be further reduced.
- Based on 1) the use in the majority of the event H7-1 seed production of the trait on the male-sterile female; 2) results of sugar beet pollination outcrossing data in the published scientific literature; 3) site-specific modeling; 4) the relationship between expected seed purity levels and isolation distances determined by the OSCS; 5) the results of experience and testing in the Willamette Valley seed production area since 2007 and, 6) the analysis and conclusions of qualified scientists who specifically addressed this issue, the 4-mile isolation distance (Interim measure Item 2) is expected to result in eliminating any significant risk that cross-pollination of organic or conventional red beet or chard crops will occur, and if it happens, make the rate of outcrossing very low if not undetectable – likely at rates of less than 1 in 10,000 (less than one seed in 10,000 with the event H7-1 trait). This is, for example, far less than the non-GMO Project proposed tolerance levels for sugar beet and other *Beta* seed (0.25%) (Non-GMO Project, 2010),
- The use of hybrids with the event H7-1 trait on the female, in combination with the disclosure requirements regarding male fertile event H7-1 seed crops (Interim measure Item 3) will drastically reduce the potential for cross-pollination. For the large majority of H7-1 seed fields (with the trait on the female), there is essentially zero risk of crossing with a red beet or chard seed crop. For those fields with the H7-1 gene on the male pollinator, the isolation distances will reduce any risk significantly, and producers of red beet and chard can ascertain what those distances are and take appropriate measures (to position their fields, scout for off-types, conduct genetic testing, or through other means discussed herein) if they are concerned about any level of risk.
- The interim measure to prevent seed mixing (Interim measure Item 4), which makes current seed and steckling production and handling practices mandatory (described in Section 2), will make the potentially low level presence of event H7-1 in conventional sugar beet seed negligible and will eliminate adventitious presence of event H7-1 in other *Beta* seeds.

Conventional sugar beet seed will continue to be available as long as growers continue to choose it in the variety trials. Growers who purchase seed purchase a specific variety, which is labeled as such.

In addition, in the event unwanted transmission of H7-1 traits to a red beet or chard crop did occur, there are multiple means for a seed producer to address it. First, because a seed producer of red beet or chard growing beta species typically will inspect each plant remove any off-types from his production fields, any preexisting unwanted cross between a sugar beet and red beet or chard plant can be addressed before seed is produced with an unwanted trait

(Stander, 2010, pp. 3 - 4). Second, once seed is produced, a grower typically will perform grow-out tests on a sample of the seed to confirm that the seed is producing plants without undesired off-types. This can also identify any issues. Third, multiple types of genetic testing can be conducted to confirm the lack of any H7-1 trait (Hovland, 2010, pp. 2 - 3). While PCR testing is available with a very high level of sensitivity (to 0.01%), inexpensive genetic strip tests capable of identifying H7-1 are also available for $2 to $4 per test, with a sensitivity of approximately 0.1% (Stander, 2010, pp. 4 - 5). Such testing may be utilized in a manner that employs samples from multiple seed plants and reduces the number of tests required per field. In the event of a positive test, the seed producer may use additional testing to isolate the source of the portion of his field producing that result (*Id).* Further, retailers of seed with sensitivity to H7-1 content may also conduct grow out tests, or utilize the same genetic testing methods to address any concerns they may have (*Id*)

As discussed in Section 3.17, in light of the above factors, the socioeconomic impacts on farmers growing red table beet and Swiss chard seed are negligible.

3.10 LIVESTOCK PRODUCTION SYSTEMS

The only impacts to livestock production systems would be related to animal feed, which is discussed in Section 3.11.

3.11 FOOD AND FEED

Both food (sugar and molasses derivatives) and animal feed (molasses and beet pulp) are derived from sugar beets. In this section we summarize the large body of scientific evidence that has been developed that supports the conclusion that food and feed derived from event H7-1 sugar beets are as safe and healthy as food and feed derived from conventional sugar beets. While the evidence has largely been developed by Monsanto and/or KWS and the contract research organizations supported by Monsanto and/or KWS, it has been evaluated and peer reviewed by panels of government scientists from the US, Canada, the European Union (EU), Japan, Australia, New Zealand, Mexico, South Korea, the Russian Federation, China, Singapore, Colombia and the Philippines, all of whom have approved, or recommended for approval, the use of products from event H7-1 in their countries (FSANZ, 2005; Monsanto/KWS 2007; Berg 2010).

We begin with a summary of FDA's authority and policy under the federal Food, Drug and Cosmetic Act (FFDCA) with regard to ensuring the safety of food and feed derived from new plant varieties developed using rDNA methods. We then document each element FDA

evaluated in its consultation process. Then we summarize the evaluations and conclusions of several other international scientific oversight groups.

3.11.1 FDA authority and policy

FDA policy statement. In 1992, the FDA issued a policy statement clarifying its interpretation of the FFDCA, regarding foods (including animal feed) derived from new plant varieties, including plants developed by the newer methods of genetic modification, including rDNA. The purpose of the policy is "to ensure that relevant scientific, safety, and regulatory issues are resolved prior to the introduction of such products into the marketplace" (FDA, 1992). FDA is the "primary federal agency responsible for ensuring the safety of commercial food and food additives, except meat and poultry products" and "FDA has ample authority under the act's [FFDCA] safety provisions to regulate and ensure the safety of foods derived from new plant varieties, including plants developed by new techniques. This includes authority to require, where necessary, a premarket safety review by FDA prior to marketing of the food" (FDA, 1992). Under section 402(a)(1) of the FFDCA, a food is adulterated and thus unlawful "if it bears or contains an added poisonous or deleterious substance that may render the food injurious to health or a naturally occurring substance that is ordinarily injurious" (FDA, 1992).

FDA has the authority to ensure safety of new foods. FDA considers its existing statutory authority under the FFDCA and its implementing regulations "to be fully adequate to ensure the safety of new food ingredients and foods derived from new varieties of plants, regardless of the process by which such foods and ingredients are produced" (FDA, 1992). "The existing tools provide this assurance because they impose a clear legal duty on producers to assure the safety of foods they offer to consumers; this legal duty is backed up by strong enforcement powers; and FDA has authority to require premarket review and approval in cases where such review is required to protect public health" (FDA, 1992).

Developers have the responsibility to evaluate the safety of new foods. "It is the responsibility of the producer of a new food to evaluate the safety of the food and assure that the safety requirement of section 402(a)(1) of the act is met. FDA provides guidance to the industry regarding prudent, scientific approaches to evaluating the safety of foods derived from new plant varieties, including the safety of the added substances that are subject to section 402(a)(1) of the act. FDA encourages informal consultation between producers and FDA scientists to ensure that safety concerns are resolved" (FDA, 1992).

Foods developed by new methods do not present greater safety concerns. "FDA believes that the new techniques are extensions at the molecular level of traditional methods and will be used to achieve the same goals as pursued with traditional plant breeding. The agency is not aware of any information showing that foods derived by these new methods differ from other foods in any meaningful or uniform way, or that, as a class, foods developed by the new techniques present any different or greater safety concern than foods developed by traditional plant breeding" (FDA, 1992).

FDA's goal is to ensure the safety of all food and feed. "The goal of the FDA's evaluation of information on new plant varieties provided by developers during the consultation process is to ensure that human food and animal feed safety issues or other regulatory issues (e.g. labeling) are resolved prior to commercial distribution" (FDA, 1997).

3.11.2 FDA biotechnology consultation note to the file BNF 000090

FDA makes the contents of its biotechnology notification files (BNFs) available on the internet (see reference FDA, 2004; event H7-1 is BNF 000090)[35]. FDA documented its consultation with Monsanto/KWS on event H7-1 in a note to the file dated August 7, 2004 (Bonette, 2004). That information is summarized below.

Characterization, inheritance, and stability of the introduced DNA

Using standard analytical techniques, Monsanto/KWS verified that event H7-1 contained a single copy of the EPSPS cassette, and that all components were intact (Bonnette, 2004; Schneider, 2003, p. 43).

Monsanto/KWS conducted crosses using conventional breeding techniques resulting in 27 breeding experiments over four generations. These studies indicate that the introduced trait (glyphosate tolerance) was stably inherited as a dominant trait (Bonette, 2004; Schneider, 2003, p. 44).

Using standard analytical techniques, Monsanto/KWS demonstrated the stable integration of the T-DNA over three generations (Bonette, 2004; Schneider, 2003, p. 47).

Introduced substance – CP4 EPSPS enzyme

As discussed in Section 3.1.1, EPSPS is a catalyst for a reaction necessary for the production of certain aromatic amino acids essential for plant growth and has a similar function in bacteria

[35] http://www.accessdata.fda.gov/scripts/fcn/fcnDetailNavigation.cfm?rpt=bioListing&id=19

and fungi (for example, baker's yeast). While EPSPS is present in plants, bacteria and fungi, it is not present in animals; animals do not make their own aromatic amino acids, but rather obtain them from the foods they consume. Thus, EPSPS is normally present in food and feeds derived from plant and microbial sources (Harrison et al, 1996). There are variations in the genetic makeup (amino acid sequences) of EPSPS among different plants and bacteria. The EPSPS from *Agrobacterium* sp. strain CP4 is just one variant of EPSPS. A unique characteristic of the CP4 EPSPS is that, unlike EPSPS enzymes commonly found in plants, it retains its catalytic activity in the presence of glyphosate (Bonnette, 2004; Schneider, 2003, pp 50-51; Padgette et al, 1995).

Concentrations in sugar beet. In 1999, field trials were conducted at six distinct field locations distributed across Europe in the major sugar beet production areas. The event H7-1 sugar beets were treated with a Roundup agricultural herbicide. Samples of brei (root tissue processed using standard sugar beet industry methods) and top (leaf) tissues were collected and analyzed for levels of the CP4 EPSPS protein. On average, concentrations of the CP4 EPSPS protein, on a fresh weight basis, were similar in the leaf tissue (161 µg/g) and in the root tissue (181 µg/g). The range of mean levels of the CP4 EPSPS protein in top (leaf) tissue was 112 to 201 µg/g and in root (brei) were 145 to 202 µg/g across the sites (Schneider, 2003).

Toxicity of CP4 EPSPS. Studies were conducted on mice, using CP4 EPSPS doses of 400, 100 and 40 milligrams (mg) of CP4 EPSPS per kilogram of body weight per day (mg/kg body wt –d). For a typical 0.03-kg mouse, the 400 mg/kg body wt/d dose equated to 12 mg CP4 EPSPS per mouse per day. The study was designed to reflect a 1,000-fold factor of safety on the highest possible human exposure to CP4-EPSPS, based on assumed exposures to soybean, potato, tomato and corn at the time the study was done (Harrison et al, 1996)[36]. The daily CP4 EPSPS content in the maximum mouse exposure was equivalent to the amount in approximately 160 pounds of H7-1 sugar beets. No treatment-related adverse effects were observed, and there were no significant difference in any measured endpoints between the CP4 EPSPS treated mice and the control group (Harrison, et al, 1996, p. 735).

Monsanto/KWS also compared the amino acid sequence of CP4 EPSPS to protein sequences in the public domain ALLPEPTIDES database using the FASTA algorithm, and reported no biologically relevant sequence similarities between CP4 EPSPS protein and known protein

[36] Note that this was a theoretical exercise as no glyphosate tolerant potatoes or tomatoes are commercially grown.

toxins were observed (Bonnette, 2004). A peptide is a molecule consisting of several linked amino acids (GMO Safety, 2010a).

Allergenicity. Allergens can be derived from many sources: in animal hair, pollen, insect bites, dust mites, plants, pharmaceuticals, and food. Approximately 20,000 allergens have been identified. Most allergens in food are high molecular weight proteins and are rather resistant to gastric acid and digestive enzymes (GMO Safety, 2010a).

Monsanto/KWS searched a comprehensive database of allergens (Hileman et al, 2002) containing sequences of known allergens, for amino acid homology to the CP4-EPSPS protein, and concluded that there was no immunologically significant amino acid sequence homology between the CP4 EPSPS protein and amino acid sequences of allergens in the database (Bonnette, 2004).

Monsanto/KWS discussed two studies relevant to the mammalian digestibility of CP4 EPSPS. In the first study, the CP4 EPSPS protein was exposed to simulated gastric (stomach) and intestinal fluids that were prepared according to the US Pharmacopoeia (1990). The half-life of the CP4 EPSPS protein was reported to be less than 15 seconds in the gastric fluid, greatly minimizing any potential for the protein to be absorbed in the intestine. The half-life was less than ten minutes in the simulated intestinal fluid (Harrison et al, 1996, p 738). The second study reported similar results (Bonnette, 2004).

Food and feed uses of sugar beet

The main food use of sugar beet is for the extraction of sucrose from sugar beet roots through a process involving hot water extraction, followed by purification, evaporation, and centrifuge separation of sucrose crystals (granular sugar). Refined sucrose does not contain protein or other genetic material. This process also yields sugar beet molasses and sugar beet pulp, which are often pelleted and used in animal feed. The leafy sugar beet "tops" are usually left in the field, but they may occasionally be fed to ruminant animals (Bonnette, 2004).

Compositional analysis

To assess whether sugar beet event H7-1 is as safe and nutritious as conventional sugar beet varieties, Monsanto/KWS compared the composition of the hybrid lines containing event H7-1, produced through conventional breeding, to the composition of the corresponding non-transgenic, control. Tops (leaves) and brei (processed roots) were analyzed using standard methods or other suitable methods (Bonnette, 2004).

These analyses included proximate values (crude ash, crude fiber, crude fat, crude protein and dry matter), carbohydrates, quality parameters, saponins (naturally-occurring antinutrients that have a bitter taste and can act as a deterrent to foraging), and eighteen amino acids. Quality parameters measured in root samples included percent sucrose, invert sugar, sodium, potassium and alpha-amino nitrogen. All analyses were conducted as a single analysis for the root (brei) and top (leaf) samples collected as three replica samples from each of five field trials sited. Fifty-five statistical comparisons were made with the control line, of which seven were found to be statistically different ($p<0.05$). Based on the statistical methods, three of these seven would have been expected based on chance. In all seven cases, the ranges for the statistically different components in event H7-1 significantly overlapped or fell completely within the range of values observed for the control, the conventional reference varieties and for available published values from conventional sugar beet varieties (Schneider, 2003, Section C).

Conclusion

Based on the data submitted, the FDA considered the consultation process to be complete, and acknowledged this in a note to the file and a letter to Monsanto (Bonnette, 2004; Tarantino, 2004).

3.11.3 Health Canada approval 2005

Health Canada's Food Directorate has legislated responsibility for premarket assessment of "novel foods." Under Canadian regulations, sugar derived from event H7-1 sugar beet is a novel food because it is derived from a plant that has been genetically modified to exhibit characteristics that were not previously observed in the plant (Health Canada, 2005).

Health Canada "conducted a comprehensive assessment of this sugar beet according to its *Guidelines for the Safety Assessment of Novel Foods*," reviewing the same information Monsanto/KWS provided to FDA in its consultation, and made the following conclusion (Health Canada, 2005:

> Health Canada's review of the information presented in support of the food use of sugar from glyphosate tolerant sugar beet lines containing event H7-1 concluded that the food use of sugar from sugar beet lines containing this event does not raise concerns related to safety. Health Canada is of the opinion that sugar from sugar beet lines containing event H7-1is as safe and nutritious as sugar from current commercial sugar beet varieties.

3.11.4 Canadian Food Inspection Agency (CFIA) approval 2005

The CFIA evaluated event H7-1 both as a crop to be potentially grown in Canada, and as livestock feed, and approved both uses in 2005. Based its evaluation of data provided by Monsanto/KWS, and as summarized in its Decision Document DD2005-54, the CFIA "determined that this plant with a novel trait (PNT) and novel feed does not present altered environmental risk nor does it present livestock feed safety concerns when compared to currently commercialized sugar beet varieties in Canada" (CFIA, 2005).

3.11.5 EFSA risk assessment and EC authorization

The European Food Safety Authority (EFSA) is an independent European agency funded by the EU budget for the purpose of assessing risks associated with the food chain. Risk assessment is a specialized field of applied science that involves reviewing scientific data and studies to evaluate risks associated with certain hazards (EFSA 2010). EFSA conducts risk assessment, but does not have authority to authorize use. The European Commission (EC), which is the executive body of the EU, determines whether or not a genetically modified item will be authorized for use in the EU.

Scope and process. The scope of the Monsanto/KWS application to the EFSA was for food and feed, and not as a crop intended for cultivation in the EU (EFSA, 2006, p. 1). The EFSA used the same data Monsanto/KWS provided to the FDA, Health Canada, and the CFIA, and also requested additional information. The Scientific Panel on Genetically Modified Organisms (GMO Panel) developed an opinion that was then adopted by the EFSA. Subsequently, in 2007, the EC authorized "the placing on the market of food and feed produced from genetically modified sugar beet H7-1" (EC, 2007). During the EFSA risk assessment process, Member states comment on the draft decisions and can request further analysis; the GMO Panel also can request additional information from the applicant.

Detectable presence of CP4 EPSPS. The GMO Panel reported that if the CP4 EPSPS protein was present in the sugar, which was unlikely, it was below the detection limit of 0.004 parts per million (ppm). No DNA was detected in the sugar and the molasses is also "free from DNA and protein (limit of detection 0.002 ppm)." The CP4 EPSPS protein is present in pulp at levels around 500 ppm on a dry weight basis (EFSA, 2006, p. 9).

Safety of the CP4 EPSPS protein. The GMO Panel noted the "long history of dietary exposure to EPSPS proteins" for humans and animals the fact that "previous applications for glyphosate tolerant crops containing the CP4 EPSPS protein have been evaluated and found to be safe for human and/or animal consumption in previous [EFSA] opinions." The GMO Panel concluded that "a toxicological assessment of new constituents is not applicable" (EFSA, 2006, p 10).

Additional toxicity study. In response to EFSA information requests, Monsanto/KWs conducted a 90-day toxicity study, feeding processed pulp to rats, which did not indicate any adverse effects. The GMO Panel reported additional studies of sugar beet pulp to sheep, also with no adverse effects (EFSA, 2006)[37].

Allergenicity. In addition to evaluating the potential allergenicity of the CP4 EPSPS protein, the GMO Panel considered whether the insertion of the transgene could result in modifications of the pattern of expression of other potentially allergenic proteins within the sugar beet plant. The Panel did not consider the issue to be relevant, as sugar beet is not a major allergenic food, and overexpression of an existing protein "would be unlikely to alter the overall allergenicity of the whole plant (EFSA, 2006, p. 12).[38]

No need for post-market monitoring. The GMO Panel noted "No risks to human and animal health were identified in studies of the CP4 EPSPS protein expressed in sugar beet H7-1, and in studies of the genetically modified sugar beet itself. Thus, foods and feeds produced from sugar beet H7-1 is as safe and nutritious as foods and feeds derived from conventional sugar beets." The Panel recommended no post-market monitoring (EFSA, 2006, p. 13).

Conclusions. The GMO Panel stated the following in its conclusions (EFSA, 2006, p. 13):

- Sugar and molasses have been shown to be free from DNA and protein
- Animals fed with pulp will be exposed to the CP4 EPSPS protein
- The CP4 EPSPS protein has been evaluated and found to be safe for human and/or animal consumption
- The molecular characterization and the comparative compositional analysis did not indicate the occurrence of any unintended effects due to the genetic modification
- Products from sugar beet H7-1 are safe as food and feed
- The nutritional value of the sugar beet H7-1 and the derived sugar beet products is comparable to that of the analogous products from conventional sugar beet
- The risk of allergenicity is of no concern with this product

3.11.6 Other approvals

Japan approved the use of event H7-1 in feed 2003, in food in 2005, and the environmental in 2007 (Sato, 2008). Studies by the Japanese National Food Research Institute have confirmed that there is no detectable DNA in sugar from sugar beets, with the conclusions that "sugar beet

[37] http://jas.fass.org/cgi/content/full/83/2/400
[38] http://jas.fass.org/cgi/content/full/83/2/400

DNA was degraded at an early stage of sugar processing" (Oguchi et al, 2009). Event H7-1 has also been approved for food and feed use in Mexico, South Korea, Australia, New Zealand, China, Colombia, the Russian Federation, Singapore and the Philippines (FSANZ, 2005; Monsanto/KWS 2007; Berg 2010).

3.11.7 Willingness of the buyer to accept sugar from event H7-1

Market concerns about willingness of buyers to accept sugar, molasses, and/or pulp derived from event H7-1 have not resulted in any perceptible change in the demand for US-produced beet sugar or other fractions. Based on the regulatory approvals obtained in domestic and international markets, sugar, molasses, and pulp derived from event H7-1 is being successfully marketed.

As summarized above, there is a large body of scientific evidence that has been reviewed and validated by several international scientific panels that supports the safety of the sugar and other fractions derived from event H7-1 for food and feed use. If there are consumers who do not wish to purchase sugar made from event H7-1 for reasons other than safety and health, they have the option of buying sugar made from sugarcane, which is not currently produced using lines that were developed using modern biotechnology. However, the majority of food products containing beet sugar, such as cakes, candy, ice cream and other sweets, are likely to contain sugar derived from sugar beet varieties containing event H7-1. Most commercial food and beverage products are also likely to contain corn or soy products derived from biotech crops (Goldsbrough, 2000).

3.11.8 Impacts

Based on the scientific evidence summarized in this section, impacts on food and feed are not expected with either alternative. Food and feed derived from event H7-1 is equivalent to food and feed derived from conventional sugar beets. Because both conventional and event H7-1 sugar beets are processed in the same facilities, there is no distinction in the US between food and feed derived from conventional and event H7-1 sugar beets. Markets are available for all the food and feed produced. Because there is no commercial organic sugar beet industry in the US, organic sugar beet production is not impacted in any way.

Aside from sugar, the other products from sugar beets (molasses and pulp) are not major consumer items and can easily be avoided by consumers who do not wish to be exposed to GE products. As discussed above, there is no detectable DNA in processed sugar; however, consumers who wish to avoid all products derived from GE crops can purchase cane sugar rather than beet sugar. While processed foods, the situation is similar to that for corn and soy

products: even without event H7-1, it would be very difficult for a consumer to avoid products derived from GE crops.

3.12 WEED CONTROL AND GLYPHOSATE RESISTANCE

As indicted in Section 1, EPA is responsible for regulation of glyphosate and thus for issues of weed resistance to glyphosate (EPA, 2003).. This report nevertheless analyzes those issues. APHIS's 2005 EA did so as well, and the court did not find a deficiency in that analysis. APHIS has performed other herbicide resistance analyses in many E As conducted as part of the petition review process (see http://www.aphis.usda.gov/biotechnology/not_reg.html).

3.12.1 Herbicide-resistant weeds

As explained in Section 2.5, not all weed species respond the same to every herbicide mode of action. Instead, a weed species can have a natural resistance to a particular mode of action, and if a grower employs only that mode of action, over time, the naturally resistant species will overtake other weed species in that area. This is often referred to as a shift in the weed population. It is for this reason that growers may need to use multiple products to control the full spectrum of weeds in a field.

Sugar beet weed management, including major weeds in sugar beets, herbicides used, herbicide mode of action and herbicide resistance, was discussed in Section 2.4. Table 3-1 summarizes the major sugar beet weeds in terms of resistance to herbicide groups used in sugar beets for the states where sugar beets are grown commercially. A weed is listed for a state when herbicide resistance has been confirmed. The table does not show the extent of the weeds with the noted resistance; this would vary widely. References for the table are included at the bottom of the table.

As of June 27, 2010, 194 herbicide-resistant weed species (341 herbicide resistant weed biotypes) have been documented worldwide (Heap, 2010). These species have been reported to be resistant to 19 different herbicide modes of action (Heap, 2010). Approximately five

Table 3-1 Major sugar beet weeds with resistance to herbicides groups used in sugar beets[1]

California

Species	Common Name	Year[2]	Herbicide Mode of Action
1. *Echinochloa crus-galli*	Barnyardgrass	2000	ACCase inhibitor
2. *Echinochloa crus-galli*	Barnyardgrass	2000	fatty acid synthesis inhibitor.

Colorado

Species	Common Name	Year[2]	Herbicide Mode of Action

[2] *Year resistance was first reported.*

percent of resistant species have resistance to EPSPS inhibitors (glycines, which include glyphosate). Refer to Figure 2-3 for the distribution by herbicide mode of action.

Measures to reduce the development of herbicide resistance are discussed in Section 2.5.

3.12.2 Glyphosate-resistant weeds

As discussed in Section 2.5, herbicide resistance is not a unique or new phenomenon. The development of weeds resistant to a particular herbicide mode of action is an issue that growers have faced for decades. As with other herbicide modes of action, not all weeds respond the same to glyphosate, and some species naturally vary in their tolerance to the herbicide.

Because of the nature of glyphosate and its high degree of specificity, generally speaking, there is a reduced potential that there will be a selection for weed resistance. Glyphosate is a nonselective, foliar-applied, broad spectrum, post-emergent herbicide compared to many other herbicide groups. It operates by binding to a specific enzyme in plants thereby interfering with the plant's required metabolic process. Glyphosate is the only herbicide that binds with this enzyme, and therefore it is highly specific (Cole, 2010a, p5).

Currently in the U.S., there are two known mechanisms of glyphosate resistance. The first is the exclusion mechanism in which glyphosate is either prevented from moving to growing cells or from reaching the target protein. Mechanisms that confer this form of resistance are relatively rare and are not common across plant species. The second mechanism, gene amplification, results from an increase in enzyme gene copies in the plant which leads to higher levels of resistance to glyphosate (Cole, 2010a, p.5).

Accordingly, while glyphosate has been used extensively for over three decades, there have been relatively few cases of resistance development, as compared to many other herbicides and when considering the substantial glyphosate-treated acreage worldwide (approximately 1 billion acres) and the total number of weeds that the herbicide can control. In the U.S., there are ten weed species where glyphosate-resistant biotypes are known to exist in certain areas of the country (19 weeds have been reported to have developed glyphosate resistance at some location worldwide). These resistant weeds represent a relatively small minority of the overall weed population. For example, in 2009, approximately 135 million of the 173 acres of corn, soybeans and cotton in the U.S. were planted with a herbicide tolerant variety, with the most common tolerance trait being glyphosate tolerance (USDA NASS, 2009a). At the same time, only about 6% of the total planted corn, soybean and cotton acres in the U.S. are estimated to

have some level of presence of weeds resistant to glyphosate (Ian Heap as reported by WSSA, 2010).

A weed scientist from the University of Wyoming who specializes in sugar beet weed control, has testified that in the coming years, "it is highly unlikely that the use of glyphosate in connection with GR [glyphosate resistant] sugar beet will result in the same conditions that have led to GR weeds in other GR crops" (Kniss, 2010, p. 3). This is in part because of the fundamentally different growing practices with sugar beet. Kniss reports that more diverse cropping systems (with more rotations and herbicide modes of action), such as those used with sugar beets "are less likely to result in weed resistance issues" (Kniss, 2010, p. 3). Approximately half of the GR weeds noted worldwide to date have been found in non-GR cropping systems (such as orchards). In the U.S., of the confirmed GR weeds, two evolved where there was no GR crop use (roadsides, vineyards, and tree crops) (Kniss, 2010a, p. 2).

GR sugar beet production systems are different than other GR crops, in part because multiple year crop rotations are an integral component of effect weed and pest management programs for the sugar beet crop in all sugar beet growing regions (Kniss, 2010a, p. 3). Given that the sugar beet crop is susceptible to many diseases, nematodes, and insects, multiple crop rotation is required to limit the economic impact of those pests. As such, sugar beet production grower agreements with sugar processers will typically prohibit growers from planting a sugar beet crop in consecutive years (Kniss, 2010a, p. 3).

Instead, sugar beets are generally grown on a three- to four-year rotation. While other GR crops may be included in the rotation with GR sugar beets (with the exact rotation varying in different sugar beet growing regions) (Table 2-2), "the crop rotation in itself will reduce the potential for herbicide resistant weed development due to changing cultural practices between crops (such as planting date, harvest date, tillage practices, etc.)" (Kniss, 2010, p. 4).

As discussed above, the characteristics of glyphosate itself reduce the potential for the development of herbicide resistance as compared to other herbicide families. As such, certain herbicide families have been classified according to their risk of resistant weed development. Beckie (2006) lists acetolactate synthase (ALS) and acetyl CoA carboxylase (ACCase) inhibiting herbicides as "High" risk for resistance development, while glyphosate is considered a "Low" risk herbicide for the development of herbicide resistant weeds. ALS and ACCase inhibiting herbicides are commonly used in conventional sugar beet production, and weeds resistant to these two herbicide groups are widely distributed across sugar beet growing regions of the U.S.

(Kniss, 2010a, p4) (Figure 2-4). Glyphosate tolerant sugar beets can help delay resistance to these herbicides (Kniss, 2010, pp. 4 - 5):

> In fact, glyphosate resistant sugar beet adds to the diversity of herbicide modes of action in many sugar beet crop rotations because it introduces a new mode of action (glyphosate) into the rotation with non-glyphosate-resistant crops, that tend to rely heavily upon acetolactate synthase ("ALS") inhibitors. ALS inhibiting herbicides pose a far greater risk of developing weed resistance than does glyphosate. By adding glyphosate to their crop rotations, growers of GR sugar beet actually decrease the likelihood of developing resistance to ALS inhibitors, just as the use of other crops and alternative modes of action in rotation with GR sugar beet reduce the likelihood of glyphosate resistant weeds.

Use of herbicides with different modes of action, either concurrently or sequentially, is an important defense against weed resistance (Weed Science Society of American [WSSA], 2010b). "Use of a single product or mode of action for weed management is not sustainable. Some of the best and most sustainable approaches to prevent resistance include diversified weed management practices, rotation of modes of action and especially the use of multiple product ingredients with differing modes of action" (WSSA, 2010).

The WSSA reports higher levels of awareness among growers regarding the need to minimize the potential for development of glyphosate resistance: "In a market research study that surveyed 350 growers in 2005 and again in 2009, in response to the question, 'are you doing anything to proactively minimize the potential for resistance to glyphosate to develop,' 67% said yes in 2005 and 87% said yes in 2009" (David Shaw, as reported in WSSA, 2010). "In a 2007 survey of 400 corn, soybean and cotton growers, resistance management programs were often or always used by 70% or more of all three grower groups" (Frisvold and Hurley as reported by WSSA, 2010). There is widespread information available from universities and other sources regarding glyphosate resistance. Public universities (i.e. North Dakota State University, University of Minnesota), herbicide manufacturers (i.e. www.weedresistancemanagement.com, www.resistancefighter.com) and crop commodity groups (i.e. National Corn Growers Association, American Soybean Association) have internet web sites with information on prevention and management of herbicide resistance. An example of information provided by public universities is Dr. Don Morishita, a weed scientist at the University of Idaho, who advises sugar beet growers on weed resistance management strategies (Dumas, 2008). The Sugar Industry Biotech Council provides weed resistance resources on its website. Monsanto includes information on weed resistance management practices in its Technology Use Guide that is mailed annually to all licensed growers. The sugar beet industry associations also hold annual

meetings where weed resistance management practices and other stewardship measures are included as part of the proceedings.

Sugar beet growers in particular have strong financial and practical interests in managing weeds effectively to reduce the development of herbicide resistance in order to maximize yield potential. Sugar beets are a high-value crop, and competition from weeds for moisture and light can negatively impact yields and the overall value of the crop. The development of glyphosate-resistant weeds harms the economic return per acre for the individual farmer and the entire sugar beet industry (Cole, 2010a, p11).

As such, strategies and recommendations to delay the development of glyphosate-resistant weeds have been developed for event H7-1 sugar beets (TUG, Appendix E). Specifically, the TUG recommends the use of "mechanical weed control/cultivation and/or residual herbicides" with event H7-1 sugar beets, where appropriate, and "additional herbicide modes of action/residual herbicides and/or mechanical weed control in other Roundup Ready® crops" rotated with event H7-1 (TUG, 2010, p. 40). In addition to the financial incentive to follow these recommendations, all Roundup Ready technology users, including sugar beet growers, are contractually obligated through the Monsanto Technology Stewardship Agreement to follow the TUG.

3.12.3 Impact summary

Alternative 1

Under Alternative 1, there would be no effect of event H7-1 on the potential for weeds to develop resistance to glyphosate, given that glyphosate use is minimal with conventional sugar beets. Growers would continue to use conventional weed control methods, including other herbicide modes of action, to the extent such conventional herbicides are available (see Section 2.5). A return to conventional herbicides could have consequences for development of further resistance to those herbicides.

As discussed above, glyphosate use in GR sugar beet has proven to be an effective tool against weeds resistant to non-glyphosate herbicides, such as ALS-inhibitors and ACCase-inhibitors. If the planting of H7-1 sugar beets is substantially curtailed, a valuable tool for herbicide resistant weed management will be unavailable to sugar beet growers, and the impact of weeds resistant

to other herbicides may increase, although the impact would likely be small since sugar beets are a relatively small crop (Kniss, 2010a, p. 7).

Alternative 2

Under Alternative 2, impacts, if any, with respect to the development of glyphosate-tolerant weeds in sugar beet crops in the timeframe considered in this ER are expected to be very small. First, sugar beets are a relatively small crop, (event H7-1 accounts for less than one percent of the glyphosate-resistant crops grown in the US), suggesting that the likelihood for the development of new glyphosate-resistant weed populations when compared to other herbicide resistant crops is smaller. Second, as discussed above, the nature of glyphosate itself and the growing practices for sugar beets makes it less likely that new glyphosate-resistant weed populations will develop in sugar beets as a result of the use of glyphosate in sugar beets. Additionally, there is a high level of awareness about the potential for glyphosate resistant weeds and many readily available resources to assist growers with management strategies. Indeed, event H7-1 growers are required to follow Monsanto's TUG, including its recommendations for adopting growing practices aimed at reducing the development of glyphosate-resistant weed populations. Finally, because herbicide resistance is a heritable trait, it takes multiple growing seasons for herbicide tolerant weeds to emerge and become the predominant biotype in a specific area (Cole, 2010a, p. 4). Researchers have concluded that even if growers completely relied on only one herbicide, it is likely to take at least five years for a herbicide-resistant weed population to develop (Kniss, 2010a, p4; Beckie 2006, Neve, 2008; Werth et al., 2008). This is a reason why crop monitoring and follow up by University and industry weed scientist in cases of suspected resistance are important parts of all herbicide resistance stewardship programs.

3.13 PHYSICAL

3.13.1 Land Use

As discussed in Section 2.3, acreage planted in sugar beets in the US has changed little over the past 50 years (since 1961), ranging from a low of 1.1 million acres in 1982 (slightly less than the 2008 acreage) to a high of 1.6 million acres in 1975. Table 3-2 shows planted sugar beet acreage for the last six years. While there have been changes within individual states, overall the range is small. As discussed in Section 2, a small part of the sugar beet crop was event

Table 3-2 Sugar Beet Acres Planted 2005 to 2010

Location	2005	2006	2007	2008	2009	2010

US Total	1,299,800	1,366,200	1,268,800	1,090,700	1,185,800	1,174,200

Source: USDA NASS, 2010

H7-1 in 2007, and in 2010, 95 percent of the planted crop was event H7-1. During this time period, the planted sugar beet acreage remained within the range of pre-event H7-1 plantings since 1961.

As discussed in Section 2, sugar beet production is highly structured, vertically integrated, and centered on production facilities that are grower owned.. To maintain a healthy industry, production cannot fluctuate much from year to year: a certain level of production is needed to support the major investment of a processing facility, and a processing facility has limited capacity. The sugar beet grower is bound to the local processing facility and the local processing facility is bound to the sugar beet grower. Barring some unusual disruption in the industry, large fluctuations from year to year would not be expected.

