

DEPARTMENT OF DEFENSE APPROPRIATIONS FOR FISCAL YEAR 2015

WEDNESDAY, MARCH 5, 2014

U.S. SENATE,
SUBCOMMITTEE OF THE COMMITTEE ON APPROPRIATIONS,
Washington, DC.

The subcommittee met at 9:58 a.m., in room SD-192, Dirksen Senate Office Building, Hon. Richard Durbin (chairman) presiding.
Present: Senators Durbin, Feinstein, Cochran, and Shelby.

NATIONAL SECURITY SPACE LAUNCH PROGRAMS

**STATEMENT OF CRISTINA CHAPLAIN, DIRECTOR, ACQUISITION AND
SOURCING MANAGEMENT, GOVERNMENT ACCOUNTABILITY OF-
FICE**

OPENING STATEMENT OF SENATOR RICHARD J. DURBIN

Senator DURBIN. Good morning, and welcome to this meeting of the Defense Appropriations Subcommittee. We're going to start a minute or two early, which is unprecedented in the Senate because we have votes scheduled, and I want to try to get as much testimony in as possible before we might have to break for a vote, should that occurrence arise soon. So I'll make my opening statement. I want to acknowledge at the beginning that Senator Cochran is not late; no one is late at this point. I'm starting a minute or two in advance.

Today, the defense subcommittee will receive testimony on national security space launches, with a focus on the Evolved Expendable Launch Vehicle, or the EELV, program. Our questions expose some of the core tradeoffs in defense policy and highlight several challenges we face as a Nation.

What is the best use of taxpayers' money? How do we promote and reward innovation? How do we safeguard the viability of our industrial base? How do we protect our competitive edge against other nations? We'll return to these questions and many others throughout the year as we review the President's fiscal year 2015 defense budget, which we received just this week.

Today, we discuss the EELV program, which was created almost 20 years ago when the costs and risks of launching satellites were out of control. EELV missions launch the most important satellites developed by the Air Force, National Reconnaissance Office, and the Navy, not to mention NASA (National Aeronautics and Space Administration) and a few number of commercial customers.

The program has been extremely successful in launching satellites that cost the U.S. taxpayers literally billions of dollars. The safety record of the Atlas V and Delta IV rockets made by the United Launch Alliance (ULA) is remarkable. But we do have some concerns about the acquisition strategy and costs and future of that program. From 2011 to 2014, the amount the Air Force budgeted for an average of six satellite launches per year grew by 60 percent in that 3-year period.

There are many answers as to why the program became more expensive, but the important question is: What should we do about it? Over the past 3 years, the Air Force has tried to control costs by stabilizing ULA production with a block buy of 36 rockets from ULA, while fostering competition from entrants such as SpaceX.

The subcommittee needs to better understand the cost of the current program, how to ensure that competition is fair and presents the best value to the Government, and whether we need to do more to ensure that we can deliver satellites on orbit in the most efficient and affordable manner.

These decisions on how to purchase access to space could have lessons that are applicable to many other defense capabilities. Could the Pentagon learn to live with only one major supplier of rockets by better managing that industrial capability with smarter buying and better negotiating? Or should the Department of Defense (DOD) be more forward-leaning and embrace companies that challenge the rules on how we normally run defense programs?

It's been the general practice of the Appropriations Committee to direct questions about acquisitions programs to the Government officials responsible for the use of taxpayer money. Today we're taking a different approach by going into the details of the EELV program with the two companies most involved in the upcoming competition, as well as two distinguished experts in space acquisitions.

Their views and insights on the EELV program will inform the subcommittee's deliberations on the fiscal year 2015 budget request and also shape our thinking about how the Department of Defense can best maintain access to space in a fiscally constrained environment.

I'm going to welcome our witnesses, Cristina Chaplain, Director of Acquisition Sourcing and Management at the Government Accountability Office (GAO); Michael Gass, President and CEO of United Launch Alliance; Elon Musk, CEO and Chief Designer of Space Exploration Technologies; Dr. Scott Pace, Director of the Space Policy Institute at the Elliott School of International Affairs, George Washington University.

I am going to ask the witnesses to provide their 5-minute opening statements, but I note the presence of the ranking member of the full Appropriations Committee, Senator Shelby of Alabama. I'd like to give you an opportunity, if you wish, for an opening statement.

Senator SHELBY. Thank you very much. I will try to be brief because we have a distinguished panel here.

Delivering national security satellites safely to orbit is one of our more important national security missions. This requirement is precisely why the Department of Defense focuses on mission suc-

cess and reliability in the Evolved Expendable Launch Vehicle, or what we call EELV, program.

This focus and the work of the EELV sole-source contractor, the United Launch Alliance, have resulted in 68 consecutive successful missions—68 consecutive successful missions. I recognize this achievement, not just as a Senator from Alabama, where the ULA performs its engine-assembly work, but as someone who has watched the defense industry for decades and knows that a 100 percent success rate is no small feat.

As the Department of Defense moves forward with a new acquisition strategy for the EELV program, I believe we must ensure that the program's record of success is maintained. Much of today's discussion will focus on competition, and I agree that competition typically results in better quality and lower-priced contracts. But the launch market is not typical. It is limited demand. In its limited demand, it is framed by Government industrial policies.

While the goal of competition is to lower the cost of access to space, which I think is good, combined with the need to maintain performance and reliability, such as we have today, competition may not actually result in a price reduction for the Federal Government.

I believe that much of the costs associated with the EELV program today can be attributed to the Department of Defense decisions about the structure of the program, including the practice of purchasing one launch vehicle at a time rather than a lack of competition. Simply modifying this buying strategy alone and moving into a new block-buy approach has already resulted in significant savings and will ultimately be saving billions of dollars.

The Air Force, for example, has estimated \$4.4 billion savings so far. The wise stewardship of taxpayer resources is essential in all Government programs, and oftentimes competition is key. In this case, the safety and security of our national security payloads is paramount.

PREPARED STATEMENT

I'm not convinced yet that a wholesale change in the EELV program is the answer when we've witnessed significant results from a minor modification to purchasing practices in the existing program.

But I do look forward to the testimony of our witnesses on the role of competition in this unique market and an exchange as to why a sea change in the program is necessary to achieve savings, if it is.

Thank you, Mr. Chairman.

Senator DURBIN. Thank you very much, Senator Shelby.

Senator Cochran has submitted a statement to be included in the record.

[The statement follows:]

PREPARED STATEMENT OF SENATOR THAD COCHRAN

Mr. Chairman, I am pleased to join you, this morning, in welcoming our distinguished panel of witnesses for the Defense Subcommittee's first hearing of the year. I am happy to see that our panel today includes independent witnesses from GAO and the Space Policy Institute, as well as, the CEOs of two companies, ULA and

SpaceX, who participate in the valuable space work occurring in Mississippi, at the Stennis Space Center.

Today's hearing is quite timely, as recent events in the launch industry are bringing about rapid and complex changes to the Evolved Expendable Launch (EELV) program, the primary provider of launch vehicles and services for U.S. military and intelligence satellites. The Air Force is implementing a strategy to reintroduce competition into the EELV program, while at the same time ensuring that the significant mission success achieved by United Launch Alliance, the sole-source launch provider since 2006, is maintained.

This will not be an easy feat. I have been informed that yesterday the GAO finalized a report on the challenges of competition, and I anticipate that Ms. Chaplain and all of our witnesses will discuss those challenges today. I look forward to the testimony of our witnesses.

Senator DURBIN. Now we will have our witnesses give an opening statement. Their written statement will be made part of the record. If they will take 5 or 6 minutes to summarize it, we can then open it to questions.

The first person to testify, Cristina Chaplain, as I mentioned, Director of Acquisition Sourcing and Management at the Government Accountability Office, which has done a comprehensive review of this issue, which I commend to my colleagues and those who are following this debate.

Ms. Chaplain, please proceed.

SUMMARY STATEMENT OF CRISTINA CHAPLAIN

Ms. CHAPLAIN. Mr. Chairman, thank you for inviting me today. I'm very pleased to be here to discuss the EELV program.

The program itself has been through different contract arrangements and acquisition strategies. There was competition at the beginning of the program with the aim of ultimately selecting one company, though the Government opted to keep two companies, based on the assumption that there would be a surge in commercial demand that would allow the Government to benefit from lower costs.

Fixed-priced contracts were used also in the early part of the program, and the Government was able to benefit from prices that were lower because the companies purchased items in bulk, key items in bulk, in anticipation of the predicted high demand of the commercial market.

After the commercial market did not materialize as expected, however, there were several significant changes. Two suppliers merged into one. The Government began using a fixed-price contract to acquire launch services and a cost-type contract to acquire the capability to launch that hardware.

In view of launch failures that occurred in the late 1990s with the heritage launch program, the Government placed most of its focus on mission success and not as much on controlling costs. As you mentioned, there has been a good record of success since then.

In 2011, the Air Force embarked on a block-buy strategy in anticipation of significant price increases. However, the GAO found that the Government did not have the knowledge it needed to make such a significant commitment, particularly with respect to program costs and the launch industrial base. At the time, there were also mixed views within DOD about the value and viability to introduce competition to help lower prices, but DOD ultimately set out to do so.

Since our 2011 report, DOD has made strides in gaining knowledge about costs and other issues surrounding EELV, and it has achieved significant savings in negotiating the block buy. There may be a debate as to the validity and extent of the savings, but we do know that the DOD performed the analyses and the studies that better armed it for negotiations. Further, the program now benefits from auditable business systems and greater oversight. DOD deserves much credit for these efforts.

There were also significant positive changes in the new contracts, but the basic way of acquiring launch services remains the same. There is a fixed-price arrangement for the vehicles themselves and a cost arrangement for the capability to launch the vehicles, which includes things like systems engineering and integration.

It is important to keep in mind that the capability contract maximizes the Government's flexibility, which is beneficial when there are delays in satellite deliveries. The block-buy contract is for 35 rocket cores, and DOD plans to compete up to 14 cores starting as early as 2015.

There are a number of ways DOD could run this competition. We looked at two ways at each end of the spectrum for some recent work we did for the Congress. One is to contract similar to the way it currently contracts with ULA. The other is to follow a commercial approach. My statement details the benefits and challenges of both.

In short, if DOD contracts similar to the way it contracts with ULA, DOD could retain insight into contractor cost or pricing data, which would lend itself to a better bargaining position in future negotiations. But this approach could also add costs for the new entrants, including a cost-plus portion and bid proposals, for instance, would require them to develop and install new business systems to fulfill Government data requirements.

If DOD followed a commercial approach, it could have an avenue to decrease launch prices and increase efficiencies. However, it would also likely lose access to contractor cost and pricing data and some flexibility in rescheduling launches of satellites should deliveries slip.

We did not recommend an approach. It is not GAO's role to do so, and there are other possible approaches. The goal of introducing competition is being achieved, though the competitors may prefer different paths.

PREPARED STATEMENT

The factors that DOD will need to weigh as it makes its choice likely include the need to maintain a high degree of reliability, as the satellites being launched are expensive and are vital to national security; the need for flexibility in launches; the importance of retaining costs and pricing data; the need to keep costs down; and considerations about the future Government's demand for launch services.

This concludes my statement, and I'm happy to answer any questions you have.

[The statement follows:]

PREPARED STATEMENT OF CRISTINA CHAPLAIN

INTRODUCTION

The Department of Defense's Evolved Expendable Launch Vehicle (EELV) program is the primary provider of launch vehicles and services for U.S. military and intelligence satellites. The launch vehicles used by the EELV program are also used to launch civilian and commercial satellites.

GAO was asked to examine issues related to DOD's effort to introduce competition into EELV acquisitions. Doing so is a significant challenge given the way contracts are currently structured, the fact that new providers are not yet certified to carry sensitive national security satellites and sensors—or payloads—into space, and other complications. The issues GAO was asked to examine include the way that DOD determines costs for launch services with its current contractor and how DOD will compare future offers from different launch services contractors.

Program Description and History

The EELV program started in 1995 when DOD awarded contracts to four companies for preliminary launch vehicle system designs; at that time, DOD's acquisition strategy was to select the one company with the most cost-effective design.

Given commercial forecasts that predicted sufficient demand to support two launch vehicle providers, in 1997 the Secretary of Defense approved maintaining competition between the two top companies: Lockheed Martin, and what would become Boeing.

In 2006, following years of projected commercial demand for launch vehicles that did not materialize and increasing launch costs, the two EELV contractors formed a separate company as a joint venture—the United Launch Alliance (ULA).

From 2006–2013, DOD had two types of contracts with ULA, the sole-source provider, to support the EELV program:

- a cost-plus-incentive-fee EELV launch capability contract (ELC);¹ and
- a firm-fixed-price EELV launch services contract (ELS).²

Since 2006, ULA has launched 50 government missions on EELVs, with an extremely high rate of success, and DOD values this reliability. However, in 2010, program cost estimates indicated launch prices were expected to increase at an unsustainable rate, and DOD began an effort to develop a new EELV acquisition strategy.

The November 2011 strategy was designed to maintain mission success and incentivize price reductions through steady production rates, long-term commitments, opportunities for competition and reductions in workforce redundancy.

In December 2013, DOD and ULA signed a contract modification, committing DOD to buy 35 launch vehicle booster cores from ULA over a 5-year period, and to pay ULA for the associated capability to launch them.³

According to DOD, two primary goals of this long-term sole-source commitment were to increase production stability for ULA and its suppliers, and to reduce the price per launch vehicle.

The most recent independent cost estimate projects the program will cost close to \$70 billion through 2030.⁴

¹In July 2011, the EELV program awarded a Launch Capability contract as a cost-plus incentive fee contract; the prior Launch Capability contract was a cost-plus award fee contract. A cost-plus incentive fee contract is a type of cost reimbursement contract that pays the contractor for allowable costs to the extent prescribed in the contract, and allows for the initially negotiated fee to be adjusted later, based on a formula in the contract. The fee is based on the relationship of total allowable costs to total target cost.

²A firm-fixed-price contract provides for a price that is not subject to any adjustment on the basis of the contractor's cost experience in performing the contract.

³The booster core is the main body of a launch vehicle. In the EELV program, common booster cores are used to build all of the Atlas V and Delta IV launch vehicles. Medium and intermediate launch vehicles use one core each, while the Delta IV Heavy launch vehicle requires three.

⁴The Office of the Secretary of Defense, Cost Assessment and Program Evaluation conducted an independent cost estimate based on the EELV programmatic forecast dated June 2012.

FIGURE 1: EELV PROGRAM TIMELINE

Reimbursement to DOD for Use of ULA Facilities by Other Customers

DOD has historically paid all fixed costs for ULA. Prior to the December 2013 contract modification, when ULA sold a launch to another customer, and not through the EELV program office, ULA provided a small reimbursement to DOD for the other customer's use of ULA facilities and infrastructure. There have been concerns that the reimbursement was too small.

New Entrants to the Launch Market

In recent years, companies other than ULA have begun developing new launch vehicles to compete with ULA for EELV-class payloads, and DOD set aside up to 14 launch vehicle booster cores from fiscal years 2015 to 2017 for competition.⁵ This competition is expected to begin in fiscal year 2015.

In order to compete for any of the 14 additional launches these cores represent, new entrant companies have to follow the process outlined by DOD in its Launch Services New Entrant Certification Guide to certify a new vehicle to launch national security missions.

At this point, none of the likely competitors are able to launch the full range of EELV-class payloads, though at least one company plans to meet the full requirements through further launch vehicle development.

Given the use of different contract types and launch vehicle cost allocation practices among contractors, DOD is currently developing a methodology for comparing proposals from all competitors. DOD officials may include this methodology as part of their first request for proposal from launch companies in the competition.

OBJECTIVES

This briefing addresses the following questions:

- (1) What insight did DOD have into launch costs under past EELV contracts?
- (2) How do recent changes to EELV contracts affect accounting for costs?
- (3) How is DOD compensated for costs when ULA sells launches to other customers?
- (4) What are the implications if DOD requires competitors to submit offers using the same structure it currently uses with ULA or a commercial approach?

SUMMARY OF FINDINGS

GAO found:

- (1) The previous two-contract structure paid ULA for continuing launch capability to enable the U.S. to readily gain access to space, but one consequence of the structure was that DOD had difficulty determining the cost of an individual launch, as direct launch costs were not separated from other costs.
- (2) In the December 2013 EELV contract modification with ULA, DOD leveraged better insight into contractor costs to negotiate lower prices, and incentivized ULA to increase efficiencies, but DOD may have difficulty identifying the total cost of an individual launch.
- (3) The December 2013 contract modification stipulates that when ULA sells a launch to customers outside the EELV program office, ULA will adjust the value of the EELV contract by a pre-negotiated amount for each outside launch it sells. Historically the reimbursements have been small compared to the overall launch capability paid for, but DOD recently negotiated larger reimbursements with some direct costs tied to individual launches.
- (4) Even with greater insight into contractor costs, DOD may not be immediately poised to take full advantage of competition in the launch market, because, in part, it cannot determine an accurate price for an individual ULA launch.

BACKGROUND: PAST GAO FINDINGS ON EELV

In 2008, we reported that the EELV program faced numerous oversight challenges, including uncertain launch vehicle reliability, disruption from the consolidation of Boeing and Lockheed Martin manufacturing and operations under the ULA joint venture, and limited programmatic insight due to the elimination of various reporting requirements resulting from the designation of the program as in sustainment. We also reported that DOD was adjusting the EELV budget using pre-

⁵ EELV-class payloads range from 6,000 to 28,000 lbs to Geosynchronous Transfer Orbit (GTO). They are divided into intermediate (6,000–18,000 lbs to GTO), and heavy (18,000–28,000 lbs to GTO) classes.

mature savings estimates, and made three recommendations to improve DOD oversight.

DOD reinstated reporting requirements and completed a new life-cycle cost estimate, but did not assess the EELV program's staffing needs to confirm whether shortages exist (GAO-08-1039).

In 2011, we found that DOD was using insufficient data, particularly data on costs and on the launch industrial base, and relying on contractor-supplied information to inform the development of a new EELV acquisition strategy. We recommended seven actions that would help address critical knowledge gaps.

In response, DOD reassessed the block buy contract, examined broader launch issues, incentivized the contractor to implement efficiencies without affecting mission success, indicated it does not intend to waive future data requirements, is working with the National Aeronautics and Space Administration (NASA) on heavy launch decisions and conducting an independent assessment of the launch industrial base, but has not developed a science and technology plan for evolving launch technologies (GAO-11-641).

In 2012, we reported that DOD had numerous efforts in progress to address the knowledge gaps and data deficiencies we identified in our 2011 report, and that these improvements would allow DOD to make more informed decisions on how to proceed with the EELV program (GAO-12-822).

Additionally, in 2013, we reported that DOD's implementation of its New Entrant Certification Guide, while generally satisfactory to the new entrants, posed some challenges to launch vehicle certification (GAO-13-317R).

OBJECTIVE 1: ACCOUNTING FOR COSTS UNDER PAST EELV CONTRACTS

Reasons for the Two-Contract Structure

In 2005, DOD modified the way it contracted for EELV launches.

