Advantages: Targeting the PH domain improves specificity against Akt kinase in comparison to inhibitors of the ATP domain which typically are unspecific.

Inventors: Phillip A. Dennis (NCI) et al.

**Government-Owned Inventions; Availability for Licensing**

**AGENCY:** National Institutes of Health, Public Health Service, HHS.

**ACTION:** Notice.

**SUMMARY:** The inventions listed below are owned by an agency of the U.S. Government and are available for licensing in the U.S. in accordance with 35 U.S.C. 207 to achieve expeditious commercialization of results of federally-funded research and development. Foreign patent applications are filed on selected inventions to extend market coverage for companies and may also be available for licensing.

**ADDRESSES:** Licensing information and copies of the U.S. patent applications listed below may be obtained by writing to the indicated licensing contact at the Office of Technology Transfer, National Institutes of Health, 6011 Executive Boulevard, Suite 325, Rockville, Maryland 20852–3804; telephone: 301/496–7057; fax: 301/402–0220. A signed Confidential Disclosure Agreement will be required to receive copies of the patent applications.

**Spontaneously Transformed Mouse Epithelial Cancer Cell Lines Serving as Mouse Models: A New Model for Cancer Research**

**Description of Invention:** Investigators at the NIH have created a collection of 45 mouse epithelial cancer cell lines derived from six organs: Bladder, cervix, colon, lung, kidney, and mammary glands. These cell lines were obtained from spontaneously transformed primary cell cultures without genetic, viral or chemical manipulation so they can serve as mouse models for studying the natural process of oncogenesis.

The cell lines were characterized cytogenetically during their transformation from normal to spontaneously immortalized and were found to recapitulate many of the changes observed in human cancer cells such as the deregulation of oncogenes (Myc, Mdm2) and tumor suppressor genes (Cdkn4a/Ink4a/p16, Rb).

Carcinomas that arise from the epithelial cells lining organs lead to the most common cancers in humans. However, research on cellular transformation has largely relied on fibroblast cells which are not of epithelial origin and therefore, may not reflect the changes that lead to epithelial oncogenesis. The availability of these mouse epithelial cancer cell lines should allow for a more accurate analysis of this process.

**Applications:** These cell lines serve as “ideal” murine tumor models as they show evidence of progression, permitting analysis of the genetic and biological changes observed in the equivalent human carcinomas and associated with tumor progression. Their tumor histology is comparable to human cancers.

The cell lines have unique properties that make them suitable for study of the following:

- Unlimited replicative potential.
- Exhibit tumorigenic potential and EMT (Epithelial Mesenchymal Transition).
- Exhibit high degree of chromosome instability (chromosome rearrangements, amplifications) in regions orthologous to those altered in human cancers.
- Use in mapping mouse genes homologous to human cancer genes and for the study of the effects of deregulation of cancer associated genes, through silencing or overexpression.
- For use in gene expression studies of tumor progression, comparing profiles to human cancers involving the same tissue types.
- Use as experimental controls in the analysis of oncogene signaling pathways.
- Use in the studying telomerase pathway regulation (200-fold expression difference between cell lines).
- Use of mouse as model of epithelial carcinomas and specifically cancers of the bladder, cervix, colon, lung, mammarys and kidney cancers.
- These mouse models serve as vehicles to test the efficacy of new therapies, targeting specific targets associated with the transformation of six different mouse epithelial tissues.
• Use for discovering drugs that alter the tumorigenic potential, invasiveness, and the Epithelial–Mesenchymal Transition state.

Advantages:
• Cytogenetically defined epithelial cell lines from mouse that model human carcinomas.
• Spontaneously transformed primary cell cultures were generated from isogenic mouse strain that has a low propensity for epithelial tumors in vivo, thereby not involving other mouse strains potentially influencing the genetic background.
• These cell lines were generated without viral, chemical or genetic manipulation and thus can serve as mouse models for studying the natural process of oncogenesis and as mouse models of human cancers.
• Genomically defined colon, bladder, and kidney cell lines showing oncogene deregulation (i.e., Mdm2 and Myc overexpression).

Development Status:
• Ready for use.
• Pre-clinical.

Market: Cancer is the second most common cause of death in the United States. More than half a million Americans are expected to die of cancer. The cell lines will serve as a valuable tool for cancer researchers.

Inventors: Hesed AM. Padilla-Nash et al. (NCI).

Publications: None currently available for this technology.

Licensing Status: Available for licensing under a Biological Materials License Agreement.

Licensing Contact: Sabarni Chatterjee, PhD; 301–435–5587; chatterjeea@mail.nih.gov.

Collaborative Research Opportunity: The National Institute of Child Health and Human Development, Division of Intramural Research, is seeking statements of capability or interest from parties interested in collaborative research. Please contact J. Hewes, PhD at 301–435–3131 or hewesj@mail.nih.gov for more information.

Akt-Ser473 Phosphorylation as a Marker for Predicting Taxane Chemotherapy Outcome

Description of Invention: Over the past decades, taxanes such as paclitaxel and docetaxel have emerged as effective chemotherapy agents for breast cancer and other malignancies. Taxanes are effective in many patients, however, not all patients benefit from this type of chemotherapy. A significant need remains for a means of predicting clinical outcome from taxane-based chemotherapy.

Akt, a serine/threonine kinase that can block apoptosis, has been implicated in the regulation of microtubule dynamics and organization. Akt phosphorylation and its transducing downstream events play a central role in cell survival and cell cycle progression at the G1/M transition. Paclitaxel or docetaxel inhibits Akt-Ser473 phosphorylation (pAkt) and induces mitotic arrest. Therefore, taxanes may cause more damage to tumor cells that are dependent on pAkt for survival and cell cycle progression, significantly impacting treatment outcome.

Researchers at the National Cancer Institute, NIH, have identified pAkt as having predictive significance for paclitaxel chemotherapy outcome in patients with early stage breast cancer. The researchers have developed an immunohistochemistry method for determining pAkt status with appropriate controls for assay performance and cutoff for pAkt positivity. They also discovered methods of correlating pAkt expression with clinical outcome (disease-free survival and overall survival). pAkt is a novel predictive marker of taxane chemotherapy, and can be applied to indicate which patients should receive taxane-based chemotherapy.

Advantages: pAkt is a useful clinical predictive marker to determine which patients should or should not receive taxane-based chemotherapy for cancer. Determining pAkt status would allow patients with pAkt-positive tumors to elect taxane therapy for whom are likely to benefit, and allow patients with pAkt-negative tumors for whom are unlikely to benefit to be spared from taxane therapy as well as toxicity, and earlier use of other therapies that could be more effective. The application of this invention may potentially reduce the cost of cancer care.