Crop data also provides no indication that the introduction and widespread adoption of GE crops in general has resulted in any significant change to the total US acreage devoted to agricultural production. The acres in the US planted to principal crops, which include corn, sorghum, oats, barley, winter wheat, rye, durum, spring wheat, rice, soybean, peanuts, sunflower, cotton, dry edible beans, potatoes, canola, proso millet, and sugar beets, has remained relatively constant over the past 25 years (USDA NASS, 2010). From 1983 to 1995, the average yearly acreage of principal crops was 328 million (USDA NASS, 2010). Biotechnology-derived crops were

introduced in 1996, and in 2009, 321 million acres of principal crops were planted, which is not a significant change (USDA NASS, 2009a).

Alternative 1

Under Alternative 1, plantings of event H7-1 sugar beet would be limited and only occur under notification or permit issued by APHIS. Growers would not have the option of planting event H7-1 sugar beets. Since sugar beet growers are farmers who also grow other crops, those who would have grown sugar beets could most likely grow some crop, but they could nevertheless suffer significant losses as a result (See Section 2.3). They may choose to grow conventional beets or other crops. A number of factors may influence this decision, including availability of herbicides for conventional sugar beets, availability and cost of specialty cultivating equipment, availability of desirable varieties of sugar beet, and the potential penalty or lost ownership shares in the cooperative for not growing sugar beets. In the short term (the term considered by this ER), Alternative 1 could potentially result in a large decrease in sugar beet production. However, changes in land use would not be expected and the land use is likely to remain agricultural.

Alternative 2

Under Alternative 2, growers who choose to do so could continue to plant event H7-1 sugar beets. Sugar beet acreage would be expected to be similar to the levels of the past 50 years. Land use that is agricultural would be expected to remain so and other land use would not be impacted.

3.13.2 Air Quality and Climate

Alternative 1

Under Alternative 1, plantings of event H7-1 sugar beet would be limited and only occur under notification or permit issued by APHIS. Because the use of glyphosate as a post-emergence herbicide has resulted and is expected to continue to result in an increase in conservation tillage practices, an increase in the use of mechanical tilling would be expected under Alternative 1, if growers would choose to plant conventional sugar beets. If growers would choose other crops, the effects would depend on what the other crops would be. Emissions related to global

warming, ozone depletion, summer smog and carcinogenicity, among others, were found to be lower in glyphosate-tolerant crop systems than conventional systems (Bennett et al., 2004). Therefore, Alternative 1 would be expected to have slightly greater impacts on air quality and climate, if growers planted conventional sugar beets rather than event H7-1 sugar beets.

Alternative 2

Under Alternative 2, growers who choose to do so could continue to plant event H7-1 sugar beets. The continued use of event H7-1 sugar beets may result in continued increases in conservation tillage, as discussed in Section 2 (changing to conservation tillage practice is gradual, as it often requires different management practices and often requires new equipment). Therefore, Alternative 2 would lead to a small but positive impact on air quality and climate relative to Alternative 1.

3.13.3 Surface water quality

Surface water may be impacted from sugar beet production by runoff from sugar beet fields that carries soil particles and herbicides or other pesticides to streams, rivers, lakes, wetlands and other water bodies. As discussed below, based on existing data, the soil component of runoff is a much more important contributor to surface water impacts than is the pesticide component.

Alternative 1

Under Alternative 1, plantings of event H7-1 sugar beet would be limited and only occur under notification or permit issued by APHIS. Under Alternative 1, growers who are now growing event H7-1 sugar beets and who would choose to grow conventional sugar beets would need to use other practices for weed management. These practices would likely consist of some combination of herbicide use and increased tillage (beyond conservation tillage).

If Alternative 1 would result in increased use of tillage for weed control, overall adverse surface water impacts are likely to be greater than with Alternative 2. Tillage causes widespread soil disturbance. Thus, wind and water erosion, topsoil loss and the resulting sedimentation and turbidity in streams are likely to increase with increased tillage. In 2009, based on the states' water quality reports, EPA identified sedimentation and turbidity as two of the top 10 causes of impairment to surface water in the U.S. in general; in 2007, EPA identified sedimentation/siltation as the leading cause of impairment to rivers and streams in particular (EPA, 2009, p. 15; EPA, 2007, p. 9). Although a comprehensive data set has not yet been developed to prove the point, EPA has projected conservation tillage to be "the major soil

protection method and candidate best management practice for improving surface water quality" (EPA, 2002). EPA identifies conservation tillage as the first of its CORE 4 agricultural management practices for water quality protection (EPA, 2008a).

Based on the states' water quality reports to EPA, which EPA makes available through its National Assessment Database, pesticides in general and herbicides in particular are a relatively minor contributor to impairment of surface water in the U.S., compared to sedimentation/siltation and turbidity (EPA 2008b). Of the pesticides that were reported as contributing to impairment, almost all are previously used, highly persistent chemicals that are no longer registered for use in the U.S. Only one herbicide, atrazine, was found (EPA 2008b).

In summary, based on EPA data, herbicides in general are very minor contributors to surface water impairment in the U.S., whereas sedimentation/siltation and turbidity are major contributors. Alternative 1, compared with Alternative 2, would likely result in a different mix of herbicides used and may result in increased tillage. Increased tillage could contribute to adverse surface water impacts through increased runoff of soil particles to surface water bodies.

Alternative 2

Alternative 2 would result in continued application of glyphosate herbicides to event H7-1 sugar beets. Herbicides that adsorb strongly, such as glyphosate, are less likely to degrade or volatilize (USDA APHIS, 2009).

Other herbicides used on sugar beets have varying chemical fates, but, in general, most are more persistent and are characterized by higher mobility in soils, making them more apt to continually contaminate surrounding water systems.

3.13.4 Groundwater quality

Alternative 1

Under Alternative 1, if growers choose to grow conventional sugar beets, the potential for impacts to groundwater would be similar to that prior to the widespread adoption of event H7-1 sugar beets. If herbicides are used that do not bind strongly to soil particles, and have a higher potential to leach into groundwater, the potential for migration to groundwater may be higher than with Alternative 2.

Alternative 2

Because glyphosate binds strongly to soil, and has a low potential to leach into groundwater, it is unlikely to impact groundwater.

3.14 BIOLOGICAL

Potential environmental effects of pesticide use are carefully considered as a part of the FIFRA pesticide registration process. Prior to the approval of a new pesticide or a new use of that pesticide (including a change in pesticide application rates and/or timing) and before reregistering an existing pesticide, EPA must consider the potential for environmental effects and make a determination that no unreasonable adverse effects to the environment will be caused by the new pesticide, new use or continued use.

To make this determination, EPA requires a comprehensive set of environmental fate and ecotoxicological data on the pesticide's active ingredient (US 40 CFR Part 158). EPA uses these data to assess the pesticide's potential environmental risk (exposure/hazard). The required data include both short- and long-term hazard data on representative organisms that are used to predict hazards to terrestrial animals (birds, nontarget insects, and mammals), aquatic animals (freshwater fish and invertebrates, estuarine and marine organisms), and nontarget plants (terrestrial and aquatic).

Information regarding the impacts of glyphosate on the biological environment is summarized below. Additional information on this topic is also being considered in the USDA APHIS Draft Environmental Impact Statement (DEIS) on the Deregulation of Glyphosate Tolerant Alfalfa (Docket No. APHIS-2007-0044). This information is applicable to the use of glyphosate in event H7-1 sugar beet since the maximum single in-crop application rate for GT alfalfa (1.55 lb a.e./A) is greater than the maximum single in-crop application rate for sugar beet (1.125 lb a.e./A).

3.14.1 Plant and Animal Exposure to Glyphosate

Animals

The equivalence of the CP4 EPSPS enzyme to native EPSPS except for tolerance to glyphosate is discussed in Sections 3.1 and 3.11. A number of researchers have conducted laboratory investigations with different types of arthropods exposed to genetically engineered crops containing the CP4 EPSPS protein (Goldstein, 2003; Boongird et al., 2003; Jamornman,

et al., 2003; Harvey et al., 2003). Representative pollinators, soil organisms, beneficial arthropods and pest species were exposed to tissues (pollen, seed, and foliage) from GE crops that contain the CP4 EPSPS protein, to evaluate potential toxicity. These studies, although varying in design, all reported a lack of toxicity observed in various species exposed to these crops (Nahas et al., 2001; Dunfield and Germida, 2003, Siciliano and Germida 1999).

As a part of the reregistration evaluation under FIFRA, EPA conducted an ecological assessment for glyphosate. This assessment compared the results from toxicity tests with glyphosate conducted with various plant and animal species to a conservative estimate of glyphosate exposure in the environment, the Estimated Environmental Concentration (EEC). .

Glyphosate is practically nontoxic to slightly toxic to birds, freshwater fish, marine and estuarine species, aquatic invertebrates and mammals and practically nontoxic to honey bees (which are used to assess effects on nontarget insects in general) (EPA, 1993, pp. 50, 38 - 40, 45, 47, 48 - 50). Glyphosate has a low octanol-water coefficient, indicating that it has a tendency to remain in the water phase rather than move from the water phase into fatty substances; therefore, it is not expected to accumulate in fish or other animal tissues.

In the Reregistration Eligibility Decision (RED) for glyphosate (EPA, 1993, p. 53), the exposure estimates were determined assuming an application rate of 5.0625 lb a.e., which exceeds the maximum labelled use rate for a single application for agricultural purposes. When the EECs were calculated for aquatic plants and animals, the direct application of this rate to water was assumed. Based on this assessment, EPA concluded that effects to birds, mammals, fish and invertebrates are minimal based on available data (EPA, 1993).

The glyphosate end-use products used in agriculture contain a surfactant to facilitate the uptake of glyphosate into the plant (Ashton and Crafts, 1981). Depending on the surfactant used, the toxicity of the end-use product may range from practically nontoxic to moderately toxic to fish and aquatic invertebrates (EPA, 1993, pp. 42 - 45). For this reason, the 1993 Glyphosate RED stated that some formulated end-use products of glyphosate needed to be labeled as "Toxic to fish" if they were labeled for direct application to water bodies. Due to the associated hazard to fish and other aquatic organisms, glyphosate end-use products that are labeled for applications to water bodies generally do not contain surfactant, or contain a surfactant approved for direct application to water bodies.

Soil Microorganisms

Microorganisms produce aromatic amino acids through the shikimate pathway, similar to plants. Since glyphosate inhibits this pathway, it could be expected that glyphosate would be toxic to microorganisms. However, field studies show that glyphosate has little effect on soil microorganisms, and, in some cases, field studies have shown an increase in microbial activity due to the presence of glyphosate (USDA FS, 2003).

Based on the data available on glyphosate usage, chemical fate, and toxicity, glyphosate is not expected to pose an acute or chronic risk to the following categories of wildlife: (EPA, 1993)

- birds,
- mammals,
- terrestrial invertebrates,
- aquatic invertebrates, and
- fish
- soil microorganisms

Alternative 1

Under Alternative 1, the potential for impacts to animal species may be greater than with Alternative 2 because of the return to greater use of additional herbicides, potentially with higher toxicities.

Alternative 2

As stated previously, Alternative 2 is expected to result in the continued use and application of glyphosate-based herbicide formulations. This could result in continued glyphosate exposure to animal species within and adjacent to those fields through drift, as discussed previously, and a decrease in exposure to other herbicides from runoff and/ or drift (USDA APHIS, 2009).

. . . . .Considering the potential for aquatic exposure to glyphosate formulations from terrestrial uses, EPA recently evaluated the effect of glyphosate and its formulations on another amphibian species, the California red-legged frog, and concluded that aquatic exposure to

glyphosate or its formulations posed no risk to this threatened species (EPA, 2008b). Because EPA considered a wide range of application rates in their evaluation for the red-legged frog, this conclusion can also be applied to amphibians exposed to glyphosate from applications on event H7-1 sugar beet. Any possible adverse impacts to amphibians resulting from the deregulation of event H7-1 sugar beet may be offset by the shift from other herbicides used in sugar beet cultivation, which are considered to have higher environmental impacts in general. . Additionally, amphibian habitat in watersheds where event H7-1 sugar beet is produced could be improved through conservation tillage, resulting in decreased soil erosion, decreased sedimentation in runoff, and decreased turbidity in ponds, lakes, and rivers fed by surface waters.

Plants

Glyphosate is a non-selective herbicide with post-emergence activity on essentially all annual and perennial plants. As discussed in Section 3.1.1, this activity is due to inhibition of EPSPS, an enzyme involved in aromatic amino acid synthesis. As with any herbicide, a risk exists that spray drift could pose issues for plants on the borders of the target fieldHowever, EPA takes the potential for spray drift into account when conducting the risk assessment it uses to establish pesticide application rates and direction for use, which are designed to minimize spray drift risks.. As discussed earlier, glyphosate binds tightly to agricultural soils and is not likely to move offsite dissolved in water. Moreover, glyphosate is not taken up from agricultural soil by plants. However, because drift is a potential means of exposure to non-target plants adjacent to an event H7-1 sugar beet field; Monsanto conducted a threatened and endangered (TE) species risk assessment to evaluate the impacts to plants (and animals) from the use of glyphosate-based herbicides in conjunction with glyphosate-tolerant plants. The complete assessment was submitted to APHIS and has been reviewed by APHIS scientists to support the petition for deregulation of glyphosate-tolerant alfalfa. The assessment is available on the APHIS, BRS website at http://www.aphis.usda.gov/biotechnology/alfalfa_documents.shtml

The assessment identified some plant, but no animal, species for which glyphosate when aerially applied could pose issues in areas bordering fields in certain locations where sugar beets are grown. To address any such risks, Monsanto developed Pre-Serve, a web-based program designed to eliminate any potential impacts on TE plants resulting from the agricultural use of herbicides that contain glyphosate.

Pre-Serve instructs growers to observe specific precautions when spraying glyphosate herbicides on Roundup Ready® crops near TE plant species that may be at risk. Only a very small percentage of glyphosate applications will require mitigation measures. This is because the vast majority of U.S. cropland is outside of the Pre-Serve Use Limitation Areas – areas where threatened or endangered plant species may be present – and most glyphosate applications are made using ground application equipment at rates below 3.5 pounds of active ingredient per acre (lb a.e./acre), which will not impact the TE plant species.

Growers who are licensed to purchase and use seeds containing Roundup Ready® technology are required contractually to follow the requirements in Monsanto's Technology Use Guide. This includes the requirement to access the Pre-Serve website (www.pre-serve.org) or contact Monsanto before applying glyphosate-based herbicide products to crops grown from these seeds. This website will guide growers and applicators through a user-friendly, four-step process to determine whether their fields are located within Use Limitation Areas and, if so, to identify the mitigation measures that must be taken. For fields located within Use Limitation Areas, the following mandatory steps must be taken to reduce potential risks to TE plant species:

- Ground applications are limited to rates of less than 3.5 lb a.e./acre (most uses).
- Aerial applications may be prohibited in buffer zones along perimeters of fields. The size of buffer zones can be minimized by employing a coarser spray droplet size.
- In specified counties, aerial applicators will be required to observe a new maximum use rate of 0.92 lb a.e./acre (26 fl. oz/A Roundup PowerMAX® or WeatherMAX®) if using medium spray droplets[39], but can apply the current full labeled rate (1.55 lb a.e./acre or 44 fl. oz/acre of Roundup PowerMAX or WeatherMAX) if using coarse spray droplets.

In addition to the instructions provided by Pre-Serve, mitigations from local, state or federal protection programs and/or landowner agreements may apply. Monsanto's licensees are required to follow these measures where applicable. .

® Roundup Ready is a registered trademark of Monsanto Technology LLC.

[39] In counties where listed plant species observations were present, but not within 250 ft of a relevant land use, actual separation distance was not assessed. In these counties aerial application rates with medium sized droplets are restricted to 0.92 lb a.e./acre to avoid exposure to listed TE plant species that might be within 417 ft of the application area, and thus within an area where aerial application at 1.55 lb a.e./acre using medium-sized spray droplets would present a potential risk based on the Tier 1 assessment. This restriction will be eliminated in many cases by further distance assessments.

The Pre-Serve web-based system, as described above, enables growers and applicators to take steps where necessary to avoid potential effects to TE plant species from application of glyphosate-based agricultural herbicides.

Alternative 1

Under Alternative 1, the rates and volumes of glyphosate applications on sugar beet crops would likely return to the level of use that existed prior to the deregulation of event H7-1 sugar beets. Growers would use an array of other herbicides, some of which may be applied at greater volumes compared to glyphosate. The herbicides used in conventional sugar beet systems have been found, in general, to have somewhat greater human health or environmental impacts than glyphosate (USDA, 2004). This is consistent with the EPA decision to grant reduced risk status for glyphosate use in glyphosate-tolerant sugar beets.**Error! Bookmark not defined.** Comparison of results from terrestrial and aquatic plant studies with predicted exposure from herbicide use suggests that most of the herbicides used in conventional sugar beet systems may have more effect than glyphosate on aquatic or terrestrial plant species. These herbicides are selective herbicides that kill only particular groups of plants such as annual grasses, perennial grasses, or broadleaf weed species and thus require the use of more than one herbicide to achieve satisfactory weed control.

Alternative 2

Alternative 2 is expected to result in continued use and application of glyphosate-based herbicide formulations. This could result in some incidental glyphosate exposure to terrestrial and aquatic plants in the vicinity of event H7-1 beet fields by spray drift. The EPA has concluded that glyphosate use on event H7-1 sugar beet can be considered to pose reduced risk compared to other herbicides used for weed control in conventional sugar beets.[40]

. . Hundreds of millions of acres of other GT crops have been treated with glyphosate for over ten years with minimal impact to adjacent non-target terrestrial plants including crops when appropriate drift minimization measures are practiced. Because glyphosate binds strongly to soil particles and has no herbicidal activity after binding to soil, no effects on aquatic plants will result from surface water runoff from glyphosate use on event H7-1 sugar beet in accordance with labeled directions for use.. Conservation tillage and no tillage practices that are possible

[40] A reduced risk decision is made at the use level based on a comparison between the proposed use of the pesticide and existing alternatives currently registered on that use site. A list of decisions regarding Reduced Risk Status can be found at: http://www.epa.gov/opprd001/workplan/reducedrisk.html

when glyphosate is used have the potential to decrease surface water runoff and sedimentation which further benefits aquatic organisms.

3.14.2 Threatened and Endangered Species

As the action agency for pesticide registrations EPA has the responsibility to conduct an assessment of effects of a registration action on endangered species. The EPA Endangered Species Protection Program web site, http://www.epa.gov/espp/, describes the EPA assessment process for endangered species. Some of the elements of that process, generally taken from the web site, are summarized below.

When registering a pesticide or reassessing the potential ecological risks from use of a currently registered pesticide, EPA evaluates extensive exposure and ecological effects data to determine how a pesticide will move through and break down in the environment. Risks to birds, fish, invertebrates, mammals and plants are routinely assessed and used in EPA's determinations of whether a pesticide may be licensed for use in the U.S.

EPA's core pesticide risk assessment and regulatory processes ensure that protections are in place for all populations of nontarget species. Because endangered species may need specific protection, EPA has developed risk assessment procedures described in the Overview of the Ecological Risk Assessment Process (U.S. EPA, 2004d, p. 7) to determine whether individuals of a listed species have the potential to be harmed by a pesticide, and if so, what specific protections may be appropriate. EPA's conclusion regarding the potential risks a pesticide may pose to a listed species and any designated critical habitat for the species, after conducting a thorough ecological risk assessment, results in an "effects determination."

As a part of the endangered species effects assessment for the California red-legged frog, EPA evaluated the effect of glyphosate at rates up to 7.95 lb a.e./A on fish, amphibians, aquatic invertebrates, aquatic plants, birds, mammals, and terrestrial invertebrates. This assessment determined that at the maximum application rate for in-crop applications of glyphosate to GT sugar beets (1.125 lb a.e./A) there would be no effects of glyphosate on the following taxa of threatened and endangered species: fish, amphibians, birds, and mammals. EPA also determined that glyphosate formulations would have no effect on threatened or endangered fish, amphibians, birds, and mammals. Although not specifically discussed in the assessment, from the EEC's and effects endpoints presented, it can also be determined that there would be

no effects of glyphosate or its formulations on threatened or endangered vascular aquatic plants, and aquatic invertebrates (EPA, 2008b).2008). non-endangered small .H7-1 .

Monsanto has designed a web-based program (www.Pre-Serve.org), designed to ensure no effect of glyphosate applications on threatened and endangered plant species. Pre-Serve instructs growers to observe specific precautions when spraying glyphosate herbicides on glyphosate-tolerant crops near threatened and endangered plant species that may be at risk. According to the U.S. Fish and Wildlife Service Endangered Species website, there are no TE terrestrial invertebrates in Colorado, Idaho, Nebraska, North Dakota, South Dakota, and Wyoming. [41] In other states, TE small terrestrial invertebrates, if present, are at no more risk than from applications of glyphosate to conventionally grown sugar beets.

Alternative 1

Under Alternative 1, the potential for impacts to threatened and endangered species may be greater than with Alternative 2 because of the use of certain herbicides with potentially higher toxicities.

Alternative 2

As indicated, EPA is responsible for and has previously conducted analyses regarding glyphosate impacts. Only two percent of glyphosate is applied aerially to all agricultural crops in the US (USDA APHIS, 2009). Given that aerial application in event H7-1 sugar beets is not expected to be any different than other agricultural production systems, approximately two percent of glyphosate used in event H7-1 sugar beets is expected to be applied aerially. Additionally, the use of buffer zones, based on the Pre-Serve program, between the sugar beet field and any potential threatened or endangered plant populations can prevent any adverse impacts due to drift of glyphosate from aerial applications (USDA APHIS, 2009), so that there will be no effect on endangered species.

We evaluated the potential for deleterious effects or significant impacts on non-target organisms, including those on the US Fish and Wildlife Service (USFWS) threatened and endangered species list, from cultivation of event H7-1 sugar beet and its progeny. The enzyme CP4 EPSPS that confers glyphosate tolerance is from the bacterium Agrobacterium sp. strain CP4. This gene is similar to the gene that is normally present in sugar beets and is not known

[41] http://www.fws.gov/endangered/species/index.html

to have any toxic property (Schneider, 2003). Field observations of event H7-1 sugar beet event H7-1 revealed no negative effects on non-target organisms (Schneider, 2003). The lack of known toxicity for this enzyme suggests no potential for deleterious effects on beneficial organisms such as bees and earthworms. The high specificity of the enzyme for its substrates makes it unlikely that the introduced enzyme would metabolize endogenous substrates to produce compounds toxic to beneficial organisms (Schneider, 2003).

3.15 HUMAN HEALTH AND SAFETY

3.15.1 Consumer Health and Safety

Alternative 1

Under Alternative 1, the potential for impacts to consumers may be greater than with Alternative 2 because of the use of herbicides with higher toxicities.

Alternative 2

The general public is not at a high risk of exposure to substantial levels of glyphosate under typical use conditions (EPA, 1993; USDA FS, 2003). Under Alternative 2, exposure to glyphosate would not increase beyond that currently experienced, since 95 percent of sugar beet is already event H7- 1. According to the EPA Glyphosate Fact Sheet (1993) glyphosate is of relatively low oral and dermal acute toxicity and has been placed in Toxicity Category III for these effects (Toxicity Category I indicates the highest degree of acute toxicity, and Category IV the lowest). The acute inhalation toxicity study was waived by EPA because glyphosate is nonvolatile and available adequate inhalation studies with end-use products show low toxicity.

The use of glyphosate herbicide does not appear to result in adverse effects on development, reproduction, or endocrine systems in humans and other mammals. Under present and expected conditions of use, glyphosate herbicide does not pose a health risk to humans (EPA, 1993).

Additionally, the nature of glyphosate residue in plants and animals is adequately understood, and studies with a variety of plants indicate that uptake of glyphosate from soil is limited. The material that is taken up is readily translocated throughout the plant. In animals, ingested or absorbed most glyphosate is essentially not metabolized and is rapidly eliminated in urine and feces. Enforcement methods are available to detect residues of glyphosate in or on plant commodities, in water, and in animal commodities (EPA, 1993).

EPA conducted a dietary risk assessment for glyphosate based on a worst-case risk scenario, that is, assuming that 100 percent of all possible commodities/acreage were treated, and assuming that tolerance-level residues remained in/on all treated commodities. Based on the assessment, EPA concluded that the chronic dietary risk posed by glyphosate food uses is minimal (EPA, 1993).

The addition of another GT crop to agricultural production may lead to a greater chance that a GT crop, including GT sugar beets may be grown near other food crops. This could lead to higher exposure to glyphosate in the diet of the general public because there would be a greater chance for glyphosate residue to reach food crops via spray drift. Nonetheless, such increase risk of exposure to glyphosate residue will not result in increased risks to the general population because the current upper estimates of risk are based on highly conservative fruit and vegetable intake rates with an assumed high estimated amount of glyphosate residue. Glyphosate is registered for use as a direct application to weeds in several fruits and vegetables and tolerances are established in the consumable commodities of these crops. The current aggregate dietary risk assessment completed by EPA concludes there is no concern for any subpopulation regarding exposure to glyphosate, including the use on many fruits and vegetables and GT sugar beet (71 FR 76180, 2006). Moreover, the potential exists for decreases in the applications and subsequent residues of more toxic herbicides if GT sugar beet is deregulated.

3.15.2 Hazard Identification and Exposure Assessment for Field Workers

Alternative 1

Under Alternative 1, the potential for impacts to field workers may be greater than with Alternative 2 because of the increased need for hard labor to remove weeds and the use of herbicides with higher toxicities.

Alternative 2

According to the RED document for glyphosate (EPA, 1993), glyphosate is of relatively low oral and dermal acute toxicity. For this reason, glyphosate has been assigned to Toxicity Categories III and IV for these effects (i.e., Toxicity Category I indicates the highest degree of acute toxicity, and Category IV the lowest). An acute inhalation study was waived by EPA because glyphosate is a non-volatile solid, and the studies conducted on the end-use product formulation are considered sufficient (EPA, 1993). Expert toxicological reviews from US EPA (1993) and the World Health Organization (WHO, 2004) are in agreement that glyphosate does not pose

any human acute exposure concerns for dietary exposures and thus negated the need to establish an acute reference dose.

With regard to subchronic and chronic toxicity, one of the more consistent effects of exposure to glyphosate at high doses is reduced body weight gain compared to controls. Body weight loss is not seen in multiple subchronic studies, but has at times been noted in some chronic studies at excessively high doses ≥ 20,000 ppm in diet (WHO, 2004). Other general and non-specific signs of toxicity from subchronic and chronic exposure to glyphosate include changes in liver weight, blood chemistry (may suggest mild liver toxicity), and liver pathology (USDA FS, 2003). Glyphosate is not considered a carcinogen; it has been classified by EPA as a Group E carcinogen (evidence of non-carcinogenicity for humans) (EPA, 1993; 2006).

EPA has considered in its human health analysis the potential applicator and bystander exposure resulting from increased glyphosate use. Based on the toxicity of glyphosate and its registered uses, including use on glyphosate-tolerant crops, EPA has concluded that occupational exposures (short-term dermal and inhalation) to glyphosate are not of concern because no short-term dermal or inhalation toxicity endpoints have been identified for glyphosate (71 FR 76180, 2006).

Additional evidence to support the EPA conclusion can be found in the *Farm Family Exposure Study*, a biomonitoring study of pesticide applicators conducted by independent investigators (Acquavella, et al. 2004). This biomonitoring study determined that the highest estimated bodily adsorption of glyphosate as the result of routine labeled applications of registered glyphosate-based agricultural herbicides to crops, including glyphosate-tolerant crops, was approximately 400 times lower than the RfD established for glyphosate. Furthermore, investigators determined that 40 percent of applicators did not have detectable exposure on the day of application, and 54 percent of the applicators had an estimated bodily adsorption of glyphosate more than 1000 times lower than the RfD (Acquavella, *et al.*, 2004). Use patterns and rates for glyphosate tolerant sugar beet are typical of most glyphosate agronomic practices. Therefore, the deregulation of glyphosate-tolerant sugar beet would not significantly increase the exposure risk to pesticide applicators.

Finally, the biomonitoring study also found little evidence of detectable exposure to individuals on the farm who were not actively involved in or located in the immediate vicinity of labeled applications of glyphosate-based agricultural herbicides to crops. Considering the similarity of the use pattern and application rates of the glyphosate products in this study compared to those

registered for use on glyphosate-tolerant sugar beet and glyphosate-tolerant crops in general, bystander exposure attributed to the use of glyphosate on glyphosate-tolerant crops is expected to be negligible. Therefore, the use of currently registered pesticide products containing glyphosate in accordance with the labeling will not pose unreasonable risks or adverse effects to humans or the environment. In general, the herbicidal activity of glyphosate is due primarily to a metabolic pathway that does not occur in humans or other animals, and, thus, this mechanism of action is not directly relevant to the human health risk assessment. EPA considers glyphosate to be of low acute and chronic toxicity by the dermal route of exposure. Glyphosate is considered a Category IV dermal toxicant and is expected to cause only slight skin irritation (USDA APHIS, 2009).

3.16 ECONOMIC IMPACTS

3.16.1 Sugar beet processing

Approximately 54% of the U.S. domestic sugar production comes from sugar beets (USDA Farm Service Agency [FSA], 2010). Refined sugar from sugar beets is the product of a multi-year cycle and involves beet seed suppliers, sugar beet growers, sugar beet processors, sugar users and consumers (USDA FSA, 2010). As part of that process, beet seed suppliers plant the commercial sugar beet seed crop in the fall of Year 1, which produces the commercial seeds harvested in the fall of Year 2. The commercial seed is processed over the winter and sold to sugar beet growers who plant it in the spring. Sugar beet growers harvest the beet root in the fall of Year 3 and deliver them to beet processing facilities owned by the beet processors. Beet sugar is extracted by beet processors beginning in the fall of Year 3 and throughout Year 4. The sugar produced from these beets is purchased by food manufacturers and consumers (USDA FSA, 2010).

Of the sugar beet root crop planted in the spring of 2009, 95 percent was reported to be event H7-1 sugar beet seed. This is also the same for the sugar beet root crop planted in the spring of 2010, and harvested in the fall of 2010. This represents 98 percent of the sugar beet root crop outside of California, where, as discussed in Section 2, event H7-1 has not been grown (USDA FSA, 2010). The harvesting of the 2010 root crop will begin between late August and early September, depending of the projected size of the sugar beet crop. The bigger the crop, the earlier the harvest will begin to make sure it is completed before the ground freezes. By late August, most of the crop's sugar will have been contracted for sale (USDA FSA, 2010). The economic impact of preventing that crop from being harvested and processed is discussed below.

3.16.2 USDA's role in sugar marketing

The domestic sugar market is closely managed by USDA's sugar program and therefore, not governed solely by supply and demand. USDA controls domestically produced sugar through the Flexible Sugar Marketing Allotment Program, and controls foreign imports through the raw and refined sugar tariff-rate quotas (TRQs). Unlimited amounts of refined sugar can be imported under a high duty of 16.3 cents per pound and raw sugar of 15.36 cents per pound. Under section 156 of the Federal Agriculture Improvement and Reform Act of 1996, as amended by the Food Conservation, and Energy Act of 2008 (the Farm Bill), and the Harmonized Tariff Schedule of the United States (HTS), USDA is required to establish a range of acceptable market conditions, which means maintaining a price floor in potentially oversupplied situations by removing surplus supply, and maintaining "adequate supply" in potentially undersupplied market situations (USDA FSA, 2010). The minimum raw and refined sugar prices that the sugar program must support are the levels that would cause sugar beet and sugarcane processors to forfeit their sugar that was put up as collateral under the USDA sugar nonrecourse loan program. Sugar nonrecourse loans support raw cane sugar prices at 21 cents per pound and refined beet sugar prices at 24 cents per pound. The nonrecourse loans support price because forfeiting the sugar collateral completely extinguishes the borrower's debt, thus sugar beet and sugarcane processors are assured of getting at least the USDA loan proceeds for their sugar. Loan collateral forfeiture also removes surplus sugar out of the market because the government is limited by the Farm Bill in its sugar disposal options (USDA FSA, 2010).

At the other end of the range, the objective of maintaining "adequate supply" (as described in the Farm Bill) or "adequate supply at reasonable prices" (described in HTS) requires USDA to increase supply under tight markets, which will make domestic prices lower than they would otherwise be. However, there is no maximum sugar price strategy stipulated in federal law, as there is a minimum sugar price. Under the Flexible Sugar Marketing Allotments Program, the sugar beet processors are guaranteed a market share of 46 percent of the domestic market. If the sector cannot fulfill its quota, USDA is required to increase imports to maintain adequate supply (USDA FSA, 2010).

3.16.3 Economic Impacts

Alternative 2 is not expected to result in adverse economic impacts. Growers and seed producers would continue to use and sell event H7-1 seed and crops and seek return on their investments. This section discusses the economic impacts of Alternative 1.

Economic implications of a halt in event H7-1 sugar beet cultivation

Should the unrestricted use of event H7-1 sugar beets be impacted, effectively removing the product from the market, an estimated 4.25 million tons of beet sugar would be removed from the market (USDA FSA, 2010). This sugar is expected to supply about 40 percent of U.S. sugar consumption during 2011.

Because the federal government has a major effect on sugar supply, and hence sugar price, the market reaction to a reduction in refined beet sugar is somewhat determined by USDA's supply management response. USDA has recently reacted to two similar, but smaller, events in 2005 and 2008 (temporary loss of cane refineries) that demonstrate the potential effect from a reduction in sugar. In both cases, U.S. refined sugar prices averaged about 18 cents per pound above the world refined sugar price, even as USDA increased the world refined quota to moderate U.S. sugar prices (USDA FSA, 2010). However, an action that effectively precludes further planting, cultivation, processing, or other use of event H7-1 sugar beets would cause greater disruption and greater harm to the U.S. sugar market than caused by the 2005 or 2008 disruptions because the reduction, 4.25 million tons, is 20 times larger than the loss of supply in 2005 and 10 times larger than the loss in 2008 (USDA FSA, 2010). Prices increased substantially in those years, but were never high enough to cause sugar to be imported off the world market at the high tariff rate of 16.3 cents per pound. Under the scenario where event H7-1 sugar beet is effectively precluded, world sugar could enter under a high tariff and set the refined price in the U.S. market (USDA, 2010).

Additionally, USDA learned from the temporary loss of cane refineries in 2005 and 2008 that many U.S. food manufacturers have difficulty using imported refined sugar because of differences in product quality or packaging. After the 2005 and 2008 events, a new business developed to clean, repackage, or liquefy imported refined sugar for domestic use. This was required because domestic food companies would not use the crystallized imported sugar in its original packaging (USDA FSA, 2010).

U.S. sugar cane refiners are expected to run at near full capacity in 2011, therefore, they will not have the capacity to refine imported raw cane sugar to replace the 4.25 million tons of beet

sugar lost. Normally, USDA would increase the raw sugar TRQ to alleviate domestic sugar shortages. However, in 2011, domestic needs for sugar would have to be filled by increasing refined sugar imports by 6 times from an average of 690,000 tons over the past 3 years (USDA FSA, 2010). This increase in refined sugar imports may cause an extensive disruption in the current refined sugar distribution system. For example, the 2.6 million tons would require about 250,000 containers on at least 330 ships by the end of September 2010 (USDA FSA, 2010).

If sugar beet root crop growers cannot harvest, they will experience an economic hardship because they will have incurred all the costs of producing the 2010 root crop except for harvesting. Further, they would incur the cost to destroy the crop to prepare the land for the next crop, and to prevent the sugar beet root crop from overwintering and reaching the flowering stage in 2011. Sugar beet processors are currently contracting FY 2011 beet sugar at 38 cents per pound (USDA FSA, 2010). Therefore, sugar beet growers and cooperative owners would also experience lost revenue estimated at $3.23 billion (4.25 million tons X 0.38 $/lb X 2000 lbs/ton) (USDA FSA, 2010).