—The need for flexibility in launch schedules encouraged DOD to pay for launch capability (primarily labor) separately from the launch hardware, as DOD wanted to avoid additional costs associated with the frequent launch delays they were experiencing as new satellites were being developed and produced.⁶

By paying for a capability to launch, or “standing army” of personnel (particularly engineers), separately from the launch hardware, DOD believed it was ensuring itself access to space in a timely manner, regardless of payload delays.

Basic Contract Structure of Past EELV Contracts

From 2006–2013, ULA had two types of contracts with DOD through which it provided launch services for national security space launches:

- EELV launch capability (ELC): cost-reimbursement contracts which funded items that, according to DOD officials, were not easily acquired under a fixed-price contract, such as overhead on launch pads and engineering support.⁷
- EELV launch services (ELS): firm-fixed-price contracts that paid for launch vehicle hardware and labor directly associated with building and assembling launch vehicles.

TABLE 1: DETAILS OF THE EELV TWO-CONTRACT STRUCTURE

	EELV Launch Capability (ELC)	EELV Launch Services (ELS)
Contract type	Cost-plus incentive fee	Firm-fixed price.
Purpose	To acquire launch capability—the “standing army” required to maintain assured access to space for 8 launches per year.	To acquire launch hardware.
Items covered by the contract.	Includes items not included in ELS such as: mission integration, systems engineering, production management, propellants, transportation, labor to conduct launches, etc.	Launch vehicle hardware, production, and directly associated touch labor.
Number of active contracts.	Only one contract active at any time	Multiple contracts with ULA active at any time.

⁶ We have frequently reported that many of these satellite development and production delays could have been reduced or avoided by using best practices in space acquisition processes.

⁷ As previously noted, in July 2011 DOD awarded a Launch Capability contract as a cost-plus incentive fee contract; prior to that award, the contract was a cost-plus award fee contract.

TABLE 1: DETAILS OF THE EELV TWO-CONTRACT STRUCTURE—Continued

	EELV Launch Capability (ELC)	EELV Launch Services (ELS)
Length of contract term.	The contract covers one year of launch capability.	Varies; ELS contracts can be for one launch or multiple launches, and some can last for many years as the launches included in the contract are launched.

Source: GAO analysis of DOD contracts and related documents, and discussions with DOD officials.

Obscured Costs Under the Two-Contract Structure

ELC contracts did not require the contractor to break out costs associated with each launch; therefore, DOD was unable to calculate specific costs for individual EELV launch missions. For example, while each of the following costs could have been tied directly to an individual launch, DOD contracting officials included these items in the scope of the ELC—a cost-type contract—but did not require the contractor to separate them by individual launch:

- Propellants.*—Fuel expenses for each launch.
- Transportation.*—The cost of transporting a completed launch vehicle from the factory to the launch site.
- Mission Integration.*—The work involved in mating the satellite to the launch vehicle could be tied to the overall costs of a specific launch.

Challenges Encountered Under the ELC/ELS Structure

The EELV program under the ELC/ELS structure had some significant outcomes, but presented challenges to the program:

- Through the ULA joint venture and subsequent consolidation of operations, the government realized some significant savings. However, given the lack of incentive to identify efficiencies in the program's prior cost-reimbursement contract structure, and in an environment where no viable competition existed, program cost estimates showed launch prices were expected to rise.
- The program earned a record of consistent launch successes but, according to DOD, the focus of the program became primarily mission success, and not efficiencies or cost savings.
- According to DOD officials, the ELC contract structure was not transparent, and DOD had limited insight into some contractor costs, leading to:
 - insufficient knowledge to negotiate fair and reasonable launch prices,
 - lack of understanding of the total costs of any given launch, and
 - inadequate ability to account for costs reimbursed to DOD when ULA sold launches to non-DOD customers.

OBJECTIVE 2: RECENT CHANGES TO EELV CONTRACTS AND IMPACTS

Better Information to Support Contract Negotiations

As part of its effort to re-evaluate the EELV acquisition strategy, DOD has taken significant steps between 2010 and 2013 to obtain information to help it better identify the costs of EELV launches, and has made progress in reducing contract prices.

We reported in 2012 that detailed investigations, or “deep-dives,” into engine prices and other subcontractor costs have provided DOD better information with which to support contract negotiations with ULA. This insight was absent in past contract negotiations, in part because DOD waived rights to some contractor data in exchange for lower prices from large commercial hardware purchases.

Additionally, DOD has scrutinized launch processes to identify and eliminate potentially redundant activities.

DOD had better information in its recent contract negotiations with ULA, affording DOD a stronger bargaining position to lower overall contract costs than in recent years. As noted earlier, we recommended DOD obtain better data to strengthen DOD's bargaining position.

Gaining greater insight into contractor costs and reducing inefficiencies could have also benefited the program from the start of the joint venture in 2006, as program costs continued to rise.

Additionally, we reported in 2011 that competition could spur ULA efficiencies and incentivize ULA pricing. The presence of potential competition for launch services—a recent development—likely provided the context to help DOD negotiate lower prices.

Key Tenets of the New Contract

The December 2013 contract modification with ULA, sometimes referred to as a “block buy” contract, represents a major change from past year-to-year contracting approaches, and buys:

- Production of 35 launch vehicle booster cores over 5 years, from fiscal years 2013 through 2017.
- Launch capability for 6 years, from fiscal years 2014 through 2019.

Instead of two separate ELC/ELS contracts, the new single contract structure covers the entire EELV program, with contract line items for different aspects of the program, such as:

- launch vehicle hardware;
- launch capability, including systems engineering and production management;
- mission integration; and
- propellants.

According to DOD, some changes to the modified contract include:

- Better attribution of direct costs to launch vehicles, such as propellants and mission integration, into separate contract line items.
- More representative compensation to DOD when ULA sells a launch to a non-DOD customer.
- Compensation to DOD is roughly three times what it was under previous contracts with ULA (dollar amount is proprietary).
- DOD officials estimate about \$4.4 billion savings over the fiscal year 2012 President’s Budget estimate.
- Stable unit pricing for all launch vehicles.

However, while DOD can identify the cost of launch capability by year, it may be unable to determine the total cost of an individual launch because the majority of launch capability costs are not allocated to individual launches. Additionally, according to DOD, it is to pay for launch capability for 8 launches, even if fewer launches actually take place that year.

OBJECTIVE 3: COMPENSATION TO DOD FOR NON-DOD LAUNCHES

Historical Reimbursements

The 2004 U.S. Space Transportation Policy instructed DOD to fully fund the fixed costs of the EELV program. However, the 2013 National Space Transportation Policy does not instruct DOD to fully fund the fixed costs of the EELV program.

Prior to the December 2013 contract modification:

- ULA provided a small reimbursement to DOD for the resources used to launch missions sold to other customers, such as NASA or other government or commercial customers.
- DOD and ULA annually negotiated the value of the reimbursement.
- Reimbursements, also known as offsets:
 - represented the average 30-day cost of launch vehicle boosters on the launch pad for a given fiscal year, and not actual expenses.
 - differed based on which launch vehicle is used, and from which launch range the vehicle is flown.
 - were made through price reductions on the invoices ULA submitted to DOD.

Changes Under the December 2013 EELV Contract Modification

According to DOD officials, the December 2013 contract modification changes how launches sold to other customers are handled.

One significant change is the method by which DOD is to be compensated when ULA sells launches to other customers. Specifically, ULA and DOD will adjust the EELV contract value at the start of each fiscal year, based on the number of non-DOD launches ULA expects to sell that year.

DOD officials told us the EELV program intends to pay only for the capability it requires, that is, eight launches per year for the duration of the contract.

The contract also includes provisions for more representative compensation for non-DOD launches. For example, compensation to DOD will:

- be based in part on discrete, allocable costs per launch, and
- amount to roughly three times what was under previous contracts, though it still represents a small percentage of total capability paid for.

Although DOD negotiated larger dollar amounts in the current contract, DOD may not know if it is receiving fair and representative compensation because many ELC costs are not allocated by launch.

OBJECTIVE 4: IMPLICATIONS OF REQUIRING COMPETITORS TO BID LAUNCH PROPOSALS
USING AN ELC/ELS STRUCTURE OR COMMERCIAL APPROACH

Best Value Comparison

Based on our discussions with DOD, DOD plans to conduct a best value procurement where price is not the only consideration. DOD will likely consider several factors when comparing proposals for up to 14 additional launches available for competition between ULA and new entrants, including the following:

—*Price.*—Companies may be required to offer proposals that include capability (cost-reimbursement) and launch hardware (fixed-price) components, similar to the current ELC/ELS contract structure with ULA.

—*Mission risk.*—DOD will likely take past launch performance into account.

—*Mission Integration.*—DOD will likely consider any additional work required to integrate satellites onto each company's launch vehicles.

DOD has not yet decided whether to require competitors to submit offers using an ELC/ELS structure, a commercial approach, or some other type of proposal.

IMPLICATIONS TO DOD OF REQUIRING AN ELC/ELS STRUCTURE FOR LAUNCH PROPOSALS

Benefits to DOD	Challenges to DOD
DOD is familiar and experienced with the ELC/ELS approach of funding launches; this approach would not disrupt the current contractual arrangement with ULA. By requiring all companies to bid using an ELC/ELS structure, DOD would have a straightforward basis on which to compare proposals. Greater insight into contractor cost or pricing data could lend itself to a better bargaining position in future contract negotiations.	DOD has greater insight into current EELV costs than in the past, but may find itself funding an under-utilized launch capability with ULA if they select a new entrant for some or all of the 14 launches. This is because the current contract pays for annual ULA launch capability for eight launches, even if fewer launches actually take place in a given year. If DOD buys a launch from another provider, it may be paying for duplicate capabilities. Allowing new entrants to compete on a commercial, fixed-price basis could yield more efficient business practices and cost savings to DOD than it would otherwise obtain through cost-type contracts. This is because government cost-type contracts require more data and government insight than commercial contracts, which can be expensive.

IMPLICATIONS TO ULA IF DOD REQUIRES AN ELC/ELS STRUCTURE FOR LAUNCH PROPOSALS

Benefits to ULA	Challenges to ULA
DOD's recent block buy contract with ULA buys launch capability for 6 years, and affords ULA the opportunity to offer only the incremental cost to ULA of launching any of the 14 available missions. This is because under the current EELV contract, DOD has already bought ULA launch capability for eight launches per year, even if fewer launches actually take place. ULA may get the benefit of an excellent launch record of 67 consecutive successful launches of government (defense and civil) and commercial missions on Atlas V and Delta IV launch vehicles since 2002.⁸ Satellite integration requirements for ULA's Atlas V and Delta IV launch vehicles are generally known, given ULA's role as the EELV program's sole launch provider.	New entrants are expected to compete for up to 14 launches before they have been certified to launch the full range of EELV missions, meaning they have not paid the developmental costs of standing up their heavy launch vehicles and pads. This could give new entrants a price advantage over ULA, which is required to provide launch services for all variants of EELVs, including heavy launch vehicles, the most expensive to build and launch.

⁸ Lockheed Martin and Boeing launched Atlas V and Delta IV launch vehicles, respectively, beginning in 2002, prior to the formation of ULA in 2006.

IMPLICATIONS TO NEW ENTRANTS IF DOD REQUIRES AN ELC/ELS STRUCTURE FOR LAUNCH PROPOSALS

Benefits to new entrants	Challenges to new entrants
New entrants are expected to compete for up to 14 launches before becoming certified to conduct the full range of EELV missions. This affords them a potential price advantage over ULA, as new providers have not yet had to pay for the development, production, and demonstration of each type of launch vehicle. While new entrants cannot demonstrate a long past performance record for EELV-class launches as can ULA, the Federal Acquisition Regulation (FAR) prohibits a lack of a performance history from being considered a negative.⁹	DOD does not currently fund launch capability for new entrant companies, as it does for ULA. If DOD requires a similar structure for new entrants, they may ultimately have to stand up their own capability to meet DOD requirements, which could be costly. New entrants prefer to submit proposals on a commercial, fixed-price basis instead of duplicating ULA's ELC/ELS business model, which they view as inefficient and expensive. Particularly, the cost-reimbursement portion of the contract would require development and installation of business systems to gather required data, at additional cost to the new entrants.

⁹ FAR Section 15.305(a)(2)(iv).

Using a Commercial Approach for Launch Proposals

New entrants would prefer to submit proposals on a commercial, fixed-price basis in accordance with FAR Part 12, in order to focus the EELV competition on price without DOD having to pay separately for ELC costs.¹⁰

DOD is reluctant to use a FAR Part 12 approach because DOD believes this approach limits DOD's insight into contractor costs. Officials indicate a lack of insight into these costs led to problems in the past.

DOD also points out that a FAR Part 12 approach would have fewer cost and data reporting requirements for new entrants than are currently placed on ULA, leading to an unfair cost advantage for the new entrants who would not have to develop and install business systems to manage a cost-reimbursement contract.

However, if a robust competitive environment exists in the post-block buy phase beginning in fiscal year 2018, DOD has noted that it may depart from the ELC/ELS construct while requiring all companies to submit offers in a full and open competition for launch services.

Potential benefits to DOD	Potential challenges to DOD
Use of a fixed-price contract identifies the cost of the contract at time of award. Could facilitate a straightforward comparison of launch vehicle prices between companies without having to account for ULA's ELC contract structure. Full and open competition could help to decrease launch prices and increase efficiencies.	Under a fixed-price commercial-type contract, DOD access to cost data would be very limited. DOD believes there may not be sufficient demand in fiscal year 2018 and beyond to support multiple launch providers. Given the national imperative for an assured access to space, DOD may be forced to continue funding for launch capability if multiple launch providers cannot be sustained by the launch market, making a commercial approach impractical. DOD may lose some flexibility in its launch schedule, as rearranging and rescheduling launches due to satellite delays or other factors could incur added cost, according to DOD officials.

SCOPE AND METHODOLOGY

We interviewed or obtained information from:

- Air Force Space Command, Peterson Air Force Base, Colorado Springs, Colorado.
- Air Force Space and Missile Systems Center, Launch Systems Directorate, Los Angeles Air Force Base, El Segundo, California.
- Defense Contract Audit Agency, Littleton, Colorado.
- Defense Contract Management Agency, Littleton, Colorado.

¹⁰ FAR Part 12 outlines processes for acquiring commercial items, which are defined as items that are customarily used by the general public or by nongovernmental entities for purposes other than governmental purposes. Some features of FAR Part 12 contracts include less insight into cost or pricing data, and fixed-price contract types.

- Office of the Secretary of Defense, Cost Assessment and Program Evaluation, Washington, District of Columbia.
- Orbital Sciences Corporation, El Segundo, California.
- Program Executive Officer for Space Launch, Washington, District of Columbia.
- Space Exploration Technologies, Inc., Hawthorne, California.
- United Launch Alliance, Centennial, Colorado.

To determine the insight DOD had into launch costs under past EELV contracts:

- We reviewed the two most recent ELC and ELS contracts and examined the contract structure and breakdown of costs included in the contract.
- We received an in-depth verbal and written briefing on the ELC contract from DOD, and discussed with senior Air Force officials the history, context, and makeup of the EELV contracts.
- We interviewed other DOD and incumbent contractor officials regarding direct launch vehicle and other supporting activities performed under the contracts.
- We reviewed Defense Contract Audit Agency audit reports of EELV launch contracts, report dates ranging from 2005 to 2012.
- We reviewed past GAO reports and identified previous recommendations and their implementation to determine DOD insight into contracts.

To determine how recent changes to EELV contracts affect accounting for costs:

- We discussed the new EELV contract with DOD contracting officials and received an in-depth briefing on the structure of the new contract, including changes from previous contracts.
- We reviewed the modified EELV contract, and compared its contents and dollar amounts to previous versions of EELV contracts.
- We discussed the modified EELV contract, and changes from previous contracts, with the incumbent contractor.

To determine how DOD is reimbursed for costs when the incumbent provider sells launches to other customers:

- We examined ELC contracts from fiscal years 2012–2014 to determine reimbursements.
- We interviewed DOD and incumbent contractor officials to identify how any reimbursement amounts were calculated and the extent to which ELC costs were included.
- We analyzed the reimbursement amounts and calculated the percentages of total ELC costs that the reimbursements represented annually.

To determine the implications of possible DOD approaches to comparing launch proposals between the incumbent and new launch providers:

- We discussed DOD's plans to make the comparison in interviews with DOD officials who are developing the plan.
- We reviewed draft DOD performance work statement related to the proposed EELV competition.
- We discussed the implications of DOD's plan with DOD officials, new entrant launch service providers and the incumbent provider.
- We reviewed FAR requirements for various types of contracts, including fixed-price and cost—reimbursement-type contracts.

We obtained technical comments from DOD to ensure the accuracy of the slides, and incorporated changes as appropriate.

Senator DURBIN. Thank you very much, Ms. Chaplain. We will have some questions.

But next, we're going to hear from Michael Gass, President and CEO of United Launch Alliance.

Mr. Gass.

STATEMENT OF MICHAEL C. GASS, PRESIDENT AND CEO, UNITED LAUNCH ALLIANCE

Mr. GASS. Chairman Durbin, Ranking Member Cochran, members of the subcommittee, thank you for the opportunity to appear today to talk about the EELV program and the future of space launch. On behalf of the men and women of United Launch Alliance, and the entire EELV supply team, we are honored to be en-

trusted with the responsibility of safely delivering critical national security capabilities to orbit.

ULA also supports customers outside of national security. For NASA, we have launched science missions to the moon, Mercury, Jupiter, and Pluto, and even sent the Rovers on to Mars. Our customers extend beyond the Government to the commercial sector, with nine commercial missions to date and several more on the manifest.

I am also pleased to report that ULA and the Government team have consistently delivered 100 percent mission success over 68 times since the inception of the program, delivering over \$60 billion of taxpayer-funded satellites. We are currently at a tempo of a launch of one launch every month. ULA's Atlas V and Delta IV are the most powerful and most reliable rockets in the world. They are the only rockets that fully meet the unique needs of the national security community.

The Air Force EELV program was openly and fairly competed in the late 1990s, with a unique acquisition strategy at the time that required significant upfront investment by industry. Lockheed Martin's Atlas and Boeing's Delta products were the winners of that competition. Over the past 17 years, the program has continued to deliver, meeting the needs of our Nation effectively and efficiently.

The EELV program is entering a new era. The Air Force's new acquisition strategy aims to maintain reliability and stabilize the industrial base, while reducing costs and potentially reintroducing competition. The new strategy is a welcome improvement from the highly inefficient and costly approach of buying rockets one at a time.

The next phase of the Air Force's strategy is to reintroduce competition. I believe there are important questions about how EELV competitions will be structured to ensure they are fair and open, and whether competition will actually save the savings that is promised.

Ultimately, the central question is whether savings from competition will be sufficient to offset the cost of duplicating existing capabilities. ULA was formed to enable assured access to space with two separate launch systems, with the recognition that market demand was insufficient to sustain two companies. We went from two competing teams and a redundant and underutilized infrastructure to one team that has exceeded the savings of consolidation expectations.