Sugar beet processing factories, and the local economies organized around them, would experience economic hardship if beet processing factories were prevented from purchasing, processing, or selling sugar from event H7-1 sugar beets. The sugar beet processing factories would be idled, thousands of jobs would be lost and the livelihoods of many rural communities would be at stake (USDA FSA, 2010)Dr. Richard Sexton, an agricultural economist and an authority on agricultural cooperatives, recently conducted an investigation as to what the economic impact would be on growers and processors if the growing of GT sugarbeets was enjoined in 2011 and 2012. His results are particularly insightful because they rely, in part, on direct interviews and written surveys with each of the eight sugarbeet processing companies. Dr Sexton estimated that the consequences on a ban of GT sugarbeets in 2011 are: 1) 8 of 21 sugarbeet processing plants would close (and unlikely to reopen); 2) grower crop income would be reduced by approximately $253 million; 3) sugarbeet processor worker salaries would be reduced by about $138 million dollars; and 4) the adverse economic impact on the local economies where sugarbeets are grown and processed would be approximately $1.1 billion. If a ban continued through 2012, Dr. Sexton estimated that processor full-time and seasonal employment would be lowered by approximately 1,570 workers, grower income would be reduced further by another $282 million and the adverse economic impact would be $964 million in lower net revenue to growers and their communities (Sexton 2010). Also, a. A 2004 study by the University of Idaho found that if sugar beet production and processing ceased in Idaho and

alternative crops were planted instead, Idaho would lose over 3,000 jobs and farm incomes would decline (given returns to corn, wheat, and other production options based on 2004 projections). Sugar beet growers generally produce other crops, and their land would not remain idle; they have the equipment and expertise to produce other crops. The longer-term concern, however, is in terms of the impact on infrastructure, as some companies may not survive closing down for one season (USDA FSA, 2010).

Additionally, individual sugar cooperative shareholders are significantly penalized for not fulfilling their contract. For example, one cooperative member stated that, "I currently own 485 shares that are valued at $350 each and I am required to produce 485 acres of sugar beets annually to Western for processing. By contract, I am subject to an economic penalty of $350 per share if my annual share of sugar beets is not delivered to Western for processing. Western has enforced this penalty against growers in the past" (Hofer, 2010).

Sugar Beet Seed Production and Availability

Only sugar beets grown from approved varieties can be utilized by growers for sugar beet production. The processor seed committee will establish a list of approved varieties from which growers may select. Once a variety has been approved for commercial production by the processor seed committee, the seed producer produces the seed in the quantities projected to be sold to the processor's growers. Seed suppliers must predict years in advance the likely demand for new varieties. If a seed supplier over predicts likely demand, the excess seed may be inventoried for a period that does not exceed the viability of the seed (Manning, 2010).

The approved varieties have undergone extensive multi-year planting trials to determine how well each variety tolerates exposure to particular diseases and pests known to infest the growing region, particular growing conditions such as exposure to particular weather conditions, and the variety's ability to deliver acceptable yields per ton and sugar content (Manning, 2010).

The approved variety list denotes sugar beet varieties that may be delivered to the processor for sugar production. As a cooperative member, a grower has a contract to deliver sugar beet from a specified number of acres. Sugar beet varieties that do not make the approved variety lists cannot be delivered to the processor for sugar production because they do not meet the standards set forth by the processor. A grower is not permitted by the processor to plant a sugar beet variety not on the approved list (Manning, 2010).

When event H7-1 sugar beet was deregulated in 2005, the industry began production of event H7-1 sugar beet seed. The majority of conventional seed varieties and seed available for the 2011 crop year originated prior to 2007. Consequently, some approved varieties, including the genetic traits of those seed, and the inventory of some conventional seed now available were based on production decisions made many years ago (Manning, 2010). Certain seed producers have not engaged in new varietal development for conventional sugar beet since 2006/2007. Some processors have no conventional seed on their current approved variety list, while others still list some conventional seed varieties (Manning, 2010). Manning looked at the availability of sugar beet seed should event H7-1 sugar beet seed be unavailable. Based on Manning's analysis, all sugar beet growing regions in the U.S. would experience a shortfall of sugar beet seed to plant (Manning, 2010). The USDA FSA (2010) also stated that domestically-produced conventional sugar beet seed is in short supply because domestic seed companies have reduced production of conventional beet seed in recent years.

Sugar beet seed produced outside the United States may not be suitable for commercial production in the U.S. Certain sugar beet seed varieties produced in the European Union (EU) or elsewhere have not undergone extensive multi-year variety trials in the U.S to determine if that variety meets the standards for disease resistance required by growers and beet processors.

The limited availability of conventional seed could severely restrict plantings of sugar beets in 2011 and sugar production in 2012 (USDA FSA, 2010). Based on information provided by sugar beet seed producers and buyers, UDSA FSA (2010) estimates that prohibiting the harvest of event H7-1 sugar beet seed in 2010, would reduce projected sugar beet root crop acreage by 37 percent in 2011. Based on that estimate, the reduction in acres planted for sugar beet production would lower beet sugar production by an estimated 1.6 million tons in 2012 (lost acreage with unchanged yields and unchanged sugar recovery)(USDA FSA, 2010). The economic impact of a reduction in beet sugar supply on consumer costs and grower incomes in 2012 would be severe (USDA FSA, 2010). However, the severity would be mitigated depending on the degree to which sugar users and consumers reduce their consumption of sugar or switch to non-sugar sweeteners. Manufacturers and consumers will have time to reduce their beet sugar use and manufacturing costs if a decision to prohibit event H7-1 sugar beets is announced at least a year before it affects domestic supply. USDA FSA (2010) estimates that U.S. demand for sugar could fall 1 percent due to the higher sugar costs in 2012.

If event H7-1 sugar beet seed could not be planted in the spring of 2011 to grow the root crop, the 2012 U.S. refined sugar price is expected to rise from 33 cents per pound to 41 cents per pound, which includes transportation, product modification costs necessary to be suitable for American users, and the premium the U.S. Sugar Program provides domestic growers. Sugar users and consumers would pay a total of $1.6 billion additional for sugar in 2012 even if they consume less due to the higher sugar prices. Growers and processors are projected to experience a loss of 700 million in lost 2012 sugar beet and sugar sales (USDA FSA, 2010).

A summary of the projected costs from an action that effectively precludes the planting, cultivation, and processing of event H7-1 sugar beets on sugar users and consumers and sugar beet growers and processors over the next two years is shown in Table 3-3.

Herbicide Shortages

The availability of herbicides is another factor that will likely affect a growers' decision to plant conventional sugar beet varieties. The advent of event H7-1 sugar beets caused a decline in the use of certain herbicides that were used with conventional sugar beet crops. The manufacturers of these herbicides have reduced production. Should growers plant conventional seed, the herbicides may not be available unless the manufacturers ramp up production to meet anticipated demands. This decision must be made far in advance of when the herbicides would be needed (Manning, 2010).

Table 3-3. Production Loss and Project Costs from an event H7-1 Sugar Beet Injunction

Parent Seed Planted	Commercial Seed Produced	Commercial Seed Planted	Harvest/ Sales Year	Expected Sugar Production	Sugar Production Lost	Cost to Growers	Cost to Users/ Consumers
				(1,000 tons)		(Million $)	
fall 2008	fall 2009	spring 2010	2011	4,477	4,253	3,232	2,972
fall 2009	fall 2010	spring 2011	2012	4,396	1,627	658	1,592

3.17 SOCIAL AND ECONOMIC IMPACTS ON RED BEET AND CHARD GROWERS

Seed Production

In contrast to the very significant social and economic impacts identified in section 3.16 if H7-1 sugarbeet cultivation were halted, the effect of continued cultivation subject to the proposed interim measures would be minimal. As indicated in Section 2.8, most red beet and chard seed crops are grown in areas outside the Willamette Valley in Oregon where the large majority of sugarbeet seed crops are grown. The geographic limitations in the interim measures would preclude H7-1 seed cultivation in those areas and remove any chance of gene transfer between the crops. In the Willamette Valley, there is limited production of red beet and chard seed. See Section 2.8. The majority of such seed producers in those areas have agreed to and comply with the existing Willamette Valley Specialty Seed Association isolation distances for those areas, and have not reported issues or losses due to genetic transfer. There appears to be only very limited organic red beet and chard seed production in the Willamette Valley, and no indication of genetic transmission in the years since H7-1 seed cultivation began on a large scale in 2006. Although one identified organic grower has chosen to grow chard (among other organic crops) in the Western margins of the Valley, that grower has tested his crops on repeated occasions with PCR tests over multiple years and found no indication of gene flow from H7-1 crops.

In addition, in the years since 2006, seed companies producing H7-1 seed in the Willamette Valley have increasingly employed a "gene on the female" nonpollinator approach for H7-1 production fields, meaning that those fields shed virtually zero pollen that could transmit H7-1 genetic material. As a consequence, as discussed in Section 1.5, even an organic grower who chose to market and sell chard seed with a "zero tolerance" for H7-1 genetic material would face no risk from such fields.

The organic community's consensus Non-GMO Project Working Standard does not require zero tolerance – it contemplates a tolerance for GE traits in verified Non-GMO seed or 0.25%. The National Organic Program is a process-based standard; no organic grower has ever lost organic certification due to an unintended trace presence of a GE trait. Further, if an organic grower sensitive to H7-1 genetic material wished to ensure "zero tolerance," relatively inexpensive testing is available to do so, and common seed production methodologies can be employed to maintain a "zero tolerance" for organic seed if desired. This is discussed in Sections 1.5 and 1.6. There is also no realistic prospect of mechanical mixing between red beet and chard seed

and H7-1 seed because the two production processes are entirely separate. As discussed in Section 2.7, seed is processed in different facilities, and no common equipment is used.

Under APHIS's proposed interim measures, each seed company producing H7-1 would be subject to third party audits of compliance with the standards to ensure that the measures remained in place and were effective. Accordingly, Alternative 2 would have no or negligible social or economic impacts on red beet and chard crops, Alternative 1, by contrast, would have highly significant negative impacts on nationwide sugarbeet production, as discussed above.

Root Crop Production

As indicated above, including in Sections 2.8 there is little or no overlap of H7-1 root crop production and red beet and chard seed production. To the extent certain red beet or chard seed savers may exist in root crop production areas (none have been identified), the measures for roguing bolters and related stewardship render the potential for genetic transmission from H7-1 negligible. As indicated, Alternative 2 would have no or negligible social or economic impacts on red beet and chard crops, By contrast, Alternative 1 would have highly significant impacts across multiple growing areas.

Consumer Acceptance of the Sugar from Event H7-1 Sugar beets

Since wide-scale production of event H7-1 sugar began, there has been no indication of significant concern regarding acceptance of H7-1 sugar producers of food products with sugar derived from these products or from consumers. The sugar is identical chemically to sugar from conventional sugarbeets (Baker, 2010a, pp. 2-3; Hoffman, 2010a, p. 10). In addition as indicated in Section 3.11.2, food and feed issues have been reviewed by FDA. This FDA review has not been challenged

For any consumers who are nevertheless concerned about the source of this sugar, there are alternatives available. Cane sugar and other sweeteners are readily available for instance. And certain public interest groups, including the Institute for Responsible Technology, have publicized the readily available alternatives to sugarbeet sugar and other sweeteners derived from biotechnology (Burkam, 2010, p. 58).

CUMULATIVE IMPACTS

This section discusses the cumulative impacts that may be associated with Alternative 2, when combined with other recent past, present, and reasonably foreseeable future actions within the affected environment. Alternative 2 is expected to be maintained for a short time duration, and an EIS will specifically address the environmental impacts associated with full deregulationin . Cumulative impacts that will occur before the EIS is completed are expected to be negligible. By contrast, as indicated in Section 3.16, the specific and cumulative impacts of Alternative 1 are expected to be significant for growers nationwide.

Cumulative impacts occur when the effects of an action are added to the effects of other actions occurring in a specific geographic area and timeframe. The cumulative impact analysis follows CEQ's guidance: Considering Cumulative Effects Under the National Environmental Policy Act (CEQ, 1997). The steps associated with the analysis include:

- Specify the class of actions for which effects are to be analyzed.
- Designate the appropriate time and space domain in which the relevant actions occur.
- Identify and characterize the set of receptors to be assessed.
- Determine the magnitude of effects on the receptors and whether those effects are accumulating.

4.1 CLASS OF ACTIONS TO BE ANALYZED

This analysis addresses large, regional and national-scale trends and issues that have impacts that may accumulate with those of the proposed interim measures.

4.2 GEOGRAPHIC AND TEMPORAL BOUNDARIES FOR THE ANALYSIS

As described in Section 2, over the past 10 years, the number of acres planted annually in sugar beets in the US has ranged from 1.1 to 1.4 million (USDA ERS, 2009, Table 14). Event H7-1 sugar beets are produced in five major regions in the US, and commercial production of seeds takes place in the Willamette Valley of Oregon. Therefore, the spatial domain for past, present, and reasonably foreseeable future actions considers the five growing regions for issues associated with growing event H7-1 sugar beets; the Willamette Valley for issues associated with seed production; and the nation, and in some cases international areas, for issues associated with consumption of sugar beet food and feed products. Also, as indicated, the measures at issue would apply for a limited time period, estimated at less than 2 years.

RESOURCES ANALYZED

Issues evaluated in this cumulative impacts analysis include some of the resource areas discussed in Chapters 2 and 3 including land use, air quality and climate, water quality,

biological, and human health and safety. In addition, specific topics analyzed include: cumulative impacts related to any possibility of development of glyphosate resistant weeds, and cumulative impacts of potential increased glyphosate usage with the cultivation of glyphosate tolerant crops.

4.3 PARTIAL.CUMULATIVE IMPACTS RELATED TO THE DEVELOPMENT OF GLYPHOSATE RESISTANT WEEDS

Glyphosate offers many benefits to the grower as a weed control product. Glyphosate controls a broad spectrum of grass and broadleaf weed species present in sugar beet production fields, has flexible use timings, and when used in glyphosate-tolerant crops, has a very high level of crop safety (see petition 03-323-01p, Tables VII-4 and VII-4, pages 90 and 92, respectively). As the adoption of glyphosate-tolerant crops has grown, the use of glyphosate has increased over the past several years. With the increased use of glyphosate, there is also the potential for increased selection pressure for the development of glyphosate-resistant weeds (Section VIII).

Because a glyphosate-based herbicide program is currently being used with event H7-1 sugar beet, glyphosate use for event H7-1 is not expected to increase beyond current levels, as market penetration is already at 95 percent. Current levels of glyphosate use in event H7-1 sugar beets are a minor (approximately 0.7 percent) amount of total US glyphosate use. Additionally, with Alternative 2, growers still would have the currently available weed control tools (e.g., non-glyposate herbicides and cultural practices described in Section VII.B of petition 03-323-01p on page 88) needed on a small scale to manage any glyphosate-resistant weeds, whether they are present in sugar beet or other crop production fields.

4.4 CUMULATIVE IMPACTS OF POTENTIAL INCREASED GLYPHOSATE USAGE WITH THE CULTIVATION OF GLYPHOSATE TOLERANT CROPS

Studies of the relationship between genetically engineered crops and herbicide use has shown that an increase in glyphosate tolerant crops can result in a decrease in mechanical tillage (Brimner et al., 2005; Fernandez-Cornejo, 2006; Gianessi and Reigner, 2006; Kleter et. al., 2007; Sankula, 2006; Johnson et al., 2008). The potential cumulative impact from this reduction in mechanical tillage is discussed in the following sections.

According to the USDA ERS (2009), US farmers have adopted genetically engineered crops widely since their introduction in 1996. Soybeans and cotton genetically engineered with herbicide-tolerant traits have been the most widely and rapidly adopted GE crops in the US, followed by insect-resistant cotton and corn. Figure 4-1 shows the percentage of acres of genetically engineered crops in the US between 1996 and 2009.

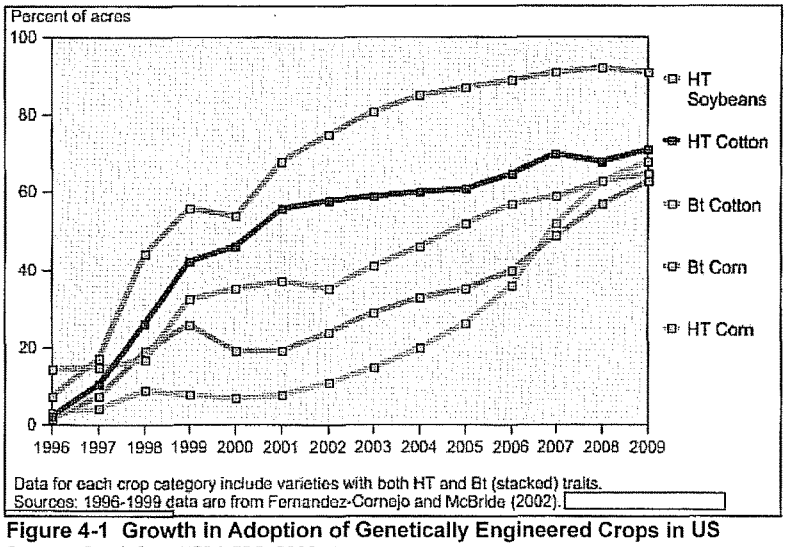

Figure 4-1 Growth in Adoption of Genetically Engineered Crops in US
Source: Graph from USDA ERS, 2009

Herbicide-tolerant crops, which are engineered to survive application of specific herbicides that previously would have damaged the crop , provide farmers with a broader variety of options for effective weed control. Based on USDA survey data, herbicide tolerant soybeans went from 17 percent of US soybean acreage in 1997, to 68 percent in 2001 and 91 percent in 2009. Plantings of herbicide tolerant cotton expanded from approximately 10 percent of US acreage in 1997 to 56 percent in 2001 and 71 percent in 2009. The adoption of herbicide tolerant corn, was slower in previous years, but has reached 68 percent of US corn acreage in 2009 (USDA ERS, 2009).

Corn growers use the largest volume of herbicides. Approximately 96 percent of the 62.2 million acres used for growing corn in the 10 major corn-producing States were treated with

more than 164 million pounds of herbicides in 1997 (USDA ERS, 2009). Soybean production in the US also uses a large amount of herbicides. Approximately 97 percent of the 66.2 million soybean acres in the 19 major soybean producing States were treated with more than 78 million pounds of herbicides in 1997 (USDA ERS, 2009). Cotton production relies heavily on herbicides to control weeds, often requiring applications of two or more herbicides at planting and postemergence herbicides later in the season (Culpepper and York, 1998). Close to 28 million pounds of herbicides were applied to 97 percent of the 13 million acres devoted to upland cotton production in the 12 major cotton-producing States in 1997 (USDA ERS, 2009).

Pesticide use on corn and soybeans has declined since the introduction of GE corn and soybeans in 1996. Several studies have analyzed the agronomic, environmental, and economic effects of adopting GE crops, including actual pesticide use changes associated with growing GE crops (McBride and Brooks, 2000; Fernandez-Cornejo, Klotz-Ingram, and Jans, 1999, 2002; Giannessi and Carpenter, 1999; Culpepper and York, 1998; Marra et al., 1998; Falck-Zepeda and Traxler, 1998; Fernandez-Cornejo and Klotz-Ingram, 1998; Gibson et al., 1997; ReJesus et al., 1997; Stark, 1997). Many of these studies have concluded that herbicide use is reduced with herbicide-tolerant varieties (USDA ERS, 2009).

Studies conducted by the USDA also show an overall reduction in pesticide use related to the increased adoption of GE crops. Based on the adoption of GE crops between 1997 and 1998 (except for herbicide-tolerant corn, which is modeled for 1996-97), the decline in pesticide use was estimated to be 19.1 million acre-treatments, 6.2 percent of total treatments (USDA ERS, 2009). Most of the decline in pesticide acre treatments was from less herbicide used on soybeans, accounting for more than 80 percent of the reduction (16 million acre-treatments) (USDA ERS, 2009).

The adoption of herbicide-tolerant crops such as event H7-1 sugar beets, glyphosate-tolerant soybeans, and glyphosate-tolerant corn results in the substitution of glyphosate for previously used herbicides. The glyphosate tolerant crops allow farmers to limit and simplify herbicide treatments based around use of glyphosate, while a conventional weed control program can involve multiple applications of several herbicides. In addition, and more importantly, herbicide-tolerant crops often allow farmers to use more benign herbicides (USDA ERS, 2009).

There are known benefits associated with the use of glyphosate herbicides compared to herbicides currently used by sugar beet producers. Glyphosate has documented favorable characteristics with regard to risk to human health, non-target species, and the environment

(Malik et al., 1989; Geisy et al., 2000; Williams et al., 2000). Glyphosate is classified by the EPA as a Group E pesticide (evidence of non-carcinogenicity for humans) (57 FR 8739). In 1998, the EPA granted Reduced Risk status for an expedited review of the submitted residue data package supporting the use of glyphosate, as Roundup Ultra herbicide (EPA Registration No. 524-475) for use in glyphosate tolerant sugar beets. Reduced Risk status was granted by EPA based on a detailed hazard comparison of glyphosate to alternative herbicides available for weed control in sugar beet production (Reduced Risk petition document: MRID 44560501), and an overall conclusion that weed control with Roundup Ultra herbicide offers a substantial benefit to sugar beet growers in the form of reduced risk to human health, non-target species, and the environment.

4.4.1 Land Use, Air Quality and Climate

As discussed in Section 3, sugar beet acreage has fluctuated little for the past 50 years, was not impacted by the introduction of event H7-1, and is not expected to be impacted by continued use of event H7-1. Therefore, as discussed in Section 3, Alternative 2 is not expected to impact land use. As it is not expected to directly or indirectly impact land use, Alternative 2 would not have cumulative impacts on land use.

As discussed in Section 3, Alternative 2 is expected to continue to have small positive impacts on air quality and climate, primarily resulting from reduced tillage. Consequently, Alternative 2 is not expected to have any adverse cumulative impacts on air quality or climate.

4.4.2 Water Quality

As discussed in Section 3, the advent of glyphosate tolerant crops and the use of post-emergent herbicides that could be applied over a crop during the growing season have facilitated the use of conservation tillage farming practices, since weeds could be controlled after crop growth without tilling the soil (USDA ERS, 2009). The use of glyphosate tolerant crops (particularly soybeans) has intensified that trend since it often allows a more effective and less costly weed control regime than using other post-emergent herbicides (USDA ERS, 2009; Carpenter and Gianessi, 1999).

The impact of conservation tillage (including no-till, ridge-till, and mulch-till) in controlling soil erosion and soil degradation is well documented (Edwards, 1995; Sandretto, 1997). By leaving substantial amounts of plant matter over the soil surface, conservation tillage 1) reduces soil erosion by wind; 2) reduces soil erosion by water; 3) increases water infiltration and moisture

retention; 4) reduces surface sediment and water runoff; and 5) reduces chemical runoff (USDA ERS, 2009).

Glyphosate maypotentially be found in surface water runoff when erosion conditions lead to the loss of surface particles. However, as discussed in Section 3, partial deregulation of glyphosate tolerant crops typically leads to an increase in conservation tillage and no tillage systems, which would result in less mechanical disturbance of the soil during sugar beet cultivation and thereby decrease the loss of surface soil. Because of this, and the fact that glyphosate binds strongly to soil particles, no-tillage and conservation tillage are expected to further reduce the likelihood of any impact surface water runoff (Wiebe and Gollehon, 2006). Therefore, no cumulative adverse impacts to surface water or groundwater are anticipated.

4.4.3 Biological

For non-target terrestrial species, available ecological assessments in EPA RED (EPA, 2003) documents or registration review summary documents provide the support that the use of glyphosate represents reductions in chronic risk to birds compared to trifluralin and sethoxydim, in acute risk to small mammals in comparison to EPTC, in chronic risk to mammals from quizalofop-p-ethyl, in acute risk to endangered birds and mammals from pyrazon, and in chronic risk to mammals and potentially birds from cycloate. For all other sugar beet herbicide products, as well as glyphosate, no significant risks to birds or other non-target terrestrial species were indicated in the available information.

For non-target aquatic species, Tables 4-1, 4-2, and 4-3 provide summaries of the estimated exposure and hazard information for the traditional herbicides used in conventional sugar beet production, and present quantitative comparisons of the derived Risk Quotients. Exposure, defined as the EEC, was calculated for all products using the standard assumptions (assuming aerial application) of 5 percent drift of spray applied to a one-acre field onto water and 5 percent runoff from 10 treated acres into a one-acre pond six feet in depth. Herbicide treatments were based on the maximum single application rate taken from product labels. Hazard information (LC50 or EC50) for each active ingredient was taken from the EPA Ecotoxicology One-Liner Database (if available) or other EPA source documents and summarized in Tables 4-1, 4-2 , and 4-3 as the upper and lower values from the range of values reported. Hazard information for the end-use formulated products is generally not readily available, thus this analysis is a comparison based solely on the active ingredients. Any label warnings and other available hazard and/or risk descriptions for non-target aquatic species are also included. The Risk

Quotient is determined for each active ingredient by dividing the EEC by the hazard (LC50 or EC50) value.

Plants potentially at risk from the use of glyphosate are potentially at risk from the use of any herbicide. Like most herbicides, plants are highly sensitive to glyphosate. Monsanto has developed a program named Pre-Serve to address aerial spraying in areas where threatened plants may be located. Following label use instructions and use limitations described in Pre-Serve swould address any such risk of exposure. Federal law requires pesticides to be used in accordance with the label.. Because glyphosate binds strongly to soil particles, conservation tillage and no tillage practices provide additional assurance that the impact to aquatic plants through decreasing soil-laden runoff are negligible.

The labels for products containing desmedipham, phenmedipham, sethoxydim, clethodim and trifluralin include warnings of toxicity or adverse effects to fish, and/or aquatic invertebrates and/or aquatic plants. Risk Quotients that exceed the Trigger Value of 0.5 for aquatic animals and 1.0 for aquatic plants are highlighted in bold text in Tables 4-1, 4-2, and 4-3 as exceeding a Level of Concern, based on EPA Ecological Effects Rejection Analysis and Deterministic Risk Characterization Approach. Current sugar beet herbicide products containing triflusulfuron, trifluralin, and pyrazon are shown to exceed these Levels of ConcernAs supported by the EPA designation of reduced risk for application of glyphosate to H7-1 sugar beet,. glyphosate is a more environmentally preferred herbicide compared to other herbicides currently used in sugar beet production since glyphosate is generally less toxic and has favorable degradation properties.

4.4.4 Human Health and Safety

A tolerance increase was required to support approval for the use of glyphosate in the event H7-1 sugar beet-cropping system compared to the limited pre-emergent use of glyphosate in conventional sugar beet production. However, the potential health effects of pesticide residues that may be present in food, regardless of whether they result from uses in conventional or glyphosate tolerant crops, are carefully considered by EPA before establishing maximum residue limits or tolerances.

Before establishing a tolerance in an agricultural commodity, EPA must find that the potential resulting residues covered by the proposed tolerance will be "safe". Section 408(b)(2)(A)(ii) of the FFDCA [21 USC 346a(b)(2)(A)(i)] defines "safe" as a reasonable certainty that no harm will result from aggregate exposure to the pesticide chemical residue. As part of this determination,

the total maximum theoretical level of residue present in all food commodities with approved uses for the pesticide must not exceed the EPA established Reference Dose (RfD), or chronic Population Adjusted Dose (cPAD). Following a comprehensive review of the results of toxicological studies conducted on the pesticide, the RfD is set by applying appropriate uncertainty factors to the most appropriate No-Observed-Adverse-Effect-Level (NOAEL).

In 1999, EPA conducted a dietary exposure risk assessment and concluded that the incremental dietary exposure associated with the use of glyphosate on glyphosate tolerant sugar beet did not pose a concern to human health (64 FR 18360, 1999). . .

1367

In a recent risk assessment supporting establishment of certain new food crop tolerances for glyphosate, EPA estimated that chronic (daily dietary) exposure to glyphosate from all food and water sources would use only 2 percent of the glyphosate RfD (1.75 mg/kg/day) for the general US population and 7 percent of the RfD for the highest potentially exposed subgroup population (71 FR 76180, 2006).

The cumulative impacts from use of glyphosate on sugar beets was considered. ,

Biomonitoring of pesticide applicators conducted by independent investigators has shown that bodily adsorption of glyphosate as the result of routine, labeled applications of registered glyphosate-based agricultural herbicides to crops, including to glyphosate tolerant sugar beet, was thousands of times less than the allowable daily intake level established for glyphosate (Acquavella et al., 2004). Given similarity to current use pattern, herbicide label rates, and the percentage of cultivate acres for sugar beets, the continued use of event H7-1 sugar beet through partial deregulation will not significantly increase the exposure risk to pesticide applicators. Furthermore, EPA, the European Commission, the WHO, and independent scientists have concluded that glyphosate is not mutagenic or carcinogenic, not a teratogen nor a reproductive toxicant, and that there is no evidence of neurotoxicity associated with glyphosate (EPA, 1993; EC, 2002; WHO, 2004, and Williams et al., 2000).

Bystander exposure to glyphosate as a result of pesticide application to event H7-1 sugar beet would be negligible, since such applications would occur in an agricultural setting in relatively rural sugar beet fields, not in an urban setting.

Presented below is an brief, comparative analysis of the hazard/risk characteristics of glyphosate, the active ingredient in Roundup WeatherMAX® herbicide (EPA Registration No. 524-537), to the most commonly used herbicides applied in conventional sugar beet production, based on total pounds of active ingredient applied (USDA-NASS, 2001). A detailed assessment of the potential chronic human health risks compared to traditional products will not be presented in this comparison. The assessment is based on information obtained from various sources, including product-specific labeling, EPA Reregistration Eligibility Documents (RED, EPA, 1993), EPA RED Fact Sheets, product-specific Federal Register publications, the EPA

® Roundup UltraMAX is a registered trademark of Monsanto Technology LLC

Ecotoxicology One-Liner database[42], the USDA Pesticide Properties database[43], and other public sources of product-specific toxicological and environmental profile information. The assessment shows that in the majority of cases, weed control with glyphosate, formulated and sold as Roundup WeatherMAX herbicide, in the event H7-1 sugar beet system offers the benefit of less risk from potential exposure for applicators and handlers of concentrated product and a reduced potential to impact non-target species and water quality.

Table 4-4 provides a comparison of product-specific labeling for herbicides commonly used for weed control in sugar beet production, including required precautionary statements associated with acute exposure hazards and environmental risk concerns. Although most alternative products carry the same signal word as Roundup WeatherMAX herbicide (CAUTION), the associated precautionary statements of each of the alternative herbicide products are indicative of toxicity findings that represent a greater acute exposure risk than Roundup WeatherMAX. Nearly every sugar beet herbicide product evaluated has more restrictive requirements for the use of Personal Protective Equipment (PPE) than those required for Roundup WeatherMAX herbicide, indicating a greater need to reduce the risk of acute exposure, and, in some cases, the risk of longer-term or chronic exposure, for applicators and handlers of these other products.

The comparative analyses provided in this section are summarized in Table 4-5 and show those areas for which glyphosate (designated with a checkmark ✓), using Roundup WeatherMAX herbicide in the comparison, offers the benefit of potential risk reduction compared to the most commonly used sugar beet herbicides in sugar beet production. In this cumulative comparison, glyphosate offers potential benefits over all the traditional sugar beet herbicides in at least one and up to four risk assessment categories. These comparisons demonstrate the benefits to applicators, mixers and non-target organisms from the use of glyphosate in the event H7-1 sugar beet system.

4.4.5 Summary of Potential Cumulative Impacts from Increased Use of Glyphosate

When considering the impact that the use of glyphosate in the event H7-1 sugar beet system could have on the human environment in conjunction with the use of glyphosate in other glyphosate tolerant crops already being cultivated in the same affected environments, the facts suggest that this use will have little or noadditive effect Additionally, use of glyphosate.

[42] EPA Ecotoxicology One-Liner database: http://www.ipmcenters.org/Ecotox/index.cfm
[43] USDA Pesticide Properties database: ttp://www.ars.usda.gov/Services/docs.htm?docid=14199

Alternatively, this has the potential to reduce risks to the affected environment from the use of other, more harmful, herbicides. This is supported by the assessment of the environmental and worker safety hazards associated with glyphosate when compared to other available herbicides used for weed control in sugar beet production. Based on such an assessment, EPA granted reduced risk status for this use of glyphosate, and expedited the review of supporting residue data. Therefore, there is no reasonably anticipated adverse cumulative impact on human health or the environment from the use of glyphosate associated specifically with the deregulation of event H7-1 sugar beets

For a discussion of coexistence of H7-1 and conventional beta species crops, see Sections 1.6 and 2.4..

Table 4-4 Alternative Herbicides for Weed Control in Sugar Beets - Label Comparison / Exposure Mitigation

Active Ingredient(s)	Product Brand	Label Signal Word	Sugar Beet PHI[a] (days)	Max. lb ai/acre (single appl.)	Max. lb. ai/acre (season)	Label Precautionary Statements / Special Directions / Other Information	Applicator and Handler PPE[b] Required to Mitigate Exposure Risks
Glyphosate	Roundup WeatherMAX	Caution	30	1.125	6	Causes moderate eye irritation. Harmful if inhaled. Do not store in steel. Four resistant weed biotypes confirmed to date.	Long-sleeved shirt, long pants, shoes plus socks. When handling this concentrated product or its application solutions of 30% or greater, must also wear chemical-resistant gloves.
Clethodim[c]	Select 2 EC or Prisim	Warning	40	0.09	0.25	Causes substantial, but temporary, eye injury. Harmful if swallowed or inhaled. Potential skin sensitizer. Warnings and precautions for runoff and drift. Use of the product may pose hazard to federally listed endangered plant species. Warnings for repeated use leading to selection of resistant weed biotypes. Crop injury warnings.	Long-sleeved shirt, long pants, shoes plus socks, chemical-resistant gloves, protective eyewear. Do not reuse heavily contaminated clothing.
Clopyralid	Stinger	Caution	45	0.25	0.25	Causes eye injury. Harmful if inhaled or absorbed through skin. Warning for leaching to groundwater under certain conditions. Crop injury warnings for 1) use of treated plant material or manure from animals grazed in treated areas, as mulch or compost; and 2) spreading of treated soil. Up to 18-month rotation restrictions to many crops due to risk of injury; field bioassay recommended.	Long-sleeved shirt, long pants, waterproof gloves, shoes plus socks.

1371

Table 4-4 Alternative Herbicides for Weed Control in Sugar Beets - Label Comparison / Exposure Mitigation

Active Ingredient(s)	Product Brand	Label Signal Word	Sugar Beet PHI[a] (days)	Max. lb ai/acre (single appl.)	Max. lb. ai/acre (season)	Label Precautionary Statements / Special Directions / Other Information	Applicator and Handler PPE[b] Required to Mitigate Exposure Risks
Cycloate	Ro-neet	Caution	NA; preplant incorporation	4	4	Harmful if swallowed. Avoid contamination of food or feed. Soil incorporation or soil injection required. Crop injury concerns dependent on soil type.	Long-sleeved shirt, long pants, chemical-resistant gloves, shoes plus socks. Added PPE in California for a non-closed system; for mixers/loaders: chemical resistant clothing, full face respirator; for applicators: coveralls, plus half-face respirator, 93 gallon limit for 21-day period.
Desmedipham[d]	Betanex	Caution	75	1.2	1.92	Harmful if swallowed. Causes moderate eye irritation. Prolonged or frequent repeated skin contact may cause allergic reaction. This product contains the toxic inert ingredient isophorone. This product is toxic to fish. Do not apply where runoff is likely to occur. Sugar beet injury possible under many situations.	Long-sleeved shirt, long pants, chemical-resistant gloves, shoes plus socks, protective eyewear.

1372

Table 4-4 Alternative Herbicides for Weed Control in Sugar Beets - Label Comparison / Exposure Mitigation

Active Ingredient(s)	Product Brand	Label Signal Word	Sugar Beet PHI[a] (days)	Max. lb ai/acre (single appl.)	Max. lb. ai/acre (season)	Label Precautionary Statements / Special Directions / Other Information	Applicator and Handler PPE[b] Required to Mitigate Exposure Risks
Desmedipham/ phenmedipham	Betamix	Warning	75	1.2	1.92	Causes substantial, but temporary, eye injury. Harmful if swallowed or absorbed through skin. This product contains the toxic inert ingredient isophorone. This product is toxic to fish and aquatic organisms. Drift and runoff...may be hazardous to fish and aquatic organisms. Physical hazard: Combustible. Sugar beet injury possible under many situations; evening applications recommended. Rotation restriction of 120 days for cereals.	Long-sleeved shirt, long pants, chemical-resistant gloves, shoes plus socks, protective eyewear.
EPTC[e]	Eptam	Caution	NA; preplant incorporation or very early postemergence	4.2	5.6	Harmful if swallowed. Avoid breathing spray mist. Incorporation or soil injection required unless applied through irrigation.	Long-sleeved shirt, long pants, chemical-resistant gloves, shoes plus socks.
Ethofumesate	Nortron	Caution	90	3.6	4	Harmful if swallowed, inhaled or absorbed through skin. Rotation restrictions of 6 to 12 months for crops other than sugar beets or ryegrass. Do not graze livestock on treated crops.	Long-sleeved shirt, long pants, waterproof gloves, shoes plus socks.

1373

Table 4-4 Alternative Herbicides for Weed Control in Sugar Beets - Label Comparison / Exposure Mitigation

Active Ingredient(s)	Product Brand	Label Signal Word	Sugar Beet PHI[a] (days)	Max. lb ai/acre (single appl.)	Max. lb. ai/acre (season)	Label Precautionary Statements / Special Directions / Other Information	Applicator and Handler PPE[b] Required to Mitigate Exposure Risks
Pyrazon	Pyramix DF	Caution	0	7.3	7.3	Harmful if swallowed, inhaled or absorbed through skin. Avoid breathing dust or spray mist. Causes moderate eye irritation. Significant crop injury warning statements, depending on soil moisture level, soil type (organic matter content, loam, sandy, etc.), and temperature at time of application, application method, and tank mix products.	Long-sleeved shirt, long pants, chemical-resistant gloves, shoes plus socks. Do not reuse clothing heavily contaminated with this product's concentrate.
Quizalofop-p-ethyl	Assure II	Danger	45 days, except 60 days for feeding of tops	0.17	0.17	Causes severe eye irritation. May irritate skin, nose and throat. May be harmful if absorbed through skin, swallowed or inhaled. This product contains petroleum-based distillates. Rotation restriction of 120 days for crops not labeled. Need spray adjuvant added.	Long-sleeved shirt, long pants, chemical-resistant gloves, shoes plus sock, protective eyewear. Do not reuse clothing heavily contaminated with this product's concentrate.
Sethoxydim[f]	Poast	Warning	60	0.40	0.8	Causes substantial, but temporary, eye injury. Harmful if swallowed. This product is toxic to aquatic organisms. Crop injury warnings. Multiple confirmed resistant weed biotypes.	Coveralls over short-sleeved shirt and short pants, chemical-resistant gloves, chemical-resistant footwear, protective eyewear, chemical-resistant headgear for overhead exposure, chemical-resistant apron for cleaning, mixing, loading.

1374

Table 4-4 Alternative Herbicides for Weed Control in Sugar Beets - Label Comparison / Exposure Mitigation

Active Ingredient(s)	Product Brand	Label Signal Word	Sugar Beet PHI[a] (days)	Max. lb ai/acre (single appl.)	Max. lb. ai/acre (season)	Label Precautionary Statements / Special Directions / Other Information	Applicator and Handler PPE[b] Required to Mitigate Exposure Risks
Trifluralin[g]	Treflan HFP	Caution	NA; one application between first true leaf and 6 inch stage	0.72	4.0	Causes moderate eye irritation, harmful if swallowed, potential skin sensitizer. This product contains aromatic hydrocarbon and can be extremely toxic if swallowed. This pesticide is extremely toxic to freshwater marine and estuarine fish and aquatic invertebrates. Soil incorporation required within 24 hrs of application. Crop injury warnings. Crop rotation restrictions ranging from 5 to 21 months. Confirmed multiple resistant weed biotypes.	Long-sleeved shirt, long pants, shoes plus socks, chemical-resistant gloves, protective eyewear. Do not reuse clothing heavily contaminated with this product's concentrate.
Triflusulfuron	Upbeet	Caution	60	0.008	0.08	Resistant weed biotypes; multiple MOA resistance. Need spray adjuvant added.	Long-sleeved shirt, long pants, chemical-resistant gloves, shoes plus socks.

NA indicates not applicable.

[a] PHI – Post Harvest Interval.

[b] PPE – Personal Protective Equipment.

[c] Based on recent clethodim tolerance action (67 FR 46893, Final Rule, July 17, 2002) percent-crop-treated market data necessary to refine chronic dietary exposure estimates; per label statement: concern for risks to endangered plant species.

[d] 1996 desmedipham RED: concern for Margins of Exposure (MOE) for dermal exposure to mixers and loaders; additional concern for applicator inhalation exposure to wettable-powder formulations requiring limits on application rate per acre and number of acres treated per day; low to moderate chronic risk to birds.

[e] 1999 EPTC RED ; 10x FQPA UF retained due to neurotoxic effects; developmental neurotoxicity study required; reversible Cholinesterase inhibitor; Tier 3 refinements using average residues and percent crop treated data for chronic dietary assessment; concern for risk to applicators and handlers from dermal and inhalation exposure; concern for risks to small mammals and non-target plants, including endangered species from run-off and spray drift.

[f] Based on recent sethoxydim tolerance actions (66 FR 51587, Final Rule, Oct.10, 2001), aPAD includes additional 3x FQPA UF for acute exposure to females 13+ yrs of age, due to fetal effects seen in rat developmental tox study; anticipated residues and percent-crop-treated data necessary to refine chronic exposure assessment.

[g] 1995 Trifluralin RED: concern for cancer risk to applicators, handlers and field workers; moderately to highly toxic to fish and aquatic invertebrates; chronic risk concern for birds due to evidence of egg cracking in avian study.

1375

Table 4-5 Potential Reduction in Risk from Use of Glyphosate Compared to Traditional Herbicides Used in US Sugar Beet Production

Active Ingredients[1]	Human Health Risk		Non-Target Species Risks					Groundwater Contamination	Total Number of Areas for Potential Risk Reduction

Appendix A

Willamette Valley Specialty Seed Association (WVSSA) specialty seed production isolation guidelines and Columbia basin vegetable seed field isolation standards

WVSSA Specialty Seed Production Isolation Guidelines

***Beta* species (Beets and Swiss chard)**
Must be pinned at the Beta species maps
Four Separate Groups: Sugar beets, Table beets, Fodder beets, Swiss chard

Between one O.P. and another of the same color and group	1 mile
Between Hybrid of the same color and group	1 mile
Between Hybrid and O.P. of the same color and group	2 mile
Between different colors within a group	3 mile
Between stock-seed and a Hybrid within a group	2 mile
Between stock-seed and O.P. within a group	3 mile
Between Hybrids of different groups	3 mile
Between Hybrid and O.P. of different groups	4 mile
Between GMO's and any other Beta species no closer than (And is excluded from exception to lessen this distance)	3 mile

***Brassica* species (Fall types – 9 chromosomes)**
Includes: Cabbage, Kale, Kohlrabi, Brussel Sprouts, etc.

Between O.P. of the same color and group	1 mile
Between O.P. of different color	2 mile
Between O.P. cabbage and non-heading cultivars (Savoy, Kale, Brussel Sprouts, Collards and Cauliflower)	2 mile
Between Hybrids and Hybrids and O.P. of the same color and group	2 mile
Between Hybrids and O.P. of different colors or group	3 mile
Between Hybrid cabbage and non-heading cultivars	3 mile

***Brassica* species (Spring types – 6 groups)**

1 Turnip types – 10 chromosomes (Japanese type, purple top, strap leaf, Shogoin)
2 Chinese Mustard types – 10 chromosomes (komatsuna, mizuna, mibuna, tatsoi)
3 Chinese Cabbage types – 10 chromosomes (heading, semi-heading, non-heading)
4 Pak Choi types – 10 chromosomes
5 Choi Sum types – 10 chromosomes
6 Indian Mustard types – 18 chromosomes (Florida broadleaf, southern giant curled, red mustard, Chinese mustard, leaf mustard)

SPECIAL ATTENTION MUST BE PAID TO THESE CROPS AS THERE IS A VERY WIDE RANGE OF PHENOTYPES THAT CAN CROSS. IF THERE IS ANY DOUBT, CHECK WITH THE OTHER COMPANY REP. BEFORE PINNING & PLANTING.

Between any 10 chromosome and any 18 chromosome types	Physical separation
Between O.P. of the same group	1 mile
Between O.P. of different groups	1.5 mile
Between Hybrids or Hybrids and O.P. of same group and phenotype	2 mile

Between Hybrids of different groups or phenotype	2.5 mile
Between Hybrids and O.P. of different groups or phenotype	3 mile

***Brassica* species Canola**

Must be grown under permit from Oregon Department of Agriculture. GMO type Canola or Rapeseed is not allowed to be grown between any other specialty seed crops.	3 mile
Allium cepa (Onion) Male parent used to pin hybrids	

Onion Hybrid

Between Hybrid and O.P. of different color	3 mile
Between Hybrid and O.P. of same color, different shape	2 mile
Between Hybrid and O.P. of same color, shape and type	2 mile
Between Hybrid of same color, shape and type	1 mile
Onions Open Pollinated	
Between Hybrid and O.P. of different color or shape	3 mile
Between O.P. of different color	3 mile
Between O.P. of same color, but different shape	2 mile
Between Hybrid of same color and shape	2 mile
Between O.P. of same color, type and shape	1 mile

Allium fistulosum (Bunching Onions)

Between another variety of fistulosum	1 mile

Allium porrum or Allium ampleoprasum (Leek)

Between another variety of Leek	2 mile

***Allium* other species (Chives)** no distance

***Umbelliferous* other species (Parsley, Dill, Parsnips, etc.)**

Between same types	1 mile
Between Hybrid and O.P. of similar types	2 mile
Between different types	3 mile

Rhaphanus sativus (Radish)

Between O.P. varieties of same color and or shape	1 mile
Between Hybrids or Hybrid and O.P. type	2 mile
Between Hybrid and O.P. of different colors and or shape	3 mile
Between Red globes or from White tip type	1 mile
Between Long Red from any other Red type	2 mile
Between Any Red from any other White type	3 mile
Spinacit used to pin hybrids	
Between O.P. of the same leaf shape type	1 mile
Between O.P. of different leaf shape type	3 mile
Between Hybrid and O.P. type	3 mile

Cichorium intybus **(Chicory)**
Includes: raddichio, chicory, witloof, fodder root

Between O.P. type or endiva species	1 mile
Between Hybrids or Hybrid and O.P. type	2 mile

Cichorium endiva **(Endive)**
Includes: endive, escarole, frizze

Between O.P. type or intybus species	**1 mile**

Cucumis sativus **(Cucumber)**

Types: Slicer, Pickle, White spine, Black spine, Beta alpha.

Between O.P. of the same type	1 mile
Between O.P. of different type or spine color	2 mile
Between Hybrid and O.P. type	3 mile
Between Hybrid of different type or spine color	3 mile

Cucurbita **species (Squash)**

Includes: pepo, moshchata, mixta, maxima

Between Similar types, shape and color	1 mile
Between Same or Different species	1 mile
Between another Hybrid of similar variety	1 mile
Between Hybrid and O.P. of similar type and shape	1.5 mile
Between O.P. or Hybrid of different type, shape or color	2 mile

Flowers

All Flowers need to be pinned
Between ones that cross pollinate 1 mile
Includes: Chrysanthemums, Sunflowers, Helianthus, Poppies, etc.
Multiple non-crossing flowers at one location can be pinned with one pin denoting flowers
Consult company representatives on general pinned flower locations

All other seed crops need to be pinned.

For isolation distances consult company representatives

WVSSA

Specialty Seed Production

Pinning Rules

To facilitate communication and protect the specialty seed industry in the Willamette and Tualatin Valleys of Oregon, isolation mapping procedures have been drafted and agreed upon

by the Willamette Valley Specialty Seed Association (WVSSA). The procedures and isolation distances as outlined below have been set up to ensure quality seed production of all vegetable and other specialty seed in the designated areas from potential cross pollination. The isolation control area of interest referred to as the Willamette and Tualatin Valleys includes the counties of; Multnomah, Washington, Clackamas, Yamhill, Polk, Marion, Benton, Linn, and Lane.

Maps

The association has four separate maps for the purpose of pinning and maintaining appropriate isolation distances. There are two for non-*Beta* species, and two for *Beta* species. The maps are then divided by the North and South valley isolation areas. They are established at four different locations as follows:

Non-*Beta* Species Locations

Map1 - North Valley Pinning
OSU Extension Service Marion County Phone: 503-588-5301
At: 3180 Center NE, Salem, Oregon 97301 Room 1361

Map 2 - South Valley Pinning
OSU Extension Service Linn County Phone: 541-967-3871
At: 104 4th Ave SW, Albany, Oregon 97321 Room 102

***Beta* Species Locations**

Map 3 - North Valley Pinning
West Coast Beet Seed Phone: 503-393-4600
At: 2380 Claxter Rd NE, Salem, Oregon 97303.

Map 4 - South Valley Pinning
Betaseed, Inc. Phone: 541-926-0161
At: 34303 Hwy 99 E, Tangent, Oregon 97389

The non-*Beta* types are to be pinned at the non-*Beta* locations in respect to their valley area.
The North map is for pinning isolations: Including and North of Township 9 South.
The South map is for pinning isolations: Including and South of Township 9 South.
Fields located within Township 9 S. must be pinned on both North and South maps.

The *Beta* types are to be pinned at the *Beta* locations in respect to their valley area.
The North map is for pinning isolations: Including and North of Township 11 South.
The South map is for pinning isolations: Including and South of Township 12 South.

Pinning Procedures

To identify production fields for location on the map, pins and flags will be used to mark the isolation. On the non-*Beta* maps, different color flags are used to separate the major crop types.

1. Must have approved pinning rights and abide by the guidelines of the WVSSA.
2. Observe the dates covered under the priority pinning.
3. Check for acceptable isolation distance on the maps.
4. Use proper flag to pin the field.

Written on each flag will be: Party name, Crop type, Hybrid or O.P., Legal location.

5. Fill out pinning card at time of pinning.

6. At non-*Beta* maps, have Extension personal date stamp card and place in lock box.
7. At *Beta* maps, pin as set up at each location, date stamp card and place in lock box.
8. Contact any companies involved if isolation guidelines are in question.

Pins will be placed as close to the center of the field to be planted as possible. This will be done to facilitate proper isolation distances to other fields. The isolation is not valid if that isolation is pinned incorrectly.

The map cannot be pinned until an established agreement has been made with the grower for planting the crop. The map cannot be pinned on a speculative basis in order to reserve isolation. Upon cancellation of an intended production prior to planting the pin must be removed within 5 days. Upon abandonment of an established production, the pin must be marked failed. A penalty may be assessed of $50.00 if in violation and payment is required to remain a member in good standing.

Pinning Priority
The WVSSA allows the grower to hold the right to the isolation in his perspective farming area for the following year, to produce the same crop within a one-mile radius to the prior year's isolation. The grower maintains the right to elect the contracting company. The isolation right, known as a prior year's priority can only be held for the specific grower until the dates specified below.

A prior year's priority is only valid until the following dates:
For non-*Beta* species: Annuals - March 1st Biennials - August 1st
For *Beta* species: Transplants - February 1st Direct seeded - August 1st
After these dates, all isolations are available on a first come basis.

Pinning Rights:
The contracting company or responsible seed representative, who is a member of the WVSSA, may do the pinning. The intent is for the contracting company or responsible seed representative to do the pinning. The representative appointed by a company may also do the pinning if the company is a member of the WVSSA. Oregon State University is considered here as a non-due paying member that has pinning privileges.

The contracting company or responsible seed representative with a grower agreement acts as the grower's appointed representative in establishing the isolation. Individual growers are to allow their contracting company or responsible seed representative who is a member of the WVSSA, to establish the isolation. Growers are allowed to be members of the WVSSA and would be considered as a responsible seed representative and as a member would be allowed to pin isolations for their farms under their own agreements. The contracting company or responsible seed representative agrees to abide by the pinning and isolation guidelines of the WVSSA.

New pinning parties need to contact an officer of the WVSSA for eligibility approval a membership is required prior to pinning. The responsible party may be required to have membership approval by the association. The association may elect to appoint a representative to meet with the new parties at the appropriate isolation map to clarify pinning practices.

Membership and Pinning Fees:
The member or responsible party for the seed is subject to fees as established by the WVSSA. Fees are inclusive of the WVSSA annual membership dues of $150.00 per year, or a Homestead membership fee of $5.00 per year. The pinning fees are; $10.00 per OP crop, $25.00 per Hybrid crop, and $25.00 Multi-crop fee. Annual dues for the current year and pinning fees for the prior year's pinning are assessed at the beginning of each year. If dues and pinning fees are not received, pinning rights may be revoked.

A multi-crop fee may apply when producing multiple crop species of an OP in one location, and one acre or less. Only one per member is allowed and is intended for research farms, and small commercial farms used for seed production. The multi-crop fee is not a pin, crop pins must be used to pin different species, and multi-crop must be designated on each card turned in.

A Homestead membership fee and no pinning fees may apply for a Homestead non-voting member when producing in one location non commercial OP seed crops. Intended for the seed saver this member is not eligible for the pinning priority and is required to follow WVSSA rules and to be accompanied by a designated appointee when pinning the map. Crop pins must be used to pin different species, and Homestead must be designated on each card turned in.

Exceptions Agreements
There are two exception agreements, the Isolation Distance Encroachment, and the One Year Isolation Deferral. The Encroachment exception applies to an established crop isolation where one company agrees to allow another company to produce a like crop under less than the set isolation distance. The deferral applies to an established crop isolation where one grower and company agrees to allow another grower and company to produce a like crop for one year, and the established grower retains the isolation priority.
The parties involved prior to planting a specific crop must agree upon any exception to the established isolation for the specific crop year. The exception agreement needs to be in writing annually and to include the right to the isolation the following year. There are exception agreement forms available for this use. All parties must agree and all other WVSSA isolation rules must be followed.

Securing Isolations
At all maps a system of cards and a lock box will be used and parties using the maps must follow the WVSSA rules. Fields must be currently identified for both the past and present crop year. Failure to pull pins will result in a penalty under the WVSSA.

At the non-*Beta* maps, at the time of opening the lock box, a representative from two different companies of the WVSSA, in addition to an Extension Agent, are required to be present. The lock box will be emptied annually when the prior crop year's map is cleared.

At the *Beta* maps, the procedures for pinning must be followed at each location. The cards will be date stamped, except not by an Extension Agent, and placed in lock box. The lock box can only be opened and will be emptied annually by two members of the WVSSA.

The purpose of the lock box is: 1.To use as the archive and formal record of posting of pins. 2. To review established pinning priority rights. 3. To be used for pinning dispute resolutions. Any discrepancies over pinning locations will be solved through the cards. The cards will be used for accuracy of pinning and in case of arbitration. Pinning cards will be archived indefinitely.

Arbitration
Should all precautions fail in preventing potential cross-pollination problems between seed companies or responsible seed representative, and or growers, the WVSSA suggests the following system or arbitration: Fields not pinned will be considered at fault in event of arbitration. If the parties agree to arbitration by the three-person committee, they agree to abide by the committee's recommendation. The two contesting seed companies or responsible seed representative, in consultation with their growers, each chooses an outside field representative from the WVSSA. The arbitrators, A and B, are suggested to a neutral facilitator who notifies them of their role. They do not know whom they represent and together choose a third committeeman. Arbitrators A, B and C agree to hear the facts of each seed company. Maximum would be two representatives on each side of the issue. After both parties present the facts, only the arbitration committee, A, B and C, remain in the room to discuss the facts fully. They agree to a solution before leaving the room and the chairman will deliver the recommendation immediately to both parties.

Columbia Basin Vegetable Seed Field Isolation Dates[1]

With a valid "release"[2], vegetable seed company representatives may reserve fields for vegetable seed production as follows:

Annuals and carryover onions[3]	February 1 or closest weekday thereafter
Onion and other biennials (except carrots)	March 1 or closest weekday thereafter
Carrots and fall planted annuals	June 1 or closest weekday thereafter

[1] These dates for crops are as per agreement at the January 21, 2005 meeting of the Columbia Basin Vegetable Seed Field Representatives Association.

[2] A release must include the production company, crop, and crop year for placement in Columbia Basin production and either the number of fields or number of acres.

[3] Carryover onion crops may be repined with priority between February 1 and March 1, after which priority is lost.

Columbia Basin Vegetable Seed Field Isolation Standards*

All genetically modified crops will be designated as GMO.

CARROT FAMILY (*Apiaceae*)

CARROT (Pinned by Group and Type)

Groups: Hybrid and Open Pollinated

Types:
Chantenay (Danvers, Red Cored, Royal, etc.)
American Market (Imperator, etc.)
Early (Amsterdam, Baby Carrot, etc.)
Medium (Nantes, etc.)
Late (Flakkee, Berticum, etc.)
Round and Odd Shapes (Paris Forcing, etc.)
Oriental (Usually short Chantenay shape)

Distance: Between Hybrids.....2 miles
Between Hybrids and Open Pollinated.....2 miles ♦
Between Types within Groups.....1 mile
Between Varieties of same Type.....½ mile
Between same Varieties for different companies.....¼ mile

Off-color carrots should be grown outside main production area and pinned by color with a minimum isolation distance of 5 miles from other colors.

♦ Note: A 3 mile isolation will be permitted between Hybrid and Open Pollinated carrots where requested.

PARSLEY Between all Types and Varieties.....1 mile

CORIANDER (cilantro or Chinese parsley) Between all Types and Varieties 1 mile

MUSTARD FAMILY (*Cruciferae*)

RADISH (Pinned by Group and/or Type...Understood to be O.P. unless otherwise noted)

Groups: Hybrid and Open Pollinated

Types:
Round Red
Round Red Forcing
Crimson Giant
Round Red White Tip
Half Long White Tip
Long Red
Icicle (and related forms)
Round White
Purple
Black
Other

* Standards as of March 1, 2006 as agreed upon by the Columbia Basin Seed Field Representatives Association. Revised 03/06.

RADISH **Cont'd.**

Daikon (assumed to be white rooting type unless specified)
Daikon Sprouting
Daikon, Red
Daikon, Green

Distance: .....Between Hybrid and Open Pollinated.....2 miles
Between any red Type and any white type.....2 miles
Between any round white, icicle Type, purple, black, or any Daikon Types and any other radish.....2 miles
Between Round Red, Crimson Giant, Long Red, round White Tip, and Half Long White Tip.....1 mile
Between Daikon, Sprouting, and any other Daikon of same color 1 mile
Between Round Red and Round Red Forcing.....½ mile
Between Round Red Varieties (unless negotiated between companies) ½ mile

RAPESEED

Canola and other Oilseed Types .....3 miles

Genetically modified Canola and other Oilseed Types will be designated as GMO

OTHER CRUCIFERS (Pinned by crop name and chromosome number)

All Groups or Types .....2 miles

ONION FAMILY (*Alliaceae*)

ONION (Pinned by Group and Type)

(*Allium cepa*)

Groups: Hybrid and Open Pollinated

Hybrid: (Should be posted as male parent)
From Hybrid or O.P. of different color.....3 miles
From Hybrid or O.P. of same color, but different shape (i.e. Globe vs. Flat) 2 miles
From O.P. of same color and shape.....2 miles
From Hybrid of same color, but different shape.....2 miles
From Hybrid of same color, shape, and Type (i.e. Yellow Spanish vs. Yellow Spanish) 1 mile
From *Allium fistulosum*, Chives, or Leek.....None

Open Pollinated:
From Hybrid or O.P. of different color or shape.....3 miles
From O.P. of same color, but different shape (i.e. Yellow Globe vs. Yellow Ebenezer) 2 miles
From Hybrid of same color and shape.....2 miles

From O.P. of same color, but different Type (i.e. Yellow Spanish vs. Yellow Globe) 1 ½ miles
From O.P. of same color, Type, and shape (i.e. Yellow Spanish vs. Yellow Spanish) 1 mile
From *Allium fistulosum*, Chives, or Leek.....None

(*Allium fistulosum*)

Open Pollinated:
From *Allium cepa*, Chives, or Leek.....None
From another variety of *Allium fistulosum* (i.e. Tokyo Long White vs. He-Shi-Ko) 1 mile

ONION Cont'd.

Hybrid:
From any O.P. or Hybrid *A. fistulosum*.....2 miles

(*Allium cepa-fistulosum* cross) CFC
tetraploid double chromosome

Open Pollinated:
From *Allium cepa* or *Allium fistulosum* of the same color.....None
From *Allium cepa* or *Allium fistulosum* of a different color.....None
From another Variety of CFC of the same color.....1 mile
From another Variety of CFC of a different color.....3 miles

CHIVES

From *Allium cepa, Allium fistulosum,* or Leek.....None
From another Variety of chives.....1 mile

LEEK

From *Allium cepa, Allium fistulosum*, Chives.....None
From another Variety of Leek.....1 mile

GOOSEFOOT FAMILY (*Chenopodiaceae*)

BEETS

Between all Beets, Swiss Chard, and Mangels.....3 miles

Sugar Beet Types:
Diploid
Tetraploid

From Sugar Beets of the same or different Type.....2 miles

Genetically modified Sugar Beets will be designated as GMO

Appendix B

West Coast Beet Seed Company protocol for genetically modified (GM) seed production and GM grower guidelines

PROTOCOL FOR GENETICALLY MODIFIED (GM) SEED PRODUCTION
(Direct-Seeded, Transplants, Nurseries, Plots)

DETECTION

1. West Coast Beet Seed Company will request the help of Members to set up assay for QC (detection) of Roundup Ready (RR) gene in sugar beet seed lots.

2. West Coast Beet Seed Company will, from time-to-time, add additional assay of QC (detection) for other events as needed.

3. West Coast Beet Seed Company will conduct the assay for QC of RR on all RR seed lots. For the protection of West Coast Beet Seed Company and to learn if the processes are meeting the desirable criteria, random testing of non-GMO seed lots will be conducted. West Coast Beet Seed Company may consider using zones, based on distances from the GM source, for determining this random testing. Members have the option of requesting all of their lots be tested. Members have the option of requesting this information in written form.

4. The shipping document will indicate that the shipment contains GM seed.

5. West Coast Beet Seed Company assigns a lot number to the potential seed lot prior to the item being planted. This number stays with the seed lot and becomes a permanent record for this lot.

6. West Coast Beet Seed Company will inform members of all past events grown so members can test their seed lots.

ISOLATION

1. West Coast Beet Seed Company's goal is to develop an agreement with sugar beet, chard, and red beet seed companies to avoid cross contamination and to develop a program to inform each other as to the locations of present and past GM and non-GM seed productions.

2. Within a three mile radius of any RR field, West Coast Beet Seed Company will monitor for any volunteers in any fields used for sugar beet production, over a minimum of the past five years or until no volunteers are observed.

3. West Coast Beet Seed Company will monitor GM fields for a minimum of five years or until no volunteers are present. This will protect chard, red beet, and sugar beet seed production in the area. The removal of the volunteers will be done under the supervision of West Coast Beet Seed Company representatives and recorded in a log book. The costs will be shared between West Coast Beet Seed Company and the grower.

4. West Coast Beet Seed Company will maintain a minimum three-mile isolation between GM and non-GM sugar beet production. The isolation between GM pollinators/productions where the same event is present will be a minimum of one mile.

The isolation between sugar beet, chard, and red beet will be a minimum of three miles until an agreement can be reached with the other companies.

STOCK SEED/STECKLINGS/SEED TAGS

1. West Coast Beet Seed Company has adopted an orange color tagging system to visually identify GM material (GM stock seed, GM stecklings, GM seed in tote boxes, cotton or burlap bags, GM seed samples, and member's shipping containers). The orange colored tags identify the product as GM and it is to be treated according to the protocol. In respect to each Member company's policies, GM material going to or coming from West Coast Beet Seed Company will be tagged with the preferred identification of that member company.

Member Requirements:

1. Prior to GM stock seed being shipped to West Coast Beet Seed Company, the members will send a document (Movement Traceability Form) identifying the stock seed items (I. D. code number, etc.) that will be GM.

2. Each GM stock seed bag arriving from members will already contain an orange tag marked in writing, stating it is GM seed. The stock seed bags can also contain the Member company's GM identifying colored tag, code, symbol, etc.

    A. If stock seed arrives and there are any inconsistencies in the paperwork, orange tagging, non-orange tagging, or any other inconsistency of labeling, the warehouse personnel will notify the Manager and the seed will be put on hold until the member clears the issue and backs it up with the proper documents. The seed will be stored on a separate pallet in the GM portion of the warehouse. The pallet will be marked clearly in a manner to prevent it from being prepared for planting.

West Coast Beet Seed Company's Requirements:

1. The GM stock seed will be stored separately from the conventional stock seed. The area will be in the main building, along the east wall, near the Warehouse Manager's office and will be identified in a clear manner.

    A. Non-GM seed will be stored in the northwest warehouse, of the main building, by the main dock.

2. The GM stock seed will be prepared for grower disbursement in the main building, along the east wall, near the Warehouse Manager's office.

    A. A sample of the GM stock seed will be held in a separate area of the warehouse for five years. This sample will be labeled with the orange colored tag and the preferred identification of the member company.

3. Once the GM stock seed is prepared for the grower, it will be labeled with an orange tag indicating to the grower that they have in their possession GM seed.

4. Accompanying the GM stock seed will be a written document declaring that the seed is GM.

5. The stock seed for GM and non-GM productions will not be transported to the growers in the same vehicle at the same time. The field staff will be trained properly at least once a year in the handling of GM seed and all seed movement will be documented.

6. The field supervisors are responsible for collecting the remaining stock seed from the growers immediately after planting. The Warehouse Manager will log in the stock seed. When GM stock seed is returned from the growers after planting, sealed bags will be returned to the member. Opened bags will be incinerated at the County garbage burning facility to prevent use of potentially grower-contaminated seed.

   The Member will be informed, in writing, of the amount, location, and date destroyed. The Member also will be informed, in writing, as to amount being returned to them.

GM NURSERY

1. The GM nursery will be kept separate from the conventional nursery.

   A. The owner of the nursery ground will have given West Coast Beet Seed Company written permission to plant GM stock seed.

2. The GM stock seed for the nursery will be handled the same as any other GM stock seed (information from member, orange tag, stored in separate area, etc.) (see above "STOCK SEED/STECKLINGS/SEED TAGS").

3. The digging equipment will be completely clean of any stecklings before entering or leaving the GM nursery. West Coast supervisors will sign a document stating they have personally inspected the equipment after cleaning and found it to be free from any stecklings.

4. All GM stecklings will be stored in sacks that are marked with a GM orange tag. The stecklings will be stored in a cooler or warehouse separate from non-GM stecklings.

5. There will be a separate GM observation nursery and it will be isolated in the area where GM productions of the same event(s) are being grown.

GROWING THE CROP
(Planters, tillers/flail, sprayers, separators, male removal, swathers, combines, tote boxes, hauling, tarps/lids)

Any equipment (planter, transplanter, sprayer, flail, tiller, tractor, irrigation equipment, vehicle, separator, clipper, swather, combine, tote box, post-harvest tilling equipment, seed cleaning equipment, or any other equipment) must be monitored, treated, cleaned, and the process documented, according to West Coast Beet Seed Company's policies.

The intent is to prevent seed, pollen, or stecklings from being transferred out of the area of control or transferred to where they could contaminate other Beta species productions (details of the methods are found in other parts of this protocol).

1. West Coast Beet Seed Company will use only designated totes for GM seed harvest by growers. Phase one will be metal totes only. Phase two will be metal totes and designated wood totes.

   A. During transportation, the totes will be covered with a West Coast Beet Seed Company approved high-quality tarp or high-quality lid.

2. Trucks transporting commercial GM seed will not carry non-GM seed on the same load.

3. Growers will not be allowed to transfer bulk seed to totes at third party locations (i.e. grain elevators) unless, in the opinion of West Coast Beet Seed Company and upon approval of the member company(ies), the seed can be transferred in a manner that would allow complete and easy transfer without contamination of equipment or surrounding area. To avoid spillage, growers must not transfer seed from one tote to another.

4. Any pesticide application made during the flowering period needs to be done by aerial applications. If aerial application is not possible, then West Coast Beet Seed Company will use its operator and modified equipment to spray. If the grower has high clearance spray equipment that does not leave his farm, then we can consider using this equipment.

   The Member will be notified in advance as to which productions West Coast Beet Seed Company will use its equipment for spraying after flowering begins.

5. When the GM production is in bloom, any person who enters the field (grower or their workers if they would be going to any other Beta species production, West Coast Beet Company staff or temporary workers, Member or their representatives), will wear disposable coveralls. They are to be removed and disposed of after each use. The disposable clothing will be stored in a separate, closed container so that live pollen cannot escape the area or be transferred into another field.

   A. Clean, disposable, coveralls will be kept in a closed container prior to use. These coveralls will be furnished at West Coast Beet Seed Company's expense. West Coast Beet Seed Company's field supervisor is responsible for the disbursement of the disposable clothes, for having people wear them, for training people how to dispose of them, and finally to control the good use of them.

SEED CLEANING, STORAGE, SHIPPING CONTAINERS, AND SCREENINGS DISPOSAL

1. GM seed will be delivered in designated totes. The totes will be affixed with all appropriate tags, including a GM orange tag which will designate it as containing GM seed.

A. These totes will be stored in a designated portion of the warehouse(s) physically separated from non-GM seed. The seed will also be unloaded in a separate area and only GM designated and marked equipment (brooms, conveyors, etc.) will be used for GM seed.

B. The field-run samples also will be affixed with a GM orange tag and these samples will be stored separately from non-GM samples. This requirement will be added to the scale house procedures and policies. Scale house personnel will be trained in these procedures, each year, prior to seed delivery.

2. West Coast Beet Seed Company will, in the beginning years, utilize one or two of the cleaning lines to process GM seed. The GM seed will be cleaned at the end of the processing period to avoid potential problems.

A. The Company shall not clean conventional and GM seed simultaneously, except in an emergency. In the event of an emergency and the Company must clean conventional and GM seed simultaneously, a physical barrier, such as a plastic wall, shall be put in place to avoid contamination.

B. All cleaning equipment will be thoroughly cleaned prior to and after cleaning GM seed. This will ensure that all GM seed has been removed from equipment prior to any non-GM seed being introduced after that point. (Detailed instructions of cleaning the equipment are already in place).

C. A permanent log is kept for the cleaning sequence.

3. West Coast Beet Seed Company will draw a representative clean seed sample and tag it with a GM orange tag.

A. Part of this sample will be tagged with a GM orange tag and sent to Agri Seed Testing for germination and purity testing. Agri Seed Testing will be informed that the seed is GM. Agri Seed Testing holds their samples for three (3) years and then will destroy them by incineration in the County garbage burning facility.