Looking to the future, ULA is investing in new technology and concepts to make our products better and more affordable. We are investing internal funds to develop a capability to launch two GPS satellites at once, cutting launch costs almost in half. ULA, along with our Government customers, is reviewing every requirement and every process to eliminate any unnecessary or inefficient elements.

ULA also is aggressively expanding its customer base, both at NASA and the commercial sector, with additional launches, because improved utilization of the fixed infrastructure improves the cost for all customers. ULA and our industry partners are working closely with NASA's space launch system and other DOD programs to find opportunities to improve product designs and efficiently uti-

lize existing industrial base infrastructure to lower the costs for all programs.

On a personal note, I've been in this business for 35 years. I've worked with the Government in every imaginable approach to buying launch services, from the traditional DOD contracting approaches to the commercial approaches, from buying rockets in blocks to buying them individually. I've also worked extensively in the international and commercial sectors. I was there in the 1990s when the commercial demand for launch was projected to be dozens of launches per year, only to have the projected commercial demand evaporate overnight.

I believe leveraging the demand of the commercial sector is smart. But relying on commercial demand to enable national security carries huge risks, both to the rocket supplier and to its Government customers.

I've also experienced some of the launch industry's darkest days, such as in the late 1990s, prior to the EELV program, when the U.S. suffered a series of six major launch failures over a 10-month period. Those losses totaled billions of dollars and were a harsh reminder that launch is risky and extremely unforgiving. It's difficult to overemphasize the loss of national security those failures caused.

I believe the impressive successes we achieved on EELV stem from the difficult lessons learned from those failures. These lessons include sustaining a laser focus on technical rigor and the importance of an open and transparent relationship with our Government customers, and the acquisition strategies that align with customers' priorities.

PREPARED STATEMENT

In summary, I believe the EELV program has been a major success for the Nation. We will continue to provide the assured access the Nation needs to deliver critical capabilities to orbit reliably and on schedule. We look forward to working with our Government customers to further drive down costs without compromising the reliability and readiness.

Thank you for the opportunity, and I look forward to your questions.

[The statement follows:]

PREPARED STATEMENT OF MICHAEL C. GASS

Chairman Durbin, Ranking Member Cochran, and members of the subcommittee, thank you for the opportunity to appear today to discuss the Evolved Expendable Launch Vehicle (EELV) program and the future of space launch.

On behalf of the men and women of United Launch Alliance and the entire EELV supplier team, we are honored to be entrusted with the responsibility of safely delivering critical national security satellites to orbit. These satellites provide capabilities vital to nearly every aspect of U.S. national security. ULA also supports customers outside of national security. For NASA, we have launched science missions to the Moon, Mercury, Jupiter, and Pluto, and even sent the rovers on their way to Mars. Our customers extend beyond government to the commercial sector with nine commercial missions to date and several more on the manifest.

I am pleased to report that ULA and the Government team have consistently delivered 100 percent mission success over 68 launches since the inception of the program. We are currently at a tempo of about one launch every month. ULA's Atlas V and Delta IV rockets are the most powerful and most reliable in the world. They are the only rockets that fully meet the unique and specialized needs of the national security community.

The Air Force EELV program was competed in the late 1990s with a unique acquisition strategy that required significant upfront investment by industry. Lockheed Martin's Atlas and Boeing Company's Delta products were the winners. Over the past 17 years the program has continued to deliver. Meeting the needs of our Nation effectively and efficiently—delivering capabilities on time, on budget and while delivering on all of the programs original requirements.

Looking forward, the EELV program is entering a new era. The Air Force's new acquisition strategy aims to maintain reliability and stabilize the industrial base, while reducing costs and introducing competition. We welcome the new strategy, as the previous approach of buying rockets one-at-a-time was highly inefficient and costly.

The Air Force implemented the first phase of the new strategy with a block-buy commitment which will save several billions of dollars over the next 5 years. The block-buy created efficiency through economies of scale, eliminated repetitive administrative contracting actions, and provided stability and predictability that enabled informed investment decisions on product and process improvements that were incorporated into our pricing.

The next phase of the Air Force strategy is to introduce competition. I believe there are substantive questions about how EELV competitions will be structured to ensure the competition is fair and open and whether it will actually deliver savings to our Nation. Ultimately, the central question is whether savings from competition will be sufficient to offset the cost of duplicating existing capabilities. ULA was formed to enable assured access to space with two separate launch systems, with recognition that the market demand was insufficient to sustain two competitors. We went from two competing teams with redundant and underutilized infrastructure to one team that has delivered the expected savings of this consolidation.

Looking to the future, we are investing in new technology and concepts to make our products better and more affordable. We are investing internal funds to develop a capability to launch two GPS satellites at a time which will cut launch costs almost in half. ULA, along with our Government customers, is reviewing every requirement and every process to eliminate any unnecessary or inefficient elements.

ULA is also aggressively expanding its customer base, both at NASA and in the commercial sector with additional launches because improved utilization of the fixed infrastructure improves the cost for all customers. ULA and our industry partners are going to work closely with NASA's SLS, and other DOD programs to find opportunities to improve product designs and utilize industrial base infrastructure more efficiently to lower the cost for all programs.

On a more personal note, I have been in this business for 35 years. I have worked with the Government in every imaginable approach to buying launch services, from traditional DOD contracting approaches to commercial approaches; from buying rockets in blocks to buying them individually. I've also worked extensively in the international and commercial sectors. I was there in the 1990s when the commercial demand for launch was projected to be dozens of launches per year, only to have the projected commercial demand evaporate overnight. I believe leveraging the demand from the commercial sector is smart, but relying on commercial demand to enable national security carries huge risks, both to the rocket supplier and to its government customers.

I've also experienced some of the launch industry's darkest days, such as in the late 1990s when the U.S. suffered a series of six major launch failures over a 10-month period. These included three consecutive Titan IV failures and the loss of some of the Nation's most critical systems. Those losses totaled many billions of dollars and were a harsh reminder that launch is risky and extremely unforgiving. It's difficult to overemphasize the depth of the loss to national security those failures caused.

I believe the impressive successes we've achieved on EELV stem from the difficult lessons-learned from the 1990s. These lessons include sustaining a laser focus on technical rigor, the importance of an open and transparent relationship with our government customers, and acquisition strategies that align with our customers' priorities.

In summary, I believe the EELV program has been a major success for the Nation. We will continue to provide the assured access the Nation needs to deliver critical capabilities to orbit reliably and on-schedule. We look forward to working with our government customers and stakeholders to significantly drive down cost further while maintaining reliability and readiness.

Thank you for the opportunity to appear before you today. I will be honored to answer your questions.

Senator DURBIN. Thanks, Mr. Gass.

Elon Musk, CEO and Chief Designer of Space Exploration Technologies, the floor is yours.

STATEMENT OF ELON MUSK, CEO AND CHIEF DESIGNER, SPACE EXPLORATION TECHNOLOGIES CORPORATION (SPACEX)

Mr. MUSK. Thank you. Mr. Chairman, Ranking Member Cochran, members of the committee, thank you for having me here today.

SpaceX was founded to make radical improvements to space transport technology, with particular regard to reliability, safety, and affordability. Today it is arguably one of the leading aerospace companies in the world, with nearly 50 missions contracted at a value of approximately \$5 billion.

We have launched our Falcon 9 rocket eight times, with 100 percent success rate, including four launches for NASA, three of which docked with the International Space Station, and have launched a sophisticated geostationary satellite for the world's leading satellite companies.

We are restoring America's competitive in the global commercial space launch market as the only U.S. company that is consistently winning head-to-head competitions for launch opportunities at the world level.

With respect to the EELV program, I have five points to make.

The first is that the Air Force and other agencies are simply paying too high a price for launch. The impacts of relying on a monopoly provider since 2006 were predictable, and they have borne out. Space launch innovation has stagnated, competition has been stifled, and prices have risen to levels that General Shelton has called "unsustainable."

When the merger between Boeing and Lockheed's business occurred, the merger promised, in the press release, \$150 million of savings. Instead, there were billions of dollars of cost overruns and a Nunn-McCurdy breach for the program exceeding 50 percent of its cost projections.

According to congressional records, in fiscal year 2013, the Air Force paid an average of \$380 million for each national security launch, while subsidizing ULA's fixed costs to the tune of more than \$1 billion a year, even if they never launch a rocket.

By contrast, SpaceX's price is well under \$100 million, meaning a savings of almost \$300 million per launch, which in many cases would pay for the launch and the satellite combined. So if you took something like a GPS satellite, which is about \$140 million, you could actually have a free satellite with the launch. So our launch plus the satellite would cost less than just their launch, which is

an enormous difference. And we seek no subsidies to maintain our business.

To put this into perspective, had SpaceX been awarded the missions ULA received under its recent noncompeted 36-core block buy, we would have saved the taxpayers \$11.6 billion.

Point number two: Competition is coming to the national security market; this has been acknowledged. And we are ready to compete for that. In order to be certified as EELV providers, SpaceX had to meet a number of requirements that were never demanded of the incumbent provider.

We were required to successfully launch three flights of our upgraded Falcon line vehicle, which we achieved in January. Under our EELV certification agreement, we are undertaking vigorous engineering reviews with the Air Force. To date, we have delivered more than 30,000 data items to the Air Force and provided total access to our internal systems to more than 300 Government officials for certification. And we hope to complete that certification this year.

Point number three: We really believe that robust competition must begin this calendar year. We applaud the early steps the Air Force and National Reconnaissance Office (NRO) have taken to reintroduce competition into the EELV program. In 2012, the Air Force, under direction from the Secretary of Defense, committed to competing up to 14 missions, with 5 missions available for competition this year.

Of course, we would greatly have preferred that the Air Force open all of its missions for competition. And we have serious concerns that the five missions that will be competed this year will not actually be—that these five missions will not actually be awarded this year. We recently learned that perhaps only one will be awarded this year.

Point number four: With the advent of competition, a launch should really be viewed as a commodity. And any competition between new entrants and ULA should properly acknowledge the launch subsidy received by the incumbent. Consistent with Federal procurement regulations and DOD acquisition directives, when a competitive environment exists, the Government should use firm fixed-price Federal Acquisition Regulation (FAR) Part 12 contracts that properly incent contractors to deliver on time and on budget. That means eliminating the \$1 billion annual subsidy to ULA, which creates an extremely unequal playing field.

And the final point is that our Falcon 9 and Falcon Heavy launch vehicles are truly made in America. We design and manufacture the rockets in California and Texas, with key suppliers throughout the country, and launch them from either Vandenberg Air Force Base or Cape Canaveral Air Force Station. This stands in stark contrast to the United Launch Alliance's most frequently flown vehicle, the Atlas V, which uses a Russian main engine, and where approximately half the air frame is manufactured overseas. In light of Russia's de facto annexation of Ukraine's Crimea region and the formal severing of military ties, the Atlas V cannot possibly be described as providing assured access to our space for our Nation, when supply of the main engine depends on President Putin's permission.

PREPARED STATEMENT

Given this development, it would seem prudent to reconsider whether the 36-core uncompetited sole-source award to ULA is truly in the best interests of the people of the United States.

I thank the committee for this opportunity and look forward to addressing any questions.

[The statement follows:]

PREPARED STATEMENT OF ELON MUSK

Chairman Durbin, Ranking Member Cochran, and members of the committee: Thank you for the opportunity to participate in this important hearing. I also want to thank this committee for its continued support for competition in the Evolved Expendable Launch Vehicle (EELV) program. This committee's commitment to reliability, transparency, and cost-effectiveness coupled with clear and sustained support for New Entrant competition will ensure mission success, reduce launch costs, spur innovation in the national security launch enterprise, and provide true assured access to space for our warfighters as they defend our Nation. To be clear at the onset, I believe that competition in the EELV program will save the taxpayers in excess of \$1 billion per year.

I founded SpaceX in 2002 to radically improve the reliability, safety, and affordability of space transportation. Twelve years later, SpaceX is the fastest growing launch services company in the world, with nearly 50 missions contracted at a total contract value of approximately \$5 billion. We have now successfully launched our Falcon 9 rocket eight times, including four successful launches for NASA and three successful launches for leading commercial satellite companies.¹ Our Dragon spacecraft has berthed with the International Space Station (ISS) three times, and we are scheduled to conduct another resupply mission to the ISS for NASA this month.

SpaceX has achieved massive, unprecedented reductions in the cost of launch and spacecraft development, all while achieving 100 percent mission success, scaling our production operations to produce 40 rocket cores and nearly 400 rocket engines annually later this year—we are today the largest rocket engine manufacturer in the world. Meanwhile, we continue to push the envelope on rocket technology as we advance toward fully reusable launch vehicles, design the safest crew transportation system ever produced, and begin testing on the world's next-generation rocket engine at Stennis Space Center. Critically, all of this innovation is occurring in the United States and our launch vehicles (including engines and fairings) and spacecraft are made in America. We do not rely upon Russia for any element of the launch vehicle.

SpaceX today is serving the Nation's space program by routinely resupplying cargo to and from the International Space Station with our Dragon spacecraft and integrating numerous satellites for government launches to occur in the next 2 years. We are restoring America's competitive position in the global commercial space launch market, recapturing market share that U.S. launch companies long ago surrendered to our French, Russians, and Chinese competitors. With NASA, we are poised to develop a new human spaceflight system that will restore America's domestic capability to launch our astronauts from our own soil. And we are dedicated—if given a fair opportunity—to successfully executing missions in furtherance of the Nation's defense and space priorities, while offering the Air Force and other defense agencies the means to achieve mission success at a fraction of the cost they are paying for launch today.

To that end, SpaceX is working aggressively to achieve Air Force certification to become a certified provider of national security space launches with our Falcon 9 and Falcon Heavy launch vehicles. As a threshold matter, we have been required to successfully launch three upgraded Falcon 9 launch vehicles, two consecutively. Importantly—in just 5 months—we successfully and consecutively launched all three of the three required Falcon 9 launches as required by the Cooperative Research and Development Agreement (CRADA) with the Air Force and the New Entrant Certification Plan. One has already been declared a successful certification flight. We continue working with our Air Force partner as they conclude the data and engineering reviews from the remaining two flights, and we look forward to

¹The first launch of the Falcon 9 was a successful SpaceX-funded demonstration flight, which occurred on June 4, 2010.

timely certification of the Falcon 9 so that we may compete for EELV missions in 2014 for missions to be ordered in fiscal year 2015.

Although the aggressive reintroduction of competition into the EELV Program is now the established policy of the Defense Department, the details related to creating a fair, full, and open competitive acquisition environment remain unresolved. Fair competition in the EELV Program will lower the costs of launch, result in a higher quality of customer service, drive contractor-funded innovation, increase operational flexibility for the Air Force, and relieve congestion on the Air Force launch manifest. Indeed, the EELV Program was initiated in 1995 in part to introduce affordability, customer service, and flexibility to national security space launch. Unfortunately, as this committee well-knows, these goals have not been achieved as launch costs have grown dramatically since the EELV Program was established, and there is congestion in the ULA manifest.

By fiscal year 2013, the Government was forced to budget in excess of \$380 million per launch, while subsidizing ULA's fixed costs to the tune of more than \$1 billion per year if the company never launches a rocket.² Several recent cost analyses have determined the EELV Program will double in price over initial estimates to \$70 billion.³ This sustained cost growth triggered multiple "critical" Nunn-McCurdy breaches, most recently in 2012 when the program exceeded 58 percent unit cost growth.⁴ These cost increases have been exacerbated by an opaque and confusing contracting structure that made it difficult to understand the true cost of a launch service to the Government. By contrast, SpaceX's Falcon 9 price for an EELV mission is well under \$100 million—a \$280 million per launch difference—and SpaceX seeks no subsidies to maintain our business.

Recently, some have claimed that the Air Force's block buy of 36 booster cores from the incumbent will save the taxpayer "\$4.4 billion over the next several years." Any "savings" resulting from a block buy of 36 rocket cores from the incumbent provider are derived directly from a 50 percent year-over-year budget projection increase in fiscal year 2012, which was purposefully based on worst-case assumptions for a single-launch buy, and acknowledged at the time by the incumbent as being inflated.⁵ If SpaceX had contracted for these missions, using the same baseline, we would have saved the taxpayer a total of \$11.6 billion. That is a 77 percent reduction from the projected \$15 billion procurement total from which ULA is claiming its savings. If we all use the same baseline, it is accurate to say that the absence of full and open competition actually has resulted in a \$7.2 billion penalty to the taxpayer, and untold consequences for important defense priorities that might otherwise have been funded.

Despite the continuing promise of lower costs since 2006, the fact is that the current situation of sole-source providers has become unsustainable, a fact now recognized by most observers and the Defense Department. The EELV program is now the largest single item in the unclassified Air Force space budget, comprising more than 40 percent of all Air Force space funding. General William Shelton, the head of U.S. Air Force Space Command, acknowledged that these costs are "unsustainable."⁶ These issues stem from the current reliance on a single-provider, and a contracting structure that disincentivizes affordability, innovation, and adherence to schedule.⁷ Further, the Government Accountability Office (GAO) has commented in depth on these problematic aspects of the program.⁸

Mr. Chairman, we appreciate this Committee's timely review of the EELV Program. We commend the Air Force and NRO efforts to reintroduce competition into the EELV Program as a means to counter the rising costs of national security space launch and the stagnant innovation in this critical sector. In order for true, mean-

ingful competition to occur, we respectfully suggest the EELV Program be further reformed to adopt contracting practices and other acquisition reforms consistent with a competitive procurement environment, as follows:

- Most importantly, every single mission capable of being launched by qualified new entrants should be competed this year and every year moving forward. There should be no reason that a mission is sole-sourced to ULA, whether as part of the recent 36-core deal or any other arrangement. And if competition opportunities are being delayed, we should understand why that is so, and we should fix it immediately;
- Introduce a FAR Part 12 commercial contract structure that creates rational incentives for both the contractors and the government to achieve reliable, cost effective on-time launches;
- Leverage commercial practices wherever possible—a philosophy and acquisition approach that NASA has successfully employed in its launch programs. Fundamentally, the Air Force should establish clear requirements for launch services and associated activities, but it should not dictate how those requirements are implemented. Rather, contractors should be empowered to meet requirements in a manner best suited to their organization’s strengths; and
- Eliminate payments—more properly called subsidies—under the EELV Launch Capability (ELC) contract line item that are exclusively in support of the incumbent provider. And when conducting competitions for launches, properly account for the subsidies that the incumbent enjoys so that an even playing field is created. The long-term elimination of the ELC is paramount if an efficient acquisition approach is to be created. As was noted in DOD’s recertification of the EELV program after its 2012 “critical” Nunn-McCurdy breach, cost-plus contracting and the ELC has funded “effectively idle personnel” at ULA.⁹

SPACEX COMMITMENT TO RELIABILITY AND MISSION SUCCESS

Mission success is paramount to SpaceX, as our eight consecutive successful Falcon 9 launches to date have demonstrated. The Falcon 9 is designed for the highest reliability starting at the architectural level. Because 91 percent of launch vehicle failures in the past two decades can be attributed to engine failures, avionics failures or stage separation anomalies, the Falcon 9 design incorporates robust, fault-tolerant propulsion systems, fault-tolerant avionics and controls systems with internal triplication and redundant harnessing, and a minimum number of separation events. With its nine-engine configuration, Falcon 9 features a unique engine-out capability, and is designed to permit the loss of up to two engines in flight without compromising the mission. The Falcon 9 is the only American rocket since the Saturn V with any engine-out capability; any other launch vehicle in the world, including the current EELV fleet, that encounters a major engine anomaly on ascent will almost certainly fail its mission.