B. Part of the sample will be tested via the QC assay method for the event(s). (This will be expanded to include how this information will be disseminated). See DETECTION category number 3, paragraph 1 above.

C. A minimum of one (1) pound will be stored in a separate area for five years labeled with an orange tag and the preferred identification of the member company.

D. Members at their request will be sent their requested amount of properly labeled, clean seed samples.

4. Screenings from GM production will be delivered to either the pellet mill or composting facility.

A. West Coast Beet Seed Company will check yearly with the pellet mill company to see if the feed pellets will be sold where GM is presently not allowed (Europe)[44]. West Coast Beet Seed Company will keep members informed on the result of this discussion.

B. In the future, regulated screenings can be delivered to a landfill if required.

5. Shipping of GM seed to members will be in new containers (boxes, poly tote bags, etc.). The containers will be affixed with a GM orange tag and the preferred identification of the member company. Shipping containers (cardboard boxes and poly bags), because they are known to hold some seed in crevices, will not be allowed to be reused at this time. Therefore, West Coast Beet Seed Company would prohibit GM shipping containers from being returned for reuse.

A. The paperwork that goes with the seed will indicate seed in truck contains GM seed.

B. For the protection of West Coast Beet Seed Company and its members, GM and non-GM seed will not be shipped on the same truckload to the Members' facilities.

GM GROWER GUIDELINES

The policy for the grower guidelines will include the following revised requirements:

1. The policy will be a part of the Grower Contract.

2. The grower will have only a GM production (of one event) or a non-GM production; not both in a given year. This applies to growers who grow only for West Coast Beet Seed Company and to those growers who grow for both West Coast Beet Seed Company and another sugar beet seed company.

A. The grower will not raise a GM crop and a chard or red beet seed production in the same year.

3. The grower will use precaution in the field to eliminate seed from remaining loose on the transport deck prior to leaving the field.

A. Clean off deck of loose seed prior to leaving field. This is part of the protocol that will be reviewed with the Grower.

B. (West Coast Beet Seed Company will work on designing a method to prevent seed from falling between boxes. We may also promote bulk hauling to the plant and transfer to boxes).

4. Grower cannot use/share any equipment that might be used in a non-GM sugar beet, chard, or red beet seed production in the same growing year.

[44] Import of food and feed products derived from Roundup Ready sugar beet event H7-1 was approved by the European Union in October, 2007.

5. Grower cannot use same combine to combine GM sugar beet, non-GM sugar beet, chard, or red beet seed in same year.

   A. The grower will combine 200 acres of another crop between combining any beta species.

6. We want a rotation of five crop plantings since the last beta species was grown on the field for seed.

7. Grower training on all aspects of GM growing handling will be conducted by management and field staff.

RECORDKEEPING

1. West Coast Beet Seed Company will continue to maintain a permanent GPS computerized mapping system to record all productions including year, item number, and lot number.

2. West Coast Beet Seed Company maintains a yearly and ongoing computerized log where all important activities of the production are recorded (Crop Tracker). The Grower may collect information, but the final responsibility for this data collection is the field supervisor.

3. Crop histories of herbicide and crop are collected each year prior to planting.

4. West Coast Beet Seed Company will develop a method for tracking all movement of GM seed from the time West Coast Beet Seed Company receives the stock seed, to the final processing and shipment to the member. This information will be communicated to the members upon request. The members may also request additional information when necessary for stewardship of the GM crops.

INSPECTION

New disposable clothing will be used by West Coast personnel, grower, custom contractor, and member company personnel when entering the field when pollen is present. After each use, the clothing will be discarded into a sealed container and then disposed of in customary container (garbage can, dump box).

RISK ANALYSIS

The protocol needs to be continually reviewed. During the review and handling of the crop, new areas of concern may become evident. When this occurs, the concern must be addressed and solutions implemented. Final approval of any changes to the contracts must be approved by the Contract Committee and recommended by the committee to the Board of Directors in a timely fashion.

TRAINING

1. All West Coast Beet Seed Company employees will be trained in all areas of the protocol. Date, time, personnel attending, type of training and instructor should be recorded for all training sessions and appropriately filed.

   A. West Coast will train personnel on these policies and procedures. Written training documents will be reviewed and approved by the board.

2. West Coast Beet Seed Company employees that deal with specific areas will have extensive and continual training in the specific area.

3. Both West Coast Beet Seed Company growers and personnel will be trained in the relevant areas of the protocol. Date, time, attendees, type of training and instruction should be recorded for all training sessions and appropriately filed.

4. Part of the training will include the following West Coast Beet Seed Company policy: Operators discovering evidence of spillage or GM seed out of place immediately will inform their supervisor, the head of department, and the West Coast Beet Seed Company Manager. At first evidence of the problem, appropriate action will be taken to halt the release of any additional seed, pollen, or plant material. The problem will be evaluated immediately to prevent a reoccurrence. Appropriate individuals or companies will be informed of the situation.

GM Grower Guidelines

I. The following are guidelines to which all West Coast Beet Seed Company commercial growers are required to adhere in the contract production of genetically modified (GM) sugar beet seed. If questions arise with this production, contact West Coast Beet Seed Company's fieldmen for clarification or explanation.

   Direct seeded and transplant productions will adhere to the guidelines, except with reference to transplanting. West Coast Beet Seed Company will perform the transplanting in winter/spring.

   A. **Field Selection:** Genetic purity is of the utmost concern with this type of seed production. Field selection encompasses many characteristics, but the main features that are necessary include fields with required isolation of at least three miles from non-GM productions and one mile between GM pollinators/productions, the least chance of having volunteer beets from previous productions, good fertility, favorable location (not likely to flood), available for timely plantings into pre-irrigated conditions, good irrigation systems, and good water availability. At a minimum, a rotation of five crops since the last beta species were grown for seed is required.

   B. **Planting:** Stock seed will carry an orange tag to indicate GM. The goal is to plant into fertilized, pH adjusted as necessary, and pre-irrigated fields to ensure timely establishment of desired stands. It is desirable to have a population of 4-5 beets per foot of row in all lines for direct-seeded production.

Stock seed normally is limited in supply, so close monitoring of seed drop is essential to establishing uniform stands across the entire planting. Stock seed will be stored safely to ensure no seed is lost inadvertently or released into the environment inadvertently. All unused stock seed will be returned to company personnel in a timely manner.

Planters must be monitored both before and after planting to ensure that the proper seed is being planted. After planting, the planter and the tractor need to be cleaned in the field to remove 100% of the seed prior to moving the planter to another location. The intent is to prevent seed from being transferred out of the area of control or transferred to where it could contaminate other beta species productions.

C. **Irrigation:** Fall irrigation of direct-seeded production should start after planting, as necessary, and continue through emergence and stand establishment.
Spring irrigation of direct seeded and transplant production should begin as the soil moisture drops and crop growth requires supplemental moisture. Spring irrigation should continue as the crop grows and matures to the point that additional moisture is no longer beneficial to production of a quality crop.

West Coast Beet Seed Company personnel will determine the timing of the last irrigation.

Irrigation equipment will be cleaned of any live GM pollen before leaving the field. If this is not possible, then irrigation equipment should be left by the field for 24 hours before moving to another location.

D. **Disposable Clothing Requirements:** When the GM production is in bloom, any person who enters the field, and who may enter another Beta species production that same day, will wear disposable coveralls. These will be furnished at West Coast's expense and they are to be removed and disposed of after each use. This will prevent live pollen from being transferred to another field.

E. **Care of the Crop:** The crop will be cared for in the best interest of obtaining a high quality and high-yielding production. Management practices of individual fields vary and shall be approved by West Coast Beet Seed Company's field staff. Recommendations by Company representatives will be carried out in a timely and efficient manner.

1. Any pesticide application made during the flowering period needs to be done by aerial applications. If aerial application is not possible, then West Coast Beet Seed Company will use its operator and modified equipment to spray. If the grower has high clearance spray equipment that does not leave his farm, then we can consider using this equipment.

F. **Pollinator Removal:** Removal of pollinator in a timely manner is very important to production of high quality seed. Pollinator destruction will be completed within the time frame agreed upon with West Coast Beet Seed Company representatives. West Coast Beet Seed Company representatives will approve destruction methods and equipment. Equipment **will not** be used in another

beet field until thoroughly cleaned of pollen and/or seed and inspected by West Coast Beet Seed Company field supervisor or his representative.

1. Any equipment (flail, tiller, separator, tractor, vehicle) must be cleaned to kill all live pollen before leaving the field according to West Coast Beet Seed Company's policies.

   The intent is to prevent pollen from being transferred out of the area of control or transferred to where it could contaminate other Beta species productions.

G. **Swathing:** Swathing will be done in a timely manner as directed by West Coast Beet Seed Company representatives. Swathers will be inspected by West Coast Beet Seed Company's field supervisor for cleanliness prior to and after cutting. Swathers will be cleaned in the field after swathing to ensure that no seed is released into any adjacent field or area.

H. **Combining:** West Coast Beet Seed Company will approve the cleanliness of the growers combine. Before use, the combine must have threshed at least 200 acres of another crop since it was used last to combine any other Beta species. Approval for grower combine usage will be determined on a case-by-case basis and will depend on previous crops combined and acreage.

Combines must be cleaned before they leave the field to ensure no seed is moved into adjacent areas. Combined seed will be placed in designated tote boxes within the confines of the existing field. Grower will clean off the truck deck in the field to ensure seed is not spilled during transport. West Coast Beet Seed Company's supervisor will approve the cleanliness of the grower's combine before leaving the field.

I. **Bulk Seed:** Growers will not be allowed to transfer bulk seed to totes at third party locations (i.e. grain elevators) unless, upon approval of West Coast Beet Seed Company, the seed can be transferred in a manner that would allow complete and easy transfer without contamination of equipment or surrounding area. To avoid spillage, growers must not transfer seed from one tote to another.

J. **Hauling Seed:** All loads of seed shall be covered with West Coast Beet Seed Company approved, high-quality tarps and/or sealed with lids so no seed can be lost during transport. GM and non-GM seed **will not** be hauled simultaneously on the same truck.

K. **Post-Harvest Field Management:** Fields will be shallow tilled after harvest to a depth of not more than 3". To promote sprouting of the shattered seed, full irrigation is required, unless a West Coast Beet Seed Company representative determines adequate rainfall has occurred to promote the required sprouting. Fields will not be fall plowed for any reason. Control of sprouted seed is essential to prevent any pollen release and seed formation in future crops.

All tractors and tillage equipment must be monitored and cleaned according to West Coast Beet Seed Company's policies before leaving the field.

The intent is to prevent seed from being transferred out of the area of control or transferred to where it could contaminate other Beta species productions.

L. Fields will be inspected by West Coast Beet Seed Company for a minimum of five years or until no volunteers are noted.

M. All of these actions will be recorded at West Coast Beet Seed Company in order to establish a record of adherence to GM policy, whether the actions were taken by the grower, the company, or by both in a shared responsibility.

Appendix C

International Seed Federation Code of Conduct

CODE OF CONDUCT
(adopted by the ISF Sugar and Fodder Beet Commission)

Principles of quality assurance in beet seed production.
(Final version of 22 October 2007)

Summary

The principles and measures highlighted in this paper aims to the adventitious presence of GM[45] beet seed in conventional sugar beet and fodder beet, as well as the adventitious presence of other GMOs[46] in GM sugar beet and fodder beet seed. The adventitious presence of GMOs can only be minimized but not totally excluded because seed production occurs in open fields under natural conditions. There is a strong necessity for practicable rules and regulations governing a high level of purity for seed of conventional varieties relating to adventitious presence of GMOs and for seed of GM varieties relating to adventitious presence of other GMOs.

1. Objective

The objective of this industry position paper for the quality assurance of sugar beet and fodder beet (hereinafter referred to as "beet seed") is to describe the measures the seed industry has taken to minimize the likelihood of adventitious presence of GM beet seed in conventional seed or adventitious presence of different GMOs in GM beet seed. The Industry recommends to apply the same measures to table beet and/or Swiss chard seed production[3].

This objective is accomplished by implementing guidelines and operating procedures (preventive measures) covering every step from the stage of R&D activities up to delivery of commercial beet seed to the customer. In addition to these measures, actions are undertaken to control the various steps of this process.

2. Deregulation of GM beet events

The status of deregulation of GM sugar beet events varies according to territories. Similarly, requirements set up by regulators may vary by country. Therefore principles adopted by the industry must reflect these regional differences.

---

[45] GM: Genetically modified
[46] GMO: Genetically modified organism
This code of conduct has up to now been agreed upon by the following companies: Danisco Seed, Dieckmann GmbH & Co. KG, Fr. Strube Saatzucht GmbH & Co. KG, Maison Florimond Desprez S.A.S., KWS SAAT AG, SESVanderHave, Syngenta Seeds and their affiliated companies. It is open for adoption by other seed companies producing sugar and/or fodder beet seeds.

2.1. USA

There are three GM sugar beet events which have been deregulated in the USA. One of the three events is commercialized since 2007.

2.2. Europe

No GM beet events are deregulated at this moment in Europe. As of today no commercialization of GM beet seed can take place in Europe. There is one sugar beet event undergoing the European deregulation process. This process has not been finalized. Similarly there is one fodder beet event undergoing deregulation but the process is still in progress.

2.3. Other territories in the world

There is one sugar beet event undergoing a deregulation process in certain countries.

3. Adventitious presence of GM beet seed

3.1. Adventitious presence in conventional seed

Adventitious presence of GM sugar beet seed in conventional beet seed cannot be totally excluded. As of today, there are no official thresholds governing the adventitious presence of GM seed in conventional seed in Europe. There is an urgent need for such a threshold to be in place in Europe due to the market introduction of the first GM sugar beet in the US. Thresholds will vary and some territories or countries may not regulate adventitious presence.

Adventitious presence of GM seed in conventional seed would result from the presence of GM seed or GM plants in other beet seed production at some stage of seed production or processing.

Three possible main sources of adventitious presence of GM seed in conventional seed productions are identified:

- Spread of GM pollen to multiplications of conventional seed.
- Unintentional mixing-up of plants during transplanting.
- Unintended traces of GM seed during harvest, transport, processing or storage.

Quality assurance systems have been implemented to address the issues posed by the adventitious presence. These consist in preventive measures and testing procedures for adventitious presence. They are presented in section 5.

3.2. Adventitious presence in GM seed

Adventitious presence of unintended GM seed in GM seed production would result from the presence of GM seed of another event in a production of a given event at some stage of seed production or processing of GM seed.

Similar measures as above in point (3.1) are addressing this case.

4. Pre-commercial and commercial production of GM beet seed

4.1. Europe

There are currently no pre-commercial or commercial productions of GM beet seed in Europe.

Until now, production of GM beet seed in Europe is limited to R&D[47] activities only.

Quality assurance measures that would be taken in the future for commercial seed production in Europe will be focused on the separation of GM seed and conventional seed during the whole production procedure (e.g. multiplication and processing steps).

In addition to this, tests for adventitious presence and traces of GM beet seed in commercial beet seed lots are performed.

4.2. USA

There are commercial productions of GM beet seed of one deregulated event in the USA.

Quality assurance systems to prevent adventitious presence and traces of GM seed as presented in the data sheet of the Annex have been implemented by the seed industry.
These measures are focused on the separation of GM seed and conventional seed during the whole production procedure (e.g. multiplication and processing steps).

In addition to this, tests for adventitious presence of GM seed in the GM commercial seed lots were implemented (this refers to traces of another event in a GM seed production based on an intended event).

5. Principles for preventive measures and testing procedures for adventitious presence in R&D, in conventional and in GM beet seed production

This section describes main measures (preventive measures and testing procedures) to ensure a high level of purity for beet seed regarding AP[48] of GM. Three base cases cover all situations encountered either as producer of conventional seed or as producer of GM seed.

The guidelines for preventive and control measures have thus been divided into three parts:

1. R&D activities related to GM seed (all stages of the seed development up to the basic seed production) – Data sheet in Annex 1
2. Production of conventional seed for commercialization – Data sheet in Annex 2
3. Production of GM seed for commercialization – Data sheet in Annex 3

The following sections outline general preventive and control measures to ensure a high level of purity regarding AP for conventional seed and/or GM seed.

5.1 Preventive measures

[47] R&D: Research and development
[48] AP: adventitious presence

Several principles are implemented in all types of activities and operations by each company:

- A quality assurance system is implemented, whereby every GM plant material is recorded and can therefore be traced.
- SOPs[49] are written for all aspects of the handling of GM beet plants and GM beet seed and the staff is trained and briefed on their use and application.
- Conventional and GM seed are handled separately, and specific labels or the unique identifier will be used for all GM material.
- The above mentioned breeding companies have agreed in sharing information on the locations and traits of their respective GM seed production worldwide.

5.2 Testing procedures

- Testing for adventitious presence of GM in conventional seed lots and for unintended events in GM seed lots.
- Exchange information on detection methods of such traits which are shortly before production.

More detailed information can be found in the Annexes.

Annex 1
Data sheet for "R&D activities for GM and Non-GM (all stages of seed development up to the basic seed production of regulated and deregulated GM beet)".

Preventive measures

- All activities involving GM beet plants and GM beet seed are subject of national and international regulations which are adhered to by the breeding companies.
- By sharing information between breeding companies about the locations and traits of their respective GM seed production, companies will have the opportunity to redefine their location of seed production in case it is located close to a conventional seed or another GM event production area.
- Minimum of four years of rotation between GM beet seed-crop and conventional beet root-crop.
- Isolation distance of at least 1.5 miles between GM and conventional or other GM event seed production.
- Bolting plants of *Beta* species are removed within a radius of at least 1000 m around GM multiplications before flowering.
- SOPs are written for all aspects of the handling of GM beet plants and GM beet seed and the staff is trained and briefed on their use and application.
- Transport of GM seed only in closed containers or bags.
- Storage of GM seed in dedicated areas separated from conventional seed.
- Careful cleaning of all machinery is carried out before and after each step in the production process of a GM seed lot or separate production lines (different GM, Non-GM) are used in the production process.
- Monitoring for volunteer beets is done at fields or locations used for GM seed production
- Shallow post harvest tillage

[49] SOP: standard operating procedure

Testing procedures

- Seed lots are tested for the adventitious presence of GM and GM seed lots for unintended GMO before shipment to third parties, for example:
    - Testing of conventional seed lots used for variety trials.
    - Testing of GM seed lots used for variety trials.
    - Testing of conventional seed lots used in field trials by research institutes and/or industry.
    - Testing of GM seed lots used in field trials by research institutes and/or industry.

- Basic seed lots used for commercial production are tested by either PCR or immunological tests and/or herbicide application in case of herbicide tolerance traits.
- Seeds are sampled after harvesting or before pelleting according to internationally accepted sampling techniques.

Annex 2
Data sheet for "Production of conventional beet seed for commercialization"

Preventive measures

- The above mentioned breeding companies have agreed in sharing information on the locations and traits of their respective GM seed multiplications worldwide.
- In addition, as part of the information sharing, breeding companies will exchange information on detection methods of such traits which are shortly before production.
- Isolation distance of at least 1.5 miles between GM and conventional seed production.
- Bolting plants of *Beta* species are removed before flowering within a radius of 1000 m around GM multiplications.
- Minimum of four years crop rotation in seed production.
- Separation of conventional and GM seed during processing
- The order of lots processed and pelleted is thoroughly recorded.
- Careful cleaning of all machinery is carried out before and after each step in the production process or use of separate production lines (GM, Non-GM) in the production process

Testing procedures

- Conventional seed lots are tested for adventitious presence of GM seed by either PCR or immunological tests and/or herbicide application.
- Seeds are sampled after harvesting or before pelleting according to internationally accepted sampling techniques.

Annex 3
Data sheet for "Production of GM seed for commercialization"

Preventive measures

- All activities involving GM beet plants and GM beet seed are subject of national and international regulations which are adhered to by the breeding companies.
- SOPs are written for all aspects of the handling of GM beet plants and GM beet seed and the staff is trained and briefed on their use and application.
- The above mentioned breeding companies have agreed in sharing information on the locations and traits of their respective GM seed multiplications worldwide.
- In addition, as part of the information sharing, breeding companies will exchange information on the appropriate detection method for GM traits.
- A quality assurance system is implemented, whereby every GM plant material is recorded and can therefore be traced.
- Isolation distance of at least 1.5 miles between GM and conventional seed production.
- Bolting plants of *Beta* species are removed before flowering within a radius of 1000 m around GM multiplications.
- The order of lots processed and pelleted is thoroughly recorded.
- Careful cleaning of all machinery is carried out before and after each step in the production process or use of separate production lines (GM, Non-GM) in the production process

Testing procedures

- GM seed is tested by either PCR or immunological tests and/or herbicide application in case of herbicide tolerance traits.

Seeds are sampled after harvesting or before pelleting according to internationally accepted sampling techniques.

Appendix D

Sugar Beet Production by County and State

Commodity	Year	State	County	Planted All Purposes (Thousands of Acres)	Harvested (Thousands of Acres)	Yield (Tons)	Production (Thousands of Tons)	Sucrose (Percent)
Sugarbeets	2008	California	Fresno	6,000	5,200	31.7	154,000	16.26
Sugarbeets	2008	California	Kings	1,100	1,000	36.0	36,000	16.66
Sugarbeets	2008	California	D51 Combined Counties	500	500	36.0	18,000	15.82
Sugarbeets	2008	California	D51 San Joaquin Valley	7,600	7,300	32.6	238,000	16.26
Sugarbeets	2008	California	Imperial	15,500	18,100	42.5	770,000	16.65
Sugarbeets	2008	California	D60 Southern California	15,500	15,100	42.5	770,000	16.65
Sugarbeets	**2008**	**California**	**State Total**	**28,100**	**25,400**	**39.7**	**1,008,000**	**16.56**
Sugarbeets	2008	Colorado	Boulder	500	500	22.6	11,300	16.78
Sugarbeets	2008	Colorado	Larimer	2,800	2,100	24.0	50,400	16.17
Sugarbeets	2008	Colorado	Logan	4,300	3,800	24.7	93,600	15.75
Sugarbeets	2008	Colorado	Morgan	1,800	1,800	24.8	55,900	14.86
Sugarbeets	2008	Colorado	Sedgwick	1,400	1,300	27.4	35,600	16.62

*Pesticides registered by the U.S. EPA will not cause unreasonable adverse effects to man or the environment when used in accordance with label directions.

RE:NEW

YOUR ABILITY TO ENHANCE YOUR CROPS TODAY!

It's time to ReNEW your license

If you haven't renewed your Monsanto Technology/Stewardship Agreement (MTSA) in the past nine months, **take care of it today!**

Signing the MTSA ensures you'll have access to current and next-wave technologies. These innovations will enhance plant drought tolerance, cold tolerance, nitrogen use efficiency, yield and much more!

CALL

1-800-768-6387, Option 3

You'll then have the option to complete the process online or through conventional mail.

Paper MTSA's will continue to be accepted.

Introduction

This 2010 Technology Use Guide (TUG) provides a concise source of technical information about Monsanto's current portfolio of technology products and sets forth requirements and guidelines for the use of these products. As a user of Monsanto Technology, it is important that you are familiar with and follow certain management practices. Please read all of the information pertaining to the technology you will be using, including stewardship and related information. Growers must read the Insect Resistance Management (IRM)/Grower Guide prior to planting for important information on planting and IRM.

This technical guide is not a pesticide product label. It is intended to provide additional information and to highlight approved uses from the product labeling. Read and follow all precautions and use instructions in the label booklet and separately published supplemental labeling for the Roundup® agricultural herbicide product you are using.

Included in this guide is information on the following:

Stewardship Overview	4
Introducing Genuity™	6
Insect Resistance Management	8
Weed Management	10
Coexistence and Identity Preserved Production	12
Corn Technologies	15
YieldGard® and Genuity™ Corn Technologies Product Descriptions	
Roundup Ready® Technology in Corn	
Cotton Technologies	21
Genuity™ Bollgard II® and Bollgard® Cotton

Genuity™ Roundup Ready 2 Yield® and Roundup Ready Soybeans	31
Genuity™ Roundup Ready® Alfalfa	35
Genuity™ Roundup Ready® Spring Canola	38
Genuity™ Roundup Ready® Winter Canola	39
Genuity™ Roundup Ready® Sugarbeets	40

If you have any questions, contact your Authorized Retailer or Monsanto at 1-800-768-6387.

STEWARDSHIP OVERVIEW

A Message About Stewardship - SEED AND TRAITS

Monsanto Company is committed to enhancing farmer productivity and profitability through the introduction of new agricultural biotechnology traits. These new technologies bring enhanced value and benefits to farmers, and farmers assume new responsibilities for proper management of these traits. Farmers planting seed with biotech traits agree to implement good stewardship practices, including, but not limited to:

- Reading, signing and complying with the Monsanto Technology/Stewardship Agreement (MTSA) and reading all annual license terms updates before purchase or use of any seed containing a trait.
- Reading and following the directions for use on all product labels.
- Following applicable stewardship practices as outlined in this TUG.
- Reading and following the IRM/Grower Guide prior to planting.
- Observing regional planting restrictions mandated by the U.S. Environmental Protection Agency (EPA).
- Complying with any additional stewardship requirements, such as grain or feed use agreements or geographical planting restrictions, that Monsanto deems appropriate or necessary to implement for proper stewardship or regulatory compliance.
- Following the Weed Resistance Management Guidelines to minimize the risk of resistance development.
- Complying with the applicable IRM practices for specific biotech traits as *mandated* by the EPA and set forth in this TUG.
- Utilizing all seed with biotech traits only for planting a single crop.
- Selling crops or material containing biotech traits only to grain handlers that confirm their acceptance, or using those products on farm.
- Not moving material containing biotech traits across boundaries into nations where import is not permitted.
- Not selling, promoting and/or distributing within a state where the product is not yet registered.

CROP OR MATERIAL HANDLING STEWARDSHIP STATEMENT

Monsanto Company is a member of Excellence Through Stewardship® (ETS). Monsanto products are commercialized in accordance with ETS Product Launch Stewardship Guidance, and in compliance with Monsanto's Policy for Commercialization of Biotechnology-Derived Plant Products in Commodity Crops. This product has been approved for import into key export markets with functioning regulatory systems. Any crop or material produced from this product can only be exported to, or used, processed or sold in countries where all necessary regulatory approvals have been granted. It is a violation of national and international law to move material containing biotech traits across boundaries into nations where import is not permitted. Growers should talk to their grain handler or product purchaser to confirm their buying position for this product. Excellence Through Stewardship® is a registered trademark of Biotechnology Industry Organization.

WHY IS STEWARDSHIP IMPORTANT?

Each component of stewardship offers benefits to farmers:

- Signing the MTSA provides farmers access to Monsanto's biotech trait seed technology.
- Following IRM guidelines guards against insect resistance to *Bacillus thuringiensis (B.t.)* technology and therefore enables the long-term viability of this technology, and meets EPA requirements.
- Proper weed management maintains the long-term effectiveness of glyphosate-based weed control solutions.
- Utilizing biotech seed only for planting a single-commercial crop helps preserve the effectiveness of biotech traits, while allowing investment for future biotech innovations which further improves farming technology and productivity.

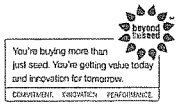
Practicing these stewardship activities will enable biotechnology's positive agricultural contributions to continue.

Farmers' attitudes and adoption of sound stewardship principles, coupled with biotechnology benefits, provide for the sustainability of our land resources, biotechnology and farming as a preferred way of life.

SEED PATENT INFRINGEMENT

If Monsanto reasonably believes that a farmer has planted saved seed containing a Monsanto biotech trait, Monsanto will request invoices and records to confirm that fields in question have been planted with newly purchased seed. If this information is not provided within 30 days, Monsanto may inspect and test all of the farmer's fields to determine if saved seed has been planted. Any inspections will be coordinated with the farmer and performed at a reasonable time to best accommodate the farmer's schedule.

If you have questions about seed stewardship or become aware of individuals utilizing biotech traits in a manner other than as noted above, please call 1-800-768-6387. Letters reporting unacceptable or unauthorized use of biotech traits may be sent to:



Monsanto Trait Stewardship
800 N. Lindbergh Boulevard NC3C
St. Louis, MO 63167

For more information on Monsanto's practices related to seed patent infringement, please visit: www.monsanto.com/seedpatentprotection.

Provide Anonymous or Confidential reports as follows:

"Anonymous" reporting results when a person reports information to Monsanto in such a way that the identity of the person reporting the information cannot be identified. This kind of reporting includes telephone calls requesting anonymity and unsigned letters.

"Confidential" reporting results when a person reports information to Monsanto in such a way that the reporting person's identity is known to Monsanto. Every effort will be made to protect a person's identity, but it is important to understand that a court may order Monsanto to reveal the identity of people who are "known" to have supplied relevant information.

The Beyond the Seed Program was launched by the American Seed Trade Association (ASTA) to raise awareness and understanding of the value that goes beyond the seed. The future success of U.S. agriculture depends upon quality seed delivered by an industry commitment to bring innovation and performance through continued investment. For more information about seed technology, visit ASTA's Beyond the Seed Program at www.beyondtheseed.org.

INTRODUCING GENUITY™

Genuity™ Unites the Best Traits*

As a purchaser of Monsanto biotech trait products, your investment helps fuel the research and development engine that leads to the discovery and delivery of new technologies for agriculture. Current and future Genuity™ traits are designed to deliver high yield potential, maximize return on seed investments and consistently deliver future trait innovations.

CORN

Higher yields come from quality grain. Genuity™ VT Triple PRO™ was the next generation of corn technology available for the 2009 growing season. Genuity™ VT Triple PRO™ provides dual modes of action against above-ground pests such as corn earworm, European and southwestern corn borers, sugarcane borer, southern cornstalk borer and fall armyworm. Reduced kernel damage from corn earworm means the potential for reduced Aflatoxin contamination. Genuity™ VT Triple PRO™ dual modes-of-action also allows for a reduction in refuge acres required in southern cotton-growing regions while providing long-term effectiveness and consistency.

GENUITY™ SMARTSTAX™

Scheduled for launch in 2010, Genuity™ SmartStax™ is the most-advanced, all-in-one corn trait system that controls the broadest spectrum of above- and below-ground insects and weeds. Genuity™ SmartStax™ provides control of corn earworm, European corn borer, southwestern corn borer, sugarcane borer, fall armyworm, western bean cutworm, black cutworm, western corn rootworm, northern corn rootworm and Mexican corn rootworm. Genuity™ SmartStax™ contains Roundup Ready® 2 Technology and LibertyLink® herbicide tolerance. Genuity™ SmartStax™ also allows for a reduction in refuge acres in the corn belt from 20% down to 5% for above- and below-ground refuge. Genuity™ SmartStax™ is also approved for a 20% refuge in the cotton belt.

SOYBEAN

Genuity™ Roundup Ready 2 Yield® soybeans are taking yield to a higher level. They were developed to provide farmers with the same simple, dependable and flexible weed control and crop safety they've come to rely on with the first-generation Roundup Ready® soybean system, but with higher yield potential. This is possible because of advanced insertion and selection technologies.

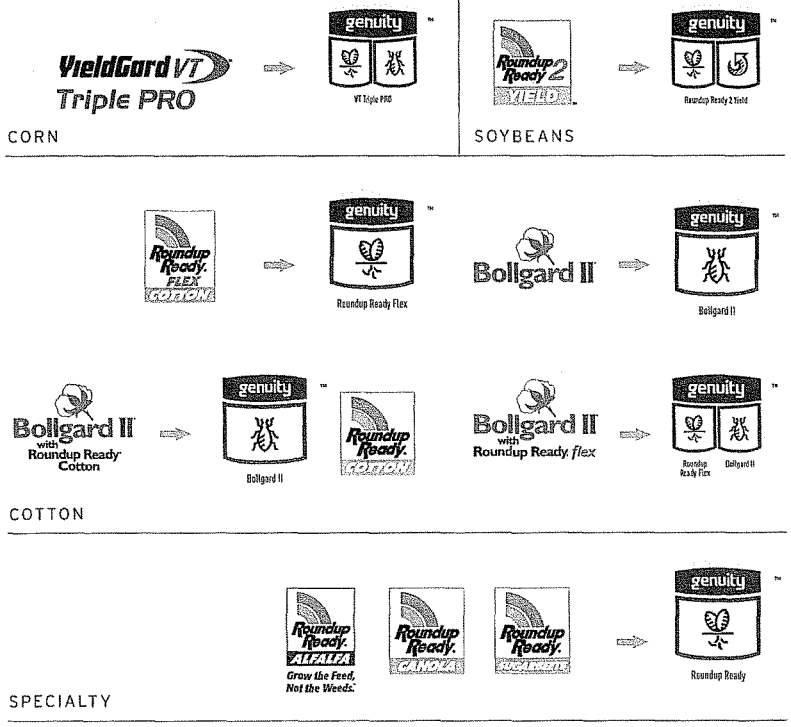
COTTON

Genuity™ Roundup Ready® Flex and Genuity™ Bollgard II® offer the ultimate combination of peace of mind and flexibility. They contain unrivaled built-in worm control to stop the most leaf- and boll-feeding worm species, including bollworms, budworms, armyworms, loopers, saltmarsh caterpillars and cotton leaf perforators. Protecting just one additional boll per plant can result in significantly higher lint yield. The convenience and savings from fewer or no sprays for worms can make a big difference when it comes to the bottom line.

SPECIALTY

Genuity™ Roundup Ready® alfalfa: Bred from an innovative germplasm pool, it offers outstanding weed control, excellent crop safety and preservation of forage quality potential.

Genuity™ Roundup Ready® canola: Offers excellent control of broadleaf weeds and grasses, even in tough weather conditions. Also features excellent crop safety and broad application flexibility.



Genuity™ Roundup Ready® sugarbeets: Excellent in-plant tolerance to over-the-top applications of labeled Roundup agricultural herbicides. Offers outstanding weed control, excellent crop safety and preservation of yield potential.

*See pages 16 and 17 for additional traits.

NOTE: Farmers must read the IRM/Grower Guide prior to planting for information on planting and Insect Resistance Management.

Monsanto's New Generation of Technologies

As Monsanto continues to develop new generations of technologies, several of our newer technologies are migrating to the Genuity™ brand. These products and their new logos are presented below.

INSECT RESISTANCE MANAGEMENT (IRM)

An **EFFECTIVE** IRM program is a vital part of responsible product stewardship for insect-protected biotech products. Monsanto is committed to implementing an effective IRM program for all of its insect-protected *B.t.* technologies in all countries where they are commercialized, including promoting farmer awareness of these IRM programs. Monsanto works to develop and implement IRM programs that strike a balance between available knowledge and practicality, with farmer acceptance and implementation of the plan as critical components.

The U.S. EPA requires that Monsanto implement, and farmers who purchase insect-protected products follow, an IRM plan.* IRM programs for *B.t.* traits are based upon an assessment of the biology of the major target pests, farmer needs and practices, and appropriate pest management practices. These **mandatory regulatory programs** have been developed and updated through broad cooperation with farmer and consultant organizations, including the National Corn Growers Association and the National Cotton Council, extension specialists, academic scientists, and regulatory agencies.

*In some areas, a natural refuge option is available for Bollgard II. See the current IRM/Grower Guide for details.

The IRM programs for planting seeds containing *B.t.* traits contain several important elements. One key component of an IRM plan is a refuge. A refuge is simply a portion of the relevant crop (corn or cotton) that does not contain a *B.t.* technology for the control of the insect pests which are controlled by the planted technology(ies). The lack of exposure to the *B.t.* proteins means that there will be susceptible insects nearby to mate with any rare resistant insects that may emerge from *B.t.* products. Susceptibility to *B.t.* products is then passed on to offspring, preserving the long-term effectiveness of the technology.