The Merlin engine—which is designed and manufactured by SpaceX and powers the Falcon 9 first and second stages—is a human-rated engine with high structural margins and a highly reliable, redundant ignition system. A hold-before-release system verifying nominal operations of the first-stage engine before liftoff has been successfully demonstrated multiple times. Rigorous qualification and acceptance testing from the component to the vehicle system level are part of SpaceX’s “test what you fly” approach, and the company uses liquid-fueled engines and non-pyrotechnic, resettable separation systems that allow testing of actual flight hardware before flight. Notably, SpaceX does not rely on any foreign companies for critical components or subsystems. There is absolutely zero dependence on Russia with this rocket. To state the obvious, the same cannot be said of ULA.

Demonstrating our long-held commitment to launching national security payloads, SpaceX designed the Falcon 9 and its follow-on, the Falcon Heavy, from the outset to meet the EELV design specifications, including the EELV Standard Interface Specification (SIS) and System Performance Requirements Document (SPRD), at no charge to the U.S. Air Force. Separately, SpaceX has passed rigorous certification efforts by NASA in order allow the Dragon spacecraft to berth with the International Space Station, as it has now successfully achieved three times, with another mission scheduled later this month. This accomplishment demonstrates that SpaceX can be trusted with extremely critical national and international assets.

⁹Kendall, Frank. “Evolved Expendable Launch Vehicle Nunn-McCurdy Certification: Basis of Determination and Supporting Documentation.” Memorandum to Congressional leadership. 12 Jul. 2012.

The Falcon Heavy, which SpaceX will debut in 2015, will leverage the same engines, tooling, and launch facilities to enhance reliability, while also being the most powerful launch vehicle in the world.

EELV NEW ENTRANT CERTIFICATION

To validate our singular emphasis on mission success and to earn the confidence of the Air Force, SpaceX formally submitted Statements of Intent to become a certified provider of national security space launches with our Falcon 9 and Falcon Heavy launch vehicles. SpaceX subsequently entered into a formal CRADA with the Air Force to become certified under the EELV Program for the Falcon 9, with plans to execute a similar agreement for the Falcon Heavy. The Falcon 9 certification will enable SpaceX to compete for the 14 EELV missions that have been identified for competition, and with the Falcon Heavy certification, SpaceX intends to compete in 2018 and beyond for the entire spectrum of national security space missions.

As part of our certification plan for the Falcon 9, SpaceX was required to conduct three successful flights, with two consecutive successes. I am proud to say that SpaceX successfully completed the third flight needed for EELV certification on January 6, 2014, and we achieved 100 percent mission success for each flight. Importantly, all three missions were for commercial customers, eliminating any risk or cost to the Government for these certification flights. In early February, the Air Force recognized our CASSIOPE mission, launched on Sept. 29, 2013, as having met all mission requirements and qualified the flight under the EELV Certification CRADA; we are now awaiting an Air Force decision on the subsequent two flights. Here, it bears noting that the New Entrant Certification requirements that SpaceX must live up to exceed the requirements that the Atlas V and Delta IV launch vehicles had to meet in 1998, prior to their ability to compete for and be awarded EELV launch service orders.

At this point, the Air Force must complete independent verification activities, audits of our processes, and engineering review boards (ERBs) to conclude the certification process. SpaceX has committed personnel and resources to support these technical interchanges. The Air Force kicked off the first ERB process as of late February of 2014, but there are many more to conduct and we hope that the Air Force will be able to support the schedule to conclude the certification process in 2014. This will allow SpaceX to compete for the fiscal year 2015 missions. Consistent with DOD and Air Force directives, these risk reduction activities can and should occur in parallel with the early competition phases for the Phase 1A competed missions.¹⁰ This method is consistent with NASA's Launch Services Program (LSP), which requires certification prior to launch rather than contract award.

SpaceX has taken multiple other actions to ensure we meet all EELV certification requirements, including:

- Building and debuting a new launch facility last year at Vandenberg Air Force Base (VAFB), CA with a successful September 2013 Falcon 9 launch. This was self-funded by SpaceX;
- Agreeing to incorporate the ability to provide vertical integration at both launch sites for NSS payloads that require their space vehicles to be processed in this manner. SpaceX will self-fund this capability;
- Providing the Air Force with the ability to observe or receive data from our contracted commercial launch service activities at no cost to the Government; and
- Being awarded and working on a lease with NASA for the use Launch Complex 39A to increase SpaceX's ability to meet a growing launch manifest and outfitting the launch pad to serve additional customers, including the national security community, at our own expense to further reduce EELV manifest congestion.

CHALLENGES TO EELV COMPETITION

The Air Force is now taking a major step forward in addressing the challenges of reintroducing competition into the EELV Program by outlining a plan that takes advantage of the recent significant advances that have taken place in the U.S. launch services business. SpaceX commends the Air Force for moving to certify New Entrants and take advantage of new, commercially developed reliable launch systems. As the Air Force moves to restructure the EELV program to on-ramp New Entrants for competition in the intermediate term, and contemplates the format for

¹⁰Kendall, Frank. "Evolved Expendable Launch Vehicle Program Quantity Buy Decision Acquisition Decision Memorandum." Memorandum to the Secretary of the Air Force and the Director, Cost Assessment and Program Evaluation. 27 Nov. 2012. Secretary Kendall directs the reintroduction of competition into the EELV Program "as soon as possible." 2

full and open competition beginning with the fiscal year 2018 Phase 2 acquisition, a number of key issues must be addressed to ensure a fair and level competition:

—*Number of Competitive Missions.*—In his November 27, 2012 Acquisition Decision Memorandum (ADM), Under Secretary of Defense Frank Kendall clearly directed that up to 14 missions be made available for competition to certified New Entrants. This directive was designed to “aggressively introduce a competitive procurement environment in the EELV program.” SpaceX strongly supports the decision to compete these 14 missions, but remains concerned that, faced with a difficult budget environment, the Air Force may push many of the 14 missions out of the fiscal year 2015–fiscal year 2017 competition, even while leaving the 36-core block buy for the incumbent untouched. Such a decision would materially slow progress toward the ADM’s goal of aggressively transitioning to a competitive environment and further delay real savings that can be realized with competition. Undersecretary Kendall’s acquisition directive is quite specific about the need to “aggressively” introduce competition. His directive does not require buying 36 cores from ULA. Rather, every mission capable of being launched by qualified new entrants should be competed this year and every year moving forward.

—*EELV Launch Capability Funding.*—ULA receives on average \$1.2 billion annually primarily on a cost-plus basis to fund “facility and facility support costs, launch and range operations, mission integration, mission unique development and integration, subcontract support engineering, factory engineering, etc.”¹¹ ULA receives these “EELV Launch Capability” (ELC) payments whether they launch zero rockets or eight; if they launch more than eight times, they are paid additional funds. Essentially, the Government supports all of ULA’s fixed costs. Such funds are not provided to SpaceX, and SpaceX has not sought them. Rather, SpaceX has self-funded its EELV efforts.

ELC funding provides ULA with a major competitive advantage for national security missions, as well as civil and commercial missions. ULA can, and most likely will, marginally price launch services for commercial and civil customers because ELC funding allows ULA to maintain its operations and covers its fixed costs. In fact, ULA appears to have marketed a marginal launch services price for the MEXSAT mission. Here, it appears the Mexican government will be paying substantially less for an Atlas launch service than does the Air Force. In these challenging economic times—or any economic times for that matter—why should American taxpayers subsidize a launch for the Mexican government or a commercial purchaser of launch services?

—*Sole Source, Non-Compete Block Buy to ULA.*—The Air Force’s decision to provide ULA with a sole-source block buy guarantee of 36 rocket booster core from fiscal year 2013–fiscal year 2017 provides the incumbent with unprecedented business stability and presents New Entrants with a substantial competitive disadvantage. An early reason for the block buy was to save on launch costs, but it is not clear that the Air Force has created savings over the last acquisition, known as “Buy 3.” In a head-to-head competition against New Entrants, the incumbent is well-positioned to leverage this guaranteed order to impact the competition outcome. The 36 core block buy gives ULA an extreme and unfair competitive advantage relative to New Entrants by allowing ULA to allocate its operating costs to the block buy and offer marginally priced launches to other customers (e.g. NASA, commercial customers) as well as future bids for EELV missions.

—*Cost-Plus Contract Elements.*—The EELV Launch Services contract line item, which basically represents the cost of the launch vehicle hardware and production, is structured as a fixed-price, incentive fee (FPIF) line item. The ELC, which funds the engineering and infrastructure costs to actually execute the launch, is now contained in multiple contract line items, many of which are cost-plus types. It should be noted that the EELV Program is the only U.S. Government launch program that utilizes any cost-plus features. As a New Entrant provider, SpaceX does not seek out similar ELC funding. Rather, SpaceX believes that the utilization of a FAR Part 12 commercial contracting structure, with payments based on achievement of results at pre-negotiated prices—rather than costs expended, which has no limit—should be the preferred acquisition approach for the EELV Program. This contracting mechanism rewards organizations that spend more time and more money, rather than being efficient and achieving results. A contracting mechanism that drives efficiency and innovation will improve quality of service at much better value for the customer. It

¹¹“Department of Defense fiscal year (FY) 2014 President’s Budget Submission, Missile Procurement, Air Force.” Apr. 2013. Vol. 1, 230.

bears noting that the current contract structures add substantial overhead cost to the taxpayer for oversight of a largely mature booster core. Further, New Entrants will be forced to adopt these higher overhead cost structures or be at a disadvantage to the incumbent. In today's budget environment, it would be far better to buy these mature products as commercial systems and use lower overhead procedures such as FAR-based commercial contract structures.

—*Government-Funded Upgrades to Incumbent Systems.*—The Air Force continues to provide ULA with development funding for numerous items, such as the RL-10C, common upper stage, and has discussed potential funding for dual payload adaptors and other efforts which give ULA a competitive advantage relative to New Entrant competitors. Launch service providers are also affected by range modernization and programs such as Automatic Flight Termination Systems or GPS metric tracking. ULA is funded by the Air Force to upgrade their launch vehicles for these programs while New Entrants are expected to bear the burdens of these costs. ULA should be required to self-fund these upgrades in a competitive procurement environment.

RECOMMENDATIONS TO REFORM THE EELV PROGRAM

To achieve real and continuous competition and address the challenges outlined above, the EELV Program must transition from its current sole-source, non-commercial contracting structure to an acquisition approach that employs competition and makes use of meaningful aspects of commercial business practices and contract structures that reward success, efficiency and innovation.

The Air Force should begin the transition to a standard, commercially oriented procurement process which can be supported by a commercial business model, and place its emphasis on achieving mission success rather than maintaining legacy contract structures that give its incumbent provider a competitive advantage. As it has done with other major procurements, such as the Wideband Global Satcom (WGS), the Air Force can achieve significant capability at substantially lower costs by incorporating competitive, commercial practices into its acquisition approach. A commercial approach, however, is hindered by the contractual structures that are currently in place and which provide a material competitive advantage to the incumbent provider. Should the Air Force transition to a new model and fully embrace competition, it will be in a position to support U.S. launch companies as they win commercial business from foreign competitors, while leveraging the broader launch services market to absorb fixed costs and reduce the overall costs to the U.S. Government. Congress should continue robust oversight of the program to ensure these acquisition reforms are implemented.

(a) *Eliminate the ELC*

No competition will be fair, full, and open so long as the Air Force continues to utilize contract line items to fund ULA's fixed costs to maintain its launch capability. There are reasonable ways to address this competitive inequity now. At minimum, the fixed cost funding must be accounted for in a meaningful way in competitions for EELV launches and must be completely offset in non-EELV competitions. This near-term approach should be leveraged as the ELC is ultimately phased out. The Air Force must eliminate the funding of ULA's launch capability prior to the Phase 2 EELV Acquisition or there can be no fair competition, and Congress should conduct continuous oversight to ensure the elimination of the ELC.

The original rationale for incorporating the ELC concept in the EELV program was to maintain the capability and assured access to space with Atlas and Delta when both Lockheed and Boeing threatened to exit the launch business. With the later formation of ULA, the Air Force implemented the ELC as a means to secure assured access to space in a single-supplier environment, opting to insulate its provider from market conditions by fully funding its infrastructure and business overhead. In addition, many national security space programs were having development challenges that were resulting in significant delays in satellite delivery, resulting in a low launch rate and supporting arguments in support of a launch capability payment structure. Notwithstanding whether or not the ELC was an appropriate mechanism to achieve assured access to space when it was instituted, it is clear now that the prevailing conditions which were used to justify it no longer exist. Critically, the newly revised National Space Transportation Policy eliminates a 2005 policy that called for the DOD to fund the annual "fixed costs" of the EELV provider.

In 2014, these conditions have materially changed in virtually every respect. For example, as the Air Force determined in the course of adjusting its Acquisition Strategy to support a transition to competition, most national security satellites are out of development and into production, with delivery now being somewhat predictable. The rate of national security space launch has increased significantly, which

eliminates the need for continuous launch capability funding support and enable a transition to a fully loaded launch services price offered by each competitor. Finally, the EELV program is emerging from its reliance on a single provider with a limited ability to compete on the open market, and transitioning to a model with potentially multiple certified providers. With respect to the commercial market, the market is robust and forecasts are predicated on rational market assumptions and analysis. With the onset of at least two viable new entrants, the existence of a robust and durable commercial launch market, and stability achieved in major NASA space programs with cargo resupply, commercial crew, SLS and numerous science missions, there is no remaining rationale for maintaining the ELC.

SpaceX recognizes that a transition away from the ELC will take significant planning and time. In the intervening period, however, as the Air Force on-ramps New Entrants and allows those certified to compete for 14 identified missions beginning to be ordered in fiscal year 2015, the Air Force must require the incumbent provider to account for the derived financial and non-financial benefits it is afforded through the ELC payments it receives from the Government. The ELC contract line items total roughly \$1 billion annually in direct payments to ULA to fund its annual sustaining engineering, manufacturing, operations, and overhead costs. These payments constitute a substantial competitive advantage for ULA, and Congress should insist that actions to mitigate this structural competitive inequity be imposed on ULA.

(b) Return to Fixed-Price Services for the EELV Program

Unlike the past 10 years, the commercial space launch market is robust, stable, and predictable, and the U.S. is recapturing market share previously surrendered to international competitors. The Air Force should change its existing contracting structure to leverage the commercial market and allow for alternate business models to be utilized for the acquisition of launch services. While potentially appropriate in a development or sole-source environment, cost-plus contracting does not incentivize contractors or the government to control and reduce cost, nor does it foster contractor innovation, as the EELV Program has plainly demonstrated. The requirements associated with launch services and mission assurance for the EELV Program are well-understood at this time. Indeed, prior to the execution of the “Buy 3” contracts, the EELV program fully and successfully implemented the enhanced mission assurance requirements that are used today based upon the recommendations from the Space Launch Broad Area Review (BAR 1). However, given the continued existence of legacy contracting structures like the ELC, the EELV Program is currently the only U.S. Government program utilizing a cost-plus arrangement for the execution of launch services. Consistent with the direction in the FAR and pursuant to Public Law 103-355, SpaceX recommends that the EELV Program be transitioned back to a FAR Part 12 commercial-item acquisition approach, which will then achieve parity in the contracting structure among all potential competitors.

Although the FAR Part 12 acquisition authority was employed in 1998 in the EELV program, it was not the use of FAR Part 12, or any shortcomings resulting from its use, that prompted the restructure of the EELV program. The need to restructure the program was driven by the original business decisions of the EELV contractors 1998, which included an overly optimistic forecast of the commercial market. Today, the situation is materially different in two significant ways. First, the commercial market is far more predictable, robust and stable than it was in the early 2000s.¹² Second, the commercial market has largely moved overseas as foreign competitors have filled the commercial space launch services business in light on uncompetitive pricing by U.S. launch providers. Bringing competition and continuous improvement to the EELV program, along with additional manifest availability, will help enable U.S. launch providers win back that business from foreign competitors. This is, in fact, what SpaceX is doing right now.

In 2005, both the launch vehicles used by EELV lacked flight-proven maturity in their designs and the number of executed launches on the EELV program was low. Eight years later, the EELV Program has now demonstrated performance in managing a complex launch and mission integration environment, successfully launching all “first of a kind” satellite payloads. Future launches will be for satellites that have all been previously integrated, with some (WGS, GPS IIF, DMSP) launched on both EELV Systems provided by ULA. Consequently, most requirements are well-understood and the need to continue on a cost-plus basis no longer exists.

¹²The commercial launch market available for U.S. competition is stable and averages approximately 30 satellites per year, with a total value of nearly \$3 billion annually.

A separate rationale for maintaining cost-plus elements has been the uncertainty in launch schedule. Clearly, the situation existed in 2005 when the Air Force could not necessarily predict when new satellites would be ready for launch, and when they would be, there was a sense of urgency for these systems to be launched to replace aging national security assets or to provide new capabilities in order to support national need. In 2011, the EELV Program began the transition to a “launch slot concept” that enables the Air Force to have improved flexibility to determine as late as 6 months prior to launch which satellite has the highest priority for the launch slot. Up until that point, the Air Force maintains through the integration process the ability to consider alternative missions as “back-ups” should the primary mission encounter a schedule problem. Further, as the Air Force has recently assessed, most satellites today are moving out of development and into production, which should have a positive impact with respect to on-time satellite delivery and the ability to launch on time. As a result, this rationale for a cost-plus contract element is no longer valid.

Consequently, the use of a commercially focused contracting approach for the integration, mission assurance, and launch operations elements of the EELV Program is appropriate and consistent with the guidance contained in FAR Part 16. In addition, as referenced above, the FAR plainly instructs (see FAR Part 12.101) the Government to acquire commercial items when they are available to meet the needs of the agency. Launch services are clearly commercially available and are routinely sold on the commercial market. Nearly 60 percent of SpaceX’s manifest of 50 launches is for commercial customers. Indeed, Lockheed Martin Commercial Launch Services (LMCLS) recently sold an Atlas V launch vehicle commercially to the Mexican government, subcontracting with ULA to execute the launch service. LMCLS has stated publicly its intent to market at least two Atlas vehicles annually, leveraging the Government’s 36-core block buy and the Launch Capability payments to reduce its price for commercial customers.¹³

As such, the Air Force should execute launch services procurement under a FAR Part 12 commercial-item acquisition, as is required under the FAR. This approach will allow for the elimination of the non-valued items that have no impact to mission success, but add costs to program execution.

SpaceX intends to demonstrate the benefits associated with competition—including timely support to the warfighter, contractor-funded improvement and excellent value—and provide truly assured access to space through two distinct launch providers. By providing launch services on a commercially available, proven launch vehicle under a FAR-based commercial-item contract, SpaceX can help alleviate manifest congestion and reintroduce cost competition and the accompanying improvements it provides. As a commercial launch services provider with a manifest of almost 50 launches representing over \$4 billion in contracts, SpaceX is able to share its fixed cost among a strong customer base in national and international commercial and government markets.

(c) Competitive, Commercial Acquisition Model for Space Launch is Proven

In the mid-2000s, NASA, like the DOD, faced the challenge of unacceptably high launch costs. To contain this problem, the agency partnered with private industry to produce new launch vehicles that were not only highly reliable, but also affordable. This collaboration, known as the Commercial Orbital Transportation Services (COTS) program, was structured under firm fixed-price, milestone-based development agreements that leveraged private sector innovation and capital with Government investment and technical expertise. For less than the cost of a single Space Shuttle flight, COTS produced two new launch vehicles and spacecraft and reestablished American capability to reach the International Space Station (ISS). The SpaceX Dragon developed under this program is currently the only spacecraft in the world capable of bringing substantial cargo both up and back from space.

NASA further endorsed this approach when it awarded 20 ISS cargo missions to multiple providers under the Commercial Resupply Services (CRS) program. Using firm fixed-price, FAR Part 12 contracts, NASA is able to ensure the safety of the astronauts and equipment onboard the \$160 billion International Space Station, while also maintaining cost-control and benefiting from contractor innovation. This contracting approach is an unmitigated success, with SpaceX’s cargo delivery prices

¹³Fester, Warren. “New ULA–Lockheed Relationship Helps Atlas 5 Compete for Commercial Launches.” Space News. September 23, 2013. “Robert Cleave, president of Lockheed Martin Commercial Launch Services, said . . . the company expects to be able to capture two commercial contracts per year starting in 2015.” And: “Cleave credited the U.S. Air Force’s planned block buy of up to 36 Atlas 5 and Delta 4 launch vehicle cores from ULA for Lockheed Martin’s ability to bring its commercial launch prices to more competitive levels. The block buy is intended primarily to generate volume-based price discounts for government customers.”

the lowest per pound in the history of the ISS. SpaceX has already completed its first two CRS missions and is on track to conduct its third in the coming weeks.

NASA properly approached launch acquisition as a “commercial item,” consistent with the FAR and the Commercial Space Act of 1998.¹⁴ There exists a robust and competitive global launch market that grants the Government deep insight into price reasonableness. This approach has proven highly successful for the agency. It conducts many science missions through the NASA Launch Services (NLS) II program (and its predecessor NLS I program), where launch services are competed between a stable of providers operating under indefinite delivery, indefinite quantity (IDIQ) task order contracts. This structure enables NASA to weigh a variety of factors, including risk, technical capability, and price prior to issuing any mission award. It further encourages launch providers to continually innovate throughout program life by permitting them to “introduce launch vehicles or technologies that were not available at the time of the award of the initial contract.”¹⁵ Consequently, NASA is able to take advantage of a continually refreshed portfolio of launch vehicles for its diverse missions without resorting to arcane contracting approaches. Importantly, NASA does not pay for the ELC, but rather pays for each launch service. ULA, Orbital Science, and SpaceX are all part of this competitive launch services contract.

In 2012, the Air Force awarded SpaceX two missions under the Orbital/Suborbital Program (OSP-3). These EELV-class missions, which were designated as New Entrant missions for EELV, utilized a firm fixed-price contracting approach requiring compliance to Air Force mission assurance, mission integration, and launch operations requirements, with performance-based payment structure. It is important to note that for CRS, NLS II, and OSP-3, NASA and the Air Force conduct mission assurance (MA) activities on a firm fixed-price basis. This demonstrates a strong confidence that safety and reliability can be achieved without compromising affordability.

BENEFITS OF COMPETITION FOR DOD LAUNCH

The Air Force has attempted to contain cost-growth through an economic order quantity “block buy,” sole-sourced to ULA for 36 rocket booster cores to be ordered through 2017. Although SpaceX is pleased that the Air Force made the decision to reinstate competition for 20 percent of the DOD launch manifest through 2017 (though would far prefer fair and open competition for all missions), the competitive advantage created by its sole-source block buy of 36 rocket booster cores to ULA must be recognized. It is a factor that challenges a level playing field for competition and one which will have limited long-term impacts on cost reduction. As has been recognized by numerous Government and independent reports, competition is the only true mechanism for achieving both performance and affordability. This approach is consistent with “commercial item” requirements under the FAR and the Defense Federal Acquisition Regulation Supplement (DFARS).¹⁶ The Weapon Systems Acquisition Reform Act of 2009 (WSARA) further requires competition as “a means to improve contractor performance” through program lifecycle, and the DOD’s Better Buying Power 2.0 initiative calls competitive procurement and firm fixed-price contracting “the motivation to control and reduce cost.”¹⁷

Competition drives notably lower costs than a block buy when multiple certified companies exist in a program. If launches were awarded today, the DOD would save at least one billion dollars per year by selecting SpaceX over the incumbent. Competitive pressures will further induce certified providers to continually improve on both cost and reliability. These savings would not result in diminished Government insight into provider processes and mission assurance, as commercial item acquisitions still include substantial insight between companies and relevant agencies. There is no connection between cost-plus contracting and consistent mission assurance, as has been successfully demonstrated in NASA’s COTS, CRS, and NLS pro-

¹⁴ “Special Requirements for the Acquisition of Commercial Items,” FAR Part 12, Subpart 2, Section 207; “To encourage the development of a commercial space industry in the United States, and for other purposes (Brief title: Commercial Space Act of 1998).” (Public Law 105–303, 28 Oct. 1998). grams and the Air Force's OSP-3 program. However, there is a direct correlation between complicated, opaque cost-plus contract structures and higher program costs.

Consistent with the initial goals of the EELV program, competition ensures that in the event of a launch vehicle anomaly or national emergency, the U.S. still maintains its access to space with another independent launch vehicle capability, something which is absent with the consolidation of ULA and the increasing commonality between the Atlas and Delta launch vehicles. An independent report by the MITRE Corporation in September 2012 affirms that multiple providers establish an "insurance for transition in case of performance failure."¹⁸ Even without any anomalies, multiple providers with separate launch sites decrease manifest congestion at a time when DOD's launch needs are at their highest in years. The recently issued National Space Transportation Policy (NSTP) dictates that "competition among providers" is critical to "assure access to space for [the] United States Government."¹⁹

Critically, competition also reduces national dependence on a foreign supply chain. The Atlas V rocket utilizes the first stage Russian RD-180 engine and a Swiss 5 meter payload fairing. Further, the Delta IV is dependent on Japanese suppliers for its upper stage liquid hydrogen tanks. This foreign reliance introduces obvious risk into the national security launch enterprise. Indeed, it was reported late last year that Russia's Security Council was considering discontinuing the supply of the RD-180 engine for the Atlas V over unrelated foreign policy issues with the United States.²⁰ As mentioned previously, Falcon 9 and Falcon Heavy are manufactured entirely in the United States and do not rely on foreign companies for major subsystems and components.

Much is made of the shrinking defense industrial base, specifically with respect to space industrial base. Competition is one remedy to this challenge. Excluding SpaceX, the U.S. industrial base averages only five liquid rocket engines per year capable of lifting a medium- or heavy-lift payload. In contrast, SpaceX produces 120 such rocket engines per year, with annual manufacturing capacity growing to 420 engines by the end of this year, far exceeding all other liquid rocket engine producers in the United States and Russia combined. This all-American production maintains critical skills in the U.S. and sustains important suppliers around the country.

In the monopoly cost-plus environment that has existed in the EELV program since just prior to the 2006 formation of ULA, there is little incentive for contractor innovation, and little has been seen. Any launch vehicle upgrades, most recently with the RL-10C, were initiated and paid for by the Government with little return to the taxpayer. Reestablishing competition in the program will return the spirit of self-funded innovation by forcing providers to consistently invest in launch vehicle improvements to win contracts, else they be awarded to their competitors. NASA has certainly benefited from this approach, with both companies in the COTS program putting their own capital into the program; as a result, Falcon 9 emerged as the lowest cost medium-to-intermediate lift launch vehicle in NASA's portfolio.

Mr. Chairman, I appreciate your invitation to testify before the committee today. Leveraging SpaceX's current Air Force, NASA, and commercial contracts, SpaceX plans to demonstrate heritage, reliability, and safety over a relatively short period of time. SpaceX has demonstrated its commitment to support national security space launches with significant internal investments in launch vehicle improvements and launch infrastructure to support the full spectrum of EELV program requirements, as well as the commitment and allocation of resources to the Air Force New Entrant Certification process.

With fully American-made launch vehicles and launch sites on both East and West coasts, SpaceX's objective is to establish an enduring U.S. launch industry, consistent with the National Space Transportation Policy and the Commercial Space Launch Act. As a result, SpaceX seeks to provide the U.S. Government with true assured access to space with a new launch vehicle family and launch infrastructure and without reliance on foreign suppliers for rocket engines, fairings or other major launch vehicle components.

With a mature commercial launch market ready to support national security launch needs, the time has come for the EELV program to live up to its name and evolve. Conducting competition in a fair and level playing field will significantly and immediately reduce costs for the Government, while enhancing vehicle reliability and national assured access to space capability.

Senator DURBIN. Thank you very much.

Our last witness: Dr. Scott Pace, Director of Space Policy Institute, Elliott School of International Affairs at George Washington University.

Dr. Pace.

STATEMENT OF DR. SCOTT PACE, DIRECTOR, SPACE POLICY INSTITUTE, ELLIOTT SCHOOL OF INTERNATIONAL AFFAIRS, GEORGE WASHINGTON UNIVERSITY

Dr. PACE. Thank you, Chairman Durbin and Ranking Member Cochran, and members of the committee, for providing this important opportunity to discuss the topic of national security space launches.

As called for in the U.S. national policy, the United States and the DOD in particular need to decide how it best assures the existence of “two U.S. space transportation vehicle families capable of reliably launching national security payloads.” A space industrial base meeting all Government needs cannot presently be sustained by private market demand alone. Thus, a significant degree of Government support will be necessary for the foreseeable future.

The EELV program as it exists today is the result of technical, economic, and policy decisions made over several decades. Today, fiscal constraints, rising launch costs, limited demand, and strict Government requirements have combined to create a complex, ongoing debate about the role of competition and the procurement of EELV-class launch services.

The national space policy states, “U.S. commercial space transportation capabilities that demonstrate the ability to launch payloads reliably will be allowed to compete for U.S. Government missions on a level playing field, consistent with established inter-agency new entrant certification criteria.”

I emphasize the phrase “level playing field,” as the determination of just what this means is central to the question of competition going forward. Industry competition is a tool, not an end in itself. Depending on market conditions, competition can result in meeting DOD needs that lower costs, or failing to meet those needs and merely shifting Government costs to other accounts.

The EELV program as managed by ULA today represents a high degree of experience and capability. As a potential competitor for national security launches, SpaceX brings, in my view, an intense focus on cost control, while meeting customer launch needs.

The policy issue is not one of SpaceX and other potential new entrants versus ULA as much as it is one of deciding what the role of DOD should be. What are the Government’s policy priorities? Should we be trying to, for example, get the lowest price for reliable transportation to orbit for a particular mission? Get the lowest price for all national security missions? Get the lowest price for all Government-funded missions? Assure access to space for all needs with the U.S. industrial base at least-cost? So the question really is one of scope that this committee wants to take.

The Launch Services New Entrant Certificate Guide is a thoughtful and prudent approach to assessing potential entrants. The more difficult question comes with what happens after a new entrant is certified. Will incumbents and new entrants with very different histories compete under the same rules? And whether

they do or do not, what may be said about the rules themselves? Reliability and readiness have been the top priority for national security launches. Can the critical need for mission assurance be achieved at lower cost than the way we do it today?

This certainly seems desirable, even plausible. But careful thought needs to be given as to what responsibilities and capabilities ought to remain within the Government. Will the Government have the authority to order a stand-down of a vehicle family in the event of failure? Are agencies willing to relax or modify their use of cost-accounting rules and other FAR-based requirements for all launch service providers?

In short, how much is the Government willing to pay for process, and how much is it willing to pay for performance? I would note here the GAO's report, I thought, was very germane on this point in terms of pointing out some of the issues.

Defense acquisition reform is a much larger topic than the present hearing, but it's nonetheless relevant. Deciding how to best acquire space launch services may provide opportunities for pilot testing, some forms of regulatory relief. For example, the Government could pay separately for noncommercial processes and deliverables rather than having all costs bundled into the launch costs or company overhead. The Government may still pay more for its launches than a commercial buyer would, but the cost drivers would be more visible and accountable and would more easily allow cost-benefit trades for Government decisionmaking.

PREPARED STATEMENT

The most important consideration for any policy choice in implementing approach is that it be clearly stated and adequately funded, with clear priorities as to which requirements, schedules, and goals will be relaxed if resources or regulatory relief is not forthcoming. To do otherwise is to invite failure.

Thank you very much for your attention, and I'd be happy to answer any questions that you might have.

[The statement follows:]

PREPARED STATEMENT OF DR. SCOTT PACE

Thank you, Chairman Durbin, Ranking Member Cochran, members of the committee, for providing an opportunity to discuss the important topic of national security space launch programs, and in particular, the Evolved Expendable Launch Vehicle Program which is central to maintaining assured access to space for the Department of Defense.

The Evolved Expendable Launch Vehicle (EELV) program as it exists today is the result of technical, economic, and policy decisions made over several decades. After the loss of the Space Shuttle *Challenger* in 1986, the Reagan Administration limited the Shuttle to flying only those payloads that required its unique capabilities. Additional launch failures and subsequent decisions in the 1990s led to the creation of the EELV program and the Atlas V and Delta IV launch vehicles to meet U.S. national security needs for expendable vehicles. Boeing and Lockheed Martin formed United Launch Alliance (ULA) in 2006 at the behest of the Government in an effort to reduce duplicative costs in separate launch vehicle programs.

In late 2012, the Department of Defense (DOD) announced that it would invite competition for its EELV-class payloads beginning in 2015. The Air Force would proceed with a "block buy" of up to 36 "launch cores" from United Launch Alliance while competing up to 14 cores from potential new U.S. entrants such as SpaceX. The Air Force separately signed a contract with SpaceX for two launches in 2014 and 2015 to support the certification process for Space X's Falcon 9 v1.1 vehicle. The criteria for certification are set forward in a Launch Services New Entrant Certifi-

cation Guide. There are several potential ways to achieve certification, through combinations of successful flights and/or detailed analyses showing compliance with Air Force requirements.

CURRENT ISSUES AND POLICIES

Fiscal constraints, rising launch costs, limited demand, and strict Government requirements have combined to create a complex, on-going debate about the role of competition in the procurement of EELV-class launch services by the DOD. Private companies, whether Boeing, Lockheed, or potentially SpaceX, Orbital, and other companies yet to emerge must provide these services as the Air Force does not own and operate its own launch vehicles in contrast to its ownership and operation of air cargo transports. The Government clearly has an interest in getting the most value for the taxpayer dollar while at the same time requiring a high degree of mission assurance given the criticality of national security payloads. The Government also has an interest in understanding the implications of its purchasing decisions on the U.S. aerospace industrial base.

Due to the size and scope of DOD launch purchases and the requirement to use U.S. suppliers, DOD decisions have a major impact on the U.S. space launch industrial base. National space policy calls for maintaining assured access to space, with the DOD having the largest share of this responsibility. NASA and commercial providers also require assured access to space and they too are concerned about the U.S. launch industrial base. However, they purchase the best available launch services meeting individual mission needs, with NASA limited to U.S. suppliers unless specifically exempted, and commercial satellite firms purchasing the best globally available launch services, unless limited by export controls or other regulations.

DOD, NASA, and commercial satellite firms all rely on the same industrial base such that decisions made in one U.S. sector nearly always affect others, often in unanticipated ways. The DOD decision to end the use of the Delta II launch vehicle meant that fixed costs that had been shared by DOD and NASA now fell completely on NASA. This increased the cost to NASA and made the Delta II uneconomic for a large class of science missions that had relied upon it for many years. Similarly, the retirement of the Space Shuttle together with the cancellation of the follow-on Constellation program by NASA ended the sharing of certain fixed costs with DOD and drove up the cost of solid and liquid rocket propulsion systems, including those used by EELVs.

The 2013 National Space Transportation Policy does not specifically address the EELV program. Rather, it directs the Secretary of Defense to: “Ensure, to the maximum extent practicable, the availability of at least two U.S. space transportation vehicle families capable of reliably launching national security payloads”. This condition is met today by the existence of the Atlas V and Delta IV, and in the future may (or may not) include SpaceX, Orbital, or even NASA’s Space Launch System. There is no requirement that these vehicle families be privately owned, although that is at present the most plausible assumption.

U.S. national policy addresses the space launch industry base by stating that the health the industrial base, broadly defined, is a consideration that goes beyond the needs of any specific mission in awarding contracts or setting the parameters of competition. Specifically, the policy states that:

“To promote a healthy and efficient United States Government and private sector space transportation industrial base, departments and agencies shall:

- Make space transportation policy and programmatic decisions in a manner that considers the health of the U.S. space transportation industrial base; and
- Pursue measures such as public-private partnerships and other innovative acquisition approaches that promote affordability, industry planning, and competitive capabilities, infrastructure, and workforce.”

It should be noted that the policy includes both Government and private sector industrial bases, although in practice it is difficult to clearly separate the two. The only Government-led launch system development at present is the Space Launch System, and even in that case private contractors are doing the work in commercial as well as Government facilities. With regard to private sector competition for Government contracts, the policy states that:

“U.S. commercial space transportation capabilities that demonstrate the ability to launch payloads reliably will be allowed to compete for United States Government missions *on a level playing field, consistent with established interagency new entrant certification criteria*. Any changes to these new entrant criteria shall be coordinated with the Assistant to the President and National Security Advisor and Assistant to

the President for Science and Technology and Director of the Office of Science and Technology Policy before they may take effect.” [Emphasis added]

I have emphasized to the phrase “level playing field” as the determination of just what this means is central to the question of competition going forward. Policy alone cannot answer the dilemma of how industrial base and competition objectives should be traded so as to assure the existence of at least two “U.S. space transportation vehicle families capable of reliably launching national security payloads.” The judgment as to what constitutes acceptable reliability is left to the DOD and the Air Force. I will briefly address three primary factors that are driving possible trade-offs and the uncertainties around them: market structure, mission assurance needs, and options for reducing launch costs.