Farmers who purchase seeds containing *B.t.* traits must plant an appropriately designed refuge. Refuge size, configuration, and management is described in detail in the sections on those products in the 2010 IRM/Grower Guide.

Failure to follow IRM requirements and to plant a proper refuge may result in the loss of a farmer's access to Monsanto technologies. Monsanto is committed to the preservation of *B.t.* technologies. Please do your part to preserve *B.t.* technologies by implementing the correct IRM plan on your farm.

MONITORING PROGRAM

The U.S. EPA requires Monsanto to take corrective measures in response to a finding of IRM non-compliance. Monsanto or an approved agent of Monsanto must monitor refuge management practices. The MTSA signed by a farmer requires that upon request by Monsanto or its approved agent, a farmer must provide the location of all fields planted with Monsanto technologies and the locations of all associated refuge areas as required, to cooperate fully with any field inspections, and allow Monsanto to inspect all fields and refuge areas to ensure an approved insect resistance program has been followed. All inspections will be performed at a reasonable time and arranged in advance with the farmer so that the farmer can be present if desired.

IRM GUIDELINES

Farmers must read the current IRM/Grower Guide prior to planting for information on planting and IRM. If you do not have a copy of the current IRM/Grower Guide, you may downloaded it at **www.monsanto.com**, or you may call 1-800-768-6387 to request a copy by mail.

WEED MANAGEMENT

Monsanto considers product stewardship to be a fundamental component of customer service and responsible business practices. As leaders in the development and stewardship of Roundup® agricultural herbicides and other products, Monsanto invests significantly in research to continuously improve the proper uses and stewardship of our proprietary herbicide brands.

This research, done in conjunction with academic scientists, extension specialists and crop consultants, includes an evaluation of the factors that can contribute to the development of weed resistance and how to properly manage weeds to delay the selection for weed resistance. Visit **www.weedtool.com** for practical, best practices-based information on reducing the risk for development of glyphosate-resistant weeds. Developed in cooperation with academic experts, the website provides options for managing the risk on a field-by-field basis.

Glyphosate is a Group 9 herbicide based on the mode of action classification system of the Weed Science Society of America. Any weed population may contain plants naturally resistant to Group 9 herbicides. The following general recommendations help manage the risk of weed resistance occurring.

WEED RESISTANCE MANAGEMENT PRACTICES:

- Scout your fields before and after herbicide application
- Start with a clean field, using either a burndown herbicide application or tillage
- Control weeds early when they are small
- Add other herbicides (e.g. a selective in-crop and/or a residual herbicide) and cultural practices (e.g. tillage or crop rotation) as part of your Roundup Ready® cropping system where appropriate
- Rotation to other Roundup Ready crops will add opportunities for introduction of other modes of action
- Use the right herbicide product at the right rate and the right time
- Control weed escapes and prevent weeds from setting seeds
- Clean equipment before moving from field to field to minimize spread of weed seed
- Use new commercial seed that is as free from weed seed as possible

Monsanto is committed to the proper use and long-term effectiveness of its proprietary herbicide brands through a four-part stewardship program: developing appropriate weed control recommendations, continuing research to refine and update recommendations, education on the importance of good weed management practices and responding to repeated weed control inquiries through a product performance evaluation program.

GLYPHOSATE-RESISTANT WEEDS

Monsanto actively investigates and studies weed control complaints and claims of weed resistance. When glyphosate-resistant weed biotypes have been confirmed, Monsanto alerts farmers and develops and provides farmers with recommended control measures, which may include additional herbicides, tank-mixes or cultural practices. Monsanto actively communicates all of this information to farmers through multiple channels, including the herbicide label, **www.weedscience.org**, supplemental labeling, this TUG, media and written communications, Monsanto's website, **www.weedresistancemanagement.com**, and farmer meetings.

Farmers must be aware of, and proactively manage for, glyphosate-resistant weeds in planning their weed control program. When a weed is known to be resistant to glyphosate, then a resistant population of that weed is by definition no longer controlled with labeled rates of glyphosate. Roundup® agricultural herbicide warranties will not cover the failure to control glyphosate-resistant weed populations.

Report any incidence of repeated non-performance on a particular weed to your local Monsanto representative, retailer or county extension agent.

Note: Always read and follow all pesticide label requirements.

ROUNDUP BRAND AGRICULTURAL OVER-THE-TOP HERBICIDE PRODUCTS

Read and follow all product labeling before using Roundup agricultural herbicides over the top of products with Roundup Ready Technology.

You may use another glyphosate herbicide, but only if it has federally approved label instructions for use over that specific Roundup Ready crop, and the product and the use label for that Roundup Ready crop has been approved by your specific state. Contact the product manufacturers, the local retailers or the local extension agents for confirmation that the products carry EPA and state approved labeling for this use. **MONSANTO DOES NOT MAKE ANY REPRESENTATIONS, WARRANTIES OR RECOMMENDATIONS CONCERNING THE USE OF GLYPHOSATE PRODUCTS SUPPLIED BY OTHER COMPANIES WHICH ARE LABELED FOR USE OVER ROUNDUP READY CROPS. MONSANTO SPECIFICALLY DENIES ALL RESPONSIBILITY AND DISCLAIMS ANY LIABILITY FOR ANY DAMAGE FROM THE USE OF THESE PRODUCTS IN ROUNDUP READY CROPS. ALL QUESTIONS AND COMPLAINTS CAUSED BY THE USE OF GLYPHOSATE PRODUCTS SUPPLIED BY OTHER COMPANIES SHOULD BE DIRECTED TO THE SUPPLIER OF THE PRODUCT IN QUESTION.**

MONSANTO BRANDS OF SELECTIVE OVER-THE-TOP HERBICIDE PRODUCTS

Herbicide products sold by Monsanto for use over the top of Roundup Ready crops for the 2010 crop season are as follows:

Roundup WeatherMAX®

Roundup PowerMAX®

Read and follow all product labeling before using Roundup agricultural herbicides over the top of Roundup Ready traits. To learn more about applicable supplemental labels or fact sheets, call 1-800-768-6387.

Tank-mixtures of Roundup agricultural herbicides with insecticides, fungicides, micronutrients or foliar fertilizers are not recommended as they may result in reduced weed control, crop injury, reduced pest control or antagonism. Refer to the Roundup agricultural herbicide product label, supplemental labeling or fact sheets published separately by Monsanto for tank-mix recommendations.

Do not add additional surfactants and/or products containing surfactants to these Roundup agricultural herbicides unless otherwise directed by the label. Other glyphosate products labeled for use in Roundup Ready technologies may require the addition of surfactants, or other additives to optimize performance, that may increase the potential for crop injury. Monsanto will label and promote only fully tested brands that do not require surfactants and other additives for over-the-top applications to Roundup Ready Crops.

GLYPHOSATE ENDANGERED SPECIES INITIATIVE

Before making applications of glyphosate-based herbicide products, licensed farmers of crops containing Roundup Ready technology must access the website **www.pre-serve.org** to determine whether any mitigation requirements apply to the planned application to those crops, and must follow all applicable requirements. The mitigation measures described on the website are appropriate for all applications of glyphosate-based herbicides to all crop lands.

Farmers making only ground applications to crop land with a use rate of less than 3.5 lbs of glyphosate a.e./A are not required to access the website. If a farmer does not have web access, the seed dealer can access the website on behalf of the farmer to determine the applicable requirements, or the farmer can call 1-800-332-3111 for assistance.

RECOMMENDATIONS FOR MANAGING GLYPHOSATE-RESISTANT WEEDS IN ROUNDUP READY CROPS

In certain areas, populations of ryegrass, johnsongrass, marestail, common ragweed, giant ragweed, *Palmer Amaranth* and waterhemp are known to be resistant to glyphosate. For control recommendations for resistant biotypes of these weeds, refer to www.weedresistancemanagement.com or call 1-800-768-6387. When approved, supplemental labeling for specific herbicide products can also be viewed on www.cdms.net or www.greenbook.net or obtained by calling 1-800-768-6387.

COEXISTENCE AND IDENTITY PRESERVED PRODUCTION

Coexistence in agricultural production systems and supply chains is not new. Different agricultural systems have coexisted successfully for many years around the world. Standards and best practices were established decades ago and have continually evolved to deliver high purity seed and grain to support production, distribution and trade of products from different agricultural systems. For example, production of similar commodities such as field corn, sweet corn and popcorn has occurred successfully and in close proximity for many years. Another example is the successful coexistence of oilseed rape varieties with low erucic acid content for food use and high erucic acid content for industrial uses.

The introduction of biotech crops generated renewed discussion of coexistence focused on biotech production systems with conventional cropping systems and organic production. These discussions have primarily focused on the potential economic impact of the introduction of biotech products on other systems. The health and safety of biotech products are not an issue because their food, feed and environmental safety must be demonstrated before they enter the agricultural production system and supply chain.

The coexistence of conventional, organic and biotech crops has been the subject of several studies and reports. These reports conclude that coexistence among biotech and non-biotech crops is not only possible but is occurring. They recommend that coexistence strategies be developed on a case-by-case basis considering the diversity of products currently in the market and under development, the agronomic and biological differences in the crops themselves and variations in regional farming practices and infrastructures. Furthermore, coexistence strategies are driven by market needs and should be developed using current science-based industry standards and management practices. The strategies must be flexible, facilitating options and choice for the farmer and the food/feed supply chain, and must be capable of being modified as changes in markets and products warrant.

Successful coexistence of all agricultural systems is achievable and depends on cooperation, flexibility and mutual respect for each system. Agriculture has a history of innovation and change, and farmers have always adapted to new approaches or challenges by utilizing appropriate strategies, farm management practices and new technologies.

The responsibility for implementing practices to satisfy specific marketing standards or certification lies with that farmer who is growing a crop to satisfy a particular market. Only that farmer is instructed to employ the practices appropriate to assure the integrity of his/her crop. This is true whether the goal is high-oil corn, white/sweet corn or organically produced yellow corn for animal feed. In each case, the farmer is seeking to produce a crop that is supported by a market price and consequently that farmer assumes responsibility for satisfying reasonable market specifications. That said, the farmer needs to be aware of the planting intentions of his/her neighbor in order to gauge the need for management practices.

IDENTITY PRESERVED PRODUCTION

Some farmers may choose to preserve the identity of their crops to meet specific markets. Examples of Identity Preserved (I.P.) corn crops include production of seed corn, white, waxy or sweet corn, specialty oil or protein crops, food grade crops and any other crop that meets specialty needs, including organic and non-genetically enhanced specifications. Farmers of these crops assume the responsibility and receive the benefit for ensuring that their crop meets mutually agreed contract specifications.

Based on historical experience with a broad range of I.P. crops, the industry has developed generally accepted I.P. agricultural practices. These practices are intended to manage I.P. production to meet quality specifications, and are established for a broad range of I.P. needs. The accepted practice with I.P. crops is that each I.P. farmer has the responsibility to implement any necessary processes. These processes may include sourcing seed appropriate for I.P. specifications, field management practices such as adequate isolation distances, buffers between crops, border rows, planned differences in maturity between adjacent fields that might cross-pollinate and harvest and handling practices designed to prevent mixing and to maintain product quality. These extra steps associated with I.P. crop production are generally accompanied by incremental increases in cost of production and consequently of the goods sold.

General Instructions for Management of Pollen Flow and Mechanical Mixing

For all crop hybrids or varieties that they wish to identity preserve, or otherwise keep separated, farmers should take steps to prevent mechanical mixing. Farmers should make sure all seed storage areas, transportation vehicles and planter boxes are cleaned thoroughly both prior to and subsequent to the storage, transportation or planting of the crop. Farmers should also make sure all combines, harvesters and transportation vehicles used at harvest are cleaned thoroughly both prior to and subsequent to their use in connection with the harvest of the grain produced from the crop. Farmers should also make sure all harvested grain is stored in clean storage areas where the identity of the grain can be preserved.

Self-pollinated crops, such as soybeans, do not present a risk of mixing by cross-pollination. If the intent is to use or market the product of a self-pollinated crop separately from general commodity use, farmers should plant fields a sufficient distance away from other crops to prevent mechanical mixture.

Farmers planting cross-pollinated crops, such as corn or alfalfa, who desire to preserve the identity of these crops, or to minimize the potential for these crops to outcross with adjacent fields of the same crop kind, should use the same generally accepted practices to manage mixing that are used in any of the currently grown I.P. crops of similar crop kind.

It is generally recognized in the industry that a certain amount of incidental, trace level pollen movement occurs, and it is not possible to achieve 100% purity of seed or grain in any corn production system. A number of factors can influence the occurrence and extent of pollen movement. As stewards of technology, farmers are expected to consider these factors and talk with their neighbors about their cropping intentions.

Farmers should take into account the following factors that can affect the occurrence and extent of cross-pollination to or from other fields. Information that is more specific to the crop and region may be available from state extension offices.

- Cross-pollination is limited. Some plants, such as potatoes, are incapable of cross-pollinating, while others, like alfalfa, require cross-pollination to produce seed. Importantly, cross-pollination only occurs within the same crop kind, like corn to corn.
- The amount of pollen produced within the field can vary. The pollen produced by the crop within a given field, known as pollen load, is typically high enough to pollinate all of the plants in the field. Therefore, most of the pollen that may enter from other fields falls on plants that have already been pollinated with pollen that originated from plants within the field. In crops such as alfalfa, the hay cutting management schedule significantly limits or eliminates bloom, and thereby restricts the potential for pollen and/or viable seed formation.
- The existence and/or degree of overlap in the pollination period of crops in adjacent fields varies. This will vary depending on the maturity of crops, planting dates and the weather. For corn, the typical pollen shed period lasts from 5 to 10 days for a particular field. Therefore, viable pollen from neighboring fields must be present when silks are receptive in the recipient field during this brief period to produce any grain with traits introduced by the out-of-field pollen.
- Distance between fields of different varieties or hybrids of the same crop: The greater the distance between fields the less likely their pollen will remain viable and have an opportunity to mix and produce an outcross. For wind-pollinated crops, most cross-pollination occurs within the outermost few rows of the field. In fact, many white and waxy corn production contracts ask the farmer to remove the outer 12 rows (30 ft.) of the field in order to remove most of the impurities that could result from cross-pollination with nearby yellow dent corn. Furthermore, research has also shown that as fields become further separated, the incidence of wind-modulated cross-pollination drops rapidly. Essentially, the in-field pollen has an advantage over the pollen coming from other fields for receptive silks because of its volume and proximity to silks.
- The distance pollen moves. How far pollen can travel depends on many environmental factors, including weather during pollination, especially wind direction and velocity, temperature and humidity. For bee-pollinated crops, the farmer's choice of pollinator species and aplary management practice may reduce field-to-field pollination potential. All these factors will vary from season to season, and some factors from day to day and from location to location.
- For wind-pollinated crops, the orientation and width of the adjacent field in relation to the dominant wind direction. Fields oriented upwind during pollination will show dramatically lower cross-pollination for wind-pollinated crops, like corn, compared to fields located downwind.

CORN TECHNOLOGIES

Advanced breeding and biotechnology have had a major impact on farming production. From 1971 to 1995, average corn yields were increasing at a rate of 1.5 bushels per acre, per year. Since the advent of biotech in 1996, corn yields have increased at a rate of 2.6 bushels per acre, per year, for a total increase of 32 bushels per acre.*

Excellence Through Stewardship

Monsanto Company is a member of Excellence Through Stewardship® (ETS). Monsanto products are commercialized in accordance with ETS Product Launch Stewardship Guidance, and in compliance with Monsanto's Policy for Commercialization of Biotechnology-Derived Plant Products in Commodity Crops. This product has been approved for import into key export markets with functioning regulatory systems. Any crop or material produced from this product can only be exported to, or used, processed or sold in countries where all necessary regulatory approvals have been granted. It is a violation of national and international law to move material containing biotech traits across boundaries into nations where import is not permitted. Growers should talk to their grain handler or product purchaser to confirm their buying position for this product. Excellence Through Stewardship® is a registered trademark of Biotechnology Industry Organization.

IRM GUIDELINES

For specific refuge requirements for *B.t.* corn and cotton, see the current IRM/Grower Guide, sent with this TUG. If you have not received a copy of this Guide, it can be downloaded at www.monsanto.com, or call 1-800-768-6387 to request a copy be mailed to you.

Before opening a bag of seed, be sure to read and understand the stewardship requirements, **including applicable refuge requirements for insect resistance management,** for the biotechnology traits expressed in the seed as set forth in the Monsanto Technology Agreement that you sign. By opening and using a bag of seed, you are reaffirming your obligation to comply with those stewardship requirements.

* USDA Yields were calculated using 3 year rolling averages (32 Yield is 2.6 bu/ac *12 years). 2008 Yield is from Doane Ag Services forecast in April 8, 2008 Quarterly Crop Outlook.

Genuity™ Trait Products and YieldGard® Corn Technologies Product Descriptions

GENUITY™ SMARTSTAX™

Scheduled to launch in 2010, Genuity™ SmartStax™ is the most advanced, all-in-one corn trait system that controls the broadest spectrum of above- and below-ground insects and weeds. Genuity™ SmartStax™ hybrids will contain *B.t.* proteins that represent three separate modes of action for control of lepidopteron, above-ground insect pests, as well as combined modes of action for control of coleopteran, below-ground insect pests. Providing multiple *B.t.* proteins for control will dramatically decrease the probability that insects will become resistant to the traits, resulting in enhanced durability of transgenic insect control via *B.t.* genes. Based on this multiple gene approach, Genuity™ SmartStax™ is approved for reduced refuge in the corn belt from 20% down to 5% for both above- and below-ground pests. The cotton belt refuge for Genuity SmartStax™ is also reduced, from 50% down to 20%.

GENUITY™ VT TRIPLE PRO™

(Formerly YieldGard VT Triple PRO™) — Genuity™ VT Triple PRO™ is available in selected southern corn- and cotton-growing areas. It includes broad-spectrum insect control against corn earworm, European and southwestern corn borers, sugarcane borer, southern cornstalk borer, fall armyworm, western corn rootworm, northern corn rootworm and Mexican corn rootworm. Its advanced control of ear pests can result in higher grain quality and higher-yielding crop potential. The dual mode-of-action of Genuity™ VT Triple PRO™ allows for lower corn borer refuge acres in southern cotton-growing areas compared to other registered *B.t.*-traited products. It includes the same Roundup Ready® 2 Technology as Monsanto's previous product, YieldGard VT Triple. Seed containing Genuity™ VT Triple PRO™ technology is treated with seed-applied insecticide.*

YIELDGARD VT TRIPLE®

YieldGard VT Triple technology combines YieldGard Corn Borer and YieldGard VT Rootworm/RR2® technology into a single plant. YieldGard VT Triple corn hybrids control European and southwestern corn borer, sugarcane borer, southern cornstalk borer, western corn rootworm, northern corn rootworm and Mexican corn rootworm. YieldGard VT Triple technology suppresses corn earworm, fall armyworm and stalk borer. By providing in-plant protection against the above insect pests, the genetic yield potential of YieldGard VT Triple corn hybrids is preserved. YieldGard VT Triple corn hybrids also include Roundup Ready 2 Technology. This trait allows a farmer to experience the benefits of utilizing Roundup agricultural herbicides in a weed control system that provides the broadest weed control spectrum available, better application flexibility, and superior crop safety. Seed containing YieldGard VT Triple technology is treated with seed-applied insecticide.*

GENUITY™ VT DOUBLE PRO™

Genuity™ VT Double PRO™ is a new corn technology scheduled for launch in 2010. It includes broad-spectrum insect control against corn earworm, European and southwestern corn borers, sugarcane borer, southern cornstalk borer and fall armyworm. The dual mode-of-action of Genuity™ VT Double PRO™ allows for lower corn borer refuge acres compared to other registered *B.t.*-traited products. Seed containing Genuity™ VT Double PRO™ technology is treated with seed-applied insecticide.*

*A seed-applied insecticide can protect seed, roots and seedlings from insects such as black cutworm, wireworm, white grubs, seed corn maggots, chinch bug and early flea beetles.

YieldGard VT Rootworm/RR2

YIELDGARD VT ROOTWORM/RR2®

YieldGard VT Rootworm/RR2 technology is the current YieldGard stacked-trait product for control of western corn rootworm, northern corn rootworm and Mexican corn rootworm. Protecting the root of the corn plant from feeding by corn rootworm larvae decreases lodging and protects the genetic yield potential of YieldGard VT Rootworm/RR2 corn hybrids. The Roundup Ready 2 Technology allows a farmer to experience the benefits of utilizing Roundup agricultural herbicides in a weed control system that provides the broadest weed control spectrum, better application flexibility and superior crop safety. Seed containing YieldGard VT Rootworm/RR2 technology is treated with seed-applied insecticide.*

YIELDGARD® CORN BORER

YieldGard Corn Borer corn hybrids contain an insecticidal protein from *B.t.* that protects corn plants from European corn borer, southwestern corn borer, sugarcane borer and southern cornstalk borer resulting in full yield potential.

YIELDGARD® CORN BORER WITH ROUNDUP READY® CORN 2

YieldGard Corn Borer with Roundup Ready Corn 2 offers farmers all the benefits of both traits combined in one crop. These hybrids exhibit the same insect protection qualities as YieldGard Corn Borer and, like Roundup Ready Corn 2, are tolerant to over-the-top applications of Roundup® agricultural herbicides.

YIELDGARD PLUS

YieldGard Plus corn technology combines YieldGard Corn Borer and YieldGard Rootworm technology into a single plan.

YIELDGARD PLUS WITH ROUNDUP READY CORN 2

YieldGard Plus with Roundup Ready Corn 2 offers farmers all the benefits of all three traits combined in one crop. These hybrids exhibit the same insect protection qualities of YieldGard Corn Borer and YieldGard Rootworm and, like Roundup Ready Corn 2, are tolerant to over-the-top applications of Roundup® agricultural herbicides. Seed containing YieldGard Plus technology is treated with seed-applied insecticide.*

YIELDGARD ROOTWORM

YieldGard Rootworm corn hybrids contain an insecticidal protein from *B.t.* that protects corn roots from larval feeding by western, northern and Mexican corn rootworm.

YIELDGARD ROOTWORM WITH ROUNDUP READY CORN 2

YieldGard Rootworm with Roundup Ready Corn 2 offers farmers all the same insect protection qualities as YieldGard Rootworm and, like Roundup Ready Corn 2, is tolerant to over-the-top applications of Roundup agricultural herbicides.

*A seed-applied insecticide can protect seed, roots and seedlings from insects such as black cutworm, wireworm, white grubs, seed corn maggots, chinch bug and early flea beetles.

ROUNDUP READY® Technology in Corn

WEED CONTROL RECOMMENDATIONS

Roundup Ready® Corn 2 (RR2) and corn with Roundup Ready® 2 Technology are equivalent in their tolerance to Roundup agricultural herbicides. Products with Roundup Ready Technology contain in-plant tolerance to Roundup agricultural herbicides.

The Roundup Ready® Technology system's flexibility, broad-spectrum weed control and proven crop safety offer farmers weed control programs that allow them to use the system in the way that provides the greatest benefit. Farmers can select the program that best fits the way they farm. Options include the use of a residual herbicide with a Roundup® agricultural herbicide, tank-mixing other herbicides with Roundup agricultural herbicides where appropriate and a total postemergence program.

AGRONOMIC PRINCIPLES

Corn yield is very sensitive to early-season weed competition. Weed control systems must provide farmers the opportunity to control weeds before they become competitive. The Roundup Ready Technology system provides a mechanism to control weeds at planting and once they emerge. Farmers are provided excellent crop safety and full yield potential, with applications made from planting through 48" of corn height. Drop nozzles must be used between 30" and 48" of corn height. Failure to control weeds with the right rate, at the right time and with the right product, can lead to increased weed competition, weed escapes and the potential for decreased yields. Use other approved herbicide products with Roundup agricultural herbicides if appropriate for the weed spectrum.

PROGRAM	INSTRUCTIONS AND USE RATES*	ADDITIONAL INFORMATION
For use where residual herbicides are typically used for early-season weed control: **Residual Herbicide Plus Roundup WeatherMAX®**	Use the proper Roundup Ready RATE™ of Bullet®, Degree®, Degree Xtra®, Harness®, Harness Xtra, Harness Xtra 5.6L, Micro-Tech™, or Lariat® (no post) as defined in the table below and the individual product labels, either pre or postemergence to the crop.** Follow with Roundup WeatherMAX at 16 to 22 oz/A post sequentially after preemergence application or tank-mixed in-crop with the residual. Applications should be made before weeds exceed 4" in height. **Roundup Ready RATEs***** Harness 1.5 Pints Degree 3.0 Pints Harness Xtra 1.2 Quarts Harness Xtra 5.6L 1.5 Quarts Degree Xtra 2.0 Quarts Micro-Tech 2.0 Quarts Lariat 2.0 Quarts Bullet 2.0 Quarts	Use full labeled rate of residual when application is 14 days or more prior to planting or when tough grasses are present, e.g., barnyardgrass, shattercane, seedling johnsongrass, sandbur. Use a minimum of 2.5 pt/A of Harness on woolly cupgrass and wild proso millet. Products containing atrazine will provide improved control of cocklebur, giant ragweed, *Palmer Amaranth* and morningglory. Tank-mix products such as 2,4-D, dicamba or Status® herbicide with Roundup WeatherMAX for control of glyphosate-resistant marestail (horseweed), *Palmer Amaranth* and other difficult-to-control weeds. Use 22 to 32 oz/A of Roundup WeatherMAX* when morningglory or perennial weeds are present or when broadleaf weeds are 4" in height or taller.
For use where total postemergence programs are effective and sustainable: **Roundup WeatherMAX Sequential**	Apply Roundup WeatherMAX at 16 to 22 oz/A before weeds exceed 4" in height and follow with a second application at 16 to 22 oz/A for an additional flush of weeds before they exceed 4" in height.	Use 22 to 32 oz/A of Roundup WeatherMAX when morningglory or perennial weeds are present. Tank-mix products such as 2,4-D, dicamba or Status herbicide with Roundup WeatherMAX for control of glyphosate-resistant marestail (horseweed), *Palmer Amaranth* and other difficult-to-control weeds.
Maximum Use Rates For Roundup WeatherMAX	**Products with Roundup Ready 2 Technology In-crop:** • 32 oz/A per single application • Total: 64 oz/A from emergence through 48" height of corn, drop nozzles must be used from 30" to 48" corn.	**Products with Roundup Ready 2 Technology Total Season:** The combined total of preplant, in-crop and preharvest applications of Roundup WeatherMAX can not exceed 5.3 qt/A. The combined total of in-crop and preharvest applications can not exceed 66 oz/A.

*If using another Roundup agricultural herbicide, you must refer to the label booklet or Roundup Ready Corn 2 Technology supplemental label for that brand to determine appropriate use rates. If using Roundup PowerMAX®, application rates are the same as for Roundup WeatherMAX. If using another residual herbicide, follow the labeled use rate instructions applicable to Roundup Ready Corn 2. Follow all pesticide label requirements.

**Atrazine may also be used as a residual herbicide in the Roundup Ready Corn 2 System.

***You may apply up to the full residual herbicide labeled rate for corn.

WEED RESISTANCE MANAGEMENT FOR CORN WITH ROUNDUP READY TECHNOLOGY

Follow all pesticide label requirements and the guidelines below to minimize the risk of developing glyphosate-resistant weed populations in a Roundup Ready Technology system.

- Start clean with a burndown herbicide or tillage. Early-season weed control is critical to yield.
- Apply pre-emergence residual herbicides such as Harness Xtra, Degree Xtra or other residual herbicides at the recommended rate.
- Or apply a pre-emergence residual herbicide at the recommended rate tank-mixed with Roundup WeatherMAX® at a minimum of 22 oz/A in-crop before weeds exceed 4" in height.
- Follow with a postemergence in-crop application of Roundup WeatherMAX at a minimum of 22 oz/A for additional weed flushes before they exceed 4" in height.
- Roundup WeatherMAX may be tank-mixed with other herbicides for postemergence weed control.
- Report repeated non-performance to Monsanto or your local retailer.

RECOMMENDATIONS FOR MANAGING GLYPHOSATE-RESISTANT WEEDS IN PRODUCTS WITH ROUNDUP READY TECHNOLOGY

WEEDS	INSTRUCTIONS AND USE RATES*
Glyphosate-Resistant Marestail (Horseweed)	Start clean with a burndown program or tillage. -Tank-mix Roundup agricultural herbicides with 2,4-D, or dicamba, according to the label directions. In-crop, tank-mix 22 ounces per acre of Roundup WeatherMAX with Clarity® (8 to 16 fluid ounces per acre) or 2,4-D (0.5 to 1.0 lb active ingredient per acre) from corn emergence to the 5-leaf stage of corn growth (approximately 8" tall). Or tank-mix 22 ounces per acre of Roundup WeatherMAX with 5 ounces per acre of Status® herbicide when the corn is 4" to 36" tall (V2 to V10). Marestail should not exceed 6" in height at the time of in-crop application.
Glyphosate-Resistant *Amaranthus* Species - *Palmer Amaranth* - Waterhemp	Start clean with a burndown program or tillage. Use a residual herbicide such as Harness Xtra, Harness Xtra 5.6L, Degree Xtra or other residual herbicide either preemergence or in-crop for control of *Amaranthus* species. In-crop, tank-mix Roundup WeatherMAX with other herbicides such as 2,4-D, dicamba (Clarity or Banvel®) or Status herbicide to control emerged weeds. Applications of Status herbicide should be made when the corn is between 4" and 36" tall (V2 to V10). Follow all label directions. *Amaranthus* species should not exceed 3" in height at the time of in-crop application.
Glyphosate-Resistant *Ambrosia* Species - Giant Ragweed - Common Ragweed	Start clean with a burndown program or tillage. Use a residual herbicide such as Harness Xtra, Harness Xtra 5.6L, Degree Xtra or other residual herbicide either preemergence or in-crop for control of *Ambrosia* species. In-crop, tank-mix Roundup WeatherMAX with other herbicides such as 2,4-D, dicamba (Clarity or Banvel) or Status herbicide to control emerged weeds. Applications of Status herbicide should be made when the corn is between 4" and 36" tall (V2 to V10). Follow all label directions. *Ambrosia* species should not exceed 3" in height at the time of in-crop application.
Glyphosate-Resistant Johnsongrass	Start clean with a burndown program or tillage. Use a residual herbicide such as Harness Xtra, Harness Xtra 5.6L, Degree Xtra or other residual herbicide containing atrazine preemergence to reduce the competition from seedling johnsongrass prior to the emergence of corn. In-crop, tank-mix Roundup WeatherMAX with a herbicide such as Accent®, Equip™ or Option® for control of emerged weeds including seedling and rhizome johnsongrass. Follow all label directions of tank-mix partners, especially those related to weed size.

In certain areas, Italian ryegrass is known to be resistant to glyphosate. For control recommendations, refer to **www.weedresistancemanagement.com** or call 1-800-768-6387. When approved, supplemental labeling for specific herbicide products can also be viewed on **www.cdms.net** or **www.greenbook.net.**

*Follow all pesticide label requirements.

Genuity™ Bollgard II® and Bollgard® Cotton Descriptions

GENUITY™ BOLLGARD II® COTTON

Genuity™ Bollgard II® cotton contains two distinct insecticidal proteins from *Bacillus thuringiensis (B.t.)* that increase the efficacy and spectrum of control and reduce the chance that resistance will develop to the *B.t.* insecticidal proteins, relative to Bollgard® cotton. Genuity™ Bollgard II® cotton normally provides excellent, season-long control of tobacco budworm, pink bollworm and cotton bollworm. Genuity™ Bollgard II® cotton provides good protection against fall armyworm, beet armyworm, cabbage and soybean loopers and other secondary leaf- or fruit-feeding caterpillar pests of cotton. Applications of insecticides to control these insects are substantially reduced with Genuity™ Bollgard II® cotton.

BOLLGARD® COTTON

Bollgard cotton contains a single insecticidal protein from *B.t.* that provides good control against three major lepidopteran insect pests of cotton. Specifically, Bollgard cotton provides excellent, season-long control of tobacco budworm and pink bollworm, and suppression of cotton bollworm. When the above-mentioned insect larvae feed on Bollgard cotton plants, the *B.t.* protein protects the plants from damage by reducing larval survival. Under high infestation, application of insecticides may be necessary to protect Bollgard cotton.

BOLLGARD PHASE OUT

The U.S. Environmental Protection Agency has mandated the following terms and conditions:*

- Bollgard® cotton may be sold through September 30, 2009. After that date, all sales of Bollgard cotton are prohibited.
- All Bollgard cotton seed must be planted by midnight of July 1, 2010 (the expiration date of the Bollgard cotton registration). After July 1, 2010, planting of Bollgard cotton seed is prohibited. Any Bollgard cotton seed not planted on or before July 1, 2010, must be returned to either the retailer or to Monsanto. No refunds are to be issued on Bollgard cotton seeds bought for planting in 2010 and returned by growers.
- An adequate amount of refuge seed must be purchased for planting an appropriate refuge for Bollgard cotton. Purchase of refuge seed with the Bollgard cotton seed is mandatory, and such seed must be purchased by growers in advance of their receipt of Bollgard cotton seed. Any seed purchased for use as a refuge is non-refundable, unless the proportional amount of Bollgard cotton seed that the refuge seed would have supported is returned at the same time.
- Any order for replacement or additional Bollgard cotton seed for the 2010 planting season, that does not conform to the requirements stated above must be filled with Genuity™ Bollgard II® cotton seed (or other products with current registrations).
- On-farm IRM assessments will be conducted during the planting season.
- In 2010, Bollgard cotton may only be planted in: Alabama, Arkansas, Florida (North of Florida Route 60), Georgia, Kentucky, Louisiana, Maryland, Missouri, Mississippi, North Carolina, South Carolina, Tennessee, Texas (excluding the ten prohibited Texas panhandle counties of: Dallam, Sherman, Hansford, Ochiltree, Lipscomb, Hartley, Moore, Hutchinson, Roberts, and Carson) and Virginia.

*It is a violation of federal law to sell or distribute an unregistered pesticide.

NOTE: Sale or commercial planting of Bollgard® cotton is prohibited in certain states, including: Arizona, California, Colorado, Kansas, New Mexico and Oklahoma.

Sale or planting of Bollgard is prohibited in the Texas counties of: Carson, Dallam, Hansford, Hartley, Hutchison, Lipscomb, Moore, Ochiltree, Roberts, and Sherman.

Sale or commercial planting of both Genuity™ Bollgard II® and Bollgard is prohibited in Hawaii, Puerto Rico, the U.S. Virgin Islands, and in Florida south of Route 60 (near Tampa).

The *B.t. delta endotoxin* protein expressed in this cotton targets certain cotton insect pests. Routine applications of insecticides to control certain insects are usually unnecessary when cotton containing the *B.t. delta endotoxin* protein is planted. However, if insecticide applications are necessary to control certain cotton insect pests, follow all label requirements.

Genuity™ Bollgard II® and Bollgard® Cotton

INSECT RESISTANCE MANAGEMENT (IRM)

Lepidopteran cotton pests have demonstrated the ability to develop resistance to many chemical insecticides. As a preemptive measure, Genuity™ Bollgard II® and Bollgard® cotton must be managed in ways that will retard insect resistance development. These practices are designed to ensure that some lepidopteran populations are not exposed to the *B.t.* proteins so they can maintain susceptibility in select populations. In order to achieve this, refuge cotton that does not contain *B.t.* proteins must be planted.