STRUCTURE OF THE LAUNCH MARKET

Given that private firms provide U.S. launch services, how many launch providers can the market sustain? It should be recalled that ULA was formed because launch demand, U.S. and foreign, was inadequate to sustain two independent competing launch providers with separate infrastructures. The structure and size of the market has not changed in the last decade; U.S. Government demand has remained flat at best. There has not been growth on the commercial side for EELV- class payloads, although there has been an increase in small “nanosats” and “cubesats.”

Historically, the demand for space transportation has often been overestimated, whether from projections in the early 1980s of the need for 24 Shuttle flights per year, or the 1990s expectations of hundreds of small satellites for mobile satellite services. Virtually all of those “big LEO” and “little LEO” systems disappeared or went bankrupt in the face of the rapid expansion of ground-based cellular communications. In 2013, the FAA’s commercial space transportation advisory committee (COMSTAC) predicted a small increase in commercial launches in 2014 and 2015, followed by a decline to a relatively steady state for the rest of the decade.

Mass tourism to orbit, not just suborbital flights, would be a “game changer” in terms of bringing significant new commercial demand to the space transportation market. In the Government civil sector, the market for transportation of cargo and crew to the International Space Station is quite modest however, a U.S. commitment to human lunar exploration, with procurement of private launchers to deliver cargo to the Moon, could greatly strengthen demand for U.S. launchers. Both tourism and lunar logistics would occur outside of the DOD budget, and thus would have the potential to benefit DOD, but it is unknown when, if ever, either new source of demand might occur.

The recently successful SpaceX launches of communication satellites are a case in point, taking back market share from European and Russian providers that had largely driven the United States out of international competitions. A shift in demand toward the United States would, of course, drive up costs for competitors in Europe and Russia, who would have less demand for their services. This would also create partial disincentives for new countries seeking to develop launch capabilities and offset some of their costs through export of launch services. In this way, U.S. pricing power can be a barrier to entry for developing space launchers.

While the success of the SpaceX Falcon and, more recently, Orbital’s Antares launcher is welcome, it should be kept in mind that governments, not private industry, drive much of global launch demand. Most foreign government launch opportunities are inaccessible to U.S. launch providers, just as U.S. Government launch opportunities are inaccessible to foreign launch providers. In general, competition is a good thing. However, the launch market is not a classic one of “many buyers and many sellers,” but is instead characterized by very thin demand, few suppliers, and multiple government-driven industrial policies (U.S., European, Russian, Chinese, Indian, and Japanese). Major spacefaring countries have shown a willingness to retain their launch autonomy, even if it makes no commercial sense.

In space transportation, price is among several factors, such as schedule, reliability, and risk that affect demand. In conventional markets, falling prices create increased demand. Space launch demand has, however, proven to be remarkably flat over a very wide range of prices. Past studies have estimated that launch prices would have to fall to a few hundred dollars per pound, from the thousands of dollars per pound levels of today, to induce new demand, notably in space tourism. A consequence of flat demand is that a lower cost supplier, able and willing to offer a lower price, can displace a higher priced incumbent. However, once accomplished, the new supplier has every incentive to raise prices to gain revenue and profit margin. The buyer does not necessarily benefit from lower prices once a new set of suppliers is established. Said another way, the prices experienced by buyers in a thin

market, with flat demand and high barriers to entry, generally do not drop after the exit of the former incumbent.

The attainment of lower launch costs and hence lower prices with present-day expendable launchers can create disincentives to the private development of new reusable launchers. As expendable prices drop, the economic break-even point for investing in reusable launch systems increases; that is, more flights of the reusable system are required to “pay back” the investment in its development. This is an especially difficult barrier given current and foreseeable launch markets, where demand is essentially flat. Thus, new reusable launch vehicle technology resulting in dramatically lower operational costs would seem to be out the reach of private development. It is not the availability of capital but rather the lack of an attractive business case that is the problem.

High prices and low volumes characterize today’s launch market such that industry revenue is maximized when demand is (nearly) linear with prices. If prices were to be cut by half and volume only doubles, total revenue would be constant. This creates a classic market failure in that there is no market incentive to invest. The space launch market thus has some similarity to other historical transportation technologies, from canals and railroads to automobiles and airplanes. Faced with these issues in the past, the Government has taken action to overcome “market failure,” with incentives that move the market to prices at which demand is capable of driving prices lower rather than higher. Thus, the early transcontinental railroads profited from the sale of former Federal land, not the operation of the railroads themselves. The air transportation system enabled by Government support for airports and the air traffic control system benefits the economy as a whole far more than it does the airline owners and operators.

The point of these examples is that space launch is a strategic national capability that serves public as well as private objectives. Despite its criticality, however, the economic structure of today’s space launch market results in a classic “market failure” that justifies Government intervention. However the purpose, degree, and scope of that intervention is a subject of debate, as we will discuss.

MISSION ASSURANCE AND THE COST OF FAILURE

Launch vehicles are a means to an end, the reliable placement of payload into space. The loss of a national security payload is unlike a commercial loss in which an insurance payout can compensate for the loss. The cost of failure in the national security arena is tremendous, in terms of direct hardware losses, failure investigations and corrective measures, replanning and rebuilding, delayed mission capabilities, and indirect loss of national and international confidence. The stakes are even higher, of course, where human life is concerned.

The EELV program has an excellent reliability record, with 68 successful launches since 2002. Launch vehicle reliability records, whether for Atlas, Delta, Titan, Soyuz, Proton, Long March, Zenit or Ariane, develop over time. A launch vehicle may be designed to be reliable, and the tools of probabilistic risk assessments can help predict relative reliabilities among different designs. But it is only with accumulated flight experience over time that one can actually know what the reliability of a vehicle is. This is a challenge for developing vehicles in which the configuration of the vehicle may be changing from flight to flight. The actual flight heritage and confidence of individual subsystems, such as engines, electrical, guidance, and separation devices, can vary substantially in a vehicle that appears outwardly unchanged.

If mission assurance is critical and the costs of failure are high, it makes sense to be willing to incur additional costs to assure launch vehicle reliability—and to want to have actual flights to prove that reliability. The current Air Force approach of requiring combinations of either demonstrated performance or documentation is a reasonable one for giving new entrants an opportunity while protecting national security interests. That said, the United States incurs considerable cost to ensure that it can place national security payloads reliably into space, with extensive documentation requirements, audits, and inspections, not only of technical matters but of financial and business processes as well. Do all of these additional costs add value for the Government? What are the cost/risk/benefit trade-offs of doing something different?

Government oversight is costly, but reliance on the private sector when commercial demand is very thin is also risky. During the defense reforms of the 1990s, the Government stopped requiring its standards for radiation-hardened electronics, assuming an experienced industry could and would apply more cost efficient commercial standards. Government needs proved to be both unique and limited, such that there was little economic incentive to meet Government standards in the much larg-

er commercial markets. The result was a series of costly failures in Government programs that necessitated rebuilding, at public expense, an industrial capability that had withered.

I am not saying that we should accept less reliability for lower launch prices; or that some level of failure in space is acceptable. It is difficult to identify a viable product or service that thrives with low reliability. However, there is suggestive evidence that the cost of Government-driven mission assurance and current Federal Acquisition Regulations (FAR) increase costs by factors of 3–5 times, not just 20–30 percent.¹ Thus debate should be about the cost of assuring reliability and whether or not that can be accomplished in a more cost-effective way.

The traditional FAR process is not inherently dysfunctional—nothing in the FAR requires Government program managers to act inefficiently. Unfortunately, the penalties imposed on Government managers who try to expedite development by tailoring the application of FAR processes can be so severe that, in practice, most persons in authority will not take the risk. The typical Government acquisition cycle is structured with far more emphasis on eliminating any possible cause of failure, than achieving success in a timely and cost-effective manner. In reality, the cost of broken hardware and the required rework can easily be less onerous in the long run than the cost and schedule overruns that so typically plague Government procurement. But cost and schedule overruns, as long as they are in some sense “moderate,” e.g., factors of two or less, are not considered to be “failures,” whereas broken hardware emphatically is.

As a result, Government procurement can become so dysfunctional that innovative approaches such as NASA Space Act Agreements are sought out for use in situations well beyond their originally intended sphere of applicability. The DOD and intelligence communities have their own “other transactional authorities” which can be used in place of FAR-based procurements, and have at times sought their own approaches to operating more efficiently in performing critical missions, such as classification and the establishment of special programs under DARPA or the Strategic Defense Initiative Organization.

Expedited approaches to Federal acquisition are structured so as to sacrifice a certain amount of formal, documented accountability for the expenditure of public funds in exchange for significantly expedited results obtained at substantially lower cost. While this has worked extremely well in particular cases, it remains broadly true that public funds must be carefully accounted for, and the Government must be a “smart buyer” on behalf of the taxpayer. Experiences with programs such as the Future Imagery Architecture demonstrate the consequences of agencies having inadequate internal skills and capacities to oversee major program acquisitions.

This raises a key but widely misunderstood point: much of what has been labeled “commercial space transportation” at NASA in recent years is really just innovative contracting with new contractors. It is, largely, *not* private capital being put at risk to compete in private markets; the arrangements involved might far more accurately be described as “private-public partnerships.” There is nothing inherently wrong with such arrangements, but we should use accurate terminology in describing them, and we should require that in exchange for the public funds that are advanced, the Government benefits accordingly. For example, the development of two new cargo suppliers for the International Space Station—Falcon 9 and Antares—has been a success. The DOD may thus be in a position to benefit from the capabilities of SpaceX and Orbital that NASA has helped to develop with its innovative combination of public money and private talent.

By all observations, the new private entities are intensely focused on reducing costs, and this includes the cost of compliance with Government regulations that are now imposed on United Launch Alliance. If a private entity can demonstrate reliability without traditional levels of Government oversight, it could have a sizable cost advantage. This then raises the question of whether the Government will allow one set of rules for so-called “new entrants” and a different set for incumbents. Looking forward to the potential 14-core competition, the question for the Government will be what costs it wishes to impose on suppliers of national security space launch services, and whether those rules are applied on a “level playing field” as called for in U.S. policy.

¹ Comparison of actual private costs to development costs predicted by Government cost models have indicated wide gaps in some cases of small launch vehicles, communications satellites, and cargo aircraft. The data are sparse however as few direct public-private product analogues exist.

REDUCING LAUNCH COSTS

How does one actually reduce launch costs? Clearly, anyone with deep pockets can reduce launch *prices*—e.g., sovereign nations, wealthy entrepreneurs or philanthropists—but how can the actual *cost* of launches be cut? The rocket equation and propulsion mass fractions are as unforgiving as private capital markets. Process improvements, in design, production, and operations can help, such as vertical component integration, horizontal payload processing, and streamlined launch checkout and operations. However the amount of “touch labor” required per pound of launch vehicle is stable across a wide range of masses, so improvements tend to be of marginal, not break-through, benefit.

Increasing production volume through large buys can achieve economies of scale. However, without new demand, large buys are not sustainable without Government support. As mentioned earlier, demand is relatively flat, so there are limits to the size of buys that could be justified. Launch costs might be made cheaper if some lower level of reliability could be traded for cost, but no payload owner would want to use them. Large-scale space tourism is only possible at levels of reliability and safety even greater than what we have today.

Various teams are exploring how existing engines such as the RS-68, RS-25, and even the old Saturn V F-1, could be manufactured more efficiently. The production line for Merlin engines at SpaceX is very large, with 10 engines being used on each Falcon 9 flight. This helps build operational experience more rapidly than if using a fewer number of more powerful engines. Whether this multi-engine approach is reliable and executable as flight rates increase remains to be seen.

New concepts such as reusable “flyback” boosters that return expensive elements (propulsion, avionics) for re-use are promising. Electric propulsion for in-space movement of satellites is developing rapidly. During the Government shutdown last year, a space electric propulsion conference was held at my university. It attracted about 400 participants, U.S. and foreign, industry and academia. Commercial satellite companies are moving to take advantage of electric propulsion. This could have great impact on the commercial launch markets, as a dedicated upper stage would no longer be needed to place a satellite in its final orbit. I am speculating, but a two-stage vehicle with a reusable first stage could be a serious competitor in that future world.

New technology seems to be the long-term answer, in particular, advanced propulsion with much higher specific impulse, than current chemical propulsion. DARPA has pioneered work in high energy density materials that may the potential to dramatically increase the performance of chemical rockets. DARPA also does not seem to think that re-engineering existing engine designs will enable major cost reductions. Instead, they are looking at reusable systems such as two-stage to orbit concepts. Single-stage to orbit vehicles using air-breathing engines still look to be beyond the state-of-the-art. As mentioned earlier, the economic break-even point for reusable launch vehicles is greater than for expendable launchers. Assuming expendable launch prices do decline, this will make the economic case for reusable more challenging without dramatic technology advancements. Thus investments in new space launch R&D are likely going to have to come from the Government, not private industry.

CONCLUDING OBSERVATIONS

The United States and the DOD in particular need to decide how it best assures the existence of at least two “U.S. space transportation vehicle families capable of reliably launching national security payloads.” In doing so, the DOD has to be mindful of the overriding need for mission assurance, fiscal constraints, and the need for a U.S. industrial base that can assure access to space for all payloads.

In this context, industry competition is a tool, not an end in itself. Depending on its terms and conditions, competition can result in meeting DOD needs at lower cost or failing to meet those needs and merely shifting costs to other accounts. The EELV program as managed by ULA today represents high degree of experience and capability that are vital to assuring access to space for all national security needs. As a potential competitor for national security launches, SpaceX is innovative, real, and brings an intense focus on cost control while meeting customer launch needs.

How will any new entrant, do in the future? Only repeatable, configuration-controlled flight experience will tell. The Launch Services New Entrant Certification Guide is a thoughtful and prudent approach that is being applied to SpaceX and should be to any candidate new entrant. The more difficult question is what comes after a new entrant is certified. Will current FAR-based procurements be used, or will the DOD procure future services in a more commercial-like manner, perhaps paying for additional specific services not required by private sector customers?

Will incumbents and new entrants, with very different histories, compete under the same rules? And, whether they do or do not, what may be said about the rules themselves? Do today's rules appropriately reflect the nearly 60 years of lessons learned in space transportation? I do not know the answers to these questions, and I suspect no one else does either at this time. In this connection, I am reminded of the comment made some years ago by Wayne Hale, former Space Shuttle Flight Director and, later, Program Manager—"I am not sure I know how to make space transportation more reliable, but I do know how to make it more expensive."

In the end, the policy issue is not one of SpaceX and other potential new entrants versus ULA as much as it is one of deciding what the role of the DOD should be, and what are the Government's policy requirements. Should we be trying to:

- Get the lowest price for reliable transportation to orbit for a particular mission?
- Get the lowest price for all national security missions?
- Get the lowest price for all Government-funded missions?
- Assure access to space for all needs with a U.S. industrial base at least cost?

The last question is a consequence of the fact that a space launch industrial base meeting all Government needs, civil as well as national security, cannot presently be sustained by private market demand. Thus, a significant degree of Government support will be necessary for the foreseeable future.

Reliability and readiness have been the top priorities for national security launches. Given the importance of national security missions, what is the most cost-effective way for the DOD to assure mission success? Can mission assurance be achieved at lower cost than the way we do it today? This certainly seems plausible, but careful thought needs to be given as to what responsibilities and capabilities ought to remain within the Government. Will the Government have the authority to order a stand-down of a vehicle family in the event of a failure? Are agencies willing to relax or modify their use of cost-accounting rules and other FAR-based requirements for all launch service providers? In short, how much is the Government willing to pay for "process" in addition to "performance"?

Defense acquisition reform is a much larger topic than the present hearing, but nonetheless bears directly upon the present case. Thus, the question of how best to acquire space launch services may provide an opportunity for pilot-testing some forms of regulatory relief, as opposed to direct subsidies. The Government could pay separately for non-commercial processes and deliverables, rather than having all such costs bundled into the launch cost or company overhead as is done at present. The Government may still pay more for its launches than a commercial buyer would, but the costs drivers would be more visible and accountable and would more easily allow cost-benefit trades to be performed.

Most critically, the United States needs to ensure that its space policies, programs, and budgets are in alignment, since to do otherwise is to invite failure. The first consideration for any policy choice and implementing approach is that it be clearly stated and adequately funded—with clear priorities on which requirements, schedules, and goals will be relaxed if resources or regulatory relief are not forthcoming.

Thank you for your attention. I would be happy to answer any questions you might have.

Senator DURBIN. Dr. Pace, thank you very much. I think you can tell from the opening statements that this is a subject that I've found challenging to the committee and to Congress that really called for a much different approach in hearing, to bring together two companies from the private sector to express their points-of-view.

I've done something that's a little unorthodox here. I've invited each of the companies represented, ULA through Mr. Gass, and SpaceX through Mr. Musk, to submit 10 questions to the other side so that we can hear what they consider to be the strengths and weaknesses of their position. And those will be submitted for the record, and I encourage each of them to respond appropriately and in a timely fashion.

Let's get down to some specifics if we can.

RD-180 ENGINE

Mr. Gass, Russia's in the news. And the question about sanctions by the United States against Russia for their adventurism in Crimea raises a question about our future relationship with this country. I ask you, when it comes to your use of the RD-180 engine on your Atlas V missions, what do you think is the reliability of that engine being available from Russia for the immediate future and whether the United States, in the interest of its own defense, should take that into consideration when it awards these contracts?

Mr. GASS. Thank you, Senator Durbin, and we all are watching and caring for the people in Ukraine in this situation.

First, let me kind of give a little bit of history on the engine. We went to the former Soviet Union with the encouragement from two presidential administrations more than two decades ago to look at capabilities that were in Russia, that were in the former Soviet Union. And what we found was an engine that was more advanced in technology and could be bought in a cost-competitive way than we had here in our country.

What we have done to protect, for that concern, since the day we started with that relationship more than two decades ago, we protected the Nation. And what do we do from United Launch Alliance? First and foremost, we have 2 years of safety stock inventory. Actually, today we have greater than that in-country, and our ability to launch any of the near-term satellites that we need to do for national security.

At United Launch Alliance, we have another product that is fully compliant and ready to support any of the missions. So from the Nation, we are not at any risk for supporting our national needs. We've always kept our ability not to be leveraged in the case of any kind of supply interruption.

Senator DURBIN. So I understand, for clarity here, you're saying that you have warehoused or stockpiled engines for 2 years' possible launches? What about the capacity to produce that same engine in the United States?

Mr. GASS. Thank you, Senator Durbin. We have, as part of the deal that we signed with a company called RD-Amross, was the joint venture of United Technologies and the company in Russia called NPO Energomash.

We had a business deal where we could buy—co-produce that engine. We bought all the blueprints and specifications, brought them into the country, and demonstrated that we can take the blueprints and specifications that were written in Russian, translated them, and at full arms-length relationship, demonstrate we can build the most difficult products.

And we've done that over several years. We invested hundreds of millions of dollars to prove that we have the capability to demonstrate our ability to build that exact engine.

I've always encouraged the Nation to kind of follow what we saw in Russia; that they as a country invested consistently in propulsion technology. We have kind of fallen behind in advanced technology. When we went to Russia, there were things that they were doing that we found in our textbooks said was impossible. So, you know, it just shows that you can break the bounds of technology,

and we have the ability, now that we know how to do it and are ready to do it.

The people at United Launch Alliance industry, the work that's being done at Marshall Space Flight Center and at the Air Force research labs have been pushing our envelope of technology. We need to stay on that constancy of purpose.

SPACEX LAUNCHES

Senator DURBIN. Mr. Musk, one cannot help but be impressed by the numbers that you've given us in terms of the cost of your product, measured against ULA.

We start with the premise that Senator Shelby noted. ULA has a flawless record. It's been able to achieve the goals that we've set for them time and time and time again. Your suggestion is we've paid dearly for it and could pay a lot less now.

I guess the question I need to ask, the premise of this is, goes back to the creation of ULA. Do you believe it is possible to maintain two companies in competition for future launches? And could your company, with a record of success, but more limited because of the time that you've been around, be able to compete without, for example, commercial business to sustain you when Government budgets cannot?

Mr. MUSK. Yes, absolutely. At first I should mention that the premise of perfect success is not quite correct for ULA. They certainly have a very good track record. But the first Delta IV Heavy failed, and there was a partial failure of one of the Atlas missions, which resulted in a satellite having a reduced life. So it's certainly a good, but it's not quite correct to say that it's perfect.

What I think is a logical sort of thing going forward is that there would be two families of rockets, but not three families of rockets. So, currently, ULA has both the Atlas and the Delta, but those are redundant. You don't need both of those rocket families. And I think it would make sense, you know, for the long-term security interests of the country, to probably phase out the Atlas V, which depends on the Russian engine, and have ULA operate the Delta family, SpaceX operate the Falcon family, giving the Defense Department a shared access to space with two completely different rocket families.

And I think that's the logical thing to do moving forward. And I think it would be the best thing in every respect for the country.

EELV LAUNCH CAPABILITY ACCOUNT (ELC)

Senator DURBIN. Mr. Gass, before I was chair of this subcommittee, we looked closely at the EELV Launch Capability (ELC) account, the cost-plus account that basically has been described in many different ways, to maintain the capability, infrastructure necessary. So we are dealing, when we deal with ULA, with the actual fixed price of the product, the launch, that we are purchasing, and then at ELC, which has been characterized as an infrastructure investment, a subsidy, a cost-plus item.

What I hear from Mr. Musk is that he doesn't need that cost-plus item. He doesn't need that subsidy in order to compete with you. So the question for the taxpayers: Why should we give your com-

pany a special break when it comes to these launches if you can't meet competition head-on?

Mr. GASS. Well, first, again, thank you for that question, and I knew it was coming. And, you know, I was listening to Mr. Musk and an ironic moment came back to me. It was probably more than a decade-and-a-half that I was sitting in the back of a room like this when there were some generals and some industry leaders sitting here explaining to Senators like yourself about why there were some of these failures that cost billions of dollars of lost capability, and they were held accountable. And most of them, their careers ended, and we changed the acquisition strategy.

The ELC was an outgrowth of that event. And I want to put you in the shoes of the director of the National Reconnaissance Office and the Air Force in 2004. The two companies competed. We were in a FAR-12 fixed-price type contract, as Mr. Musk is advocating. All the national security satellites that Congress funded that were being new stocks were significantly behind schedules. The capabilities in orbit were significantly deteriorating.

We were not sure when the satellites were going to come out of the factories. They were going through final tests. They were having problems. And the Nation needed the launch vehicle company to stand ready. Whenever that satellite came, the Nation needed that satellite to be launched successfully whenever it was ready.

In a fixed-price business, we were losing money. There were no satellites to be launched. We had people standing around. We would have furloughed our workforce for awhile and come back when there was enough demand when those satellites were ready, pool up the demand. So we had to come up with a solution that provided the national security capability.

So the ELS is just that capability that gives the flexibility to the war fighter to make critical decisions when they need it. It's not; it's categorically not a subsidy. I wish I had a contract that Mr. Musk has, that from the NASA commercial cargo activity, much better for making us competitive in the true commercial market, because it doesn't come with any of the constraints and burdens of accounting that I think Ms. Chaplain articulates that comes with a lot of restrictions.

So ELC is not a subsidy. It's about providing national security capability with a laser focus on mission success.

I would also encourage the committee to think about it as a pendulum. We swung at one point in time to a very commercial model. We swung to a very classical DOD contract. And the pendulum is moving back to the middle. We need to find that right equilibrium that brings that balance of critical missions, and it promotes cost competitiveness.

Senator DURBIN. Thank you. I'll have some more questions in the second round.

Senator Cochran.

Senator COCHRAN. Mr. Chairman, thank you very much for convening this hearing. It's obviously very appropriate and timely.

EELV COMPETITION

I wonder what the reaction of the panel is to the Air Force's new strategy to reintroduce competition in the EELV program, at the

same time recognizing that we have significant mission success which has been achieved by United Launch Alliance, the sole-source launch provider since 2006. What is your reaction to that situation? Should we continue to support this as it is? Or should we make changes?

Mr. MUSK. Who would you like to answer that, sir?

Senator COCHRAN. Whoever wants to answer it.

Ms. CHAPLAIN. I think when we did our report in 2011, the idea of having competition in this program arose. And over time, DOD did recognize that this was a way to lower costs. The costs were a real issue back in 2011.

Just to quote Frank Kendall, who is the acquisition leader at DOD, "With no threat of competition, DOD, the EELV, and the prime contractor are in a poor negotiating position and pay the price demanded." So, competition is one avenue to put pressure to lower prices. It's not the only avenue.

The other avenue is to gain insight into costs and pricing and to take actions to gain more efficiencies within the program you have. The Air Force is doing both. The NASA side uses competition to do its launches. It works pretty effectively. And ULA and SpaceX are both used to working under those arrangements. It's worked well for other Government agencies.

Senator COCHRAN. Mr. Gass, do you have an impression to share with us?

Mr. GASS. Absolutely. The measures of success should not be how widely competition is employed, but how wisely competition is employed. When we started this program; we had two competing companies Lockheed Martin and, the Boeing Company, and it wasn't working. So can we formulate competition that could work that's actually going to save the taxpayer money?

When you deal with a limited demand of the Nation and some of the unique requirements that the Nation has, how are we going to have that competition to be on a fair and level playing field?

Some of the most unique missions clearly don't need multiple capabilities in this country. And if we talk about fair, level competition, is it two companies? Is it three companies? Is it four companies? When does it stop, and how do you limit other companies from wanting to participate and taking a niche of the product?

I shared the story of when I was here about a decade-and-a-half ago. I was running the program called the Atlas II. It was supporting DOD programs on a FAR competitive basis. And we were launching, basically, the military satellite constellation. We had a block buy of discus and UHF, which have been replaced by the WGS and MUOS in today's constellation.

We have a block-buy fixed-price commercial contract. With that contract, we were able to compete for NASA, for commercial missions fairly successfully. After those disasters, I was promoted and I now had all of—many launch capabilities. And I was cleared for some classified missions and recognized those missions can't work in a competitive, commercial environment. Those capabilities are so unique that it just would not work. It would have cost the Government excess funds to stand up multiple companies to have that redundant capability.

I always go back, when I share with acquisition officers the story, many years ago I worked on the Tomahawk cruise missile program. And the country wanted to dual-source and have competition. Well, the demand wasn't there. They told the companies, "You're going to stay in business." It quickly became a competition to win the losing share. There was no incentive to win the majority share because if you don't have a winner-take-all survival-of-the-fittest kind of competition, and you know that you're going to be kept around, it also doesn't work.

Ms. Chaplain talks about the lessons learned in the balance. I'm all for that pendulum moving to the right spot for our Nation and delivers taxpayers a better and a more efficient activity.

Senator COCHRAN. Thank you.

Mr. Musk, what is your reaction to that?

Mr. MUSK. Well, I think as a country we've generally decided that competition and the free market is a good thing and that monopolies are not good. And it's interesting to note that from the point at which Boeing and Lockheed's launch business merged, the point at which they stopped being competitors, the costs doubled since then.

And I think the reality is: When competition is introduced, reliability is a key factor in competition. So that would be a deciding factor in who wins what launches. It doesn't become less important; it becomes more important. But the costs to the U.S. taxpayer will drop substantially. I think they will drop at least to the level that they were before Boeing and Lockheed became a monopoly in the launch business, and perhaps even better than that.

And frankly, if our rockets are good enough for NASA, why are they not good enough for the Air Force? It does not make sense.

Senator COCHRAN. Dr. Pace.

Dr. PACE. Well, I think the previous two comments have highlighted the importance of looking at this as more than just DOD. That is, what actions occur in the commercial market? What actions occur with NASA? All affect the same industrial base. There isn't really a DOD space-launch industrial base. There's a U.S. launch industrial base. So what actions other agencies pursue have an impact here.

As is mentioned, NASA has been successful in using more streamlined processes for buying its launches. I think it's also fair to say that NASA doesn't have the same policy requirements for assured access to space that DOD does. I dealt, when I was at NASA, with a lot of the science mission community. And they were plainly opportunistic. They would buy the best, most reliable vehicle they could at least cost. But they did not have the same policy imperatives for assured access to space for all their payloads that DOD does.

So the question is: What does the Government want? How much is it willing to give regulatory relief to move that pendulum back? And how much does it still want to have the kind of cost and data and pricing insights that it's traditionally asked for? And whatever it does, it needs to be done beyond just DOD, but needs to be looking at other Government purchases, you know, such as NASA practices.

That would be my response.

Senator COCHRAN. Yes. Thank you.

Thanks, Mr. Chairman.

Senator DURBIN. Senator Feinstein.

Senator FEINSTEIN. Thank you very much for holding this hearing. I'm not a newcomer to this issue. I think it was several years ago that ULA came in and talked to me. And all of these companies are in California in one way or another. And so, I've had a great interest in trying to follow this, Mr. Chairman. And I don't believe that the promised savings of eliminating competition have materialized. The cost to the Government, to the taxpayer really has skyrocketed.

Behind me is a chart from the GAO's written testimony for this morning's hearing. It depicts of the EELV program since its inception. The red line shows when ULA was formed. So the cost of this program before and after competition for space launch, depicted by the red line, is startling. Since 2006, when ULA was formed, space-launch costs have increased from \$613 million to \$1.63 billion in fiscal year 2014. That's a 166-percent increase for the program overall.

Mr. Musk mentioned, and he's correct, that in 2012, this program triggered a Nunn-McCurdy breach when average procurement unit costs grew 58.4 percent against both the original 2004 and 2007 modified baseline. Most startling, the most recent independent cost estimates from the Cost Assessment and Program Evaluation of DOD projects the program will cost close to \$70 billion through 2030.

I welcomed Secretary Kendall's acquisition decision memorandum dated November 27, 2012. And I'd like to submit this for the record, if I may, Mr. Chairman.

[The information follows:]

	FOR OFFICIAL USE ONLY THE UNDER SECRETARY OF DEFENSE 3010 DEFENSE PENTAGON WASHINGTON, DC 20301-3010	NOV 27 2012
	ACQUISITION, TECHNOLOGY AND LOGISTICS	
MEMORANDUM FOR SECRETARY OF THE AIR FORCE DIRECTOR, COST ASSESSMENT AND PROGRAM EVALUATION		
SUBJECT: Evolved Expendable Launch Vehicle Program Quantity Buy Decision Acquisition Decision Memorandum		
Purpose: The Air Force has requested approval of the quantity rate across FYs 2013-2017 for Evolved Expendable Launch Vehicles (EELV) cores for the EELV Program. The Program Manager is Colonel William Hodgkiss; the Program Executive Officer is Mr. Scott Correll; and the Secretary of the Air Force, the Honorable Michael B. Donley, is performing the duties of the Service Acquisition Executive.		
Decisions:		
• I authorize the Air Force to negotiate with United Launch Alliance (ULA) based on an acquisition strategy that plans to procure up to 36 EELV cores across 5 years (FY 2013 – FY 2017) from ULA and up to an additional 14 cores from ULA under the Variation in Quantity and Configuration provisions if competition is not viable at time of need. The Air Force may not exceed the obligation authority established by my Acquisition Decision Memoranda (ADMs) of July 12, 2012, and September 25, 2012, until the Acquisition Program Baseline (APB) is approved. • I direct the Air Force to aggressively introduce a competitive procurement environment in the EELV program by competing up to 14 cores with initial contract awards as early as FY 2015 for missions that can be flown as early as FY 2017.		
Tasking/Action Items:		
The Secretary of the Air Force shall:		
• Within 30 days of this ADM, submit for my approval the date or event(s) that will trigger the release of a competitive Request for Proposal (RFP) for the 14 cores available for competition. Prior to Milestone (MS) C re-approval and prior to releasing the competitive RFP, the Air Force shall provide an acquisition strategy (or addendum to the current acquisition strategy) for my approval that addresses procuring up to 36 EELV cores, and also for competition for launch services, ensuring the benefits of competition are retained while maintaining the required mission assurance and assured access. • Take action to compete missions in such a way as to start awarding them as soon as possible after a new entrant is certified for the EELV program. After a new entrant's first successful		
FOR OFFICIAL USE ONLY		

FOR OFFICIAL USE ONLY

certification launch, the Air Force shall consider awarding an early integration contract to that new entrant for one or more candidate satellite missions.

- Provide EELV detailed programmatic assumptions for the development of the MS C baseline to Director, Cost Assessment and Program Evaluation (D,CAPE) in writing.

I request D,CAPE use a streamlined process to develop an Independent Cost Estimate (ICE), within 15 working days of receipt of the Air Force's programmatic assumptions and consistent with my decision on quantity and rate commitment in support of the MS C re-approval decision.

Discussion: This ADM authorizes an approach to contract negotiations on the size and duration of the EELV quantity over the Future Years Defense Program and allows the Air Force to proceed towards a plan for awarding a requirements contract and developing a competition plan in FY 2013. In addition, this ADM allows D,CAPE to complete an ICE and enables the Air Force to prepare the APB, both of which are required before I can re-approve MS C.

My intent with this decision is to maintain required mission assurance, obtain the positive effects of competition as quickly as possible, and also reduce the cost of the launch services we must procure from ULA. The 36 EELV cores designated to be procured from ULA require capabilities no emerging new launch entrant has developed or capabilities that are required for operational needs before the earliest new launch entrant's anticipated availability.

The acquisition strategy contains up to 14 cores available for competition if emerging new entrants have the required launch capability on a schedule to support all or some of these launches. In addition, the Air Force will enable this competition by planning for early integration of the candidate satellite missions.

My points of contact are Colonel Gregory B. Gonzalez, Deputy Director, Acquisition Management, at 703-697-0476 or Gregory.Gonzalez@osd.mil, and Colonel Carolyn Campbell, Chief, Enabling Systems Division, Space and Intelligence Office, at 703-692-6249 or Carolyn.Campbell@osd.mil.

Frank Kendall

DAB Advisors

FOR OFFICIAL USE ONLY

Senator FEINSTEIN. The memo states, and let me read it. "I direct the Air Force to aggressively introduce a competitive procurement environment in the EELV program by competing up to 14 cores with initial contract awards as early as 2015 for missions that can be flown as early as 2017."

Then it gave specific directions to the Secretary of the Air Force, which I think will be interesting to read. Unfortunately, it appears the Air Force is not living up to the direction provided by the Under Secretary. According to information provided to my office, it appears the Air Force is going to delay and reduce the number of cores that will be competitively procured before fiscal year 2017. And I think that's really a shame.

I have three quick questions.

AIR FORCE CERTIFICATION

Mr. Musk, SpaceX has achieved, as you just pointed out, three consecutive successful launches of its Falcon 9 rocket. That's the major requirement for being certified for competition for EELV contracts by the Air Force. So, what challenges, if any, do you expect from the Air Force certification process?

Mr. MUSK. The Air Force certification process appears to be going quite well. And we're not aware of any issues that would prevent us from being certified to fly missions, completing that certification this year. We aren't concerned about any delays in the contracting. Hopefully, those delays don't materialize. And as I mentioned in my earlier testimony, I think in light of recent events on the international stage, it may be wise to consider whether procuring the Atlas as part of the 36-core block buy, which is a 5-year buy, as mentioned earlier by Mr. Gass, they only have a 2-year supply of engines. Yet, this contract is a 5-year contract for the 36 cores.

So, if there were any sanctions or if there is any issue with supply of those engines, they will not be assured access to space for the Atlas V.

Senator FEINSTEIN. Now, according to the Kendall memo that I just mentioned, new entrants should be able to begin competing for up to 14 EELV launches by fiscal year 2015. Do you expect the Air Force to live up to the requirement imposed upon it by Under Secretary Kendall?

Mr. MUSK. I'm very hopeful that the Air Force will adhere to that requirement.

Senator FEINSTEIN. So you believe that you will be able to compete for 14 EELV launches by fiscal year 2015?

Mr. MUSK. I'm highly confident that we will be able to do so, yes.

Senator FEINSTEIN. Good.

Thank you very much, Mr. Chairman.

Senator DURBIN. Thank you, Senator Feinstein.

Senator Shelby.

Senator SHELBY. Thank you, Mr. Chairman.

AUDITING AND OVERHEAD COSTS

Mr. Musk, you recognized in your statement for the record that the Air Force's acquisition approach requiring detailed cost data, accounting, auditing, and other mission assurance requirements

and, these are your words, “adds substantial overhead costs to the taxpayer for oversight of a largely mature booster core.”

Yet, when you compare SpaceX and the ULA launch prices, do you ignore the fact that the ULA currently complies with the mandates that you acknowledge add substantial overhead costs? It seems like your price estimates compare apples and oranges. Mr. Musk, why should SpaceX be exempt from the same auditing, oversight, and accounting rules that DOD requires of the United Launch Alliance? If SpaceX is required to comply with those specific requirements, how will that impact the cost of your launch vehicle? Do you understand?

Mr. MUSK. Certainly. We provide full and detailed insight into all of our costs. And we’ve been doing so for a long time, to NASA. And we’re also providing that to the Air Force. So the Government has complete insight into our cost structure.

There are additional costs for U.S. Government missions due to the mission assurance process, because the U.S. Government does not buy launch insurance. So in order to improve the probability of success, there is quite a substantial mission assurance overhead that’s applied, which is why our launch costs are estimated to be 50 percent higher for Air Force flights than for commercial flights. So instead of \$60 million for a commercial mission, it’s \$90 million. But that compares to more like \$380 million for United Launch Alliance.

So even when you add the Air Force overhead, there is still a huge difference. In fact, all of the numbers I was referring to are including the Air Force overhead.

Senator SHELBY. Should you have the same rules to apply to your company that the United Launch has applied to them? I guess is the question.

Mr. MUSK. Absolutely.

Senator SHELBY. Okay.

Mr. MUSK. Yes.

CONTRACT COST

Senator SHELBY. Ms. Chaplain, I’ve got to direct this to you and GAO. You’ve explained to the committee that a fixed-price commercial contract, in accordance with FAR Part 12, limits the DOD’s insight into contract costs, which has caused problems in the past.