GENUITY™ BOLLGARD II - DUAL EFFECTIVE DOSE

Resistance management is critical to the long-term viability of our technology and the benefits realized by our farmer customers. 2010 is a transition year for Monsanto *B.t.* cotton products as we shift all U.S. cotton acres toward the two-gene insect control product, Genuity™ Bollgard II® cotton. The move to multiple-gene products, including Genuity™ Bollgard II®, offers dual effective modes of action against target insect pests, increasing the longevity of the technology.

INTEGRATED PEST MANAGEMENT (IPM)

Integrated Pest Management (IPM) is an effective and environmentally sensitive approach to pest management that relies on a combination of common-sense practices. IPM programs use current, comprehensive information on the life cycles of pests and their interaction with the environment. This information is used to manage pests in a manner that is least harmful to people, property and the environment.

Prevention

Using the best agronomic management practices in conjunction with the appropriate cotton varieties will yield the greatest benefits.

Use varieties, seeding rates and planting technologies appropriate for each specific geographical area. As much as possible, manage the crop to avoid plant stress.

- Employ appropriate scouting techniques and treatment decisions to preserve beneficial insects that can provide additional insect pest control.
- Manage for appropriate maturity and harvest schedules. destroy stalks immediately after harvest to avoid regrowth and minimize selection for resistance in late-season infestations.
- Use soil management practices that encourage destruction of over-wintering pupae.

Monitor and Identify

Fields should be carefully monitored for all pests, including cotton bollworms, to determine the need for remedial insecticide treatments. For target pests, scouting techniques and supplemental treatment decisions should take into account the fact that larvae must hatch and feed before they can be affected by the *B.t.* protein(s) in either Genuity™ Bollgard II® or Bollgard cotton. Fields should be scouted regularly, following periods of heavy or sustained egg lay, especially during bloom, to determine if significant larval survival has occurred. Scouting should include a modified whole-plant inspection, including terminals, squares, blooms, bloom tags and small bolls. Larvae larger than 1/4 inch (3- to 4-days old) are generally recognized as survivors that may not be controlled by Genuity™ Bollgard II® or Bollgard cotton.

Read the IRM/Grower Guide prior to planting for information on planting and Insect Resistance Management. If you do not have a copy of this Guide, you may download it at **www.monsanto.com**, or **call 1-800-768-6387** to request a copy by mail.

Control

Monsanto recommends the use of appropriate remedial insecticide treatments to ensure desired levels of control if any cotton insect pest reaches locally established thresholds in Genuity™ Bollgard II® or Bollgard cotton.

Although Genuity™ Bollgard II® and Bollgard cotton will sustain less damage from some of the most troublesome lepidopteran pests, they will not provide protection against non-lepidopteran species. These insects should be monitored and treated with insecticides when necessary, using recommended thresholds. Whenever possible, select insecticides that are least harmful to beneficial insects.

NOTE: In 2010, sale or commercial planting of Bollgard® cotton is prohibited in the following states: Arizona, California, Colorado, Kansas, New Mexico and Oklahoma.

In 2010, sale or planting of Bollgard® is prohibited in the Texas counties of: Carson, Dallam, Hansford, Hartley, Hutchison, Lipscomb, Moore, Ochiltree, Roberts, and Sherman.

In 2010, sale or commercial planting of both Genuity® Bollgard II® and Bollgard® is prohibited in Hawaii, Puerto Rico, and the U.S. Virgin Islands, or in Florida south of Route 60 (near Tampa).

Roundup Ready® Cotton, Genuity™ Bollgard II® with Roundup Ready® Cotton and Bollgard with Roundup Ready Cotton

ROUNDUP READY COTTON

Roundup Ready® cotton varieties contain in-plant tolerance to Roundup® agricultural herbicides, enabling farmers to make in-crop applications of Roundup WeatherMAX® or Roundup PowerMAX® according to label requirements.

GENUITY™ BOLLGARD II WITH ROUNDUP READY COTTON AND BOLLGARD WITH ROUNDUP READY COTTON

Genuity™ Bollgard II® with Roundup Ready® cotton and Bollgard with Roundup Ready varieties offer farmers the benefits of both insect protection and glyphosate tolerance combined in one crop. These varieties exhibit the same insect protection qualities as Genuity™ Bollgard II® and Bollgard cotton and enable farmers to make in-crop applications of Roundup WeatherMAX or Roundup PowerMAX according to label requirements.

MARKET OPTIONS

Gin by-products of cotton containing Monsanto's biotech traits, including cottonseed for feed uses, are fully approved for export to Canada, Japan, Mexico and South Korea. Cottonseed containing Monsanto traits may not be exported for the purpose of planting without a license from Monsanto.

It is a violation of national and international law to move material containing biotech traits across boundaries into nations where import is not permitted.

RECOMMENDED MANAGEMENT PRACTICES

Managing Roundup Ready cotton, Bollgard with Roundup Ready cotton and Genuity™ Bollgard II® with Roundup Ready® cotton requires that a farmer follow the recommended management practices associated with cotton containing each individual trait. Farmers of Bollgard with Roundup Ready cotton and Genuity™ Bollgard II® with Roundup Ready® cotton varieties must follow the same guidelines for establishing required refuge options, practicing IRM and managing target and non-target pests as described for Bollgard and Genuity™ Bollgard II® cotton in the IRM/Grower Guide.

APPLICATION OF ROUNDUP WEATHERMAX® AND ROUNDUP POWERMAX®

Roundup Ready cotton is genetically improved to provide tolerance to glyphosate, the active ingredient in Roundup agricultural herbicides. Roundup Ready cotton can receive over-the-top applications of Roundup agricultural herbicides only through the four-leaf stage. With the introduction of Genuity™ Roundup Ready® Flex cotton, there is the potential for both Roundup Ready cotton and Genuity™ Roundup Ready® Flex cotton to be used on a farmer's farm. This creates concern for the crop safety of Roundup Ready cotton. Monsanto recommends that farmers:

- Maintain accurate records of which technologies have been planted and where they have been planted.
- Communicate the field plan with other members of their work force to ensure proper applications for each technology.
- Clearly mark fields to indicate which technology has been planted.

TRACK IT. COUNT IT. More than Four, Post-Direct.

WEED RESISTANCE MANAGEMENT GUIDELINES

Follow all pesticide label requirements and these guidelines to minimize the risk of developing glyphosate-resistant weed populations in a Roundup Ready cotton system:

- Scout fields before and after each burndown and in-crop application.
- Start clean with a burndown herbicide program or tillage.
- Use the right herbicide product at the right rate and right time.
- Add soil residual herbicide(s) and cultural practices as part of a Roundup Ready weed control program.
- In-crop, apply Roundup WeatherMAX at a minimum of 22 oz/A when weeds are less than 6" in height.
- Tank-mix other approved herbicides with Roundup WeatherMAX if necessary for postemergence weed control.
- Clean equipment before moving from field to field to minimize the spread of weed seed (as well as nematodes, insects and other cotton pests).
- Should repeated non-performance occur, report to Monsanto or your local retailer.

WEED CONTROL RECOMMENDATIONS

Weed control in cotton is essential to help maximize both fiber yield and quality potential. Cotton is very sensitive to early-season weed competition, which can result in unacceptable stands and/or reduced yield potential. The Roundup Ready* cotton system provides farmers with the right tools to control weeds before they become competitive.

PROGRAM	INSTRUCTIONS AND USE RATES*	ADDITIONAL INFORMATION
Preplant Burndown	Always start clean by planting into a weed-free field using either tillage or a burndown application. In no-till and reduced-till systems, apply a preplant burndown application of Roundup WeatherMAX®** at 22 to 44 oz/A in a tank-mix with dicamba or 2,4-D. See the dicamba and 2,4-D product label for rates and time intervals required between application and cotton planting. State restrictions may apply.	Early-season weed competition can result in unacceptable stands and/or reduced yield potential. This tank-mix is recommended for control and management of glyphosate-resistant marestail (*Conyza sp.*) or other tough-to-control weeds. Burndown application should be made far enough in advance of planting to control existing weeds.
Residual Herbicides	Apply residual herbicide(s) as part of a Roundup Ready cotton weed control program. Use the recommended label rate and timing of the residual herbicide applied. Refer to individual product labels for list of residual herbicides that may be used.	The residual herbicide(s) may be applied as either a preemergence (including preplant incorporated), postemergence, and/or layby application as allowed on the label of the specific product being used.
Over-The-Top through Fourth Leaf	Apply Roundup WeatherMAX over the top from crop emergence through the fourth true-leaf (node) stage (until the fifth true leaf reaches the size of a quarter). Two applications can be made during this period at a maximum rate of 22 oz/A per application. Refer to the "Annual Weeds Rate Table" in the Roundup WeatherMAX label for rate recommendations for specific annual weeds.	In-crop over-the-top applications must be at least 10 days apart and the cotton must have at least two nodes of incremental growth between applications. Care should be taken to record growth stage at first application. In situations where the potential for weed infestations is high (including perennial weeds), make the first application early enough to allow a second application before cotton exceeds the fourth true-leaf stage. Over-the-top applications after the fourth true-leaf stage can result in boll loss, delayed maturity, and/or yield loss.
Selective Equipment	After the fourth true-leaf stage through layby, Roundup WeatherMAX may be applied using precision post-directed or hooded sprayers which direct the spray to the base of the cotton plant. Two post-directed applications can be made during this period at a maximum rate of 22 oz/A per application.	Place nozzles in a low horizontal position to permit spray pattern to overlap in the row while contact of spray solution with cotton leaves should be avoided to the maximum extent possible. Excessive foliar contact can result in boll loss, delayed maturity, and/or yield loss. There must be two nodes of growth and at least 10 days between applications.
Preharvest Over-The-Top Applications	Before harvest and after cotton reaches 20% boll-crack, if needed, apply up to 44 oz/A of Roundup WeatherMAX. This treatment is effective in controlling late-season perennial weeds and can improve harvest efficiency.	Applications must be made at least 7 days prior to harvest. Roundup agricultural herbicides are not effective for preharvest cotton regrowth in Roundup Ready cotton. Do not apply Roundup agricultural herbicides preharvest to crops grown for seed under contract at an authorized cotton seed company.

Roundup Ready cotton has excellent vegetative tolerance to Roundup WeatherMAX allowing early-season over-the-top applications. Incomplete reproductive tolerance requires that applications after the 4-leaf (node) stage be properly post-directed.

ATTENTION: Use of Roundup agricultural herbicides in accordance with label directions is expected to result in normal growth of Roundup Ready cotton, however, various environmental conditions, agronomic practices, and other factors make it impossible to eliminate all risks associated with the product, even when applications are made in conformance with the label specifications. In some cases, these factors can result in boll loss, delayed maturity, and/or yield loss.

*Follow all pesticide label requirements.

**If using another Roundup agricultural herbicide, you must refer to the label booklet or Roundup Ready cotton supplemental label for that brand to determine appropriate use rates. If using Roundup PowerMAX®, application rates are the same as for Roundup WeatherMAX.

RECOMMENDATIONS FOR MANAGING GLYPHOSATE-RESISTANT WEEDS

WEEDS	INSTRUCTIONS AND USE RATES*
Glyphosate-Resistant Marestail (Horseweed)	Start clean with a burndown herbicide program or tillage. -Tank-mix Roundup agricultural herbicides with dicamba or 2,4-D (consult label for plant back timing). If you have dense stands of marestail, use a preplant residual herbicide at the recommended rate and timing, such as diuron (Direx®) or flumioxazin (Valor®). Use Roundup WeatherMAX in-crop, as needed, at a minimum of 22 oz/A to control other weeds. In-crop, if applying post-directed to glyphosate-resistant marestail, Roundup WeatherMAX can be tank-mixed with other herbicides, such as diuron or MSMA. Marestail should be less than 6" in height at the time of in-crop application.
Glyphosate-Resistant *Amaranthus* Species **- *Palmer Amaranth*** **- Waterhemp**	Start clean with a burndown herbicide program or tillage. Apply a preemergence residual herbicide such as pendimethalin (Prowl®) plus fluometuron or fomesafen (Reflex®) or flumioxazin (Valor) for control of *Amaranthus* species. In-crop, tank-mix Roundup WeatherMAX at 22 oz/A with metolachlor or other labeled chloracetamide herbicide before *Amaranthus* species emerges. Use Roundup WeatherMAX in-crop, as needed, at a minimum of 22 oz/A to control other weeds. A post-directed application of Roundup WeatherMAX tank-mixed with MSMA and a residual such as diuron (Direx) or flumioxazin (Valor) should be made to control *Amaranthus* species 3" or smaller in height and prevent additional flushes.
Glyphosate-Resistant *Ambrosia* Species **- Giant Ragweed** **- Common Ragweed**	Start clean with a burndown herbicide program or tillage. Apply a preemergence residual herbicide such as pendimethalin (Prowl) plus fluometuron or fomesafen (Reflex)for control of *Ambrosia* species. In-crop, tank-mix Roundup WeatherMAX at 22 oz/A with metolachlor before *Ambrosia* species emerges. Use Roundup WeatherMAX in-crop, as needed, at a minimum of 22 oz/A to control other weeds. A post-directed application of Roundup WeatherMAX tank-mixed with MSMA and a residual such as diuron (Direx) or flumioxazin (Valor) should be made to control *Ambrosia* species 3" or smaller in height and prevent additional flushes.
Glyphosate-Resistant Johnsongrass	Start clean with a burndown herbicide or tillage. Preplant incorporate a residual herbicide such as pendimethalin or trifluralin for control or suppression of seedling johnsongrass. Apply Roundup WeatherMAX in a tank-mix with herbicides such as SelectMAX®, Assure® II or Poast Plus for the control of emerged weeds including seedling and rhizome johnsongrass. Follow all label directions of tank-mix partners, especially those related to weed size.

In certain areas, Italian ryegrass is known to be resistant to glyphosate. For control recommendations, refer to **www.weedresistancemanagement.com** or call 1-800-768-6387. When approved, supplemental labeling for specific herbicide products can also be viewed on **www.cdms.net** or **www.greenbook.net.**

*Follow all pesticide label requirements.

Genuity™ Roundup Ready® Flex Cotton and Genuity™ Bollgard II® with Roundup Ready® Flex Cotton

GENUITY™ ROUNDUP READY® FLEX COTTON

Genuity™ Roundup Ready® Flex cotton varieties possess improved reproductive tolerance to Roundup® agricultural herbicides. This technology gives farmers the opportunity to make over-the-top broadcast applications of labeled Roundup agricultural herbicides from crop emergence up to seven (7) days prior to harvest.

GENUITY™ BOLLGARD II® WITH ROUNDUP READY® FLEX COTTON

Genuity™ Bollgard II® with Roundup Ready® Flex varieties offer farmers the benefits of both insect protection and glyphosate tolerance combined in one crop. These varieties exhibit the same insect protection qualities as Genuity™ Bollgard II® and are tolerant to over-the-top applications of Roundup WeatherMAX® and Roundup PowerMAX®.

MARKET OPTIONS

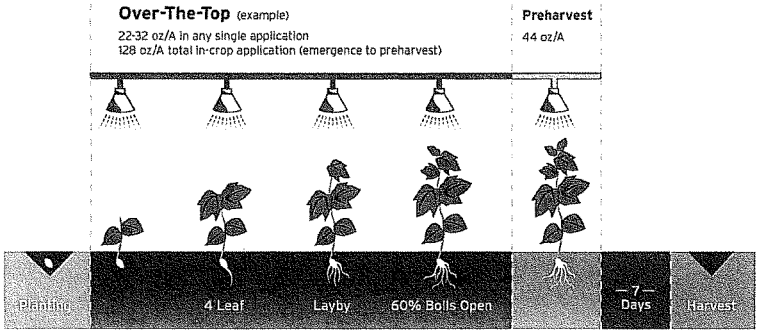
Genuity™ Roundup Ready® Flex cotton and Genuity™ Bollgard II® with Roundup Ready Flex cotton have regulatory clearance in the United States, but do not have import approval in all export markets. Processed fractions from these products, including linters, oil, meal, cottonseed and gin trash, must not be exported without all necessary approvals in the importing country. It is a violation of national and international law to move material containing biotech traits across boundaries into nations where import is not permitted.

RECOMMENDED MANAGEMENT PRACTICES

Managing Genuity™ Roundup Ready® Flex cotton and Genuity™ Bollgard II® with Roundup Ready® Flex cotton requires a farmer to follow the recommended management practices associated with cotton containing each individual trait. Farmers of Genuity™ Bollgard II® with Roundup Ready® Flex cotton must follow the same guidelines for establishing required refuge options, practicing IRM and managing target and non-target pests as described for Genuity™ Bollgard II® cotton in the IRM/Grower Guide.

WEED RESISTANCE MANAGEMENT GUIDELINES

Follow all label requirements and the guidelines below to minimize the risk of developing weed resistance in a Genuity™ Roundup Ready® Flex cotton system:



- Scout fields before and after each burndown and in-crop application.
- Start clean with a burndown herbicide program or tillage.
- Use the right herbicide product at the right rate and right time.
- Add soil residual herbicide(s) and cultural practices as part of a Genuity™ Roundup Ready® Flex cotton weed control program.
- In-crop, apply Roundup WeatherMAX at a minimum of 22 oz/A when weeds are 3" to 6" in height.
- Tank-mix other approved herbicides with Roundup WeatherMAX if necessary for postemergence weed control.
- Should repeated non-performance occur, report to Monsanto or your local retailer.
- Clean equipment before moving from field to field to minimize the spread of weed seed (as well as nematodes, insects and other cotton pests).

APPLICATION OF ROUNDUP WEATHERMAX® AND ROUNDUP POWERMAX®

- May be applied over-the-top and/or in-crop, from crop emergence up to 7 days prior to harvest.
- A maximum rate of 32 oz/A per application may be applied using ground application equipment while the maximum is 22 oz/A per application by air.
- There are no growth or timing restrictions for sequential applications.
- Four (4) quarts/A is the total in-crop volume allowed from emergence to 60% open bolls.
- A maximum total volume of 44 oz/A may be applied between layby and 60% open bolls.
- Post-directed equipment may be used to achieve more thorough spray coverage of weeds or if herbicides not labeled for over-the-top application will be tank-mixed with Roundup WeatherMAX or Roundup PowerMAX.

PREHARVEST APPLICATIONS

- Up to 44 oz/A may be applied after cotton reaches 60% open bolls and before harvest, if needed.
- Applications must be made at least 7 days prior to harvest.

CROP SAFETY OF OVER-THE-TOP GLYPHOSATE APPLICATIONS

Monsanto has determined that a combination of components in glyphosate formulations have the potential to cause leaf injury when applied during later stages of crop growth. Roundup WeatherMAX and Roundup PowerMAX are the only Roundup agricultural herbicides labeled and approved for new labeled uses over the top of Genuity™ Roundup Ready® Flex cotton.

Leaf injury may occur if the products are not used according to the product label, used at higher than recommended rates or if overlap of spray occurs in the field. **Farmers must confirm that any glyphosate formulation to be used on Genuity™ Roundup Ready® Flex cotton has been labeled for use on Genuity™ Roundup Ready® Flex cotton and should confirm that it has been tested to demonstrate crop safety.**

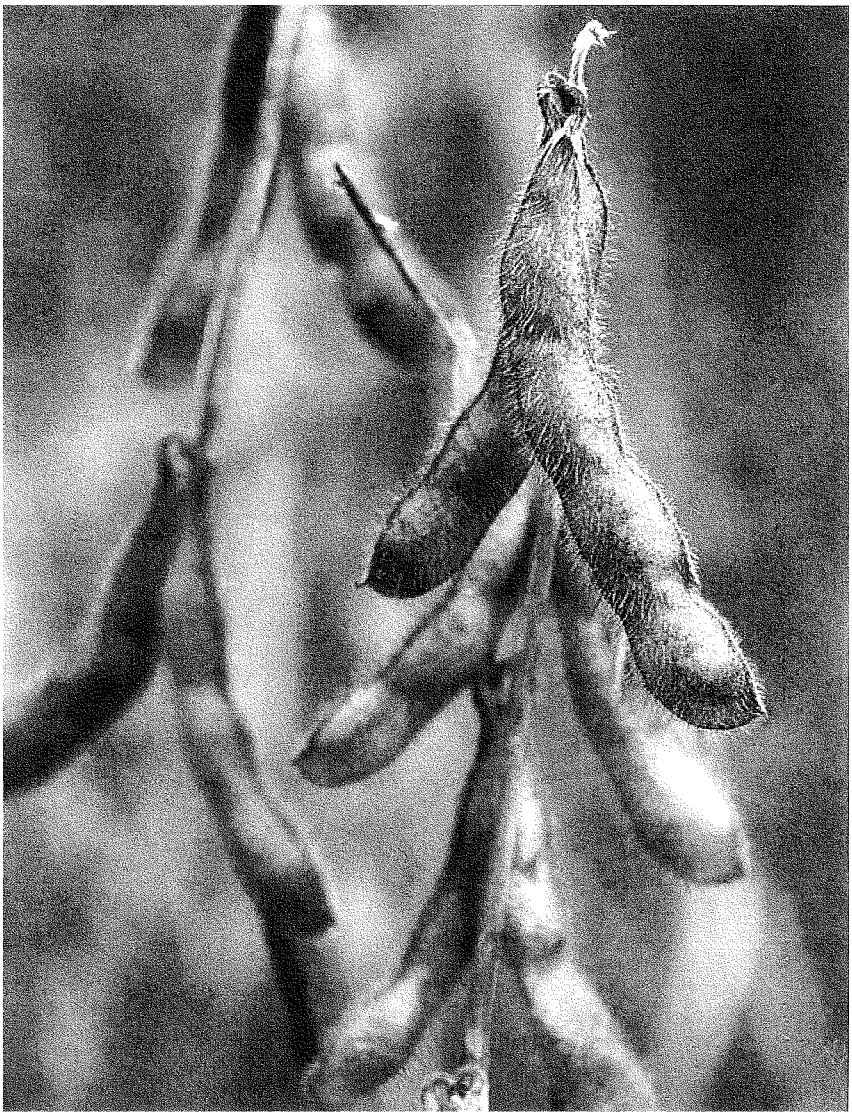
WEED CONTROL RECOMMENDATIONS

Weed control in cotton is essential to maximize both fiber yield and quality potential. Cotton is very sensitive to early-season weed competition, which can result in unacceptable stands and/or reduced yield potential. The Genuity™ Roundup Ready® Flex cotton system, with improved reproductive tolerance to Roundup® agricultural herbicides, provides farmers with the right tools to control weeds.

PROGRAM	INSTRUCTIONS AND USE RATES*	ADDITIONAL INFORMATION
Preplant Burndown	Always start clean by planting into a weed-free field using either tillage or a burndown application. In no-till and reduced-till systems, apply a preplant burndown application of Roundup WeatherMAX®** at 22 to 44 oz/A in a tank-mix with dicamba or 2,4-D. See the dicamba and 2,4-D product label for rates and time intervals required between application and cotton planting. State restrictions may apply.	Early-season weed competition can result in unacceptable stands and/or reduced yield potential. This tank-mix is recommended for control and management of glyphosate-resistant marestail (*Conyza sp.*) or other tough-to-control weeds. Burndown application should be made far enough in advance of planting to control existing weeds.
Residual Herbicides	Apply approved residual herbicide(s) as part of a Genuity™ Roundup Ready® Flex cotton weed control program. Use the recommended label rate and timing of the residual herbicide applied. Refer to individual product labels for list of residual herbicides that may be used.	The residual herbicide(s) may be applied as either a preemergence (including preplant incorporated), postemergence, and/or layby application as allowed on the label of the specific product being used.
In-Crop Weed Control	Target the first application of Roundup WeatherMAX on 1-2 leaf cotton when weeds are small. Apply a minimum of 22 oz/A of Roundup WeatherMAX in-crop. The need for sequential applications of Roundup WeatherMAX will depend upon the occurrence of subsequent weed flushes. Refer to the "Annual Weeds Rate Table" in the Roundup WeatherMAX label booklet for rate recommendations for specific annual weeds.	Early-season weed competition can reduce yield potential in cotton. Select timing of application based on the most difficult to control weed species in your field. Post-direct or hooded sprayers can be used to achieve more thorough spray coverage on weeds.
Preharvest Over-The-Top Applications	Before harvest and after cotton reaches 60% open bolls, if needed, apply up to 44 oz/A of Roundup WeatherMAX. This treatment is effective in controlling late-season perennial weeds.	Applications must be made at least 7 days prior to harvest. Roundup agricultural herbicides are not effective for preharvest cotton regrowth in Genuity™ Roundup Ready® Flex cotton.

*Follow all pesticide label requirements.

**The maximum volume of Roundup WeatherMAX and Roundup PowerMAX® that may be used in a single season is 5.3 quarts per acre.



RECOMMENDATIONS FOR MANAGING GLYPHOSATE-RESISTANT WEEDS

WEEDS	INSTRUCTIONS AND USE RATES*
Glyphosate-Resistant Marestail (Horseweed)	Start clean with a burndown herbicide program or tillage. -Tank-mix Roundup agricultural herbicides with dicamba or 2,4-D (consult label for plant back timing). If you have dense stands of marestail, use a preplant residual herbicide at the recommended rate and timing, such as diuron (Direx®) or flumioxazin (Valor®). Use Roundup WeatherMAX in-crop, as needed, at a minimum of 22 oz/A to control other weeds. In-crop, if applying post-directed to glyphosate-resistant marestail, Roundup WeatherMAX can be tank-mixed with other herbicides, such as diuron or MSMA. Marestail should not exceed 6" in height at the time of in-crop application.
Glyphosate-Resistant *Amaranthus* Species **- *Palmer Amaranth*** **- Waterhemp**	Start clean with a burndown herbicide program or tillage. Apply a preemergence residual herbicide such as pendimethalin (Prowl®) plus fluometuron or fomesafen (Reflex®) or flumioxazin (Valor) for control of *Amaranthus* species. In-crop, tank-mix Roundup WeatherMAX at 22 oz/A with metolachlor or other labeled chloracetamide herbicide before *Amaranthus* species emerges. Use Roundup WeatherMAX in-crop, as needed, at a minimum of 22 oz/A to control other weeds. A post-directed application of Roundup WeatherMAX tank-mixed with MSMA and a residual such as diuron (Direx) or flumioxazin (Valor) should be made to control *Amaranthus* species 3" or smaller in height and prevent additional flushes.
Glyphosate-Resistant *Ambrosia* Species **- Giant Ragweed** **- Common Ragweed**	Start clean with a burndown herbicide program or tillage. Apply a preemergence residual herbicide such as pendimethalin (Prowl) plus fluometuron or fomesafen (Reflex) for control of *Ambrosia* species. In-crop, tank-mix Roundup WeatherMAX at 22 oz/A with metolachlor before *Ambrosia* species emerges. Use Roundup WeatherMAX in-crop, as needed, at a minimum of 22 oz/A to control other weeds. A post-directed application of Roundup WeatherMAX tank-mixed with MSMA and a residual such as diuron (Direx) or flumioxazin (Valor) should be made to control *Ambrosia* species 3" or smaller in height and prevent additional flushes.
Glyphosate-Resistant Johnsongrass	Start clean with a burndown herbicide or tillage. Preplant incorporate a residual herbicide such as pendimethalin or trifluralin for control or suppression of seedling johnsongrass. Apply Roundup WeatherMAX in a tank-mix with herbicides such as SelectMAX®, Assure® II or Poast Plus for the control of emerged weeds including seedling and rhizome johnsongrass. Follow all label directions of tank-mix partners, especially those related to weed size.

In certain areas, Italian ryegrass is known to be resistant to glyphosate. For control recommendations, refer to **www.weedresistancemanagement.com** or call 1-800-768-6387. When approved, supplemental labeling for specific herbicide products can also be viewed on **www.cdms.net** or **www.greenbook.net.**

*Follow all pesticide label requirements.

GENUITY™ ROUNDUP READY 2 YIELD® AND ROUNDUP READY® SOYBEANS

Genuity™ Roundup Ready 2 Yield® and Roundup Ready® soybean varieties contain in-plant tolerance to Roundup® agricultural herbicides. This means you can spray Roundup agricultural herbicides in-crop from emergence through flowering.

Spray labeled Roundup agricultural herbicides over the top from emergence (cracking) through flowering (R2 stage soybeans) for unsurpassed weed control, proven crop safety and maximum yield potential. R2 stage soybeans end when a pod 5 millimeters (3/16") long at one of the four uppermost nodes appears on the main stem along with a fully developed leaf (R3 stage).

WEED CONTROL RECOMMENDATIONS

Starting clean with a weed-free field, and making timely post-emergence in-crop applications, is critical to obtaining excellent weed control and maximum yield potential. The Roundup Ready soybean system provides the flexibility to use the herbicide tools necessary to control weeds at planting and in-crop. Failure to control weeds with the right rate, at the right time and with the right product, can lead to increased weed competition and the potential for decreased yield.

PROGRAM	INSTRUCTIONS AND USE RATES*	ADDITIONAL INFORMATION
Preplant Burndown	To start clean in no-till systems, apply a burndown application of Roundup WeatherMAX®** at 22 to 44 oz/A before planting. See the label for appropriate rates by weed species. For control and management of glyphosate-resistant marestail (*Conyza sp.*) or other difficult-to-control weeds present at burndown, apply 22 oz/A of Roundup WeatherMAX in a tank-mix with 1 to 2 pt/A 2,4-D. Make applications 7 to 30 days before planting and before marestail reaches 6" in height.	Always start with a weed-free field. In no-till and reduced-till systems, apply a Roundup WeatherMAX* burndown application to control existing weeds before planting. Adding 2,4-D in the burndown can significantly reduce broadleaf weed pressure at post-emergence timing. Read the 2,4-D product label for time intervals required between application and soybean planting.
Residual Herbicide Plus Roundup WeatherMAX	Use the recommended label rate of a soil-applied residual herbicide applied preemergence to soybeans as defined in the individual product's labeling. The residual product may be tank-mixed with Roundup WeatherMAX at burndown. Refer to individual product labels for list of residual herbicides that may be used. Follow with 22 oz/A Roundup WeatherMAX in-crop when weeds are 2" to 8" tall. Refer to the "Annual Weeds Rate Table" in the Roundup WeatherMAX label for rate recommendations for specific annual weeds. Crop rotation following Genuity™ Roundup Ready 2 Yield® and Roundup Ready soybeans is strongly encouraged. Use of a residual herbicide is encouraged especially if the cropping system is a continuous Roundup Ready system.	A residual program is encouraged when agronomic conditions favor the practice. Reducing Roundup WeatherMAX rate when tank-mixing with a residual or use of premixes utilizing a reduced rate of glyphosate (such as Extreme®) is not recommended. If the in-crop application is delayed and weeds are larger, apply a higher rate of Roundup WeatherMAX.
Roundup WeatherMAX	Apply a minimum of 22 oz/A of Roundup WeatherMAX** in-crop when weeds are 2" to 8" tall. Refer to the "Annual Weeds Rate Table" in the Roundup WeatherMAX label for rate recommendations for specific annual weeds. Choose the rate to control the most difficult-to-control weed in your field. A sequential application of this product may be required to control new flushes of weeds in the Roundup Ready soybean crop. If a sequential application is necessary, apply 16 to 22 oz/A of Roundup WeatherMAX** when weeds are 3" to 6" tall.	In-crop application of Roundup WeatherMAX provides control of labeled weeds. For best results, apply 3 to 4 weeks after planting or when weeds are less than 8" tall. If initial application is delayed and weeds are larger, apply a higher labeled rate of Roundup WeatherMAX.

*Follow all pesticide label requirements.

**If using another Roundup agricultural herbicide, you must refer to the label booklet or Genuity™ Roundup Ready 2 Yield® soybean or Roundup Ready soybean supplemental label for that brand to determine appropriate use rates. If using Roundup PowerMAX, application rates are the same as for Roundup WeatherMAX.

GENUITY™ ROUNDUP READY 2 YIELD® AND ROUNDUP READY® SOYBEANS

PROGRAM	INSTRUCTIONS AND USE RATES*	ADDITIONAL INFORMATION
Glyphosate-Tolerant Volunteer Corn	Tank-mix Roundup WeatherMAX® with 6 to 12 oz/A of Select Max™ and apply to 4" to 36" glyphosate-tolerant volunteer corn.	Choose your Roundup WeatherMAX rate based on the weed species and size listed in the "Annual Weeds Rate Table" of the Roundup WeatherMAX Label.
Maximum Use Rates for Roundup WeatherMAX	**In-Crop:** • 44 oz/A per single application • 44 oz/A during flowering • 64 oz/A emergence through flowering (R2 stage soybeans) **Preharvest:** • 22 oz/A application	**Total Season:** The combined total of preplant, in-crop and preharvest applications of Roundup WeatherMAX can not exceed 5.3 qt/A. The combined total of in-crop and preharvest applications can not exceed 64 oz/A.

*Follow all pesticide label requirements.

Herbicide products sold by Monsanto for use over the top of soybeans with Genuity™ Roundup Ready 2 Yield® Technology for the 2010 crop season are as follows:

- Roundup WeatherMAX
- Roundup PowerMAX

WEED CONTROL RECOMMENDATIONS

KEY WEEDS	INSTRUCTIONS AND USE RATES*	ADDITIONAL INFORMATION
Weeds that Tend to Have Multiple Emergence Events	Where dense stands of weed species such as common lambsquarters, tall and common waterhemp, *Palmer Amaranth*, redroot pigweed, common ragweed, and giant ragweed are expected, the following agronomic practices are recommended: • Start clean with tillage or burndown in no-till and reduced till systems. Include 2,4-D in the burndown. • Plant soybeans in narrow rows (<20"). • Use a pre-plant residual herbicide. • Use the right rate of Roundup WeatherMAX at the right time (proper weed size).	Weeds such as lambsquarters, waterhemp, pigweed, and giant ragweed tend to emerge throughout the season. Sequential Roundup WeatherMAX applications or the addition of a soil residual herbicide may be required for control of subsequent weed flushes.
Difficult-to-Control Weeds	Black nightshade, velvetleaf, waterhemp, morningglory, lambsquarters, Florida pusley, giant ragweed, Pennsylvania smartweed, groundcherry, hemp sesbania and spurred anoda are difficult-to-control weeds. Please refer to the Roundup agricultural herbicide label for specific rates and weed sizes for control of these weeds.	These weed species require special attention be paid to Roundup WeatherMAX rate and application timing (proper weed size) to obtain excellent weed control. A sequential application may be required if a new weed flush occurs, especially in soybeans planted in wide rows (>20").
Perennial Weeds	An in-crop application of 22 to 44 oz/A of Roundup WeatherMAX** will provide suppression and/or control of nutsedge and perennial weeds like Canada thistle, field bindweed, hemp dogbane, horsenettle, johnsongrass, milkweed, quackgrass, etc.	For additional information on perennial weeds, see the "Perennial Weeds Rate Table" in the label booklet for Roundup WeatherMAX. For best control, allow perennials to achieve at least 6" or more of growth before spraying.