Could you describe for the committee the problems that have occurred in the past and your view of the utility in ensuring that DOD continues to acquire detailed cost data going forward, whoever is doing it?

Ms. CHAPLAIN. Okay. I would like to say when there were commercial contracts used at the beginning of the EELV program, the suppliers did not have to follow those requirements.

When the EELV program transferred into using a cost-type arrangement for one of its contracts, then they were required to have those systems. And the reason those systems are there is when you have a cost-type contract, the Government needs to validate those costs. They’re not just paying some price. They are paying the costs incurred. So you need standard, certified systems to ensure those costs incurred are valid.

They include things, overhead, pensions, everything that's allowable that the company incurs while it's making that product or producing that service.

If going into this competition, DOD chooses the commercial approach, those requirements will not be required of either party. If they choose the approach they're using now, the requirements will be imposed on both parties. The systems do provide good data. They give you insight into costs. They give you a uniform way of measuring. They help impose discipline on a program. There's a lot of value. And it was a long, hard fight to get those in the current program. It was not easy. It's not an easy accomplishment to do after a time period where you aren't required to do that.

That was also tied to these lot buys early on in the program. So it's reasonable why that wasn't required in the very beginning.

So there's value to these requirements. But under a commercial approach, the bottom line is price. And those requirements wouldn't be required of either party.

SUCCESSFUL LAUNCHES

Senator SHELBY. Mr. Musk, would you concede that 68 consecutive launches is a great record?

Mr. MUSK. I would, although I'd like to point out that there were two highly publicized failure investigations, one for Delta IV Heavy and one for Atlas. The Air Force conducted failure investigations. But ULA has a very good track record. It is just not quite as perfect as 68 perfect launches.

Senator SHELBY. Mr. Gass, do you have any response to that?

Mr. GASS. We measure the mission success by our customer's declaration. And so if they declare that the satellite and the mission is success, we use the same record. And why it is that important, because our profit is tied to our mission success. If we don't deliver it, it's not only a loss, we forfeit our profit, but potentially also get penalized. So the declaration is about the on-orbit capability. And that's how we measure success.

Senator SHELBY. Mr. Musk, in October 2012, I believe this is right, a secondary payload aboard a SpaceX Falcon 9 rocket was sent into the wrong orbit because one of the nine Merlin engines powering the rocket failed.

What recourse did the owner of the secondary payload have in that situation to recover damages? In other words, what's next? What was next?

Mr. MUSK. Right. Well, by ULA's definition of success, that mission was perfect.

Senator SHELBY. That was perfect, although you went into the wrong orbit and so forth?

Mr. MUSK. Right.

Senator SHELBY. You're saying that's perfect?

Mr. MUSK. So, the primary mission, which I was to deliver the CASSIOPE satellite, was 100 percent successful. There was a secondary satellite that was an optional objective that was not part of the primary mission.

But, as I said, if you accept ULA's definition of perfect success, then that mission was perfectly successful.

Senator SHELBY. Mr. Gass.

Mr. GASS. It would not be declared successful. If that was a contracted requirement, we would——

Senator SHELBY. He would say it was successful by his criteria, but you would say it was not successful by yours?

Mr. GASS. Right. You know, we can have a debate about “success.” But if it was considered an experiment and the rocket was supposed to perform all the capabilities and it didn’t, you know, that’s a different kind of business arrangement.

But in our measure of success, we put margins in. The anomalies that Mr. Musk referred to that we had on United Launch Alliance were designed margins. The margins came into play, and we were able to successfully deliver the satellite.

It is an incredibly risky business. And everything needs to work perfectly.

Senator SHELBY. Dr. Pace, do you have any comment on that?

Dr. PACE. I would add, more from as a former analyst, you know, with NASA, that getting detailed understanding of the prices and costs, we understood, I think with SpaceX. Understanding all the costs, I think, was somewhat more difficult, that SpaceX should not have, when I was at NASA, the detailed level of business accounting systems that we were used to on other projects. So we had a very robust dialog with SpaceX people, and we got a lot of information. There was a lot of cooperation.

But I would have to say that really understanding all those costs to the same level of detail was hard to come by. And so, eventually, in some areas, we said, you know, “There’s some magic going on in SpaceX. We don’t fully understand. But we appreciate the results.”

Again, how much is the Government willing to pay and impose on SpaceX on its contracts? If it’s not willing to impose those kind of detailed reporting requirements, are they willing to relax them, you know, on other players?

Senator SHELBY. Thank you.

Thank you, Mr. Chairman.

Senator DURBIN. Thank you, Senator Shelby.

In this round, I’m going to take what I’ve considered, after listening to the testimony and reading the background here, the best arguments on both sides and ask you each to address them.

BUDGET CONSTRAINTS AND COMPETITION

I’ll preface my question to Mr. Musk as follows: In this new job, I’m traveling around the United States, seeing some amazing capacity that we have developed: Newport News, the very best when it comes to building submarines, aircraft carriers; Connecticut, in their production of helicopters. Wherever you go in this country, California, as well, Boeing in the Midwest, you see some exceptional companies doing exceptional work keeping us as safe as possible.

And they all say to me, “Mr. Chairman, if you keep cutting these budgets, we’re going to be laying off the best workers in the world. When you need us, if you ever need us, we won’t be there. So you’ve got to find a way to maintain our capacity to build, even if we’re not at war, even if our budgets are going down.”

When I heard Mr. Gass explain the ELC, I think that's what I heard. He suggested there was a time when the workers were idle. They weren't being called to have as many launches as they were in the past. And so the ELC, some call it a subsidy, some call it something else, is basically there to maintain capacity even if the demand is not there.

So let me ask you this: What kind of risk do we run as a country to jeopardize the capacity of ULA by eliminating the subsidy or not factoring it into the bid so that, ultimately, war, no war, good budget, bad budget, when we need them, they'll be there?

Mr. MUSK. Sure. Well, the reality is that today there's a steady cadence of Air Force and NRO missions every year. So you don't really have the wide difference from 1 year to the next that you had in the past. So I think the prior justification of needing that for stability is no longer there, because there is the stable launch demand from the Air Force and the intelligence community.

Secondly, I go back to the point that there's really not a need for ULA to maintain two families of rockets, both the Delta and the Atlas. And given that the Atlas is dependent upon a Russian-made engine which can be cut off at any time, the logical thing to do is to eliminate the Atlas family, have the Delta and Falcon family. And that will provide the greatest amount of assured access and the great reliability and the cost savings that the Government is looking for.

Senator DURBIN. Mr. Gass, you saw the chart that Senator Feinstein produced. When it comes to competition, it usually means lower cost. When there's no competition, a monopoly situation or anything close to it, buyer beware. Consumer, consider the possibilities here that your costs are going to go up unbridled.

So, what we hear from Mr. Musk is that if we went into price competition, we could save a lot of money in a hurry, that in fact, ULA, based on his estimates, is overcharging the taxpayers. Now, here we're facing a budget situation which is awful. We're seeing limited increases in defense spending and, slightly over the horizon, another sequestration coming our way.

So, why shouldn't we, as good stewards of taxpayers' dollars, say, "Well, let's put some competition at this. That's the American way. That's the free market. Let's make sure that ULA is not overcharging us"?

When we look at the mountains on Senator Feinstein's chart, it suggests that, without competition, your costs have gone up dramatically. So why wouldn't the taxpayer be better served with competition?

Mr. GASS. Thank you for that question. It's important. And may I ask you to put the chart back up? First, for the record, I heard Mr. Musk use all kinds of numbers that were categorically wrong. And I'll be glad to share with the committee the right calculation.

I saw this chart last night in the GAO report when it was released, and I noted it as well. And that's an accurate representation of appropriation. It's not an accurate representation of cost or cost performance.

Let me just point your attention to the red line. In a period of time we're launching one or two a year, satellites were late, and as you described, we were being paid for a capability to stand

ready. As we go out to the outer years, we're now buying rockets and launching at about 10 or 11 a year. So if you just do division, all of a sudden it would be different.

The other thing that's interesting to note, that when we converted the contract in 2006, the stewards for this country, the acquisition professionals, required Lockheed and Boeing, and then into ULA, that when we signed up the contracts prior to that red line, there was losses. We actually had to give credits about almost \$1 billion that we took off the contract price so you didn't have to appropriate during that time, and the company took that as losses because they were overly aggressive in the pre-red line activities, but with that expectation of commercial.

So you talk about the good stewards of taxpayers, you know, give a compliment to the incredibly hardworking acquisition professionals that go through the data and provide and make sure that the Nation is getting a good value.

Senator DURBIN. But take me down to the basic question here. Price competition is going to give the taxpayers a lower cost, is it not?

Mr. GASS. It can if it's on a fair and open playing field. And everybody has to have the same requirements. The problem with that statement is: If everybody has to have the same requirements, and the certain requirements that you do not need—there will be excess capacity because there is just not enough work for two. And if everybody has to have it, it could create excess costs.

The other example that I gave before when we talked about the Tomahawk cruise missile, if you know you're not going to lose, it's not a winner-take-all, you may not have the right kind of incentives.

At the same time that Ms. Feinstein shows the increase in the appropriation, there was a period of time where we had a contract that was not incentivizing cost performance. We had what we call an award-fee contract, where requirements could creep up. And as a company, an award-fee, if we said no and pushed back in the requirements, we'd get negatively rewarded on your profit rate.

Today, the Air Force fixed that. We have a very clear contract that's aligned on the priorities. That's one, mission success is a major portion of our profit, and we have a cost incentive contract on ELC. We have to year-over-year improve. We signed up to a greater than 5 percent year-over-year improvement. It's already in the contract. And we're incentivized to improve upon that. So it's the right kind of contract for the time frame.

The period of time where the satellites were not coming at a regular basis has a different time frame than where we are today. I came into the building and talked to the officials as early as 2008, seeing that things were going to get more stable, that we needed to change the acquisition strategy. And it took us to 2012 for us to do that. But it's on the right path.

Senator DURBIN. Senator Cochran.

Senator COCHRAN. Mr. Chairman, thank you for convening this hearing. I think it's been a very helpful exercise. I have no further questions. But I want to compliment the efforts that the contractors are making to produce products which protect the security interests of our country at a reasonable price.

Senator FEINSTEIN. To Mr. Gass, I'm trying to remember how many years ago we met. But it was quite a few. And when we met, you know, I was surprised that this was essentially a monopoly. And I think we talked about it. And you assured me that these costs would go down.

Now, if I understand you correctly today, what you're saying is, "Well, we have to follow one set of restrictions, and they follow another set of restrictions." And I don't quite understand this.

Would you oppose an open competition if all the rules across the board were the same? Would ULA actually say, "We don't want to compete with SpaceX"?

Mr. GASS. Absolutely not. The ULA is ready and willing and able to compete on any field of open competition.

Senator FEINSTEIN. See, I would think that would be your answer. And I would think that that would be satisfactory, because, after all, competition is the American basic demand for the accordance of a contract.

So, what keeps us from doing this?

Mr. GASS. Basically, SpaceX doesn't have all the capabilities nor the requirements. So if you think about it, if SpaceX's requirements have to come down and some of our requirements have to be eliminated till we get that level playing field.

Senator FEINSTEIN. Okay.

Mr. Musk, respond to that. If this is the heart of the matter, respond to it.

Mr. MUSK. Yes. I believe SpaceX has—can manage all of the Air Force requirements. We might argue that maybe some of those requirements shouldn't be there. But we will meet whatever requirements the Air Force asks of us. And we believe we can manage all of the Air Force's satellites, and then some.

Senator FEINSTEIN. How much of this is in the fixed-price competition versus cost-plus?

Mr. MUSK. Well, I think fixed-price competition is the better way to go. When there is competition, then the logical thing to do is to go for a fixed price, because otherwise if you compete it and it's cost-plus, then it gives the companies the opportunity to raise their prices effectively, as their costs grow, subsequent to the competition.

Senator FEINSTEIN. Do you have a problem with that, Mr. Gass?

Mr. GASS. I think it's important that the Government understands what it's buying. I shared the story about the times when we had failures and I was working on a fully fixed-price contract. And then when I was cleared for some missions that I know that you're well aware of, those kinds of missions are very difficult to support on a fixed-price basis, the operational needs, the changes in schedules, the care and feeding that some of the satellites need.

The unique facilities—we talk about the rockets, but we're required to have special handling equipment, nitrogen purges for some of the—to protect some of the most sensitive sensors that are in some of these satellites, very unique capabilities that only the national security needs. They're not commercial commodities.

And right now, the way we're doing the contracting today, when we use the term "ELC," we're applying those costs to all missions. And it goes back to the roots of how the EELV program was estab-

lished. And it comes from a general report in the 1990s. And the goal was to lower costs for the Nation across all of our national launch security needs, not one mission area or not.

So on average, our costs have come down. The program is greatly successful, and we're continuing to drive the costs down, and the productivity is improving. But the key about—your question was about fixed price—is can you really apply it to everything? And it's about choices the Nation needs to make. We can use it. I talked about the pendulum swinging. We can go back that way, and we'll see some of the areas. Ms. Chaplain's team has done a great job on the report of laying out the balances, the trades that the Nation has to make.

It's not about what companies want. It's about what the country needs and how the Government and leaders make choices of how to deliver that.

Senator FEINSTEIN. So I'm trying to understand what you're saying. What you're saying is if the requirements for bid were all the same across the board, we would have no problem. Is that correct or not?

Mr. GASS. It would be fine for the competition. But just yesterday, the 14th Air Force out in California had to make some mission switches between NASA and the Air Force. They just gave direction. A NASA mission was late. An Air Force mission moved in. Another Air Force mission took priority. Another NASA mission was moved out.

If we were on a fixed-price world, that would be a series of contractual actions, potentially not having the capability to accommodate that because it took some money to create that flexibility. In a fixed-price world, that operational flexibility is not there for the war fighter. But it works for competition.

Senator FEINSTEIN. May Mr. Musk respond to that?

Would you respond to that?

Mr. MUSK. Certainly. So, I think the logical thing to do is to do a fixed-price competition for the basic vehicle. And then to the degree that there are mission-unique requirements, there is a fairly small part of the mission, that that would be cost-plus.

So if the Air Force says, "Well, there's a unique national security satellite. It's going to require these additional changes to the rocket or to the mission, or it's going to require priority," then just that incremental piece would be—it would be logical to make that cost-plus.

But the vast majority of the contract would be fixed-price.

Senator FEINSTEIN. Thank you. Thank you very much.

Senator DURBIN. Senator Shelby.

Senator SHELBY. Thank you, Mr. Chairman.

We're talking about competition, real competition. And if you can get it, it's the best thing in the market. We all know that.

Dr. Pace, in a classic market of multiple buyers and sellers, competition generally produces quality products and lower prices. The launch market is characterized by limited demand, few suppliers, and multiple Government industrial policies.

Therefore, lowering the cost of access to space while retaining performance and reliability may not result in price decrease for buyers; we don't know. If DOD has to pay, for example, new en-

trants for the infrastructure and labor costs now included in the EELV launch capability contract, how would duplication of existing infrastructure result in lower launch costs for DOD?

A lot of us are concerned that recreating the wheel could actually increase overall costs compared to what DOD is currently paying. Would you have a comment on that?

Dr. PACE. Sure. That's certainly possible. I think what we could see happening is that the introduction of competition could lower the costs, as a virtue of lower prices, for a wide category of services. There are a number of missions that I think SpaceX, for example, could certainly compete for. There are a number of missions that it may take awhile before SpaceX can compete, as mentioned, the Delta IV class systems, although eventually, may compete for those as well.

So, the question is, what do you want the industrial base to actually look like? If you break these costs out, and if you charge extra for noncommercial processes, is the Government willing to pay for that? Or do they prefer the convenience of bundling all that up?

I could imagine a situation where Atlas exits the market, as described, where Falcon takes over for most of that. We're still retaining the Delta IV's. And that is a much more segmented market. But as a result of that segmentation, you'll simply have a new set of monopolies. You'll have areas where only the Delta is going to be meeting that until SpaceX develops new products. You may have situations where only the Falcon is meeting other needs. So you'll be swapping the number of players around. You'll be breaking costs out in a more clean way.

But whether total costs go down for the Government, I think, is still something that may remain to be seen.

Senator SHELBY. How important is quality? In other words, the 68 straight launches, successful launches—important to DOD, for example?

Dr. PACE. Well, I think it's absolutely, absolutely crucial because what's happened so far is that we've paid the—we as the Government have paid for reliability and readiness. I would also say that SpaceX is accumulating launch experience at a very, very rapid rate. Every one of those Falcons that goes off, that's 10 engines, as I understand, that are being qualified. So their rate of experience is building up quickly.

But ULA has a longer range of experience with a wider range of payloads. So it's really two things that are quite different from each other.

ADDITIONAL COMMITTEE QUESTION

Senator SHELBY. Thank you.

Thank you, Mr. Chairman.

Mr. Chairman, I do have a number of other questions I'd like to submit for the record.

Senator DURBIN. Certainly.

[The following question was not asked at the hearing, but was submitted to the Department for response subsequent to the hearing:]

QUESTION SUBMITTED TO CRISTINA T. CHAPLAIN

QUESTION SUBMITTED BY SENATOR ROY BLUNT

Question. Does SpaceX's Falcon 9 rocket meet all of the requirements of the EELV program?

Answer. The SpaceX Falcon 9 v1.1 launch vehicle currently under Air Force review for new entrant certification does not, and is not intended to, meet all EELV program requirements. For example, to meet EELV program key system requirements, launch providers must demonstrate a mass-to-orbit lift capability of 26,100 lbs. to the geosynchronous transfer orbit. The Falcon 9 v1.1 configuration is designed to launch missions requiring lift capability of up to 12,789 lbs to the same orbit. Each of the up-to 14 national security space launches originally set aside for competition in the Air Force's upcoming launch vehicle competition were, at the time they were identified, within the Falcon 9 v1.1 launch vehicle's predicted lift capability. Some missions in the national security space launch manifest require greater lift capability than this, however, so the Falcon 9 v1.1 launch vehicle will not be able to compete for the entire EELV launch manifest. SpaceX is currently developing a Falcon Heavy launch vehicle that is intended to meet higher-weight EELV program lift requirements. The Falcon Heavy launch vehicle is expected to achieve certification in 2016, according to SpaceX. We did not assess whether the Falcon 9 v1.1 is able to meet all other EELV program requirements.

SUBCOMMITTEE RECESS

Senator DURBIN. And if there are no further questions in today's panel, I want to thank all of you for being with us, Dr. Pace, Mr. Musk, Mr. Gass, and Ms. Chaplain. Thank you for your contribution today. There will be written questions coming your way, and we hope that you will respond to them in a timely fashion so we can make this report available to the public.

And this meeting of the subcommittee will stand adjourned.

[Whereupon, at 11:15 a.m., Wednesday, March 5, the subcommittee was recessed, to reconvene subject to the call of the Chair.]