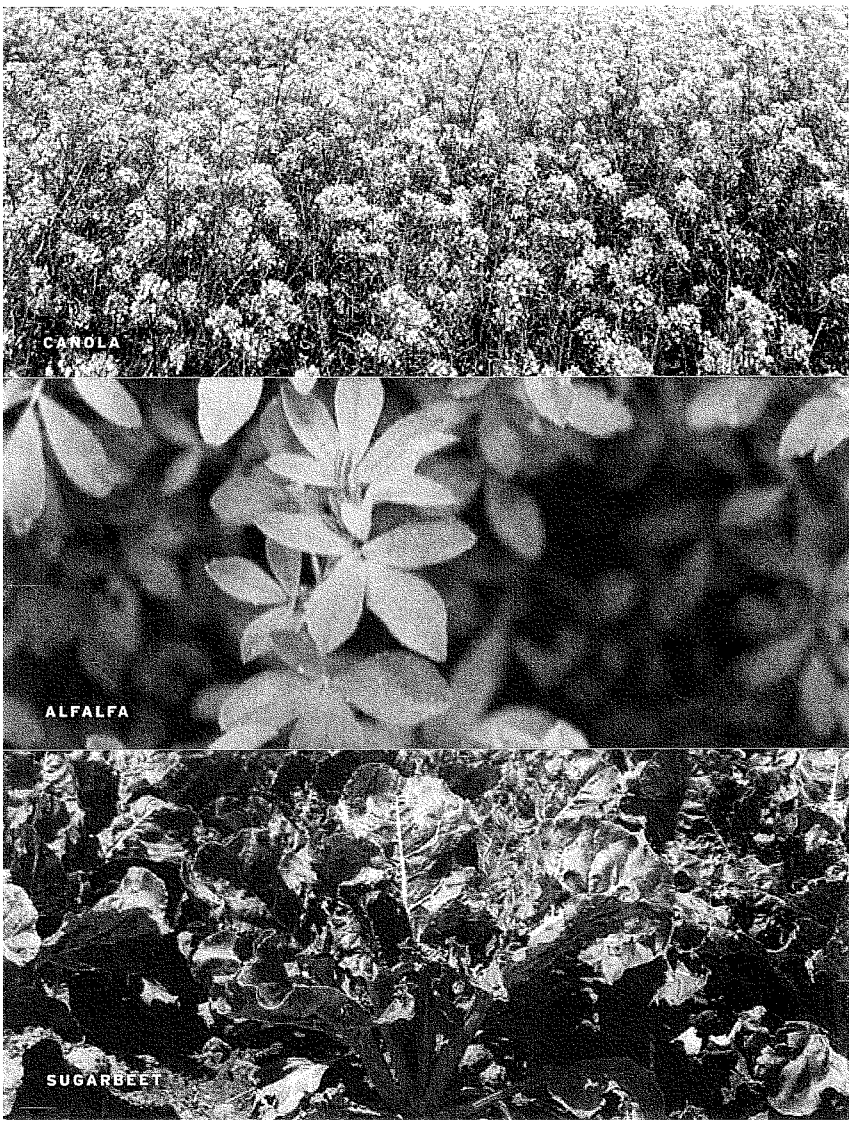
*Follow all pesticide label requirements.

**If using another Roundup agricultural herbicide, you must refer to the label booklet or Roundup Ready Soybean or Genuity™ Roundup Ready 2 Yield® Soybean supplemental label for that brand to determine appropriate use rates. If using Roundup PowerMAX, application rates are the same as for Roundup WeatherMAX.

WEED RESISTANCE MANAGEMENT GUIDELINES

Follow all pesticide label requirements and the guidelines below to minimize the risk of developing glyphosate-resistant weed populations in a Roundup Ready Soybean System:

- Crop rotation is strongly encouraged.
- Scout fields before and after each burndown and in-crop application.



- Start clean with a burndown herbicide or tillage.
  - Tank-mix with 2,4-D to control glyphosate-resistant marestail or other tough-to-control broadleaf weeds.
- Use the recommended label rate of a soil-applied residual herbicide such as INTRRO®, Valor®, Valor XLT® or Gangster®.
- In-crop, apply Roundup WeatherMAX at a minimum of 22 oz/A before weeds exceed 8" in height.
- If an additional flush of weeds occurs, a sequential application of Roundup WeatherMAX at 22 oz/A may be needed before weeds exceed 6" in height.
- Refer to individual product labels for a list of recommended tank-mix partners.
- Clean equipment before moving from field to field to minimize the spread of weed seed.
- Report repeated non-performance to Monsanto or your local retailer.

RECOMMENDATIONS FOR MANAGING GLYPHOSATE-RESISTANT WEEDS

WEEDS	INSTRUCTIONS AND USE RATES*
Glyphosate-Resistant Marestail (Horseweed)	**Preplant:** Apply a tank-mixture of 22 oz/A Roundup WeatherMAX® with 1 pt/A 2,4-D before marestail exceeds 6" in height. See the 2,4-D product label for time intervals required between application and planting. **In-crop:** It is strongly encouraged that marestail should be controlled prior to planting using recommended preplant burndown treatments. In-crop, apply a tank-mixture of 22 oz/A Roundup WeatherMAX with 0.3 oz/A FirstRate®. This treatment should be used as a salvage treatment only for a marestail infestation that was not controlled preplant. Application should be made between full emergence of the first trifoliate leaf and 50% flowering stage of soybeans. At the time of treatment, marestail should not exceed 6" in height.
Glyphosate-Resistant *Amaranthus* Species **- *Palmer Amaranth*** **- Waterhemp**	**Preplant:** Apply a tank-mix of 22 oz/A Roundup WeatherMAX with a preemergence residual herbicide such as alachlor (INTRRO®), flumioxazin (Valor®) or another residual herbicide for preemergence control of *Amaranthus* species. 2,4-D may be added to the tank-mix to help control emerged *Amaranthus* species and other broadleaf weeds preplant only. Follow label instructions regarding application timing relative to soybean planting. **In-crop:** It is strongly encouraged that a preemergence residual product be used to control *Amaranthus* species prior to emergence. If there is emerged *Amaranthus* in-crop, apply a tank-mixture of 22 oz/A Roundup WeatherMAX with a postemergence product with activity on *Amaranthus* such as lactofen (Cobra®), fomesafen (Flexstar®) or cloransulam (FirstRate). Applications should be made on emerged *Amaranthus* that does not exceed 3" in height. Read and follow all product label instructions. It is likely that visual soybean injury will occur with these tank-mixtures.
Glyphosate-Resistant *Ambrosia* Species **- Giant Ragweed** **- Common Ragweed**	**Preplant:** Apply a tank-mix of 22 oz/A Roundup WeatherMAX with a preemergence residual herbicide such as cloransulam (FirstRate) or cloransulam + flumioxazin (Gangster®) or another residual herbicide for preemergence control of *Ambrosia* species. 2,4-D may be added to the tank-mix to help control emerged *Ambrosia* species and other broadleaf weeds preplant only. Follow label instructions regarding application timing relative to soybean planting. **In-crop:** It is strongly encouraged that a preemergence residual product be used to control *Ambrosia* species prior to emergence. If there is emerged *Ambrosia* in-crop, apply a tank-mixture of 22 oz/A Roundup WeatherMAX with a postemergence product with activity on *Ambrosia* such as lactofen (Cobra) or fomesafen (Flexstar). Applications should be made on emerged *Ambrosia* that does not exceed 3" in height. Read and follow all product label instructions. It is likely that visual soybean injury will occur with these tank-mixtures.
Glyphosate-Resistant Johnsongrass	Start clean with a burndown herbicide or tillage. Preplant incorporate a residual herbicide such as pendimethalin or trifluralin for control or suppression of seedling johnsongrass. Apply Roundup WeatherMAX in a tank-mix with herbicides such as SelectMAX®, Assure® II or Poast Plus for the control of emerged weeds including seedling and rhizome johnsongrass. Follow all label directions of tank-mix partners, especially those related to weed size.

In certain areas, Italian ryegrass is known to be resistant to glyphosate. For control recommendations, refer to **www.weedresistancemanagement.com** or call 1-800-768-6387. When approved, supplemental labeling for specific herbicide products can also be viewed on **www.cdms.net** or **www.greenbook.net.**

*Follow all pesticide label requirements.

CANOLA
ALFALFA
SUGARBEET

GENUITY™ ROUNDUP READY® ALFALFA

ATTENTION: Pursuant to a Court Order issued on May 3, 2007, Genuity™ Roundup Ready® alfalfa seed **CAN NOT be commercially sold or planted** until further administrative regulatory actions are completed. For more information, and the latest updates on Genuity™ Roundup Ready® alfalfa, go to www.roundupreadyalfalfa.com.

Genuity™ Roundup Ready® alfalfa varieties have in-plant tolerance to Roundup® agricultural herbicides, enabling farmers to apply labeled Roundup agricultural herbicides up to 5 days before cutting for unsurpassed weed control, excellent crop safety and preservation of forage quality potential.

Hay and Forage Management Practices

Genuity™ Roundup Ready® alfalfa must be managed for high quality hay/forage production, including timely cutting to promote high forage quality (i.e. before 10% bloom) and to prevent seed development. In geographies where conventional alfalfa seed production is intermingled with forage production and the agronomic conditions (climate and water/irrigation availability) are such that forage alfalfa is allowed to stand and flower late in the season, Genuity™ Roundup Ready® alfalfa must be harvested at or before 10% bloom to minimize potential pollen flow from hay to common or conventional alfalfa seed production. Farmers who are unwilling to or who can not make this commitment to stewardship should not continue to grow Genuity™ Roundup Ready® alfalfa.

Genuity™ Roundup Ready® alfalfa varieties have excellent tolerance to over-the-top applications of labeled Roundup agricultural herbicides. An in-crop weed control program using Roundup WeatherMAX® or Roundup PowerMAX® will provide excellent weed control in most situations. A residual herbicide labeled for use in alfalfa may also be applied postemergence in alfalfa. Contact a Monsanto Representative, local crop advisor or extension specialist to determine the best option for your situation.

Stand Takeout and Volunteer Management

Crop rotations can be divided into two main groups, alfalfa rotated to: 1) grass crops (e.g. corn and cereal crops); and 2) broadleaf crops. More herbicide alternatives exist for management of volunteer alfalfa in grass crops. The recommended steps for controlling volunteer Genuity™ Roundup Ready® alfalfa are:

- Diligent Stand Takeout
- Start Clean
- Plan for Success
- Timely Execution

DILIGENT STAND TAKEOUT

Use appropriate, commercially available herbicide treatments alone for reduced tillage systems or in combination with tillage to terminate the Genuity™ Roundup Ready® alfalfa stand. Refer to your regional technical bulletin for specific stand takeout recommendations. **NOTE:** Roundup® agricultural herbicides are **not** effective for terminating Genuity™ Roundup Ready® alfalfa stands.

START CLEAN

If necessary, utilize tillage and/or additional herbicide application(s) after stand takeout, and before planting of the subsequent rotational crop to manage any newly emerged or surviving alfalfa.

PLAN FOR SUCCESS

Rotate the crops with known and available mechanical or herbicidal methods for managing volunteer alfalfa, keeping in mind that Roundup agricultural herbicides will not terminate Genuity™ Roundup Ready® alfalfa stands.

- Rotations to certain broadleaf crops are not advisable if the farmer is not willing to implement recommended stand termination practices.
- In the event that no known mechanical or herbicidal methods are available to manage volunteer alfalfa in the desired rotational crop, it is suggested that a crop with established volunteer alfalfa management practices be introduced into the rotation.

TIMELY EXECUTION

Implement in-crop mechanical or herbicide treatments for managing alfalfa volunteers in a timely manner; that is, before the volunteers become too large to control or begin to compete with the rotational crop.

Planting Requirements

Genuity™ Roundup Ready® alfalfa is not permitted to be planted in any wildlife feed plots.

Stewardship

All Genuity™ Roundup Ready® alfalfa farmers shall sign the Monsanto Technology/Stewardship Agreement (MTSA) limited-use license application which provides the terms and conditions for the authorized use of the product. Due to special circumstances, alfalfa farmers in the Imperial Valley of California will also sign an Imperial Valley Use Agreement (IVUA) with specific stewardship commitments. The MTSA or IVUA must be completed before purchase or use of seed.

Both the MTSA or IVUA explicitly prohibit all forms of commercial seed harvest on the stand. Every alfalfa farmer producing seed of Genuity™ Roundup Ready® alfalfa must possess an additional, separate and distinct seed farmer contract to produce Genuity™ Roundup Ready® alfalfa seed. Genuity™ Roundup Ready® alfalfa seed may not be planted outside of the United States, or for the production of seed or sprouts.

Any product produced from a Genuity™ Roundup Ready® alfalfa crop or seed, including hay and hay products, must be labeled and may only be used, exported to, processed or sold in countries where regulatory approvals have been granted. It is a violation of national and international laws to move material containing biotech traits across boundaries into nations where import is not permitted.

Pursuant to a Court Order issued on May 3, 2007, Genuity™ Roundup Ready® alfalfa farmers must adhere to the requirements set out in the December 18, 2007 USDA Administrative Order **(http://www.aphis.usda.gov/brs/pdf/RRA_AB_final.pdf)** until the USDA completes its regulatory process.

These requirements include, but are not limited to:

- Pollinators shall not be added to Genuity™ Roundup Ready® alfalfa fields grown only for hay production.
- Farm equipment used in Genuity™ Roundup Ready® alfalfa production shall be properly cleaned after use.
- Genuity™ Roundup Ready® alfalfa shall be handled and clearly identified to minimize commingling after harvest.

For additional information visit the USDA website:
http://www.aphis.usda.gov/biotechnology/alfalfa_history.shtml

For more information and the latest updates on Genuity™ Roundup Ready® alfalfa, go to **http://www.roundupreadyalfalfa.com**

To meet sales reporting requirements, the seed supplier is required to identify and list all Genuity™ Roundup Ready® alfalfa field locations. Therefore, all farmers MUST PROVIDE their seed supplier with the GPS coordinates of all their Genuity™ Roundup Ready® alfalfa fields.

WEED RESISTANCE MANAGEMENT GUIDELINES

Follow all pesticide label requirements and the guidelines below to minimize the risk of developing glyphosate-resistant weed populations in a Genuity™ Roundup Ready® alfalfa system:

- Scout fields before and after each herbicide application.
- Use the right herbicide product at the right rate and at the right time.
- To control flushes of weeds in established alfalfa, make applications of Roundup WeatherMAX® or Roundup PowerMAX® herbicide at 22 to 44 oz/A before weeds exceed 6" in height, up to 5 days before cutting.
- Use other approved herbicide products tank-mixed or in sequence with Roundup agricultural herbicide if appropriate for the weed spectrum present as part of a Genuity™ Roundup Ready® alfalfa weed control program.
- Report repeated non-performance to Monsanto or your local retailer.

WEED CONTROL RECOMMENDATIONS

In established stands, to preserve the quality potential of forage and hay, applications should be made after weeds have emerged but before alfalfa re-growth interferes with application spray coverage of the target weeds.

PROGRAM	INSTRUCTIONS AND USE RATES*	ADDITIONAL INFORMATION
Established Stands	After the first harvest of a newly established stand, up to 44 oz/A of Roundup WeatherMAX®** herbicide per cutting may be applied up to 5 days before each subsequent cutting. The combined total per year for all in-crop applications in established stands must not exceed 132 oz/A (4.1 qt/A) of Roundup WeatherMAX.	Applications between cuttings may be applied as a single application or in multiple applications (e.g. 2 applications of 22 oz/A). Sequential applications should be at least 7 days apart.
Weeds Controlled	For specific application rates and instructions for control of various annual and perennial weeds, refer to the Roundup WeatherMAX** herbicide label booklet. Some weeds with multiple germination times or suppressed (stunted) weeds may require a second application of Roundup WeatherMAX** herbicide for complete control. For some perennial weeds, repeated applications may be required to eliminate crop competition throughout the growing season.	In addition to those weeds listed in the Roundup WeatherMAX® label booklets, this product will suppress or control the parasitic weed, dodder (*Cuscuta spp.*) in Genuity™ Roundup Ready® alfalfa. Repeat applications may be necessary for complete control. For tough-to-control weeds or weeds not controlled by Roundup® agricultural herbicides use labeled rates of other approved herbicides, alone or in tank-mixtures, with Roundup agricultural herbicides.
Maximum Use Rates	**In-Crop:** • 44 oz/A per single application. • Established Stand Total: 44 oz/A per cutting up to 5 days before harvest.	**Total Per Year:** The combined total per year for all in-crop applications in established stands must not exceed 132 oz/A (4.1 qt/A) of Roundup WeatherMAX.

*Follow all pesticide label requirements.

**If using another Roundup agricultural herbicide, you must refer to the label booklet or separately published Genuity™ Roundup Ready® alfalfa supplemental label for that brand to determine appropriate use rates. If using Roundup PowerMAX, application rates are the same as for Roundup WeatherMAX.

GENUITY™ ROUNDUP READY® SPRING CANOLA

Genuity™ Roundup Ready® spring canola hybrids contain in-plant tolerance to Roundup agricultural herbicides, enabling farmers to apply Roundup® agricultural herbicides over the top of Genuity™ Roundup Ready® spring canola anytime from emergence through the 6-leaf stage of development.

The introduction of the Roundup Ready® trait into leading spring canola hybrids and varieties gives farmers the opportunity for unsurpassed weed control, proven crop safety and maximum profit potential. With Genuity™ Roundup Ready® spring canola, farmers have the weed management tool necessary to improve spring canola profitability, while providing a viable rotational crop to help break pest and disease cycles in cereal-growing areas.

WEED RESISTANCE MANAGEMENT GUIDELINES

Follow all pesticide label requirements and the guidelines below to minimize the risk of developing glyphosate-resistant weed populations in a Genuity™ Roundup Ready® spring canola system:

- Scout fields before and after each burndown and in-crop application.
- Start clean with a burndown herbicide or tillage.
- In-crop, apply Roundup WeatherMAX® herbicide before weeds exceed 3" in height.
- A sequential application of Roundup WeatherMAX herbicide may be needed.
- Clean equipment before moving from field to field to minimize the spread of weed seed.
- Report repeated non-performance to Monsanto or your local retailer.

WEED CONTROL RECOMMENDATIONS (SPRING-SEEDED)

PROGRAM	INSTRUCTIONS AND USE RATES*	ADDITIONAL INFORMATION
Two-Pass Program– For Annual and Perennial Weed Control	For broad-spectrum control of annual and perennial weeds, use an initial application of 11 oz/A of Roundup WeatherMAX**, in 5 to 10 gal/A water volume. No surfactant is required. Make a second application of 11 oz/A of Roundup WeatherMAX** no less than 10 days after initial application up to the 6-leaf stage (prebolting). Do not exceed 11 oz/A per application.	Spray when canola is at the 0- to 6-leaf stage of growth. To maximize yield potential, spray Genuity™ Roundup Ready® spring canola at the 1- to 3-leaf stage to eliminate competing weeds. Short-term yellowing may occur with later applications, with little effect on crop growth, maturity, or yield. Wait a minimum of 10 days between applications. Two applications of Roundup WeatherMAX will: • Control late flushes of annual weeds such as foxtail, pigweed, and wild mustard. • Provide season-long suppression of Canada thistle, quackgrass, and perennial sow thistle. • Provide better yields by eliminating competition from both annuals and hard-to-control perennials.
Single Application– For Annual Weed Control	For broad-spectrum control of annual and easy-to-control perennial weeds, make a single application of 16 oz/A of Roundup WeatherMAX.**	For best results, spray Genuity™ Roundup Ready® spring canola at the 2- to 3-leaf stage. Can be applied up to 6-leaf stage; yellowing may occur with later application with little effect on crop growth, maturity, or yield. No additional over-the-top applications can be made.
Maximum Use Rate For Roundup WeatherMAX	Two over-the-top applications: Do not exceed 11 oz/A per application. Single over-the-top applications: Do not exceed 16 oz/A. No additional application can be made.	

*Follow all pesticide label requirements.

**If using another Roundup agricultural herbicide, you must refer to the label booklet or separately published Genuity™ Roundup Ready® canola supplemental label for that brand to determine appropriate use rates. If using Roundup PowerMAX, application rates are the same as for Roundup WeatherMAX.

GENUITY™ ROUNDUP READY™ WINTER CANOLA

Genuity™ Roundup Ready® winter canola varieties have been developed for seeding in the fall and harvesting the following spring/summer.

Genuity™ Roundup Ready® winter canola varieties contain in-plant tolerance to Roundup® agricultural herbicides, enabling farmers to apply Roundup agricultural herbicides over the top of Genuity™ Roundup Ready® winter canola from crop emergence to the pre-bolting stage. The introduction of the Roundup Ready trait into winter canola varieties gives farmers the opportunity of unsurpassed weed control, crop safety and maximum yield potential. Genuity™ Roundup Ready® winter canola offers farmers an important option as a rotational crop in traditional monoculture winter wheat production areas. Introducing crop rotation is an important factor in reducing pest cycles, including weed and disease problems.

WEED RESISTANCE MANAGEMENT GUIDELINES

Follow the same guidelines as stated for spring canola.

WEED CONTROL RECOMMENDATIONS (WINTER-SEEDED)

PROGRAM	INSTRUCTIONS AND USE RATES*	ADDITIONAL INFORMATION
Sequential Applications	The two-pass program gives the greatest flexibility in controlling late emerging weeds. For broad-spectrum weed control, apply 11 to 22 oz/A of Roundup WeatherMAX** herbicide to 2-leaf or larger Genuity™ Roundup Ready® winter canola in the fall. Use 5 to 10 gallons/A water volume. Do not add surfactants. Apply a second application of Roundup WeatherMAX** at 11 to 22 oz/A at a minimum interval of 60 days after the first application and before bolting in the spring. Do not exceed 22 oz/A per application.	Spray when Genuity™ Roundup Ready® winter canola is at the 2-3 leaf stage of growth. Early applications can eliminate competing weeds and improve yield potential. Two applications of Roundup WeatherMAX will provide control of early emerging annual weeds and winter emerging weeds such as downy brome, cheat and jointed goatgrass.
Single Application	For broad-spectrum control of annual and easy-to-control perennial weeds, make a single application of 16 to 22 oz/A of Roundup WeatherMAX**, preferably in the fall.	For best results, spray Genuity™ Roundup Ready® winter canola at the 2-3 leaf stage and when weeds are small and actively growing. Applications must be made prior to bolting. Use the higher rate in the range when weed densities are high, when weeds have over wintered or when weeds become large and well established.
Maximum Use Rate for Roundup WeatherMAX	Any single over-the-top application of Roundup WeatherMAX** should not exceed 22 oz/A. No more than two over-the-top applications may be made from crop emergence to canopy closure prior to bolting in the spring.	Applications of greater than 16 fluid ounces/A prior to the 6-leaf stage may result in temporary yellowing and/or growth reduction.

*Follow all pesticide label requirements.

**If using another Roundup brand herbicide, you must refer to the label booklet or Genuity™ Roundup Ready® winter canola supplemental label for that brand to determine appropriate use rates. If using Roundup PowerMAX, application rates are the same as for Roundup WeatherMAX.

GRAZING

It is recommended that Genuity™ Roundup Ready® winter canola not be grazed. While Genuity™ Roundup Ready® winter canola may provide farmers additional opportunity as a forage for grazing livestock, at the present time insufficient information exists to allow safe and proper grazing recommendations. Preliminary data suggest that excessive grazing can significantly reduce yield, and that careful nitrate management is critical in managing Genuity™ Roundup Ready® winter canola as a forage to limit the risk of livestock nitrate poisoning. State universities are assessing the potential and the instructions for grazing Genuity™ Roundup Ready® winter canola and they will provide grazing management guidelines when their research is completed.

GENUITY™ ROUNDUP READY® SUGARBEETS

Genuity™ Roundup Ready® sugarbeet varieties have in-plant tolerance to Roundup® agricultural herbicides, enabling farmers to apply labeled Roundup agricultural herbicides from planting through 30 days prior to harvest for unsurpassed weed control, excellent crop safety and preservation of yield potential.

MANAGEMENT PRACTICES

Sugarbeets are extremely sensitive to weed competition for light, nutrients and soil moisture. Research on sugarbeet weed control suggests that sugarbeets need to be kept weed-free for the first eight weeks of growth to protect yield potential. Therefore, weeds must be controlled when they are small and before they compete with Genuity™ Roundup Ready® sugarbeets (exceed crop height), that is from less than 2" up to 4" in height, to preserve sugarbeet yield potential. *More than one in-crop herbicide application will be required* to control weed infestations to protect yield potential as Roundup agricultural herbicides have no soil residual activity. Bolting sugarbeets must be rogued or topped in Genuity™ Roundup Ready® sugarbeet fields.

Genuity™ Roundup Ready® sugarbeet varieties have excellent tolerance to over-the-top applications of labeled Roundup agricultural herbicides. A postemergence weed control program using Roundup WeatherMAX® or Roundup PowerMAX® will provide excellent weed control in most situations. A residual herbicide labeled for use in sugarbeets may also be applied preemergence, preplant or postemergence in Genuity™ Roundup Ready® sugarbeets. Contact a Monsanto Representative, local crop advisor or extension specialist to determine the best option for your situation.

WEED RESISTANCE MANAGEMENT FOR GENUITY™ ROUNDUP READY® SUGARBEETS

Follow all pesticide label requirements and the guidelines below to minimize the risk of developing glyphosate-resistant weed populations in a Genuity™ Roundup Ready® sugarbeet system:

- Start clean with tillage and follow-up with a burndown herbicide, such as Roundup WeatherMAX, if needed prior to planting.
- Early-season weed control is critical to protect sugarbeet yield potential. Apply the first in-crop application of Roundup WeatherMAX at a minimum of 22 oz/A while weeds are less than 2" in height.
- Follow with additional postemergence in-crop application of Roundup WeatherMAX at a minimum of 22 oz/A for additional weed flushes before weeds exceed 4" in height.
- Add spray grade ammonium sulfate at a rate of 17 lbs/100 gallons of spray solution with Roundup® agricultural herbicides to maximize product performance.
- Use mechanical weed control/cultivation and/or residual herbicides where appropriate in your Genuity™ Roundup Ready® sugarbeets.
- Use additional herbicide modes of action/residual herbicides and/or mechanical weed control in other Roundup Ready crops you rotate with Genuity™ Roundup Ready® sugarbeets.
- Report repeated non-performance of Roundup agricultural herbicides to Monsanto or your local retailer.

AGRONOMIC PRINCIPLES IN SUGARBEETS

Sugarbeets are very sensitive to early-season weed competition. It is important to select the appropriate herbicide product, application rate and timing to minimize weed competition to protect yields. The Genuity™ Roundup Ready® sugarbeet system provides a mechanism to control weeds at planting and once Genuity™ Roundup Ready® sugarbeets emerge. Failure to control weeds with the right rate, at the right time and with the right product, can lead to increased weed competition, weed escapes and the potential for decreased yields. Tank-mixtures of Roundup agricultural herbicides with fungicides, insecticides, micronutrients or foliar fertilizers are not recommended as they may result in crop injury and reduced pest control or antagonism.

PLANTING REQUIREMENTS

Genuity™ Roundup Ready® sugarbeets are not permitted to be planted in any wildlife feed plots.

STEWARDSHIP

All Genuity™ Roundup Ready® sugarbeet farmers shall sign the Monsanto Technology/Stewardship Agreement (MTSA) limited-use license application which provides the terms and conditions for the authorized use of the product. The MTSA must be signed and approved prior to purchase or use of seed.

WEED CONTROL RECOMMENDATIONS

PROGRAM	INSTRUCTIONS AND USE RATES*	ADDITIONAL INFORMATION
Preplant Burndown	After preplant tillage or bedding operations have been completed, a preplant burndown application of Roundup WeatherMAX®** at 22 to 44 oz/A may be applied to control weeds that have germinated after tillage and prior to planting. See the label for appropriate rates by weed species and weed size.	Always utilize tillage to start with a weed-free field.
Over-The-Top Applications up to eight-leaf Genuity™ Roundup Ready® Sugarbeets	Up to two applications of Roundup agricultural herbicides may be made prior to the 8-leaf stage of Genuity™ Roundup Ready® sugarbeets. The first application of 22 to 32 oz/A of Roundup WeatherMAX** should be made when weeds are less than 2" in height to protect yield potential. Make an additional application of 22 to 32 oz/A of Roundup WeatherMAX before weeds exceed 4" in height. Maximum in-crop Roundup WeatherMAX prior to 8-leaf stage must not exceed 56 oz/A.	Sugarbeets are sensitive to weed competition and can lose yield rapidly if weeds are not controlled early. More than one in-crop Roundup WeatherMAX application will be required to control weed infestations to protect yield potential as Roundup agricultural herbicides have no soil residual activity. Add ammonium sulfate at a rate of 17 lbs/100 gallons of spray solution with Roundup agricultural herbicides to maximize product performance. Tank-mixtures of Roundup agricultural herbicides with fungicides, insecticides, micronutrients or foliar fertilizers are not recommended. Sequential applications should be at least 10 days apart.
Over-The-Top Applications to greater than eight-leaf Genuity™ Roundup Ready® Sugarbeets	Up to two additional applications of 22 oz/A of Roundup WeatherMAX can be made after the eight-leaf stage up to 30 days prior to harvest. Maximum in-crop Roundup WeatherMAX from 8-leaf stage up until 30 days prior to harvest must not exceed 44 oz/A.	Add ammonium sulfate at a rate of 17 lbs/100 gallons of spray solution with Roundup agricultural herbicides to maximize product performance. Tank-mixtures of Roundup agricultural herbicides with fungicides, insecticides, micronutrients or foliar fertilizers are not recommended. Sequential applications should be at least 10 days apart.
Maximum Use Rates	**In-Crop:** • Two applications of Roundup WeatherMAX prior to the 8-leaf stage of Genuity™ Roundup Ready® sugarbeets - 32 oz/A per single application up to the 8-leaf stage. - Combined maximum of 56 oz/A in-crop prior to the 8-leaf stage • Two applications of Roundup WeatherMAX after the 8-leaf stage up to 30 days prior to harvest - 22 oz/A per single application after the 8-leaf stage. - Combined maximum of 44 oz/A in-crop after the 8-leaf stage until 30 days prior to harvest	**Total Per Year:** The combined total per year for all Roundup WeatherMAX applications including pre-plant must not exceed 5.3 qt/A. Total in-crop application must not exceed 3 qt/A. Add ammonium sulfate at a rate of 17 lbs/100 gallons of spray solution with Roundup agricultural herbicides to maximize product performance. Tank-mixtures of Roundup agricultural herbicides with fungicides, insecticides, micronutrients or foliar fertilizers are not recommended.

*Follow all pesticide label requirements.

**If using another Roundup agricultural herbicide, you must refer to the label booklet or separately published Genuity™ Roundup Ready® sugarbeets supplemental label for that brand to determine appropriate use rates. If using Roundup PowerMAX, application rates are the same as for Roundup WeatherMAX.

This guide was printed using Utopia II XG Cover and Text which contains 30% post-consumer waste. Savings derived from using 30% post-consumer fiber in lieu of 100% virgin fibers:

- Saves the equivalent of 585 mature trees
- Reduces solid waste by 35,308 pounds
- Reduces waste water by 213,390 gallons
- Reduces greenhouse gas emissions by 199,989.75 pounds

Before opening a bag of seed, be sure to read, understand and accept the stewardship requirements, **including applicable refuge requirements for insect resistance management,** for the biotechnology traits expressed in the seed as set forth in the Monsanto Technology Agreement that you sign. By opening and using a bag of seed, you are reaffirming your obligation to comply with the most recent stewardship requirements.

Roundup Ready® Alfalfa seed is currently not for sale or distribution. The movement and use of Roundup Ready® Alfalfa forage is subject to a USDA administrative Order available at http://www.aphis.usda.gov/brs/pdf/RRA_AB_final.pdf.

This stewardship statement applies to all products listed herein except Genuity™ VT Double PRO™, Genuity™ VT Triple PRO™ and Genuity™ SmartStax™. See restrictions related to Genuity™ Double PRO™, Genuity™ VT Triple PRO™ and Genuity™ SmartStax™ below:

Monsanto Company is a member of Excellence Through Stewardship® (ETS). Monsanto products are commercialized in accordance with ETS Product Launch Stewardship Guidance, and in compliance with Monsanto's Policy for Commercialization of Biotechnology-Derived Plant Products in Commodity Crops. This product has been approved for import into key export markets with functioning regulatory systems. Any crop or material produced from this product can only be exported to, or used, processed or sold in countries where all necessary regulatory approvals have been granted. It is a violation of national and international law to move material containing biotech traits across boundaries into nations where import is not permitted. Growers should talk to their grain handler or product purchaser to confirm their buying position for this product. Excellence Through Stewardship® is a registered trademark of Biotechnology Industry Organization.

IMPORTANT: Grain Marketing and Seed Availability: Genuity™ VT Double PRO™ has received the necessary approvals in the United States, however, as of October 22, 2009, approvals have not been received in certain major corn export markets. **Genuity™ VT Double PRO™** will not be launched and seed will not be available until after import approvals are received in appropriate major corn export markets. **B.t. products, including Genuity™ VT Double PRO™** may not yet be registered in all states. Check with your Monsanto representative for the registration status in your state.

IMPORTANT: Grain Marketing and Seed Availability: Genuity™ VT Triple PRO™ has received the necessary approvals in the United States however, as of October 22, 2009, approval has not been received in all major corn export markets. Monsanto anticipates that all such approvals will be in place for the 2010 growing season. If all approvals are not in place, **Genuity™ VT Triple PRO™** seed will only be available as part of a commercial demonstration program that includes grain marketing stewardship requirements. It is a violation of national and international law to move material containing biotech traits across boundaries into nations where import is not permitted. Consult with your seed representative for current regulatory and stewardship information status.

IMPORTANT: Grain Marketing and Seed Availability: Genuity™ SmartStax™ has received the necessary approvals in the United States, however, as of October 22, 2009, approvals have not been received in certain major corn export markets. **Genuity™ SmartStax™** will not be launched and seed will not be available until after import approvals are received in appropriate major corn export markets. **B.t. products, including Genuity™ SmartStax™** may not yet be registered in all states. Check with your Monsanto representative for the registration status in your state.

Cottonseed containing Monsanto traits may not be exported for the purpose of planting without a license from Monsanto.

Individual results may vary, and performance may vary from location to location and from year to year. This result may not be an indicator of results you may obtain as local growing, soil and weather conditions may vary. Growers should evaluate data from multiple locations and years whenever possible.

Growers may utilize the natural refuge option for varieties containing the Bollgard II® trait in the following states: AL, AR, FL, GA, KS, KY, LA, MD, MS, MO, NC, OK, SC, TN, VA, and most of Texas (excluding the Texas counties of Brewster, Crane, Crockett, Culberson, El Paso, Hudspeth, Jeff Davis, Loving, Pecos, Presidio, Reeves, Terrell, Val Verde, Ward and Winkler). The natural refuge option does not apply to **Bollgard II** cotton grown in areas where pink bollworm is a pest, including CA, AZ, NM, and the above listed Texas counties. It also remains the case that **Bollgard®** and **Bollgard II** cotton cannot be planted south of Highway 60 in Florida, and that **Bollgard** cotton cannot be planted in certain other counties in the Texas panhandle. Refer to the Technology Use Guide and IRM/Grower Guide for additional information regarding Bollgard II, Bollgard, natural refuge and EPA-mandated geographical restrictions on the planting of *B.t.* cotton.

ALWAYS READ AND FOLLOW PESTICIDE LABEL DIRECTIONS. Roundup Ready® crops contain genes that confer tolerance to glyphosate, the active ingredient in Roundup® brand agricultural herbicides. Roundup® brand agricultural herbicides will kill crops that are not tolerant to glyphosate. Degree® and Harness® are not registered in all states. Degree® and Harness® may be subject to use restrictions in some states. Bullet®, Degree Xtra®, Harness®, INTRRO®, Lariat®, and Micro-Tech™ are restricted use pesticides and are not registered in all states. The distribution, sale, or use of an unregistered pesticide is a violation of federal and/or state law and is strictly prohibited. Check with your local Monsanto dealer or representative for the product registration status in your state.

Tank mixtures: The applicable labeling for each product must be in the possession of the user at the time of application. Follow applicable use instructions, including application rates, precautions and restrictions of each product used in the tank mixture. Monsanto has not tested all tank mix product formulations for compatibility or performance other than specifically listed by brand name. Always predetermine the compatibility of tank mixtures by mixing small proportional quantities in advance.
